Methods: A systematic search was conducted using PubMed and Web of Science in October 2018 (Prospero Registration No. CRD42018118605). Eligible studies were randomised controlled trials (RCT) including adults with fibromyalgia (population), who received exercise (intervention) compared to usual care (comparator). Outcomes of interest were fatigue and/or sleep quality. No restrictions were applied for language nor for publications date. Random effects meta-analyses were conducted. The Cochrane Collaboration’s tool was used for assessing risk of bias in the included studies. The quality of evidence was evaluated using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) framework.

Results: Twenty RCTs were included, 17 included measures of fatigue (n=1003) and 12 measures of sleep quality (n=731). In comparison to usual care, exercise had beneficial effects on fatigue (Figure 1, P<0.001) but not on sleep quality (Figure 2, P=0.06). The most beneficial interventions for fatigue and improving sleep quality were those in which fatigue was the primary outcome and those based on body-mind interventions, respectively (both, P<0.001). A moderate risk of bias was present in most of the included studies.

Conclusion: According to the GRADE framework, this review provides low-to-moderate quality evidence that exercise is moderately effective for improving fatigue, and moderate evidence of no-meaningless effects of exercise to improve sleep quality. Further high quality RCTs are required to determine the effectiveness of exercise on fatigue, and in particular, sleep quality in fibromyalgia.

PATIENT PERSPECTIVES ON HOW TO IMPROVE MEDICATION EDUCATION

Mirjam Hegeman, Jolanda Delsing, Jacqueline Luttikholt, Harald Vorkenmann. Ziekenhuis Medisch Spectrum Twente, Rheumatology, Enschede, Netherlands

Background: EULAR recommends that people with inflammatory arthritis should have access to and be offered patient education throughout the course of their disease (1). The content and delivery of patient education should be individually tailored (2). Patients should be educated on their medication and know its purpose, mode of action, possible side effects and monitoring guidelines (3). Improving patients’ ability to make informed choices and to use medication effectively and safely should result in significant benefits for the health service and improve patient well-being (4). Our institute’s yearly Consumer Quality Index (CQI) revealed that our current medication education needs improvement.

Objectives: To improve medication education from the patient perspective.

Methods: A representative cross-sectional sample of 100 rheumatoid arthritis patients was invited to complete a specially designed questionnaire based on the Satisfaction with Information about Medicines Scale (SIMS) questionnaire (5). All caregivers at our Rheumatology unit (rheumatologists, trainees, rheumatology nurses) participated in single-blinded structured observational sessions of their regular patient consultation with the patient’s consent. Data was collected on the type and content of medication information that was given during the consultation. Local ethical approval was obtained and patient confidentiality was assured.

Results: At present 40 (40%) patients returned the questionnaire. Overall, patients are satisfied with the medication education provided (average overall satisfaction score of 7.4 (0–10). However patients experienced insufficient education on the following topics:
- whether the medication has influence on sex life
- the risk of having side effects
- how to act when side effects occur
- possible interaction with concomitant medication
- whether the medication can cause drowsiness

Between December 2018 and January 2019 caregivers at our unit (4 rheumatologists, 2 trainees, 1 nurse) participated in multiple single-blinded observational sessions. In 100% of observed consultations medication information was provided. However, most caregivers did not address the topic of side effects during their consultation. Furthermore, in all cases caregivers failed to document in the electronic patient file which information was provided.

Conclusion: Rheumatoid arthritis patients express overall satisfaction with medication education but experience an unmet need for information on possible medication effects on their sex life, medication side effects and interaction with concomitant medication. Further analysis of the questionnaires will be performed and a plan of improvement will be implemented to meet the patients need for more and better education on medication. Patient medication education will be implemented in a continuous cycle of improvement.
Efficacy of Graded Activity with and without Comparison of Biopsychosocial Status of Patients with Ankylosing Spondylitis with and Without Anti-TNF Treatment

**Background:** It is known that anti-TNF therapy is given to patients with persistently high disease activity despite conventional treatments according to the ASAS recommendations (1). Although biopsychosocial symptoms were well known, biopsychosocial assessments are insufficient in the literature.

**Objectives:** The aim of this study was to compare the biopsychosocial status between patients with AS who were decided to be treated with anti-TNF treatment and patients with AS who did not receive any anti-TNF treatment. Also, it was aimed to investigate the effectiveness of 3 months anti-TNF treatment on biopsychosocial status.

**Methods:** 74 AS patients who are decided to receive anti-TNF treatment and 38 AS patients, who didn’t, were included in the study. Socio-demographic informations of patients were collected. The mean age of the patients (n = 112) was 41.9±19.8 years. Health Assessment Questionnaire (HAQ) was used to assess functional status and daily living activities. The Hospital Anxiety and Depression Scale (HADS) was used to assess anxiety and depression levels. Biopsychosocial status of the patients was evaluated by the BETY-Biopsychosocial Questionnaire (BETY-BQ). The same evaluations were repeated after 3 months in 36 patients using anti-TNF.

**Results:** A statistically significant difference was observed in BETY-BQ, HADS anxiety and HAQ scores, when the groups were compared. There was no statistically significant difference in HADS depression scores (Table 1). The difference after 3 months of anti-TNF treatment was significant in all parameters (Table 2).

**Conclusion:** It was observed that the patients who were decided to be received anti-TNF treatment had worse functionality, anxiety, and biopsychosocial status than the patients who did not receive anti-TNF treatment. Anti-TNF treatment was found to be effective in three months period in terms of these biopsychosocial symptoms that the patients had.

A PILOT NURSE-LED TELEPHONE TRIAGE LINE OF PATIENTS WITH RHEUMATOLOGIC RARE DISEASES IN A TERTIARY CENTER

Evka Kiss1,2, Gabriela Ciursic1, Blanca Jurjul1, Ileana Filipescu1, Laura Muntean1, Siao-Pin Simon1, Simona Rednic1, Laura Damian1,2, Emergency Clinic County Hospital Cluj, Rheumatology, Cluj-Napoca, Romania; 3Emergency Clinic County Hospital Cluj, Quality Insurance, Cluj-Napoca, Romania

Background: The general rheumatology outpatient clinics are facing an increasing workload. The patients already in evidence with rare or complex inflammatory diseases, such as inflammatory myopathies, systemic lupus erythematosus, mixed connective tissue diseases, systemic sclerosis, Sjogren’s syndrome, relapsing polychondritis, systemic vasculitides and other collagen-vascular diseases are being scheduled for outpatient or hospital assessment at the current visit. However the patients may need earlier appointments, given the possibility of flares or other issues.

Objectives: To assess the role of a nurse-led telephonic triage line in patients with rare rheumatologic diseases.

Methods: The nurses accepting to be enrolled in the programme answered the phone for the patients already in the department’s and their follow-up with rare or complex inflammatory rheumatic diseases. A 2-hours training programme with attending physicians was completed. Respecting confidentiality agreement regulations, the calls were registered with the name, diagnosis and phone number on a standard form. The calls reasons were recorded: appointments scheduling, medical issues or others. The alarming symptoms and signs requiring doctor advice or earlier appointments were checked on a short form: aggravating dyspnea, dysphagia, weakness or Raynaud’s phenomenon, ulcerations, etc. Other issues, such as lumbar pain, joint pain, nausea, heartburn, etc requiring counselling, were registered as well.

Results: Over 2 months, 280 calls from patients with rare rheumatologic diseases were received, out of which 171 (61%) were for scheduling or changing appointments. The rest were for medical advice regarding minor ailments, medication side effects, regular blood tests or other investigations performed after the last visit, issues regarding travelling etc. The triage nurses referred the patients to Emergency in 2 cases (0.7%), to the General Practitioner in 28 cases (10%) or planned an early appointment. However the patients may need earlier appointments, given the possibility of flares or other issues.

Conclusion: When designing PA programs for people with RA, the AR PA guidelines for people who have inflammatory arthritis [3] should be followed. However, it should be noted that engagement and participation in PA interventions is increased when the intervention is of low impact PA and starts at a low-moderate intensity. Individualising the activity to the person and applying behaviour change techniques have also been found to improve participation.

FACTORS WHICH IMPACT COMPLETION AND NON-COMPLETION OF PHYSICAL ACTIVITY INTERVENTIONS FOR PEOPLE WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW

Louise Larkin, University of Limerick, Limerick, Ireland

Background: Rheumatoid arthritis (RA) is a systemic inflammatory condition which results in pain, fatigue, joint stiffness and an increased risk of cardiovascular issues. Physical activity (PA) has been proven to help reduce the severity of these symptoms and the risk of cardiovascular disease [1]. However, recent literature has shown that people with rheumatoid arthritis do not meet PA guidelines [2]. The systematic review aims to determine the factors which affect the completion rates of adults with RA in PA interventions.

Objectives: 1) Review the effect of the frequency, intensity, time and type of exercise (FITT principle) on participation rates. 2) Review the reasons for dropping out of an intervention and consider how this can be avoided in planning future interventions. 3) Examine the effect of behaviour change techniques used on completion rates.

Methods: A systematic review of the literature was carried out in February 2018. Inclusion criteria were: detailed intervention information, completion rates reported, published between 1998-2018 and published in English. Included papers were assessed using the Cochrane risk of bias tool by two assessors. The relevant data was then extracted, compared and conclusions were drawn.

Results: Nine studies with varying levels of quality were included in this review. Reasons for not completing an intervention could be divided into modifiable and non-modifiable factors; modifiable factors include the FITT principle, the behaviour change component and controlling for adverse outcomes. Non-modifiable factors included the environment, illness/flare-up and accidents. The results found that when people with RA had an individualised PA program that started at a low-moderate intensity they had higher participation rates than those who followed a generalised program, with no behaviour change component. Altering the intervention in response to patient’s pain levels improved completion rates of the intervention.

Conclusion: When designing PA programs for people with RA, the AR PA guidelines for people who have inflammatory arthritis [3] should be followed. However, it should be noted that engagement and participation in PA interventions is increased when the intervention is of low impact PA and starts at a low-moderate intensity. Individualising the activity to the person and applying behaviour change techniques have also been found to improve participation.

A COMPARISON OF THE EFFECTIVENESS OF CORE STABILIZATION EXERCISE AND COMBINED EXERCISE ON PAIN, FATIGUE, SLEEP PROBLEM AND HEALTH STATUS IN WOMEN WITH FIBROMYALGIA

Özgül Mele, Seyda Toprak Celenay, Bahar Anatolergülü Kükrekoglu. Department of Physiotherapy and Rehabilitation, Health Sciences Faculty, Ankara Yildirim Beyazit University, Ankara, Turkey.

Background: Fibromyalgia (FM) is a syndrome characterized mainly by chronic widespread pain, fatigue, sleep disorders and decrease in health status. Exercise, one of the non-pharmacological approach, has favorable effects on clinic findings in FM, but studies investigating which types of the exercise are more effective in FM are limited.

Objectives: This study aimed to compare the effectiveness of core stabilization exercise (CSE) and combined exercise (CE) on pain, fatigue, sleep problem and health status in women with FM.

Methods: A total of 34 women with FM were included, allocated into the CSE (n:18, age: 43.05±9.23 years, body mass index (BMI): 27.25±5.23 kg/m²) and the CE (n:16, age: 38.43±9.55 years, BMI: 25.62±3.68 kg/m ²) groups. Both the CSE and the CE programs were carried out 2 days a week for 6 weeks under the supervision of a physiotherapist. Pain, fatigue and sleep problems with Visual Analog Scale and health status with Fibromyalgia Impact Questionnaire were evaluated at baseline and after 6-weeks program.

Results: Physical characteristics of the groups were similar (pBMI=0.313). After the program, it was found that pain (p=0.001; p=0.014), fatigue (p=0.002; p=0.011), and sleep problem (p=0.007; p=0.039) decreased, health status (p=0.001; p=0.001) improved in both the CE and the CSE groups, respectively. Moreover, sleep problem decreased in the CE group in comparison to the CSE group (p=0.038); but pain (p=0.003), fatigue (p=0.178), and health status (p=0.098) did not differ between groups.

FR0718-HPR THE EFFECT OF THE BIOPSYPHOCOSOCIAL EXERCISE PROGRAM ON PAIN COPING SKILL AND FATIGUE IN RHEUMATIC DISEASES

Ayşuko Çığdem Yılmaz, Gamze Annı, Yasemin Özel Arslan, Fatma Birgül Kumburğanlı, Nur Baru Karaca, Aybige Seven, Sedat Kiraz, Ali Akdoğan, Edibe Ünal, 1 Hacettepe University Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; 1 Hacettepe University Faculty of Medicine, Department of Rheumatology, Ankara, Turkey.

Background: Although the trend towards biopsychosocial approaches is increasing today, studies on psychosocial effects of exercise are limited in the literature. There is a need for framed exercise programs to assess the clinical effectiveness of biopsychosocial approaches. The reason why biopsychosocial programs are important may be due to multidimensional features of symptoms such as pain, fatigue.

Objectives: The purpose of this study is to investigate the effectiveness of the biopsychosocial exercise program on pain coping skill and fatigue in rheumatic patients.

Methods: Ninety-one patients with the rheumatic disease were included in this study. The patients were divided into two groups based on a prospective cohort (BETY group, n = 56; and control group, n = 35). BETY is a biopsychosocial exercise approach (1). It was performed in a period of one hour, 3 times a week for 12 weeks and included clinical pilates exercises, dance therapy-authentic movement and pain management information. The control group did not take any exercise treatment. The BETY-Biopsychosocial Questionnaire (BETY-BQ) was used to evaluate the pain coping skill and fatigue as well as assessing whole biopsychosocial status of individuals (2). The answers were given to the 5th question (I don’t know how to control my pain), and the 11th question (I feel tired) of the BETY-BQ were recorded as a 5-point Likert at ranging from ‘yes, always’ to ‘no, never’. Also, the total score of BETY-BQ was recorded. Demographic data were given as mean ± standard deviation (X ± SD), and answers given to the questionnaire were expressed in frequency tables.

Results: The mean ages of BETY group and control group were 49.63 ± 11 and 39.74 ± 10 years and body mass indexes were 26.93 ± 3 kg/m² and 26.54 ± 4 kg/m², respectively. The frequency of answers to the 5th and 11th question and the total score of the BETY-BQ on the first assessment (pre-treatment) and the second assessment (post-treatment) were shown in Table 1.

</table>
Conclusion: It was concluded that BETY as a biopsychosocial exercise approach is effective in reducing fatigue and improving the pain coping skill as well as the biopsychosocial status of rheumatoid patients. BETY should be kept in mind for further studies in terms of biopsychosocial aspects of pain coping, fatigue, etc.

FR10720-HPR DEVELOPMENT AND VALIDATION OF A SELF-ADMINISTERED QUESTIONNAIRE MEASURING ESSENTIAL KNOWLEDGE FOR PATIENTS WITH RHEUMATOID ARTHRITIS: THE RHEUMATOID ARTHRITIS ASSESSMENT KNOWLEDGE QUESTIONNAIRE (RAKE)

RODERER Malory1, Bruno Pereira1, Martin Soubrier1, Sonia Tropl2, Françoise Fayet1, Jean David Cohen3, Muriel Piperno4, Beatrice Pallot Prades5, Sophie Poupl6, Pascal Coquerelle7, Laurent Grange8, Christelle Sordel1, Laure Gossec9, Catherine Beauvais10, University Hospital, Clermont-Ferrand, France; ANDAR, Montpellier, France; University Hospital, Montpellier, France; University Hospital, Lyon, France; University Hospital, Saint Etienne, France; University Hospital, Rouen, France; University Hospital, Béthune, France; University Hospital, Grenoble Alpes, France; University Hospital, Strasbourg, France; Pitié-Salpêtrière Hospital, Sorbonne university, Paris, France; Saint Antoine University Hospital, APHP, Paris, France

Background: Improving knowledge and skills is required for patients with rheumatoid arthritis (RA) to enhance self-management. Measuring knowledge is also part of the educative approach. However, the available Knowledge questionnaires (KQs) (ref 3) needed to be updated according to recent recommendations for RA management and the patients’ needs (ref 3).

Objectives: To develop and validate a new KQ in RA.

Methods: 4 steps. Step1. Selection of knowledge considered essential for patients with RA through Delphi rounds by a working group of rheumatologists, health professionals (HPs) and patients leading to a list of consensus items (ref3). Step2. Two rheumatologists and a rheumatology nurse constructed the first version of the KQ, each question of the KQ referring to a selected item on the list. The formulation was then amended by the working group. A new version was elaborated during a face-to-face meeting of 3 HPs and one patient. Step 3. The KQ was submitted to ten patients for cognitive debriefing, comments were analysed and a the final version was elaborated. Step 4. Multicentric validation in 11 rheumatology departments: acceptability was measured by the rates of missing data per item, reproducibility and sensitivity to change were assessed respectively by test/retest at a 2 weeks interval (Lin’s concordance correlation coefficient) and by testing the KQ before and after patient education sessions. The sample size estimation and statistical analyses were conducted according to COSMIN recommendations, especially concerning thresholds of metrological indexes.

Results: Step1 obtained 45 knowledge items, 32 considered essential and 13 considered useful, selected respectively by more than 2/3 and more than 50% of participants to the Delphi rounds, leading to the RAKE: a 45-items questionnaire, with a 32-items short form. The RAKE contains 6 knowledge domains: disease knowledge (10 items), pharmacological treatment (14), non-pharmacological treatment (7), comorbidities (1), self-care for pain and fatigue (5), adaptive skills to psychosocial and professional issues and health care system (8). The validation included 130 patients, 108 (83.4%) women, mean age 56.4±12.10 years, median disease duration 9 years [4; 23]. The missing data rate per item was <0.05. The RAKE’s internal validity (Kuder-Richardson) was 0.90. Reproducibility (in 72 patients) was 0.86 [0.80; 0.92]. Sensitivity to change was measured in 54 patients. A statistically significant difference in total knowledge score was observed between the two assessment times: 30.1±7.4 vs. 37.7±5.7 (p<0.001), representing an effect size >1.1 [0.7; 1.6]. The RAKE’s
external validity was confirmed by correlation with the RAID score of 0.16 (p=0.08).

**Conclusion:** This study enabled the development and the validation of the RAKE, a Knowledge questionnaire for patients with RA, with a good acceptability, reproducibility and sensitivity to change. This KQ will be helpful to assess the process of knowledge acquisition in patient education approaches.

**EFFECTIVENESS OF NON-PHARMACOLOGICAL AND NON-SURGICAL INTERVENTIONS ON THE IMPACT OF RHEUMATOID ARTHRITIS: AN OVERVIEW OF REVIEWS**

Eduardo Santos1, Catia Duarte1, Andrea Marques2, Daniela Cardoso3, João Apóstolo1, P José Antonio. Da Silva3, Maria Do Céu Barbieri-Figueiredo4.

1Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Health Sciences Research Unit: Nursing, Coimbra, Portugal; 3Nursing School of Porto, Porto, Portugal.

**Background:** Impact of disease persists in many patients with rheumatoid arthritis (RA) even after inflammatory remission is achieved, requiring the need for adjunctive interventions targeting the uncontrolled domains of disease impact. Several systematic reviews have addressed nonpharmacologic interventions, but there is still uncertainty due to scarce or conflicting results or significant methodological flaws.

**Objectives:** To determine the effectiveness of non-pharmacological and non-surgical interventions upon the impact of RA.

**Methods:** A comprehensive search strategy for 13 databases and grey literature was developed. This review included quantitative systematic reviews that examined the effectiveness of non-pharmacological and non-surgical interventions of any form, duration, frequency and intensity, alone or in combination with other interventions designed to reduce the impact of disease in adult patients with RA. The outcomes were pain, functional disability, fatigue, emotional well-being, sleep, coping, physical well-being and global impact of disease. Critical appraisal and data extraction were performed independently by two reviewers and summarized using a narrative synthesis approach.

**Results:** Eight systematic reviews were included (Figure 1), with a total of 91 RCT’s and nine observational studies (6740 participants). Four systematic reviews examined the effects of multicomponent or single exercise/physical activity interventions, two examined the effects of hydrotherapy/balneotherapy, two evaluated the effects of psychosocial interventions and one assessed the effects of custom orthoses for the foot and ankle. Multicomponent or single exercise/physical activity interventions, psychosocial interventions and custom orthoses appeared to be effective in improving pain and functional disability. Fatigue also improved with the implementation of multicomponent or single exercise/physical activity interventions and custom orthoses. Only exercise/physical activity interventions appeared to be the effective in improving the global impact of disease. None of the included systematic reviews reported on emotional well-being, sleep, coping or physical well-being as an outcome measure. Other types of interventions were not sufficiently studied and their effectiveness is not yet established.

**Conclusion:** Only multicomponent or single exercise/physical activity interventions, psychosocial interventions and custom orthoses seems to be capable of reducing the impact of rheumatoid arthritis. Future evidence should be created and synthesized in the fields identified as knowledge gaps, namely emotional well-being, sleep, coping and physical well-being. Further investigation should be encouraged on the effects of interventions that have not been assessed at all or sufficiently to established their effectiveness, so that robust decisions and recommendations can be made.

**THE INVESTIGATION OF THE RELATIONSHIP BETWEEN PSYCHOSOCIAL AND FUNCTIONAL STATUS OF CHILDREN WITH JIA**

Aybüke Seven1, Aykut Özcüder1, Fatma Bingül Kümbardoğru1, Gamze Ann1, Nur Banu Karaca1, Yasemin Özel Aslıyüz1, Selcan Demir1, Yetla Bilginer1, Edibe Ünal1, Sezai Özen1, Hacettepe University Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey.

**Background:** JIA is the most common rheumatic disease in children and may result in significant morbidity with joint deformity, growth disorder, and persistence of active arthritis to adulthood (1). According to the model of biopsychosocial pain, emotions affect the degree of functional impairment (2).

**Objectives:** The aim of this study is to investigate the relationship between the psychosocial and functional status of children with juvenile idiopathic arthritis (JIA).

**Methods:** 382 children with JIA were included in the study. Individuals were assessed with the Juvenile Arthritis Biopsychosocial Questionnaire (JAB-Q) (3) and Children Health Assessment Questionaire (CHAQ) applied for functional status (4).

**Results:** The mean age of the subjects included in the study (n = 386) was 12.48 ± 3.81 years. The median value of the JAB-Q functional status was 2 (min: 0 max: 34), psychosocial status was 10 (min: 0 max: 38). And the median value of the CHAQ was 0.25 (min: 0 max: 3). Correlation coefficients and statistical significance were calculated by using Pearson’s test. There was a low positive correlation between BETY-BQ functional status and BETY-BQ psychosocial status (r = 0.347, p <0.001), a low positive correlation between CHAQ and BETY-BQ psychosocial status (r = 0.395, p <0.001). There was a good positive correlation between BETY-BQ functional status and CHAQ (r = 0.679, p <0.001) (Table 1).

**Conclusion:** Only multicomponent or single exercise/physical activity interventions, psychosocial interventions and custom orthoses seems to be capable of reducing the impact of rheumatoid arthritis. Future evidence should be created and synthesized in the fields identified as knowledge gaps, namely emotional well-being, sleep, coping and physical well-being. Further investigation should be encouraged on the effects of interventions that have not been assessed at all or sufficiently to established their effectiveness, so that robust decisions and recommendations can be made.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2019-eular.942
Conclusion: The psychosocial status of children is not affected by functional status. Psychosocial status may be affected by different variables. It was concluded that children should be encouraged to participate in social activities independently their functional problems. Further studies are needed to examine the other variables’ effects on psychosocial status in children with JIA.

A MIXED METHOD STUDY TO EXPLORE THE FEASIBILITY AND PATIENT SATISFACTION OF TWO DIFFERENT EXERCISE PROGRAMS IN SYSTEMIC SCLEROSIS ASSOCIATED MICROSTOMIA

Ellinor Sydow, Sabien Severi, Kristien Van der Elst, Patrick Verschueren, Jan Lenaerts, Rene Weshovens, Ellen De Langhe. University Hospitals Leuven. Rheumatology, Leuven, Belgium

Background: Systemic sclerosis (SSc) is a severe autoimmune disease and fibrotic cutaneous involvement of hands and face is a typical characteristic. Oral involvement with reduced oral aperture is frequent and associated with impaired food intake, oral hygiene and secondary dental problems. Several studies have shown that stretching (placing the thumbs in opposite corners of the mouth hand, pulling outward) and oral augmentation (tongue depressors between the back molars) exercises can increase oral aperture but is often hampered by low adherence rates.

Objectives: The aim of this descriptive explorative mixed method study was to explore feasibility, patient satisfaction and effectiveness of two exercise programs, Therabite and orofacial exercises, in systemic sclerosis associated microstomia.

Methods: We included adult patients suffering from systemic sclerosis (fulfilling the ACR/EULAR 2013 criteria) and microstomia (maximal oral aperture <40mm). We discerned two groups: Group A exercised with a passive jaw motion device (Therabite®), and Group B performed mouth-stretching exercises. Patients were expected to exercise for 10 minutes, 3 times/day for 3 months. Patients were contacted 4 times by telephone to address encountered problems and completed an exercise diary to document the adherence rate. Patients were evaluated at baseline, 3 months (period without intervention), 6 months (after 3 months of intervention) and at 9 months (post-intervention visit). At time point 6 months, semi-structured one to one interviews were conducted. Interviews were recorded, transcribed verbatim and systematically analyzed using Qualitative Analysis Guide of Leuven.

Results: We included 6 women and 3 men, with a median age of 60 years (range 40-75) and a median disease duration of 8 years (range 3-22). At time point 6 months, all patients in group A (n=4) and 4 patients in group B (n=5) improved with a median of 9mm (range 2-10) and 7mm (range 4-11), respectively. One patient had a decrease of 2mm. The compliance, measured as the ratio of executed exercises relative to the planned number of exercises ranged between 63.7% and 98.9% in group A and between 48.5% and 97.4% in group B. Details are shown in Table 1. In the follow-up period, we documented maintenance of the observed increase in oral aperture in those patients that continued exercising daily. In all others, maximal oral aperture declined again. All 9 patients attended the interview. Three main themes emerged from the data: drivers, challenges and perceived improvement. Patients highlighted several drivers to perform the exercises at home, such as the motivation to improve current disability caused by microstomia. Furthermore, they equally highlighted several challenges regarding feasibility, such as the struggle to exercise multiple times a day. Most of the patients were hoping that they could keep their improvement. They were willing to continue practicing if necessary, but with a lower frequency.

Conclusion: This study suggests that both types of intervention can improve maximal oral aperture. The adherence to therapy was higher than expected but none of the patients considered it feasible to continue practicing 3 times/day in the long-term resulting in a decline of improvement post-intervention. This is the first study to report the feasibility of the exercises for the patients and can be very useful for health professionals giving guidance. Future studies are needed in order to define exercise programs that are feasible and can be sustained in the long term.

THE EFFECTIVENESS OF TAI CHI CHUAN IN OSTEOARTHRITIS OF THE KNEE: A SYSTEMATIC REVIEW

Kevin Tai, Ingrid Merlin Balita de Souza, Amelia Pasqual Marques. University of São Paulo, Physical Therapy, Speech Therapy and Occupational Therapy, São Paulo, Brazil

Background: Osteoarthritis (OA) is the most prevalent joint disease in the elderly. The signs and symptoms are degeneration of joint surface, stiffness, swelling, and decrease in physical function. Knee OA is the most common joint disease and more prevalent among older adults. Tai Chi Chuan is a safe exercise modality of Chinese origin, which may be a potentially in reducing symptoms.

Objectives: The aim of systematic review was to identify the effects of Tai Chi Chuan in the elderly with knee osteoarthritis.

Methods: This systematic review was registered in Prospero (CRD42018096699). MEDLINE, EMBASE, PEDro, Cochrane, Scopus, Scielo, Lilacs and Web of Science, were screened between May 2008 to May 2018 in English, Spanish, Portuguese and Mandarin language. Randomized controlled trials (RCTs) comparing Tai Chi to control conditions were included. All authors independently assessed risk of bias using the risk of bias tool recommended by Jadad index. Outcome measures included were pain, stiffness, muscular strength, functionality and quality of life.

Results: In the search we found 161 studies, MEDLINE (29), Pedro (58), Web of Science (17), Embase (29), Cochrane (6), Scopus (18), Manual search (4). Eight articles were included and seven showed the effectiveness of Tai Chi Chuan, being higher to the interventions of the control groups, consisting of self-care educational activities, or strengthen- ing and endurance exercises of knee flexors and extensors. Only one study, that patients received a lower limb resistance training program, presented better results in pain, stiffness and physical function scores. Tai Chi Chuan was not associated with adverse events.

Conclusion: Tai Chi Chuan was effective in improving pain, stiffness and physical function of sleep quality, in addition to increased speed and step length during gait, and strength gain of knee extensor muscles in elderly patients with knee OA. This systematic review found moderate...
Evidence for short-term improvement of pain, physical function and stiffness in patients with knee AO. More high quality RCTs are urgently needed to confirm these results.

FRIO725-HPR | A TAILOR-MADE EXERCISE PROGRAM DESIGNED FOR IMPROVING CARDIORESPIRATORY FITNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INCREASED CARDIOVASCULAR RISK

Joëlle van den Hoek1, Martin van der Esch1, Marthe van der Leeden2, Willem Lems3, George Metsios4, George D Kilas5, Joost Dekker6, Wilma Scholte op Reimer6, Harald Jorstad7, Merel J L’Ami8, Maaike Heslinga9, Michael Nurmohamed10, 1Amsterdam Rehabilitation Research Center | Reade, Amsterdam, Netherlands; 2VUMc, Amsterdam, Netherlands; 3Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; 4Russell’s Hall Hospital, Dudley, United Kingdom; 5Russell’s Hall Hospital, Dudley, United Kingdom; 6University of Amsterdam, Faculty of Health, Amsterdam, Netherlands; 7AMC, Amsterdam, Netherlands.

Background: Rheumatoid arthritis (RA) is associated with low levels of cardiorespiratory fitness (CRF), especially in patients with RA and cardiovascular (CV) risk. The optimization of management of CV risk in patients with RA is an important aim in the treatment, including also exercise, particularly in patients with RA with a high CV risk, defined as a 10-year CV risk of 20% or higher. However, exercise to improve CRF in these patients is challenging since professionals should take multiple factors into account, such as comorbnd conditions related to CV risk. It is unknown which intensity of exercise improves CRF and is safe for patients with RA and CV risk.

Objectives: To design a tailor-made exercise therapy program to improve CRF for patients with RA and CV risk >20%.

Methods: To design a tailor-made exercise therapy program, patients and experts’ opinions were collected, and a systematic literature search on exercise programs in RA and CV risk factors was performed. The ACSM guidelines were also used to gain insight into frequency, intensity, type and progression of the exercises. In addition, a cardiology rehabilitation team and an arthritis rehabilitation team were consulted during the development of the program. The designed program was partly based on cardiac rehabilitation protocols and especially the way the training load was progressively increased, and the tolerability was assessed at every training.

Results: The exercise program, based on the individual maximum HR, is tolerable and safe and might increase cardiorespiratory fitness in patients with RA

FRIO726-HPR | DOES ART THERAPY MAKE A DIFFERENCE IN THE MANAGEMENT OF CHILDREN AND YOUNG PEOPLE WITH RHEUMATIC DISEASES: A MULTI-SITE SERVICE REVIEW TO EXPLORE THE IMPACT OF ART THERAPY IN TWO TERTIARY PAEDIATRIC RHEUMATOLOGY SERVICES IN SCOTLAND

Patricia Watts1,2, Emily Famgija3, Joyce Davidson2, Krissin Leith1. 1The Teapot Trust, Musselburgh, United Kingdom; 2Royal Hospital for Children, Glasgow, United Kingdom; 3Royal Hospital for Sick Children, Edinburgh, United Kingdom.

Background: Art therapy interventions in various medical settings are known to contribute to the mental health and wellbeing of patients. In paediatric rheumatology, there is a well documented unmet need for psychological support for children and families coping with chronic disease and its treatment. The role that art therapy could have in this provision is unknown and there is no evidence-based research to help understand its potential contribution. The Teapot Trust is a Scottish charity working with paediatric rheumatology services offering art therapy to children and young people with rheumatic diseases.

Objectives: This project aimed to evaluate the service provided by art therapists in two tertiary paediatric rheumatology units in Scotland. The objective was to better understand which patients were referred for art therapy; why they were referred; levels of engagement and acceptability of therapy and benefit resulting in improved outcome.

Methods: A retrospective review was conducted of referrals received in the period 2012-2018 to art therapy from paediatric rheumatology services. A mixed method approach was used for gathering quantitative, secondary and qualitative data. Quantitative data was collected by collating numerical and demographic information from referral forms; art therapist service databases; and patient medical records. Secondary and qualitative data has been gathered from pre-existing service information; the use of outcome measurement tools; end of therapy evaluations; end of therapy reports and patient feedback forms.

Results: The demographics of children seen were as expected in a paediatric rheumatology service with the majority being females with juvenile idiopathic. To guarantee safety, the training load was progressively increased, and the tolerability was assessed at every training. Exercises consisted of aerobic and muscle strength exercises. The first four weeks patients trained 30 minutes (which were spread over three exercises) on 65% of the HR max which was gradually increased until 75% of the HR max in the sixth week. From the fifth week three exercises to improve muscle strength were added to the program. From the seventh week interval training started, with a peak of 85% of the HR max and a rest of 65% of the HR max. The program also included motivational interviewing because one of the main reasons for a high CV risk is the inactivity during daily life. All patients were motivated to perform 30 minutes of moderate exercises every day at home.

Conclusion: A tailor-made exercise program to improve cardiorespiratory fitness in patients with RA and CV risk is developed, based on the opinion and expertise of patients and health professionals and supported by a literature review and guidelines. A progressively increase in intensity of the exercise program, based on the individual maximum HR, is tolerable and safe and might increase cardiorespiratory fitness in patients with RA and CV risk.

Disclosure of Interests: Joëlle van den Hoek: None declared, Martin van der Esch: None declared, Marthe van der Leeden: None declared, Willem Lems Speakers bureau: Amgen Inc., Merck, Eli Lilly and Pfizer, George Metsios: None declared, George D Kilas: Speakers bureau: GDK, Has received honoraria for lectures, participation in advisory boards and/or hospitality by Roche, AbbVie, Mundipharma, Pfizer, Roche, Sanofi and UCB, Consultant for: AbbVie, Bristol-Myers Squibb, Celgene, Eli Lilly, Janssen, Menarini, MSD, Mundipharma, Pfizer, Roche, Sanofi and UCB, Consultant for: AbbVie, Bristol-Myers Squibb, Celgene, Eli Lilly, Janssen, Menarini, MSD, Mundipharma, Pfizer, Roche, Sanofi and UCB, Consultant for: AbbVie, Bristol-Myers Squibb, Celgene, Eli Lilly, Janssen, Menarini, MSD, Mundipharma, Pfizer, Roche, Sanofi and UCB.

Conclusion: This retrospective multi-site service review demonstrated that art therapy was well used by clinicians as an appropriate psychological support for children and young people with rheumatic diseases. Engagement with the service was good and feedback positive. The review highlighted the challenge of objectively assessing outcomes, with the need to use validated and standardised assessment tools to collect this systematically. A standardised service evaluation framework will be developed to facilitate future service reviews and is hoped that this represents a first step in developing evidence-based research to investigate the impact and benefit of art therapy in supporting children and young people in paediatric rheumatology.

HPR Patients’ perspectives, functioning and health (descriptive: qualitative or quantitative)

FR107268-HPR

INVESTIGATION OF PHYSICAL ACTIVITY LEVELS OF PATIENTS WITH BEHÇET’S DISEASE

Nejla Uzungül, Ella Tarakçı, Nilaş Arman, Serdar Uğurlu, Istanbul University-Cerrahpasa Postgraduate Education Institute, İSTANBUL, Turkey; Istanbul University-Cerrahpasa, Faculty of Health Sciences, Department of Neurological Physiotherapy and Rehabilitation, İSTANBUL, Turkey; Istanbul University-Cerrahpasa Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İSTANBUL, Turkey; Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty, Department of Rheumatology, İSTANBUL, Turkey

Background: Behcet’s disease (BD), which is followed by a chronic course, is characterised by recurrent mucocutaneous lesions, oral aphthae, genital ulcers, and eye lesions. BD affects skin and mucosal lesions, joint involvement and eye involvement which can cause visual loss. It disrupts the physical and mental health of the individual as well as the disability of the physical functions and can affect the quality of life negatively (1, 2). There is strong evidence for the benefits of Physical activity (PA) on improvements in disease activity, activities and participation; however, people with rheumatic and musculoskeletal diseases (RMDs) are in general less active compared with healthy controls (3-5).

Objectives: The aim of the study was to evaluate PA in patients with BD and also to compare status of PA with healthy controls.

Methods: 67 patients (female=49, male=18) with BD and 66 healthy peers (female=43, male=23) were enrolled in the study. The subjects were recruited in a rheumatology clinic. They were diagnosed with BD by a rheumatologist based on the clinical diagnostic criteria. PA was evaluated with International Physical Activity Questionnaire-Short Form (IPAQ-SF) in all participants. Metabolic Equivalent (MET) values were calculated due to IPAQ-SF. In addition, the pain and fatigue status of patients with BD was asked.

Results: The mean age of the patients was 42.95±10.60 years. The mean disease duration was 14.14±5.13 years. The means of physical activity MET scores were 699.74±508.09 and 2006.75±1162.16 in patients with BD and healthy peers, respectively. It was found that the means of PA MET scores in BD was significantly decreased compared with healthy peers (p<0.001). While 53.7% of patients with BD had low levels of PA and 46.3% had moderate levels of PA, 9.1% of healthy subjects had low level of PA, 47% of them had moderate levels of PA and 43.9% high levels of PA (p<0.001). 86.6% of patients with BD reported pain, 73.1% of them also reported fatigue.

Conclusion: This is the first study to evaluate PA in patients with BD. The level of PA was significantly lower in patients with BD compared to their healthy peers. Decreased PA may be associated with pain and fatigue frequently seen in patients with BD. In future studies, it is recommended to investigate the factors affecting PA in patients with BD.

The co-author Ela Tarakci was supported to participate to EULAR 2019 by Turkish Academy of Sciences as a winner of the Young Scientists Award Programme (GEBIP) 2018.

HPR PATIENTS’ PERSPECTIVES, FUNCTIONING AND HEALTH (DESCRIPTIVE: QUALITATIVE OR QUANTITATIVE)

FR10727-HPR

PREDICTORS OF FUNCTIONAL CAPACITY AT 24 MONTHS FOLLOW-UP IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Juan P. Ford, Susana Buceta, Ricardo Russo. Garrahan Pediatric Hospital, CABA, Argentina

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in childhood and it causes short and long-term disability. Periodic assessment of functional capacity is important to determine the presence or absence of physical disability.

Objectives: To identify predictive factors of absence of functional disability after 24 months follow-up in a cohort of children with JIA treated at a tertiary referral hospital.

Methods: Longitudinal, retrospective, analytical, and observational study. Patients who met the following criteria were included in the study between 2013 and 2016:1 to 16 years old, diagnosis of JIA according to the International League of Associations for Rheumatology (ILAR); recently initiated (3 months) care at our clinic, complete C-HAQ (Childhood Health Assessment Questionnaire) records throughout the follow-up period. Patients were treated according to current guidelines for pharmacological and physical therapy. Functional capacity was assessed according to the C-HAQ every 3 months. For the analysis, the C-HAQ scores were divided into 3 categories: 0 - 0.49 (absence of disability), 0.5 - 1.5 (mild to moderate disability), and 1.51 - 3 (severe disability). Univariate comparisons were made to determine the relationship between different variables with the dependent variable ‘absence of functional disability at 24 months of follow-up’. Independent variables included: disease activity, functional capacity, and treatment-related outcome measures. Those with p values <0.05 were included in a multiple logistic regression analysis. The model was adjusted for basal functional capacity and inflammatory activity at 6 months. Items with a p value <0.05 were considered significant. Adjusted odds ratios (adjOR) and 95% confidence intervals (95% CI) are reported as a measure of association. The precision of the model was analyzed through the Area under the Curve (AUC).
Results: Of a total of 148 patients, 122 met the inclusion criteria. Median age: 7.4 years (IQR 1.1-16.9), 69 female (56.6%). Most patients had Polyarticular (44 patients, 36.1%) or oligoarticular (33 patients, 27%) JIA. At the beginning of the study, 36 patients (29.5%) did not show functional disability; 70 (57.4%) exhibited mild/moderate disability and 16 (13.1%) severe disability. At 24 months, 73 patients (59.8%) had no disability; 37 (30.3%) moderate/mild disability and 12 (9.8%) severe disability. In the multiple logistic regression model, performing regular physical therapy (PT) (adjOR 6.83 [95% CI 2.26 - 20.61], p = 0.001), starting PT within 12 months after diagnosis (adjOR 5.45 [95% CI 1.83 to 16.18], p = 0.002), baseline pain Visual Analogue Scale (pVAS, 0-10) less than 3 (adjOR 4.55 [95% CI 1.58 to 13.12], p = 0.005) and adherence to pharmacological treatment (adjOR 15.23 [95% CI 1.86 to 124.8], p = 0.011) were independent factors for not presenting functional disability at 24 months. The area under the model curve was 0.92 (95% CI 0.88 to 0.97).

Conclusion: The findings of this study reinforce the need of early and regular PT and medical treatment in children with JIA, in order to maintain or improve functional capacity over time. These results are not only statistically significant but clinically relevant since they reflect impact in functional skills in this population. Further studies are needed to confirm these outcomes in larger cohorts with longer follow-up.

FR0728-HPR | PERCEPTIONS OF PHYSICAL ACTIVITY IN INDIVIDUALS WITH RA – A QUALITATIVE THEMATIC SYNTHESIS
Nina Brodin1,2, Emma Swärdh1.1Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Division of Physiotherapy, Huddinge, Sweden; 2Danderyd Hospital Corp., Department of Orthopaedics, Division of Physiotherapy, Stockholm, Sweden

Background: The effects of physical activity (PA) in rheumatoid arthritis (RA) are well documented and PA is besides pharmacological interventions considered a cornerstone in the treatment. Despite this, many individuals with RA do not reach recommended levels of PA. To highlight aspects involved in supporting a positive PA behavior it is important to understand the patients’ perceptions of the phenomenon. Several qualitative studies have been conducted throughout the years, describing perceptions on physical activity in RA.

Objectives: The aim of this study is to review and synthesize the qualitative literature on physical activity in rheumatoid arthritis.

Methods: A purposive search in electronic databases (MEDLINE, CINAHL, and PEDro) using combinations of terms such as “qualitative methods, qualitative study, interviews, physical activity, exercise and rheumatoid arthritis”, from inception to July 2018 was carried out. Title/abstract and full-text screening were conducted independently by 2 researchers. Further, back-tracking of reference list of retrieved articles was made, and contacts were taken with known experts in the field. Studies were eligible if they qualitatively explored perceptions of different aspects of PA in individuals with RA. Eligible articles were appraised using the McMaster Critical review form. All relevant data were extracted from eligible articles and analyzed inductively using thematic analysis.

Results: 11 primary studies met the inclusion criteria. Studies were conducted in Denmark, Ireland, New Zealand, Sweden, United Kingdom and the United States of America. The sample included 170 individuals with rheumatoid arthritis (129 women, 41 men, aged 21-83). Across the studies, preliminary themes were found: worries and fear (increasing symptoms, worries the disease, safety), awareness of PA (knowledge, information, discussion), social support (competence, guidance, demands, joy), effects on health (retain independence, decrease symptoms, coping with the disease), body awareness (adaptation, pacing, listen to the body, self-efficacy) and determination (motivation, focus, goals, priorities, responsibility). A preliminary synthesis was performed and the continuous interrelation between the themes and the disease itself was described.

Conclusion: It is important that the promotion of PA in individuals with RA is in line with individual challenges and resources, in order to enhance adoption and maintenance of PA behavior. In RA, the disease seems to pervade all aspects related to the individuals’ perception of physical activity. Strategies to enhance this behavior should therefore include minimizing negative perceived consequences of physical activity by raising both cognitive and physical awareness. Another strategy could be focusing on finding proper social support either within health care or preferably outside of health care but with a sense of affinity. Finally, strengthening the individual’s ability to use self-regulation strategies to overcome barriers should be emphasized.

FR0729-HPR | LIVING EVERY-DAY LIFE IN THE SHADOW OF PAIN OR LIVE EVERY-DAY LIFE WITH THE PAIN IN THE SHADOW – A CONSTANT BALANCING
Malin Westergård1, Karolina AR2,3*, Ingri Larson2,3.1Karolinska University, School of Health and Welfare, Halmstad, Sweden; 2RandD Spenshult, Halmstad, Sweden; 3Karolinska Institute, Unit of occupational medicine, Institute of Environmental Medicine, Stockholm, Sweden

Background: Approximately 10% of the population report chronic widespread pain (CWP), the condition is more common in women than in men. Long-term pain is a public health problem. For most women, the pain interferes with many aspects of every-day life and implies large consequences. Thus, knowledge about how to facilitate life for these women is important.

Objectives: To explore women’s experiences of how CWP influence their daily life.

Methods: The study has a latent qualitative content analysis design. Individual interviews were conducted in 19 women 45-67 of age, who had reported CWP in a survey 2016. CWP was defined according to the 1990 ACR criteria for fibromyalgia. Pain that had lasted for more than three months, during the last 12 months, was considered chronic. A latent qualitative content analysis was used to analyze the main questions “Can you describe your experiences of living with CWP?” and “How do the CWP influence your life today?” The interviews were recorded, transcribed verbatim and coded into eight subcategories and three categories; represent the manifest content, and a latent theme exploring the interpreted content of women’s experiences of how CWP influence their every-day life.

Results: The interviewed women expressed a life with CWP as “Living every-day life in the shadow of pain” or “Living every-day life with the pain in the shadow” including three categories; the experience of alienation, limitations and plasticity.

1) The experiences of alienation appeared in the subcategories; suspicion and loneliness. Suspicion meant a feeling of not being seriously by healthcare and authorities and loneliness meant not being able to participate in social contexts. 2) The experiences of limitations in daily life includes the subcategories; barriers, stress, and dependence of other people. Barriers meant that fatigue limits the activities in every-day life, stress that constitutes limitations in life and dependence of other people’ support. 3) The experiences of plasticity referred to the subcategories resignation, adjustment and resistance. Resignation meant refraining from activities that could affect the pain, such as gardening, walking and dancing. Adjustment were manifested by making the best of the situation, and resistance meant to resist letting the pain set the terms, to give the pain a fight.

Conclusion: Women with CWP have to deal with their physical, mental, social and spiritual environment in every-day life. They express a constant balancing in their life between mastering the pain in order to continue living as normal, and allowing the pain to set the terms, i.e. living every-day life in the shadow of pain or live every-day life with the pain in the shadow. Healthcare professionals may consider supporting the patients in finding their individual counterweight to manage life in order to reach better treatment outcome.
Background: Pts with systemic lupus erythematosus (SLE) have an increased risk for cardiovascular diseases (CVD) that cannot be explained by traditional risk factors only. Its relevant to search novel cardiovascular risk markers in those pts.

Objectives: We aimed to evaluate carotid atherosclerosis presence in females with SLE and its relationship with traditional and nontraditional cardiovascular risk factors.

Methods: 52 females with low-activity SLE (the median age – 48.2 [41.8; 52.9] years, the median duration of SLE 89.4 [68.9; 101.5] month) without verificated coronary artery disease were enrolled. Control group included 30 pts without SLE compared by risk factors profile. The cardiovascular risk was calculated using SCORE. The total cholesterol (TC), lipoproteins, triglycerides (TG) were measured in the blood. Carotid ultrasound, endothelial-dependent flow mediated vasodilatation (EDVD) by D. Celemajer method were performed. In all pts was calculated body mass index (BMI) and measured blood pressure (BP). All pts received steroid therapy.

Results: High levels of TC, LDL and TG were in 55.8%, 61.5% and 25% of pts with SLE (the median levels 5.9 [5.2; 6.4] mmol/l, 4.1 [3.7; 4.8] mmol/l and 1.8 [1.3; 2.4] mmol/l respectively). The obesity and hypertension were estimated in 51.9% and 63.5% respectively (median BMI – 31.6 [28.4; 33.2] kg/m^2, median systolic BP – 154.2 [138.4; 162.3] mm Hg, median diastolic BP – 90.2 [82.4; 93.7] mm Hg). EDVD was impaired in 32.6% pts with SLE and 16.7% control pts (p<0.05). Carotid atherosclerosis was established in 41 (78.8%) pts with SLE and 48 (54%) control group pts (p<0.05). The majority of pts with SLE have stable carotid atherosclerotic plaques - 32 (61.5%), unstable plaques - 6 (11.5%) pts, in control group – 10 (33.3%) and 2 (6.7%) pts respectively. In the same time the median cardiovascular level matched by SCORE was 2.1 [1.5; 2.9]% in females with SLE, in control group - 1.8 [1.3; 2.5]% (p<0.05). The presence of carotid atherosclerotic plaques in females with low-activity SLE was associated with endothelial dysfunction (OR=2.5, p<0.002), obesity (OR=1.5, p<0.004), duration of steroid therapy (OR=2.8, p<0.0005).

Conclusion: Females with low-activity SLE and moderate cardiovascular risk level are characterized by high frequency of carotid atherosclerosis. The carotid ultrasound may be useful additional tool for the evaluating of cardiovascular risk in these patients.

SAT0001
FOSL-2 IS A REPRESSOR OF FOXP3 EXPRESSION DURING TREG DEVELOPMENT AND CONTROLS AUTOIMMUNITY

Florian Renoux1, Mara Stellato1, Alexander Vogtsgeder2, Ruying Huang3, Arun Subramaniam3, Przemyslaw Bliszczuk4, Jörg Distler1, Gabriela Kania1, Onur Boyman1, Olof Karlsson1, Jörg Distler1. 1Center of Experimental Rheumatology, University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland; 2Luzerner Kantonsspital pathology, Lucerne, Switzerland; 3Immune Mediated Diseases, Sanofi-Genzyme, Framingham, United States of America; 4Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany; 5Department of Clinical Immunology, Zurich, Switzerland

Background: Fos like 2 (Fosl-2) is a transcription factor belonging to the AP-1 transcription complex. We have recently described a Fosl-2 transgenic (tg) mouse model which develops a multi-organ inflammatory and autoimmune phenotype. In these mice, we have characterized a decrease in regulatory T cells (Tregs), which preceded the activation of T cells and the development of inflammation.

Objectives: To analyze how Fosl-2 reduces the Treg population and triggers autoimmunity in Fosl-2 tg mice.

Methods: We used previously generated Fosl-2 tg overexpressing and Fosl-2 T cell specific knock out (Fosl-2 ko) mice. For mixed bone marrow transfer experiments, lethally irradiated recipients received a one to one mix of Fosl-2 tg (CD45.2) and wt (CD45.1) bone marrow to create Fosl-2 tg-wt chimera. We addressed the contribution of Tregs to the inflammatory phenotype by co-transferring Fosl-2 tg CD4 T cells and wt Tregs to Rag2-/- recipient mice. Tregs and T cell populations were analyzed by flow cytometry and inflammation was addressed by CD45 staining on paraffin-embedded sections. RNA-sequencing was used to compare wt, Fosl-2 tg and Fosl-2 ko CD4 T cells 24 hours after stimulation with anti-CD3 (2 μg/ml) and anti-CD28 (2 μg/ml).

Results: We first addressed whether Fosl-2 affected Tregs in a cell intrinsic way using mixed bone marrow experiments. In these animals, the CD45.2 Fosl-2 tg CD4 T cells showed a much lower proportion of Tregs compared to the CD45.1 wt population, both in the spleen (0.73%±0.15 vs. 31.6%±3.6, P=0.002) and thymus (1.3%±0.04 vs 3.23%±0.78, P=0.001). This demonstrates that Fosl-2 overexpression represses Treg development in a cell intrinsic way.

In T cell transfer experiments, Rag2-/- mice receiving 10^6 Fosl-2 tg CD4 cells developed lung inflammation 5 weeks after transfer, confirming that T cells are inducers of inflammation in Fosl-2 tg mice. Moreover, co-transfer of either 3*10^6 or 10^7 wt T cells resulted in a dose dependent reduction of inflammation. These data indicated that the decrease in the Treg population in Fosl-2 tg mice is responsible for the induction of inflammation.

We then analysed Fosl-2 transcriptional targets in T cells by RNA-seq. Using a fold change > 1.5 and False Discovery Rate (FDR) of 0.05, we identified 191 differentially expressed genes in both Fosl-2 tg and Fosl-2 ko cells compared to wt. Interestingly, one of the top target genes of Fosl-2 was Foxp3. This unbiased approach thus revealed that Foxp3 expression is repressed by Fosl-2, with a 6.5 fold reduction in Fosl-2 tg cells and a 2.5 fold increase in Fosl-2 ko cells. This effect was confirmed on the protein level with a reduction in Foxp3 induction in Fosl-2 tg cells treated with TGFβ. The repression of Treg development observed in Fosl-2 tg mice could thus be explained by a direct transcriptional control of Foxp3 expression. Additionally, we found that Fosl-2 repressed a set of genes known to be important for Tregs and other T helper cells. This included Nr4a2, a transcription factor involved in Treg development, IRF8 and Eomes, two genes involved in the polarization of Th1 and Th17 cells, or Ccl1 a chemokine important for Treg homeostasis.

Conclusion: Fosl-2 is involved in the control of Foxp3 expression in T cells. Through this, overexpression of Fosl-2 represses Treg development and induces a Treg dependent autoimmune phenotype in mice. This mechanism could thus be involved in the pathogenesis of autoimmune diseases and might represent a therapeutic target to modulate the Treg population.

References

Background: We previously showed PIM1, among other STAT3-target genes, to be strikingly upregulated in circulating CD4+ T cells of treatment-naïve ‘early’ rheumatoid arthritis (eRA) patients. PIM1 has a recognized role in T cell development, has been implicated in the pathogenesis of autoimmune disorders, and is the target of specific inhibitors in clinical development in oncology; for example PIM1 was recently identified as a promising target in triple-negative breast tumours.

Objectives: We sought to understand the relevance of dysregulated PIM1 gene transcription for T-cell pathobiology during disease initiation and to determine the effects of its inhibition on T cell function. We hypothesised that, amongst a readily-identifiable, high PIM1 expressing subgroup of eRA patients, PIM1 overexpression in CD4+ T cells is a targetable early event in pathogenesis that lies downstream of STAT3-mediated IL-6 signalling.

Methods: Peripheral blood was obtained from consenting treatment-naïve arthritis patients or healthy donors and highly pure CD4+ T cells were isolated. PIM1 knock-down (SMARTpool siRNA, Dharmaco) or protein inhibition (small molecule inhibitors; PIM1-selective TCS-PIM-1, Tocris and panPIM AZD1218) was undertaken. Flow cytometric analysis was then used to assess activation and proliferation following CD3/CD28-mediated stimulation.

Results: In eRA, ex vivo CD4+ T cells exhibited an activated, hyper-proliferative phenotype compared to those isolated from healthy donors. Significantly higher PIM1 mRNA expression in CD4+ CD4+ T cells was seen using PrimeFlow (flow cytometry) compared to that of other inflammatory arthritides. Both PIM1 knock-down, PIM1-specific and panPIM inhibition decreased the activation and proliferation of stimulated eRA (Figure 1A) and healthy donor CD4+ T cells. Moreover, in eRA, PIM1 and panPIM inhibition increased FoxP3 expression (Figure 1B) and increased the proportion of regulatory T cells (Figure 1C).

Conclusion: Taken together, these data implicate PIM1 as prominent among genes whose induction may ‘pre-programme’ CD4+ T cells to function aberrantly in disease. Conceivably, targeting PIM1 may prove an attractive approach to regulating aberrant CD4+ T cell effector function in an identifiable sub-population of early RA patients that exhibit high CD4+ T cell PIM1 expression in their peripheral blood.

DETECTION OF HIGHLY EXPANDED T CELL CLONES IN THE PERIPHERAL BLOOD OF AT RISK INDIVIDUALS FOR RHEUMATOID ARTHRITIS BEFORE THE CLINICAL ONSET OF THE DISEASE

Céline Lamacchia1, Zuleika Caldén1, Delphine Courvoisier1, Denis Mongin1, Stéphane Buher1, Gaby Palmer1, Olivia Studé1, Cem Gabay1, Jean Villard1, Axel Finchi1
1University Hospitals of Geneva, Geneva, Switzerland

Background: Rheumatoid arthritis (RA) is an autoimmune disease with unknown etiopathogenesis. Systemic autoimmunity precedes clinical disease onset, and current evidence suggests that the immune onset of RA takes place out of the joints several years before clinical manifestations. Expanded T cell clones can be found in the synovial tissue of established RA patients. The mechanisms by which systemic immune abnormalities progress to joint-specific autoimmunity are not yet understood.

Objectives: To examine if expanded T cell clone signatures can be detected in the peripheral blood before the development of clinical RA.

Methods: Next-generation sequencing of the T Cell Receptor β (TCRβ) CDR3 repertoire was performed on genomic DNA isolated from blood samples of individuals genetically at risk for RA, namely first-degree relatives of RA patients (RA-FDR) at different pre-clinical phases of disease development (SCREEN-RA cohort), and of matched RA patients used as a control group (SCQM cohort). All individuals were matched for age and sex, and categorized into four groups (n=20/group): Group 1: healthy asymptomatic RA-FDR without autoantibodies or symptoms associated with possible RA. Group 2: Asymptomatic RA-FDR with evidence of systemic autoimmunity associated with RA defined by high levels of anti-citrullinated peptide antibodies (ACPA; 3x> ULN). Group 3: RA-FDR having presented undifferentiated arthritis (n=8) or having developed classifiable RA after inclusion (n=12). Group 4: patients with established RA of less than 3 years duration. T cell clones were identified by their unique TCRβ CDR3 sequence. Clones with a frequency over 0.5% were considered to be highly expanded clones (HEC). Both absolute number and frequency of productive T cell clones was compared between the 4 groups using mixed effect regression models to account for matching.

Results: As expected, the large majority of clones in the peripheral blood were detected at very low frequency (<0.1%) in all groups (Figure 1A). Interestingly, expanded clones (>0.1% of total TCR analysed) tended to occur more frequently in later preclinical phases and established disease. A significant difference among groups was observed for highly expanded clones (HEC) (p=0.001). Specifically, the absolute number of HEC was significantly higher in RA patients (group 4; mean 4.65, p=0.003) and tended to be higher in symptomatic RA-FDR (group 3; mean 3.4, p=0.07) compared to “healthy” RA-FDR (group 1; mean 1.55, Figure 1B). A trend towards a higher frequency of the top 50 expanded clones was also observed in symptomatic RA-FDR (group 3; mean 0.17%) compared to “healthy” RA-FDR (group 1; mean 0.11%). At risk individuals defined by the presence of high ACPA levels (group 2) did not differ from “healthy” RA-FDR in terms of absolute number and frequency of clones.

Conclusion: For the first time, highly expanded T cell clones were detected in the peripheral blood of at risk individuals before the clinical onset of RA, in particular in the later pre-clinical phases of RA development. Tracking these dominant T cell clones in longitudinal analyses and elucidating their role might help to better understand the earliest pathogenic events in RA.

REFERENCE

(n=8) were analysed by flow cytometry. Intrasubject differences were assessed by paired parametric t tests and comparison with PBMC from HV (n=6) by unpaired parametric t test. Parametric data are reported as mean differences (MD) [95%CI]. P values < 0.05 were considered significant.

Results: Among memory prone T cells (CD3+CD4+CD45RO+) in SFMC, the percentage of Tim-3+ cells was increased compared with similar gated PBMC from patients (MD 17.4%, [10.7;24.1], p<0.005) and HV (MD 12.9%, [4.1;21.8], p=0.007). In the joint, more of these Tim-3+ cells co-expressed PD-1 compared with similar gated PBMC (MD 42.8%, [27.8;57.9], p<0.005) (Figure 1). On average, sTim-3 plasma levels were higher in eRA compared with HV (MD 4.6 ng/ml, [3.3;5.9], p<0.005) (Figure 2). In eRA, baseline sTim-3 levels correlated with DAS28CRP (rho=0.28, p=0.048), eRA patients with TSS progression within 24 months of treatment decreased more in plasma sTim-3 during 3 months of treatment compared with patients without TSS progression (median [progression] -1.4 ng/ml, median [no progression] -0.5 ng/ml (U=649.5), p=0.048). The decrease in plasma sTim-3 was not influenced by treatment (median [MTX+ADA] -1.2 ng/ml (U=1015), p=0.4). In SF, sTim-3 levels were increased compared with plasma (MD 37.4 ng/ml, [26.3;48.4], p<0.0001).

Conclusion: Tim-3 expression is upregulated in memory prone T cells in RA joints and the majority co-express PD-1. Levels of sTim-3 are increased in SF. In eRA, baseline sTim-3 plasma levels are elevated and correlate with DAS28CRP. Decrease of sTim-3 during treatment associates with future radiographic progression. We suggest, that Tim-3 expression in memory T cells increased compared with patients without TSS progression (median [progression] -1.4 ng/ml, median [no progression] -0.5 ng/ml (U=649.5), p=0.048). The decrease in plasma sTim-3 was not influenced by treatment (median [MTX+ADA] -1.2 ng/ml (U=1015), p=0.4). In SF, sTim-3 levels were increased compared with plasma (MD 37.4 ng/ml, [26.3;48.4], p<0.0001).

IL-23 DRIVES PATHOGENIC TH17 CELLS THROUGH EPIGENETIC REGULATION BY STAT3 IN SLE PATIENTS

Lee Seunghyun1, Shingo Nakayamada1, Satoshi Kubo1, Yamagata Kaoru2, Kitanaga Yukifiro3, Yoshiya Tanaka1. University of Occupational and Environmental Health, Japan; School of Medicine, Kitayushu, Japan; Astellas Pharma Inc, Tokyo, Japan.

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by loss of self-tolerance and by broad immune dysregulation, which result in overproduction of autoantibody and immune complexes, leading to the development and progression of SLE. Mechanism underlying their pathogenicity remains widely elusive in human.

Methods: Human naive CD4+ T cells were cultured by Th17 polarizing condition (TGF-β, IL-6, and IL-1β) for 5 days in vitro. To examine the role of specific cytokine, we measured the expression of IL-23 in the response to Th17 cells. We added various cytokines including IL-23 at the late time point (72h), Expression of characteristic markers of pathogenic Th17 cell and STATs phosphorylation (p-STATs) were analyzed by flow cytometry and qPCR. The effect of baricitinib which is Jak1/2 inhibitor on maturation of Th17 cell was investigated. Histone modifications were assessed by chromatin immuno-precipitation (ChIP)-PCR. To define the signals mediated by cytokine required for expansion of Th17 cell in SLE, Th17 phenotype and pSTATs were analyzed from blood samples of lupus patients by multi-color flow cytometry.

Results: In vitro, re-stimulation of Th17 cells with IL-23 markedly induced the characteristic markers of pathogenic Th17 cells such as RORγt and IL-17. IL-23-orientated cytokine response drives p-STAT3, not p-STAT4 for development of mature Th17 cells. IL-23-induced p-STAT3 was inhibited by baricitinib. In addition, proliferation of Th17 cells was suppressed by baricitinib in concentration-dependent manner. The loci of RORγt at STAT binding sites were marked by bivalent histone modifications. After IL-23 stimulation, STAT3 exclusively bound on RORγt gene loci supplemented by activating H3K4me3 and repressing H3K27me3 modifications. In memory Th17 cells, high proportion of IL-23R expression and STAT3/4 activation were identified from SLE patients compared with healthy individuals. Moreover, p-STAT3 was hypersensitively activated by IL-23 stimulation in memory Th17 cell only from lupus patients but not from healthy controls.

Conclusion: This study proves that IL-23 serves as a pivotal factor that drives expansion of pathogenic Th17 cells. IL-23-mediated STAT3 alter histone modification, resulting in inflammatory function of pathogenic Th17 cell that are characteristic in patients with SLE. These findings could be one of the underlying mechanisms of pathogenesis of SLE and helpsful evidence toward novel therapeutic targets for SLE.

THE EFFECT OF FCGR3A POLYMORPHISM ON THE INITIAL DEPTH OF B-CELL DEPLETION BY RITUXIMAB, FUNCTIONAL NK-CELL MEDIATED KILLING AND CLINICAL RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOSUS

Md Yuazulif Md Yusuf1,2, James Robinson1, Yasser El-Sherbiny3, Andy C. Rawstron1, Paul Emery1,2, Ann Morgan1,2, Edward Vital1,2. University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 3Leeds Teaching Hospitals NHS Trust, Haematological Malignancy Diagnostic Service, Leeds, United Kingdom

Background: Antibody-dependent cellular-mediated cytotoxicity (ADCC) is an important effector mechanism that contributes to the depletion of therapeutic antibody-opsonised cells in vivo. Rituximab (RTX) is an anti-CD20 antibody with a native IgG1 Fc, which crosslinks Fc receptors (FcγRs) expressed on immune effector cells. NK cells, which express FcγRIIIa, are believed to play an important role with less-well-characterised contribution from monocytess/macrophages and neutrophils. A genetic variant in FCGR3A (158V) with an increased affinity for IgG1 has been reported to correlate with clinical response to RTX in RA[1]. Data in SLE are limited as the FCGR locus is characterised by structural variation making genotyping challenging.

Objectives: To assess the effect of FCGR3A-F158V polymorphism on (i) the initial depth of B-cell depletion by RTX; (ii) its functional effect on NK cell-mediated killing (iii) clinical response and (iv) 10-year RTX retention for the treatment of SLE.

Methods: A prospective longitudinal study was conducted in RTX-treated SLE patients in Leeds. B-cells were measured at baseline and 6 weeks using highly sensitive flow cytometry. Complete depletion was defined as total B-cell count<0.001 x 10^9/L. A major clinical response (MCR) was defined as improvement of all active BILAG-2004 domains to grade C/better and no A/B flare at 6 months. We measured qualitative polymorphism for FCGR3A using a multiplex ligation-dependent probe amplification as previously described[2]. Median expression of FcγRIIIa on NK cells in the presence of RTX-coated Raji cells (B-lineage cell line) were assessed using flow cytometry.

Results: 85 SLE patients with at least 2 x BILAG B were studied [Female: 82(96%); mean age (SD): 40(14) years; 60(71%) on concomitant DMARDS; ANA positive: 100%]. In cycle 1 RTX, 64/85(75%) achieved BILAG response [major=36%; partial=39%]. Both complete depletion and MCR were associated with carriage of the FCGR3A allele (158FV or 158VF), OR 2.73 (95% CI 1.13-6.58) and 3.06 (95% CI 1.19-7.58) vs 158FF, respectively. Patients who had complete B-cell depletion post-RTX had higher level of FcγRIIIa on NK cells vs incomplete depletion; p=0.006. Comparing patients with FCGR3A-158V allele carriage vs FF genotype, there was a trend to higher expression of CD3-CD56-CD16+ in the former p=0.073. Moreover, degranulation as defined by ratio between%CD107a+NK cell in Raji cells vs incomplete depletion; p=0.006. Comparing patients with FCGR3A-158V allele carriage vs FF genotype, there was a trend to higher expression of CD3-CD56-CD16+ in the former p=0.073. Moreover, degranulation as defined by ratio between%CD107a+NK cell in the presence of Raji cells + RTX and%CD107a+NK cell in Raji cells only, was higher in the V allele carriers vs FF genotype; p=0.024. Over 10-year follow-up, 27/85 (31.8%) had stopped RTX [primary inefficacy=7; secondary inefficacy=8; HACA=10; death=2]. FCGR3A-158FF genotype was associated with increased risk of RTX discontinuation; OR 2.36 (95% CI 1.08-5.18) after adjusting for age and DMARDS.

Conclusion: An ADCC-enhancing FcγRIIIa variant was associated with initial complete B-cell depletion and MCR in RTX-treated SLE patients. This was supported by functional data on NK cell-mediated cytotoxicity and 10 year outcomes. These results elucidate one mechanism of resistance to rituximab in SLE and may guide development of more effective B-cell targeted strategies. With further validation, this polymorphism may be used to stratify SLE patients for therapy.

SA0010
FUNCTIONAL BIOMARKER DEVELOPMENT FOR CELL- BASED THERAPY IN RHEUMATOID ARTHRITIS

Maya Breitman1, Tracey Bortfeld2, Susan Lasalvia1, Hillard Lazarus1, Arnold Caplan1, Nora Singer1. 1MetroHealth System at Case Western Reserve University, Medicine division of rheumatology, Cleveland, United States of America; 2Case Western Reserve University School of Medicine, Cleveland, United States of America; 3Case Western Reserve University School of Medicine, University Hospitals Cleveland Medical Center, Cleveland, United States of America; 4Case Western Reserve University School of Medicine, Skeletal Research Center, Cleveland, United States of America.

Background: Rheumatoid Arthritis (RA) is an autoimmune disease in which faulty treatment prevents joint damage. Autoantibodies such as rheumatoid factors (RF) and anti-citrullinated peptide antibodies (APCA) define a subset of RA patients at the highest risk for damage. Reduction of RA disease activity is associated with improvement in function(s) of regulatory T cells (Treg) and attenuated responses of pro-inflammatory T effector cells (Teff). Human Mesenchymal Stem Cells (hMSC) isolated from bone marrow and culture-expanded have strong immunomodulatory properties; we hypothesize that therapeutic use of hMSC may skew the immune system to resemble its pre-RA state. Lack of available biologic correlates measured early-on that indicate response to treatment limits efficacy assessment of cell-based therapy. Use of clinical response criterion requires large numbers of patients and may be impractical in early stage clinical trials. This work was performed in anticipation of conducting a Phase I safety trial of cell-based therapy in early RA.

Objectives: We set out to develop functional assay(s) as biomarkers of response that would indicate early-on that hMSC were or were not modulating immune function in a manner that could potentially predict potency and efficacy in RA patients.

Methods: Sero-positive female patients with active early RA (RAPID 3 avg 5.7/10 (high severity)) and healthy donor age and sex-matched controls were enrolled. Second passage bone marrow hMSCs were obtained from healthy donors < 30 y.o. (Case Comprehensive Cancer Center Hematopoietic Biorepository and Cellular Therapy Core), Peripheral blood CD4+ T cells were stimulated by cross-linking CD2/CD3/CD28 for 5 days. CD4+ T-cell proliferation rates were measured, and suppression indices defined a subset of RA patients at the highest risk for damage. Autoantibodies such as rheumatoid factors (RF) and anti-citrullinated peptide antibodies (APCA) define a subset of RA patients at the highest risk for damage. Reduction of RA disease activity is associated with improvement in function(s) of regulatory T cells (Treg) and attenuated responses of pro-inflammatory T effector cells (Teff). Human Mesenchymal Stem Cells (hMSC) isolated from bone marrow and culture-expanded have strong immunomodulatory properties; we hypothesize that therapeutic use of hMSC may skew the immune system to resemble its pre-RA state. Lack of available biologic correlates measured early-on that indicate response to treatment limits efficacy assessment of cell-based therapy. Use of clinical response criterion requires large numbers of patients and may be impractical in early stage clinical trials. This work was performed in anticipation of conducting a Phase I safety trial of cell-based therapy in early RA.

Objectives: We set out to develop functional assay(s) as biomarkers of response that would indicate early-on that hMSC were or were not modulating immune function in a manner that could potentially predict potency and efficacy in RA patients. Serial serum from healthy donors and RA patients were studied in vitro to determine if hMSC-conditioned medium could modulate cell activity. hMSC were cultured with and without hMSC-conditioned medium. Results: hMSC-related suppression 32.2 ±7.8 (mean +/- SE) percent in RA CD4+ T-cells compared to 45.7± 8.9 percent for healthy donors CD4+ T cells. We demonstrated that soluble products from hMSC can inhibit proliferative responses of CD4+ T cells from patients with active RA though the studies were not powered to detect differences between RA and healthy donors. With limited number of early RA patients, correlation between level of MSC-related suppression and antibody status were not possible. That being said, the data trend appears promising.

Conclusion: Our ex vivo experiments demonstrated that hMSCs may be suppressive in RA as well as in healthy donors. To our knowledge, this study is the first demonstration of the potential for using ex vivo suppression assays to predict response to cell-based therapy in early RA. Such assays might be performed to predict the efficacy of selected hMSCs to treat RA.

SAT0011
TRANSCRIPTOMICS UNVEILS UNIQUE BIOLOGICAL PROFILE OF TERTIARY LYMPHOID STRUCTURES GERMINAL CENTERS

Sergina Colallrancesco1, Elena Pip2, Saba Nayary3, Joana Campos2, Valentina Iannizzotto1, Francesca Arienzo1, Roberta Priori1, Guido Valesini1, Benjamin Fisher2, Francesca Barone2, Sapienza University of Rome, Rome, Italy; 2University of Birmingham, Birmingham, United Kingdom.

Background: The development of the B cell repertoire is regulated by the process of affinity maturation occurring within the inner part of the B cell follicles [germinal centers (GCs)] within secondary lymphoid organs (SLOs). In autoimmunity, this process might occur within aberrant aggregates of lymphocytes in target organs, such as the ectopic lymphoid structures (ELS) found in the salivary glands of patients with Sjogren’s Syndrome (SS) (1). The phenotypical and functional features supporting ELS which may sustain the development of autoimmune diseases have not been identified. Moreover, functional proof that ELS contribute to the development of autoimmunity independently from SLOs has not been provided.

Objectives: To characterise the transcriptome profile of human ELS isolated from SS salivary glands in comparison with SLOs.

Methods: Frozen minor salivary gland biopsies were obtained from SS patients and selected for presence of GCs+ ELS. Human tonsils were obtained by volunteers undergoing tonsillectomy for clinical need and used as SLO control. In order to detect GCs, all samples were stained for CD21, bcl6, CD20 and CD3. Sequential sections, were stained by Cressyl Violet and GCs (CD21+ infiltrates) from both salivary glands and tonsil were selectively microdissected (Laser Capture Microdissection). Salivary gland small infiltrates and large CD21- infiltrates were microdissected too. RNA was isolated and transcribed. RNA sequencing studies were performed using ClonTech SMARTseq v4 kit. Changes and differences in the expression of specific genes of interest were confirmed with targeted PCR studies.

Results: Transcriptomics analyses revealed that GCs from ELS and SLO exhibit markedly different gene expression profiles. Of note, sequencing unveiled that GCs from ELS are characterized by an aberrant cell-proliferation profile with downregulation of BCL6 and AID, the enzymes responsible for B cell affinity maturation (both p<0.0001). Also in ELS, progressive upregulation of CD21 transcript mirrored increases in infiltrate size and organization (being lowest in small infiltrates and progressively higher in large CD21+ infiltrates, p=0.002). Similar data were obtained for AID, whose expression was significantly higher in large CD21+ infiltrates compared to small infiltrates (p=0.0006). A cytokine signature was identified in ELS GCs based on the expression of TNF, INFγ, BAFF, APRIL, CXCL12, CXCL13, FAS, and FASL, all of which were upregulated compared to GCs from tonsils.

Conclusion: Our studies reveal that GCs forming in ELS exhibit marked transcriptional differences from classic GCs observed in SLOs. Main features characterizing ELS include lower levels of Bcl6 and AID, aberrant apoptosis, and a pathogenic inflammatory cytokine signature. Despite similarities in the anatomical organization and appearance of GCs in ELS and SLO, critical transcriptional differences emerge, which are likely functionally implicated in impaired regulation of the B cell cycle and survival of autoreactive B cell clones, ultimately leading to the development of autoimmune disease.

DISTRIBUTION OF CIRCULATING PR3-SPECIFIC B CELLS IN PATIENTS WITH ACTIVE ANCA-ASSOCIATED VASCULITIS

Divu Conne1, Alvise Berti2, Amber Hummel3, Eva Carmona4, Tobias Peiker4, Carol Langford5, Paul Monach6, Peter Merkel7, Philip Seo8, Robert Spiera9, E. William St. Clair10, Fernando Fervenza11, Kristina Harris1, John H. Stone12; Jacques-Olivier Pers13, Peter Heeringa14, Wayel Abdulahad15, Ulrich Specks16

OBJECTIVES: To determine CD4+CD25+Foxp3+T regulatory (Treg) cell levels in peripheral blood (PB) of patients with autoimmune diseases (AID) and age- and sex-matched healthy controls, and to explore the correlation between the levels of peripheral Treg cells and clinical parameters in AID.

Methods: A total of 1561 AID patients, and 196 age- and sex-matched healthy controls were enrolled. The absolute numbers of CD4+CD25+Foxp3+Treg and other T subsets [total T, CD4+T, CD8+T, T helper 1 (Th1), T helper 2 (Th2), and T helper 17 (Th17) cells] in PB were measured by Flow Cytometer (FCM). Erythrocyte sedimentation rate (ESR) was analyzed by the Westergren method. Serum concentrations of C-reactive protein (CRP) were measured by monoclonal immunoassay.

Results: The absolute numbers of Treg cells in PB of patients with AID [22.90 (18.31, 36.47); p<0.05], which was also seen in rheumatoid arthritis (RA), Sjogren’s syndrome (SS), systemic lupus erythematosus (SLE), systemic vasculitis (SV), idiopathic inflammatory myopathy (IIM) and other diseases. The levels of CD4+T, Th1/Treg, and Th2/Treg in PB of AID patients were higher than those of healthy controls. (2) The absolute numbers of most T cell subsets in PB of most AIDs were lower than those of healthy controls, but the Treg cells were greatly decreased, significantly. The ratio of Treg to other T lymphocyte subsets were higher than those of healthy controls. (3) The levels of inflammatory indicators were inversely associated with numbers of Tregs, total T, CD4+T, CD8+T, Th1 and Th17/Treg cells.

Conclusion: The absolute numbers or function of CD4+CD25+Foxp3+Treg cells were decreased, so it cannot effectively maintain immune tolerance or inhibit inflammatory response, which may be one of the important mechanisms of disease. Treatment promoting CD4+CD25+Foxp3+Treg cell function may become a new strategy for AID therapy.

DECREASED CIRCULATING CD19+CD24+CD38hi REGULATORY B CELLS IN ACPA POSITIVE RHEUMATOID ARTHRITIS: EFFECT OF IL-6 RECEPTOR BLOCKADE

Paula Fortea-Gordo1, Alejandro Villalva1, Laura Nuño1, María-Jose Santos-Bornez1, Irene Monjo1, Diana Peleleado2, Amaya Puig-Kröger1, Paloma Sanchez-Mateos2, Alejandro Balsa1, Maria-Eugenia Miranda-Carus1,1.

1 Hospital La Paz – IDIPAZ, Rheumatology, Madrid, Spain; 2 Gregorio Marañón Hospital, Immunology-Oncology, Madrid, Spain

Background: CD19+CD24+CD38hi B cells have a regulatory capacity and their frequency is altered in the peripheral blood of patients with various autoimmune conditions, including RA.

Objectives: To determine the frequency of circulating CD19+CD24+CD38hi regulatory B cells (cBreg) in ACPA vs ACPA- patients with RA, and its possible modification by IL-6R blockers.

Methods: Peripheral blood was drawn from ACPA+ (n = 37) or ACPA- (n = 19) RA patients treated with conventional synthetic DMARDs (csDMARDs), and from ACPA+ (n=31) or ACPA- (n=12) RA patients treated with tocilizumab; in addition one age and gender-matched healthy control was studied alongside with each patient (n= 99). After isolation by Ficol–Hypaque gradient, PBMCs were stained with antibodies to CD3, CD4, CD19, CD24, and CD38, and examined by flow cytometry.

Results: A decreased frequency of cBreg cells was observed in ACPA+ but not ACPA- RA patients treated with csDMARDs. Interestingly, the frequency of Breg cells showed a significant negative correlation with ACPA titers (r = -0.44, p = 0.021). In contrast, no correlation was found between the frequency of cBreg cells and either RF titres or disease activity as determined by the DAS28 score. However, not only in ACPA+ but also in ACPA- patients receiving tocilizumab, the percentage of cBreg cells was not different from that observed in HC. Four ACPA+ patients treated with csDMARDs who initiated tocilizumab, demonstrated a significant elevation of their cBreg frequency at 12 months.

Conclusion: A decreased frequency of cBreg cells is apparent in ACPA+ but not ACPA- RA patients receiving csDMARDs, that is related with ACPA titres but not with RF titres or disease activity. In contrast, in ACPA+ patients treated with tocilizumab, the frequency of CD19+CD24+CD38hi B cells is comparable to that observed in HC, suggesting that IL-6R blockade is able to modify the altered Breg cell balance.

SAT0015 TREATMENT WITH ABACETAPDT BUT NOT WITH TNF BLOCKERS, IS ASSOCIATED WITH A REDUCTION OF CONSTITUTIVELY ELEVATED CIRCULATING FOLLICULAR HELPER T CELLS IN RHEUMATOID ARTHRITIS

Paula Fortea-Gordo, Laura Nuño, Alejandro Villalva, María-Jose Santos-Bornez, Diana Peleleado, Irene Monjo, Alejandro Balsa, Maria-Eugenia Miranda-Carus.

Hospital La Paz – IDIPAZ, Madrid, Spain

Background: Circulating CD4 T cells that express CXCR5 together with PD-1 and/or ICOS are considered as counterparts of bona fide Th cells and function as B cell helpers. In addition, circulating CD4+CXCR5+PD-1+ICOS+ T cells can be subdivided into three subpopulations: CXCR5+CXCR3+CCR6- (Th1-Th), CXCR5+CXCR3+CCR6+ (Th1-Th) and CXCR5-CXCR3-CCR6- (Th2-Th). Only Th1-Th and Th2-Th but not Th1-Th cells seem to provide B cell help. Altered frequencies of circulating Th cells (cTh) and of cTh cell subpopulations have been associated with autoimmune conditions. We previously described that patients with RA treated with conventional synthetic DMARDs (csDMARDs), demonstrate constitutively altered frequencies of cTh and cTh cell subpopulations that are observed not only in patients with an active disease but also in patients who are in remission.

Objectives: To determine if treatment with biological agents (TNF blockers or abactecept) is able to modify the constitutively altered cTh and cTh subpopulation numbers, observed in RA patients receiving csDMARDs.

Methods: Peripheral blood was drawn from RA patients receiving csDMARDs (n=22), TNF blockers (n=21: 10 infliximab, 6 etanercept, 3 certolizumab, 2 adalimumab), or abactecept (n=17). For each patient, an age and gender-matched healthy control was also studied (n=60). cTh and plasmablast frequencies were determined by flow cytometry of freshly isolated PBMCs.

Results: As described, RA patients receiving csDMARDs demonstrated, whether they had an active or inactive disease, an increased frequency of CD4+CXCR5+PD-1+ and CD4+CXCR3+PD-1+ICOS+ cells, together with an increased frequency of circulating plasmablasts. In addition, the frequency of Th1-Th cells was significantly decreased and the frequency of Th1-Th1 and Th1-Th2 cells were significantly increased as compared with HC; subsequently, the ratio (Th1-Th17+Th1-Th2)/Th1-Th1 was increased in RA: that is, RA patients demonstrated a higher proportion of Th cell subsets bearing a phenotype associated with B cell helping capacity. Interestingly, these alterations were also observed in RA patients treated with TNF blockers, whether they had an active or inactive disease. In contrast, in patients receiving abactept, the frequencies of cTh, cTh cell subpopulations and plasmablasts, were not different from those observed in HC.

Conclusion: Patients with RA receiving csDMARDs or TNF blockers demonstrated a constitutively increased frequency of cTh cells and an overrepresentation of cTh subsets bearing a B cell helper phenotype, suggesting that altered germinal center dynamics play a role in RA pathogenesis. Remarkably, in RA patients treated with abactept these frequencies and ratio were not altered, indicating that costimulation blockage is able to revert the increased generation of Th cells in RA; conversely, TNF neutralization does not seem to affect the generation or recirculation of cTh.

SAT0016 RHEUMATOID ARTHRITIS PATIENTS DISPLAY B-CELL DYSREGULATION ALREADY IN THE NAÏVE REPERTOIRE

Yan Wang1, Katja A, Lloyd1, Ioannis Melas2, Daniel Ramköld2, Diana Zhou1, Radha Thayyarkan1, Karin Lundberg1, Lars Kläreskog1, Anca Catrina1, Stephen Rapecki2, Vivianne Malmström1, Caroline Grönwall1,1 Karolinska Institutet, Division of Rheumatology, Department of Medicine, Stockholm, Sweden; 2 UCB Pharma, Slough, United Kingdom

Background: Seropositive rheumatoid arthritis (RA) is associated with autoreactivity to citrullinated proteins and rheumatoid factor activity. The adaptive immune system and B cells are postulated to be central in RA pathogenesis, yet possible B-cell dysregulations have not been extensively studied. Here, we use exploratory mass cytometry and next generation sequencing to study overall B cell repertoire shifts in RA patients compared to healthy individuals.

Objectives: We hypothesized that there are an underlying B cells repertoire distortion in RA that may be an important key to understanding the autoimmune pathogenesis.

Methods: B cells enriched from PBMCs from nine ACPA pos., seven ACPA neg. RA patients, and six matched healthy controls were phenotyped with mass cytometry (CyTOF) using a 35-marker panel. Single cell data from all samples were pooled clustered via flowSOM in R to identify distinct cell populations, and visualized with ISNE. Cell numbers in each superpopulation were calculated to identify over-representation in patient groups or controls. ANOVA was performed to account for confounding factors.

Results: A decrease in naive B cell subset numbers was apparent in RA patients compared to healthy controls, with a trend towards a shift in the B cell repertoire in RA patients. RA patients showed an increase in the frequencies of plasma cells and a decrease in the frequency of naive B cells. RA patients also showed an increase in the frequency of CD27- B cells, which are likely to represent memory B cells.

Conclusion: These findings suggest that B-cell dysregulation occurs early in the course of RA, and may be an important contributor to the autoimmune pathogenesis.
Factors such as age, sex, and cell preparation date and differential expression of markers between groups was calculated via t-test. In parallel, PBMC B cell receptor (BCR) repertoires were investigated in 13 ACPA pos. RA patients and six age-matched healthy donors using the Illumina MiSeq platform and PCR multiplex amplification libraries with a molecular barcode strategy to generate full variable region coverage. Sequences were filtered using pRESTO, annotated by IMGT and Change-O, finally generating 587,000 unique V-regions. Total serum IgM levels were screened by sandwich ELISA in 157 population controls, 153 AC帕 pos., and 50 AC帕 neg. RA patients. Variable gene frequency was analyzed by Chi-square with Yates correction and serum IgM levels with Kruskal-Wallis test.

Results: Several B-cell phenotypes were found to be significantly different in AC帕 pos. RA compared to controls including an increase in HLA-DR across subsets, CD11c in IgM memory and CD22 expression in clusters of mature naïve IgM positive B cells. Moreover, we could see lower circulating cell counts in AC帕 pos. RA compared to healthy controls (p = 0.01) and trends for elevation in an CXCR5/CCR6 high transitional B cell cluster (p = 0.06), with parallel lower number of transitional B cells with lower CCR6 expression (p = 0.06). Notably, AC帕 neg. RA generally had an intermediate phenotype between healthy controls and AC帕 pos. RA.

Several significant shifts in the RA BCR repertoire could be observed, including an expected higher frequency of VH N-linked glycosylation in highly mutated B cells (p = 0.0001). Yet, the most striking difference was a significantly higher frequency of VH with low somatic hypermutation (SHM) levels in RA-derived B cells (<5 mutations, p = 0.0001, 14.7% vs 8.7). This was seen in all sequences, both IgM and class-switched, but was especially prominent in IgG1 rearrangements (9.6% vs 18.8% low mutation, p = 0.0001 OR = 2.2 CI: 2.0-2.35). In line with an IgM and low mutation profile in RA, we also observed that both AC帕 pos. (p = 0.0001) and AC帕 neg. (p = 0.001) RA patients have a significant increase in total IgM levels compared to controls (1.4 ± 0.7 vs 1.3 ± 0.7; 1.0 ± 0.6 mg/ml, respectively).

Conclusion: Previous studies have shown that anti-citrulline autoreactivity in RA is primarily originates from memory B cells and characterized by high somatic mutations and N-glycosylation sites. However, here the largest B-cell distortions in AC帕 positive RA are observed in the naïve B cell population that have not undergone germinal center responses. These differences result in extreme baseline shifts and elevated natural autoreactivity as an underlying mechanism in RA pathogenesis.

REFERENCE

BACKGROUND: Relapsing polychondritis (RP) is an rare inflammatory disease of unknown causes, characterized by recurrent inflammation in cartilaginous tissues of the whole body [1]. The histologic features of the disease include loss of basophilic staining of the cartilage matrix, perichondrial inflammation, cartilage destruction with replacement by fibrous tissue, and perivascular cellular infiltration with plasma cells and lymphocytes. Additional clinical features of the disease include ocular inflammation, vasculitis, audiodesribular dysfunction, myocarditis, cardiac valvular insufficiency, and nonerosive inflammatory arthritis. Many studies have shown that the imbalance of helper T cell 17(TTh17) and regulatory T cell (Treg) is involved in the pathogenesis of autoimmune diseases such as SLE and RA. But little is known about the roles of peripheral immune cell subsets peripheral in RP patients. Up to now, just few studies focus on this issue.

OBJECTIVES: We aimed to analyse the distribution and phenotype of CD4+ T cell subsets in the peripheral blood of patients with RP.

METHODS: The proportion and absolute counts of circulating immune cells were assessed in 14 patients diagnosed as RP and 14 healthy controls. CD4+ T cell subsets were also analysed in 9 untreated RP patients and 9 healthy volunteers by flow cytometry. All statistical analyses were performed with SPSS v. 22.0. Continuous variables were reported as median. For all study variables, comparison among controls and RP subsets was based on the non-parametric Wilcoxon Mann-Whitney exact test. For all analyses, we used two-sided tests, with p-values <0.05 denoting statistical significance.

RESULTS: Proportion and absolute counts of Treg cells were significantly reduced in RP patients in comparison with controls (proportion, 3.61% vs. 5.24%, p<0.001; absolute counts, 27.36/μl vs. 46.56/μl, p<0.001). But there were no significant difference between the percentage and number of Th17, Th1 or Th2 cells in patients with RP and healthy controls. Thus, the ratio of Th17/Treg increased in RP patients (0.25 vs. 0.14, p<0.001), as did the ratio of Th2/Treg (0.28 vs. 0.22, p=0.001) and Th1/Treg (2.75 vs. 1.92, p=0.019)(Figure 1). Similarly, the proportion and absolute counts of Treg cells in untreated RP patients were significantly lower than that in healthy controls (proportion, 3.76% vs. 5.66%, p=0.008; absolute counts, 32.24/μl vs. 50.76/μl, p=0.001).And the ratio of Th17/Treg also increased in untreated RP patients (0.25 vs. 0.15, p=0.003), as did the ratio of Th1/Treg (2.35 vs. 1.88, p=0.014)(Figure 2).

CONCLUSION: Our data suggested that the immune-inflammation in RP patients may be related to the decrease of Treg cells and the imbalance of Th17 or Th1 or Th2 and Treg cells.Reduction of peripheral Treg cells may exacerbate the disease progression by not being inhibited Th cells.

**SAT0020** **BLOOD RNA SEQUENCING REVEALS IMMUNOLOGICAL PROCESSES ASSOCIATED WITH THE RESPONSE TO ABATACEPT IN RHEUMATOID ARTHRITIS**

Antonio Julía1, María Lopez Lasanta1, Antonio Gómez2, Raimon Sanmarti2, Carlos Marmas Fernandez Cd3, José Manuel Pina Salvador4, Susana Romero-Yuste15, Raul Maria Velga Cabello10, Pilar Navarro10, Carme Moragues Pastor9, Silvia Martinez Pardo13, Javier de Toro-Santos16, Ana Maria Sanchez13, Dacia Cerda17, Alejandro Prada17, Raúl Erra7, Albert Graziano18, Antonio Gómez: None declared, Raimon Sanmarti: None declared, Raúl Cortes: None declared, Ekaterina Kurteva: None declared, Rumen Stilov: Speakers bureau: Abbvie, Pfizer, Angen, UCB, Novartis.

**Background:** Abatacept (CTLA4-Ig) is an approved biological therapy for the treatment of rheumatoid arthritis (RA). Similar to other biological agents, most patients (60%) respond significantly to this therapy. To date, however, the biological mechanisms underlying the lack of efficacy for this drug are unknown.

**Objectives:** The objectives of the present study were to characterize the biological processes underlying the lack of efficacy of abatacept and to evaluate the blood transcriptome as a valid source for drug response prediction.

**Methods:** A total of n=57 patients diagnosed with RA were recruited for this study from 16 rheumatology departments in Spain. All patients were >18 years old and, had >6 months of disease evolution. The primary clinical response to abatacept was defined at week 12 using the EULAR criteria. Good and moderate responders were aggregated into a single response group, and compared to the no response group of patients. Blood RNA was collected from all patients at baseline. From a subgroup of patients (n=31), blood RNA was also obtained at weeks 12, 24 and 48 of treatment with abatacept. Gene expression levels were determined using paired-end RNA-seq (Illumina). Differential gene expression, association to biological processes, longitudinal association analysis and building of the multigeneric predictor were performed using the R software and the specialized Bioconductor libraries. The the prediction accuracy was evaluated using the ROC AUC.

**Results:** From the 57 patients treated with abatacept, n=10 (17.5%) were good EULAR responders, n=24 (42%) moderate EULAR responders and n=23 (40.5%) non-responders at week 12 of therapy. Biological process analysis identified two significantly distinct biological profiles between responders and non-responders. In responders, we found an association to pathways associated with the effector phase of T cells (e.g. interleukin-15 and Th17 signaling). n=5 non-responders showed instead a strong association to biological processes associated with antigen presentation and activation of T cells (P < 0.005). Using the baseline gene expression profiles, we built a multigeneric predictor of response to abatacept with an AUC > 75%. In the longitudinal cohort, patients were stratified as based on achieving an inactive state (i.e. DAS28 < 3.2). Using this endpoint measure, the longitudinal analysis of the 4 time points corroborated the association of response with antigen presentation (P < 0.01).

**Conclusion:** The analysis of blood RNA profiles of RA patients has enabled the identification of specific biological processes associated with the lack of response to abatacept. Also, we demonstrate that blood expression profiles can be predictive of the response to the drug at week 12 of therapy.

**SAT0021** **ELEVATED NUMBERS OF C-TYPE LECTIN CD161 POSITIVE PR3-SPECIFIC T-CELLS IN GPA**

Sebastian Klapa1,2, Anja Kerstein1, Andreas Koch2, Silke Pitann1, Relana Nieberding1, Gabriela Riemekasten3, Antje Müller1, Peter Lampecht4. University of Lübeck, Clinic of Rheumatology and Clinical Immunology, Lübeck, Germany; Christian Albrechts University Kiel, Institute of experimental Medicine co/ German Naval Medical Institute, Kronschnagen, Germany.

**Background:** Various alterations of the peripheral T-cell compartment have been reported in granulomatosis with polyangiitis (GPA) such as elevated populations of CD4+CD8+ double-positive and CD4+CD161+ and CD28- single-positive effector memory T-cells (TEM) within the total CD3+ T-cell population. Analysis of antigen-specific T-cell subpopulations shows, that PR3-specific T-cells display Th2-type, Th17 and Th22 cytokine profiles in GPA (2). Moreover, concomitant cellular CMV- and Epstein Barr virus (EBV)-infection has been found to be associated with the expansion of CD28- TEM in GPA (1,2). Notably, C-type lectin CD161+ (CD28-CD161+ double-positive) T-cells displaying a polyfunctional memory profile directed against several common viruses have been reported. Furthermore, CD161+ T-cells are involved in the pathogenesis of early stage autoimmune hepatitis (3). CD161 expression on proteinase 3 (PR3)-specific T-cells in comparison to other antigen-specific T-cells has not been described in GPA as yet.

**Objectives:** To determine the amount of C-type lectin CD161 on antigen-specific CD8+ single-positive and CD4+CD8+ double positive T-cells in patients with GPA.

**Methods:** In this study, we analyzed the expression of CD161 and CD28 on circulating antigen-specific CD8+ single-positive and CD4+CD8+ double positive T-cells in HLA-A2 positive patients with GPA (n=21) and healthy controls (n=21) using flow cytometry. Antigen-specific T cells were detected using peptide/MHC class I dextramers containing major peptide epitopes for PR3, Epstein Barr virus (EBV) BMLF1, and Cytomegalovirus (CMV) pp65 (aa 196-177, aa 280-288, and aa 495-504, respectively).

**Results:** Patients with GPA showed a higher frequency of circulating CD8+ single-positive and CD4+CD8+ double positive T-cells displaying a polyfunctional memory profile directed against increased expressions of CD161 compared to HC. Compared to EBV- or CMV-specific T-cells, there was an increased expression of CD161 on PR3-specific T-cells in GPA. In contrast to HC and EBV- or CMV-specific T-cells, the percentage of CD28+ T-cells was expanded within the PR3-specific CD8+ T-cell subset in GPA.

**Conclusion:** These findings suggest a potential role of CD161 as an additional TCR-independent co-stimulatory receptor on PR3-specific T-cells in GPA. The role of these cells in the pathophysiology and as a potential therapeutic target remains to be further investigated.

THE SUBPOPULATION FEATURES OF DENDRITIC CELLS AS A POTENTIAL BIOMARKER OF EARLY RHEUMATOID ARTHRITIS

Maxim Komlev, Yuliya Kurochkin, Nadezda Banshikova, Vitaly Omelchenko, Anna Akimova, Elena Letyagina, Maryya Surutseva, Alexander Lykov, Olga Poveschenko. Research Institute of Clinical and Experimental Immunology – branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, 2, Tymakovka street, Novosibirsk, Russian Federation

Background: Dendritic cells (DCs) are professional antigen-presenting cells (APCs), which play important role in immune responses. DCs are a heterogeneous population and can be divided into groups: myeloid (mDCs) and plasmacytoid (pDCs). Furthermore, DCs are important in rheumatoid arthritis (RA) pathogenesis through antigen presentation and activation autoreactive T-lymphocytes. As established the different subpopulation DCs can promote different immune reactions. That’s why, it may be possible to consider them as a potential target for the development of new target of the immunopathological disorders therapy.

Objectives: To investigate the subpopulations of peripheral blood DCs (myeloid and plasmacytoid) in patients with early RA as a predictor of responsibility to disease-modifying antirheumatic drugs (DMARDs) treatment.

Methods: Forty nine patients with early RA (duration of the disease up to 12 months) were included in the study. All patients fulfilled ACR/ EULAR criteria (2010) and received methotrexate, leflunomide, sulfasalazine. The study included 16 RA patients with osteoarthritis (OA) used as a control group. Analysis of the content of the B-lymphocytes, myeloid and plasmacytoid DCs, labeled by antibodies against surface markers, was carried out by flow cytometry. B-lymphocytes, subtypes of peripheral blood DCs were characterized by the following phenotypes: myeloid DCs (CD3-CD14-CD19-HLA-DR + CD11c + CD123+), plasmacytoid DCs (CD3-CD14-CD19-HLA-DR + CD11c+CD123+), B-lymphocytes (CD19+). Analysis were performed before treatment and after 3 and 6 months.

Results: Patients with early RA are characterized by significant evaluation of the population of plasmacytoid DCs in comparison of patients with moderate stages of rheumatoid arthritis and osteoarthritis (3.8 vs 2.1 vs 1, p=0.0042). Furthermore, the difference was found in the number of cells with the phenotype B-lymphocytes: 7.95 * 10^6/l vs. 3.6* 10^6/l, respectively (p = 0.014). No significant differences were observed in the number of myeloid DCs. After 6 month of observation we detected reducing amount of plasmacytoid DCs (3.8 before treatment and 2.1 in 6 month, p=0.0042) and B-cells that correlated with activity of disease.

Conclusion: The obtained data indicated that plasmacytoid DCs are predominant in patients with inflammatory arthritis especially in early RA and correlate with activity of disease that can use as a predictor of good response on DMARDs treatment.

THE DIFFERENTIAL PRODUCTION OF REACTIVE OXYGEN SPECIES IN T CELL SUBSETS IN PERIPHERAL BLOOD OF RHEUMATOID ARTHRITIS PATIENTS

Hg-Paum Lee, Su-Jin Yoo, Jinhyun Kim, In Seol Yoo, Chan Keol Park, Seong Wook Kang. Chungnam National University College of Medicine, Department of Internal Medicine, Daejeon, Korea, Rep. of (South Korea)

Background: T cells play a regulatory role in rheumatoid arthritis (RA) through inducing the homeostasis maintenance and self-tolerance (1). Specifically, the production and the oxidation mechanism of reactive oxygen species (ROS) were out of balance.

Objectives: The aim of the study was to compare ROS productions in T cell subset, which are helper T (Th) cell, cytotoxic T (TC) cell, T helper 17 (TH17) cell and regulatory T (Treg) cell in peripheral blood mononuclear cells (PBMC) of RA patients with RA activity.

Methods: Blood samples were collected from 30 RA patients and 10 healthy adult volunteers under IRB approval. RA activity was divided according to clinical parameter DAS28 (2). PBMC cells were obtained from the whole blood using lymphocyte separation medium density gradient centrifugation. For separation between the live and dead cell populations, PBMC was stained with Live/Dead stain dye. After PBS washing, cells were incubated with antibodies for CD3, CD4, CD8, and CD25. Following fixation and permeabilization, and further stained with antibodies for FoxP3 and IL-17A. For ROS staining, CellRox and MitoSox were used.

Results: The frequency of TH cell was increased and that of TC cell was decreased in the peripheral blood of RA patients. TH17 and Treg cell population were significantly increased more than about 2-3 folds in active and inactive RA than healthy control. When the whole of cellular ROS production was measured, only Treg cell population was significantly increased in RA than control. Although ROS level was steadily increased with RA activity, there was a slight decline in severe RA compared to moderate and low RA. This difference is lager in mitochondrial specific ROS than total cellular ROS. The mitochondrial complex inhibitor reduced Treg cell frequency in PBMC from RA patients.

Conclusion: Treg is the most sensitive to ROS production among T cell subsets in RA. These findings provide a novel approach to regulate Treg function in RA through mitochondrial metabolism related ROS production.

TRANSCRIPTOMIC PROFILING OF THE MICROENVIRONMENT DRIVEN RE-SHAPING OF PATHOGENIC CIRCULATORY AND SYNOVIAL HLA-DR+ CD4 T SUBSETS IN ACTIVE JUVENILE IDIOPATHIC ARTHRITIC PATIENTS

Ting Yao Leong1, Pavanish Kumar1, Phyllis Chen2, Joo Guan Yeo1, Camillus Chua1, Shafrah Nur Hazinah3, Thaschawee Arkachaisri1,4, Alessandro Consolaro5, Marco Gattorno6, Alberto Martini7, Salvatore Aliberti1, Translational Immunology Institute, Singapore National Medical Centre, Singapore, Singapore; 2KK Women’s and Children’s Hospital, Singapore, Singapore; 3Second Paediatric Division, University of Genoa and G Gaslini Institute, Genova, Italy

Background: We have previously identified two pathogenic circulatory CD4 subsets in both Teff (CPLs), and Treg (iaTreg) compartments of JIA patients that are HLA-DR+, antigen experienced, pro-inflammatory, correlated positively with disease activity and possessing strong synovial TCR sequence coverage. Despite being two functionally discordant T cell subsets (Teff/iaTreg), their immune-phenotype and association with clinical data suggests that these subsets may originate from a common precursor.

Objectives: We seek to understand how the microenvironment could potentially influence and drive these subsets (CPLs/iaTregs) towards their pathophysiological state. In an attempt to elucidate the common pathological gene drivers, we decided to perform next-generation RNA sequencing on sorted CPLs/iaTregs and conventional Teff/iaTreg counterparts in both circulation and synovium.

Methods: CPLs were sorted as CD3+CD4+CD14- HLA-DR+ CD25-CD127 Teff gate, and iaTregs were sorted as CD3+CD4+CD14- HLA-DR+ CD25+CD127+ Treg gate with FACS Aria II from n=16 active JIA PBMCs, n=8 paired JIA SFMCs, and n=8 healthy paediatric PBMCs. As a comparative control, similar HLA-DR+ counterparts were respectively sorted from the same patients. Sorted cells were lysed and extracted for RNA, and cDNA conversion/amplification were then carried out using SMART-seq v4. Libraries are prepared and multiplexed using Nextera XT DNA library preparation kit, and ran on the Illumina HiSeq High output platform.

Results: Comparative differential gene expression (DEG) analysis within the circulatory compartment indicate transcriptomic convergence between CPLs/iaTreg and divergence away from conventional Teff/iaTreg pools. Circulatory CPLs/iaTregs exhibit (a) common pathway dysregulation in T cell signalling (IFN-g, PD1, CD28 costimulation), (b) restriction in TCR oligo-clonality and (c) common transcription factor drivers (SP1L and E2F1) within the gene regulatory network, suggesting a common driving source acting on these two disparate compartments.

To understand how this convergence originate, we compared CPLs/iaTreg and conventional Teff/iaTreg subsets from (a) healthy circulatory PBMCs, (b) JIA circulatory PBMCs and (c) paired JIA synovium. There was a gradual increase in transcriptomic convergence between Teff/iaTreg, Treg/iaTreg and CPLs/iaTreg across the spacial/disease continuum, that is paralleled by an antigenic convergence in shared TCR clonotypes in CPLs/iaTreg.
The effect of dimethyl fumarate on immune pathways associated with epigenetic regulation, RUNX1 signalling, Rho and GTPase signalling were upregulated.

Conclusion: Our results show that Dimethyl Fumarate exerts a significant inhibition on SLE plasmablast differentiation and antibody production. The transcriptional analysis allowed to dissect B cell transcriptional programmes activated in the context of autoimmune B cell differentiation in SLE. The transcriptional perturbations induced by DMF highlighted some of the gene expression pathways necessary for plasmablast differentiation and survival. In addition, these data provide new insight into DMF pharmacodynamics and may support the repositioning of DMF in the treatment of SLE.

SAT0025
THE EFFECT OF DIMETHYL FUMARATE ON PLASMABLAST DIFFERENTIATION TRANSCRIPTIONAL PROGRAMMES IN SYSTEMIC LUPUS ERYTHEMATOSUS

Daniele Mauro1,2, Felice Rivellese1, Sotiria Manou-Stathopoulou1, Katrina Goldmann1, Debasish Pyne2, Francesco Coccia1, Costantino Pitzalis1,2, Myles Lewis1,2. 1Queen Mary University of London – William Harvey Research Institute, Centre for Experimental Medicine and Rheumatology, London, United Kingdom; 2University of Palermo, Dipartimento biomedico di Medicina Interna e Specialistica Sezionale di Reumatologia, Palermo, Italy; *Mile End Hospital, Barts Health NHS Trust, Rheumatology Department, London, United Kingdom; 1University of Campania ‘Luigi Vanvitelli’, Rheumatology, Naples, Italy

Background: Dimethyl fumarate (DMF), is an immunomodulatory drug approved for the treatment of Multiple Sclerosis (MS) and Psoriasis. The exact mechanism of action of DMF is not entirely known. Anti-inflammatory and immunomodulatory effects have been observed, including the upregulation of NRF-2, the inhibition of TIGAR and the block of the E2 ubiquitin-conjugating enzyme UBE3L. Further evidence from MS patients suggest a modulation on B cell activation. Although beneficial effects of DMF have been observed in animal models of lupus nephritis and limited cases human cutaneous lupus, the effect of DMF on B cell maturation transcriptional programmes in systemic Lupus Erythematosus (SLE) has not been fully investigated.

Objectives: To examine the effect of DMF on SLE plasmablast differentiation and identify the transcriptional changes in cultured SLE B cells after DMF administration.

Methods: B cells were isolated from the peripheral blood of SLE patients (n=15) by negative magnetic sorting. B cell differentiation toward plasma blasts was induced in-vitro by stimulation with TLR-7 agonist Resiquimod, CD40L, IL-2, IL-10 and IL-15 for 5 days in the presence of DMF 25 uM and azathioprine and methotrexate (n=8) or with anti-IL-6 receptor antibody tocilizumab (n=7). The blood samples were taken at baseline and week 24 after treatment. The peripheral immune cell subset was defined based on comprehensive 8-color flow cytometric analysis for human immune system termed “the Human Immunology Project” by NIH and FOCSIT1, and the correlation with clinical characteristics and responsiveness to the therapies were evaluated.

Results: The proportion of CD3+CD4+CXCR3+CCR6+CD38+HLA-DR+ activated Th17 cells and CD3+CD4+CXCR5+ICOS+CD38+ activated Tfh cells in patients with TAK and that of activated Th17 cells and CD19+CD20-CD27+CD7+ double negative effector B cells in patients with GCA were significantly higher compared with HD. At baseline, the frequency of activated Th17 cells showed positive correlation and that of CD4+CD45RA-CD25+CD127+ Th regulatory (Treg) cells showed negative correlation and that of Tfh cell activation was correlated with disease activity of LVV. Although Tfh cell activation was not changed by the conventional immunosuppressive agents. By contrast, tocilizumab reduced Th17 cells and increased Treg cells, indicating that IL-6 blockade may correct the impaired balance of Th17 and Treg cells in patients with LVV.

Disclosure of Interests: Shingo Nakayama, Yusuke Miyazaki, Hiroko Yoshinari, Aki Kabawe, Ippei Miyagawa, Satoshi Kudo, Shunji Fujiko, Shigewa Iwata: None declared, Kazuhiro Nakano, Yoshiya Tanaka, University of Occupational and Environmental Health, Japan, School of Medicine, First Department of Internal Medicine, Kitakyushu, Japan.

Background: The pathogenesis of large vessel vasculitis (LVV) such as Takayasu arteritis (TAK) and giant cell arteritis (GCA) consists of the immune abnormalities including the interaction between vascular dendritic cells, macrophages and T cells. It is reported that genetic polymorphisms in the immune-modulating cytokine genes such as IL-6 and IL-12B are associated with LVV. However, little is known about pathological immune cell subsets targeted by immunosuppressants and/or molecular-target therapy such as IL-6 blockade.

Objectives: The aim of this study was to assess the relationship between the phenotype of peripheral immune cells with clinical manifestations and responsiveness to the treatment in patients with LVV.

Methods: Peripheral blood mononuclear cells were obtained from 22 patients with active LVV (TAK 7, GCA 15) and 19 healthy donors (HD). All patients were treated with high dose glucocorticoid (GC). The study included the patients treated with immunosuppressive agents such as azathioprine and methotrexate (n=8) or with anti-IL-6 receptor antibody tocilizumab (n=7). The blood samples were taken at baseline and week 24 after treatment. The peripheral immune cell subset was defined based on comprehensive 8-color flow cytometric analysis for human immune system termed “the Human Immunology Project” by NIH and FOCSIT1, and the correlation with clinical characteristics and responsiveness to the therapies were evaluated.

Results: The proportion of CD3+CD4+CXCR3+CCR6+CD38+HLA-DR+ activated Th17 cells and CD3+CD4+CXCR5+ICOS+CD38+ activated Tfh cells in patients with TAK and that of activated Th17 cells and CD19+CD20-CD27+CD7+ double negative effector B cells in patients with GCA were significantly higher compared with HD. At baseline, the frequency of activated Th17 cells showed positive correlation and that of CD4+CD45RA-CD25+CD127+ Th regulatory (Treg) cells showed negative correlation with disease activity scores such as Indian Takayasu Activity Index (ITAS)2010 and ITAS.A (CRP) in both TAK and GCA. The immunosuppressive therapy improved the disease activity in all patients. The frequency of activated Th17 cells was reduced by 24-week treatment with high dose GC and immunosuppressants in TAK and GCA. However, the frequency of Th17 cells was not changed by those treatments. Of note, tocilizumab decreased the proportion of activated Th17 cells and increased the proportion of Treg cells in both TAK and GCA.

Disclosure: Consistently, IgG and IgM secretion were significantly reduced (p<0.001). DMF treatment induced significant transcriptional changes in both PBs and Naïve B cells, with 269 and 652 genes modulated in PBs and Naïve B cells, respectively (Paj <0.05). Pathway analysis highlighted the downregulation of a number of pathways: detoxification of reactive oxygen species, transcriptional regulation of cell cycle inhibitor and P21, mitophagy and P53/Parkin Mediated mitophagy, interleukin-12 signaling, TP53 and p53 regulation, PERK mediated endoplasmic unfolded protein response, and NF-kB mediated cell survival. Conversely, pathways related to epigenetic regulation, RUNX1 signaling, Rho and GTPase signaling were upregulated.

Conclusion: Overall the data indicate immune-phenotypic convergence between CPLs/Tregs, that is strengthen across disease/spatial states. These findings underscore a potential mechanistic role of the inflammatory microenvironment in shaping two different dichotomous populations, relevant to disease pathogenies and progression.

Circulating CD3+CD31+CXCR4+ T cells in rheumatoid arthritis patients: correlation with retinal microvascular damage and potential effect of abatacept therapy

Silvia Piantoni1, Francesca Regola1, Stefano Caletti2, Rajesh Kumar3, Cecilia Nalli1, Chiara Bazzani1, Claudia Rossini2, Carolina De Ciuceis2, Tatjana Radnic1, Katarina Pasalic1, Mirjana Sefik Bukilica1, Ivanka Markovic3, Damiano Rizzoni2, Angela Tincani2, Paolo Arlì1, U.O. Internal Medicine, ASST Spedali Civili of Brescia, Clinical and Experimental Sciences, BRESCIA, Italy

Background: T-cells play a role in pathogenesis of rheumatoid arthritis (RA) and in its cardiovascular (CV) comorbidities [1]. CD3+CD31+CXCR4+ T-cells may be involved in damaged endothelium repair [2]. The percentage of these cells in the peripheral blood was reported to be lower in RA than in healthy controls, as an effect of disease activity rather than of traditional CV risk factors [3]. Abatacept (ABA), a T-cell co-stimulator, is approved for the treatment of RA. In addition to its effect on disease activity, it may have a CV protective action [4].

Objectives: To evaluate CD3+CD31+CXCR4+ T-cells in a cohort of RA patients in correlation with disease activity, CV parameters, and the potential effect of ABA therapy.

Methods: Thirty-one RA patients (median[10th-90th percentile] age=60[40-70] years, baseline C-reactive protein (CRP)=DAS28=43[5.4], body mass index (BMI)=2[17.3-28.6] kg/m², rheumatoid factor (RF) positive:55%, anti-citrullinated peptide autoantibodies (ACPA) positive:77%) were enrolled. Thirteen patients were evaluated before and after 6 months of ABA therapy. Among them, in 5 patients without known CV risk factors (history of arterial hypertension, diabetes, hypercholesterolemia, previous CV events and smoking), a morphological evaluation of retinal arteriules was performed by adaptive optics, a validated technique quantifying microvascular damage [5]. The response to treatment was evaluated with the EULAR response criteria. Phenotypic analysis of peripheral blood T lymphocytes was made by flow-cytometry.

Results: At baseline, no correlation was found between relative CD3+CD31+CXCR4+ T-cell number and age, BMI, CRP DAS28, RF and ACPA titers. However, a negative correlation was observed with retinal wall thickness (Figure 1). After ABA therapy (n=13), no significant differences were found between good-moderate responders (n=10) and non-responders (n=3), but the two groups seemed to show an opposite trend (T0 vs T6: from 23.8[4.5] to 11.9[3.7] and from 20.4[3.2] to 27.4[7.8] mm). The percentage of these cells in the peripheral blood of patients with active RA was detected in the Treg lymphocytes in relation to the control group to total T-reg lymphocytes) in the peripheral blood of patients with active RA was detected in the Treg lymphocytes in relation to the control group (5123.3[4027.8-6145.5] vs 4852.3[3554.9-5788.2] mm²/p=0.04).

Conclusion: In a subgroup of patients without known CV risk factors, CD3+CD31+CXCR4+ T-cell number was inversely related to the possible presence of subclinical CV involvement, as evaluated by retinal microvascular damage. This improved after ABA therapy. These findings may suggest a possible value of CD3+CD31+CXCR4+ T-cell number in the evaluation of microvascular damage, and a possible beneficial effect of ABA on the microcirculation in RA patients.

References
to a healthy control group (7.6% versus 5.85%, p = 0.129). After a 12-week treatment with alfalcacidol in patients with RA, an increase in the percentage of activated Treg cells (HAL-DR positive to total T-reg lymphocytes) was observed in relation to the values detected at the beginning of the study, up to the level recorded in the group of healthy controls 6.13% vs. 4.76%, p = 0.219.

Conclusion: It is believed that functional blockade of Treg cells plays the most important role in RA immunopathogenesis, most likely due to inhibition of their function by proinflammatory cytokines or due to an increase in the number of activated effector T cells, or perhaps to the fact that some completely differentiated T reg cells can be very unstable. Our data show that B cells reactive with a citrullinated peptide derived from P.gingivalis (Pg) to express a PAD enzyme that can citrullinate both bacterial and human proteins, it has been hypothesised that the ACPA response may be triggered in the gum mucosa in response to Pg.

Objectives: The main purpose of this study was to investigate if citrulline-reactive B cells reside in inflamed gingival tissue, and to examine ACPA cross-reactivity between citrullinated bacterial and human epitopes on a monoclonal level.

Methods: Using a single-cell antibody cloning approach, 55 recombinant monoclonal antibodies (mAbs) were generated from gingival tissue (GT) CD19+ B cells (n=1 ACPA+ RA/PD patient). Citrulline reactivity was determined using the anti-CCP2 kit (EuroDiagnostics AB), and in-house peptide ELISAs (including a citrullinated peptide derived from Pg PAD (CP3)) and citrullinated peptides derived from human α-ename, fibrinogen, vonwillebrand, fillagrin and histone H3. Reactivity against CP3 and CP2 was also investigated in: 19 mAbs from bronchoalveolar lavage (BAL) CD19+ B cells (n=2 ACPA+ RA patients); 29 mAbs from bone marrow (BM) plasma cells (n=4 ACPA+ RA patients); 142 mAbs from synovial fluid (SF) plasma cells (n=5 ACPA+ RA patients); and 36 mAbs from peripheral blood memory/plasma cells (n=4 ACPA+ RA patients). Predicted germline variants were produced for two of the mAbs.

Results: Among 55 GT mAbs, 14 unique clones (25%) were reactive to the bacterial CP3 peptide. We also detected CP3-reactive mAbs from BAL (n=9/19), BM (n=3/29), SF (n=1/142) and peripheral blood (n=1/36). Interestingly, 11 out of 28 (39%) CP3-reactive clones also bound citrullinated peptides derived from human proteins. Notably, three of these clones were positive in the clinical anti-CCP2 test, and when converted back to the predicted germline sequence, these clones became CCP2 negative, while maintaining reactivity against the bacterial CP3 peptide.

Conclusion: Our data show that B cells reactive with a citrullinated peptide derived from Pg PAD are present in gingival tissue, lungs, bone marrow, and the inflamed joint of ACPA+ RA patients. Moreover, the finding that a number of these clones are cross-reactive with citrullinated peptides derived from human proteins as well as the gold standard CCP2 test suggests mechanisms of molecular mimicry in the generation of ACPA. Importantly, the germline versions of these ACPA were CP3-reactive but not autoreactive, supporting the hypothesis of a bacterial origin for this ACPA response.

VITAMIN B3 (NAM) SUPPRESSES T CELL ACTIVATION IN AN PRODUCTION OF PRO-INFLAMMATORY CYTOKINES IN VITRO IN A DOSE DEPENDENT MANNER INDICATING THERAPEUTIC POTENTIAL FOR THE TREATMENT OF JIA

Ivana Zvyagin1,2, Lotte Nijhuis1, in vitro inhibits proliferation and activation of Teff cells numbers and functioning, this data demonstrates that VitB3 treatment also CD4+ and CD8+ T-cells was inhibited with VitB3 treatment in a dose ERK phosphorylation was decreased. Furthermore, proliferation of both surface activation markers were downregulated after VitB3 incubation, and significantly decreased the production of the pro-inflammatory cytokines IL-2 Results: Methods: T-cells were isolated from the blood of healthy controls and JIA patients, as well as from the synovial fluid from JIA patients. Cells were stimulated with and cultured in the presence of increasing concentrations of VitB3 (0-9mM) for 1-4 days. Proliferation and expression of activation makers in primary T cells were determined using flow cytometry. Cytokine production was determined by qPCR, Luminex and confocal microscopy, and their mRNA levels were analyzed by semi-qPCR. Cytokines, transcription factors and cell markers related to pathogenic profile of Th cells were analyzed by semi-qPCR, ELISA and flow cytometry. To study the signalling pathways, pull-down assays (Rap1), western-blot (CREB) and ELISA (cAMP) were performed. Expression of different chemokines were analyzed by flow cytometry whereas cell migration assays were performed using transwell membranes.

Results: In vitro VitB3 treatment of JIA patient CD4+ Teff-cells significantly decreased the production of the pro-inflammatory cytokines IL-2 and IFNγ measured both on mRNA and protein level. Correspondingly, surface activation markers were downregulated after VitB3 incubation, and ERK phosphorylation was decreased. Furthermore, proliferation of both CD4+ and CD8+ T-cells was inhibited with VitB3 treatment in a dose dependent manner. Murine reporter cells showed similar results. Experimental outcomes were verified using another SIRT1 inhibitor; EX-527. Conclusion: In addition to the previously demonstrated increase of Treg numbers and function, this data demonstrates that VitB3 treatment also inhibits proliferation and activation of Th cells in vitro. VitB3 treatment could therefore modulate the immunological balance by both increasing tolerance and suppressing immune activation. We envision that VitB3 treatment as an adjuvant therapy has the potential to benefit JIA patients and potentially patients with other autoimmune diseases. To assess the clinical relevance of these findings, we are currently in the preparation of a phase III clinical trial.

SCIENTIFIC ABSTRACTS - SUNDAY, 16 JUNE 2019

ARTHRITIS PATIENTS: VIP RECEPTORS IN HEALTHY DONORS AND EARLY PATTERN EXPRESSION AND CELLULAR LOCATION OF CYTOKINES IN VITRO IN A DOSE DEPENDENT MANER INDICATING THERAPEUTIC POTENTIAL FOR THE TREATMENT OF JIA

Lotte Nijhuis1,2, Álvaro2, José Miguel Rodríguez Frade3, Mario Mellado3, María Del Ekaterina Komech1,2, Anastasia Koltakova3, Alena Novikova1, Elena Loginova3, Tatiana Korotaeva3, Tatiana Korotaeva3, Ivan Zvyagin1,2, Lotte Nijhuis1, in vitro inhibits proliferation and activation of Teff cells numbers and functioning, this data demonstrates that VitB3 treatment also CD4+ and CD8+ T-cells was inhibited with VitB3 treatment in a dose ERK phosphorylation was decreased. SAT0031 Activation of Th lymphocytes alters the pattern expression and cellular location of VIP receptors in healthy donors and early arthritis patients

Paul Villanueva Romero1, Irene Gutiérrez-Cañas2, Mar Carrion1, Ildoer Gonzalez-Alvaro1, José Miguel Rodríguez Frade1, Mario Mellado1, María Del Carmen Martinez2, Rosa P. Goram2, Yasmina Juarranz2, Cellular and Molecular bases of autoimmune diseases (UCM), Prognostic markers and predictions of therapeutic response in autoimmune diseases (HLP), Chemokine receptors; new targets for therapeutic intervention (CNB), UCM School of Biological Sciences, Madrid, Spain; Hospital de La Princesa, Madrid, Spain; Centro Nacional de Biotecnología, Madrid, Spain

Background: CD4+ T helper cells are decisive in the struggle against pathogens and in the maintenance of immune homeostasis. Their activation and differentiation can take many forms and generate immune memory in which the extracellular environment plays a critical role in both homeostatic and pathological states. VIP is one of the best-studied neuropeptides with anti-inflammatory and immunomodulatory actions in normal and pathological conditions [1,2]. There are evidences that VIP...
Methods: We collected paired PB and SF samples from HLA-B*27+ (n=5) and HLA-B*27- (n=7) patients. All patients fulfilled the CASPAR criteria. TCR beta profiling for total P/SFM C samples and T cell subsets was performed using high throughput sequencing of 5’-RACE double-barcoded TCR beta cDNA libraries following by repertoire reconstruction with molecular barcode-based error correction [5].

Results: Clonal diversity in SF was largely restricted compared to PB, with significant enrichment of mostly expanded SF clonotypes compared to PB, suggesting antigen-driven migration and expansion of the T cells into inflamed site. Major clonal expansions of SF were private for each patient, yet SF shared significantly more clonotypes than PB independently from HLA-B*27 status. Most important, in CD8+ subsets from PB and SF we identified the previously described AS-associated T-cell clonotypes. These clonotypes were detected in SF of all HL A-B*27+ patients but not in samples from HLA-B*27- patients, suggesting the HLA-B*27 restriction of the TCR beta motif. The clonotypes were enriched in SF compared to PB, representing up to 1.6% of CD8+ SF T cells. All HLA-B*27+ patients had several variants of the TCR beta clonotypes in SF, suggesting the selection of the TCRs during disease development.

Conclusion: Our results further support the supposed role of the CD8+ T cells in SpAs and suggest that similarity of clinical phenotype between AS and HLA-B*27+ PsA patients could be associated with autoimmune response to similar antigens, represented by HLA-B*27 molecule.

IMPACT OF RHEUMATOID ARTHRITIS IN LIVER DAMAGE, INVOLVEMENT OF ANTI-CITRULLINATED PROTEIN ANTIBODIES

Iván Arias de la Rosa, Carmen Torres-Granados, Carlos Perez-Sanchez, María del Carmen Abalos-Aguilera, Alejandro Patiño-Trives, María Luque-Tevar, Alejandro Ibañez-Costa, Rafaela Ortega Calvo, Jerusalem Calvo Gutiérrez, Eduardo Collantes Estevez, Chary Lopez-Pedrera, Nuria Barbarroja Puerto, IMIBIC/Reina Sofia Hospital/University of Cordoba, CORDOBA, Spain; Department of Medicine, University of Cambridge, School of Clinical Medicine, Addenbrooke’s Hospital, Cambridge Institute for Medical Research, CORDOBA, Spain

Background: Liver damage in rheumatoid arthritis (RA) is most common in the form of asymptomatic abnormal liver biopsies. It is difficult to differentiate between hepatic manifestations of the primary disease and potential hepatotoxicity of the therapies. Inflammation, oxidative stress, apoptosis and loss of lipid droplets are involved in the hepatic fibrogenesis.

Objectives: 1) To analyze the impact of RA in the liver function and 2) To evaluate the direct effect of anti-citrullinated protein antibodies (ACPs) in the liver fibrosis.

Methods: 150 RA patients and 100 healthy donors (HD) were included. Aspartate aminotransferase (AST), alanine aminotransferase (ALT), phosphatase alkaline (ALP), albumin and levels of autoantibodies and inflammatory markers were evaluated in serum. In vitro studies: Hep G2 cells were treated with IgG-ACPAs isolated from RA patients. Molecules involved in lipid metabolism, insulin resistance, oxidative stress and inflammation were analyzed by RT-PCR and Western blot. Activation of intracellular pathways involved in fibrogenesis was analyzed. Lipid accumulation was evaluated by fluorescence microscopy. Mouse model: 20 CB57BL/6 mice were used; 5 mice were used non-diseased group, and 15 were used in CIA modelling. Liver samples were collected. Genes involved in insulin signal, lipid accumulation, macrophage infiltration and polarization and inflammation were evaluated. Activation of intracellular pathways related to fibrogenesis were analyzed. Immunohistochemistry was used to evaluate the percentage of fibrotic cells.

Results: Within the normal range of hepatic enzymes, the percentage of RA patients with levels of AST, ALT and ALP above the mean was significantly higher compared to HD. In contrast, percentage of RA patients displaying levels of albumin below the mean was significantly elevated compared to HD. Differences remained significant after adjusting for potential confounders (treatment). Moreover, high levels of AST and ALT were associated with ACPAs and inflammatory markers. IgG-ACPAs induced the expression of inflammatory and oxidative stress markers and decreased genes involved in insulin signal and lipid accumulation in Hep G2 cells. In addition, lipid content decreased after IgG-ACPAs treatment. The phosphorylation of intracellular pathways involved in fibrogenesis was modulated by IgG-ACPAs. The induction of arthritis in mice elevated inflammatory cytokines and markers of macrophages presence and polarization state M1 and reduced genes related to lipid droplets in the liver. Phosphorylation of ERK and mTOR was increased in the liver of CIA mice. Additionally, the percentage of cells positive for α-smooth muscle antibody was increased in the liver of CIA mice.

Conclusion: 1) RA patients displayed a subclinical alteration of the hepatic enzymes levels associated with levels of autoantibodies ACPAs, which may suggest that RA is associated with an abnormal liver function induced by autoantibodies. 2) ACPAs may induce alterations in hepatic cells, increasing inflammation and oxidative stress, reducing lipid accumulation and activating intracellular pathways, processes closely involved in fibrogenesis. 3) In a CIA mice, arthritis induced inflammation, infiltration of macrophages, reduction of genes involved in lipid accumulation and activation of intracellular pathways involved in fibrogenesis.

INCREASED CARDIOMETABOLIC RISK FACTORS ARE RELATED TO THE ABNORMAL ADIPOCYTOKINE PROFILE AND AUTOIMMUNITY IN RHEUMATOID ARTHRITIS, MODULATION BY TNFALPHA AND IL6 INHIBITORS

Iván Arias de la Rosa, María del Carmen Abalos-Aguilera, Rafaela Ortega Calvo, Jerusalem Calvo Gutiérrez, Carlos Perez-Sanchez, Alejandro Ibañez-Costa, Alejandro Patiño-Trives, María Luque-Tevar, Eduardo Collantes Estevez, Chary Lopez-Pedrera, Alejandro Escudero Contreras, Nuria Barbarroja Puerto, IMIBIC/Reina Sofia Hospital/University of Cordoba, CORDOBA, Spain; 2Department of Medicine, University of Cambridge, School of Clinical Medicine, Addenbrooke’s Hospital, Cambridge Institute for Medical Research, Cambridge, UK, Cambridge, United Kingdom

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by excess morbidity and mortality from cardiovascular disease. In addition, metabolic alterations have been observed in these patients, which significantly contributes to the cardiovascular risk burden. Thus, the identification of therapies able to mitigate the cardiometabolic alterations in RA is essential. In addition, numerous studies suggest that cardiometabolic risks are mediated through adipocytokines. However, this relationship is not completely defined in RA.

Objectives: 1) To evaluate the relationship among cardiometabolic risk factors and the levels of adipocytokines and autoantibodies in RA patients. 2) To analyze the effects anti-TNFα and anti-IL6 therapies on the cardiometabolic alterations.

Methods: 1- A cross-sectional study including 100 RA patients and 50 age-matched healthy donors was carried out. Different parameters related to the cardiometabolic risk were analyzed, including: lipid profile, atherogenic index, ratio ApoB/ApoA, insulin resistance (IR), obesity, hypertension, and the SCORE. Levels of adipocytokines (TNFα, IL6, IL1β, visfatin, adiponectin, leptin and resistin) were evaluated in serum. Carotid intima media thickness (CIMT) was evaluated as atherosclerosis marker. 2- A prospective study in 15 RA patients before and after 3 months of anti-TNFα therapy and 15 RA patients before and after 3 months of treatment with tocilizumab (TCZ) was performed. All the parameters evaluated in the cross-sectional cohort were tested in this prospective study.

Results: RA patients had elevated levels of leptin/adiponectin ratio, visfatin, resistin and inflammatory markers in serum. Our cohort of RA patients displayed increased rates of cardiometabolic risk factors, such as insulin resistance, hypertension, SCORE, pathologic CIMT, atherogenic index and ratio apoB/apoA. The alteration in the levels of adipocytokines were closely related to the autoimmunity, disease activity and clinical inflammatory markers. Of note, visfatin and C3 complement levels were determinant for IR, high levels of SCORE, increased parameters of CVD risk defined by apoB/apoA ratio and pathologic CIMT.

Both biological therapies reduced clinical inflammatory markers and disease activity after 3 months of treatment. Anti-TNFα therapy modulated the cytokine profile, reducing serum levels of IL6, IL-1β, resistin and visfatin, decreasing IR.

Conclusion: 1) Altered adipocytokine profile is closely related to increased cardiometabolic risk factors associated with RA, where autoimmunity and systemic inflammation play a key role. 2) Anti-TNFα and anti-IL6 therapies, administered for 3 months, could have beneficial effects in the reduction of cardiometabolic risk factors in RA.

SEMAPHORINS: FROM ANGIOGENESIS TO INFLAMMATION IN RHEUMATOID ARTHRITIS

Jerôme Avouac1,2, Sonia Pezet2, Eloise Vandebeuque1, Yannick Allanore1,2
1Paris Descartes University, Cochin Hospital, Rheumatology, Paris, France; 2INSERM U1016, Paris, France

Background: Sympatral neoangiogenesis is an early and crucial event to promote the development of the hyperplastic proliferative pathologic synovium in rheumatoid arthritis (RA). A recent microarray analysis of Endothelial cells (ECs) issued from patients with RA and matched controls has revealed a differential expression of semaphorin family in RA ECs, which is known to contribute to angiogenesis and autoimmunity/inflammation.

Objectives: Our aim was to study the potential implication of semaphorins in RA pathogenesis.

Methods: mRNA levels of class 3 and 4 Semaphorins (SEMA) SEMA3A, SEMA3E, SEMA4A and SEMA4E, as well as their receptors Plexin-D1 (PLXND1) and Neurothin-1 (NRPI), were measured by real-time quantitative PCR in RA (n = 15) and control (n = 15) ECs. Protein expression of these 4 semaphorins and their receptors was evaluated in ECs of 10 RA patients and controls by western blot, and in the synovial tissue of 10 RA patients and 5 controls by immunohistochemistry and immunofluorescence. Serum concentrations of these 4 semaphorins were measured by sandwich ELISA in a cohort of 130 patients with RA (85% women, mean age: 58 ± 12 years and mean disease duration: 11 ± 30 years) and 30 age- and sex-matched (20%) women) matched controls.

Results: SEMA3A and SEMA4E and their receptors PLXND1 and NRP1 mRNA (Real time quantitative PCR) and protein (western blot analyses) levels were found to be markedly increased in RA ECs compared to control ECs. The expression of SEMA3A, SEMA3E, SEMA4A, PLXND1 and NRP1 was strikingly increased in the synovial tissue of patients with RA. Confluent microscopy with double labeling for CD31 confirmed the prominent endothelial expression of these class 3 and 4 semaphorins and their receptors. SEMA3A serum levels were significantly lower in RA compared to controls (13.93±5.69 vs. 18.29±6.69 ng/mL, P=0.023, r=0.21, P=0.013, r=0.39, P=0.006, r=0.23, respectively). In addition SEMA3A and SEME4D correlated with CRP levels (r=-0.36, P<0.001, r=-0.23, respectively). In addition SEMA3A and SEME4D also correlated with the Disease Activity Score (DAS)-28, (r=0.27, P=0.006 and r=0.23, respectively). SEMA3A, SEMA4A and SEMA4D also correlated with the Global OMERACT-EULAR Synovitis Score, reflecting the intensity of synovial vascualarization measured by power Doppler ultrasonography (r=-0.22, P=0.023, r=0.21, P=0.030 and r=-0.242, P=0.013, respectively). In addition serum levels of the angiogenic markers Tie-2, angiopoietin, Interleukin-6 and soluble Vascular Cell Adhesion Molecule.

Conclusion: Gene expression profiling of ECs identified semaphorins as potential biomarkers and therapeutic candidates in RA. Class 3 and 4 semaphorins are overexpressed in RA ECs, synovial vessels and the serum of patients with RA. They also correlated with validated markers of inflammation and angiogenesis. Thus, semaphorins might be novel and appealing EC-derived inflammatory and proangiogenic targets in RA.

PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-GAMMA COACTIVATOR-1B FACILITATES PSEUDOPOD FORMATION OF FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS VIA ACTIVATING RHO GTPASES

MA Jialia1, Jun Jing1, Tao Yan1, Junwei Wang1, Lei Dai1, 1Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China; 2Zhejiang School of Medicine, Sun Yat-Sen University, Guangzhou, China

Background: Fibroblast-like synoviocytes (FLS) play critical roles on joint inflammation and destruction of cartilage and bone in rheumatoid arthritis (RA) due to their aggressive behavior including increased migration. The Rho family of small GTPases are the master regulators of actin cytoskeleton remodeling which leads to pseudopodia formation and migration. Peroxisome proliferator-activated receptor-gamma coactivator-1 (PGC-1) is a transcriptional regulator which plays important roles on regulating multiple signaling pathways. Our previous study revealed that elevated PGC-1 in RA-FLS promoted their migration and invasion. However, the underlying mechanism remains elusive.

Objectives: To investigate the role of PGC-1 in regulating pseudopodia formation of FLS in RA-FLS and its possible mechanisms.

Methods: Synovial tissues were obtained from six patients with active RA and FLS were isolated and cultured in vitro. RA-FLS were transfected with a lentivirus vector for PGC-1 and/or over-expression, and the effects were investigated. The change of cytoskeleton was stained with fluorescein phallolidin to visualize polymerized actin in lentivirus-transfected RA-FLS.

Results: In preliminary experiments, we found that partial ZAP-70 deficiency (in ZAP-70 heterozygous (ZAP-70 +/-) knockout mice, then stimulated in vitro for 72 hours with anti-CD3/anti-CD28-coated beads. After stimulation, cells were lysed and the homogenates were subjected to Western-blotting using antibodies against activated Caspases-3, -8, and -9, respectively, and other apoptotic markers (cytochrome C, and some important regulator molecules (Cbl-2, Bim and Cbl).

Disclosure of Interests: None declared

by qPCR. Their activity was measured using a Rac1, RhoA or Cdc42 Pulldown & G-Lisa Activation Assay Kit.

Results: 1) PGC-1α knockdown inhibited lamellipodia and filopodia formations of RA-FLS compared with Lv-sh-GFP transfection group (cells with lamellipodia: 34% ± 4% vs. 49% ± 4%, P=0.041), while PGC-1α over-expression promoted lamellipodia and filopodia formations of RA-FLS compared with Lv-GFP transfection group (cells with lamellipodia: 50% ± 4% vs. 34% ± 6%, P=0.040; cells with filopodia: 67% ± 7% vs. 52% ± 6%, P=0.045, Figure 1A). 2) PGC-1α knockdown or over-expression did not affect the mRNA expression of Rac1, RhoA or Cdc42 (all P>0.05, Figure 1B). However, PGC-1α knockdown suppressed the activity of Rac1, RhoA and Cdc42 (Pulldown assays: 65%-78% reduction; G-LISA assays: 28%-53% reduction, all P<0.05), while PGC-1α over-expression significantly increased their activity (Pulldown assays: 1.55-1.72 folds; G-LISA assays: 1.43-1.68 folds, all P<0.05, Figure 1C, D).

Conclusion: Our findings revealed that elevated PGC-1α in RA-FLS promotes pseudopodia formation by activating Rho family proteins which imply a novel target on regulating RA-FLS migration.

GENOTYPE OF THE RHEUMATOID ARTHRITIS SEVERITY LOCUS, RS26232, IS ASSOCIATED WITH INVASIVENESS OF RASFs IN VITRO

Emma Dorn1, Eimear Flanagan1, Eimear Linnehan1, Michelle Treilmann1, Karen Creveley1, Douglas Veale1, Ursula Fearon1, Gerry Wilson1, 1University College Dublin, Centre for Arthritis Research, Dublin, Ireland, 1University College Dublin, Rheumatology, Dublin, Ireland, 1Trinity College Dublin, Molecular Rheumatology, Dublin, Ireland

Background: The single nucleotide variant rs26232 has been associated with both the susceptibility to, and severity of, rheumatoid arthritis (RA). There is an allele dose response between rs26232 and radiological damage, with the minor T allele being protective against disease severity. Rs26232 is situated in the first intron of C5orf30, which is a negative regulator of tissue damage and inflammation in RA.

Objectives: The objective of this study is to elucidate the mechanism by which rs26232 may mediate disease severity. We also aimed to determine the genotype-phenotype association of rs26232 in rheumatoid arthritis synovial fibroblasts (RASF).

Methods: RASF were derived from knee biopsies of RA patients taken at arthroscopy (n=33). RASFs were used between passages 3-8. Matrigel-coated Boyden transwell chambers were used to measure invasion. Wound healing (scratch assays) were used to measure migration, whereas proliferation was measured via crystal violet staining of fixed RASF. Intracellular cytokine staining and cell surface markers were measured via flow cytometry. Secreted cytokines were measured in the supernatant of RASF using ELISA. Rs26232 genotype was determined by PCR genotyping assay with allelic discrimination analysis. Anticitrullinated protein antibody (ACPA) status was measured for each participant. Quantitative real-time PCR was used to measure gene expression. Mann-Whitney U test was used to compare two independent groups, Kruskal-Wallis test was used to compare groups of greater than two.

Results: 49% (n=16) of our RASF cohort where homozygous for the major allele CC, 42% (n=14) were heterozygous CT, 9% (n=3) were TT. Rs26232 is associated with invasion of RASFs with the CC genotype being more invasive than the CT genotype (p=0.021). RASFs with the CC genotype had increased ICAM1 and VEGF cell surface expression compared to CT genotype (p<0.001, p=0.05 respectively). MCP1/CCL2 was decreased in CC compared to CT (p=0.013). No association was found between rs26232 genotype and migration, proliferation, or expression of MMP3, TIMP3, IP10 or MIP1a.

Conclusion: Our findings revealed that elevated PGC-1α in RA-FLS promotes pseudopodia formation by activating Rho family proteins which imply a novel target on regulating RA-FLS migration.
seropositive eRA patients. Whereas cTph are related with disease activity, cTfh cells seem to be constitutively elevated.

SAT0044
HIGH THERAPEUTIC EFFICACY OF ORAL RAS INHIBITORS IN COLLAGEN INDUCED ARTHRITIS: INHIBITION OF RELEVANT MAP-KINASES AND THE CONSEQUENT INDUCTION OF AUTOACTIVE PATHOGENIC T CELLS AND AUTOANTIBODIES

Moraz Zayoud1, Iris Barshack2, Einav Vax2, Iramar Goldstein3, 1, 2Sackler Faculty of Medicine, Tel Aviv University, Medicine, Tel Aviv, Israel; 3Chaim Sheba Academic Medical Center, Pathology, Ramat Gan, Israel

Background: The Ras family of GTPases plays an important role in signaling nodes downstream to T cell antigen receptor (TCR) and CD28, potentially lowering the threshold for TCR activation by autoantigens [1]. Somatic mutation in NRAS or KRAS may cause a rare autoimmune disorder coupled with abnormal expansion of lymphocytes. T cells from Rheumatoid Arthritis (RA) patients show excessive activation of Ras/MEK/ERK pathway. The small molecule Farnesylthiosalicylic acid (FTS) interferes with the interaction between Ras/GTPases and their prenyl-binding chaperones to inhibit proper plasma membrane localization and effective downstream signaling. Previous studies in the Lewis rat adjuvant induced arthritis show that FTS attenuates arthritis development and that the inhibition of pathogenic Th17-type cells is a central mechanism of action of this compound [2].

Objectives: To further study the therapeutic efficacy and molecular mechanisms that mediate the immunomodulatory effects of FTS in DBA/1 mouse collagen type-II induced arthritis (CIA) the pre-clinical model.

Methods: Arthritis was induced in 8-10 week old male DBA/1 mice by immunization with collagen type-II (CII) and complete Freund’s adjuvant.

Objectives: 

- Inhibition of relevant MAP-Kinases and the consequent induction of autoactive pathogenic T cells and autoantibodies
- Inhibition of relevant MAP-Kinases and the consequent induction of autoactive pathogenic T cells and autoantibodies
- Inhibition of relevant MAP-Kinases and the consequent induction of autoactive pathogenic T cells and autoantibodies

RESULTS: We found that the clinical scores of mice in the FTS and MTX arms was significantly reduced (by ~80%), area under curve) compared to the control arm. Accordingly, FTS therapy significantly reduced joint pathology scores for inflammation, pannus formation, bone resorption, and cartilage damage. FTS also significantly inhibited the production of pathogenic anti-CII autoantibodies, anti-citrullinated peptide antibodies, and notably the de-sialylation of these autoantibodies as compared to control mice (Figure 1). The analysis of the effect of FTS on the T cell response to CII immunization, revealed strong attenuation of IL-22, IL-17, IL-9, GM-CSF, TNF, and IFN-gamma producing pro-inflammatory CD4+ Th cells. Importantly, we found that in vitro FTS treatment during TCR-stimulation (anti-CD3/CD28 mAbs) significantly inhibited the ensuing phosphorylation of multiple critical MAP kinases such as Erk, Akt, p38, and mTOR.

CONCLUSION: We determined in the preclinical CIA model that FTS, a first-in-class oral Ras-GTPase inhibitor, is a potent immune modulator, via the inhibition of TCR/CD28/Ras-dependent activation of critical MAPKs, consequently attenuating the generation of pro-inflammatory autoreactive T cells.

A NOVEL SMALL MOLECULE, MBS2133, MODULATES OSTEOCLAST PRE-CURSOR METABOLISM TO INHIBIT OSTEOCLAST DIFFERENTIATION: AN ALTERNATIVE THERAPY FOR OSTEOCLYTIC PATHOLOGY IN RA

Shatakshi Sood1, Lisa Patel2, Martyn Foster3, Louise Jopling3, Johan Askling4, Lars Aliefden5, Carl Goodyear1.1University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2Istituto Ltd, London, United Kingdom; 3Johnson and Johnson Innovation, London, United Kingdom; 4University of Liverpool, Institute of Ageing and Chronic Disease, Liverpool, United Kingdom; 5University of Aberdeen, Institute of Medical Sciences, Aberdeen, United Kingdom.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with substantial local and systemic bone loss. Despite the availability of several treatment options many patients do not reach low disease activity. Furthermore, current therapeutics generally target inflammation rather than erosive pathology. Thus, there remains a need for new therapies that can target both aspects of the disease. Prior studies have shown that biphynicarboxylic acid small molecule derivatives not only inhibit murine osteoclastogenesis but also attenuate inflammation and bone destruction in murine models of RA.1,2

Objectives: To evaluate a novel small molecule derivative, MBS2133, on human osteoclastogenesis, osteoanastheniaogenesis and cellular function, and to investigate the in vitro mechanism of action.

Methods: Osteoblasts were derived from human mesenchymal stem cells. Cells were differentiated in the presence or absence of MBS2133 and mineralization assessed by Alizarin Red staining. Human CD14+ blood monocytes were differentiated into osteoclasts (OCs) with M-CSF and RANK-L, in the presence or absence of MBS2133, and/or metabolites. Mature OCs were stained with tartrate-resistant acid phosphatase (TRAP) and quantified by light microscopy. Osteolytic activity was assessed on mineral-coated surfaces. Western blot analysis was used to assess down-stream signalling pathways. Changes in the metabolic profile of pre-osteoclasts following 4h exposure to MBS2133 was carried out by liquid chromatography mass spectrometry.

Results: MBS2133 had no effect on the differentiation and function of primary human osteoblasts. In comparison, exposure of RANK-L stimulated CD14+ monocytes to MBS2133 significantly reduced OC differentiation and osteolytic activity of mature OCs. Notably, exposure of pre-OCs to MBS2133 for 2h at initiation of osteoclastogenesis, was sufficient to significantly reduce subsequent OC differentiation. Evaluation of treated pre-osteoclasts revealed that RANKL-mediated phosphorylation of p38 was reduced. Metabolic analysis of pre-osteoclasts revealed that MBS2133 induced a substantial reduction in a range of metabolites associated with glycolysis, oxidative phosphorylation and fatty acid oxidation pathway. Notably, L-carnitine, which facilitates the transportation of fatty acids to the mitochondrial matrix and enables processing and entry into tricarboxylic acid cycle for further energy production, was significantly reduced. In vitro supplementation of L-carnitine inhibited the ability of the compound to switch off OC differentiation and osteolytic activity.

Conclusion: The results of this study demonstrate that MBS2133 specifically modulates the metabolism of myeloid cells, which has a substantial impact on their ability to differentiate into mature osteoclasts. These findings highlight the importance of modulating the glycolysis/oxidative phosphorylation axis in osteoclastogenesis and suggest that targeting the metabolic state of pre-osteoclasts could offer a new therapeutic approach to treat bone resorption in rheumatic diseases.

ARE THERE OF SOCIAL SUPPORT AND LOW DECISION LATITUDE AT WORK LINKED TO RISK OF RHEUMATOID ARTHRITIS, AND IF SO, HOW DO THEY RELATE TO OTHER RISK FACTORS? RESULTS FROM THE SWEDISH EIRA STUDY

Louise Hedenstig1,2, Christina H. Opava1, Sofia Emmstam1, Johan Asklund1, Lars Aliefden2, Lars Alfredsson2.1Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Unit of translational epidemiology, Stockholm, Sweden; 2Centrum for rheumatology, Stockholm, Sweden; 3Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Unit of physics and physical activity, Stockholm, Sweden; 4Karolinska Institutet, Stockholm, Sweden; 5Rheumatology unit, Department of medicine, Stockholm, Sweden

Background: The role of psycho-social factors in the development of rheumatoid arthritis (RA) is debated. Objective: We investigated whether psychosocial stress measured as low sense of social support, and low decision latitude at work, were linked to risk of RA, and whether they related to known lifestyle risk factors for RA.

Methods: The Swedish population-based EIRA study included incident RA cases (N=3724) and controls (N=5937), matched for age, sex and residential area. Responders filled in questionnaires regarding self-reported social support, decision latitude at work and life-style factors.

Results: There were 898 cases with low social support and 285 cases with low decision latitude at work (latter only available in first part of study). Low social support was not associated with RA risk in unadjusted analyses (OR=1.05, 95%CI=0.95-1.15). Low decision latitude at work did associate with a higher RA risk in the unadjusted analyses (OR=1.52, 95% CI=1.20-1.94), but this association was no longer significant after further adjustment for smoking, obesity and university degree (adjusted OR=1.24, 95% CI=0.93-1.63). Associations between those lifestyle risk factors and RA were confirmed (no university degree, OR=1.50; smoking OR=1.71; obesity OR=1.15).

Next, we evaluated whether low social support or low decision latitude at work differed by previously established risk factors. Cases with RA reporting low sense of social support were more often men (OR=1.60, 95% CI=1.40-1.83), current smokers (OR=1.46, 95% CI=1.26-1.70), obese (OR=1.29, 95% CI=1.09-1.54), physically inactive (OR=2.78, 95% CI=1.86-3.90) and without a university degree (OR=2.04, 95% CI=1.77-2.36), with similar pattern among the controls. For working-conditions, cases reporting low decision latitude at work were also more often current smokers (OR=2.05, 95% CI=1.33-3.16) and with no university degree (OR=6.23, 95% CI=5.13-13.22), but less often male (OR = 0.40, 95% CI=0.26-0.60).

Again, the pattern was similar among controls. RF/ACPA-positivity did not associate with low social support or low decision latitude. Conclusion: Neither low social support nor low decision latitude at work were associated with an increased risk of RA after adjustment for other known lifestyle risk factors for RA. An initial crude association between
low decision latitude at work and risk for RA was explained by differences in smoking and educational level. However, both low social support and low decision latitude at work associate strongly with known, and here validated, risk factors for RA (smoking, obesity, no university degree) with similar pattern among both cases and controls.

SAT0047 PRIMARY LYMPHOID TISSUE FROM RHEUMATOID ARTHRITIS PATIENTS HARBOUR CITRULLINE SPECIFIC PLASMA CELLS

Radha Thyagarajan1, Aase Hensvold2, Lena Israelsson2, Johanna Steen2, Heidi Wåhlin2, Annika van Vollenhoven2, Khaled Amara1, Anca Catrina2, Vivianne Malmström2, Caroline Grönwall2. 1Rheumatology Unit Karolinska; 2Center for Rheumatology, Academic Specialist Center, Stockholm Health Services, Stockholm, Sweden

Background: Anti-citrullinated protein antibodies (ACPA) are specific markers with pathological effects in rheumatoid arthritis (RA). ACPA-specific B-cells have been identified in synovial joint fluid and peripheral blood. An increased concentration of ACPA is found in synovial fluid and lung tissue compared to blood suggest local production, partly confirmed by detection of ACPA synovial plasma blasts, but primary lymphoid tissue have not previously been examined.

Objectives: In this study we investigated the plasma cell repertoire in the bone marrow and occurrence of autoantibody producing plasma cells.

Methods: For this study we developed a method to collected and process bone marrow samples from proximal femur in RA patients undergoing hip joint replacement. Bone marrow samples were processed and monoclonal cells were obtained by Ficoll separation. CD138+ plasma cells were single cell sorted by flow cytometry. Paired heavy and light chains were PCR amplified, sequenced, and analyzed by V-Quest and IgBLAST database to annotate variable gene usage. To enrich for ACPA, sequences were selected based on high somatic hypermutation numbers and Fab N-glycosylation sites. Selected sequences were cloned and expressed as Igκ in Expi293 cells. Monoclonal antibody reactivity to citrullinated and arginine form of vimentin, enolase, fibrinogen, histone, tenascin C peptides; carboxymethylated and malondialdehyde-acetaldehyde bovine serum albumin, and tetanus toxoid antigens were examined by ELISA. Included patients were clinical examined and obtaining peripheral blood samples.

Results: After method development and quality analysis we were able to include five bone marrow samples in this study. The five included RA patients, median age 74 (range 66-82) years, had in median 20 (range 4-44) years of destructive disease, all were RF positive, four were females and anti-CCP2-positive, and all except one were treated with anti-rheumatic drugs.

Overall, from the processed bone marrow, 465 paired heavy-light IgG plasma cell sequences were obtained, in total 368 (range 20-194) from ACPA positive patients and 97 from the ACPA negative patient. We observed statistically significant changes in heavy chain variable gene usage with lower usage of VH-1 and higher VH-3 frequency in sequences from ACPA positive RA patients compared to sequences from the ACPA negative RA patient. We also found statistically significant increase in VH N-glycosylation in sequences from the ACPA positive RA patients (22.6% ACPA positive vs 12.4% ACPA negative; p=0.03) but no difference in mutation numbers. From obtained sequences, 34 interesting clones were selected for monoclonal antibody-expression. Among the 34 clones we found two citrulline specific reactive clones (reactivity towards CCP2, citrullinated vimentin and fibrinogen peptides) and one malondialdehyde-acetaldehyde (MAA) reactive clone, originating from three different ACPA positive patients with the most longstanding disease. None of these clones had reactivity towards control antigens such as arginine versions of peptides.

Conclusion: Plasma cells producing ACPA are present in primary lymphoid tissue from RA patients. Further studies of difference in characteristics, Igκ gene usage and N-glycosylation, between ACPA-positive and ACPA-negative patients are needed.

Disclosure of Interests: Radha Thyagarajan: None declared, Aase Hensvold: None declared, Lena Israelsson: None declared, Johanna Steen: None declared, Heidi Wåhlin: None declared, Annika van Vollenhoven: None declared, Khaled Amara: None declared, Anca Catrina Grant/research support from: Yes, but not for the presented study., Vivianne Malmström: None declared, Caroline Grönwall: None declared

SAT0048 ANTI-FRACTALKINE MONOCLONAL ANTIBODY AMELIORATE JOINT DESTRUCTION AND SYNOVITIS THROUGH SUPPRESSION OF OSTEOCLAST PRECURSOR MIGRATION AND INDUCTION OF SYNOVIAL CELL DEATH IN COLLAGEN-INDUCED ARTHRITIS MODEL

Naoo Isli1, Kana Hoshino-Negishi1, Masayoshi Okihoro2, Tomoya Nakataki2, Wataru Reda1, Yoshikazu Kuboi1, Nobuyuki Yasuda1, Toshio Ima1. 1KAN Research Institute Inc., Kobe, Japan; 2EA Pharma Co., Ltd., Kawasaki, Japan

Background: In the Phase 1/2 clinical study, E6011, a novel humanized anti-fractalkine (FKN) mAb demonstrated a promising efficacy in active RA patients who were inadequately controlled by MTX and/or TNF-α inhibitors (NCT 02196558). In RA joint tissue, increased expression of fractalkine (FKN) and abundant infiltration of CX3CR1-positive cells were observed. FKN is expressed on endothelial cells and fibroblast-like synovocytes in synovium and also expressed on osteoclasts. CX3CR1 is expressed on monocytes/macrophages and osteoclast precursors (OCPs). Therefore, FKN-CX3CR1 interaction could play pivotal roles in migration, differentiation and activation of those cells. However, the precise mechanism(s) of FKN-CX3CR1 axis in RA, especially on joint destruction resolution to be elucidated.

Objectives: To elucidate the roles of FKN-CX3CR1 axis in cartilage destruction, bone damage and proliferated synovial cells by using anti-FKN mAb.

Methods: For the induction of CIA, mice were immunized with bovine type II collagen. Anti-FKN mAb was injected twice a week. The clinical arthritis score was monitored, and joint destruction was evaluated by soft x-ray and histology. The mRNA expression levels were assessed by quantitative RT-PCR. Blood parameters were measured using ELISA. In vivo, effect of immobilized FKN on RANK ligand (RANKL)-induced osteoclast differentiation was examined. In vivo, bone marrow-derived OCPs were fluorescente-labeled and transferred to CIA mice to evaluate the migration of OCPs into synovium. Inhibitory effect of anti-FKN mAb, etanercept or tofacitinib against OCP migration was assessed. To examine the effect of anti-FKN mAb against proliferated synovial cells, propidium iodide (PI) was injected to anti-FKN mAb-treated CIA mice to evaluate the synovial cell death.

Results: Anti-FKN mAb significantly reduced the arthritis and soft x-ray scores in both prophylactic and therapeutic treatment. Anti-FKN mAb histologically improved synovitis, cartilage destruction and bone damage, with marked reduction of osteoclast numbers. Plasma levels of CCMP and MMP-3 were also decreased. Interestingly, anti-FKN mAb significantly suppressed Trf and Il6 mRNA expression in the affected joints. In vitro, RANKL-induced osteoclast differentiation was enhanced by immobilized FKN, and anti-FKN mAb suppressed FKN-dependent osteoclast formation. In vivo, anti-mFKN mAb strongly inhibited the migration of OCPs into the proliferated synovial cells of mice with CIA, whereas etanercept or tofacitinib had no significantly effect. Importantly, synovial cell death was abundantly found in proliferated synovial cells of mice with CIA after the anti-mFKN mAb treatment.

Conclusion: Anti-FKN mAb remarkably ameliorated the joint destruction with the marked reduction of osteoclasts by the inhibition of both OCP survival and OCP migration in inflamed joint tissues. In addition, anti-mFKN mAb immediately induced synovial cell death in the proliferated synovial cells, suggesting the direct inhibitory effect in the synovium. These results strongly indicate that inhibition of FKN-CX3CR1 axis by a humanized anti-FKN mAb, E6011, is an attractive and affected joints-selective therapeutic strategy for the treatment of both inflammatory synovitis, cartilage destruction and bone damage in RA patients.

Baricitinib improves joint mobility after injury in a rodent forced-ambulation model

Kelly Knopp, Aihiko Kato, Theron Wall, Jeff S. Mc Dermott, Eric S. Nisenbaum, Benjamin Adams, Michael Johnson. Eli Lilly and Company, Indianapolis, United States of America

Background: Movement-evoked pain and impaired joint mobility are common comorbidities in inflammatory diseases such as Rheumatoid Arthritis (RA) and Osteoarthritis. The Janus kinase (JAK) pathway has been implicated in both inflammation and chronic pain. Clinical data suggests that baricitinib, a selective JAK 1/2 inhibitor, can robustly and rapidly alleviate pain in RA. Utilizing a rodent forced-ambulation model, we have previously shown attenuation of gait deficits with analgesics such as opioids, nonsteroidal anti-inflammatory drugs (NSAIDs), and an anti-NGF (Nerve Growth Factor) antibody. However, in this same model a fusion protein blocker of TNFα (tumor necrosis factor alpha) signaling failed to demonstrate efficacy though inflammation was decreased. The present work investigated the potential of baricitinib, recently approved for treatment of RA, to reduce inflamman-induced joint pain and gait impairment in this model of joint inflammation mediated pain.

Objectives: To determine if JAK 1/2 pathway inhibition is effective in treating inflamman-induced joint pain and gait impairment.

Methods: Unilateral joint injury was induced in female Sprague Dawley rats (Harlan, Indianapolis, IN, USA) by unilateral intra-articular injection of 20 μg Complete Freund’s Adjuvant (CFA). Using the GaitScan (CleverSys Inc., Reston, VA) treadmill system, a composite gait score comprising of range of motion, normalized stance distance, stance/swing ratio, and paw size was evaluated over 3 days post-injection. 2 Rats were treated on Day 0 with vehicle, positive control (40 mg/kg Tramadol), or clinically relevant doses of baricitinib (10 mg/kg p.o., 2-hrs prior to each test, q.d.). Dorsal root ganglion (DRG) were harvested post-gait evaluation and Total STAT3 (Cell Signaling, #4904) and phospho-STAT3 (Y705) (Cell Signaling, #9131) protein levels were examined via immunoblotting. The p-values were derived from repeated measures ANOVAs.

Results: In rat DRG homogenates, baricitinib significantly decreased phospho-STAT3 (Y705) protein levels in a dose-dependent manner (p<0.01) with a significant effect after a 3 mg/kg dose and a maximal response after a 10 mg/kg in both the ipsilateral (right) and contralateral (left) sides. Total STAT3 protein levels remained unchanged. Similarly, treatment with baricitinib significantly improved composite gait score at the 10 mg/kg dose (p<0.05) by Day 3.

Conclusion: These data indicate that treatment with baricitinib attenuates CFA-induced joint deficits, a surrogate measure of joint pain. This effect correlated with the pharmacodynamic inhibition of JAK-STAT signaling in DRGs. These data support a role for JAK-STAT signaling in pain signaling and provide an opportunity to investigate the potential mechanism of action of baricitinib in joint pain.

Photodynamic therapy targeting activated fibroblasts induces synovial cell death in experimental arthritis

Daphne Dorst1, Mark Rijksekena, Mikele Buitinga2, Peter Laverman1, Marti Boss1, Christian Klein2, Anne Freimoser-Grundschoben3, Birgitte Walgreen1, Peter van der Kraan1, Martin Gothardt4, Marie Koenders4, 1Radboudumc, Nijmegen, Netherlands, 2KULeuven, Leuven, Belgium, 3Roche Pharmaceutical Research and Early Development, Innovation Center Zurich, Switzerland, 4Radboudumc, Nijmegen, Netherlands

Background: Activated synovial fibroblasts (SF) contribute to rheumatoid arthritis (RA) by producing a multitude of cytokines, chemokines and proteases thus aggravating disease. Activated SF can be distinguished from quiescent fibroblasts by their expression of fibroblast activation protein (FAP). Selective depletion of FAP+ SF in inflamed joints could decrease their contribution to the arthritis process and thus constitute a viable treatment option. Further focussing of the treatment to only those areas affected by the disease can be accomplished by applying targeted photodynamic therapy (PDT). In iPDT a light sensitive molecule, a photosensitizer (PS), is conjugated to a targeting moiety. Upon activation by light this construct produces reactive oxygen species, killing the targeted cells.

Objectives: To this end we developed and tested a therapy that selectively depletes activated SF by targeting FAP on these cells with an
antibody, 28H1, to which the PS, IRDye700DX, for iPDT is attached. Here we investigated the feasibility of using FAP-iPDT to induce cell death in murine articular synovium ex vivo.

**Methods:** After conjugation of the IDRy700DX to 28H1 (28H1-700DX), binding and specificity of the conjugate was determined. Subsequently, iPDT efficiency in vitro was established using a 3T3 fibroblast cell line stably transfected with FAP. Biodistribution using an [111In] In-DTPA-28H1 conjugate with and without IRDye700DX was performed in healthy C57BL/6J mice as well as in CD74+BL6 mice with antigen induced arthritis (AIA). Finally, the potential of FAP-iPDT to induce targeted cell death in the synovial lining was determined by treating knee joints from mice with AIA ex vivo.

**Results:** Conjugation of IDRy700DX to the antibody did not negatively influence the immunoreactive fraction or binding capacity of the conjugate (94.7% for 28H1-700DX). 28H1-700DX was able to efficiently induce FAP-specific cell death in vitro. At 17.6 J/cm² radiant exposure, 89.24% (94.7% for 28H1-700DX). 28H1-700DX was able to efficiently induce Conjugation of IRDye700DX to the antibody did not negatively stably transfected with FAP. Biodistribution using an [111In] In-DTPA-28H1 conjugate with and without IRDye700DX was performed in healthy C57BL/6J mice as well as in CD74+BL6 mice with antigen induced arthritis (AIA). Finally, the potential of FAP-iPDT to induce targeted cell death in the synovial lining was determined by treating knee joints from mice with AIA ex vivo.

**Conclusions:** Here we demonstrated the feasibility of conjugating a PS to an antibody targeting FAP on activated SF without negatively impacting the binding capacity thereof. Furthermore we showed that this construct can then be used to deliver cell specific cytotoxicity through iPDT both in vitro and ex vivo in a mouse model of arthritis. This approach may have therapeutic potential in the treatment of RA.

**GLYCOSYLATION IN MAMMALS PROTECTS CITTULLINATED CHEMOKINES FROM PARTIAL DEGRADATION**

Oxandre Korchnytskyi 1,2,3

1 Rzeszow University, Medical Faculty, Rzeszow, Poland; 2 Institute of Cell Biology, Natl.Acad.Scie. of Ukraine, Lviv, Ukraine; 3 Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands

**Background:** Citrullination is a posttranslational modification of specific proteins by peptidylarginine deiminase (PAD) activities. Nowadays citrullination is recognized as a hallmark of rheumatoid arthritis and other autoimmune diseases. In our recent study we have shown a presence of citrullinated chemokines epithelial-derived monocyte chemotactic protein-1 (MCP-1/CCL2), macrophage inflammatory protein-1α (MIP-1α/CCL3) and neutrophil-activating peptide 78 (ENA-78/CXCL5) in biological fluids collected from quick degradation. Chemokines MCP-1/CCL2, MIP-1α/CCL3 and ENA-78/CXCL5 cannot be efficiently used as the standards in modified ELISA assays as chemokines MCP-1/CCL2, MIP-1α/CCL3 and ENA-78/CXCL5 underwent quick partial degradation upon their in vitro citrullination by PAD2 and cannot be detected with either Western blotting or mass-spectrometry. At the same time mammalian cellularly produced specifically glycosylated MCP-1/CCL2, MIP-1α/CCL3 and ENA-78/CXCL5 can be efficiently citrullinated and successfully used as the standards in modified ELISA assays as well as in bioassays.

**Conclusion:** Glycosylation that is lacking in bacterially-produced proteins but occurs in mammalian cells stabilizes citrullinated chemokines thus protecting them from quickly ongoing partial degradation.

**Disclosure of Interests:** None declared

**INVESTIGATING MECHANISMS OF AUTOANTIBODY INDUCED PAIN, BONE LOSS AND ARTHRITIS DEVELOPMENT**

Akarin Krishnamurthy 1, Yogen Kisten 1, Katlan Sandor 2, Alexandra Circiucanu 1, Gustad Wigerstad 2, Peter Damberg 2, 2, Koji Sakunabaz 3, Heidi Wildmanaz 3, Patrik Javov 4, Juan Jimenez Jimenez Andrade 5, Vivianne Malmstrom 1, Lars Klareskog 6, Camilla Svensson 2, Benè Réthi 7, Anca Catrina 8, Karolinska Institutet, Rheumatology unit, Medicine, stockholm, Sweden; 9 Karolinska Institutet, Physiology and Pharmacology, Stockholm, Sweden; 1 Karolinska Institutet, Karolinska Experimental Research and Imaging Centre (KERIC), Stockholm, Sweden; 2 Karolinska Institutet, Stockholm, Sweden; 3 Universidad Autonoma de Tamaulipas, Reynosa, Tamaulipas, Mexico

**Background:** In rheumatoid arthritis (RA), autoantibodies against citrullinated proteins (ACPAs) have been reported to be associated with bone loss, pain and tenosynovitis prior to disease onset.

**Objectives:** We aimed to investigate if transfer of human ACPAs into mice could reproduce these clinical observations.

**Methods:** Monoclonal ACA (1325:04C03 and 1325:01B09) and control (1362:01E02) antibodies (mAbs) were generated from synovial plasma or serum of B cells from RA patients. In combination of monoclonal ACPAs or control antibody were injected in BALB/c female mice (12-16 Weeks) with or without a consequent intra-articular injection of LPS after 8 days. Pain-like behavior was monitored by measuring mechanical hypersensitivity using von Frey filaments every 3 days and estimation by up-down Dixon method. Bone mineral density was measured by micro-CT. Using specially designed mobilization casts, dedicated mouse MRI imaging were scanned and evaluated for any signs of soft tissue joint inflammation. Blinded to ACPA and controls, the MRI images were scored for the presence of synovial thickening, effusion and tendon inflammatory changes by 3 readers in consensus.

**Results:** ACPAs (1325:04C03 and 1325:01B09) induced significantly more pronounced pain-like behavior (lasting for at least 4 weeks) and reduction of the trabecular bone thickness in the hind limbs, whereas no such effect was seen with the control mAbs generated in the same way as the monoclonal ACPAs. While no macroscopic sign of joint inflammation could be detected, preliminary MRI data shows that sub-clinical joint inflammation (such as tenosynovitis) in mice injected with ACPAs but not those injected with control mAb. Intra-articular LPS injection resulted in significantly increased prolonged mechanical hypersensitivity in mice initially receiving sub-optimal doses of monoclonal ACA as compared to those receiving control mAb. This was associated with higher levels of sub-clinical arthritis diseases and demonstrated citrullination of ENA-78/CXCL5 as an efficient macrophage chemoattractant in a contrast with non-citrullinated ENA-78/CXCL5. In our current work we found that citrullinated in vitro bacterially produced chemokines cannot be efficiently used as the standard in modified ELISA assays (ELISA) assays designed to detect citrullinated chemokines.

**Objectives:** In our work we aimed generate a procedure for preparation of stable citrullinated chemokines suitable for research applications and to validate a hypothesis that posttranslational modifications occurring in mammalian cells can stabilize chemokines can also protect citrullinated chemokines from quick degradation.

**Methods:** MCP-1/CCL2 and MIP-1α/CCL3 were cloned from total RNA isolated from synovial fibroblasts obtained from RA patient. Both bacterially-produced and mammalian cells-produced recombinant human chemokines were citrullinated by commercial rabbit PAD2. Success in citrullination was confirmed with Western blotting and mass-spectrometry. Citrullinated chemokine concentrations were measured by modified sandwich ELISA assays.

**Results:** Both commercially available and self-made bacterially produced chemokines MCP-1/CCL2, MIP-1α/CCL3 and ENA-78/CXCL5 undergo quick partial degradation upon their in vitro citrullination by PAD2 and cannot be detected with either Western blotting or mass-spectrometry. At the same time mammalian cellularly produced specifically glycosylated MCP-1/CCL2, MIP-1α/CCL3 and ENA-78/CXCL5 can be efficiently citrullinated and successfully used as the standards in modified ELISA assays as well as in bioassays.

**Conclusion:** Glycosylation that is lacking in bacterially-produced proteins but occurs in mammalian cells stabilizes citrullinated chemokines thus protecting them from quickly ongoing partial degradation.

**Disclosure of Interests:** All human subject samples were collected after approval by the Institutional Review Board of the Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands (Protocol MEC 07/079 #10.17.0708) and provision of informed consent by the patients.

**REFERENCE**

‘Defense response’ (p=8.11×10^{-22}) and ‘cytokine activity’ (p=1.27×10^{-23}) were the most significantly enriched gene ontology terms for genes regulated in TNF stimulated hand SF. These processes were less prominently enriched in stimulated knee (1.58×10^{-15} and 8.64×10^{-16}) and shoulder SF (2.02×10^{-11} and 3.20×10^{-11}), where ‘cell cycle’ (p=2.29×10^{-20} in knee and p=2.18×10^{-20} in shoulder), and ‘DNA packaging complex’ (p=4.63×10^{-29} in knee and p=8.91×10^{-20} in shoulder) were the most significantly enriched gene ontology terms. These processes were not significantly enriched in stimulated hand SF.

**Conclusion:** SF from different joints in RA react differently to TNF stimulation. In particular hand SF reacted different to TNF stimulation than shoulder and knee SF, which appeared more similar. These qualitative and quantitative differences of the inflammatory response might translate into joint-specific pathotypes of synovitis with distinct therapeutic responses and disease outcomes.

TASS315, A NOVEL BRUTON’S TYROSINE KINASE INHIBITOR, DEMONSTRATES POTENT EFFICACY AGAINST BONE DESTRUCTION IN AN ANIMAL MODEL FOR RHEUMATOID ARTHRITIS

Naruto Noma, Fumihito Hosoi, Satoru Iuchi, Ryuusuke Kaneko, Yohei Yoshiga, Yasunobu Arima, Daichi Akasaka, Kenji Tanaka, Akihito Saito, Teruhito Utsgui, Koichi Ikizawa. TAHO PHARMACEUTICAL CO., LTD, Tsukuba, Japan

Background: Bone erosions and cartilage damages are a pathological hallmark of rheumatoid arthritis (RA) and are associated with poor functional outcome. Aberrant activations of osteoclasts induced by receptor activator of nuclear factor-kappa B ligand (RANKL), are involved in the bone erosions of RA. It has also been recently shown that under chronic inflammatory conditions such as RA, inflammatory cytokines in joints induce pathological osteoclast differentiation and cause excessive bone resorption independent of RANKL-RANK signaling. The Bruton’s tyrosine kinase (BTK) signaling pathway plays a pivotal role in inflammatory response and bone resorption. Thus, targeting BTK may be efficacious against not only inflammation but also bone erosion by regulating activation of effector cells such as B cells, macrophages and osteoclasts in RA. We have already shown the inhibitory effects of TASS315 on RANKL-dependent osteoclast activation. However, it remained uncertain whether TASS315 inhibits osteoclast activation induced by inflammatory cytokines.

Objectives: In this study, we evaluated the effects of TASS315 on osteoclast activation induced by inflammatory cytokines (in vitro) and the infiltration of tartrate-resistant acid phosphatase (TRAP)-positive osteoclasts in the joint of a mouse CIA model.

Methods: In vitro biochemical assay was performed using available kinase assay panels. The BioMAP® Diversity PLUS panels were used to determine the profile of TASS315 in primary human cell systems. The effects of TASS315 on osteoclasts were assessed by examining osteoclast-mediated bone resorption. TASS315 was orally administrated once a day in an established mouse CIA model. TRAP-positive osteoclasts were counted manually. Bone mineral density (BMD) and bone erosion were assessed using micro-CT analysis. The mechanical properties of the tibia were evaluated by a compression test of proximal metaphysis using a material testing machine.

Results: TASS315 selectively inhibited the enzyme activity of BTK and had less off target inhibition against other kinases. In BioMAP® systems, TASS315 decreased the production of IgG and the expression of cytokines (TNF-α, IL-6, IL-17A). TASS315 also inhibited osteoclast-mediated bone resorption induced by inflammatory cytokines. On the other hand, anti-RANKL antibody did not inhibit bone resorption induced by inflammatory cytokines. Furthermore, in the mouse CIA model, TASS315 significantly ameliorated paw swelling and pathological changes. TASS315 significantly decreased the infiltration of TRAP-positive osteoclasts in the joint and also showed improved BMD and bone erosion by time-dependent micro-CT analysis. In vehicle-treated mice, the mechanical strength of tibia was decreased compared with normal mice. TASS315 treated mice recovered the decreased parameters of the mechanical strength compared with vehicle-treated mice. These results show that TASS315 improves bone erosion in murine model for RA through direct inhibition of osteoclast activation induced by inflammatory cytokines as well as RANKL.

Conclusion: Our study demonstrates that TASS315 would be an attractive RA therapeutic drug that could improve bone destruction as well as inflammation.

CREASED MICRONORNA-155 IS ASSOCIATED WITH A SPECIFIC DEFECT OF ANTI-INFLAMMATORY M2 MACROPHAGES POLARIZATION BOTH IN HUMAN RHEUMATOID ARTHRITIS AND IN COLLAGEN-INDUCED-ARTHRITIS MICE

Audrey Paoletti1, Françoine Reynaud2, Julien Rohmer3, Juliette Pascaud4, Bineta Ly5, Elodie Rivière6, Nicolas Traspi5, Elias Fattah7, Gaetane Nocturne7, Xavier Manet1,1, Université Paris-Sud, INSERM U1184, Le Kremlin Bicêtre, France, 2Université Paris-Sud, Institut Gallien, Châtenuay-Malabry, France

Background: Monocytes/macrophages are key players in the pathogenesis of Rheumatoid arthritis (RA). Monocytes can differentiate into pro-inflammatory macrophages (M1-like) or into anti-inflammatory, macrophages (M2-like). We previously found a defect of monocytes polarization into M2-like macrophages, in RA patients and not in healthy donors (HD) or in patients with other inflammatory diseases (such as connective tissue diseases or spondyloarthritides), and a propensity for preferential maturation towards M1-like pro-inflammatory macrophages that could contribute to synovial inflammation.

M1-155 expression has been shown elevated in RA synovial macrophages and in blood monocytes. M1-155 inhibits mRNA of 2 important proteins involved in programming of M2 macrophages (SOG and C/EBP-β).

Objectives: We assessed if miR-155 could play a role in the defect of monocytes polarization into M2-like macrophages both in human RA and in a mouse model of collagen-induced-arthritis (CIA) mice.

Methods: Monocytes were isolated from PBMCs for HD and RA by negative selection. Purified monocytes were transfected using AMAXA technologies with mir-155 mimic (for HD) or anti-miR155 (for RA) or controls mits. Then monocytes were incubated in the presence of human serum (SAB) (M2-like) for 6 days. Expressions of total macrophages markers (CD11b and CD71), M2-like macrophages markers (CD163, CD206 and Arg-1), M1-like macrophage marker (iNOS) were evaluated by flow cytometry, ELISA or immunofluorescence.

A. Monocytes from healthy donors
B. Monocytes from RA patients
C. Monocytes from CIA or control mice

Science Abstracts
The defect of monocytes capacity of differentiation into M2-like phenotype was also found in in CIA mice as compared to controls, with a decreased expression of CD206, IL-10 secretion and Arginase-1 expression (Fig. 1C). MR155 was also involved in this defect in mice: its expression level was the same in M1-like macrophages between controls and CIA mice, whereas it was increased in M2-like CIA macrophages compared to controls mice (Fig. 1C).

Conclusion: MR155 plays a key role in the specific defect of anti-inflammatory M2 macrophages polarization found both in human rheumatoid arthritis and in CIA mice. MR155 could represent a new therapeutic target in RA that can be tested in the mouse model of CIA.

Disclosure of Interests: Audrey Paolotti: None declared, franneley reynaud: None declared, julien rohmer: None declared, juliette pascaud: get in RA that can be tested in the mouse model of CIA.

TREATMENT ACTIVE RHEUMATOID ARTHRITIS AND THE EFFECT OF THE TYPES AND PREVALENCE OF ENDOSTEAL DNA DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

Maria Papa1, Nikolaos Vlachogiannis1, Alexandra Angyriou1, Vassilis L. Souliotis1,2, Petros Sfikakis1,2. 1First Department of Propaedeutic Internal Medicine and Joint Rheumatology Program, National and Kapodistrian University of Athens, Medical School, Athens, Greece; 2Institute of Biology, Medicinal Chemistry and Biotechnology, National Hellenic Research Foundation, Athens, Greece

Background: Increased endogenous DNA damage poses a serious threat to cell health, since it may lead to mutagenesis, genomic instability and cellular apoptosis. DNA damage accumulation in immune cells occurs in patients with chronic inflammatory diseases, however; little is known on the types and prevalence of endogenous DNA damage in patients with Rheumatoid arthritis (RA).

Objectives: To study DNA damage response and repair network in patients with active RA and to test the hypothesis that anti-rheumatic treatment influences this network.

Methods: Peripheral blood mononuclear cells were isolated from 15 patients with active RA and 65 apparently healthy controls; 8 patients were re-examined after 12-week treatment. Endogenous DNA damage was determined using alkaline comet assay. Specific markers for single-strand DNA breaks (SSBs; RPA32) and double-strand DNA breaks (DSBs; γH2AX, 53BP1) were measured using western-blot. Formation of DNA damage was assessed by oxidative stress and abasic DNA sites measurements. Chromatin organization and the two subpathways of the fundamental nucleotide excision repair mechanism, namely, transcription-coupled repair (TCR) and global genome repair (GGR), were assessed along the N-ras gene.

Results: A 3-fold increase of endogenous DNA damage levels (Olive Tail Moment reflecting both SSBs and DSBs) was evident in active RA [mean±SD: 12.8±7.5 versus 4.5±2.4, p<0.001], as well as induction of RPA32, γH2AX and 53BP1, higher oxidative stress levels and increased abasic sites, compared to controls. While TCR capacity was preserved, GGR capacity was deficient in all active RA patients. Moreover, a more condensed chromatin structure was found in active RA compared to controls. Following treatment, chromatin structure loosened, GGR capacity was restored, oxidative stress and abasic sites decreased and levels of endogenous DNA damage reached control values in all patients.

Conclusion: Deregulated chromatin organization, deficient DNA repair capacity and augmented formation of DNA damage contribute to the accumulation of endogenous DNA damage in patients with active RA and are reversible after treatment. Additional studies to better understand the negative impact of DNA endogenous damage accumulation may create new therapeutic opportunities for patients with RA.

Apolipoprotein B derived peptides inhibit production of pro-inflammatory cytokines in PBMC of rheumatoid arthritis (RA) patients and improve arthritis in animal model of RA

Ji-Soo Park1,2, Joo Youn Lee1,2, Hyun Jung Yoo2, Jeong Yeon Kim3,2, Ji-Hye Lee1,2, Seon Uk Kim1,2, Ra Ham Kim1,2, Jin Kyun Park1, Eun Young Lee2, Eun Bong Lee2, Eugene C. Yi1, Yeong Wook Song1,2. 1Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Seoul National University, Seoul, Korea; Rep. of (South Korea); 2Division of Rheumatology, Department of Internal Medicine, College of Medicine, Seoul National University Hospital, Seoul, Korea, Rep. of (South Korea)

Background: Alpha-enolase (ENO1) is a multifunctional glycolytic enzyme. The cell-surface expression of ENO1 is increased in monocytes isolated from peripheral blood mononuclear cells (PBMCs) of RA patients. In previous experiments, we reported apolipoprotein-B (apoB) to be a novel ligand of cell surface expressed ENO1 and to enhance chronic inflammation in RA (1).

Objectives: This study was performed to evaluate agonistic or antagonistic function of peptide sequences within apoB, which modulated severity of arthritis in K/BxN serum transfer arthritis mouse model.

Methods: Peptides binding to ENO1 were evaluated by peptide microarray. Peptides were designed to have twelve amino acids overlap. Levels of pro-inflammatory cytokines produced by PBMCs were measured after treatment with peptides in RA patients and healthy controls (HCs). To evaluate the agonistic function of peptides, RA PBMCs pre-treated with peptides were stimulated with apoB and pro-inflammatory cytokines were measured in culture supernatant. Peptides PBMCs stimulated with apoB. These three peptides were named IP (inhibitory peptide)1, IP2 and IP3. IPs were injected after induction of the arthritis in K/BxN serum transfer mice in vivo. Ankle thickness and arthritis score to determine whether peptides could reduce arthritis severity.

Results: Among eighty five peptides from apoB, five peptides exhibited strong binding to ENO1. Two peptides increased production of pro-inflammatory cytokines, IL-1β, IL-6 and TNF-α, but three peptides did not change levels of pro-inflammatory cytokines in RA and HCs. How- ever the three peptides reduced production of pro-inflammatory cytokines in RA PBMCs stimulated with apoB. These three peptides were named IP (inhibitory peptide)1, IP2 and IP3. IPs were injected after induction of the arthritis in K/BxN serum transfer mice in vivo. Ankle thickness and arthritis scores were substantially reduced in IPs treated group than control group, and synovial inflammation, bone erosion and cartilage damage of arthritis were less severe in the IPs-treated groups. Especially, IP2 showed the most significant effect.

Conclusion: The apoB derived peptides interacting with ENO1 could have novel therapeutic effect in RA.

Disclosure of Interests: None declared

CHOLESTEROL SEQUESTERING IN MACROPHAGES CONTRIBUTES TO THE LIPID PARADOX IN CHRONIC ARTHRITIS

Sandra Pérez-Bagos1, Junko Arakawa2, Raquel Largo-Carazo1, Katsunori Ikewaki3, Gabriel Herrero-Beamonte3, Bone and Joint Research Unit, Rheumatology Dept., IIS-Fundación Jiménez Díaz UAM, Madrid, Spain
3Division of Anti-aging and Vascular Medicine, Internal Medicine Dept., National Defense Medical College, Tokorazawa, Japan

Background: Patients with active rheumatoid arthritis (RA) have increased cardiovascular mortality, paradoxically associated with reduced circulating lipid levels (1-3). Several disease-modifying antirheumatic drugs (DMARDs), such as the JAK inhibitor tofacitinib, ameliorate disease activity along with an increase in serum lipids (4, 5). We previously demonstrated in vitro that tofacitinib favored cholesterol efflux from macrophages through an ABCA1-dependent mechanism (6). Furthermore, tofacitinib-treated chronic arthritic rabbits showed increased circulating lipids and decreased lipid accumulation within the synovium (6).

Objectives: Our aim was to explore in vivo whether inflammation impedes cholesterol efflux from macrophages, and whether tofacitinib restores macrophage cholesterol release during chronic arthritis. For that purpose, we assessed the ability of intraperitoneally-injected 3H-cholesterol labelled macrophages to efflux cholesterol to circulating lipoproteins in collagen-induced arthritis (CIA) mice treated with tofacitinib or placebo, as compared to healthy controls.

Methods: DBA/1J mice were randomly assigned to healthy controls (Control, n = 9), CIA (CIA, n = 6) and CIA mice receiving 50 mg/kg/day tofacitinib, orally, for three consecutive days, starting on day 39 after CIA induction and coinciding with disease peak (CIA+TOFA, n = 6). The day after, 3H-cholesterol labeled RAW264.7 macrophages were intraperitoneally injected into mice and tracer appearance was monitored in plasma lipoprotein fractions, synovium, liver, bile and feces.

Results: The CIA group showed higher C-Reactive protein levels (CRP, µg/ml; Control: 10.50±5.9; CIA: 13.86±1.05, p≤0.03 vs. Control) and lower circulating 3H-cholesterol levels (% of injected disintegrations per minute (dpm)/ml; Control: 1.29±0.11, CIA: 0.92±0.11, p≤0.04 vs. Control). Both serum CRP and 3H-cholesterol –particularly the HDL fraction– were restored to baseline after the treatment with the JAK inhibitor (CIA+TOFA: 10.97±0.67 µg/ml and 1.37±0.20 % of injected dpm/ml, respectively, p≤0.05 vs. CIA). Concomitantly, we observed an upward trend in 3H-cholesterol accumulation within the synovium of CIA animals as compared to controls, which tended to normalize with the treatment.

Conclusion: Systemic inflammation induces cholesterol sequestering within macrophages in vivo by acting on cholesterol efflux transporters (6). Tofacitinib favors cholesterol release to plasma lipoproteins, hence increasing circulating cholesterol. This is not only due to a decrease in inflammation –as the effect is likely shared with some other shared, DMARDs may have, but also to a direct mechanism on ABCA1 transporters that favors cholesterol efflux. To our knowledge, this is the first report suggesting that cholesterol dynamics in the macrophage may contribute to the overall circulating cholesterol levels, especially considering that this phenomenon may occur in other cell types, such as adipocytes.

IMPORTANT ROLE OF CD11C+ CELLS IN INFLAMMATORY ARTHRITIS

Antonia Puchner1, Elisabeth Simader1, Victoria Saferding1, Gerhard Krönke2, Rene Pfeifle2, Daniel Aletaha1, Josef S. Smolen 1, Stephan Blüml1.
1Medical University Vienna, Internal Medicine III, Vienna, Austria
2Medical University Erlangen, Erlangen, Germany

Background: Dendritic cells (DCs) are important antigen presenting cells (APCs) and therefore they play an important role in bridging the innate and the adaptive immune response. DCs can be divided in different sub-sets with specific functions. As powerful APCs, DCs are thought to play an important role in the induction of autoimmune diseases such as rheumatoid arthritis. However, the active role of DCs in joint inflammation is not known yet.

Objectives: Investigation of the role of DCs cells in joint inflammation and destruction.

Methods: We analyzed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of CD11c+ cells by immunohistochemistry. We used CD11c-diphtheria toxin receptor (DTR) transgenic mice. K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BARF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

Results: Both CD8+CD11c+ and CD11b+CD11c+ can be found in synovial tissue in TNF driven arthritis. Upon depletion of CD11c+ cells clinical signs of K/BxN serum transfer arthritis were significantly reduced. Histological analysis found reduced synovial inflammation after the depletion of CD11c+ cells in K/BxN arthritis. In addition, local bone destruction and the number of osteoclasts was also significantly reduced. In addition to K/BxN arthritis, we found that also in TNF-driven arthritis depletion of CD11c+ cells led to a striking reduction of synovial inflammation and a complete depletion of osteoclasts.

Conclusion: These data show that in addition to initiating an adaptive immune response, CD11c+ dendritic cells, are also involved in innate effector mechanisms of inflammatory arthritis. Especially CD11b+CD11c+ and monocyte derived inflammatory seem to play a role in inflammatory arthritis, suggesting that they could be an important therapeutic target.

SAT0062

STRATIFIED MEDICINE FOR RHEUMATOID ARTHRITIS: PREDICTING RESPONSE TO BIOLOGIC THERAPY USING IMMUNE CELL SIGNATURES

Gemma Radøy1, Ben Muheem2,3, Laura Donlin1, Jennifer H. Arndt1, Michael Brenner1, Soumya Raychaudhuri3, Kimme Hyrich1, 2, Ansur Morgan1, Gerry Wilson1, Joyce Ayis1, Tracy Russell1, Anne Barton1, Sebastian Viate1.
1University of Manchester, Arthritis Research UK Centre for Genetics and Genomics, Manchester, United Kingdom1University of Manchester, Manchester Collaborative Centre for Informat Research, Manchester, United Kingdom1Well Cornell Medical College, Department of Medicine, New York, NY, United States of America, 2University of Rochester, Department of Medicine, Rochester, NY, United States of America, 3Brigham and Women’s Hospital and Harvard Medical School, Boston, MA, United States of America, 4University of Manchester, Arthritis Research UK Centre for Epidemiology, Manchester, United Kingdom6University of Manchester, UK, United Kingdom7Chapel Allerton Hospital, NHS Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom1University College Dublin, Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland, 8Newcastle-upon-Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle-upon-Tyne, United Kingdom

Background: Treatment selection of biologic therapy for patients with rheumatoid arthritis (RA) is currently a trial and error process, with approximately 40% failing to respond well to the first biologic. The lack of biomarkers to predict treatment response leads to further pain, joint damage, patient anxiety and is cost ineffective for those who are non-responders.

Objectives: We aim to identify immune signatures from a pre-treatment blood test to inform the choice of treatment strategies for stratified medicine.

Methods: RA patients with active disease (DAS28 > 5.1) who failed to respond to conventional DMARDs and were due to commence biologic treatment were included in the BRAGGSS cohort. Peripheral blood mono-nuclear cells (PBMCs) taken before the initiation of biologic treatment were available for 300 patients (good (60%), moderate (25%), and non-

Scientific Abstracts
responders (15%) to various biologics (anti-TNFs (68%), Rituximab (16%), Tocilizumab (13%), Abatacept (3%)). PBMCs were left unstimulated (anti-CD3/CD28 beads or 10 ng/mL LPS) and stained with three flow cytometry panels including specific surface, intracellular and intranuclear markers to deeply characterise the function of several subsets of monocytes, NK cells, T cells and B cells (e.g. disease-associated cell populations such as PD-1+CXCR5 peripheral T helpers (Rao DA Nature 2017), CD27+HLA-DR+ effector CD4+ T cells (Fonseka CY Sc Transl Med 2018) and cytotoxic PD-1+CXCR5 CD8+ T cell subsets. Total CD11c+ autoimmune-associated B cells, CD14+IL-18+ pro-inflammatory monocytes (Zhang F BioRxiv 2018)). Hypothesis-free clustering algorithms were also used for data analysis to identify unreported cell populations. Statistical association testing was performed using mixed effects ordinal (EULAR responder status and linear (DAS28 or its components)) regression models.

**Results:** Preliminary interim analysis identified associations between pan-biologic non-response and spontaneous expression of pro-inflammatory cytokines (Th1, Th17 lineage) by CD4+ T cells (p < 0.003). Good response to all biologic drugs was independently associated with the number of CD56dimCD16+ NK cells (p < 0.001). Good response to anti-TNFs was associated with TNFα, IFNγ and perforin producing CD4+ T cells after in vitro stimulation with anti-CD3/CD28 (p < 0.02).

**Conclusion:** Ongoing work involves the replication of these results. The identification of immune cell types associated with response to a particular class of biologic drugs (e.g. anti-TNFs, but not other classes) might inform the choice of first line biologic drugs based on individual patients' immune profiles (stratification to treatment response categories or cytokines generally associated with non-response to all biologics could represent new therapeutic targets, at least in some patient groups).

**Background:** The contribution of cigarette smoking to the risk of rheumatoid arthritis (RA) is large for seropositive than for seronegative patients. Current pathogenic models explain this difference via the production of anti-citrullinated protein antibodies (ACPA) induced by protein citrullination of monocytes, NK cells, T cells and B cells (e.g. disease-associated cell populations. Although their relevance to CV disease is uncertain. Recently, the expression of angiotensin-converting enzyme (ACE) expression has been significantly larger than with two antibodies (OR = 1.54, p = 1.4 x 10^{-6}), whereas the association with the presence of two antibodies was not larger than with one autoantibody (OR = 1.11, p = 0.3). In the patients remaining after exclusion of the triple seropositive, the smokers were exclusively associated with the RF (OR = 1.28, p = 0.003) and OR = 1.30, p = 0.004 in the double and single positive patients, respectively. This association was independent of the reference, either the triple seronegative (OR = 1.29, p = 0.001) or all the RF patients (OR = 1.32, p = 0.002).

**Conclusion:** Smoking increases RA susceptibility by promoting pathways leading to the concurrent presence of the three RA autoantibodies and, in its defect, to the production of RF. These actions are not covered by current pathogenic models and suggest that smoking accelerates epitope spreading.

**SAT0064** EXPANSION OF CD16+ MONOCYTE SUBSETS AND ACE EXPRESSION ARE ASSOCIATED WITH ARTERIAL THICKENING AND VASCULAR FUNCTION IN VERY EARLY RHEUMATOID ARTHRITIS

Javier Rodriguez-Carrio1,2, Mercedes Alperó-López3, Patricia López4, Ángel Pérez-Alvarez4, Lorena Benavente5, Francisco Javier Ballinac-Garcia6, AnaSuárez1,1

1University of Oviedo, ISPAA, Area of Immunology, Oviedo, Spain; 2Hospital Universitario Central de Asturias, Bone and Mineral Research Unit, Instituto Reina Sofia de Investigación Neurofisiológica, REDINRHI del ISCIII, Oviedo, Spain; 3Hospital Universitario Central de Asturias, Department of Rheumatology, Oviedo, Spain; 4Hospital Universitario Central de Asturias, Department of Neurology, Oviedo, Spain

**Background:** monocytes are largely recognized as drivers of the atherosclerosis development, the leading determinant of cardiovascular (CV) morbidity in rheumatoid arthritis (RA). Far from being a unique population, functionally and phenotypically subpopulations can be distinguished, although their relevance to CV disease is uncertain. Recently, the expression of angiotensin-converting enzyme (ACE) expression has been significantly larger than with two antibodies (OR = 1.54, p = 1.4 x 10^{-6}), whereas the association with the presence of two antibodies was not larger than with one autoantibody (OR = 1.11, p = 0.3). In the patients remaining after exclusion of the triple seropositive, the smokers were exclusively associated with the RF (OR = 1.28, p = 0.003) and OR = 1.30, p = 0.004 in the double and single positive patients, respectively. This association was independent of the reference, either the triple seronegative (OR = 1.29, p = 0.001) or all the RF patients (OR = 1.32, p = 0.002).
described, with some heterogeneity being observed across monocyte sub-sets. However, although previously linked to blood pressure control, the significance of ACE expression on monocytes remains obscure.

**Objectives:** To evaluate whether monocyte subsets and ACE expression are associated with surrogates of CV subclinical disease in very early RA patients.

**Methods:** Patients were recruited upon early referral to the rheumatology department. All patients were untreated at the time of sampling. The frequency of classical (CD14+CD16-) and non-classical (CD14/CD16+) monocyte subpopulations and ACE expression were assessed by flow cytometry in peripheral blood. Plaque occurrence, CIMT and stiffness parameters were analyzed by Doppler ultrasound in internal carotid, middle cerebral and basilar arteries.

**Results:** 53 patients were recruited, 47 fulfilling 2010 ACR/EULAR classification criteria for RA (36 women, 26 FRI+ and 26 ACFA+) and 6 fulfilling criteria for Clinically Suspected Arthralgia (CSA) (6 women, 3 FRI+ and 2 ACFA+). Non-classical and intermediate monocytes were positively associated with CIMT (r=0.413, p=0.005 and r=0.353, p=0.018, respectively), as well as with pulsatility (r=0.332, p=0.026 and r=0.323, p=0.030) and resistivitiy indices (r=0.286, p=0.050 and r=0.277, p=0.045) at the left internal carotid artery. Expansion of CD16+ monocytes was not associated with disease activity, measured as DAS28 or SDAI (all p>0.050), but frequency of intermediate monocytes paralleled duration of the symptoms (r=0.324, p=0.020). ACE expression was higher in CD16+ monocyte subsets than in their classical counterparts. ACE expression was not associated with blood pressure, individual traditional CV risk factors, body mass index nor with mSCORE (all p>0.050). ACE expression on intermediate and classical monocytes was correlated with CIMT (r=0.382, p=0.010 and r=0.349, p=0.019, respectively). Moreover, ACE expression in all monocyte subsets was strongly associated with resistivity and pulsatility indices at the inter- nal carotid artery (all p<0.010).

**Conclusion:** The expansion of CD16+ monocyte subsets and the ACE expression are associated with arterial wall thickening and vascular functionality in treatment-naive RA patients, hence suggesting a very early role for monocyte traits in this scenario. None declared

**SAT0065**

**WNT5A INCREASES RHEUMATOID SYNOVIOCYTE MIGRATION THROUGH RYK RECEPTOR AND RHO-ROCK PATHWAY**

Antonio González, Carmen Conde.

**Background:** Fibroblast-like synoviocytes (FLS) are pivotal in inflammation and joint damage of rheumatoid arthritis (RA). These cells acquire an aggressive phenotype of rheumatoid synoviocytes. To analyse the molecular mechanisms involved in the activation of AKT and GSK3 against native chicken CII were significantly higher in T-bet -/- mice. However, IgG2a antibody production was significantly lower in T-bet -/- mice compared to B6 wild-type mice and the incidence of arthritis was around 1.5-fold higher. 2) The levels of total IgG2, IgG3 antibodies against native chicken CII were significantly higher in T-bet -/- mice. However, IgG2a antibody production was significantly lower in T-bet -/- mice compared to B6 mice. 3) The number of CD4+ T (CD3+CD4+), CD8+ T (CD3+CD8+) and CD19+ B (CD19+) cells, as well as macrophages (CD11c+CD11b+Gr1-), neutrophils (CD11c+CD11b+Gr1+), NK cells (CD3+CD56+) in the lymph node was not different but the number of NKT (CD3+CD1+IL-2+) cells was significantly decreased in T-bet -/- mice.

**Results:** 1) CIA developed in the T-bet -/- mice was more severe than that of B6 wild-type mice and the incidence of arthritis was around 1.5-fold higher. 2) The levels of total IgG2, IgG3 antibodies against native chicken CII were significantly higher in T-bet -/- mice. However, IgG2a antibody production was significantly lower in T-bet -/- mice compared to B6 mice. 3) The number of CD4+ T (CD3+CD4+), CD8+ T (CD3+CD8+) and CD19+ B (CD19+) cells, as well as macrophages (CD11c+CD11b+Gr1-), neutrophils (CD11c+CD11b+Gr1+), NK cells (CD3+CD56+) in the lymph node was not different but the number of NKT (CD3+CD1+IL-2+) cells was significantly decreased in T-bet -/- mice. 4) T-bet knockout (T-bet -/-) mice (C57BL/6, B6 background) were generated as previously described (3). T-bet -/- mice were immunized with CIA and CFA, and the incidence and severity of CIA was assessed. 2) Anti-CII antibodies in the sera from T-bet -/- mice on day 60 after the first immunization were measured. 3) Lymph node cells from B6 or B- bet -/- mice immunized with CIA were analyzed by flow cytometry using antibodies specific for CD3, CD4, CD8, CD11b, CD11c, CD19, Gr1 and NK1.1. 4) The lymph node cells described above were cultured in the CIA containing medium, then the cytokine production was assayed by ELISA.

SECRETORY ANTIBODIES TO CITRULLINATED PEPTIDES IN PLASMA AND SALIVA FROM RHEUMATOID ARTHRITIS PATIENTS AND THEIR UNAFFECTED FAMILY MEMBERS
Anna Svärd, Karin Roos Ljungberg, Mikael Brink, Solbritt Rantapää Dahlqvist, Center for Clinical Research Dalarna, Uppsala university, Falun, Sweden. 2. Department of Rheumatology and Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden. 3. Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden

Background: Mucosal involvement in early phases of rheumatoid arthritis (RA) pathophysiology has emerged as an attractive hypothesis, supported by several findings. Elevated levels of antibodies against citrullinated peptides/proteins (ACPAs) can be found during a long pre-symptomatic period, preceding manifest arthritis. Secretory antibodies are produced at mucosal surfaces, but can also be detected in the circulation. Secretory ACPA in plasma has been demonstrated in patients with RA (1). First-degree relatives (FDRs) of patients with RA can be regarded as potential pre-RA patients or at-risk individuals. In a previous study, a higher prevalence of ACPA was found in FDRs than in healthy controls (2), with IgA-ACPA being more common than IgG-ACPA. We hypothesized that formation of secretory ACPA is an early step in RA development, preceding the occurrence of regular non-secretory ACPA, and consequently secretory ACPA would be prevalent in a large proportion of FDRs.

Objectives: To evaluate secretory ACPA in plasma and saliva from patients with RA and FDRs.

Methods: We analyzed secretory antibodies to 2nd generation cyclic citrullinated peptides (anti-CCP) in plasma from 194 patients with RA and 191 FDRs unaffected by RA and saliva samples from 25 RA patients, 21 first-degree relatives and 11 controls. In plasma, cutoff for secretory ACPA was set at the 99th percentile of healthy blood donors. In saliva, a positive test was defined as a difference between optical density values for IgA anti-CCP and IgA anti-cyclic arginine peptide (delta OD value) >2 SD above the mean delta OD value of the controls. Mann-Whitney U test was used for continuous variables and Pearson Chi-square for categorical variables.

Results: Secretory ACPA occurred in 37 (19.1%) of RA patients but only in 2 (1%) of FDRs (table 1). Salivary IgA ACPA was found in 3/25 (12%) of patients with RA, but not in any of the 21 FDRs. 27% of FDRs were positive for regular non-secretory IgA ACPA in plasma, and out of them, only 2 individuals (5%) were positive for secretory ACPA in plasma. Among FDRs negative for regular ACPAs, no one was positive for secretory ACPA. Secretory ACPA had the highest PPV for identifying patients, while IgG ACPA had the highest negative predictive value (table 2).

Conclusion: Secretory ACPA in plasma and saliva was rare in FDRs. Circulating secretory ACPA had the highest PPV of the RA-related antibodies tested to identify RA in these families. This implies that mucosal production of ACPA is not common in an at-risk population, but may be important in the transition from increased risk to actual RA disease.

SA10068
CIRCADIAN RHYTHMS OF IMMUNE SYSTEM IN HEALTHY INDIVIDUALS AND PATIENTS WITH RHEUMATOID ARTHRITIS
Siska Williard, Cindy Streli, Dimas Abidinama, Timo Gaberi, Frank Buttger, Charité – Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany. 2. Deutsches Rheuma-Forschungszentrum (DRFZ), AG Buttger (Glucocorticoid and Bioenergetics), Berlin, Germany

Background: Chronobiological aspects play an important role in rheumatoid arthritis (RA), with major symptoms such as joint pain and stiffness follow a day-night-cycle that peak in the early morning. The circadian behavior of symptoms has been attributed to the rhythmic expression of cytokines and hormones1,2. Animal models of autoimmune inflammation demonstrated that immune cells, which belong to the vast producers of such cytokines, circulate in a circadian manner and that the circadian rhythm of circulating immune cell is different in health and disease3. Moreover, coordinating timing of glucocorticoid therapy (chronotherapy) results in a greater reduction of morning stiffness and pain compared with the same glucocorticoid dose taken in the morning4.

Objectives: Here, we aim to analyse the circadian rhythms of circulating immune cell populations in the periphery of healthy individuals and RA patients in order to optimize treatment strategies.

Methods: We performed a 24-hours study involving 14 eligible RA patients and 12 healthy individuals to monitor the dynamic occurrence of diverse immune cells in the periphery. A week prior to study day, the biological rhythms were synchronized by scheduled activities and food intakes. On the study day, blood was drawn every 2 hours throughout 24 hours using peripheral venous catheter. The participants were provided with regular meal, allowed to eat snacks ad libitum and carry passive activities. Blood samples were subsequently analyzed by flow cytometry using TruCount Beads to count absolute cell numbers. RNA from CD14+ monocytes was analyzed by real-time PCR to monitor the circadian clock genes expression.

Results: We investigated major immune populations and found chronobiological differences in NK T cells, NK cells, CD8 T cells, CD4 T cells and regulatory T cells (Tregs) of healthy individuals and patients with RA. In RA Tregs showed a lag phase of 5 hours, while CD8 and CD4 T cells showed a mild reduction of the amplitude. NK T cells and NK cells did not circulate in a circadian manner in healthy individuals, but they exhibited circadian pattern in RA. In addition, the qPCR data also indicated a disrupted circadian rhythm on RNA level. Among ten clock genes that were examined, REVERBx, PER1, and PER2 showed altered expression in RA patients. The expression of REVERBx was suppressed by 50% and the rhythm of PER1 was diminished in RA patient.
Furthermore, the rhythm of PER3 was present exclusively in RA patients, but not in healthy participants.

Conclusion: Taken together, we conclude that the circadian rhythms of immune cells in RA patients are different from that in healthy individuals. The alteration can be observed on both cellular and RNA level. We postulate that the alterations in circadian rhythms may contribute to disease manifestations and may have impact for optimizing diagnosis and therapy in RA. Further analysis is required to expand the data set. It is also of interest to investigate the functionality of circadian clock genes in immune cells.

SAT0069 PROTECTIVE EFFECT OF PROTOCATECHUIC ACID RICH FRACTION OF TRIANTHEMA PORTULACASTRUM AGAINST COLLAGEN INDUCED RHEUMATOID ARTHRITIS VIA GUT MICROBIOTA MODULATION

Ekta Yadav, SHUAT, Allahabad, India

Background: Rheumatoid arthritis, a chronic inflammatory joint disease affects people all over the world. Triantehma portulacastum (TP) has been traditionally utilized for the treatment of rheumatism. Abeer Abdelal1, Rasha Ghazali2, Rehab Elzem3, Fatema Dwedaw4, Reham Shams-Eldeen5, Noah Kandeer6. 1Department of Internal Medicine, Rheumatology Unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt; 2Department of Medical Biochemistry, Faculty of Medicine, Alexandria University, Alexandria, Egypt; 3Department of Physical Medicine, Rheumatology and Rehabilitation, Faculty of Medicine, Alexandria University, Alexandria, Egypt; 4Department of Chemical Pathology, Medical Research Institute, Alexandria University, Alexandria, Egypt

Methods: Hydroethanolic extract of TP was fractionated with three different solvents (ethyl acetate, chloroform and n-butanol) and quantitatively analyzed with HFLC-DAD method which revealed n-butanol fraction of TP (BFTP) is rich in protocatechueic acid along with other phenolic compounds. Animals were randomly divided into five groups. Four groups were injected with bovine type-II collagen (BTC-II; 100 μg) in Freund’s complete adjuvant (0.1 ml) intradermally. On day 21, animals were again treated with BTC-II along with booster incomplete Freund’s adjuvant injection. After 24 hrs, animal groups were administered intraperitoneally with their respective drug treatment, i.e., vehicle, BFTP (100, 200 and 400 mg/kg b.w) and methotrexate (3 mg/kg b.w), respectively once in a day for next 21 days. At the end of experiment serum level of pro-inflammatory cytokines was determined, and gut microbiota was analyzed by using illumina HiSeq.

Results: Results revealed BFTP preadministered group exhibited significantly reduced level of paw swelling and arthritis score as compared to vehicle group. Immunohistological studies of mice ankle soft tissue also supported the protective effect of BFTP. Additionally, BFTP repair altered gut microbial communities by reducing relative loads of inflammatory microbes such as Mucispirillum, Helicobacter and Lachnospiraceae.

Conclusion: The results conclude that BFTP possess beneficial anti-inflammatory response in arthritic model and can be used as a potential anti-arthritis agent for the management of arthritis.

Rheumatoid arthritis – prognosis, predictors and outcome

SAT0070 PROTEOMIC SPECTRUM PROFILE IN INFLAMMATORY AND DEGENERATIVE ARTHRITIS

Abeer Abdelal, Rasha Ghazali, Rehab Elzem, Fatema Dwedaw, Reham Shams-Eldeen, Noah Kandeer. 1Department of Internal Medicine, Rheumatology Unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt; 2Department of Medical Biochemistry, Faculty of Medicine, Alexandria University, Alexandria, Egypt; 3Department of Physical Medicine, Rheumatology and Rehabilitation, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: The identification and quantification of protein biomarkers present in tissues and body fluids is a new area of interest in the clinical management of rheumatic diseases. Proteomics may identify novel biomarker(s) which assist in understanding the pathogenesis of rheumatic disorders with diagnostic and prognostic implications. In addition, proteomic techniques in RA may be helpful to identify newer autoantibodies and inflammatory acute phase proteins.

The integration of potential biomarkers resulting from rheumatoid proteomics analyses in differential diagnosis of rheumatologic disorders is not yet fully established and so several studies are needed to confirm the efficacy of these approaches.

Objectives: The purpose of this study was to use Matrix Assisted Laser Desorption Ionization – Time of Flight – Mass Spectrometry (MALDI-TOF-MS) to identify differentially expressed disease-related and condition-specific peptide in serum of patients with Rheumatoid arthritis (RA) and osteoarthritis (OA).

Methods: Hundred participants were divided into three groups as following: RA group (35 patients with Rheumatoid arthritis representing patients with inflammatory arthritis); OA group (35 patients with Osteoarthritis representing patients with non-inflammatory arthritis); healthy control group (30 healthy volunteers). All participants were subjected to full history taking; clinical examination; and clinical Assessment of disease activity in RA patients using Disease activity score 28 (DAS-28); routine laboratory investigations; Acute phase reactants; serological tests; plain x-ray of affected joints, as well as serum proteomic profile using Magnetic beads (MB) separation and (MALDI–TOF–MS). Using the spectral data from the three groups, three different classification models for the three groups were generated using OA, SNR and QC algorithms. The OA model showed the best sensitivity and specificity in the three trials (RA versus control, OA versus control, and RA versus OA).

Results: In comparing RA versus control group; the results revealed 101 peaks that discriminated the RA from the control group; 53 were significant (PWKW p<0.05) and 48 nonsignificant. Three peaks (14;25;62) were significant and peak 75 and 23 were nonsignificant. Finally the RA group was discriminated from the OA group, the trial showed 113 peaks 73 were significant (PWKW p<0.05) and 40 nonsignificant. Five peaks were integrated (75:7767.82 40:2953.29 41:2991.59 48:4054.75 68:6434.51), and all integrated peaks were significant. The integrated peaks showed that all peaks were downregulated except peak 40 was upregulated.

Conclusion: Data obtained from proteomic analysis allow differentiation between RA, OA, and healthy subjects. Because of its simplicity and accuracy, (MALDI–TOF–MS) is a promising method for identifying differentially expressed inflammatory versus degenerative disease-related peptide.

**ANALYSIS OF CHRONOLOGICAL CHANGES IN JAPANESE VERSION OF HEALTH ASSESSMENT QUESTIONNAIRE SCORE AND FACTORS ASSOCIATED WITH J-HAQ REMISSION AT 5 YEARS AFTER DISEASE ONSET IN PATIENTS WITH RHEUMATOID ARTHRITIS USING THE IORRA COHORT**

Mai Abe1, Eichi Tanaka1, Eisuke Inoue1,2, Mikawa Kano1, Eri Sugano1, Naohiro Sugitani1,2, Kumiko Saka1, Yoko Shimizu1, Moeko Ochiai1, Rei Yamaguchi1, Naoki Sugimoto1, Katsunori Ikari1, Ayako Nakajima1,3, Atsuo Taniguchi1, Hisashi Yamakawa1,3, Tokyo Women’s Medical University, Department of Rheumatology, Tokyo, Japan; 2St. Marrianna University School of Medicine, Division of Medical Informatics, Kanagawa, Japan; 3Mie University Hospital, Center for Rheumatic Diseases, Mie, Japan

**Background:** Recent advances in rheumatoid arthritis (RA) treatment including the introduction of biologics have greatly affected treatment strategies for RA, achieving remission as a realistic treatment target. However, few reports have been concerned chronological changes in long-term physical dysfunction among large numbers of RA patients in daily practice.

**Objectives:** To evaluate chronological changes in Japanese version of Health Assessment Questionnaire score (J-HAQ) score and J-HAQ remission rates at 5 years after RA onset using the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort.

**Methods:** RA patients who developed RA between 2000 and 2010 and who first visited our hospital during the year of RA onset were divided into two groups: 1) former onset group (RA onset between 2000 and 2005) and 2) recent onset group (RA onset between 2006 and 2010). J-HAQ scores and J-HAQ remission rates at baseline and at 5 years after onset were investigated for each group, and factors associated with J-HAQ remission after 5 years were assessed by logistic regression analysis. Methotrexate (MTX), corticosteroid (steroid) and biologic DMARDs user (bDMARDs) was defined as the patients if they were used each medication during the observation period.

**Results:** The former onset group and recent onset group included 357 and 291 RA patients, respectively. For the former onset group, the average J-HAQ score/J-HAQ remission rate at baseline and 5 years after the onset was 0.659/54.6% and 0.430/71.4%, respectively. The recent onset group showed significant improvements relative to the former onset group in J-HAQ score/J-HAQ remission rates at baseline and 5 years of 0.705/52.2% and 0.316/78.4%, respectively (p < 0.001). Significant factors associated with achieving J-HAQ remission at 5 years after RA onset were: patients in the recent onset group (p < 0.001), male (p < 0.001), lower J-HAQ score (p < 0.001) at baseline, and non-steroid user (p < 0.001).

**Conclusion:** In daily practice, J-HAQ scores for RA patients remarkably improved with recent advances in RA treatment strategies. To achieve J-HAQ remission at 5 years of RA onset, beginning treatment in the early disease stage is needed to prevent deterioration of J-HAQ and treatments that avoid steroid use appear to be important.

**Acknowledgement:** We thank all patients who participated in the IORRA survey and all of the members of the Institute of Rheumatology, Tokyo Women’s Medical University, for the successful management of the IORRA cohort.

**SAT0072**

**EVALUATION OF RHEUMATOID ARTHRITIS TREATMENTS AND JOINT OUTCOMES IN RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE**

Evo Areela1, Tracy Doyle2, Jeffrey Sparks2, Aari Rao2, Yogesh Saini2, Christine Iannaccione3, Michael E. Weinblatt2, Nancy Shadick4, Bristol-Myers Squibb, Princeton, United States of America; 2Brigham and Women’s Hospital, Boston, United States of America; 3Mu Sigma, Bangalore, India

**Background:** RA-associated interstitial lung disease (RA-ILD) is an extra-articular manifestation of RA and is one of the leading causes of death in patients with RA.1 Previous studies have indicated that clinical factors such as age, sex, smoking and autoantibody positivity are strongly associated with RA-ILD.2 There is also evidence of active RA being related to increased risk for clinically apparent ILD.3 However, there are limited data on how pts with RA-ILD are managed for their joint conditions and joint outcomes.

**Objectives:** To evaluate RA treatment patterns in pts with subclinical and clinical RA-ILD compared with pts with RA without ILD, and to assess joint disease activity at baseline and change in disease activity by treatment in all cohorts.

**Methods:** Data from adult pts with RA enrolled in a longitudinal sequential RA registry were analysed. Pts in the registry were evaluated annually by a rheumatologist for disease activity and treatment, and semi-annually on multiple clinical patient-reported outcomes (PROs) and resource utilisation parameters. Pts with chest computed tomography (CT) scans performed during treatment were considered for ILD and with blood samples were included in this analysis. Pts with chest CT scans that were indeterminate for ILD were excluded from the study. Pts were then divided into two mutually exclusive groups: non-ILD RA pts and RA-ILD pts. RA-ILD pts were further divided into subclinical and clinically evident ILD. Date of chest CT scan was considered the index date. The two cohorts were compared using descriptive statistics to summarise baseline differences in demographics, disease activity measures, serostatus and treatments. Kruskal–Wallis test for continuous variables and chi-square test for categorical variables were performed, with two-sided significance level of 0.05. Multivariable linear regression was used to evaluate change from baseline to 12 months in joint disease activity for pts with available data at baseline and follow-up.
Results: 75 pts with chest CT scans were included in the analysis. Of these, 38.7% (n=29) were non-ILD RA and 61.3% (n=46) had some manifestation of RA-ILD. Of the RA-ILD cohort, 63.0% (n=29) and 37.0% (n=17) were classified as subclinical and clinically evident RA-ILD, respectively. At the time of chest CT scan, RA-ILD (vs non-ILD RA) pts were older with longer disease duration, a greater proportion were male and had higher anti-citrullinated protein antibody and RF titres (Table 1). In terms of RA treatments, a significantly greater proportion of RA-ILD (vs non-ILD RA) pts were on corticosteroids (CS; 47.8% vs 29.7%) and a significantly greater proportion of clinically evident RA-ILD (vs non-ILD RA) were on non-TNF inhibitor (TNFi) biologics. RA-ILD (vs non-ILD RA) pts had numerically higher joint disease activity and modified HAQ score at baseline (Table 1). However, the change in joint disease activity and PROs in RA-ILD pts was numerically greater vs non-ILD RA pts. In a multivariable analysis, RA-ILD status did not impact change in joint disease activity, but baseline joint disease activity was significantly associated with reduction in joint disease activity at 12 months (Table 2).

Conclusion: RA-ILD pts compared with non-ILD RA pts in clinical practice are more likely to be managed with CS therapy and non-TNFi bDMARDs. The improvement in joint disease activity was similar between RA-ILD and non-ILD RA pts. The analysis was limited by small sample size; further studies with larger pt numbers are required to confirm the findings.

SAT0074

DAS-28 DISEASE ACTIVITY DEFINES THE TNFRI/2 CO-EXPRESSION PROFILE IN RHEUMATOID ARTHRITIS PATIENTS

Aline Alshehky\textsuperscript{a,b,1}, Julia Lopatinkova\textsuperscript{1}, Julia Zhukova\textsuperscript{1}, Oksana Chumravoska\textsuperscript{1}, Nadezhda Shkaruba\textsuperscript{1}, Alexey Sizikov\textsuperscript{1}, Sergey Senikov\textsuperscript{1,2} \textsuperscript{1Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation; \textsuperscript{2Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation; \textsuperscript{3Novosibirsk State University, Novosibirsk, Russian Federation

Background: TNF-\alpha acting as main proinflammatory cytokine in rheumatoid arthritis (RA) immune processes. However, TNF-\alpha activity and functions may be regulate not only by soluble receptors (which act as decays) but also by number, density, and co-expression of its membrane-bound receptors type 1 and 2 (TNFR1 and TNFR2).

Objectives: To analyze the TNFR1/2 co-expression profile in RA patient with different disease activity in comparison to healthy donors (HD).

Methods: PBMC were analyzed from 46 HD and 84 patients with RA using flow cytometry. Patients were divided according to the DAS-28 index into groups with high (n=22, 34.4%), moderate (n=30, 46.9%) and low (n=12, 18.6%) disease activity. Co-expression of TNFR1/2 was evaluated as percentage of cell with different receptors. Number of receptors of each type per cell was counted using QuantItone PE beads (BD, USA). The following populations were analyzed: total monocyte pool; common pool of B lymphocytes; common pool of T lymphocytes; cytotoxic T cells (CD8\textsuperscript{+}), T helper cells (CD4\textsuperscript{+}), activated (CD25\textsuperscript{+}) and naive T cells (CD4CD25\textsuperscript{+})

Methods: Early RA (ERA) and LS-RA patients with conventional DMARDs insufficient response were enrolled in this observational, investigative, monocentric, non-randomized, no profit study, and treated with CTLA4-Ig in combination with methotrexate. Each enrolled RA patients underwent peripheral blood sampling and CD4+ cells isolation using magnetic micro-beads at baseline and after 6-12 months follow-up.

Flow cytometric analysis (FACS) for CD4 positive cells phenotype was performed to assess T-regulatory cells (Treg) as CD4+/CD25+/CD127- and CD4+/CD25+/Foxp3+, respectively. STAT3/STAT5 gene expression on CD4+ cells was performed by RT-PCR for each enrolled patient at every time-point follow-up. Low disease activity (LDA) and disease remission (DAS) achievement were assessed at 6 and 12 months follow-up (FU), respectively.

Results: A total of 35 patients were enrolled in the study (16 ERA and 19 LS-RA, respectively). At baseline, ERA and LS-RA did not differ based on clinical parameters. Eight (22.9%) withdrew from the study because of treatment failure (n=6), severe infection (n=1) and death (n=1). LDA or DAS remission within twelve months follow-up were achieved in 28/34 (82.4%) and 16/34 (47.1%) patients, respectively, without any significant difference among ERA and LS-RA. There were no significant differences in the demographic and clinical characteristics of RA patients at study based on LDA or DAS remission status achievement within 12 months FU, even stratifying patients based on disease duration. FACS analysis showed CD4+/CD25+/CD127- and CD4+/CD25+/Foxp3+ cells decrease during CTLA4-Ig treatment (p<0.01 and p<0.02, respectively after 12 months FU), despite disease duration and severity (R=0.549, p=0.02, respectively). Moreover, baseline STAT3/STAT5 ratio in PB patients directly correlates with Treg cells percentages (CD4+/CD25+/CD127- cells %): R=0.518, p=0.03; CD4+/CD25+/Foxp3+ cells %: R=0.349, p<0.02, respectively. Finally, baseline STAT3/STAT5 expression ratio on CD4+ cells > 0.93 (obtained by ROC analysis: AUC=0.754 +/- 0.100; Sensitivity 70.0%, Specificity: 80.0%) arose as baseline predictor factor of LDA achievement in RA patients treated with CTLA4-Ig [OR(95%CI): 12.0 (1.98-72.89)].

Conclusion: STAT3/STAT5 expression ratio in T cells at baseline identify RA patients better responding to CTLA4-Ig, which decreases Treg cells.

BACKGROUND: Patients with rheumatoid arthritis (RA) have a higher risk of cardiovascular diseases (CVD) and stroke. More knowledge about associated factors is needed since it could have implications on different treatment strategies.

Objectives: To study factors associated to CVD and stroke development in patients with established RA.

Methods: A questionnaire was sent twice to patients with established RA in the BARFOT cohort, in 2010 (n=1525) and in 2017 (n=1046) with a response rate of 73% and 68% respectively. 950 patients responded to the first questionnaire and 898 patients to the second. In a multivariate regression analysis, age, OR (66.7 vs 62.8%); mean DAS28-CRP (4.4 vs 4.7); mean HAQ (1.0 vs 1.1) were associated to CVD. Patients that developed stroke at both questionnaires. In a multivariate regression analysis age, OR (95% CI) 1.071 (1.015-1.129), male gender 7.459 (2.664-20.883) and reporting treatment with conventional DMARD 0.510 (0.259-1.004) were associated to stroke at the second questionnaire. There were no associations between reported use of NSAIDs and development of CVD or stroke in this study.

Conclusion: Knowledge about factors associated to cardiovascular disease is important when treating patients with RA. Long-term treatment with corticosteroids seems to increase the risk to develop CVD. Treatment with DMARDs, especially conventional DMARDs, seems to decrease the risk to develop stroke. There were no association between developing CVD or stroke and NSAIDs in this study.

SAT0076 EARLY REMISSION IS ESSENTIAL TO PREDICT LONGTERM REMISSION: CLINICAL RESULTS OF THE BELGIAN CAP48 RA COHORT

Tatiana Sokolova1, Aleksandra Avramovska2, Pascalis Sidinis3, Sandra Kleinberg4, Stephanie Dierickx5, Laurent Merci de Belfe6er, Serge Schreiber7, Clio Ribe8, Michael Malaise9, Maria Stoenn9, Silvana Di Romena10, Valérie Bado7, Patrick Durez11, Coordinator arthritis medical research CAP 48, supported by the RTBF, Brussels, Belgium; 2Rheumatology department, Cliniques universitaires Saint-Luc – Université catholique de Louvain – Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium; 3Rheumatology department, Hôpital Enfance, Cliniques universitaires de Bruxelles, ULB, Brussels, Belgium; 4Rheumatology department, CHU UCL Namur, Vivô, Belgium; 5Rheumatology Department, CHU Saint-Pierre, Brussels, Belgium; 6Rheumatology department, Hôpital de Jolimont, Jolimont, Belgium; 7Rheumatology department, CHU de Liège, Site du Sart-Tilman, ULg, Liège, Belgium; 8Rheumatology department, CHU UCL, Brussels, Belgium

Background: Early therapeutic intervention is crucial for patients with early rheumatoid arthritis (ERA). The goal of remission is achievable in a proportion of ERA patients.

Objectives: To evaluate the rate of patients in remission at 6 months and to correlate the 3 year remission rate. To identify baseline characteristics differences between patients achieving remission or not, and to report the best remission composite criteria to be used in daily care.

Methods: The Belgian CAP48 cohort supported by the French speaking radiotelevision (RTBF) is a unique prospective observational study of patients less than 50 years old with a recent diagnosis of ERA. All patients are native to DMARD therapy and were recruited in different rheumatologic centers in Brussels and Wallonia. At baseline and every 6 months, demographic, specific clinical evaluation, questionnaires and laboratory were completed and treatment was adapted according each physician decision.

Results: 207 RA patients from 16 centers were analysed (162 F, 45 M, mean age 36.0 years, 27.8% with baseline erosion, 62.3% with ACPA, 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI 59.9% with FR, mean HAQ 1.9, mean DAS28-CP 4.54, mean SDAI was older and more often not treated with any DMARD, 30% vs. 18%, p=0.069. There were no other significant differences between the groups. In a multivariate regression analysis age, OR (95% CI) 1.081 (1.047-1.117) and reporting treatment with conventional DMARD 0.510 (0.259-1.004) were associated to stroke at the second questionnaire. There were no associations between reported use of NSAIDs and development of CVD or stroke in this study.

Conclusion: Knowledge about factors associated to cardiovascular disease is important when treating patients with RA. Long-term treatment with corticosteroids seems to increase the risk to develop CVD. Treatment with DMARDs, especially conventional DMARDs, seems to decrease the risk to develop stroke. There were no association between developing CVD or stroke and NSAIDs in this study.

Disclosure of Interests: None declared

The time for diagnosis and treatment initiation is statistically shorter in “long term remission” group compared to the “no remission group” (mean of 1.4 months vs 3.4 months; p=0.042).

Additionally, global remission (DAS28-CRP<2.6, HAQ<0.5 and no X-ray progression) was observed in 41.5% of the long term remission group. The majority of these patients (79%) are treated with Methotrexate.

**Conclusion:** Early and long term remission is an achievable goal in our observational CAP 48 study cohort. Early diagnosis is critical in standard of care. At 6 months, DAS28-CRP and SDAI were the best remission criteria to predict long term remission.

Acknowledgement: We are grateful to all participating investigators and clinical staffs which have made crucial contributions to the development of this Project.

**Disclosure of Interests:** Tatiana Sokolova: None declared, Aleksandra Avramovska: None declared, Pascales Sidiras: None declared, Sandra Kleinberg: None declared, Stephanie Dierckx: None declared, Laurent Meric de Bellefon: None declared, Serge Schreiber: None declared, Cila Ribbens: None declared, Michel Malaise: None declared, Maria Stoennou Grant/research support from: Abbvie, Roche, Wyeth, Silvana Di Romana: None declared, Valérie Badot: None declared, Patrick Durez Speakers bureau: Bristol-Myers Squibb, Eli Lilly, Sanofi, Celltrion

**DISCLAIMER:** The time for diagnosis and treatment initiation is statistically shorter in “long term remission” group compared to the “no remission group” (mean of 1.4 months vs 3.4 months; p=0.042).

**Results:** Baseline characteristics and follow-up duration of each ACPA/erosions group are shown in table 1. Baseline DAS and HAQ were slightly higher in erosions+ patients. Follow-up duration was similar between the 4 groups. We found statistically significant differences in DAS and HAQ change over time between the 4 groups, both after maximum follow-up durations of 6 months and of 1 year (table 1), but differences were small and not clinically relevant.

Patients who were erosions-/ACPA- were less likely to switch treatment [HR (95% CI) 0.79 (0.69; 0.90)] compared to a reference group of erosions-/ACPA+ patients. Patients who were erosions+/ACPA- [HR (95% CI) 0.92 (0.79; 1.08)] or erosions+/ACPA+ [HR (95% CI) 1.01 (0.92; 1.10)] were not statistically significantly different from the reference group in their likelihood to switch treatment. No effect modification was found by country, medication or symptom duration.

**Conclusion:** In this analysis of worldwide real life data, we found statistically significant, but no clinically relevant differences in treatment response to initial DMARD therapies as measured by DAS and HAQ in ACPA-/erosions-, ACPA+/erosions-, ACPA+/erosions+ and ACPA-/erosions+ RA patients. However, ACPA-/erosions- patients were less likely to switch treatment. Thus, in newly diagnosed RA patients who are treated according to modern treatment strategies, the (combined presence of) ACPA and erosions was no risk factor for worse disease activity or physical functioning, although ACPA-/erosions- patients had fewer treatment changes.

**Disclosure of Interests:** Sytske Anne Bengstra Grant/research support from: Bristol-Myers Squibb provided funding for the completion of this Project.

**SAT0077 IMPACT OF THE COMBINED PRESENCE OF EROSIONS AND ACPA ON 6 AND 12 MONTHS CLINICAL OUTCOMES OF RHEUMATOID ARTHRITIS: RESULTS FROM THE METEOR REGISTRY**

Sytske Anne Bengstra; Maura Couto; Nirmisha Govind; Anvird Chopra; Karen Solomon-Escoto; Elizabeth Murphy; Thomas Huizinga; Cornelia Allar1; 1LUMC, Leiden, Netherlands; 2Hospital Sao Teotónio, Viseu, Portugal; 3University of the Witwatersrand, Johannesburg, South Africa; 4CRD, Pune, India; 5University of Massachusetts/UMass Memorial MC, Worcester, United States of America; 6University Hospital Wishaw, Wishaw, United Kingdom

**Background:** Despite efforts to predict treatment response, treatment of rheumatoid arthritis (RA) patients remains mostly a case of trial and error. Presence of erosions and ACPA are often considered poor prognostic factors based on their association with radiographic damage progression, but with the introduction of treat-to-target ever fewer patients develop significant radiographic damage. Therefore research into prognostic factors should focus on clinical outcomes.

**Objectives:** To investigate in newly diagnosed RA patients if presence of erosions and/or ACPA are associated with functional ability, disease activity and treatment survival during the first year of treatment in daily practice.

**Methods:** Newly diagnosed patients with a clinical diagnosis of RA, ≥3 months follow-up and available data on ACPA, erosions and medication were identified in the international, observational METEOR registry (n=4,623). Timing and frequency of follow-up visits were according to daily practice. We focused at results after a maximum follow-up duration of 6 months or of 1 year from baseline. Associations between the presence of erosions and/or ACPA (4 groups) with the change of DAS and HAQ over time were assessed using linear mixed models.

**Results:** Baseline characteristics and change of DAS and HAQ over time were assessed using linear mixed models. Presence of erosions and/or ACPA were associated with functional ability, disease activity and treatment survival during the first year of treatment in daily practice.

**Conclusion:** Early and long term remission is an achievable goal in our observational CAP 48 study cohort. Early diagnosis is critical in standard of care. At 6 months, DAS28-CRP and SDAI were the best remission criteria to predict long term remission.

**Disclosure of Interests:** Sytske Anne Bengstra Grant/research support from: Bristol-Myers Squibb provided funding for the completion of this Project.
MAJOR CHANGES IN THERAPY PRODUCE SIGNIFICANT CLINICAL IMPROVEMENT ACROSS A BROAD RANGE OF CLINICAL DISEASE ACTIVITY IN US VETERANS WITH RHEUMATOID ARTHRITIS

Grant Cannon1, Wei Chen2, Jincheng Shen2, Neil Accortt3, David Collier3, Brian Sauer4, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, United States of America; 2University of Utah, Biostatistics, Salt Lake City, United States of America; 3Amgen Inc., Thousand Oaks, United States of America

Background: Our recent work showed that 41% of patients with moderate/severe rheumatoid arthritis (RA) by Disease Activity Score for 28 joint count (DAS28) did not have changes in RA therapy as recommended by current guidelines (1). Reasons identified for the decision not to escalate therapy was provider’s opinion that RA disease was adequately controlled despite moderate/severe disease activity by DAS28, and that changes in therapy may not produce significant improvements in disease activity (1).

Objectives: 1) Compare short-term differences in ACR20 response between patients with and without a major therapeutic change (MTC) over a range of disease activity; 2) Determine whether ACR20 responses vary by disease activity measures (DAMs) used to assess disease activity (i.e., DAS28, Clinical Disease Activity Index [CDAI], Routine Assessment of Patient Index Data 3 [RAPID3]);

Methods: Each clinic visit for US Veterans enrolled in the VA Rheumatoid Arthritis (VARA) registry was evaluated if the visit had: 1) a complete set of DAMs (DAS28, CDAI, RAPID3) recorded; 2) two other visits with all DAMs between the preceding 18 months separated by at least 60 days and one visit with all DAMs between 60 and 180 days following the visit date; 3) clinical data available for 18 months prior to visit date; and 4) ≥6 tender and ≥6 swollen joints at visit date. Each patient was assessed for MTC within 1 week before and 30 days after visit date. MTC was defined as any of the following: 1) initiation of new biologic or nonbiologic disease-modifying antirheumatic drug (DMARD) or prednisone (as new agent or after 90-day gap during baseline); 2) escalation of DMARD dose by ≥25%; or 3) increase in monthly average prednisone dose by ≥25%; and/or 4) injection of 2 or more joints with corticosteroids.

Clinical improvement was defined as an ACR20 response comparing each eligible visit DAM to the DAM at the first follow-up visit DAM observed between 60 and 180 days of the eligible visit DAM. ACR20 response was compared between eligible visits with and without a MTC and stratified by quartiles of disease activity by each DAM. The Generalized Estimating Equations (GEE) model was fitted using the exchangeable working covariance structure to account for clustering of visits within patients. Models for each DAM were adjusted for age, disease duration, race, seropositive status, comorbidities, disease stability, and recent medication changes in the observations period prior to the visit date.

Results: There were 383 patients (92% were male, mean age was 62.9 years, mean disease duration was 12.5 years, 83% tested positive for rheumatoid factor, and 79% positive for anti-cyclic citrullinated peptide antibodies) who contributed 1,193 eligible visits. Visits with a MTC had a higher rate of ACR20 response in comparison to visits without a MTC at all levels of disease activity. A MTC at a visit with the highest disease activity (quartile 4) consistently had the largest proportion of follow-up visits with an ACR20 response. The overall effect for MTC was statistically significant across all 3 DAMs. Across quartiles, the MTC group consistently had a higher proportion of follow-up visits with ACR20 response compared to the group without a MTC. Risk Ratios from the adjusted analysis are presented in the table.

Conclusion: All patients with active RA have a significant potential to benefit with a MTC. This potential for improvement was seen across all degrees of disease activity and with all three DAMs.

SAT0079 PREDICTING PATIENTS WITH HIGH PAIN & PSYCHOLOGICAL SYMPTOMS (P&PSS) IN EARLY RHEUMATOID ARTHRITIS USING LATENT CLASS ANALYSIS. RESULTS FROM THE TACERA, A LONGITUDINAL COHORT

Lewis Carpenter, Katie Bechman, Andrew Cope, Elena Nikiphorou, James Galloway, Sam Norton, On behalf of all the researchers of the Towards A Cure for Early Rheumatoid Arthritis (TACERA) working group. King’s College London, London, United Kingdom

Background: Despite advances in the treatment of rheumatoid arthritis (RA), pain and psychological symptoms remain a burden for many patients. The precise relationship between inflammation and patient reported symptoms, such as pain, fatigue and mental health in the disease is unclear. However, evidence suggests that over time there may be discordance between inflammation markers and levels of P&PSS. Therefore, to better understand the relationship between inflammation and patient reported symptoms, such that some patients with low inflammation will experience persistent symptoms. It is hypothesised that three distinct patient sub-groups exist; low inflammation/low symptoms, low inflammation/high symptoms, and high inflammation/high symptoms.

Objectives: To identify sub-groups of patients with respect to inflammatory markers and levels of P&PSS over time.

Methods: Demographic, clinical and laboratory data were recorded at baseline (pre-treatment), 6, 12, and 18-months from 239 early RA patients recruited to the Towards A Cure for Early Rheumatoid Arthritis (TACERA) cohort. Individual components of the DAS28 (tender joints, swollen joints, ESR, CRP and patient global) were used to identify sub-groups using longitudinal latent class analysis (LCA). Logistic regression models identified variables associated with class membership at 6, 12 and 18-months follow-up.

Results: LCA indicated two rather than the hypothesised three sub-groups; low inflammation/low symptoms and low inflammation/high symptoms. This was likely because ESR and CRP were well controlled by 6-months and maintained by 18-months for the majority of individuals. There were 86 (36%) 59 (35%) and 41 (39%) classified as having high symptoms at 6, 12 and 18-months. 78% of patients initially in the low symptom group remained in the low symptom group between 6 and 18-

Data presented with 95% confidence intervals.
months. Rheumatoid Factor (RF) positivity and higher baseline fatigue were associated with high symptoms at 6months; decreasing ESR from 6 to 12-months was associated high symptoms at 12months, and having high symptoms at 12-months, along with reduced Swollen Joint Count (SJC), CRP and MCSI from month 12 to 18 was associated with high symptoms at 18-months.

Conclusion: Tight treatment control resulted in controlled Inflammation by 6-months, resulting in just two main patient sub-groups; those with low and high PAPS. Over one-third of patients experienced high pain and psychological symptoms. Membership of the high symptom group was associated with RF positivity but was mainly driven by prior symptom experience. Whilst inflammatory control remains a primary target, other treatments targeting pain, fatigue and mental health must be considered to reduce the burden of disease.

SAT0080 COMPARISON OF INFLAMMATORY CYTOKINES LEVELS IN RHEUMATOID ARTHRITIS WITH CAROTID PLAQUE; CASE-CONTROL STUDY

Karla Paola Cuello-Calderón1, Dionicio Ángel Galarza-Delgado1, José Ramón Azpíri-López, Iris Jazmin Colunga-Pedraza, Jeeana Cecilia Reynosa-Silva1, Marta Elvia Castro-González, Carolina Marlene Martínez-Flores2, Raymundo Pineda1, Geisa García-Arellano3, Rosa Arivizú Rivera1.

Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico

Background: There is a 50% increase in cardiovascular mortality in RA compared to controls. Chronic inflammation causes endothelial dysfunction and accelerated atherosclerosis. Key molecular pathways in this process are dependent on cytokines like TNF-α, IL-1, IL-6, among others, which are shared with RA. Increased disease activity could contribute to atherosclerosis. Carotid ultrasound (US) has recently been recommended as a screening tool for early detection of subclinical atherosclerosis.

Objectives: To compare different cytokines between Mexican-mestizo RA-subjects with/without carotid plaque (CP).

Methods: An observational cross-sectional trial was designed. Inclusion criteria: age between 40-75 years old, fulfillment of the 2010 ACR/EULAR classification criteria, and detection of a CP during a carotid US. Subjects with a prior diagnosis of cardiovascular disease or a poor US window were excluded. RA subjects were matched to controls (RA patients without CP) by age and cardiovascular (CV) comorbidities. Every subject had a carotid US performed; reviewed by two board-certified radiologists. Cytokines measured were IL-1, IL-6, TNF-α, VCAM-1, ICAM-1 and MMP-9, using an ELISA reader (GloMax E9022). Descriptive analysis was done with frequencies (%), median (q25-q75), and comparisons between groups with Chi square test and Mann U Whitney’s test.

Results: 71 subjects were included, 95.8% were females, with a median age of 58 years (54.65). Levels of cytokines in Table 2. Comparisons between groups are in Table 2. Groups were well balanced, with no differences in CV comorbidities (p>0.05). No significant differences among cytokine levels regarding CP were found. Subjects in remission (n=12, 33%) had a lower prevalence of CP (p=0.05, OR: 0.3; 95% CI; 0.1-0.9) and a lower median IL-1 level than those with higher disease activity (p=0.05). No significant differences were found among any of the compared cytokines.

</table>

Conclusion: In our cohort subjects in remission had a lower prevalence of CP (OR= 0.3, 0.1-0.9). No difference was found between cytokines regarding CP. Subjects with active disease had a higher level of IL-1 than subjects in remission. To our best knowledge, this is the first study to evaluate levels of cytokines in Mexican RA-subjects.

SAT0081 BOTH OVERFAT AND MYOPENIA ARE ASSOCIATED WITH PHYSICAL DYSFUNCTION IN RHEUMATOID ARTHRITIS PATIENTS

Chutao Chen, Jian-Zi Lin, Lijuan Yang, Li Qian-Hua, MA Jianda, Le-Feng Chen, Yingqian Mo, Lei Dai. Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Department of Rheumatology, Guangzhou, China

Background: Comprehensive disease control has been recommended by EULAR guidelines for rheumatoid arthritis (RA) which includes simultaneous achievement of stringent control of the signs and symptoms of inflammation, the absence of radiographic progression and normal physical function. Identifying those patients at high risk of disability at a sufficiently early stage of their disease course presents a major challenge. The associations of body mass index (BMI) and body composition (BC) with physical activity function in RA patients still obscure.

Objectives: To investigate the characteristics of BC and BMI in RA patients and their association with physical activity function.

Methods: Consecutive RA patients were recruited and clinical data including disease activity, function and radiographic assessment were collected. BC was assessed by bioelectric impedance analysis. Overfat was defined by body fat percentage (BF%) as ≥25% for men and ≥35% for women. Myopenia was defined by appendicular skeletal muscle mass index (ASMli) ≤7.0kg/m² in men and ≤5.7kg/m² in women. Subjects were categorized by BMI as underweight (BMI<18.5 kg/m²), normal weight (18.5 kg/m² ≤BMI<24 kg/m²), overweight (24 kg/m² ≤BMI<30 kg/m²) and obese (BMI≥30 kg/m²) according to Chinese criteria. Physical dysfunction was defined by HAQ-DI>0.5.

Results: There were 516 RA patients (mean age 49.8±12.9 years old with 83% women) recruited, and 37% with physical dysfunction. Compared with those with normal physical function, RA patients with physical dysfunction
were older with longer disease duration, and had higher disease activity indicators including timing of morning stiffness, 28TJC, 28SJC, PIGA, PGa, PanVAS, ESR, CRP, DAS28-CRP, SDI and CDAI, as well as higher radiographic assessment including mTSS, JSN subcore and JE subcore (all \(P<0.05\)). As for BMI and BC, RA patients with physical dysfunction had higher BF% (mean 31.05\% vs. 29.02\%, \(P=0.007\)) and prevalence of overweight (44\% vs. 27\%, \(P<0.001\)), lower ASMI (mean 5.73 vs. 6.11, \(P<0.001\)) and higher prevalence of myopenia (55\% vs. 38\%, \(P<0.001\)) than those with normal physical function, while no difference in BMI between two groups. After adjustment confounding factors, multivariable logistic regression analysis showed overweight (OR=2.990, 95\%CI: 1.695-5.274) and myopenia (OR=1.960, 95\%CI: 1.191-3.225) were positively associated with physical dysfunction respectively. Further compared with patients with normal fat, patients with overweight had significantly higher rates of dysfunction of all eight physical activities including dressing, rising, eating, walking, hygiene, reaching, gripping and activities respectively (all \(P<0.01\)), with the highest rate 57.5\% in eating dysfunction and the lowest rate 38.6\% in dressing dysfunction. Comparisons between patients with and without myopenia showed similar results with the highest rate 52.4\% in eating dysfunction and the lowest rate 37.7\% in rising dysfunction in those with myopenia.

Conclusion: Overfat and myopenia are present in near half RA patients with physical dysfunction which are associated with dysfunction of all eight physical activities especially eating.

ASOCIATIONS OF BASELINE CLINICAL AND SLEEP INTERVENTION WITH AUDIBILITY IN RHEUMATOID ARTHRITIS IN AN ACPA POSITIVE COHORT

Kevin D. Dean1*, Sunil Nagpal2, Navin Rao2, Frederic Barzideh3

1CU Anschutz Medical Campus, Aurora, United States of America; 2Janssen Research and Development, LLC, Spring House, United States of America; 3Benaroya Research Institute at Virginia Mason, Seattle, United States of America; 4University of California San Diego, La Jolla, United States of America

Background: Subjects who are in the preclinical rheumatoid arthritis (RA) state can be identified through serum elevation of circulating RA-related autoantibodies, including rheumatoid factor (RF) and antibodies to citrullinated protein antigens (ACPA), prior to the clinical appearance of inflammatory arthritis (IA) and RA. Studying Preclinical RA may identify factors and pathways to disease development, and help to identify therapeutic targets for prevention. Furthermore, trials in ACPA+ subjects have been completed or are underway with the primary goal to prevent future IA/RA. However, relatively few individuals have been studied through the evolution of the Preclinical ACPA+ state to Classified RA. As such there are still many gaps in the understanding of the clinical and immunologic evolution from Preclinical to Classified RA.

Objectives: The study objective is to identify the clinical, environmental and immunologic factors/paths that are associated with incident IA/RA development in individuals with ACPA elevations.

Methods: We created a cohort of 86 ACPA+ subjects who at their baseline study visit did not have a historical or examination (66/68 count) evidence of IA/RA. ACPA+ was defined as a serum elevation of anti-CCP3 (IgG, Innova) on \(>2\) occasions above the established cut-off \(>20\) units). These subjects were recruited over 18 months through community health fair screening. ACPA testing of first-degree relatives of patients with RA, and rheumatology clinics. Clinical, environmental and biomarker factors, including RF IgA and IgM [Inova] and high-sensitivity C-reactive protein [hsCRP], were assessed at the baseline visit. Herein we present interim analyses of baseline visits on the whole ACPA+ cohort and longitudinal follow-up on a subset of subjects, with a specific focus on factors that are associated with baseline symptoms and rates of self-reported joint pain, morning stiffness or fatigue. hsCRP positivity (\(>3\) mg/L) was associated with increased rates of self-reported fatigue of \(>0\) on VAS (20\% vs. 41\%, \(p=0.04\)). Ever smoking was associated with increased rates of self-reported morning joint stiffness (18\% vs 50\%, \(p<0.01\)). In addition, in analyses of longitudinal follow-up data available to date, 10/86 subjects (12\%) developed IA classified as RA (2010) a median of 293 days after baseline BMI and BC, RA individuals with incident RA exhibited a higher BMI compared to those who did not (27 vs. 32, \(p=0.03\)). In addition, positivity for hsCRP and RF, and higher median anti-CCP3 levels, were present in those who developed incident IA/RA although not statistically significant.

Conclusion: Within this new cohort of prospectively followed ACPA+ individuals, smoking and an elevated hsCRP are associated with clinical symptoms of stiffness and fatigue, respectively. The relationship of stiffness and smoking suggests this factor is related to early joint symptoms, and the association of high BMI with incident RA may indicate this is a modifiable risk factor for RA (de Hair 2013). This prospective study will continue, with further study of the factors/pathways that may influence well-being in ACPA+ individuals as well as may influence predictive of or causally linked to the future IA/RA.

PREVALENCIA DE FRAILTY Y SU ASOCIADA FACTORES EN PACIENTES CON RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL ANALYSIS

Marco Di Carlo1*, Sonia Frangi1, Eleonora Di Donato1, Marina Carotti1, Fausto Salati1, Hospital “Carlo Urbani” clinica reumatologica, Dipartimento scienze cliniche e molecolari, Jesi, Italy; “Caspedali Ruini Torente Di Ancona, Dipartimento Radiologia, Torente, Ancona, Italy

Background: The concept of frailty is a recent issue in the rheumatologic field, but, by now, the prevalence of frailty among individuals with rheumatoid arthritis (RA) has not been extensively examined and few studies on frailty in RA adults have been completed. Moreover, the relationship between frailty and sociodemographic or disease characteristics in RA are unknown.

Objectives: The aims of the present research were to assess the prevalence of frailty and its potential associated factors in adult patients with RA.

Methods: Consecutive RA patients and healthy controls were recruited according the Survey of Health, Ageing and Retirement in Europe Frailty Instrument (SHARE-FI) (1), and classified as frail, pre-frail or non-frail. Patients underwent to a clinical assessment in order to establish disease activity (Simple Disease Activity Index [SDAI]), function (Health Assessment Questionnaires Disability Index [HAQ-DI]), comorbidities (modified Rheumatic Disease Comorbidity Index [mRDCCI])(2), and radiographic damage (Simple Erosion Narrowing Score [SENS]). Chi-square, analysis of variance (ANOVA), and multinomial logistic regression analyses were used to test the prognostic value of frailty for the outcomes of interest.

Results: 210 consecutive RA patients were included (72 male, 138 female) and the mean age was 60.4 years. The study group was composed by 100 healthy controls (63 females and 47 males). The mean age of RA patients was \(59.1\) years. According to SHARE-FI criteria, 35 RA patients (16.6\%) were categorized as frail, 68 (32.4\%) as pre-frail, and 107 (51\%) as non-frail; while 8 control subjects were categorized as frail, (8\%), 17 as pre-frail (17\%), and 75 as non-frail (75\%) (chi-squared 12.6; \(p=0.0016\)). The results from logistic regression analysis revealed that age (odd ratio [OR] = 1.12, 95\% confidence interval [CI] = 1.07-1.17; \(p<0.0001\)), comorbidities (OR = 1.51, 95\% CI = 1.01-2.27; \(p= 0.0446\)), and high disease activity (OR = 1.10, 95\% CI = 1.04-1.16; \(p=0.0006\)) were independently associated with frailty in IA/RA patients (Fig. 1).

Conclusion: Frailty or pre-frailty are common in RA. The SHARE-FI may be a specific tool for the screening of frailty in RA and may summarize...
the results of a comprehensive RA assessment providing a marker of deficits accumulation. Future studies will need to examine longitudinal relationships between frailty and health outcomes in RA.

The correlations (Spearman’s rho) between Survey of Health, Ageing and Retirement in Europe Frailty Instrument (SHARE-FI) and age (A), modified Rheumatic Disease Comorbidity Index (mRDCI) (B), and Simplified Disease Activity Index (SDAI) (C).

SAT0084 IDENTIFICATION OF POOR PROGNOSTIC JOINT LOCATIONS IN AN EARLY, RAPIDLY PROGRESSING RA COHORT: A POST HOC ANALYSIS OF THE AGREE STUDY

Patrick Durez1, Rene Westhovens2, Yedid Elbez3, Sofie Robert4, Harris A. Ahmad5. 1Cliniques Universitaires Saint-Luc, Institut de Recherche Experimentale et Clinique (IREC), Brussels, Belgium; 2UZ KU Leuven, Leuven, Belgium; 3Excelya, Boulogne-Billancourt, France; 4Bristol-Myers Squibb, Braine L’Alleud, Belgium; 5Bristol-Myers Squibb, Princeton, United States of America

Background: Early RA patients (pts) often present with different areas of joint involvement, but limited data exist to identify which specific joint locations may be indicative of greater disease severity.

Objectives: This analysis investigated the baseline (BL) prevalence of swelling and erosions in individual joint locations and their possible association with disease characteristics and prognostic factors in a unique cohort of early erosive RA patients using the AGREE study population.

Methods: In this post-hoc analysis of the Phase III AGREE study where methotrexate (MTX) naïve RF and/or ACPA seropositive pts with early (≤2 years [yrs]) erosive RA were treated with abatacept (ABA) plus MTX (n=256) or MTX (n=253), prevalence of BL swollen joint status (present, absent) was analysed for 6 large and 14 small joint locations: respectively wrists, elbows, shoulders, jaw, knees, ankles and MCP1-5, PIP2-5 and MTP1-5. Similarly, prevalence of BL erosive joint status was analysed for wrist; MCP1-5, PIP2-5 and MTP1-5. The association between BL disease characteristics and BL swelling or erosions was investigated for the individual joints.

Results: In this cohort of early, seropositive erosive RA (n=509), BL swelling was most frequently observed in the wrist (91.90%) and MCP2 joint (90.1%), whereas BL erosion was most frequently observed in the MTP5 joint (43.5%) (Table 1). BL swelling in the knee, jaw, wrist and elbow was highly associated (p<0.001) with higher tender and swollen joint counts, higher DAS28 (CRP) and higher SDAI and CDAI. As expected, patients with BL presence of erosions had a higher total Genant-modified Sharp score (TSS) whatever the joint location. Overall, men seem more prone for erosions, and this is seen in all joint locations, except for the wrist. Moreover, in this already highly seropositive cohort, patients with BL erosions were more ACPA, but not RF, positive for all evaluated joints of the feet. BL swelling does not seem to be associated with erosive status, neither in the individual joint nor in the TSS, except for the MCP2 joint (erosion positivity was 21% and 4% and TSS was 7.4 [9.5] and 4.7 [5.6] in swollen and non-swollen MCP2 joints respectively).

Conclusion: In this cohort of early, seropositive erosive RA, swelling in the knee, jaw, wrist and elbow seems to be associated with the poorest prognosis, whereas BL MCP2 swelling seems to be associated with joint damage. While the data require further validation, a difference in joint location presentation may identify patients for an intensive treatment or a personalized treatment approach.

SAT0085
A MATRIX RISK MODEL FOR PREDICTING 5-YEAR RADIOGRAPHIC PROGRESSION IN A COHORT OF EARLY RHEUMATOID ARTHRITIS TREATED ACCORDING TO T2T STRATEGY
Anna Laura Fedele, Daniele Bruno, Barbara Tolusso, Luca Pellico, Gianfranco Ferraccioli, Elisia Gremsene. Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Background: In the treatment strategy of early rheumatoid arthritis (ERA) it is of pivotal importance to detect those patients who are at risk of radiographic progression (RP) in order to avoid decline in both functional capacity and quality of life.
Objectives: To identify baseline predictive factors for 5-year RP in an observational cohort of ERA treated according to treat-to-target (T2T) strategy, and to create a matrix risk model including the strongest predictors.
Methods: A total of 212 ERA patients with less than 12 months of disease duration (mean age 52.8±13.9 years, 75% female, 74.5% seropositive) and with available radiographs at 5 years of follow-up (FU), were enrolled in the study. ERA patients fulfilled the 2010 ACR criteria for RA and were followed according to the T2T strategy. At baseline, and every three months, the ACR/EULAR core data set variables were recorded. At baseline and every year, hand and foot radiographs were examined according to modified Total Sharp score (mTSS). At each visit, clinical improvement and remission were evaluated according to EULAR criteria. The achievement of Comprehensive Disease Control (CDC) (28-joint Disease Activity Score using C reactive protein <2.6, Health Assessment Questionnaire <0.5) was assessed every year of FU.
Results: Fifty-six ERA patients (26.4%) had erosions on hand and foot radiographs performed at baseline. At 5 years of FU additional 56 subjects (26.4%) developed RP. ERA patients showing RP were in higher percentage ACPA positive (78.6%) and erosive at baseline (41.1%) compared to subjects not manifesting RP (65.4%) ACPA positive, p=0.07; 21.2% erosive at baseline, p=0.004, respectively. Moreover, radiographic progressors had a VERA disease (disease duration less than three months) with lower frequency (21.4%) compared to non progressors (34.6%, p=0.07). CDC was achieved at twelve months of FU more frequently by non progressors (52.6%) compared to non progressors (34.6%, p=0.07). CDC is the advisable treatment goal, the radiological damage is not fully prevented in case of ACPA positivity.

SAT0086
EVALUATION OF MEDICATION PERSISTENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH NON-TNF INFLAMMATION-MODIFYING ANTI-RHEUMATIC DRUGS
Leticia Ferri1, Evo Alemao1, Sonie Lama1, Aarti Rao2, 1Bristol-Myers Squibb, Princeton, United States of America; 2Mu Sigma, Bangalore, India
Background: Persistence to prescribed biologic (b)DMARDs, such as TNF inhibitors (TNFi), in patients (pts) with RA has been suboptimal, with rates ranging from 30–80%. There are limited data on the persistence of non-TNFi bDMARDs and targeted synthetic DMARDs, such as tofacitinib (TOF).
Objectives: To compare medication persistence in pts with RA treated with different non-TNFi DMARD treatment options including abatacept (ABA), TOF and tocilizumab (TOC), and to evaluate characteristics (e.g. demographics, comorbidities, baseline treatments) of these pts.
Methods: Pts (≥18 years) from the Truven MarketScan® administrative claims database with RA (≥2 claims for RA identified with International Classification of Diseases [ICD]-9 or ICD-10) being treated with a non-TNFi DMARD from Jan 2006 to Sep 2017 were included. The date of the first claim of a drug of interest on or after diagnosis of RA was considered the index date. Pts were required to have at least 6 months of continuous enrolment prior to the index date (baseline). Pts with claims of other bDMARDs at the index date were excluded from the study. Persistence was defined as the number of days from the index date to the first switch or discontinuation of the index date DMARD, or end of the study period, or end of enrolment, whichever came first. Pts were stratified by prior TNFi use (TNFi-naïve or TNFi-experienced) and by prior corticosteroid (CS) use. Pairwise comparison of persistence between the non-TNFi DMARDs was performed, with ABA as the reference using Kruskal–Wallis test. A p value of <0.05 was considered statistically significant.
Results: A total of 30,556 pts satisfied the inclusion and exclusion criteria, of which 20,410, 5048 and 5098 were initially treated with ABA, TOF and TOC, respectively. Overall, the ages of therapy initiation for the ABA and TOF cohorts were similar, while the TOC cohort was slightly younger. The majority (80%) of the study population was female. The proportion of pts with prior CS use was lower in the ABA cohort vs the other cohorts. Overall, the comorbidity index between treatment cohorts was similar; however, there were some differences in types of comorbidities at baseline (Table 1). The ABA cohort tended to have a lower proportion of pts with chronic obstructive pulmonary disease/emphysema, pulmonary nodules, dyslipidaemia and osteoarthritis, while the proportions of pts with heart failure, ischemic heart disease and lupus were higher relative to other cohorts (Table 1). Overall, mean (SD) time on therapy for pts in the ABA cohort was longer compared with pts in the TOF (338 [418] vs 257 [288] days) and the TOC cohorts (338 [418] vs 294 [345] days). Similar differences were observed when further stratified by pts’ prior use of TNFi and CS (Table 2).
Conclusion: Based on the analysis of a large US claims database, pts with RA who were prescribed abatacept had higher persistence with therapy compared with other non-TNFi DMARDs such as TOF and TOC, regardless of prior use of TNFi and CS. Further analysis of medication persistence adjusting for pt characteristics is warranted.

SAT0087 REAL-LIFE GOLIMUMAB PERSISTENCE IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: FINAL RESULTS OF THE GO-PRACTICE STUDY

Results: 770 patients selected from January 2015 to March 2016 at 134 sites, of which 754 included in the analysis. Mean age was 46 years and 61% were female. Most had AS (63%), followed by RA (23%) and PsA (14%). Mean duration of rheumatic disease was 7.6 years and 37% had previously received biologics. The proportion of patients who received 1, 2, 3 and 4 biologics were 18%, 11%, 6% and 2%, respectively. Most patients were prescribed 50mg GLM monthly (97%). Concomitant treatments included disease-modifying anti-rheumatic drugs (38%), corticosteroids (19%) and NSAIDs/analgesics (71%). Persistence of GLM at 2 years was 52.4% (56.5%, 45.1% and 52.6% for RA, PsA and AS respectively), and in the AS group was higher for biologics naïve than biologics pretreated patients (59.2% vs. 42.7%, P<0.01).

Conclusion: GLM persistence in real-life is satisfactory at 2 years and accompanied by clinical improvements in RA, PsA and AS patients.

COMPARISON OF THE INITIAL DIAGNOSTIC FINDINGS AND ONSET FACTORS OF RHEUMATOID ARTHRITIS (RA) IN ELDERLY ONSET RA AND ADULT ONSET RA BY MULTICENTER COHORT – ARE THERE ANY DIFFERENCES OF ONSET FACTORS? –

Koko Funahashi1, Tsukasa Matsubara2, Esuka Shono3, Motohiro Obrie4, Keniie Hashimoto5, Akira Sagawa6, Tanimami Yoshitama7, Takeshi Mitsuka8, Tomohiko Yoshida9, Atsuko Imai10, Nobuki Miyake11, Kazuyasu Ushio12, Izumihara Tomomi13, Tsunori Tomo14, Yosuke Nishida15, Shigeto Kiyokawa16, Norhiro Nishimoto17, Matsubara Mayflower Hospital, Clinical research, Kato, Japan; 2Matsubara Mayflower Hospital, Rheumatology, Kato, Japan; 3Shono Rheumatism clinic, Fukuo, Japan; 4Oribe Rheumatology clinic, Oita, Japan; 5Hashimoto Rheumatology clinic, Kobe, Japan; 6Sagawa Akira Rheumatic clinic, Sapporo, Japan; 7Yoshitama rheumatology clinic, Kitagawa, Japan; 8Mitsuka clinic, Narashino, Japan; 9Yoshida clinic, Setagaya-ku, Tokyo; 10Izichibanoch Rheumatology clinic, Matsuyama, Japan; 11Ushio clinic, Shizuoka, Japan; 12Ushio clinic, Osaka, Japan; 13Izumihara rheumatology clinic, Kitagawa, Japan; 14PS clinic, Fukuoka, Japan; 15Awaike memorial central clinic, Shima, Japan; 16Fujimori clinic, Hachiouji, Japan; 17Osaka Rheumatology clinic, Osaka, Japan

Background: In recent years, it has been reported that elderly onset RA (EORA) is a pathology different from that adult RA (AORA) 1). It has been reported that RA is due to genetic background, and many other factors. However it is not clear whether EORA and AORA share onset factors.

Objectives: We compared the initial diagnostic finding of EORA and AORA patients who were diagnosed by RA specialist at their own hospi- tal. We also compared the presence or absence of the onset factors between EORA and AORA.

Methods: 1185 patients at 18 facilities who were initially diagnosed with RA were included. EORA (n=398) was defined by disease onset at over 60 years and AORA (n=732) was defined by disease onset from16 to 59 years. We compared blood examination, clinical findings, presence of bone erosion, gender, age, and background factors pre-onset (family his- tory, history of smoking/operation, presence of periodontal disease/gyneco- logical diseases/digestive system diseases) between EORA and AORA.

Clinical findings were analyzed with Mann-Whitney U-test and frequency of pre-onset history were analyzed by 2 × 2 Chi square test.

Results: The average age of EORA and AORA were 72 years and 54 years old. The ratio of female was 75% in EORA, but 84% in AORA, a significant difference (P<0.01). The average values of CRP (ug/ml) were 2.0 in EORA, but it is 1.3 in AORA, significantly lower (P<0.001). Also ESR (mm/1h and MMP-3 (ng/ml) of EORA were 46 and 83, whereas those of AORA were 36 and 29 significant as CRP. On the other hand, TJC, SJC, PaGA and PhGA were not significantly different.

We also compared the prevalence of onset factors between EORA and AORA. There was no clinical significant difference in smoking history and gynecological conditions. The presence rate of stress and family history in AORA were 71% and 38%, whereas that in EORA was 54% and 26%, significantly lower (P<0.001). On the other hand, the presence rate of history of gastrointestinal disease, periodontal disease and operation history in AORA were 43%, 36% and 40%, but those in EORA were 49%, 46% and 52%, significantly higher(P<0.01).

As in previous reports2), the ratio of men and those who have inflammatory values in EORA were significantly higher, but there was no difference in SJC, PaGA, and PhGA. This study verified in Japanese EORA as the other reports. There were differences in the presence rate of onset factors between the two groups, whereas EORA had many external factors such as surgical history, whereas AORA had genetic factors and stress in their backgrounds. Regarding the presence of bone erosion, it was caused by the period from the appearance of the symptoms until the diagnosis and was unrelated to age at onset.

Conclusion: This study suggests that the onset of EORA is more likely to be attributed to external factors than genetic factors.

SAFETY AND EFFICACY OF LY3373641, A BRUTON'S TYROSINE KINASE INHIBITOR IN PATIENTS WITH RHEUMATOID ARTHRITIS: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, 2-PART PHASE 2 STUDY

Mark C. Genovese1, Alberto Spindler2, Akira Sagawa3, Won Park4, Anna Dudnek5, Jeanne Liao6, Rahul Shinh7, Melanie Chan7, William Barkhuizen8, Ajay Nirula7.

LY3373641 is an irreversible covalent inhibitor of Bruton’s tyrosine kinase (BTK), a key signaling molecule in the B-cell-receptor and Fc-receptor pathways and mediator of B-cell– and myeloid-cell-dependent inflammatory arthritis.1,2 RA-JUVENATE was a multicentered, randomized, double-blind, placebo-controlled, 2-part Phase 2 trial with long-term extension (LTE) in adult patients (pts) with rheumatoid arthritis (RA).

Objectives: The objective of this analysis is to present the primary results from Part B of the study.

Methods: In Part A, 36 pts with at least mildly active RA were randomized 1:1:1:1 to receive oral LY3337641 5, 10, or 30 mg or placebo (PBO) once daily (QD) for 4 weeks (wks) with the primary objective of safety and tolerability. There were no safety signals to preclude moving to Part B; pts in Part A were not eligible to participate in Part B. In Part B, 250 pts with active moderate to severe RA were randomized 1:1:1:1:1 to receive oral LY3337641 5 (N=63), 10 (N=62), or 30 mg (N=63) or PBO (N=62) QD for 12 wks. The primary endpoint of Part B was the proportion of pts achieving ≥20% improvement in American College of Rheumatology criteria (ACR20) at Wk 12. A logistic regression model was used to compare each LY3337641 dose to PBO for primary and secondary endpoints. Nonresponder imputation was used to impute missing data. After an interim analysis showed a low likelihood of demonstrating efficacy at the conclusion of the trial, the sponsor discontinued Part B of the study, including the LTE. Efficacy results (except analysis of low disease activity and remission) included pts who completed through Wk 12 at the time of study discontinuation; safety was results included all pts who received ≥1 dose of study drug. Results: Of the 250 pts (mean age 51.0 years; 86.4% female; mean disease duration 11.2 years) randomized in Part B, 189 (75.6%) completed 12 weeks and 180 entered the LTE (72.0%); 61 discontinued study treatment in Part B. The most common reasons for discontinuation were drug-related (27 [10.8%]), withdrawal by subject (8 [3.2%]), adverse event (8 [3.2%]), and lack of efficacy (4 [1.6%]). There was no statistically significant difference in the ACR20 response between any treatment group of LY3373641 and PBO at Wk 12 (p=0.05 for all comparisons; Table); a high placebo rate was noted, but no underlying reason was identified in post hoc analyses. There were 5 serious adverse events; 2 in PBO pts (joint dislocation and cholecystitis acute) and 3 in 30-mg pts (foot fracture, multiple injuries, and venous thrombo- sis). There was 1 death (30-mg pt, multiple injuries after a 4-story fall down elevator shaft). There were no safety findings that precluded continuation of the study.

Conclusion: Although there were no safety findings that precluded continuation of the study, the study sponsor determined that the observed benefit-risk profile of LY3373641 in the study did not warrant its continuation.

Results: Microbiota composition analysis showed that RA patients had a decrease in the gut microbial species richness compared to HC (p<0.01). In particular, the principal coordinate analysis (PCoA) visualization of UniFrac distances and analysis of group similarities (ANOSIM) showed that faecal microbiota composition differs between RA and HC (p<0.01) confirmed by the LEfSe analysis showing that RA microbiota is enriched of Bacteroidetes and Proteobacteria, whereas HC were enriched of Verrucomicrobida and Firmicutes. Considering the RA cohort, no significant differences in microbiota composition were found stratifying patients based on autoantibody profile, disease duration and BMI category. However, considering the disease phase, RA patients with active disease (DAS<3.7) showed significant differences in α-diversity compared to RA patients in LDA score in sustained clinical remission (p<0.01) with a relative abundance of Haemophilus parainfluenzae in high disease activity patients (p=0.01). A slightly higher α-diversity in RA patients with the higher adherence to Mediterranean diet (p=0.10).

Conclusion: Despite limited sample size, this study strengthens the concept of significant microbiota differences in RA, contingent with disease phases, compared to HC. The evaluation of microbiota composition in the patients follow-up according to response to therapies is ongoing.

SAT0090 GUT MICROBIOTA COMPOSITION IS CONTINGENT WITH DISEASE PHASES IN RHEUMATOID ARTHRITIS

Elisa Grenesca1, Stefano Alivernini2, Barbara Tolusso3, Brunella Posteraro4, Maurizio Sanguinetti5.

Background: Increasing evidences suggest that alterations in the gut microbiota may contribute to the pathogenesis and influence the clinical outcome of Rheumatoid arthritis (RA).

Objectives: To characterize the gut microbiota composition in RA patients in different disease phases contingent to therapeutic regimens.

Methods: Forty-four RA patients (7 naïve to treatment, 13 MTX-IR and 24 in sustained clinical and ultrasound remission under conventional and biMARD combination therapy, respectively) (age 55±11.4 years, 79.5% female and 59.1% positive for ACPA and/or RF) and 20 age/sex matched healthy controls (HC) were enrolled in the study. At study entry, RA specific data set were collected and dietary habits were recorded using the 14-items Mediterranean Diet Adherence Screener (MedDAS) questionnaire. DNA was extracted from stool samples of each patient amplified and 16S rRNA gene V3–V4 region was sequenced using an Illumina MiSeq10 platform. For downstream sequence analysis, a combination of software packages QIIME (v1.9.1) and VSEARCH (v1.1) was used and a biological observation matrix (BIOM) at different taxonomic levels (from phylum to genus) was produced. The BIOM was analysed using the Web-based program Microbiome Analyst. Statistical analyses were performed using the R phyloseq software package. Differences in the relative abundance of individual bacterial taxa between a priori defined groups were assessed by LEfSe analysis.

Results: Microbiota composition analysis showed that RA patients had a decrease in the gut microbial species richness compared to HC (p<0.01). In particular, the principal coordinate analysis (PCoA) visualization of UniFrac distances and analysis of group similarities (ANOSIM) showed that faecal microbiota composition differs between RA and HC (p<0.01) confirmed by the LEfSe analysis showing that RA microbiota is enriched of Bacteroidetes and Proteobacteria, whereas HC were enriched of Verrucomicrobida and Firmicutes. Considering the RA cohort, no significant differences in microbiota composition were found stratifying patients based on autoantibody profile, disease duration and BMI category. However, considering the disease phase, RA patients with active disease (DAS<3.7) showed significant differences in α-diversity compared to RA patients in LDA score in sustained clinical remission (p<0.01) with a relative abundance of Haemophilus parainfluenzae in high disease activity patients (p=0.01). A slightly higher α-diversity in RA patients with the higher adherence to Mediterranean diet (p=0.10).

Conclusion: Despite limited sample size, this study strengthens the concept of significant microbiota differences in RA, contingent with disease phases, compared to HC. The evaluation of microbiota composition in the patients follow-up according to response to therapies is ongoing.

Low serum level of vitamin D at time of diagnosis is associated with higher one-year remission rate in patients with newly diagnosed RA, treated aggressively during follow-up: post-hoc analyses of the CIMESTRA trial

Mette Hørrup1, Kristian Stengaard-Pedersen2, Peter Vestergaard3, Robin Christensen4, Mikkel Stergaard5, Peter Junger6, Mette L. Hørrup7, Kim Harslev-Petersen1, Torkell Ellingsen2, 1University of Southern Denmark, Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark; 2Aarhus University and Aarhus University Hospital, Department of Rheumatology, Institute of Clinical Medicine, Aarhus C, Denmark; 3Aalborg University, Departments of Clinical Medicine and Endocrinology, and Steno Diabetes Center North Jutland, Aalborg, Denmark; 4Bispebjerg and Frederiksborg Hospital, Copenhagen University Hospital, Department of Musculoskeletal Statistics Unit, The Parker Institute, Frederiksborg, Denmark; 5Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 6University of Southern Denmark, Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark; 7Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 8University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Gosaen, Denmark; 9University of Southern Denmark, Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark

Background: Vitamin D is often low in Rheumatoid Arthritis (RA), and immunomodulatory properties of vitamin D might be associated with disease course in RA (1).

Objectives: To evaluate association between baseline vitamin D metabolites and one-year remission, in newly diagnosed, treatment-naïve RA patients, aggressively treated during follow-up.

Methods: The CIMESTRA-cohort comprises 160 newly diagnosed RA patients, treated aiming at remission with methotrexate and intraarticular steroid, further randomized 1:1 to cyclosporine or placebo-cyclosporine (2). A total of 158 patients had vitamin D metabolites measured at time of diagnosis. Dietary vitamin D supplementation was recommended in accordance with the national guidelines. Serum vitamin D_total (sum of 25OHD2 and 25OHD3) and 1,25(OH)2D at time of diagnoses were measured by LC-MS/MS or RIA. D_total were dichotomized at 50 nmol/l, and 1,25(OH)2D categorized in tertiles. Primary outcome was remission (DAS28-CRP < 2.6) after one year. Associations were calculated using logistic regression, presented as Odds Ratios with 95% Confidence Intervals (95%CI). Adjustment of analyses included sex, age, symptom duration prior to diagnosis, DAS28-CRP and season of diagnosis.

Results: In univariate analyses, neither D_total nor 1,25(OH)2D at time of diagnosis predicted remission at year one. In adjusted analysis, D_total < 50 mmol/l at time of diagnosis showed better odds for achieving one-year remission, compared to sufficient D_total. OR 2.56, 95%CI (1.11; 5.90) p = 0.03. 1,25(OH)2D was not associated to remission.

Conclusion: Low D_total at time of diagnosis is associated to increased odds for achieving remission at year one in early, treatment naïve RA patients, treated aggressively during follow-up.

number of color pixels to all the pixels in a selected range of interest (ROI). The study was approved by the proper ethics committee. Statistical analysis: differences between groups were analyzed using U Mann-Whitney test (continuous variables). Correlations between quantitative variables were assessed with the Spearman correlation coefficient. Statistical significance was set at p<0.05.

Results: DAS28: mean 6.0 (SD=0.9); median 6.1 (IQR: 5.5 - 6.6); SDAI: mean 61.1 (SD=36.3); median 51.3 (36.8 - 76.4). No correlation was found between CFI and age, platelet count, CRP, RF, ACPA, DAS28 and SDAI as well as with the disease duration. But there was a strong positive correlation between CFI and PDUS results, r = 0.71; p < 0.05. As expected, DAS28 and SDAI strongly correlated with inflammatory markers (ESR, CRP). The results showed, that CFI between 2.6% ia an equivalent of PDUS grade 1, CFI 8-50% of PDUS grade 2 and CFI > 50% of PDUS grade 3.

Conclusion: although PDUS is a method to assess synovial inflammation, through the determination of the synovial vascularization, its results, regardless of the scoring system employed, do not correlate with the systemic inflammation indicators, such as ESR and CRP or with the disease activity – which needs further explanation. The approximate equivalence of CFI and of PDUS scoring system is as follows: CFI > 50% - PDUS grade 3, CFI 8-50% - PDUS grade 2, CFI 0-8% - PDUS grade 1, which confirms previously published research.

Disclosure of Interests: None declared

UNITED STATES RHEUMATOLOGY PRACTICE-BASED REAL-WORLD EVIDENCE OF METHOTREXATE UTILIZATION AND RESPONSE TO THERAPY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH INTRAVENOUS GOLIMUMAB

Aaron Broadwell1, Vance Bray2, Douglas Conway3, Joy Schechtman4, George Karpouzas1, Elizabeth Hernandez1, Vibeke Strand2, Sarah Ormseth1.

1Harbor UCLA Medical Center, West Carson, United States of America; 2Stanford, Palo Alto, United States of America; 3Carolina Health Specialists, Myrtle Beach, United States of America; 4Sun Valley Research & Development, LLC, Palo Alto, United States of America; 5Atherosclerosis and Osteoporosis Center, Altoona, United States of America; 6Janssen Scientific Affairs, LLC, Horsham, United States of America; 7Janssen Research and Development, LLC, Spring House, United States of America

Background: AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is an ongoing Phase 4 comparative study designed to provide a real-world assessment of intravenous golimumab (GLM) and intravenous infliximab (IFX) in patients (pts) with rheumatoid arthritis (RA). The primary objective of AWARE is to assess the incidence of infusion reactions, the concomitant use of methotrexate (MTX) is also reported. The FDA approved label for GLM states that it is indicated for the treatment of patients with moderately to severely active RA in combination with MTX; however prospectively obtained real world evidence based data on the rate of GLM use without MTX has not been reported.

Objectives: Here we compare patient demographics, disease characteristics, response to therapy and discontinuation of GLM treated patients with and without concomitant MTX from an interim analysis (IA) of the AWARE study.

Methods: AWARE is a prospective, noninterventional, observational, multicenter 3-year study conducted in the US. RA pts (1,200 adults) were enrolled at the time of initiating treatment with GLM or IFX. All treatment decisions including MTX utilization are made at the discretion of the treating rheumatologist. Imputations of CDAI data were not performed at this IA. Data shown are mean ± standard deviation.

Results: 678 GLM pts were enrolled; of these 487 (71.8%) were GLM Plus-MTX and 191 (28.2%) were GLM No-MTX. Demographics are shown in the table. Response to therapy was assessed with CDAIs and shown in the figure below. Overall, 92.6% of GLM Plus-MTX and 91.5% of GLM No-MTX pts had a baseline (BL) categorical CDAI disease activity of moderate or high, and 7.4% of GLM Plus-MTX and 8.5% of GLM No-MTX pts had a BL categorical CDAI disease activity of low or remission. Discontinuation from the study during the period of this IA was similar between the GLM Plus-MTX (173/487; 35.5%) and GLM No-MTX (64/191; 33.5%). 7.9% of GLM No-MTX pts reported leflunomide use.

Conclusion: At BL 28.2% of pts on GLM did not report concomitant MTX use. The demographics of the GLM Plus-MTX pts did not differ remarkably from GLM No-MTX pts. The reported early response to treatment, assessed by CDAI score after 3 months and 6 months was similar in the GLM Plus-MTX and GLM No-MTX groups. These preliminary IA data suggest that in a real-world rheumatology practice setting, use of GLM with or without concomitant MTX led to similar CDAI scores at 3 and 6 months in RA pts with predominantly moderate to high BL CDAI disease category.

SA0095

MEDIATION NECESSITY AND CONCERN BELIEFS ARE DISTINCT, INTERACTIVE PREDICTORS OF TREATMENT ADHERENCE IN RHEUMATOID ARTHRITIS

George Karpouzas1, Elizabeth Hernandez1, Vibeke Strand2, Sarah Ormseth1

1Harbor UCLA Medical Center, West Carson, United States of America; 2Sun Valley Research & Development, LLC, Palo Alto, United States of America

Background: Medication adherence is instrumental for the successful management of rheumatoid arthritis (RA) to a goal of remission. Awareness of medication necessity and concerns regarding its use influence adherence and respectively foster or undermine the achievement of treatment goals.

Objectives: We explored the unique and interactive roles of patient beliefs about the necessity of RA medications and concerns about them in predicting adherence to prescribed treatments.

Methods: We evaluated 316 patients with established RA from a single center. Beliefs about the necessity of RA medications and concerns regarding their use were evaluated with the Beliefs about Medicines Questionnaire-Specific (BMQ) Necessity and Concerns scales (range 5-25). Self-reported rheumatoid arthritis treatment adherence was assessed using the Simplified Medication Adherence Questionnaire (SMAQ, range 0-6). Multivariable linear regression evaluated the effects of necessity, concerns and their interactions with adherence. A latent profile analysis (LPA) subsequently classified patients in groups according to patterns of necessity and concerns; adherence scores were then compared across latent groups using ANCOVA.

Results: Full adherence (SMAQ score 6/6) was reported by 101 (32%) patients. Necessity and concerns had independent and opposing contributions to adherence (β=0.21 and β=0.28 respectively, p<0.001 and figure 1a) even after adjustments for age, gender and disease duration. An interaction between necessity and concerns with adherence was also observed (p<0.009), post-hoc simple-slope tests showed that necessity predicted adherence with increasing concerns. Johnson-Neyman technique revealed that while concerns were significantly associated with adherence across the entire range of necessity scores, necessity was significantly related to adherence only at BMQ Concerns scores >13. LPA revealed four latent patient groups: Low necessity/Low concerns (indifferent, n=33), Low necessity/High concerns (skeptical, n=70), High necessity/High concerns (ambivalent, n=92) and High necessity/Low concerns (accepting, n=121). Adherence varied across groups even after adjusting for between group differences (p<0.002, Figure 1b); adherence was highest in the accepting group and lowest in the skeptical group.

Conclusion: The relationship between necessity and concern beliefs regarding RA medications significantly influences adherence behavior and may further direct physicians to effectively target their education efforts. A message aimed at reducing concerns might be more effective in the ambivalent subgroup, whereas emphasizing medication necessity may be more fruitful in the skeptical group.

Figure 1. Interaction between Necessity and concerns on medication adherence in RA

SAT0096 CORRELATION OF GROWTH FACTORS WITH RHEUMATOID ARTHRITIS CLINICAL COURSE INDICATORS

Elena Komarova, Boris Rebrov, Anna Blagodarenko, Natalia Bludova, Galina Bekrka, Lugsanik State Medical University, Lugansk, Ukraine

Background: The evaluation of early destruction markers in rheumatoid arthritis (RA) is of significant clinical importance for improving the patient’s life quality. One of the immunological markers of RA early diagnosis and of severe disease is antibodies to cyclic citrullinated peptide (ACCP). Instrumental methods for early diagnosis of RA include the ultrasound of joints and bone-cartilage erosions (US), vascular endothelial growth factor (VEGF), fibroblast growth factor (FGF) and surrounding synovial vascularization. These parameters of blood and cartilage erosions, the growth of pannus mass and contribution to the development of bone and cartilage erosions.

Objectives: to establish the correlation of growth factor indicators with markers of the destructive course of rheumatoid arthritis.

Methods: 194 patients with a diagnosis of RA were examined, among the examined patients women prevailed - 86.6%, the age was 47.7 ± 10.22 years. Positive by the presence of ACCP (>20 U/ml) was 77%, and negative - 23.2%. The ELISA in the serum was determined by the concentration of CRP and TNF-α (Vector-Test, Russia), antibodies to cyclic citrullinated peptide (ACCP) (Euroimmun, Germany), VEGF and FGF (BCM Diagnostic, Canada). Ultrasound of the joints was performed by the device “ESAOTE MyLAB40” (Netherlands, 2011) with a linear sensor of 7.5 L 70 (frequency 7.5 MHz), semi-quantitative evaluation of indicators was used: effusion into the joint space (JS), synovial thickness, vascularization of the synovial membrane (SM), the presence of pannus and bone-cartilage erosion.

Results: Direct correlations with CRP and ACCP levels (p = 0.02; p = 0.01, respectively), TNFα and DAS28 (<0.001) were established during analysis of the correlation between VEGF and RA clinical course indicators. Analysis of the correlation of VEGF and ultrasound indices of the joints in the examined patients RA established strong direct links with the JS effusion parameters and the SM vascularization assessment (p <0.001, in all cases), and a direct interaction of weak force with the indicator of pannus (p = 0.04) was found. Regression analysis revealed the dependence of the variability of the SM vascularization assessment on the level of VEGF in the blood showed a sufficient value of the coefficient of determination (0.57), and the data of the normalized index DW = 2.59 reliably indicate the absence of autocorrelation (0.06). Direct correlations with R6 stage (p <0.001) and the rate of CRP (p = 0.02) were established during analysis of correlation links of FGF with the RA clinical course. Analysis of the correlation of FGF and ultrasound indices of the joints in the examined RA patients established strong direct correlations with the indicators of the thickness of SM, pannus, and bone-cartilage erosion (p <0.001, in all cases), the direct correlation of weak force (p = 0.04) was with the SM vascularization assessment index. Regression analysis of the dependence of the variability of the SM thickness indicator on the FGF blood level showed a sufficient value of the multiple correlation R² = 0.47. Also showed a regression analysis of the dependence of the variability of pannus and bone and cartilage erosion indices on the FGF blood level (R² = 0.51; R² = 0.46, respectively), which evidences the regression line approximation to the observed data.

Conclusion: According to the correlations of VEGF, FGF levels with CRP, ACCP, assessment of synovial vascularization and bone-cartilage erosions - the high levels of VEGF, FGF in the blood can be used as markers of severe destructive course of RA and of the high rate of disease progression, which requires the early aggressive basic therapy of RA with the use of genetically engineered biologic drugs prescription.

SAT0097 ASSOCIATION BETWEEN PHYSICAL ACTIVITY AND SUBSEQUENT CHANGES IN DISEASE ACTIVITY IN PEOPLE LIVING WITH RHEUMATOID ARTHRITIS

Kiera Lee-Pil1,2, Hui Xie1,2, Yueyi Zheng2, Li Linda1,4, Diane Lapointe1,4, Arthritis Research Canada, Richmond, Canada; 2Queen’s University, Kingston, Canada; 3Simon Fraser University, Burnaby, Canada; 4The University of British Columbia, Vancouver, Canada

Background: Various studies have found that rheumatoid arthritis (RA) patients perform less physical activity than the general population, likely due to joint pain and impaired physical function. However, recent studies suggest that physical activity may have a beneficial effect on inflammatory and could therefore contribute to reducing RA disease activity. A greater understanding of the relationship between physical activity levels and RA disease activity would be valuable for physical activity counseling of RA patients.

Objectives: The aim of this study was to evaluate the association between baseline physical activity levels and subsequent changes in measures of disease activity in patients with RA using self-reported data.

Methods: We conducted a longitudinal study using 2015-2017 data from a postal survey administered to an RA cohort derived from a population-based cohort for BC originally assembled using physician billing data and a previously validated algorithm. Subjects were grouped into three levels (Low, Medium and High) of physical activity (PA) at the baseline year (2015) according to the specifications of the International Physical Activity Questionnaire. We examined whether physical activity at baseline was associated with a change over time in RA disease activity outcomes.
from 2015 to 2017. We fitted linear mixed models for Rheumatoid Arthritis Disease Activity Index (RADA), Fatigue visual analog scale (VAS), and Pain VAS scores separately with/without adjusting for age, sex, sociodemographic factors, body mass index, RA duration, physical function (Modified Health Assessment Questionnaire [mHAQ]), smoking, depression and other comorbidities at baseline. Models include the outcome at three years (2015-2017) as the dependent variables, an indicator variable representing the year of measurement (2015-17), PA level at baseline, their interactions, and baseline characteristics as covariates. Models include random effects for subjects to account for correlations among within-subject repeated measures. Missing values were imputed using multiple imputation methods. The analyses were conducted using R 3.5.

**Results:** Of the 169 patients who responded to the 2015 survey, 29.6%, 42.0%, and 28.4% had low, medium, and high levels of PA in 2015, respectively. There were no significant differences in RADA (p=0.67), Fatigue (p=0.78), and Pain (p=0.98) at baseline (Figure 1). The low PA group experienced significant worsening of disease activity outcomes over time, including yearly increases of 0.31 in RADA (p=0.007), 0.41 in Fatigue (p=0.007), and 0.43 in Pain (p=0.007). Those in the medium and high PA groups at baseline experienced either a decrease or no change in their disease activity outcomes over time. The interaction terms for PA level and year show that the low PA group had significantly different time trends for RADA, Fatigue, and Pain compared to the medium and high PA groups (all p values <0.05). The results remain robust after adjusting for age, sex, and other covariates.

**Conclusion:** Across RADA, Fatigue VAS, and Pain VAS scores, RA patients with a low PA level demonstrated a significant increase in disease activity over the span of three years. The trends for both the high and medium PA groups differ significantly from that of the low PA group, showing small, overall decreases in disease activity over time. These results add to the accumulating evidence that physical activity may reduce disease activity and is an essential aspect of RA management.

**Disclosure of Interests:** Kiera Lee-Pii: None declared, Hui Xie: None declared, Yufei Zheng: None declared, Linda Li: None declared, Diane Lacaille Grant/research support from: Bristol-Myers Squibb and Eli Lilly Canada

**Background:** RA patients who are ACPA-positive (ACPA+) are known to have worse prognosis. Less is known regarding predictors of treatment outcomes in ACPA-negative (ACPA-) patients.

**Objectives:** We investigated whether autoantibodies captured on a custom array were associated with response to therapy in ACPA RA patients.

**Methods:** RA patients were recruited to either the Biologics in RA Genomics and Genomics Study Syndicate (BRAGGSS, starting adalimumab, established disease) or the RA Medication Study (RAMS, starting methotrexate, early disease). Serum samples were collected at pre-treatment and 3/6 months in BRAGGSS/RAMS, respectively. Treatment groups were pooled for analysis. ACPA was measured using a commercially available ELISA (Axis-Shield Diagnostics Ltd, Dundee, UK). Pre-treatment RA and healthy blood donor control (HC) serum samples were incubated on a bead-based assay (Luminex FlexMap 3D) containing 376 human protein antigens associated with autoimmune disease (39 in citrullinated [cit] form) to detect autoantibodies. Median fluorescence intensity (MFI) values were calculated for each autoantibody for RA and HC, then normalised and log2-transformed. The 95th percentile for each autoantibody in HC was used to determine whether an RA sample was positive/negative for that autoantibody. Proteins with <10% frequency in RA patients were excluded from analysis. Linear regression was used to determine autoantibodies differing in MFI between RA and HC; p-values were adjusted using the Benjamini-Hochberg correction. Significant autoantibodies (adjusted p<0.05) were tested for associations with treatment outcomes in RA patients only using: (i) linear regression for improvement in DAS28; (ii) logistic regression for good/poor vs all EULAR response. All regression was adjusted for age, gender, disease duration and baseline disease activity.

**Results:** 168 patients with RA were included in analysis (mean age 59.6 years, mean disease duration 14.3 years, 126 (75%) female patients, 90 (53.6%) ACPA+ patients). 34 autoantibodies were differentially expressed in RA patients, only one of which (TNP2, a superfamily member 13, TNFSF13) was lower than in HC, 93/34 autoantibodies were in cit-form. In multivariate models of all differently expressed autoantibodies, heterogeneous nuclear ribonucleoprotein A1 (HNRNPA1) was significantly associated with EULAR response (coefficient (coef) 0.7, 95% CI 0.1-1.3), and cit-vimentin (VIM) was significantly associated with poor EULAR response (ORadj 4.2, 95% CI 1.1-18.3) and reduced odds of good EULAR response (ORadj 0.2, 95% CI 0.1-0.8). ACPA remained the best predictor of treatment response. In a subanalysis of the 78 ACPA—patients, cit-cleavage and polyadenylation specificity factor subunit 6 (CPSF6) was significantly associated with worse DAS28 (coef -1.8), 95% CI (-3.6) (-0.1). cit-Dnaj homolog subfamily B member 1 (DNAJB1) was significantly associated with DAS28 improvement (coef 2.2, 95% CI 0.6-3.8). No autoantibody was associated with EULAR response.

**Conclusion:** A subset of ACPA-patients have ACPA fine specificities not seen by a commercial assay. Larger ACPA profiling may provide additional information on treatment response. This requires validation with larger sample sizes and replication in an independent cohort.

SAT0099 THE RELATIONSHIP OF RHEUMATOLOGY ATTITUDES INDEX WITH OUTCOME MEASURES OF RHEUMATOID ARTHRITIS IN AN ASIAN PATIENT POPULATION

Jia Zhen Low1, Chia Mun Woo2, Chien Joo Lim3, Khai Pang Leong1, Ee Tzun Koh1,2. 1Ministry of Health Holdings (Singapore), Singapore, Singapore, Singapore; 2Clinical Research and Innovation Office, Tan Tock Seng Hospital, Singapore, Singapore, Singapore; 3Department of Rheumatology, Allergy and Immunology, Tan Tock Seng Hospital, Singapore, Singapore, Singapore

Background: The Rheumatology Attitudes Index (RAI) is a questionnaire comprising of fifteen questions that assesses a patient’s beliefs and perception of helplessness and the ability to control rheumatoid arthritis (RA). However, the relationship between RAI and patient demographics, disease activity and functional status is inadequately explored.

Objectives: We analysed the association of RAI with educational level, Physician’s Global Assessment of Activity (DGA), Patient’s Global Assessment of Activity (PGA), Disease Activity Score (DAS 28), and Health Assessment Questionnaire (HAQ). We also investigated if RAI is sensitive to change over a six-month period in comparison with DGA, PGA, DAS28 and HAQ.

Methods: All patients from Tan Tock Seng Hospital, a tertiary hospital in Singapore, who fulfilled the 1987 ACR criteria for RA, and completed the self-administered RAI questionnaire twice over six months were included. We analysed the DAS28, DGA, PGA and HAQ. Repeated measure ANOVA was used to analyse the association between RAI and educational level. Spearman correlation was used to study the association between RAI and the parameters DAS 28, HAQ, DGA and PGA, both cross-sectionally and longitudinally. We used SPSS version 19.0 (IBM Corp, Armonk, NY). P-value <0.05 was considered statistically significant.

Results: There were 501 patients suitable for study. The mean age of disease onset was 43 years and mean disease duration was 15 years. The majority were Chinese (83.4%), married (68.5%) and most (79.4%) received fewer than 10 years of education. About half (50.7%) of the participants suffered from hypertension, 13.6% diabetes mellitus, 61.5% hyperlipidaemia, 20.8% renal disease, 21.6% liver disease and 16.6% thyroid disorder. Patients with <10 years education have higher RAI scores (p<0.001) compared to those with ≥10 years of education. Cross-sectionally, weak positive correlation was found between RAI and DAS 28 (r = 0.225, p<0.001), DGA (r = 0.107, p=0.017) and PGA (r = 0.283, p<0.001). On the other hand, there was moderate positive correlation between RAI and HAQ (r=0.440, p<0.001). Weak positive correlation was found between the change in RAI compared to changes in DAS 28 (r = 0.114, p=0.011), HAQ (r = 0.249, p<0.001), DGA (r = 0.163, p<0.001) and PGA (r = 0.155, p<0.001).

Conclusion: Higher RAI scores denoting greater perceived helplessness were associated with higher RA activity. HAQ, PGA and DGA, RAI was responsive to change over a six-month period compared with these four parameters. High RAI score was also associated with lower educational level. Higher RAI scores reflects higher disease activity and worse functional status in a cross-sectional cohort and for the same patient level. Higher RAI scores reflects higher disease activity and worse functional status cross-sectionally and longitudinally. We used SPSS version 19.0 (IBM Corp, Armonk, NY). P-value <0.05 was considered statistically significant.

SAT1000 IN THE ABSENCE OF GUIDELINES, HOW ARE RHEUMATOLOGISTS MANAGING ANTI-CCP POSITIVE PATIENTS WITHOUT CLINICAL SYNOVITIS?

Kulveer Markajo1, Christopher Briggs2, Paul Emery2. 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, Rheumatology, Leeds, United Kingdom; 2NHIR Leeds Biomedical Research Centre, Leeds, United Kingdom; 3Leeds Teaching Hospitals NHS Trust, Rheumatology, Leeds, United Kingdom

Background: The emphasis on early referral and treatment of rheumatoid arthritis (RA) means rheumatologists are now seeing patients earlier in the natural history of RA. Despite clear guidelines for the management of early arthritis, there are no guidelines on how to manage anti-CCP positive (CCP+) patients with symptoms but no clinical synovitis who are at-risk of developing RA. Given the frequent use of ultrasound (US) in early arthritis clinics, we hypothesised that imaging is being used by rheumatologists to guide the management of these at-risk patients.

Objectives: To survey national practice to identify, in the absence of any guidelines, how CCP+ patients without clinical synovitis are being managed by rheumatologists in the UK and specifically to investigate how imaging is being used to guide management in the ‘pre-arthritis’ phase of RA.

Methods: Anonymous questionnaires were completed by rheumatologists working in 39 different UK hospitals. 44/47 (94%) rheumatologists reported they are referred CCP+ patients who have musculoskeletal (MSK) symptoms but no clinical synovitis in their routine clinical practice. Of these, 32/44 (73%) were referred <5 patients per year. In CCP+ patients with ‘inflammatory symptoms’ but no clinical synovitis, 36/44 (82%) would request an US scan to help guide management and 2/44 (5%) would request an MRI scan. All respondents would follow these patients regularly and 5/44 (11%) would consider a clinical trial. In CCP+ patients with ‘non-inflammatory’ symptoms and no clinical synovitis, 18/44 (41%) would request an US scan, 13/44 (30%) would observe in clinic and 12/44 (27%) would discharge back to primary care. When specifically asked about use of high-resolution imaging in CCP+ patients without clinical synovitis, 40/44 (91%) reported they used imaging, with most (37/40, 93%) using US. In patients where power Doppler (PD) signal is present on US in at least one joint, most (55%) would start disease-modifying anti-rheumatic drug (DMARD) treatment (figure 1) and 16% would treat according to RA guidelines. In patients with US tenosynovitis but no US synovitis, most (73%) would treat with either corticosteroids alone (48%) or a DMARD (48%). In contrast, in patients with no US synovitis or US tenosynovitis, 23/37 (62%) would observe without therapy while 12/37 (32%) would discharge the patient (figure 1).

Conclusion: UK rheumatologists are routinely referred CCP+ patients in the pre-arthritis phase of RA and often treat these patients with synthetic DMARDs, guided by US findings. Whether this pragmatic approach is an appropriate one needs to be tested in clinical trials with RA prevention as the ultimate ambition. Guidance on management of these patients would clearly be helpful.

SAT0101  INTRAHOSPITAL MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL STUDY AT THE NATIONAL LEVEL OVER A 17-YEAR PERIOD (TREND-AR STUDY)

Ramón Mazzucco1;1; Elisa Pérez-Fernandez2; Carmen Barbadiño; Natalia Crespi-Villarias3; Manuel Fernández-Prada4; María Galindo-Izquierdo5; Alberto García-Vadillo6; Hilda Godoy7; Angelés Herranz Varela5; Cristina Macia-Vila; Concepción Morado Quirós8; José Luis Morel Hita9; Javier Quiroús10; Virginia Villaverde11; Cristina Martínez-Prada12; María Espinosa13; HospitalUniversitariFundacióAlcorcón, Rheumatology, Alcorcón, Spain; 2Hospital Universitario Albacete, Rheumatology, Albacete, Spain; 3Hospital Universitario de Alcázar de San Juan, Rheumatology, Alcázar de San Juan, Spain; 4Hospital Universitario de Andorra, Rheumatology, Andorra, Spain; 5Hospital Universitario de Astorga, Rheumatology, Astorga, Spain; 6Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain; 7Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain; 8Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain; 9Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain; 10Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain; 11Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain; 12Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain; 13Hospital Universitario de Badajoz, Rheumatology, Badajoz, Spain

Background: There have been important changes in the management of RA in the last 20 years, such as T2T strategy or new biologic agents. The potential impact of these therapeutic strategies on important outcomes such as inhospital mortality due to different causes is not known.

Objectives: To analyze the incidence and tendency of mortality by different causes (global, cardiovascular, infectious, neoplasm, and others) in patients with RA, in Spain, during the period 1999-2015.

Methods: Retrospective cohort study based on the exploitation of the database that collects a minimum basic set of data (MBDS) of all patients with RA during the 17 years of the study period, corresponding to a total of 18,641 hospital exitus (5.5% of the incomes). 63.4% were women. To analyze cases of inhospital death and the main diagnosis of these cases. The causes of death in the hospital, global, by sex and in periods 1999-2001, 2003-2006, 2007-2010 and 2011-2015 are described. The results are expressed in absolute numbers and in proportion to the total number of deaths.

Results: There was a total of 338,343 hospital admissions in patients with RA during the 17 years of the study period, corresponding to a total of 176,097 patients (117,985 women and 58,112 men). There was a total of 18,641 hospital exits (5.5% of the incomes). 63.4% were women. The mean age was 74.6 (SD 10.1) (in females of 77.2 (SD 10.2) and in males 71.9 (SD 9.9) p <.001). The mean of Charlson index was 3.2 (SD 2.4). The mean age increased linearly from 73.5 (1999-2002) to 78.23 (2011-2015). The following table shows the causes of death grouped by sex and period:

Conclusion: The main causes of inhospital mortality in patients with RA in Spain were cardiovascular (24%), infections (20%), respiratory-non-infectious (15%) and neoplasms (12%). The average age of death increased 5 years in the study period. The deaths from infections, respiratory and neoplasms have increased, while those of digestive origin and AR extrarticular have decreased.

Disclosure of Interests: None declared

SAT0102  ASSOCIATION BETWEEN BASELINE HAEOMOBLOGIN LEVELS AND RADIOGRAPHIC JOINT DAMAGE PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BARICITINIB OR STANDARD OF CARE

Budhirdo Moelg1, Patrick Durez2, Axel Finck3, Pedro López-Romero4, Clementine Perrier5, Francesco de Leonardi6, Inmaculada De La Torre7, Peter C. Taylor2;1; UniversityHospital of Bern, Bern, Switzerland; 2UCL Saint Luc, Brussels, Belgium; 3University Hospital of Geneva, Geneva, Switzerland; 4St Lilly and Company, Indianapolis, United States of America; 5Bod representations, Uni of Oxford, Headington, United Kingdom

Background: In patients with active rheumatoid arthritis (RA), haemoglobin (Hb) levels have been inversely associated with radiographic progression of structural joint damage.1-3 In two randomized 52-week (wk) studies, baricitinib (BARI), a selective JAK1/JAK2 inhibitor, reduced radiographic progression in patients with moderate to severe active RA who had received no/minimal prior methotrexate (MTX; RA-BEGIN)4 or had inadequate response to MTX (RA-BEAM).5

Objectives: To assess the association between baseline Hb levels and structural damage progression and to study the effect of BARI 4-mg once daily on structural damage progression at 52 wks based on baseline Hb levels.

Methods: Data from the modified intention-to-treat (mITT) populations of RA-BEGIN (MTX=210, BARI 4-mg=159, BARI 4-mg + MTX =215 patients) and RA- BEAM (placebo [PBO]=488, adalimumab [ADA]=328, BARI 4-mg=487 patients) were included for analysis. Structural damage progression was defined as change from baseline (CFB) greater than the smallest detectable change (SDC) in the modified total Sharp score (mTSS) at wk 52. In RA-BEGIN SDC was 1.4 and in RA-BEAM SDC was 1.5. Missing mTSS data at wk 52 were imputed using linear extrapolation based on baseline data and the most recent radiographic data prior to the missed radiograph. Observed proportions of patients with CFB in mTSS >SDC at wk 52 were calculated for low (males <13.0g/dL, females <12.0g/dL) or normal baseline Hb for each treatment arm from both studies. Multivariate logistic regression (MLR) was used to study the association of baseline Hb with structural joint damage at 52 wks. The MLR included treatment, baseline Hb (g/dL), baseline hsCRP (Normal £3mg/L; Elevated >3mg/L), baseline CDAI, baseline HAQ-DI, BMI, smoking status; structural progression at 52 wks was more pronounced in patients with moderate to severe active RA who had received no/minimal prior methotrexate (MTX; RA-BEGIN)4 or had inadequate response to MTX (RA- BEAM).5

Conclusion: In patients with RA, lower baseline Hb levels were associated with increased structural damage progression. Treatment with BARI 4-mg reduced structural progression, irrespective of patient baseline Hb status; structural progression at 52 wks was more pronounced in patients with low baseline Hb receiving MTX alone (RA-BEGIN) or PBO and background MTX (RA- BEAM).

REFERENCE
Objectives: To explore if achieving T2T biological remission and individual patient treatment goals overlap in RA patients with initially low, moderate, or high disease activity (LDA, MDA, or HDA). Disease activity was measured with the Clinical Disease Activity Index (CDAI) and the Disease Activity Score (DAS28). Individual patient goals were assessed with the Goal Attainment Scale (GAS) at baseline and after three to five months. The number and proportion of patients who reach the T2T target, but not their individual goals and vice versa were calculated.

Results: We enrolled 162 patients in the study (131 [80.9%] women, median age 59.0, IQR= 49-71). 101 patients (62%) had a follow up visit with no missing data after three months. Of these, 48 (47.6%) patients had low disease activity (LDA), 43 (42.6%) had MDA, and 10 (9.9%) had HDA at baseline. Median age 59.0, IQR= 49-71). 101 patients (62%) had a follow up visit with no missing data after three months. Of these, 48 (47.6%) patients had low disease activity (LDA), 43 (42.6%) had MDA, and 10 (9.9%) had HDA at baseline.

Conclusion: Our results indicate that most patients achieving T2T attain their individual treatment goals but a respectable part of T2T outcomes might be more important for patients to set individual treatment goals which are related to their specific life context. For this reason, Ferreira at al [2] recently proposed a dual T2T strategy including both biological remission and individual patient goals and vice versa.
had to be supplemented by the individual patient reported treatment goals.

SAT0105 HAND DISABILITY IN RHEUMATOID ARTHRITIS: AN ENGINEERED GLOVE FOR THE COMPUTERISED QUANTIFICATION OF THE DAMAGE
Massimo Palatini1, Luca Carmisciano2, Emanuele Gotti1, Veronica Tomatis1, Federica Goergan1, Elisa Alessandri2, Massimo Ghio1, Alessio Signor1, Maurizio Cuto11, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, IRCCS Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy; 2Biotastistics Unit, Department of Health Sciences, University of Genova, Genoa, Italy

Background: Tenderness, swelling and loss of motility of the joints are the main determinants of the disability function (DF) of Rheumatoid Arthritis (RA) patients (RApts). The evaluation of DF is performed by Patient Reported Outcomes (PROs), like Health Assessment Questionnaire (HAQ). The lack of objective evaluation of DF is one of the most important “unmet needs” in RA. The Hand Test System (HTS, ETT) is an engineered glove, nowadays applied for neuroscience studies to evaluate hands motility with interesting perspectives of use in other clinical research fields.

Objectives: To quantify the DF of RApts by the analysis of speed and right execution of fingers opposition movement in both hands, evaluated by HTS. To verify the correspondence with the HAQ.

Methods: In this pilot study 14 consecutives RApts (3 males, 11 females, age 61 ± 11.5 years, mean duration of disease 11.21 ± 5.07 years, classified according to 2010 ACR/EULAR criteria, and 13 healthy controls (HC – 7 males, 6 females, age 50 ± 15 years) were enrolled from the RA clinic. After consent, all participants undergone HTS test that recognized the touches between the finger tips during the opposition movements of the hands in standard sequences of movements, after dressed the glove. A multiple finger evaluation (MFE) and a single finger evaluation (SFE) were performed using a dedicated software that provided the physician the following quantitative parameters: Touch Duration (TD), Inter Tapping Interval (ITI) and Movement Rate (MR). Average time for hand 2 minutes. RApts compiled the HAQ and a tender and swollen joint count of the hands was performed. Continuous variables were summarized as mean and standard deviation (SD) or median and interquartile range (IQR), discrete variables were summarized with count and percentage. Variables with skewed distribution was converted to natural logarithm. T-test was used to compare log glove parameters between groups. Pearson's r and p value were used to report the correlation between log-converted glove parameters and HAQ score.

Results: In MFE, glove parameters TD and ITI were significantly higher in RApts (TD 257.34 ± 123.93 ms, ITI 377.8 ± 211.35 ms) than HC (TD 172.25 ± 59.36 ms, ITI 177.98 ± 78.53 ms) (p = 0.004 and p < 0.001) and MR was significantly lower in RApts (1.51 ± 0.47 Hz) compared to HC (2.87 ± 0.9 Hz) (p <0.001). TD of RApts had a significant correlation with the total score of the HAQ (Pearson r = 0.79, p = 0.001). In SFE non-active fingers (NAF, not swollen and not tender) of RApts seemed to perform slightly better than a clinically active finger (AF) but significantly worse than average HC finger (ANOVA, p < 0.001).

Conclusion: HTS is a new easy and totally safe tool that seems to quantify in an objective manner the hand DF in RApts. The significant correlation found with HAQ underlines the value and versatility of self-assessment tools in clinical practice. Further studies are ongoing with larger number of RApts to validate its application to monitor the improvement or the worsening of RA in order to optimize pharmacological treatments. The study is now extended in other Rheumatic and Musculoskeletal Diseases.

SAT0106 NOVEL SUBCLASS OF INTRAVASCULAR NON-CLASSICAL SYNOVIAL MONOCYTES ARE CRITICAL FOR RHEUMATOID ARTHRITIS
Anna Montgomery, Deborah Winter, Harris Perlman, Northwestern University, Medicine/Rheumatology, Chicago, United States of America

Background: There are at least three populations of circulating monocytes: classical, intermediate and non-classical. We demonstrated that circulating non-classical monocytes are required for the effector phase of arthritis and spontaneous models of arthritis in mice. While the vast majority of studies on monocytes have focused those in circulation, very little is known about the monocytes in the synovium.

Objectives: The aim of this study was to examine the heterogeneity of tissue monocytes with those circulation and determine their involvement in inflammation.

Methods: Female 8-10-week-old NRR1A1–/–, C57Bl/10 TCR14Dmaly.J2D4, and C57Bl/6 mice were used in all studies. C3XR1-Cre mice were utilized for cell tracking studies and joint shielded bone marrow chimeras via administration of tamoxifen (tam). Intravascular monocytes were identified using fluorescent anti CD45 antibody before perfusion. STIA was induced via I.V. KBxN sera. Monocyte populations were quantified by flow cytometry and FACS sorted for RNA-sequencing (RNA seq). Nonclassical tissue mono- cytes were identified CD45+CD11b+Ly6G TIM4 CD64 Ly6C– and subdivided into intravascular (CD45-labeled, CD43+), trans-vascular (CD45-labeled CD43–) and extravascular (no CD45-labeled). Human synovium was obtained from ultrasound guided synovial biopsies and CD45+ cells were FAC-Sorted for single cell RNA seq.

Results: NRR1A1–/– mice exhibit a 95% reduction in circulating Ly6C– monocytes but retain Ly6C+ cells in the joint and develop STIA. The transcriptional profiling of bulk populations of Ly6C+ cells in the synovium are distinct from those circulating in the blood. We then identified three populations of Ly6C+ monocytes in the joint; extra-vascular, trans-vascular cells, and intra-vascular cells using 18 color flow cytometry. Lineage tracing studies reveal that the origin of extra-vascular and trans-vascular synovial monocytes are from the embryo while the intravascular monocytes are derived post-natally. The intravascular monocytes are depleted with clodronate loaded liposomes while the extravascular and trans-vacular remain unaffected. Moreover, the intravascular monocytes rapidly expand during the first hour of STIA, increasing by 30x in population size. RA patients also display similar populations of non-classical monocytes using single cell RNA seq.

Conclusion: We have identified and described three previously uncharacterized populations of non-classical monocytes cells in the joint, an intravascular adherent, a trans-vascular population and an extra-vascular
BIOMARKERS OF CLINICAL RELAPSE AND RADIOLOGICAL PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REMISSION: OBSERVATIONAL STUDY OF 5 YEARS OF FOLLOW-UP

Julio Ramirez1, Andrea Cuervo1, Raquel Celis1, Raúl Castellanos-Moreira2, Sebastián C. Rodríguez-García3, Virginia Ruiz-Esquide3, José Gomez Puerta4, Raimón Santamariá1, D Juan Cañete1, 1Hospital Clinica de Barcelona, Barcelona, Spain; 2Hospital Clin, Barcelona, Spain; 3Hospital Clinic, Barcelona, Spain

Background: Patients with Rheumatoid Arthritis (RA) in remission will present flares during the evolution of the disease. Definitive biomarkers have not been identified to predict flares and radiographic progression (RP) in this kind of patients

Objectives: To search biomarkers of clinical relapse and RP in patients with RA in clinical remission

Methods: RA patients in clinical remission (DAS28-ESR<2.6 for >6 months) were selected. Clinical, epidemiological and serological data were analyzed. MRI of dominant hand, ultrasound assessment of knees and hands and serum levels of inflammation and angiogenesis biomarkers were evaluated at 0 and 48 weeks. Synovial biopsy was performed in patients with subclinical synovitis. Patients were follow-up for 5 years. Radiological data were collected. Clinical relapse was defined as the loss of remission status involving a therapeutic intervention. RP was defined as the change of baseline therapy for RA. Only 10% of RA patients lost clinical remission (DAS28-ESR) after 5 years of follow-up. BMI, baseline bone edema, PD signal at 12 months and first-year rate of CXCL16 and VSG levels were predictors of joint flares. BMI, baseline bone edema, PD signal at 48 weeks, Synovial mast cells were associated with structural progression. Macrophages and T cells in ST were higher in patients suffering structural progression. Only 10% of RA patients had RP along the study. Sinovial mast cells were associated with disease flares. Macrophages and T cells in ST were higher in patients with RP in an exploratory analysis.

CHARACTERISTICS OF MULTIRESISTENT PATIENTS TO BIOLOGICAL TREATMENTS IN RHEUMATOID ARTHRITIS, AND ASSOCIATED FACTORS: AN OBSERVATIONAL AND RETROSPECTIVE STUDY IN 385 PATIENTS

Richard Letizia1,2, Henri Gonde1, Agathe Devauchelle1, Pascal Rotterbro1, Gilles Avenel1, Macha Kozyreff-Meurice3, Sophie Pouplin4, Olivier Vittécoq5, Thierry Lequeree6, 1Rouen University Hospital, Rheumatology, ROUEN, France; 2Jacques Monod Hospital Center, Rheumatology, MONTIVILLIERS, France; 3Rouen University Hospital, Pharmacy, ROUEN, France

Background: Despite a wide range of biological treatments (bDMARDs) in the management of rheumatoid arthritis (RA), some patients fail in different lines of treatment. Currently, there is no consensus definition of multiresistance to bDMARDs in RA.

Objectives: The aim of our study was to describe the characteristics of “multiresistant” patients and to establish associated factors with multiresistance to bDMARDs in RA.

Methods: In this observational and retrospective study were identified patients who had failed for administration of a bDMARD at Rouen University Hospital (France) between January 2007 and July 2017 (sources: diagnostic coding using International Classification of Diseases 10th revision and traceability of intra-hospital pharmacy). In the absence of a consensus definition, multiresistance to bDMARD was defined in this study by failure, primary and/or secondary, to at least 2 bDMARDs. The clinical and paraclinical characteristics of these patients at the initiation of the first bDMARD were collected using data from their standardized monitoring, then compared to those of patients who received a single bDMARD effective for 10 years or more, constituting the “responder” group.

Results: We identified 794 patients; 385 constituted our active RA file under bDMARD, 192 patients excluded for different reasons (6 patients not fulfilling the ACR/EULAR 2010 criteria, 18 followed in another department, 45 for missing data at bDMARD’s initiation, 50 not found in computerized file, 73 for whom the expected bDMARD was never started) and 217 lost to follow-up. Among our active RA file under bDMARD (385 patients), 53 were “multiresistant” (at least 2 bDMARDs failed), and 50 patients received a single and effective bDMARD for 10 years or more, after excluding some patients for missing data (Figure 1). The mean age of “multiresistant” patients at initiation of bDMARD was 50.3 years (±13.2 years), and the sex ratio was 2.8 women/1 man. They presented erosive RA (77.4%), rheumatoid factor and anti-citrullinated peptide antibodies positive (73.6%), highly active (median number of tender and swollen joints 8/28, median visual analog scale disease activity 70/100, median C-Reactive protein (CRP) 21 mg/L, mean Disease Activity Score 28 CRP mean 5.36±1.28), and with high functional impact (Health Questionnaire Median Assessment: 1,500/3). The age of disease onset was significantly later in “multiresistant” patients than in “responder” patients (43±14.2 years versus 37.9±10.7 years, p = 0.042). No demographic, anamnestic, clinical and paraclinical characteristics differed significantly between “multiresistant” and “responder” patients.

Conclusion: It is an original work, counting in the literature as a single similar study [1], with nevertheless significant methodological differences. There is no consensus definition of multiresistance to bDMARD in RA, and its mechanisms remain misunderstood. Identifying predictive factors would make it possible to early identify patients with a refractory profile, in order to adapt the therapeutic strategy. Multidrug resistance in RA remains one of the challenges in the management of this pathology.

Background: Smoking is a major risk factor for development of both cardiovascular disease (CVD) and rheumatoid arthritis (RA) and causes an attenuated response to antirheumatic treatment.

Objectives: The aim of this study was to compare disease activity and CVD risk factors across smoking status in RA patients. Further to evaluate the impact of smoking cessation on risk of future CVD events in these patients.

Methods: RA disease characteristics, CVD risk factors and relevant medication were recorded in patients from 10 countries (Norway, UK, Netherlands, USA, Sweden, Greece, South Africa, Spain, Canada and Mexico). Information on CVD events were collected after a median follow-up of 3.54 years (inter-quartile range 2.51 – 6.06). Adjusted analysis of variance, logistic regression and COX proportional hazards analyses with time to event as response variable were applied to compare RA disease activity (measured by DAS28), CVD risk factors and CVD event rates across current, former and never smokers.

Results: Among the 3311 included RA patients (1012 former, 887 current and 1412 never smokers), 235 experienced a CVD event(s) during follow-up. At enrollment into the study current smokers were more likely to have moderate/high disease activity compared to former and never smokers (p<0.001 for both) (Figure 1). There was a gradient of worsening CVD risk factor profiles (lipoproteins and blood pressure) from never smokers, via former smokers, to current smokers. Furthermore, after 3.54 years of follow up former and never smokers had significantly lower CVD event rates compared to current smokers (hazard ratio (95% confidence interval): 0.70 (0.51, 0.95), p=0.02 and 0.48, (0.34, 0.69), p<0.001, respectively) (figure 2). The CVD event rates for former and never smokers were comparably.

Conclusion: We show for the first time that smoking cessation in RA patients was associated with lower disease activity, improved lipid profiles and was a predictor of reduced rates of CVD events.

HIGH SERUM LONG-CHAIN OMEGA-3 FATTY ACIDS ARE ASSOCIATED WITH 6-MONTH LOWER DISEASE ACTIVITY IN EARLY RA: RESULTS FROM THE ESPOIR COHORT

Johanna Sigaux1, Camille de Brauer Buscai2, Chantal Julia2, Rene Marc Filipp3, Alain Cantagrel4, Bernard Bannwarth5, Francois Laporte6, Marie-Christophe Boisnier7, Luca Semerano8, INSERM UMR 1125, Université Paris 13, Bobigny, France; 2EREN UMR U1153 Insermi U125 Inra/Cnam/Univ Paris 13, Bobigny, France; 3Department of Rheumatology, Lille University Hospital, 59037, Lille, France; 4Centre de Rhumatologie, CHU de Toulouse, 31059, Toulouse, France; 5Service de rhumatologie, hôpital Pellegrin, CHU de Bordeaux, Bordeaux, France; 6Département de Biochimie- Pharmacologie-Toxicologie CHU de Grenoble, Grenoble, France

**Background:** Dietary long-chain polyunsaturated fatty acids (PUFAs) of the n3 and n6 families are involved in immune homeostasis and can contribute to modulate inflammatory processes. Dietary intake of n3PUFA (by either supplementation or fish consumption) has been inversely associated with RA incidence in different populations. Some evidence suggests that, in subject at high risk of developing rheumatoid arthritis (RA), high erythrocyte membrane content in long-chain n3PUFA is associated with lower ACPA prevalence and progression to RA. While long-chain n6PUFA are considered mainly proinflammatory, some, like gamma-linolic acid (GLA), are endowed with anti-inflammatory activity, and the erythrocyte content in n6 linoleic acid was inversely associated with the development of RA in a nested-case control study. No study hitherto evaluated the longitudinal association between individual PUFA profile and disease activity in early RA.

**Objectives:** To characterize serum profiles of PUFA and to determine their association with baseline variables and with 6-month disease activity in a cohort of patients with early RA.

**Methods:** Serum PUFAs were quantified by gas chromatography-mass spectrometry (GCMS) in 594 patients with early RA at the time of recruitment in the French Etude et Suivi des POlyarthrites Indifférenciées Récentes (ESPOIR) cohort. Principal component analysis on 19 serum fatty acids with 14 to 22 carbon atoms allowed to determine 3 orthogonal patterns of baseline serum PUFA. Pattern 1 included high proportions of short-chain fatty acids, pattern 2 was high in n3 long-chain PUFA (EPA et DHA), pattern 3 was rich in n6 long-chain fatty acids (among which, GLA had the highest concentration). Patients were stratified in tertiles according to how much they fitted into each pattern, with tertile 1 meaning lowest and tertile 3 highest fitting into the pattern. The association of PUFA patterns with baseline variables was tested in univariate analysis. The association with 6-month disease activity (with high disease activity defined as DAS28≥5.1) was tested in multivariable analysis after adjustment on baseline CRP, corticosteroid and/or NSAIDs use, socioecon-omic status, ACPA and RF positivity, traditional and biologic DMARDS treatment between 0 and 6 months after inclusion.

**Results:** In baseline univariate analysis, pattern 1 was associated with high BMI, active smoking and with non-Caucasian origin. Profile 2 was associated with higher socioeconomic status and inversely associated with DAS28 and CRP. Profile 3 was associated with ACPA positivity and higher baseline CRP. In multivariable analysis, fitting into pattern 2 and 3 was associated with lower odds of having active disease after 6 months (OR for tertile 3 vs. tertile 1: 0.49 [95% CI 0.25 to 0.97, p=0.05] for pattern 2 and 0.51 [0.28 to 0.95] for pattern 3, respectively).

**Conclusion:** In a cohort of early RA patients, we could identify a high serum long-chain n3PUFA profile associated with low disease activity between 0 and 6 months of follow-up in the cohort. This is consistent with a presumed immunomodulatory action of n3PUFA. Despite the base- line association with disease severity features, like ACPA positivity and high CRP, a high serum long-chain n6PUFA profile is also associated with 6-month lower disease activity, possibly due to the presence of high concentrations of GLA in this profile.

**SAT0111**

RED CELL DISTRIBUTION WIDTH IS A MARKER OF EARLY RESPONSE TO METHOTREXATE IN RHEUMATOID ARTHRITIS

Daniele Soddu1, Mattia Bellani1, Erika Zecca1, Alessandro Cioce1, Roberta Pedrazzoli1, Daniele Sola1, Mario Pirisi1, Pierpaolo Sainaghi1, AOU “Maggiore della Carità” Hospital, Internal Medicine Division, Immunorheumatology Unit, Novara, Italy; Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; Interdisciplinary Center of Autoimmune Diseases- IRCAD, Novara, Italy

**Background:** Red blood cell distribution width (RDW) has recently emerged as a possible surrogate biomarker of inflammation. Its potential role as prognostic biomarker has not been evaluated yet in Rheumatoid Arthritis (RA).

**Objectives:** The following study aims to evaluate the potential prognostic role of RDW in the prediction of early response to methotrexate (MTX).

**Methods:** We performed a retrospective analysis of clinical records of patients affected by RA, according to ACR/Eular classification Criteria. The baseline RDW was recorded and correlated with disease activity scores and inflammatory markers. The response to treatment was evaluated at the 3-months follow-up visit according to Eular response criteria.

**Results:** We selected 88 patients (58 females, 65.9%), with a median age of 62 [52-69] years. 61 patients were positive for Rheumatoid Factor (RF) and/or anticitrullinated antibodies – anti-CCP (69.3%). The median DAS28 for Erythrocyte sedimentation rate (DAS28ESR) at the diagnosis was 4.16 [3.33-5.00] while the median RDW was 14.0 [13.1-14.9]%. The baseline RDW was directly associated to CRP (r=0.250; p=0.02), but not with ESR (p=0.02) or DAS28ESR (p=0.40). All the patients received methotrexate (MTX) at a median dose of 10 [5-10] mg/week, 79 (89.8%) also received prednisone (median dose 5 [5-10] mg/day) and 20 hydroxychloroquine in addition to MTX. A significant trend towards a larger RDW was reported from patients with a good Eular response at three months (13.5 [13.0-14.4]%) to those with a moderate response (14.0 [13.2-14.7]%) and finally to those with a poor response (14.6 [13.6-16.0%]; p=0.004). At logistic regression, RDW (p=0.02), but not CRP or ESR (p=0.70 and p=0.37 respectively), was a predictor of a good Eular response. Moreover, in a further logistic regression model, baseline RDW (p=0.03) and baseline DAS28ESR (p=0.0009) were the only predictors of a good Eular response at three months, while age, gender, MTX and prednisone dosage and seropositivity did not fit the model.

After the treatment RDW significantly increases (14.7 [14.0-15.7%]) and the variation of RDW from baseline is inversely related to the variation of DAS28ESR (r=0.263; p=0.02). The increase of RDW is significantly higher in patients with a good Eular response, with a trend towards a smaller increase in case of moderate and poor response (0.95 [0.35-1.35%] vs. 0.65 [0.1-1.9%] vs. 0.2 [0.62-0.77%]; p=0.015).
Conclusion: RDW is a promising predictor of early response to MTX in RA; in this context, it performs better than classical inflammatory markers. Moreover, RDW significantly increases after MTX initiation, proportionately to response to treatment, suggesting a potential role for RDW as a marker of MTX effectiveness.

SAT0112

NO DIFFERENCE IN TREATMENT CONTINUATION OF DIFFERENT BIOLOGICS IN ELDERLY PATIENTS > 70 YEARS COMPARED TO YOUNGER PATIENTS ≤ 65 YEARS

Anja Strangfeld1, Klaus Krueger2, Bernhard Manger3, Christian Kneitz4, Angela Zink1, Martin Schaefer1.1 German Rheumatism Research Center, Epidemiology Unit, Berlin, Germany; 2Rheumatologist, Munich, Germany; 3Scientific Advisory Board, Erlangen, Germany; 4Rheumatologist, Schwerin, Germany

Background: Due to demographic changes an increasing number of persons reach an age above 70 years. Therefore, the adequate therapy of elderly patients with rheumatoid arthritis (RA) is an increasingly important topic.

Objectives: To compare treatment continuation of several biologic DMARDs in patients ≤ 65 with elderly patients > 70 years, stratified by onset of disease (young onset (<65 years) and late onset (>65 years)) and by seropositivity.

Methods: The German register RABBIT is a prospective longitudinally followed cohort of RA patients enrolled with a new start of a DMARD after at least one csDMARD failure. For the current analysis patients who were enrolled with a biologic DMARD between 01/2007 and 04/2018 were included. Kaplan Meier methods were applied to analyse treatment continuation.

Results: Among the 9,819 RA patients included in the analysis, 7,972 were ≤ 65 years old and 1,847 were older than 70 years (among them 180 patients above 80 years). Among the patients ≤ 65 years, 28% received a csDMARD and 72% a bDMARD, while among the patients above 70 years, 35% received a csDMARD and 65% a biological. Elderly patients with a young disease onset (YORA) were more frequently women and more frequently seropositive, on average had a higher number of prior treatment failures, a worse physical function and were more likely to have joint erosions than elderly patients with late onset (LORA) (Table 1). On all bDMARD treatments investigated, elderly RA patients showed the same treatment continuation as seen in younger patients. While neither the age of the patients nor the age at disease onset changed the continuation of biologics, patients being seronegative had a significantly lower continuation with rituximab and abatacept treatment, irrespective of age (Figure 1).

Conclusion: These results suggest that bDMARD treatment may be used for elderly patients with the same effectiveness as in younger patients.

SAT0113

LIMITING FACTORS OF REACHING ACR/EULAR BOOLEAN REMISSION IN EARLY RA PATIENTS TREATED ACCORDING TO CURRENT GUIDELINES

Nina Sundlisater1, Anna-Birgitte Aga1, Ulrik Sundin1, Hilde Berner Hammer1, Till Uhlig2, Tore K. Kvien1,2, Espen Haavardsholm1,2, Siri L. Løkkevang1, Espen Haavardsholm1,2, Diakonhjemmet Hospital, Oslo, Norway; 1University of Oslo, Faculty of Medicine, Oslo, Norway

Background: Abrogation of inflammation is important to prevent irreversible joint damage and maximize health-related quality of life in early RA patients. The ACR/EULAR Boolean remission criteria have the most stringent remission definition. (1) It has been reported that patient global assessment (PGA) is the variable most commonly scored above the cut-off in patients who almost fulfill the ACR/EULAR Boolean remission criteria. (2)

Objectives: To assess which components of the ACR/EULAR Boolean criteria that most often limit attainment of remission in modernly treated
early RA, and quantify the extent of subclinical inflammation in these patients.

Methods: DMARD-naive early RA patients included in the treat-to-target ARCTIC trial were followed by a strict tight control regime aiming for DAS remission and no swollen joints, with an additional target of ultrasound remission in half of the patients.(3) Examination of all patients included 44SJJC, Ritchie articular index (RAI), laboratory tests, patient reported outcomes included physical function (PROMIS), ultrasound (US) of 32 joints and magnetic resonance imaging (MRI) of the dominant hand and wrist (scored according to RAMRIS). Patients with complete clinical data at the 2-year follow-up visit were included in the current analyses. We assessed the proportion of patients fulfilling ACR/EULAR Boolean remission (based on 44 joints) and the proportion of patients fulfilling three out of four remission criteria, and in such cases, which were the limiting factors. We compared physical function and imaging inflammation (assessed by US power Doppler score, US grey scale score, MRI synovitis and bone marrow edema) in patients reaching complete ACR/ EULAR Boolean remission to patients not reaching ACR/EULAR Boolean remission due to the most often limiting factors. We compared physical function and imaging inflammation (assessed by US power Doppler score, US grey scale score, MRI synovitis and bone marrow edema) in patients reaching complete ACR/EULAR Boolean remission to patients not reaching ACR/EULAR Boolean remission due to the most often limiting factors. Chi2 test and Wilcoxon rank sum test were used for the comparisons.

Results: Of the 203 patients included, 62% were females, mean (SD) age was 52 (13) years, and 81% were ACPA positive. ACR/EULAR Boolean remission was achieved by 112 of 203 patients after 24 months (55%), while 49 (24%) fulfilled three of the four remission criteria. Among these 49 patients, the major limiting factor for not reaching remission was PGA (n=29, 59%), with tender joints as the second most common limiting factor (n=11, 22%) (Figure). In patients not achieving remission due to PGA, the median [IQR] PGA value was 3.1 [2, 4.4]. Subclinical inflammation measured by ultrasound and MRI was not significantly different in patients from achieving ACR/EULAR Boolean remission compared to patients not achieving remission due to PGA and/or tender joints (Table), but the latter reported more subjective symptoms such as fatigue and impaired physical function.

Conclusion: PGA and tender joints are the variables most often limiting patients from achieving ACR/EULAR Boolean remission, also in a treat-to-target setting with high remission rates. The level of subclinical inflammation is not elevated in these patients compared to patients in ACR/ EULAR Boolean remission. Further research is still needed to assess which clinical remission criterion is best suited to guide treatment.

FLARING OF RHEUMATOID ARTHRITIS DUE TO TAPERING OF DMARDS: HOW DOES IT AFFECT PATIENTS' WELL-BEING? A STUDY ON PATIENT REPORTED OUTCOMES

Elise van Mulligen1, Angelique Weel1,2, Martijn Kuiper1, Johanna Hazes1, Annette van der Helm - van Mil1, Pascal de Jong1,2, Erasmus MC, Rheumatology, Rotterdam, Netherlands; 1Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; 2Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands

Background: Previous studies have shown that it is possible to taper DMARDs in RA patients with an inactive disease, but this is accompanied with a high chance of disease flares. Current recommendations advise to taper DMARDs from a clinical viewpoint. However, data on the feasibility of tapering DMARDs from a patient’s perspective are sparse.

Objectives: To determine the impact of flare after DMARD-tapering on patients quantifying the changes in patient relevant domains e.g. functional ability, fatigue, quality of life, and worker productivity, and to explore the duration of the effect.

Methods: Data were used from all 113 patients that flared after tapering DMARDs in the TARA study, a multicenter randomised controlled trial in which patients in sustained remission (DAS28<2.6 & SJC<10) tapered either their csDMARDs or TNF-inhibitor per protocol. For the current analysis, we compared the following secondary outcomes before and after flare over time: DAS44, functional ability (HAQ-DI), fatigue (BRAF-MDQ), quality of life (EQ-SD and SF36), anxiety and depression (HADS), morning stiffness, VAS general health, and worker productivity. Follow-up started three months before flare, at the moment of flare, and every 3 months thereafter. These were compared to baseline values, calculated by taking the average of 12, 9 and 6 months before flare. We used Linear Mixed Models (LMMs) with a random intercept and an autoregressive covariance matrix to determine an overall effect of flare. We adjusted for multiple testing with a Bonferroni correction. For determining the duration of the effect of a flare, we tested if the separate time points differed from the baseline with the same model. For the worker productivity we used descriptive statistics.

Results: In total, 113 patients experienced a flare. Patients who had a flare had a less stable course of the outcomes over time, compared with patients without flare (Figure 1A-G). When comparing all time points to baseline, statistical significant differences were found for DAS44 (p<0.0001), VAS general health (p<0.0001), morning stiffness (p<0.0001), HAQ-DI (p<0.0002), EQ-SD (p<0.0001), BRAF-MDQ (p<0.04), and the SF36 physical component scale (p<0.0004) (Figure 1A-H). The duration of these effects was more than 12 months for the DAS44, morning stiffness, and VAS general health. For the HAQ-DI, EQ5D, BRAF-MDQ, and SF36 PCS the duration of the effect of a flare was 6 months (Figure 1H). The effect sizes, expressed as differences with baseline, are indicated in Figure 1H and were rather small for most outcomes. The number of patients with paid work and unemployment were not affected by flare. The amount of sick leave increased from 1 to 1.3 days per month after flare had a less stable course of the outcomes over time, compared with patients in sustained remission. The amount of sick leave increased from 1 to 1.3 days per month after flare. These were compared to baseline values, calculated by taking the average of 12, 9 and 6 months before flare. We used Linear Mixed Models (LMMs) with a random intercept and an autoregressive covariance matrix to determine an overall effect of flare. We adjusted for multiple testing with a Bonferroni correction. For determining the duration of the effect of a flare, we tested if the separate time points differed from the baseline with the same model. For the worker productivity we used descriptive statistics.

Conclusion: Having a flare does affect patient reported outcomes. It affects DAS44, VAS general health, morning stiffness, functional ability, quality of life, and fatigue. This effect lasted for more than 6 months. Although we only found minor differences with baseline on group level, on the individual patient level this can still be of great importance.

SAT0116 DYNAMIC PREDICTION OF FLARES IN RHEUMATOID ARTHRITIS USING JOINT MODELLING AND MACHINE LEARNING: SIMULATION OF CLINICAL IMPACT WHEN USED AS DECISION AID IN A DISEASE ACTIVITY GUIDED DOSE REDUCTION STRATEGY

Paco Weelings1, Alfons den Broeder2, Janneke Tekstra3, Marlies van de Goes4, Floris Labebe5, Johannes W. G. Jacobs1, Oj Medina6, Asmir Vodencarev1, Marcus Zimmermann-Rittereiser1, Saskia Hailjema1, Jacob M. van Laar1,2
1University Medical Center Utrecht, Utrecht University, Utrecht, The Netherlands, Department of Rheumatology and Clinical Immunology, Utrecht, The Netherlands; 2St. Maartenskliniek, Nijmegen, The Netherlands, Department of Rheumatology, Ubbingen, Netherlands; 3University Medical Center Utrecht, Utrecht University, Utrecht, The Netherlands, Applied Data Analytics in Medicine programme, Utrecht, The Netherlands; 4Digital Services, Siemens Healthcare GmbH, Erlangen, Germany, Erlangen, Germany; 5University Medical Center Utrecht, Utrecht University, Utrecht, The Netherlands, Laboratory of Clinical Chemistry and Haematology, Utrecht, Netherlands

Background: Most rheumatoid arthritis (RA) patients on a biological DMARD achieve and maintain remission or low disease activity. Then, tapering the drug is safe and cost-effective, but with increased risk of short-lived flares and joint damage progression. We developed so-called dynamic prediction models, using joint-modelling (JM) and machine learning (ML) respectively to predict an individual patient’s risk of flaring. These models can make short-term (e.g. 3 month) predictions repeatedly at every clinic visit, based on routine care data, i.e. the longitudinal course of the patients’ disease activity and medication, demographic and disease characteristics.

Objectives: To externally validate the JM and ML model and evaluate the clinical impact on flare occurrence and bDMARD use, when using predictions as decision aid for tapering bDMARDs in a protocolised disease activity guided tapering strategy.

Methods: For external validation, an RCT comparing protocolised dose reduction (stepwise increase injection interval, until flare or discontinuation, n=121) with usual care (n=59) was used.1 Both models were applied to the trial data and AUC-ROC and calibration were assessed. To simulate our dose-reduction strategy, first, we defined optimal cut-offs for predictions using Youden’s index as well as a cut-off at higher/lower predicted risks. Thereafter we applied them to the dose reduction arm of the trial. Assumptions were that 1) no further tapering was performed when the cut-off was reached without any flares occurring over time in the simulation and 2) when in the trial a flare occurred for which the bDMARD dose was increased to a value higher than when tapering was stopped in simulation, this flare occurred and the higher dose was used in simulation as well.

Results: AUC-ROC’s in external validation were, as expected, somewhat lower than in the development cohort: 0.76 (95%CI 0.61—0.88) and 0.67 (0.52—0.77) versus 0.78 (0.70—0.85) for JMML and ML respectively, and still satisfactory. Calibration was better for ML, resulting in different cut-offs for the models. Results show that about 40% and 50% of flares can be prevented respectively and that the majority (66% and 76%) of the dose reduction can be maintained using the optimal cut-offs in our prediction aided dose reduction strategy over 18 months. Table 1 shows the proportion of full dose used, mean number of flares per patient, and percentage of patients experiencing a flare for several cut-offs as well as in the disease activity guided dose reduction strategy (in bold). As context values are also shown for usual care (trial control arm; in italic).

Conclusion: Both models proved to be externally valid. Using them to aid decisions on biological dose reduction has the potential to reduce the occurrence of flares significantly while largely retaining the reduction in dose as obtained by a disease activity guided dose reduction strategy.

Background: Currently, with increased awareness of early diagnosis and intervention and the identified association of early remission with a better clinical outcome in patients with rheumatoid arthritis (RA), shorter time to remission appears to be a more attractive goal. There are several studies reported the prevalence of early remission, no study so far has demonstrated the issue in Chinese population. Moreover, further investigative studies need to be performed due to limited and conflicting predictors of early remission in previous studies.

Objectives: To assess rates of early remission and investigate the concordance across different remission definitions, and to identify predictors of early remission in Chinese patients with RA.

Methods: For this study, clinical records were retrospectively reviewed for RA patients at rheumatologic clinic in Peking University First Hospital from 2009 to 2018. Disease activity and remission were determined according to DAS28-ESR, CDAI, SDAI, and Boolean criteria. Early remission was defined as time to remission < 6 months. A secondary definition evaluated early remission as ≤ 3 months. Logistic-regression analyses were performed to identify determinants of early remission.

Results: 869 consecutive patients contributing 8,640 clinic visits were studied. Early remission rates were respectively 42.0% (DAS28-ESR), 25.0% (CDAI), 29.4% (SDAI), and 26.1% (Boolean). Notably, patients achieving remission within 6 months more frequently attained sustained remission by contrast to those not achieving early remission (68.7±7.5% vs. 31.2±33.1%, P<0.0001). Further logistic-regression analyses revealed male (OR=1.421-1.74, p<0.05), early RA (OR=1.64-2.22, p<0.05), as well as initial hydroxychloroquine treatment (OR=1.41-1.81, p<0.05) were independently associated higher probability of early remission, as demonstrated by nearly all definitions, while a higher baseline disease activity (DAS28-ESR, CDAI, and SDAI) lowered the possibility of early remission in corresponding remission indices. However, the significant associations of treatment-naive, serological features with early remission were not confirmed.

Conclusion: Early remission was strongly associated with sustained remission, however infrequently achievable in real-life practice. Male, early RA, a low baseline disease activity, and initial hydroxychloroquine treatment were stable independent predictors of early remission.
Background: Combination therapy with DMARDs for treating RA is standard of care. However, certain rates of adverse events (AEs) are unavoidable. The stigmas are how to predict the risk and how to define drug withdrawal sequence based on data mining from the SSDM.

Methods: SSDM is an interactive mobile disease management tool, including two application systems (Apps) for both the doctors and the patients. The patients can input medical records (including medication and laboratory test results) and perform self-evaluation (DAS28, HAQ) via App. The data synchronizes to mobiles of authorized rheumatologists through cloud and advises could be delivered. In previous studies, we demonstrated that patients could master SSDM after training. In order to develop a prediction model and the master algorithm, abnormal white blood cell counts (WBC) and alanine aminotransferase (ALT) elevation were targeted. Data was collected, extracted, validated, and Bayesian networking, data mining, modeling were performed. WBC under 4k/ml is defined as leukopenia (LP), over 10k/ml as infection predisposing (IP), and ALT > 40 U/L as ALT elevation.

Figure 1: Bayesian network and data processing: Patients master (black in boxes) and the rate of LP, IP and ALT elevation in 31 regiments.

Figure 2: Bayesian network and data processing: Patients master (black in boxes) and the rate of LP, IP and ALT elevation in 31 regiments.

Rheumatoid arthritis – biological DMARDs

COMPARATIVE EFFECTIVENESS OF TOFACITINIB AND TNF INHIBITORS SINCE 2014, IMPACT OF COMBINATION WITH METHOTREXATE

Denis Choquette1, Louis Bessette, Loi Chouquette Sauvageau1, Isabelle Ferdinand1, Paul Harouli1, Frédéric Massicotte1, Jean-Pierre Pelletier1, Jean-Pierre Raynauld1, Marie-Anais Rémiillard1, Diane Sauvageau1, Édith Villeneuve1, Louis Coupal2

1Institut de Recherche en Rhumatologie de Montréal (IRRIM), Rheumatology, Montréal, Canada; 2Centre de l’Ostéoporose et de Rhumatologie de Québec (CORQ), Québec, Canada

Background: Tofacitinib (TOFA), a targeted synthetic DMARD, has been approved for the treatment of rheumatoid arthritis (RA) in Canada since April 2014. This oral agent preferentially inhibits signalling by cytokine receptors associated with JAK1 and JAK3 subunits. It is also indicated for the treatment of PsA and UC since October 2018. Clinical experience with this molecule has been increasing, and questions relating to its efficacy and long-term safety are of interest. Data collection through RHumatologie de Québec (CORQ), a Quebec based clinical database and registry, allows comparison of newer options with more traditional agents such as tumor necrosis factor inhibitors (TNFi).

Objectives: The current analysis compares TOFA to TNFi used with and without methotrexate (MTX) among patients with RA.

Methods: Data collected since January 1, 2014 (when TOFA became available in Canada) at the Institut de Recherche en Rhumatologie de Montréal (IRRIM) and the Centre de l’Ostéoporose et de Rhumatologie de Québec (CORQ) was extracted from Rhumatologie de Québec (CORQ) on January 7, 2019. Patients initiated on TOFA or a TNFi (adalimumab, certolizumab, etanercept, golimumab, infliximab) without or with MTX were selected. Data include baseline characteristics (socio-demographic variables, concomitant and past medication, comorbidities and the Charlson comorbidity index (CCI)), variables measured over time (lab results, patient and physician-reported outcomes, and disease activity measures) and persistence data (treatment duration, reason for cessation). The groups were compared to identify potential confounder, and persistence data were analyzed using Kaplan-Meier and Cox methods.

Results: A total of 480 patients were prescribed TOFA (n=162) or a TNFi (n=318) since January 1, 2014. Of those, 57% (n=92) and 70% (n=224) were treated with MTX in the TOFA and TNFi group respectively and mean disease duration was 12.1 (standard deviation=11.0) and 7.2 (8.1) years. TOFA and TNFi represent the first treatment following csDMARD-IR for 33% (TOFA) and 62% (TNFi). In the TOFA group, 84% were women, 15% were smokers and the mean age at treatment initiation was 57.7 (11.5) years. In the TNFi group, 77% were women, 12% were smokers and the mean age at treatment initiation was 54.2 (13.7) years. At treatment initiation, patient global, pain and fatigue assessments, made on a visual analogue scale ranging from 1 to 10, were 5.6 (2.5), 5.9 (2.7) and 5.7 (2.9) in the TOFA group and 5.0 (2.9), 5.5 (3.0) and 5.1 (3.1) in the TNFi group. Baseline disease activity was assessed as moderate or high/severe in 85.9% and 76.7% of TOFA (7 patients (DAS28/4-ESR criteria). Among the 56 (35%) TOFA and 146 (46%) TNFi patients ceasing therapy, reasons for cessation were “inefficacy” (TOFA: 64% vs TNFi: 56%) and “adverse events” (TOFA: 16% vs TNFi: 11%). Patients remaining on TOFA and TNFi therapy at last follow-up had an average treatment duration of 1.7 (1.1) and 2.7 (1.5) years and no difference in retention was observed between TOFA and TNFi treated patients (log-rank p=0.41). Patients treated with a TNFi in combination with MTX had better treatment retention than those treated without MTX (log-rank p=0.04) while patients treated with TOFA+MTX had similar retention (log-rank p=0.96). These results remain unchanged when adjusted for gender, age at treatment initiation, disease duration, and comorbidities.

Conclusion: In our real-world data registry, treatment with TNFi and TOFA yielded similar retention over time. Subjects treated with TNFi and MTX remained on treatment longer than those treated without MTX while subjects treated with tofacitinib with or without MTX had similar retention.

SAT0122 COMPARISON OF REAL-WORLD PERSISTENCE OF SUBCUTANEOUSLY ADMINISTERED BIOMATIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUG (DMARD) THERAPY AMONG PATIENTS WITH RHEUMATOID ARTHRITIS (RA) SWITCHING FROM ANOTHER BIOLOGIC

Background: The EULAR and ACR clinical guidelines recommend switching to a different disease-modifying antirheumatic drug (DMARD) when biologic treatment failed. Experience treatment failure or toxicity. Lack of efficacy and adverse events are among the most commonly reported reasons for switching biologic therapies. Limited information is available regarding biologic drug persistence among subcutaneously administered (SC) biologic agents in the real-world setting, as well as for comparative information on biologic persistence for SC biologics among patients with rheumatoid arthritis (RA) who are naive to biologic treatment.

Objectives: To compare persistence of SC biologic DMARDs (i.e., bDMARDs) in patients with RA as subsequent-line therapy following a failure of first line bDMARDs.

Methods: US administrative claims data were used to create a longitudinal cohort of adult patients with RA initiating SC biologic between 1/1/2012 and 6/30/2017 (initiation date = index). Patients were required to have failed 1st bDMARD to enter study (but could later switch therapy) and to have 6 and at least 3 months of continuous enrollment pre- and post-index (date of prescription for bDMARD). Those with other autoimmune conditions were excluded from the study. Outcomes were biologic persistence, defined as number of days between initiation date and last supplied day of last fill. Parametric survival models with exponential distribution with robust variance estimator were used to compare outcomes for tocilizumab versus other biologics, adjusting for differences in baseline characteristics, accounting for correlation among different bDMARD episodes.

Results: There were 10,301 patients with 12,704 bDMARD episodes: abatacept (n=2,998), adalimumab (n=3,599), certolizumab (n=982), etanercept (n=2,760), golimumab (n=745), or tocilizumab (n=1,630). Mean age was 51.0-53.3. Mean [SD] Elixhauser comorbidity scores were significantly higher (p<0.001) for tocilizumab (2.8 [2.3]) compared to abatacept (2.5 [2.2]), adalimumab (2.5 [2.1]), certolizumab (2.4 [2.0]), etanercept (2.4 [2.0]), or golimumab (2.4 [2.2]). Adjusted median days (95% CI) of persistence were: abatacept 320 (305, 335); adalimumab 280 (268, 293); certolizumab 282 (261, 284); etanercept 289 (274, 304); golimumab 304 (274, 333); and tocilizumab 333 (311, 356). Tocilizumab had significantly higher persistence compared to adalimumab, certolizumab, and etanercept (Figure 1). Of patients who were observed for 12 months, 45% of patients initiated tocilizumab bi-weekly and 55% initiated weekly. Of the 347 patients initiating bi-weekly tocilizumab, 33% switched to weekly over 12-month follow up; the mean time to switch was 177 days. After 12 months of follow-up, approximately 68% of patients finished on weekly dosing and 32% on biweekly dosing.

Conclusion: Among patients with RA who previously used ≥1 other biologic, tocilizumab-treated patients had similar or statistically significantly better biologic persistence compared with other biologics.

SAT0123 RISK FOR TUBERCULOSIS DURING TREATMENT WITH BIOLOGIC THERAPY: IS IT TIME FOR REVIEWING SCREENING PROTOCOL? – RESULTS FROM BRAZILIAN REGISTRY OF BIOLOGICAL THERAPIES IN RHEUMATIC DISEASES (BIOBADABRASIL)

Background: As Brazil is accountable for 33% of the tuberculosis (TB) burden in Americas, with an annual incidence of 3.35/100,000 in 2017[1], the occurrence of tuberculosis infection in patients with rheumatic diseases in use of biological therapy is a recurrent concern.

Objectives: To assess incident TB among patients with rheumatic disease in use of biological therapy in a country with high incidence of TB.

Methods: BiobadaBrasil is a multicentric prospective cohort study involving patients with rheumatic diseases who started the first biologic or a synthetic disease modifying anti-rheumatic drug (DMARD)[6]. This analysis includes patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) recruited from Jan 2009 to Aug 2018 and followed-up for one or multiple courses of treatment until censoring or incident TB. The primary outcome was the incidence of tuberculosis (in any organ site). The history of exposure to tuberculosis, chest Rx, screening and treatment for latent tuberculosis infection (LBTI), and use of prophylactic isoniazid were evaluated before each course of treatment. Multivariate Cox proportional hazards models (with DMARDs included as time-varying covariates) were used to estimate hazard ratios (HR) and 95% confidence intervals (CI); analyses were performed with the Survival package of R.

Results: Sample: 2858 patients (female =70.2%; RA = 72%, AS=20%, and PsA = 8%). A total of 31 (1.1%) patients developed tuberculosis during treatment. One patient on abatacept and one on tocilizumab developed TB while all the others were on TNF-inhibitors[29]. The median (interquartile range) exposure to the current DMARD course was 11.1 (5.9-20) months. TB patients did not significantly differ from others regarding disease duration, sex or age. Almost half (n=14,45%) of TB patients did not present evidence of previous exposure or any screening positive test for TB; 9 (29%) TB patients had received adequate LTBI treatment (isoniazid) recently or in the past. Furthermore, 8(26%) had incomplete/ inconsistent screening. The overall incidence of TB was 1.9/1000 patients/year, and was not significantly different among the diseases (1.63 for RA, 2.06, for AS, and 3.79/1000/year for PsA). In univariate analysis, exposure to anti-TNF monoclonal antibodies (HR 3.1, 95%CI 1.18-8.15, p=0.02) and presence of any marker of previous contact with TB (positive history of TB, known contact with TB, positive TST, or abnormal chest X-ray: HR 4.2 (2.1-8.5, p<0.001) were positively associated with the risk of TB. Including simultaneously these variables in the Cox model, they were independent risk factor for TB (p<0.05).

Conclusion: Monoclonal anti-TNF antibodies and previous exposure/diagnosis of TB are independent risk factors for developing TB in Brazil. TB
cases occurred both early and lately during treatment courses, suggesting LTBI screening failures, treatment non-adherence or re-exposure. Current application and content of the protocol for screening and treatment of LTBI needs to be reviewed.

PATIENTS. EFFECTS OF BIOLOGICAL DRUGS.

Objectives: 1- To characterize the serum molecular profile associated to the increased cardiovascular risk in Rheumatoid Arthritis (RA) patients. 2- To evaluate the in vivo and in vitro effects of biological drugs on the reestablishment of this altered molecular profile.

Methods: Serum samples of 280 RA patients and 100 healthy donors (HD) were studied. miRNomes were identified using next-generation sequencing miRNA assay (HTG EdgeSeq technology). The inflammatory profile, Nefosis-derived products, and circulating biomolecules related to oxidative stress were quantified using commercial kits. The Cardiovascular Risk SCORE for RA patients was calculated following EULAR recommendations. Current circulating miRNAs were evaluated as early atherosclerosis marker. The in vivo effects of biologic drugs such as Infliximab (IFX), Tocilizumab (TCZ) and Rituximab (RTX) were evaluated before and after 6 months of therapy in 45, 20 and 25 RA patients, respectively. Serum from RA patients with high and low CV risk scores - either before and after IFX, TCZ and RTX therapies-, were further added to HUVECs, monocytes, and neutrophils purified from HD, and activity profiles were evaluated.

Results: The mRNA whole transcriptome assay identified 104 circulating miRNAs altered in RA patients. Functional classification (IPA) established those miRNAs with altered expression, reducing the CV risk in RA patients. Mechanistic in vitro studies showed that levels of a number of those altered biomolecules and circulating microRNAs were predictors of a high Cardiovascular Risk SCORE and the presence of a pathologic CIMT in RA patients.

The in vivo treatments with IFX, TCZ and RTX for six months reduced disease activity and induced the re-establishment of normal levels in those altered biomolecules in RA patients. Mechanistic in vitro studies showed increased pro-inflammatory profiles of leukocytes subsets and HUVECs after treatment with serum from high CV risk score-RA patients. These profiles were reversed by incubation with serum from those patients after biologic drugs treatment.

Conclusion: 1. Specific mediators of inflammation, oxidative damage and Nefosis, along with the microRNAs modulating their expression, coordinately contribute to the higher CV risk score present in RA patients. 2. Biologic drugs such as IFX, TCZ and RTX, restore the normal levels of these altered biomolecules, reducing the CV risk in RA patients.

LONG-TERM SAFETY WITH SARILUMAB PLUS CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS AND SARILUMAB MONOTHERAPY IN RHEUMATOID ARTHRITIS: AN INTEGRATED ANALYSIS WITH 9,000 PATIENT-YEARS OF FOLLOW-UP

Roy Fleischmann1, Yong Lin2, Gregory St John3, des loneliness and her independence, and in combination with csDMARDs in Phase 3 trials.

Objectives: We assessed long-term safety from the sarilumab clinical development program in adult patients with RA who received subcutaneous (SC) sarilumab in eight clinical trials and their open-label extensions: MOBILITY (NCT01061736), TARGET (NCT01197597), ASCERTAIN (NCT01768752), EASY (NCT02057250), COMPARE (NCT01764997), ACT11575 (NCT01217814), COMPARE (NCT02325290), ONE (NCT02121210), and the open-label extension EXTEND (NCT01146652).

Methods: Data (cut-off Jan 15, 2018) were pooled from patients on sarilumab+csDMARD (N=2867) or sarilumab monotherapy (N=471). Patients had received sarilumab 200 mg or 150 mg q2w SC, except for 151 patients from MOBILITY Part A who received 100 mg qw, 150 mg qw, or 100 mg q2w. Treatment-emergent (TE) adverse events (AEs), AEs of special interest (AESIs), and discontinuations were assessed.
Results: Demographics were similar between combination and monotherapy pools (mean age 52 years; 81–83% female), and 38.7% and 8.5% of patients had received prior bDMARDs. Cumulative drug exposure was 7,985.5 and 796.7 patient-years (PY), with maximum duration 7.3 and 3.5 years. Exposure-adjusted rates of TEAEs, serious AEAs, and TEAEs leading to discontinuations were similar (Table). Infections were the most common AEIs. Rates of serious infection were 3.7 and 1.0/100 PY for combination and monotherapy, respectively, and were not associated with decreased absolute neutrophil counts (ANCs). Incidences of ALT > 3× upper limit of normal and ANC <1.0 giga/L were 10.3% and 12.7% for combination, respectively, and 5.5% and 14.9% for monotherapy. Rates of confirmed GI perforation for combination and monotherapy were 0.1 and 0/100 PY. Analyzing data by 6-month intervals showed no increase in rate over time for serious infections, malignancy, major adverse cardiac events, or ANC <1.0 giga/L.

Conclusion: The long-term safety profile of sarilumab, either as monotherapy (observed for >3.5 years) or as csDMARD (observed for >7 years), remains stable and consistent with the anticipated profile of an IL-6R blocker.

SAT0126

A PHASE 2 STUDY OF E6011, AN ANTI-FRACTALKINE MONOCLONAL ANTIBODY, IN PATIENTS WITH RHEUMATOID ARTHRITIS INADEQUATELY RESPONDING TO BIOLOGICS

Yoshiya Tanaka1, Tsurumori Takeuchi2, Hisashi Yamanaka3, Yoshihiro Nanki4, Hiroshi Umezawa1, Nobuyuki Yagi2, Fumihiko Tago1, Yasumi Kikuragi1, Makoto Kawakubo1, Hayato Hisaki2, Seiichiro Hojo4, Tetsu Kawano5, Toshio Imaj6

Background: Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to both actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1, during their migration. We have conducted clinical trials of E6011, a novel humanized anti-FKN monoclonal antibody, for patients with rheumatoid arthritis (RA) in Japan1. This is the first report of a Phase 2, multicenter, randomized, double-blind, placebo-controlled, parallel-group comparison study of E6011 in RA patients inadequately responding to biologics (NCT02960490).

Objectives: To evaluate efficacy and safety of E6011 compared with placebo.

Methods: During the 24-week double-blind period, patients with moderately to severely active RA of inadequate response to biologics were randomly assigned to E6011 400 mg or placebo groups at a 1:1 ratio. Patients who continued the study beyond Week 12 were further allocated to E6011 200 mg or 400 mg at a 1:1 ratio within the initially assigned group. Patients received either E6011 400 mg or placebo at Weeks 0, 1, 2, and every 2 weeks subsequently until Week 10 and then E6011 200 mg or 400 mg every 2 weeks between Weeks 12 and 22 in a double- blind manner. This abstract reports the results from the first 12-week placebo controlled period.

Results: A total of 64 subjects (33 in the placebo group and 31 in the E6011 400 mg group) received study drug. Of the 64 subjects, 55 completed and 9 discontinued study treatment prematurely during the 12-week placebo controlled double-blind period. The ACR20 response rate at Week 12 (non-responder imputation), the primary endpoint, was 27.3% (9/ 33 subjects) in the placebo group and 22.6% (7/31 subjects) in the E6011 group. ACR50 and ACR70 response rate at Week 12 were 3.0%, 0% in the placebo group and 9.7%, 3.2% in the E6011 group, respectively. Numerically greater improvement from baseline was found for some parameters of the ACR components in the E6011 group, however, no statistically significant differences were found in any of the ACR compo- nents between the placebo and E6011 groups. From the exploratory PK exposure analysis, there was a tendency that the effect of E6011 became clearer in the subjects who achieved higher serum trough E6011 concentration. Adverse events that occurred in at least 2 subjects in the E6011 group were stomatitis, injection site erythema, nasopharyngitis, and blood creatine phosphokinase increased. As a result, E6011 was well tolerated with no notable safety concerns at doses of 400 mg when administered subcutaneously for 12 weeks.

Conclusion: E6011 400 mg was well tolerated but did not show clear efficacy at Week 12 compared with placebo in RA patients with inadequately responding to biologics. Further investigation to seek an optimal clinical dose and evaluation period of E6011 are warranted.

LONG-TERM OUTCOME OF CHILDREN BORN TO MOTHERS WITH CHRONIC ARTHRITIS WHO WERE EXPOSED IN UTERO TO TNFi WITH THOSE OF UNEXPOSED CHILDREN BORN TO PATIENTS WITH THE SAME AGE AT CONCEPTION AND DISEASE.

Methods: An ad-hoc created questionnaire was used to collect data on birth and growth parameters, breastfeeding, weaning, developmental milestones, vaccinations and illnesses.

Results: 122 live births in 97 women with chronic arthritis (65 RA and 32 SpA) were observed: 59 pregnancies were exposed to TNfi at the time of conception and 63 pregnancies were TNFi-naive. In 57/59 (97%) pregnancies, TNFi was discontinued at positive pregnancy index. In 2/59 (3%) pregnancies TNFi was maintained throughout pregnancy due to active disease at conception. TNFi was restarted in 16/57 pregnancies (28%) (10 ETA, 5 CTZ, 1 ADA) during the 2nd-3rd trimester due to moderate/severe flare (median exposure 22 weeks). In second group, TNFi (1 ETA, 1 CTZ) was introduced in 2/63 (3%) pregnancies during the 2nd trimester due to a severe flare. In 16/63 (25%) pregnancies were managed with an increase of prednisone (max 10mg/day). To investigate the long-term follow-up of children exposed in utero to TNFi, 61 children exposed to TNFi at conception or during 2nd-3rd trimester (median age 29 months) and 61 unexposed children (median age 49 months) were compared. No significant differences in growth parameters and developmental milestones were observed. No excess nor particular pattern of congenital defects/malformations were observed. In both groups, vaccinations were performed according to the national schedule (no live vaccines in the first year of life) without relevant complications (Figure 1).

Conclusion: TNFi may be required in patients that experienced flare during pregnancy and they are effective in controlling maternal disease and ensures a good pregnancy outcome without complications for the health and growth of exposed children.

The disease of bDMARDs,1,2 However, there are limited data indicating which factors, if any, are prognostic of flares after tapering. Moreover, association between underlying inflammation and disease flare following tapering remains unclear. Objective: To investigate association between residual disease activity at double-blind (db) bi identified by MRI and occurrence of flares in SCA RA pts randomized to an adalimumab (ADA) dose tapering regimen controlled by ADA withdrawal (w/d).

Methods: Pts in SCR (DAS28[ESR] or CRP ) >2.6 for at least 6 mos and at screening (DAS28[ESR] <2.6) on ADA 40 mg eow were enrolled in this phase 4, randomized, db, parallel group study. Following 4-wksol open-label lead-in (OL-LI) during which SCR was confirmed, pts were randomized to tapering and w/d arms for 36 wks. Pts experiencing flare (defined as either DAS28[ESR] >2.6 and DAS28 [ESR] increase >0.6 from bl or DAS28[ESR] increase >1.2 from bl, irrespective of absolute DAS28[ESR]) received rescue OL ADA 40 mg eow for up to 16 wks. The primary endpoint was the association between bl hand and wrist synovitis and bone marrow edema (BME) RAMRIS scores and their composite with flare occurrence. Secondary endpoints were association between pt and disease characteristics and occurrence of flare, time to and occurrence/severity of flares, maintenance of remission, and time to and regain of clinical remission following flare. Logistic regression, descriptive statistics (counts and proportions with 95% CI) and Kaplan-Meier estimates are provided. Last observation carried forward was used for missing data. Treatment-emergent adverse events were monitored.

Results: Of 146 pts who entered the OL-LI period, 122 were in SCR at wks 0 and 4 and were randomized to taper (n=102) or w/d (n=20) arm. Pts were female (75%) with ~13 yrs of active disease, received ADA for >3 yrs (75% >2 yrs in SCR). Bl disease activity measures were: DAS28[ESR] >1.7; composite synovitis and BME RAMRIS score: 4.0, and >85% pts were in CDAI and/or SDAI remission. In the taper and w/d arms, 37% (36%) and 9% (45%) pts experienced flare, respectively. Time to flare was 18.0/13.3 wks (Q1 for taper/w/d withdrawal arm). At wks 12/24/36, flare rates were 13.1/24.7/34.9% in the taper arm and 10.0/35.0/40.0% in the w/d arm. Neither of the bl RAMRIS scores nor their composite was associated with flare occurrence in the taper arm (Table). Only bl HAO-DI was associated with flare occurrence. Through 16 wks of OL rescue with ADA 40 mg eow, 38% and 50% of pts in the taper and w/d arms, respectively, regained clinical remission; approximately 85% in both arms were in clinical remission by DAS28[ESR] <2.6 at week 40. No new serious risks or safety signals were identified.

Conclusion: A relatively low flare rate was observed among this established RA population in longstanding SCR who tapered or withdrew ADA. Baseline HAO-DI, but not MRI inflammation, was found to be associated with flare occurrence, which may be reflective of the very low bl MRI inflammation scores in this sustained remission cohort. A relatively low flare rate was observed among this established RA population in longstanding SCR who tapered or withdrew ADA. Baseline HAO-DI, but not MRI inflammation, was found to be associated with flare occurrence, which may be reflective of the very low bl MRI inflammation scores in this sustained remission cohort. A relatively low flare rate was observed among this established RA population in longstanding SCR who tapered or withdrew ADA. Baseline HAO-DI, but not MRI inflammation, was found to be associated with flare occurrence, which may be reflective of the very low bl MRI inflammation scores in this sustained remission cohort.
ANTI-CITRULLINATED PEPTIDE ANTI-BODIES TITERS DECREASE AFTER RITUXIMAB BUT NOT AFTER ABATACEPT OR TNF BLOCKERS TREATMENT: A REAL-LIFE ANALYSIS

Stephane Hilliquin1, Loriane Guttermann2, Claire Goulvestre3, Jerome Avouac4
1Hopital Cochin, Pharmacy, Paris, France
2Hopital Cochin, Pharmacy, Paris, France
3Hopital Cochin, Immunology laboratory, Paris, France

Background: There is an increasing body of evidence suggesting a direct pathophysiological role of ACPA in Rheumatoid Arthritis (RA). Therefore, on the top of clinical, biological and imaging remission, one target could be immunological remission, defined as the normalization of the ACPA titers after therapy. In this sense, data related to the capacity of different biologics to normalize ACPA are contradictory.

Objectives: To evaluate the changes in ACPA titers before and after treatment with different biologics.

Methods: RA patients treated with biologics were identified via the hospital’s pharmacy and/or the Electronic Medical Record of the patients; thereafter, for each patient, ACPA titers before/after treatment were retrieved from the department of biology. To be included, patients had to be diagnosed with RA, to have received a biologic (either abatacept IV or SC, TNF-inhibitors(TNFi) (Infliximab iv and Etanercept SC), or Rituximab IV) and to have at least two dosages of ACPA (at least one before and one after biologic treatment). ACPA titers were compared before and after treatment in each of the treatment groups. A mixed model analysis including an interaction between the drug and time was performed. A mixed model analysis including an interaction between the drug and time was performed. A mixed model analysis including an interaction between the drug and time was performed. A mixed model analysis including an interaction between the drug and time was performed.

Results: Among the 328 selected RA patients 92 patients (female: 84%, mean age: 62 years) had enough biological data to be included for the analysis: 36 patients had received rituximab, 21 abatacept, 35 TNFi. Mean (Standard deviation) ACPA levels in the whole group before treatment was 904.8 (1164.6) UI/L. ACPA titers (summarized in figure 1) decreased significantly after Rituximab (from 1287 (1322) to 301(387) UI/L; p<0.005) but not after Abatacept (from 857(1166) to 1352(1241) UI/L) or TNF blockers (from 593(881) to 1116(1241) UI/L). ACPA titers (summarized in figure 1) decreased significantly after Rituximab (from 1287 (1322) to 301(387) UI/L; p<0.005) but not after Abatacept (from 857(1166) to 1352(1241) UI/L) or TNF blockers (from 593(881) to 1116(1241) UI/L). Modelling of ACPA titers over follow-up (mixed models) revealed a significant interaction between drug and time, suggesting a drug effect of such variation (Figure).

Conclusion: In this real-life study, ACPA titers decrease slightly only after Rituximab therapy. These data suggest that there is potentially a huge unmet need in RA if the target is to achieve an immunological remission.

SA10131 SAFETY AND EFFECTIVENESS OF DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (bDMARDs) IN OLDER ADULTS WITH RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY

Rupa Aksle1, Walter P. Makowskyč2, Liam Martin2, David Hogan1
1University of Calgary, Department of Medicine, Division of Geriatric Medicine, Canada
2University of Alberta, Division of Rheumatology, Department of Medicine, Canada

Background: Rheumatoid arthritis is common among older adults and biological disease-modifying antirheumatic drugs (bDMARDs) are effective in treating this population. However, older patients reportedly experience more adverse events (AEs) with effectiveness being either equivalent or worse than younger patients.

Objectives: Our primary objective was to compare the AEs associated with the use of bDMARDs and their relative effectiveness in three age groups: Group 1 (75+), Group 2 (65-74 years) and Group 2 (55-64 years) patients. We explored if sex, disease activity, baseline functional impairment, and the type of bDMARDs used differed across the three age groups as a secondary objective.

Methods: A retrospective cohort study of adults 55+ with RA seen between Jan 1, 2007 and July 31, 2009 was performed utilizing the RAPPORT (Rheumatoid Arthritis Pharmacovigilance Program and Outcomes Research in Therapeutics) database housed in Edmonton, Alberta, Canada. Baseline characteristics (age, sex, DAS28 score, HAQ score, types of bDMARDs used), drug effectiveness (based on DAS28 score) and associated AEs were compared across the three age groups. Descriptive statistics (Mean, SD, percentages) were used. An intention to treat analysis with chi-square testing for categorical variables and t testing for continuous ones were used to test for the significance of differences found.

Results: A total of 333 patients met our entry criteria (69.4% female, 30.6% male) with 52, 125 and 156 from groups 1, 2 and 3 respectively. Group 1 patients had a significantly higher mean HAQ score (2.16) compared to the younger groups (P<0.005) and a mean DAS28 (5.52) score significantly higher than the 55-64 group (P<0.05). Group 1 patients were more likely to experience AEs (p<0.05), which were more likely to be infectious (p<0.05), life threatening/severe (p<0.05), cause discontinuation of treatment (p<0.05) and multiple (p<0.05) compared to the younger groups. We also interestingly found the remission rate to be significantly higher in Group 1 patients compared to Group 2 (p<0.05). Etanercept was the most commonly used drug among all age groups. Rituximab and abatacept were much less frequently used. Rate of AEs and therapy effectiveness did not differ significantly by sex across the three age groups.

Conclusion: Older adults aged 75+ treated with bDMARDs for RA are at a significantly higher risk of AEs, which should be included in the treatment discussion. The higher remission rate in those 75+ compared to those 65-74, which has not been reported previously, warrants further study.

LONG-TERM SAFETY, IMMUNOGENICITY AND EFFICACY IN RANDOMIZED, DOUBLE-BLIND, AND OPEN-LABEL EXTENSION STUDIES COMPARING FKB327, AN ADALIMUMAB BIOSIMILAR, WITH THE ADALIMUMAB REFERENCE PRODUCT IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

Rieke Alten1, Mark C. Genovese2, Ara3, Rafael Muniz4, Herbert Kellner5.

1University Medicine Berlin, Berlin, Germany; 2Stanford University Medical Center, Palo Alto, CA, United States of America; 3Fujitum Kyowa Kirin Biologics Co., Ltd., Tokyo, Japan; 4Mylan Inc., Canonsburg, PA, United States of America; 5Specialist Practice in Rheumatology and Gastroenterology, Munich, Germany

Background: FKB327 is a biosimilar of adalimumab reference product (RP). Studies with adalimumab biosimilars have shown no increase in safety signals or immunogenicity versus RPs studied at 52 weeks. Objectives: To study the long-term safety, immunogenicity and efficacy of FKB327 compared with Adalimumab RP in a randomized double blind (DB) phase 3 study in patients (pts) with active rheumatoid arthritis (RA) inadequately controlled with methotrexate (MTX) and in a subsequent randomized, open-label extension (OLE) study with treatment switching assessed long-term safety, efficacy, PK, and immunogenicity.

Methods: Pts aged ≥18 years with moderate-to-severe, active RA (2010 ACR/EULAR criteria) for ≥3 months and receiving a stable dose of MTX were randomized 1:1 to FKB327 or RP (40 mg subcutaneously [SQ]) every other week with MTX. In the OLE study, pts who completed the DB study with clinical response and no serious adverse events (AEs) were rerandomized in a 2:1 ratio to FKB327 or RP. All pts received FKB327 through week 76 (Period 2). The primary end point was safety; the secondary end point was efficacy. Pooled data for up to 2 years were analyzed to assess long-term safety, Incidence rates of treatment-emergent AEs were adjusted by overall exposure to enable safety comparison of FKB327 and RP.

Results: Of 728 pts in the DB study, 645 were enrolled in the OLE; of those, 572 and 515 pts completed periods 1 and 2, respectively. Safety results from the pooled data were comparable between treatment sequences. Mean serum drug concentrations appeared to be in steady-state in all treatment sequences in Period 1 and comparable among sequences in Period 2. The proportion of pts with positive antidrug antibody (ADA) status in Period 1 was comparable between treatment sequences, and the majority of patients with positive ADA status had neutralizing activity. The mean proportion of patients achieving an ACR20 response remained stable between studies and was similar for all treatment sequences.

Conclusion: The safety, immunogenicity, and efficacy of FKB327 were maintained over long-term treatment and after switching between the biosimilar and RP.

SAT0133
TREATMENT PATTERNS, PERSISTENCE, AND DURABILITY IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (BDMARDS)

1University of California, San Francisco, CA, United States of America; 2Gilead Sciences, Foster City, United States of America; 3IQVIA, Falls Church, United States of America; 4IQVIA, Plymouth meeting, United States of America; 5Stanford University, Stanford, United States of America

Background: EULAR and ACR recommend bDMARDS, as monotherapy or in combination with methotrexate, in patients whose rheumatoid arthritis (RA) remains active despite methotrexate use.1 Treatment options for bDMARD inadequate response (IR) patients vary. Understanding the real-world treatment patterns and treatment duration in bDMARD IR patients may help identify the most suitable next treatment.

Objectives: We studied treatment patterns, treatment persistence, and treatment durability in bDMARD IR patients who switched to another treatment regimen.

Methods: In US health plan claims data, this study selected adult RA bDMARD patients: those with ≥2 RA diagnoses ≥30 days apart, who newly initiated a bDMARD (1/1/2012 - 3/31/2017; baseline) and then switched to another bDMARD or JAKi (index date, ID). All patients had continuous ≥1-year enrollment before and after ID. Patient characteristics were evaluated at baseline; treatment patterns, persistence, and durability (duration) were evaluated during pre- and post-index periods. Kaplan-Meier curves were used to evaluate treatment persistence.

Results: Among 105,039 patients who were initiated on bDMARDS, 19,085 (18%) demonstrated IR; among those, 4,656 met all the selection criteria: median age 54 years, 22% male, 17% from Northeast, 26% Midwest, 42% South, 15% West. At baseline, 26% used tumor necrosis factor inhibitors (TNFi) monotherapy and 64% used TNFi in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARD). Baseline median treatment duration was 8.3 months overall, including 5.6 months for monotherapy and 9.4 months for combination therapy. Upon switch, 46% of patients used monotherapy (28% TNFi, 11% other bDMARD, 7% janus kinase inhibitors [JAKi]), and 54% used bDMARD in combination with csDMARD (37% TNFi + csDMARD, 12% other bDMARD

+ csDMARD, 4% JAKI + csDMARD). Median treatment duration was longer for combination therapy than monotherapy (13.1 vs. 5.8 months, p<0.001). TNFi showed a trend towards shortest treatment duration and lowest 12-month treatment persistence among monotherapies and combination therapies. (Table) JAKI showed best treatment persistence among monotherapies (Figure 1; p-value=0.0004) and combination therapies (Figures 2; p-value<0.0001).

Conclusion: In biologic DMARD IR patients, the first bDMARD treatment lasted, on average, for 8.3 months before switch. Post-switch, TNFi showed a trend towards the shortest durability and JAKI showed the longest durability. The data suggest substantial unmet need in bDMARD patients. A well-tolerated effective therapy, with potent clinical efficacy and improved treatment durability may benefit this patient population.

SAT0134 COMPARING REAL-WORLD RETENTION RATES IN A MATCHED COHORT OF RHEUMATOID ARTHRITIS PATIENTS WHO EITHER REMAINED ON THE ETANERCEPT ORIGINATOR OR SWITCHED TO A BIOSIMILAR

Lisa Baganz1, Anja Strangfeld1, Peter Herzer2, Andreas Krause3, Hans-Peter Tony4, Angela Zink1,5. 1German Rheumatism Research Center, Berlin, Germany; 2Scientific Advisory Board, Munich, Germany; 3Immanuel Krankenhaus, Berlin, Germany; 4Universitätsklinikum Würzburg, Würzburg, Germany; 5Charité University Medicine, Berlin, Germany

Background: In Germany, the first etanercept biosimilar was licensed in 2016. In contrast to other European countries there is no uniform recommendation for the prescription of biosimilars.

Objectives: To compare treatment survival between patients who were switched from the etanercept originator to the etanercept biosimilar SB4 and patients who stayed on the originator treatment.

Methods: We used data of rheumatoid arthritis patients observed in the prospective, longitudinal RABBIT (Rheumatoid Arthritis: Observation of biologic therapy) cohort until November 2018 who were treated with the etanercept originator (oETA) for at least six months. Patients who thereafter were switched to the biosimilar SB4 (bsETA) were matched (1:n) to patients who stayed on the original treatment using prescription time distribution matching [1] to control for survival bias. Matching criteria were sex, time of switch or corresponding duration of originator treatment in non-switchers and age as well as DAS28 at the time of switching or corresponding time point in non-switchers. The retention rates over one year were analyzed using Kaplan-Meier curves.

Results: Overall, 1,751 patients fulfilled the inclusion criteria of whom 113 were switched to bsETA. Of these, 102 switchers could be matched to 598 patients who remained on oETA. In both groups, 78% of the patients were female, mean age was about 59 years, DAS28 was 3.2 and physical function as well as numbers of prior biologics were similar. Patients who remained on oETA were more often rheumatoid factor positive (71% vs. 63%), had more erosions (56% vs. 47%) and had more frequently three or more comorbidities (34% vs. 28%) than those who were switched to bsETA. The most common reason for switching was costs (79%). After one year, 35% of the patients in both groups had stopped the respective treatment (oETA: n=210, bsETA: n=36). The main reasons for withdrawal were loss of efficacy (oETA: 57%, bsETA: 26%) and adverse events (oETA: 20%, bsETA: 42%). In both groups about the same portion of the adverse events that led to treatment discontinuation were serious events (24% vs. 27%). Kaplan-Meier curves showed similar retention rates over 12 months for bsETA and oETA (figure). Nine bsETA patients were switched back to oETA.

Conclusion: Retention rates of etanercept treated RA patients who were either switched to the biosimilar SB4 or who stayed on the originator are comparable. Only few patients switched back to the originator.

SA81035 MAINTAINING REMISSION IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS WHILE TAPERING ETANERCEPT: AN INSIGHT IN THE TAPERING TRIAL

Delphine Bertrand1, Julie Mannaerts1, Valérie Badot1, Stephanie Bond1,2, Laurel Young1, Katherine Poulsen1, Helen L. Barrett3, Andrew L. Taylor4, Claire Barrett1.

Background: EULAR 2016 recommendations for the management of Rheumatoid Arthritis (RA) suggest to consider tapering of biological Disease-Modifying Antirheumatic Drugs (bDMARDs) in patients in sustained remission. More insight on the effect of tapering strategies is needed in daily practice.

Objectives: To investigate maintaining disease control after spacing dosages of etanercept 50mg from weekly to every other week (EOW) in a pragmatic randomized controlled trial (RCT).

Methods: Patients with RA who were in remission according to the disease activity score 28 (DAS28) remission criteria for at least 6 months and treated with etanercept 50mg weekly for at least a year were included in the one-year non-blinded multicentre TapERA (Tapering Etanercept in RA) RCT (EudraCTnumber 2012-004631-22). Patients were 1:1 randomly assigned to continue etanercept 50mg weekly or to taper to 50mg EOW. Patients who lost remission (DAS28 C-Reactive Protein (CRP) > 2.6) received nonsteroidal anti-inflammatory drugs and if needed were re-escalated to etanercept weekly. If remission was still not reached, treatment had to be adapted, at the discretion of the treating rheumatologist. The outcomes were proportion of patients in DAS28 remission at 6 and 12 months, proportion in sustained remission and proportion regaining remission after reintroducing weekly etanercept (intention to treat analysis). Missing components of DAS28 were imputed using expectation maximization.

Results: In total, 69 patients (69.6% female) with a mean ± standard deviation (SD) age of 55.7 ± 11.3 years and a mean ± SD disease duration of 14.7 ± 8.0 years were included. The weekly and EOW group consisted of 35 and 34 patients respectively. At the month 6 visit 77.1% of patients in the weekly and 76.5% of the EOW group were in remission (p=0.547) and 68.6% and 58.8% respectively maintained remission on every visit (p=0.400) (Table 1).

Three (8.6%) patients of the weekly and 11 (32.4%) of the EOW group required a treatment adaptation, which was statistically significantly different (p=0.014) and there was no difference between the weekly and EOW group in the mean ± SD DAS28 CRP at the first time of losing remission in patients flaring, namely 3.1 ± 0.6 and 3.1 ± 0.5 respectively (p=0.957).

Eleven patients were re-escalated to a weekly treatment after a mean ± SD duration of 4.5 ± 3.1 months. Of these, 54.5% (6/11) regained remission after a mean ± SD duration of 4.7 ± 1.7 months. Of the 5 patients not regaining remission, 1 switched to a weekly regimen on the last trial visit, 1 required switching to another bDMARD and 3 patients had no additional treatment changes (mean ± SD DAS28 CRP at month 12: 3.4 ± 0.2). Two patients of the EOW group restarted weekly etanercept while still being in remission.

Conclusion: Approximately half of the EOW group was in sustained remission after 1 year and two thirds remained on their reasigned treatment. Further, one in two patients in sustained remission after reintroducing etanercept weekly. Therefore tapering of etanercept in EOW seems a feasible strategy in patients with RA in sustained remission, potentially leading to a beneficial cost-saving and safety profile.

SA81036 CONSISTENCY WITH INTERNATIONAL GUIDELINES REGARDING MOTHERS WITH RHEUMATOLOGIC DISEASES EXPOSED TO TUMOUR NECROSIS FACTOR INHIBITORS (TNFI) DURING THE ANTE- AND POSTNATAL PERIODS AND CHANGE OVER TIME

Stephanie Bond1,2, Laurel Young1, Katherine Poulsen1, Helen L. Barrett3, Andrew L. Taylor4, Claire Barrett1.

Background: Many women with rheumatologic diseases require ongoing treatment with TNFI during pregnancy to maintain remission or low disease activity. Until recently, there has been a paucity of published evidence regarding the safe use of these medications during the ante- and postnatal periods to guide clinical practice.

Objectives: To observe compliance with current guidelines for TNFI therapy in Australian women with rheumatologic diseases during the ante- and postnatal periods and change over time.

Methods: All Australian women with rheumatologic diseases, exposed to biologics (bDMARDs) and targeted synthetic disease modifying antirheumatic drugs (tsDMARDs) during the preconception, antenatal and/or post-partum periods were eligible to participate in the Pregnancy Exposed to Biological (PEB) study. Commencing in 2015, recruitment was via invitation from patient’s treating rheumatologists, community groups, and social media. Following self-referral to the study, retrospective data was collected, including rheumatologic condition and management recommendations made by health professionals.

Results: Preliminary data is available for 37 infants born to 29 mothers from Feb 2009-Dec 2018. Of these, 32 women received TNFI. We assessed 3 outcomes – TNFI continuation during pregnancy, TNFI continuation during lactation and vaccination practice in infants exposed to TNFI. Women exposed to non-TNFI bDMARDs and tsDMARDs were excluded from this abstract, as these are not recommended for use during the perinatal period (2).

Specialist Society Guidelines from the British Society of Rheumatology and the British Health Professional in Rheumatology were published in 2016 regarding the safety of TNFI during pregnancy (2). Prior to guideline publication, 67% (n=16/24) of the women in PEB ceased their TNFI pre-conception. Of those in PEB who became pregnant subsequent to guideline publication, only 25% (n=2/8) ceased TNFI pre-conception. Overall, 40.6% (n=13/32) women received a TNFI during the antenatal period consistent with guidelines, which improved from 33.3% (n=8/24) pre-publication, to 62.5% (n=5/8) post publication. 84.4% (n=27/32) women exposed to TNFI breastfed their infants. Prior to availability of evidence regarding the safety of TNFI during lactation, 79.2% (n=19/24) of infants were breastfed. After publication, 100% (n=8/8) infants exposed to TNFI were breastfed.

In total, 96.9% (n=31/32) of the infants exposed to TNFI in PEB were vaccinated. Rotavirus vaccine should have been delayed in 43.8% (n=14/ 32) infants, but was not. 9.4% (n=3/32) infants had live vaccines deferred until only 3 months; 3.1% (n=1/32) infants had live vaccines unnecessarily delayed. Only 3.1% (n=1/32) infants had live vaccines appropriately delayed until 7 months. Compliance with vaccination recommendations increased from 43.5% (n=10/24) pre-publication to 62.5% (n=5/8) post publication of guidelines.

Conclusion: Preliminary data from PEB suggests that there has been a shift in practice following the publication of Specialist Society Guidelines, with increasing numbers of women continuing TNFI therapy during pregnancy and the postpartum period, in keeping with current evidence. Compliance with vaccination recommendations could be improved to be more consistent with published international guidelines.

SAT0137  PATIENTS (PTS) SWITCHED TO SARILUMAB FROM ADALIMUMAB ACHIEVE CLINICALLY IMPORTANT IMPROVEMENTS IN RA DISEASE ACTIVITY: RESULTS FROM MONARCH TRIAL OPEN-LABEL EXTENSION (OLE)

Gerd Rüdiger Burmester1, Howard Amital2, Andrea Rubbert-Roth3, Hubert van Hoogstraten4, Leon M. Gervitz5, Karthinathan Thangavelu6, Gregory St John7, Mark C. Genovese7.

1Charité University Medicine, Berlin, Germany; 2Sheba Medical Center, Ramat Gan, Israel; 3Kantonsspital St. Gallen, St. Gallen, Switzerland; 4Sanofi Genzyme, Bridgewater, NJ, United States of America; 5Sanofi Genzyme, Boston, MA, United States of America; 6Regeneron Pharmaceuticals, Inc., Tarrytown, NY, United States of America; 7Stanford University Medical Center, Palo Alto, CA, United States of America

Background: In MONARCH (NCT02332590), sarilumab monotherapy (200 mg subcutaneously [SC] every 2 weeks [q2w]) demonstrated superior benefit to adalimumab monotherapy (40 mg SC q2w) in DAS28-ESR, ACR20/50/70 response, HAQ-DI, and CDAI in pts with RA and inadequate response/intolerance to methotrexate.

Objectives: To assess long-term safety/efficacy in RA pts continuing sarilumab or switching from adalimumab to sarilumab monotherapy in the ongoing OLE of MONARCH.

Methods: Pts completing MONARCH were eligible for the OLE, in which they received sarilumab 200 mg SC q2w. Efficacy and safety data were reported up to OLE Wk 48 and March 2017, respectively. Responder rates were based on the intent-to-treat population. Continuous efficacy endpoints were based on the observed population.

Results: Of 369 pts enrolled in MONARCH, 320 (87%) entered OLE (switch: n=155; continuation: n=165). By safety data cut-off, pt attrition was similar in switch (24; 15.5%) and continuation groups (22; 13.3%), as were treatment-emergent adverse events (AEs) (switch: 76.1%, 267.4/100 PY; continuation: 70.9%, 230.2/100 PY) and infections (switch: 41.9%; continuation: 35.8%). For DAS28-ESR and CDAI endpoints, >40% of switch pts achieved a minimally important difference (MID) improvement from OLE baseline by OLE Wk 12, increasing to >50% by OLE Wk 48. Additionally, >40% of switch pts achieved a MID in DAS28-CRP and a minimally clinically important difference (MCID) in HAO-DI from baseline to OLE Wk 12, increasing to >50% by OLE Wk 48. Additionally, >40% of switch pts achieved a MID in DAS28-CRP and a minimally clinically important difference (MCID) in HAQ-DI from baseline to OLE Wk 48. Of pts achieving CDAI ≤10 from baseline to OLE Wk 24 of the OLE, 70.7% (switch group) and 83.5% (continuation group) achieved sustained response at OLE Wks 36 and 48. In the randomized controlled phase, response rates were higher in sarilumab-treated than adalimumab-treated pts, hence fewer pts in the continuation group achieved additional MID during OLE (data not shown). AEIs of special interest are reported (Table). Two deaths occurred in the switch group (malignancy; cerebrovascular accident) versus one in the continuation group (subarachnoid hemorrhage). No GI-related AEIs (ulcers/perforations/diverticulitis) were observed.

Conclusion: Pts switched from adalimumab to sarilumab experienced clinically meaningful improvements in signs and symptoms of RA. Safety observations in OLE were generally consistent with those in MONARCH.

Abatacept (ABA) is a biologic DMARD (bDMARD) used to treat rheumatoid arthritis (RA) since 2006. There are limited data on clinical efficacy of ABA, and on predictors for ABA treatment response.

**Methods:** In an observational cohort study, based on data from a large national quality register database, patients with RA diagnosis who initiated treatment of RA between bionaïve patients and patients with previous bDMARD experience. Male sex also predicted LUNDEX corrected HAQ response, more likely to have significant HAQ disability, measured by HAQ, were less likely to remain on treatment and achieve EULAR good response to abatacept. Patients with extensive disability, measured by HAQ, were less likely to remain on treatment and achieve a EULAR Good Response, but more likely to have significant HAQ improvement.

**PREDICTORS OF CLINICAL EFFICACY OF ABATACEPT IN RHEUMATOID ARTHRITIS: DATA FROM A LARGE OBSERVATIONAL STUDY**

**Giovanni Cagnotto,**1,2 Minna Willim,3 Lennart Jacobsson,4 Michele Compagno,2,5 Saeds Saevarsdottor,6 Carl Turesson

**Background:** Abatacept (ABA) is a biologic DMARD (bDMARD) used to treat rheumatoid arthritis (RA) since 2006. There are limited data on clinical efficacy of ABA, and on predictors for ABA treatment response.

**Objectives:**

- To compare the effectiveness of ABA in the treatment of RA between bionaïve patients and patients with previous bDMARDs.
- To investigate predictors of clinical response to ABA.

**Methods:**

- In an observational cohort study, based on data from a large national quality register database, patients with RA diagnosis who initiated treatment with ABA between April 2006 and November 2017 were included.
- LUNDEX corrected response was defined as the fractions remaining on the drug and achieving the outcome among all who initiated treatment (1). Clinical response at 6 and 12 months was evaluated by means of LUNDEX corrected EULAR (L-EULAR) Good Response and LUNDEX corrected HAQ response (change of ≥0.3 from baseline) (L-HAQ). Predictors for clinical response were investigated using logistic regression, with significance based backwards selection of variables for the final multivariate model. The study was supported by an unrestricted grant from Bristol Myers-Squibb.

**Results:**

- 2716 RA patients were included in the study. More patients in the bionaïve population achieved L-EULAR Good Response and L-HAQ response at 6 and 12 months than bDMARDs experienced patients (Fig. 1a and 1b).
- Male sex, no previous bDMARD exposure and a low HAQ score were independent predictors of L-EULAR Good Response at 6 and 12 months (Table 1). Lack of previous bDMARD exposure also predicted L-HAQ response at 6 and 12 months. There was a positive associations between baseline HAQ and L-HAQ response at 6 months (multivariate adjusted odds ratio 1.73; 95% CI 1.46-2.05).

**Conclusion:** In patients with RA, response rates for treatment with abatacept were substantially higher in bionaïve patients than in those with previous bDMARD experience. Male sex also predicted LUNDEX corrected EULAR good response to abatacept. Patients with extensive disability, measured by HAQ, were less likely to remain on treatment and achieve a EULAR Good Response, but more likely to have significant HAQ improvement.
SAT0139  A MULTICENTRE, RANDOMISED, DOUBLE-BLIND, PARALLEL ACTIVE-CONTROLLED CLINICAL TRIAL COMPARING PHARMACOKINETICS, PHARMACODYNAMICS, SAFETY AND EXPLORATORY EFFICACY BETWEEN HLX01 AND EUROPE-SOURCED RITUXIMAB AS A NEW INDICATION IN CHINESE MODERATE TO SEVERE PATIENTS WITH RHEUMATOID ARTHRITIS

Xiaofeng Zhang1, Yongyu Wang2, Zhenyu Jiang2, Zhouch Zhang2, Lan He2, Xiao Zhang2, Xin Li3, Xumei Liu3, Jian Xu4, Cibo Huang1, Rui Liu1, Xiaoxia Zuo1, Baogeng Zhao3, Wenting Gu1, Katherine Chai3, Xinjun Guo3, Xin Zhang3, Eugene Liu10, Alvin Liu11, Weidong Jiang3, Scott Liu3, Pei Hu11, Xiao Chen12.

Background: Biologic products, such as rituximab and adalimumab, have revolutionized the treatment for chronic inflammatory disorders, providing an option to patients who were non-responsive to conventional systemic therapies. In China, rituximab is only approved for the treatment of certain haematologic malignancies. At present, there are several approved biosimilars in Europe but none in China. HLX01, a China-manufactured proposed rituximab biosimilar, was first developed for patients with non-Hodgkin’s lymphoma later as a new drug for the treatment for autoimmune diseases. Currently, HLX01’s biosimilar NDA for the treatment of non-Hodgkin’s lymphoma is being reviewed by authorities in China.

Results: Evaluation of clinical PK, safety and exploratory efficacy in RA patients to support the development of HLX01 for the treatment of autoimmune diseases.

Methods: We conducted a multi-centre, randomised, double-blind, parallel active-controlled clinical trial to compare the PK, PD safety and exploratory efficacy (ACR20 and DAS28-CRP) between HLX01 and EU-RTX in patients with moderately to severely active RA. All patients had an inadequate response to treatment with disease-modifying antirheumatic drugs (DMARDs). The PK equivalence was achieved if 90% confidence intervals (CIs) for the test-to-reference ratios of area under the curve from time zero to infinity (AUC(0-inf)) and maximum observed concentration (Cmax) fall within the pre-defined 80-125% equivalence margin.

Conclusion: We report successful demonstration of similarity in PK, safety and efficacy between first China-manufactured biosimilar of rituximab, HLX01, and Europe-sourced rituximab in patients with moderate to severely active rheumatoid arthritis. These results support the Phase 3 confirmatory clinical trial for the development of HLX01 for the treatment of rheumatoid arthritis.

Background: Tofacitinib (TOFA), a targeted synthetic DMBD, has been approved for the treatment of rheumatoid arthritis (RA) in Canada since April 2014. This oral agent preferentially inhibits signalling by cytokine receptors associated with JAK1 and JAK3 subunits. It is now indicated for the treatment of psoriatic arthritis (PsA) and ulcerative colitis (UC) since October 2018. Clinical experience with this molecule has been increasing both in RA and other rheumatic conditions and long-term safety are of interest. Data collection through RHUMADATA, a Quebec based clinical database and registry, allows comparison of various advanced treatment options including TOFA and non-TNFi biologic agents (i.e., agents with other modes of action - OMA) such as fusion proteins (abatacept), and IL-6 (sarilumab, tocilizumab) and CD20 inhibitors (rituximab).

Objectives: This analysis compares TOFA and OMA used with and without methotrexate (MTX).

Methods: Data collected since January 1, 2014 (since TOFA became available in Canada) at the Institut de Recherche en Rhumatologie de Montréal (IRRMM) and the Centre de l’Ostéoporese et de Rhumatologie de Québec (CORQ) was extracted from the Rhumadata® on January 7, 2019.
2019. The selected patients had initiated therapy with either TOFA or OMA (either without or in combination with MTX). The collected data include baseline characteristics (socio-demographic variables, concomitant and past medication, comorbidities and the Charlson comorbidity index (CCI)), variables measured over time (laboratory test results, patient and physician-reported outcomes), and disease activity measures such as CDAI and DAS28(4)-ESR and persistence data (treatment duration, reason for cessation). The groups were compared to identify potential confounders, and persistence data were analyzed using Kaplan-Meier and proportional hazard methods.

Results: A total of 483 patients were initiated on TOFA (n=162) or an OMA (n=321) since January 1, 2014. Of those, 57% (n=92) and 59% (n=191) were treated with MTX in the TOFA and OMA group respectively. These represent the first treatment following csDMARD inadequate response for 33% (TOFA) and 29% (OMA) of these patients. These patients had a mean disease duration of 12.1 (standard deviation=11.0) and 11.1 (10.3) years. In the TOFA group, 84% were women, 15% were smokers, and the mean age at treatment initiation was 57.7 (11.5). In the OMA group, 75% were women, 18% were smokers, and the mean age at treatment initiation was 57.3 (12.0) years. Patient global, pain and fatigue assessments, made on a visual analogue scale ranging from 1 to 10, were 5.6 (2.5), 5.9 (2.7) and 5.7 (2.9) in the TOFA group and 5.7 (2.5), 6.1 (2.7) and 6.0 (2.8) in the OMA group. Disease activity was assessed as moderate or high/severe in 85.9% and 88.3% of patients (DAS28(4)-ESR criteria). Among the 56 (35%) TOFA and 149 (46%) OMA patients ceasing therapy, reasons for cessation were “inefficacy” (TOFA: 64% vs OMA: 59%) and “adverse events” (TOFA: 16% vs TNFi: 17%). Patients remaining on TOFA and OMA therapy at last follow-up had an average treatment duration of 1.7 (1.1) and 2.6 (1.4) years. No difference in retention was observed between TOFA and OMA treated patients (log-rank p=0.6138). Patients treated with an OMA/MTX had with an OMA/MTX had similar retention (log-rank p=0.2640) as did patients treated with TOFA/MTX (log-rank p=0.9553). These results remain unchanged when we adjust for age at treatment initiation, gender, disease duration, and comorbidities (CCI) using Cox models.

Conclusion: OMA and TOFA have similar retention as do subjects treated with OMA or TOFA with or without MTX.

**SAT0141**

**FREQUENCY AND REASONS FOR SWITCHING BACK TO BIOLOGIC ORIGINATOR FOLLOWING INITIAL SWITCH TO BIOLOGIC BIOSIMILAR**

Rebecca Davies, Lianne Kearsley-Fleet, Mark Lunt, Kath Watson, Kimme Hyrich, BSRBR-RA Contributors Group. University of Manchester, ARUK Centre for Epidemiology, Manchester, United Kingdom

**Background:** Since February 2015, a number of biosimilar drugs have been introduced for treatment of rheumatoid arthritis (RA) in the UK. Biologics are required to have no clinically meaningful differences in efficacy or safety from the originator product. There are clear cost-saving implications when switching patients to a biosimilar product as it is the longer-term implications of switching have yet to be studied.

**Objectives:** To describe the frequency of switching back to biologic-originator (BIO-O) in patients who initially switch from BIO-O to biologic biosimilar (BIO-B), focusing on etanercept (ETA) and infliximab (INF).

**Methods:** The study population comprised RA subjects recruited to BSRBR-RA from 30/11/2018 who had switched from BIO-O to BIO-B (INF and ETA) and had completed at least one further study follow-up following switch. Baseline characteristics at point of switch and the proportion of patients who were recorded as switching back to BIO-O or discontinuing BIO completely following switch with reasons are described.

**Results:** Nine hundred and sixty six patients were included (760 switching from ETA-O; 206 switching from INF-O). After a median follow-up of 22.5 months post-switch, the majority of patients remained on BIO-B (ETA-B = 95% (81%), INF-B =166 (81%)). Seven percent of patients switched back to originator, with a majority following reports of ineffectiveness or feeling generally unwell (Table). Eleven percent stopped BIO completely, with a majority stopping for serious adverse events such as malignancy or infection. Similar results were seen for both ETA and INF. Six ETA and 3 INF reported injection or infusion related reactions following switch (0.9% overall) leading to switch back (4 ETA) or biologic discontinuation (2 ETA/3 INF).

**Conclusion:** Data from this study show that the majority of patients who switched from BIO-O to BIO-B remain on the biosimilar over the short term. A small proportion of patients have switched back to the originator drug with the majority doing so for reports of ineffectiveness rather than safety concerns. Hypersensitivity reactions, such as infusion reactions were rare reasons to stop either drug completely or switch back to originator.

**SAT0142**

DIFFERENCES IN PATIENT CHARACTERISTICS AND PATTERNS OF TREATMENT BY DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (DMARD) IN BDMARD NAIVE VERSUS EXPERIENCED PATIENTS

Robin K. Dore1, Leslie Harold2, Taylor Blakeley, Ketichi Emezuamun2, Derya Anttimezora, Joel Kremer1,2. 1Private Practice, Tustin, United States of America; 2University of Massachusetts Medical School, Worcester, United States of America; 3Corona, LLC, Waltham, United States of America; 4Gleed Sciences, San Francisco, United States of America; 5Abbany Medical College, Albany, United States of America

**Background:** For RA patients (pts), EULAR and ACR recommend various DMARDs. Available treatments have short durability and low persistency.

For RA patients (pts), EULAR and ACR recommend various DMARDs. Available treatments have short durability and low persistency. For RA patients (pts), EULAR and ACR recommend various DMARDs. Available treatments have short durability and low persistency.
biologic naive vs experienced may help clinicians tailor treatment decisions to pts needs.

**Objectives:** This study aimed to compare DMARD initiation events in biologic naive vs experienced pts.

**Methods:** In the Corrona registry (as of 2/28/2018), we selected DMARD initiation events (with at least one 6-month follow up) and stratified them on whether the initiator was biologic naive or experienced. We compared pts baseline characteristics (demographic, clinical, treatment) between strata. We used Kaplan-Meier curves to describe time to discontinuation and log rank test to assess differences in persistence.

**Results:** For 48,246 RA pts, 10,347 DMARD initiations (index date, baseline; on 11/2012 or thereafter) in 6,858 adults were identified. Within initiations, 38% (n=3,931) occurred in bDMARD naive pts. Females comprised 76% (naive) vs 80% (experienced). Despite comparable age and retirement status (Table), the bDMARD experienced initiators had RA for longer (mean: 12.6 vs 5.4), were more likely to be disabled (19.6% vs 11.0%), had marginally higher CDAI scores (mean: 19.1 ± 17.8), more likely to discontinue index treatment due to elevated CDAI (15.5% vs 10.9%), and had a shorter treatment duration (mean: 13.8 vs 15.1 months) than bDMARD naïve initiators. Persistency was higher in the bDMARD naive than in experienced initiators (Figure)

**Conclusion:** The marked difference in RA duration and pts disability status, despite comparable age, confirms prior reports that bDMARD experienced pts do not respond as well to therapy as bDMARD naïve pts. The increased CDAI scores and shortened durability of response suggests that there is still a need for new efficacious and well-tolerated RA therapy.

**SAT0143 SAFETY AND EFFECTIVENESS OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS**

**Raquel Freitas**1, Joao Euruco Fonseca2, Joaquim Poldoro-Pereira2, Nathalie Madeira1, Luís Cunha Miranda2, Miguel Benardes1, Bruno Miguel Fernandes1, Flavio Costa1, Mariana Santiago2, Agna Neto2, Soraia Azevedo1, João Madurga Dias2, Maria Couto3, Graça Sequeira5, Maria Jose Santos1, 1Hospital Garcia Orta, Rheumatology, Almada, Portugal; 2Hospital Santa Maria, Rheumatology, Lisbon, Portugal; 3Instituto Portugues Reumatologia, Lisboa, Portugal, 4Hospital São João, Rheumatology, Porto, Portugal; 5Hospital Coimbra, Rheumatology, Coimbra, Portugal, 6Hospital Egas Moniz, Rheumatology, Lisbon, Portugal; 7ULSAM, Rheumatology, Ponte de Lima, Portugal; 8Centro Hospitalar Médico Tejo, Rheumatology, Torres Novas, Portugal; 9Hospital São Teotónio, Rheumatology, Viseu, Portugal, 10Hospital Faro, Rheumatology, Faro, Portugal

**Background:** Elderly population with rheumatoid arthritis (RA) is increasing. However, these patients are frequently excluded from clinical trials and data on effectiveness and safety of biologic Disease-Modifying Anti-Rheumatic Drug (bDMARD) is scarce.

**Objectives:** To assess the persistence of 1st bDMARD and the effectiveness and safety of bDMARD among elderly (≥65 years).

**Methods:** Prospective multicenter cohort-study of RA patients starting a 1st bDMARD registered at Reuma.pt. Demographic and disease characteristics, comorbidities, medications, disease activity at baseline and follow up (3, 6 and 12 months) and adverse events (AE) were compared between elderly and adult (<65 years) patients. Treatment persistence was estimated using Kaplan-Meier analysis. Effectiveness was measured as EULAR crude response rates, LUNDEX corrected, and adjusted for baseline characteristics.

**Results:** 2400 patients were included, of which 486 aged ≥65 years (table 1). Crude median persistence in bDMARD was 19.7 months (95% CI 14-25) in adults and 14.5 (95%CI 3-26) in elderly patients (log rank test, p=0.46) (figure 1). EULAR response (crude and LUNDEX corrected) was similar in the two groups at 3 and 6 months (figure 2). After adjustment for baseline characteristics, response rate was inferior in elderly at 12 months (p=0.01). There were 697 AE reported. Except for infections, more common in elderly patients (p=0.03), the rates of severe AE, opportunistic infection, allergic reactions, cancer or hospitalizations were similar in the two groups, as well as the time to 1st AE occurrence (figure 2).

**Conclusion:** Our findings showed that persistence of 1st bDMARD was similar in adults and elderly RA patients. Though elderly had more severe disease and comorbidities at baseline, bDMARD treatment was equally effective and safe in the short term. However, it is necessary to consider the greater risk of infection in elderly when prescribing a biologic.

**Table 1:** Baseline characteristics. SAT0144 UNDERSTANDING THE LONG-TERM OUTCOME OF RITUXIMAB – IMPLICATIONS FOR MANAGEMENT
Leticia Garcia-Montoya, MD Yuzaiful MD Yusof, Jean Baptiste Candelier, Andrew Rawstron, Edward Vital, Paul Emery. Leeds Institute for Rheumatic and Musculoskeletal Medicine, Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: In patients with rheumatoid arthritis (RA), rituximab (RTX) is often prescribed after loss of response to TNF inhibitors; however, little is known about the long-term outcome of patients receiving treatment with RTX. Previous work [1,2] has shown that aiming for “complete B-cell depletion with clinical response” (CD-R) leads to an optimal management of the disease but unfortunately not all patients maintain this status. Whether CD-R can be regained with RTX retreatment remains unclear.

Objectives: To assess the outcome of RA patients treated with consecutive cycles of RTX, focusing on those who achieved complete B-cell depletion with clinical response.

Methods: A prospective 12 year observational study was conducted in RA patients who were treated with RTX in Leeds. Consecutive cycles of RTX consisting of 2 infusions of 1000mg were administered either on clinical relapse or a 6-monthly basis. B-cells were measured using highly sensitivity flow cytometry at 0 and 2 weeks post-RTX. Complete depletion (CD) was defined by total B-cell count <0.0001x10⁹/L at week 2. Clinical response was defined by EULAR response criteria and CD-R was seen as the optimal outcome.

Results: 755 patients participated in the study of which 723 had complete data (see fig.1). The mean (range) number of RTX cycles administered was 3.8 (1-14). 76% (549/723) of patients reached CD-R at some stage during therapy while 24% (174/723) never did. The latter patients had a shorter period of RTX treatment vs CD-R with an OR of 7.98 after adjusting for age, gender, prior therapy with TNF-I and concomitant DMARDs (95% CI 5.86-10.86); p<0.001 (see fig.2). 84% of those who were retreated with RTX recovered CD-R (77% of them did it in the following cycle). Half of the patients that reached CD-R maintained it in prospective cycles but 47% lost it subsequently. A third of the patients that lost either clinical response or B-cell depletion were switched to other medication without receiving further cycles. Overall, at the end of the study, 55% of all patients treated with RTX (400/723) remained in CD-R.

Conclusion: Most patients treated with RTX will achieve CD-R, but approximately half of them will lose this optimal status at some point. In patients who achieve CD-R but subsequently lose it, retreatment with RTX appears to be an effective strategy since 80% of them will regain it and will maintain long-term treatment with therapy

SAT0145 ON TAPERING THERAPY FOR RA PATIENTS IN CLINICAL REMISSION; FLARE ON CS-DMARDS IS PREDICTED BY CLINICAL PARAMETERS AND ULTRASOUND, WHEREAS T-CELL ABNORMALITIES ARE PREDICTIVE FOR B-DMARD TAPERING
Hanna Gul, Frederique Ponchel, Paul Emery. Leeds Institute of Rheumatic and Musculoskeletal Medicine, Rheumatology, Leeds, United Kingdom

Background: Tapering of disease-modifying therapy (DMARDs) is recommended by EULAR/ACR for rheumatoid arthritis (RA) patients who achieve sustained remission on stable therapy(1,2). However, there is no guidance on how to manage this in clinical practice.

Objectives: We aimed to assess flare over 12 months in RA patients in sustained remission who were offered structured tapering of either conventional synthetic (cs) or biologic (b) DMARDs.

Methods: A prospective 12 year observational study was conducted in RA patients who were treated with RTX in Leeds. Consecutive cycles of RTX consisting of 2 infusions of 1000mg were administered either on clinical relapse or a 6-monthly basis. B-cells were measured using highly sensitivity flow cytometry at 0 and 2 weeks post-RTX. Complete depletion (CD) was defined by total B-cell count <0.0001x10⁹/L at week 2. Clinical response was defined by EULAR response criteria and CD-R was seen as the optimal outcome.

Results: 755 patients participated in the study of which 723 had complete data (see fig.1). The mean (range) number of RTX cycles administered was 3.8 (1-14). 76% (549/723) of patients reached CD-R at some stage during therapy while 24% (174/723) never did. The latter patients had a shorter period of RTX treatment vs CD-R with an OR of 7.98 after adjusting for age, gender, prior therapy with TNF-I and concomitant DMARDs (95% CI 5.86-10.86); p<0.001 (see fig.2). 84% of those who were retreated with RTX recovered CD-R (77% of them did it in the following cycle). Half of the patients that reached CD-R maintained it in prospective cycles but 47% lost it subsequently. A third of the patients that lost either clinical response or B-cell depletion were switched to other medication without receiving further cycles. Overall, at the end of the study, 55% of all patients treated with RTX (400/723) remained in CD-R.

Conclusion: Most patients treated with RTX will achieve CD-R, but approximately half of them will lose this optimal status at some point. In patients who achieve CD-R but subsequently lose it, retreatment with RTX appears to be an effective strategy since 80% of them will regain it and will maintain long-term treatment with therapy

inflammation related cells, IRC) data were collected. Flare over a period of 12 months was assessed using several definitions in order to evaluate their relevance for clinical outcomes. Associations with baseline characteristics were assessed using univariate statistics (Mann-Whitney-U and Chi-square). No correction for multiple testing was attempted.

Results: 98 patients (cs-DMARDs n=66, b-DMARDs n=32) accepted tapering and achieved at least 12 months follow-up. In the cs-DMARD group 55% were female; the median age was 64 years and median remission duration 25 months. For b-DMARDs 63% were female; the median age was 61 years and median remission duration 28 months. There was great heterogeneity in terms of flare rate according to the definitions used (Figure 2). Flare on tapering b-DMARDs was more commonly observed (29-70%) compared to cs-DMARDs (24-52%). Demographics were not associated with flare by any definition (except longer disease duration for cs-DMARD patients who lost Boolean remission status). Clinical (notably seropositivity) and US measures were associated with flare for cs-DMARDs. Reduced Treg and higher IRC' at baseline were associated with flare in patients tapering b-DMARDs.

Conclusion: Flare rate varied with the definition used and was more great heterogeneity in terms of flare rate according to the definitions used (Figure 2). Flare on tapering b-DMARDs was more commonly observed (29-70%) compared to cs-DMARDs (24-52%). Demographics were not associated with flare by any definition (except longer disease duration for cs-DMARD patients who lost Boolean remission status). Clinical (notably seropositivity) and US measures were associated with flare for cs-DMARDs. Reduced Treg and higher IRC' at baseline were associated with flare in patients tapering b-DMARDs. These results will help formulate further tapering strategies.

EFFECTS OF BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUG TREATMENT ON PHYSICAL ACTIVITY, MUSCLE POWER, AGILITY AND INHIBITION OF FALL IN PATIENTS WITH RHEUMATOID ARTHRITIS

Yui Hirano¹, Ayako Morikako², Dai scaffold Khina³, Sinti Inzuka⁴, Takeshi Kamiyama⁵, Hiroki Mori¹, Naohito Norishima³, Tomomi Ishikawa³, Toyohashi Municipal Hospital, Toyohashi, Japan; Toyohashi Municipal Hospital, Rehabilitation Center, Toyohashi, Japan; Toyohashi Municipal Hospital, Rehabilitation Medicine, Toyohashi, Japan.

Background: It has been demonstrated that biological DMARDs treatment rapidly improved sign and symptom in patients with rheumatoid arthritis (RA). Those were evaluated using composite measures or biomarkers in daily clinical practice or clinical studies. Although rapid improvement of composite measures or biomarkers is important in the treatment of RA, primary important goal of treatment is improvement of long term health-related quality of life (HR-QOL) [1]. HR-QOL is based on physical function such as muscle power and agility.

Objectives: This study investigated the efficacy of bDMARDs on physical function and fall risk in patients with RA.

Methods: Periodic evaluation of physical function by the staffs in rehabilitation center in our institute has been performed in addition to routine rheumatology evaluation (SDAI, biomarkers, mHAQ) in RA patient initiated their first bDMARDs treatment from Oct. 2015 to Feb. 2018. 47 cases was registered in total. Evaluation of physical function included evaluation of muscle power (grasping power [GP] and knee extension power [KEP]), agility (Time up and go test [TUG] and 10m walking time [10mW]) and questionnaire using mHAQ, portable fall risk index [2] and the 25-question geriatric locomotive function scale (locomo25) [3] at baseline (initiation of bDMARDs), 1month, 3months, 6months and 12months. Disease activity of RA (SDAI, CRP, MMP-3) was evaluated at same time point. Although 26 cases have passed one year from initiation of bDMARDs treatment, 9 cases dropped out from evaluation of physical function due to stopping of bDMARDs treatment or patient’s hope not to e evaluated on physical function or major joint surgery performed in patient which was influence physical function. Results of early 17 cases who completed evaluation at 12 months were investigated in this study.

Results: Baseline patients characteristics was as follow (n=17): mean age 59.1 years old, RA duration 13.7 years. Mean SDAI 19.6, mean CRP 1.9mg/dl. Used bDMARDs were tocilizumab in 5 cases, golimumab in 4 cases, etanercept in 3 cases, abatacept in 3 case, certolizumab in 1 case and infliximab-biosimilar in one case. Date is presents as mean values at baseline-1-3-6-12 months below. SDAI and CRP were significantly improved on and after one months except KEP at 3 months (GP [kg]: 12.3-14.1-15.9-16.9; KEP [kg]: 2.6-3.1-3.1-3.4-3.5). TUG at 10mW significantly improved on and after one months except TUC at 3months and 10mW at 3 months (TUG [s]: 9.3-8.0-8.2-7.3-7.4; 10mW[s]: 8.3-7.7-7.5-6.9-6.8). MHAQ significantly improved on and from 6 months (0.46-0.33-0.19-0.20-0.12). Locomo25 significantly improved on and from 1 month (31.7-30.6-28.5). Portable fall risk index significantly improved at only 12 months (8.8-8.6-7.8-7.6-6.8).

Conclusion: Signs and symptoms of RA were rapidly improved after the initiation of bDMARDs treatment and improvement of physical function was also rapidly improved. The changes from baseline and one month were more drastic in composite measure or biomarker of inflammation than that in muscle power and agility in respect with p-values. Inhibition of fall were achieved 12 months after bDMARDs initiation. These results suggested that physiotherapy might play an important role in RA patients treated with bDMARDs to gain more rapid improvement of physical function.

SAT0148 IMMUNOGLOBULIN A LEVELS IN ADDITION TO RHEUMATOID FACTOR PREDICTS REMISSION ACHIEVEMENT WITH ABATACET IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Jun Inamo, Yuko Kaneko, Jun Kikuchi, Tsutomu Takeuchi, Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan.

Background: Biological disease modifying antirheumatic drugs (bDMARDs) now play an important role of clinical practice for patients with rheumatoid arthritis (RA). Abatacept (ABT) has a biologic agent that has an unique mechanism of action suppressing T lymphocyte activation. Although many prediction studies about therapeutic responses to bDMARDs for RA have been conducted to date [1], few studies has focused on ABT.

Objectives: The aim of this study was to identify predictive clinical biomarkers for remission achievement with ABT in RA patients.

Methods: We retrospectively reviewed consecutive patients with RA who started ABT from 2010 through 2018 in Keio University Hospital. We defined early ABT use as the initiation of ABT within two years from diagnosis without radiographic progression in hand X rays, and stratified the patients into the early ABT users and the late ABT users. Baseline characteristics were compared between patients who achieved CDAI remission achievement at 6 months and those who did not in both groups.

Results: One hundred and seven RA patients who were treated with ABT with baseline information available were enrolled in the study. Among them, 15 patients were classified into the early ABT users and 92 were the late ABT users, and the remission rates at 6 months were 40% and 24%, respectively. In the early ABT users, patients who achieved CDAI remission at 6 months showed significantly higher IgA levels than those who did not achieve remission (390 mg/dL vs 279 mg/dL, P=0.04, respectively). The difference in IgA disappeared in the late ABT users (332 mg/dL vs 313 mg/dL, P=0.60, respectively). Principal compont analysis revealed that in the early ABT users, patients who...
achieved remission and those who did not could not be clearly separated by the levels of IgA, IgG, rheumatoid factor, and albumin (Figure), whereas those baseline characteristics were mostly overlapped in the late ABT users (cut-off value for predicting remission with sensitivity and specificity in the early ABT users: IgA 342 mg/dL with 83% and 100%, IgG 1880 mg/dL with 50% and 100%, rheumatoid factor 152 IU/mL with 50% and 100%, albumin 3.7 g/dL with 88% and 67%, respectively). The area under the curves of receiver operating characteristic curves to predict remission were 0.833 of IgA and 0.778 of rheumatoid factor to predict response of ABT.

Conclusion: We identified serum IgA titer was the novel predictive factor for response of ABT.

Efficacy of Tocilizumab for Suppressing Radiographic Progression of Cervical Lesions in Patients with Rheumatoid Arthritis: Comparison with Methotrexate; Three Years of Follow-Up - A Multicenter Registry Study -

Yasuhide Kanayama1, Yoshifumi Kojima2, Yuji Hirano3, Yuichiro Yabe4, Nobunori Takahashi1, Naoki Ishiguro5, TBCR study group. 1-Toyama Municipal Hospital, Rheumatology, Toyohashi, Japan; 2-Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan; 3-UCHO Tokyo Shinkuji Medical Center, Rheumatology, Tokyo, Japan

Background: Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with biological agents are more clinically effective than the DMARDs that were in use previously, in particular, with their efficacy in suppressing joint destruction having been emphasized. We reported the efficacy of infliximab, anti-tumor necrosis factor antibodies for suppressing the radiographic progression of RA cervical lesions at ACR2009, EULAR2010, 11, 12, 13, 14, 16 and 18. However there is still few studies of efficacy of against RA cervical lesions of Tocilizumab (TCZ), anti-interleukin 6 receptor antibody.

Objectives: To evaluate the efficacy of TCZ for suppressing the radiographic progression of RA cervical lesions comparison with MTX for 3 years.

Methods: We used TCZ or MTX for treating Japanese patients with active RA who fulfilled the ACR criteria in 1987. The final study cohort of each 50 and 75 patients received continuous TCZ and MTX treatment for at least 3 years. For evaluation of cervical lesions, the atlanto-dental interval (ADI), the space available for the spinal cord (SAC), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at initiation and Year 1,2 and 3.

Results: In the patients receiving TCZ (n=50) and MTX (n=75), the number of female were each 38(76%) and 52(69%) cases(p<0.046); the mean age was 58.7 ± 13.0 and 63.6 ± 11.0 years old (p=0.046); disease duration was 7.7 ± 7.8 and 8.0 ± 9.5 years (p = 0.027) and the mean dose of MTX was 9.2 ± 3.6 and 8.2 ± 2.9 mg/w (p=0.146). Clinical findings related to RA were as follows: CRP 4.2±3.4 and 1.7±2.3 mg/dl(p<0.001); ESR 55.0±24.0 and 31.9 ± 21.8 mm/h(p<0.001); MMP3 401 ± 311 and 223 ± 350ng/ml(p<0.001); the number of RF-positive 40 (80%) and 60(80%) cases(p<0.001); 2) During the follow up: joint pain (p < 0.0001), high HAQ (p < 0.001), high CRP (p<0.001), high ESR (p<0.001), high MMP3 (p<0.001), high RF (p<0.001), high anti-CCP (p<0.001) were increased. The number who was able to suppress progression of RA cervical lesions more than MTX treatment.

Conclusion: this study suggested that TCZ treatment can be used to suppress the progression of RA cervical lesions more than MTX treatment.

SAT0151

TIME TO INITIATION OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN THE FRENCH COHORT ESPOIR

Kedra Joanna1, Benjamin Granger2, Stephanie Emile3, Cecile Gajouj-Viala4, Anne-Christine Raf6, Bernard Combé2, Bruno Fauret5, 1Sorbonne Université, Institut Pierre Louis d’Épidémiologie et de Santé Publique (IPLESP), UMR S1136, Paris, France; 2AP-HP, Pitié Salpêtrière hospital, Biostatistics department, Paris, France; 3AP-HP, Pitié Salpêtrière hospital, Rheumatology department, Paris, France; 4Nîmes University Hospital, Nîmes, France; 5University of Lorraine, EA 4360 APEMAC, and Rheumatology department, Nancy, France; 6Montpellier University, CHU Montpellier, Rheumatology Dept, Montpellier, France

Background: Access to biologic Disease-Modifying Anti-Rheumatic Drugs (DMARDs) of early rheumatoid arthritis (RA) patients is highly variable across countries and may depend on patient characteristics, disease expression, physicians behaviors as well as care organization in the patient region of living.

Objectives: 1) To assess the time to initiation of bDMARDs in the French cohort ESPOIR, and 2) To assess the factors associated with the timing of bDMARD initiation.

Methods: In this national multicenter cohort, 813 adult patients with suspected or confirmed early RA were included between December 2002 and March 2005, and followed up during 10 years. In the present analysis, we considered only patients who were fulfilling the ACR-EULAR 2010 criteria for RA at baseline. The primary outcome was the time to initiation of a biologic DMARD, in months, since diagnosis. It was assessed by Cox model based survival analysis with time dependent covariates; the threshold used for p-value was 0.05. Predictors colinearity was then assessed by adjusted tests. All statistical analysis were done with R version 3.5.1.

Results: Among the 658 patients fulfilling the ACR-EULAR 2010 criteria for RA (77% women, 52% smokers at baseline, mean-aged 48 at diagnosis, with positive RF in 46.6%, positive ACPA in 43% and polyarticular presentation at baseline in 54.5%), 178 patients (31%, CI 95%=27%-34.7%) initiated a biologic DMARD during the 10-year follow-up (Figure 1). Variables associated with an earlier bDMARD initiation included: 1) at baseline: younger age (p = 0.0016), younger age of first joint pain (0.0014), younger age of first joint swelling (0.0014), 2) during the follow up: joint pain (p < 0.0001), high HAQ (p < 0.0016).

SAI0153
1,25(OH)₂D AND IL-6 BLOCKADE SYNERGISTICALLY REGULATES RHEUMATOID ARTHRITIS VIA SUPPRESSION OF TH17 AND OSTEOCLASTOGENESIS
Moon Young Kim, Jennifer Lee, Sung-Hwan Park. Seoul St Mary’s Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Immune cells express vitamin (vit) D receptor and vit D is known as a potent immune-modulator.

Objectives: To assess the prevalence and success of subcutaneous bDMARDs in routine care, per disease indication and bDMARD class, and the cost saving implications.

Methods: Dose interval information was collected prospectively in patients on subcutaneous bDMARDs with RA, PsA and AS attending for routine review at St George’s University Hospitals NHS Foundation Trust from October – November 2018. Department practice is that bDMARD dose reduction is discussed (but not mandated) with patients in sustained remission on a ‘try and see’ basis, without TDM.

Results: Data on 88 patients (female 46) were collected, RA 39, PsA 36, AS 13, mean age 50 years (range 24-78), TNFi n=75, other bDMARDs n=13. The dose interval was per licence in 79.5%, less frequent in 18% and more frequent in 2.5%. In those taking a bDMARD less frequently than per licence, the dose interval was increased by a mean 2.15 x licenced interval (range 1.14 – 6 x); in RA 1.88x, PsA 2.12x and AS 2.64x. Dose reduction had been attempted in 32%, but failed due to loss of efficacy in 43% of these (13.6% of entire cohort), including 50% with RA, 46% PsA and 20% AS. In those attempting a dose reduction, there was no difference in the% sustaining this for Etanercept 57% (8/14) and Adalimumab 50% (5/10) but lower for all TNFi (54%, 13/24) treated patients compared to other bDMARDs (75%, 3/4).

Dose reduction had not been attempted at any stage in 66% (RA 72%, PsA 61%, AS 62%). Cost savings from 16 patients with sustained dose reduction over 3 years in this cohort were £97,653, extrapolated to 18% of the entire population (~1500) on subcutaneous bDMARDs at our Trust makes £1.65 million saving over 3 years.

Conclusion: ‘Try and see’ dose reduction of subcutaneous bDMARDs has been attempted in one third of patients in routine care, with more success in AS where 80% sustained a lower dose at a mean 2.64 x licenced interval, compared to 50% of RA and 54% PsA patients at 1.88 and 2.12 x licenced interval respectively. Guidelines, possibly based on TDM, are needed to optimise current practice which falls short of the success of dose reduction in clinical trials (3). Even with a ‘try and see’ approach failing in 43% of attempts, the cost savings are very substantial to the healthcare economy.
seems to suppress Th17 and osteoclasts differentiation in RA patients in synergy with tocilizumab.

SA10154
STABILIZATION OF RHEUMATOID ARTHRITIS ASSOCIATED INTERSTITIAL LUNG DISEASEBY RITUXIMAB: A SINGLE CENTER EXPERIENCE WITH LONG-TERM FOLLOW-UP

Nikolaos Koupis, Nestor Avgoustidis, Anastasios Eskitzis, Styliani Polia, Ioannis Papapoulos, Irini flour, Argyro Reina, Amour Mollra, Ismail Sali, George Bertsias, Prodromos Sidiroopoulos. University Hospital of Heraklion, Crete, Greece, Rheumatology, Clinical Immunology and Allergy, Heraklion, Greece

Background: Interstitial lung disease (ILD) is the most significant pulmonary manifestation of Rheumatoid Arthritis (RA) [1], contributing to decreased quality of life, progressive chronic disability and high utilization of healthcare resources. Treatment is challenging with mixed results from different biologics while Riluximab (RTX) has the most encouraging data based on retrospective observational studies. [2]

Objectives: To evaluate the efficacy and safety of RTX in patients with RA-ILD in the context of daily practice.

Methods: Observational retrospective study (2009-2019) of patients with a diagnosis of RA-ILD from a cohort of RTX-treated RA patients in the University Hospital of Heraklion. ILD was diagnosed by HRCT and monitored by means of pulmonary function tests (PFTs), HRCT and 6-minute walking test (6MWT, clinically important difference >50 m). RTX was used at standard dose (1 gr x2/6 months). ILD progression was defined by any of: decrease of pre-RTX forced vital capacity (FVC) >10%, or diffusion capacity of carbon monoxide (DLCO) >15% predicted score, or death from progressive ILD. Improvement was defined by any of: increase of pre-RTX FVC >10% or DLCO >15% predicted. All other patients were classified as having stable disease. RA activity was assessed by DAS28 (ESR).

Results: Of 247 RA patients treated with RTX, 16 (11 women, 5 men) had RA-ILD (prevalence 6.5%). 12/16 (75%) had radiographic pattern of UIP and 4/16 (25%) had NSIP. 9/16 (56%) were positive for ACPA and/or RF. The median (IQR) age at RTX initiation was 66 (54-77) years, ILD duration prior to RTX was 5.2 (1-15) years. Number of prior biologics was 1 ± 4 and 11/16 (69%) had been treated with concomitant DMARDs. 1/16 (6.25%) had previously received Cyclophosphamide. Concomitant COPD was present in 3/16 (19%) of the patients. Follow-up while on RTX was 37 (6-136) months. The overall dose of RTX was 13 (2-40) q. Following RTX treatment, new-onset ILD was diagnosed in 3/247 patients (incidence=1.2%). During follow-up, data for ILD were available for 13/16 patients. Post-RTX, 10/13(76%) showed stabilization, 1/13 (7.7%) had improvement, while 2/13(15.3%) had progression of RA-ILD. 1/16(6.25%) switched to Cyclophosphamide. During follow-up period, 6 admissions were recorded due to infections (4 for community-acquired pneumonia and 2 for hospital-acquired pneumonia) and 1/16(6.25%) patient died after progression of ILD.

Conclusion: In this cohort of RA-ILD, the majority of patients treated with RTX showed stabilization of lung disease, while RA improved significantly, over a prolonged follow-up period. RTX appears to be an acceptable and safe therapeutic choice for patients with RA-ILD. Nevertheless, randomized studies are warranted to prove any clinical effectiveness of RTX in RA-ILD.

SA10155
THE PRESENCE OF ANTI-NUCLEAR ANTIBODIES BEFORE ANTI-TNF THERAPY IS A RISK FACTOR FOR THE APPEARANCE OF ANTI-DRUG ANTIBODIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Shunichi Kumagai1,2, Ayano Mor2, Toshinori Saito2, Miho Takahashi2, Katsumiho Yoneda1,1, Yasuyuki Noda1, Souji Takahashi1, Miwa Nishida1, Saori Hatachi1, Goh Tsui1, 1Shinko Hospital, Center for Rheumatic Diseases, Kobe, Japan, 2Shinko Hospital, Shinko Institute for Medical Research, Kobe, Japan

Background: TNF inhibitors (TNFi) revolutionized the treatment of rheumatoid arthritis (RA), but have often developed anti-drug antibodies (ADrA) and also induced other autoimmune pathology. [1, 2].

Objectives: To determine whether the presence of anti-nuclear antibodies (ANA) predict the development of ADrA and clinical efficacy in RA patients treated with TNFi, infliximab (IFX) or adalimumab (ADA).

Methods: A total of 92 RA patients, 38 cases treated with IFX and 54 cases with ADA, were prospectively enrolled. Observation period of IFX-treated group was 3 years, and that of ADA-treated group was 1 year. ANA were measured by indirect fluorescent assay using a Computer-aided microscope system with HEp20-10 cells. The concentrations of anti-IFX antibodies (HACA) and anti-ADA antibodies (AAA) were measured by radioimmunoassay at Sanquin Diagnostic Services, Netherlands. Clinical response to therapy was judged by EULAR response criteria based on Disease Activity Score (DAS) 28-CRP.

Results: Thirteen (34.2%) of 38 patients in IFX group and 18 (33.3%) of 54 patients in ADA group became positive for HACA and AAA, respectively, during the treatment. All of the ADA-positive patients were ANA-positive before the therapy. In contrast, none became ADA-positive after treatment in 15 RA patients negative for ANA before therapy (6 cases in IFX group and 9 cases in ADA group), and the positive rate for ADrA was significantly different between ANA-positive and negative patients (p=0.0018). In addition, the positive rate for HACA was significantly higher in patients positive for ANA titers of ≥640 (p=0.034), but that for AAA was not related to ANA titers. Next, ANA became positive in 4 of 6 ANA-negative patients and AAA titers increased in 21 of 32 ANA-positive patients after IFX treatment. HACA positive rate was significantly higher in patients with ANA titers of ≥640 after IFX treatment (p=0.0045). AAA titers of patients in ADA group were mostly unchanged after treatment, and were not related to the appearance of AAA.

Disclosure of Interests: None declared
Continuation rate of TNFi (IFX and ADA) treatment was significantly lower in ADRa-positive patients than in those negative (p = 0.0066 and p = 0.0127, respectively). In IFX group, patients with ANA titers of ≥160 before treatment and those with ANA titers of ≥320 after treatment positive showed worse EULAR treatment response (p = 0.037 and p = 0.033, respectively). In ADA group, 7 of 9 ANA-negative patients before treatment showed moderate or good EULAR response, but positive ANA both before and after treatment was not connected with to the clinical response.

Conclusion: The presence of ANA before IFX or ADA is a risk factor for the appearance of ADRa, while ADRa did not appear in any patient negative for ANA before treatment. ANA of high titers before and after IFX treatment predicted existence of ADRa and possibly leading to the treatment failure.

METHOTREXATE DISCONTINUATION AND DOSE DECREASES AFTER THERAPY WITH TOCILIZUMAB: RESULTS FROM THE CORRONA RHEUMA TOID ARTHRITIS REGISTRY

Dimitrios A. Pappas1,2, Taylor Blachley2, Steve Zlotnick3, Jennie H. Best3, Kelechi Emereunru5, Joel Kremer4,5. 1Columbia University, New York, United States of America; 2Corrona, LLC, Southborough, United States of America; 3Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, United States of America; 4Albany Medical College and The Center for Rheumatology, Albany, United States of America

Background: Methotrexate (MTX) is frequently prescribed with biologic disease-modifying antirheumatic drugs. Evidence has shown that tocilizumab (TCZ) monotherapy is effective in the treatment of patients with rheumatoid arthritis (RA). Similar outcomes have been shown in patients responding to TCZ combination therapy who discontinued MTX or remained on combination therapy.

Objectives: To examine MTX discontinuation and dose decreases in patients with RA initiating TCZ and to describe disease activity outcomes in a real-world setting.

Methods: TCZ-naive patients enrolled in the Corrona RA Registry who initiated TCZ and had a 6-month follow-up visit without discontinuation of TCZ were included. Patients were grouped by MTX dose at the time of TCZ initiation (≤ 10 mg, > 10 to ≤ 15 mg, > 15 to ≤ 20 mg, > 20 mg). The primary outcome was the proportion of patients with changes in MTX use at 6 months. Changes in disease activity (Clinical Disease Activity Index [CDAI]) and patient-reported outcomes (PROs) over the follow-up period were described.

Results: Of 444 eligible patients, 82.7% were female, and 83.7% were white, with a mean (SD) disease duration of 11.6 (9.3) years and a baseline CDAI score of 24.0 (15.4). The mean (SD) MTX dose at baseline was 17.7 (5.8) mg. Overall, a total of 139 patients (31.3%) discontinued or decreased MTX at 6 months (overall mean [SD] dose change, −3.0 [7.5] mg); across baseline MTX dose groups, the proportion of patients who discontinued or decreased MTX at 6 months ranged from 28.2% to 38.2%. Improvements in CDAI scores and PROs were observed at 6 months for all baseline MTX dose groups and in patients who discontinued, decreased, maintained, or increased MTX doses at 6 months (Table 1). Similar patterns and results were observed at 12 months (not shown).

Conclusion: A considerable proportion of patients initiating TCZ were able to discontinue or decrease the dose of MTX after TCZ initiation. Patients who were able to discontinue or decrease MTX experienced similar improvements in disease activity and functionality. Discontinuing or decreasing MTX may be an effective treatment strategy for patients initiating TCZ combination therapy.

REAL-WORLD EVALUATION OF PERSISTENCE WITH EARLY-LINE ABATACEPT VERSUS TUMOR NECROSIS FACTOR-INHIBITORS FOR RHEUMATOID ARTHRITIS COMPLICATED BY POOR PROGNOSTIC FACTORS

Damian Del Puello1, Ilina Yermilov2, Sarah Gibbs2, Michael Broder2, 1Bristol-Myers Squibb, Lawrenceville, NJ, United States of America; 2Partnership for Health Analytic Research, LLC, Beverly Hills, CA, United States of America

Background: Abatacept reduces signs and symptoms, inhibits the progression of structural damage, and improves physical function in adult patients with moderately to severely active rheumatoid arthritis (RA). Real-world data on its use as an early-line biologic agent are limited.

Objectives: To assess 12-month treatment persistence in early-line abatacept versus tumor necrosis factor inhibitor (TNFi) treated patients with RA complicated by poor prognostic factors.

Methods: We performed a multicenter retrospective medical record review of adult RA patients with poor prognostic factors treated at 5 United States clinics located in the West, Midwest, and Southeast. Patients were treated with abatacept or TNFi as the first biologic treatment at the clinic (defined as early line). Poor prognostic factors included positive anti-cyclic citrullinated peptide antibodies, positive rheumatoid factor antibodies, increased C-reactive protein levels, elevated erythrocyte sedimentation rate levels, or presence of joint erosions. TNFis included adalimumab, etanercept, infliximab (and their biosimilars), certolizumab pegol, or golimumab. Data were collected from biologic treatment initiation (between 8/9/11 and 11/4/16), for ≥1 year. Patients with Crohn’s disease, ankylosing spondylitis, psoriatic arthritis, or anul fistula were excluded. Demographic, disease, and treatment information (start, stop, reason for discontinuation) was abstracted. Treatment persistence (continuation of index treatment with gap ≤60 days) at 12 months and time to discontinuation were reported. Multivariate logistic and Cox regressions were used to compare 12-month persistence and overall discontinuation rate between abatacept and TNFi, controlling for demographic and clinical characteristics (age, sex, Charlson comorbidity index, RA duration), baseline utilization, and clinic.

Results: Data on 209 patients (88 abatacept, 121 TNFi) were collected. Abatacept patients were older than TNFi patients (64.36 vs. 57.23 years, p = 0.001). There were no significant differences in either gender (79.55% vs. 72.73% female, p = 0.257) or duration of treatment at the clinic (5.79 vs. 5.10 years, p = 0.226) in the abatacept and TNFi cohorts. Median time to discontinuation was 1,672 days for abatacept vs. 612 days for TNFi (p = 0.002). At 12 months, 86.36% of abatacept patients were persistent
vs. 65.29% of TNFi patients (p<0.001). In the Cox model, rate of discontinuation was 77% higher in TNFi patients (Hazard Ratio 1.767, 95% Confidence Interval (CI) 1.133-2.806, p=0.0158). In the logistic regression, the odds of TNFi patients being persistent at 12 months was 52% lower than abatacept patients, although this statistic was not statistically significant (Odds Ratio 0.485, 95% CI 0.208-1.33, p=0.0947). Reasons for discontinuation of index treatment differed between cohorts, including discontinuation due to disease progression (27.76% vs. 53.85%), insurance coverage (15.44% vs. 12.82%), and adverse events of medication (27.8% vs. 11.54%) in abatacept and TNFi patients, respectively (p<0.001).

Conclusion: In a real-world setting, RA patients with poor prognostic factors are significantly less likely to discontinue abatacept compared with TNFi patients. This difference may be explained by the lower proportion of patients discontinuing abatacept due to disease progression or adverse events related to medication.

Gómez-Reino: None declared, Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain; Spanish Society of Rheumatology (SER), Madrid, Spain; Rheumatology (SER), Madrid, Spain; Hospital Principe de Asturias, Madrid, Spain; Hospital Clínico Universitario de Salamanca, Salamanca, Spain; Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas, Spain; Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain; Merck Sharp and Dohme, Madrid, Spain.

Background: Survival, or persistence in treatment with a biological drug can be considered an indirect measure of efficacy, safety and tolerability.

Objectives: We assessed the probability of persistence (survival) of treatment with golimumab in patients with rheumatic diseases and the factors associated to persistence with up to 6 years of follow-up.

Methods: BIOBADASER is the Spanish registry of biological drugs of the Spanish Society of Rheumatology and the Spanish Medicines Agency. A data-base analysis was done in December 2018 on all the patients aged 18 years or more who had initiated golimumab for one of the approved indications (rheumatoid arthritis [RA], axial spondyloarthritis [SpA] or psoriatic arthritis [PsA]). The probability of persistence was calculated with a Kaplan-Meier test. Factors related to persistence were analyzed with a Cox-regression model.

Results: 581 patients were included (165 [29.4%] RA, 249 [42.9%] axial SpA and 167 [28.7%] PsA), mean age 51 [12] years, 53% women. Median duration of disease at the onset of golimumab was 8.0 (3.0-14.7) years. Golimumab was prescribed as first biological drug in 37.9% of the patients, as second in 32.1% and as third or further in 30.0%. Concomitant medications at golimumab initiation included steroids (28.2%), methotrexate (MTX) (35.5%), sulphasalazine (7.2%) and leflunomide (13.9%). The probability of persistence of treatment with golimumab since treatment initiation included steroids (28.2%), MTX (35.5%), sulphasalazine (7.2%) and leflunomide (13.9%).

The probability of persistence of treatment with golimumab since treatment initiation was 74.3% at year 1 (95% CI 70.3 – 77.8), 63.5% at year 2 (59.0 – 67.8), 60.5% at year 3 (55.9 – 65.8), 54.5% (49.1 – 59.7) at year 4 and 5, and 52.1% (44.9 – 57.7) at year 6. Persistence was higher when golimumab was used as first biological agent (p-log rank <0.001) and for the treatment of axial SpA or PsA compared to RA (p-log rank <0.001). As first biological drug the probability of persistence was 82.8% (year 1) and 66.5% at year 4. At year 5, survival rates (all lines of therapy) were 59.7, 63.4% and 37.3% for axial SpA, PsA and RA respectively. Cox-regression analysis (table) showed that the probability of persistence in treatment with golimumab therapy was higher in first vs second or third biological line patients (Hazard Ratio [HR] for discontinuation: 1.78 for second and 2.41 for third or further line versus first line), in SpA and PsA patients (HR discontinuation of RA patients: 1.94 versus PsA), and lower in women (HR: 1.62), in those needing steroids (HR: 1.47) or DMARDs different to MTX (HR: 2.17). Patients treated with MTX had higher but non-significant persistence rate (HR discontinuation 0.79, table).

Conclusion: The probability of persistence (survival) on therapy with golimumab was high up to 6 years of follow-up and was higher in patients treated with golimumab vs PsA and SpA, and lower in those needing steroids, DMARDs different to MTX and in women.

Table. Cox-regression analysis. HR for discontinuation of golimumab
PREFERENCES OF EUROPEAN RHEUMATOLOGISTS ON THE DISCONTINUATION OF BIOLOGICAL DISEASE- MODIFYING ANTIRHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Lukas Schlager, Michaela Loiskandl, Daniel Aletaha, Helga Radner. Medical University of Vienna, Department of Rheumatology, Vienna, Austria

Background: The introduction of biologic disease-modifying antirheumatic drugs (bDMARDs) revolutionized the treatment of rheumatoid arthritis (RA) and made remission (REM) or low disease activity (LDA) a realistic goal for most patients. It was shown that the discontinuation of bDMARDs in patients in REM or LDA is feasible (1,2) and that the physician’s opinion plays an important part in the decision to discontinue (3). However, there is no reliable way of identifying patients who would benefit from bDMARD discontinuation after reaching REM or LDA.

Methods: A systematic literature review was conducted with the aim of identifying predictors of successful bDMARD discontinuation in RA patients. Rheumatologists were asked to state whether they find the presented parameter important to support their decision to discontinue bDMARD therapy or not. They also had the opportunity to state parameters they consider important.

Results: 313 rheumatologists from 29 different European countries responded. Most of the participants have been practicing for 10 to 20 years and see 10 to 25 RA patients per week. The majority of the parameters were considered important by the participants, with 19 out of the 34 presented parameters being considered important by $\geq 70\%$. The most commonly considered parameters were (percentage of participants who considered the parameter important): Time in REM or LDA (99%), disease activity score – 28 joints (90%), smoking status (35%), gender (13%), interleukin-6 (9%), rheumatoid factor (41%), and shared epitope (8%). An overview of responses is given in figure 1 and figure 2. The most frequently mentioned parameter in the comments was the patient’s opinion on discontinuation (n=28).

SUSTAINED MODERATE DISEASE ACTIVITY (SMDA) IN RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGIC THERAPIES IS ASSOCIATED WITH 5 YEARS FUNCTIONAL LIMITATION AND SERIOUS ADVERSE EVENT DEVELOPMENT: EVIDENCE TO SUPPORT TREAT-TO-TARGET APPROACH FOR PATIENTS IN SMDA AND ESPECIALLY THOSE IN HIGH SMDA

Irini Genisbarid1,2, Irini Flour2, Kostantinos Marias3,4, Dimitris Ptokeoussakis2,5, Alexandros Drosos2, Dimitrios Bourmpas1, George Bertis1,2,3, Prodromos Sidripou2,3,4,5, (1)University of Crete, Medicine, Heraklion, Greece; 2Foundation for Research and Technology – Hellas, ICS, Heraklion, Greece; 3University of Crete, Medicine, Heraklion, Greece; 4University of Crete, Computer Science, Heraklion, Greece; 5University Hospital of Ioannina, Rheumatology, Ioannina, Greece; 6University Hospital Aftelon Rheumatology Clinic and BRFAA, Heraklion, Greece; 7Foundation for Research and Technology – Hellas, IMBB, Heraklion, Greece

Background: Registry data have shown that treatment with biologic disease modifying antirheumatic drugs (bDMARDs) induces remission or low disease activity in up to 50% of Rheumatoid Arthritis (RA) patients, yet 30-50% of patients remain in moderate disease activity (MDA) with limited data on their long-term prognosis 1.

Objectives: To assess the long-term outcome of RA patients with sustained MDA on bDMARDs, in clinical practice.

Methods: We analyzed data from the Hellenic Registry of Biologic Therapies. Disease activity, function, treatments of patients starting a bDMARD are recorded prospectively every 3-6 months. Herein, we included patients with at least 5 years of follow-up, irrespective of treatment switches. If DAS28-ESR was at the same disease activity range for at least 50% of the follow-up time, patients were assigned to one of 3 main groups: sustained remission or low disease activity (sRLDA) with DAS≤3.2, sustained moderate disease activity (sMDA) with 3.2<DAS≤5.1 and sustained high disease activity (sHDA) with DAS>5.1. Patients in sMDA were further divided into subgroups low and high sMDA (50% of follow-up has DAS lower or greater than 4.2 respectively). Function at 5 years based on Health Assessment Questionnaire (HAQ) was the primary outcome, while cumulative serious adverse events (SAEs) and bDMARDs switches were also analyzed.

Results: Out of 527 patients with available data, 90 (17%), 295 (56%) and 142 (27%) were assigned to sRLDA, sMDA and sHDA groups respectively. At baseline, sMDA patients were older, more often women, had received more csDMARDs and had higher DAS, HAQ and EuroQol status compared to sRLDA group. During follow-up, sMDA patients had more bDMARDs switches as compared to sRLDA (mean t sd: 1.82 ±1.03 vs 1.26 ±0.53, p<0.0001). Notably, patients in sMDA had significant improvement in HAQ at 5 years compared to baseline (p<0.0001), yet they presented significantly higher HAQ compared to sRLDA group (mean t sd: 0.55 ±0.47 vs 0.30 ±0.31, p<0.0001). Trajectories of longitudinal HAQ for groups sRLDA, sMDA and sHDA, were clearly differentiated during treatment course (Figure 1). Clusters sRLDA, sMDA and sHDA also displayed differential 5 years outcomes (p<0.0001) regarding SAEs (Figure 1). Interestingly, within sMDA patients, the low sMDA patient subgroup had better long-term outcome (p<0.05) concerning both HAQ at 5 years and cumulative SAEs as compared to patients in high sMDA subgroup.

Conclusion: In clinical practice 56% of RA patients on bDMARDs have sustained MDA in spite of bDMARDs switches, presenting 5 years worse functional status and more SAEs compared to patients in sRLDA. These data support the treat-to-target approach for patients in sMDA and especially those with high sMDA.

SAT0162

A POOLED ANALYSIS OF 1-YEAR CLINICAL OUTCOMES AMONG 6-MONTH RESPONDERS AND NON-RESPONDERS FROM THREE RANDOMISED CONTROLLED STUDIES OF TNF INHIBITOR BIOSIMILARS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Josel S. Smolen1, Michael E. Weinblatt2, Paul Emery1, Jung-Yoon Cho1, Jonathan Kay3, Jeun Lee5, Gihyun Myung5, Hyoyeon Seo5, Jeehoon Ghil6, Jonathan Cay3

1Medical University of Vienna, Vienna, Austria; 2Brigham and Women’s Hospital, Boston, United States of America; 3Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 4Catholic University of Daegu School of Medicine, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea); 5University of Massachusetts Medical School, Worcester, United States of America; 6Samsung Bioepis Co., Ltd., Incheon, Korea, Rep. of (South Korea)

Background: SB4, SB2, and SB5 are biosimilars of etanercept, infliximab, and adalimumab. Phase III randomised, double-blind studies were conducted to compare efficacy and safety between biosimilars and reference products.

Objectives: Assess and compare 1-year outcomes among 6-month responders and non-responders.

Methods: Patients who had 6-month data from each phase III study were pooled and categorised, based on their disease status at 6 months (week 24 for etanercept and adalimumab and week 30 for infliximab) and 1 year (week 52 for etanercept and adalimumab and week 54 for infliximab).

Responders included patients who achieved an ACR20 response or low disease activity (including remission) by DAS28, SDAI, and CDAI at 6 months. Those who did not or dropped out were considered non-responders.

Primary outcome was the proportion of responders who maintained responses from 6 months to 1 year or non-responders at 6 months who achieved responses at 1 year.

Results: Data from 1461 patients were included in the analysis. For all treatments combined, 81.1% of ACR20 responders, 69.6%, 77.8%, and 77.0% of responders with DAS28, SDAI, and CDAI low disease activity (LDA) at 6 months maintained their responses at 1 year, and 33.9%, 18.8%, 26.7%, and 24.9% of 6-month non-responders achieved responses at 1 year, respectively. The proportions of patients maintaining or achieving an ACR20 response or DAS28, SDAI, and CDAI LDA at 1 year were similar across different treatment groups (Table 1).
Conclusion: A pooled analysis of TNF inhibitor biosimilars and reference products showed that about 20-30% of responders lost their response, while about 20-30% gained it. Thus, the overall stability of disease fluctuation in our 1-year phase III studies is a consequence of a similar success and failure rate. The validity of the data can be seen by the similarities in these outcomes between different types of TNF-inhibitors and similarity between biosimilars and respective reference products.

Background: Rheumatoid arthritis (RA) patients (pts) have a 1.5 to 2-fold increased risk for cardiovascular (CV) events and CV mortality [1]. Traditional risk factors as well as underlying disease, including therapy with glucocorticoids (GC) contribute to the increased CV risk. Typical risk factors include age, male sex, hypertension, adiposity, and diabetes mellitus [2].

Objectives: The exploratory post-hoc analysis of the non-interventional study (NIS) ICHIBAN (NCT 01194401, final dataset) investigated the CV risk of RA pts during intravenous tocilizumab (TCZ) treatment over 2 years. Materials: Data of 3164 pts (total) who received at least one dose of TCZ were available. Analysis focuses on the CV events myocardial infarction (MI), coronary heart disease (CHD), and stroke. The incidence of respectively treatment-emergent adverse events (TEAEs) (according to MedDRA preferred term) and/or AESs of special interest (AESIs, recorded by the investigator) was evaluated. The following risk factors (at baseline (BL)) were analysed: sex, age, smoking status, RA duration, DAS28, CDAI, seropositivity, CRP, comorbidities, previous therapies, concomitant therapies, and combinations thereof.

Results: At BL, pts were more frequently female (74.8%), on average 55.5 years old, had a mean BMI of 26.9 kg/m2, and mean RA duration of 9.7 years. 72% of pts suffered from comorbidities (37% hypertension, 17% osteoporosis, 10% diabetes mellitus). The majority (66.4%) was pre-treated with TNF inhibitors, while 30.0% received csDMARDs only. Co-medication was csDMARDs in 50.7% of pts and GC in 60.6%. Overall, 46.6% of pts experienced at least 1 TEAE. The rate of pts who experienced a CV event was 0.8% for MI, 0.4% for CHD, and 0.6% for stroke (Table 1).

Table 1 Treatment-emergent adverse events (TEAEs) during TCZ treatment

<table>
<thead>
<tr>
<th>Event</th>
<th>Rate of pts (%)</th>
<th>Rate of AEs per 100 patient years</th>
</tr>
</thead>
<tbody>
<tr>
<td>MI</td>
<td>0.4</td>
<td>4.6 (1474)</td>
</tr>
<tr>
<td>CHD</td>
<td>0.6</td>
<td>14.9 (472)</td>
</tr>
<tr>
<td>Stroke</td>
<td>0.5</td>
<td>6.9</td>
</tr>
</tbody>
</table>

For patients with typical risk factors a higher rate of CV events was observed: male pts, pts of higher age, pts who were anti-CCP negative, and pts who suffered from diabetes mellitus, coronary heart disease (only for CHD), asthma, and renal insufficiency (see Table 2 for details; exploratory p-values are given).

Interestingly, no differences were observed between subgroups of smoking status, RA duration, DAS28, CDAI, CRP, previous therapies, concomitant therapies, and combinations thereof (data not shown).

Conclusion: In the NIS ICHIBAN, with its long-lasting patient population, the rate of CV events during TCZ treatment was comparable to former
investigations [1, 3, 4]. In pts with the typical risk characteristics at BL, i. e. male sex, higher age, diabetes mellitus, and CHD, higher rates of CV events were observed. In addition, increased rates were also found in anti-CCP negative pts and in pts with asthma or renal insufficiency

SAT0164

COMPARISON OF THE RETENTION RATE OF EACH BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUG GROUP ACCORDING TO THE STATUS AND CONCENTRATION OF ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODY AND RHEUMATOID FACTOR: DOUBLE CENTER CLINICAL STUDY

Akitake Suzuki1, Kenta Sato2, Masanobu Yoshida1, Takahiro Oka1, 1Mitsui Memorial Hospital, Department of Rheumatology, Tokyo, Japan; 2Mitsui Memorial Hospital, Department of Medical Information, Tokyo, Japan; 3Kawakita General Hospital, Department of Rheumatology, Tokyo, Japan

Background: Although biological disease-modifying antirheumatic drugs (bDMARDs) have markedly improved the clinical course for patients with rheumatoid arthritis (RA), there are no reliable predictors of treatment response in individual patients. The drug retention rate in observational studies can be considered as a composite measure and index of drug effectiveness1).

Objectives: The aim of this study was to investigate potential predictors for bDMARDs by clarifying and comparing the retention ratio of bDMARDs according to the status and concentration of anti-cyclic citrullinated peptide antibody (anti-CCP), rheumatoid factor (RF), and anti-nuclear antibody (ANA).

Methods: We included consecutive RA patients from Mitsui Memorial Hospital and Kawakita General Hospital (both in Tokyo) who received bDMARD treatment between April 2018 and August 2018. We obtained data on the administered bDMARDs and the reason for discontinuation for each patient, and collected patient information, including the status of RF and ANA, at the initiation of each bDMARD, as well as the baseline status and concentration of anti-CCP. We categorized infliximab, etanercept, adalimumab, golimumab, and certolizumab pegol as TNF inhibitors (TNFi), and compared the TNFi group with the tocilizumab (TCZ) group and abatacept (ABT) group in terms of patient characteristics and retention rate. Statistical analysis of the group comparison was performed using one way ANOVA and Kruskal-Wallis tests, and categorical data were assessed by Fisher’s exact test. The retention ratio was compared using the Kaplan-Meier generalized Wilcoxon test.

Results: This study included 214 patients (male 34, female 180, mean age 66.8) and 305 bDMARD cases were analyzed. The TNFi group included 160 cases, and the TCZ group and ABT group comprised 66 and 79 cases, respectively. Overall, the ABT group had the highest retention rate compared with the TNFi and TCZ groups, and the persistency rate of the ABT group at 60 months was 66.1%. Reasons for discontinuation of bDMARDs were insufficient efficacy (63.0%) and adverse events (29.4%). There was no significant difference regarding to the retention rate between anti-CCP negative and positive patients or between RF-negative and positive patients in each bDMARD group. After stratifying all patients according to anti-CCP status and concentration, among the three bDMARD groups, the ABT group (n=70) had the highest retention rate (p<0.05) in the anti-CCP-positive category, whereas the TCZ group (n=12) had the highest retention rate (p=0.27) in the anti-CCP-negative category. The persistency rates of the ABT group in the ≥ 100 U/ml category at 60 months was 73.4%. Moreover, the ABT group (n=59) had the highest retention rate (p<0.05) in the RF-positive category, whereas the TCZ group (n=20) had the highest retention rate in the RF-negative category (p=0.15). The persistency rate of the ABT group in the RF-positive category at 60 months was 68.3%. There were no significant differences in the retention rate among the three bDMARD groups in the ANA-negative or positive categories.

Conclusion: The status and concentration of anti-CCP, and the status of RF were found to be useful predictors for bDMARD efficacy in patients with RA.

PERSPECTIVES OF WOMEN WITH CHRONIC RHEUMATIC DISEASES ON THEIR JOURNEY TO MOTHERHOOD: COMPARISON OF SURVEYS FROM ASIA-PACIFIC AND EUROPE

Yoshiya Tanaka1, Claire Barrett2,3, Yuji Hirano4,5, Kei Ikeda6, Kathy Paizis7,7, Azusa Samejima8,9, Yu-Jin Su,10 Canee Saadoun11, Picrolla C. Wong12.

1University of Occupational and Environmental Health, Kitakyushu, Japan; 2Redcliffe Hospital, Redcliffe, Australia; 3University of Queensland, St Lucia, Australia; 4Tohohashi Municipal Hospital, Toyohashi, Japan; 5Chiba University Hospital, Chiba, Japan; 6Austen Health and Mercy, Hedelberg, Australia; 7Western Health, St Albans, Australia; 8University of Toyama, Toyama, Japan; 9Kochanghang Chang Gung Memorial Hospital, Kschung, Taiwan, Republic of China; 10UCB Pharma, HK, Hong Kong (SAR); 11The Chinese University of Hong Kong, HK, Hong Kong (SAR)

Background: The onset and diagnosis of chronic rheumatic disease (CRD) in women often overlap with their peak reproductive years. A previous survey1 reported fears and misconceptions amongst women with CRD in Germany, France, UK, Italy and Spain (EUS) on their journey to motherhood.

Objectives: To explore the perspectives of women with CRD in Asia-Pacific (APAC) regarding disease management and pregnancy, and the support they receive compared with patients in Europe.

Methods: Women of childbearing age (18-45 years) with self-reported moderate to severe CRD (rheumatoid arthritis [RA], psoriatic arthritis [PsA], axial spondyloarthritis [axSpA]) from Australia (AUS), Japan (JPN) and Hong Kong (HKG) completed a 20-min online survey (Sep–Nov 2018), similar to the previous EUS survey. Participants had been pregnant in the past 2–5 years.

Results: 210 APAC participants had CRD (RA: n=122, PsA: n=48, axSpA/AS: n=40); 306 EUS participants had CRD. Most APAC participants had moderate CRD (77%; severe: 23%). In their most recent pregnancy, 40% of the women were actively trying to get pregnant, 40% were neutral and 20% were either not thinking about a pregnancy or were actively trying to avoid it. Prior to pregnancy, women consulted rheumatologists (62%) or primary care physicians (26%) or OB/ONs (20%; multiple responses were possible). Pregnancy planning was first discussed with a healthcare professional (HCP) at diagnosis (33%), at treatment initiation.
Golimumab as First, Second or at Least Third Biologic Agent in Patients with Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Ankylosing Spondylitis (AS): Post Hoc Analysis of a Non-interventional Study in Germany

Klaus Krueger1, Gerd Rüddiger Burmester2, Siegfried Wasserberg3, Astrid Theile4, Mathias Thomas5,1,2, Rheumatologisches Praxiszentrum, München, Germany; Charity-Universitätsmedizin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; Rheumazentrum Ratingen, Ratingen, Germany; St. Josef Krankenhaus, Wuppertal, Germany; MSD Sharp and Dohme GmbH, Medical Affairs, Haar, Germany

Background: Golimumab (GLM) has demonstrated efficacy in RA, PsA, and AS in several randomized clinical trials with biologic-naïve patients. Data from real world practice comparing biologic naïve and experienced patients are lacking.

Objectives: The aim of this post hoc analysis is to assess effectiveness of GLM used as first, second, or at least third biologic agent in RA, PsA and AS in a real-life setting.

Methods: Post hoc analysis of the non-interventional, prospective, 24-month GO-NICE study with RA, PsA and AS patients (pts.) starting GLM 50mg SC once monthly in a real practice setting in Germany, details were shown earlier (1,2). Endpoint measures DAS28-ESR, PsARC, and BASDAI are shown as observed.

Results: In 1458 pts. with RA, PsA or AS GLM was administered as first (n=305, 286, 292, resp.), second (n=104, 136, 130, resp.), or at least third biologic agent (n=64, 79, 58, resp.). Biologic agents in previous treatments included Adalimumab (348), Etanercept (287), Infliximab (139), Tocilizumab (27), Rituximab (15), Certolizumab (14), or Abatacept (n=12, 43.0, 30.8, 34.2, 34.2% with PsA, and 53.8, 49.2, 41.4% with AS completed the study until month 24. RA pts: (n=473) RF was positive in 78.9%, 70.2%, and 59.4%, AC/P + in 76.2%, 78.4%, 59.0%, and disease duration was 9.7, 10.1, 14.3 years, in pts. with GLM use as 1st, 2nd, at least 3rd line respectively. DAS28 score at BL was 5.0, 4.9, 5.1 in first, second, and at least third line use of GLM, respectively and dropped significantly in all groups (table). After 3 months of treatment 27.5%, 19.5%, 14.5% of pts. were in remission (<2.6), after 24 months 45.3%, 50.0% or 33.3%, respectively. PsA pts: (n=501) Disease duration was 12.4, 13.7, 13.8 yrs in pts. with GLM use as 1st, 2nd, at least 3rd line respectively. PsARC response was achieved in 74.9%, 51.0% and 50.0% in first, second, and at least third line use of GLM, respectively. AS pts: (n=483) HLAB27-positive in 81.2%, 80.8%, and 74.1%, in pts. with GLM use as 1st, 2nd, at least 3rd line respectively. At BL 162 pts. had extra-articular manifestations, most commonly iritis, enthesitis, IBD, and dactylitis (in 31.2%, 35.9%, and 43%, pts. respectively. Pts. with at least 2 previous bDMARDs had higher BASDAI at BL than pts. with GLM use in 1st or 2nd line: 5.7 vs. 5.0, and 4.9. After 24 months of treatment the mean BASDAI scores decreased significantly (>0.001 vs. BL) to 2.1, 2.9, 2.9 in 1st, 2nd, and at least 3rd line use of GLM, respectively. Overall safety findings were comparable to those reported in controlled trials and no new safety signals were detected.

Conclusion: In this non-interventional study of pts. with RA, PsA and AS, golimumab therapy was effective, with better outcomes achieved in biologic-naïve pts. Significant improvement of DAS and BASDAI was also achieved with GLM use in second line. Third line use of GLM results in less benefit.

INCREASED HIGH MOLECULAR WEIGHT ADIPONECTIN AND LEAN MASS DURING TOCILIZUMAB TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS. A 12 MONTH MULTICENTER STUDY

TOUSSIROT ERIQ1, Hubert Marote2, Denis Mulleman3, Gregoire Cornier4, Fabienne Courty-Lucas5, Philippe Gaudin5, Emmanuelle Deris5, Christophe Bernard6, Richard Damade7, Luc Girhan18, Tassadit Ait-Abdesseml11, Caroline Guillibert Karras12, Frederic Liolé13, Pascal Hilliquin14, Antoinette Sacchi15, Marie Jean Bertheilot16, Marc Puyraveau5, Gilles Mullem16, 1University Hospital, Rheumatology, BESANCON, France; 2University Hospital, Rheumatology, St Etienne, France; 3University Hospital Hospital, Rheumatology, Tours, France; 4CH, Rheumatology, Roche sur Yon, France; 5University Hospital, Rheumatology, Lyon, France; 6University Hospital, Rheumatology, Grenoble, France; 7CH, Rheumatology, Le Mans, France; 8University Hospital, Rheumatology, Limoges, France; 9CH, Rheumatology, Chartres, France; 10CH, Rheumatology, Montelmar, France; 11CH, Rheumatology, Meaux, France; 12CH St Joseph, Rheumatology, Marseille, France; 13University Hospital Laboisiere, Rheumatology, Paris, France; 14CH Sud Francillon, Rheumatology, Corbeil, France; 15CH, Rheumatology, Mantes le Jolie, France; 16University Hospital, Rheumatology, Nantes, France; 17University Hospital, biostatistics, BESANCON, France; 18University Hospital, Endocrine and metabolic chemistry, BESANCON, France

Background: Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular (CV) diseases. TNFa blockade in RA patients has been associated with weight gain, increase in fat mass and variations in serum adipokines. Adiponectin (Adp), a protein produced by adipocytes, plays a beneficial role in insulin sensitivity and CV disease prevention, especially its high molecular weight (HMW) isoform.

Objectives: To analyse the changes in serum adipokines and especially Adp (total and HMW) and body composition during TCZ therapy in RA patients.

Methods: Multicenter open-label study. All patients enrolled had active RA (2010 ACR/EULAR criteria and DAS28 <3.2) with previous inadequate response to a csDMARDs and/or bDMARDs. They all were TCZ naïve (2010 ACR/EULAR criteria and DAS28 <3.2) with previous inadequate response to a csDMARDs and/or bDMARDs. They all were TCZ naïve

Results: A total of 2531 patients were included: 1154 RA (45.59%), 680 PsA (26.87%), and 697 AS (27.54%). Age groups: there were 64 young patients (25.52%), 2166 adults (85.57%), 243 elderly adults (9.6%), and 58 very elderly adults (2.29%). Comorbidities increased with age, while smoking rates decreased. Methylxate use was similar in all age groups (33.99% in the total sample), but corticosteroid treatment increased with age (young 27.7%, adults 47%, elderly adults 64.36% and the very elderly 70.21%). 77.87% received anti-TNF treatment, and 22.13% other biological treatment. Methotrexate use was similar in all age groups.

Conclusion: These variations in Adp during TCZ treatment may have a positive impact on the CV risk of RA patients and may contribute to the protective role of TCZ against the CV burden in RA.

IMPACT OF AGE ON THE APPEARANCE OF ADVERSE EVENTSAT THE BEGINNING OF BIOLOGICAL TREATMENT: DATA FROM THE BIOBADASER 3.0 REGISTRY

Paloma Vela-Casasempere1, 2, 3, 4, Carlos Sánchez-Piedra2, Carolina Perez-García2, Sara Manrique Arija2, María del Carmen Castro Villegas2, Blanca Garcia-Magallon2, Javier Manero2, Silvia Gomez-Sabater3, Rocío Caño-Amameda2, Fernando Sánchez-Nonso2, Le Federico Diaz-Gonzalez4, Jesus Gomez-Juan2, Reir05, 1ALICANTE UNIVERSITY GENERAL HOSPITAL, RHEUMATOLOGY, Alicante, Spain; 2IBALIC, ALICANTE UNIVERSITY, RHEUMATOLOGY, Alicante, Spain; 3IBALIC, ALICANTE UNIVERSITY, RHEUMATOLOGY, Alicante, Spain; 4Miguel Hernández University, CLINICAL MEDICINE, San Juan, Spain; 5SPANISH RHEUMATOLOGY SOCIETY, RESEARCH UNIT, MADRID, Spain; 6HOSPITAL DEL MAR, RHEUMATOLOGY, BARCELONA, Spain; 7HOSPITAL CARLOS HAYA, RHEUMATOLOGY, MALAGA, Spain; 8HOSPITAL REINA SOFIA, RHEUMATOLOGY, CORDOBA, Spain; 9HOSPITAL SAN JORGE, RHEUMATOLOGY, HUESCA, Spain; 10HOSPITAL MIGUEL SERVET, RHEUMATOLOGY, Zaragoza, Spain; 11HOSPITAL DE SANTIAGO, RHEUMATOLOGY, SANTIAGO DE COMPOSTELA, Spain

Background: Current medical advances are allowing patients with chronic arthritis to live to advanced ages. Although the risks of biological therapies in elderly patients have been previously evaluated, data are scarce since they are mainly derived from clinical trials, in which elderly populations are often underrepresented or event excluded (patients up to 75 years old). In addition, comparisons between such studies are difficult due to the absence of a consensus in defining the groups’ age.

Objectives: To evaluate the impact of age on the appearance of adverse events (AE) in patients with rheumatic diseases (rheumatoid arthritis -RA-, ankylosing spondylitis -AS- and psoriatic arthritis -PsA) at the start of biologic treatment.

Methods: Multicenter prospective study in a real-world setting. Information was obtained from BIOBADASER, a national safety registry of patients with rheumatic diseases treated with biologics or targeted synthetic disease modifying anti-rheumatic drugs. For this analysis, all patients included in this registry since 2000 and diagnosed with RA, AS or PsA were included, and classified into four categories according to age at initiation of biologic treatment: young (< 25 years-old), adults (25-64 years-old), elderly (65-75 years-old) and very elderly (> 75 years-old). Data collected included: 1) patient’s data 2) data on treatment and 3) data on AE. Proportions, means and standard deviations were used to describe the population. Poisson regression model was carried out to explore factors associated with the appearance of AEs. Crude and adjusted incidence rate ratios (IRR) were calculated.

Results: A total of 2531 patients were included: 1154 RA (45.59%), 680 PsA (26.87%), and 697 AS (27.54%). Age groups: there were 64 young patients (25.52%), 2166 adults (85.57%), 243 elderly adults (9.6%), and 58 very elderly adults (2.29%). Comorbidities increased with age, while smoking rates decreased. Methylxate use was similar in all age groups (33.99% in the total sample), but corticosteroid treatment increased with age (young 27.7%, adults 47%, elderly adults 64.36% and the very elderly 70.21%). 77.87% received anti-TNF treatment, and 22.13% other biological drugs. Poisson regression model showed an increased probability of suffering a first adverse event with increasing age regardless of the...
A NOVEL FORMULATION OF CT-P13 FOR SUBCUTANEOUS ADMINISTRATION: WEEK RESULTS FROM A PART 2 OF PHASE III RANDOMIZED CONTROLLED TRIAL IN PATIENTS WITH RHEUMATOID ARTHRITIS

Rene Westhooven1, Pieter Wiltard2, Marek Zawadzki2, Delina Ivanova3, Alfredo Berrocal4, Elias Chaloub5, Eva Balazs6, Sergi Shevchuk7, Larisa Elerieva8, Mykola Stanislavichuk9, Roman Yatsyshyn10, Sangsoon Lee11, Jeehye Suh11, Seung Lee11, Yunah Kim10, Daehyun Yoo10, KU Leuven, Leuven, Belgium; 2Medical University, Dept of Rheumatology, Wnclaw, Poland; 3Diagnostic-Consultative Center Aleksandrowska ECOOD, Sofia, Bulgaria; 4Bio Cienças Peru S. RL., Lima, Peru; 5Clinica Internacional Sede Lima, Lima, Peru; 6Dr. Bugyi Istitut Hospital, Sztentes, Hungary; 7Clinic of SRIF of Invalid Rehab. ESTC of VNMU n.a. M.I.Pyrohov, Vinnytsia, Ukraine; 8Sberian State Medical University of Roszkow, Tomsk, Russian Federation; 9National Progov Memorial Medical University, Vinnytsia, Ukraine; 10Ivano-Frankivsk National Medical University; 11Sberian State Medical University of Roszkow, Tomsk, Russian Federation; 12Ivano-Frankivsk National Medical University; 13Cheltchin, Inc., Incheon, Korea, Rep. of (South Korea); 14Hanyang University Medical Center, Seoul, Korea, Rep. of (South Korea)

Background: CT-P13 subcutaneous (SC) formulation showed comparable efficacy and safety with CT-P13 intravenous (IV) formulation in rheumatoid arthritis (RA)1 and Crohn’s disease2 preliminary studies (Part 1).

Objectives: The purpose of this study was to demonstrate non-inferiority (NI) of efficacy and compare safety profiles of CT-P13 SC to CT-P13 IV in RA patients over 30 weeks of Part 2.

Methods: In this randomized, controlled, double blinded, phase III study, RA patients received CT-P13 IV 3 mg/kg at Weeks 0 and 2 and were randomized at Week 6 to receive CT-P13 SC 120 mg every 2 weeks or CT-P13 IV 3 mg/kg every 8 weeks. From Week 30, all patients received CT-P13 SC 120 mg every 2 weeks. The primary efficacy endpoint, change of DAS28 (C-reactive protein [CRP]) from baseline to Week 22, would be non-inferior to the IV arm with a margin of 0.22.

Results: 121 RA patients were randomized to receive CT-P13 SC 120 mg (n=61) or CT-P13 IV 3 mg/kg (n=60). Demographics and baseline characteristics were well balanced between the groups. The primary efficacy endpoint was non-inferior (95% CI 0.88, 1.26). No differences were observed in the safety endpoints.

Conclusion: The CT-P13 SC 120 mg formulation was non-inferior to the IV arm in terms of efficacy and had a comparable safety profile.
Conclusion: The study demonstrated NI of efficacy for CT-P13 SC to the CT-P13 IV. Also, CT-P13 SC showed similar efficacy and safety profiles to CT-P13 IV up to Week 30. CT-P13 SC could provide a favorable benefit to patients with an alternative convenient way of administration.

A RETROSPECTIVE ANALYSIS OF LONG TERM SAFETY UP TO FIVE YEARS OF INFILXIMAB BIOSIMILAR CT-P13 IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

Tae-Hwan Kim1, Shin-Seek Lee2, Won Park2, Yeong Wook Song3, Chang-Hee Suh4, SooYoung Kim5, Youngnam Lee3, Daehyun Yoo1, Hanyang University Hospital for Rheumatic Diseases, Rheumatology, Seoul, Korea, Rep. of (South Korea); 1Chonnam National University Medical School and Hospital, Rheumatology, Gwangju, Korea, Rep. of (South Korea); 2Inha University Hospital, Rheumatology, Inchon, Korea, Rep. of (South Korea); 3Seoul National University Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea); 4Ajou University School of Medicine, Rheumatology, Suwon, Korea, Rep. of (South Korea); 5Celltrion Healthcare, Inchon, Korea, Rep. of (South Korea)

Background: Long term safety and efficacy of anti-TNF inhibitors in rheumatic diseases is an important aspect of patient treatment. CT-P13 is the first infliximab biosimilar approved by EMA and FDA and has demonstrated comparable efficacy and safety with reference infliximab in rheumatoid arthritis (RA)1,2 and ankylosing spondylitis (AS)3,4. However, long term data of infliximab biosimilar to date has been limited to two years.5,6

Objectives: To demonstrate drug survival and long term safety and efficacy of CT-P13 up to 5 years in patients with RA or AS, including patients who switched from reference infliximab to CT-P13 (switched patient). Primary endpoints were safety and drug survival up to 5 years analyzed by Kaplan-Meier curve.

Results: We identified 1579 patients (515 RA and 337 AS) who were switched from reference infliximab to CT-P13 (switched patient). We observed no new safety signals. The frequency of serious adverse events (SAEs) was similar between groups and the occurrence of SAEs of respiratory tract infection was 3.90% in patients with RA and 4.15% in patients with AS. The most common reason for discontinuation for both RA and AS was not related to infliximab biosimilar-CT-P13.

Disclosure of Interests: Tae-Hwan Kim1, Shin-Seek Lee2, Won Park2, Yeong Wook Song3, Chang-Hee Suh4, SooYoung Kim5, Youngnam Lee3, Daehyun Yoo1, None declared.

SLE, Sjögren’s and APS – clinical aspects (other than treatment)
Conclusion: Higher renal gallium uptake predicts higher active inflammation in LN. Changes of gallium uptake ratio were correlated with histopathological parameters and daily urine protein. Renal gallium scan appears to be a valuable non-invasive tool in assessing activities of LN.

REFERENCES

Background: In the last few decades many studies have investigated the role of major salivary glands ultrasound (SGUS) in the diagnostic work-up of patients with suspected primary Sjögren’s syndrome (pSS). Recent development of ultra-high-resolution ultrasound systems (UHFUS), with frequencies as high as 70 MHz and capability resolution as fine as 30 μm, has permit new diagnostic applications to a variety of superficial targets including labial salivary glands (LSGs). To date, however, no information are available regarding the use of UHFUS for the study of LSGs in humans.

Objectives: To evaluate the feasibility and the diagnostic accuracy of UHFUS of LSGs in patients with suspected SS and to assess the correlations between LSG histopathology, UHFUS and SGUS.

Methods: Consecutive patients with clinically suspected pSS were included in this study. All patients underwent a complete diagnostic work-up including conventional SGUS and LSG biopsy. The same expert pathologist calculated for all the samples the focus score (FS), number of foci and evaluated the presence of ectopic germinal centers (GCs). UHFUS of LSG was performed by specialized radiologists scanning first the central compartment of the inferior lip, and then both peripheral compartments. The following parameters were evaluated: distribution of the glands, parenchymal inhomogeneity (score 0-3, from normal to evident), fibrosis and eco color-Doppler vascular pattern and grade of vascular intensity.

Results: We included 32 patients with suspected pSS. At the end of the work-up, pSS diagnosis was confirmed in 12/32 (37.5%) cases. No differences between pSS patients and no-SS sicca controls were observed in UHFUS findings related to LSG distribution and eco color-Doppler vascular parameters. By contrast, pSS patients presented statistically significant differences in peripheral UHFUS inhomogeneity (p<0.006), and a higher degree of fibrosis (p<0.01). Considering a score ≥2 in parenchymal inhomogeneity as suggestive for pSS, UHFUS appeared less specific than conventional SGUS (UHFUS Sp=70% vs SGUS Sp=95%) but more sensitive (UHFUS Se=83.3% vs SGUS Se = 58.3%). In addition, when we investigated the relationship between UHFUS, SGUS and LSG histopathology we found that the correlation coefficients between UHFUS inhomogeneity and LSG FS (UHFUS r=0.706** vs SGUS r=0.393*), number of foci (UHFUS r=0.712** vs SGUS r=0.445*), and number of ectopic GCs (UHFUS r=0.525** vs SGUS r=0.141), were significantly higher than those observed with conventional SGUS.

Conclusion: The application of UHFUS to the study of LSG in pSS appeared feasible and sensitive. Because of the anatomical details obtained with this technique and its stronger correlation with LSG histopathology, UHFUS might offer unique advantages over the existing major salivary gland imaging modalities in pSS assessment.

Objectives: This case report is presented to emphasize that the deterio-
ration of certain clinical and laboratory findings of an SLE patient should
alert the physician for development of MAS.

Methods: We reported a monogenic lupus patient with MAS clinic with
acute pancreatitis, who had c1qA gene mutation.

Results: A 9-year-old male was first referred with photosensitivity and
erythematous crusted lesions on his extremities and face while he was 2
years old. ANA was positive (1/1000 dilution) and skin biopsy from
lesions was compatible with subacute lupus. Steroid, methotrexate and
hydroxychloroquine were administrated. Patient’s male identity and atypical
age for lupus was further evaluated with “whole exome sequencing” method.
Complement c1qA gene mutation was detected. Monthly fresh
frozen plasma and IVIG treatments were added, which able to control
the disease to some extent.

He had acute gastroenteritis and fever, leading to activation of skin and
oral mucosa lesions with on bilateral parotitis in his last visit (Figure-A).
His body temperature was 39.9°C. USG confirmed the parotitis. Regard-
ing infectious gastroenteritis, IVIG and plasma with broad-spectrum antibi-
ocitics were administrated. Despite treatment, high fever persisted. He had
hypotension, irritability, and hepatosplenomegaly with abdominal tenderness
on physical examination. Abdomen CT was compatible with acute pan-
creatitis (Figure-B), and he had high amylase and lipase levels. Despite
IV hydration with intense therapy, developing pancytopenia, hypoalbumine-
ria, increase in hepatic enzymes, decrease in fibrinogen and ESR with
erased CRP and ferritin levels were alerts for MAS. Bone marrow aspi-
ration demonstrated hemophagocytosis (Figure-C). Pulse high dose IV
methyl prednisolone treatment was started. Clinical and laboratory find-
ings, particularly ferritin level, improved in the third day of treatment. Ste-
roids were gradually reduced while cyclosporine was added. He is under
remission with low dose steroid, cyclosporine-A and regular plasma infu-
sions per 3 weeks.

Figure A. Bullous and crusted lesions on face and around oral mucosa. B. Shortening of
the pancreas tail in CT. C. Hemophagocytic cells in the bone marrow.

Conclusion: MAS is rarely seen in course of monogenic J-SLE, but may
be serious. It is the first juvenile monogenic lupus case with MAS in the
English literature, to best of our knowledge. It is important to distinguish
this mortality clinical condition from the flare of disease and appropriate
management should be started as soon as possible.

SAT0178
THE EFFICACY AND SAFETY OF ANTI-PNEUMOCOCCAL VACCINATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: SYSTEMATIC REVIEW AND META-ANALYSIS

Mohammad Adawi1, Nicola Luigi Bragazzi2, Dennis Megenagle3, Naim Mahroum4, Giovanni Damiani5, Charlie Bridgewood6, Howard Amital7, Abdullah Watad8, Ilan University, Ramat Gan, Israel, 2University of Genova, Genova, Italy, 3University of Leeds, Leeds, United Kingdom; 4Tel Aviv University, Tel Aviv-Yafo, Israel. 5Ospedale Maggiore, Milano, Italy

Background: Systemic lupus erythematosus (SLE) is a complex, multi-factorial chronic systemic autoimmune disease, characterized by a clinically relapsing and remitting course, affecting women more commonly than men. It has an estimated prevalence of 20 to 150 cases per 100,000 persons. The immune system dysregulation in SLE patients is associated with a higher risk of infections, including pneumococcal pneumonia. Anti-pneumococcal vaccines represent a valuable and effective preventative tool to mitigate and counteract pneumococcal pneumonia. However, the efficacy and safety of anti-pneumococcal immunization in SLE patients is both controversial and not completely agreed upon. Indeed, several epidemiological studies investigating the anti-pneumococcal vaccine safety and efficacy in patients suffering from SLE have reported short-term immunogenicity with elevated anti-pneumococcal antibody titres but inconsistent long-term findings, with some studies finding poor responses, mainly for long-term immune protection.

Objectives: We conducted a systematic review and meta-analysis to better understand the efficacy and safety of pneumococcal vaccination administered to SLE patients.

Methods: A comprehensive literature search in accordance with the ‘Preferred Reporting Items for Systematic Reviews and Meta-Analysis’ (PRISMA) guidelines was performed. We mined also the gray literature and searched also for unpublished studies, presented at congresses either as oral communications or posters. We were able to identify 18 studies. All studies were designed as longitudinal investigations, in particular, of high quality, being randomized, double-blind trials. Four studies had control groups.

Results: Total sample size included 601 participants. Vaccine immunogenicity in terms of subjects with protective antibody titers ranged from 36% to 97.6%. According to our systematic review and meta-analysis, high erythrocyte sedimentation rate (ESR), older age, earlier SLE onset, high disease activity, and immunosuppressive therapy were found to be statistically significant predictors of poor immunogenicity, although belimumab was found to have no significant impact. With regard to safety, no serious adverse events were found, with up to one third of cases reporting mild/low-grade complaints.

Conclusion: Due to the high risk of pneumococcal infection in SLE patients and the safety and, at least partial, effectiveness, according to our systematic review and meta-analysis, in such patients, preventive strategies mainly by immunization, are required in all age groups and, in those needing immunosuppressive therapy, immunization should be given prior the initiation of the treatment.

SAT0179
CHANGE IN IMMUNOLOGICAL PARAMETERS DURING FOLLOW-UP OF PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: DATA FROM THE FRENCH ASSESS COHORT

Paulina Szafors1, Cédric Lukas1, Jacques-Eric Gottenberg2, Xavier Mariette3, Bernard Combe3, Jacques Morel1. 1164 Saturday, 15 June 2019

Background: Primary Sjögren’s Syndrome (pSS) is associated with a biological panel of B cell activity markers such as hypergammaglobulinemia, rheumatoid factor (RF), decreased C3/C4 complement, cryoglobulinemia, and an increase in IgM-microglobulin, used to calculate the biological domain of The EULAR Sjögren’s Syndrome Disease Activity Index (ESS-DAI). In 80% of patients, anti-nuclear autoantibodies, especially anti-Ro/SSA and anti-La/SSB, are also observed. The change in these biological tests during follow-up of pSS patients has been poorly investigated.

Objectives: The objectives of our study were to assess the change in immunological parameters during the follow-up of pSS and to analyse the association with the clinical evolution.

Methods: We analysed data from the French prospective multicenter ASSESS cohort, including 395 patients with pSS. Clinical and biological data were collected at the baseline, then annually. Patients were included if at least two biological assessments and concomitant CineESSDAI activity scores were available, based on standardized clinical evaluations of the patients. Anova, Wilcoxon and Chi-square tests were used to analyse the relationship between the clinical evolution and immunological profile.

Results: 362 of 395 patients had required data to allow their inclusion. The mean number of visits was 5.5. In 81.7% of patients, the biological status did not change throughout the 5-year follow-up (Table 1). The clinical evolution was not related to the immunological changes observed between the previous two visits (p>0.30). There was no significant difference between the number of abnormal immunological markers and the CineESSDAI activity score (p=0.437) at the same visit. Disease activity according to the CineESSDAI score remained stable in 257 patients (out of 351 with available data) during follow-up: 175 patients (49.8%) were in remission and 82 (23.3%) had an active disease. The number of abnormal biological markers at baseline was associated with subsequent clinical evolution: detection of ≥5 B cell activity markers at baseline was a bad prognostic marker, (present in 12.4% of patients having persistent disease activity, versus 3.6% among patients with clinical favourable outcome) (p=0.04).

Conclusion: The biological profile of pSS patients is usually stable over time, especially if the initial assessment is negative, but a higher immunological activity profile might be a bad prognostic factor. Changes in biological parameters do not predict the subsequent clinical course. In conclusion, it is not relevant to systematically repeat the complete immunological screening in pSS patients.

SAT0180  EVALUATION OF FRAILTY IN SJÖGREN’S SYNDROME: CREATION OF A FRAILTY INDEX

Raffaella Izzo¹, Marco Canevelli², Serena Colafrancesco¹, Antonina Minniti¹, Angelica Gattamelata¹, Francesca Arzenio¹, Federica Quaranta², Francesca Renidí², Valeria Raparelli², Giuseppe Brundo², Roberta Priori¹, Guido Valesini¹, ¹Pollicino Umberto I, Rheumatology, Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome, Italy, ²Roma, Italy, ³Pollicino Umberto I, Neurology and Psychiatry, Department of Neuroscience, Sapienza University of Rome, Rome, Italy, ⁴Roma, Italy, ⁵Pollicino Umberto I Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy, Roma, Italy

Background: Frailty is a condition characterized by the reduction of the individual’s homeostatic reserves, leading to an increased vulnerability to stressors and an increased risk of unfavourable events. The aging of the population and the consequent need to implement new paradigms of care and assistance, have given this tool a growing interest in many medical disciplines. In rheumatology, however, the interest is still limited. The Frailty Index (FI), developed on an arithmetical model of deficit accumulation, is an accurate tool for assessing frailty, providing an estimate of the biological aging.

Objectives: Creation of a FI to be used in clinical practice in patients with Sjögren’s syndrome (SS) and evaluation of the correlations with patient’s age, duration of illness, activity and disease damage at baseline and in the following 5 years.

Methods: The FI is composed by a checklist of non-predefined variables (deficits) constituted by symptoms, signs, diseases, disabilities, and laboratory findings. The deficits must meet these criteria: age-related; associated with negative outcomes; multidimensional (referring to different domains of the health status); present in at least 1%, but not more than 80% of the sample. To each variable is assigned the value of 0 (no deficit) or 1 (deficit). The FI is the ratio between deficits present by the individual and the total number of deficits considered, thus providing a measure of frailty ranging between 0 (no frailty) and 1 (maximum of frailty). A FI was developed for patients with SS consisting of 43 items (17 comorbidities, 14 signs and symptoms, 5 disabilities and 7 laboratory findings). Statistical analysis was performed with Spearman’s test for correlation assessment, the Mann Whitney test for comparing non-parametric variables and the Pearson test for correlation.

Results: FI was administered to a first small group of 30 female consecutive patients recruited as outpatients at the clinic dedicated to SS. The average age was 57.2 yrs, mean age at diagnosis 52.7 yrs and average disease duration 4.7 yrs. At the time of completing the FI, the average disease activity (ESSDAI) was 3.4, the mean value of the damage (SjDDI) 1.6 and the average score of FI equal to 0.21. A statistically significant correlation between FI and age has been reported (p = 0.017). No significant correlations between frailty and duration, activity and disease damage have been highlighted at the moment.

Conclusion: For the first time a FI was developed for patients with SS consisting of 43 items. The data shows a relationship between age and FI. The correlation is statistically significant, similarly to what is reported in the literature for other conditions. This confirms that FI is indeed an objective marker of aging and even though the sample population is young (average age = 57.2 years), FI maintains its main properties. This tool can be used to assess the health status of patients, making it possible to identify those at greater risk of trajectories or unfavourable outcomes. It is currently being administered the FI to patients with SS whose clinical course will be evaluated in the next 5 years (complications, mortality, hospitalization, institutionalization and disability).

SAT0181 CONTRACEPTIVE COUNSELING AND USE AMONG WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT RISK FOR UNPLANNED PREGNANCY

Francisca Aguilar¹, Rui Costa², Iva Brito³, ¹Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal, ²Centro Hospitalar Universitário São João, Physical and Rehabilitation Medicine, Porto, Portugal, ³Faculdade de Medicina da Universidade do Porto – FMUP, Porto, Portugal

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that primarily affects women of reproductive age. Disease activity and medication use can complicate pregnancies in SLE, due to the disease itself and/or exposure to teratogenic medications. Therefore, these patients should be counseled and are candidates for highly effective contraceptive methods.

Objectives: To examine contraceptive counseling and use among SLE patients attending our Rheumatology Department.

Methods: Cross-sectional study in which women aged 15-50 followed in our Rheumatology Centre with SLE diagnosis completed a researcher-administered survey. Premenopausal women who were sexually active were considered at risk of pregnancy. We compared self-reported rates of contraceptive counseling and use, stratified by treatment with teratogenic medications, and by history of thrombosis or antiphospholipid antibodies (aPL). The statistical analysis was performed using SPSS 23.0, and p<0.05 was taken to indicate statistical significance.

Results: 95 women were interviewed, of these, 60 were considered to be at risk for unplanned pregnancy. Their mean age was 36 years (range 17-48), and median disease duration 9.9 years (range 0.25-37.0). 85% were aware of the complications associated with pregnancy in their medical condition and 73.3% had received contraceptive counseling. Fifty-six patients (93.3%) reported consistent contraceptive use. Younger patients were more likely to have received contraceptive counseling (55.0 [17-46] years versus 42.5 [20-48] years, p=0.021). Counseling was more frequently reported by patients with higher educational level (p=0.026). Those who were counseled were using more effective contraceptives and in logistic regression contraceptive counseling was a predictor of highly effective contraceptive use (OR=13.1, p=0.001).

Women using teratogenic medications or with a history of thrombosis were no more likely to have received contraceptive counseling or to use more effective contraceptive methods. Those with positive aPL were using more effective contraceptives (p=0.024). In our model, having a high school degree and positive lupus anticogulant predicted contraceptive counseling (OR=12.6, p=0.041; OR=3.1, p=0.02, respectively).

Conclusion: This study highlights the importance of contraceptive counseling in SLE patients at risk for unplanned pregnancy. A multidisciplinary team including rheumatologists, gynecologists and family physicians is needed to improve the education and provision of adequate contraceptive counseling to these women.

SAT0182 DYSLIPIDEMIA, HYPERTENSION, LUPUS NEPHRITIS AND HIGHER PREDIOSOMAL USAGE CONTRIBUTES TO EVOLUTION OF CAROTID INTIMA-MEDIA THICKNESS IN MILD SYSTEMIC LUPUS ERYTHEMATOSUS: A 7-YEAR FOLLOW-UP STUDY

Sofia Agerano¹,², Thomas Gustafsson², Tomas Jogestrand², Ingåld Haltström², Johan Frostegård³, ¹Vrije Universiteit Brussel, Brussel, Belgium, ²Karolinska Institute, Stockholm, Sweden

Background: In SLE accelerated progression of carotid plaque and contribution of inflammatory factors for premature vascular changes have been reported. Effect of classical risk factors on progression of carotid intima-
media thickness (cIMT) in patients with SLE in comparison with population controls is not clear.

**Objectives:** To examine in SLE and population controls (1) prevalence of risk factors over time; (2) evolution of cIMT; (3) risk factors promoting cIMT evolution.

**Methods:** The study sample originated from the SLEVIC cohort (SLE vascular impact cohort study) which included consecutive patients with SLE and age and sex matched population controls. Seven years after inclusion all participants were asked to take part in the follow-up investigation. The standardized data collection and carotid ultrasound were performed at two assessments, 7 years apart. Effect of risk factors on cIMT over-time was examined with linear mixed models adjusted for age, sex and traditional CV risk factors.

**Results:** A total of 77 patients with SLE (68% of original cohort), 87% females, at inclusion mean age 47 years, disease duration 11.4 years, SLEDAI 3.0, SLICC/ACR 1.1, and 74 controls (61% of original cohort), 89% females, mean age 51 years, completed 7-years follow-up. At inclusion, patients with SLE were younger and had lower levels of LDL than controls but were more likely to have hypertension and higher levels of triglycerides (TG). Between the assessments both groups were measured with an increase in blood pressure, levels of total cholesterol (TC), LDL, but at follow-up the patients still had lower TC, LDL and HDL levels and higher TG than controls. At both assessments, patients used more frequent antihypertensive and aspirin than controls, p<0.001. The mean cIMT increased statistically significant in patients and controls, average increase during progression of 0.009 mm/year in patients and 0.011 mm/year in controls, p<0.001 for change in both groups, with no inter-group difference, p=0.867 age- and sex-adjusted.

In multivariate analysis, the patients showed a statistically significant association between mean cIMT over-time and higher systolic blood pressure, lower levels of HDL, higher TC/HDL- and LDL/HDL-ratio, higher triglycerides, dyslipidemia and detection with (any) carotid plaque at inclusion. In the control group, lower levels of HDL, history of dyslipidemia and finding with bilateral plaque at inclusion were associated with cIMT over-time. At follow-up, hypertension and blood lipid measures in patients (with exception for TG) and HDL in controls were still significantly associated with cIMT over-time. Of all, the strongest association was shown for HDL in both patients and controls. Effect of other cardiometabolic risk factors at inclusion and cumulative risks were not significantly after adjustment for age and sex.

In the patients, history of nephritis at inclusion and follow-up, and a higher average dose of prednisone used since diagnosis, but not other treatments, were associated with cIMT over-time.

**Conclusion:** We observed similar progression of cIMT over 7 years in patients with long-standing mild well-controlled SLE disease and population controls. Our findings suggest importance of recognition of dyslipidemia and hypertension, and support recommendation to limit use of corticosteroids in patients with SLE as a part of CV risk management. The factors protecting or promoting atherosclerotic progression should be further explored.

**LUPUS NEPHRITIS: A RETROSPECTIVE LONGITUDINAL STUDY LOOKING FOR CHRONIC RENAL DISEASE ASSOCIATED FACTORS, FROM THREE SOUTH-EUROPEAN COHORTS OF PATIENTS IN FOLLOW-UP SINCE 2000**

Irene Altabás González1, Jose M. Pego-Reigosa1, Jose María González2, Francisco Rubriño3, Chiara Stagnaro3, Chiara Tani3, Carlos Rodriguez-Lozano2, Irene Altabás González1, Jose M. Pego-Reigosa1, Jose María González2, Francisco Rubriño3, Chiara Stagnaro3, Chiara Tani3, Carlos Rodriguez-Lozano2, Maria Celia Erausquin2, Juan Carlos Quevedo-Abeledo2, Iñigo Hernández1, Doctor Negrín, Las Palmas de Gran Canaria, Spain; 1Hospital do Meixoeiro, Vigo, Spain; 2Hospital of Nephrology, Istanbul, Turkey

**Background:** Renal involvement in systemic lupus erythematosus (SLE) is the most frequent severe manifestation and carries a bad prognosis.

**Objectives:** To analyze the outcome of lupus nephritis (LN) in terms of chronic kidney disease development (CKD).

**Methods:** Design: multicentre retrospective observational study. Patients: SLE patients (ACR97) with biopsy proven LN attending to three South European Rheumatology departments. Variables: demographics, SLE related variables, including global activity (SLEDAI-2K), renal flares, therapies, ACR response criteria and CKD. Statistical analysis: descriptive bivariate and multivariate analysis exploring factors associated to CKD.

**Results:** Seventy-six patients with biopsy-proven LN were included, 90.7% female; mean age: 33 years; mean disease: duration 14 years; mean follow-up time (since LN diagnosis): 8,5 years. LN class III, IV and V were present in 22%, 75% and 3% of the cases, respectively. At LN diagnosis 68 (89%) patients had a severe renal flare. Forty-one (56.1%) and 49 (64.4%) had HTA and nephrotic syndrome, respectively. The mean 24h proteinuria levels at LN diagnosis was 4.6g. Mean SLEDAI-2K at the time of flare was 20.3, with 69 (65.7%) patients having an extrarenal flare.

The treatments used to induce remission were: glucocorticoids (100%); pulses M-prednisolone in 49 (64%) and oral prednisone (mean starting dose): 43 mg/day (±20.6); intravenous cyclophosphamide in 42 (55%) patients; mycophenolate mofetil (MMF) in 21 (27%) patients; calcineurin inhibitors in 5 (11%) patients; rituximab in 4 (5.2%) patients; and oral cyclophosphamide in 4 (5.2%) patients. Forty-eight (63%) patients were receiving hydroxychloroquine. MMF was the immunosuppressant (IS) more frequently used (52%) as maintenance therapy.

At 3, 6 and 12th months, the mean proteinuria was 2.93/24h, 1.53g/24h, 1.1g/24h, respectively (p<0.001). Fifty-five (77.5%) of patients achieved complete response and 61 (84.7%) presented complete or partial response. Median time to renal remission: 12.5 months (6,17.5). In 32 patients (42%) it was possible to discontinue IS. Sixteen (21.9%) patients developed CKD, 4 (5.3%) needing dialysis and 1 (0.76%) renal transplantation. Serious infection was recorded in 23 (34.8%) patients. Five (6.6%) patients died (2 cardiovascular cause).

In the bivariate study, the following variables were significantly associated with CKD: male sex, hypertension, ACEI drugs, severe infection after LN, temporal dysalisis, non ACR renal response, non use of hydroxychloroquine, time to achieve 10mg/day of prednisone, previous creatinine to LN, maximum creatinine at LN, hyperlipidemia at 3 months of LN, active urinary sediment at 12 months, creatinine at 6 and 12 months, proteinuria at 6 and 12 months.

In the logistic regression model, using genetic algorithms, we found that proteinuria at 6 months was significantly associated with CKD (OR:2.95; 95%CI 1.9:9.29, p= 0.03). Hypertension and male sex were marginally associated (p=0.06, both).

**Conclusion:** A considerable percentage of LN patients developed renal chronic failure (21.9%). A high percentage of ACR response was achieved using medium dose (40mg) of glucocorticoids for induction. A significant reduction of proteinuria was achieved at 3 months, but proteinuria at 6 months was the only factor finally associated with CKD.

**SAT1018 ASSOCIATION OF SERUM AND URINE LEVELS OF TWEAK, MCP-1 AND NGAL WITH DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS**

Safak Mirioglu1, Suanz Çinar2, Halil Yazici3, Ahmet Gök4, Murat Inanc4, Bahar Atilm-Esen1, 1Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey; 2Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey; 3Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 4Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

**Background:** TWEAK, MCP-1 and NGAL, mediators in pathogenesis of systemic lupus erythematosus (SLE), are proinflammatory cytokines/chemokines that are thought as potential biomarkers reflecting disease activity (1).

**Objectives:** In this study, we aimed to investigate the association of serum (s) and urine (u) levels of TWEAK, MCP-1 and NGAL with disease activity in both renal and non-renal SLE.

**Methods:** Thirty active patients with SLE (15 renal and 15 non-renal) were recruited. Thirty-one inactive patients with SLE (16 renal and 15
non-renal), 14 patients with ANCA-associated vasculitis (AAV) all of whom had active renal involvement and 20 healthy volunteers were selected as control groups. Serum and urine levels of TWEAK, MCP-1 and NGAL were tested using ELISA.

**Results:** Sixty-one SLE patients, 51 (83.6%) of whom were female, with a median disease duration of 83 (23.5-135) months and a median age of 35 (27-47.5) were included in the study. Serum and urine levels of TWEAK and NGAL were significantly higher in the active SLE group compared with the inactive SLE (n=31) group (tTWEAK: p=0.005; uTWEAK: p=0.026; sNGAL: p<0.001; uNGAL: p=0.002); whilst no significant differences regarding serum and urine MCP-1 levels were observed (p=0.189 and p=0.106), tTWEAK (p=0.237), sMCP-1 (p=0.141), uMCP-1 (p=0.208), sNGAL (p=0.419) and uNGAL (p=0.443) levels did not differ between patients with active LN and non-renal active SLE; yet levels of sTWEAK were higher in patients with active LN (p=0.006). There were no differences between active LN and renal active AAV. Levels of all biomarkers were correlated with SLEDAI (tTWEAK: p=0.001; uTWEAK: p=0.006; sMCP-1: p=0.049; uMCP-1: p=0.014; sNGAL: p=0.001; uNGAL: p=0.002).

**Conclusion:** sTWEAK, uTWEAK, sNGAL and uNGAL are significant biomarkers showing disease activity in SLE. However, our results implicate that these biomarkers may not be specific for SLE, and can be elevated in patients with active renal involvement of AAV. sTWEAK may be of use for discriminating active nephritis from non-renal active disease in SLE. Further studies are awaited to confirm these results (This study was funded by Istanbul University with the project number TTU-2017-24738 and Turkish Society for Rheumatology).

**THE EFFECTS OF DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS ON COGNITIVE FUNCTION**

Michelle Barracough1, 2, Rebecca Elliott3, 2, Shane McIke4, Ben Parker1, 2, Ian N. Bruce1, 2, 3. 1The University of Manchester, Arthritis Research UK Centre for Epidemiology, Manchester, United Kingdom; 2Manchester University NHS Foundation Trust, NIHR Manchester BRC, Manchester Academic Health Science Centre, Manchester, United Kingdom; 3The University of Manchester, Division of Neuroscience and Experimental Psychology, Manchester, United Kingdom; 4The University of Manchester, FBMH Research and Innovation, Manchester, United Kingdom

**Background:** Cognitive dysfunction (CD) affects up to 90% of systemic lupus erythematosus (SLE) patients and significantly impacts patient quality of life. The cause is multifaceted with many factors common across chronic diseases. It is thus difficult to ascertain the direct impact active disease in SLE has upon immediate cognitive function.

**Objectives:** The aim of this study was to investigate the effects of active disease in SLE on CD. We compared cognitive measures in SLE patients with stable disease activity (SLE-S) to those with active disease (SLE-F).

**Methods:** 34 SLE-S and 24 SLE-F were recruited, all meeting 1997 ACR criteria. Active disease was defined as BILAG A or B with a change in SLE-S and 24 SLE-F were recruited, all meeting 1997 ACR criteria. SLEDAI-2K £ criteria. Active disease was defined as BILAG A or B with a change in

**Results:** There were no differences between the SLE-S and SLE-F groups or between v1 and v2 on demographic and clinical measures except disease activity. The SLE-F group scored higher than the SLE-S group on the MADRS depression scale (p=0.003) but no other significant differences in psychiatric symptoms were observed. There were no significant differences on the CANTAB® for either comparison (table 1). The fMRI showed a SLE-S vs SLE-F difference in n-back related response in the medial prefrontal cortex (p=0.012; figure 1). No v1 vs v2 differences were found, nor for either comparison for the FERT.

**Conclusion:** In a cohort well matched on confounding factors these results suggest that active disease does not impair cognitive function. However, the differences in the medial frontal cluster during the working memory task may indicate the use of compensatory mechanisms to maintain cognitive function as has been found elsewhere. Alternatively, as this is a default mode network region, often implicated in self-reflective processes it may be that CD is more directly associated with differences in mood. As such when treating SLE patients with self-reported CD it is important to consider factors other than disease activity.

SAT0186  Ω MORTALITY IN CHILDREN WITH JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS IN AN ARGENTINE PEDIATRIC CENTRE.

Cristina Battaglia1, Hospital de Niños Dr Orlando Alassia. 1Argentina, Santa Fe, 2Santa Fe, Argentina

Background: Juvenile systemic lupus erythematosus (JSLE) is a complex multisystemic autoimmune disease, often causing irreversible damage, reduced quality of life and life expectancy. Data on causes of death and time trends in infant lupus mortality are limited.

Objectives: The aim of this study was to determine mortality in a pediatric cohort.

Methods: This retrospective study included patients with childhood onset lupus (fulfilling ACR 1997) who were diagnosed at the Paediatric centre in Santa Fe Argentine, Alassia Children Hospital from 1991 to 2018 and had 15 years of age at presentation.

Results: This study included 54 JSLE children (FM:12.5:1) with a mean age of onset lupus 12 years (range 4-15 years). During a mean follow-up in our centre of 3 years (range 12m–10 years), 12 patients (24%) was died; 5 during the follow-up in our centre and 7 in adult centre, 4 lost to follow-up.

The average age of death was 16 years (range 10-29 years) and the average since diagnose time was 17 months (range 3m-15 years).

The principal system involved was renal (100%), 10 patients with diffuse proliferative lupus nephritis (WHO class IV), 2 membranous lupus nephritis (WHO class V), 5 patients (41.6%) with hematomal disorders (2 pancytopenia, 2 leukopenia, 1 Macroage Activation Syndrome). 3 patients had thrombosis. 5 patients (41.6%) with neurological involvement (4 psychosis, 1 depression). One patient with liver dysfunction. There one death related to renal biopsy.

The principal cause of mortality was active disease and infection. Menin- gococcal meningitis, Klebsiella peritonitis, Pneumococcal cellulitis of the neck, peritonitis and 1 patient with disseminated tuberculosis.

Conclusion: Over all, similar trends were observed for RA and pSS cohorts despite minor changes in pSS therapy. Work participation has improved significantly over two decades in pSS. A greater perception of pSS without systemic manifestations may have caused a shift towards less severely affected patient cohorts today.

SAT0187  TRENDS IN EMPLOYMENT AND HOSPITALIZATION IN PATIENTS WITH SJÖGREN’S SYNDROME 1993–2016: RESULTS FROM THE GERMAN NATIONAL DATABASE

Johanna Calhoff1, Katja Thielemann2, Thomas Dörner3, Angela Zink1,2, Jörg Henes3,4, Julia Richter4, Katinka Albrecht1.

1German Rheumatism Research Centre, Berlin, Germany; 2University Hospital Tübingen, Rheumatology, Tübingen, Germany; 3Heinrich-Heine-University, Department of Rheumatology and Hiller Research Unit, Düsseldorf, Germany

Background: During the last 20 years, employment rates increased substantially in the German population and also in patients with arthritis [1]. Whether patients with primary Sjögren’s syndrome (pSS) also show this trend is less clear in the absence of new treatment options.

Objectives: To assess trends in treatment and outcomes in patients pSS, focusing on employment, hospitalization and medical treatment in the past two decades.

Methods: From 1996 to 2016, ~300 patients with pSS were documented annually in the National Database of the German Collaborative Arthritis Centres. Data on treatment, physician assessment of disease activity, patient-reported outcomes, hospitalization and employment were collected and compared to patients with rheumatoid arthritis (RA), matched 1:1 for age, sex and disease duration for each calendar year.

Results: Patients with pSS (>90% female, age ~44 years at disease onset, disease duration ~10 years) were more frequently assessed to be in low disease activity in 2016 (93%) than in 1996 (62%, p<0.01). Treatment with antimalarials increased (31% to 50%, p<0.01) and less patients were on glucocorticoids (50% to 34%, p<0.01); Less than 5% were treated with biologics in 2016. The percentage of employed patients (>65 years) increased by 21 percentage points (43% to 64%, p<0.001), exceeding the increase observed for RA patients (+15 percentage points).

In 2016, significantly less patients compared to 1996 were on early retirement (22% and 10%, p<0.01), hospitalized/year (13 and 7%, p<0.08) or on temporary sick leave (27% compared to 39%, p<0.09). This trend is comparable to RA patients.

Conclusion: Overall, similar trends were observed for RA and pSS cohorts despite minor changes in pSS therapy. Work participation has improved significantly over two decades in pSS. A greater perception of pSS without systemic manifestations may have caused a shift towards less severely affected patient cohorts today.

SAT0188  WHOLE BLOOD VERSUS SERUM HYDROXYCHLOROQUINE LEVELS FOR DRUG MONITORING OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: PRELIMINARY RESULTS OF A PHARMACOLOGICAL STUDY

Benefit Blanchet1, Moez Jallouli1, Marie Allard1, Pascale Ghillani Dalbir2, Lionel Galièvre3, Veronique Le Guern1, Noel Zahr1, Claire Goulvestre1, Zahir Amoura1, Jean-Charles Piette2, Noemie Jourde-Chiche2, Nathalie Costedoat-Chalumeau1, Group PLUS1, 1Cochin Hospital, Paris, France; 2Pitié Salpêtrière Hospital, Paris, France; 3Saint Louis Hospital, Paris, France; 4Aix-Marseille Univ, ISMIR, INSERM, INPA, AP-HM Centre de Néphrologie, Marseille, France

Background: In order to assess the pharmacokinetic/pharmacodynamic relationship of hydroxychloroquine (HQC) in patients with systemic lupus erythematosus (SLE), HQC levels have been measured in whole blood as well as in serum but both methods have never been compared. In addition, cut offs for non-adherence (classically 200ng/mL but also 100 ng/mL) have been established only in whole blood.

Results: Patients with pSS (>90% female, age ~44 years at disease onset, disease duration ~10 years) were more frequently assessed to be in low disease activity in 2016 (93%) than in 1996 (62%, p<0.01). Treatment with antimalarials increased (31% to 50%, p<0.01) and less patients were on glucocorticoids (50% to 34%, p<0.01); Less than 5% were treated with biologics in 2016. The percentage of employed patients (>65 years) increased by 21 percentage points (43% to 64%, p<0.001), exceeding the increase observed for RA patients (+15 percentage points).

In 2016, significantly less patients compared to 1996 were on early retirement (22% and 10%, p<0.01), hospitalized/year (13 and 7%, p<0.08) or on temporary sick leave (27% compared to 39%, p<0.09). This trend is comparable to RA patients.

Conclusion: Overall, similar trends were observed for RA and pSS cohorts despite minor changes in pSS therapy. Work participation has improved significantly over two decades in pSS. A greater perception of pSS without systemic manifestations may have caused a shift towards less severely affected patient cohorts today.

Disclosure of Interests: Johanna Calhoff: None declared, Katja Thiele: None declared, Thomas Dörner: Grant/research support from: Eli Lilly, Janssen, Roche, UCB Pharma, Consultant for: Eli Lilly, Janssen, Roche, UCB Pharma, Speakers bureau: Eli Lilly, Janssen, Angela Zink: Speakers bureau: Speakers fees from AbbVie, Janssen, Pfizer, Roche, Sanofi, Jörg Henes: None declared, Jutta Richter: Grant/research support from: GlaxoSmithKline and UCB Pharma for performing the LuLa-study., Katinka Albrecht: None declared

Objectives: The aims of this study were (1) to compare these two pharmacological approaches, and (2) since it would be very interesting to retrospectively assess severe non-adherence in clinical trials or in large cohort of patients in which only serum samples are usually available, to determine if serum HCQ level cut offs could be established for identification of severe non-adherent patients.

Methods: The HCQ and desethylchloroquine (DCQ) levels were measured in serum and whole blood from 573 SLE patients. The risk factors for active SLE (SLEDAI score >4) were identified using multiple logistic regression. HCQ serum level was also measured in 51 non-adherent patients (whole blood HCQ level <200 ng/mL).

Results: The mean HCQ and DCQ levels were 916 ± 449 and 116 ± 55 ng/mL in whole blood, respectively; and 469 ± 223 and 63 ± 31 ng/mL in serum, respectively. The mean ratio of serum/whole blood level for HCQ and DCQ were 0.53 ± 0.15 and 0.57 ± 0.21, respectively. A strong positive correlation was found between serum and whole blood levels of HCQ (rho=0.837 [95% CI 0.810-0.860], p<0.0001), and DCQ (rho=0.771 [95% CI 0.736-0.802], p<0.0001). In the multivariate analysis, only corticosteroids (p=0.044), immunosuppressant (p=0.027), HCQ whole blood level (p=0.023) and hemoglobin (p=0.009) were identified as an independent risk factor of active SLE but serum HCQ level was not. Given the mean ratio of serum/whole blood level for HCQ was 0.53, we extrapolated that serum HCQ level cut offs of 106 and 53 ng/mL would correspond to the previously used cut-off of 200 and 100 ng/mL of HCQ in whole blood. Using HCQ serum level cut off of 106 ng/mL, 43 of 51 patients (84%) with blood HCQ levels <200 ng/mL would also have been considered as non-adherent. The positive and negative predictive value of HCQ serum level <100 ng/mL to detect non-adherence were 96.6% and 63.6%, respectively. Of these 51 patients, 25 patients (49%) exhibited HCQ whole blood concentration below 100 ng/mL. Using HCQ serum level cut off of 53 ng/mL, 23 of 25 patients (92%) with HCQ whole blood level<100 ng/mL, would also have been considered as non-adherent. The positive and negative predictive value of HCQ serum level <53 ng/mL to detect non-adherence were 82.1% and 90.9%, respectively.

Conclusion: Our data support the use of whole blood rather than serum as the matrix for drug monitoring of HCQ levels in SLE patients. However, when whole blood is not available, our results support the use of HCQ serum level to assess non-adherence with a cut off of 106 ng/mL, corresponding to 200 ng/mL in whole blood.

A NOVEL DEVICE FOR RAPID MINOR SALIVARY GLAND BIOPSY IN SUSPECTED SJÖGREN’S SYNDROME

Alexandre Dumusc1, Bettina Bannert2, Diana Dan1, Thomas Huegle1.

Objectives: To describe and compare clinical, serological and histological features of patients with primary Sjögren’s syndrome (pSS) associated non-Hodgkin’s lymphomas (NHLs) in 3 cohorts, from Greece (1) and Italy (2).

Methods: 140 consecutive pSS patients with NHLs who fulfilled the 2002 AEG criteria for Sjögren’s were included in the study. Patients were recruited from 3 centers (Udine, Pisa, Athens, cohort named UPA), two from Italy (Udine and Pisa University Hospitals with a total of 63 cases, named cohort UP) and one from Greece (University of Athens with 77 cases, named cohort A). Age at NHL onset, NHL subtype and distribution, SS disease duration until lymphoma development, serum anti-SSA/SSB antibodies and rheumatoid factor, history of salivary gland enlargement, cryoglobulinemia with or without vasculitis and C4 hypocomplementemia before the onset of NHL were recorded and compared.

Results: The Greek cohort (A) had a median age at lymphoma diagnosis 58 years (range: 28-90 years) and the (UP) cohort a median age at diagnosis of lymphoma 55.6 years (range: 25-77 years). The median time from SS to lymphoma diagnosis was 65.8 months (range: 0-456 months) vs 48 months (range: 0-276 months) for (A) and (UP) cohort respectively. The commonest histologic subtypes such as, MALT (mucosa associated lymphoid tissue), diffuse large B cell (DLBCL) and nodal or splenic marginal zone (MZ) lymphomas were observed in similar frequencies between

LYMPHOMA IN PRIMARY SJÖGREN’S SYNDROME: A RETROSPECTIVE CLINICAL STUDY WITH PATIENTS FROM THE UPA (UDINE, PISA, ATHENS) GROUP

Andreas Goules1, Chiara Baldini1, Saviana Gandolfo2, Aristea Papageorgiou3, Dimitris Zogias1, Francesco Ferro1, Valentina Donati1, Cathryn Scott2, Salvatore De Vitis1, Michael Voulgarakis1, Afhanasios Tzioufas2, 1Athens School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Pathophysiology, Athens, Greece, 2University of Pisa, Rheumatology Unit, Department of Internal Medicine, Pisa, Italy, 3University of Udine, Department of Medical and Biological Sciences, Rheumatology Clinic, Udine, Italy, “Athens School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Pathophysiology, Athens, Greece, “Athens School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Pathophysiology, Athens, Greece

Background: Lymphoma development in Sjögren’s syndrome has significant impact on morbidity and mortality of the disease.

Objectives: To describe and compare clinical, serological and histological features of patients with primary Sjögren’s syndrome (pSS) associated non-Hodgkin’s lymphomas (NHLs) in 3 cohorts, from Greece (1) and Italy (2).

Methods: 140 consecutive pSS patients with NHLs who fulfilled the 2002 AEG criteria for Sjögren’s were included in the study. Patients were recruited from 3 centers (Udine, Pisa, Athens, cohort named UPA), two from Italy (Udine and Pisa University Hospitals with a total of 63 cases, named cohort UP) and one from Greece (University of Athens with 77 cases, named cohort A). Age at NHL onset, NHL subtype and distribution, SS disease duration until lymphoma development, serum anti-SSA/SSB antibodies and rheumatoid factor, history of salivary gland enlarge-

Disclosure of Interests: None declared, Alexandre Dumusc: None declared, Bettina Bannert: None declared, Diana Dan: None declared, Thomas Huegle Grant/ research support from: AbbVie, Lilly, Novartis and Pfizer, Speakers bureau: AbbVie, Lilly, Novartis and Pfizer

the 2 cohorts. The proportion of pSS NHLs patients with MALT lymphomas and >1 involved sites was significantly higher in cohort (A) compared to (UP) cohort [25/51 (49%) vs 5/40 (12.5%), p=0.0003] while extranodal localization of DLBC lymphomas was less frequent in Greek compared to Italian patients [2/12 (16.7%) and 4/10 (40%) respectively]. No significant differences were observed regarding anti-Ro/SSA, anti-La/SSB, rheumatoid factors (RF) or history of parotid gland enlargement. Interestingly, no significant difference was also observed in the frequencies of serum cryoglobulinemia (without vasculitis) and C4 hypocomplementation. Importantly, cryoglobulinemic skin vasculitis was significantly more frequent in cohort (A) than in cohort (UP) [33/77 (42.9%) vs 12/63 (19.0%), p=0.0027] as well as bone marrow involvement by lymphoma [21/77 (27.2%) vs 4/63 (6.3%) respectively, p=0.0015].

Conclusion: The similar lymphoma histologic subtypes, coupled with the differences in the frequency of cryoglobulinemic skin vasculitis and bone marrow involvement by lymphoma between Greek and Italian patients, suggest potential diversities in genetic background, environmental factors, disease progression and pathologic pathways in different cohorts, offering novel perspectives to study the biology of SS associated lymphomagenesis.

SAT0191 LOW SOCIOECONOMIC STATUS AND HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
Sebastian Herrera1, Juan Camilo Diaz-Coronado1,2, Deicy Hernandez1, Laura Betancur-Vasquez2, Ricardo Pineda.Tamayo1.

1Grupo de informacion clinica, Arthritis, Antiologia, Medellin, Colombia; 2Departamento medicina interna, Universidad CES, Medellin, Colombia

Background: Socioeconomic factors have been considered as possible confounding factors in the attribution of greater damage accrual in Afro-Caribbean and Hispanic patients with Systemic lupus erythematosus (SLE). Patients with SLE often experience long-term morbidity that can adversely affect their health-related quality of life (HRQoL).

Objective: To analyze the relation between socioeconomic status, damage accrual and HRQoL

Methods: Analytic study in a cohort of SLE patients that were closely monitored in an autoimmunity program in Colombia. We stratified patients with damage (SDI ≥1) and no damage (SDI <1) and according to socioeconomic status as a surrogate value for economic income with dichotomization in low and medium/high income. We performed a non-parametric analysis of related simples of Wilcoxon in each of the dimensions of quality of life in EuroQol 5d.

Results: We analyzed 400 Colombian patients. Baseline median age was 49 years (15 IQR) with median age at diagnosis and disease duration of 37 years (17 IQR) and 9 years (13 IQR) respectively. There were 94% female patients and 17.3% late onset SLE. Most frequent clinical manifestations were hematological (82.8%), mucocutaneous (75.3%) and nephritis (33.8%). Only 4.5% had neurological involvement. The mean SLEDAI were 1.18 and 0.65 at first and second measurement respectively, in the first measurement 97.1% of the patients had a SLEDAI ≤4. The mean SDI was 0.7275 at first measurement and 0.985 at the second measurement. When comparing the intervention in patients with SDI ≥1 there was a significative improvement in the Quotidian Activities, Pain/Discomfort, Anxiety/Depression domains, independent of economic income. In patients with medium-high income there was also a significative improvement in the mobility and personal care domains. In the no-damage groups there was only a positive impact in the Anxiety/Depression domain in a statistically significant manner, and the medium-high income subgroup had improvement in the Pain/Discomfort domain. We didn’t find other statistically differences in the other domains. Low economic income seems to exert a negative influence in the different HRQoL domains with independance regarding treatment strategy, specially in patients with no damage accrual. In patients with higher income and damage accrual the opposite seems to appear, which could be related with a better ability or resources to cope with the consequences of the disease.

Conclusion: In Colombian patients with SLE, socioeconomic status (as a reflection of income) might be related with HRQoL. This relationship could be influenced by damage accrual

MYOSITIS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: DATA FROM A FRENCH NATIONWIDE SURVEY

Camille Houssais1, Jean-Baptiste Noury2, Yves Allenbach1, Laure Gallay1, Florence Assan2, Olivier Berveniste1, Jonathan Broner3, Pierre Duffau4, Alexandre Espilia-Thibault5, Anne Grasland6, Sébastien Sanges6, Gilles Hayem7, Véronique Le Guen2, Nihal Marts2, Kuberaa Marikanipilai8, Denis Mulleran9, Gaëtane Nocturne5, Alain Meyer10, Valérie Devauchelle-Pensec1, Divi Comerc9, Dewi Guellec1, University Hospital, CERANOF, Brest, Rheumatology, Brest, France; 2University Hospital, CERANOF, Brest, Neurology, Brest, France; 3Pitié-Salpêtrière University Hospital, Paris, Internal Medicine and Clinical Immunology, Paris, France; 4Edouard Herriot University Hospital, Lyon, Lyon, France; 5Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, France; 6Nîmes University Hospital, Internal Medicine, Nîmes, France; 7Centre Hospitalier Universitaire de Bordeaux, HU AGRONIM, Bordeaux, France; 8Hôtel-Dieu, CHU de Nantes, Internal Medicine, Nantes, France; 9Hôpital Louis Mourier, APHP, Colombes, France, Paris, France; 10Hôpital Henri CHRU de Lille, Internal Medicine, Lille, France; 11CHU Ambroise-Pare, AP-HP, Rheumatology, Boulogne-Billancourt, France; 12CHU Cochin, Paris, France; 13Côte d’Azur University, Nice, France; 14Pitié-Salpêtrière University Hospital, Paris, Internal medicine and Clinical Immunology, Paris, France; 15University of Tours, Rheumatology, Tours, France; 16CHU de Strasbourg, Département de Physiologie, Strasbourg, France

Background: Myositis is recognized as a manifestation of primary Sjögren’s syndrome (pSS). Grading muscle involvement using the EULAR Sjögren Syndrome Disease Activity index (ESSDAI) does not require biopsy-proven active myositis or extensive immunological investigations. However, several studies have reported that a high proportion of pSS-associated myositis is either inclusion body myositis (IBM) or an overlap syndrome (n=7). Among the 29 patients without associated condition likely to explain inflammatory muscle involvement were included. They were categorized and sub-classified. The symptom checklist section of the MDHAQ can provide clues that help discriminate between SLE patients with and without FM. The most discriminating symptoms were muscle pain, swelling (of hands, ankles and in other joints), back pain, neck pain, problems with thinking and dry mouth (all p<0.001). Grouping the above 8 symptoms, a cut-off of ≥4 gave a sensitivity of 91% and specificity of 88%, correctly classifying 89% of patients when compared to FM criteria. Overall, patients with FM reported a mean total of 23.6 items on the symptom checklist, compared to 8.09 for patients without FM.

Conclusion: The symptom checklist section of the MDHAQ can provide clues that help discriminate between SLE patients with and without FM. Clinicians can find valuable information in the specific symptoms experienced by the patient, as well as the overall number of symptoms. Grouping the discriminatory symptoms together in the questionnaire may assist clinicians to consider the diagnosis of FM more easily in patients with SLE.

THE USE OF A SYMPTOM CHECKLIST TO RECOGNISE PATIENTS WITH COMORBID FIBROMyalgia ON A BACKGROUND OF SYSTEMIC LUPUS ERYTHEMATOSUS

Frank Huang1, Sean O’Neill2, Ray Fang3, Matthew Nguyen1, Kathryn Gibson3. 1University of New South Wales, Sydney, Australia; 2Liverpool Hospital, Sydney, Australia; 3Ingham Research Institute, Sydney, Australia

Background: Fibromyalgia (FM) and systemic lupus erythematous (SLE) are both characterised by non-specific symptoms such as pain and fatigue. To make diagnosis even more challenging, fibromyalgia is over-represented in the SLE population.

Objectives: To identify which symptoms can discriminate between patients with comorbid FM and patients without comorbid FM in the SLE population, using a routinely distributed questionnaire.

Methods: Patients with SLE (n=88) completed a Multi-Dimensional Health Assessment Questionnaire (MDHAQ) [1] and the 2011 FM Criteria questionnaire [2]. FM status was determined using the 2016 modification of the 2010/2011 FM criteria [3]. The MDHAQ contains a 60-item symptom checklist section, giving a score of 0-60. Patients with complete data were analysed for specific symptoms that were discriminating for FM using student’s t test with Bonferroni correction.

Results: SLE patients with FM reported a higher prevalence of positive responses for every symptom except for ‘dark or bloody stools’ and ‘burning in sexual organs’. Nineteen symptoms demonstrated a significant difference between those with and without FM. The most discriminating symptoms were muscle pain, swelling (of hands, ankles and in other joints), back pain, neck pain, problems with thinking and dry mouth (all p<0.001). Grouping the above 8 symptoms, a cut-off of ≥4 gave a sensitivity of 91% and specificity of 88%, correctly classifying 89% of patients when compared to FM criteria. Overall, patients with FM reported a mean total of 23.6 items on the symptom checklist, compared to 8.09 for patients without FM.

Conclusion: The symptom checklist section of the MDHAQ can provide clues that help discriminate between SLE patients with and without FM. Clinicians can find valuable information in the specific symptoms experienced by the patient, as well as the overall number of symptoms. Grouping the discriminatory symptoms together in the questionnaire may assist clinicians to consider the diagnosis of FM more easily in patients with SLE.

EVALUATION OF PSYCHOMETRIC PROPERTIES OF THE PATIENT-REPORTED OUTCOMES MEASUREMENT INFORMATION SYSTEM (PROMIS) PHYSICAL FUNCTION 10-ITEM SHORT FORM IN SYSTEMIC LUPUS ERYTHEMATOSUS

Zara Irazu, Julia Kay, Gabriela Schmajuk, Jinoos Yazdany. University of California, San Francisco, San Francisco, United States of America

Background: While the PROMIS (Patient-Reported Outcomes Measurement Information System) physical function short form 10a (PF10a) is both practical and acceptable for implementation in routine clinical practice, its psychometric properties have not been evaluated in Systemic Lupus Erythematosus (SLE).

Objectives: The objectives of our study were to examine the validity and responsiveness of PF10a in SLE among a racially/ethnically diverse clinic population and develop estimates of the minimally important difference (MID).

Methods: Data were derived from electronic health records for all SLE patients seen in a university-based rheumatology clinic between 2013 and 2018. We evaluated the PF10a’s floor and ceiling effects among different racial/ethnic groups. Construct validity was assessed by examining Spearman’s correlation coefficients between the PF10a and other patient-reported pain (scale 0-10) and pain visual analogue scale (VAS) (scale 0-100), physician-reported (SLE disease activity index (SLEDAI)) and laboratory (erythrocyte sedimentation rate (ESR)) measures. Known-group validity was assessed by evaluating effect size (Cohen’s d) between categories of pain (no pain vs. moderate-severe pain). We used standardized response means to examine the responsiveness of the PF10a to longitudinal changes in pain and SLEDAI. MID was estimated using distribution based and anchor-based methods.

Results: We included 612 patients in cross-sectional analyses of validity and 462 patients in longitudinal analyses of responsiveness. Mean age was 40.5±14.6, 87% were female and 32% Caucasian. The PF10a had ceiling effects above the commonly accepted criteria of 15% among Caucasian (23%), Asian (23%) and Other (17%) race/ethnicities, and no floor effects. Construct validity analyses showed strong correlations (r=0.66, p<0.05) with pain VAS, moderate correlations (r=0.58, p<0.05) with pain, and weak correlations with ESR (r=0.25, p<0.05) and SLEDAI (r=0.16, p<0.05). Construct validity analyses showed large differences among pain groups (Cohen’s d=1.49, p<0.05). The PF10a was responsive to improvements in pain (SRM=0.5) and SLEDAI (SRM=0.49). Distribution-based MIDs were +2 for improvement and -7 for deterioration. Anchor-based MIDs were +2 for improvement, -3 for deterioration with pain as anchor and +5 for improvement, -5 for deterioration with SLEDAI as anchor.

Conclusion: Although the PF10a showed some ceiling effects, it had good validity in this young racially/ethnically diverse sample with SLE. The PF10a was responsive to improvements in pain and disease activity. The anchor-based MIDs appear to be similar to those reported for PF10a in rheumatoid arthritis(1). This information supports the use of the PF10a in SLE and provides important information to facilitate interpretation of scores.

SAT0196
SYSTEMIC DISEASES ASSOCIATED WITH AUTOIMMUNE LIVER DISEASES
hela KHCHR1, Dhoula Cherfi1, Dhiel Issaoui1, Maha Mitb, Diha Kaffel2, Faten Limaiem3, Nadia Maamouri1. ‘La Rabta Hospital, Gastroenterology B, Tunis, Tunisia; 2Kassab Institute, Rheumatology, Tunis, Tunisia; 3Mongi Slim Hospital, Pathology, Tunis, Tunisia

Background: Autoimmune liver diseases are considered as a group of hepatobiliary injuries mediated by abnormal immunity in subjects with genetic predisposition. It mainly includes autoimmune hepatitis, primary biliary cholangitis, primary sclerosing cholangitis and overlap syndrome. They are oftenly associated with different manifestations of autoimmune systemic diseases such as systemic lupus erythematosus, CREST syndrome ....

Objectives: The aim of this study was to evaluate the prevalence and the characteristics of systemic diseases associated with autoimmune hepatopathies.

Methods: We carried out a retrospective study from January 1996 to December 2018 including all patients with autoimmune liver diseases followed in our department: 64 primary biliary cholangitis (PBC), 22 autoimmune hepatitis (AIH), 23 overlap syndrome (OS), 15 primary sclerosing cholangitis (PSC).

Results: One hundred and twenty four patients were included in our study: 107 women and 17 men with an average age of 55 years (18-87 years). An immunological disorder was found in 58 cases (48%): [20 PBC/12 AIH/12 OS/6 PSC] with a female predominance (Sex ratio (Men/Women) = 0.09). Systemic diseases included respectively: Sjögren’s syndrome in 20 cases, systemic lupus erythematosus in 7 cases, rheumatoid arthritis in 5 cases, CREST syndrome in 11 cases and autoimmune thyroiditis in 2 cases. The discovery of autoimmune disorder was in most cases concomitant to the diagnosis of the autoimmune liver disease (87%). Our study showed biological assessment perturbation in 20 cases with positivity of : anti-centromere antibodies (11 cases), anti-SSA antibodies (5 cases), anti-cardiolipin antibodies (4 cases) and rheumatoid factor (5 cases).

Conclusion: Our study shows a strong prevalence of systemic disease during autoimmune hepatopathies. A systematic screening for clinical and biological immune manifestations are highly recommended in those patients.

INCIDENCE AND OUTCOME OF NON-TYPHOID SALMONELLA BACTEREMIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN COMPARISON WITH RHEUMATOID ARTHRITIS AND PRIMARY SJÖGREN’S SYNDROME

Cheng-Hung Liu 1,2, Li Ko-Jen 1, Cheng-Han Wu 3, Song-Chou Hsieh 4, National Taiwan University Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China; National Taiwan University, Graduate Institute of Clinical Medicine, College of Medicine, Taipei, Taiwan, Republic of China

Background: Non-typhoid Salmonella (NTS) infection is an important problem in patients with systemic lupus erythematosus (SLE) [1, 2]. However, less is known about the incidence rate (IR) for NTS bacteremia. Objectives: To evaluate the IR of NTS bacteremia in patients with SLE, in comparison to rheumatoid arthritis (RA) and primary Sjögren’s syndrome (SjS), and by comparison with other Gram-negative bacilli (GNB) bacteremia including Escherichia coli (E. coli) and Pseudomonas aeruginosa (PsA). Furthermore, to access the survival outcome after NTS bacteremia.

Methods: In this single-center retrospective cohort study, we analyzed the registry of catastrophic illnesses database for patients fulfilled the criteria of SLE, RA, and SjS in National Taiwan University Hospital. The patients aged over 20 years, with adequate follow-up during January 1, 2008 to December 31, 2017 were included. Only new episodes of positive blood cultures during the observation period were taken into analysis. Cox proportional hazards regression model was applied for calculating the incidence rate ratio (IRR) of bacteremia between different diseases, and the hazard ratio (HR) of mortality.

Results: This study included 5953 patients. NTS bacteremia happened in 33 cases, among which 27 (81.8%) were group D1 and 4 (12.1%) were group B Salmella. The baseline characteristics, IR of each GNB bacteremia, and the IRR adjusted for age, sex, diabetes mellitus (DM) as well as chronic kidney disease (CKD) are shown in Table 1. Compared to patients with RA, the IRR for NTS bacteremia was highest in SLE. The IRR for E. coli bacteremia in patients with SLE also increased in comparison with RA, although not as high as for NTS bacteremia. When compared to SjS, patients with SLE still had an elevated IRR of 3.52 (95% CI: 1.29–9.63, p=0.014) for NTS bacteremia. In SLE patients, DM increased the IR for NTS bacteremia (IRR: 4.43, 95% CI: 1.71–11.43, p=0.002; adjusted for age and sex).

In the 33 cases with NTS bacteremia [male: 21.2%; age: 49.0 (37.9–64.2) years], the median observation time to event was 11.1 (IQR, 3.0–38.1) months. No recurrent bacteremia was found. There were 14 (42.4%) deaths, and 7 (21.2%) died within 60 days after NTS bacteremia. The median time to all-cause mortality was 54 (IQR, 17–153) days. In survival analysis, an abnormal body mass index (BMI) (BMI, normal >18.5 and ≤24) at the onset of bacteremia had a crude HR of 6.20 (95% CI: 1.64–23.52, p=0.007). The diagnosis of SLE, age, gender, DM, CKD, levels of C-reactive protein and white blood cell count did not significantly increase HR.

Conclusion: Among the GNB bacteremia, patients with SLE were especially susceptible to NTS bacteremia when compared to RA and SjS. DM was a risk factor. The mortality rate after NTS bacteremia was high, and an abnormal BMI may predict it.

SAT0198
PERIPHERAL NERVOUS SYSTEM INVOLVEMENT IN PRIMARY SJÖGREN’S SYNDROME—UNCOMMON OR UNDERESTIMATED PROBLEM?

Marta Jaksolska, Magdalena Chylinska, Anna Masial, Zenobia Czuszynska, Katarzyna Galecka, Mariusz Sieminski, Zbigniew Zdrojewski, Medical University of Gdansk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdansk, Poland

Background: Systemic manifestations are common in primary Sjögren’s syndrome (pSS) and play a major role in the prognosis. Neurological complications may affect both the peripheral (PNS) and central nervous system (CNS). The incidence varies from several to several dozen per cent. The course of the disease and the severity of the symptoms may be mild and self-limiting or progressive, leading to permanent neurological deficits. It is worth remembering that the symptoms of nervous system involvement may precede the onset of symptoms of dryness, and diagnosis of pSS may be delayed after a certain duration of neurological symptoms.

Objectives: The aim of the study was to determine the prevalence of PNS involvement among symptomatic and asymptomatic patients with the diagnosis of pSS in our University Clinical Centre.

Methods: We studied a consecutive group of fifty unselected patients aged from 33 to 74 years (mean 55.8 years). All patients fulfilled the criteria for the diagnosis of pSS. Additional connective tissue diseases and diabetes were the exclusion criteria. Disease activity was evaluated according to the EULAR Sjögren’s syndrome disease activity index (ESS-DAI). All patients underwent clinical neurological examination and nerve conduction study (NCS) of nine peripheral nerves. For the classification of polymyopathies the ESTEEME (European Standardized Telerematic Tool to Evaluate Electrodiagnostic Methods) guidelines were used. Clinical examination and nerve conduction study were performed and evaluated by one certified neurologist.

Results: Of our 50 patients, 48 were female with a mean (±SD) age 53.6±10.5 years and mean disease duration 7.9±5.3 years. Two were male with mean age 43.7±25.8 years and mean disease duration 5.7±1.6 years. The mean age at diagnosis was 50.4±14 years. 23 (46%) patients fulfilled the criteria for the diagnosis of neuropathy. The most common PNS manifestation was sensorimotor neuropathy 11/23 (47%), mononeuropathy was present in 6/23 (26%) patients, pure axonal sensory neuropathy was present in 1/23 (4.3%) patient, axonal motor neuropathy in 1/23 (4.3%), SFN in 1/23 (4.3%) and cranial nerve involvement was present in 4/23 (17.4%) (one of the patients both had cranial and sensorimotor neuropathy). Neurological symptoms preceded the diagnosis of pSS in 8 (35%) of 23 PNS+ patients. The frequency of following symptoms and extradural manifestations was significantly higher in PNS+ compared to PNS- patients: salivary gland enlargement (74% vs 44% p<0.05), respiratory tract involvement (65% vs 37% p<0.05) and myelophenopathy (61% vs 19% p<0.05). The mean ESSDAI in patients with and without neurological involvement was 7.6±8.2 and 4.7±4.58 respectively (p=0.245). In this subgroup the use of cyclophosphamide, due to extradural manifestations, was increased (p=0.05).

Conclusion: We found that PNS involvement is a common extradural manifestation of pSS (46% in our group). Sensorimotor neuropathies were most frequent. Involvement of the PNS seems frequent but remains underestimated. NCS is a non-invasive test which might be useful at diagnosis and follow-up. Guidelines for the diagnosis and treatment of peripheral neuropathies in patients with pSS are needed.

POLYAUTOIMMUNITY IN SYSTEMIC LUPUS ERYTHEMATOSUS. DATA FROM A LARGE SPANISH COHORT: SPANISH SOCIETY OF RHEUMATOLOGY REGISTRY OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (RELESSER).

Natalia Mené-Vázquez1, Antonio Fernández-Nebro1, Inigo Ruíz-Figueroa2, María Galindo-Izquierdo2, Juan Ovallés3, Alejandro Olíve4, Jaime Calvo5, Raúl Menor-Almagro1, Eva Tomero Muriel6, Esther Uriarte Isacelaya7, Alina Boteanu8, Mariano Andres9, Mercedes Freire González10, J. Narváez11, Tomas Vazquez Rodríguez12, Ricardo Blanco13, José A. Hernandez-Berian14, Jesús Ibáñez15, Enrique Raya16, Joan Calvet17, Jose M. Pego-Reigosa18

Methods: The basis for defining polyautoimmunity was the presence of at least 2 SLE criteria associated with other autoimmune diseases. Main outcome: Polyautoimmunity was defined as patients who fulfilled criteria for SLE and other autoimmune disease: autoimmune thyroiditis, rheumatoid arthritis, systemic sclerosis or inflammatory myopathy and mixed connective tissue disease. Multiple autoimmunity syndrome (MAS) was defined as patients who met SLE criteria and at least two other autoimmune diseases.

Results: From 3679 (91.4%) patients included in the registry, 501 (12.8%) had polyautoimmunity in patients with SLE. A family history of SLE was 12.4% and MAS in 12.7% for antiphospholipid syndrome.

Conclusion: SLE patients associated polyautoimmunity in 14%, MAS in 2%. More studies are needed to better understand the increase of polyautoimmunity in these patients.

UNUSUAL SYSTEMIC LUPUS ERYTHEMATOSUS/ SJOEGREN'S SYNDROME PHENOTYPE IN A PATIENT WITH A TNFAIP3 GENE MUTATION

Kerstin Noll1, Yonne Glackin1, Stephen D. Marks2, Paul Brogan2, Sandrine Comperry-Lacassagne3, Great Ormond Street Hospital, Rheumatology, London, United Kingdom, Great Ormond Street Hospital, Renal Unit, London, United Kingdom, University College London Great Ormond Street Institute of Child Health, Infection, Inflammation and Rheumatology Section, London, United Kingdom

Background: Mono-allelic mutation in tumor necrosis factor alpha induced protein 3 (TNFAIP3) has been found to cause haploinsufficiency of A20 protein, the cause of an early-onset auto inflammatory disease resembling Behcet’s Disease (BD). Single nucleotide polymorphism in TNFAIP3 may also contribute to susceptibility to systemic lupus erythematosus (SLE). Several mutations in TNFAIP3 have been shown to be disease-causing, including a single case with heterozygous mutation in the TNFAIP3 gene for c.811C>T: p.(arg271?) with a BD-like phenotype.

Objectives: To report the case of a child with heterozygous mutation TNFAIP3 (c.811C>T: p.(arg271?) with an unusual SLE/SS (Sjogren syndrome) phenotype, thus expanding the phenotype associated with this mutation; and describe the disease course and treatment.

Methods: Clinical details were retrospectively collated using routine clinical records. The molecular cause of the phenotype was investigated using a targeted gene next generation sequencing (NGS) panel (the vasculitis and inflammation panel, VIP). Confirmation of findings detected by NGS were confirmed using conventional Sanger sequencing in the index case and subsequently in the parents.

Results: A 4yr old Caucasian female presented with a 2-year history of photosensitive malar rash, mouth ulcers, hair loss, arthralgia, livedo reticularis, cervical lymphadenopathy and hepatosplenomegaly. Laboratory tests revealed anemia, raised inflammatory markers and hypocomplementemia; RF, ANA and anti Ro positivity, raised C1q antibodies and low C1Q level. 7 out of 11 classification criteria for SLE were met and treatment with hydroxychloroquine was commenced. Subsequently she developed blepharitis, acute anterior uveitis, chilblains and discoid skin lesions. Azathioprine and oral steroids were added. Due to young age at disease onset, NGS screening was performed and revealed heterozygous mutation in TNFAIP3 c.811C>T: p.(arg271?) Screening of both parents revealed the same mutation in the mother, who is asymptomatic. The child further developed Raynaud’s and underwent renal biopsy for intermittent proteinuria which revealed ISN/RPS Class III and V lupus nephritis. Azathioprine was switched to mycophenolate mofetil. One year later her skin symptoms continue to improve, uveitis is in remission and her renal function is normal. Prednisolone was tapered off.

Figure: chilblain and discoid skin lesions, Raynaud’s and histopathological changes from a renal biopsy consistent with glomerulonephritis.
Cardiovascular Events in Systemic Lupus: The Role of Cardiovascular Risk and SLE-Related Factors

Anna Maria Paglionicia, Valentina Varriano, Luca Petricca, Clara Di Mario, Maria Rita Gigante, Giacomo Tanti, Barbara Tolusso, Gianfranco Ferraccioli, Elisa Gremese, Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Rheumatology, Rome, Italy; Università Cattolica del Sacro Cuore, Division of Rheumatology, Rome, Italy

Background: Patients with SLE may have an increased risk of cardiovascular (CV) events due to the contribution of disease-related factors.

Methods: Two hundred and sixty two consecutive SLE patients (age 42.9 ± 14.5 years, 89% female, disease duration 11.5 ± 8.2 years) have been evaluated, 240 (92%) with articular, 226 (86%) with cutaneous, 167 (64%) with hematological, 61 (23%) with serositis involvement respectively and 86 (33%) with lupus nephritis (LN) and 105 (40%) with neuropsychiatric SLE (NPSLE). The follow-up data were collected and information on traditional CV risk factors (age, sex, diabetes, smoking, arterial hypertension, dyslipidemia), disease-specific parameters (SLEDAI-2K, chronic steroid therapy, current antimalarial and other immunosuppressive therapy) and autoantibody profile (ANA, anti-SSa/Ro, anti-SSb/La, IgA and IgM Rheumatoid factor (RF), complement reduction, anticardiolipin (ACLA), anti-beta2-glycoprotein 1 (anti-B2GPI), lupus anticoagulant (LAC)) were analyzed for each patient. As CV manifestations, acute cardiac and cerebrovascular ischemic events and chronic ischemic heart disease were considered.

Results: Twenty-seven SLE patients (10.3%) experienced CV events during the follow-up period with a significantly higher rate of male sex (24% in males vs 8.6% in females, p=0.001) among the considered demographical parameters. Among those patients, 10 (37%) presented cerebrovascular accidents, 6 (22%) acute cardiac ischemic events, 7 (26%) chronic ischemic heart disease and 4 (15%) both cardiac and cerebrovascular events during the follow up period. In particular, SLE patients who experienced CV events during the follow up were older at disease onset than patients who did not experience CV events during the follow-up (42.2 ± 19.4 vs 29.8 ± 13.1 years, p<0.001). Considering the traditional CV-related risk factors, among the SLE cohort, patients who experienced CV events during the follow up were more likely having concomitant dyslipidemia (p=0.03), diabetes mellitus (p=0.01) and arterial hypertension (p=0.001) compared to SLE patients who did not experience CV events. Considering the disease-related parameters, no significant association between CV events development and ANA, anti-SSa/Ro, anti-SSb/La positivity and complement reduction was found (p=0.05) despite SLE patients who experienced CV events during the follow-up were more likely with concomitant neurological involvement (p=0.002) and ongoing chronic corticosteroid therapy (p=0.03) compared to SLE patients who did not experience CV events.

Finally, considering the anti-phospholipid antibodies (aPL) profile, SLE patients who experienced CV events during the follow-up were more likely positive for anti-B2GPI (p <0.001), ACLA (p=0.0001) and LAC (p <0.0001) compared to SLE patients who did not experience CV events. In addition, multivariate analysis revealed that, aPL positivity arose as an independent risk factor associated with CV events development in SLE patients contingent to the number of aPL positivities (single aPL positivity, OR 4.52 (0.97-21.18); double aPL positivity, OR 23.95 (4.39-130.76); triple aPL positivity, OR 34.01 (7.64-151.40)).

Conclusion: in SLE patients, aPL positivity significantly increases the risk of CV events development regardless to the traditional CV risk factors contingent to the number of aPL positivities.

Evaluation of Left Atrial Myocardial Deformation as Marker of Subclinical Damage in Patient with Systemic Lupus Erythematosus

Silvia Perez-Topete, Tomas Miranda-Aquino, Jorge Hernandez-del Rio, Sergio Gutierrez-Ureña, Gloria Martinez-Bonilla, Veronica Gonzalez-Diaz, Sergio Cerpa-Cruz, Civil Hospital Fray Antonio Alcalde, Rheumatology, Guadalajara, Mexico; Civil Hospital Fray Antonio Alcalde, Cardiology, Guadalajara, Mexico

Background: The left ventricle diastolic dysfunction (LVDD) may be the only manifestation of cardiac involvement in patients with systemic lupus erythematosus (SLE), preceding systolic dysfunction. The myocardial deformation of left atrium (LA) through the evaluation of LA global longitudinal strain (LALS) may be useful in assessing diastolic function since the lower the LALS the worse is the diastolic function.

Objectives: The main objective of this study was to evaluate the LA function through myocardial deformation by strain and strain rate derived from speckle tracking echocardiography in patient with SLE without any cardiovascular symptoms and compare with Control Group (CG). To compare LA strain of patients with active, inactive SLE disease and control group and determine the independent factors associated with depressed LALS.

Methods: A cross sectional study was performed. Fifty patient that fulfilled 2012 SLICC classification criteria for SLE were included and they were compared with fifty age- and gender-matched healthy subjects as control group. Myocardial deformation was measured by transthoracic...
Correlation between the serum 1,25(OH)2D3 level and clinical data of patients with primary Sjögren’s syndrome.

Shi Qiao1, Hong-Yan Wen1, Wenjuan Ni1, Yang Li2, Yaran Duan1, Chong Gao2, Li Xiaofeng1, 1The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China; 2Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America

Background: The role of vitamin D in regulating immune function in autoimmune diseases has been extensively studied. While there is less research on vitamin D in Sjögren’s syndrome. This study will explain the relationship between vitamin D and Sjögren’s syndrome.

Objectives: To explore the relationship between the serum 1,25(OH)2D3 level and the changes of disease activity in patients with Primary Sjögren’s Syndrome (PSS) [1], and to explore whether supplementation of VD could be a potential therapy for the treatment of PSS.

Methods: PSS patients (n=60, according to the 2002 International Classification (Diagnostic) Standard for Sjögren’s Syndrome) were enrolled and health individuals were normal controls. Laboratory examinations were analyzed including that serum levels of 1,25-dihydroxycholecalciferol [1,25(OH)2D3], lymphocytes and CD4+ T cell subsets by flow cytometry, urine pH value, ALT, AST, BUN, Cr, IgG, C3, C4, ESR, CRP, serum levels of 1,25(OH)2D3. Physical examination data include Salivary flow rate, secretion of tears, breakup time of tear film (BUT), and labial glands biopsy.

Results: Compared with that in normal controls, the levels of serum VD in patients with PSS was decrease significantly, Z=-7.367, P<0.001(Figure 1). Spearman correlation analysis and comparison with the collected indexes, showed that VD was significantly correlated with secretion of tears (r=-0.455, p<0.002), IgG (R=-0.581, p<0.000), B cell absolute count (R=-0.474, p=0.002), B cell percent (R=-0.391, p=0.005), Th1 absolute count (R=0.318, p=0.003), Th17 absolute count (r=-0.297, p=0.034), Th17
diabetic retinopathy.

SAT0204 LUPUS LOW-DISEASE ACTIVITY STATE VS SLE RESPONDER INDEX IN A “REAL-LIFE” SETTING

1,2Giuseppe Alvise Ramirez*, Valentina Caris*, Lucia Moiola3, Marco Magnoni2, Patrizia Rovere-Querini3,4, Lavinia A. Coletto4, Lorenzo Dagna1,2, Angelo Manfredi1,2, Enrica Bozzolo2, Università Vita-Salute San Raffaele, Milan, Italy; 1IRCSc Ospedale San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; 2IRCSc Ospedale San Raffaele, Department of Neurology, Institute of Experimental Neurology, Division of Neuroscience, Milan, Italy; 3IRCSc Ospedale San Raffaele, Cardiothoracic Department, Milan, Italy

Background: Systemic lupus erythematosus (SLE) is a chronic multi-organ autoimmune disease characterised by a heterogeneous pathogenic background and by protein clinical manifestations. Recent efforts in identifying novel agents for therapeutic interventions have led to disappointing results and designing a reliable way to assess drug efficacy and verify the achievement of remission, has become itself a major challenge. The SLE responder index (SRI) is a composite tool developed and validated in clinical trials to define in patients with active disease an acceptable response to investigational agents. The role of SRI outside clinical trials has not been defined. The lupus low disease activity state (LLDAS) has been originally validated in a cohort-based setting and it focuses on the achievement of fixed conditions rather than variations from baseline. A formal comparison of these tools outside clinical trials has not been performed.

Objectives: To prospectively assess the performance of SRI and LLDAS in a “real world” observational setting.

Methods: One hundred-thirty-one consecutive patients SLE were subdivided into two groups based on the need or not to escalate their immune suppressive treatment. Clinimetrics including Physician Global Assessment scale (PGA), SLE Disease Activity Index 2000 (SLEDAI-2K) and British Isles Lupus Assessment Group index (BILAG) 2004 version were measured at baseline and at six and 12 months, together with laboratory data and treatment changes. LLDAS and SRI were calculated at each time point.

Results: LLDAS achievement correlated with treatment de-escalation over 12 months (p<0.2, p=0.034, OR=4.1 with 95%CI=1.2-14.4), whereas SRI-4 achievement did not. LLDAS responses were more frequent in patients with lower basal SLEDAI-2K (i.e SLEDAI-2K=6; 2y=21.5, p=0.001, RR=8.4 with 95%CI=3.2-25.0), while SRI-4 responses were more prevalent among patients with higher basal SLEDAI-2K and/or severe renal activity at baseline (y=5.9, p=0.025, RR=10.8 with 95%CI=1.1-103.1).

Conclusion: The level of serum VD in PSS patients was significantly lower than that in normal controls, which was negatively correlated to secretion of tears, IgG, the absolute number of B, Th1, and Th17, the percentage of B and Th17, and ratios of Th1/Th2 and Th17/Tregs. Raising serum VD levels by supplementation of VD, may be a potential Therapy for Sjogren’s syndrome.

Lupus Low Disease Activity State vs SLE
A CYKOTINE “SCAR SIGNATURE” CHARACTERIZES PATIENTS WITH FATIGUE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND SJÖGREEN’S SYNDROME

1,2,3Carlo Maria Rossi, Alice Horisberger2, Laura Moi2, Khalid Chmili2, Malthei Perreau2, Giuseppe Pantaleo2, Camillo Ribi3. 1ASST Grande Ospedale Metropolitano Niguarda, Allergy and Immunology Unit, Milano, Italy; 2Centre Hospitalier Universitaire Vaudois (CHUV), Division of Immunology and Allergology, Lausanne, Switzerland

Background: Fatigue is highly prevalent in systemic lupus erythematosus patients (SLE) and primary Sjögren’s syndrome (pSS) and represents one of its unmet needs.[1] Its pathogenesis is multifactorial, with the activity of the underlying disease exerting a prominent role, along with psychological factors and co-morbid conditions. Previous studies evaluating fatigue and cytokines in patients with SLE and pSS have yielded inconclusive results.

Objectives: We aimed to evaluate patient-reported outcome measures reflecting fatigue and their correlation to serum cytokines in patients with SLE and pSS and healthy volunteers (HV). A panel of circulating cytokines, chemokines and growth factors was compared between groups, correlated to the level of fatigue and within SLE and pSS to global disease activity. The objective was to identify cytokines reflecting the degree of fatigue, which could be exploited as biomarkers and therapeutic targets.

Methods: We performed a cross-sectional study on subjects included in the Swiss SLE Cohort Study (SSCS). All subjects were evaluated clinically and had a serum sample taken. Fatigue was assessed by FAS (Fatigue Assessment Scale) and by the vitality subscale (VT) of the Med-ics Outcomes Study 36-Items Short Form Healthy Survey. Clinical activity in SLE and pSS patients was determined by a 4-point Likert-scale Physician’s Global Assessment (PGA). SLE activity was assessed with the SLE Disease Activity Index score with the Safety of Estrogens in SLE National Assessment modification (SELENA-SLEDAI). Serum cytokines were assessed by multiplex bead array analysis (ProcartaPlex, Thermo-fisher Scientific, USA). P values were adjusted for multiple comparisons.

Results: Fifty-six patients with SLE, 18 with pSS and 18 healthy volunteers (HV) were included between November 2015 and June 2016. There were no significant differences between groups regarding to age, gender and body mass index (BMI), FAS and VT correlated strongly (Spearmann’s rho -0.87, p<0.01). FAS was significantly higher in patients than in healthy individuals (median FAS 23 [16-31], 28[20.5-35], 17 [15-27] in SLE, pSS and HV respectively; p=0.02). Patients with SLE and pSS displayed higher serum levels of interferon (IFN)-gamma (median [IQR] 10.29 [4.94-15.25] pg/mL in SLE, 9.64 [6.25-13.86] pg/mL, undetectable in HV; p<0.01). Interleukin (IL)-10 also was only detected in pSS and SLE. Hepatocyte growth factor (HGF) was more expressed in patients than in controls (p< 0.01). The levels of most other cytokines (IFN-alpha, IL-1 alpha, IL-2, IL-4, IL-6, IL-17, IL-21 and IL-23) were not detectable. Only HGF displayed a significant correlation with FAS (P Pearson 0.29, p< 0.01).

Conclusion: Patients with SLE and pSS display a molecular pattern of chronic inflammatory conditions, with higher serum levels of IFN-gamma, IL-10 and HGF. The latter two are both involved in regeneration and tissue repair (“scar signature”).[2] HGF levels correlated independently with...
the degree of fatigue. More studies are needed to understand the role of this pleiotropic growth factor in self-perceived fatigue in SLE and pSS.

SAT0206 FACTORS ASSOCIATED WITH HYDROXYCHLOROQUINE USE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH END STAGE RENAL DISEASE
Maria Salgado Guerrero1, Alejandra Londono Jimenez2, Chisanna Dobrowolsky2, Shudan Wang2, Anna R. Broder2. 1Jacobi Medical Center/Albert Einstein College of Medicine, Internal Medicine, Bronx, NY; United States of America; 2Montefiore Medical Center/Albert Einstein College of Medicine, Rheumatology, Bronx, NY; United States of America

Background: Hydroxychloroquine (HCQ) use in SLE has been associated with a lower risk of end-organ damage, SLE flares, and thrombosis, with potential mortality benefit among SLE with end stage renal disease (ESRD)1, 2, 3. However, fewer than 30% of SLE continue HCQ after ESRD onset4. It has not been studied what factors are associated with HCQ use after ESRD. Understanding these factors may inform future studies assessing the safety and efficacy of HCQ in SLE-ESRD. However, fewer than 30% of SLE continue HCQ after ESRD. Understanding these factors may inform future studies assessing the safety and efficacy of HCQ in SLE-ESRD.

Methods: We performed a retrospective chart review of SLE patients with ESRD at a single tertiary care center between 2010-2017. All included patients met ACR and/or SLICC criteria for SLE and had at least one visit with rheumatology, nephrology, or primary care, before and after the development of ESRD. SLE-related symptoms, serologic markers of disease activity, and rheumatology visits were identified, both pre- and post-ESRD onset. Transplanted patients were excluded at the time of their first renal transplant.

Results: A total of 69 patients were included, 58 had pre-ESRD data. Of these patients, 33/58 (57%) were taking HCQ prior to ESRD onset. Following the diagnosis of ESRD, 40/58 (53%) were prescribed HCQ within six months after ESRD onset. Of these, 60/69 (%) were taking HCQ prior to ESRD onset. The last documented visit, and one patient initiated HCQ six months after ESRD onset (prescribed by a rheumatologist). At the last documented visit, 35/69 (51%) had an active HCQ prescription.

Patients taking HCQ were younger, more likely to be followed by a rheumatologist, had a higher frequency of documented arthritis, higher frequency of corticosteroid use and immunosuppressive medication use (Table 1). A history of oral ulcers, cytopenias, and elevated levels of dsDNA at any point (either pre or post-ESRD onset) was not significantly associated with HCQ use at the last visit.

Conclusion: HCQ is more likely to be continued among patients with signs of persistently active SLE. HCQ was more likely to be prescribed by a rheumatologist and was associated with the presence of arthritis. Limited systemic evaluation and documentation by the different providers may have resulted in under-reporting of some of the SLE symptoms. However, these findings reflect the “real-world” experience with HCQ use after ESRD in a large tertiary care center.

SAT0207 DEVELOPMENT OF QUESTIONNAIRES TO ASSESS HEALTHCARE UTILIZATION AND ACCESS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME AT THE DIAGNOSIS AND DURING THE DISEASE COURSE
Chiara Seghiri1, Chiara Baldi2, Themis Exarchos2, Luca Quaruccio5, Elena Bartoloni Bocci1, Roberta Priori3, Francesco Carubbi2, Francesco Ferro2, Saviana Gandolfo4, Stefano Bombardieri2, Salvatore De Vita2, Athanasios Tzioufas3, 1 Sant’Anna, Pisa, Italy; 2University of Pisa, Pisa, Italy; 3University of Ioannina, Ioannina, Greece; 4University of Udine, Udine, Italy; 5University of Perugia, Perugia, Italy; 6University of Roma, Roma, Italy; 7University of L’Aquila, L’Aquila, Italy; 8University of Athens, Athens, Greece

Background: The geographic variation in healthcare spending, utilization and quality, across and within countries is well documented. Objectives: In this study, we develop and validate a tool to collect comparable information in Europe to establish practice profiles in the disease management and treatment of patients with Primary Sjögren’s Syndrome (pSS). Methods: Two questionnaires, one to newly diagnosed patients and one for patients at their follow-up visits, have been developed and validated through a pilot survey. The questionnaires aim to assess the pSS patients’ experience and satisfaction with the primary care and specialist services received. The questionnaires consist of 30 items and collect patient-reported data on: type and intensity of treatments and services received, costs, patients’ satisfaction, patients’ overall health and socio-demographic characteristics. A narrative-based medicine section is also included to explore patients’ journey to pSS diagnosis. The questionnaires are administered to a sample of pSS patients attending >20 clinical centers within the European Horizon2020 project “Harmonics”. Additionally, a short questionnaire is administered to the specialists of the clinical centers to collect data on their organization.

Results: Preliminary results of pilot survey based on questionnaires administered to 164 pSS patients (157 F; 7 M, mean (SD) age = 60 (12.2) years) from 5 clinical centers have been analyzed. The majority of the respondents had a primary or secondary school (59%). Both the total number of specialists involved in the care other than the rheumatologist and the number of treatments received in the last 12 months before the interview varies among patients and across centers (p<0.001). Although, as expected, the most frequently involved specialists were the ophthalmologist (90%) followed by the gynecologist and the dentist. Additionally, patients with lower education have attended on average less specialists (p<0.001). Findings from the survey to clinicians also show significant geographic variations in the organization of the care to pSS in the participating centres and in the level of integration among different professionals and care settings. On average, 4 professionals (i.e. clinicians and nurses) per centre are involved in care of pSS patients although with significant differences among centre (min=1, max=10) also in the mix of the staff. In 80% of the centres clinicians use written documentation to exchange patients’ information, followed by periodic meetings with colleagues (58%) and phone calls with the family doctor (37%). In 54% of the centres the newly diagnosed patients are provided with information pamphlet and...
patients health education is performed in 35% of the center through periodic individual meetings.

Conclusion: Preliminary results confirm that the questionnaire is a valid tool to assess and compare patterns of care for pSS patients in terms of the use of treatments and services across and within providers. Once available the questionnaires from all the centres, patient-reported data linked with information from clinical records will allow to measure the patients journey more comprehensively along the care pathway and to identify best practices in terms of the level of perceived quality and the way the care is delivered and, moreover, opportunities for increasing value for patients.

TEN-YEAR OVERALL SURVIVAL AND STANDARIZED MORTALITY RATIO IN THE LONGEST SINGLE CENTER COHORT OF PATIENTS WITH PRIMARY SJOGREN’S ASSOCIATED LYMPHOMAS

Marina Sikara, Dimitris Zogas, Ourania Argyropoulou, Arietta Papageorgiou, Athanasios Tzioufas, Michael Voulgarelis, Athens School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece

Background: The development of non-Hodgkin’s Lymphoma (NHL) in Sjögren’s syndrome (SS) contributes to an inferior survival compared to SS patients without lymphoma.

Objectives: To record the long-term outcomes of SS patients with and without NHLs with 10-year survival curves and standardized mortality ratio (SMR) for first time in the literature.

Methods: In order to estimate the effect of NHL development in SS outcome, we expanded the follow-up time of the previously published cohort of SS-associated NHL cases and we retrospectively compared them with age- and sex-matched SS patients without NHL from our center. As outcome end-points, overall and event-free survivals (OS and EFS, respectively) were used. An event was defined as disease relapse or progression, histological transformation or death. Ten-year survival plots and SMR compared to General Greek population was calculated. The impact of rituximab in the outcome of SS-associated NHL treated patients was also studied.

Results: From a total of 712 consecutive SS patients who fulfill the 2002 AECG classification criteria for Sjögren’s, 77 were diagnosed with NHL. The prevalence of MALT and DLBCL lymphoma in the total SS cohort was 7.1% and 1.7% respectively. The median follow-up time from SS diagnosis was 16.67 years (range: 4.00-38.91 years) corresponding to a total of 1263.71 person-years for SS-associated NHL patients and 17.92 years (range: 2.00-34.00 years) with a total of 1380 person-years for SS patients without NHL. The median time from SS to lymphoma diagnosis was 5.5 years (range: 0.38 years) and the median follow-up time after lymphoma diagnosis was 8.2 years (range: 0.1-26.2 years) months. During follow-up, 15 patients from the SS-NHL group died, 11 of whom due to lymphoma-related causes, while only 2 patients died in the control group (one due to advanced ovarian cancer and one due to cardiac arrest) (p=0.0013). Patients with SS associated NHL displayed a significantly higher risk of death (HR=5.95, 95%CI: 1.66 - 21.38, log-rank test, p=0.0006) compared to their counterparts without lymphoma. The corresponding age-adjusted SMR of SS with and without NHLs versus the general Greek population was 7.94 (95%CI: 6.82-9.06) and 1.06 (95%CI -0.06-2.18) respectively. In addition, 18 patients with SS-associated NHL (23.38%) experienced lymphoma relapse or progression and 2 (2.6%) lymphoma transformation; The vast majority of recorded events (27 of 29 events) were observed within the first ten years from NHL diagnosis and DLBCL was associated with the worst outcome; The 10-year EFS% and OS% for DLBCL was 22.22% and 48.61% respectively while for MALT were 68.15% and 82.03%, respectively. Interestingly, the introduction of rituximab in the anti-lymphoma chemotherapeutic regimens didn’t offer any long-term survival benefit.

Conclusion: Herein, we present the longest, to our knowledge, follow-up time of patients with SS-associated NHL; The majority of events that determine the morbidity and mortality of SS-NHL patients have already occurred within the first ten years from NHL diagnosis. In individuals with SS, the evolution of NHL was found to have a detrimental effect in patients’ survival. Among them, DLBCL patients experienced the worst outcome.

Disclosure of Interests: Marina Sikara: None declared, Dimitris Zogas: None declared, Ourania Argyropoulou: None declared, Arietta Papageorgiou: None declared, Athanasios Tzioufas Grant/research support from: ABBVIE, PFIZER, AMGEN, NOVARTIS, GSK, Michael Voulgarelis: None declared

A SIMPLIFIED APPROACH FOR SLE PATIENTS TO REPORT DISEASE ACTIVITY USING A REVISITED VERSION OF THE SWEDISH SYSTEMIC LUPUS ACTIVITY QUESTIONNAIRE

Susanne Pettersson1, 2, Vera Ilieva-Bäcklin7, Andreas Jonsen1, Iva Gunnarsson1, Estelle Trysberg2, Dag Leonard3, Christopher Siwal1, Elisabet Svenungsson1, Karolinska Institute, Department of Neurobiology Care Sciences and Society, Stockholm, Sweden; Karolinska University Hospital, Inflammation and Infection Theme, Karolinska University Hospital, Stockholm, Sweden; Karolinska Institutet, Karolinska University Hospital, Rheumatology Unit, Department of Medicine, Solna, Stockholm, Sweden; Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; Sahlgrenska University Hospital, Department of Rheumatology, Göteborg, Sweden; Academic Hospital, Rheumatology, Uppsala, Sweden; Linköping University, Rheumatology/Division of Neuro and Inflammation Sciences, Department of Clinical and Experimental Medicine, Linköping, Sweden

Background: The Systemic Lupus Activity Questionnaire (SLAQ) is a validated questionnaire, which captures patients’ assessments of SLE-related symptoms and disease activity (1). However, it is extensive and in a recent study we found that some questions were difficult to answer, added little information, or had poor correlation with physicians’ assessments (2). Thus, herein we revised the Swedish version of the questionnaire (SWE-SLQAR), building on previous results and we also asked patients for input. Our aim was to get an improved and shorter version, more suitable for clinical work and online registries. The original SLAQ includes 26 items, while SWE-SLQAR includes 20 items.

Objectives: We compared patients’ assessments of SLE disease activity, as reported in the SWE-SLQAR, with physicians’ assessments using SLE activity measure (SLAM) and SLE disease activity index (SLEDAI-2K). In addition, we evaluated the performance of the symptom items of SWE-SLQAR as compared to the corresponding items in SLAM.

Methods: Patients filled out SWE-SLQAR prior to physicians’ assessments. Correlations between SWE-SLQAR-total, subscales, (Symptom score, Patients global) and SLAM-excluding the 7 laboratory items (SLAM-nolab), SLAM and SLEDAI-2K as well as between the corresponding items in SLAM and SLE-DAQ, were evaluated using Spearman’s ρ.

Results: We included 101 patients, 85% women, median age 43 (IQR 22) years, disease duration 14 (IQR 15) years. Patients reported more symptoms than recorded by doctors. Correlations between patients’ and physicians’ assessments were for SLE-nolab: SWE-SLQAR total, ρ=0.674, Symptom score, ρ=0.670, and Patients global, ρ=0.667, as expected the correlations were lower for SLAM: SWE-SLQAR total, ρ=0.472, Symptom score, ρ=0.467, and Patients global, ρ=0.501. No correlations were found between patients’ and physicians’ assessments when using SLEDAI-2K (p>0.09 for all). Of symptom items fatigue (p=0.741), alopecia (p=0.695) and weight loss (p=0.517) showed highest degree of correlation. Notably, symptoms of dyspnea/pleuritic chest pain had no correlation between patients’ and physicians’ assessments (p=0.152, p=0.130).

Conclusion: We conclude that SWE-SLQAR performed equally well as SLAQ (2), demonstrating that it can be used to monitor disease activity. We encourage further use of SWE-SLQAR and recommend its implementation in clinical care, we believe it is especially well suited to support digital and telephone contacts. However further attention is needed to evaluate the discrepancy between physicians’ and patients’ evaluation of thoracic pain/symptoms.

Background: Sjögren syndrome (SjS) is an autoimmune disorder characterized by inflammation and destruction of exocrine glands. The presence of autoantibodies (AA) against the Ro52/TRIM21, an RNP complex binding to the stem-loop structure of human cytoplasmic RNA, might be relevant in the SjS pathology. It has been suggested that distinguishing between antibody reactivity against Ro60 and Ro52/TRIM21 could be helpful in terms of evaluating clinical course, features and even pre-symptomatic stages of the disease (1).

Objectives: To evaluate the prevalence of anti-Ro52/TRIM21 antibodies in a cohort of patients diagnosed with primary SjS.

Methods: In this cross-sectional study we evaluated 179 patients with primary SjS according to the ACR classification criteria who had been admitted between December 2008 and December 2018 to our outpatient clinic. All patients had ANA titers higher than 1:320 (2) in at least two positive determinations for any pattern. ANA, anti-Ro52, anti-Ro60, anti-La and rheumatoid factor (RF) were tested by immunoblot (Euroimmun, Lübeck, Germany).

Results: In our cohort the median age at diagnosis was 57 years (range: 20–85 years) with a clear dominance of females (n=160, 89%). The most frequent reported ANA patterns were speckled (93%), while only few patients had a homogeneous (6%) pattern. 177/179 were positive for Ro60, and 52/179 for Ro52/TRIM21. Anti-La and rheumatoid factor (RF) were tested by immunoblot (Euroimmun, Lübeck, Germany).

Conclusion: Our results showed that anti-Ro52/TRIM21 but not anti-Ro60 is present in virtually all patients with SjS and had the most prevalent antibody reactivity. This finding needs to be considered in the current classification criteria of SJS (2), which include the presence of anti-Ro60, rather than anti-Ro52/TRIM21. Also, including the anti-Ro52/TRIM21 measurement in larger cohorts and longitudinal studies would also help us in improving the knowledge of its pathogenic role and to define of more focused diagnostic/therapeutic strategies.

3Hacettepe University, Faculty of Medicine, Cardiovascular Surgery, Ankara, Turkey

Background: Arterial aneurysmatic lesions are one of the unique features of Behçet’s disease (BD). However, it is difficult to determine which BD patients will develop an aneurysm.

Objectives: In this study, we aimed to determine the differences between BD patients with and without an arterial aneurysm.

Methods: Data of the 23 BD patients with an arterial aneurysm was published as an abstract in 2013 (1). We retrospectively reviewed the medical records of 441 patients with BD according to International Study Group (ISG) criteria between January 2013 and June 2018. Totally, we determined 45 BD patients with an arterial aneurysm. Six patients with isolated carotid and/or cranial arterial aneurysms who were followed by other clinics excluded from the analysis. Overall, 39 BD patients with an extracranial and extra carotid aneurysmal involvement studied in the data. Study regarding demographic features, clinical, laboratory and vascular imaging findings were collected.

Results: A total of 39 BD patients (Male: 76.9%) with an arterial aneurysm were analyzed in this study. Mean age, mean age of diagnosis and a median follow-up of patients were 40.9±11.0 years, 29.7±7.7 and 71.8 (2-186) months, respectively. The mean age at the onset of the arterial aneurysm was 36±11.5 years. The median time lag between the onset of BD and detection of an aneurysm was 63.6 (0-482) months. The prevalence of male patients in BD with aneurysms, without aneurysms and only mucocutaneous involvement was 76.9%, 52.3%, and 34.3%, respectively. Comparison of BD patients with and without an aneurysm shown in table 1. Multivariate analysis, having a venous thrombosis was the sole risk factor for the development of arterial aneurysm (OR 10.53, 95% CI 1.53-72.71) (Table). Distribution of aneurysms was shown in the figure. At the first diagnosis, a median number of the aneurysm was 1 (1-4), the median number of an aneurysm was 39 mm (10-80) and median diameter of an aneurysm was 39 mm (10-80) and 16 (41%) patients had more than one aneurysm. Type of the firstly detected aneurysm was as follows; 38.5% sacular, 17.9% fusiform, 15.4% pseudoa neurysm and 26% dissecting aneurysm. Aneurysm type was not known in 17% and only mucocutaneous involvement in 21% of BD patients.

Conclusion: Aneurysm was the diagnostic symptom in 25% of BD patients with an aneurysm. The median time lag between the onset of BD and detection of an aneurysm was almost 5 years. In aneurysm BD, there may exist sex dominance and having venous thrombosis is the most important risk factor. Although pulmonary arteries have an important role in the BD course, the involvement of the aorta and iliac arteries can be seen frequently.

APREMLAST IN REFRACTORY ORAL AND/OR GENITAL ULCERS IN BEHÇET’S DISEASE. MULTICENTER STUDY OF 49 CASES IN CLINICAL PRACTICE

Background: Oral and/or genital aphthous ulcers are the most common symptoms of Behçet’s disease (BD), and are often refractory to conventional treatment. The inhibitor of phosphodiesterase-4 Apramast (APR) has demonstrated efficacy in the treatment of these manifestations.

Objectives: To assess the efficacy and safety of APR in BD patients with oral and/or genital ulcers refractory to conventional treatment.

Methods: National multicenter open-label study on 49 BD patients treated with APR at maintained standard dose of 30 mg twice daily, with the initial 5-day titration schedule in 38 cases. The main outcome was achievement of oral and/or genital ulcers remission.

Results: We included 49 patients (35 women/14 men), mean age of 44.5 ±13.4 years. Before APR, all patients had received several systemic conventional and/or biological drugs: oral corticosteroids (n=45), colchicine (n=48), NSAIDs (n=21), methotrexate (n=27), azathioprine (n=23), cyclosporine (n=9), dapson (n=6), adalimumab (n=12), infliximab (n=8), tocilizumab (n=3), etanercept (n=3), sulfasalazine (n=2), cyclophosphamide (n=2) and/or others (pentoxifylline, thalidomide, mycophenolate mofetil, hydroxychloroquine, golimumab, 1 each). The main clinical symptoms for starting APR were oral (n=18) and genital (n=22) aphthous ulcers or both (n=29). After a mean follow-up of 8.3±6.8 months, most of the patients experienced main clinical improvement and prednisone dose was reduced or discontinued (TABLE). In this period of time, 31 patients developed any side-effect, most of them transitory: nausea (n=12), diarrhea (n=11),
SAT0216  PATIENT PERCEPTIONS OF PHYSICAL ACTIVITY AFTER A DIAGNOSIS OF GIANT CELL ARTERITIS: A SECONDARY ANALYSIS OF MULTINATIONAL QUALITATIVE DATA

Keziah Austin1, Emma Dures2, Celia Almeida3, Fiona Cramp3, Kate Gilbert3, Catherine Guly4, Catherine Hill5, Sarah Mackie5, Anne O’Brien5, Richard Watts7, Joanna Robson1.

1 Santa Chiara Hospital, Trento, Italy; 2 University of the West of England; 3 University of Leeds, Leeds, United Kingdom; 4 Keele University, Keele, United Kingdom; 5 University of East Anglia, Norwich, United Kingdom;

Background: Giant cell arteritis (GCA) is the most common vasculitis in the UK, with an incidence of 220 cases/million in adults over 50 years of age. The physical symptoms as well as the side effects of glucocorticoids may impact patients’ ability to exercise. Maintaining physical activity (PA) has been shown to be beneficial to disease activity in other inflammatory conditions, and is also a specific priority for GCA patients.

Objectives: To explore patient perceptions of physical activity in GCA.

Methods: A cross-sectional study of patients with proven GCA in the UK and three other European countries. Mixed methods approach using a survey and qualitative interviews. A thematic analysis of the qualitative data was performed.

Results: 127 patients completed the survey, and 15 interviews were conducted. Overall, patients reported significant barriers to PA, including fear of exercise and physical symptoms, lack of facilities, and limited time. Education, motivational interviewing, and personalised strategies may be beneficial components of an intervention to support physical activity in patients with GCA.

ARTERITIS: A QUALITATIVE STUDY

Jennie H. Best1, Ivan Nunez2, Kristina Woodburn3, Abby Breyer2, Mike Conway2, Margaret Michalska1, Genentech, Inc., South San Francisco, United States of America; 2 Azul Seven, Minneapolis, United States of America; 3 Azul Seven, Minneapolis, United States of America

Background: Giant cell arteritis (GCA) is the most common form of vasculitis. Diagnosis is difficult due to multiple presenting symptoms: headache, jaw and limb claudication, myalgia and visual impairment. Access to care may be delayed because often multiple providers are involved in the diagnosis of GCA and disease management. Treatment with high-dose glucocorticoids (GCs) can relieve symptoms and prevent vision loss, but GC-related adverse events are common; GCA often relapses once GCs are tapered.

Objective: To understand the GCA patient care pathway and unmet needs in GCA through in-depth patient interviews.

Methods: US patients with GCA were recruited through outreach to physicians and The Vasculitis Foundation, which used email newsletters and social media to recruit 50% of participating patients. Extensive individual interviews with patients were conducted by qualitative researchers by phone or in person and explored patients’ perspectives and experiences from the onset of GCA symptoms to diagnosis and disease management. Patients were asked open-ended questions and encouraged to share their stories to provide additional insights into the patient journey and their individual perspectives. The qualitative data collected were analyzed using human-centered design methodology, including patient typologies (personas: optimist, fearful, stoic or despondent), forced temporal journey maps, forced semantic zoom (stakeholder system mapping) and affinity mapping for pattern recognition of unmet needs.

Results: A total of 28 patients were interviewed; 23 (82%) were women and mean age was 69 years (Table). The number of patients in each persona category is shown in the Table. Stoic and optimist personas had medium to high levels of self-advocacy and a positive-engaged attitude about their condition, while fearful and despondent personas had low levels of self-advocacy with disengaged/negative attitudes toward their condition. Patients often ascribed their milder GCA symptoms to causes such as stress and did not consult a physician until they developed moderate to severe symptoms, such as persistent headache, jaw pain or visual disturbances. Patients with existing inflammatory disorders were less likely to share symptoms of GCA unless the symptoms substantially worsened. In most cases, physicians diagnosed GCA based on abnormal erythrocyte sedimentation rate, often followed by a temporal artery biopsy. After diagnosis of GCA, all patients received GS with little information on the chronicity of GCA. Few patients were offered treatment alternatives to GCs. Overall, patients managed their GCA independently, with moderate support from friends or family, and sought to balance relief of GCA symptoms with the adverse effects of GCs. Patients concentrated on tapering and discontinuing GCs, with less concern about relapse. Furthermore, patients who were most uncomfortable with the adverse effects of GCs often waited until their GCA symptoms became debilitating before telling their physician. Almost all patients reported searching for a support group after the diagnosis.

Conclusion: Patients with GCA experience adverse effects from GCs and remain focused on reducing their GC dose. For those with inflammatory comorbidities, diagnosis of GCA is another burden in a debilitating journey that results in a sense of disempowerment and resignation toward their condition and paucity of therapeutic options. Patients with GCA want a clearer understanding of treatment options and access to support groups. Patients’ attitudes and self-advocacy vary depending on their personas; recognizing these personas may help HCPs coordinate patient care. Increased awareness of GCA among patients and HCPs may accelerate the path to diagnosis and treatment, and emerging therapies may help reduce GC burden.

EFFICACY AND SAFETY OF TOCILIZUMAB IN GIANT CELL ARTERITIS INDEPENDENTLY OF THE INITIAL PREDNISONE DOSE

Background: Tocilizumab (TCZ) has been approved for the treatment of Giant Cell Arteritis (GCA). It showed to be effective to induce remission, prevent relapses and decreases the cumulative prednisone dose. However, the glucocorticoids are the mainstay in the acute treatment of GCA.

Objectives: Our aim was to compare the efficacy and safety of the initial dose of prednisone at the onset of TCZ treatment.

Methods: Retrospective, multicenter study on 134 patients with GCA in treatment with TCZ. We compared two subgroups of patients according to the initial dose of prednisone at TCZ onset. Clinical efficacy, analytical improvement and safety was studied.

Results: We studied 134 patients (101 w/33 m) and made a comparative study between 2 groups: a) TCZ and ≤ 15 mg of prednisone; 68 (50.7%) cases, and b) TCZ and > 15 mg of prednisone, 66 (49.3%) patients. It is summarized in Table 1. It was not a statistical significance according to age, sex and evolution time of disease. In the group receiving > 15 mg of prednisone, the patients presented more visual involvement (p<0.001) at TCZ onset. In terms of prolonged remission and relapses no significant difference was seen between both groups. The risk of presenting adverse effects (11.8% vs 36.4%) and severe infections (4.4% vs 19.7%) was related with the prednisone dose, being more frequent in the group with > 15 mg of prednisone (p=0.001 and p=0.006, respectively).

TABLE 1

<table>
<thead>
<tr>
<th>TABLE 1</th>
<th>PREDNISONE ≤ 15 mg (n=68)</th>
<th>PREDNISONE &gt; 15 mg (n=66)</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Conclusion: According with our results, we can conclude that TCZ is equally effective in terms of prolonged remission and relapses, with ≤ 15 mg of prednisone at treatment onset. Being the most important data, the higher risk to develop adverse effects, as well as infections with higher doses of prednisone.

USE OF TOCILIZUMAB IN AORTITIS. A MULTICENTER STUDY OF 79 PATIENTS

Rheumatology, Internal Medicine and Pathology Units, Santander, Navarra, Madrid, Torrelavega, León, Pontevedra, Barcelona, Mondragón, Santiago de Compostela, Vigo, Alicante, Lugo, Badalona, Palencia, Alcázar de San Juan, A Coruña, Granada, Bilbao, Avilés, Castellón, Salamanca, Zaragoza, Valencia, Menorca, Málaga, Ávila, Gijón, Guipuzcoa, Tenerife, Seville, Lérida, Spain

Background: Aortitis can be idiopathic or associated with other conditions. It is frequently refractory to conventional immunosuppressive therapy. Tocilizumab (TCZ), an anti-IL-6 receptor antibody seems to be effective and safe.

Objectives: Our aim was to assess the efficacy and safety of TCZ at short and long follow-up in a series of patients with Aortitis.

Methods: Retrospective, multicenter study of 79 patients diagnosed of inflammatory aortitis based on imaging techniques (PET/CT, CT angiography and/or MR angiography).

Results: Studied 79 patients (61 w/ 18 m), 59 (74.7%) cases were Aortitis secondary to Giant Cell Arteritis (GCA), while 20 (25.3%) were Aortitis secondary to Polyarteritis Nodosa (PAN). TCZ proved to be effective in both pathways, allowing clinical and analytical improvement, as well as a reduction of corticoid dose, without increasing the risk of relapse. However, the improvement in imaging techniques seems to be slower.

Conclusion: Our results show that idiopathic aortitis occurs in younger patients compared with aortitis secondary to GCA. TCZ proved to be effective in both pathways, allowing clinical and analytical improvement, as well as a reduction of corticoid dose, without increasing the risk of relapse. However, the improvement in imaging techniques seems to be slower.

OFF-LABEL USE OF BIOLOGICAL THERAPIES IN RELAPSING AND/OR REFRACTORY POLYARTERITIS NODOSA

Alice Canzian1, Omer Karadag2, Anne Corint3, François Maurier4, Silvia Saritore5, Laure Denis6, Sébastien Sangés7, Claire De Moreuil8, Cécylle Audrey Duret9, Stephanie Durup10, Marie-Josée Rouzaud11, Carlo Salvarani12, Bruno Flusin13, Franco Schiavon14, Lorenzo Dagna15, Fabrice Bonnet16, David Jayne17, Loïc Guéville18, Benjamin Terrier19,1, University of Parma, Parma, Italy; 2Hasselt University, Arkara, Tunisia; 3CHU de Bordeaux, Bordeaux, France; 4Private Metz Hospital, Metz, France; 5IRCCS San Raffaele Hospital, Milan, Italy; 6CHU de Clermont-Ferrand, Clermont-Ferrand, France; 7CHU de Lille, Lille, France; 8CHU de Brest, Brest, France; 9CHU de Lyon, Lyon, France; 10Paris, Paris, France; 11Université de Modena e Reggio Emilia, Reggio Emilia, Italy; 12University of Padova, Padova, Italy; 13University of Cambridge, Cambridge, United Kingdom; 14Université Paris Descartes, Paris, France; 15Paris Descartes University, Paris, France

Background: Polyarteritis nodosa (PAN) is a rare systemic necrotizing vasculitis of medium- and small-sized arteries, not associated with anti-neutrophil cytoplasmic antibodies (ANCA). Conventional treatments include glucocorticoids (GCs) for non-severe disease and a combination of GCs and immunosuppressive agents for severe disease. Nevertheless, some patients have refractory and/or relapsing disease.

Objectives: We examined the use of off-label biological therapy for relapsing/refractory PAN.

Methods: This retrospective European collaborative study included patients with PAN meeting ACR criteria and/or Chapel Hill Consensus Conference 2012 definitions. Treatment efficacy and safety were recorded. Remission was defined as the absence of vasculitis manifestations (BVAS = 0) with a prednisone dose ≤5 mg/day. Partial response was defined as a BVAS = 0 with a prednisone dose between 6 and 10 mg/day.

Results: Fifty-one patients (24 men, 27 women; median age 51 years) were included. Eighteen (35%) patients received TNF-alpha blockers, 16 (31%) received rituximab (RTX), 9 (18%) tocilizumab (TCZ), and 8 (16%) other biologics (including alemtuzumab in 2 and abatacept in 1). Previous treatments were: GCs in all patients, cyclophosphamide (61%), azathioprine (53%), methotrexate (45%) and mycophenolate mofetil (47%). At inclusion, median BVAS was 5 (range 0-18), including 5 (2-12) in the TNF-alpha blockers group, 5 (2-12) in the RTX group and 4 (0-6) in the TCZ group. After median follow-up of 34.4 months (IQR 21.5-59.5), remissions, partial responses and treatment failure, respectively, were noted in 41%, 6% and 53% for TNF-alpha blockers recipients, 25%, 12% and 63% for RTX recipients, and 57%, 0% and 43% for TCZ recipients. No remission was noted in patients treated with anakinra, alemtuzumab and abatacept. Median BVAS dropped to 3 at 6 months, 0 at 12 months and 0 at last follow-up in the TNF-alpha blockers group, to 3.5, 0 and 2 in the RTX group, respectively, and 0, 0 and 0 in the TCZ group. A GC-sparing effect seemed more important with TNF-alpha blockers and TCZ. Median GCs dose decreased from the baseline 15 mg/day to 10 at 6 months, 5 at 12 months and 5 at last follow-up in the TNF-alpha blockers group, from 15 mg/day to 10 at 6 months, 5 at 12 months and 5 at last follow-up in the RTX group, and from 15 mg/day to 7 at 6 months, 5 at 12 months and 5 at last follow-up in the TCZ group. Four (22%) patients stopped TNF-alpha blockers because of allergic reaction in one and refractory disease in 3. Six (38%) stopped RTX because of refractory disease. Finally, 4 (44%) stopped TCZ because of adverse effects.
events in 2 (testicular abscess and worsening renal failure) and refractory disease in 2.

Conclusion: The results of this study suggest that TNF-alpha blockers and TCZ may achieve higher rates of remission and GC-sparing in relapsing and/or refractory PAN than other biologics. Our data warrant further study to confirm or not these findings.

SA0223 COOPERATION OF T FOLLICULAR HELPER CELLS AND B CELLS IN TERTIARY LYMPHOID STRUCTURES IN TAKAYASU ARTERITIS

Desbois Anne-Claire1, Anna Maciejewski-Duval2, Paul Reginier2, Valentin Quinou3, Clod Comarmond3, Hélène Vallet3, Patrick Buret3, Pierre Fourrel4, Michele Rosenzwag5, David Klatzmann6, Fabien Kossak6, Marlène Garido7, Guillaume Darrasse-Jèze8, Patrice Bacouë9, David Saadoun10, 1GHPS, Paris, France; 2Groupe Hospitalier La Plète Salpêtrière, Paris, France; 3HÉGIP, Paris, France

Background: Takayasu's arteritis (TA) and giant cell arteritis (GCA), the two most common types of large vessel vasculitis (LVV), are characterized by an inflammatory granulomatous infiltrate mainly located in the media and the adventitia. However, distinct histological features of the immune response are poorly known.

Objectives: To investigate distinct pathological mechanisms of the immune response in patients with GCA and TA.

Methods: We performed comparative immunohistochemistry analysis of aorta of GCA and TA patients. We performed microarray gene analysis of purified CD4+ T cells of TA and GCA patients. Reverse transcriptase PCR, flow cytometry analysis and cell culture were used to investigate T and B cells subpopulations in 54 patients with TA, 52 with GCA and 60 controls.

Results: We found higher proportion of tertiary lymphoid structures composed of CXCR5+ CD4+, PD-1+ and CD20+ cells in inflammatory aortic lesions in TA as compared to GCA. We demonstrated increased proportion of aortic B cells in TA.

We next evaluated differentiation of circulating CD4+ T cells in both diseases. Among circulating T cells, seven genes differentially expressed in CD4+ T cells of TA compared to GCA patients, we identified a specific “T follicular helper” (Thf) signature in TA patients. We also found a specific Tfh signature in TA patients. Flow cytometry analysis confirmed increased circulating Thf, defined as CXCR5+ CD4+ T cells, in TA patients as compared to GCA and healthy donors (HD) [median of 15.4 (10.30-8.1%) versus 5.3 (1.4; 12.2%) and 9.7 (5.6; 12.5%) (-p<0.0001 and -p=0.0001)] in TA, GCA and HD, respectively. Among Tfh subpopulations, Thf-17, CXCR5+ CXCR6+, CXCR3- CD4+ cells, were specifically increased in TA. Functionally, CXCR5+ CD4+ T cells of TA patients helped B cells to differentiate into memory cells, to proliferate and to secrete type G immunoglobulins.

We sequenced the TCR repertoire αβ in CD3+CD4+CXCR5- and CD3+CXCR5+ cells, in aortic and blood samples from 2 patients. In both patients, we identified oligoclonal profile of TCR repertoire only for aortic CXCR5+ cells, suggesting antigenic selection of CXCR5+ CD4+ T cells.

Conclusion: We provide evidence of the presence of tertiary lymphoid structures composed of Tfh and B cells in TA aorta. We identified a specific Tfh signature in circulating CD4+ T cells that distinguishes TA and GCA patients. The key cooperation of Tfh and B cells in TA and the oligoclonal repertoire of CXCR5+ CD4+ T cells strongly suggest the role of antigenic trigger.

SA0222 FACTORS ASSOCIATED WITH DAMAGE PROGRESSION IN BEHÇET’S SYNDROME UVEITIS

Yilmaz Ozyazgan1, Didar Ucar1, Mustafa Ergoçoğlu2, Yesim Cigüzel2, Giden Hasmeci3, Sebahattin Yurdakul2, Vedat Harmuyun3, Izet Fresko5, Melike Melektoglu4, Emire Seyahi4, Serdal Ugurki4, Hasan Yazici4, Istanbul University – Cerrahpaşa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey; Istanbul University – Cerrahpaşa, Cerrahpaşa Medical Faculty, Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: Uveitis in Behçet’s syndrome (BS) follows a recurrent disease course with inflammatory exacerbations causing damage in the uvea, retina and optic nerve even with treatment. Frequent attacks and posterior involvement are considered as predictors of poor visual outcome.

Objectives: The aim of this study is to delineate the predictors of damage in more detail using a standard screening method among a group of BS patients with long term regular follow-up.

Methods: Patients with uveitis who were registered in our multidisciplinary BS clinic between 1990 and 2018 were screened. Among these, 50 patients who were followed for at least 10 years, who were regularly seen in our clinic at least once in every 4 months, who did not have > Grade 2 damage at baseline, and who represented different levels of damage severity during the last visit (between Grade 0 and 5) were selected. The damage severity was graded according to a validated damage grading instrument (5-worst) specifically developed for BS uveitis (Ozyazgan et al. in preparation). One patient was later excluded because it was realized that he did not fulfill these criteria. A standard form was used for retrieving data on demographics, baseline and final visual acuities, number and localization (anterior/posterior/panuveitis) of attacks during follow-up, presence of retinal inflammation, retinal hemorrhage and hypopyon uveitis. Candidate factors for damage progression were compared between patients who had a progression in damage score and those who did not.

Results: 98 eyes of 49 patients (M:F=35:14, mean age at baseline 27.8 years, mean follow-up duration 20.9±5.5 years, mean number of visits 79±32.4) were evaluated. The mean visual acuity was 0.02±0.08 at baseline and 0.47±0.52 at the final visit. The mean number of attacks was 13.2±9.4. Damage grades at baseline were Grade 0 in 79, Grade 1 in 16 and Grade 2 in 3 eyes. Damage grades at final visit were Grade 0 in 15, Grade 1 in 21, Grade 2 in 32, Grade 3 in 12, Grade 4 in 10 and Grade 5 in 8 eyes. There was damage progression in 81/98 eyes at the final visit. Isolated anterior uveitis attacks were not associated with progression of damage (2.5±2.9 vs 2.8±5.5; p=0.7). Parameters that were significantly more frequent among patients with damage progression were: number of attacks (14.5±10.8 vs 23.3±12.3; p=0.008), number of posterior attacks (0.4±1.2 vs 6.5±4.9; p<0.001), number of panuveitis attacks (0.8±3.1 vs 6.6±5.0; p<0.001), number of attacks with severe vitrous opacity preventing examination of the retina (0 vs 1.4±1.9; p<0.001) and retinal hemorrhages in the arcuate area (0.1±0.2 vs 0.7±1.4; p<0.001), and the number of hypopyon attacks (0.2±1.0 vs 0.9±1.3; p=0.019).

Conclusion: This study confirmed that the anterior uveitis attacks were not associated with progressive damage in BS, whereas posterior and panuveitis attacks, attacks causing severe vitreous opacity, retinal infarcts and hemorrhage in the arcuate area and hypopyon attacks are important predictors of damage. Patients showing these features should be treated more aggressively.

SAT0224 PRESENTATION, MANAGEMENT AND OUTCOME OF ANCA ASSOCIATED VASCULITIDES IN ITALY: A 20-YEAR FOLLOW-UP STUDY

Mara Felletti, Roberto Padoan, Mariagrazia Lorenzin, Augusto Ortolan, Franco Schiavon. Rheumatology, Unit, University of Padova, Italy, Department of Medicine DIMED, Padova, Italy

Background: ANCA associated vasculitis (AAV) are systemic diseases with a wide spectrum of clinical presentation and organ involvement.

Objectives: To analyze presentation, management and 5-years-outcomes of AAV patients diagnosed between 2000 and 2018 in the monocentric cohort of Padova Vasculitis Center.

Methods: We retrospectively collected all AAV patients diagnosed between 2000 and 2018 and followed in the Vasculitis Center of Padova University. We focused on demographic and clinical features at baseline, first line immunosuppressive (IS) treatment, 6 months mortality, 5-years-relapse rate and survival rate.

In the analysis, we kept separate eosinophilic granulomatosis with polyangiitis (EGPA) from granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA).

Results: We identified 171 patients (F/M 93/78) with AAV diagnosed since 2000 (61 between 2000-2010 and 110 between 2011-2018, % of increase in diagnosis rate +183%): 82 (48%) were GPA, 28 (16%) MPA and 61 (36%) EGPA. The patients were mostly Caucasian (98%), with a mean age at diagnosis of 58±16.1 years, slightly younger if diagnosed in the second decade (2010-2018) than in first decade (2000-2010) (59.5±16.6 years vs 61±14.7 years, p=0.049). ANCA were tested in 163 patients: 23% ANCA negative, 37% cANCA/PR3, 39% pANCA/MPO and 1% double positive.

GPA/MPA patients were mostly ANCA positive at diagnosis (96/110 patients), in particular we counted 12 (15%) GPA/ANCA negative patients, 55 (68%) GPA-PR3, 13 (16%) GPA-MPO, 1 GPA with double positivity while MPA resulted only ANCA positive, 22 (82%) MPA-MPO and 5 (19%) MPA-PR3. In EGPA group, only 28/54 presented with ANCA positivity, all p-ANCA/MPO specificity.

Disease severity at diagnosis was assessed only in GPA/MPA patients: 12/101 limited disease, 34 early systemic, 29 generalized and 26 severe. In particular, GPA/MPA more frequently presented with systemic symptoms (76%), ENT and lung involvement (respectively 62% and 66%). Renal vasculitis was reported in 65% of patients with a mean eGFR of 50.2±39.6 ml/min. Moreover, we registered 17 alveolar haemorrhages, 4 cardiac involvement and 3 gastrointestinal (GI) disease. EGPA patients, instead, presented more frequently with ENT (85%) and lung involvement (96%) (mostly uncontrolled asthma and pulmonary infiltrates), 31 (54%) EGPA presented nerve involvement (4 with CNS involvement) and 9 (16%) with cardiac involvement. Interestingly, no renal or GI vasculitis was reported. The first line IS treatment administered was: cyclophosphamide (CYC) in 66 (38%), rituximab (RTX) in 14 (8%), azathioprine (AZA) in 27 (16%), methotrexate (MTX) in 25 (14%) and mycophenolate (MMF) in only 5 (3%).

Mortality rate at 6 months in all cohort resulted of 1.2% (2 event), while the 5-years survival calculated with Kaplan Meier method was 94.3% (8 events). All deaths occurred in the GPA/MPA group. A relapse occurred in 36% of patients, with a significant higher frequency in GPA/MPA than in EGPA (46.3% vs 17%, P=0.017).

Conclusion: Our cohort is characterized by significant higher rate of AAV diagnosis in the last decade and this could reflect the increasing incidence and prevalence reported in literature. Interestingly, GPA diagnosis, especially with CANCA/PR3 specificity, was prevalent in our cohort despite some authors reported an higher prevalence of MPA in Mediterranean area. Finally, EGPA confirmed a better outcome at last follow up than GPA and MPA, but we noted that no renal and GI involvement was observed in our EGPA patients.

SAT0225 TARGETED SERUM METABOLIC PROFILE IN PATIENTS WITH TAKAYASU ARTERITIS

Dinesh Kumar1, Harikrishnan Gangadharan Nair2, Avinash Jain2, Anupama Guleria1, Umesh Kumar1, Durga Misra1, Ramnath Misra1. CBMR, Lucknow, India, Sanjay Gandhi Post graduate Institute of Medical Sciences, Clinical Immunology, Lucknow, India

Background: Takayasu arteritis (TAK) is a chronic inflammatory arteritis that mainly affects aorta and, its major branches. Often the course is unpredictable and it remains a challenge to assess disease activity despite the availability of acute phase reactants and imaging modalities. Management heavily relies on physician global assessment. Analysis of serum metabolites using nuclear magnetic resonance spectroscopy is a promising exploratory approach towards identifying new biomarkers in TAK which may cast some light on disease pathogenesis and disease activity.

Objectives: Aim of the study was to evaluate the performance of serum amino acids as determinants of disease activity in TAK.

Methods: Patients with TAK fulfilling ACR 1990 criteria were enrolled and disease activity assessed using ITAS2010 and ITAS-A[2]. Samples were analysed using 1D 1H 800 MHz Nuclear magnetic resonance spectrometer equipped with a Cryoprobe (at 300 K). The spectra were processed and the concentration of amino acids were measured with respect to internal reference metabolite formate assuming its concentration 10 µM in commercial software program CHENOMX (www.chenomx.com) and the resulting normalized values were compared using Tukey’s multiple comparison test and diagnostic potential was evaluated using receiver operating characteristic (ROC) curve analysis.

Results: 45 active TAK patients with ITAS-A ≥4 and 59 inactive TAK patients with median age 27 years [IQR, 22-35 and IQR, 23-37 years respectively] were enrolled. Female to male (F:M) ratio was 3.5:1 and 4.9:1 and median duration of illness 5 [IQR, 2-9] years and 3 [IQR, 1-6] years in active and inactive group respectively. Majority had class V disease. 43 individuals served as health control (HC) with mean age 30±4 years and F:M ratio of 4.3:1. Serum levels of Phenylalanine (Phe), Tyrosine (Tyr), Histidine (His), Valine (Val) and Alanine (Ala) were found to be decreased in TAK patients suggesting augmented utilization in the immune-metabolic pathways mainly to replenish the energy demand and self-repair mechanism under conditions of inflammation and oxidative stress. An analysis of amino acids ratio revealed significantly higher His/Tyr, Ala/Tyr and Val/Tyr ratio in HC when compared to active TAK patients. Ratio were lower in active TAK when compared to inactive TAK patients but only Val/Tyr ratio was significant (AUCRO, 0.64 and p, 0.01). Ratio served as a gradient with lowest value in active disease and gradually increasing and moving towards HC as disease was getting controlled.

Figure 1: Comparison of various amino acid ratio in active and inactive TAK patient with respect to healthy control. Ratio served as a gradient with lowest in active disease and gradually moving towards HC as disease was getting controlled.
Conclusion: The present targeted NMR based metabolomics study demonstrated that the serum metabolic profiles of amino acid may help guide therapy and ratio of Val/Tyr can differentiate active from inactive patients. However, future studies on large patient cohorts are required to establish its clinical utility.

SAT0226
INFILXIMAB FOR THE TREATMENT OF REFRACTORY POLYARTERITIS NODOSA
Shira Ginsberg1, Izlach Rosner1, Gile Sobodin1, Michael Rosenbaum1, Lisa Kaly1, Nizar Jiries1, Nina Boulan1, Abid Awisat1, Haya Hussein1, John Greenwood4, Maya Buch2,3, Jacqueline Andrews3.

Background: Polyarteritis Nodosa (PAN) is a necrotizing vasculitis predominantly affecting medium and small size arteries (1). Cyclophosphamide, a drug with narrow therapeutic range and poor safety profile, constitutes the treatment of choice for PAN vasculitis with major organ involvement. (2)

Objectives: To describe our clinical experience in treating refractory PAN with infliximab (a TNF inhibitor), a drug with good tolerability and better safety profile than cyclophosphamide.

Methods: Twenty-six PAN patients were admitted to our rheumatology unit between 2006 and 2017, of whom 9 patients, with severe and refractory disease, were treated with infliximab after failure of standard treatment. We describe herein the patients’ characteristics, clinical manifestations, severities and response to infliximab treatment and review the current literature.

Results: Complete remission was defined as the absence of features of active disease and withdrawal of prednisone therapy. Significant improvement was defined as clinical improvement and prednisone dose reduction of at least 50% or a 50% reduction in immunmodulatory medications other than prednisone. After 4 months of treatment, 8/9 (89%) patients achieved significant improvement, with two of them achieving complete remission.

Conclusion: We suggest anti TNF agents, and in particular infliximab, are relatively safe and efficacious treatment options in refractory PAN. A randomized controlled trial should be done in order to objectively evaluate infliximab in PAN.

†Continuous data are presented as mean (interquartile range).

Conclusion: Patients with GPA had significant myocardial abnormalities on CMR compared to HV; ANCA status, systemic organ involvement and disease severity were associated with CMR markers of myocardial fibrosis. CMR could be a useful tool for identification and future risk stratification of myocardial involvement of GPA.

glucocorticoids. Currently, only limited data on dynamics of peripheral leukocytes and leucocyte subset composition before, during and after treatment is available.

**Objectives:** To gain insight into the dynamics of leucocytes during the entire disease course and to determine whether patients in treatment-free remission resemble healthy controls.

**Methods:** Newly-diagnosed, treatment-naïve GCA (N=42) and PMR (N=31) patients were prospectively followed for up to 7 years. Absolute numbers of leucocyte subpopulation, both myeloid (neutrophils, monocytes) and lymphoid (CD4 and CD8 T-cells, B-cells and NK-cells) were measured at fixed time points. Laboratory inflammation markers (CRP, ESR, platelets and haemoglobin) were assessed as well. Values were compared with age-matched healthy controls (N=51) and infection controls (N=13). A stable treatment-free remission group for at least 6 months was defined.

**Results:** Neutrophil and monocyte numbers were higher in baseline GCA and PMR patients compared to healthy controls, whilst NK-cell numbers were reduced. In baseline GCA patients, CRP correlated positively with monocyte numbers. In baseline PMR patients, B-cell numbers were lowered and B-cell and NK-cell numbers correlated negatively with CRP. During glucocorticoid treatment, fluctuations in numbers of all leucocyte subsets were observed but neutrophil and monocyte numbers remained elevated and NK-cells numbers remained lowered during the entire treatment period (fig. 1). CRP and ESR were reduced by GC treatment and only moderately elevated during relapses. GCA patients in treatment-free remission still had elevated neutrophil and monocyte numbers. In addition, ESR and CRP numbers, were elevated whilst haemoglobin was lowered. PMR patients in treatment-free remission still had elevated monocytes while NK-cell and CD8+ T-cell numbers were decreased. Inflammatory markers and haemoglobin was normal.

**Conclusion:** In baseline GCA and PMR patients a shift towards the myeloid lineage is observed. This myeloid bias persisted in spite of GC treatment and also in treatment-free remission, suggesting a long-term effect of inflammation (an inflammatory imprint) on the peripheral blood compartment. Only GCA patients showed persistently elevated inflammatory markers; whether this reflects ongoing subclinical disease remains to be investigated.
The mean time from onset of GCA to intracranial involvement was 17 months (±38). All patients had neurologic symptoms, 33% (n:3) had a stroke and 22% (n:2) had a transient ischemic attack. IC-GCA was diagnosed by cranial imaging in 8 patients and by autopsy in one. Cranial imaging modalities used included magnetic resonance angiography (n=8), CT angiography (n=2) and cerebral angiography (n=2). Intracranial vasculitis most commonly affected the internal carotid artery 78% (N=7) followed by the vertebral artery 56% (n=5), posterior cerebral artery 56% (n=5), middle cerebral artery 44% (n=4), anterior cerebral artery 33% (n=3) and posterior inferior cerebral artery 11% (n=1). Stenosis was present in 89%, occlusion in 33%, dilatation in 11%, and wall thickening in 11%.

All patients received glucocorticoids. For treatment of intracranial disease, additional agents included: cyclophosphamide (67%), Tocilizumab (22%). Despite treatment, outcomes for patients with IC-GCA were poor. Five of nine patients died during a mean length of follow-up of 2.4 months. Additional agents included: cyclophosphamide (67%), Tocilizumab (22%).

**Conclusion:** Although rare, IC-GCA is associated with significant morbidity and mortality. In our cohort, the incidence of IC-GCA was 1.2 per 100,000 individuals per year. Nine patients died during a mean length of follow-up of 2.4 months. All patients had neurologic symptoms, 33% (n:3) had a stroke and 22% (n:2) had a transient ischemic attack.

**SAT0231 AGE AND THE CLINICAL FEATURES OF ADULT IGA VASCULITIS**

1,2Hocevar Alzizija, Jaka Ostozenski1, Ziga Rotar1, Matija Tomsic1,2.1University Medical Centre Ljubljana, Dept. of Rheumatology, Ljubljana, Slovenia; 2University of Ljubljana, Medical Faculty, Ljubljana, Slovenia

**Background:** IgA vasculitis (IgAV) is a common vasculitis of adult populations, and the disease in adults is still poorly defined.

**Objectives:** The aim of our study was to evaluate the potential influence of age on the presentation of adult IgAV.

**Methods:** We analyzed medical records of adult, histologically proven IgAV cases, diagnosed and followed at our tertiary referral rheumatology center between January 2010 and December 2018. We stratified IgAV cases into four groups, based on the patient's age at presentation (18-39, 40-59, 60-79, ≥80 years). The clinical features were compared between the groups.

**Results:** During the 10-year observation period we identified 265 new IgAV cases (60.0% males, median (IQR) age 64 (45–77) years). Skin, joint, gastrointestinal tract (GIT), GIT and renal involvement developed in 265, 103 (38.9%), 80 (30.2%), and 118 (44.5%) cases, respectively. Younger adults (≤40 years) more frequently reported an infection prior to IgAV, and developed arthritis or GIT involvement. Severe renal involvement was less common under the age of 40 years. The incidence of skin limited IgAV and of necrotic purpura increased with patient age. Follow-up data were available for 189 patients. During a median (IQR) follow-up of 12 (6-24) months, 29 (15.3%) patients relapsed. Relapsing disease was more frequent in younger adults (≤40 years), compared to older ones.

**SAT0232 DISTRIBUTION OF MACROPHAGE SUBSETS IN TEMPORAL ARTERY BIOPSY OF PATIENTS WITH GIANT CELL ARTERITIS**

William Fabry Jimmy1, Yannick van Steen2, Annemieke Boeckx2, Riemer Sarter1, Peter Heeringa1, Elisabeth Brouwer1.1University Medical Center Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands; 2University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands

**Background:** Giant cell arteritis (GCA) is a granulomatous vasculitis characterized by recruitment of T-cells and monocytes to the vessel wall. Upon recruitment, monocytes are activated and differentiate into macrophages. These leishmanial macrophages take on different phenotypes depending on cues from the microenvironment. These macrophages are known to produce pro-inflammatory cytokines, chemokines, matrix-metallo-proteinases (MMPs), and growth factors contributing to amplification of the inflammatory response, vessel wall injury and remodeling. However, current knowledge regarding macrophage subsets in GCA lesions is limited.

**Objectives:** To examine the distribution of macrophage subsets in GCA lesions.

**Methods:** Immunohistochemistry was performed on consecutive sections of paraffin-embedded temporal arteries of biopsy-confirmed GCA patients (n = 11) with antibodies to selected markers of inflammation and tissue remodeling (Table 1). Positive cells were scored in three layers of the vessel wall (adventitia, media-intima, inner-intima) using a semi-quantitative scoring system. Expression by macrophages was confirmed by double staining with the macrophage transcription factor PU.1.

**Table 1. Immunohistochemistry panel. AB019**

<td>MMP-2</td>
</tr>
</tbody>
</table>

**Results:** The pro-inflammatory marker CD64 and pro-inflammatory cytokines (IL-12, IL-23 and IL-1β) were strongly expressed by macrophages throughout the vessel wall, most prominently in the adventitia. However, subsets of these CD64+ macrophages also showed concomitant expression of the tissue remodeling markers CD206 and FR-β in specific compartments of the lesions. More specifically, CD206+ macrophages were mainly found along the media borders which co-localized with positive MMP-9 staining. Interestingly, FR-β positivity was also found in the inner-intima of TABs with a high degree of intimal hyperplasia. FR-β expression was significantly higher in the inner-intima region in TABs with...
massive intimal hyperplasia compared to TABs with mild intimal hyperplasia (p = 0.01).

Conclusion: Based on the expression of markers of inflammation and tissue remodeling, different subsets of infiltrating macrophages can be distinguished. Macrophages in vascular lesions of GCA patients display a distinct spatial distribution pattern within the inflamed vessel wall (Figure 1). Adversarial macrophages express highest level of pro-inflammatory cytokines indicating pro-inflammatory functions of these macrophages. Co-localization of CD206 and MMP-9 along media borders indicates a role for CD206+ macrophages in collagen digestion and angiogenesis. Additionally, the association of increased numbers of FR-β+ macrophages with extensive intimal hyperplasia suggests that FR-β+ macrophages promote myofibroblast proliferation.

SAI10231 VALIDATION OF A NOVEL DISEASE CLASSIFICATION IN HACETTEPE TAKAYASU ARTERITIS COHORT

Ertuğrul Çağrı Bölek, Selcan Demir, Alper Sari, Ummusen Kaya Akca, Levent Kılıç, Ali Akoçkan, Sedat Kiraz, Omer Karadag, Seza Özen, Hacettepe University Vasculitis Center (HUVAC), Hacettepe University Vascularis Center, Ankara, Turkey.

Background: Takayasu Arteritis (TAK) is a rare idiopathic granulomatous large vessel vasculitis and it is a clinically heterogeneous disease. Various classifications and subsets which based on distribution of arterial lesions were defined in the literature in order to exhibit and predict different disease courses.

Objectives: We aimed to validate a new disease subsets developed by Goel et al in our TAK series (1).

Methods: We retrospectively evaluated the medical records of 164 TAK patients followed at Department of Rheumatology and Department of Pediatric Rheumatology in Hacettepe University, Ankara, Turkey between August 2005 and October 2018. The pediatric-onset (< 18 years of age at disease diagnosis) and adult-onset patients fulfilled the Ankara 2008 and the American College of Rheumatology (ACR) 1990 criteria for TAK, respectively. Patients were assigned to three clusters (Cluster 1: Abdominal Predominant, Cluster 2: Aortic Arch Predominant, Cluster 3: Focal Disease) using a decision tree defined in the original study (1). Demographics, clinical and laboratory features, treatment regimens were compared between in three groups.

Results: There were forty-two (25.6%), sixty-three (38.4%) and fifty-nine (36%) patients in Cluster 1, 2 and 3, respectively. Demographic and clinical data was summarized in Table-1. Cluster 1 included approximately half of patients (45.6%) with pediatric-onset TAK (p = 0.048), Baseline acute phase reactants (Enzyme Sedimentation Rate:ESR and C-reactive protein:CRP) and age at disease diagnosis were slightly lower in Cluster 1, however none of them did not reach statistical significance (p = 0.94, p = 0.99 and 0.56, respectively). In contrast, cerebrovascular accident rates were slightly higher in Cluster 2 (p = 0.24). Although anti-TNF biological agents were more frequently used for treatment in Cluster 1 (p =0.004), cyclophosphamide and/or overall biological agents usage was similar in three groups (p =0.15).

Conclusion: Decision tree which defined by Goel et al. was applied to our single center pediatric and adult TAK cohort. In contrast to original validation cohorts, there was no difference among three clusters of our cohort except pediatric-onset disease and anti-TNF usage. Dissimilarities among the cohorts in terms of new classification system may be caused either of patients or ethnic/regional differences.

REFERENCE
b/c. -378a, -423, -3184; p_adj < 10^{-9}), whereas 60 miRNAs were decreased (e.g. miRNA-128, -937, -30c, -328, 26a, p_adj < 0.005), thereby representing the IgAV-associated serum miRNA signature. The mirROR platform identified 426 protein-coding genes as targets of the 54 DE miR- NAs (log2 fold change ≥ 1), p_adj < 0.01. As analyzed by STRING, these miRNA target genes were enriched in distinct molecular networks and biological pathways, including “Phosphoproteins (FDR 7.4∗10^{-4}), “Alternative splicing” (FDR 2.8∗10^{-7}), “Regulation of actin cytoskeleton” (FDR 0.008), “Proteoglycans in cancer” (FDR 0.009) and “Fagomma receptor dependent phagocytosis” (FDR 0.01) (Figure 2). Additionally, miRNA gene targets formed three distinct molecular clusters, specifically “Chemokines and their receptors”, “Ubiquitination process” and “Vesicle, endocytosis, lysosomes and their trafficking” (Figure 2). This suggests that the altered miRNAs in IgAV regulate diverse cellular functions, reflecting or contrib-uting to the key aspects of disease pathogenesis.

Conclusion: Here we report for the first time an IgAV-associated serum miRNA signature. The altered miRNAs clearly discriminate IgAV patients from HC, and might play a key role in the pathogenesis of IgAV. Our study sets the basis for the identification of novel, serum-based disease biomarkers in vasculitis.

Narváez7, Angel Ramos Calvo3, Francisca Sivera4, Enrique Raya4, Norberto Ortego5, Jose Luis Celles-Jubilo5, Ana María Brandy-Garcia6, Alejandro Oliver7, Sabela Fernández8, Ricardo Gómez de la Torre7, Ignacio Torre-Salaberri8, Julio Sánchez9, Ana Urruticoechea-0

Background: Behçet’s disease (BD) is a variable vessel vasculitis and typically presents with mucocutaneous involvement. However, any organ can be affected, being the neurological affection (neurobehçet, NB) one of the most serious manifestations. 

Objectives: Our aim was to assess the efficacy and safety of biological therapy as treatment of NB.

Methods: We set up a multicenter observational study of 29 patients with NB on treatment with biological therapy (BT). NB diagnosis was made by neuroimaging, CSF analysis and/or suggestive clinical signs of central and/or peripheral nervous system involvement, excluding infectious causes or more prevalent pathology. Results are expressed as means±SD or as median and interquartile range (IQR) as appropriate.

Results: 29 patients (15♂/14♀) with an average age of 39.6 ± 10.5 years. HLA-B51 was positive in 48.3% of the patients.

We set up a multicenter observational study of 29 patients with NB on treatment with biological therapy (BT).

Figure 1. Heatmap based clustering analysis of serum miRNA expression

Figure 2. STRING Protein networks of gene targets of DE miRNAs
brainlessment (n=1), encephalopathy (n=4), optic neuritis (n=2), dysphasia (n=1), polyneuropathy (n=6), cognitive impairment (n=4), and non-steroidal psychosis (n=1), while the remaining 6 patients (20.7%) presented aseptic meningitis as a non-parenchymal affection (Table). Prior to BT, patients had received the following treatment: Abbbvie, Pfizer, Roche, Bristol-Myers, Janssen, Speakers bureau: Consultation fees/participation in company sponsored speaker’s bureau from Pfizer, Lilly, Sobi, Celsege, Novartis, Roche and Sanofi., Ricardo Blanco Grant/research support from: Abbv, MSD, and Roche, Consultant for: Abbbvie, Pfizer, Roche, Bristol-Myers, Janssen, Speakers bureau: Abbvie, Pfizer, Roche, Bristol-Myers, Janssen

**Conclusion:** BT, especially anti-TNF, seems effective and safe for treatment in NB.

**Table.**

After a median of 31 [10-60] months since the beginning of the neurologic symptoms, the following BT was initiated: infliximab (IFX)(n=17), adalimumab (ADA)(n=7), tocilizumab (TCZ) (n=2), golimumab (GOL) (n=2) and Etanercept (ETN) (n=1). A first switch to ADA was necessary in 8 patients with IFX due to primary failure. In addition, 2 of them needed a second switch to TCZ, getting a partial response. The BT was discontinued in 5 patients, 2 of them for obtaining clinical remission and the remaining 3 for inefficacy. After a median follow-up of 5.4±4.6 years, complete response was obtained in 15 patients, partial response in 11 and no response in the remaining 3. We observed an anaphylactic reaction and psoriasis induced by IFX, without other serious adverse events (Table).

**Conclusion:** BT, especially anti-TNF, seems effective and safe for treatment in NB.

Figure 1. Simulations of ANCA-time profile in patients with MPO-ANCA (red line) and PR3-ANCA (purple line), using typical pharmacodynamic parameters. The central curve are the median dynamics of ANCA and the shadow are 90% prediction intervals.

**Background:** Rituximab is approved in patients with anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV). Antibodies to proteinase 3 (PR3-ANCA) or myeloperoxidase (MPO-ANCA) decrease with therapy (1) and may therefore be used as biomarkers.

**Objectives:** To investigate the relationship between rituximab concentration and ANCA levels in AAV patients.

**Methods:** 92 AAV patients from the RAVE trial (rituximab for ANCA-associated vasculitis) were assessed. Both MPO-ANCA, and PR3-ANCA antibody levels were used as biomarkers. ANCA levels were measured at baseline, at months 1, 2, 4, 6, 9, 18, and every 6 months until the second rituximab cycle if any, using ELISA supplied by Euroimmun. A semi-mechanistic model including a deep compartment which was sensitive to rituximab and a feedback mechanism, and a blood compartment were tested to describe the concentration-ANCA autoantibodies relationship. A population modeling approach using sequential methods was used for model building. Influence of sex, body surface area (BSA), BVAS/WG score, newly diagnosed status, major renal involvement at baseline, and relapse were investigated as covariates on pharmacodynamics parameters.

**Results:** A two compartment model including feedback mechanism from the circulating ANCA well described the concentration autoantibody relationship. The mean (interindividual standard deviation) estimated rituximab IC50, assessing potency, in patients with MPO-ANCA and PR3-ANCA were 21.9 mg/l (28%) and 11.2 mg/l (48.6%), respectively. Moreover, among patients with PR3-ANCA, rituximab IC50 was higher in patients with major renal involvement at baseline (p=2.47 x 10-2) and newly 6 months until the second rituximab cycle if any, using ELISA supplied by Euroimmun. A semi-mechanistic model including a deep compartment which was sensitive to rituximab and a feedback mechanism, and a blood compartment were tested to describe the concentration-ANCA autoantibodies relationship. A population modeling approach using sequential methods was used for model building. Influence of sex, body surface area (BSA), BVAS/WG score, newly diagnosed status, major renal involvement at baseline, and relapse were investigated as covariates on pharmacodynamics parameters.

**Results:** A two compartment model including feedback mechanism from the circulating ANCA well described the concentration autoantibody relationship. The mean (interindividual standard deviation) estimated rituximab IC50, assessing potency, in patients with MPO-ANCA and PR3-ANCA were 21.9 mg/l (28%) and 11.2 mg/l (48.6%), respectively. Moreover, among patients with PR3-ANCA, rituximab IC50 was higher in patients with major renal involvement at baseline (p=2.47 x 10-2) and newly diagnosed status (p=6.42 x 10^{-5}) than in others.
SAT0237 MYOCARDIAL FDG-PET/CT FINDINGS IN CHILDREN WITH TAKAYASU ARTERITIS

Kenichi Nishimura, Seira Hattori, Ayako Murase, Ai Ohnishi, Ryoki Hara, Shuichi Ito. Fukaura 3-9, Yokohama, Japan

Background: Takayasu arteritis (TAK) is a chronic large-vessel vasculitis affecting the aorta and its major branches. In Japan, 18F-fluorodeoxyglucose positron emission tomography with computed tomography (FDG-PET/CT) was approved since April 2018. Recently, usefulness of FDG-PET/CT to diagnose TAK or assess disease activity has been reported. However, the findings in children with TAK except for vascular lesions remain unknown.

Objectives: We aimed to retrospectively analyse the FDG-PET/CT findings in children with TAK except for vascular lesions.

Methods: This is a single-center retrospective observational study. We evaluated 9 children with TAK and compared them with 10 children with other rheumatic disease (systemic juvenile idiopathic arthritis; 5, polyarticular juvenile idiopathic arthritis; 1, juvenile dermatomyositis; 1, Crohn’s disease; 2, Klüver’s disease; 1) (control group). All children underwent FDG-PET/CT before the treatment. We compared the two groups for the age at performed FDG-PET/CT, sex, duration of onset to performed FDG-PET/CT, FDG-PET/CT findings. Binary data were analyzed by Fisher’s exact test.

Results: Median age of the performed FDG-PET/CT was 13.9 (range: 11.1-14.9) years old in TAK children and 5.4 (1.4-12.4) years old in control group. Both groups included 6 females. Median duration of onset to performed FDG-PET/CT was 1 (range: 0-12) months in TAK children and 0 (0-12) months in control group. FDG accumulation in bone marrow was observed in 7 TAK patients (78%) and in 7 (70%) of control group. Moreover, FDG accumulation in spleen was observed in 7 TAK patients (78%) and in 10 (100%) of control group. These findings were common in both groups. The other hand, FDG accumulation in left ventricular myocardium was observed in 8 TAK patients (89%) but in 3 (30%) of control group (p<0.02). Six TAK children received follow-up FDG-PET/CT. Myocardium FDG accumulation was continued in 3 children but resolved in 2. TAK children with persistent accumulation in myocardium had ascending aorta dilation later. A two compartments model including feedback mechanism.

Conclusion: FDG accumulation in left ventricular myocardium would be a characteristic finding in children with TAK, and possibly related to later ascending aorta dilation.

PREDICTION OF LONG-TERM EVOLUTIONARY PROFILES IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (CHURG–STRAUSS) BASED ON BASELINE AND FOLLOW-UP CHARACTERISTICS

Matthias Paep1, Renato A. Sinico2, Vitor Teixeira3, Maria Letizia Urban4, Juliane Mahrhof1, Sara Monti1, Giulia Cassone1, Franco Schiavon1, Benjamin Seeliger1, Thomas Neumann15, Claus Kroegel12, Chiara Marvisi3, Maxime Samson16, Barbara12, David Jayne5, Bernhard Helmich16, Carlonaurizio Montuccio1, Carlo Salvarani1, Jean-Emmanuel Kahn11, Bernard Bonnotte1, Cécile-Audrey Duru1, Luc Mouthon11, Xavier Puelch1, Loïc Guillevin1, Giacomo Emmi13, Augusto Vaglio13.

Background: Eosinophilic granulomatosis with polyangitis (EGPA) (Churg–Strauss) is a small-vessel necrotizing vasculitis characterized by blood and tissue eosinophilia and asthma. Glucocorticoids (GCs) control the disease, but GC-dependence is frequent. Evolving concepts distinguish vasculitis-related symptoms from asthma and/or ENT manifestations. That distinction has become even more important since the development of B-cell and eosinophil-targeted therapies.

Objectives: This study aimed to describe and identify characteristics predicting long-term EGPA outcomes.

Methods: We set up a multicenter European cohort that included 636 EGPA patients. Based on recent consensus, we distinguished 4 EGPA-evolutionary profiles: GC-dependent asthma and/or ENT manifestations (requiring prednisone >7.5 mg/d), GC-dependent asthma and/or ENT manifestations (BODI)

Development and Preliminary Validation of the Behçet’s Syndrome Overall Damage Index (BODI)

Matteo Piga1, Alberto Floris1, Gerard Espinosa1, Nikolaos Koukias3, Andrea Lo Monaco1, Giuseppe Lopaca2, Idal Orlando1, Vittorio Pirani4, Emesins Santos2, Lulisa Serpa Pinho2,9, George Bertisias2, Lucas Cantarini3, Alberto Caúli1, Ricardo Cervera2, João Correia10, Maria-Letizia Urban4,9, Luca Cantarini6, Carlos Vasconcelos10, Monica Mutontori13, Alessandra Mathieu1, University of Cagliari, Rheumatology, Monserrato, Italy; 2University of Barcelona, Autoimmune Diseases, Barcelona, Catalonia, Spain; 3University of Crete, Rheumatology, Clinical Immunology and Allergy, Heraklion, Greece; 4University of Ferrara, Rheumatology, Ferrara, Italy; 5University of Bari, Rheumatology, Bari, Italy; 6University of Siena, Rheumatology, Siena, Italy; 7Università Politecnica delle Marche, Ophthalmology, Ancona, Italy; 8Centro Hospitalar do Porto/Hospital de São Santos, Neurology, Porto, Portugal; 9University of Porto, UMB, Abel Salazar Biomedical Sciences Institute, Porto, Portugal; 10Hospital Santo Antonio Centro Hospitalar do Porto, Unidade de Imunologia Clínica, Porto, Portugal; 11Cleveland Clinic Abu Dhabi, Eye Institute, Abu Dhabi, United Arab Emirates; 12Patient delegate, Cagliari, Italy.

Background: Irreversible organ damage is considered a core outcome by the OMERACT working group. However, no specific tools are currently available to detect and measure damage accrual in Behçet’s syndrome (BS) patients.

Objectives: To develop and preliminarily validate the Behçet’s syndrome Overall Damage Index (BODI).

Methods: A preliminary version of the instrument (p-BODI) was developed by reviewing pre-existing tools (e.g. Vasculitis damage index (VDI)) and through an extensive literature review. p-BODI was then reviewed and implemented by a multi-rounds Delphi process, involving an international and multidisciplinary (5 rheumatologists, 4 internists, 1 ophthalmologist, 1 neurologist) panel of experts in BS management and a patients’ delegate. A group of clinicians (CG), not involved in the BODI development, was asked to independently score a set of clinical vignettes, in order to test the instrument reliability, after a training process consisting of a user manual and a video-tutorial. Then, Cohen’s K and intra-class correlation coefficient (ICC) between assessors and gold standard were calculated. Afterwards, BODI validation was conducted according to the OMERACT Filter 2.0 in a multicenter BS cohort.

Results: Starting from a list of 120 candidate items, the final version of BODI consisted of 4 overarching principles, 30 items and 12 sub-items (each of them scores one point) grouped in 8 domains (figure).

In terms of reliability, the mean K coefficient was 0.84 (95%CI 0.78 to 0.90) and the ICC was 0.88 (95%CI 0.80-0.95). Validation cohort consisted of 228 BS patients (41.9% males), with a median (IQR) age and disease duration of 46.9 (35.5-55.0) and 11.7 (5.8-20.7) years, respectively. Overall, prevalence of any BODI damage (BODI >1) was 56% with a median score of 1.0 (0-2.0). In regard of construct validity, BODI score significantly correlated with VDI (Spearman’s rho 0.693, p<0.001). Besides, BODI score did not correlate with BDCAF (rho 0.016, p=0.807), contrary to VDI (rho 0.141, p<0.034). Such results support the validity of BODI, unlike VDI, in discriminating damage from current disease activity in BS. On multiple regression analysis, factors independently associated to higher BODI damage score were male gender (β coefficient 0.143; p=0.014), longer disease duration (β coefficient 0.221; p<0.001), past major organ involvement (β 0.377; p<0.001) and required use of anti-TNFα inhibitors (β 0.222; p<0.001). Full agreement among the CG was reached in judging BODI as a credible comprehensive, easy to use instrument. Thomas Bonnotte: None declared. Xavier Puéchal: None declared.
HEALED TEMPORAL ARTERITIS. ANALYSIS OF CLINICAL FEATURES

Objectives: We analyzed clinical features of patients with healed TA, but these are non-specific and can also be seen in other conditions that are unlikely to benefit from prolonged steroid treatment. It is not clear if a pathological diagnosis of healed TA helps to support treatment. Unfortunately a biopsy does not always strengthen support for treatment. At the end of the day, the diagnosis of TA remains a clinical one and early involvement of Rheumatology may help avoid unnecessary biopsies and treatment. Ultrasound, MRA, and PET-CT scan may be able to fill the gap when biopsy fails to confirm the diagnosis.

SAT0242
SENSITIVITY OF TEMPORAL ARTERY BIOPSY IN giant cell arteritis: systematIc literature review and meta-analySIs of clInical data

Emma Rubenstein1, Carla Moldini1, Solange Gonzalez-Chiappe1, Sylvie Chevret2, Alfred Mahi3, Saint Louis University Hospital, Department of Internal Medicine, Paris, France; 2Saint Louis University Hospital, Department of Biostatistics, Paris, France

Background: The role of temporal artery biopsy (TAB) as a reference test for the diagnosis of giant cell arteritis (GCA) is currently questioned by the use of non-invasive imaging techniques such as temporal artery ultrasonography (TA-US). Although TAB is highly specific, a subset of patients with a clinical diagnosis of GCA does not show the characteristic histopathological signs. The lack of knowledge of the proportion of GCA cases with positive findings on TAB hampers comparisons of the sensitivity of TAB and imaging tests for diagnosing GCA.

Objectives: We performed a systematic literature review and meta-analysis to estimate the sensitivity of TAB in GCA and to identify factors that may influence the estimate.

Methods: We searched MEDLINE via PubMed, EMBASE and CENTRAL databases for articles reporting TAB in GCA that were published from 1990 to 2017, with no language restriction. Eligibility criteria included studies with >30 GCA cases fulfilling the original or modified 1990 ACR classification criteria for GCA. From eligible publications, two independent researchers extracted the main methodological, geographic, demographic, and clinical characteristics and the number of TAB-positive cases among all cases with interpretable results for TAB. By meta-analysis, we computed the pooled proportion of TAB-positive GCA cases by using a random-effects model with a binomial-normal distribution and assessed heterogeneity by the I² statistic. Subgroup and meta-regression analyses were used to examine the effect of 16 covariates (e.g., geographic, demographic, clinical and study descriptors) on TAB positivity.

Results: Among 3820 screened publications, 32 independent studies (3092 GCA patients in total) were used for the analysis. The pooled proportion of TAB positivity was estimated at 77.3% (95% confidence interval 71.8–81.5%), with high between-study heterogeneity (F=90%). Subgroup analysis suggested a potential influence of year of publication (Table). This result was confirmed by univariate (P=0.0008) and multivariate meta-regression (P=0.0004). No other analyzed covariate significantly influenced the sensitivity of TAB in GCA.

Conclusion: The 77% estimated sensitivity of TAB in GCA indicates that it is not inferior to that of TA-US (1). The decline in TAB-positive GCA cases over time could reflect an increasing propensity of clinicians to accept GCA diagnosis in the absence of proof by TAB. The unexplained high between-study heterogeneity could also reflect differences in TAB sampling, processing or interpretation.

Effects of tofacitinib suppressed pulmonary vasculitis in a murine model

Nobuhito Saga, Kohei Yamashita. Iwate Medical University School of Medicine, Morioka, Japan; Division of Pulmonary Medicine, Allergy and Rheumatology, Department of Internal Medicine, Morioka, Japan

Background: We reported allergic granulomatous vasculitis with eosinophil infiltration in an asthma model of C57BL/6 sensitized with ovalbumin (OVA). TGF-beta and IL-6 are thought to play an important role in fibroblast proliferation and is critical to vascular remodeling in vasculitis. Tofacitinib inhibits vascular endothelial cells proliferation and canalization.

Methods: C57BL/6 mice (6-8 weeks) were sensitized with ovalbumin (OVA) and alun. The positive controls (n=9) were exposed to aerosolized OVA daily for 7 days. The other group of mice (tofacitinib treated mice (n=9)) were administered with tofacitinib (100mg/kg intraperitoneal administration) in parallel with daily exposure to aerosolized OVA for 7 days. On 7th day, bronchoalveolar lavage (BALF) was performed and the lungs were excised for pathological analysis. Cytokines in BALF were measured.

Results: The total cell number and the number of Eosinophils in BALF on the 7th day were decreased significantly in the tofacitinib-treated mice compared with those of the control-positive mice. The blood eosinophil counts in the tofacitinib treated mice were lower on the than those in the positive control.

Conclusion: Tofacitinib suppressed pulmonary vascular remodeling in a murine model of allergic vasculitis with eosinophil infiltration. Tofacitinib is a hopeful therapeutic drug for Eosinophilic granulomatosis with polyangiitis.

Conclusion: The spectrum of clinical presentations in Indian patients is different from those reported in previous cohorts. Anti TNF therapy was effective in majority.

SAT0245 CHOROIDAL EVALUATION IN PATIENTS WITH CHILDBIRTH POLYARTERITIS NODOSA (PAN) AND ADENOSINE DEAMINASE-2 DEFICIENCY (DADA-2)
Hafize Emin Sonmez1, Abdullah Ağın2, Sibel Kadayıfçilar3, Ayta Batayorğlu4, Özge Deliktaş5, Selcan Demir6, Yelda Bilginer7, Bora Eldem2, Seza Özen1. 1Hacettepe University Faculty of Medicine, Department of Pediatrics, Pediatric Rheumatology Unit, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Department of Ophthalmology, Ankara, Turkey; 3Çekic State Hospital, Department of Ophthalmology, Van, Turkey

Background: Polyarteritis nodosa (PAN) is a systemic necrotizing vasculitis affecting small or medium arteries with a negative ANCA serology and no evidence of glomerulonephritis.

Objectives: The aim of this study was to evaluate the choroid with optical coherence tomography (OCT) in children with polyarteritis nodosa (PAN) and adenosine deaminase-2 deficiency (DADA-2).

Methods: The study included all PAN and DADA-2 patients (n=15), examined between June 2017 and September 2018, and an age and gender-matched control group (n=15). After oculomotor evaluation, choroidal images taken with sd-OCT (Heidelberg Spectralis) were evaluated with regard to choroidal thickness (ChT) at five points (750 and 1500 microns from the center of the fovea both in the temporal, nasal quadrant and under the fovea), total subfoveal choroidal area (TCA), luminal area (LA), stromal area (SA) and choroidal vascularity index (CVI).

Results: None of the patients had active ocular complaints or findings. The mean (±SD) age was 8.4 ± 3.69 years. ChT at 3 points, TCA, LA, and SA were found to be higher in patients with PAN and DADA-2. The CVI values were similar in both groups. No correlations were found between the OCT findings, activity score index (PVAS) and the biochemical parameters (Erythrocyte sedimentation rate, leukocyte, C-Reactive Protein).

Conclusion: The results of this study showed that the choroid was thicker in patients with PAN and DADA-2 than in the control group, suggesting that PAN and DADA-2 may affect the choroid. Ophthalmologic evaluation is important in PAN and DADA-2 patients, even in the absence of relevant complaints.

SAT0246 USING BONE MINERAL DENSITY VERSUS THE RATIO OF BODY MASS INDEX TO BONE MINERAL DENSITY TO PREDICT FRACTURE RISK IN POLYMYALGIA RHEUMATICA
Khojesta Talebi, Marwan Bukhari. Royal Lancaster Infirmary, Lancaster, United Kingdom

Background: Polymyalgia Rheumatica (PMR) is the commonest inflammatory rheumatic condition that affects the elderly population and treatment with long-term corticosteroids is common. Whilst steroid treatment is beneficial in managing symptoms, it has many side effects including increasing the risk of osteoporosis and hence fractures. There has been recent research that suggests using the ratio of BMI to Body Mass Index (BMI) is a better marker of predicting fracture risk in obese patients than BMI alone.

Objectives: Our research set out to find out whether BMI alone or the ratio of BMI to BMI is a better predictor of fracture risk in patients with PMR.

Methods: Data were used from a cohort of PMR patients referred for DEXA scan to a District General Hospital between June 2004 and October 2010. The following were recorded: age, sex, whether a fracture was sustained, whether they had had steroid therapy at any point, BMI, BMD at L1-L4, BMI at femoral neck (left and right) and BMI at hip (left and right). Logistic regression models were fitted using fracture as the dependent variable. The independent variables for the first set of logistic regression models were BMI at each level and for the second set BMI: BMD ratio at the same levels. Data were adjusted for sex and age at scan. Logistic models were compared using area under the ROC curves (AUC).

Results: 714 patients were used in the study, of whom 532 (75%) were female. Mean age was 70.5 (SD 8.84) with age range 45.8 to 96.5 years. 703 (98%) were recorded to have had steroid therapy at any point. Mean BMI was 28.2 kg/m² (SD 5.24), 156 (22%) had sustained a fracture. Odds ratios and AUC values for each level were as shown in the table. The fit of the models using the BMI alone was superior to the fit of the models using the ratio as the AUC values were greater for BMI alone.

</tbody>
</table>

Conclusion: This study identifies that the BMI:BMD ratio does not provide better indication of fracture risk than BMI alone in our cohort of patients with PMR. We have previously shown that the same is true for patients with rheumatoid arthritis. A limitation of this study is not stratifying by steroid use.

Further work will be done to study the role of the ratio in predicting fracture risk in patients with other conditions.

FEMALE SEX AND AGE AT DIAGNOSIS ARE ASSOCIATED WITH A DECREASED POSSIBILITY OF DRUG DISCONTINUATION IN GIANT CELL ARTERITIS: DATA FROM A MULTICENTER PROSPECTIVE COHORT OF 177 PATIENTS

Tsanapali Christina1, Argyro Lazaris2, Maria Tektoridou3, Petros Sikakis4, Vassiliki Diani5, Kyriaki Boki6, Evripidis Kafountidis7, Paraskevi V, Voulgaris8, Gerasimos Evangelatos9, Alexis Iliopoulos1, Evangelos Theotikos2, Antonia Exekiouli1, Charalampos Papagoras1, Theodora Dimitroulas2, Alexandros Garyfallo3, Dimitrios Boumpas4, Georgios Vovoskalis15, Dimitrios Vassilopoulos11, 1Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, University of Athens, School of Medicine, Athens, Greece; 2Joint Rheumatology Program, First Department of Propedeutic Internal Medicine, University of Athens, School of Medicine, Athens, Greece; 3Sismanoglio Hospital, Rheumatology Unit, Athens, Greece; 4Rheumatology Clinic, University of Ioannina, Ioannina, Greece; 5NIMTS Hospital, Rheumatology Unit, Athens, Greece; 6Askipion General Hospital, Rheumatology Unit, Athens, Greece; 7Democritus University of Thrace, Rheumatology Clinic, Thrace, Greece; 8Aristotle University, 4th Department of Medicine, Thessaloniki, Greece; 9Joint Rheumatology Program, 4th Department of Medicine, Atikon Hospital, University of Athens, School of Medicine, Athens, Greece; 10Private Practice, Thessaloniki, Greece

Background: Giant cell arteritis (GCA) usually requires long-term therapy with corticosteroids and/or Disease Modifying Anti-rheumatic Drugs (DMARDs) but the exact factors that are associated with drug discontinuation in these patients have not been well defined.

Objectives: To evaluate the baseline or on-treatment factors that influence drug survival in GCA.

Methods: Data were derived from an ongoing, multicenter, prospective cohort study of patients with GCA. During the 1st phase of the study, data regarding demographic and clinical characteristics at baseline, type of treatment, adverse events of therapy and co-morbidities were retrospectively collected and analyzed. Predictors of drug discontinuation were examined by univariate and multivariate logistic regression analyses.

Results: One hundred and seventy seven patients were included in the study; 70% (n=120) were women with a mean age at diagnosis of 74 ± 8.4 years. Diagnosis was established by temporal artery biopsy in 127 patients (72%), ultrasound of temporal arteries in 37 patients (21%) and large vessel imaging in 10 patients (6%). At diagnosis, the median ESR and CPR were 103 mm/h and 63 mg/L, respectively. All patients were treated initially with prednisone: 41 mg, while 12 (7%) of patients received pulse steroids. At the 1st patient evaluation (median follow-up from diagnosis: 3 years), the median daily steroid dose was 5 mg, while in 34% (n= 62) and 8% (n= 14) of patients a synthetic or biologic DMARD had been added, respectively. During that period, 24% (n=43) of patients had discontinued corticosteroids and 18% (n=32) all treatments by the 1st patient evaluation. By univariate analysis, DMARD use was associated with a higher possibility for corticosteroid discontinuation (OR=2.3, p=0.017) but by multivariate logistic regression analysis only female sex (OR=0.49, p=0.07) and age at diagnosis (OR=0.94, p=0.01) were associated with a decreased risk for corticosteroid discontinuation. Similar results were found for discontinuation of all drugs [female sex (OR=0.4, p=0.05) and age at diagnosis (OR=0.9, p=0.046)].

Conclusion: In this large GCA cohort, only one out of four patients managed to discontinue corticosteroids and 20% all treatments -3 years after diagnosis. Multivariate analysis revealed only female sex and age at diagnosis as independent factors for treatment discontinuation.

Acknowledgement: Supported by grants from the Greek Rheumatology Society and Professional Association of Rheumatologists.

SAT0248 CLINICAL OUTCOMES OF PATIENTS WITH GIANT CELL ARTERITIS TREATED WITH TOCILIZUMAB IN REAL-WORLD CLINICAL PRACTICE

Sebastian Unizony1, Jinglan Pei2, Farid Pinkash3,4, Jennie H. Best5, Christine Birchwood6, John H. Stone1,7, Massachusetts General Hospital, Harvard Medical School, Boston, United States of America; 2Genentech, Inc., South San Francisco, United States of America

Background: Previously, the GIACTA study demonstrated the superiority of subcutaneous (SC) tocilizumab (TCZ) plus prednisone vs prednisone alone in achieving sustained glucocorticoid (GC)-free remission in patients with giant cell arteritis (GCA). 1

Objectives: To evaluate the effectiveness and safety of SC and intravenous (IV) TCZ in real-world clinical practice.

Methods: We performed a retrospective analysis of GCA patients treated with TCZ at a single center (MGH) between 2010-2018. Annual relapse rate, time to disease relapse, number of relapses, prednisone use, and adverse events (AE) before and after TCZ initiation were assessed. Disease relapse was defined as the re-appearance of clinical manifestations of GCA (e.g., cranial symptoms) that required treatment modification.

Results: A total of 60 GCA patients were included in the analysis. Table 1 depicts the baseline characteristics and the treatments received by this cohort. The median (IQR) disease duration before TCZ use was 0.6 (0.2-1.6) years. Fifty-eight patients (96.7%) received concomitant prednisone (mean [SD] dose: 30 [18.3] mg daily) at the time of TCZ initiation. Patients received TCZ for a median (IQR) period of 7.0 (3.3-14.9) years.

Seven patients (11.7%) successfully tapered off prednisone during TCZ treatment.

Previously, the GiACTA study demonstrated the superiority of TCZ in patients with GCA as indicated by a reduced incidence of relapses and by the ability to discontinue prednisone. The occurrence of AEs and SAEs (many due to GC) did not differ substantially while patients were on or off TCZ. These real-world findings support the previously reported efficacy and safety profile of TCZ in patients with GCA.

nists: a study in 39 patients in France. Joint, bone, spine : revue du rhu-
culitides in patients with inflammatory bowel diseases: A study of 32 patients and systematic review of the literature. Seminars in arthritis and rheu-
tions in inflammatory bowel disease: a single institution study of non-neo-
LAR/PRINTO/PRES criteria for Henoch-Schonlein purpura, childhood polyar-
Results: 134 cases were reviewed, concerning 80 PMR (mean age 67.9) and 54 “controls” (mean age 68.1). Overall, PET muscle damage was observed in 27 cases (34%) in PMR and 6 cases (11%) in controls (p<0.004). The damage is bi or multi-focal in 16/27 cases. The affected sites are: thighs and ischium-leg (n = 10), spinal (11), pectoral/subscapular (5), deltoid (1), trapezius (1). Fasciitis was found in 4 cases. As expected, PMR patients exhibited higher TEP scores than controls (p<0.001). In PMR patients, PET muscle involvement was associated with higher ESR values (p<0.05), but not with age, CRP or global PMR PET score.

Conclusion: Muscle involvement assessed by 18F-Fluorodeoxyglucose PET-CT is frequent in PMR (1/3), located at usual sites of symptoms of the disease, without association with age, CRP levels or global PET score for PMR. Muscle should be carefully evaluated during PET in cases of PMR; these pictures may be a new diagnosis feature of the disease.

SEX- AND AGE-RELATED DIFFERENCES IN CLINICAL MANIFESTATIONS OF BEHÇET’S DISEASE IN A LARGE COHORT OF CHINA PATIENTS

Background: Behçet’s disease (BD) is a systemic vasculitis with multiple symptoms such as recurrent oral and genital ulceration, skin lesions, ocular lesions, and other systemic affections. Studies have been conducted to reveal sex- and age-related differences in clinical characteristics of BD in different countries, but up to now sex and age influence for Chinese BD patients is very limited.

Methods: We retrospectively reviewed the medical records of BD patients followed up in the Departments of Rheumatology, Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China; General Hospital of Tianjin Medical University, Department of Rheumatology, Tianjin, China.

Results: A total of 489 BD patients were included in our database: 286 males (58.49%) and 203 females (41.51%). Sex ratio M/F was 1.41, with a median age of 34 years (interquartile range: 28-44 years). Recurrent oral ulceration was the most common manifestation (90.32%), followed by genital ulceration (71.17%), skin lesions (57.67%), vascular lesions (25.36%), and ocular involvement (24.13%). Gastrointestinal (GI) involvement (15.13%), positive pathergy test (14.11%), and neurological involvement (5.93%) were less frequently observed. The comparative study between males and females revealed that ocular lesions (28.67% vs 17.73%, P=0.005), vascular lesions (31.47% vs 16.75%, P< 0.001) and positive pathergy test (17.83% vs 8.37%, P=0.002) were more common in male, while genital ulceration was more common in female (64.34% vs 80.79%, P<0.001). Regarding age difference, ocular lesions (P<0.017) were more frequently observed in younger patients, while vascular lesions (P=0.002) and GI symptoms (P=0.010) were more frequent in older patients. Gender differences of these manifestations were more prominent in certain age groups among 20-50 years old than other groups.

Conclusion: These analyses support that the clinical features of Chinese BD were different depending on sex and age.

AN EVALUATION OF THREE DIFFERENT METHODS TO EVALUATE SKIN IMPAIRMENT IN SYSTEMIC SCLEROSIS PATIENTS

Background: One of the characteristics of systemic sclerosis (SSc) is an increase in dermal thickness (DT) (1-3). Although the standard method to evaluate the extent of skin involvement is the modified Rodnan skin score (mRSS) (3,4), high frequency ultrasounds (US) and the plicometer skin test (Plicometry) (5-8) are now being used in SSc patients.

Methods: The aim of this study was to determine any correlations between mRSS, US and Plicometry during the evaluation of skin impairment in SSc patients.

Results: A significant positive correlation was observed between the three methods used to evaluate DT in the SSc patients (mRSS vs US r=0.64, p<0.0001; mRSS vs Plicometry r=0.97, p<0.0001; US vs Plicometry r=0.55, p<0.0001). Conversely, there was no correlation between these parameters in the CNT group (p>0.05). The intraclass correlation coefficients for mRSS was 0.95, 0.97 for US and 0.96 for Plicometry. Data collection for mRSS took almost 10 minutes, 15 minutes for Plicometry and 20 minutes for US.

Conclusion: This study demonstrates a significant relationship between mRSS, US and Plicometry in the DT evaluation of SSc patients. The SSc patients had statistically significantly higher values than HS when the 3 techniques were used to evaluate the seventeen skin areas.

PROGNOSTIC VALUE OF CARDIAC MAGNETIC VASODILATOR THERAPY IN THE LONG TERM PROGNOSTIC VALUE OF CARDIAC MAGNETIC VASODILATOR THERAPY IN THE LONG TERM

Late Gadolinium Enhancement 3.871 (1.289 – Mass
Right Ventricular End-Diastolic Indexed Right Atrial Area 1.384 (1.059 – Right Ventricular Ejection Indexed Left Atrial Area 1.244 (1.007 –

Background: Cardiac involvement is frequent in patients with systemic sclerosis (SSc). It is often subclinical, but significantly affects the prognosis of the disease. Cardiovascular magnetic resonance (CMR) is the non-invasive gold standard to quantify biventricular functional parameters and to perform a myocardial tissue characterization.

Objectives: To evaluate the prognostic value of CMR for cardiac events in SSc.

Methods: Two hundred and seventy-three SSc patients with a thorough clinical assessment underwent a CMR exam using a 1.5 T GE scanner. We quantified biventricular function parameter by SSFP cine images, oedema by STIR T2 images, and macroscopic fibrosis by late gadolinium enhancement (LGE) technique. Patients were followed-up and cardiac events were recorded as new onset of pulmonary arterial hypertension (PAH), new onset of heart failure (HF), or at least sustained ventricular tachycardia.

Results: Mean follow-up was 23.9 ± 17.0 months. During the follow-up a total of 14 events occurred (3 new onset PAH, 5 new onset HF, 6 ventricular tachycardia). CMR predictors of cardiac events by univariate analysis were left and right ventricular ejection fractions, indexed left and right atrial areas, and LGE (see Table). Myocardial fibrosis by LGE was the only independent predictor at multivariate analysis (hazard ratio 3.175; 95% CI 1.021-9.870, see Figure).

Conclusion: Cardiac magnetic resonance anatomical and functional parameters of both the left and right heart have significant prognostic value in patients with SSc.

VASODILATOR THERAPY IN THE LONG TERM PREVENTION OF MYOCARDIAL MANIFESTATIONS IN SYSTEMIC SCLEROSIS (SSC): RESULTS FROM DESSCIIPHER INCEPTION COHORT STUDY

Antonella Riccardi1, Dorte Husher2, Serena Fasano3, Valentina Messini3, Yannick Allarone4, Jérôme Avouac5, László Czirják6, Veronika Lorand7, Francesco Del Galdo8, Giuseppe Abignano9, Christopher Dentor10, Svetlana Niyttvanova11, Oliver Distler12, Britta Mauren13, Marco Mautucci-Cerinic14, Serena Guiducci14, Gabriela Riemekasten14, Elise Siegert14, Ulrich Walker14, Veronika Jaeger14, Marc Freix14, Ingo Helmut Tanne14, Ulf Müller-Ladner14, Gabriele Valentini14, Marco Matucci-Cerinic10, Serena Guiducci10, Valentina Messiniti1, University of Campania, Precision Medicine, Naples, Italy; “University Hospital Charité, Biometry and Clinical Epidemiology, Charité, Germany; “Cochin Hospital, Rheumatology, Paris, France; “University of Pécs, Rheumatology and Immunology, Pécs, Hungary; “University of Leeds, Biomedical Research Centre, Leeds, United Kingdom; “University College London, Centre for Rheumatology and Connective Tissue Disease, London, United Kingdom; “University College London, Centre for Rheumatology and Connective Tissue Disease, London, United Kingdom; “University Hospital Zurich, Rheumatology, Zurich, Switzerland; “University Hospital Zurich, Rheumatology, Zurich, Switzerland; “University of Florence, Experimental and Clinical Medicine, Florence, Italy; “University of Lübeck, Rheumatology and Clinical Immunology, Lübeck, Germany; “University of Basel, Rheumatology, Basel, Switzerland; “University of Basel, Epidemiology, Basel, Switzerland; “University Giessen, Rheumatology and Clinical Immunology, Bad Nauheim, Germany

Background: Calcium channel blockers (CCB) and angiotensin-converting enzyme inhibitors (ACEinh) are known to improve in the short term, cardiac perfusion and function in patients with SSc (Paris JU. et al. Rheum Dis Clin North Am 2014). No study has been carried out so far to investigate the long-term effectiveness of these drugs.

Objectives: To address this topic and other aspects of the management of SSc, the DeSSciipher (To decipher the optimal treatment of SSc) project was submitted to and financed by the European Community (FP7-HEALTH n°305495).

Methods: From Dec.1, 2012 to Nov. 30, 2015, 512 SSc patients who, as inclusion criterion, had no significant gut or lung or kidney involvement, were treated for 0.5-4 years (median 2.31) with either (n= 359: group 1) vasodilator therapy (i.e. CCB, or ACE-inh or Angiotensin II receptor blockers [AgIIrb] or a combination of them i.e. CCB plus either ACEinh or AgIIrb) or (n= 153: group 2) no vasodilator therapy. The 296 patients of the 2 groups, who had been assessed at baseline and along the follow-up for conduction blocks (CB), ventricular arrhythmias (VA), pacemaker implantation (PMI), left ventricular ejection fraction (LVEF) < 55% and angioscopic heart failure (CHF), and sudden cardiac death (SCD) during follow-up, were investigated for the cumulative incidence rate (IR) of all these events. The IR of single manifestations were calculated in the patients investigated for each of them. Cox regression analysis was carried out in the 296 patients with a missing value to identify independent predictors of the occurrence of any myocardial manifestation.

Results: During 1164 patient-years follow-up, 6/508 were implanted a PM,10/506 developed a LVEF<55%, 2/492 a CHF,11/325 a VA, 36/305 a CB, none underwent a SCD, any of these manifestations intervening in 59 out of the 296 investigated for all the manifestations. The IR of PM and VA was greater in group 2 patients as compared with group 1 (1.3 vs 0.2x100 pts/year; p=0.02) and (2.7 vs 1.1x100 pts/year; p=0.077). In stepwise Cox regression analysis, male gender (HR 2.44, 95%CI 1.3-4.6; p=0.005), age at enrollment (HR 2.97, 95%CI 1.7-5.2; p=0.007) and vasodilator therapy (HR 0.41, 95%CI 0.2-0.7; p=0.002) were independent positive and respectively, negative predictors of new onset cardiac manifestations.

Conclusion: Long term vasodilator therapy is likely to have a preventative role on the occurrence of myocardial manifestations of SSc.

### SAT0255

**EVALUATION OF THE CARDIOVASCULAR INVOLVEMENT OF SYSTEMIC SCLEROSIS USING NON-INVASIVE CARDIAC IMAGING TECHNIQUES**

Carina Espinol; 1, Maria Nazarena Pizzi; 1, Alfredo Guillén del Castillo; 1, Albert Rogué; 1, Víctor Pineda; 1, Isidro Sanz; 2, Eduardo L. Callejas-Moraña; 2, María Rocío; 2, Santiago Aguado; 2, Patricia Simeón-Aznar; 2, Hospital Universitari Vall Hebron, Barcelona, Spain 2 Parc Taulí Hospital, Badalona, Spain

**Background:** Systemic sclerosis (SSc) is a systemic disease that may affect many organs; among them, cardiac involvement. The prevalence of cardiac involvement in SSc varies depending on the sensitivity of the methods used for its detection. Indirect evidence suggests that subclinical cardiac involvement may eventually occur in the vast majority of patients with SSc. Early detection and monitoring of myocardial involvement are integral to SSC management, as cardiovascular involvement is known to be a poor prognostic indicator when present.

**Objectives:** To describe myocardial perfusion abnormalities and potentially associated coronary arteries lesions using non-invasive imaging techniques in a group of patients with SSc and suggestive symptoms of myocardial involvement (symptomatic) in comparison with a control group of patients with SSc without cardiac symptoms.

**Methods:** A retrospective observational study was performed including a total of 61 patients diagnosed with SSc, 52 symptomatic, with dyspnea and/or chest pain (57.98 ± 12.3 years, 45 women) and 9 asymptomatic controls (50.2±15.21 years, 8 women).

All patients underwent a post-stress (treadmill or pharmacological) myocardial perfusion gated-SPECT, a cold-induced stress SPECT, that were compared to a rest SPECT (to assess ischemia and/or necrosis), as well as a cardiac CT-angiography (to assess significant coronary arteries lesions, considering stenosis of more than 50%)

**Results:** Twenty-one out of the 52 symptomatic patients (50%) showed myocardial perfusion defects in the stress-rest SPECT: 13 (25%) showed ischemia, 10 (19.2%) had myocardial perfusion abnormalities; 13 (25%) fibrosis/necrosis, and 6 (11.5%) ischemia and necrosis. In the cold-induced SPECT, 17 patients (32.7%) showed mycardial perfusion abnormalities: 10 (19.2%) showed ischemia, 13 (25%) fibrosis/necrosis, and 6 (11.5%) ischemia and necrosis. In the other hand, of the 9 asymptomatic patients only 1 (11%) had ischemia and necrosis in the stress-rest SPECT, being only positive for necrosis in the cold-induced SPECT images. In the cardiac CT-angiography, 7/52 patients (13.4%) showed significant coronary lesions, 4 (57.2%) of them with perfusion defects in the SPECT images, and 3 (42.6%) without significant perfusion alterations.

Of the 9 asymptomatic patients, 1 (11%) had significant coronary lesions, being the same patient who presented perfusion defects in myocardial SPECT images.

**Conclusion:** The gated-SPECT is a sensitive tool for detecting myocardial perfusion alterations, normally with no associated significant coronary lesions, suggesting microvascular abnormalities. In this cohort, myocardial perfusion abnormalities were detected in 50% of symptomatic patients, whereas in only 11% of non-symptomatic patients.

### SAT0256

**EFFICACY AND SAFETY OF ANTIINFECTIVE THERAPY IN DIFFUSE INTERSTITIAL PULMONARY DISEASE ASSOCIATED WITH SYSTEMIC AUTOIMMUNE DISEASES**

Marta Aguilar-Zamora; 1, Juan Navarre; 2, Juanjo Aljibe-Sanche; 1, Vanesa Vicenc; 1, Maria Molina; 1, Joan Miquel Nolí; 1, Hospital Universitari Dr. Peset, Rheumatology, Valencia, Spain; 2 Hospital Universitat de Bellvitge, Rheumatology, Bellvitge, Spain; 3 Hospital Universitat de Bellvitge, Pulmonology, Bellvitge, Spain

**Objectives:** Assess the efficacy and safety of antiinfective agents (pifierine-done and niteranib) in refractory diffuse interstitial lung disease (DILD) associated with systemic autoimmune diseases (SAD).

**Methods:** Open observational study in patients with active symptomatic DILD-SAD (evidence of clinical and functional impairment) despite treatment with glucocorticoids (GC) and immunosuppressant therapy.

**Results:** We included 13 patients (8 women) with a mean age (± SD) of 55 ± 12 years (range, 7-71). The baseline SAD were: eight systemic sclerosis, one rheumatoid arthritis, one ankylosing spondylitis, one microscopic polyangiitis with pulmonary fibrosis and one interstitial lung disease with autoimmune characteristics (IPAF). Mean time from diagnosis to initiation of antiinfective therapy was 3 ± 8.2 years (IOR 25-75%: 1.6-9.5).

The histopathological patterns found were: seven cases (54%) of usual interstitial pneumonia (UIP), three (23%) nonspecific interstitial pneumonia (NSIP), two cases (15%) combined pattern of pulmonary fibrosis and emphysema (CPFE), and one (8%) non-classifiable pulmonary fibrosis (without histospecific radiological pattern).

In addition to GC, the previous therapy tested for DILD was mycophenolate mofetil (MMF) in 77% of the patients, cyclophosphamide (8 cases, and/or bleomycin) in 46%, and rituximab (RTX) in 54% (the number of RTX cycles administered were 4 ± 3.3 range, 1-9). Despite this, during the year prior to start the antiinfective drugs, all patients presented a worsening in the values of % pFVC (-8.77%) and% pDLCO (-6.71%) in 10 patients (77%) and with rituximab in 3 (23%). In addition to GC at doses between 5 and 20 mg/ day in 10 patients (77%) and with rituximab in 3 (23%). In addition to GC at doses between 5 and 20 mg/ day in 10 patients (77%) and with rituximab in 3 (23%).

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2019-eular.4592

**1204 Saturday, 15 June 2019**

**Scientific Abstracts**
duration of follow-up was 15 months (range 3-59). At the end of the follow-up period, 10 of the 13 patients (77%) were still in treatment. In 2 patients (15%) the therapy failed, requiring lung transplantation in 1 case (after 7 months of therapy), while an autologous hematopoietic stem cell transplantation was conducted in the other patient (after 13 months of anabiotic). In one patient (8%) the treatment was discontinued due to adverse effects.

When quantifying the degree of response in patients who continued treatment, only 9 of the 10 patients were included in the analysis, since 1 had only 3 months of therapy. In these 9 patients there was an improvement of pFVC (mean: ±5.13; SD: 8.38) and pDLOD (±4.42; SD: 5.06). The evolution of the efficacy variables analyzed is shown in the table.

The response in the Pulmonary function testing (PFT) in these 9 patients categorized according to the definitions of the American Thoracic Society was as follows: A) pFVC: stabilization in 5 cases and improvement in 4; B) pDLOD: stabilization in 7 cases and improvement in 3.

The frequency of adverse effects was 31% (413), but only the treatment was withdrawn in 1 patient (8%). Three patients presented digestive discomfort that forced to reduce the dose of the anabiotic. One patient developed a toxic hepatitis due to nintedanib after 4 months of treatment that forced the withdrawal of the drug, replacing it 1 month ago with placebo and the follow-up died.

Conclusion: Our data provides evidence of the safety and tolerability of both pirfenidone and nintedanib in patients with DIDL-SAD refractory to GC and immunosuppressant therapy.

SAT0257 THE SIGNIFICANCE ON THE TRANSITION THROUGH DIFFERENT PATTERNS OF NAILFOLD MICROVASCULAR DAMAGE ON THE COURSE OF SYSTEMIC SCLEROSIS
Slavica Pavlov-Djoljanovic, Nemanja Damjanov, Nada Vujasovic-Stupar, Institute of Rheumatology, School of Medicine University of Belgrade, Belgrade, Serbia

Objective: To investigate the timing of transition through different patterns of nailfold microvascular damage in systemic sclerosis (SSc) patients and to determine the significance of this transition.

Methods: In the period January 2012 to December 2017, 400 SSc patients were followed up by nailfold videocapillaroscopy (NVC) the same operator (SPD) every 6 months. Demographic, clinical and laboratory data were recorded. The capillaroscopic findings were classified as normal, nonspecific or scleroderma pattern (‘early’, ‘active’, or ‘late’). The evolution on the NVC pattern over time was monitored and recorded.

Results: The transition of microangiopathy was seen in 53/400 (13.25%) SSc patients. At the baseline 11/53 (21%) patients had the non-specific changes, the early pattern had 25/53 (47%) patients, and the active pattern had 17/53 (32%) SSc patients. The mean ± SD time of progression from one to another NVC patterns was 27.68 ± 35.11 months. Improvement of the NVC patterns was found in 15/53 (28%) patients and deterioration in the remaining 38 (72%) patients. The mean time of progression from nonspecific to early pattern (in 10 patients) and nonspecific to active pattern (in 1 patient) was 14.5 ± 9.73 vs. 12 months, respectively. Time of changed from early to nonspecific (in 7 patients), early to active (in 17 patients) and early to late pattern (in 1 patient) was 30.65 ± 22.56 vs 22.29 ± 16.61 vs 24 months, respectively. Time of changed from active to early (in 8 patients) and active to late pattern (in 9 patients), was 26.25 ± 11.11 vs 18.00 ± 13.97 months, respectively. Progression of nonspecific to early or active NVC pattern was related with limited form of SSc (91%), diffuse hand swelling (54%), arthralgia/arthritis (45%) and involvement of lungs (48%). Also, progression of early to active NVC pattern was related with limited form of SSc (64%), sclerodactyly (48%) and involvement of lungs (48%). In contrast, progression of active to late NVC pattern was related with diffuse form of SSc (53%), digital ulcerations (35%) and more frequent involvement of lungs (65%). These differences in the frequency of involvement of certain organs were not statistically significant.

Conclusion: These results demonstrate dynamic transition of microvascular damage through different NVC patterns of microangiopathy in about 13% of SSc patients. Patients with rapid progression from the early to active, as well as active to the late NVC patterns (>2 years) should be monitored closely, because they are at risk of further significant damage to the internal organs.

SAT0258 SEXUAL HEALTH IMPAIRMENT IN WOMEN WITH SYSTEMIC SCLEROSIS
Barbora Hejčková1, Maja Šprlíková1, Hana Smrucová2, Sabina Oresku2,3, Hana Storkánová2,1, Kristýna Bubová2,3, Karel Pavelka2,3, Jiří Vencovsky2,3, Ladislav Šerofil1,2, Radim Bečvář2,3, Michal Tomcik2,3, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic; Institute of Rheumatology, Prague, Czech Republic; 1st Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease that may affect all aspects of life including sexual function.

Objectives: To assess sexual function, pelvic floor function and sexual quality of life women with SSc compared to age-sex-matched healthy controls (HC). To subanalyze sexual function in sexually active individuals.

Methods: In total 47 women with SSc (mean age: 50.5, disease duration: 5.6 years, lcsSc/idcsSc: 27/20, mRSS: 12.7, ESSG activity index: 2.5), who fulfilled the ACR/EULAR 2013 criteria, and 47 healthy women (mean age: 50.5) filled in 11 well-established and validated questionnaires assessing sexual function, pelvic floor function, quality of life, fatigue, physical activity and depression. Data are presented as mean±SEM.

Results: Compared to HC, patients with SSc had significantly higher prevalence and greater severity of sexual impairment (FSFI, BISF-W), pelvic dysfunction (PISO-12, PFQ07), and worse sexual quality of life (SQol-F) (table 1). There were no significant differences in sexual function between limited and diffuse SSc. Even sexually active SSc patients reported significantly greater sexual health impairment compared to sexually active HC. Sexual health impairment in SSc was associated with dis-
ease activity/duration, health status, physical activity, fatigue and depression (table 2).

Conclusion: Women with SSc reported significantly impaired sexual function, sexual quality of life and pelvic floor function than age-matched HC. Worse scores in SSc were associated with disease activity/duration/health status, physical activity, fatigue, and depression.

PREDICTIVE FACTORS FOR TREATMENT RELATED MORTALITY AND MAJOR ADVERSE EVENTS AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR SYSTEMIC SCLEROSIS: RESULTS OF A LONG TERM FOLLOW-UP MULTI-CENTRE STUDY

Sandra van Bijnen1, Maaike Boonstra2, Cornelia van den Enden1, Julia Sperigros2, Annette Schouffoer, Jacob M. van Laar, Thomas Huizinga, Alexandre Voskuyl3, Walter van der Velden4, Frank van den Hoegen5, Jeska de Vries6, Madelon Vork7, Leiden University Medical Center, Rheumatic diseases, Nijmegen, Netherlands; 2Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; 3Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 4VUMc, Department of Medicine, Amsterdam, Netherlands; 5Radboud University Medical Center, Hematology, Nijmegen, Netherlands

Background: Autologous hematopoietic stem cell transplantation (HSCT) has shown superior efficacy to cyclophosphamide pulse therapy in systemic sclerosis (SSc) but its application is hampered by high treatment related mortality (TRM). To date factors, other than smoking, predicting TRM has shown superior efficacy to cyclophosphamide pulse therapy in systemic subtype who were treated because of interstitial lung disease. The aims of this study were to analyse possible differences correlated with major events.

MUSCULAR INVOLVEMENT OF THE LOWER LIMBS IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: A MRI EVALUATION

Simone Barosi1, Barbara Mugellini2, Alessandra Tripoli3, Giacomo Aringhieri2, Chiara Cardelli1, Elisa Cioffi1, Vanna Zampa1, Davide Caramella1, Marta Mosca1, Rossella Neri1, University of Pisa, Rheumatology Unit, Pisa, Italy; 2University of Pisa, radiology Unit, Pisa, Italy; 3University of Pisa, radiology Unit, Pisa, Italy

Background: Since many years, muscular magnetic resonance imaging (MRI) has been used in the diagnosis and follow-up of patients with idiopathic inflammatory myopathies (IIM), but the clinical significance and the pattern of the muscular alterations (edema, fatty infiltration and atrophy) in different subsets of the disease are still not well defined.

Objectives: The aims of this study were to analyse possible differences in the involved muscles between dermatomyositis (DM) and polymyositis (PM); the correlations between the pattern of muscular involvement in different subsets of the disease and disease parameters in a monocentric cohort of patients.

Methods: We retrospectively collected data from 85 patients with poly and dermatomyositis (EULAR/ACR criteria) who performed pelvic and thighs muscle MRI from January 2010 to December 2018: 27 had DM and 58 PM, mean age 58.6±13.4 years, mean disease duration of 45±73 months. The images in 22 muscles for the presence of muscular edema, fatty infiltrates and atrophy were assessed by a dedicated radiologist. Moreover, data about serum creatine kinase (CK) and manual muscle

Conclusion: In this national cohort study of HSCT in patients with SSc and poor prognosis we observed a median event-free survival of 4.3 years. TRM was 10.8% and major events occurred in 13%. TRM was correlated to male gender. Low LVEF, male gender and older age were correlated with major events.
CHARACTERISTICS ASSOCIATED TO SCLERODERMAL RENAL CRISIS, AND INCIDENCE VARIATION OVER TIME IN THE RESCLE REGISTRY

Xavier Pla Sala1, Carlos Tolosa2, Eduardo L. Cañellas-Moriga2, Álvaro Guillén del Castillo5, Jose Antonio Todoli Parra3, Luis Trapella Martínez3, Mónica Rodríguez Corbalanera4, Adria Martín Bath1, Isabel Parrales Fraile2, Vicent Fontollosa-Pi4, Carmen Pilar Simeón-Aznar2, On Behalf of Rescle Investigators, Autoimmune Diseases Study Group (Geas)1,2, Consorci Hospitalari de Vic, Unit of Systemic Autoimmune Diseases, Department of Internal Medicine, Vic, Spain; 3Hospital Corporación Sanitaria Universitaria Parc Taulí, Unit of Internal Medicine, Sabadell, Spain; 4Hospital Vall d’Hebron, Unit of Autoimmune Diseases, Department of Internal Medicine, Barcelona, Spain; 5Hospital Universitario y Politécnico La Fe, Department of Internal Medicine, Valencia, Spain; 6Hospital de Castres, Unit of Systemic autoimmune diseases, Department of Internal Medicine, Gijón, Spain; 7Hospital Universitario Mutua de Terrassa, Department of Internal Medicine, Terrassa, Spain; 8Hospital Clínico Universitario Lozano Blesa, Unit of Autoimmune Diseases, Department of Internal Medicine, Zaragoza, Spain; 9Hospital Universitario Rey Juan Carlos, Department of Internal Medicine, Madrid, Spain; 10Hospital Universitario Vall d’Hebron, Unit of Autoimmune Diseases, Department of Internal Medicine, Barcelona, Spain; 11Sociedad Española de Medicina Interna (SEM), Madrid, Spain

Background: Scleroderma Renal Crisis (SRC) is a serious complication of Systemic Sclerosis (SSc). Nowadays, it seems that there is a reduction in its prevalence and mortality1. Objectives: To evaluate the characteristics of patients with SSc in a large cohort of SSc patients. To investigate predictors of SRC, and epidemiologic differences over time. Methods: 1933 patients were collected in ongoing registry of Spanish SSc patients – RESCLE. We did descriptive study and epidemiologic analysis. Results: Out of 1933 SSc, 43 (2.2%) developed SRC. Univariate analysis showed significant differences of SRC vs. non-SRC population: SSc subtypes: diffuse cutaneous SSc (dcSSc), 72% vs. 19%; limited cutaneous SSc (lCSSc), 26% vs. 61%. Demographics: Female gender, 77% vs. 89%; time from SSc onset to SRC diagnosis, 3.0±8.0 vs. 6.6±9.5 years; arterial hypertension (HT), 56% vs. 32% 1st manifestation: Raynaud’s phenomenon (RP), 68% vs. 82%. Clinical manifestations: RP, 88% vs. 96%; digital ulcers, 70% vs. 38%; arthritis, 45% vs. 20%; myositis, 30% vs. 13%; joint contractures, 45% vs. 18%; intestinal involvement, 24% vs. 11%; malabsorption, 24% vs. 7%; interstitial lung disease 58% vs. 41%; pulmonary HT, 56% vs. 29%; periarticular effusion, 28% vs. 7.4%; periarticular stiffness, 24% vs. 8.3%; ischiadic neuropathy, 31% vs. 12%; diastolic dysfunction, 67% vs. 34%. Capillaroscopy: active pattern 77% vs. 33%. Immunological data: anti-Topoisomerase I, 39% vs. 20%; anti-centromere, 15% vs. 49%; anti-ARNAPol III, 45% vs. 11%. Prognosis: Overall mortality, 56% vs. 18%; SSc-related mortality, 83% vs. 49%. Survival at 5, 10, 20, and 30 years was 73% vs. 96%, 56% vs. 92%, 28% vs. 80%, and 28% vs. 67%, respectively. Treatment: ACEI use, 35% vs. 14%, corticoid use, 51% vs. 25%. Multivariate analysis: dcSSc subtype, RR 22.68 (5.81-88.51) p<0.001; intestinal malabsorption, RR 7.35 (2.55-21.18) p<0.001, and active capillaroscopy pattern RR 7.26 (1.61-32.7) p<0.010. Prevalence of SRC in dcCSSc subtype 7.8%, and in lCSSc subtype 0.9%. P over decades: P-80’s, 3.8%; P-90’s, 2.7%; P-00’s: 2.3% and P-10’s: 0.9%, achieving statistical significance in the last decade PRR: 0.33 (0.13-0.85) = 0.014.

Conclusion: In RESCLE cohort, SRC predominated in dcSSc patients, and it was associated to intestinal malabsorption, and an active pattern by capillaroscopy. SRC showed a very poor prognosis. Finally, we evidenced a decreasing prevalence of SRC over time in our cohort.

GAZE PATTERN ANALYSIS IN THE ASSESSMENT OF DIGITAL ULCERS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Thomas Moser, Quentin Lohmeyer, Mirko Meboldt, Oliver Distler, Mike O. Becker

University Hospital Zürich, Rheumatology, Zürich, Switzerland; ETH Zürich, Mechanical and Process Engineering, Zürich, Switzerland

Background: The assessment of chronic wounds such as digital ulcers (DUs) in systemic sclerosis relies heavily on visual aspects. However, inter-rater variability in the assessment and definition of digital ulcers is low and there are no evidence-based data concerning the visual assessment of digital ulcers.

Objectives: We analysed gaze pattern data in order to evaluate differences in the visual assessment of digital ulcers in systemic sclerosis patients.

Methods: We analysed gaze pattern data from 36 subjects: 9 expert medical professionals (EMP), 8 non-expert medical professionals (NEMP), 9 medical graduates (MG) and 10 lay persons (novices). Assessment was done using a mobile eye-tracking device that tracks eye movements of subjects. Twenty pictures from digital ulcers of SSC patients were presented to each subject, 30 seconds each and characteristics of gaze pattern data were analysed. The analysis comprised the scan path and the dwell times (for areas of interest, AOI), fixation counts and the entry time for each picture and subject. Areas of interest were defined as the wound area, wound margin, wound surroundings and distracting non-relevant parts of the pictures. The visual assessment of the digital ulcers was accompanied by questions for each subject about their assessment of the DUs, the expected healing of the ulcer, the medical treatment of the patient.

Results: Most significant differences were found between novices and medically educated groups (expert medical professionals, non-expert medical professionals, medical graduates - EMP, NEMP, MG). Dwell times in the wound area for novices differed statistically significantly from all medically educated groups (1.76s-3.1s less). Above all, novices had lower dwell times in wound margin and wound surrounding and spent more time in areas with other distracting features of the picture and white space (up to 1.92s longer). Correspondingly, they had less fixation points and longer overall scan paths in wound areas. Similar gaze pattern data were observed for medically educated groups, however NEMP had a statistically significantly lower dwell time in the wound area than EMP. Questionnaire responses were compared to an expert opinion (gold standard) and EMP had significantly more correct answers on prognosis and treatment than MG for wound assessment, but not better than NEMP.

However, treatment and prognosis were best in the EMP group with statistical difference to the NEMP and MG group.

Conclusion: For the first time, we provide evidence-based data on the visual assessment of digital ulcers in SSC. These data will be useful for the development of a structured educational programme for young physicians, rheumatology trainees and medical graduates. A key finding is that the visual assessment of digital ulcers should increasingly emphasize the importance of pathologic changes in the wound margin and surrounding area of the wound. Hence a structured approach should focus on all areas of the wound while discarding distracting visual information. An adequate terminology should be used alongside.

**Determinants of Renal Resistive Index (RRI) at Renal Artery Doppler Ultrasound in Systemic Sclerosis (SSc): More than General Population Factors**

Cosimo Bruni¹, Edoardo Rosato², Antonietta Gigante², Vanessa Maestripieni¹, Glulia Tesei¹, Marco Chiostrò¹, Gemma Lepe¹, Silvia Belfando Randone¹, Serena Guiducci¹, Sergio Castellani¹, Maria Boddi¹, Marco Matucci-Cerinic¹, ¹Careggi University Hospital, Firenze, Italy; ²Sapienza University of Rome, Roma, Italy

**Background:** RRI can be measured on renal artery Doppler ultrasound, showing the difficulty blood flows encounter distally from where it is measured. RRI can be determined by vascular and interstitial renal features: studies on the general population showed arterial hypertension, arteriosclerosis, low-grade inflammation, diabetes mellitus, hyperuricaemia as possible causes of renal vasculopathy or tubular-interstitial nephropathy, thus determining altered RRI values. Studies on SSc have shown increased RRI values, associated with nailfold-videoendoscopy pattern and history of digital ulcers.

**Objectives:** To identify determinants of RRI in SSc patients.

**Methods:** SSc patients fulfilling the 2013 ACR/EULAR criteria were enrolled from two SSc-care units. Data regarding SSc clinical manifestations, instrumental, and laboratory evaluation for renal, cardiac and cardiovascular involvement were collected. RRI was measured at least once in each patient. Linear regression analysis was carried out to determine predictors for baseline RRI and change in RRI in time (ΔRRI).

**Results:** 380 patients [aged 57 (46-68) years, 12% males] were enrolled in the study. On univariate analysis, both general population determinants (age, arterial hypertension, diabetes mellitus, hyper-lipidaemia, and hyper-uricaemia) and SSc specific features [time from Raynaud’s phenomenon onset, ACA positivity, scleroderma renal crisis history, estimated systolic pulmonary arterial pressure on Echo (sPAP), presence of dyspnea, %DLCO and presence of lower intestinal symptoms] predicted RRI values, with only age and sPAP being significant independent predictors at baseline. Follow-up RRI, available for 230 patients, showed that none of the general population determinants was predictive for ΔRRI.

**Conclusion:** Data show that among general population determinants, age is the only predictive factor for RRI in SSc patients. However, only age and sPAP were predictive for ΔRRI. Therefore, the use of specific age-adjusted cut-offs (table 1) are recommended when assessing SSc patients.

**Digital Ulcer (DU) and Ventricular Arrhythmias Predict the Late Gadolinium Enhancement (LGE) in Cardiac Magnetic Resonance (CMR) in Systemic Sclerosis (SSc): Proposal of Candidate Red Flags for Early Referral**

Cosimo Bruni¹, Luna Gargani², Alessia Pepe³, Antonella Mekoni⁴, Daniele De Marchi⁴, Giancarlo Todiene⁴, Gennaro D’angelo⁵, Alberto Moggi Pignone⁵, Serena Guiducci⁵, Marco Matucci-Cerinic⁵, ¹Careggi University Hospital, Firenze, Italy; ²CNR IFC Istituto di Fisiologia Clinica, Pisa, Italy; ³Fondazione Toscana Gabriele Monasterio, Pisa, Italy

**Background:** In SSc, cardiac involvement either primary or secondary, is frequently subclinical. In myocardial diseases, CMR is considered the non-invasive gold standard to diagnose myocardial tissue involvement and LGE has a significant impact on prognosis.

**Objectives:** To identify the predictors of the presence of LGE in SSc patients.

**Methods:** Patients fulfilling the 2013 ACR/EULAR classification criteria were assessed with CMR (1.5 T GE scanner) when clinically indicated. Data on demographics, clinical SSc features, laboratory and instrumental tests for cardio-pulmonary, microvascular and renal involvements were recorded at the time of CMR evaluation. Binary regression analysis was performed with SPSS version 25.0.

**Results:** 317 SSc patients (284 women, mean age 52±14) were enrolled in the study. LGE-CMR was present in 32.9% and Myocardial edema (ME-CMR) in 6.1% of patients. On univariate regression analysis, %DLCO values, NYHA functional class, history of DU (hDU), TAPSE and couples of ventricular premature beats (VPBc) were predictors of LGE-CMR or ME-CMR. At multivariate analysis, TAPSE (OR 0.832, 95% CI 0.727-0.951, p=0.007), hDU (OR 3.893, 95% CI 1.614-9.387, p=0.002) and VPBc (OR 2.38, 95%CI 0.959-18.738, p=0.057) were independent predictors for LGE-CMR. Presence of pericardial effusion was the only predictor for ME-CMR (OR 3.379, 95% CI 1.018-12.988, p=0.047).

**Conclusion:** DU history, ventricular ectopic beats on 24 hours ECG, TAPSE impairment and pericardial effusion on echocardiography may predict myocardial LGE. More studies are necessary to further verify and validate these “red flags” to refer the patients to CMR.

**Serum Anti-Heterogeneous Nuclear Ribonucleoprotein Antibody Characterizes Systemic Sclerosis with Anti-centromere Antibody and Severe Raynaud’s Phenomenon with Digital Ulcers**

Natasa Isailovic¹, ²Angela Cerbelini, Carolina Golinò³, Elena Generali³, Maria De Santis³, Marta Caprioli³, Giacomo Maria Guidelli³, Piercarlo Sarzì-Puttini³, Minou Satoh¹, Carlo Selmi¹, ³Humanitas Clinical and Research Hospital, Rheumatology and Clinical Immunology, Rozzano (MI), Italy; ²Luigi Sacco University Hospital, Rheumatology, Milan, Italy; ³University of Milan, Milan, Italy; ⁴University of Occupational and Environmental Health, Clinical Nursing, School of Health Sciences, Kitakyushu, Japan

**Background:** Systemic Sclerosis (SSc) is characterized by the presence of serum autoantibodies (autoAbs) which may be crucial in the diagnosis, prediction of organ involvement, follow-up, and treatment choices. However, SSc sera can be negative for autoAbs identified using commercially available tests, and several new and rare autoAbs have been identified in the last decade with immunoprecipitation (IP) techniques. We recently reported a new IP pattern corresponding to anti-heterogeneous nuclear ribonucleoprotein (anti-hnRNP) antibodies in a cohort of SSc patients.

**Objectives:** To analyze the IP pattern of anti-hnRNP antibodies in SSc sera and determine their clinical and laboratory correlations.

**Methods:** We investigated sera from 63 consecutive patients with SSc attending our Unit between 2014 and 2018, using protein-IP of 35S-methionine-labeled K562 cell extract followed by SDS-PAGE and autoradiography, and IP-Western Blot for hnRNP-L and C1+C2 following

CLINICAL FEATURES OF INTERSTITIAL LUNG DISEASE

Sang Won Chung1, Jooyun Kim2, In Seol Yoo3, Seung-Jae Hong4, Yeon-Ah Lee5, Seoing Wook Kang6, Seungcheol Shim7, Seong Wook Kang2, Seungcheol Shim2, In Ah Choi6, Sung Hae Chang7.

Background: Myositis-specific and myositis-associated autoantibodies (MSA and MAA) have been used for more detailed classification and prediction of clinical course of idiopathic inflammatory myopathies (IIM). Interstitial lung disease (ILD) is known to be complicated with approximately 50% of IIM patients, having poor prognosis.

Objective: The aim of this study is to investigate clinical features of ILD in Korean adult patients with IIM according to the autoantibody profile including MSA and MAA.

Methods: We conducted a multicenter cohort study including 108 adult patients (age≥18 years) who have been diagnosed as IIM by ENMC criteria MSA and MAA were screened with Immunoblot assay using Euroimmun antibody line strip (EUROIMMUN, Germany). Clinical information including the time of developing ILD and imaging findings of chest CT was reviewed using medical record.

Results: ILD was found in about half (52.8%, 57 of 108) of enrolled patients and closely associated with the presence of anti-ARS Abs, anti-MDAS and anti-Ro52. Among 43 patients, Anti-ARS Abs were most common (46.5%) and included anti-Jo-1 (23.3%), -OJ (2.3%), -EJ (9.3%), -PL7 (14%), and -PL12 (7%) (Figure 1). To analyze the correlation of autoantibodies with pattern of ILD onset, we stratified the 43 patients into three groups: into ILD-preceding (7/43, 16.3%) and myopathy-preceding group, 50% of patients (6/12) were UIP and a half of patients had pulmonary function which required treatment (DLCO<65%).

Conclusion: In our study, ILDs were accompanied by over half of the cases of IIM and most of them had autoantibodies. There are characteristic clinical features by onset time of ILD, so paying attention to them will help early diagnosis and prognosis prediction of ILDs.

REFERENCE

SOT0268 CLINICAL FEATURES OF INTERSTITIAL LUNG DISEASE ASSOCIATED WITH KOREAN IDIOPATHIC INFLAMMATORY MYOPATHIES ACCORDING TO THE AUTOANTIBODY PROFILE

Disclosure of Interests: Natasa Isailovic: None declared, Angela Ceribelli: None declared, Carolina Gorlino: None declared, Elena Generali: None declared, Giacomo Maria Guidelli: None declared, Piercarlo Sarzi-Puttini: None declared, Minoru Satoh: None declared, Carlo Selmi Grant/research support from: AbbVie, Janssen, MSD, Novartis, Pfizer, Consultant for: AbbVie, Sanofi-Genzyme, UCB, Speakers bureau: AbbVie, Alfa-Sigma, Biogen, Bristol-Myers Squibb, Celgene, Eli-Lilly, Janssen, Merck Sharp and Dohme, Novartis, Pfizer, Roche, Sanofi-Genzyme, UCB

Objective: To develop a comprehensive ICF core set for SSc and to conceive a patient-centered ICF-based questionnaire assessing activities and participation in patients with SSc.

Methods: The development of the ICF comprehensive core set followed 2 steps (2). In the first step, meaningful concepts related to SSc were collected using data source triangulation from patients (N=18), experts (N=10) and literature (N=174 articles). In the second step, concepts were linked to the best-matching ICF categories by 2 independent reviewers according to prespecified linking rules (3). Finally, patient-reported activities and participation categories of the comprehensive ICF core set were translated into understandable questions.

Results: After linking concepts to ICF codes, 151 ICF categories were collected from focus groups, 22 from experts and 82 from literature. After fusion of the sources and removal of duplicates, the comprehensive ICF core set included 165 categories: 1 at the first level, 158 at the second level, 6 at the third level, with 50 categories on body functions, 15 on body structures, 53 on activities and participation and 47 on environment and health.

Conclusion: We developed a comprehensive ICF core set that offers a conceptual framework for SSc patients’ care and health policy. Using a patient-centered approach, we conceived a patient-centered ICF-based questionnaire, the Cochin Scleroderma ICF-65 questionnaire, assessing activities and participation in patients with SSc.

RELATIONSHIP BETWEEN ANTI-MDA5 ANTIBODIES AND CANCER: RETROSPECTIVE ANALYSIS OF AN INTERNATIONAL AND MULTIDISCIPLINARY COHORT

Ludovico De Stefano1, Santos Castañeda2, Ellen De Langhe3, Jörg Distler4, Johannes Knitza5, Ilaria Cavazzana6,7, Alain Meyer7, Jorge Rojas-Serrano8, Eugenio Arigoni9, Federica Furini10, Marcello Govoni11, Paola Parrocchini11, Giovanni Zanframundo1, José Antonio P. da Silva12, Elisa Pedrollo13, Florenzo Iannone14, Carlomaurizio Montecucco1, Lorenzo Cavagna1.

Objectives: To describe the relationship between malignancy and anti-MDA5 antibodies in IIMs.

Methods: Patients with anti-MDA5+ IIMs and a history of cancer were included in this study. Data were retrospectively collected. Because of the lack of RP-ILD shared definitions, we defined RP-ILD as an admission to the Intensive Care Unit (ICU) for IIMs related respiratory insufficiency.

Results: In our cohort (n=133, 67% females) we identified 17 patients (13%) with a history of cancer (8 males [47%], 9 females [53%]; median age at IIMs onset 62 years [IQR 53-67], at cancer diagnosis 56 years [IQR 51-66]). All but 1 patient had solid tumours, 5 (29%) had breast cancer. The 13 surviving patients had a median rheumatological follow-up of 47 and 66 (infection after RP-ILD in ICU) months after cancer diagnosis. The 0.1136 annrheumdis-2019-eular.4565

Conclusion: This is the first study addressed to tackle the relationship between cancer and anti-MDA5+ IIMs. Although in some cases no clear relationship could be established, IIMs and cancer can be proved because of the time gap, in others the timing of occurrence of cancer and IIMs was very close, suggesting a link between these manifestations. Finally, we emphasize the importance of an accurate neoplasm screening in anti-MDA5+ RP-ILD, because treatment refractoriness could suggest the paraneoplastic nature of the manifestation.

RITUXIMAB SIGNIFICANTLY DIMINISHES CD66+ B CELLS IN SYSTEMIC SCLEROSIS

Barbara Drego1, Barbara Prieß2, Selina Köffler3, Harald Souraj4, Angelika Lackner4, Florentine Fürst-Moazzedi5, Monica D’orazio6, Martin Stradner7, Winfried Graninger1, Hans-Peter Brezinsek8, Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria; 1Clinical Department – Center for Biomarker Research in Medicine, Graz, Austria; 2Medical University of Graz, Division of Endocrinology and Diabetology, Graz, Austria.

Background: Rituximab (RTX) is a monoclonal antibody that targets the CD20 surface marker. This results in a reduction of CD20+ immune cell populations, foremost B cells. B cell depletion via RTX was found to be beneficial for patients suffering from systemic sclerosis (SSc), leading to an improvement of skin fibrosis and autoimmunity (1). However, little is known about the influence of RTX on specific B subsets in SSc.

Objective: The purpose of this study was to further characterize the effect of RTX on B cell populations in patients with SSc.

Methods: Peripheral blood samples from 37 patients suffering from SSc (mean age: 54 ± 1.64 SEM, female ratio: 0.78) and 10 age-matched healthy participants were drawn over a sampling period of 2 years. 20 SSc patients in this study group were at the time under RTX treatment and the modified Rodnan Skin score (mRSS) was measured before and after treatment start. The percentage of CD19+ / CD20+ lymphatic cells and CD19+CD20+ B cells co-expressing either CD5, CD24, CD27 or CD86 on their surface was done by surface freshly isolated PBMCs. A quantitative flow cytometric bead-based assay (QuantiBRITE PE kit from Becton Dickinson) was used for the estimation of CD19 antibodies bound per cell. All cytometric measurements were performed using a standardized BD LSIRfortessa platform.

Results: RTX induced a significant decrease in mRSS from 19.7 ± 2.8 to 8.1 ± 1.7 (mean ± SEM; p<0.000). In addition, CD19+CD20+ cells were diminished as a result of the treatment. Thus, the frequency of CD19+CD20+ cells in the non-treatment group was 13% ± 0.3% compared to 0.7% ± 0.2% (p = 0.048). Within the B cell population 33.3% ± 3.6% were positive for CD26, a checkpoint molecule for the activation of T cells during an immune response. RTX treatment significantly decreased this B cell population to 11.2% ± 4.7% (p = 0.039). Quantification of the number of CD19 molecules on the surface of CD19+CD20+ B cells revealed a significantly lower number in SSc patients compared to healthy participants. The mean ± SE of molecules per cell was 6862 ± 625 and 7449 ± 569, respectively (p = 0.001).

Conclusion: RTX treatment in SSc might not only be effective by reducing B cells but also by down regulation of the CD86 B cell surface marker on B cells. This would indicate that B cells under RTX treatment are less capable of activating T cells.

PREDICTIVE VALUE OF THE REVISED EUROPEAN SCLERODERMA TRIALS AND RESEARCH GROUP ACTIVITY INDEX (EUSTAR-AI)

Serena Fasano1, Veronica Giacco2, Antonella Riccardi3, Valentina Messiniti1, Gabriele Valentini1, European Scleroderma Trials and Research group (EUSTAR) co-authors.

1University of Campania; 2University of Bari; 3University Hospital Zurich, Rheumatology, Zurich, Switzerland

Background: Disease activity as measured by the European Scleroderma Study Group Activity Index (EScSG-AI) (1) has been recently found to predict the development of damage over time in an early systemic sclerosis (SSc) cohort (2). The European Scleroderma Trials and Research Group Task Force for the Development of Revised Activity Criteria for SSc recently succeeded in identifying a preliminarily revised activity index (EUSTAR-AI) that had a greater construct validity than the EScSG-AI i.e. performing better in identifying patients with active disease (3).

Objectives: To assess in patients with SSc the predictive value of the EUSTAR-AI for disease severity accrual.

Methods: SSc patients from the EUSTAR database with a disease duration from the onset of the first non-Raynaud sign/symptom to 5 years were first extracted. Patients were considered for the study if they presented the following features: a) availability of items included in the EUSTAR-AI, in the EScSG-AI and in the Medsger severity scale at baseline and yearly for 2 consecutive years; b) availability of vital status at the last observation; c) availability of other disease features known to predict disease progression (male sex, clinical and serological subset).

To capture the disease activity variations over time, we calculated the EUSTAR-AI and EScSG-AI adjusted mean (area under the curve over time). Disease progression was based on the Medsger severity scale and included accrual of a Δ≥1 summed severity score and of a Δ≥1 severity in each organ systems at the 2 year follow-up visit compared with the initial visit. To explore specific determinants of disease progression, logistic regression analysis was carried out.

Results: A total of 549 patients satisfied the entry criteria. Univariate logistic regression analysis (among sex, age, clinical and serological subset, EScSG-AI and EUSTAR-AI adjusted mean and baseline severity score), EScSG-AI adjusted mean (OR 1.41 95%CI 1.20-1.67), antinuclear antibody positivity (OR 1.72 95%CI 1.20-2.47), diffuse subcutaneous (OR 1.46 95%CI 1.01-2.10) and EUSTAR-AI adjusted mean (OR 1.41 95%CI 1.23-1.61) predicted disease severity accrual. Multivariate analysis revealed that the EUSTAR-AI adjusted mean was the best predictor of disease progression (Table1). Moreover, when logistic regression analysis the EUSTAR-AI adjusted mean also predicted severity accrual of lung (OR 1.32), heart (OR 1.40), skin (OR 1.48) and peripheral vascular disease (OR 1.45).

Conclusion: The adjusted mean EUSTAR-AI has a distinct predictive value for disease progression and development of severe organ involvement in SSc and works better than EScSG-AI.

THE EFFECT OF RITUXIMAB ON LUNG FUNCTION AND SKIN SCORE IN SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE. LONG-TERM OBSERVATION

Ludmila Garzanova1, Lidia P. Ananyeva1, Olga Konaya1, Oxana Desinova1, Olga Osvyannikova1, Maya Starova1, Alexander Volkov2, Svetlana Glukhova3.

1A. Nasonova Research Institute of Rheumatology, Laboratory of microcirculation and inflammation, Moscow, Russian Federation; 2V. A. Nasonova Research Institute of Rheumatology, Diagnostic department, Moscow, Russian Federation

Background: There is a large clinical experience about the efficiency of rituximab (RTX) for the treatment of systemic sclerosis (SSc). There are several studies showing the decrease in skin induration and interstitial fibrosis in the lungs as the effect of therapy. However, there are not many long-term observations.

Objectives: To describe the efficacy of RTX on lung function and skin score in patients with systemic sclerosis-associated interstitial lung disease, in long-term follow-up.

Methods: This study included 71 patients (pts) with SSc. Data were collected prospectively. The mean follow-up period was 42 mo (12-72). Mean age was 46 years (17-66), female-59 (83%), diffuse cutaneous subset of the disease had 42 (59%), Scl-70 positivity-73% of pts. Duration of the disease was 5,6±4,4 yrs. All pts received concomitant treatment with low dose prednisolone and 45% - with immunosuppressants. The following indicators were evaluated: forced vital capacity,% predicted (FVC), diffusing capacity for carbon monoxide,% predicted (DLCO) and Rodnan skin score (mRss) over a periods of 12-18 months (point 1), 24-30 months (point 2), 36-42 months (point 3), 48-54 months (point 4) and 60-72 months (point 5) after the start of therapy. The results are presented in the form of mean values, delta, median, upper and lower quartile.
PERFORMANCE OF THE ANTISYNTHETASE

Francisco Rubiño1, Juan Manuel Díaz1, Félix Francisco1, Soledad Ojeda1, Loreto Carmona2.

1Universitario Central de Asturias, Oviedo, Spain
2Hospital Universitario Germans Trias i Pujol, Barcelona, Spain
3Hospital Universitari Germans Trias i Pujol, Barcelona, Spain; 4Hospital Universitat Rovira I Virgili, Tarragona, Spain

Objectives: We performed an observational retrospective study in one center during the period 06/2008-06/2018. We searched all the myositis immunoblots (Euroimmun assay) requested by the Rheumatologists under suspicion of ASSD or myositis. We assessed: 1) the rate of cases with positive ARS; 2) the rate of cases with both positive ARS and swollen myositis. Results: 140 myositis immunoblots were searched. Twenty-seven cases (19.3%) presented positive ARS: anti-Jo1 (n=13), anti-PL-12 (n=7), anti-PL-7 (n=1), anti-EJ (n=2), and anti-OJ (n=4). Twenty-five of these cases (76.9%) fulfilled Connors’ criteria, and 15 (50.0%) additionally met Solomon’s criteria. Thus, the fulfillment of Connors’ and Solomon’s criteria in patients with a positive ARS was of 92.6% and 55.5%, respectively.

Conclusion: The presence of a cytoplasmic pattern was considerably higher in patients with ASSD than when only a nuclear pattern is presented. However, the presence of a cytoplasmic pattern does not exclude the detection of ARS in the myositis immunoblot and the fulfillment of Solomon’s criteria.

SAT0275

PERFORMANCE OF THE ANTISYNTHETASE SYNDROMES AND THEIR INDIRECT IMMUNOFLUORESCENCE PATTERNS IN THE ANTISYNTHETASE SYNDROME DIAGNOSIS

Marín Grecó1, María Jesús García de Yébenes2, Inmaculada Alarcón3, Anaíy Brandy-García4, Estibaliz Loza5, Teresa Oton6, Francisco Rubíno7, Felix Manuel Diaz7, Soledad Ojeda1, Loreto Carmona2.

1Hospital Universitario Germans Trias i Pujol, Barcelona, Spain; 2Hospital Universitario Germans Trias i Pujol, Barcelona, Spain; 3Hospital Universitat Rovira I Virgili, Tarragona, Spain

Background: The antisynthetase syndromes (ASSD) are characterized by the presence of anti-aminoacyl transfer RNA synthetase (ARS) autoantibodies, which disturb the binding of amino acids to the transfer RNA during the protein synthesis. ARS can be detected by indirect immunofluorescence (IIF), and can be identified by immunoblot assay and ELISA (Enzyme-Linked ImmunoSorbent Assay) and immunoblotting. The main clinical features of the ASSD are myositis, arthritis, interstitial lung disease, Raynaud’s phenomenon, mechanic hands, and fever. Two ASSD diagnosis criteria have been developed; those proposed by Connors, and the stricter criteria proposed by Solomon (1, 2). Objectives: To evaluate the performance of the ARS and their IIF patterns in the ASSD diagnosis.

Methods: We performed an observational retrospective study in one center during the period 06/2008-06/2018. We searched all the myositis immunoblots (Euroimmun assay) requested by the Rheumatologists under suspicion of ASSD or myositis. We assessed: 1) the rate of cases with positive ARS; 2) the rate of cases with both positive ARS and swollen myositis. Results: 140 myositis immunoblots were searched. Twenty-seven cases (19.3%) presented positive ARS: anti-Jo1 (n=13), anti-PL-12 (n=7), anti-PL-7 (n=1), anti-EJ (n=2), and anti-OJ (n=4). Twenty-five of these cases (76.9%) fulfilled Connors’ criteria, and 15 (50.0%) additionally met Solomon’s criteria. Thus, the fulfillment of Connors’ and Solomon’s criteria in patients with a positive ARS was of 92.6% and 55.5%, respectively.

All cases (100%) with positive ARS presented positive immunofluorescence: 19 (70.4%) showed a cytoplasmic pattern (10 of them with an associated nuclear pattern) and 8 cases (29.6%) presented only a nuclear pattern. On the other hand, 99 of the 113 cases (87.6%) with negative ARS presented positive IIF: 29 (25.7%) showed a cytoplasmic pattern (21 of them with an associated nuclear pattern) and 42 cases (37.2%) presented only a nuclear pattern.

Correlating the ARS positivity, IIF pattern and the diagnosis criteria fulfillment:

- 13 of 15 cases (86.6%) with positive ARS and Solomon’s criteria fulfilled a cytoplasmic pattern; and 2 of 15 cases (13.3%) presented only a nuclear pattern.
- 13 of 19 cases (68.4%) with positive ARS and cytoplasmic pattern fulfilled Solomon’s criteria; and 6 only fulfilled those from Connors’.

Conclusion: One-fifth of the immunoblots requested by Rheumatologists presented positive ARS; almost all these cases fulfilled Connors’ criteria, and more than a half fulfilled the stricter Solomon’s criteria. All patients with positive ARS, and a high rate of those without ARS, presented positive IIF. The presence of a cytoplasmic pattern was considerably higher in patients with ARS positivity and in those that met Solomon’s criteria. Thus, our results suggest that in patients evaluated by a Rheumatologist, with clinical suspicion of ASSD or myositis and with ARS positivity, the probability of fulfilling Solomon’s criteria is higher when the IIF presents a cytoplastic pattern than when only a nuclear pattern is observed. Nevertheless, presenting only a nuclear pattern does not exclude the detection of ARS in the myositis immunoblot and the fulfillment of Solomon’s criteria.

SAT0276

STUDY OF THE EPIDEMIOLOGICAL, CLINICAL AND ANALYTICAL CHARACTERISTICS IN PATIENTS WITH SYSTEMIC SCLEROSIS AND CANCER IN VALL D’HEBRON HOSPITAL

María Roca Herrera1, Alfredo Guiltién del Castillo2, Eduardo Cañelas Moraga3, David Bernál Bello1, Jorge Hernando Cubero1, Natalia Irarte Gay de Montefi1, Vicent Forollola Pla3, Carmen Pilar Simeón-Azam1, Vall d’Hebron Hospital, INTERNAL MEDICINE, Barcelona, Spain; 2Parc Taulí Hospital, INTERNAL MEDICINE, Sabadell, Spain; 3Fuenlabrada Hospital, INTERNAL MEDICINE, Fuenlabrada, Spain; Vall d’Hebron Hospital, ONCOLOGY, Barcelona, Spain

Background: Scleroderma or systemic sclerosis (SSc) is a systemic, chronic autoimmune disease characterized by a great clinical heterogeneity. In recent years, studies have proven that there is a relationship between SSc and neoplasia. SSc is associated with an increased risk of certain types of cancer, particularly lung, liver, hematological, non-melanoma skin and urothelial cancer. Despite this increase, the relative risk of developing cancer is still low in these patients. In the literature, neoplasms have been described in 3-11% of patients with SSc.

Objectives: Our objective is to analyze the epidemiological, clinical and analytical characteristics previously described as possibly linked to the development of a cancer in patients with systemic sclerosis (SSc) in the Vall d’Hebron Hospital cohort.

Methods: We analyzed 583 patients in the Vall d’Hebron Hospital cohort of SSc. The inclusion criteria were age > 18 years and the diagnosis of SSc limited, diffuse and SSc sine scleroderma. The different variables were analyzed by univariate statistical analysis with SPSS v21.
THE 100 MOST INFLUENTIAL PUBLICATIONS IN STUDY OF QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS: A BIBLIOMETRIC STUDY

Priyanka Iyer1, Petar Lenert1, Jawad Bilal1. 1University of Iowa Hospitals and Clinics, Rheumatology, Iowa City, United States of America; 2University of Arizona, Rheumatology, Tucson, United States of America

Background: In recent years, a large volume of important clinical and scientific papers about systemic sclerosis can be found in the most influential journals. Bibliometric analysis is a statistical method that enables researchers to analyze citation patterns and highlight characteristics of highly cited scholarly work. It has been infrequently utilized in Rheumatology1,2. Prior studies have not addressed the bibliometric literature gap in the field of systemic sclerosis. Objectives: This study aims to identify the 100 most cited papers in systemic sclerosis and to describe their characteristics. Methods: We sought to assess the characteristics of the top 100 most referenced citations in systemic sclerosis. We searched the Scopus and Web of Science databases to identify all articles relating to ‘Scleroderma’, ‘limited’ or ‘diffuse Systemic Sclerosis’ and ‘CREST syndrome’. Articles were arranged in descending order of citations and were scrutinized by two independent reviewers. Selected articles were analyzed with respect to number of citations, publication year, journal characteristics, research type, focus area, authors and countries of authors of publications. Results: Retrieved articles were published mostly in rheumatology journals (n=42) with impact factors ranging between 3.47 and 12.35 in these journals, followed by journals in general medicine, pulmonology, and experimental biomedical research. Journals with the highest number of top-cited articles included Arthritis and Rheumatism (n=25), followed by the New England Journal of Medicine (n=8) and Annals of the Rheumatic Diseases (n=6). Studies conducted in USA, UK, and Italy that were published in high-impact journals had the highest citation count. Temporal analysis indicated that the majority of top-cited articles were published between 1996 and 2014 (n=65). The most productive 5-year time period was between 2000 and 2005 when 23 of the 100 most cited publications were produced. Among retrieved citations, guidelines and recommendations comprised 5% of all articles, narrative reviews 21%, randomized clinical trials 12%, observational studies 35%, non-randomized clinical studies (basic and translational research) 24%, case series 1%, and meta-analyses 2%. Our analysis shows that articles defining the classification criteria of Systemic Sclerosis were among the most cited work followed by those describing the pathophysiology of the disease. Other highly cited areas included cellular and molecular mechanisms of fibrosis (with special emphasis on the role of TGF-β) and Randomized Controlled Trials for Bosentan and Epoprostenol in the treatment of pulmonary hypertension. Regarding individual organ manifestations, Pulmonary and Cardiac complications (pulmonary hypertension, lung disease, myocardial effects) (n=21) were of highest interest, while other articles focusing on Cutaneous (ulcers, skin changes, Raynaud’s phenomenon) (n=16), Renal (renal crises) (n=3) and Gastrointestinal complications (dysmotility) (n=1) were cited to a lesser extent. Interestingly, articles primarily describing hematopoietic stem cell transplants as a viable treatment option did not feature on this list. Conclusion: Our study provides the first bibliometric overview of the most highly cited scientific papers on systemic sclerosis. These findings provide useful insights into trends of published work and may serve as a useful guide to researchers in this field.

To find out the contributing factors to impaired QoL, with the help of a newly developed patient reported questionnaire.

Methods: In this cross-sectional study, all consecutive adult patients with SSc, satisfying 2013 ACR/EULAR classification criteria, attending a tertiary rheumatology clinic in Western India from January 2016 to March 2017 were compared to age and sex-matched controls. A new questionnaire [Indian Systemic Sclerosis QoL questionnaire (Indian SyS-QoL)] was developed to identify the contributing factors to impaired QoL with feedback from 15 SSc patients and 11 rheumatologists. This questionnaire had 10 factors and each was scored by individual patients between 0-3 (0-no impact; 3-severe impact on QoL in previous month). Demographic data, clinical profile and relevant investigations were recorded. Patients filled Medical Outcomes Trust Short Form 36 version 2 (SF-36v2) questionnaire, Indian SyS-QoL questionnaire and Indian Health Assessment Questionnaire – (Indian QAQ).

Results: 94 SSc patients (7 males; 87 females) were compared to 100 age and sex-matched controls. QoL was significantly impaired in patients with SSc compared to healthy controls in all 8 domains of SF-36 (p<0.001), the finding similar to other studies (Table 1). There was no statistically significant difference in mean scores in any domain between patients with dcSSc [56 patients (59.6%) and lcSSc [38 patients (40.4%)]; between patients with disease duration ≤5 yrs [43 patients (45.7%)] and >5 years [51 patients (54.3%)] and in those with ILD [56 patients (59.6%)] and without ILD [38 patients (40.4%)]. Two most important factors responsible for poor QoL based on Indian SyS-QoL questionnaire score (mean±SD) were feeling of dependency on family (1.4±1.3) and ‘cost of treatment’(1.3±1.2)(Fig 1).

Table 1: SF-36 Scores in SSc patients among different studies:

Discussion: This maiden study from India showed that QoL was significantly affected in patients with SSc compared to the general population; but there was no significant difference in QoL in patients with different subsets of SSc; disease duration ≤ 5 yrs and > 5 yrs, and presence or absence of ILD. The new graded scale devised to assess the impact of SSc on QoL using a simple patient-reported questionnaire showed ‘feeling of dependency’ and ‘cost of treatment’ as the 2 most important factors affecting QoL in Indian patients with SSc. This would help direct more resources to support the patients both mentally and financially.

MULTICENTER DOUBLE-BLIND, PROOF-OF-CONCEPT, RANDOMIZED PLACEO-CONTROLLED TRIAL OF RIOCIUGAT IN SYSTEMIC SCLEROSIS-ASSOCIATED DIGITAL ULCERS (RESCUE)

Dinesh Khanna1, Cathie Spino1, Vivek Nagaraja1, Robin Domsici2, Robert Lalayas1, Virginia Steen1, Jessica Gordon3, Tracy Fresh4, Pei-Suen Tsou1.

1University of Michigan, Ann Arbor, United States of America; 2University of Pittsburgh, Pittsburgh, United States of America; 3Georgetown University, DC, United States of America; 4Hospital of Special Surgery, New York City, United States of America; 5University of Utah, Salt Lake City, United States of America.

Background: The soluble guanylate cyclase stimulator riociguat (RIO) is a vasodilator and has antifibrotic effects in animal models and efficacy in patients with pulmonary arterial hypertension associated with connective tissue diseases.

Objectives: We present results from a randomized placebo-controlled trial (NCT02915835), which evaluated the efficacy and safety of RIO in patients with systemic sclerosis-associated digital ulcers (SSc-DU).

Methods: Eligible subjects (with active or painful indeterminate DU) were randomized in 1:1 ratio to either placebo (PLA, n = 8) or RIO (n = 9) in individualized doses (maximum of 2.5 mg three time daily) during an 8-week titration period, followed by an 8-week stable dosing period. PDE5 inhibitors were not allowed. The primary end point was the change from baseline to week 16 in net ulcer burden (NUB), analyzed using an ANCOVA model, accounting for baseline NUB. Other outcome measures included change from baseline to week 16 in the Raynaud’s Condition Score (RCS), RP attack number, symptom severity during RP attack, patient global assessment, and proportion of subjects with treatment-emergent adverse events (AEs). Eleven plasma biomarkers were measured by ELISA and changes were tested using ANCOVA, after testing for normality.

Results: We randomized 17 participants with SSc-DUs between January 2017 and March 2018. Baseline characteristics were comparable between treatment groups, except participants randomized to PLA were older (mean 61 vs. 43 yrs) and had longer disease duration (mean 17.5 vs. 7.1 yrs). At baseline, the mean (SD) NUB was 2.5 (2.0) in the PLA and 2.4 (1.4) in the RIO. No significant difference was observed between RIO and PLA in change from baseline to 16 weeks in NUB [p=0.70; Table]. No significant treatment effect was observed in the secondary outcome measures. All 17 participants reported ≥1 adverse event, with the vast majority being mild or moderate. There were 4 SAEs, 3 in RIO (worsening DU, NSTEMI, and non-Hodgkin’s lymphoma) and 1 in PLA (digital ischemia; none of SAEs were related to the study medication). Statistically significant elevation of cGMP was observed at 16 weeks [p<0.05]; no other biomarkers showed statistically significant changes.

Conclusion: In participants with SSc-DU, treatment with RIO did not reduce the number of NUB compared with PLA. The safety profile of RIO was similar to that previously reported. There is evidence of target engagement. The negative results may reflect small number of patients, low number of NUB at baseline, moderate-to-severe vasculopathy with long-term disease, and difficulty to recruit patients in the era of widespread use of PDE5 inhibitors.

SAT0280 ESOPHAGEAL DYSMOTILITY AND PULMONARY DISEASE IN PATIENTS WITH SCLERODERMA: A RETROSPECTIVE STUDY

Navya Kuchipudi1, Shweta Kishore2, Chia-Ling Kuo3.

1University of Connecticut, Rheumatology, Farmington, United States of America; 2University of Mississippi Medical Center, Jackson, United States of America; 3University of Connecticut, Community Medicine and Health Care, Farmington, United States of America.

Background: Systemic sclerosis (SSc) is a connective tissue disease with pulmonary involvement seen in 75% of patients and esophageal involvement in 90% of the patients. Pulmonary disease has overtaken renal disease as the leading cause of death (1). There is conflicting evidence about the association between esophageal dysmotility and lung involvement (Interstitial Lung Disease (ILD) and Pulmonary Artery Hypertension (PAH)).

Objectives: Our aim was to evaluate the relationship between esophageal dysmotility and lung disease by correlating the results of Echocardiogram and Pulmonary Function Test (PFT) with Esophageal Transit Study (ETS).

Methods: Charts of SSc patients fulfilling 2013 ACR/EULAR classification criteria seen in Rheumatology clinic from 2004 to 2015 were reviewed. Patient demographics, ETT result, FVC and DLCO data from PFT as well as pulmonary pressures from echocardiogram were collected at baseline, years 1, 3, 5 and 10. Patients were divided based on their initial ETT findings into normal and abnormal ETT groups. Using logistic regression models, we compared elevated PASP with ETT status at baseline, and years 3 and 5. Linear mixed effects model was used to adjust for covariates (disease subtype, smoking, obesity, use of immunomodulator) when analyzing PFT outcome with time period and ETT status.

Results: 130 patients were identified with either Limited Cutaneous SSc (109) or Diffuse Cutaneous SSc (21) with a mean age of 52.65 years ± 12.59. ETT was normal in 67(52%) and abnormal in 63(48%) patients. Number of patients with abnormal PASP was not statistically different between the two groups (p values 0.104, 0.178, 0.653 at baseline, years 3 and 5 respectively). Likewise, the odds ratio for abnormal PASP was 2.75 in patients with abnormal ETT compared to normal ETT, but the results were not statistically significant (p: 0.428), and the odds ratio did not vary with time (p: 0.731). Sample size was too small to conduct separate longitudinal analysis for adjusted models. The mean DLCo was statistically worse in abnormal ETT patients [p value <0.0001 and 0.0004 for unadjusted and adjusted models] as were the progression rates per year for DLCo at -1.95 (p-value: 0.023) and -2.25 (p-value: 0.019) for unadjusted and adjusted models respectively. The Mean FVC was not statistically different between the two groups, although it’s progression rate per year was statistically worse only in the adjusted model (p value: 0.018).

Conclusion: Esophageal dysmotility was associated with increased pulmonary involvement in the form of abnormal DLCo with worsening progression rates per year. Interestingly, neither PASP nor FVC were statistically different even though progression rate for FVC was worse in adjusted models. We postulate that the small sample size for Echo and differences in the factors determining DLCo vs. FVC and PASP explains the disparity in the results. Larger prospective trials are needed to investigate if there is a causal relationship between esophageal dysfunction and pulmonary involvement.

SAT0281 RELATIONSHIP BETWEEN AUTOANTIBODIES AND CYTOKINE PROFILES IN PATIENTS WITH MYOSITIS

Kazuhiro Kurasawa, Satoko Arai, Yuta Takamura, Tomoyuki Miyao, Ayae Tanaka, Ruyuto Yamazaki, Takayoshi Owada, Reika Maezawa, Masanori Arima. Dokyo Medical University, Rheumatology, Mibu, Tochigi, Japan

Background: By(auto)antibodies, myositis is recently classified into subgroups with distinctive clinical features. Cytokines play critical roles in the development of the clinical features. However, it is not fully unknown whether myositis subgroups defined by autoantibodies have unique cytokine profiles.

Objectives: To clarify the relationship between cytokine profiles and autoantibodies in myositis.

Methods: Subjects were myositis patients who admitted Dokyo Medical University and whose serum before starting therapy were available. Serum cytokine levels (IL-1α, 1b, 2, 4, 5, 6, 10, 12, 13, 15, 17, 23, IFN-g, TNF-a, IFN-a, b, IP-10 and MCP-1) in sera from the patients and controls were measured using Q-Plex™ Mplex Arrays. Demographic and clinical data were obtained by reviewing medical record retrospectively.

Results: Subjects were 45 myositis patients with male/female: 22/23 and age 36.1±12.5 years. ETT was normal in 67(52%) and abnormal in 63(48%) patients. Antibodies were anti-MDA5+ in 21, anti-ARS+ in18 and anti-TIF1g+ in 5 cases. ILD and malignancy was complicated in 39 and 5 cases, respectively. Serum cytokine levels were measured. As shown in Fig.1, IP-10 levels were increased in all types of myositis patients, but not in controls. In anti-MDA5 Ab+ myositis, IL-6, IL-10, IL-15, TNF-a, IFN-a and MCP-1 levels were increased. In anti-ARS Ab+ cases, IFN-b levels were elevated as well as TNF-a and MCP-1. Through the correlation analysis between cytokine levels, cytokine groups were identified (Fig.2). In anti-MDA5 Ab+ cases, 2 cytokine groups were identified: one includes IFN-a, IL-15, TNF-a and IL-10, and the other involved IL-6, MCP-1. Both groups connected with IP-10. In In anti-ARS

CLINICAL AND SEROLOGICAL FEATURES OF SYSTEMIC SCLEROSIS IN ITALIAN AND EGYPTIAN PATIENTS

Vasiliki Liakoudi1, Hesham Hamoud2, Piero Ruscitti1, Mahmoud Ibrahim Risha3, Mohamed Elsayed Hanafi4, Khaled Elnoafly3, Mervat Abogabal5, Sameh Mobasher5, Aya Shams University, Cairo, Egypt; 5Ain Shams University, Cairo, Egypt

Background: Clinical and serological variations exist in the severity of Systemic Sclerosis (SSc) patients, according to different geographic areas.

Objectives: To evaluate clinical and serological features in 2 cohorts of Italian and Egyptian SSc patients and to identify factors associated with Interstitial lung disease (ILD), a leading cause of mortality, by using multivariate logistic regression analysis.

Methods: An Italian center and 3 Egyptian centers participated in SSc patient recruitment in 2017. The cross-sectional demographic, clinical, and laboratory data were collected and defined according to severity score and activity index, previously developed [1, 2]. The database included 152 consecutive Italian patients, 135 women (88.8%) and 17 men (11.2%) and 197 consecutive Egyptian SSc patients, 177 women (89.8%) and 20 men (10.2%), all of whom fulfilled the classification criteria proposed by LeRoy and Medsger [3].

Results: We found that Egyptians SSc patients were younger (41.18±12.5 vs 58.59±12.6 yrs), had an earlier onset of the first non Raynaud’s Phenomenon symptom (7.28±5.69 vs 14.99±11.11) and a more severe Modified Rodnan Skin Score (MRSS=14) (79.27% vs 13.6%). A greater percentage of Egyptian patients presented the active form of the disease (33.3% vs 15.5%) and had a Pulmonary Arterial Pressure (PAPs) estimated by echocardiography ≥40mmHg (37.5% vs 9.5%) in the Italian patients. Furthermore, Egyptian patients affected from the limited form of the disease (lcSSc), presented a higher MRSS (67.2% vs 2.6%), higher PAPs levels (34.5% vs 9.2%), an active form (41.7% vs 7.8%) and history of past/current ulcers (62.2% vs 30.6%) than Italian lcSSc patients.

Conclusions: Clinical and serological comparisons between Italian and Egyptian patients, point to different factors associated with ILD, which should be further investigated.

Disclosure of Interests: None declared.
CD123+ PLASMACYTOID DENDRITIC CELLS (pDCs) FROM SYSTEMIC SCLEROSIS PATIENTS ARE SUSCEPTIBLE TO THE CYTOTOXIC ACTIVITY OF TAGRAXOFUSP, A CD123-TARGETED THERAPY

ROSS LINDSAY1, Janice Chen1, Robert Spiera2, Jessica Gordon3, Marie Dominique Ah Kioon4, Frank Barrat4, Christopher Brooks1,2. Stemline Therapeutics, Research and Development, New York, United States of America;
2Hospital for Special Surgery, New York, United States of America

Background: Tagraxofusp is a novel targeted therapy directed to the interleukin-3 receptor (CD123). Tagraxofusp is comprised of human IL-3 recombinantly fused to a truncated diphtheria toxin (DT) payload engineered such that IL-3 replaces the native DT receptor-binding domain. In this way, the IL-3 domain of tagraxofusp directs the cytotoxic DT payload to cells expressing CD123. Upon internalization, tagraxofusp irreversibly inhibits protein synthesis and induces apoptosis of the target cell.

Tagraxofusp was recently approved by the FDA for the treatment of patients with blastic plasmacytoid dendritic cell neoplasm (BPDCN), a malignancy derived from the plasmacytoid dendritic cell (pDC) precursor. pDCs are immune cells that express CD123, secrete IFN-α, and play a role in inflammation and disease pathogenesis observed in systemic sclerosis (SSc) patients.

Objectives: To assess the ability of tagraxofusp to selectively deplete pDCs from SSc patients ex vivo.

Methods: Patients fulfilled the 2013 ACR/EULAR classification criteria for SSc4. PBMCs from either SSc patients or healthy volunteers (HV) were prepared using Ficol-Paque density gradient from fresh blood. pDCs were isolated from PBMCs as previously described and used to enrich the frequency of pDCs in an additional draw of PBMCs. pDC-enriched PBMCs (3-16% pDCs) were cultured at 2x10^4 cells per well in the presence of absence of CpG-274 (0.5 μM) to activate pDCs and then incubated with tagraxofusp (0.01-100 ng/ml, 0.17 pM-1.7 nM) at 37°C, 5% CO2, and 95% humidity. After 24 h of culture, pDC survival was assessed by flow cytometry (CD14, CD3, BDCA4, CD123+), and supernatants were collected for cytokine quantification by a multiplexed Luminex assay.

Results: Tagraxofusp was cytotoxic towards pDCs from both HV (n=5) and SSc donors (n=5) to a similar extent. The ED50 of tagraxofusp in pDCs from HV and SSc was 4.3 and 3.2 ng/ml (74.4 and 55.4 pM), respectively; no effect was observed on B or T cells across the tagraxofusp dose range tested (Fig.1A). Tagraxofusp-mediated pDC depletion was further accompanied by a 68-fold reduction in secreted IFN-α and a 3-fold downregulation of GBP, a type 1 IFN-induced gene (Fig.1B).

Conclusion: Tagraxofusp is a novel CD123-targeted therapy that is cytotoxic towards pDCs from SSc patients. These data present a novel approach of targeting pDCs in the treatment of SSc, and a clinical trial is under design.

Evaluation of Chronic Pain in Patients with Systemic Sclerosis Compared to Those with Chronic Headache and Rheumatoid Arthritis

LUCA MAGNANI1, Federica Lunetti2, Emanuele Cocchiara3, Amelia Spinella3, Carla Barbaldi4, Luigi Alberti Pin2, Giancarlo Pellei2, Gialui Baiocchi1, Carlo Salvadori1, Dilia Giuggioli1, IRCC Santa Maria Nuova Reggio Emilia, Reggio Emilia, Italy; 1University Of Modena and Reggio Emilia, MODena, Italy

Background: Systemic Sclerosis (SSc) is a chronic systemic disease frequently leading to disability and low quality of life. Chronic pain (CP), due to severe disease complications and internal organs involvement, is often underestimated. Based on available data around a 60-70% of patient with SSc suffer of chronic pain but we still lacking of fire tools to better evaluate it and follow up patients.

Objectives: Evaluate pain in SSc patients, in terms of its intensity, sensory and affective components, the interference with physical and social activities, impact on quality of life and correlation with main SSc clinical manifestations.

Methods: From January 2013 to January 2018 we retrospectively evaluated 98 patients with a diagnosis of SSc [F/M=47/11; Limited/Diffuse SSc 63/35 anti-Scl70/ACA/ANA nuclear positivity 45/39/14; mean age 55.6 ± 12.6 DS; mean disease duration 9.9 ± 7.6 DS] according to 2013 ACR/EULAR criteria: 47 patients with a diagnosis of chronic headache (CH) as defined by the International Classification for Headache Disorders, Third Edition beta version (ICHD-3 beta) criteria [F/M=37/10; mean age 52.6 ± 14.2 DS; mean disease duration: 7 ± 2 yrs DS] and 46 patients with Rheumatoid Arthritis [F/M=36/10; mean age 41±13, mean disease duration 10±2 yrs, DS]. All patients fulfilled self-completing questionnaires for the evaluation of pain and quality of life: Visual Analogic Scale (VAS), Generic Rating Scale (NRS), Short Form-McGill Pain Questionnaire (SF-MPQ), Brief Pain Inventory Score (BPI) e Health Assessment Questionnaire (HAQ).

Results: SSC patients started to suffer of CP in younger ages compared to AR/CH cohort but patients suffering of CH have higher mean scores in all questionnaires compared to AR/SSc. CH patients, have higher mean score in SFMPQ-sensory and affectory. Hundred percent (100%) of AR patients suffered of chronic pain. They, generally, had higher scores than SSc patients with a prevalence of the affectory component. The 83.9% (67/79 pts) of SSc patients experienced chronic pain [SF-MPQ PRI: 6.2±5.8;SF-MPO PPI: 1.69±1.34DS; BPI-factor1: 13.37 ±1.28DS; VAS: 40.7±29.6DS; NRS: 4.08±2.98DS] and in a great majority (84%) that pain interfered with their working activities and social lifes. Fortyeight percent of SSC patients had digital ulcers and 41.3% had musculoskeletal involvement. Pain used to correlate with both of them [p>0.004; p=0.041]. In patients with DUs, affectory component of pain overruled on the sensory one.

Conclusion: SSC patients frequently experience chronic pain and particularly those who have a history of active DUs and musculoskeletal involvement. By the way, it seems that the BPI questionnaire could be more suitable than VAS or NRS in assessing DUs involvement. By the way, it seems that the BPI questionnaire could be more suitable than VAS or NRS in assessing DUs involvement. In fact, FESS could help the identification of different problems leading to dysphagia occurrence and to related dysphagia problems. Thanks to these characteristics, FESS for ENT specialists is the gold standard technique for evaluating swallowing functions. However, no studies so far have investigated the role of FESS in the assessment of IIMs and we are completely lacking a semiotic description of FESS findings in these patients.

Objectives: To provide the first semiotic description of swallowing alterations in patients with idiopathic inflammatory myopathies.

METHODS: We retrospectively reviewed the FEES findings of IIMs patients performed at our hospital.

Results: We enrolled 19 patients with a diagnosis of IIMs (10 patients were positive for a myositis specific antibody), of these 16 (84%) reported symptomatic dysphagia. We divided patients into 3 groups based on levels of peripheral muscle strength. Six patients (32%) had no clinical sign of active muscle disease (MRC scale 4, median CK 51 mU/ml, IQR 35-235), 5 patients (26%) had a mild reduction in muscle strength (MRC scale 3, median CK 150 mU/ml, IQR 62-618). The 67% of patients without muscle disease activity showed an impairment in the oral phase of swallowing for solids and fluids; 40% showed signs of penetration, aspiration or pharyngeal phase of swallowing for both solids and fluids; 40% of patients showed signs of penetration, aspiration or pharyngeal residue for both solids and fluids. In the group of patients with moderate muscle activity, 80% of patients showed impairment in the oral phase of swallowing for solids and 40% for fluids; 60% had a reduction in the activation of the pharyngeal phase of swallowing for solids while 40% for fluids; 40% of patients showed signs of penetration, aspiration or pharyngeal residue for both solids and fluids. Finally, in the group of patients with severe muscle disease activity, 88% of patients showed an impairment in the oral phase of swallowing for solids and 50% for fluids; 63% had a reduction in the activation of the pharyngeal phase of swallowing for solids while 50% for fluids; 75% of patients showed signs of penetration, aspiration or pharyngeal residue for both solids and fluids. The 15% of all patients (3 cases, 1 from each group of muscle activity) showed a dysfunction in the upper esophageal sphincter. Of note, 3 patients (15%; 1 with moderate and 2 with severe muscle disease activity) required nutrition through nasogastric tube.

Figure 1: swallowing alteration for solids and fluids in patients divided by muscle disease activity regarding muscle disease activity (green), moderate muscle disease activity (blue) and severe muscle disease activity (red).

Conclusion: We showed that FESS study identified swallowing dysfunctions in both the oral and pharyngeal phases of swallowing. Swallowing dysfunctions were more prevalent in patients with greater muscle involvement; however, alterations were not rare also in patients with no clinical signs of muscle activity and, in particular, in the few patients without reported symptoms of dysphagia. FESS appears as a useful tool for the evaluation of dysphagia in IIMs.
outcome of PM/DM-ILD. High levels of serum IL-6, IL-8, IL-10, IL-18, CCL2, CXCL10, TNF-α, and IFN-α were detected in PM/DM-ILD cases, suggesting the pathological involvement of activated macrophages, type 1 T helper (Th1) cells, and neutrophils (ref 1, 2). However, investigation of the pathomechanism using serum cytokines remains insufficient in PM/DM-ILD. We hypothesised that multiple inflammatory cytokine pathways related to the above inflammatory cells would be involved in the pathomechanism of PM/DM-ILD.

Objectives: We measured serum cytokine levels before and during treatment of patients with PM/DM-ILD and examined the associated pathomechanism.

Methods: Serum cytokines were collected from 40 PM/DM-ILD patients. Principal components analysis (PCA) and cluster analysis were used to classify patients into subgroups. We compared cytokine profile of the survivors and dead patients as well as anti-MDAS antibody-associated ILD and anti-ARS antibody-associated ILD. We also examined the association of various cytokines with disease activity indicators and prognosis of ILD.

Results: PCA revealed that the diversity of cytokines was driven by three groups: (1) neutrophilic and M1-macrophage-driven cytokines, (2) Th1 cell-driven and M2-macrophage-induced cytokines, and (3) M2-macrophage-driven cytokine. Based on cluster analysis, patients were classified into two subgroups according to the cytokine levels of all groups (Figure A). Ninety percent of patients who died of ILD were included in clusters with high cytokine levels (Figure B). Serum cytokine levels of all groups were significantly higher in the anti-MDAS antibody-positive patients than in the anti-ARS antibody-positive patients. Factors of poor prognosis in PM/DM-ILD correlated significantly with serum cytokine levels of groups 1 and 2. Among the 3 groups, serum cytokine levels of group 1 were significantly higher initially and at 2 and 4 weeks in the death group.

Conclusion: These findings suggest that the activation of monocytes, macrophages, and Th1 cells, and neutrophils plays a role in the pathomechanism. Group 1 cytokines could be efficient biomarkers for predicting prognosis of PM/DM-ILD.

A SYSTEMATIC REVIEW OF SYSTEMIC SCLEROSIS CLINICAL TRIALS SINCE 2005. LACK OF EARLY DISEASE TARGETING, CONFUSION RELATED TO DISEASE DURATION DEFINITION AND LOW LEVEL OF INCORPORATION OF THE NEW CLASSIFICATION CRITERIA

Konstantinos Melisaropoulos1, Dimitrios Daoussis2, Ioannis Antonopoulos1, Alexandra Filippopoulou1, Stamatis-Nick Loizos2. Patras University Hospital, Rheumatology, Patras, Greece; 2Patras University Hospital, University of Patras Medical School, Rheumatology, Patras, Greece

Background: It is still unknown whether treatment in very early systemic sclerosis (SSc) can affect long term outcomes. 

Objectives: To systematically review clinical trials in SSc during the last 14 years aiming at answering the following questions: 1) how many clinical trials in SSc have targeted early disease and whether treatment of patients with early disease leads to better clinical outcomes, 2) how is disease duration defined in SSc clinical trials and whether data on duration since Raynaud’s onset are provided and 3) whether the new 2013 ACR/EULAR SSc criteria have been incorporated in clinical trials throughout the last 5 years.

Methods: A search in published studies indexed in MEDLINE was performed from Jan-2005 to Dec-2018. The Clinical Trial filter was activated and the terms “systemic sclerosis treatment” used. Studies were included if they evaluated adult patients with systemic sclerosis, concerned systemic treatments, presented data for clinical endpoints assessing fibrosis and were prospective in design.

Results: Seventy-three studies with a total number of 3078 patients met the inclusion criteria and were subjected to data extraction. The total weighted mean disease duration (adjusted to the number of patients in each study) was 38.55 months which is more than 3 years, the usual threshold for defining early disease. Baseline total weighted mean mRSS was 21.54 indicating that most patients had full blown fibrotic disease. Only 24 studies (32.9%) recruited early (<36 months disease duration) cohorts, with only 4 studies among them concerning very early disease (<18 months disease duration). We next focused on studies that did not specifically target early disease (n=49) and explored whether disease duration associated with clinical outcomes. We identified such an analysis only in 13 studies. In 8/13 studies there was no difference regarding outcomes according to disease duration. Nevertheless, in 4/13 studies investigators reported better outcomes in patients with shorter disease duration with only one study showing the opposite. Significant heterogeneity was found regarding disease duration definition. Four separate definitions were identified: 1) “From first non-Raynaud’s symptom” (49.3%), 2) “From disease diagnosis” (11%), 3) “From skin thickening onset” (5.5%), 4) “From first symptom” (11%). The remaining studies (23.3%) presented no clear definition in their manuscript for disease duration in their cohorts. The stratification of the studies according to year of publication showed a tendency for greater consistency regarding the definition used in recent years since most studies published from 2015 and onwards use the definition “From first non-Raynaud’s symptom”. Data regarding the duration since Raynaud’s onset were available only in 9 studies (12.3%). A separate analysis of all articles published from 2014 until 2018 was performed to explore the incorporation of the new 2013 ACR/EULAR criteria. Only 6 studies (25%) incorporating the new criteria were identified.

Conclusion: 1) The majority of patients recruited in clinical trials throughout the last 14 years do not have early disease, 2) Only one third of the studies were specifically designed to target early disease, 3) The question of whether early implementation of therapy may lead to better clinical outcomes cannot be definitely answered based on existing data, 4) there is confusion related to disease duration definition across SSc clinical trials but an obvious trend towards improvement was evident throughout the last few years and 5) there is still a very low level of incorporation of the new classification criteria in SSc trials.

Disclosure of Interests: None declared

THE ROLE OF CAPILLAROSCOPY IN THE EARLY DIAGNOSIS OF SYSTEMIC SCLEROSIS

Aisa movasat Hajibak, Henry Monuro, Ana Isabel Turrión, Cristina Bohórquez, Ana Pérez Gómez, Fernando Albarrán, Eduardo Cuende, Ana Sánchez Alío, Lucía Ruiz, Paula Pretel, Laura Barrio, Valentina Emperiale, Adrián Abbasi, Melchor Álvarez de Mon. Princesa de Asturias University Hospital, Álcalá de Henares, Madrid, Spain

Background: Systemic Sclerosis is a multisystem autoimmune disease characterized by fibrosis of the skin and internal organs and vascular damage. The diagnosis is usually made in the late stages, when irreversible damage has already occurred. Recently, we have established new criteria to detect early cases of the disease. Performing capillaroscopy and its findings are crucial in the diagnosis of early systemic Sclerosis or “prescleroderma” and there may be changes seen in capillaries of patients without skin manifestations.

Objectives: To analyze the nailfold capillaroscopy findings in patients with anti-centromere or anti-topoisomerase antibodies and evaluate their usefulness for the diagnosis of systemic sclerosis.

Methods: Of a total of 255 capillaroscopy performed in our Rheumatology department, those patients with positive anti-centromere or anti-topoisomerase ase were selected. In all cases, capillaroscopy was performed in eight fingers, always by the same observer. The following findings were considered pathological or scleroderma pattern: Local or global capillary loss (> 20%), hemorrhages: two or more in at least two fingers and enlarged capillaries: two or more capillary with double or more caliber in at least two different fingers. Statistical analysis was performed with SPSS 19.0 program.

Results: The study included 69 patients: 5 (7.2%) males and 64 (92.8%) women, 14 (20.3%) smokers, 47 (68.1%) non-smokers and 8 (11.5%) quitters. The characteristics of the patients included in the study were as follows: 20 patients (30%) were previously diagnosed of systemic sclerosis (19 limited and one diffuse), of which 4 patients had concomitant primary biliary cirrhosis Syndrome (Reynolds), 1 patient with

Disclosure of Interests: None declared

primary biliary cirrhosis and positive anti-centomere without the presence of Raynaud, one patient diagnosed with Sjögren’s syndrome with positive anti-centromere without presence of Raynaud, 26 patients with suspected early systemic sclerosis and 21 patients with disease-specific autoantibodies in the absence of Raynaud. Nailfold capillaroscopy was normal in 32 patients (46.4%) and pathological (scleroderma pattern) in 37 patients (53.6%); we detected limited enlarged capillaries in 26.2%, generalized enlarged capillaries also in 26.2%, giant capillaries in 37.7%, local loss of capillaries in 27.9%, global loss of capillaries in 8.2%, hemorrhages in small claims in 29.5% and abundant hemorrhages in 9.8%. All patients previously diagnosed of systemic sclerosis had a pathological capillaroscopy except one. However, no changes were observed in capillaroscopy in patients who had only disease-specific autoantibodies in the absence of Raynaud’s phenomenon. While, the 26 patients who were referred for suspected systemic sclerosis (at least with the presence of Raynaud and autoantibodies) in 18 (69.9%) of these scleroderma pattern was observed with subsequent diagnosis of early systemic sclerosis or “prescleroderma”.

Conclusion: Nailfold capillaroscopy is a useful and inexpensive tool for the diagnosis of systemic sclerosis. The scleroderma pattern is very specific of this disease and we can make an early diagnosis even in patients who only have autoantibodies and Raynaud’s phenomenon, without the presence of other severe manifestations. We have also observed that the absence of Raynaud’s phenomenon is associated with a normal result on capillaroscopy.

TRADITIONAL AND DISEASE-RELATED RISK FACTORS FOR ARTERIAL AND VENOUS THROMBOTIC EVENTS (TE) IN IDIOPATHIC INFLAMMATORY MYOPATHIES (IIM)

Antonella Notarnicola1, Simone Barsotti2, Linnea Näsman3, Quan Tang3, Marie Holmqvist1, Ingred E. Lundberg1, Aleksandra Antovic1.

Background: Thromboembolic cardiovascular diseases (CVD), affecting both arterial and venous sides, are one of the leading causes of death in patients with Idiopathic Inflammatory Myopathies (IIM), with highest peak of mortality within the first year after diagnosis (1).

Objectives: To assess the prevalence of traditional and disease-related risk factors for arterial and venous thrombotic events (TE) in patients with IIM by comparing those reporting TE (cases) with those without history of TE (comparators). To compare clinical characteristics, autoantibody profile inclusive antiphospholipid antibodies (aPL) and serum levels of adhesion molecules (VCAM, ICAM and e-selectin) between cases and comparators as well as between cases reporting arterial vs venous TE.

Methods: Using national and international registries, and medical charts, we identified 58 cases and 195 comparators with IIM followed at Karolinska University Hospital between 1993 and 2014. Information on gender, age at the time of diagnosis, IIM subgroup, presence of interstitial lung disease (ILD), myositis specific antibodies (MSAs), was retrospectively collected. Information on traditional risk factors for arterial and venous TE (essential hypertension, diabetes, dyslipidemia, smoking, malignancy) was retrieved for both groups. Serum levels of aPL and adhesion molecules were analyzed in stored sera from the time of diagnosis in both groups, before TE in cases and in 40 age and gender matched healthy controls (HC).

Results: One out of 5 IIM patients (22.92%) had suffered from at least one TE, which was observed especially during the first 5 years after diagnosis. Myocardial infarction was the most frequent TE, followed by pulmonary embolism and deep venous thrombosis. In the multivariate analysis, male gender and older age were independent risk factors for TE. Essential hypertension had statistically significant higher prevalence in cases than comparators. Arterial TE was more common in polymyositis, while venous TE occurred more frequently in patients with dermatomyositis, history of malignancy and in those with MSAs. At time of IIM diagnosis, the prevalence of aPL was 6% with no difference between cases and comparators. Significantly higher levels of VCAM and ICAM were obtained in IIM patients compared to HG (Fig.1 and Fig.2). ICAM levels were found significantly higher in comparators than cases (Fig.2). Lower levels of e-selectin were associated with higher odds of developing TE, especially in males and older patients, with no difference between arterial and venous TE (Fig.3).

Conclusion: A high risk of arterial and venous TE should be taken into account in patients with IIM, particularly close to time of diagnosis, with extra attention in male patients and older individuals. Preventive measures should be considered especially in patients with concomitant essential hypertension and malignancy. Lower serum levels of e-selectin might predict TE in IIM patients but the mechanism for this risk factor is not known.

SAT0291  PULMONARY INVOLVEMENT AND FUNCTIONAL LIMITATION IN SYSTEMIC SCLEROSIS

Jose Elví Oller Rodríguez1, Isabel Martínez Cordelaf1, Francisco Miguel Ortíz Sanjuan1, Elvira Vicens Bernabeu1, Rosa Nguenoles Albuech1, Irmacultada Chalmeta Verdejo1, Elena Grau García1, Cristina Alcañiz Escandell1, Víctor Alegre Ituarte2, Cristóbal Pérez Perales3, Marta De La Rubia Navarro1, Roxana González Mazarío1, Jorge Juan Frago-Gil3, Inés Cánovas Olmos1, Carmen Nájera Herranz1, Luis González Puig1, José Ivorra Cortés1,2, José Andrés Román Ivorra1,2. Rheumatology Department. HUP La Fe, Valencia, Spain; 3Medical School. UCV, Valencia, Spain

Background: Pulmonary involvement is the main cause of death in Systemic Sclerosis patients (SS). However, there is little information whether its presence is capable of affecting the functional capacity of patients and if this influences the quality of life perceived by them.

Objectives: To determine whether the presence of pulmonary involvement in patients with SS (Interstitial Lung Disease and or Pulmonary Arterial Hypertension) is related to greater functional disability.

Methods: Observational and cross-sectional study, with a prospectively performed protocol, of patients diagnosed of SS according to ACR/EULAR 2013 criteria. Demographic, clinical, analytical, activity (EUSTAR index), severity (Medsger scale and modified Rodnan index), health perception (SF36) and disability (HAQ and Cochin test) variables were collected. Moreover, Videocapillaroscopy (VCL) and Respiratory Function Test were made. All the patients had pulmonary TCMD and echocardiography in order to describe pulmonary features.

Results: 42 patients were included (95.4% women), with an average age of 59.2 (SD 12.9) years. The median of years of diagnosis was 4, and 6 from the first not Raynaud symptom. Out of them, 20 were SS limited, 20 patients SS diffuse, and 2 patients SS sine scleroderma. Pulmonary hypertension (HTP) was found in 11.9% of patients, as well as EPID in 33.3% (IUP 16.7%, NSIP 14.3%, bronchiolitis 2.3%). Analyzing the subgroup of patients with EPID, we can highlight a higher score of HAQ, Cochin and activity index EUSTAR, with less influence in Rodnan index and without differences in SF36.

*RP – Raynaud’s phenomenon; RPQc – International Consensus Criteria for the Diagnosis of Raynaud’s Phenomenon questionnaire; ** Fisher-exact test

Conclusion: Overall, there was a substantial level of agreement between self-administered and interview-based application of International Consensus Criteria for the Diagnosis of Raynaud’s Phenomenon questionnaire. However, we observed that the patients were inclined to score the severity of their RP lower than the physicians.

SAT0293  SPECIFIC ALTERATIONS OF NAILFOLD CAPILLARIES MIGHT ANTICIPATE THE APPEARANCE OF THE EARLY CAPILLAROSCOPIC SCLERODERMA-PATTERN IN SYSTEMIC SCLEROSIS PATIENTS

Monica Pendlino1, Carmen Pizzomnio1, Alberto Sulli 2, Sabrina Paolino1, Veronika Tomat1, Elisia Alessandr1, Federica Goegan1,2, Yanessa Smith4, Maurizio Cutolo1. 1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, ICRCS Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; 3Department of Internal Medicine, Ghent University, Ghent, Belgium; 4Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Belgium

Background: Non-specific abnormalities (i.e. capillary enlargements) are usually found at the nailfold videocapillaroscopy (NVC) analysis in patients affected by primary Raynaud’s phenomenon (PRP). We have previously demonstrated that capillary diameter is an independent predictor for development of systemic sclerosis (SSc) associated secondary Raynaud’s phenomenon (SRP), so that progression to SRP is unlikely for subjects affected by RP when average nailfold capillary diameter is under 30 µm [1]. However, until now these findings have not been clearly classified in a defined pattern able to really predict the evolution to a sclerodema-pattern.

Objectives: This pilot study aimed to identify in a cohort of SSc patients a “very early” NVC pattern at high risk of evolution in the already defined NVC sclerodermat-patterns.

SAT0292  SELF-ADMINISTERED VERSUS INTERVIEW BASED INTERNATIONAL CONSENSUS CRITERIA FOR THE DIAGNOSIS OF RAYNAUD’S PHENOMENON QUESTIONNAIRE – A SINGLE CENTRE EXPERIENCE

Jaka Ostrovski1, Martina Plesičniklov Novljan1, Alčijza Hocevar1,2, Matija Tomasić1,2, Žiga Rotar1,1 University of Maribor, Medical Center, Ljubljana; 2Department of Rheumatology, Ljubljana, Slovenia; 3University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background: International Consensus Criteria for diagnosing Raynaud’s Phenomenon (RP) have been proposed recently (1). These criteria are based on the three-step conditional approach (i.e. a screening question, assessment of colour changes and an item of disease score calculation). It is unclear whether differences exist between the self-administered and interview-based way of questionnaire fulfilment.

Objectives: We aimed in our study to evaluate the two approaches in patients with suspected RP.

Methods: This cross-sectional study was conducted at our secondary/tertiary-rheumatology centre between 1 October 2018 and 31 December 2018. Each patient referred for the video capillaroscopy was asked to complete the RP questionnaires on the day of the referral. The same questionnaire was applied as an interview by the rheumatologist before the video capillaroscopy. Differences in answers and level of individual agreement on individual three items, as well as the result of the questionnaire, between the two ways of questionnaire completion were assessed with Fisher exact test and Kappa coefficient, respectively.

Results: During the 3-month period we included 84 consecutive patients (88.1% female, median age (IQR) 49.5 (41.9–56.5) years). Results of answers to each item, final outcome of the questionnaire and the level of individual agreement for each item are presented in Table 1.

*RP – Raynaud’s phenomenon; RPQc – International Consensus Criteria for the Diagnosis of Raynaud’s Phenomenon questionnaire; ** Fisher-exact test

Conclusion: Overall, there was a substantial level of agreement between self-administered and interview-based application of International Consensus Criteria for the Diagnosis of Raynaud’s Phenomenon questionnaire. However, we observed that the patients were inclined to score the severity of their RP lower than the physicians.

REFERENCE

Disclosure of Interests: None declared
Methods: We selected the NVCs of 273 patients affected by SSc (according to 2013 ACR criteria) who presented one of the validated NVC scleroderma patterns (81 with “Early” pattern, 84 with “Active” pattern, 92 with “Late” pattern, 16 with “scleroderma-like” pattern) (2). Among the 273 SSc patients with an established NVC scleroderma-pattern, a number of 54 subjects who had previously NVC analyses performed before the development of the scleroderma-pattern were enrolled. Time of evolution was calculated, and a detailed pilot study of capillaroscopic characteristics was random executed on 10 of those patients. The analysis included the number and the limbs diameters (arterial, venous, and apical) of capillaries with a diameter over 30 μm, together with the total number of capillaries and microhemorrhages, in 16 images per subject.

Results: All the 54 patients (100%) showed enlarged capillaries with an average diameter over 30 μm in their previous NVC. At the follow up, thirty-one patients (57%) developed an “Early” scleroderma pattern in the following 3 years, 6 patients (11%) developed an “Active” pattern in 4 years, 3 patients (6%) evolved in “Late” NVC pattern in 5 years, whereas 14 patients (26%) developed a “scleroderma-like” pattern in 4 years. The average time of evolution in a scleroderma-pattern was 4 years. The detailed pilot morphological analysis conducted on 10 patients revealed an average total number of capillaries of 6.8/mm² at last non-specific NVC analysis; among these 2.66 (31%) capillaries showed a diameter over 30 μm. The mean value diameter of the most dilated capillary was 35.74 μm (arterial limb 33.34 μm, apical limb 43.94 μm, venous limb 30 μm); the mean value for microhemorrhages was 0.6/mm². The number of capillaries reduced from 8.6±0.8 to 6.9±2.2/mm² (p=0.01) during follow-up (4 years).

Conclusion: Present detailed pilot study demonstrates that SSc patients showed a significant increase of nailfold capillary diameter over 30 μm before development of a validated NVC scleroderma-pattern at follow up. Even if this is an independent predictor for development of SSc as previously demonstrated, the data could help in intercepting patients with RP at higher risk of evolution in a validated SNC NVC pattern.

Background: Coexistence of different connective tissue diseases based on their common autoimmune base is a feasible circumstance, which is known as poliautoimmunity (PAI). Objectives: Evaluation of the occurrence of PAI in systemic sclerosis (SSc) according to subtypes in the patients included in the Spanish SSc Registry (RESCLUE). Causes of death were also analyzed.

Methods: A nationwide, cross-sectional study was carried out. All participating centers had obtained local ethics committee approval. Results: PAI was present in 46% out of 1911 patients, of whom, 33% had more than one association. Most of these patients were women (93%, p<0.001), with no significant differences regarding first manifestation: Raynaud’s phenomenon, puffy hands, arthralgia or skin sclerosis.

Table 1. Prevalence of PAI according to subsets.

Background: The European League Against Rheumatism Study Group on Microcirculation in Rheumatic Diseases is a non-profit international network of expert centres. Its main research focus is to investigate the...
morphology and function of the microcirculation with different non-invasive techniques such as nailfold videocapillaroscopy (NVC). NVC is of paramount importance for the differential diagnosis of primary and secondary Raynaud's phenomenon [1], and is part of the 2013 ACR/EULAR classification criteria for systemic sclerosis. As there is a wide variety of non-sclerodema patterns, the categorisation of capillaroscopic images as non-sclerodema patterns may be a challenge to the capillaroscopist.

Objectives: This study was designed to propose a simple fast track algorithm to differentiate sclerodema patterns from non-sclerodema patterns and to assess its interobserver reliability.

Methods: During the 8th EULAR course on capillaroscopy held in Genoa, September 2018, a lecture on teaching the fast track algorithm to categorise an image as non-sclerodema (category 1) or sclerodema pattern (category 2) (see figure) was given to all attendees (from 43 different countries): 6 experts, 68 novices, 53 moderately experienced (< 5 years of experience with capillaroscopy) and 14 experienced physicians (> 5 years of experience with capillaroscopy). Immediately after training, an examination was performed on 30 images. Classification of the images was defined by the presenter (VS) as the gold standard. Interobserver reliability was assessed by the calculation of kappa coefficients and proportion of agreement versus the gold standard.

Results: The light kappa was 1 for the independent experts (n=6) and 0.92 for the attendees (n=135). When comparing with the gold standard, an equal mean kappa of 0.96 (95%CI 0.95 – 0.98) was found for both independent experts and attendees. Analyses according to the reported level of experience on capillaroscopy revealed a mean index of reliability of 0.98 (95%CI 0.96 – 0.99) for novices, 0.96 (95%CI 0.93 – 0.99) for moderately experienced raters and 0.93 (95%CI 0.85 – 1.01) for experienced raters.

Conclusion: For the first time a fast track algorithm has been developed that was trainable within an hour to non-experienced capillaroscopists and has an excellent reliability to discern a non-sclerodema from a sclerodema pattern by medical doctors with varying levels of expertise in capillaroscopy.

SAT0299 DIAGNOSIS OF SYSTEMIC SCLEROSIS: HOW AND WHEN
Cristina Sobrino, Carlos De la Puente Bujidos. Rheumatology Department, Ramón y Cajal University Hospital, Madrid, Spain
Background: Systemic sclerosis (SSc) is a heterogeneous disease regarding its clinical expression, evolution and forms of presentation. In spite of the lack of a disease modifying therapy, there are effective treatment options to control complications such as pulmonary arterial hypertension (PAH), interstitial lung disease (ILD) or digital ulcers (DU). Early diagnosis is crucial and allows the physician to start these treatments as soon as possible. To know how and when we diagnose SSc and its clinical manifestations will help us to detect potential improvement areas.
Objectives: To study the main clinical manifestations that lead to diagnosis of SSc, the delay of the diagnosis after the beginning of the first symptom, and to analyze the role of the different clinical features in the diagnosis.
Methods: A retrospective and descriptive study was conducted, which included patients with SSc from our Rheumatology Department. Clinical data and specific autoantibodies profile (ACA, Scl-70, RNP) were recorded, paying special attention to the clinical manifestations that led to diagnosis. We classified them in eight categories: secondary Raynaud’s phenomenon (SRP), digital ischemia or DU, musculoskeletal symptoms, skin induration, ILD, PAH, specific autoantibodies detection, and others.
The date of starting of Raynaud’s phenomenon (RP), of the first non-Raynaud symptom and the date when the diagnosis was established were registered. Analysis were conducted using STATA.
Results: The sample included 149 patients with SSc, meeting the 2013 ACR/EULAR criteria. RP appeared several years prior to the diagnosis (median of 3 years, IQR 0-8), and typically before the first non-Raynaud symptom. 141 out of 149 patients (94.6%) presented RP prior to the diagnosis. However, SRP was the manifestation that led to diagnosis in only 42/149 patients (41.6%), followed by skin induration (18.1%) and DU (12.7%). Surprisingly, 30/149 patients (20.1%) were diagnosed after the appearance of severe complications such as DU, ILD or PHA. Most patients started symptoms related to SSc several years before diagnosis (details in Table 1). 40/48 patients (83%) that were diagnosed due to RP, presented abnormalities in nailfold capillaroscopy as well as specific autoantibodies (Table 2). Presenting telangiectasia, calcinosis, ILD or PAH was not associated with an early diagnosis, nor was ACA, Scl-70 or RNP positivity.
Conclusion: An early approach of RP with capillaroscopy and specific autoantibodies would avoid delays to SSc diagnosis, allowing a close follow-up and an early treatment if necessary. SSc must always be considered as a differential diagnosis in patients with DU, ILD or PAH. An adequate referral of patients from primary care physicians to rheumatologists, and a multidisciplinary approach with Vascular Surgery, Pneumology and Cardiology Units would advance the diagnosis of this complex and potentially severe disease.

SAT0299 PREVALENCE OF PERIPHERAL EOSINOPHILIA AND CLINICAL ASSOCIATIONS IN THAI SYSTEMIC SCLEROSIS PATIENTS
Chirongch Foochooran1, Patnarin Kongkulkiat1, Ajanee Mahakanokrua1, Piyawan Maleewong Irrapat2, Wanchai Maleewong3, Amonrat Junnainsong3, Natthya Tewtrakul1, Siraphop Sawanwong3, Ratanaavadee Nanagara3, Scleroderma Research Group, ‘Khon Kaen University, Department of Medicine, Khon Kaen, Thailand. ’Khon Kaen University, Department of Parasitology, Khon Kaen, Thailand. ’Khon Kaen University, Faculty of Associated Medical Sciences, Khon Kaen, Thailand
Background: Eosinophilia has been reported in systemic sclerosis (SSc) and localized scleroderma, so it might be part of the immune response in the pathogenesis of the disease.
Objectives: To determine the prevalence and clinical associations with peripheral eosinophilia in Thai SSc patients.
Methods: A cross-sectional study was conducted among Thai adult SSc patients, followed up at the Scleroderma Clinic, Khon Kaen University, Thailand, between November 1, 2016 and November 30, 2017. We excluded patients who had clinical overlap with another connective tissue disease, coexisting with localized scleroderma, eosinophilic fasciitis, or eosinophilia myalgia syndrome, and other diseases that cause eosinophilia. Peripheral eosinophilia is defined when total eosinophil count (TEC) is greater than 500 cells/μL. Clinical, laboratory tests for tissue parasite, cytokines, and others for evaluation the cause of eosinophilia were done on the study date.
Results: A total of 185 SSc patients were enrolled. Fifty-seven cases (10.1%) were peripheral eosinophilia of which 21 had the causes of eosinophilia identified by laboratory without clinical symptoms (viz. 9 adrenal insufficiency, 2 tuberculosis, and 10 parasitic infection). The total prevalence of the unknown causes of peripheral eosinophilia in SSc was 21.9% (95%CI 15.9-29.1) (36 of 164 cases). Five of the patients had TEC above 1500 cells/μm3. Of the 164 SSc patients, the majority (70.6%) had diffuse cutaneous SSc, and the female to male ratio was 2.3:1. The respective median age and median duration of the disease was 57.0 years (IQR 52.2-63.9) and 6.5 years (IQR 2.9-10.5). According to a multivariate analysis, being male and duration of disease increasing
every year were significantly associated with peripheral eosinophilia in SSc patients (OR 3.46 (95%CI 1.11-10.73) and 1.16 (95%CI 1.03-1.30), respectively), while Raynaud’s phenomenon had a significantly negative correlation with peripheral eosinophilia in SSc (OR 0.27: 95%CI 0.09-0.84). Other parameters—such as SSC subset, severity of skin tightening, serology, cytokines (transforming growth factor-β), interleukin-5)—were not correlated with peripheral eosinophilia.

Conclusion: Peripheral eosinophilia of unknown cause can be detected in 1 in 5 SSc patients. The factors associated with peripheral eosinophilia are longer disease duration and being male while vasculopathy has a negative association.

SAT0302 SINGLE-PORT THORACOSCOPIC SYMPATHICOTOMY IS VERY EFFECTIVE FOR TREATMENT RESISTANT RAYNAUD’S PHENOMENON: A ONE MONTH FOLLOW-UP
Annie van Roon1, Michiel Kuipers2, Saskia van de Zande1, Amaal Eman Abdulle1, Arie Van Roon1, Reinhard Bus3, Wobbe Bouma1, Theo Klinkenberg2, Hendrika Bootsma4, Mike Dejongste5, Massimo Mariani2, Andries Smit1, Douwe J. Mulder1.
1University of Groningen, University Medical Center Groningen, Internal Medicine, division Vascular Medicine, Groningen, Netherlands; 2University of Groningen, University Medical Center Groningen, Thoracic surgery, Groningen, Netherlands; 3Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands; 4University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 5University of Groningen, University Medical Center Groningen, Cardiology, Groningen, Netherlands

Background: In some patients, Raynaud’s Phenomenon (RP) symptoms prove resistant to conventional vasodilatory treatment. Thoracic sympathectomy is shown to be effective as treatment of RP, but is associated with surgical burden. During this procedure, the sympathetic nerve traversing to the upper extremity is dissected, subsequently leading to vasodilatation. In our centre, single-port thoracoscopic sympathectomy (SPTS) has been developed, a minimally invasive technique, extensively limiting surgical burden. [1]

Objectives: To evaluate SPTS feasibility and efficacy after one month in patients with treatment resistant RP.
Methods: In this study RP patients were their own controls, as they received an unilateral left sided sympathectomy. The effects of the SPTS was assessed at baseline and one month after the procedure. Perfusion of the hand was assessed using a cooling and recovery procedure, and laser speckle contrast analysis (LASCa) at room temperature of 23 degrees Celsius. The number and duration of RP attacks was reported over a two week period prior to reassessment by standard questionnaire.

Results: Eight patients were included in the study, 6 male/2 female, with a median (IQR) age of 45.2 (30.2–55.3) years, body mass index of 23.9 (23.4–26.8) kg/m², and RP duration of 7.0 (2.5–14.3) years. Five patients suffered from primary RP, and three patients had RP secondary to connective tissue disease (CTD) [mixed CTD (n=2) and limited cutaneous systemic sclerosis (n=1)]. All patients were very satisfied with the results and the number of attacks in the left hand decreased (p=0.018). After surgery an unilateral improvement in left hand perfusion was observed.
during the cooling and recovery procedure (p=0.008, figure 1), and in the fingertips with LASCA (p=0.023). No serious adverse events occurred.

Figure 1: Mean number of fingers per hand with normal perfusion during a cooling and recovery procedure before and after left-sided SPTS

Conclusion: SPTS, a minimally invasive technique, appears to be feasible and effective in improving hand perfusion in patients with RP after one month. Although these results are promising, long-term efficacy needs to be established and therefore follow-up is on-going.

SAT0303 DESIGN OF PHASE 3 STUDY OF LENABASUM FOR THE TREATMENT OF DERMATOMYOSITIS

Victoria Werth1,2, Chester V. Oddis2, Ingird E. Lundberg3, David Fiorentino3, Caitlin Cornwall4, Nancy Degtjark6, Scott Constantine6, Barbara White6

1Philadelphia Veteran Affairs Medical Center, Philadelphia, United States of America; 2University of Pennsylvania, Philadelphia, United States of America; 3University of Pittsburgh Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America; 4Karolinska Institute, Solna, Sweden; 5Stanford University Department of Dermatology, Redwood City, United States of America; 6Corbus Pharmaceuticals, Inc., Norwood, United States of America

Background: To date, there has not been a Phase 3 study evaluating efficacy and safety of a new chemical entity solely in subjects with dermatomyositis (DM). There is no precedence for design of such a pivotal study, including selection of patients or efficacy outcomes.

Objectives: Develop a Phase 3 study design

Methods: Lenabasum is a synthetic, non-immunosuppressive, selective cannabinoid receptor type 2 agonist that activates resolution of innate immune responses. Lenabasum had acceptable safety and tolerability and improved multiple physician-reported and patient-reported efficacy outcomes in a 16-week double-blinded, randomized, placebo-controlled Phase 2 trial in DM subjects with refractory, skin-predominant involvement, as well as in the open-label extension of that study. The Phase 3 trial design was based on Phase 2 data, input from a steering committee of experts in DM clinical trials, and recommendations made by regulatory authorities in the US, EU, Sweden, and Japan.

Results: A global, double-blind, randomized, interventional design was chosen to provide an unbiased assessment of the efficacy, safety and tolerability of lenabasum 20 mg bid and 5 mg bid compared to placebo in the treatment of DM. A 52-week treatment duration was selected to provide safety and efficacy data adequate to support chronic treatment. Subjects with DM were classified by Peter and Bohan criteria or the 2017 EULAR/ACR classification criteria for DM (both amyopathic DM and classic DM). Subjects will be required to have active disease, as assessed by an expert and based on a range of muscle, skin, and other disease manifestations. Subjects must be on stable doses of current DM treatments with any background immunosuppressive medications allowed except prednisone ≥ 20 mg per day or equivalent. This inclusivity allows testing of efficacy and safety of lenabasum in the setting of current treatment practice and reduces risk of disease flare early in the study. The primary efficacy outcome is change from baseline in 2016 ACR/EULAR Total Improvement Score (TIS) for DM and polymyositis. This composite outcome has six domains that broadly capture improvement in disease activity, is relevant to the range of manifestations in DM, and is applicable to the assessment of efficacy in the target patient population. Secondary efficacy outcomes were chosen to assess how the subject functions (Short Form – 36 physical functioning domain), major organ involvement (MMT-8, CDASI activity score, and a new Investigator Global Assessment scale of skin activity designed specifically for this study), and lung function (FVC). Change in oral corticosteroid dose also will be captured.

Conclusion: To our knowledge, this is the first Phase 3 study in DM with a new molecular entity. As such, agreement with experts and regulatory authorities on design represents a step forward in the development pathway of new treatments for DM.

SAT0304 RELATIONSHIP BETWEEN INTERLEUKIN-23 AND GASTROINTESTINAL INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS

Ana Žeković1, Misa Vreća2, Vesna Špasović2, Vesna Skodrić-Trifunović3, Ljiljana Marković-Denic4, Marina Andjelković5, Sonja Pavlović4, Nemanja DamjanovichNemanja Damjanovich1, Institute of rheumatology, Belgrade, Serbia, 2Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia, 3Clinic for Pulmonary Diseases, Belgrade, Serbia, 4Institute of Epidemiology, Belgrade, Serbia

Background: Growing evidence suggests that T-cell proliferation and cytokine secretion play an important role in the pathogenesis of systemic sclerosis (SSc). Gut involvement is the leading cause of morbidity in patients with SSc. In this study we evaluated interleukin-23 (IL-23) protein expression profiles and investigated its association with gastrointestinal involvement in SSc patients.
Spondyloarthritis - clinical aspects (other than treatment)

**Objectives:** To define IL-23 expression profiles and to explore association between IL-23 and gastrointestinal involvement in SSc patients.

**Methods:** Study included 31 SSc patients. The expression level of IL-23 mRNA was determined by qRT-PCR method and Enzyme-Linked Immunosorbent Assay (ELISA) was used for analysis of IL-23 serum protein level. We used UCLA GIT 2.0 questionnaire to assess gastrointestinal (GIT) involvement in SSc patients.

**Results:** We found a positive correlation between disease duration and expression levels of IL-23 mRNA (r = 0.49, p < 0.05). Nine SSc patients with high IL-23 levels (cut off point 6.8 pg/ml) had significantly higher UCLA GIT 2.0 score, compared to 22 SSc patients with normal IL-23 levels (p < 0.05). Serum level of IL-23 positively correlated with total GIT score (r = 0.35, p < 0.05) and distension scale score (r = 0.5, p < 0.05).

**Conclusion:** High IL-23 serum levels significantly correlated with gastrointestinal involvement (higher UCLA GIT 2.0 score) in patients with SSc.

SAT0306
COMPARISON OF MEN AND WOMEN WITH AXIAL SPONDYLOARTHRITIS IN THE US-BASED CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS (PSPA) REGISTRY

Philip J. Mease1, Mei Liu2, Sabrina Rebello2, Robert Mclean2, Blessing Dube2, Meghan Glynn2, Esther Yi5, Yu Jin Park5, Alexis Ogdie1, Robert McClain2
1Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, United States of America; 2Corrona, LLC, Waltham, United States of America; 3The University of Texas at Austin, United States of America; 4Baylor Scott and White Health, Temple, United States of America; 5Novartis Pharmaceuticals Corporation, East Hanover, United States of America; 6Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States of America

Background: Axial spondyloarthritis (AxSpA) is a chronic inflammatory rheumatic disease that primarily affects the axial skeleton and frequently affects the peripheral joints and entheses. AxSpA encompasses ankylosing spondylitis and nonradiographic AxSpA. Sex differences have been described for patient reported outcomes (PROs) in SpA; however, more research is needed to better understand the overall clinical burden of AxSpA in women, particularly in the United States.

Objectives: To compare the patient demographics, clinical characteristics, treatment profiles, disease activity, quality of life, and work productivity between men and women with AxSpA in the US-based Corrona PsA/SpA Registry.

Methods: This study included patients aged ≥ 18 years with AxSpA enrolled in the Corrona PsA/SpA Registry between March 2013 and November 2018. Patients who were concurrently diagnosed with PsA were excluded. Patient demographics, clinical characteristics, treatment profiles, disease activity, quality of life, and work productivity were characterized for all patients with AxSpA at enrollment and were compared between men and women using t tests or Wilcoxon rank-sum tests for continuous variables and χ2 or Fisher’s exact tests for categorical variables.

Results: Of 498 patients with AxSpA who were included in the study, 307 (61.6%) were male and 191 (38.4%) were female. Compared with men, women were less likely to work full time, were more likely to be normal weight/underweight, had a shorter disease duration, and were more likely to have depression, fibromyalgia, and prior csDMARD and prednisone use (Table 1; all P < 0.05). At enrollment, women with AxSpA had a shorter occiput-to-wall distance, but also had worse disease activity compared with men, as reflected by higher BASDAI and BASFI scores, higher enthesis and tender/swollen joint counts, worse pain and fatigue, worse physical function (HAQ-S) and health state today (EQ-5D), and more severe work and activity impairment (Table 2; all P < 0.05).

Conclusion: In this US registry of patients with AxSpA, women had an increased overall burden of disease compared with men, including higher patient reported symptoms, higher disease activity, and greater work productivity impairment. Women also had lower scores for spinal mobility with increased signs of peripheral arthritis (eg, higher tender/swollen joint and enthesis counts), suggesting that conventional definitions of AxSpA centered around axial symptoms may not be representative of the female population with disease. Improved awareness of sex differences in presentation of AxSpA may aid physicians in earlier identification and improved management of the disease.

SAT0307 LONG-TERM ASSOCIATION BETWEEN DISEASE ACTIVITY MEASURED BY ASDAS AND PHYSICAL FUNCTION IN A LARGE EARLY AXIAL SPONDYLOARTHRITIS COHORT

Pedro Carvalho1, Ana Marreiros2, Adeline Ruyssev-Witrand3, Pedro Machado4.
1Centro Hospitalar do Algarve – Hospital de Faro, Faro, Portugal; 2Algarve Biomedical Center, Faro, Portugal; 3Le centre Hospitalier Universitaire de Toulouse, Toulouse, France; 4University College London, London, United Kingdom

Background: The Ankylosing Spondylitis Disease Activity Score (ASDAS) has been progressively replacing the Bath Ankylosing Spondylitis Disease Activity Score (BASDAI) as the main disease activity measure to assess patients with axial spondyloarthritis (axSpA), both in the research context as well as in clinical practice. However, further evidence is needed to show its meaningfulness regarding the longitudinal relationship with physical function.

Objectives: To study the long-term association between disease activity and physical function in axSpA.

Methods: DESIR is a prospective observational cohort of patients with recent onset (<3 years) inflammatory back pain, suggestive of axSpA. We analysed data collected during the first five years of follow-up and selected patients with a definite diagnosis of axSpA according to the treating rheumatologist. Physical function was assessed using the Ankylosing Spondylitis Health Assessment Questionnaire (HAQ-AS). Disease activity was measured using the ASDAS C-reactive protein (ASDAS-CRP) and BASDAI. In a first step, associations between HAQ-AS (dependent variable) and disease activity (defined by ASDAS or BASDAI), clinical and demographic variables were tested in univariable models. Multivariable models were then built adjusting for potential confounding factors found to be significant in the univariable analysis.

In a second step, additional multivariable analysis was conducted using the Chi-square Automatic Interaction Detector (CHAID) method, with HAQ-AS as dependent variable. The following independent variables were tested: ASDAS/BASDAI, enthesitis score, arthritis, employment status, gender, symptom duration, body mass index (BMI), HLA-B27 status, treatment with non-steroidal anti-inflammatory drugs (NSAID), conventional disease modifying anti-rheumatic drugs (cDMARD) and TNF-blockers. The final model fixed as criteria: 70 parent nodes and 20 child nodes to create new generations in the decision tree.

Results: Data from 644 patients and 4944 visits were analysed. There was a significant independent association between HAQ-AS and gender, employment status, peripheral arthritis, ASDAS-CRP/BASDAI enthesitis, NSAID and anti-TNF treatment (Table 1). The decision tree revealed ASDAS as the first variable with discriminative power on HAQ-AS, according to the following cut points: 1.3, 2.2 and 2.4. In addition, for ASDAS values above 3.5 the model yield a higher number of explanatory variables setting different patients’ profiles regarding their functional status, namely: gender, anti-TNF and NSAID treatment. Notably, the ASDAS cut-offs that separated different patient profiles largely mimicked the cut-offs previously defined for ASDAS disease activity states (inactive, low, high and very high disease activity). According to this hierarchical model, gender, anti-TNF treatment and enthesitis score were the next variables explaining HAQ-AS variation, followed by employment status and NSAID treatment.

Conclusion: We have shown that disease activity contributes longitudinally to physical function and that it is hierarchically superior to any other variables or disease domains. Previously defined ASDAS-CRP disease activity categories identified different patient profiles on the hierarchical analysis.

* Not selected for this model; NA – not applicable; ** Model adjusted with the cofounders considered significant in the proposed multivariable model for ASDAS (previous column)

Disclosure of Interests: Pedro Carvalho: None declared, Ana Marreiros: None declared, Adeline Ruyssev-Witrand: None declared, Pedro Machado Consultant for: Abbvie, BMS, Celgene, Janssen, MSD, Novartis, Pfizer, Roche and UCB, Speakers bureau: Abbvie, BMS, Celgene, Janssen, MSD, Novartis, Pfizer, Roche and UCB

manifestations (B for both)\(^1\). Those cluster-based SpA phenotypes could correspond to different levels of disease severity.

**Objectives:** To assess whether cluster-based SpA phenotypes defined at baseline are conserved over time and might predict disease outcome at follow-up.

**Methods:** We analysed longitudinal data from the 586 patients who completed all follow-up visits until 5-year (mo 6, 12, 18, 24, 36, 48 and 60) out of the 679 patients included in the DESIR cohort used to define clusters at baseline. We performed a linear mixed-effect analysis for quantitative variables (using Ime4 R package) and a generalized linear mixed-effect analysis for qualitative variables (using glmer R package) with cluster and follow-up visits as fixed effects and subjects as random effect. P-values were obtained by likelihood ratio tests of the full model with cluster against the model without cluster as fixed effects.

**Results:** Over the time, both clusters continued to show sustainable consistent differences characterized by higher frequency of peripheral involvement, higher disease activity, worse patient-reported outcome, higher frequency of conventional DMARDs and TNF blockers usage in cluster B, and higher frequency of radiographic and MRI sacroilitis at 2 and 5 years in cluster A (Table).

**Conclusion:** Cluster-based SpA phenotypes defined at baseline in the DESIR cohort were predictive of severity outcome after 5 years. Patients from cluster B were more prone to develop sacroilitis despite lower disease activity over the time, whereas those from cluster B had poorer clinical outcome and higher need for conventional DMARDs and TNF blockers.

**CLINICAL, IMAGING AND BIOLOGIC FEATURES OF SPONDYLOARTHRITIS IN AN AT-RISK POPULATION: DATA FROM THE PRE-SPA COHORT**

Henriëtte de Jong\(^1\), Janneke de Winter\(^2\), Irene van der Horst-Bruinsma\(^3\), Dirkjan van Schaardenburg\(^4\), Floris A. van Gaalen\(^5\), Astrid van Tubergen\(^6\), Angelique Weel\(^7\), Robert B.M. Landewé\(^8\), Dominique Baeten\(^9\), Marleen van de Sande\(^1\), Amsterdam UMC, Amsterdam, Netherlands; St. Antonius Hospital, Nieuwegein, Netherlands; Amsterdam UMC, Amsterdam, Netherlands; Leiden University Medical Center (LUMC), Leiden, Netherlands; Academic Hospital Maastricht, Maastricht, Netherlands; Maasstad Hospital, Rotterdam, Netherlands

**Background:** Diagnosis in axial spondyloarthritis (axSpA) is challenging and often delayed by several years, resulting in a delay in treatment. Previously we reported presence of spondyloarthritis (SpA) features and imaging abnormalities in first-degree relatives (FDRs) of HLA-B27 axSpA patients, who are at risk of developing axSpA [1]. Follow up of these at risk individuals could help to identify clinical signs, imaging abnormalities or biomarkers that are predictive of development of axSpA.

**Objectives:** To investigate imaging, biologic and/or clinical signs of SpA at baseline and after 1 year follow up, as well as development of clinically manifest axSpA after 1 year follow up in at risk individuals.

**Methods:** The Pre-Spa cohort[1] is a prospective inception cohort in which FDRs of HLA-B27 positive axSpA patients are included and followed for 5 years. The main exclusion criteria were: a diagnosis of SpA at baseline and back pain with a previous non-rheumatic diagnosis, such as spinal disc herniation. Clinical and biologic characteristics were collected at baseline and after 1 year. Imaging was performed at baseline including MRI of the sacroiliac joints (SIJ) and X-rays of the cervical and lumbar spine and SIJ. MRIs were scored according to the ASAS definition for a positive MRI by two readers. X-rays were scored according to the modified New York (mNY) criteria for ankyllosing spondylitis by two readers.

**Results:** In the current study we report the characteristics of 201 participants at baseline and 123 participants after one year of follow-up. 126 (82.7%) participants reported back pain, of which 39 (19.4%) fulfilled criteria for inflammatory back pain. Median (IQR) VAS total back pain (0-100mm) was 11 (0-28). Six (2.9%) were previously diagnosed with arthritis by a physician, nine(4.4%) with enthesis and one(0.5%) with dactylitis. In none of these participants a diagnosis of SpA was made. Seven participants were previously diagnosed with an extra-articular manifestation possibly related to SpA: four with psoriasis and three with anterior uveitis. Three (1.5%) participants fulfilled the mNY criteria for sacroilitis on radiography. Ten (5%) participants had bone marrow edema on MRI of the SIJ suggestive of SpA. Fifty-six (27.8%) participants would have fulfilled ASAS classification criteria for axSpA if they would have had a clinical diagnosis of axSpA. After one year patient-reported disease activity variables remained stable; median (IQR) VAS total back pain (0-100mm) was still low: 4(0-24). During one year of follow-up, in total seven participants developed symptoms and were clinically diagnosed with axSpA.

**Conclusion:** Imaging signs and clinical signs of SpA are present in a substantial proportion of seemingly healthy FDRs of HLA-B27 positive AxSpA patients. Twelve (6.0%) participants had imaging suggestive of SpA, but a clinical diagnosis of axSpA was still rare after one year of follow up (5.7%). Future follow-up will increase numbers of individuals diagnosed with axSpA and help us identify early symptoms and signs of SpA in this at risk population.

IDENTIFICATION OF FACTORS ASSOCIATED WITH MAGNETIC RESONANCE IMAGES CHANGES SUGGESTIVE OF AXIAL SPONDYLOARTHRITIS IN THE AXIAL SKELLET OF INDIVIDUALS <45 YEARS – EVALUATION OF DATA FROM A LARGE COMMUNITY STUDY

Xenon Banilack1, Adrian Richter2,3, Daniel Feldmann1, Anne Ot1, Robin Bülow4, Carsten Schmidt4, Juergen Braun4, 1Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Heme, Germany; 2Institute for Community Medicine, Greifswald, Germany; 3German Rheumatism Research Center, Berlin, Germany; 4Department of Diagnostic Radiology and Neuroradiology, University Medicine, Greifswald, Germany

Background: Active (bone marrow edema, BME) and structural (fatty lesions, FL) MRI lesions in the spine and the sacroiliac joints (SIJ), as assessed by magnetic resonance imaging (MRI), have been described in patients with axial spondyloarthritis (axSpA) but may also occur in non-axSpA patients and healthy individuals (1,2).

Objectives: Identify factors associated with the occurrence of BME and FL in spinal- and SIJ-MRIs in the population-based Study of Health in Pomernania (SHIP).

Methods: All available spinal- (sagittal T1/T2 sequences) and SIJ- (semi-coronal STIR sequences) MRIs were evaluated by two trained readers blinded to clinical data. BME (SIJ and spine) and FL (spine) suggestive of axSpA were recorded. Disagreements were resolved by consensus. BME was quantified using Berlin MRI scores. Information was available for age (increase per decade), sex, smoking (ever vs. never), prevalence of spinal pain (NRS≥4/10 in last 3 months), CRP, HLA-B27 status and body mass index (BMI) categories (WHO definition of underweight (cat. 1), normal (cat. 2) or overweight (cat. 3)). Associations between clinical factors and MRI lesions were analyzed (a) by modeling of number and size of lesions using negative binomial count regression and (b) for presence/absence of lesions using univariate logistic regression.

Results: MRIs of 793 volunteers, 392 male (49.4%), 45 CRP-positive (5.7%), 67 HLA-B27+ (8.4%), 497 smokers (62.7%) were evaluated. BME lesions were found in 136 SIJ-MRIs (17.2%) and in 218 (27.5%) spinal MRIs, while FL were found in 645 spinal MRIs (81.3%).

A higher number and larger sized SIJ-BME lesions were associated with (wp (β, 95% CI)) with HLA-B27 (2.8, 1.5-4.9), spinal pain (1.7, 1.2-2.6), and higher BMI (cat. 1 vs 3, 1.7, 1.0-3.0). In the spine, higher number and larger sized BME were associated with age (1.5, 1.2-2.0), while FL were associated with higher BMI, (cat. 1 to cat. 3 (1.9, 1.5-2.2), age (1.6, 1.5-1.8) and male sex (1.4, 1.2-1.6).

Presence (odds ratio, 95% CI) of spinal BME (1.3, 1.0-1.7) and/or FL (1.7, 1.3-2.3) was associated with age, while FL alone were associated with a higher BMI (cat. 1 to cat.3, 3.3, 1.6-6.1).

In total, 22 subjects (16.2%) had large (>33% of surface involvement) and 114 small (<33% of surface involvement) SIJ-BME lesions. Large SIJ-BME lesions were found in 4.5% HLA-B27-positive vs. 2.6% HLA-B27-negative subjects (p=0.40). Out of 167 quadrants with BME lesions in SIJ, the majority (n=66, 35-3%) was located in the upper sacral quadrant. Most SIJ lesions (n=156, 83.4%) were small. Out of 362 spinal segments with BME, the majority n=152, 42% was located in the lower (T7/8-T11/12) thoracic spine. Most spinal lesions (n=299, 90.9%) were small.

Conclusion: In this large population-based study, higher numbers of large and small SIJ-BME lesions were significantly associated with HLA-B27, back pain and BMI. In some contrast, spinal BME and FL were associated with older age, male sex and BMI but not HLA-B27. The association for HLA B27 was only shown on the quadrant but not on the patient level. These findings are in accordance with previously published hypotheses that question the specificity of sacroiliitis and spondylitis in axSpA (3).

DIAGNOSTIC UTILITY OF INDIVIDUAL INFLAMMATORY BACK PAIN PARAMETERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Marcus de Haan1, Floris A. van der Helm2, Marleen van de Sande2, Karen Fagerien1, Lennart Jacobsen1, Dirk Elenwaert3, Désirée van der Heijde4, Filip Verhoeven5, Manouk de Hooge6, Floris A. van Gaalen7, Marleen van de Sande8

1VIB Inflammation Research Center, Ghent, Belgium; 2UZ Gent, Ghent, Belgium; 3LMC, Leiden, Netherlands; 4AMC, Amsterdam, Netherlands; 5Diakonhjemmet Hospital, Oslo, Norway; 6University of Göteborg, Göteborg, Sweden

Background: A recent study in German chronic back pain (CBP) patients (pts) with a suspicion of axial spondyloarthritis (axSpA) report on the performance of, among others, the ASAS inflammatory back pain (IBP) criteria and the individual IBP parameters. Pts were diagnosed by a rheumatologist blinded for all clinical features but IBP and by a rheumatologist with all diagnostic tests available as in daily practice (reference standard). Data show high sensitivity but low specificity of the ASAS IBP criteria.

Figure. Performance of individual parameters of the ASAS IBP criteria

SAT0310

SAT0311
GENDER CONTRASTS IN PATIENT REPORTED OUTCOMES DON'T ALTER THE DISEASE ACTIVITY SCORE IN AXIAL SPONDYLOARTHRITIS PATIENTS

1,2Ann-Sophie De Craemer, Thomas Renson1,2, Liselotte Deroo1,2, Manouk de Hooge1,2, Philippe Carron1,2, Filip van den Bosch1,2, Dirk Elewaut1,2, Be-Giant; 3VIB Inflammation Research Center, Ghent, Belgium

Background: Disease activity in axial spondyloarthritis (axSpA) is often quantified by the Axial Spondyloarthritis Disease Activity Score (ASDAS), a composite index which combines 4 patient reported outcome (PRO) parameters and C-reactive protein (CRP) as an acute phase reactant. ASDAS commonly acts as a target in treat-to-target approaches in axSpA patients.

Objectives: To identify the impact of gender on ASDAS in newly diagnosed axSpA patients and to determine whether possible differences are PRO- or CRP-driven.

Methods: Patients originate from the Be-Giant cohort, a Belgian observational registry of newly diagnosed axSpA patients (expert opinion). Included patients fulfill the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for axSpA and are anti-TNF naïve prior to inclusion. An extensive patient description was performed at baseline, including PRO and laboratory investigations with CRP (mg/L). ASDAS was calculated for each patient and subdivided in a PRO-component (ASDAS-PRO) and a CRP-component (ASDAS-CRP) (1).

Results: By January 2019, 291 axSpA patients were included (138 male, 153 female). At baseline, ASDAS could be calculated in 262 patients. ASDAS-PRO was significantly higher in women compared to men (1,66 vs. 1,48, p = 0,04), while ASDAS-CRP did not differ significantly (0,90 for both genders, p = 0,96). No significant difference was found between the total ASDAS of women and men (2,54 vs. 2,38, p = 0,09) (Figure 1). When categorizing the score into 4 disease activity states (2), 60,8% (76/125) of men show high or very high disease activity (ASDAS > 2,1) at baseline compared to 67,2% (92/137) of women (p = 0,35).

Concerning the 5 ASDAS components, the discrimination between male and female axSpA patients was most pronounced for patient global scores (Figure 2). Men reported a baseline patient global score of 4,3 (95% CI 3,8 – 4,8), compared to a score of 5,1 (95% CI 4,7 – 5,6) in women (p = 0,01).

Conclusion: Female axSpA patients report a significantly higher patient global score compared to men. This contributes to a significantly higher ASDAS-PRO in women. However, neither the ASDAS itself nor the ASDAS disease activity categories are significantly affected by gender contrasts in PRO.

ILEAL BUT NOT COLONIC INFLAMMATION IS LINKED TO FATTY LESIONS ON MRI OF THE SACROIACIAL JOINTS IN SPONDYLOARTHRITIS PATIENTS

Background: Gut and joint inflammation in spondyloarthritis (SpA) are closely intertwined. About 50% of axial SpA patients display microscopic signs of inflammation in ileum and/or colon, a risk factor to develop Crohn’s disease over time. It is currently not known if presence of microscopic gut inflammation in new onset SpA is associated with more structural lesions on magnetic resonance imaging of the sacroiliac joints (MRI-SIJ) and whether these lesions relate to the localization of gut inflammation.

Objectives: To assess whether structural lesions on MRI-SIJ (A) are associated with microscopic gut inflammation in SpA patients and (B) are preferably related to colon or ileum inflammation in case of gut involvement.

Methods: We analyzed baseline information from the Be-Giant cohort, a registry of SpA patients fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axial or peripheral SpA. MRI-SIJ was scored by 3 readers, blinded for subject characteristics. Six consecutive slices were assessed for structural lesions: sclerosis, erosions, fatty lesions and (partial) ankylosis. MRI sum scores were analyzed as 2 out of 3 (median) scores. Colon and ileum biopsies were evaluated for microscopic signs of inflammation. The effect of gut inflammation (colon and/or ileum) on MRI-SIJ lesions was investigated by general linear models (GLM), adjusted for age and gender and stratified for the SpA phenotype.

Results: By January 2019, baseline data were available on 105 patients (95 axial and 10 peripheral SpA). Gut inflammation was present in 35 patients (17 ileum, 8 colon, 10 both). Table 1 shows the slope (β1) of the GLMs for erosions, fatty lesions, sclerosis and (partial) ankylosis and the p-value for the SpA phenotype as an interaction term. Erosions, sclerosis, nor ankylosis show a significant association with gut inflammation in general. If present, colon inflammation has no significant relationship with each individual structural lesion. In contrast, presence of ileum inflammation was associated with an increase in the number of fatty lesions by 0.68 (95%CI 0.04 – 1.38). All results are independent of the SpA phenotype (p = 0.05).

Conclusion: Ileal but not colonic inflammatory gut lesions are linked to more fatty lesions on MRI-SIJ in newly diagnosed SpA patients. Baseline microscopic gut inflammation was not associated with erosions, sclerosis nor ankylosis. These data support the concept that microscopic gut inflammation was not associated with erosions, sclerosis and (partial) ankylosis. These data support the concept that microscopic gut inflammation in new onset SpA is associated with more structural lesions on magnetic resonance imaging of the sacroiliac joints (MRI-SIJ) and whether these lesions relate to the localization of gut inflammation.

IMPLEMENTATION OF AN ASSESSMENT CHECKLIST FOR PATIENTS WITH SPONDYLOARTHRITIS IN DAILY PRACTICE

ALMODOVAR RAQUEL1, Beatriz Joven-Ibarzéz2, Esther Rodríguez Almaraz2, Sheila Melchor1, Erieta Rabadán3, Virginia Villaverde3, Mª Teresa Navio4, Laura Cebrian4, Leticia Lojo5, Alejandro Prada-Ojeda5, Laura González5, Álvaro García Martos6, Victoria Navarro-Complejo6, Estíbaliz Loza1, Pedro Zarco-Montejo1, 1Fundación Hospital Alcorcón, Alcorcón, Spain; 2University Hospital 12 de Octubre, Madrid, Spain; 3Hospital de Móstoles, Móstoles, Spain; 4Hospital Universitario Infanta Leonor, Madrid, Spain; 5Hospital de Torrejón, Torrejón de Ardoz, Madrid, Spain; 6Hospital de La Jota, Jerez, Spain; 7Hospital Universitario Niño Jesús, Madrid, Spain; 8Instituto de Salud Musculoesquelética, Madrid, Spain

Background: Nowadays, despite international and national guidelines on the evaluation and management of spondyloarthritis (SpA), several studies have depicted a sub-optimal assessment of these diseases.

Objectives: To analyze the feasibility and changes in the collection of clinical measures after the implementation of a checklist designed for an optimal evaluation and monitoring of patients with SpA, including psoriatic arthritis (PsA).

Methods: An observational prospective study was performed. The feasibility of the assessment checklist (paper/on-line format) for patients with SpA was tested (time to complete the checklist, simplicity, amenability, clarity, usefullness). Through a medical files review, changes in the number of the checklist variables collected were analyzed previously to the implementation of the checklist and 6 months later. A descriptive and bivariate analysis was performed.

Results: A total 6 hospitals and 11 rheumatologists participated. The median time to checklist completion was 15 (12-20) minutes, and the mean scores for the rest of variables of the feasibility test were in general positives, 6.9±1.1 (simplicity) and 6.9±0.8 (amenity), to 7.5±1.2 (clarity) and 7.5±1.4 (usefullness). A total of 83 and 68 medical files pre-implementation and post-implementation were reviewed respectively. Patient’s features were similar. Mean age at diagnosis was 42.3±1.6 and 40.3±1.3 years respectively. In both study samples around a half of patients were men, and 20% (extra-articular symptoms) to 30% (diabetes mellitus, hyperlipidemia, gout/hyperuricemia and renal failure). Other checklist variables increased but not significantly. However, some of them like the HLA-B27 and signs or arterial hypertension) to 30% (diabetes mellitus, hyperlipidemia, gout/hyperuricemia and renal failure). Other checklist variables increased but not significantly. However, some of them like the HLA-B27 or work status were already recorded (before the implementation of the checklist) in the 82.3% and 95.2% of medical files respectively. Changes were observed irrespecitively of SpA classification.

Conclusion: The implementation of an assessment checklist in daily practice is feasible and improve the assessment of SpA patients.

*SpA subtype (axial versus peripheral SpA) as an interaction term.
Background: Ankylosing spondylitis (AS) is an inflammatory disease resulting in progressive disability due to structural damage in the spine. The identification of predictors of progression would allow treating physicians to personalize treatments but requires an approach accounting for a relatively short follow-up of clinical studies, large between-patient variability, and low sensitivity of X-ray images which generate intra-patient variability when repeated measurements are taken.

Objectives: 1) To identify patient characteristics predicting faster structural damage progression. 2) To quantify the progression over four years of secukinumab treatment, depending on dose/exposure.

Methods: Data came from the phase 3 randomized placebo-controlled trial MEASURE 1 (NCT01358175) in which patients were treated with secukinumab (intravenous loading of 10 mg/kg at weeks 0, 2, and 4, followed by secukinumab subcutaneously at a dose of either 75 mg or 150 mg every 4 weeks) over 208 weeks. Only patients treated with secukinumab with at least two assessments of structural damage were included. We explored the effect of multiple baseline demographic traits, disease stage, severity, bone cartilage biomarkers as well as prior and current treatment on change in noninvolved Spine Spondylitis Score (mSASSS) using a longitudinal Bayesian mixture model with random effects, which accounted simultaneously for the probability of progression, magnitude of progression, and inter-patient variability. Posterior predictive check was performed.

Results: Out of 249 patients randomized to secukinumab, 167 had their structural damage assessed at least twice. These patients contributed in total 409 assessments of change in structural damage between weeks 0, 52, 104 and 208. Of the factors tested, a higher baseline BASMI score was associated with faster progression rate in a statistically significant way (0.60 in mSASSS/year for each additional standard deviation of baseline BASMI (SD=1.74), 95% interval 0.03 to 1.14). Trends were also detected for association between faster mSASSS progression and younger age, prior exposure to TNF inhibitor, HLA-B27 positivity, and higher osteocalcin levels. Increased exposure to secukinumab was associated with slower structural damage progression (-0.23 in mSASSS/year for each additional standard deviation in exposure, 95% interval -0.58 to 0.10). Model estimation suggested that secukinumab 150 mg was associated with a yearly progression of -0.2 (95% interval -1.2 to 0.8) in the first two years of treatment and 0.1 mSASSS (95% interval -0.3 to 1.0) in the third and fourth year of treatment. Analogously, secukinumab 75mg (currently not approved for clinical use) was associated with a progression of -0.2 mSASSS/year (95% interval -1.3 to 0.9) in the first two years of treatment and 0.5 mSASSS/year (95% interval -0.5 to 1.6) in the third and fourth year of treatment.

Conclusion: Potential predictors of structural progression suggested by the model were higher baseline BASMI, younger age, prior exposure to TNF inhibitor, HLA-B27 positivity, and higher osteocalcin at baseline, although only baseline BASMI showed statistical significance. Further analyses using larger, deeper and real-world data are needed to confirm these findings and to estimate progression rates in AS patients in daily practice.

REFERENCE
INCIDENCE OF EXTRA-ARTICULAR MANIFESTATIONS IN ANKYLOSING SPONDYLITIS, PSORIATIC ARTHRITIS AND UNDIFFERENTIATED SPONDYLOARTHRITIS – RESULTS FROM A NATIONAL REGISTER-BASED COHORT STUDY

Karin Bengtsson1, Helena Forsblad-Delaia1,2, Eva Klingberg3, Ulf Lindström3, Mats Dehlin4, Sofia Exarchou5, Anna Deminger1, Johan Askling6, Lennart T.H. Jacobsson1.

1Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Göteborg, Sweden; 2Lund University, Department of Clinical Sciences, Section of Rheumatology, Malmö, Sweden; 3Karolinska Institutet, Department of Medicine Solna, Clinical Epidemiology Unit and Rheumatology Unit, Stockholm, Sweden

Background: Spondyloarthropathies (SpA), including ankylosing spondylitis (AS), psoriatic arthritis (PsA) and undifferentiated SpA (uSpA), are all to varying degrees associated with extra-articular manifestations (EAMs).

Objectives: To estimate incidence rates (IRs) for EAMs (anterior uveitis, inflammatory bowel disease and psoriasis) in patients with AS, PsA and uSpA, respectively.

Methods: In this nationwide cohort study, three separate cohorts of patients aged 18 to 69 years with AS (n=8517, 66% men, mean age 47 ±13 years), PsA (n=22667, 46% men, mean age 49±12 years) and uSpA (n=10245, 44% men, mean age 42±13 years) were identified 2001-2015 in the Swedish National Patient Register (NPR). The follow-up began 1 January 2006 and ended at the first date of EAM, death, emigration or 31 December 2016, respectively. Patients with a prior EAM in NPR before start of follow-up were excluded from that specific analysis.

Results: The IRs for each EAM are presented in Table 1. The overall highest IRs were noted for anterior uveitis in patients with AS (14.4 (13.2-15.5) per 1000 person-years at risk). Patients with PsA had considerably lower IRs for anterior uveitis (1.7 (1.5-1.9) per 1000 person-years at risk) and slightly lower IRs for IBD than patients with AS and uSpA. The IRs for anterior uveitis were significantly higher in men than in women in both AS and uSpA.

Conclusion: IRs for EAMs clearly differed between the SpA subtypes, and especially for anterior uveitis where the IRs were by far highest in patients with AS and uSpA compared to patients with PsA.

pattern (41.3% and 34.9%), fatigue (35.3% and 28.6%), and loss of interest in sex (21.7% and 21.9%), for AS and PsA, respectively. In univariate analysis (Table 1), female gender (OR=1.73), unemployment due to disability (OR=3.06) or other reasons (OR=2.38), increased BASDAI (OR=1.53), increased BASFI (OR=1.17), and increased morning stiffness (OR=1.01) were significantly associated [all P<0.001 except gender (P=0.009)] with baseline depression among AS patients. For PsA, significantly associated parameters included female sex (OR=2.35; P=0.001), unemployment due to disability (OR=3.57; P=0.001), increased TJC (OR=1.05; P=0.009), increased PGA (OR=1.03; P=0.001) and increased morning stiffness (OR=1.01; P=0.010). Weak correlations (P<0.05) were observed between the BDI score and BASFI (r=0.425), BASDAI (r=0.375), morning stiffness (r=0.285), and number of EAMs (r=0.014) for AS; and TJC (r=0.155), MDGA (r=0.132), and PGA (r=0.451) for PsA. In multivariate regression analysis for AS, higher BASFI (OR=1.32; P=0.001), female sex (OR=1.89; P=0.007) and being unemployed due to other reasons (OR=1.91; P=0.017); and, for PsA, lower baseline disease duration (OR=0.97; P=0.018), and higher PGA (OR=1.04; P=0.001) were identified as significant independent predictors of baseline depression.

Conclusion: Depression in AS and PsA patients was common in this real-world cohort. Female sex, unemployment, and higher disease activity for AS, and shorter disease duration along with higher PGA for PsA were significant independent predictors of depression.

SAT0319

OBESITY AND ASSOCIATED FACTORS IN NORWEGIAN AXIAL SPONDYLOARTHRITIS PATIENTS. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS SURVEY

Christian Bindslev1, Marco Garrido-Cumbraa2, Gunnstein Bakland1, Hanne Solvag Dagnærud1, EMAS working group. 1Novartis Pharma AG, Norway, Oslo, Norway; 2Universidad de Sevilla, Health and Territory Research (HTR), Sevilla, Spain; 3Spanish Federation of Spondyloarthritis Associations (CEADE), Madrid, Spain; 4University Hospital of Northern Norway, Department of Rheumatology, Tromsø, Norway; 5Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway

Background: Obesity increases the risk of developing chronic inflammatory diseases, including axial spondyloarthritis (axSpA). Information about how obesity correlates with disease activity in axSpA patients is limited.

Objectives: The objective of this survey was to investigate the association between body mass index (BMI) and patient reported disease activity in Norwegian axSpA patients.

Methods: The European Map of Axial Spondyloarthritis (EMAS), conducted from July 2017 to February 2018, was a cross-sectional on-line survey of 2,846 unselected patients with self-reported axSpA from 13 European countries (Austria, Belgium, France, Germany, Italy, Netherlands, Norway, Russia, Slovenia, Spain, Sweden, Switzerland, and the UK). Participants were recruited through an on-line panel and patient organizations. This analysis is based on data from the 509 Norwegian respondents. Sociodemographic variables (age, gender, BMI, comorbidity), and disease related variables (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) (0-10), self-reported spinal stiffness (3-12) and General Health Questionnaire (0-12) (GHQ-12) were reported.

Results: Out of the 509 Norwegian participants with axSpA, 69.7% (N=355) were women. The mean age was 48±12 years, mean disease duration was 5.3±2.0 years, 82.3% were HLA-B27 positive, and 55.2% (N=281) were university educated. In total, 35% (N=180) of the participants were normal/underweight (BMI < 25) and 65% (N=329) were overweight/obese (BMI ≥ 25). The mean (sd) disease activity, as measured by BASDAI (0-10), was 5.3±2.0. Overweight/obese patients reported significantly higher disease activity (BASDAI 5.5±1.9) compared to normal weight patients (BASDAI 5.0±2.1). Moreover, being overweight/obese was associated with a significantly higher degree of spinal stiffness, number of comorbidities and a numerically, but not significantly, higher GHQ-12 score. There was no significant differences in alcohol consumption, smoking, or prevalence of inflammatory bowel disease (Crohn’s disease or ulcerative colitis).

Conclusion: Norwegian overweight/obese axSpA patients from the EMAS survey reported significantly higher disease activity, spinal stiffness and number of comorbidities. The results highlight the serious impact of overweight and obesity on the health status of axSpA patients. Therefore, obesity should be considered as a preventable risk factor and within the disease management of axSpA.

SAT0320

FREQUENCY AND CHARACTERISTICS OF INFLAMMATORY BOWEL DISEASE IN SPONDYLOARTHRITIS WITH BIOLOGICAL THERAPY. STUDY OF 270 PATIENTS FROM THE SAME CENTER

I. Calvo1, O. Ibaranguengolia1, D. Montero1, L. Vega1, L. María1, M. E. Ruiz1, I. Torre1, O. Fernández1, J. M. Blanco1, A. R. Inchaube1, Clara Pérez1, Eduardo Cuenca1, Natalia Rivera1, María Jesús Allande1, Helena Ugarte1, Iligio Gorostiza1, E. Gainez1, Basurto University Hospital, Rheumatology, Bilbao, Spain; 2Basurto University Hospital, Research Unit, Bilbao, Spain

Background: Inflammatory bowel disease (IBD) is an extra-articular manifestation that can appear in spondyloarthritis (SpA), as well as uveitis and psoriasis. Its prevalence is 5-10%, although subclinical intestinal inflammation has been found in up to 60%. Biological therapy (BT) can be the treatment for IBD or produce it paradoxically. Fecal calprotectin (FC) is an intestinal inflammation marker, useful for early diagnosis and monitoring disease activity.

Objectives: To describe the frequency and characteristics of IBD in SpA with BT.

Methods: Descriptive and retrospective study (January 2003-January 2019) of patients with SpA that develop IBD in a single center. Epidemiological variables, type of SpA, presence of IBD and its characteristics, levels of FC, presence of BT at IBD onset and treatment received were registered. For the analysis, frequencies and percentages were used in qualitative variables and mean/standard deviation (SD) in quantitative. Statistical analysis was performed with IBM SPSS v.23.

Results: We studied 270 patients with SpA, 70.4% male with a mean age of 39.9±12 years. The subtypes of SpA were: ankylosing spondylitis (AS) (n=133; 49.3%), psoriatic arthritis (PsA) (n=116; 43%), undifferentiated SpA (n=16; 5.9%), SpA non-Rx axial (n=3; 1.1%) and reactive arthritis (n=2; 0.7%).

IBD was observed in 25 patients (9.26%), 80% male. At the time of IBD onset, they had a mean age of 39.1±9.8 years, the mean ESR was 31.15±24mm/1hr, CRP 2.7±2mg/dl and BASDAI 4.6. 16 patients had AS, 6 PsA and 3 undifferentiated SpA. TABLE 1.

Regarding SpA diagnosis, IBD appeared after in 15 patients with an average time of development of 8.39±2 years, before in 7 and was simultaneous in 3. The subtypes of IBD were: Crohn’s disease (CD) in 7 patients, ulcerative colitis (UC) in 1 and indeterminate colitis (IC) in 3. The FC was > 200µg/g in 17 patients (68%), normal (<50µg/g) in 1 and between 50-200µg/g in 7. The incidence rate adjusted for follow-up of the 25 cases was 7.7 cases/1000 patients-years.

At the time of the IBD onset, 6 patients were with BT: Etanercept (ETN) (n=2), Infliximab (IFX) (n=1), Adalimumab (ADA) (n=1), Secukinumab (SOK) (n=1) and Ustekinumab (UST) (n=1). The BT had been initiated the previous 12 months in 5 of them. The incidence rate adjusted for follow-up of the 6 cases of IBD after BT was 1.83 cases/1000 patient-years. TABLE 2.

The treatment of the 25 patients with IBD was mesalazine (n=15), oral corticoid (n=5), methotrexate (n=7) and BT in all cases. The BT was:
CARDIOVASCULAR EVENTS IN SPONDYLOARTHRITIS: AXSPA PATIENTS WITH SYMPTOM ONSET <30 YEARS

In Ah Choi.

To compare risks for cardiovascular disease including myocardial infarction (MI), ischemic heart disease (IHD), stroke and mortality of patients with SpA compared to general population using large-scale data. These findings support the reduction of inflammation as well as the management of traditional cardiovascular disease risk factors may reduce CV risk in patients with spondyloarthritis.

TABLE 1. CHARACTERISTICS OF ISD IN SPA SUBTYPES

- **Method:** A systematic search was performed in MEDLINE, EMBASE with additional manual searches for studies associated with spondyloarthritis including 13 anklyosing spondylitis (AS) studies, 3 psoriatic arthritis (PsA) studies and 1 undifferentiated spondyloarthritides study. A meta-analysis result showed a significant increase in the risk of MI (RR= 1.38; 95% CI 1.18 to 1.61), and stroke (RR= 2.04; 95% CI 1.11 to 3.78) in spondyloarthritis patients compared to general population. However, mortality related with cardiovascular disease (RR=1.19; 95% CI 0.96 to 1.48) and total mortality (RR= 1.31; 95% CI 0.8 to 2.15) results did not show significant increases in spondyloarthritis patients.

Conclusion: Our meta-analysis results showed that the risk of MI and stroke significantly increased although mortality associated with cardiovascular (CV) disease and overall mortality did not increase in spondyloarthritis compared to general population.

SAT0322
AXSPA PATIENTS WITH SYMPTOM ONSET <30 YEARS HAVE MORE STRUCTURAL LESIONS ON MRI OF THE SACROILIAC JOINTS WHEN FULLFILLING THE MODIFIED NEW YORK CRITERIA

Manon de Hooge, Ann-Sophie De Craemer, Thomas Renson, Philippe Caron, Liselotte Deroo, Dirk Elewaat, Filip van den Bosch; UZ Gent, Belgium; UZB Infarmary Research Center, Gent, Belgium.

Background: The modified New York criteria (mNY) combine clinical symptoms with radiographic sacroiliitis on conventional pelvic radiographs (X-SI) classifying radiographic axial SpA patients (r-axSpA). AxSpA is known to typically start in the third era of life but there is a diagnostic delay of ±7 years. As the mNY criteria classify the most typical and severe expression of axSpA it is suggested that the mNY criteria are less useful in younger patients.

Objectives: To explore the diagnostic utility of the mNY criteria in newly diagnosed axSpA patients with a symptom onset <30 years. In addition, describe the extent of lesions on MRI of the sacroiliac joints (MRI-SI) in mNY positive (mNY+) patients with a symptom onset <30 years.

Methods: This study involved newly diagnosed axSpA patients, age ≥18 years, from a Belgian (Be-Giant) cohort. Patients underwent diagnostic tests involving clinical examination, lab tests, and imaging assessment containing an X-SI and an MRI-SI. mNY criteria was assessed on X-SI, MRI-SI reads contained the assessment of inflammatory lesions according to the Spondyloarthritides Research Consortium of Canada (SPARCC) scoring method and erosions, fatty lesions (FL), sclerosis, ankylosis using an adapted method of the SPARCC. Also, the ASAS definition of a positive MRI-SI was evaluated. T1-weighted and STIR images were viewed simultaneously. X-SI and MRI-SI were evaluated independently by 3 trained readers who were also blinded for clinical features. Imaging scores (X-SI grading according to the mNY criteria and MRI-SI grading, and MRI-SI lesion scores) were calculated as 2 out of 3 reader scores.

Results: In the 173 patients available X-SI, the average age at symptom onset was 27.4 years old. In 114/173 (65.9%) patients, the symptom onset was below 30 years. Of those, 11 (9.6%) patients fulfilled the mNY criteria. Seven of the 11 (63.6%) patients that were mNY+ were male, which was slightly lower than in the mNY- patients (n=55; 53.4%). The presence of MLA-B27 was comparable between mNY+ and mNY- patients: 8 (72.7%) patients and 82 (79.6%) patients, respectively. Average X-SI grading in mNY+ patients was 4.7±1.3 (on a scale from 0-8) and in mNY- negative (mNY-) patients (n=103) the average X-SI grading was 1.1±1.1. When looking at the MRI-SI assessment, 8/11 mNY+ patients.
Hepatocyte growth factor is a predictor of development of new syndesmophytes in men with ankylosing spondylitis. A five-year prospective study

Anna Deminger1, Eva Klingberg1, Merja Nurkkala1, Hans Carlsten1, Lennart T.H. Jacobsson1, Helena Forsblad-Delia1, 2. Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Göteborg, Sweden. 1Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden.

Background: Patients with ankylosing spondylitis (AS) have an increased risk of new bone formation characterized by the development of syndesmophytes. Knowledge of predictors for development of syndesmophytes is limited. Hepatocyte growth factor (HGF) has regulatory effects on a variety of cells in many different organs. HGF signaling can affect both osteoclast and osteoblast lineages and has been shown to promote osteogenesis. Cross-sectional association between increased HGF and increased modified Stoke Ankylosing Spine Score (mSASSS) has previously been shown [1], whereas knowledge of HGF as a predictor for new bone formation is lacking.

Objectives: To study serum HGF as a predictor for development of new syndesmophysetes in patients with AS followed for five years.

Methods: Serum levels of HGF was analyzed using ELISA in patients with AS (modified NY criteria) and in healthy controls (HC) at baseline. Spinal lateral radiographs were obtained at baseline and at the 5-year follow-up in patients with AS followed for five years.

Results: Serum HGF and radiographs at baseline and follow-up were available for 163 patients, 88 men and 75 women, baseline mean age 50±12 years. AS patients had higher serum HGF than HC (n=80), p=0.005. In the AS group, 36 patients (22%) developed ≥1 syndesmophytes after 5 years. The baseline serum HGF of patients with ≥1 new syndesmophyte differed between those who developed ≥1 new syndesmophyte and those who did not progress, p=0.13. The baseline serum HGF of patients with ≥1 new syndesmophyte and those who did not progress, nor did it predict development of ≥1 new syndesmophyte in the univariate analysis, p=0.25. Interestingly, men who developed ≥1 new syndesmophyte had higher serum HGF than the non-progressors (1706±145 vs 1420±338 pg/mL, p=0.001) and increased serum HGF at baseline predicted development of ≥1 syndesmophyte (OR per 1 SD HGF 2.39, 95% CI 1.31 to 4.36) in the univariate analysis. Serum HGF did not predict new syndesmophysetes in women, p=0.13. Multivariable analysis for men including age, smoking, baseline syndesmophysete and serum HGF showed high HGF (OR per 1 SD 1.90, 95% CI 1.01 to 3.59) and ≥1 baseline syndesmophyte (OR 3.48, 95% CI 1.09 to 11.07) to independently predict development of ≥1 new syndesmophyte. If baseline CRP was included in the multivariable model, serum HGF and baseline syndesmophysete remained the significant predictors.

Conclusion: High baseline serum HGF was shown to independently predict the development of at least one new syndesmophyte over five years in men with AS.

SAT0324 ARTICULAR MANIFESTATIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH VEDOLIZUMAB

Anastasia Dupré1, Michael Collins1, Franck Carbonnel1, Xavier Mariette1, Gaetane Nocturne1, Raphaële Sera11, 1Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France

Background: Vedolizumab (VDZ) is a humanized IgG1 monoclonal antibody anti-a4β7 integrin agent used in inflammatory bowel disease (IBD). It has been incriminated in occurrence of articular manifestations but, as it is given in most cases after anti-TNF therapy, it is not known if these articular manifestations are linked to IBD-associated arthritis and unmasked by withdrawal of anti-TNF or are more directly linked to VDZ.

Objectives: The purpose of this study is to describe articular manifestations occurring in patients treated by vedolizumab, and to highlight risk factors for inflammatory manifestations.

Methods: In this retrospective monocentric study, we collected all the cases of incident articular manifestations occurring in the follow-up of the patients treated by VDZ for IBD.

Results: Between February 2013 and June 2017, 112 patients were treated with vedolizumab (56 women, age 39.9 ± 16 years, disease duration ≥ 9.1 ± 7.8 years). IBD cases were distributed into59 (52.7%) Ulcerative Colitis (UC), 49 (43.8%) Crohn’s disease (CD), and 4 (3.6%) Undetermined Colitis. Four patients (3.6%) had a history of spondyloarthritis and 13 (11.6%) of peripheral arthralgia associated with IBD. 102 (91.1%) patients previously received anti-TNFα. At initiation of vedolizumab, 55 (49.1%) received an associated DMARD (azathioprine in 19.6%, methotrexate in 7.1%).

After a mean follow up duration of 11.4 ± 8.6 months, 32 (28.6%) patients presented 35 types of articular manifestations, mechanical (n = 18) (mostly osteoarthritis and tendinosis) or inflammatory (n = 17). Inflammatory articular manifestations were: early reversible arthralgia mostly occurring during perfusion (n = 5), manifestations linked to IBD (n = 11), axial spondyloarthritis, n = 3, peripheral spondyloarthritis, n = 3,
SAT0325 REDUCED STRAIN AND INCREASED STIFFNESS OF COMMON CAROTID ARTERIES IN PATIENTS WITH ANKYLOSING SPONDYLITIS
Helena Forsblad-d’Elia, Lucy Law, Karin Bengtsson, Stefan Söderberg,
Per Lindqvist,1 Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden;2 Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at the University of Gothenburg, Gothenburg, Sweden;3 Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden;4 Department of Surgical and Perioperative Sciences, Umeå University, Umeå, Sweden

Background: Ankylosing spondylitis (AS) is associated with an increased risk of cardiovascular disease (CVD) which also contributes to the increased mortality observed in AS. It is therefore important to develop non-invasive, accurate methods for early detection of atherosclerotic vascular changes.

Objectives: The aim of the present study was to compare arterial stiffness and distensibility in patients with AS and age-sex-matched controls. The arterial stiffness can be examined by ultrasound. The arterial distensibility is defined by the linear regression of the radial arterial pressure and the corresponding change in arterial radius (distensibility index).

Methods: Three hundred and sixty-six patients were enrolled in the study from the Department of Rheumatology at Umeå University, Sweden during the years 2017-2019. The control group consisted of 60 age- and sex-matched patients. The mean age was 50.4 ± 10.2 years in AS patients and 52.9 ± 9.9 years in controls (p = 0.002).

Results: The circumferential systolic strain was measured and the beta stiffness index was calculated. The patients with AS had lower mean systolic circumferential strain and lower stiffness index with p < 0.05.

Conclusions: Our findings suggest that ultrasound methods can be used to evaluate the arterial wall at an early stage of AS. This may be used in the clinical setting to diagnose subclinical CVD.

SAT0326 PLANS FOR MOTHERHOOD ARE CHANGED AFTER DIAGNOSING ANKYLOSIS SPONDYLITIS (AS), AS FEMALE PATIENTS’ ATTITUDE TO THE USE OF AS MEDICATIONS DURING PREGNANCY PLANNING AND CONCEPTION
Zuleikha Gandhibora, Olga Khichenskaya, Tatiana Dubrinya. Federal State Budgetary Scientific Institution “Research Institute of Rheumatology named after V. A.Nasonova”, Moscow, Russian Federation

Background: Plans for motherhood are changed after diagnosing ankylosis spondylitis (AS). AS female patients’ attitude to the use of AS medications during pregnancy planning and conception.

Objectives: To describe the impact of diagnosis of AS on women’s plans to have children, and patients’ attitude to continuing AS therapy while planning pregnancy or after definite conception.

Methods: 302 AS female patients participated in the survey conducted from May to November 2018. Patient’s mean age was 32.4±5.0 years, average AS duration from onset of symptoms was 10.2±7.4 years. 224 (74.2%) respondents had higher education, 68 (22.5%) college education and 10 (3.3%) vocational college education.

Results: 206 women (68.2%) have changed their attitude to potential pregnancy occurring during AS: – 12 (5.8%) were firmly set to terminate an unplanned pregnancy; – 21 (10.2%) were against getting pregnant, although they yet haven’t had children; – 164 (79.6%) accepted potential pregnancy, although recognizing they would experience continuous emotional discomfort and fear for their own health and health of the unborn child. – 42 (13%) women were distinctly against getting pregnant in case they have AS.

There was a weak inverse correlation between AS status and changing patients’ attitude to pregnancy (R=0.14, p<0.05). 150 (49.7%) respondents discussed pregnancy planning with a rheumatologist. Women with university degree were more likely to consult a rheumatologist before trying for a baby compared to subjects with vocational college and secondary education (55.5%, 35.3% and 40%, respectively; p=0.02), 53 (35.3%) patients failed to receive a comprehensive answer to their questions related to AS and pregnancy mutual influence, the probability of AS inheritance by a child, safety of AS therapy at conception.
and during pregnancy; moreover, in 4 cases AS was interpreted as con- 
traindication to pregnancy. 107 (35.4%) respondents believe that AS medications should be discon- 
tinued during pregnancy planning and conception, 75 (24.8%) subjects 
accepted possible use of AS therapy during this period, while 120 
(39.8%) didn’t know the answer. 15.2% of respondents were ready to 
continue on NSAIDs, 20 (6.6%) – on glucocorticoids and sulfasalazine, 
and 21 (7%) – on biological drugs (GEBD). Of those who are ready to 
continue on AS medications at conception, 46 women (61.3%) consulted 
pregnancy planning with a rheumatologist. Respondents with higher edu- 
cation were slightly more likely to continue on AS therapy at conception 
(29%) compared to women with vocational college education (11.8%). 
Age, duration of disease, presence of spondylitis, attitude of patients’ attitude 
towards AS therapy during pregnancy planning and conception.

Conclusion: The majority of surveyed female patients changed their atti- 
tude to pregnancy after establishing AS diagnosis, although only 13% of them 
were recommended to AS therapy. No more than 50% of respondents were consulted a rheumatologist before planning pregnancy, 
and up to one third of them were not receive all expected answers to 
their questions and recommendations. Only 1/4 of participants accept the idea of continuing AS therapy during pregnancy planning and conception.

SAT0327 SEGMENタル RELATIONSHIP BETWEEN MOBILITY, 
STRUCTURAL DAMAGE AND DISEASE ACTIVITY IN 
AXIAL SPONDYLOARTHRITIS

Juan L. Garrido-Castro1, Inmaculada Concepcion Aranda-Valera1, 
Cristina Gonzalez-Navas1, Pedro Machado2, Philip Gardiner3, Joan Condell3, 
Eduardo Collantes Estevez1. 1IMIBIC, Cordoba, Spain; 2UCL, London, United 
Kingdom; 3WHIST, Londoney, United Kingdom

Background: Axial Spondyloarthritis (axSpA) is characterised by progres- 
sive loss of spinal mobility, due to inflammation and structural damage. Conventional mobility tests have been used alongside radiographic struc- 
tural damage and disease activity scores in order to explore the overall 
relationship between spinal mobility, structural damage and disease activ- 
ity. This has rarely been done at the segmental level e.g. at the level of the 
lumbar spine only. The ViMove inertial motion sensor-based system 
allows segmental spinal mobility to be directly measured, namely at the 
lumbar spine level.

Objectives: To analyse the relationship between mobility, structural dam- 
age and disease activity in the lumbar spine of patients with axSpA.

Methods: Lumbar spinal mobility was measured using the the ViMove 
system with a pair of sensors located at L1 and the sacrum. Lumbar ROM in the three planes (anterior flexion - LFF, extension - LFE, lateral 
flexion – LL, and rotation - LR) was measured. Radiographs were 
obtained to calculate the lumbar part of the mSASSS (LmSASSS). Other 
outcome measures were: BASMI, Schober and lateral flexion (measured 
with a tape), BASDAI and ASDAS-CRP. Subgroups of patients with high 
and low levels of lumbar structural damage were defined, by dichotomis- 
ing the population based on the median LmSASSS (5.5). Pearson corre- 
lations between measures, Student T tests for significant differences 
between models and fitted values (RMSE) were 3.8 units for 
LmSASSS and 7.7° for LFF.

Conclusion: Other studies have shown a relationship between mobility, 
structural damage and disease activity using a more global assessment.

Other studies have shown a relationship between mobility, 
structural damage and disease activity using a more global assessment.

Sociodemographic, disease outcomes and psychological 
associations with sociodemographic, disease outcomes and psychological 
distress were not significantly different between these groups. LmSASSS corre- 
lated (p<0.001) with all mobility measures obtained by IMU system and 
conventional metrology, especially with LFF, but not with activity indexes. 
Only a weak relation between BASDAI and LFE was found (p<0.05). A linear 
regression for analysing relationship between LmSASSS and LFF 
including as variables: age, sex, disease activity, BMI, LFE, LFF, 
therefore a LmSASSS linear regression using only LFF obtained an adjusted R2 of 0.72 (Figure-A). Introducing the rest 
of variables, the most significant for LmSASSS was LFF (p<0.001) and 
the other mobility measures (LL, LR with p<0.05) and age, PCR and 
ASDAS (p<0.01) with an adjusted R2 of 0.81(Figure-B). For LFF, 
LmSASSS was the most significant (p<0.001), with Sex (p<0.01) and 
PCR (p<0.05) included, obtaining an adjusted R2 of 0.76 (Figure-C). 
Differences between models and fitted values (RMSE) were 3.8 units for 
LmSASSS and 7.7° for LFF.

Conclusion: Other studies have shown a relationship between mobility, 
structural damage and disease activity using a more global assessment.

Rheumatism, Nicosia, Cyprus; 8Hospital Universitario La Paz, IDIAP, Madrid, Spain; 9Cardiff 
University, Cardiff, United Kingdom; 10Ankylosing Spondylitis International Federation (ASIF), 
London, United Kingdom

Background: Understanding patient disease-related attitudes plays an 
important role in effective management of axial spondyloarthritis (axSpA).

Nevertheless, the patient perspective remains insufficiently explored.

Objectives: To describe patients’ axSpA-related fears and hopes and their 
associations with sociodemographic, disease outcomes and psychological 
distress.

Methods: The European Map of Axial Spondyloarthritis (EMAS), 
conducted from July 2017 to February 2018, was a cross-sectional on-line 
survey of unselected patients with self-reported axSpA from Austria, Bel- 
gium, France, Germany, Italy, The Netherlands, Norway, Russia, Slovenia, 
Spain, Sweden, Switzerland, and the UK. Participants were recruited 
through an online panel and patient organizations. Participant’s axSpA- 
related fears and hopes were freely expressed through open-ended ques- 
tions (except in France where multiple-choice items were used). Thematic 
analysis, using the French categories and data-driven codes, was per- 
formed and frequencies of specific fears and hopes were subsequently 
calculated. Associations between disease-related fears and hopes with 
sociodemographic characteristics, disease outcomes (BASDAI, self-reported 
spinal stiffness and functional limitation), and psychological distress (Gen- 
eral Health Questionnaire, GHQ-12; with a cut-off point of ≥5) were

Axial Spondyloarthritis (axSpA) has an impact on daily life, but data in the biologics era are scarce.

Objectives: To assess the patient-reported impact of axSpA on social and family life.

Methods: Between December 2017 and February 2018, patients followed for axSpA by their rheumatologists or affiliated to the French patients association AFLAR, and self-reporting axSpA, participated in the European Map of Axial Spondyloarthritis (EMAS) cross-sectional patient survey in France. Socio-demographics and disease characteristics were collected and the impact of axSpA on personal life was evaluated through a questionnaire established by an international committee on social interactions (better/worse), frequency of social activities (less or more frequent), patient fears and the impact of flares on 10 aspects of daily life evaluated as no/low to moderate/severe. No imputation of missing data was performed and the analyses were descriptive.

Results: Data from 638 persons, mean age 41.5±11.1 years, 77% women, mean disease duration 6.9±9.2 years, 19.1% on biologics, were analyzed. The disease (axSpA) was often active (mean BASDAI: 5.9±1.7). Social interactions were reported as worse or much worse since axSpA: with friends (43%), work colleagues (39%), spouse (35%), and family (31%). AxSpA had also an impact on the frequency of social and sport activities, which were «much less frequent than before» for sport activities, «less frequent» for sport activities, and «less frequent than before» for social activities. The most frequent fears of patients were «fear of disease progression» (32.9%), «suffering pain» (30.5%), and «loss of mobility» (30.0%). Accordingly, the most frequent hopes were «improving mobility» (33.2%), «eliminating pain» (32.5%), and «effective treatment» (23.3%).

Conclusion: Axial Spondyloarthritis (axSpA) on social and family life, in a context of fears for the future. These data are important to take into account for shared decision-making.

REFERENCE

Background: Axial Spondyloarthropathies (SpA) are chronic, systemic, inflammatory diseases which affect the axial skeleton, limit chest mobility and cause serious impairments in pulmonary functions.

Objectives: In this cross-sectional study, as a new approach; diaphragm thickness is assessed by ultrasound in patients with axial SpA to determine possible relationships with pulmonary functions and disease activity.

Methods: 49 axial SpA patients enrolled in the study were assessed by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI), Erythrocyte Sedimentation Rate (ESR), serum C-Reactive Protein levels (CRP) and chest expansion (cm). 15 patients with lung diseases other than axial SpA pulmonary involvement, neuromuscular diseases, scoliosis and congenital chest deformity were excluded. Dynamic pulmonary function tests (PFT) and 6 min walk (6MW) tests were done and physical activity levels were evaluated by short form International Physical Activity Questionnaire (IPAQ). Diaphragm thickness was measured at end expiration (dFRC) and deep inspiration (total lung capacity (dTLC)). Thickness ratio (dtr: dTLC/dFRC) and thickness change (dtc: dTLC-dFRC) were calculated.

Results: The descriptive data of the patients are presented in Table 1. Patients had a moderate disease activity and all the patients were category 1 (inactivity) according to IPAQ. Mean value of dtr and PFT seem significantly correlated with dynamic pulmonary function tests, yet negatively correlated with ESR and BASMI. The CT and MR images were reviewed for the presence of erosions by 2 musculoskeletal radiologists blinded to clinical findings. After a follow-up of 2 years, 2 experienced rheumatologists confirmed or excluded the diagnosis of SpA. Diagnostic utility of erosions for diagnosis of SpA was determined by calculating sensitivity, specificity, positive and negative likelihood ratio with final clinical diagnosis made by rheumatologists as gold standard.

Conclusion: To the best of our knowledge, this is the first study evaluating the relationship between diaphragm thickness and pulmonary functions with disease activity. Even though, there was no limitation in PFT and expected values were obtained in dtr, the negative correlation with ESR makes us think about the possible effect of disease activity on dtr. With these preliminary results, it is early to conclude, but dtr assessment may be supplementary to PFT and early measures to improve diaphragm function with specific exercises should be implemented in patients with axial SpA.

Disclosure of Interests: None declared

---

Background: In the light of new therapeutic strategies, it has become essential to detect spondyloarthritis (SpA) in its earliest stages in order to institute treatment as early as possible. Magnetic resonance imaging (MRI), with its ability to detect active lesions, is usually considered as a key tool for early recognition of sacroiliitis. However, a growing number of studies reported the lack of specificity of bone marrow edema (BME) leading sometimes to a false “positive MRI” of sacroiliac joints (SIJ). In addition, many recent studies have pointed out the utility of detecting structural lesions, especially erosions, reported as the earliest structural change on SIJ in the course of sacroiliitis.

Objectives: We aimed to assess the reliability of early recognition of erosions in patients with suspected SpA.

Methods: Consecutive patients, aged 16 and over, consulting from February 2014 to February 2017 for symptoms suggestive of SpA (inflammatory back pain, enthesitis or dactylitis...) were enrolled in this cohort. They were referred for computed tomography (CT) and MRI of the SIJ. The CT and MR images were reviewed for the presence of erosions by 2 musculoskeletal radiologists blinded to clinical findings. After a follow-up of 2 years, 2 experienced rheumatologists confirmed or excluded the diagnosis of SpA. Diagnostic utility of erosions for diagnosis of SpA was determined by calculating sensitivity, specificity, positive and negative likelihood ratio with final clinical diagnosis made by rheumatologists as gold standard.

Results: Fifty-four patients were included, 13 men and 41 women. The mean age was 39 years [17-71]. The mean duration of symptoms was 75 months (6 years). Cervical, thoracic, lumbar and buttock pain were noted respectively in 46.3%, 37%, 87%, and 57.4% of the studied patients. Morning stiffness was noted in 55.5% of patients. The prevalence of HLA-B27 was 23.4%. After a follow-up of 2 years, the referring rheumatologists made a diagnosis of SpA in 77.8% of patients, whereas SpA was excluded in 22.2%. Among the 42 patients classified as having a confirmed SpA, erosions were detected on MRI or CT in 64.3% (n=27) and by MRI in (n=18) 42.85% of patients. Among the 12 patients in whom SpA was excluded, erosions were detected on MRI by CT in 25% (n=3) of patients and were not detected by MRI in any patient. Sensitivity, specificity, positive and negative likelihood ratio of erosions detected by CT were respectively estimated at 64.3%, 75%, 90% and 37.5%. Those of erosions detected by MRI were estimated at 42.9%, 100%, 100%, 33.33%. A statistically significant association was observed between erosions and rheumatologists’ diagnosis of SpA (p< 0.05 for CT and p = 0.012 for MRI). The likelihood ratio was estimated respectively for CT and MRI at 3.8 and 7.6.

Conclusion: In our study, detection of erosions showed a high specificity for recognition of sacroiliitis, especially when detected by MRI. This study highlights the utility of structural SIJ lesions, particularly erosions, to reduce the number of false positives.

SAT0332 GENDER DIFFERENCES IN DISEASE STATUS, QUALITY OF LIFE AND TREATMENT PATTERNS AMONG AXIAL SPONDYLOARTHRITIS PATIENTS: FINDINGS FROM A GLOBAL SURVEY

Irene van der Horst-Bruinsma1, Theresa Hunter2, Rebecca Bolce2, Elizabeth Holdsworth3, Nicola Boot3, Amsterdam University Medical Center, Amsterdam, Netherlands; 2Eli Lilly and Company, Indianapolis, United States of America; 3Adelphi Real World, Macclesfield, United Kingdom

Background: Axial spondyloarthritis (AxSpA) is a chronic inflammatory disease of the axial skeleton associated with impaired health-related quality of life (HRQoL) and disability.1,2 Gender differences in clinical and quality of life (QoL) measures have been demonstrated in axSpA (ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA)), but not well quantified in a real-world clinical setting.

Objectives: To compare the clinical characteristics, QoL and treatment patterns of male and female AS and nr-axSpA patients from a multinational survey.

Methods: Data from a cross-sectional, multinational survey conducted in Australia, Canada, France, Germany, Italy, Japan, Spain, United Kingdom and the United States were analyzed. Demographics, disease status and medication use were reported by the patient, while work disability and QoL measures were reported by the patient. Gender comparison analyses were conducted for AS and nr-axSpA subgroups.

Results: Data from 432 physicians (407 rheumatologists, 13 orthopedists, 2 internists) 2,300 AS patients (male: 1,673 [72.74%]; female: 627 [27.26%]), and 2,099 nr-axSpA patients (male: 1,146 [54.60%]; female: 953 [45.40%]) were included in this analysis. Male AS and nr-axSpA patients were more likely to be younger (AS: p<0.0141; nr-axSpA: p=0.0127), smokers (AS: p<0.0001; nr-axSpA: p=0.0001), have full-time employment (AS: p=0.0001; nr-axSpA: p=0.0001), and currently be in remission (AS: p<0.0001; nr-axSpA: p=0.0001) when compared to female AS and nr-axSpA patients. Male AS patients were more likely to be prescribed biologic treatment when compared to female AS patients (p=0.0070); however, rates of biologic use between male and female nr-axSpA patients were comparable (p=0.2148). Male AS and nr-axSpA patients also had lower Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores than female AS patients (AS: p<0.0001; nr-axSpA: p<0.0001), and male AS and nr-axSpA patients had more activity impairment, as assessed by the Bath Ankylosing Spondylitis Quality of Life (ASQoL) (AS: p=0.0001; nr-axSpA: p=0.0001), Assessment of SpondyloArthritis international Society Health Index (ASAS HI) (AS: p<0.0001; nr-axSpA: p<0.0001), and Work Productivity and Activity Impairment (WPAI) (AS: p=0.0006; nr-axSpA: p=0.0002).

Conclusion: Male AS patients were more likely to be prescribed biologics when compared to female AS patients, despite females experiencing worse QoL and greater activity impairment. This study highlights an unmet need among female patients for more appropriate treatment approaches.

SAT0333 THE DIFFERENCES OF CLINICAL MANIFESTATIONS BETWEEN FAMILIAL AND SPORADIC ANKYLOSING SPONDYLITIS PATIENTS

Yutong Jiang, Li Xiaomin, Dongfang Lin, Yanli Zhang, Mingcan Yang, Zetao Liao, Jieruo Gu. The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease which could lead to pain, functionally limitation and even less life expectancy. Morning stiffness often occur in the patients. Familial aggregation has been found due to genetic susceptibility of the disease. There are certain difference in the patients with or without familial AS. For example, familial AS patients were reported to show a lower frequency of oligoarthritis [1].

Objectives: Our study was to investigate the difference of morning stiffness in the patients with familial AS or sporadic AS.

Methods: Study participants were recruited from Department of Rheumatology in the Third Affiliated Hospital of Sun Yat-sen University. Each patient was assessed by at least two qualified rheumatologists, and the diagnosis was made according to 1984 Modified New York Classification Criteria for AS. Through detailed family history, AS patients with 2 or more patients in his/her family who firstly went to our clinic were included as a possible proband. Then the probands brought the affected relatives to our clinic for further examination. Of three rheumatologists and two nurses drove to the places where a possible proband’s family member lived. Baseline assessments were completed by trained by using identical questionnaires including demographic information (age, gender), disease related characteristics (back pain, morning stiffness, peripheral arthritis, uveitis, etc.), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and Bath Ankylosing Spondylitis Functional Index (BASFI). The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis. The difference between familial and sporadic AS patients were examined by using Independent T test or M-U test.

Results: Of the 264 AS patients, 175 (66.3%) were males and 89 (33.7%) were female patients. Mean age was 31.0±9.5 years, and disease duration was 7.3±6.7 years. Mean age of disease onset was 23.4±8.5 years. There was no difference between familial and sporadic AS patients in the aspects of age, sex, age of onset and disease duration. However, age of onset of male familial AS patients was significantly lower than that of female patients (21.9±8.4 VS 26.3±8.2, p<0.004), while no such sex difference was detected in sporadic patients (22.6±8.1 VS 25.3±8.6, p=0.08). Familial patients were inclined to have hip joint involvement, compared with sporadic patients (58.6% VS 9.6%, p<0.01). 186 (70.5%) patients suffered from morning stiffness with median time of 61.6 minutes. Degree of morning stiffness was 3.5±3.0. Sporadic patients had more morning stiffness than familial patients (p=0.007). There was no difference in the presentation of peripheral arthritis (p=0.05). Mean BASDAI score was 3.6±2.0, and mean BASFI score was 1.4±1.8. The BASDAI score was slightly higher in sporadic group (p=0.027).

Conclusion: Familial AS patients had more hip joint involvement, less morning stiffness and an earlier disease onset, especially in male patients, compared with sporadic patients.

SAT0334 DOES DEPRESSION PREDICT FUTURE DISEASE STATUS AND IMPROVEMENTS IN DISEASE PARAMETERS? RESULTS FROM THE COMPLETE STUDIES, A CANADIAN REAL WORLD OBSERVATIONAL COHORT

Majid Khraja1, Valenica P. Remige2, Louis Bessette3. 1Memorial University of Newfoundland, St. John’s, Canada; 2AbbVie Corporation, Montreal, Canada; 3Laval University, Centre Hospitalier de l’Université Laval, Quebec, Canada

Background: Depression is a common comorbidity in rheumatic diseases such as Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS), whereby it is associated with increased disease activity, decreased functionality, and lower persistence with treatment.

Objectives: The objective of this analysis was to assess if baseline depression in Canadian patients with PsA or AS predicts future disease status and improvement in disease parameters.

Methods: COMPLETE is a Canadian observational cohort of anti-TNFα naïve adults with PsA and AS, who require a change in their treatment. Separate analyses were performed for each disease group. Depression was defined as BDI score ≥20 (or use of anti-depressants and/or anxiolytic medication). Multivariate logistic regression was used to assess the
baseline predictors of achievement of low disease activity (LDA) in BAS- 
DAI (<4) and BASFI (<4) for patients with AS; or DAPSA LDA (≤13), 
DAS28 LDA (≤3.2), DAPSA remission (≤4), DAS28 remission (≤2.6) and 
BSA <3% for patients with PsA. The maximum improvement (highest 
change in score) at either 6 or 12 months was observed in BASDAI. BASFI, 
DAPSA, DAS28 was assessed for using multivariate linear regression and 
the least square means (LSMs). The maximum improvement in HAQ-DI 
and SF-12 physical component scale (PCS) and mental component scale 
(MCS) were also assessed among PsA patients.

Results: A total of 492 patients with AS and 333 with PsA had BDI 
assessments (or criteria for depression) at baseline and were included in 
the analysis; mean (SD) age was 42.7 (13.2) and 51.5 (12.2) years, 
respectively. Patients with AS were mostly male (54.1%) and initiated 
adalimumab treatment (70.9%) with mean (SD) disease duration of 5.4 
(9.1) years; for PsA, sex was evenly distributed (female 50.5%), 66.4% 
initiated treatment with adalimumab and mean (SD) disease duration was 
14.7 (13.7) years. The prevalence of depression at baseline was 24.6% 
and 25.5% in patients with AS and PsA, respectively.

Upon adjusting for potential confounders, presence of depression in 
patients with AS was associated with significantly lower odds of achiev- 
ing BASDAI LDA (OR: 0.51, p=0.021) and BASFI LDA (OR: 0.52, 
p=0.045) during treatment. In the treatment arm, presence of depression 
was also identified as a significant positive predictor of either outcome 
(ORBASDAI: 1.91, p=0.016; ORBASFI: 1.98, p=0.029), while older age 
was identified as a negative predictor of BASFI LDA achievement (OR: 0.98, p=0.044). Similarly, patients with depression experienced sig- nificantly lower improvements in BASDAI LDA (LSM: -1.72 vs. -2.44; 
p=0.007), and BASFI scores (-1.46 vs. -2.02; p=0.029) compared to 
those without depression.

Among patients with PsA, presence of depression appeared to be asso- ciated with lower odds of achieving DAPSA remission (OR: 0.35, 
p=0.070). No association was observed between presence of depression 
and DAPSA LDA, DAS28 LDA or remission, and BSA<3%. In terms of 
disease improvement, significant lower improvement in DAPSA score 
(LSM: -11.00 vs. -14.66; p=0.047) and SF-12 MCS (LSM: -3.01 vs. 
4.36; p=0.007) were observed among patients with depression.

Conclusion: A significant proportion of AS and PsA patients suffer from 
depression. Baseline depression seems to negatively affect treatment 
outcomes in both AS and PsA patients. Whether this is due to differences 
in the assessment of patient-reported outcomes or due to physiological 
differences remains to be confirmed.

CLINICAL COURSE OF ANKYLOSING SPONDYLITIS (AS) IN PREGNANCY: INTERIM DATA FROM PROSPECTIVE STUDY

Olga Krichenkovskaya1, Zuleykh Gandaaleva2, Anastasiya Demina3, Tatiana Dubinina4. 1V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Objectives: To study the dynamics of clinical signs, AS activity and patients' functional status during gestation.

Methods: 19 pregnant females with confirmed AS based on modified NY criteria (1984) were included. Patients' mean age was 32.2±1.1 years; mean age at AS onset was 22.6±3.1 years; mean disease duration was 147.0±27.7 months. Control visits were scheduled at 10-11, 20-21 and 31-32 weeks of pregnancy. BASDAI and ASAS-ERP calculators were used to assess AS activity, while patients' functional status was assessed using BASFI and BASMI scores, and MASES score was used for evaluation of enthesitis.

Results: Pregnancy outcomes included 18 full-term births at 37.6±1.1 weeks of gestation, and a non-developing pregnancy at 18 weeks in one case. Newborns' weight = 3518±67 g.

Inflammatory low back pain at conception was reported by 78.9% of participants, with mean pain intensity 2.2±0.4 scores by NRS. Pain during pregnancy was observed in 95% of all patients. Its intensity increased by the II trimester (4.6±0.7) and persisted at the same level in the III trimester (p<0.05 between conception and II & III trimesters). Patients reported changing pain patterns by the III trimester: 55.6% noticed pain improvement at rest, and 61.1% indicated exacerbation of pain after physical exercise. Enthesitis rates and intensity were also increasing in the course pregnancy: MASES score was higher in the III trimester (2.3 ±0.5) vs I trimester (0.4±0.22, p<0.05). Meanwhile the rates of AS others non-axial and non-skeletal manifestations were not changing during gestation.

BASDAI score was increasing from the moment of conception (1.7±0.3) until the III trimester (3.3±0.5, p<0.05), staying thereafter at the same level in the III trimester. Multivariate regression revealed BACDAI score (R²=0.7) and low back pain (R²=0.9) at conception, as well as biological therapy at 3 months prior to conception (R²=0.7) as orchestrated predictors of relevant BASDAI score in III trimester. During all pregnancy the BASDAI score was predetermined by assemblage of low back pain intensity (β=0.6), fatigue (β=0.6), and enthesitis-associated pain (β=0.3). Increasing fatigue (by 68.5%), and low back pain (by 24%) genent ASADAS-CRP score by the end of the I trimester. While during the II trimester further increase in BASDAI score was provided by exacerbation of enthesitis (20.7% increment), and back pain (27% increment). ASADAS-CRP score was relatively stable with some trend to increase in the II trimester (3.3±0.3) as compared to baseline at conception (1.7 ±0.2); CRP also showed some increase in the II trimester (9.7±2.9 mg/ml) vs I trimester (6.7±2.4 mg/ml, p<0.05).

BASMI score insignificantly changed during all 3 trimesters (1.3±0.9; 1.8 ±0.2; 2.1±0.3 – in I, II and III trimesters, correspondingly). BASFI score showed increase in the III trimester (3.9±1.0) as compared to I trimester (1.4±0.3, p<0.05). Score increase in the III trimester was due to increased AS activity interfering with habitual physical performance, and also due to pregnancy (forward bend, questions 1,2,4).

Conclusion: AS clinical activity increases by the II trimester of pregnancy and persists at moderate and high levels afterwards during all gestation period. AS activity at conception can determine AS activity during all pregnancy. 50% of pregnant patients are likely to experience low back pain in the III trimester due to increasing pressure of a growing fetus on the spine. Functional disability increases with progress in pregnancy, being caused in the III trimester by both – AS activity and pregnancy per se.

SA20336

CLINICAL DIAGNOSES OF AXIAL SPONDYLOARTHRITIS SHOW A HIGH OVERALL CONCORDANCE WITH CLASSIFICATION CRITERIA FULFILMENT, BUT ARE LESS CONSISTENT FOR DIFFERENTIATION BETWEEN SUBTYPES IN ESTABLISHED AXIAL DISEASE: RESULTS FROM THE SPARTAKUS COHORT

Elisabet Lindqvist1, Tor Olofsson1, Anna Jöö2, Mats Gejer1, Johan K. Wallman1, Elisabeth Mogard1.1University of Gothenburg, Sahlgrenska Academy, Institute of Clinical Sciences, Department of Radiology, Gothenburg, Sweden; 2University of Lund, Skåne University Hospital, Department of Occupational and Environmental Medicine, Department of Laboratory medicine, Lund, Sweden; 3University of Gothenburg, Sahlgrenska Academy, Institute of Clinical Sciences, Department of Radiology, Gothenburg, Sweden

Background: The ASAS axial SpondyloArthritis (axSpA) criteria encompass radiographic (r-axSpA) and non-radiographic (nr-axSpA) disease to enable classification early, while the modified New York criteria (mNY) for Ankylosing Spondylitis (AS) require radiographic sacroiliitis. Studies of agreement between clinical diagnoses of axSpA and classification criteria are sparse, especially for nr-axSpA.

Objectives: To study the concordance between clinical axSpA diagnoses and classification criteria fulfilment (mNY and ASAS axSpA) disease to enable classification early, while the modified New York criteria (mNY) for Ankylosing Spondylitis (AS) require radiographic sacroiliitis. Studies of agreement between clinical diagnoses of axSpA and classification criteria are sparse, especially for nr-axSpA.

Methods: Patients with clinical diagnoses (ICD-10) of AS (M45.9) or undifferentiated spondyloarthropathy (M46.0, M46.1, M46.8, M46.9)
followed at Skåne University Hospital, and living in a defined area of southern Sweden were assessed in a cross-sectional study. USpA patients had to report back pain ≥3 months before age 45, by telephone screening, to be eligible. To enable classification, included patients underwent clinical assessments, a classification questionnaire, blood testing (including HLA-B27), and scoring of plain X-rays and MRI scans of the sacroiliac joints by an experienced radiologist.

**Results:** Out of 233 patients with clinical AS or axial USpA, 196 (85%) fulfilled either mNY or ASAS axSpA classification criteria, while 35 (15%) met neither criteria set. Among 118 patients with a clinical AS diagnosis, 89 fulfilled ASAS axSpA criteria, while a higher number was classified as AS (n=48) than nr-axSpA (n=36); PPV of clinical USpA diagnosis for fulfilling mNY criteria was 71% and for ASAS nr-axSpA 69%. For 115 patients with a clinical USpA diagnosis, 89 fulfilled ASAS axSpA criteria, while a higher number was classified as AS (n=48) than nr-axSpA (n=36); PPV of clinical USpA diagnosis for fulfilling nr-axSpA criteria was 31% (Figure 1). Comparing characteristics between patients classified as radiographic axSpA (AS [mNY] or ASAS axSpA vs. ASAS nr-axSpA, few differences were observed; the former were older, more often men, had longer disease duration and worse spinal mobility (Table 1).

*Statistical comparisons by Student’s t-test or Chi-Square test

**Conclusion:** The overall concordance between clinical diagnoses and fulfilment of axSpA classification criteria was good, with >4/5 meeting any criteria. For disease subtypes, however, the agreement was substantially weaker, and a large group of patients with USpA in this established cohort fulfilled the mNY criteria for AS. The results indicate that in studies aiming to compare radiographic and non-radiographic axSpA, classification according to defined classification criteria is important.

**Disclosure of Interests:** Elisabet Lindqvist: None declared, Tor Olofsson: None declared, Anna Jöud: None declared, Mats Geijer Consultant for: Consultant for AbbVie, Novartis, and Pfizer., Johan K Wallman Consultant for: Consultant for AbbVie, Celgene, Eli Lilly, Novartis, and UCB Pharma, Elisabeth Mogard: None declared

**DOI:** 10.1136/annrheumdis-2019-eular.4010
the time between symptom onset and physician diagnosis is 5-7 years. Diagnosis delay is attributed to nonspecific presentation of chronic back pain, requiring clinical experience to recognize early AS.

**Objectives:** To identify obstacles to early diagnosis of AS by assessing the knowledge of nonrheumatology health care providers (HCPs) on inflammatory back pain (IBP) and possible barriers to referral to a rheumatologist.

**Methods:** Survey content was first conceptualized based on concept elicitation interviews with HCPs, and questionnaires were developed by the study investigators to identify clinical characteristics, symptom presentation, and diagnostic measures that lead an HCP to suspect IBP and their perspectives on the referral process. The survey was then cognitively tested with HCPs from 10 specialties (family medicine, internal medicine, dermatology, gastroenterology, ophthalmology, orthopedics, chiropractic, pain management, physical therapy, and physiatry), revised, and finalized. HCPs from these 10 specialties were invited to participate in the cross-sectional web-based survey hosted by Survey Sampling International between June 27 and July 20, 2018. HCPs who were currently licensed, actively practicing in the US, and had referred a patient with suspected IBP (except ophthalmology) or referred a patient with uveitis/iritis (ophthalmology only) within the past 12 months were eligible to participate. Descriptive statistics were used to analyze the data.

**Results:** Of 2395 HCPs screened, 1690 were eligible and included in our study. Overall, HCPs saw a median of 100 patients with chronic back pain within the past 12 months of the survey. Regarding criteria leading to suspicion of IBP, 61% of HCPs indicated morning stiffness > 30 minutes, 29% sleep disturbance due to back pain, 28% pain that improves with activity, and 16% alternating buttock pain. Among HCPs who would order diagnostic blood work, ~ 90% selected C-reactive protein, erythrocyte sedimentation rate, and rheumatoid factor (RF), while 76% selected HLA-B27 (Figure 1). Most HCPs suspected underlying conditions of rheumatoid arthritis (RA; 94%), AS (90%), and psoriatic arthritis (81%) as related to IBP. Almost 40% of HCPs would treat patients with suspected IBP themselves; of these, ~ 80% would recommend nonsteroidal anti-inflammatory drugs and physical therapy (Figure 2). Regarding referrals, 57% of HCPs would refer patients with suspected IBP to another physician, but only 13% would refer immediately; 49% would perform further evaluations, 24% would wait until initial treatment response, 11% would monitor patient for some time, and 3% would consult with another physician before referring. Upon referral, 90% of HCPs estimated a wait time of up to 2 months for their patient to see another specialist. Of 1670 HCPs queried, 80% indicated that the specialist’s expertise in treating autoimmune disease is the most important factor influencing their referral.

**Conclusion:** Most HCPs did not recognize IBP criteria in patients with chronic back pain. As most considered RA to be the underlying condition, ANA and RF were ordered as diagnostic workup. Many HCPs opted to treat and monitor patients with suspected IBP before referral, and most reported a wait time of up to 2 months for their patients to see an expert.

Characterization of Patients with Axial Spondyloarthritis by Presence of Enthesitis

Methods: This study included patients aged ≥ 18 years with AxSpA enrolled in the Corrona PsA/SpA Registry between March 2013 and August 2018. Enthesitis at enrollment was assessed via the Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index.

Results: Of 477 patients with AxSpA, 121 (25.4%) had enthesitis. Symptom and disease duration were similar between patients with and without enthesitis using fisher's exact tests for categorical variables.

Conclusions: AxSpA is common in the general population. The prevalence of enthesitis in AxSpA and its impact on disease burden was similar regardless of presence of enthesitis; however, patients with enthesitis were more likely to have prior csDMARD and biologic use, as well as current methotrexate use. Patients with enthesitis had worse disease activity and quality of life compared to patients without enthesitis.

| Activity, quality of life, and work productivity were compared between patients with and without enthesitis using t tests or Wilcoxon rank-sum tests for continuous variables and χ2 or Fisher's exact tests for categorical variables.

Results: Of 477 patients with AxSpA, 121 (25.4%) had enthesitis. Symptom and disease duration were similar between patients with and without enthesitis. In patients with enthesitis, a higher proportion were female, were more likely to have non-radiographic AxSpA and a history of depression, serious infections, and fibromyalgia vs those without enthesitis (all P < 0.05; Table 1). Current treatment with biologies or conventional synthetic disease-modifying antirheumatic drug (csDMARD) monotherapy was similar regardless of presence of enthesitis; however, patients with enthesitis were more likely to have prior csDMARD and biologic use, as well as current methotrexate use. Patients with enthesitis had worse disease activity (ASDAS, BASDAI, and BASFI scores; tender and swollen joint counts; physician global assessment; and DAPSA and cDAPSA scores), spinal mobility measures, quality of life (pain, fatigue, HAQ scores, and EQ VAS scores), and greater work impairment than patients without enthesitis (all P < 0.05; Table 1).

Conclusion: Among patients with AxSpA in this US real-world study, the presence of enthesitis was associated with worse disease activity and quality of life compared to patients without enthesitis. External validity outside of US real-world settings.

Background: Enthesitis is a common extra-axial manifestation in patients with axial spondyloarthritis (AxSpA) 1,2; however, not much is known about the prevalence of enthesitis in AxSpA and its impact on disease burden in US real-world settings.

Objectives: The study describes characteristics of patients with AxSpA who had enthesitis vs patients without enthesitis.

Methods: This study included patients aged ≥ 18 years with AxSpA enrolled in the Corrona PsA/SpA Registry between March 2013 and August 2018. Enthesitis at enrollment was assessed via the SPARCC Enthesitis Index.

Results: Of 477 patients with AxSpA, 121 (25.4%) had enthesitis. Symptom and disease duration were similar between patients with and without enthesitis using t tests or Wilcoxon rank-sum tests for continuous variables and χ2 or Fisher’s exact tests for categorical variables.

Results: Of 477 patients with AxSpA, 121 (25.4%) had enthesitis. Symptom and disease duration were similar between patients with and without enthesitis. In patients with enthesitis, a higher proportion were female, were more likely to have non-radiographic AxSpA and a history of depression, serious infections, and fibromyalgia vs those without enthesitis (all P < 0.05; Table 1). Patients with enthesitis had worse disease activity (ASDAS, BASDAI, and BASFI scores; tender and swollen joint counts; physician global assessment; and DAPSA and cDAPSA scores), spinal mobility measures, quality of life (pain, fatigue, HAQ scores, and EQ VAS scores), and greater work impairment than patients without enthesitis (all P < 0.05; Table 1).

Conclusion: Among patients with AxSpA in this US real-world study, the presence of enthesitis was associated with worse disease activity and quality of life compared to patients without enthesitis.
The prevalence of renal failure in a prospective axial spondyloarthritids cohort and possible associated factors

Xabier Michela-Vegas, Carla Marco Pascual, Xavier González Giménez, Maribel Moro, J Lluch Pons, Jesús Rodríguez, Joan Miquel Nolla, Xavier Juangola-Roura, Department of Rheumatology, Bellvitge University Hospital (IDIBELL), Barcelona, Spain

Background: Extra-articular manifestations and comorbidities are significant complications in the evolution of patients with spondyloarthritids (SpA). The presence of renal failure (RF) is a multifactorial comorbidity that has been shown to be associated with this disease, and its prevalence has been reported around 5% (COMOSPA 1). There are no prevalence studies in our environment.

Objectives: To determine the prevalence and possible factors associated with RF in patients with axial spondyloarthritids (axSpA).

Methods: Data was retrieved from a prospective database designed for the monitoring of patients with SpA from a large teaching hospital. We only included patients with axSpA. Demographic and clinical data were recorded, as well as possible risk factors associated with RF: arteral hypertension (AH), smoking status, diabetes (DM), Dyslipidemia (DL), NSAIDs use and renal function from last test available (we considered RF when eGFR<60 mL/min).

Continuous data were compared with Student t-test if the variables presented normal distribution (previous Shapiro-Wilk test) or Mann Whitney U test otherwise. Chi-square or Fisher test was performed if the variable was categorical.

Results: 339 patients were included. 73.2% were male with a mean age of 56.68 ± 14.8 years and a mean age of onset of 32.0 ± 11.4 years. The mean disease duration was 32.8 ± (IQR 11.4) years. 83.7% were HLAB27+. The clinical variables for the whole cohort were: BASDAI 3.56 ± (2.13), BASFI 5.2 ± 2.56, ASDAS-CRP 2.57 ± 0.87, ASDAS-ESR 2.66 ± 0.93, CRP median (IQR) 19.6 ± 6.65, ESR median (IQR) 15 ± 23.3.

Chi-square or Fisher test was performed if the variable was categorical.

Conclusions: There is a substantial prevalence of RF in patients with axSpA in our cohort. We should maximise our awareness of RF in old patients, those suffering from AHT and DLP, as well as subjects with high BASFI, ASDAS and ESR values.

Conclusion: About one fifth patients with UC who underwent colectomy developed arthropathy presenting predominantly peripheral type. Long follow-up period, high disease activity by endoscopic classification, and ileal pouchitis were risk factors of onset PsA, arthropathy in UC patients after total colectomy. The frequency and risk factors for developing arthropathy even after colectomy was demonstrated in this study for the first time.

SA10343 BURDEN OF DISEASE AT TREATMENT INITIATION AMONG BIOLOGIC-NAIVE PATIENTS WITH OLIGOARTICULAR VERSUS POLYARTICULAR PSORIATIC ARTHRITIS/SYNOVIALTHEMIA ARTHRITIS REGISTRY

Alexis Ogdie1, Mei Liu2, Meghan Glynn2, Kelechi Emeanu2, Leslie Harold2, Sven Richter2, Benoit Guerette3, Philip J. Mease4. 1University of Pennsylvania, Philadelphia, United States of America; 2Corrona, LLC, Waltham, United States of America; 3Celgene Corporation, Summit, United States of America; 4Swedish Medical Center and University of Washington School of Medicine, Seattle, United States of America.

Background: Oligoarticular PsA accounts for ~50% of PsA worldwide, but only a paucity of data describes disease burden among patients with this subtype. The Corrona PsA/SpA Registry, a prospective, US-based, observational cohort study, collects real-world data on characteristics and treatment of PsA patients, including those with oligoarthritis.

Objectives: To characterize demographics, clinical characteristics and patient-reported outcomes (PROs) at treatment initiation in biologic-naive patients with oligoarticular patients (≤4 swollen and ≤4 tender joints) vs. polyarticular patients (>4 swollen or >4 tender joints).

Methods: Biologic-naive patients ≥18 years of age diagnosed with PsA and enrolled in the registry who initiated apremilast, biologics and/or csDMARDs for PsA from March 2013–December 2018 were included. Data on patient demographics, disease activity, treatment history, comorbidities and PROs were analyzed at treatment initiation; comparisons between oligoarticular and polyarticular PsA patients were performed using t-tests or Wilcoxon rank-sum tests for continuous variables and chi-square tests or Fisher’s exact tests for categorical variables, as appropriate.

Results: 330 biologic-naive PsA patients initiating apremilast, biologics and/or csDMARDs were included (oligoarthritis: n=149; polyarthritis: n=181). Demographics and clinical characteristics were mostly similar for patients with oligoarthritides and polyarthritides, including mean age (51.6 vs. 54.3 years; P=0.068), proportion of females (51.0% vs. 59.7%; P=0.117), mean disease duration (3.0 vs. 3.1 years; P=0.789) and prior use of csDMARDs (13.4% vs. 21.0%; P=0.072). History of comorbidities was similar between the 2 groups, but the proportion of patients with fibromyalgia was higher in the polyarthritides group (2.0% vs. 8.8%; P=0.008).

Conclusion: This Corrona PsA/SpA Registry analysis showed similar overall disease burden and comorbidity burden in biologic-naive patients with oligoarthritides and polyarthritides. However, patients with oligoarthritides vs. polyarthritides had lower scores on disease activity and PRO measures at treatment initiation.

**STRUCTURAL RADIOLOGICAL DAMAGE MSASSS SCORE: ASSOCIATION WITH THE PRESENCE OF SUBCLINICAL CARDIOT ATHEROMATOSIS IN PATIENTS WITH AXIAL SPONDYLARTHRITIS**

Sonia Peris Montoya1, Hernandez Vanessa1, Delgado Frías Esmeralda1,2, Herrera García Ada1, Juan Carlos Quevedo-Abelado2, Iván Ferraz-Amaro2,1
1Hospital Universitario de Canarias, Rheumatology, San Cristobal de la Laguna, Spain; 2Hospital Universitario de Canarias, San Cristobal de la Laguna, Spain; 3Hospital Universitario Doctor Negrín, Rheumatology, Las Palmas de Gran Canaria, Spain

**Background:** Axial spondyloarthropathies (SpA) are associated with an increase in cardiovascular morbidity and mortality, showing an increase of 20% to 40% in the risk of cardiovascular events compared to the general population and constituting the main cause of death. The presence of subclinical atheromatosis, in the form of carotid plaques, is more frequent in patients with SpAn than in healthy controls. Axial structural radiological damage in SpA is a consequence of the inflammatory activity of the disease.

**Objectives:** To analyze whether axial radiological damage by mSASSS (Modified Stoke Ankylosing Spondylitis Spine Score) is related to cardiovascular risk factors or the presence of subclinical atheromatosis in patients with SpA.

**Methods:** 195 patients diagnosed with SpA according to ASAS criteria were included. At the level of the neck and thorax, the presence of subclinical atheromatosis was assessed by image study. Axial structural damage by mSASSS was analyzed by multivariate regression analysis.

**Results:** 36% of patients with SpA showed presence of carotid plaque and a cIMT of 0.651 ± 0.121 mm. log mSASSS disclosed a positive uni- or multivariable relationship with age (beta coefficient 0.07 [95% CI 0.06-0.08], p = 0.000) and classic cardiovascular risk factors such as abdominal waist, hypertension (0.73 [95% CI 0.31-1.16], p = 0.001), smoking (0.33 [95% CI 0.08-0.59], p = 0.010), SCORE (0.33 [95% CI 0.24-0.42], p = 0.000) and levels of C-reactive protein, glucose and C-peptide. Similarly mSASSS showed a positive relationship with the BASFI (0.18 [95% CI 0.11-0.26], p = 0.000) and BASMI (0.31 [95% CI 0.23-0.38], p = 0.000) scores, but not with ASDAS- CRP or BASDAI. The presence of carotid plaque (0.51 [95% CI 0.09-0.93], p = 0.018) and a higher cIMT (4.1 [95% CI 2.4-5.7], p = 0.000) were also significantly and positively related to a higher mSASSS. When these analyses were performed in a multivariate analysis adjusting for age and sex, the relationships of log mSASSS with cardiovascular risk factors were lost, although the relationship of the former with BASFI, BASMI and SCORE remained statistically significant. With regard to sub-clinical atheromatosis, the relationship between log mSASSS and cIMT was not significant after the multivariable analysis; however, the presence of plaque showed an almost significant relationship after adjustment for age, sex and cardiovascular risk factors (0.34 [95% CI 0.02-0.67], p=0.031).

**Conclusion:** Radiological damage by mSASSS is independently related to cardiovascular risk SCORE. A tendency to an independently significant relationship with the presence of carotid plaque was observed.

**Disclosure of Interests:** None declared.

**PREGNANCY RATES AND OUTCOMES IN EARLY AXIAL SPONDYLOARTHRITIS: ANALYSIS OF THE DESIR COHORT**

1,2Marion Pons, Nathalie Costedoat-Chalumeau2, Karine Briot1,2, Philippe Goupille2, Christian Roux1,2, Maxime Dougdos1,2, Anna Molto1,2
1Université Paris Descartes, Cochin Hospital, Paris, France; 2Inserm U1153, CRESS Paris-Sorbonne, Paris, France; 3Tour Eiffel University, Paris, France

**Background:** Only scarce data is available on regarding pregnancy rates and pregnancy outcomes in early axial Spondyloarthritis (axSpA).

**Objectives:** a) to estimate the probability of achieving a clinical pregnancy over time and its associated factors in early axSpA; b) to estimate the probability of presenting an unfavorable pregnancy outcome over time and its associated factors in this population.

**Methods:** Observational prospective French cohort (DESIR) with 6y of follow-up, including 381 of TNFi-naive women with early axSpA. Study visits were scheduled every 6 months in the first two years of follow up then yearly up to 6 years. Data on pregnancy were collected both retrospectively (before cohort inclusion) and prospectively (since inclusion) up to 6 years of follow up. Baseline characteristics of nulligravidae and uni/multi-gravidae patients where compared. The probability of achieving at least one pregnancy over time was estimated (Kaplan Meier). Associated factors were estimated by multivariable Frailty Shared Models and mixed models taking into account the correlation between several pregnancies from the same women. The probability to present an unfavorable pregnancy outcome over time (i.e a miscarriage or pre-term delivery or an elective termination of pregnancy) was estimated only during the prospective follow-up period (Kaplan Meier) since associated factors were collected also prospectively. Associated factors to an unfavourable pregnancy outcome were estimated by multivariable Frailty Shared Models and mixed models.

**Results:** Of the 381 women included in the analysis, 276 (72.4%) and 105 (27.6%) women were respectively nulligravidae and multigravidae at the end of the 6y follow-up. Multigravidae women were significantly older (37.2±8.0 vs 27.6±7.1, p<0.01), less educated (56.7% vs 71.2% university studies, p=0.01), reported higher fatigue levels (6.3±2.1 vs 5.7±2.4, p=0.02), higher BASDAI (4.9±1.9 vs 4.4±1.9, p=0.03), and higher BASFI (3.6±2.4 vs 2.8±2.2, p=0.003) scores at baseline. The probability to have at least one pregnancy throughout life was 61.8% [55.1-67.5]. The mean age at the first pregnancy was 27.3 years old. One hundred and twenty-four pregnancies occurred during follow-up. The probability to have at least one clinical pregnancy during this period was 28.5% [2.0-0.3]. Lack of TNfi use in the 6 months preceding the pregnancy outcome (HR=2.0 [95%CI 1.1-3.3], p=0.01) and a CRP >6mg/L (HR=1.79 [95%CI 1.2-2.5] p=0.01) were found to be associated with a pregnancy outcome over follow-up.

Among the 80 pregnancies occurring after inclusion with data available on the outcome, 60 (75%) presented a full-term delivery while 12 (15.0%) presented an unfavorable pregnancy outcome (6 (7.5%) and 6 (7.5%) had a miscarriage or a pre-term delivery, respectively). 2(2.5%) had a voluntary interruption of pregnancy and 6 (7.5%) were pregnancies still ongoing at the end of follow-up. Only NSAID use (HR=2.59 [95%CI 1.1-5.0], p=0.02) within 6 months of delivery was associated with an unfavorable outcome. TNfi use during pregnancy (6 patients) was not associated with an unfavorable outcome (HR= 2.29 [95%CI 0.8-5.0], p=0.10).

**Conclusion:** More than 70% patients within this early axSpA had at least one pregnancy. A favorable pregnancy outcome (i.e. full-term delivery) was observed in 75% of patients, which is comparable to the general population data. Patients who achieved a pregnancy were more likely to have stopped their TNfi 6 months prior to the pregnancy outcome and increased their CRP, probably reflecting clinical practice from 10 years ago, when recommendation was to withdraw TNFi before pregnancy. NSAID use within 6 months of delivery was independently associated with an unfavorable pregnancy outcome, while TNfi use was not.

**SAT0346**

**EARLY RECOGNITION OF AXIAL SPONDYLOARTHRITIS IN PATIENTS WITH ACUTE ANTERIOR UVEITIS:**

**COMPARISON OF TWO REFERRAL STRATEGIES**

1,2Judith Radenscher, Hildrun Haberl1, Susanne Lüders1, Burkhard Mucche1, Fabian Profi1, Mikhail Protopopov1, Valeria Rios Rodriguez2, Laura Spiller1, Sabrina Sron1, Anne Katrin Weber1, Uwe Peyerl3, Denis Podubnyy1,4, Chantele – CBF Medizinische Klinik für Gastroenterologie, Internistische u. Rheumatologie, Reumaklinik, Martin Institute of Health, Berlin, Germany; 2Charité Campus Virchow Klinikum, Ophthalmology, Berlin, Germany; 3Deutsches Rheuma-Forschungszentrum (DRFZ), Berlin, Germany

**Background:** Diagnostic delay in axial spondyloarthritis (axSpA) remains with 5 to 9 years very high. Extraarticular manifestations like acute anterior uveitis might occur as first manifestations. Up to 40% of patients with acute anterior uveitis have an undiagnosed SpA. Recently, the Dublin Uveitis Evaluation tool (DUET) was proposed as a SpA screening tool by Systematic Coronary Risk Evaluation (SCORE) and axial radiological damage (mSASSS score) were analyzed. The presence of plaques and intima-media thickness (cIMT) was determined by carotid ultrason. The relationship between mSASSS and subclinical atheromatosis was analyzed by multivariate regression analysis.

**Results:** 36% of patients with SpA showed presence of carotid plaque and a cIMT of 0.651 ± 0.121 mm. log mSASSS disclosed a positive uni-

---

**Disclosure of Interests:** None declared.

**DOI:** 10.1136/annrheumdis-2019-eular.6451
instrument for ophthalmologists [1]. At the same time, the ASAS referral tool [2] can also be used on the level of ophthalmologists.

**Objectives**: The objective of the study was to compare the performance of the DUET and the ASAS referral tools for recognition of SpA in patients with acute anterior uveitis.

**Methods**: A total of 100 consecutive patients with acute anterior uveitis of an ophthalmology clinic were included. 87 had completed a standardized rheumatological examination (including MRI of sacroiliac joints) allowing for a definite conclusion on the presence/absence of SpA. The sensitivity, the specificity and the positive predictive value of both referral tools were calculated.

**Results**: Out of the 87 patients with acute anterior uveitis 54 (62%) were diagnosed with SpA (51 with axSpA, one with peripheral SpA, one with reactive arthritis and one with psoriatic arthritis), in 36 cases the diagnosis was made for the first time. The performance of both referral tools is presented in Table 1. The ASAS referral tool showed higher sensitivity (that was especially evident in the previously undiagnosed population) but somehow lower specificity compared to the DUET. The positive predictive value was comparable for both tools indicating that approximately 2 patients with uveitis should be referred in order to diagnose one case of SpA.

In our study, MRI scans were performed on all patients including those without back pain. We thereby diagnosed axial spondylarthropathy in 5 patients, even though they did not fulfill the ASAS classification criteria as they never reported back pain (1 patient) or their back pain did not start prior to the age of 45 years (4 patients).

**Conclusion**: We revealed a high prevalence of undiagnosed SpA in patients with acute anterior uveitis. As anticipated, the more complex DUET including also psoriasis and HLA-B27 positivity showed higher specificity for recognition than the ASAS referral tool. However, the ASAS tool has a higher sensitivity (especially in undiagnosed population) and a better feasibility (purely clinical tool, does not include HLA-B27 testing and evaluation of psoriasis by an ophthalmologist).

*excluding rheumatic diseases; **except axSpA-related medication.

BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; bDMARDs, biological disease-modifying anti-rheumatic drugs; NSDAs, non-steroidal anti-inflammatory drugs.
Conclusion: Comorbid conditions are common in axSpA patients and are independently associated with higher disease activity and higher level of functional impairment. Higher disease activity and a higher level of functional disability might be indicators of a severe disease resulting in the development of comorbid conditions.

SAT0348 HOW FREQUENT IS NEUROPATHIC PAIN COMPONENT IN PATIENTS WITH SPONDYLOARTHRITIS?

Jiea Tsuchada, Saoussen Miladi, Afa Fazaa, Lilia Nasel, Kmar Ouenniche, Leila Souabni, Salma Kassab, Selma Chekkili, Zakraoui Leith, Kaouthar Ben Abdellahri, Ahmed Laatari. mong ssm hospital, rheumatology, tunis, Tunisia

Background: Criteria to define inflammatory back pain in Spondyloarthritis (SA) are multiple. Although neuropathic pain component was known to be part of disease symptoms, it has been rarely assessed.

Objectives: The aim of this study was to determine the prevalence of the neuropathic pain component in SA patients and secondarily, to detect correlation with the disease duration, activity scores and functional impairment.

Methods: A cross-sectional study including patients with radiographic axial SA defined by ASAS criteria was conducted. Patients were questioned about their neuropathic pain using painDETECT questionnaire and Douleur Neuropathique en 4 Questions (DN4) interview. Further information about their neuropathic pain using painDETECT questionnaire and Douleur Neuropathique en 4 Questions (DN4) interview. Further information about disease characteristics, activity (BASDAI, ASDASCRP) and functional impairment (BASFI) scores were assessed the same day.

Results: Forty patients were included. The average age was about 41 years old (±12.9) and the sex ratio was 12.3 (H/F). The mean disease duration was 10.7±6.9 years. Most of patients suffered from back pain and the visual analogic scale pain scale was about 3.7±2.5. The mean BASDAI score was 2.7±2.3 and the mean ASDASCRP was 2.2±1.07. The average BASFI score was 2.57±2.5. Neuropathic pain component was noted only in 7.5% of patients by DN4 interview (≥4/10) and in 10% of patients by pain DETECT questionnaire. As expected, patients with DN4≥4 were correlated to the visual analogic scale pain (p=0.04) and female gender (p=0.07). But no relation was found with the type of SA or the disease activity or the functional scores.

Conclusion: Neuropathic pain component was noted only in 10% of SA in our work. Positive correlation was found with visual analogic scale pain and female gender. Larger studies are needed to assess this type of pain since therapeutic strategy may be affected.

SAT0349 HIGHER DISEASE ACTIVITY IS ASSOCIATED WITH MORE SPINAL RADIOGRAPHIC PROGRESSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Alexandre Sepriano1, Sofia Ramiro1, Stephanie Wichau2, Praveena Chiewchanwisawat2, Tente Maccoshami3, Joel Paschke4, Désirée van der Heijde5, Robert B.M. Landewe6, Walter P. Maksymowycz7,8, LUMC. Leiden, Netherlands; 2University of Alberta, Edmonton, Canada; 3Mahidol University, Bangkok, Thailand; 4CARE Arthritis, Edmonton, Canada; 5AIRC, Amsterdam, Netherlands

Background: The association between disease activity and spinal radiographic progression in spondyloarthritis (axSpA) has been previously shown in a cohort of patients (pts) not being treated with TNFi inhibitors (TNFi).1

Objectives: To test the possible association between disease activity and spinal radiographic progression in r-axSpA in a real-life cohort, also including patients treated with TNFi.

Methods: Pts with axial spondyloarthritis (axSpA) fulfilling the modified New York criteria (mNY) were included in this prospective, observational cohort (ALBERTA FORCAST). Clinical and imaging data were collected at baseline and every 2 years up to 10 years of follow-up. Radiographs of the spine were independently scored by 2 central readers and one adjudicator (if disagreement), with known chronological order but blinded to clinical data, using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). To be included, pts had to have >1 two-year interval with data on mSASSS from ≥1 reader available as well as complete data on ASDAS and TNFi exposure at the start of the interval. The association between ASDAS at the start of the interval (t) and mSASSS 2 years later (t+1) was tested in two types of longitudinal GEE models: a 2-level (2 readers) model with the individual reader scores as outcome (2-level models); ii. Using as outcome averaged scores between readers (1-level models). Both type of models were adjusted for mSASSS at t (autoregression) and for a set of potential confounders defined a priori on clinical grounds. (Figure).

Results: In total, 314 pts (442 intervals) were included [74% males, mean symptom duration 17.8 (SD 11.7) years, 83% HLA-B27 positive and 7% previously treated with ≥1 TNFi]. At baseline the mean ASDAS was 2.7 (1.3) and the mean mSASSS 13.8 (18.8). During follow-up 213 (68%) pts received treatment with TNFi in ≥1 visit. Overall, the average 2-year progression was 1.33 (2.68) mSASSS-units per 2-year interval. In the 2-level multivariable model, 1 ASDAS-unit increase at t was associated with an increase of 0.25 mSASSS-units at t+1 [β (95% CI): 0.25 (0.08; 0.43)] (Figure). Results were similar using the averaged mSASSS as the outcome [β (95% CI): 0.25 (0.08; 0.43)].

Conclusion: These data add to previous evidence by showing that a higher ASDAS is associated with higher spinal radiographic progression in pts with r-axSpA independent of prior treatment with TNFi.

THE IMPACT OF FIBROMYALGIA ON SLEEP DISTURBANCE AND QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Iryna Shapoval, Mykola Stanislavchuk, Larysa Perebetiuk. National Pigov Memorial Medical University, Vinnytsya, Ukraine, Rheumatology, Vinnytsya, Ukraine

Background: Sleep disturbance is a very frequent symptom in patients with diseases associated with pain syndrome [1, 2]. Prevalence of sleep disorders in ankylosing spondylitis (AS) patients varies in a range of 35% to 90% [2]. One of the most common comorbid condition in patients with AS is fibromyalgia (FM), that can significantly worsen quality of life and sleep quality in patients with AS.

Objectives: The aim of this study was to evaluate the impact of FM comorbidity on sleep disturbance and quality of life in patients with AS.

Methods: One hundred and nineteen patients with AS according to modified New York criteria (mean age (M±SD) 42.23±11.5 years; 21 women and 98 men) were enrolled in the study. FM was diagnosed based on the 1990 American College of Rheumatology classification criteria. All patients were asked to complete self-report questionnaires, including the Pittsburgh Sleep Quality Index (PSQI) and Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) to assess sleep disturbance and quality of life.

Results: Of the AS patients, 23 (19.3%) met the criteria for FM. The patients were divided into two groups in terms of having or not having FM. Groups were representative for age and disease duration. Patients with AS and concomitant FM showed significantly increased frequency of sleep disturbance according to the PSQI. Only 26 patients with AS (27%) scored <5 and indicated as “good sleepers”, whereas all patients with AS and concomitant FM has poor sleep quality. In group with AS patients mean scores (M±SD) of PSQI were 7.52±3.96 and in group with AS+FM - 11.04±3.5 (P=0.01). Table 1 shows detailed information on the sleep quality of patients with and without FM.

</tbody>
</table>

In general, for each of the component scores, patients with AS scored lower than patients with AS+FM, with statistically significantly less severe sleep problems on all domains except for use of sleep medication.

Patients with AS and concomitant FM showed poorer quality of life according to ASQoL compared to patients with alone AS (13.8±2.35 vs. 8.6±1.31; P< 0.01).

Conclusion: Sleep disturbance is a frequent condition in patients with AS. Our study results demonstrate the significant impact of FM comorbidity on sleep disturbance and quality of life in patients with AS.

SAT0351 IBIS-Q (IBD IDENTIFICATION OF SPONDYLOARTHRITIS QUESTIONNAIRE): A NEW TOOL TO DETECT SPONDYLOARTHRITIS IN INFLAMMATORY BOWEL DISEASE PATIENTS

Bari Tirazza1, Angela Varaldi2, Antonino Marchetta1, Andrea Geccheri2, Pierluigi Macchion2, Dennis Mogoraniga2, 1Sacro Cuore Hospital, Negrar Verona, Italy; 2Sacro Cuore Hospital, IBD Unit, Negrar Verona, Italy; 3Unit Of Rheumatology, Reggio Emilia, Italy; 4NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals Trust, Leeds, United Kingdom

Background: Extra-intestinal manifestations (EIM) are frequent in IBD with peripheral and axial spondyloarthritis (SpA) being the commonest EIM, being reported in up to 23% of subjects. Early detection of SpA is clinically relevant to drive the therapeutic management including the right treatment at the right time to prevent disability and improve the quality of life. In the literature there are few validated Rheumatology referral models for SpA for gastroenterological use.

Objectives: The aim of this study was to develop a questionnaire to identify peripheral and axial SpA in a cohort of IBD patients (setting: IBD Unit of Sacro Cuore-Negrar Hospital Verona in a rheumatological-gastroenterology clinic).

Methods: During a preliminary meeting a group of experts in SpA-IBD (6 rheumatologists and 4 gastroenterologists) generated a list of 42 items thought to cover all possible SpA manifestations including spinal, articular and enthesal involvement. Consecutive patients referred to the IBD Unit were then enrolled from January to May 2018 without excluding patients affected by IEM. Rheumatologic assessment was performed in the same day by a Rheumatologist blinded to the medical story and to the questionnaire results in order to collect data about the 66 swollen joint count (SJC) and 68 TJC. MASEI, LEI, presence of ASAS criteria for axial and peripheral SpA, presence of diagnostic criteria for fibromyalgia (FM) and non-specific low back pain (NSLB) pain mainly due to OA. If the patient presented a tender/swollen entheses, a US imaging patients affected by EIM. Rheumatologic assessment was performed during a preliminary meeting a group of experts in SpA-IBD (6 rheumatologists and 4 gastroenterologists) generated a list of 42 items thought to cover all possible SpA manifestations including spinal, articular and enthesal involvement. Consecutive patients referred to the IBD Unit were then enrolled from January to May 2018 without excluding patients affected by IEM. If the patient presented a tender/swollen entheses, a US

Results: A final 38-items questionnaire was tested in 210 patients (excluding 17 patients for presence of other rheumatic diseases and 12 for incomplete evaluation). The psychometric analysis of the questionnaire was done on data of 181 patients. 58 patients of the enrolled patients met the ASAS criteria for SpA (13 axial, 5 both axial and peripheral 40 peripheral). The SpA prevalence in our cohort was 32% with 10 new patients identified.

Table 1

| 1. Have you ever had pain in your heels? |
| 2. Have you ever had back pain lasting at least 3 months that was not injury related? |
| 3. Have you ever had a swollen wrist without having any trauma? |
| 4. Have you ever had a swollen joint which goes down to your knee and not beyond? |
| 5. Do you wake up at night and walk because of low back pain? |
| 6. In the morning is your back stiff for more than 30 minutes? |
| 7. Have you ever had a stiff neck for some weeks or months? |
| 8. Have you ever had a pain in your thigh which goes down to your knee and not beyond? |
| 9. Is it difficult to pick things up from the floor without flexing your knees? |
| 10. Have you ever had a swollen finger like a "sausage" for some days? |
| 11. Do you find it difficult to walk because of foot pain? |
| 12. Do you feel pain when people shake your hand? |
| 13. Have you ever had swollen and painful hands? |
| 14. Have you ever had swollen and painful feet? |

In general, for each of the component scores, patients with AS scored lower than patients with AS+FM, with statistically significantly less severe sleep problems on all domains except for use of sleep medication.

Patients with AS and concomitant FM showed poorer quality of life according to ASQoL compared to patients with alone AS (13.8±2.35 vs. 8.6±1.31; P< 0.01).

Conclusion: Sleep disturbance is a frequent condition in patients with AS. Our study results demonstrate the significant impact of FM comorbidity on sleep disturbance and quality of life in patients with AS.

include in the final questionnaire (named IBIS-Q; Table 1) having a sensitivity 84.4% and specificity 80% to detect SpA (AUC 0.8803 with CI 95% 0.8305-0.9301). We propose as cut-off of 4 positive questions of the IBIS-Q for SpA patient identification.

Conclusion: IBIS-Q seems to be a useful and simple tool to use in our IBD clinic for the detection of SpA, with a good statistical performance. Further studies are needed to validate this questionnaire.

SAT0352

THE FREQUENCY OF OCULAR MANIFESTATIONS IN PATIENTS WITH ADULT VS. CHILDHOOD SPONDYLOARTHRITIS

Matthew Turk1, Jacqueline Hayworth2, Tatiana Nevskaya1, Janet Pope1.

1University of Western Ontario, London, Canada; 2University of Toronto, Toronto, Canada

Background: Adult spondyloarthritis (SpA) is characterized by abnormal bone overgrowth and inflammatory erosive osteopenia in the spine. SpA may be associated with psoriasis and psoriatic arthritis (PsA), inflammatory bowel disease, reactive arthritis, enthesitis, and ocular features such as acute anterior iritis, and chronic uveitis. Juvenile SpA onsets in children under 16 years old and may present with more peripheral enthesopathies and arthritis than adult SpA.

Objectives: This meta-analysis investigated the frequency and type of ocular involvement in childhood and adult SpA. The difference in frequency between childhood and adult SpA was also investigated.

Methods: Medline, Web of Science and Cochrane databases were searched to September, 2018 to identify publications related to spondyloarthropathy (SpA), and ankylosing spondylitis (AS) with ocular conditions (OC) (conjunctivitis, keratoconjunctivitis sicca, xerophthalmia, uveitis, eye hemorrhage, optic neuritis, papilledema, orbital disease, retinal artery/vein occlusion, macular edema, retinitis, choroiditis, xerophthalmia, choroid hemorrhage, blindness and amaurosis fugax). The rates of OC were extracted and random effects models estimated their frequency. Heterogeneity was evaluated using I². Inclusion criteria were studies in SpA of either children or adults that included a frequency of OC. Differences in frequencies of OC between childhood and adult disease were compared using chi square tests.

Results: The search process identified 3164 articles, of which 41 were eligible for inclusion. A pooled random effects model showed the prevalence of uveitis was 24% [20%-27%] in adult AS (23 studies, N= 11943 patients), 10% [7%-14%] in adult PsA (9 studies, N=1817), and 17% [10%-21%] in adult AxSpA (23 studies, N=50). In juvenile AS, the prevalence of uveitis was 27% [16%-38%] (8 studies, N=927 patients). In child onset PsA, uveitis occurred in 16% [10%-21%] (5 studies, N=498), and in juvenile undifferentiated SpA, uveitis had a frequency of 7% [1%-12%] (2 studies, N=1531). The differences in frequency of uveitis in adults vs. child onset SpA spectrum diseases were not significantly different between AS and JAS (p=0.891), PsA and JPsA (p=0.732) and between SpA and JSpA.

Conclusion: This meta-analysis compares the frequency of ocular involve- ment in seronegative spectrum diseases in adults and children where it appears that the frequency of uveitis is not statistically different in adult vs. child onset SpA and the subsets.

CARDIOVASCULAR RISK IN YOUNG PATIENTS WITH LOW AXIAL SPONDYLOARTHRITIS ACTIVITY: PROMISING SCORING TOOLS

Elizaveta Vasilenko1, Olga Nikolaeva1, Anna Dadalova1, Maxim Korolev2, V Mazurov1, Inna Gaydukova1, 1North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Cytology and Genetics, The Siberian Branch of the Russian Academy of Science, Novosibirsk, Russian Federation

Background: Patients (pts) with axial spondyloarthritis (axSpA) have increased cardiovascular morbidity and mortality, compared to the general population. However, assessment of cardiovascular risk (CVR) in axSpA is complicated, as in age < 40 years conventional CVR scales (SCORE, etc.) are not recommended, as conventional risk factors do not completely determine an increased CVR. The QRISK3 Cardiovascular Risk Algorithm (QRISK) is the only scale of measuring probability of major cardiovascular events in pts aged 25 to 40.

Objectives: To measure CVR in young pts with low activity of axSpA, and to evaluate the interrelation between CVR, measured with QRISK and gene predisposition.

Methods: The study included 46 pts 25-40 years old with axSpA (ASAS criteria 2009), achieved inactive disease on TNF-α inhibitors. AxSpA activity was measured with ASASDAS and BASDAI. CVR was calculated with the modified QRISK (QRISK3) [https://qrisk.org/three/]. All parameters of QRISK3 were collected: smoking and diabetes statuses, angina or heart attack in a 1st degree relative ≤60, chronic kidney disease (3-5 stage), atrial fibrillation, blood pressure, migraines, rheumatoid arthritis, systemic lupus erythematosus, severe mental illness, atypical antipsychotic medication, regular steroid tablets usage, erectile dysfunction, cholesterol/HDL ratio, systolic blood pressure, Standard deviation (SD) of at least two blood pressure measurements, systolic blood pressure, smoking, and gene polymorphisms in IL-6, IL17F, CC IL6-174, table 1. Interrelation of CVR with another gene polymorphisms was not significant (data are not present).

To identify the relationship between genetic factors and clinical characteristics an exploratory factor analysis was performed.

Results: Mean age ± SD of included pts was 32.5±3.87 years (26% of pts aged 25 – 30, 28.3% – 30-35, 28.3% – 35-40 years), 36 (78.3%) patient were male, symptoms duration 8.7±4.72 years, duration of TNF-α inhibitor treatment 3.1±2.4 years, ASASDAS 1.95±1.23, BASDAI 1.4±0.8. All three age groups were comparable (p>0.05). Out of the 46 pts 25 – 40 years old 34 (75.6%) had a low CVR and 11 (23.9%) had increased CVR (fig.1). Average QRISK3 score of all the patients was 1.18±1.64%. In the 25-30 year old age QRISK3 was 1.51±0.25%, in pts 30-35 years old – 1.09±0.6%, in 35-40 years old-2.31±1.0% (p<0.05 for the inter-group difference).

All patients with increased CVR had a direct associations with homozygous in CC allele IL17F-11139 gene, heterozygous in GA allele of TNF-308 and heterozygous in GG allele IL6-174. Negative associations were found between CVR and heterozygosity in His/Arg and homozygous in His/His of IL17F7, homozygosity in GG allele TNF-308, homozygosity in CC IL6-174, table 1. Interrelation of CVR with another gene polymorphisms was not significant (data are not present).

Conclusion: A quarter of young axSpA pts had an increased 10-year probability of cardiovascular events. Gene polymorphisms in IL-6, IL17F, and TNF-α locuses are strongly associated with increased CVR, QRISK3 and gene polymorphisms could be promising tools in CVR assessment in axSpA.

Further larger studies are needed for evaluation of CVR factors in axSpA.

SAT0355  IRRITABLE BOWEL SYNDROME SYMPTOMS IN AXIAL SPONDYLOARTHRITIS AND HEALTHY CONTROLS, AND THEIR RELATION TO DISEASE CHARACTERISTICS – IS IT AN OVERLOOKED COMORBIDITY?

Johan K. Wältman¹, Elisabeth Mogard¹, Jan Marsal², Kristoffer Andréasson¹, Anna Jöud³, Mats Geijer⁴, Lars Erik Kristensen⁵, Elisabet Lindqvist⁴, Tor Olofsson¹, ¹Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; ²Lund University, Department of Clinical Sciences Lund, Gastroenterology, Lund, Sweden; ³Lund University, Division of Occupational and Environmental Medicine, Lund, Sweden; ⁴University of Gothenburg, Sahlgrenska Academy, Department of Radiology, Gothenburg, Sweden; ⁵The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Frederiksberg and Bispebjerg, Copenhagen, Denmark

Background: While inflammatory bowel disease (IBD) is a well-known comorbidity in axial spondyloarthritis (axSpA), little is known about the prevalence, drivers and impact of irritable bowel syndrome (IBS). In the general population, the IBS prevalence has been estimated to ~11%.[1] Objectives: To compare the frequency of gut symptoms meeting IBS criteria between axSpA patients and controls, and to examine how such symptoms relate to disease characteristics.

Methods: Consecutive axSpA patients were examined and classified as non-radiographic axial SpA (nr-axSpA; ASAS criteria; n=63), ankylosing spondylitis (AS; modified New York criteria; n=119), excluding cases with known IBD. Proportions reporting gut symptoms meeting the Rome III IBS criteria were compared between axSpA patients and sex and age matched controls (without rheumatic disease or IBD; n=50) by logistic regression.[2] Within the axSpA group, separate logistic regression models were also applied to examine whether the presence of IBS symptoms differed according to disease subtype (nr-axSpA/AS), sex, disease activity, level of systemic and gut inflammation, NSAID and DMARD use, and comorbid fibromyalgia (according to the 1990 fibromyalgia criteria).[3] Finally, we analysed associations between the presence of IBS symptoms and standard patient-reported axSpA outcomes and evaluator’s VAS global assessment of disease activity. All analyses were sex and age adjusted.

Results: Symptoms meeting IBS criteria were significantly more common among axSpA patients (30%) than controls (16%; OR 2.5 [95%CI 1.1-5.7]; Figure 1A). Within the axSpA group, no difference was observed between nr-axSpA and AS (Figure 1B). Furthermore, no associations were observed with markers of systemic or gut inflammation, whereas the presence of IBS symptoms was significantly more frequent among patients with higher disease activity (OR 2.2 [95%CI 1.1-4.4] for ASDAS-CRP >2.1 vs. ≤2.1), in females (OR 3.0 [9.5-5.8] vs. men), among NSAID users (OR 2.3 [1.1-4.6] vs. non-users), and in patients fulfilling fibromyalgia criteria (OR 3.0 [1.0-8.6] vs. not; Figure 1B). All patient-reported outcomes, but not evaluator’s VAS global, were significantly worse in patients reporting IBS symptoms (Table).

Conclusion: In axSpA patients without an IBD diagnosis, gut symptoms meeting IBS criteria were twice as common as in healthy controls. While IBS symptoms do not appear to be driven by subclinical gut inflammation or systemic inflammation, the associations with criteria-assessed fibromyalgia, female sex, and worse levels of patient-reported outcomes indicate a link to central pain sensitization, although side effects of NSAIDs may also play a role.

SAT0356  DACTYLITIS IN EARLY SPONDYLOARTHRITIS. DATA FROM THE DESIR COHORT

Daniel Wending1, Clément Prati1, Alian Saraux², Anna Molti³, Thao Pham³, Maxime Dougados¹, Xavier Guillot¹, ¹CHRU, Rheumatology, Besançon, France; ²CHU, Rheumatology, Brest, France; ³Hôpital Cochin, Rheumatology, Paris, France; ⁴CHU, Rheumatology, Marseille, France; ⁵CHU de la Réunion, Rheumatology, Saint Denis de la Réunion, France

Background: Dactylitis is a particular feature shared across the several phenotypical forms of spondyloarthritis (SpA), part of the classification criteria. There are only few data available about impact of dactylitis in early stage of SpA, and factors associated with the presence/history of dactylitis.

Objectives: To study, at baseline and after 5 years in the DESIR cohort, the presence/history of dactylitis in an attempt to evaluate frequency of dactylitis in SpA and to look at the factors associated with presence of dactylitis.

Methods: DESIR is a prospective observational cohort of patients with recent onset (less than 3 years) inflammatory back pain, beginning before 50 years, suggestive of axial SpA, all available factors in the database (clinical, biological, imaging and medico economic) were compared between patients with and without past or present dactylitis at baseline (for categorical variables : odds-ratio +/- 95% CI and chi-square/Fisher tests, for continuous variables : unpaired t-tests/Mann-Whitney), by univariate and then multivariate analysis(logistic regression). Significance: p less than 0.05.

Results: At baseline, 708 patients were analyzed. 97 had a past history or a concomitant dactylitis [prevalence 13.7% (CI 95% : 11.6 – 16.2)]. Dactylitis occurred before axial symptoms in 41.3% and before any other symptom in 14.1% of the cases. By univariate analysis, dactylitis was significantly associated with history of arthritis, enthesitis, psoriasis, with elevated CRP and ESR, enthesitic and arthritis scores, BASDAI, ASDAS,BASFI, SF-36, HAQ, ASQoL, shorter disease duration, systemic and local steroids use, and with lower structural damage (sacro iliac, spine). Table shows the result of the multivariate analysis at baseline.
After 5 years, 138 cases were recorded in 480 patients with complete follow-up: prevalence 28.75% [CI 95% 24.75-32.75], with estimated incidence of 1.71/100 patient-years. At 5 years, dactylitis was significantly associated (multivariate analysis) with Achilles enthesitis (OR : 3.3), history of psoriasis (OR: 3.9), cumulative number of ASAS criteria (OR: 7.2), modified New York criteria fulfillment (OR: 0.35), DMARD use (OR: 2.7) and elevated CRP (OR:0.9).

Conclusion: In the DESIR cohort of patients suspected for early SpA, history of dactylitis is present in 13.7% of the cases at baseline and an estimated incidence of 1.7/100 p-y over 5 years. It is an early feature associated with peripheral involvement, and associated with more burden of the disease, more frequent use of DMARDS and steroids, but with less structural damage.

SAT0358 EROSION MIGHT INCREASE PROBABILITY OF POSITIVE AXIAL SPONDYLOARTHRITIS (SPA) DIAGNOSIS IN PATIENTS WITH EARLY INFLAMMATORY BACK PAIN(IBP), A PROSPECTIVE 3.5 YEAR FOLLOW UP OF 133 PATIENTS

Liliya Yankova Komsalova1, Pilar Martinez2, Jose Fermín Gomez2, Antonio Valdavía2. 1Hospital Marina Salud, Denia, Rheumatology, Denia, Spain; 2Hospital Marina Salud, Denia, Rheumatology, Denia, Spain.

Objectives: To analyse sensitivity, specificity and predictive values of inflammatory back pain (IBP), positive HLA B27 antigen, increased C-reactive protein (CRP), clinical features (CF) such as peripheral arthritis, dactylitis, psoriasis, uveitis, inflammatory bowel disease and enthesitis, familial history (FH) of SPA and assess probabilities to develop SPA. To evaluate the impact of chronic (T1) MRI lesions in early diagnosis of SPA.

Methods: We prospectively collected and followed up 133 patients referred to our department with suspicion of SPA from September 2014 to March 2018. Data such as IBP, HLA B27 antigen, increased CRP, CF, FH and sacroiliac X-rays were collected for each patient. STIR and T1 MRI imaging were separately and independently evaluated by a rheumatologist and two radiologists. In case of disagreement, agreement between two readers was regarded as conclusive. MRI STIR sacroiliac joints (SI) assessment was done in a semi-qualitative way as follows: 1) strongly positive MRI imaging(SPMRI): patients with at least 2 highly specific bone marrow oedema(BME) lesions, easily classifiable as SPA. 2) Weakly positive MRI imaging (WPMRI): patients with at least 2 tiny BME lesions, suggestive, but not easily classifiable as SPA. 3) Clearly negative MRI imaging: patients without any of those features. T1 SI MRI images were assessed for erosion, fat metaplasia, backfill and sclerosis in a qualitative way as positive, if there were 1 or more than one, or negative, if there were none of those lesions.

Results: The average age in our study was 38.9 years. 47(35.3%) patients received diagnosis axial SPA. Radiographic sacroiliitis had 8 (17%), Sensitivity (Sn), specificity (Sp) and predictive values of inflammatory back pain (IPB) were found as follows for each item (p=0.001): IBP: 83% SI, 81.4% SI, 71%PPV, positive HLA B27: 49% SI, 80% SI, 57.5% PPV, increased CRP: 40.4% SI, 93% SI, 76% PPV, and CF: 36.2% SI, 91% SI, 68%PPV, Multivariate logistic regression binary analysis adjusted to the group of patients with non-radiographic SPA showed Odds Ratios for positive diagnosis, 64.8 for IBP (p<0.000), 9.4 for increased CRP (p=0.005) and 11.9 for CF (p=0.006). For the total group of patients the Odds Ratios were as follows: 49.2 for IBP.

The two tests have comparable detection rates for the involvement of sternal angle with a higher kappa value (0.593). However, there were huge differences at other structures with extremely low kappa value, which suggests the routine bone scintigraphy for diagnosis cannot replace a CT scan in terms of evaluating osteoarticular lesions.

Conclusion: The agreement between CT and bone scintigraphy was poor, indicating an importance of implementing routine CT tests in Sapho syndrome.

SAT0359

THE AGREEMENT BETWEEN CT AND BONE SCINTIGRAPHY IN DETECTING OSTEOARTICULAR LESIONS IN SAPHO SYNDROME

Yueqin Ye1, Li Chen2, Yihan Cao2, Wen Zhang2, Nan Wu2, Weihong Zhang3, Wenzhi Xu1. 1Peking Union Medical College Hospital, Beijing, China; 2Peking Union Medical College Hospital, Beijing, China; 3Beijing Hospital, Beijing, China

Background: Computed tomography (CT) and 99mTc-MDP bone scintigraphy are commonly used to detect osteoarticular lesions and the typical bull’s head sign of the anterior chest in the diagnosis of Sapho syndrome. Since bone scintigraphy visualizes high radioactive uptake which basically indicates inflammatory lesions, and CT demonstrates the structural lesions in bones and joints, the findings of the two modalities usually do not correspond with each other. However, little is known about the agreement between CT and bone scintigraphy on the findings of osteoarticular lesions in the patients of Sapho syndrome.

Objectives: To determine the agreement between CT and bone scintigraphy on the findings of osteoarticular lesions in Sapho syndrome.

Methods: A total of 68 patients who met the standard criteria of Sapho syndrome proposed by Kahn and Khan [3] with simultaneous (the interval <1 month) whole spine CT scan and bone scintigraphy were recruited in Peking Union Medical College from 2015 to 2016. Every CT or scintigraphy result was evaluated by at least two specialists independently and blindly. CT scan and scintigraphy results of all patients were evaluated for whether the following osteoarticular structures were involved: the clavicle, sternoclavicular joints, sternocostal joints, sacroiliac joints and all vertebrae. The respective involvement frequencies and the kappa value of agreement were calculated.

Results: Involved vertebra on the CT scan present as corner lesions or endplate lesions. Involved vertebra on the CT scan present as narrowed articular spaces or damaged articular facets. CT scan is more sensitive to detect the involvement of vertebra and sternocostal joints, but less sensitive to sternoclavicular and sacroiliac lesions than bone scintigraphy. Kappa value was calculated to assess the agreement between CT and bone scintigraphy (Table 1). It ranges from 0.103 to 0.593 over different structures, indicating a slight to moderate agreement between the two tests.
Cardiovascular risk factors and comorbidities in patients with PsA, RA and the general population

Anton Landgren1, Lennart T.H. Jacobsson2, Mats Dehlin3, Ulrika Bergsten2, Anton Landgren1, Lennart T.H. Jacobsson2, Mats Dehlin1, Ulrika Bergsten2, Ker-Ai Lee4

Background: Patients with psoriatic arthritis (PsA) have previously been reported to have increased cardiovascular morbidity and mortality compared to psoriasis, rheumatoid arthritis (RA) and the general population (GP). Obesiy has been linked to an increased risk of developing PsA and to be higher in patients with PsA compared to those with psoriasis, RA and GP. Furthermore, obese patients with PsA are more likely to have high disease activity and a reduced response to treatment. Few studies have reported on lifestyle data in combination with traditional cardiovascular risk factors in patients with PsA compared to GP and RA in the same setting.

Methods: We performed a cross-sectional study in the Western Sweden Health Care Region (WSHCR). All individuals who were ≥18 and had at least one ICD-10 diagnosis for PsA (ICD-10 codes M073) or RA (ICD 10 codes M059 and M060), at a visit at any of three rheumatology clinics in the WSHCR during a two-year period (Jan 2015 through Feb 2017) were identified. From these we randomly selected PsA patients (n=1200) and RA patients (n=1246), with equal sex distribution and they were sent a postal questionnaire. Data for non-responders were limited to age and sex.

The questionnaire included questions on demographics, comorbidities, smoking, alcohol consumption, physical activity, medications and disease specific entities. The National public health survey from 2015, “Health on equal terms”, which was sent to randomly selected citizens in Sweden aged 16-84, was used as a sex- and aged matched reference population with five controls matched per RA and PsA case. Obesity was defined according to WHO standards as BMI >30. Daily smoking, alcohol consumption (>5 standard drinks of alcohol per week) and physical activity (>3 hours per week) were also analyzed.

Results: Response rates were n=687 (57.3%) for PsA and n=742 (59.6%) for RA. After age- and sex matching there were 432 individuals with PsA, 431 with RA and 4314 matched subjects from the general population left for analyses. Mean age was 61.1 (SD 12.0) years and 42% males in all three groups. Patients with PsA were more frequently obese, compared to both GP (p<0.001) and RA (p=0.012). Smoking was more prevalent in RA and PsA than in GP. In addition, hypertension was more common in PsA compared to RA (p=0.044) and GP (p<0.001). Diabetes was also more prevalent in PsA than in GP (p<0.007), as was hyperlipidemia (p=0.039). Patients with PsA drank more often ≥5 standard drinks of alcohol per week than patients with RA did (p=0.046).

Conclusion: In PsA, obesity and comorbidities related to CVD were increased above what was seen for both RA compared to the GP. This highlights the need to address these partly modifiable factors in particular for patients with PsA.

SAT0361

Cardiovascular risk factors and comorbidities in patients with PsA, RA and the general population

Anton Landgren1, Lennart T.H. Jacobsson1, Mats Dehlin3, Ulrika Bergsten3, Eva Klingberg1,2, Institute of Medicine, Dept of Rheumatology and Inflammation Research, Sahlgrenska Academy, Gothenburg, Sweden, Gothenburg, Sweden; Research and Development Department at Region Halland, Halmstad, Sweden, Halmstad, Sweden

Background: Patients with psoriatic arthritis (PsA) have previously been reported to have increased cardiovascular morbidity and mortality compared to psoriasis, rheumatoid arthritis (RA) and the general population (GP). Obesiy has been linked to an increased risk of developing PsA and to be higher in patients with PsA compared to those with psoriasis, RA and GP. Furthermore, obese patients with PsA are more likely to have high disease activity and a reduced response to treatment. Few studies have reported on lifestyle data in combination with traditional cardiovascular risk factors in patients with PsA compared to GP and RA in the same setting.

Methods: We performed a cross-sectional study in the Western Sweden Health Care Region (WSHCR). All individuals who were ≥18 and had at least one ICD-10 diagnosis for PsA (ICD-10 codes M073) or RA (ICD 10 codes M059 and M060), at a visit at any of three rheumatology clinics in the WSHCR during a two-year period (Jan 2015 through Feb 2017) were identified. From these we randomly selected PsA patients (n=1200) and RA patients (n=1246), with equal sex distribution and they were sent a postal questionnaire. Data for non-responders were limited to age and sex.

The questionnaire included questions on demographics, comorbidities, smoking, alcohol consumption, physical activity, medications and disease specific entities. The National public health survey from 2015, “Health on equal terms”, which was sent to randomly selected citizens in Sweden aged 16-84, was used as a sex- and aged matched reference population with five controls matched per RA and PsA case. Obesity was defined according to WHO standards as BMI >30. Daily smoking, alcohol consumption (>5 standard drinks of alcohol per week) and physical activity (>3 hours per week) were also analyzed.

DEPRESSIVE SYMPTOMS ARE ASSOCIATED WITH A GREATER CARDIOVASCULAR RISK IN PATIENTS WITH PSORIATIC ARTHRITIS.

Gerlando Natalello1, Enrico De Lorenzis1, Dario Bruno1, Giacomo Tanti1, Maria Rosana Magraro2, Barbara Tolusso3, Giuse Peluso2, Elsa Grezeme3,4, Catholic University of Sacred Heart, Institute of Rheumatology, Rome, Italy; 2Fondazione Policlínico Universitario A. Gemelli IRCCS, Department of Psychology, Rome, Italy; 3Fondazione Policlínico Universitario A. Gemelli IRCCS, Department of Rheumatology, Rome, Italy

Background: Cardiovascular (CV) events are the leading cause of death in patients with psoriatic arthritis (PsA) but current cardiovascular risk prevention strategies in these subjects appear to be inadequate. The prevalence of depressive symptoms, even in the absence of a diagnosed depressive disorder, is greater in patients with PsA than in the general population.

Objectives: The objective of the study is to evaluate the association between CV risk factors and depressive symptoms in a cohort of patients with PsA.

Methods: We enrolled consecutive patients with PsA (CASPAR criteria) without a diagnosis of major depression or history of major CV events. The presence of significant depressive symptoms was defined by the Hospital Anxiety and Depression Scale (HADS) for scores ≥8. The subjects were characterized by disease phenotype, duration and activity (according to the DAPSA index) and immunosuppressive, antihypertensive, glucose-, urate- and lipid-lowering therapy. In order to assess the prevalence of traditional CV risk factors, patients were characterized by BMI, waist and hip circumference, blood pressure (BP), smoking habits, physical activity and familiarity for myocardial infarction, lipid, glucose and serum urate. The predictive risk of CV events was calculated by the American Heart Association (AHA) Risk Score (FRS). Atherosclerotic Cardiovascular Disease (ASCVD) score and Systematic Coronary Risk Evaluation (HeartSCORE) risk charts.

Results: One-hundred patients with PsA were enrolled (males 47.0%; mean age 54.9±12.5 years, duration of illness 9.1±10.6 years) of which 20.6% were in remission, 43.3% in low disease activity, 28.8% in moderate disease activity and 10.3% in high disease activity according to DAPSA. 38% had significant depressive symptoms according to the HADS questionnaire. Patients with depressive symptoms had a higher mean age (57.8±12.3 vs 52.1±11.2 years, p=0.002) compared to patients with significant depressive symptoms but were comparable according to BMI, waist and hip circumference, blood pressure (BP), smoking habits, physical activity and familiarity for myocardial infarction, lipid, glucose and serum urate. The predictive risk of CV events was calculated by the AHA Frailty Risk Score (FRS), Atherosclerotic Cardiovascular Disease (ASCVD) score and Systematic Coronary Risk Evaluation (HeartSCORE) risk charts.

Conclusion: The presence of depressive symptoms is associated with a higher incidence of modifiable CV risk factors and a higher predicted risk of CV events in patients with PsA. Systematic research of depressive symptoms in patients with PsA could contribute to the correct assessment of CV risk, helping to implement more effective prevention strategies.

ENTHESITIS BUT NOT DACTYLITIS CONTRIBUTES TO BURDEN OF DISEASE IN PSA PATIENTS: DATA FROM THE BEPAS REAL LIFE COHORT

Kurt de Vlam1, Rik Lories1, Serge Steinfeld2, Filip van den Bosch3, Adrien Nzeusuou Toukap3, Hermine Leroi3, BEPAS working group. 1University Hospitals Leuven, Rheumatology, Leuven, Belgium; 2Clinical St Jean, Rheumatology, Gent, Belgium; 3UCL St Luc, Rheumatology, Brussels, Belgium; 4MSD Belgium, Medical Affairs

Background: Psoriatic arthritis (PsA) significantly impacts physical function and quality of life. Limited data are available to specifically evaluate the impact of the different disease domains such as arthritis, axial involvement, skin disease, enthesis and dactylitis. The BEPAS cohort, a prospective daily life cohort of PsA patients allows to study the impact of enthesitis and dactylitis on disease activity, disability and quality of life in PsA patients.

Objectives: 1) to measure the impact of enthesitis and dactylitis on health-related quality of life in PsA patients in Belgium.

Methods: At the inclusion visit, a cross-sectional analysis of dactylitis and enthesitis was performed among 462 patients from the BEPAS cohort and impact of enthesitis and dactylitis was studied. Patients were evaluated for the demographics, clinical disease manifestations, disability, disease global assessment and inflammatory markers at inclusion. Differences of tested variables between patients with and without dactylitis and/or enthesitis were evaluated by T-test or Chi-square testing.

Results: 462 patients (273 males and 189 females) with a mean disease duration of 8.53 years (SD: 9.25yrs) were recruited in 17 BEPAS centers from December 2012 to July 2014. 111 patients had enthesitis and 63 patients had dactylitis at inclusion. 17 patients had both enthesitis and dactylitis. Results are summarized in the table below.

Conclusion: Enthesitis has a larger impact on Quality of Life and Health Status than dactylitis in PsA. Patients with enthesitis and dactylitis have higher joint scores but not higher markers of systemic inflammation than those without.

EFFECT OF ACHIEVING DAPSA-LDA ON THE PROGRESSION OF BONE EROSION AND ENTHESIOPHYES IN PATIENTS WITH PSORIATIC ARTHRITIS: A LONGITUDINAL HR-pQCT STUDY

WU Dongze1, James F. Griffith2, Steven H.M. Lam1, Priscilla C. Wong2, Lin Shi2, Edmund K.L.1,2, Isaac T. Cheng1,2, K. Li Tera2, Vivian W. Hung1, Ling Ge2, Lai-Shan Tam1.
1) The Prince of Wales Hospital, The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China; 2)The Prince of Wales Hospital, The Chinese University of Hong Kong, Department of Imaging and Interventional Radiology, Hong Kong, China; 3)The Prince of Wales Hospital, The Chinese University of Hong Kong, Research Centre for Medical Image Computing, Department of Imaging and Interventional Radiology, Hong Kong, China; 4)The Chinese University of Hong Kong, Bone Quality and Health Centre, Department of Orthopaedics and Traumatology, Hong Kong, Hong Kong (SAR)

Background: Psoriatic arthritis (PsA) is characterized by structural bone damage with bone erosions and enthesiophytes. Whether achieving low disease activity (LDA) according to Disease Activity in Psoriatic Arthritis (DAPSA-LDA) limits progression of structural bone damage, as assessed by high resolution-peripheral quantitative computed tomography (HR-pQCT), is uncertain.

Objectives: To investigate the progression of structural bone abnormalities at the metacarpal head in patients with PsA over a 5-year period.

Methods: HR-pQCT examination was performed in 60 PsA patients at baseline and after 5 years. Baseline-indexed image registration and slice matching were performed to acquire precisely matched baseline and follow-up volumes of interest (VOI) at the 2nd and 3rd metacarpal heads (MCH2 & 3). A semi-automated method was used to calculate bone erosion and enthesiophyte volume [1]. Erosion and enthesiophyte progression was defined as change exceeding the smallest detectable change (SDC).

The primary objective of this study was to investigate the degree of bone erosion and enthesiophyte progression in PsA patients receiving routine care. Secondary objectives were to compare changes in bone erosion and enthesiophyte volume between patients who 1) received TNFi group or did not receive TNFi throughout the 5-year period. Comparable changes in bone erosion and enthesiophyte volume were found between the TNFi and the non-TNFi groups. After 5 years, 26 (43%) patients achieved sDAPSA-LDA. Less erosion progression (12/51 [23.5%] vs 25/60 [41.7%], P=0.047) was observed those who did rather than did not achieve sDAPSA-LDA. Similarly, enthesiophyte volume change (0.28±0.67 vs 0.61±0.80 mm³; P=0.048) and total enthesiophyte volume change (0.42±0.69 vs 1.05±1.29 mm³; P=0.019) were lower in those who did rather than did not achieve sDAPSA-LDA.

Conclusion: Once DAPSA-LDA is achieved, it should be maintained for a long period so as to minimize progression of structural bone damage in patients with PsA.

Disclosure of Interests: None declared
Conclusion: Across the Nordic countries the prescription pattern for biological therapies for PsA has changed significantly over time. The decreasing levels of both CRP scores and SJC suggest that PsA patients who initiate bDMARD treatment have changed towards a less active inflammatory phenotype from 2006-2017. Collaboration across registers will allow for robust assessment of the uptake of newer biological therapies. Overall the number of prescribed therapies increased during the observational period, indicating a previously unmet need for biological therapies in the Nordic population.

PSAID9 in Patients With Active Psoriatic Arthritis Treated With Filgotinib vs Placebo: Results From EQUATOR, a Randomized, Phase 2 Study

Ana-Maria Orbai1, Alexis Ogdie2, Laure Gossec3, William Tillett4,5, Ying Ying Leung6, Jingjing Gao7, Mona Trevi8, Chantal Tasse9, Luc Meulemans9, Robin Besuyen6, Thijs Hendriks10, Laura C. Coates10,11. 1Johns Hopkins University School of Medicine, Baltimore, United States of America; 2Renelman School of Medicine, University of Pennsylvania, Philadelphia, United States of America; 3Sorbonne Université, Pitié-Salpêtrière Hospital, AP-HP, Paris, France; 4Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; 5University of Bath, Bath, United Kingdom; 6Singapore General Hospital, Duke-NUS Medical School, Singapore, Singapore; 7Gilead Sciences, Inc., Foster City, United States of America; 8Galapagos NV, Mechelen, Belgium; 9Galapagos BV, Leiden, Netherlands; 10University of Oxford, Oxford, United Kingdom

Background: Filgotinib (FIL) is an oral, selective Janus kinase 1 inhibitor that, compared with placebo (PBO), significantly improved patient-reported outcomes in active psoriatic arthritis (PsA) in the phase 2 EQUATOR randomized controlled trial (RCT; NCT03101670) [1]. PsA Impact of Disease (PsAID) is a validated, EULAR-developed, PsA-specific questionnaire for measurement of health-related quality of life (HRQoL) [2]. PsAID is less complex than generic HRQoL tools, such as the 36-item Short Form Survey (SF–36). To our knowledge, this is the first RCT reporting efficacy results using PsAID9.

Objectives: To determine the effect of FIL vs PBO on PsAID9 in participants of EQUATOR.

Methods: EQUATOR was a multicenter, double-blind study in which patients were randomized 1:1 to FIL 200 mg or PBO once daily for 16 weeks [1]. HRQoL was assessed at weeks 4 and 16 with PsAID9 (total and individual domain scores [each scored 0–10]) and, for comparison, with the Physical Component Summary (PCS) and Mental Component Summary (MCS) of SF-36. Higher PsAID scores correspond to greater impact of PsA [2]. Analysis of covariance was used to compare outcomes between groups.

Results: There were 131 participants in EQUATOR (FIL: n=65; PBO: n=66). Mean (standard deviation [SD]) age was 49 (12.2) and 50 (10.9) years and mean (SD) baseline PsAID9 scores were 5.8 (1.6) and 5.7 (2.0) for FIL and PBO, respectively. Effects of FIL on PsAID9 total scores vs PBO; at week 16, PsAID9 total scores were 3.5 (2.3) vs 4.9 (2.2) for FIL and 4.9 (2.2) for PBO. Mean change (SD) from baseline at week 16 was −2.3 (1.8) vs −0.8 (2.2), respectively (Figure 1a); least-squares (LS) mean of group difference (95% confidence interval) was −1.48 (−2.12, −0.84), p < 0.0001. At week 16, significant improvements were observed in all nine individual domains compared with baseline in FIL vs PBO (Figure 2; p < 0.0001; **p < 0.001; ***p < 0.0001; between-group difference in change from baseline scores at week 16).

Disclosure of Interests: Elsa Vieira-Sousa Grant/research support from: MSD, Novartis, Monica Eusébio: None declared, Pedro Ávila-Ribeiro: None declared, Nikita Khmelinskii: None declared, Ana Rita Cruz-Bernardes: None declared, Daniela Faria: None declared, Joana Silva: None declared, Teresa Martins-Rocha: None declared, Mónica Eusébio: None declared, Pedro Ávila-Ribeiro: None declared, Maria Jose Santos: None declared

PsAID9 domains for FIL vs PBO, including pain (p<0.0001; Figure 1b). A significant improvement in SF–36 PCS, but not in MCS, with FIL vs PBO was observed. The mean change (SD) from baseline in PCS at week 16 was 7.4 (6.6) vs 2.4 (6.6) for FIL vs PBO, respectively (L5 mean of group difference: 4.67 [2.58, 6.76], p<0.0001).

Conclusion: Compared with PBO, FIL significantly improved disease impact in patients with active PsA, as measured by the PsA-specific PsAID9 total score and individual domain scores. Significant improvement in SF–36 PCS score was also seen with FIL.

GO-DACT: A RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED PROOF-OF-CONCEPT TRIAL OF GOLIMUMAB PLUS METHOTREXATE (MTX) VERSUS MTX MONOTHERAPY, IN IMPROVING DACTYLITIS, IN MTX NAÏVE PSORIATIC ARTHRITIS PATIENTS

Elsa Vieira-Sousa1, Pedro Alves2, Ana Maria Rodrigues3, Filipa Teixeira4, José Tavares-Costa4, Alexandra Bernardo5, Sofia Pimenta5, Fernando Pimentel dos Santos6, João Lagoa Gomes7, Renata Aguilar8, Tacialina Videira9, Patricia Pinho9, Carolina Costa10, Helena Santos10, Joana Borges10, Graça Sequeira11, Célia Ribeiro11, Lidia Teixeira12, Pedro Ávila-Ribeiro12, Ana Maria Reis12, Maria Teldeira12, Filipa Teixeira12, Ana-Maria Orbai1, M Elaine Husni2, Dafna D. Gladman3, Ying Ying Leung4, Philip J. Mease9.

Objective: To evaluate the efficacy of golimumab plus MTX versus placebo plus MTX for active dactylitis in PsA patients, in a phase 3b trial.

Method: GO-DACT was a proof-of-concept multicentric, investigator-initiated randomized, double-blind, placebo-controlled, parallel-design trial, conducted in 13 Portuguese Rheumatology Centers. PsA patients, naïve for MTX and biologic disease modifying anti-rheumatic drugs (bDMARDs), with active dactylitis, were randomly allocated to either golimumab in combination with MTX or MTX monotherapy. The primary endpoint was the change from baseline in the dactylitis severity score (DSS) assessed at week 24. Key secondary endpoints included DSS response and the magnetic resonance imaging (MRI) dactylitis score, as well as composite indexes of PsA activity.

Results: 44 patients were centrally randomized, 21 to golimumab plus MTX and 23 to placebo plus MTX, for 24 weeks, and 1 patient from each arm dropped out. Due to favorable results on a planned interim analysis recruitment was halted. The median MTX dose in the golimumab plus MTX group was 15mg/week and in the MTX monotherapy group 20mg/week. The median baseline DSS was 6 in each arm. Patients treated with golimumab plus MTX experienced significantly greater improvements in the DSS at week 24 (median change of 5) as compared to the MTX group (median change of 2) (p<0.026). At week 24, 12 (60.0%) patients treated with golimumab plus MTX and 4 (18.2%) with MTX, achieved the DSS70 response (p<0.05). Significant differences were also observed in the median changes from baseline to week 24 in MRI dactylitis score, Disease Activity Score 28 (DAS28), Disease Activity Index for PsA (DAPSA), PsA Disease Activity Score (PASDAS) and Target Nail Psoriasis Severity Index (NAPSI), favoring the golimumab and MTX association arm. Likewise, higher proportions of patients treated with golimumab plus MTX achieved DSS50 responses and the American College of Rheumatology 20/50 responses, at week 24. There were no new safety issues for golimumab during this trial.

Conclusion: GO-DACT suggests additional benefits from the combination of golimumab and MTX as first-line bDMARD therapy versus MTX monotherapy, in the treatment algorithm of PsA active dactylitis.

Background: Psoriatic arthritis (PsA) dactylitis is associated with an increased risk of erosions and higher disease activity. Dactylitis treatment strategies are however controversial due to the absence of evidence from randomized controlled trials studying dactylitis as a primary outcome.

Objectives: To assess the efficacy of golimumab plus MTX versus placebo plus MTX for active dactylitis in PsA patients, in a phase 3b trial.

Method: Difference 4.67 [2.58, 6.76], p<0.0001. Analysis recruitment was halted. The median MTX dose in the golimumab plus MTX group was 15mg/week and in the MTX monotherapy group 20mg/week. The median baseline DSS was 6 in each arm. Patients treated with golimumab plus MTX experienced significantly greater improvements in the DSS at week 24 (median change of 5) as compared to the MTX group (median change of 2) (p<0.026). At week 24, 12 (60.0%) patients treated with golimumab plus MTX and 4 (18.2%) with MTX, achieved the DSS70 response (p<0.05). Significant differences were also observed in the median changes from baseline to week 24 in MRI dactylitis score, Disease Activity Score 28 (DAS28), Disease Activity Index for PsA (DAPSA), PsA Disease Activity Score (PASDAS) and Target Nail Psoriasis Severity Index (NAPSI), favoring the golimumab and MTX association arm. Likewise, higher proportions of patients treated with golimumab plus MTX achieved DSS50 responses and the American College of Rheumatology 20/50 responses, at week 24. There were no new safety issues for golimumab during this trial.

Conclusion: GO-DACT suggests additional benefits from the combination of golimumab and MTX as first-line bDMARD therapy versus MTX monotherapy, in the treatment algorithm of PsA active dactylitis.

Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) and endorsed by Outcome Measures in Rheumatology (OMERACT), aims to improve and standardize the assessment of PsA outcomes.

Objectives: To report the efficacy of secukinumab vs placebo across individual PsA core domains at week 16 in patients naive to tumor necrosis factor (TNF) inhibitors or who were inadequate responders (TNF-IR), using pooled data from 4 phase 3 FUTURE studies.

Methods: Patients with active PsA participated in the phase 3 FUTURE 2, 3, 4, and 5 trials. Data were pooled for secukinumab 150 mg (load vs. no load), 300 mg, or placebo at the end of the 16-week double-blind period. Efficacy was assessed using multiple clinical and laboratory measures to evaluate the updated GRAPPA-OMERACT PsA core domain set for disease activity, pain, function, and quality of life (Table 1).

Results: A total of 2049 patients were included (1436 TNF naive and 613 TNF-IR). Baseline demographics and disease characteristics were broadly similar in all treatment groups. Efficacy results for the core disease domains are shown in Table 1.

Conclusion: Secukinumab demonstrated efficacy compared with placebo across GRAPPA-OMERACT PsA core domains in the phase 3 clinical trials program, regardless of prior TNF inhibitor use.

SAT0370 IMBALANCE OF TH17 AND REGULATORY T CELLS IN PATIENTS WITH PSORIATIC ARTHRITIS AND REBALANCE BY LOW-DOSE IL-2

Sheng-xiao Zhang1, Yu-Fei Hao1, Jia Wang1, He-Hua Sun1, Guang-Ying Lu1, Chong Gao2, Caihong Wang1, Li Xiao-Feng1, 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Brigham and Women's Hospital, Harvard Medical School, Department of Pathology, Boston, United States of America

Background: Psoriatic arthritis (PsA) is an T lymphocytes-mediated inflammatory condition [1]. Although regulatory T cells (Tregs) isolated from blood and psoriatic skin have been showed a functional deficiency in suppressing effector T-cells in PsA[2], absolute quantitative status of peripheral Treg or Th17 cells is still unclear. On the other hand, recent studies have revealed that low-dose IL-2 alleviates some of autoimmune disease activity by upregulating Treg cells [3, 4], which is expected to control the development of PsA.

Objectives: To assess the absolute numbers of peripheral lymphocyte subpopulations and the efficacy and safety of low-dose IL-2 therapy in PsA patients.

Methods: Total 95 PsA patients and 106 age-and sex-matched healthy controls were recruited. Of them, 22 cases received the treatment of low-dose IL-2 at 0.5 million IU per day for 5 days subcutaneously. The absolute numbers of lymphocyte subgroups and CD4+T subsets in peripheral blood were measured by flow cytometry. The clinical manifestations and laboratory indicators as well as the levels of peripheral lymphocyte and CD4+T subsets were compared before and after the treatment.

Conclusion: Secukinumab demonstrated efficacy compared with placebo across GRAPPA-OMERACT PsA core domains in the phase 3 clinical trials program, regardless of prior TNF inhibitor use.

Figure 1: Comparison of absolute numbers of peripheral CD4+ T cell subsets between PsA patients (n=95) and healthy controls (n=106). The level of Th17 was significantly increased while that of Tregs reduced in patients with PsA. Data were calculated and compared with Mann-Whitney U test. *P<0.05, **P<0.01, ***P<0.001.

Figure 2: Comparative analysis of the changes of CD4+ T cell subsets in patients with PsA between pro- and post-treatment (n=22). Low-dose IL-2 markedly raised the absolute numbers of Treg and moderately increased the level of Th17 cells in PsA patients. *P<0.05, **P<0.01, ***P<0.001.
Results: Notably, the absolute numbers of lymphocyte subpopulations in peripheral blood such as NK, CD4+T, Th17 and Tregs in PsA patients were lower than those of healthy controls (P<0.05). The absolute number of Treg was significantly and negatively correlated with the levels of disease indicators, including DAS28, the number of tender joints, visual analogue scale, physician’s global assessment, dermatology quality index, and health assessment questionnaire (P<0.05). After low-dose IL-2 treatment, compared with the baselines, there was a significant increase in the absolute numbers of NK (P<0.05), CD4+T (P<0.01), Th17 (P<0.01) and Treg cells (P<0.001). Interestingly, IL-2 markedly raised the number of Tregs in PsA patients even higher than that of healthy donors (P<0.001), leading to re-balance of Th17 and Tregs. Further, low-dose IL-2 treatment rapidly reduced the disease activity such as DAS28, the number of tender joints, visual analogue scale, physician’s global assessment, dermatology life quality index, and health assessment questionnaire (P<0.05).

Conclusion: Patients with PsA had an imbalance between pro- and anti-inflammatory cells, particularly the reduction of the absolute numbers of Tregs. Low-dose IL-2 combination treatments restored the decreased number of Treg cells and lowered disease activity indicators of these patients without over-treatment and evaluable side effect. Further studies are needed to evaluate the long-term immunoregulatory ability of IL-2 treatment.

SAT0371 CARDIOVASCULAR IMPACT OF HYPERURICEMIA IN PATIENTS WITH PSORIATIC ARTHRITIS
Ana B. Arevalo1, Faris Haddadin1, Gustavo Contreras1, Shane Murray1, Yiming Luo1, Yousaf Ali2. 1Mount Sinai St. Luke’s – West/Icahn School of Medicine, Internal Medicine, New York, United States of America; 2Mount Sinai St. Luke’s – West/Icahn School of Medicine, Rheumatology, New York, United States of America

Background: Inflammatory joint diseases (IJD) such as psoriatic arthritis (PsA) have an increased risk of cardiovascular disease (CVD) since inflammation plays a pivotal role in the pathogenesis of coronary artery disease (CAD), heart failure (HF) and atrial fibrillation (Afib). Additionally, patients with PsA have a prevalence of hyperuricemia (HUC) of 32%, 3 times greater as compared with the general population, which may be related to increased cell turnover as well as the release of pro-inflammatory cytokines and tumor necrosis factor.

Conclusions: Prolonged exposure to high levels of uric acid (UA) has been shown to result in oxidative stress causing endothelial dysfunction, ion channel changes, atrial and ventricular remodeling. There is experimental evidence indicating that uric acid stimulates renin-angiotensin-aldosterone system (RAAS), and it is associated with an increase in cardiac tissue xanthine oxidase activity, all of which induce cardiomyocyte hypertrophy, myocardial oxidative stress, interstitial fibrosis and impaired diastolic relaxation.

Objectives: The aim of this study is to assess the correlation of HUC and the clinical expression of CVD in patients with PsA.

Methods: This is a retrospective cohort study using the 2016 National Inpatient Sample (NIS) of adults diagnosed with PsA based on ICD-10 codes to detect the prevalence of cardiovascular (CV) conditions such as CAD, Afib, and HF with preserved ejection fraction (HFpEF) in patients with concomitant HUC or gout versus age matched controls. Chi square was used for point prevalence and multivariable linear regression adjusted for age, gender, race, CAD, diabetes mellitus, HTN, hyperlipidemia (HLD), smoking, chronic kidney disease (CKD) and Charlson comorbidity index for prevalence odds ratio (POR). We used STATA-15 for statistical analysis.

Results: We identified 37,315 patients with PsA, of whom 2,165 had concomitant HUC or gout (5.80%). Mean age was 61 years, 57% were females. Our results showed that PsA with concomitant HUC or gout compared to PsA without HUC or gout was associated with a higher rate of Afib (17.8% vs 6.1%, p < 0.001), CAD (35.1% vs 19.4%, p < 0.001) and HFpEF (7.2% vs 3.1%, p < 0.001). Furthermore, patients with PsA and HUC/gout appeared to have more risk of developing Afib (POR 1.78; 95%-CI 1.31-2.45; p < 0.001) and HFpEF (POR 1.56; 95%-CI 1.08-2.26; p=0.018), compared to patients with normal uric acid after multivariate-adjustment for risk factors. No statistical difference in CAD was identified between the two groups (POR 1.21; 95%-CI 0.94-1.55; p=0.131) after multivariate linear regression adjustment for confounders.

Conclusion: This study showed that HUC is independently associated with CVD, mainly with Afib and HFpEF in patients with PsA. It remains to be seen if a treat to target approach with normalization of UA in patients with PsA will result in improved CV outcomes. We believe that our findings merit further investigation and that this study adds weight to the hypothesis of UA as a potential risk factor for CVD. Prospective studies are needed to establish the role of serum uric acid level as a biomarker or predictor for CVD, including CAD, Afib and HFpEF in patients with PsA.

ABSTRACT

Our results showed that there was a significant impact of ΔFMD% found to be moderately correlated with the pain visual analog scale (VAS), Patient-Specific Index (PSI), and Chronic Illness Therapy-Fatigue scale (FACIT-F) were assessed at week 16. Analysis of covariance was used to compare changes from baseline in outcomes between groups. Proportions of patients achieving normative PRO scores or minimal clinically important differences (MCIDs) were compared using Cochran-Mantel-Haenszel tests [2, 3].

RESULTS: FIL significantly improved multiple PROs vs PBO at week 16 (Table). Proportions of patients reaching normative PRO values for FACIT-F and SF-36 PCS (+40 or 50, respectively), and achieving MCIDs in HAQ-DI and SF-36 PCS, were significantly greater for FIL vs PBO (Table). Significant improvement in 6/8 SF 36 domains was observed at week 16 with FIL vs PBO (Fig a). Improvement in most individual FACIT-F items was also observed (Fig b).

Conclusion: In EQUATOR, FIL-treated patients with active PsA reported greater and clinically meaningful improvements in most PROs at week 16 vs PBO, mirroring improvements previously reported with FIL in disease activity measures [1].

**IXEKIZUMAB, WITH OR WITHOUT CONCOMITANT METHOTREXATE, IMPROVES THE SIGNS AND SYMPTOMS OF PsA FOR UP TO 52 WEEKS OF TREATMENT**

**Bernard Combe**, Tsen-Fang Tsai, Salish Odhav, J. Eugene Huftstutter, Aubrey Trevelin Sprabery, Chen-Yen Lin, So Young Park, Matthew Hufford, Peter Nash, University of Montpellier, Montpellier, France; National Taiwan University, Taipei, Taiwan, Republic of China; Arthritis Clinic, Jackson, United States of America; Arthritis Associates, Hisson, United States of America; Eli Lilly and Company, Indianapolis, United States of America; University of Queensland, Brisbane, Australia

**Background:** Ixekizumab (IXE) is a high affinity monoclonal antibody selectively targeting interleukin (IL)-17A. It was previously demonstrated that IXE, with or without concomitant methotrexate (MTX), was superior to placebo (PBO) in improving the signs and symptoms of patients with psoriatic arthritis (PsA) for up to 24 weeks. The current study evaluated the efficacy of IXE with or without concomitant MTX therapy, for up to 52 weeks of treatment in patients with active PsA.

**Methods:** Patients with active PsA who had prior inadequate response or intolerance to tumour necrosis factor inhibitors (SPIRIT-P1; NCT0195239) or had prior inadequate response or intolerance to tumour necrosis factor inhibitors (SPIRIT-P2; NCT02349295) were randomised to PBO (N=224), 80 mg IXE every 4 weeks (IXEQ4W, N=229) or every 2 weeks (IXEQ2W, N=226), after a 160 mg starting dose. In this post-hoc analysis, efficacy was assessed up to Week 52 for the following two subgroups: (i) patients who were treated with IXE as monotherapy i.e. no concomitant conventional disease-modifying anti-rheumatic drugs and (ii) patients who received constant dose of MTX from Week 0 to 52.

**Conclusion:** In this post-hoc analysis, IXE treatment showed sustained efficacy in patients with PsA up to one year of treatment, with or without concomitant MTX therapy.

SA70375 MILD COGNITIVE IMPAIRMENT IN PSORIATIC ARTHRITIS: PREVALENCE AND ASSOCIATED FACTORS

Marco Di Carlo1,1, Andrea Becciolini2, Antonella Incorvaia1, Giacomo Beci1, Martina Biggioggero3, Ennio Giulio Favalli4, Fausto Salaffi5, 1Rheumatological Clinic, Dipartimento di Scienze Cliniche e Molecolari – Università Politecnica delle Marche, Jesi, Italy; 2Gaelano Pini-CITO Institute, Department of Rheumatology, Milan, Italy

Background: A growing body of data demonstrated that systemic inflammation is a predisposing condition for developing cognitive impairment. Different studies highlighted that psoriasis (PsO), a multisystem chronic inflammatory disorder, is associated with cognitive impairment. No data are available regarding psoriatic arthritis (PsA).

Objectives: To assess the prevalence and the factors associated with mild cognitive impairment (MCI) in patients suffering from PsA.

Methods: Consecutive PsA patients, classified as suffering from PsA with the Classification criteria for Psoriatic Arthritis (CASPAR), were enrolled in this study. For each patient were collected the sociodemographic data (age, gender, years of school attendance, years of articular disease duration, years of cutaneous disease duration, treatment), the values of C-reactive protein (CRP) and the following clinical variables: 68 tender joint count (TJC), 66 swollen joint count (SJC), the Leeds Enthesitis Index (LEI), the dactylitis digit count, the Psoriasis Area and Severity Index (PASI), 10 cm numerical rating scale (NRS) for pain and for assessment of disease activity (PsGA), the Dermatology Life Quality Index (DLQI), the 12-item Psoriatic Arthritis Impact of Disease (PsAID-12), the Health Assessment Questionnaire (HAQ), and the Self-administered Comorbidity Questionnaire (SCQ). Cognitive impairment was assessed through the Montreal Cognitive Assessment (MoCA). The exclusion criteria were represented by the presence of: age older than 70 years, major depressive disorder, dementia, Parkinson’s disease, active skin disease other than PsO, concomitant inflammatory joint conditions (such as gout or calcium pyrophosphate deposition), and comorbid fibromyalgia.

Results: The study involved 96 PsA patients, with a mean age of 52.8 years. Twenty (20.8%) patients were suffering from PsA sine PsO. The mean articular disease duration was 9.9 years, and the mean cutaneous disease duration was 14.5 years. The mean Disease Activity Index for Psoriatic Arthritis (DAPSA) was 11.8, and the mean PASI was 0.95. MCI (defined as a MoCA score <26/30) was detected in 47 (48.9%) patients, with a mean value of MoCA of 25.1±3.1. Short-term memory was the most affected domain (mean value 2.6 on 0-5 point scale). The variables under investigation significantly correlated with a worsening cognitive performance (Spearmann’s Rho) were functional capacity (MoCA vs HAQ, r = -0.227, p = 0.026) and fatigue (MoCA vs PsAID item 2, r = -0.22, p = 0.029).

Conclusion: MCI is present in a significant proportion of PsA patients, and is present in a relative young age. MCI occurrence is associated with the presence of a worse functional capacity and a greater fatigue. Short-term memory is the more frequently affected domain. Although not predominantly of rheumatological interest, the MCI presence should be carried out in all patients with PsA.

SA70376 MAKING THE NEXT STEPS IN PSORIATIC ARTHRITIS MANAGEMENT: DOMAIN DRIVEN, TREAT-TO-TARGET, TAILORED MANAGEMENT APPROACH

Yasser El Miedany1,1, Mohammed Hassan Abu-Zaid2, Waileed Hassan3, Mohammed A, Moriada4, Dalia Mekkawy2, Samah Ismail Nasef5, Nadia El Arousy6, Mervat ElSaissi7, Yssora Al-Khoti8, Eiman Dessouki9, Maha El Gaafary10, 1Darent Valley Hospital, Rheumatology, Dartford, United Kingdom; 2Tanta University School of Medicine, Rheumatology and Rehabilitation, Tanta, Egypt; 3Benha University school of medicine, Rheumatology and Rehabilitation, Benha, Egypt; 4Zagazig University school of medicine, Rheumatology and Rehabilitation, Zagazig, Egypt; 5 Ain Shams University School of Medicine, Rheumatology and Rehabilitation, Cairo, Egypt; 6Assiut University, school of medicine, Rheumatology and Rehabilitation, Assiut, Egypt; 7Alexandria University, school of medicine, Ophthalmology, Alexandria, Egypt; 8Suez canal university, Rheumatology and Rehabilitation, Ismailia, Egypt; 9Cairo University school of medicine, Rheumatology and Rehabilitation, Cairo, Egypt; 10Suez University School of Medicine, Community and Public Health, Cairo, Egypt

Background: The diverse clinical picture of psoriatic arthritis (PsA) suggests the need to identify suitable therapies to address the different combinations of clinical manifestations and comorbidities. The current treatment paradigms recommend early diagnosis and treatment, and a strategic, target orientated approach, aiming at a low disease activity status. The introduction of new treatment modalities highlighted the need for guidelines to prioritize these options for doctors and patients.

Objectives: To develop an evidence-based recommendation for the management and treatment of PsA. The management paradigm should cover all domains of psoriatic disease and provide a stepwise tailored treatment options giving clear advice on treatment from the initial diagnosis, including inclusion/exclusion criteria for treatment, monitoring requirements and how to quantity response to treatment.

Methods: A Steering Committee formulated a set of overarching principles for the management of PsA based on evidence derived from a systematic literature review. These were subsequently discussed, amended and voted on by a Task Force of 20 rheumatologists, dermatologists and patient research partners. Using the nominal group technique and Delphi method, 7 domains were identified (peripheral arthritis, axial disease, enthesitis, dactylitis, skin and nails as well as comorbidities including uveitis). A multidisciplinary, evidence- and consensus-based treatment recommendations for PsA were developed for each of the domains based on three consensus discussions. A set of recommendations for a sequential DMARD/biologic treatment algorithm for patients with PsA was also set.

Results: Literature review provided evidence regarding an optimised domain specific, treat-to-target approach to management. The guidelines addressed both drug and non-drug interventions. 20-statements regarding diagnosis, disease activity scoring, US/MRI scanning, and drug therapy were generated. Percentage of positive votes ranged between 86-100%; whereas mean±SD level of agreement was 9.6±0.3.

The main treatment outcome is to achieve remission status or at least low disease activity state, which should be based on a shared decision with parents/patients. Treatment should be adapted according to disease activity. Treatment should be also adapted if the remission state got lost.

Conclusion: Although no clear correlation exists between joint inflammation and the skin in every patient, the skin and joint aspects of the disease often must be treated simultaneously. Treatment recommendations for the cardinal physical manifestations of PsA were developed based on a literature review and consensus between rheumatologists, dermatologists and patients. It is anticipated that periodic updates will take place using this framework as new data become available.

DISCUSSION: Differences in clinical characteristics, quality of life, disability, and work productivity in Psoriatic Arthritis patients by gender: findings from a cross-sectional survey in the US and Europe.

Background: Psoriatic arthritis (PsA) prevalence is equal in men and women, although gender may play a role in driving mechanisms of PsA leading to differences in manifestations of clinical disease (1).

Objectives: Assess key differences in clinical characteristics, disability, quality of life, and work productivity by gender in real-world practice.

Methods: Cross-sectional survey of rheumatologists and dermatologists and their patients in France, Germany, Italy, Spain, UK, and US. Data were collected from Jun-Aug 2018 via physician-completed patient record forms and patient self-completed forms. Data were analyzed by gender. Demographic characteristics, treatment use, and clinical characteristics ( Tender Joint Count [TJC], Swollen Joint Count [SJC]. Body Surface Area [BSA] psoriasis) were reported by physicians, while quality of life (EQ5D and PsAID12), disability (HAQ-DI), and work productivity (WPAI) were reported by patients. Men and women were compared using parametric tests and non-parametric tests where appropriate.

Results: Data were collected for 2270 patients (95 US, 1675 Europe). Demographic characteristics, time from first symptoms to diagnosis, diagnostic treatment, and clinical characteristics were comparable between women and men (Table 1). More women reported worse quality of life, disability, and work activity impairment than men (Table 2).

Conclusion: In women and men with similar PsA disease activity and treatment rates, women experienced worse quality of life, greater disability, and greater work impairment, despite a lower burden of comorbidities.

SAT0378 Drivers of discordance in Psoriatic Arthritis when analyzing the link between patient-perceived good status and the disease activity in Psoriatic Arthritis (DAPSA) composite score: An analysis of 436 patients from the International REFLAP observational study

Laure Gossec, Maarten de Wit, Laura C. Coates, Umut Kalyoncu, Emmanuelle Demis, Adeline Ruysussen-Witrand, Ying Ying Leung, Rossana Scivo, Juan D. Cafete, Penelope Palominos, Sandra Tälli, Uta Kiltz, Martin Soubrier, Lihi Eder, Ana-Maria Orbai, Josef S. Smolen. RFP study group, PARIS, France

Background: In Psoriatic arthritis (PsA), the objective of treatment is remission or low disease which can be defined using the Disease Activity in Psoriatic Arthritis (DAPSA) (ref1). We previously showed DAPSA was associated to patient-perceived good status (i.e., self-assessed remission or low disease, yes/no) (ref2). However, some discordance was noted between patient-perceived status and the composite score. This discordance may be related to demographic elements (such as age, gender or country), disease activity components (such as skin involvement which is not assessed in DAPSA) or patient-reported outcomes (such as fatigue or depressive affects). A better understanding of this discordance would be helpful in the context of shared decision-making.

Objectives: To explore the drivers of discordance between patient-perceived remission or low disease and DAPSA-defined remission or low disease.

Methods: This is an analysis of the first visit of ReFlap (NCT03119805, ref2), an observational study in 14 countries of consecutive adult patients with definite PsA >2 years of disease duration. Discordance in assessment of remission/low disease status was defined as a disagreement between a specific patient question (are you in remission or low disease, yes/no) and DAPSA-defined remission/low disease (i.e., score <=14, yes/no). Potential drivers of this discordance were analysed through univariable then stepwise multivariable logistic regression. Variables analysed were demographic (age, gender, disease duration, gross domestic product of country of origin), disease-related (joint counts, psoriasis BSA, enthesitis, CRP) and patient-reported outcomes (pain, fatigue, depressive affect and anxiety). There was no imputation of missing data.

Results: Among 436 patients, mean age 52.3 (SD 12.5) years, mean disease duration 10.1 (8.1) years, 218 (50.8%) male; 259 (63.5%) were taking prednisone. Discordance between patient-reported status and DAPSA-defined remission or low disease was moderate: 36.1% had no current psoriasis skin lesions and mean swollen joint count was 2.2 (7.1). Remission or low disease was frequent both using the patient question (N=286, 65.6%) and using DAPSA (N=246, 56.4%). Discordance between patient-reported status and DAPSA was 12.7% (95% CI 8.4-17.3%).
Conclusion: Remission or low disease appears to be an attainable outcome in PsA. Patients widely self-reported themselves as being in a similar status as the status indicated by the DAPSA score. Discordance in assessment concerned 25.7% patients and was mainly related to CRP (driving higher DAPSA), pain and fatigue (driving patient assessment).

When faced with discordance in assessment, the health professional should assess these elements carefully.

SA10379 SUBCUTANEOUS VERSUS ORAL METHOTREXATE IN ACHIEVING MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS. CLINICAL PRACTICE: RUSSIAN PSORIATIC ARTHRITIS REGISTRY (RU-PSART) DATA
Elena Gubar1, Elena Loginova1, Anastasia Koltkova1, Yulia Korshakova1, Tatiana Korsantseva1, Evgeny Nasonov2, Alexander Lila3, Maria Sedunova2, Igor Pritstavsky1, Irina Umnova2, Irina Bondareva4, Snezana Kudishina4.
1Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2St. Petersburg Clinical Rheumatology Hospital No.25, Rheumatology, St. Petersburg, Russian Federation; 3Orsk Regional Hospital, Rheumatology, Omsk, Russian Federation; 4Kemerovo Regional Hospital, Rheumatology, Kemerovo, Russian Federation; 5Vladivostok Clinical Hospital No.2, Rheumatology, Vladivostok, Russian Federation.

Background: The aim of psoriatic arthritis (PsA) therapy is to achieve minimal disease activity (MDA) or clinical remission. Methotrexate (MTX) is the first-line treatment; however, the extent of the disease-modifying effect of MTX on PsA is a matter of debate. It has been shown that the MTX treatment achieves MDA in 6 months in <20% of patients (pts) (1). It has been demonstrated that parenterally administered MTX results in rapid and complete absorption, higher serum levels, and less variable exposure than the oral dosing (2). Clinical practice data on the results of the use of MTX for treating PsA are contradictory.

Objectives: To show the efficacy of MTX in PsA pts in clinical practice and to compare the effectiveness of oral and subcutaneous (SC) MTX treatments.

Methods: 256 pts out of RU-PSART received synthetic disease-modifying antirheumatic drugs (sDMARDs), of whom 182 (71.1%) pts (MTF=68/114) received MTX, and were included in the study according to CASPAR criteria. Their median age 42 [Min 19-Max 73] years (yrs). Pts underwent standard clinical examination of PsA activity at the baseline and the follow-up visits. All pts were biological-naïve. They all were treated with MTX monotherapy: 80 received SC and 102 oral MTX. The main purpose was to determine the cumulative frequency of achieving MDA after the MTX therapy onset. MDA is defined as: the presence of at least 5 out of the following 7 domains: tender joint count ≤1, swollen joint count (SJC ≤3, tender entheseal points ≤3, patient global disease activity measured by Visual Analogue Scale (VAS) score ≤20, and patient pain VAS ≤15. Medians and quartiles [Me (Q25; Q75)], [Min; Max], ORs with 95% CI, Breslow, Long Rank, Tarone-Ware tests were performed. Cumulative frequency was computed using the Kaplan-Meier method. All CI >1, p <0.05 were considered to indicate statistical significance.

Results: Only 16.5% of all 182 pts treated with MTX, both orally and SC, achieved MDA. In the SC MTX group 25 pts (31%) achieved MDA, while 97 (95%) did not achieve it. In the oral MTX group 5 pts (5%) achieved MDA, while 55 (69%) did not achieve it. SC MTX treated pts significantly more often achieved MDA compared with those orally treated (OR 24.3 [1.5; 265.9], p = 0.025).

Conclusion: The results of the present study confirm previous clinical practice data, that SC formulation of MTX significantly increase the cumulative frequency of achieving MDA after the MTX therapy onset. Further comparative clinical trials are needed to elucidate the MTX treatment effect on PsA.
FIBROMYALGIA IS THE STRONGEST NEGATIVE PREDICTOR FOR THE ACHIEVEMENT OF EITHER REMISSION AND MINIMAL DISEASE ACTIVITY IN NAIVE PSORIATIC ARTHRITIS PATIENTS STARTING BIOLOGIC DRUGS

Florencio Iannone, Mariangela Nivuori, Giuseppe Lopalco, Maria Grazia Anelli, Laura Coladonato, Gaetana Laselva, Crescenzio Scioscia. Rheumatology, DETO. Bari, Italy

Background: There is evidence that fibromyalgia (FM) can increase the burden of disease in patients affected with psoriatic arthritis (PsA) and interfere with the assessment of clinical disease activity, but studies focusing on the impact of FM on long-term clinical outcomes are lacking.

Objectives: We aimed at evaluating the impact of FM on the achievement of clinical remission or minimal disease activity (MDA) in naive PsA patients on treatment with a first biologic drug in real life settings.

Methods: We retrospectively assessed PsA patients, fulfilling CASPAR criteria, from 1st January 2010 through 30th June 2017, starting a first biologic drug or apremilast. At baseline and at each visit thereafter, DAPSA, PASI, MDA, ASDAS-CRP, and HAQ were evaluated. Rate of patients achieving DAPSA based low disease activity (LDA) was assessed at 3 months, and MDA or DAPSA-remission at 12 months. LOCF method was carried out for those patients who did not reach 12 months follow-up or discontinue the treatment before 12 months. The persistence on the first treatment was evaluated by Kaplan-Mayer survival curves. Estimated hazard ratios (HRs) of discontinuing therapy or achieving remission or MDA at last observation were assessed by a multivariate stepwise backward Cox regression model, adjusting for patient demographics (gender, age, BMI, comorbidities) and disease characteristics (co-therapy with MTX or glucocorticoids, DAPSA).

Results: Upon excluding pure axial PsA without peripheral involvement, 238 patients (126 female) with mean age 51 years (95% CI, 40-59), BMI 26 (95% CI, 23-30), disease duration 24 (95% CI, 10-60) months were analyzed. At baseline, 120 had polyarticular involvement (> 5 joints), 118 had oligoarticular pattern, and 64 had concomitant spine involvement. One hundred-fifteen begun a treatment with anti-TNF-receptor, n.106 with anti-TNF-mAb, n.9 with ustekinumab, n.6 with apremilast, and n.2 with secukinumab. FM was diagnosed, according to both 1990 and 2019 ACR classification criteria, in 58 (female 74%) patients. Crude drug survival rate was significantly lower in FM-PsA patients (50%) (mean survival time (MST, 95% CI) 32 (25-38) months than in PsA patients without FM (74%) MST 42 (38-45) months (log rank=15.6, p=0.001) (Figure 1a). This large difference was also seen estimating drug survival by inefficacy, FM-PsA 56.6% (MST 35 (28-42) months) vs PsA 82% (MST 45 (42-48) months) (log rank=18.5, p=0.001) (Figure 1b), but not by adverse events (data not shown). LDA at 3 months was reached by 78% of PsA patients and by 21% of FM-PsA patients (p>0.001). At 12 months, MDA was achieved by 62% of PsA and only by 2% (1 out of 58) of FM-PsA (p=0.001), and likewise remission was seen in 47% of PsA and in 2% of FM-PsA (p=0.001) Figure 2. FM was the only independent factor associated to drug discontinuation (HR 2.5, 1.6-4.1 (95% CI)), or to the achievement of either MDA (HR 0.23, 0.1-0.5 (95% CI)) and clinical remission (HR 0.26, 0.1-0.6 (95% CI)), with the first biologic drug within the time span of the study.

Conclusion: Our findings clearly demonstrate the FM has a striking negative impact on clinical outcomes in PsA, as early as 3 months of treatment. Clinicians should be aware that treating PsA patients with comorbid FM is demanding, and appropriate patient shared strategies should be adopted in these settings.
All components of PSAID12 were associated with MDA achievement on univariate logistic regression but only pain remained an independent variable on multiple logistic regression. Disease duration, age and sex were not associated with achievement of MDA.

Patients in MDA had significantly lower PSAID12 than those not in MDA (mean 2.1 ± SD 1.9 vs. 5.8 ±1.9. We also looked at individual components of PSAID (Figure1, mean values for numerical rating scales). Patients in MDA continue to report pain and discomfort despite good clinical outcomes, albeit far lower than patients not in MDA. PSAID12 of less than 4 is considered a good outcome. All components of MDA assessment were associated with low PSAID12 on univariate analysis, but only pain VAS and HAQ remained independent predictors on multiple regression analysis.

Patients with active but not severe arthritis (SJ or TJ 2.3) continued to have high PSAID (one way ANOVA p<0.001), driven by other psoriatic disease manifestations including skin and enthesis.

Conclusion:
- MDA is a relevant treatment target in psoriatic arthritis, with markedly lower PSAID12 in patients in MDA
- Patients with even low numbers of tender or swollen joints continue to have significant impact of disease, supporting the use of a multidimensional treatment target
- Pain and fatigue are dominant symptoms in patients with psoriatic arthritis, even in those in MDA

THE RISK FACTORS RELATED TO MENTAL HEALTH PROBLEMS IN PATIENTS WITH PSORIATIC ARTHRITIS IN A LARGE MULTICENTER STUDY: DATA FROM TLAR-NETWORK

Ganme Kilic1, Kemal Nas2, Erkan Kilic3, Ibrahim Teker3, Betul Sargin4, Sevtap Acer Kasman5, Hakan Akkan6, Nilay Sahin7, Gizem Cengiz8, Nihan Cuzdan9, Ilknur Ozan Volkan Yurdakul16, Meltem Alkan Melikoglu17, Yildiray Aydin2, Şahin Ayhan12, Hatice Bodur18, Mustafa Calis8, Erhan Çapkin19, Gul Devrimsel20, Figen Ayan10, Hatice Bodur21, Mustafa Calis22, Erhan Çapkin23, Gul Devrimsel24, Sami Hizmetli24, Ayhan Kamarin24, Kevser Gok22, Yasar Keskin22, Hilal Kocabas22, Oznur Kutuk23, Nesrin Sen22, Omer Faruk Sendur22, Murat Toprak22, Sena Tolu22, Trage Tuncer21, Ayhan Karahisar Health Science, Alanya, Turkey, 2Sakarya University, Sakarya, Turkey, 3Alanya Ataturk Hospital, Alanya, Turkey, 4Erciyes University, Kayseri, Turkey, 5Depo University, Konya, Turkey, 6Kirkkale University, Kirkkale, Turkey, 7Ankara TraiandRtes Hosp, Ankara, Turkey, 8Baskent University, Ankara, Turkey, 9Atatiirk University, Trabzon, Turkey, 10Recep Tayyip Erdogan University, Rize, Turkey, 11Cumhuriyet University, Sivas, Turkey, 12Numune TraiandRtes Hosp, Ankara, Turkey, 13Cankkale 18 Mart University, Cankkale, Turkey, 14Ankara University, Ankara, Turkey, 15Dipak University, Ankara, Turkey, 16Bezmialem University, Istanbul, Turkey, 17Atatiirk University, Trabzon, Turkey, 18Yeditepe University, Istanbul, Turkey, 19Kadikent University, Trabzon, Turkey, 20Cancer Research Institute, Cancer Research Institute, 21Yuzuncu Yil University, Van, Turkey

Background: Psoriatic arthritis (PsA) can lead to significant mental burden affecting several aspects of life in majority of patients. Mental health problems, such as depression and anxiety may result in poor treatment adherence and difficulty in coping with disease burden.

Objectives: The aim of this study is to determine the risk factors associated with clinically significant depression and anxiety in patients with PsA.

Methods: The data from 1128 patients with PsA who met American College of Rheumatology (ACR) criteria enrolled by Turkish League Against Rheumatism (TLAR)-Net-work derived from 25 investigating centers. All of the patients underwent clinical, radiological and also laboratory assessment by using standardized protocol. The associations between psychological variables and clinical parameters were assessed by univariate and multivariate analyses.

Results: Of the 1128 patients with PsA (the mean age 46.9 ±12.2%, 64%), 574 (%50.9) had high risk for depression (HADS-D score ≥7) and 270 (%23.9) for anxiety (HADS-A score ≥10). By univariate analysis, the highest odds ratio (OR) associated with both depression and anxiety were PSF6-MCS≤50 (OR 6.9, [95%CI:5.3–9.]) and OR 9, [95%CI:6.5–12.6], respectively. The lowest OR associated with depression belong to PASI total score (OR 1.1, [95%CI:1–1.1]), while the lowest OR associated with anxiety belong to BASMI (OR 1.2, [95%CI:1.1–1.3]). Multivariate logistic regression analysis of potential risk factors for mental health revealed that BASFI (OR 1.9, [95%CI:1.3–2.9], BASDAI (OR 1.6, [95%CI:1.2–2.3], BASRI (OR 1.1, [95%CI:1–1.2]), SF36 MCS≤50 (OR 4.7,[95%CI:3.4–6.4)), unemployment (OR 1.9, [95%CI:1–1.9]) were factors that influence the risk of depression whereas the BASDAI (OR 1.6, [95%CI:1–2.4]), SF36 MCS≤50 (OR 6, [95%CI:4–9.2], BASMI (OR 1.2, [95%CI:1–1.3]) and FIRST2e5 (OR 3, [95%CI:2–4.5]) were factors that influence the risk of anxiety.

Conclusion: This large nationwide database indicated that higher disease activity, functional disability, fibromyalgia (FMS), poor health related quality of life as well as structural damage were estimated as the important risk factors for mental disorders in PsA.

Disclosure of Interests: None declared

SA0383
COMPARISON OF THE EFFICACY AND SAFETY OF TOFACITINIB AND APREMILAST IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: A BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Young Ho Lee, Gwan Gyu Song, Korea University, Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: The therapeutic options for psoriatic arthritis (PsA) include conventional disease-modifying antirheumatic drugs and biologics. However, an unmet need exists for PsA therapies owing to drug intolerance, non-respondiveness, and therapeutic resistance. Therefore, there is a need for additional treatment options with novel mechanisms of action. Tofacitinib is an orally administered JAK inhibitor and apremilast is a novel oral phosphodiesterase 4 inhibitor that regulates inflammatory mediators.

Objectives: The aim of this study is to assess the relative efficacy and safety of tofacitinib and apremilast at different doses in patients with active PsA.

Methods: We conducted a Bayesian network meta-analysis to combine evidence from randomized controlled trials (RCTs) for examination of the efficacy and safety of tofacitinib 10 mg, tofacitinib 5 mg, apremilast 30 mg, and apremilast 20 mg in PsA.

Results: Eight RCTs including 3,086 patients met the inclusion criteria. There were 10 pairwise comparisons including 6 direct comparisons of 5 interventions. All the interventions achieved a significant American College of Rheumatology 20 (ACR20) response compared with placebo. Tofacitinib 10 mg and apremilast 30 mg were among the most effective treatments for active PsA, followed by tofacitinib 5 mg, and apremilast 20 mg. The

Scientific Abstracts
Saturday, 15 June 2019 1275
rankinig probability based on the surface under the cumulative ranking curve (SUCRA) indicated that tofacitinib 10 mg had the highest probability of being the best treatment in terms of the ACR20 response rate (SUCRA = 0.785), followed by apremilast 30 mg (SUCRA = 0.670), tofacitinib 5 mg (SUCRA = 0.596), apremilast 20 mg (SUCRA = 0.448), and placebo (SUCRA = 0.001). No significant differences were observed in the incidence of serious adverse events after treatment with tofacitinib 10 mg, apremilast 30 mg, tofacitinib 5 mg, apremilast 20 mg, or placebo.

Conclusion: In active PsA patients, tofacitinib 10 mg and apremilast 30 mg were the most efficacious interventions and not associated with a significant risk of serious adverse events.

SA0384 COMPARATIVE ANALYSIS OF FREQUENCY AND TIMING OF MINIMAL DISEASE ACTIVITY (MDA) ATTAINMENT IN EARLY AND LONG-TERM PSORIATIC ARTHRITIS (PSA) PATIENTS (PTS) AFTER BIOLOGICAL (B) DMARD TREATMENT INITIATION IN CLINICAL PRACTICE: RUSSIAN PSA REGISTRY (RU-PSART) DATA

Elena Loginova1, Tatiana Kornaleva1, Anastasia Kofaltakova1, Elena Gubareva1, Yulia Korsakova2, Maria Sedunova2, Igor Pristavsky2, Irina Umnova3, Elena Loginova1, Tatiana Korotaeva1, Anastasia Koltakova1, Elena Gubar1

Background: MDA is a treatment target of PsA. There is limited data about the frequency and the time of MDA achievement by the use of bDMARD therapy in early and long-term PsA in clinical practice. RU-PSART collected data from 25 rheumatology clinics in the Russian Federation.

Objectives: to investigate the cumulative frequency and timing of MDA attainment in early and long-term PsA after starting bDMARDs in clinical practice.

Methods: 140 (MF=77/63) bDMARD-naive PsA pts according to CASPAR criteria were included in the RU-PSART, after signing consent participation forms; median age 42 [Min 19-Max 73] years (yrs). All patients were divided into two groups based on PsA duration at the time of bDMARDs initiation: early PsA≤2 yrs (67pts) and long-term PsA>2 yrs (73pts). All pts underwent standard clinical examinations of PsA and psoriasis activity and were treated with the following bDMARDs: Infliximab (26pts), Etanercept (25pts), Adalimumab (37pts), Ustekinumab (33pts), Golimumab (19pts), Sekukinumab (4pts), Certolizumab pegol (1pts). MDA was defined as ≥ 5 of the following criteria: tender joint count ≤1, swollen joint count ≤1, PASI≤1 or BSA≤3, patient pain global assessment VAS≤15, patient’s global disease activity VAS≥20, HAQ<0.5, enthesitis count ≤1. The cumulative frequency and the time of MDA attainment were calculated in both groups. Kaplan-Meier cumulative analysis, Mean (95%CI), Min-Max,%, Breslow, Tarone-Ware, Log Rank tests were performed. All Cl>1, p<0.05, were considered to indicate statistical significance.

Results: MDA has been achieved after bDMARDs initiation in 33 out of 67 (49%) pts with early PsA and in 23 out of 73 (32%) pts with long-term PsA. The mean time of MDA achievement was significantly shorter in early PsA in comparison to long-term PsA pts: 21 (CI 95%:13.1-28.9) months and 58 (CI95%:0-118.1) months of bDMARD therapy accordingly (p<0.05 for all tests) (Fig.1).

Conclusion: Comparative analysis has shown that cumulative frequency of MDA achievement after bDMARDs initiation was significantly higher (49% vs 32%) and faster (21 vs 58 months) in early PsA than in long-term PsA. That confirms the benefit of bDMARD therapy initiation at the early stage of PsA.

SAT0385 ASSOCIATION OF SUBCLINICAL MYOCARDIAL DEFORMATION AND DISEASE ACTIVITY IN PSORIATIC ARTHRITIS

Ivan Pletkosić1, Daniela Marasović Krstulović2, Zora Suljićov Grabovac1, Darko Duplanić1, Dijana Perković1. 1Dpt. of Cardiology, School of Medicine University of Split, Split, Croatia; 2Dpt. of Internal Medicine, School of Medicine University of Split, Split, Croatia.

Background: Subclinical impaired myocardial deformation is common in patients with PsA, even with no clinical evidence for CV disease (1). Recent evidence supports the link between the extent of inflammation and CV risk in patients with PsA (2). Elevated levels of inflammatory biomarkers and high activity of joint inflammation were associated with a higher burden of atherosclerosis (2). It is suggested that patients with active disease may have an impaired myocardial deformation (3). But it is unclear if the patients with higher activity of PsA have higher grade of myocardial impairment than the patients without activity of inflammatory rheumatic disease. Speckle-tracking echocardiography (STE), an angle-independent technique, was proposed as a reliable and sensitive method for assessment of subclinical myocardial dysfunction (4).

Objectives: The aim of the study was to assess if there is an association of disease activity of PsA assessed by DAPSA with subclinical myocardial deformation measured by Specleck-tracking echocardiography (STE).

Methods: 48 PsA patients (28 females, 20 males) who fulfilled Caspar criteria, with no clinically evident CV disease or concomitant diseases, were included in the study. Patients who had classic CV risk factors or had experienced CV or cerebrovascular events were excluded. Upon clinical and laboratory evaluation, all subjects underwent conventional echocardiography and 2-dimensional speckle tracking echocardiography (STE).

Results: The results of STE analysis showed that patients with higher DAPSA result have average global longitudinal strain AM ± SD -19.44 ± 0.92, relative to patients without activity of PsA measured by DAPSA result -19.37 ± 0.98 (p=0.0036). In addition, patients with active PsA showed lower value of the variable GLS (R=0.368; p=0.016) and higher DAPSA result and lower values of the variable GLS (R=0.368; p=0.016). Global longitudinal strain of MDA achievement after starting bDMARDs in early and long-term PsA.

Conclusion: Subclinical impaired myocardial deformation is common in patients with PsA, even with no clinical evidence for CV disease (1). Recent evidence supports the link between the extent of inflammation and CV risk in patients with PsA (2). Elevated levels of inflammatory biomarkers and high activity of joint inflammation were associated with a higher burden of atherosclerosis (2). It is suggested that patients with active disease may have an impaired myocardial deformation (3). But it is unclear if the patients with higher activity of PsA have higher grade of myocardial impairment than the patients without activity of inflammatory rheumatic disease. Speckle-tracking echocardiography (STE), an angle-independent technique, was proposed as a reliable and sensitive method for assessment of subclinical myocardial dysfunction (4).

SAT0386 PREVALENCE OF SUBCLINICAL CARDIOVASCULAR DISEASE IN PSORIATIC ARTHRITIS: A MULTICENTRIC STUDY

Maria Paz Martinez-Vidal1, José Andrés Lorenzo Martín2, Mariano Andres1, Vega Jovani1, Carlos Santos Ramirez2, Cinia Romera Lopez2, Cristina Fernández-Carballedo2, Rubén Queeró Silva2, Hospital General Universitario Alicante, Alicante, Spain; 3Hospital Central Universitario Asturias, Oviedo, Spain; 2Hospital Virgen de los Lirios, Alcoy, Spain; 3Hospital del Vinalopó, Elche, Spain; 4Hospital Universitario San Juan, Alicante, Spain

Background: There are scarce data regarding subclinical vascular disease in psoriatic arthritis (PsA)(1). Similarly to rheumatoid arthritis, the real CVR could also be underestimated by clinical risk charts (2).

Objectives: To study the prevalence of subclinical vascular atheromatosis in patients with PsA; to analyze the association of carotid plaques with PsA characteristics; to study the presence of CVR factors and to evaluate the effect on the probability of plaque in PsA.

Methods: Descriptive, transversal and multicentric study, of patients with clinical diagnosis of PsA followed in 4 Spanish hospitals. Demographic data, classic CVR factors and clinical characteristics were recorded. The probability of a 10 years fatal cardiovascular event was calculated by SCORE charts adapted for Spain (3), and afterwards a systematic bilateral common carotid ultrasound (4) was conducted. The intima-media thickness of the carotid wall and the presence of atheroma plaque were registered. Patient’s characteristics were described using descriptive analysis techniques. For univariate comparisons we used Chi2 and Anova. Multivariate analyses were conducted by logistic regression. The probability of plaque according to the age and the presence of CVR factors was calculated for patients with clinical intermediate or high risk who present any classical CVR factor.

Results: 309 patients were included. The characteristics of the sample and the prevalence of CVR factors are depicted in Table 1. Patients were stratified by SCORE as follows: low risk 41 patients (13.3%), intermediate or high risk by means of logistic regression. The study was approved by the Hospital General Universitario de Elda Ethic Committee (RCV-PS-MC/26/02/2016).

Results: 309 patients were included. The characteristics of the sample and the prevalence of CVR factors are depicted in Table 1. SAT0387 CONSISTENT EFFICACY IN PATIENT SUBGROUPS ACROSS BASELINE DEMOGRAPHICS AND DISEASE CHARACTERISTICS: RESULTS FROM A PHASE 2 STUDY OF GUSELKUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

Jain M, Cuccurullo PT, Sadowski S, Feldman SM, Grigor JD, et al. (Janssen, Belgium); 2Department of Dermatology and Venerology, Geneva University Hospital and Department of Pathology and Immunology, Univ of Geneva, Geneva, Switzerland; 3Janssen Research and Development, LLC, Spring House, United States of America; 4Univ of Pennsylvania, Phila, United States of America; 5Oregon Health and Science U, Portland, United States of America

Background: Gusekumab (GUS) is a monoclonal antibody targeting interleukin-23 that has demonstrated efficacy in a phase 2 trial of psoriatic arthritis (PsA)(1).

Objectives: Here subgroup analyses were conducted to evaluate the consistency of efficacy on the primary endpoint, ACR20 response. Patients with active PsA (/>3 swollen joints, C-reactive protein >3 mg/L, body surface area [BSA] of plaque psoriasis) were randomized 2:1 to subcutaneous GUS 100 mg (n=100) or placebo (PBO, n=49) at Wk0, Wk4, and every 8 wks (q8w) through Wk44. At Wk16, pts with <5% improvement in both swollen and tender joints could escape early to open-label ustekinumab. Pts continuing BVO crossed-over to receive GUS 100mg at Wk 24, 28 then q8w through Wk44. The primary analysis was performed in a modified Intent-to-Treat (mITT) population which included all randomized subjects who received at least one administration of study agent based on their assigned treatment regardless actual treatment received. Pts who met treatment failure criteria, escaped early, or had missing data at Wk24 were considered non-responders for ACR20 at Wk24. Pre-planned subgroup analyses by demographic and disease characteristics at baseline and PsA medication use were performed, using the same data handling rules as in the primary analysis.

Results: At Wk24, 58/100 (58.0%) of pts in the GUS vs 9/49 (18.4%) in the PBO group achieved an ACR20 response (p<0.001). Efficacy was consistently observed in subgroups defined by demographics (gender, age, weight, region), disease characteristics at baseline (disease duration, PsA subtype, tender/swollen joint counts, HAQ-DI, CRP, presence of dactylitis or enthesitis, PASI, and BSA) or PsA medication use (prior use of DMARDs or anti-TNFs, concomitant use of MTX, oral corticosteroids, or NSAIDs) (Table). The treatment effect was statistically significant in the majority of subgroups with the lower bound of the 95% confidence interval of the difference between GUS and PBO exceeding 0 in favor of GUS. There are a few exceptions where small sample sizes of the subgroups limited the interpretation. All enrolled subjects were white; therefore, the effect of gusekumab in other racial groups could not be assessed. Among GUS-treated pts, pts with enthesitis, dactylitis, PASI >12, BSA >10%, tender joint count <10 or swollen joint count <10 appeared to have numerically higher ACR20 response rate than those corresponding subgroups defined otherwise, although the sample size is small and the data should be interpreted with caution.

Conclusion: In this phase 2 trial of patients with PsA, GUS demonstrated efficacy consistently across subgroups of pts according to baseline demographics, disease characteristics, and PsA- medication use. The relationship between baseline characteristics and clinical outcome will be further explored in phase 3 studies with a larger PsA population.

DISCLOSURE OF INTERESTS

**INHIBITION OF RADIOGRAPHIC PROGRESSION WAS ACHIEVED WITH INTRAVENOUS GOLIMUMAB IN ACTIVE PSA PATIENTS REGARDLESS OF CHANGES IN COMPOSITE INDICES OF DISEASE ACTIVITY IN A PHASE III TRIAL**

**Philip J. Mease**,¹ M Elaine Husni,² Shelly Kafka,² Soumya D, Chakravarty,²,4 Diane D. Harrison,⁵ Kim Hung Lo,⁶ Stephen Xu⁷, Elizabeth C. Hsia⁸,⁹

Arthur Kavanaugh¹. ¹Swedish Medical Center and Univ of Wash School of Med, Seattle, United States of America; ²Cleveland Clinic, Cleveland, United States of America; ³Janssen Scientific Affairs, LLC, Horsham, United States of America; ⁴Drexel Univ College of Med, Philadelphia, United States of America; ⁵Janssen Research and Development, LLC, Spring House, United States of America; ⁶Univ of Penn Medical Center, Philadelphia, United States of America; ⁷Univ of CA San Diego, San Diego, United States of America

**Background:** GO-VIBRANT is a Phase 3 trial of intravenous (IV) golimumab (GLM), an anti-tumor necrosis factor alpha (TNFα) monoclonal antibody, in adult patients (pts) with active psoriatic arthritis (PsA).

**Objectives:** To assess if changes in Disease Activity in PsA (DAPSA), PsA Activity Score (PASDAS), Minimal Disease Activity (MDA), Very Low Disease Activity (Vlda), and Clinical Disease Activity Index (CDAI) measures correlate with X-ray progression.

**Methods:** In this multicenter, randomized, double-blind, placebo (PBO)-controlled trial, 480 bionaive PsA pts with active disease (>5 swollen & >5 tender joints, C-reactive protein <50mg/dL, active plaque psoriasis or documented history despite treatment w/csDMARDs &/or NSAIDs) received IV GLM 2mg/kg (N=241) at Wks0/4 then q8wks or PBO (N=239) at Wks0/4/12/20 with crossover to GLM at Wk24. In a post-hoc analysis, association of disease activity measures DAPSA, PASDAS, MDA, Vlda, & CDAI with X-ray progression was examined. Total modified van der Heijde-Sharp (vdH-S) score assessed X-ray progression X-ray progression vs PBO -0.41 vs 1.27).

**Results:** Changes in all disease activity measures appeared to correlate with X-ray progression (Table). GLM-treated pts had less X-ray progression regardless of disease activity measure. GLM treated pts in remission or with low disease activity tended to have less X-ray progression at Wk52 vs pts with moderate or high disease activity (mean change in vdh-S: GLM pts. GLM: DAPSA remission or low disease activity -0.97 vs 1.38, moderate activity -0.48 vs 1.38, high disease activity -0.88 vs 1.49, moderate activity -0.48 vs 1.38, high disease activity -0.88 vs 1.49).

**Conclusion:** In this analysis, all disease activity measures generally correlated with X-ray progression from baseline to Wk24 and to Wk52. Higher disease activity was associated with increased X-ray progression. GLM-treated pts not achieving MDA & Vlda at Wk52 tended to have less X-ray progression vs PBO-GLM pts. GLM’s ability to inhibit X-ray progression, despite pts not being in clinical remission or low disease activity, illustrates an example of “disconnect” between clinical outcomes & X-ray progression seen in other studies.

GUSELKUMAB WAS MORE EFFECTIVE THAN SECUKINUMAB IN PATIENTS WITH PLAQUE PSORIASIS AND THE SUBSET OF PATIENTS WITH SELF-REPORTED PSORIATIC ARTHRITIS IN THE RANDOMIZED, DOUBLE-BLIND, HEAD-TO-HEAD COMPARISON STUDY ECLIPSE OVER 1 YEAR

Joseph F. Merola1, Li Shu2, Ming-Chun Hsu2, Chetan Karyekar3, Susan Flavin2, Bruce Randazzo2, Laura C. Coates1, Brigham and Women’s Hospital, Harvard Med School, Boston, United States of America; 2Janssen Research and Development, LLC, Spring House, United States of America; 3Janssen Medical Affairs, Horsham, United States of America; 4Oxford University, Oxford, United Kingdom

Background: Gusekumab (GUS, an antibody against IL-23) and secukinumab (SEC, an antibody against IL-17A) are both approved for the treatment of psoriasis (PsO). Up to 30% of patients with PsO may have psoriatic arthritis (PsA).

Objectives: The ECLIPSE study compared efficacy and safety of GUS vs SEC in patients with plaque PsO. Post hoc analyses examined outcomes in the subgroup of patients with self-reported psoriatic arthritis (PsA).

Methods: ECLIPSE was a randomized, double-blind trial of adults with moderate-to-severe plaque PsO who received GUS 100 mg at Weeks 0, 4, then every 8 weeks, or SEC 300 mg at Weeks 0, 1, 2, 3, and 4, then every 4 weeks, both through Week 44. The primary endpoint was the proportion of patients achieving ≥90% improvement compared to baseline in the Psoriasis Area and Severity Index (PASI) score at Week 48. Cochran-Mantel Haenszel chi-square testing stratified by investigator was used to compare treatment-group responses.

Results: Overall, treatment groups [GUS (n=534), SEC (n=514)] were comparable at baseline: weight 89kg, 24% body surface area PsO, and Investigator Global Assessment (IGA) moderate (76%) or severe (24%). These characteristics were similar to those of subgroups with self-reported PsA [GUS (n=97), SEC (n=79)]. In the overall population, the primary endpoint of PASI 90 response at Week 48 was achieved by 84.5% of GUS vs 70.0% of SEC patients (treatment difference 14.2 [95% CI=8.6%,18.8%], P<0.001). Among patients with PsA, the primary endpoint of PASI 90 response at Week 48 was achieved by 82.5% of GUS vs 63.3% of SEC patients (treatment difference 19.2% [95% CI=5.0%, 33.4%]). Beyond week 20, in both the overall study population and the PsA subgroup, GUS-treated patients maintained the PASI 90 response while SEC-treated patients had a reduction in response through week 48 (Figure). In the overall population, results of the first major secondary endpoint (proportion of patients with a PASI 75 response at both Week 12 and 48) showed non-inferiority of GUS vs SEC (GUS-84.6% vs SEC-80.2% of patients, p<0.001). Superiority was not demonstrated (p=0.062). Adverse events observed in the overall population and PsA subgroup were generally consistent with the established safety profiles for GUS and SEC.

Conclusion: In the subset of patients with self-reported PsA in the ECLIPSE study, GUS demonstrated better maintenance of response and higher efficacy at approximately one year compared with SEC in the treatment of moderate to severe plaque PsO. These findings were consistent with those for the overall study population of patients with plaque PsA. AEIs observed were generally consistent with the established safety profiles for GUS and SEC.

SAT0391

REMISSION AND DRUG RETENTION RATES OF SECUKINUMAB IN 1549 PATIENTS WITH PSORIATIC ARTHRITIS TREATED IN ROUTINE CARE – POOLED DATA FROM THE OBSERVATIONAL EUROSPA RESEARCH COLLABORATION NETWORK

Brigitte Michelsen, Cecilie Heegaard Brahe, Lennart T.H. Jacobsson, Michael Nissen, Manuel Pombo-Suarez, Helman Mann, Ziga Rotar, Joe Sexton, Maria Jose Santos, Dan Nordström, Catalin Codreanu, Björn Gudbjornsson, Carlos Sánchez-Piedra, Karel Pavelka, Matija Tomsic, Eirik Kristianslund, Helena Santos, Anna-Mari Hokkanen, Ruxandra Ionescu, Thorvardur Jon Love, Yvespehlivan, Mario Sebastiani, Gareth T. Jones, Irene van der Horst-Bruinsma, Lisa Hyldestrup, Niels Steen Krogh, Merete L. Hetland, Mikkel stergaard, EuroSA Research Collaboration, on behalf of DANBIO (Denmark), ARTIS (Sweden), SCCM (Switzerland), NOR-DMARD (Norway), ATTRA (Czech Republic), Reuma.pt (Portugal), BIOBADASER (Spain), ROB-FIN (Finland), bioi.si (Slovenia), ICEBIO (Iceland), TURKBIO (Turkey), RBBR (Romania), ARC (Netherlands), BSRBR-AS (UK), GISEA (Italy), Denmark

Background: There is a lack of data on exposure, treatment outcomes and retention rates of secukinumab in patients with psoriatic arthritis (PsA) treated in routine care.

Objectives: Primary objective: To assess the proportion of PsA patients in remission after 6 months of secukinumab treatment across Europe. Secondary objectives: To compare baseline clinical and demographic characteristics, 6-month crude and LUNDEx adjusted remission rates, 6-month remission rates and median time to secukinumab withdrawal (due to loss of efficacy/adverse events) between bDMARD naïve and non-naïve patients as well as across the participating European registries.

Methods: PsA patients starting secukinumab in routine care and followed for at least 6 months were included from 12 European registries within the European Spondyloarthritis Research Collaboration (EuroSpA). Independent t-test, Mann-Whitney U test, ANOVA, Kruskal-Wallis and Chi-square test were used for group comparisons as appropriate, and Kaplan-Meier plots with log rank test for comparison of secukinumab drug survival.

Results: A total of 1549 PsA patients starting secukinumab were included (Table). 6-month remission and retention rates were significantly different between the registries (Table). Biologic DMARD (bDMARD) naïve compared with non-naïve patients had significantly higher 6-month remission rates and a trend towards better 6-month retention rates (Table, Figure 1a-b).

Conclusion: This study of >1500 patients in 12 European countries provides real-world data on the effectiveness of secukinumab in patients with PsA, adding evidence to existing RCTs. A majority of the patients had long disease duration and was previous bDMARD users. DAS28CRP, SDAI and DAPSA28 remission at 6 months were achieved by 35%, 12% and 12%, respectively. The overall remission rate was 86%, with significant differences across the registries. bDMARD naïve compared with non-naïve patients had significantly better 6-month remission rates and a trend towards better secukinumab retention rates.

IMPLEMENTING THE PSORIATIC ARTHRITIS DISEASE ACTIVITY SCORE (PASDAS) IN ROUTINE CLINICAL PRACTICE: (IM)POSSIBLE?

Michelle Mulder1, Alfons den Broeder1,2, Bertke van Ginneken1, Johanna Vriezekolk1, Ellen Mahler1, Frank van den Hoogen1,2, Mark Wenink1.

1 Sint Maartenskliniek, Rheumatology, Utrecht, Netherlands. 2 Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands.

Background: Psoriatic arthritis (PsA) is a heterogeneous disease, with involvement of at least five health domains: peripheral joint disease, enthesitis, dactylitis, axial involvement, and skin and nail psoriasis. Because of the heterogeneity of the disease, assessment of disease activity is challenging. One of the many single or composite outcome measures that has been developed is the Psoriatic Arthritis Disease Activity Score (PASDAS). The PASDAS is a comprehensive measure that takes arthritis (66/68 joint score), dactylitis, enthesitis, CRP, physician disease activity VAS score and patient-reported outcomes into account.

Furthermore, it is a continuous outcome measure in contrast to the Minimal Disease Activity criteria (MDA), facilitating the longitudinal follow-up of disease activity. The PASDAS also has better parametric distribution and discriminative capacity compared to other outcome measures such as the Disease Activity for Psoriatic Arthritis score (DAPSA). However, feasibility of PASDAS use in routine clinical care has been questioned due to its complexity. It requires a CRP and filled-out SF36 form at time of assessment, does not include a formal skin assessment, is difficult to calculate and is time consuming for both patient and physician.

Objectives: To implement PASDAS measurements and skin assessments in routine clinical care for all 1300 PsA patients treated at our centre.

Methods: The implementation consisted of the following stages: 1) assessment of patients’ acceptability of measurement burden; 2) implementation of mathematical calculations of the PASDAS in our electronic health record; 3) PASDAS and skin assessment training of rheumatology nurses and rheumatologists; and 4) (logistic) adjustments to the outpatient visit.

Results: Our patient partners preferred comprehensive clinical assessment of skin and joints above a limited assessment (such as the DAS28-CRP), although the latter would be less time consuming. For the assessment, and to comply with international guidelines, we decided to also add assessment of skin disease, by using the Body Surface Area (BSA) and Physician Global Assessment score (PGA). Furthermore, research demonstrated that for the PASDAS calculation the physical component score (PCS) of the SF36 could be substituted by the SF12-PCS.

As the SF12 is more concise, minimizing patient burden, we chose to implement the SF12 instead of the SF36. The SF12-PCS, together with the other separate component scores and corresponding mathematical calculation of the PASDAS, was implemented in our electronic health record. Lastly, we set-up a three phase consultation that consists of laboratory tests and consultation with a rheumatology nurse who performs the physical measurements before each visit with the physician.

Conclusion: Standardized and routine measurement of the PASDAS and skin involvement at each outpatient visit of all our PsA patients before consultation with the treating rheumatologist was successfully implemented, underscoring the feasibility of this approach. In addition to improving clinical care, routine outcome measurements can be used for a variety of clinical studies.

EFFECTIVENESS AND SAFETY OF INFliximab, Golimumab and Ustekinumab in Psoriatic Arthritis Patients from a Prospective Observational Registry

Background: Long-term registries are essential to evaluate new therapies in a patient population that differs from clinical trials and usually varies over time.

Objectives: To describe the profile of psoriatic arthritis (PsA) patients selected for treatment with infliximab (IFX), golimumab (GLM) or ustekinumab (UST) treatment in Canadian routine care and to describe the long-term real-world effectiveness and safety of these agents.

Methods: 462 PsA patients treated with IFX, GLM or UST were enrolled into the Biologic Treatment Registry Across Canada (BioTRAC) registry between 2009-2015, and 2010-2017 and 2014-2017. Study visits occurred at baseline and every 6 months thereafter. Effectiveness was assessed with changes in TJC28, SJC28, skin, enthesis, dactylitis, pain, HAQ, acute phase reactants. Safety was evaluated with the incidence of adverse events (AES) and drug survival rates.

Results: Of the 111 IFX, 281 GLM and 70 UST-treated patients, the proportion of males were 52.3%, 46.3% and 37.1%, the mean age was 48.4, 52.8 and 53.1 years and the mean disease duration was 5.8, 6.1 and 5.7 years, respectively. Most patients were bio-naïve (85.6%, 77.9% and 50.0% and 55.7% for IFX, GLM and UST, respectively (p<0.001). A reduction in mean baseline duration of morning stiffness was observed in the IFX cohort (from 69.8 to 42.6 to 23 min in 2006-2008 to 2009-2012 to 2013-2015 (p<0.001). Most other baseline disease parameters remained similar over time in all three cohorts. However, UST-treated patients had lower mean baseline DAS28 CRP (3.4 vs 3.9; p=0.003), SJC (3.8 vs 5.3; p=0.0046) and higher PASI (4.8 vs 2.2; p=0.0061) compared to patients treated with GLM or UST.

Treatment with IFX, GLM and UST was associated with significant improvements in all disease parameters over time (>P<0.001) from baseline up to 84, 40 and 36 months, respectively with similar efficacy between agents. The only exception was the proportion of patients in minimal disease activity at 12, 24 and 36 months which reached 40.7%, 50.0% and 55.7% for IFX, GLM and UST, respectively (p<0.001). A reduction in mean baseline duration of morning stiffness was observed in the IFX cohort (from 69.8 to 42.6 to 23 min in 2006-2008 to 2009-2012 to 2013-2015 (p<0.001). Most other baseline disease parameters remained similar over time in all three cohorts. However, UST-treated patients had lower mean baseline DAS28 CRP (3.4 vs 3.9; p=0.003), SJC (3.8 vs 5.3; p=0.0046) and higher PASI (4.8 vs 2.2; p=0.0061) compared to patients treated with GLM or UST.

Conclusion: Differences in baseline characteristics between patients treated with an anti-TNF agent over an anti-IL12/23 agent suggest that the level of joint to skin involvement might be driving physician choice when the time comes to choose a biologic agent. IFX, GLM and UST treatment significantly reduced disease activity and improved functionality in a similar fashion and were well tolerated in patients with PsA.

POSSIBLE POTENTIAL INTERACTIONS BETWEEN OSTEOPOROSIS, QUALITY OF LIFE, PSYCHOLOGICAL STATUS AND CLINICAL PARAMETERS IN PSORIATIC ARTHRITIS

Background: Psoriatic arthritis (PsA), a chronic rheumatic disease associated with reduced quality of life. Obesity is an important clinical problem which may interfere with loss of functioning and quality of life. Obesity is usually an overlooked entity in patients with PsA. Several studies were involved in prevalence and the impact of obesity on disease activity in patients with PsA, however relationship between psychological status and quality of life have not been evaluated comparatively.

Objectives: To assess the impact of obesity on quality of life, psychological status and clinical parameters in patients with PsA.

Methods: Patients with PsA were recruited who met CASPAR classification criteria enrolled by Turkish League Against Rheumatism-NETWORK (TLAR-NETWORK) derived from 24 different centers of our country. Patients with BMI >30 kg/m2 were considered obese. Disease status and health related quality of life measures [SF-36; HAQ; Psoriatic arthritis quality of life (PsAQOL); Hospital Anxiety and Depression Scale], FACIT-Fatigue, DAS28, BASDAI, BASFI, BaMSI, Maarlyck arthritis Spondylitis Enthesitis Score (MASES) and Psoriasis area severity index (PASI) scores were compared between this groups.

Results: A total 1130 patients with PsA (36.0% male, 64.0% female) included in this cohort 37.6% obese and 62.4% non-obese. The presence of peripheral arthritis, enthesis, dactylitis, ulnae and spine involvement, PASI scores as well as MASES scores were quite similar between patients with and without obesity. Obese patients had significantly higher scores in VAS fatigue and disease activity, poorer QoL and physical functions compared to non-obese patients (p<0.05). Obese patients had high risk for anxiety and depression (p<0.05).

Conclusion: Obesity associated with the risk of depression and anxiety, fatigue, poorer QoL and higher disease activity. These findings suggest that obesity should be considered while assessing patients with PsA.

SAT0395 RESPONSIVENESS AND CLINICAL TRIAL DISCRIMINATION OF SWOLLEN AND TENDER JOINT COUNTS FOR THE MEASUREMENT OF MSK DISEASE ACTIVITY IN PSORIATIC ARTHRITIS

Ali Duarte-Garcia1, Lihi Eder2, Nill Goel3, Maarten de Welt4, Dafna D. Gladman5, Oliver FitzGerald6, Philip J. Mease7, Ying Ying Leung8, Anna-Maria Ordi9, Bev Shea10, Vibeke Strand11, Philip Helliwell12, Alisa Stephens-Shields13, William Tillett14, Laura C. Coates15, Ali Duarte-Garcia1, Lihi Eder2, Nitigoe3, Maarten de Witt4, Dafna D. Gladman5, Oliver FitzGerald6, Philip J. Mease7, Ying Ying Leung8, Anna-Maria Ordi9, Bev Shea10, Vibeke Strand11, Philip Helliwell12, Alisa Stephens-Shields13, William Tillett14, Laura C. Coates15, Ali Duarte-Garcia1, Lihi Eder2, Nitigoe3, Maarten de Witt4, Dafna D. Gladman5, Oliver FitzGerald6, Philip J. Mease7, Ying Ying Leung8, Anna-Maria Ordi9, Bev Shea10, Vibeke Strand11, Philip Helliwell12, Alisa Stephens-Shields13, William Tillett14, Laura C. Coates15

Background: While tender and swollen joint counts (TJC and SJC) are key instruments for the assessment of peripheral arthritis in PsA, little is known about the psychometric properties of TJC and SJC in randomized controlled trials (RCTs) and how these properties differ among patient subgroups.

Objectives: To assess the responsiveness and discrimination of TJC and SJC in PsA using RCT datasets and evaluate subgroups of patients with early vs. established disease and 3 or less vs 4 or more active joints.

Methods: Patient-level data from 8 phase III RCTs and the TIght COntrol of Psoriatic Arthritis (TICOPIA) trial were analyzed. The standardized response mean (SRM, mean difference between baseline and follow up divided by the standard deviation (SD) of the mean difference) and standardized mean differences (SMD, mean difference in the treated group minus the mean difference in the placebo group divided by the pooled SD for the change) were used to address responsiveness and discrimination respectively. TJC28, SJC28, TJC68, and SJC66 were the pooled SD for the change) were used to address responsiveness and discrimination respectively. TJC28, SJC28, TJC68, and SJC66 were the 3 or less vs 4 or more active joints.

Results: In traditional phase III RCTs, TJC and SJC were responsive and had good clinical trial discrimination. SRMs were similar and ranged from -0.8 to -0.4 (‘moderate’ responsiveness) (Figure 1). SMDs were similar among SJC28 and SJC66 and likewise between TJC28 and TJC68 but mostly within the small effect range (-0.2 to -0.5; not shown). PhGA and PIGA had higher SMDs than the joint counts. SRMs were substantially lower for joint counts (and also PIGA) among the low compared with the higher joint count groups (Figure 2). There were no substantial differences in SRMs between patients with early and established disease.

Conclusion: Joint counts are responsive to change and have reasonable discrimination in RCTs among patients higher disease activity at baseline. However, joint counts may not be ideal outcome measures in oligoarticular disease and have lower responsiveness and discrimination in this subgroup.

### IMPROVEMENT IN THE SIGNS AND SYMPTOMS OF PSORIATIC ARTHRITIS WITH IXEKIZUMAB COMPARED TO PLACEBO IN PATIENT SUBGROUPS DEFINED BY BASELINE DISEASE CHARACTERISTICS

Hans-Peter Tony1, Eva Galindez2, Aubrey Trevelin Sprabery3, Amanda M. Gelett4, Chen-Yen Lin1,2, So Young Park2, Clinton C. Bertram3, Alexis Ogdie4, 1University Hospital of Würzburg, Würzburg, Germany; 2Hospital de Basurto, Bilbao, Spain; 3Eli Lilly and Company, Indianapolis, United States of America; 4Penn Medicine, Philadelphia, United States of America

**Background:** Ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets interleukin-17A, was superior to placebo (PBO) in two randomized Phase 3 studies in patients (pts) with active psoriatic arthritis (PsA).1,2

**Objectives:** To assess the consistency of response of IXE across subgroups of pts defined by specific baseline disease characteristics.

**Methods:** Data were analyzed from an integrated database of 2 randomized, double-blind, Phase 3 studies in pts who were either biologic Disease Modifying Anti-Rheumatic Drug (bDMARD)-naïve (SPIRIT-P1) or who had prior inadequate response or intolerance to TNF inhibitors (SPIRIT-P2). Analyses included pts randomly assigned to the approved dosing regimen of IXE (80 mg IXE every 4 wks [IXE Q4W] with a starting dose of 160 mg IXE) or to PBO through Week 24. Efficacy was measured as the percentage of pts achieving ≥20%, 50%, or 70% improvement from baseline in the American College of Rheumatology criteria (ACR20/50/70) or minimal disease activity (MDA) in subgroups of pts defined by baseline presence of enthesitis, presence of dactylitis, percentage of psoriasis body surface area (BSA) involvement (<3% or ≥3%), and c-reactive protein (CRP >6 or ≤6 mg/L).

**Results:** Clinical response rates at Week 24 in each subgroup are summarized (Table). Significantly (p<0.05) more patients achieved ACR20, ACR50, ACR70, and MDA with IXE compared to placebo across patient subgroups defined by presence of enthesitis, presence of dactylitis, percentage of psoriasis BSA involvement, and by CRP levels at baseline.

**Conclusion:** At Week 24, IXE was superior to placebo for the treatment of PsA signs and symptoms regardless of baseline presence of dactylitis or enthesitis, BSA involvement, or CRP levels.

### DESCRIPTIVE COMPARISONS OF THE IMPACT OF APRIMELAST AND METHOTREXATE MONOTHERAPY ON PATIENTS WITH OLIGOARTICULAR PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS REGISTRY

Alexis Ogdie1, Mei Li2, Meghan Glynis3, Kleachi Emeauru2, Leslie Harrold3, Sven Richter1, Benoît Guerette4, Philip J. Mease5. 1University of Pennsylvania, Philadelphia, United States of America; 2Corrona, LLC, Waltham, United States of America; 3University of Massachusetts Medical School, Worcester, United States of America; 4Celsius Corporation, Summit, United States of America; 5Swedish Medical Center and University of Washington School of Medicine, Seattle, United States of America

**Background:** Therapeutic effectiveness has rarely been studied in a subpopulation of patients with oligoarticular PsA.

**Objectives:** To examine baseline characteristics and 6-month clinical assessments of PsA patients with oligoarthritis (≤5 swollen joints) who initiated apremilast (APR) or methotrexate (MTX) monotherapy in the Corrona PsA/SpA Registry, a prospective, US-based, observational cohort study. Patients initiating bDMARD monotherapy were also examined as a point of reference.

**Methods:** Patients >18 years of age with PsA and oligoarthritis in the registry who initiated APR, MTX or a bDMARD (reference group) monotherapy and had a 6-month follow-up visit between June 2014 and March 2018 were included. Descriptive statistics were calculated for patients’ clinical characteristics and disease assessments at treatment initiation and at the 6-month follow-up visit.

**Results:** The analysis included 150 patients initiating therapy (APR: n=34; MTX: n=15; bDMARD: n=101). Among APR and MTX initiators, 79% and 20% received at least 1 prior bDMARD, respectively. APR initiators, compared with MTX initiators, were younger (mean [SD]: 55.7 [12.6] vs. 61.5 [16.6] years), had longer disease duration (mean [SD]: 8.0 [6.7] vs. 5.4 [7.6] years), and had higher levels of disease activity

**DOI:** 10.1136/annrheumdis-2019-eular.1659

---

**NOTE:** The above text contains the abstracts of scientific research articles. For a comprehensive understanding of the research, it is recommended to read the full articles. The tables provide a summary of clinical responses at Week 24 in subgroups defined by baseline disease characteristics.
at baseline, including greater skin involvement (mean body surface area affected [SD]: 7.1% [17.6%] vs. 4.8% [9.4%]), swollen joint count (mean [SD]: 1.5 [1.5] vs. 1.0 [1.1]) and Clinical Disease Activity for Psoriatic Arthritis (cDAPSA) moderate and high disease activity (50% [APR] vs. 20% [MTX]), mean score [SD]: 14.0 [8.5] vs. 11.5 [4.9]). APR initiators also had greater disease impairments at baseline, represented by numerically higher scores on patient-reported outcome (PRO) measures, including the Health Assessment Questionnaire-Disability Index (HAQ-DI) [mean [SD]: 1.0 [0.7] vs. 0.5 [0.4]). Patient's Global Assessment of Disease Activity–Psoriasis (PIGA-PsO; mean [SD]: 47.1 [29.4] vs. 28.4 [16.6]; Patient's Global Assessment of Disease Activity–Psoriasis (PIGA-PsA; mean [SD]: 47.1 [29.6] vs. 32.5 [26.3]), fatigue (mean [SD]: 55.9 [35.0] vs. 37.3 [31.9]) and overall pain (mean [SD]: 50.5 [31.1] vs. 46.7 [26.5]). Taken together, results suggest that APR initiators had more refractory oligoarthritis compared with MTX initiators. Clinical assessments at the 6-month follow-up indicate that patients who initiated APR experienced numerically higher improvements in disease activity and various PRO measures compared with MTX, as well as achievement of ≤1 swollen joint, HAQ-DI minimal clinically important difference and cDAPSA remission or low disease activity (Table). Of note, results associated with bDMARDs were more comparable to that of APR.

Conclusion: In this analysis of the Corona PsA/SpA Registry, APR monotherapy was more often used in patients with refractory oligoarthritis compared with MTX monotherapy. Despite this, the APR treatment group experienced numerically greater improvements in disease activity measures. Improvements observed with APR treatment in patients with longstanding disease and refractory oligoarthritis were comparable to that of bDMARDs.

EVALUATION OF THE PREDICTIVITY OF THE THERAPEUTIC RESPONSE ACCORDING TO THE PRESENCE OF METABOLIC COMORBIDITIES IN PATIENTS WITH PSORIATIC ARTHRITIS: OBSERVATIONAL RETROSPECTIVE STUDY

Simone Parisi1, Davide Mohammad Reza Beigi2, Marta Priora3, Maria Chiara Ditto4, Chiara Lisa Peroni5, Angela Lagani6, Enrico Fusaro7, 1.A.O.U. Città della Salute e della Scienza, Rheumatology, Turin, Italy

Background: Psoriatic Arthritis (PsA) is a systemic chronic inflammatory disease, which leads to an increased oxidative stress and to endothelial alterations, with increased cardiovascular and metabolic risks. These conditions explain the high prevalence of myocardial infarction, cerebrovascular accidents, diabetes mellitus, obesity, steatohepatitis, alterations of lipid set and an increased prevalence of metabolic syndrome in patients with PsA. The results of other studies suggest that these comorbidities could negatively influence the disease activity and the therapy response in patients with PsA.

Objectives: The aim of the study is to evaluate a population of patients with PsA treated with biological drugs (bDMARDs) and the achievement of MDA during the observation.

Methods: Ninety-eight patients with PsA treated by DMARDs from January 2016 to January 2018 were enrolled. Data were collected for 24 months of treatment, related to the check-ups performed every three months. Demographic and clinical characteristics, cardiovascular risk factors and cardio-metabolic comorbidities, disease joint involvement at baseline and the assumed therapy were analyzed. The association with the presence of MDA at 0 months and 24 months was evaluated for each of these parameter. Age and gender were adjusted. Cardiovascular risk factors and cardio-metabolic comorbidities were analyzed at baseline and after 24 months. The aim of the study was to evaluate the population of patients with PsA treated with biological drugs (bDMARDs) and the achievement of MDA at 0 months and 24 months.

Results: Male sex was more associated with the condition of MDA both at baseline (p = 0.01) and at 24 months (p = 0.04). A statistically significant association was found between the presence of cardio-vascular accidents (stroke and TIA) and the disease status was found at baseline: amongst patients with such comorbidity, 75% were not found in MDA at time 0 (p = 0.03). The same result was not found in relation to MDA after 24 months. No other cardio-metabolic comorbidity was associated with a worse outcome. There was no association with a better outcome for any of the two classes of biological drugs considered (anti-TNF-α and not anti-TNF-α). Polycarticular involvement was associated with a worse disease status, both at baseline (p = 0.01) and after 24 months of therapy (p = 0.04).

Conclusion: In the current study, the polycarticular form of PsA present at baseline was the most associated factor (OR 0.44) with a worse outcome in a population of patients with cardio-metabolic comorbidities on bDMARDs. Cerebro-vascular accidents appeared as the only morbidity condition associated with a worse state of disease at the beginning of the observation, but this correlation disappears after 24 months. This result can be justified by the immunosuppressive treatment, which decreases the risks related to the inflammatory condition characteristic of PsA.

SAT0399

EFFECT OF DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS ON BONE STRUCTURE AND STRENGTH IN PSORIATIC ARTHRITIS PATIENTS

Background: In contrast to rheumatoid arthritis, little is known about the effect of disease modifying anti-rheumatic drugs (DMARDs) on bone structure and bone biomarkers in psoriatic arthritis (PsA).

Objectives: To address whether the use of methotrexate (MTX) and biologic DMARDs (bDMARDs) impacts bone structure and biomechanical properties in PsA patients.

Methods: Cross-sectional study in PsA patients receiving no DMARDs, MTX or bDMARDs. Volumetric bone densities (vBMD), microstructural parameters and biomechanical properties (stiffness/failure load) were determined by high-resolution peripheral quantitative computed tomography (HR-pQCT) and micro-finite element analysis. Bone parameters were compared between PsA patients with no DMARDs and those receiving any DMARDs, MTX or bDMARDs, respectively.

Results: 165 PsA patients were analyzed, 79 received no DMARDs, 86 received DMARDs, of them 52 bDMARDs (TNF, IL-17- or IL-12/23 inhibitors) and 34 MTX. Groups were balanced for age, sex, comorbidities, functional index and bone-active therapy, while disease duration was longest in the bDMARD group (7.8±7.4 years), followed by the MTX group (4.6±7.4) and the no-DMARD group (2.9±5.2). No difference in bone parameters was found between the no-DMARD group and the MTX group. In contrast, the bDMARDs group revealed significantly higher total (p<0.001) and trabecular vBMD (p=0.005) as well as failure load (p=0.012) and stiffness (p=0.012). In regression models age and bDMARDs influenced total vBMD, while age, sex and bDMARDs influenced failure load and stiffness.

Conclusion: Despite longer disease duration bDMARDs treated PsA patients benefit from higher bone mass and better bone strength than PsA patients receiving MTX or no DMARDs. These data support the concept of better control of PsA-related bone disease by bDMARD.

REAL-WORLD SWITCH RATES AMONG BIOLOGIC-NAIVE PSORIATIC ARTHRITIS PATIENTS INITIATING APREMILAST, TUMOR NECROSIS FACTOR INHIBITORS OR INTERLEUKIN INHIBITORS

David Kaplan1, Brian Ung2, Corey Pelletier2, Chuka Udede2, Marc Tian2, Adult and Pediatric Dermatology, Overland Park, United States of America; 1Celgene Corporation, Summit, United States of America

Background: Psoriatic arthritis (PsA), an inflammatory arthritis, manifests in joints and surrounding tendons and ligaments. As PsA progresses, patients may switch from 1 therapy to another, discontinue medication or use agents in combination. Previous real-world studies have demonstrated that treatment adherence and biomarker treatment rates for biologic-naive PsA patients initiating apremilast or biologics (ie, tumor necrosis factor [TNF] and interleukin [IL] inhibitors) are not different.3,4 Treatment switching is common among PsA patients.

Objectives: This study compares the rate of treatment switching among adult patients initiating treatment with apremilast, TNF inhibitor or IL inhibitors.

Methods: Adult patients with PsA were identified if they newly initiated treatment with apremilast, a TNF inhibitor (adalimumab, certolizumab, etanercept, golimumab, infliximab) or an IL inhibitor (ixekizumab, secukinumab, ustekinumab) between January 1, 2015, and December 31, 2016, and had a minimum of 12 months pre-index and post-index continuous enrollment in the Truven Health (now IBM Watson) MarketScan® Commercial and Medicare Supplemental Database. Propensity score matching, based on available demographic and clinical characteristics, up to 1:2, was utilized between apremilast and biologic patients. Switch was defined as a claim for a new PsA treatment after initiation of the index medication. Days to switch was defined as the number of days between the index date and date of switch. Adherence was assessed utilizing the proportion of days covered (PDC). Outcomes were assessed every 3 months, up to 24 months. 7,802,000 members with baseline and linkage availability were included. 2,793,604 members were included in the Truven Health Truven Health (now IBM Watson) MarketScan® Commercial and Medicare Supplemental Database.

Results: 471 biologic-naive PsA patients initiating apremilast were matched to 890 biologic-naive PsA patients initiating biologics (TNF: n=804; IL: n=86). Patient characteristics were similar between the 3 cohorts (mean age: 50 years; Charlson Comorbidity Index: 0.58 [apremilast], 0.55 [TNF] and 0.56 [IL]). There was a greater proportion of females in the apremilast vs IL cohorts (55% vs 42%; P=0.0249) and a lower proportion of patients with prior PsA systemic treatment (59% vs 79%; P=0.0048). In the TNF cohort, 64% patients received adalimumab, 29% etanercept, 4% infliximab, 2% certolizumab and 1% golimumab. In the IL cohort, 78% of patients received ustekinumab, 21% secukinumab and 1% ixekizumab. At 12 months, significantly fewer patients initiating apremilast switched treatment compared with those initiating TNF inhibitors (15.5% vs 26.6%; P=0.0001), while no significant differences were observed for apremilast vs IL patients (15.5% vs 14%; P=0.714). Similar switching trends were observed at 24 months for patients initiating apremilast vs TNF (25.0% vs 36.5%; P=0.0109) or those initiating apremilast vs IL (25.0% vs 26.7%; P=0.8465). Among those switching by 12 months, mean days to switch was similar between biologic and apremilast patients (199 vs 200 days; P=0.9759) and between IL patients (199 vs 227 days; P=3.602). Patients initiating apremilast had a similar treatment adherence rate as patients initiating a TNF inhibitor (PDC: 0.81 vs 0.84; P=0.0749) and a higher treatment adherence rate than patients initiating an IL inhibitor (0.81 vs 0.79; P=0.0071).

Conclusion: Biologic-naive PsA patients initiating apremilast demonstrated lower switch rates vs biologic-naive PsA patients initiating TNF inhibitors in a large US administrative claims database. No difference in rates of switching was observed between apremilast and IL patients.

SAT0401

USE OF AND RESPONSE TO METHOTREXATE IN EARLY PSORIATIC ARTHRITIS: RESULTS FROM THE REAL WORLD COHORT, DEPAR STUDY

Kim Wervers1, Hannah den Braanker1, Jolanda Luime1, Ilja Tchetverikov2, Andreas Gerards3, Cathelijne Appels4, Webo van der Graaff5, Hans van Groenendaal5, Linda-Anne Korswagen5, Josien Verla-Verdier7, Johanna Hantes1, Marc Kof1, Marj Vin1, CICERO, Erasmus MC, Rotterdam, Netherlands; 2Albert Schweitzer Hospital, Dordrecht, Netherlands; 3Franciscus Gasthuis and Vlietland, Schiedam, Netherlands; 4Amphia Hospital, Breda, Netherlands; 5Rivus Hospital, Gorinchem, Netherlands; 6Rehausing Zuid West Nederland, Roosendaal, Netherlands; 7Background: Methotrexate (MTX) is the preferred drug of most rheumatologists for treating psoriatic arthritis (PsA). Despite its widespread use in

Scientific Abstracts
clinical practice, scientific evidence of methotrexate on the different manifestations of psoriatic disease is limited. Specifically, data of MTX use in usual care and in early PsA patients are lacking.

Objectives: To describe the response to MTX for patients with PsA and an oligoarthritis or polyarthritis phenotype in usual care in the first year after diagnosis, and its impact on different aspects of the disease, including patients not achieving minimal disease activity (MDA) despite continuous exposure to MTX.

Methods: Data collected in the Dutch southwest Early Psoriatic Arthritis cohort (DEPAR) study were used. Patients with a new diagnosis of PsA who have not started disease-modifying antirheumatic drugs (DMARDs) for PsA were eligible to participate. In this analysis, only patients with a phenotype at time of diagnosis of oligoarthritis or polyarthritis (resp. 2-4 joints involved or 5 or more joints, as defined by the rheumatologist), and at least one year follow up were included. Research nurses collected clinical data and data on medication use every three months in the first year after diagnosis. The following outcomes were used to evaluate disease activity: MDA, EULAR active disease (at least one tender and swollen joint), disease activity index for PsA low disease activity (DAPSA-LDA: DAPSA<14), and disease activity score 28 low disease activity (DAS28-LDA: DAS28<3.2). Disease activity at six months of patients who started MTX within six months after diagnosis and have continued using MTX until one year after diagnosis was analyzed.

Results: In April 2018, 219 patients had a phenotype of oligoarthritis (n=134; 61%) or polyarthritis (n=85; 39%) at time of diagnosis, and at least one year follow up. In 183 (84%) patients, MTX monotherapy was started within six months after diagnosis. Within the first year, 23 of these used MTX intermittently, 25 switched to a different DMARD, and 45 started a different DMARD while remaining on MTX therapy. The remaining 90 patients used MTX monotherapy throughout the first year and of these we assessed disease activity at 6 months after diagnosis. At 6 months, 38 patients out of these 90 were not in MDA despite continuous MTX treatment, while 44 achieved MDA. Major differences amongst the two groups included tender joint count, physical function, evaluation of pain and global disease activity and impact on health-related quality of life scores (Table 1). Conversely, 18% of all patients started MTX monotherapy were in sustained MDA at one year while continuing MTX monotherapy.

Conclusion: The majority of patients with a new diagnosis of PsA with a phenotype of oligoarthritis or polyarthritis started MTX within a year after diagnosis. MTX is maintained as monotherapy in half of these patients, with 18% of them achieving sustained MDA using MTX monotherapy at one year. Interestingly, approximately half of the patients who had continued methotrexate monotherapy were not achieving MDA after six months and they report higher impact of disease on clinical and patient reported outcomes, suggesting need to consider improvement of therapy for these patients.

SEX DIFFERENCES ARE PRESENT IN CLINICAL CHARACTERISTICS, BUT NOT IN RESPONSE TO DIFFERENT URATE LOWERING THERAPIES IN PATIENTS WITH GOUT

Sophie Wanten1, Minke Ter Stal1, Wing-Yee Kwok2, Frank van den Hoogen1,3, Marcel Fiendrie1, Noortje van Herwaarden1,2,3, Sint Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands; Rijnstate ziekenhuis, Department of Rheumatology, Arnhem, Netherlands; RadboudUMC, Department of Rheumatology, Nijmegen, Netherlands

Background: Clinical characteristics of gout differ between women and men. Little however is known about the association between these differences and response to treatment. As women seem to have lower mean uric acid excretion compared to men, response to uricosuric agents might be better compared to xanthine oxidase inhibitors.

Objectives: To identify sex differences in clinical characteristics and response to urate lowering therapy (ULT) in patients with gout and in women difference in response to allopurinol or benzbromarone.

Methods: Patients with clinical diagnosis of gout, a first outpatient visit between January 2010 and March 2018 and a follow-up of at least 6 months were included in a retrospective cohort study, with ongoing recruitment, conducted in two rheumatology centres in the Netherlands. From this cohort, patients who started ULT were selected. Clinical characteristics and treatment outcomes of allopurinol and benzbromarone were compared between women and men, including drug survival (corrected for age and renal function) and cumulative incidence of achieving target serum uric acid (<0.36 mmol/l). In women, difference in cumulative incidence of achieving target serum uric acid while using allopurinol or benzbromarone was compared.

Results: From a total of 519 (105 women/414 men) patients, 513 (104 women/409 men) and 74 (18 women/56 men) patients were included in the allopurinol and/or benzbromarone group, respectively. Clinical characteristics are described in Table 1. Drug survival was similar for women and men for allopurinol (hazard ratio 1.08, 95% confidence interval (CI) 0.71-1.64) as well as for benzbromarone (hazard ratio 0.66, 95% CI 0.26-1.66) (Figure 1a and b). Cumulative incidences of achieving target serum uric acid while using allopurinol or benzbromarone was compared.

*P-values for categorical variables were calculated by chi-square analysis, for continuous variables the appropriate (non)parametric analysis was used based on Gaussian distribution.
failed maximal medical management, typically with xanthine oxidase inhibitors (XOI). Studies have shown a complete responder rate of 42% when defined as repeat serum uric acid (sUA) levels <6.0 mg/dL for >80% of the time during months 3 and 6 of treatment. Patients that do not maintain a low uric acid while on pegloticase therapy are presumed to have developed anti-drug antibodies (ADA) which rapidly clear the pegloticase molecule. As is routinely utilized in the treatment of other rheumatologic diseases, coadministration of immunomodulatory medications, such as methotrexate, could potentially temper the development of these ADAs (as defined by maintenance of sUA response) in patients treated with pegloticase for refractory gouty arthropathy.

Objectives: The aim of the current case series was to identify and clinically evaluate patients in a real-world practice setting in order to investigate the use of adding methotrexate to a pegloticase regimen to increase the durability of response.

Methods: In this prospective, proof-of-concept, observational case series, 10 sequential patients with refractory tophaceous gouty arthropathy being started on treatment with pegloticase 8 mg every two weeks (as per the label) were identified from 3 separate infusion centers. No inclusion/exclusion criteria were implemented or prescreening performed. Methotrexate (MTX) 15 mg orally once weekly and folic acid 1 mg orally once daily was started one month prior to the initial administration of pegloticase and continued throughout pegloticase treatment. Any infusion pre-medication, which were consistent with standard practices, were administered per the individual physician’s discretion as well as management of any gout flares which occurred during the treatment course. As per standard of care, sUA was measured every two weeks, prior to each subsequent infusion. At the completion of pegloticase treatment for all patients, the number and percentage of patients able to maintain an sUA at goal <6.0 mg/dL was recorded.

Results: Ten patients ranging in age from 35-80 were identified, from 3 separate infusion centers. There were 143 total pegloticase infusions performed within the observation period. All 10 patients received at least 10 infusions (5 months), 9 patients at least 12 infusions (6 months), 5 patients at least 16 infusions (8 months), 2 patients at least 18 infusions (9 months), and 1 patient received 19 infusions. All 10 patients completed a full course of pegloticase treatment. All patients stayed on MTX 15 mg/week. There were no dose adjustments made in the MTX doses of patients were responders as defined by >80% of sUA levels being maintained at goal <6.0 mg/dL during the observation period. None of the 10 patients stopped pegloticase therapy due to increased sUA or loss of response and there were no infusion reactions in any of the 143 infusions or safety concerns identified. Gout flares did occur, primarily following the initial infusion, with less severity/prevalence with subsequent infusions. No patients discontinued treatment because of flares.

Conclusion: In this proof-of-concept case series of 10 sequential patients, pretreatment and co-administration of methotrexate 15 mg orally once weekly and folic acid 1 mg orally once daily with pegloticase resulted in a 100% maintenance of pegloticase sUA response with no infusion reactions. Although additional studies would be needed to corroborate these results, these data support a potential paradigm shift in treatment of refractory gout with pegloticase.

COMPUTED TOMOGRAPHIC MAPPING OF SPINAL AND VASCULAR URATE DEPOSITION IN THE ABDOMEN WITH CORRELATION TO URIC ACID LEVEL

Juvel Lee1, Waheed Abdelfattah2, Sunghan Jung1, Ahmed Neiga3, Bo Gong4, Savvas Nicolaou1, Faculty of Medicine, University of British Columbia, Vancouver, Canada; 2University of British Columbia/Vancouver General Hospital, Radiology, Vancouver, Canada; 3Faculty of Medicine, Zagazig University, Zagazig, Egypt; 4Vancouver General Hospital, Vancouver, Canada; 5University of British Columbia/Vancouver General Hospital, Vancouver, Canada

Background: Gout is characterized by accumulation of monosodium urate (MSU) in joints and soft tissues. Gout prevalence is about 1-5% in the general population, predominantly in elderly men. Accurate diagnosis of gout is paramount in managing disease progression and guiding treatment. A meta-analysis in 2018 showed that Dual-Energy CT (DECT) has high sensitivity, specificity and diagnostic accuracy in MSU detection. MSU...
deposition outside ‘classic’ extremities has been scarcely investigated yet may be a potential indicator of tophus burden and impending clinical deterioration.

**Objectives:**
1. Anatomical mapping of gout deposition in the abdomen (vessels, solid organs and lumbosacral spine).
2. Determine correlation between uric acid level and vascular, solid organ and spinal MSU deposition.

**Methods:** Retrospective analysis of all DECT abdomen and pelvis scans done in our institution (from January 2007 to July 2018). The inclusion criteria were: males > 50 years with high or normal uric acid levels who were asymptomatic for gout. Validated dual-energy gout analysis software was used.

**Results:** 235 DECT cases met the inclusion criteria. Medical Record document review showed no diagnosis of gout in any patient in the sample. By the time this abstract was submitted, 166 cases were reviewed. The analyzed sample (n = 166), showed MSU deposits (1 or more deposits) in the abdominal aorta (n = 48/166; 28.92%), abdominal vessels other than aorta (n = 57/166; 34.34%) and lumbosacral spine (n = 15/166; 9.04%). No deposits were detected in the solid abdominal organs (n = 0/166; 0%). There was a statistically significant positive correlation between uric acid level and spinal deposits (r= 0.22, P= 0.004). Regression analysis showed uric acid levels can’t significantly predict the presence of aortic, vascular or spinal deposits.

**Conclusion:**
Computed tomographic mapping of MSU deposits was positive in the abdominal aorta, other abdominal vessels and lumbosacral spine in patients with normal or high uric acid levels who were asymptomatic for gout. Uric acid level was positively correlated with spinal gout, but not with aortic or vascular gout. Interestingly, uric acid levels can’t significantly predict the presence of aortic, vascular or spinal gout. Larger sample size, wider variation in uric acid levels are still needed.

comorbidities. Not believing in medication may impact on the success of achieving these treatment goals.

Objectives: To study which factors were associated to and predictive of beliefs about medicines during one year in patients with a recent gout attack and a need for ULT.

Methods: Baseline data from a prospective observational study were used in patients with crystal-proven gout after a recent gout flare and insufficiently treated serum urate (sUA) level (>360 μmol/L)/>6 mg/dl. In these patients a treat-to-target approach was planned to meet the treatment target (sUA <360 μmol/L, or <300 μmol/L if clinical tophi). Assessments included demographic and clinical data, baseline serum urate levels, medication, comorbidities, physical function (HAQ), and SF-36 mental (MCS) and physical component summary scores. The Beliefs in Medicines Questionnaire (BMQ) (1) queries patient beliefs about medicines on four subscales (necessity and concerns specific for the patient, generally on overuse and harm). Respondents indicated their degree of agreement with each individual statement about medicines on a 5-point Likert scale, (1=strongly disagree to 5=strongly agree). Scores within the four subscales were summed (ranges 5-25 for necessity and concern, 4-20 for overuse and harm). Calculation of the difference within the four subscales were summed (ranges 5-25 for necessity and concern, 4-20 for overuse and harm). Respondents indicated their view on taking medication, and was grouped as high and low relative to the median.

Using multivariate analysis with logistic regression, baseline variables were explored as predictors of high beliefs in the relative importance of medication after 12 months.

Results: 202 patients were included at baseline, 94.1% men, 90.3% Caucasian, mean (SD) age 56.6 (14.2) years, disease duration 8.0 (7.7) years. Mean sUA level was 494 (SD 86.8) μmol/L at baseline, body mass index 28.9 (4.6) kg/m², and physical function (HAQ) 0.36 (0.57), 18.8% (n=28) had tophi, and 30.4% (n=55) were previous users of allopurinol.

During the first year the beliefs in necessity of medication and the perceived importance of medication increased, while the concerns decreased.

Table: Beliefs in Medicines Questionnaire (BMQ) subscales. *=p<0.05, **=p<0.01 vs. baseline

Bivariate comparisons studying demographic, medication and clinical variables did not show consistent cross-sectional associations with beliefs in the importance of medication. However, after 12 months, bivariate comparisons revealed statistically significant differences in mental health (SF36 MCS), physical function (HAQ) and self-efficacy for symptom control. In logistic regression analyses, adjusting for age, gender, BMI and comorbidities, prediction of high beliefs in the relative importance of medication after 12 months were independently associated with baseline self-efficacy for symptom control (OR 1.04 per unit, 95% CI 1.01-1.06).

Conclusion: During one year of treat-to-target strategy in patients with gout, perceived necessity of medication and higher importance of medication increases. Self-efficacy for symptom control at baseline was an independent predictor of high beliefs in importance of medication after 12 months. These findings support that patients increase their perception of the necessity of beliefs in medication during a treat-to-target approach with ULT.

SAT0408 BODY FAT MEDIATES THE CORRELATION BETWEEN FRUCTOSE-CONTAINING BEVERAGES CONSUMPTION AND SERUM URIC ACID IN MALE GOUT PATIENTS

Li Qianhua, Lijuan Yang, Yan-Hui Xu, Chao Deng, Jinjian Liang, Jianzi Lin, Lefeng Chen, Lie Dai, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Department of Rheumatology, Guangzhou, China

Background: Fructose-containing beverages (FCB) consumption has been recognized as a promoter of hyperuricemia and gout in recent years. FCB consumption also contributes to the development of obesity which is an important risk factor of gout. However, data about the associations among FCB consumption, obesity and the level of serum uric acid (sUA) is limited.

Objectives: To investigate the associations among FCB consumption, obesity and sUA level in gout patients.

Methods: Consecutive gout patients who fulfilled the 2016 ACR/EULAR classification criteria were recruited. Demographic information, clinical characteristics and comorbidities of gout were collected. A 10-items food frequency questionnaire was developed which included alcohol, red meat, animal offal, seafood, hotpot, slow-cooking soup, FCB, tea, coffee and milk/milk products. Patients were asked to report the average consumption frequency over the one year prior to the first gout attack. Body composition was assessed by bioelectric impedance analysis and overweight was defined by body fat percentage (BF%) as ≥25% for men and ≥35% for women.

Results: 1) Among 331 recruited gout patients, 96.1% were male, so only male patients were further analyzed. The median age of male patients was 37.5 (30, 49) years and median sUA was 9.5 (7.8, 10.5) mg/dl with 18.9% presented tophi. The mean BF% was 25.6±6.2% and 54.7% male patients were overfat. The prevalence of hypertension, diabetes, dyslipidemia, metabolic syndrome and fatty liver were 34.6%, 8.5%, 62.9%, 44.3% and 46.9% respectively. 2) There were no significant differences of food intake frequency between overweight patients and normal fat patients. Spearman correlation analysis results showed that FCB consumption was positively correlated with BF% (r=0.176, P=0.002), while milk/milk products consumption was negatively correlated with BF% (r=-0.117, P=0.038). After adjusted by age, duration, family history, eGFR, hypertension, diabetes mellitus, dyslipidemia, metabolic syndrome, fatty liver and the other nine dietary factors, multivariable linear regression showed that FCB consumption was positively correlated with BF% (compared with <1 time/w, 3-4 times/w: coefficient β=2.4619, 95%CI 0.3580~4.5657, P=0.022; 4 times/w: coefficient β=2.6696, 95%CI 0.8266~4.5726, P=0.0049), and BF% was positively correlated with sUA (coefficient β=0.0784, 95%CI 0.0228~0.1239, P=0.001). However, FCB consumption was not correlated with sUA after adjusted by above confounders and BF% (P=0.079). 3) Further mediation analysis were performed to evaluate whether BF% mediated the correlation between FCB consumption and sUA. After adjusted by the confounding factors mentioned above, the total effect of FCB consumption on sUA was significant (compared with <1 time/w, >4 times/w: coefficient β=0.8813, 95%CI 0.1457~1.6169, P=0.019), BF% produced indirect effect on the correlation between FCB consumption and sUA (compared with <1 time/w, >4 times/w: indirect effect coefficient β=0.2115, 95%CI 0.0453~0.4032).

1292 Saturday, 15 June 2019

Scientific Abstracts
Conclusion: Our data show that body fat mediates the correlation between FC8 consumption and SUA in male gout patients, which imply the importance of body composition assessment.

RADIOPHARMACEUTICAL EROSION SCORE IMPROVED WITH TARGETED URATE-LOWERING THERAPY IN A PROSPECTIVE GOUT VIETNAMESE COHORT

Thomas Bardin1; Quang Dinh Nguyen2; Khoi Minh Tran3; Nghia Hieu Le3; Duc Minh Do5; Valerie Bousson4; Pascal Richelet1; Matthieu Resche-Rigon4; Hippar Larboisire, Rheumatology, Paris, France; 1Vien Gu Medical Center, French-Vietnamese research center on gout and chronic diseases, H0 Chi Minh City, Vietnam; 2University of Medicine and Pharmacy, Molecular Biology, Ho Chi Minh City, Vietnam; 3Hippar Larboisire, Radiology, Paris, France; 4Hôpital Saint Louis, Biostatistics, Paris, France

Background Urate deposition in joints of patients with neglected gout leads to destructive arthropathy, with subchondral bone erosion, bone construction, and late joint space narrowing. Gouty erosions are believed to improve under urate lowering drugs (ULDs), but their course has been little studied. We therefore performed a systematic prospective study of a Vietnamese cohort started on allopurinol at inclusion.

Objective: To characterize radiographic outcome of gouty erosions under serum urate-targeted ULDs, but their course has been little studied. We therefore performed a systematic prospective study of a Vietnamese cohort started on allopurinol at inclusion.

Methods: 120 male Sprague-Dawley rats were randomly divided into 3 groups: After establishment of acute gouty arthritis model, rats were given P2X7R agonist ATP, P2X7R inhibitor BBG and PBS, respectively. The clinical manifestations of the ankle joints were evaluated at 6h, 12h, 24h, 48h and 72h before the rats were sacrificed, and rat ankle synovial slices for H&E staining. IL-1β, IL-6 and TNF-α, suggest-

P2X7R PROMOTE THE ATTACK OF ACUTE GOUTY ARTHRITIS IN RATS FROM CLINICAL TO PATHOLOGY

Xiaojuan Dai1; Li Xiangpei2; Jinhu Tao2; Xuan Fang2; Yuan Xia2; Li Xiaomei2.
1The First Affiliated Hospital of University of Science and Technology of China, Rheumatology and Immunology, Hefei, China; 2The First Affiliated Hospital of University of Science and Technology of China, Rheumatology and Immunology, Hefei, China

Objectives: The aim of this study was to activate P2X7R signaling pathway through changes in extracellular ATP concentrations, leading to the development of acute gouty arthritis and the production of pro-inflammatory.

Methods: 120 male Sprague-Dawley rats were randomly divided into 3 groups: After establishment of acute gouty arthritis model, rats were given P2X7R agonist ATP, P2X7R inhibitor BBG and PBS, respectively. The clinical manifestations of the ankle joints were evaluated at 6h, 12h, 24h, 48h and 72h before the rats were sacrificed, and rat ankle synovial slices for H&E staining. IL-1β, IL-6 and TNF-α, in the synovial tissue of the right ankle joint of rats, at 12h, and 24h, the infiltration of mononuclear cell in ATP group was significantly higher than that in BBG group and control group (P=0.000, 0.007; P=0.000, 0.001); The neutrophils infiltration in ATP group was the highest among the three groups at 24h (P=0.001, 0.001), and the control group was higher than BBG group (P=0.04).

Conclusion: Activation of P2X7R can significantly promote the attack of acute gouty arthritis and the production of IL-1β, IL-6 and TNF-α, suggesting that P2X7R affects the development of acute gouty arthritis and regulates the secretion of pro-inflammatory cytokines.

p=0.004), -1.4 at 12 months (n=47, p=0.0001) and -4.2 at 24 months (n=14, p=0.001). Complete radiographic erosion healing was observed in only one foot joint in which a small baseline erosion disappeared on M33 radiograph. Erosion score decrease correlated with decrease of double contours at 12 months (rho=0.45, p=0.001) and with mean SUA between M3 and M12 (rho=0.59, p=0.03). A total of 41 joints (hand and foot DIPs, foot II-V PIPs) could not be scored due to score specifications. Prominent diaphysis erosions were seen in 6 patients and were not allowed scoring despite improvement. Bone construction and reappearance of bone contours were striking features of improved radiographs that were not measured by the score. Ankylosis of a toe joint was observed in 4 patients. Shrinking of 3 toes developed during dissolution of massive joint space/subchondral bone urate deposits.

Conclusion: Urate-lowering improved gouty erosion score, in correlation with decrease of uricemia and urate crystal load. However, complete erosion recovery was seldom observed during a median follow-up of 12 months. Increased bone production and massive urate dissolution under ULD occasionally led to 2 undescribed features of gouty arthropathy: joint ankylose and shrinking of involved toes respectively.

Background: Gout is associated with many metabolic and cardiorenal comorbidities. Several previous studies investigated the comorbidity patterns by cluster analysis; however, no such study has been based on the entire general population. As such, the generalizability, which is essential to these pattern analyses, remains unknown.

Objectives: We used cluster analysis on a large, representative general population sample of the United States to identify discrete phenotype patterns comorbidities observed in gout patients.

Methods: We used data from 8,607,137 participants in the 2007-2016 National Health and Nutrition Examination Survey (NHANES), a nationally representative sample of adults in the United States. Diagnosis of gout was based on survey of physician- or health professional-diagnosed gout. We used cluster analysis to identify subgroups among participants with gout with distinct comorbidity subgroups based on 9 variables: obesity, hypertension, diabetes, hypercholesterolemia, hypertriglyceridemia, coronary heart disease (CHD), heart failure (HF), chronic kidney disease (CKD), and liver disease.

Results: Cluster analysis identified 5 different subgroups (C1-C5) (Table 2). C1 had the highest proportion of patients with CKD (97%), C2 consisted of patients with gout but few other comorbidities. All patients in C3 had diabetes, but no HF, CHD, or CKD. C4 consisted primarily of patients with liver disease (85%), with high prevalences of lipid abnormalities and obesity. C5 had the highest proportion of patients with CHD and HF.

Conclusion: These findings from a nationally representative data of US adults indicate that gout comorbidities have 5 distinctive phenotypic patterns. These subgroups may have implications in pathogenesis of gout and/or for personalized care in the management of gout and comorbidities.

Disclosure of Interests: None declared

Background: Gout is a frequent and curable arthritis affecting 0.9% of adults in France. Its management remains suboptimal and less than one third of patients have efficient urate-lowering treatment (ULT). However, when individualized information were given and patients engaged in their care a treat-to-target strategy permits to achieve serum urate level (SU) at target (SU < 360 μmol/L) in more than 95% of patients. Therapeutic education sessions (TES) may improve patient knowledges, gout flare and ULT management.

Objectives: To assess the percentage of patients achieving SU target at 1 year after a TES.

Methods: TES was set up in the department since January 2014. Patients willing to participate to TES responded to a questionnaire and were interviewed with a nurse assessing their knowledges, believes and gout representations. Each TES included 5 to 8 patients and was conducted according to participants needs. We retrospectively included all patients who had attended one TES between 1st January 2014 and 31st December 2017 and who had at least one visit between 9 and 15 months later.

TES patients were matched in 1:1 with no-TES patients regarding age, sex and referent practitioner. For all patients were collected: demographics, disease duration, SU, treatments and comorbidities (type 2 diabetes, chronic kidney disease, hypertension, and cardiovascular diseases).

Results: Overall, 54 TES patients were included and matched with 54 non-TES patients. Patients’ characteristics (demographics, disease duration, SU, treatments and comorbidities) were similar at baseline except for the body mass index (BMI) and the follow-up. BMI was higher (31.0 ± 5.7 vs 28.4 ± 5.0 kg/m², p<0.03) and the final visit shorter (11 ± 3.6 vs 14.4 ± 4.8 months, p<0.001) in no-TES patients than in TES patients, respectively.

At final visit, 36 TES patients (67%) and 34 no-TES patients (63%) reached the SU target (< 360 μmol/L) (p=0.84) (Table 1). Moreover, 22 (41%) TES patients and 18 (33%) no-TES patients had a final SU < 300 μmol/L (p=0.43). There were no differences between groups (TES vs no-TES patients respectively) for: final SU (342 μmol/L ± 94 vs 338 ± 10.1136/annrheumdis-2019-eular.4032

Conclusion: The percentage of patients achieving SU target after one single TES was high compare to literature data. However, it was not different from usual care achieved in our department: a tertiary care center expert in gout management. The diffusion of our savoir-faire and the TES will improve gout management.

REFERENCE

Disclosure of Interests: Omar Al Tabaa: None declared, Etienne Gaix-Fontaine: None declared, Julia Herrou: None declared, Frederic Liote Grant/research support from: institutional grants from Grunenthal, Ipsen, Menarini, Novartis, SUA. TES will improve gout management.

Background: Patients with gout typically present to the hospital when their disease is acutely flared. It is therefore important to educate patients on the disease so that they become more aware of the importance of adhering to therapy. This can be achieved through Therapeutic Education Sessions (TES) which are patient centered, interactive, educational sessions that provide the patient with knowledge about their disease and the importance of adhering to therapy.

Objectives: The primary objective is to assess if TES will improve gout management.

Methods: TES were set up in the department since January 2014. TES was set up in the department since January 2014. Patients willing to participate to TES responded to a questionnaire and were interviewed with a nurse assessing their knowledges, believes and gout representations. Each TES included 5 to 8 patients and was conducted according to participants needs. We retrospectively included all patients who had attended one TES between 1st January 2014 and 31st December 2017 and who at least had one visit between 9 and 15 months later.

TES patients were matched in 1:1 with no-TES patients regarding age, sex and referent practitioner. For all patients were collected: demographics, disease duration, SU, treatments and comorbidities (type 2 diabetes, chronic kidney disease, hypertension, and cardiovascular diseases).

Results: Overall, 54 TES patients were included and matched with 54 non-TES patients. Patients’ characteristics (demographics, disease duration, SU, treatments and comorbidities) were similar at baseline except for the body mass index (BMI) and the follow-up. BMI was higher (31.0 ± 5.7 vs 28.4 ± 5.0 kg/m², p<0.03) and the final visit shorter (11 ± 3.6 vs 14.4 ± 4.8 months, p<0.001) in no-TES patients than in TES patients, respectively.

At final visit, 36 TES patients (67%) and 34 no-TES patients (63%) reached the SU target (< 360 μmol/L) (p=0.84) (Table 1). Moreover, 22 (41%) TES patients and 18 (33%) no-TES patients had a final SU < 300 μmol/L (p=0.43). There were no differences between groups (TES vs no-TES patients respectively) for: final SU (342 μmol/L ± 94 vs 338 ± 10.1136/annrheumdis-2019-eular.4032

Thus patients with smaller deposits were more likely to completely resolve the deposits.

Conclusion: We show that both life-style intervention and conventional urate lowering drug therapy reduce the volume of monosodium urate deposits. The size of MSU deposits, but not serum urate level, was the main factor that influenced complete resolution of deposits. This finding reemphasizes that the burden of deposits essentially defines the likelihood and time for complete resolution of gout.

CLINICAL PRESENTATION OF PAGET DISEASE OF BONE: IS IT CHANGING? A RETROSPECTIVE ANALYSIS ON 368 PATIENTS

Chiara Crofti, Francesca Zucchi, Andrea Becciolini, Luigi Sinigaglia, Massimo Varenna. ASST-Gaetano Pini-CTO, Division of Rheumatology, Milan, Italy

Background: In the last few years, it has been reported a secular change of Paget disease of bone (PDB), expressed as a reduction of prevalence and severity, assessed by disease extent.

Objectives: To retrospectively evaluate the baseline clinical and demographic characteristics of a contemporary cohort of patients affected by PDB, compared with a cohort of a previous decade.

Methods: Data were retrospectively extracted from a monocentric registry, which included PDB patients at their first evaluation in a tertiary rheumatology Center between January 2000 and September 2018. Descriptive data of baseline characteristics included demographics, presenting manifestation and diagnostic procedures (diagnosed by chance or by investigations requested for specific clinical manifestations), extent of PDB, and biochemical data. Patients were divided into two groups according to the year of first evaluation: group 1 before July 2007, group 2 after July 2007. Comparisons between the two groups were performed by T test and chi-square test; logistic regression was used to analyze the association between disease extent and other collected variables.

Results: The overall population included 368 patients (males (M) 57.6%, mean age at diagnosis [± standard deviation, SD] 62.0±12.4 yrs). Diagnosis was made by chance in 43.8% cases, 54.3% patients had symptoms at disease onset: 49.5% was monostotic, mean serum alkaline phosphatase at presentation (sALP) was 196.5±167.5 UI/L.

Group 1 included 217 patients (M 56.2%, mean age at diagnosis 61.0±11.6 yrs, 6.5% family history of PDB; 45.6% diagnosed by chance, 51.2% had symptoms at disease onset, mean sALP 218.9±11.7, 43.3% monostotic). Group 2 included 151 subjects (M 59.6%, mean age at diagnosis 64.3±11.1 yrs, 7.3% family history of PDB; 41.1% diagnosed by chance, 62.9% had symptoms at disease onset, mean sALP 162.7±14.2, 58.3% monostotic).

Poliostotic disease was significantly higher in Group 1 vs Group 2 (p=0.007), and the odd to have a poliostotic disease was higher in Group 1 (OR 1.82 (IC 1.2-2.8), p<0.005) sALP was significantly higher in Group 1 vs Group 2 (218.9±11.7 vs 162.7±14.2; p<0.003). No differences were found in sex, age at diagnosis, presence of family history of PDB between patients diagnosed incidentally or by symptoms.

Conclusion: Our data confirm the reduction of clinical severity, assessed by the proportion of skeleton involved, and the decrease of biochemical markers over time. The reduction of the disease extent is consistent with a serological biomarker of the disease, such as mean sALP levels.

SAT0414

HIGH BODY FAT OF TRUNK IS POSITIVELY CORRELATED WITH SERUM URIC ACID IN MALE GOUT PATIENTS

Li Qianhua, Lijuan Yang, Yan-Hui Xu, Chao Deng, Hui-Wen Lu, Xin-Yun Du, Jianjian Liang, Jianzi Lin, Yingqian Mo, Lie Dai. Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Department of Rheumatology, Guangzhou, China

Background: Obesity is an important risk factor of gout which is defined by body mass index (BMI). However, BMI has been challenged for the limitation of failure to differentiate comprising tissues of the body. More accurate body composition (BC) has been frequently recommended to assess metabolic status.

Objectives: To investigate the characteristics of BC in gout patients and its clinical significance.

Methods: Consecutive gout patients who fulfilled the 2016 ACR/EULAR classification criteria were recruited between June 2017 and December 2018. BC was assessed by bioelectric impedance analysis including body fat percentage (BF%), the mass and distribution of muscle and fat in trunk and appendicular extremities. Demographic information, clinical characteristics and comorbidities were collected. Overfat was defined by BF% >25% for male and >35% for female.

Results: Among 362 recruited gout patients, 96.1% were male and the median age was 38 (30, 50) years, mean serum uric acid (sUA) was 9.2±2.9mg/dl. 18.0% presented toplhi. The mean BF% was 25.8±6.4% with 53.6% overfat. Male gout patients with overweight (53.7%) showed more affecting joints, higher sUA and higher prevalence of comorbidities than those without overweight (p<0.05, Figure 1). Their BF%, trunk BF% and limb BF% were positively correlated with count of affecting joints, sUA, hypertension, metabolic syndrome and fatty liver in Spearman correlation analysis, respectively (r=0.133-0.424, a p<0.05). The male patients with overweight also presented higher BMI and waist circumference (WC), higher trunk/limb BF% ratio (p<0.05, Figure 1). Their BF%, trunk BF% and limb BF% were also positively correlated with BMI and WC, respectively (r=0.604-0.755, all p<0.05). After adjustment for age, duration, family history, eGFR, hypertension, diabetes mellitus, dyslipidemia, metabolic syndrome, fatty liver, coronary heart diseases, urolithiasis, BMI and WC, multivariable linear regression showed that BF% (β=0.072, 95%CI

SAT0417 HOW EFFECTIVE IS GOUT EDUCATION PROGRAMME TO IMPROVE GOUT KNOWLEDGE AMONG PRIMARY CARE DOCTORS?

Hadyra Bahanaudini1, Nur Ani Eddy Warmi2, Habbab Mohd Yusof3, Ing Soo Lau4, Shelyn Suajin Cheng5, Malyza Mohd Zaini6. Universiti Teknologi MARA, Department of Medicine, Sungai Buloh, Malaysia; 2Hospital Selayang, Department of Medicine, Batu Caves, Malaysia

Background: Gout is a potentially curable disease with simple pharmacological treatment, although its management remained suboptimal. A disconnection between primary care doctors who treat gout most frequently, and rheumatologists who lead the development of gout management guidelines, is one of the challenges in managing gout in primary care. A concerted effort is needed to improve the quality of care of patients with gout and this includes physician education.

Objectives: To determine the effectiveness of gout educational programme in improving gout knowledge among primary care doctors.

Methods: A gout education programme consisted of five 20-minute presentations on gout (challenges in gout, principles of gout management, treat to target, disease burden and gout diet) and a session on case discussion of two gout cases was conducted for primary care doctors. Participants were invited to complete the same set of questions distributed before (pre-test) and after (post-test) the programme. A set of 10 true/false multiple choice questions (MCQ) based on a clinical scenario of a patient with gout was constructed and vetted by two rheumatologists. Comparison between the pre-test and post-test scores were analysed using paired t-test.

Results: Forty-four primary care doctors who attended gout educational programme, answered pre-test and post-tests and the scores are shown in Table 1. The scores for recall questions were higher than application questions. The mean scores for recall questions in post-test were significantly higher compared to pre-test (4.35±0.73 vs 3.51±0.47, p<0.01) but not significant for application questions (2.91±0.71 vs 2.79±0.62, p=0.56). Less than half of participants obtained correct answers for 13 out of 50 options in the pre-test mainly in questions 2, 3, 4, 6 and 7 (Table 1).
Conclusion: Gout educational programme for primary care doctors was effective in improving recall knowledge but not in application knowledge. Some specific areas of deficiency in knowledge identified were features of gout and management of acute and stable gout.

ASSOCIATION BETWEEN ANEMIA AND HYPERURICEREMIA: KOREAN NATIONAL HEALTH AND NUTRITION SURVEY 2016

Yeonghee Eun1, Eun-Jung Park2, Ji-Young Cha2, Hoon-Suk Cha3, Eun-Mi Koh4, Hyungjin Kim1, Jaejoon Lee1.

Background: Hyperuricemia and anemia may be related in terms of shared comorbidities such as chronic kidney disease and cardiovascular disease. However, to our knowledge, no studies have been conducted on the relationship between these two conditions. For the association of gout and anemia, there was a previous cohort study reporting that patients with anemia had a 2-fold higher risk of gout compared to patients without anemia. And the risk of gout was significantly higher after adjusting for serum urate levels and kidney function. However, there is a lack of data on the relationship between anemia and hyperuricemia.

Objectives: The purpose of this study was to investigate the association between hyperuricemia and anemia using data from Korean National Health and Nutrition Examination Survey (KNHANES VII; 2016), which is representative of the Korean population.

Methods: The present study included 5887 participants aged ≥ 19 years from KNHANES VII. Logistic regression was used to examine the association between anemia and hyperuricemia. Subgroup analysis was performed to confirm whether the association between two conditions varies according to participant characteristics.

Results: In an adjusted model that corrected for body mass index, smoking, drinking, physical activity, income, and education levels, hyperuricemia was 1.4 times more than that those without anemia (HR 1.41, 95% CI 1.01-1.98). The association of anemia with hyperuricemia was not seen under 65 years of age (HR 2.68, 95% CI 1.60-4.48). In addition, this association was not clear in women, but was significant in men (HR 2.62, 95% CI 1.47-4.70). In the results of subgroup analysis according to comorbidities, the association of anemia with hyperuricemia was significant only in subgroups with chronic kidney disease, diabetes, hypertension, metabolic syndrome, and cardiovascular diseases. There was no association between anemia and hyperuricemia in obese subjects, but hyperuricemia risk was higher in non-obese subjects with anemia compared to those who did not have anemia.

Conclusion: In a Korean representative sample, the risk of hyperuricemia was higher for anemia. The association of anemia with hyperuricemia was more pronounced in subjects with older age, male population, and other comorbid conditions.

SAT0419
HAS THE INTRODUCTION OF A PRIMARY CARE GOUT GUIDELINE RESULTED IN SERUM URIC ACID (SUA) TARGETS BEING ACHIEVED?

Rashid Farid1,1, Leanne Gray2, Dean John3, Daniel Holtehouse4, Lesley Oettle5.

1 Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom; 2 Bay Medical Group, Morecambe, United Kingdom

Background: Gout is the most common inflammatory arthritis thought to affect 2.4% of the UK population. A local primary care audit in 2012 suggested suboptimal gout management. In an attempt to improve gout management we introduced a local guideline which was supported by an increase in gout education to our local primary care physicians.

Objectives: To assess the impact of a local primary care gout guideline (introduced in 2015) by comparing pre-guideline audit data (2012) to post guidelines audit data (2019). To identify if the introduction of this guideline translated into a reduction in secondary care referrals for advice on gout management.

Methods: Retrospective analysis of primary care data covering all patients with active diagnosis of gout since 2015 in a large primary care medical group (list size of 30,000 patients). This data was then compared to the results of a previous audit carried out prior to introduction of guideline (2012). As well as assessing primary care data, we carried out a secondary care audit pre and post guideline introduction.

Results: Out of a population list of 30,000 patients, 650 (2.1%) cases were coded as gout. 521 (80%) were male and 129(20%) were female. 429(66%) were on ULT. 407 (94.8%) were on Allopurinol, 21(4.8%) were on Febuxostat and only 1 patient on sulfinpyrazone. Of those on Allopurinol, 24 (5.9%) had no documented monitoring of SUA levels. Out of the remaining 383 (94.1%), 179 (46.7%) achieved target SUA levels of <360, compared to 204 (53.3%) in the previous audit. 184 (46.4%) did not achieve the target SUA levels. 178 (46.4%) patients had a previous SUA levels checked in the last year compared to 23.5% in the previous audit. 177 (28%) had SUA levels checked in last 3 years compared to 40% in the previous audit. SUA levels were not checked in the last 3 years in 98(25.6%) compared to 36.4% in the past.

Of those on febuxostat, 14 (67%) achieved target SUA levels. 7 (33%) did not achieve target SUA levels. 10 (47%) patients had their SUA levels checked in the last year. 7(33%) had their SUA levels checked within the last 3 years and 4 (20%) had not had their SUA levels checked within the last 3 years.

No patient was prescribed more than 300mg allopurinol daily by their primary care physician despite the recommended dose being up to 900mg daily.

We found a 70% reduction in the number of referrals to secondary care for gout management over the same period of time.

Conclusion: The introduction of a local primary care gout guideline and associated education appears to have improved the number of patients achieving target serum uric acid levels as well as leading to a reduction in secondary care referrals for gout.

IS THERE LIFE TO GOUT TREATMENT AFTER RHEUMATOLOGY IS OUT OF THE EQUATION?

Paula García, Boris Anthony Blanco Cáceres, Fernando Perez-Ruiz. Hospital Universitario Cruces, Barakaldo, Spain

Background: Previous studies show a low persistence rate to urate-lowering therapy (ULT), in patients diagnosed with gout, after being discharged back to primary care from Rheumatology consultations.

Objectives: To assess persistence and adherence to ULT in patients with gout, previously evaluated in specialized care, who have been discharged from Rheumatology consultations to their primary care physician.

Methods: A transverse study of primary care patients with gout included in an inception cohort and followed in a tertiary care centre. Patients were selected according to their status of discharge or loss, in case they had been referred back to their primary care centre from specialized care, or “loss”, in case they had stopped coming to Rheumatology consultations.

Data, including active prescription of ULT, time since suspension of ULT (if applicable), last serum uric acid (sUA) levels and time for that determination, were procured by electronic history. General data of patients and follow-up were obtained from the database of such cohort. Patients lacking data or deceased were dismissed from the study.

Results: A total of 518 patients, classified either as “discharge” or “loss”, with available data accessed by electronic history, followed in specialized consultations during an average time of 52 months (36, 18-72) were studied. Average time since their last visit to Rheumatology services was 90 months (76, 36-132). 88% of them had, at least, one determination of sUA; 80% within the last 12 months, with no differences between the patients with or without active treatment. 376 patients (72.6%) out of 518 had an active prescription of ULT, 338 of them ordered by primary care and 38 by specialized care.

Patients lost during follow-up showed a lower rate of ULT prescription and a higher requirement of specialized attention after than those who were discharged from Rheumatology.

Conclusion: Patients discharged from Rheumatology consultations maintain good persistence to long-term treatment with ULT, higher than those who were lost during consultation follow-up. Nevertheless, persistence and adherence in the latter group show a higher rate than the ones obtained in patients being followed by primary care, which does not exclude a beneficial influence of the previous assistance provided by Rheumatology services.

URATE VOLUME AND DISTRIBUTION BY DUAL ENERGY CT: CLINICAL AND RADIOLOGICAL CORRELATION IN GOUT PATIENTS

Bo Gong1, Mark Warwas2, Michael O’Keefe3, Nicole Tsao4,5, Mary De Vera4,5, Kamaran Shojaania6, Faisal Khosa4, Savvas Nicolaou2,3, Vancouver General Hospital, Department of Radiology, Vancouver, Canada; 2University of British Columbia, Department of Medicine, Vancouver, Canada; 3University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada; 4Arthritis Research Canada, Vancouver, Canada; 5University of British Columbia, Department of Medicine, Division of Rheumatology, Vancouver, Canada

Background: Dual-energy CT (DECT) has shown tremendous potential as a novel non-invasive method of urate detection in patients with gout.

Objectives: Our aim was to determine the concordance between urate volume and distribution measured on DECT with clinical presentation among patients with gout.

Methods: We conducted a retrospective descriptive study of patients with gout who were referred by a rheumatologist for gout DECT scans between January 2008 and February 2018. At our institution, routine DECT scans for gout consist of four sets of images with limbs scanned in pairs: the hands/wrists, elbows, knees and ankles/feet. We obtained volumetric measurements for all four anatomical regions, and assessed the concordance with clinical presentation as retrieved from patient electronic health record.

Results: A total of 182 patients were included in this study; 96 patients (52%) were male, age range: 27-90, mean age: 62) had urate deposits on DECT scans. Among urate-positive patients, the mean total volume of deposits was 2.45 cm³ (hands/wrists: 0.17 cm³, 7%; elbows: 0.62 cm³, 25%; knees: 0.70 cm³, 22%; ankles/feet: 0.96 cm³, 39%). The average number of urate-positive joints was 2.5, higher than that of clinically symptomatic joints (1.9). Discordance between DECT results and clinical symptoms were seen more often in elbows (46 urate-positive vs. 22 symptomatic) and knees (68 vs. 43), compared with hands/wrists (31 vs. 30) and ankles/feet (90 vs. 87). Only in 25 (26.0%) patients, the distribution of symptomatic joints fully matched the distribution of urate deposits. In 6 patients (6.3%), there was no overlap between these two distribution patterns.

Conclusion: On DECT scans, most urate deposits in gout patients occur in the ankles/feet, followed by knees, elbows, and hands/wrists. DECT scans can reveal urate deposit in asymptomatic joints, especially in elbows and knees. Assessing the concordance of urate distribution with clinical presentation in all limb joints in gout patients, our results can help understand the pathophysiology of urate deposition in gout, and guide the development of DECT protocols for the screening, assessment and follow-up management of gout patients.

Conclusion: In conclusion, EOG is more severe and EOG pts have less CMs. Moreover, EOG has a higher inheritability trait than CG patients suggesting different pathological mechanisms.

Disclosure of Interests: Hilde Berner Hammer Grant/research support from: AbbVie, Pfizer and Roche, Paid instructor for: AbbVie, Pfizer, UCB, Novartis, Roche, Speakers bureau: AbbVie, Pfizer, UCB, Novartis, Roche, Lars Fridtjof Karoliussen: None declared, Lene Terslev Speakers bureau: tophi or ulceration(s) over tophi were patients with gout and determine risk factors associated with ulceration. To describe clinical characteristics of ulceration over tophi in patients with gout and improve the management for such challenge problem. Will allow us to better understand the fact of ulceration over tophi and why this is becoming increasingly common in gout patients in our department between 2014 and 2018, and who had at least one visit between 9 and 15 months after first visit. At baseline, ineffective ULT was defined by a serum urate level (SUL) above target (> 360 μmol/L). Demographic characteristics, gout history and CMs, treatments were systematically recorded. Results: Among 213 pts, 39 (18.3%) had experienced a first gout flare before 30 years old. Pts and gout characteristics are summarized in table 1. Mean age of first flare in EOG was 24.8 (± 5.5) years. Familial history of gout was more frequent in EOG than in CG (60.6 vs 24.6%). First flare involved the 1st metatarsophalangeal joint in 70% of EOG pts. EOG pts had more severe gout than CG pts: CV diseases, hypertension, T2D, dyslipidemia and kidney transplantation. Non-alcoholic fatty liver disease was more frequent in EOG than CG (61.1 vs 24.1%). At final visit, 62.8 and 67.9% of EOG and CG patients, respectively, achieved SUL target (p=0.56). Proportion of pts taken ULT was similar in both groups as well as proportion of pts treated with allopurinol or FBX. Comparison of clinical characteristics and risk factors associated with ulceration were analyzed between groups.

Conclusion: In conclusion, EOG is more severe and EOG pts have less CMs. Moreover, EOG has a higher inheritability trait than CG patients suggesting different pathological mechanisms.

Results: A total of 105 patients were enrolled. 33 patients with ulcerations were older, with prolonged duration with gout and tophi, a higher rate of obesity, greater number of tophi, lower level of GFR, and higher level of serum creatinine, ESR and CRP. The mean duration of ulceration was 1.63 ± 2.32 months. The ulcerations mainly located in ankle (34.21%) and MTP (39.47%), with a mean size of 32.37 × 22.76 mm. The majority of ulcerations were categorized as stage I (42.4%) and stage II (51.5%). In univariate regression analysis, age, glucocorticoid abuse, tophi duration, tophi number and GFR were associated with ulceration. In the multivariable model, significant differences were demonstrated in glucocorticoid abuse, tophi duration, tophi number.

Conclusion: Gout patients with ulceration(s) over tophi present several different aspects of clinical characteristics compared with those without ulceration. Glucocorticoid abuse, prolonged duration with tophi and greater number of tophi are risk factors for ulceration over tophi. Avoiding indiscriminate use of glucocorticoid needs to be emphasized, and prevention of tophi formation via initiate effective urate-lowering therapy is highly recommended in patients with gout.

SAI0426  TOPHI, THE PREDICTIVE FACTOR OF ARTERIAL STIFFNESS IN PATIENTS WITH GOUT AND HYPERURICEMIA

Woosung Jeong1, Jinseok Kim2, Joonhyouk Choi2. 1Jeju National University Hospital, Jeju, Korea, Rep. of (South Korea); 2Jeju National University School of Medicine, Jeju, Korea, Rep. of (South Korea)

Background: Gout is the most common form of inflammatory arthritis and its prevalence is increasing in recent decades. Many studies have reported that gout and hyperuricemia are associated with an increase in all-cause mortality and cardiovascular mortality. Increased arterial stiffness is an independent marker of cardiovascular diseases and risk predictors. Many studies have shown a significant correlation between uric acid levels and arterial stiffness. Augmentation Index (AI) is an indirect measure of arterial stiffness. Tophi is formed when gout is left untreated for a long time.

Objectives: The aim of this study is to determine whether the presence of tophi could predict an increase in arterial stiffness.

Methods: Between June 2017 and June 2018, augmentation index was measured using Sphygmocor for patients who visited Jeju National University Hospital in South Korea with gout or hyperuricemia. Medical records, laboratory and AI data were retrospectively analyzed.

Results: One hundred twenty two patients participated in the study and AI was measured. Most (96.7%) of the patients were male. At the time of the examination, 99 patients (81.1%) were treated with uric acid lowering agent and the mean duration of the disease was 6.9 years. When the patients were divided into two groups according to the presence or absence of Tophi, the average age (60.2±11.6 vs. 53.4±15.2, p=0.023) of the patients with Tophi was significantly higher, duration of disease (13.0±6.5 vs 5.4±5.4, p=0.000) was longer and the AI (28.7±10.4 vs 20.7±10.4, p=0.001) was higher. When multiple linear regression analysis was performed to exclude the effects of other variables (DM, HTN, hyperlipidemia, age, BMI, total cholesterol, creatinine), tophi was a predictor of high AI (β = 5.478; 95% CI, 0.343-10.613; p=0.037). Multiple logistic regression analysis was performed to determine the predictors of tophi. The duration of disease and AI @ 75 values were significantly predictive of the presence of tophi (Odds ratio 1.113; 95% CI, 1.024-1.209; p=0.012)

Conclusion: This study suggests that the presence of tophi is an independent predictor of increased arterial stiffness in patients with gout and hyperuricemia.

RISK OF MALIGNANCIES IN PATIENTS WITH GOUT: A COMORBIDITIES IN AN EARLY DIAGNOSED COHORT

Analysis of the prevalence and timing of malignancy in the early diagnosed cohort

Methods: We conducted a retrospective cohort study using Korean National Health Insurance Service-Medical check-up Cohort Database, which composed of qualified individuals as of 2002 in the age of 40-79 in 2002-2003 who received general medical check-up (Approximately 510,000). We included patients newly diagnosed with gout, based on the diagnostic code and relevant medication history, who were between 40 and 65 years of age at the time of diagnosis between 2003 and 2007 (we washed out first year for newly detected cases). The gout patients (case group) were matched by 1:2 propensity score matching using confounding variables (age, sex, income group, region of residence, smoking status, alcohol intake, exercise habit, comorbidities including diabetes mellitus, hypertension and dyslipidemia, body mass index, blood pressure, serum glucose level, total cholesterol, and hemoglobin) and survival analysis was performed to estimate the risk of malignancy.

Results: A total of 4991 cases and 419992 controls were identified. The prevalence of Gout was 4991 (1.17%, male 4093 (82.01%); female 898 (17.99%)). During a mean follow-up of 12 years, malignancy was newly diagnosed in 30262 patients (7.12% of the total cohort). Gout was associated with increased risk of malignancy in the multivariable Cox proportional hazard regression analysis before propensity score matching (hazard ratio (HR) 1.248, 95% confidence interval (CI) 1.130-1.379, p<0.001), as well as after matching (HR 1.369, 95% CI 1.209-1.549, p<0.001). Conclusion: A total of 4991 cases and 419992 controls were identified. The prevalence of Gout was 4991 (1.17%, male 4093 (80.01%); female 898 (17.99%)). During a mean follow-up of 12 years, malignancy was newly diagnosed in 30262 patients (7.12% of the total cohort). Gout was associated with increased risk of malignancy in the multivariable Cox proportional hazard regression analysis before propensity score matching (hazard ratio (HR) 1.248, 95% confidence interval (CI) 1.130-1.379, p<0.001), as well as after matching (HR 1.369, 95% CI 1.209-1.549, p<0.001).

Disclosure of Interests: None declared

ANALYSIS OF THE PREVALENCE AND TIMING OF GOUT CO-MORBIDITY IN PATIENTS UNDERGOING KIDNEY TRANSPLANT

Background: Patients receiving kidney transplants are at increased risk for the development of hyperuricemia and gout compared to the general population, which is generally attributed to the frequent use of calcineurin inhibitors (cyclosporine and tacrolimus). However, the precise proportion of renal transplant patients that develop gout and the time period post-transplant in which this occurs is less established.

Objectives: To analyze a large, multi-insurance, US population database to determine gout prevalence and timing in the renal transplant population.

Methods: A retrospective review of Humana Healthcare claims data (private and Medicare) from 2007 to 2017 was undertaken to identify kidney transplant patients with at least 6 months in plan prior to transplant and at least 6 months in plan post-transplant. Diagnosis of gout (ICD 10/ICD 9 code) was evaluated in relationship to the time of kidney transplant.

Results: The database contained 6,082 patients with a kidney transplant and at least 6 months in plan both pre and post-transplant. Of the 6,082 kidney transplant patients, 1,505 (25%) had a gout diagnosis: 908 (15% of transplant patients) with gout before and after transplant and 597 (10% of transplant patients) with a gout code only after transplant. In patients developing gout post-transplant, the mean time between transplant and gout diagnosis was 1.79 ± 1.85 years.

Conclusion: As expected, gout was a common comorbidity in renal transplant patients. 15% of the patients receiving renal transplants had gout prior to the transplant, and another 10% developed new-onset gout a mean of 1.79 years after receiving a renal transplant. This retrospective analysis demonstrates that kidney transplant patients commonly suffer from gout both before and after their transplant. In addition to more research on this topic, an increased focus on screening and treatment of gout in the renal transplant population may be warranted.

COMORBIDITIES IN AN EARLY DIAGNOSED COHORT OF UNCONTROLLED VERSUS CONTROLLED GOUT: ANALYSIS OF A LARGE US PAYER DATABASE

Background: Gout is a prevalent progressive systemic inflammatory arthritis. The pathogenic cause of gout is elevated serum uric acid or hyperuricemia, and appropriate treatment of gout involves reduction of uric acid levels to a minimum goal of less than 6 mg/dL. Patients who do not achieve uric acid goals are generally described as uncontrolled gout patients and tend to do worse in terms of clinical outcomes such as occurrence of flares and persistence/worsening of tophi. Gout patients often suffer from specific comorbidities, though whether uncontrolled gout patients have a different comorbidity profile is unclear.

Objectives: The objectives of this evaluation were to compare the comorbidities and hospitalizations in uncontrolled versus controlled gout patients from a large de-identified US payer database.

Methods: A retrospective review of Humana Healthcare data from 2007 to 2016 in private pay and Medicare patients was performed to identify...
patients with at least 1 gout ICD 10/ICD 9 diagnosis code (N=539,802) and 90 days of continuous urate-lowering therapy within 1 year of diagnosis. Two cohorts of patients were categorized according to their sUA levels (≥ 1 test) after at least 90 days of gout therapy: sUA<6.0 mg/dL (controlled) and sUA ≥ 8 mg/dL (uncontrolled).

Results: The controlled gout group (sUA<6 mg/dL) included 5,473 patients and the uncontrolled gout group (sUA≥8 mg/dL) had 1,358 patients. The two groups were comparable in terms of demographic features. Chronic kidney disease (CKD) was a common comorbidity overall in this gout population with higher prevalence in the uncontrolled gout cohort (49.4% of uncontrolled vs. 32.4% of controlled population; OR 2.04; 95% CI of 1.808 to 2.301, p<0.001). The most frequent hospitalization codes were similar between the uncontrolled and controlled patients with the exception of congestive heart and acute kidney failure. 20% of uncontrolled patients were hospitalized for congestive heart failure vs. 7% in controlled (OR 3.16, 95% CI: 2.674 to 3.739, p<0.001), and 20% of uncontrolled patients were hospitalized for acute kidney failure vs. 8% in controlled (OR 2.95, 95% CI: 2.497 to 3.480, p<0.001).

Conclusion: Gout patients frequently suffer from cardiovascular and renal diseases. This large retrospective analysis suggests that when divided based on uric acid levels attained, uncontrolled gout patients are more likely to suffer from CKD and also more likely to be hospitalized for acute renal failure than controlled gout patients. Whether hyperuricemia in uncontrolled gout causes the development of specific cardiovascular and renal comorbidities, or if specific cardiovascular and renal diseases lead to hyperuricemia and uncontrolled gout is not fully established.

SAT0430 IMPACT OF GOUT ON ALL-CAUSE MORTALITY AMONG MEDICARE BENEFICIARIES WITH A HISTORY OF KIDNEY TRANSPLANTATION: A RETROSPECTIVE COHORT STUDY

Li Justin1, Marissa Suh1, Mark Brigham1, Jeff Kent2, Brian LaMereaux2, Richard J. Johnson3, Brian Mandell1, Nandini Hadker1, Herman Sanchez1, Kevin Francis1, Gavin Miyasato1. 1 Trinity Partners, New York, United States of America; 2 Horizon Pharma USA, Inc., Lake Forest, United States of America; 3 University of Colorado, Denver, United States of America; 4 Cleveland Clinic, Cleveland, United States of America

Background: Gout is a frequent comorbidity among kidney transplant recipients. A recent analysis estimated that 13% of kidney transplant recipients had an active diagnosis of gout. The clinical impact of comorbid gout in this population is not well understood, including if gout as a comorbidity associates with higher mortality rates among kidney transplant recipients.

Objectives: This retrospective patient claims analysis was performed to determine whether an association between gout and mortality exists in the prevalent kidney transplant population.

Methods: A retrospective study using administrative claims from the Medicare fee-for-service (FFS) Limited Data Set (LDS) was conducted. Multi-variable Cox proportional hazards regression assessed the relationship between gout and all-cause mortality. Given the ambiguity of the causal relationship between gout and comorbidities that make up the Charlson Comorbidity Index (CCI), three analyses were conducted assuming: 1) gout and certain comorbib conditions are associated by way of a common pathogenetic root, 2) gout is a precursor for developing these comorbid conditions, and 3) these conditions modify the effect of gout on mortality.

Results: Gout was associated with higher adjusted risk of all-cause mortality (hazard ratio, HR: 1.44, 95% CI: 1.27-1.63). After adjusting for baseline demographics and time from transplantation, the HR risk with gout was attenuated but still statistically significant (HR: 1.16, 95% CI: 1.02-1.32). Further adjustment for baseline CCI found gout was not a significant risk factor (HR: 1.03, 95% CI: 0.90-1.17). Stratified models show gout among baseline CCI=0 score was associated with a 3.5-fold increased risk of all-cause mortality (HR: 3.48, 95% CI: 1.27-9.57).

Conclusion: The presence of gout was not an independent predictor of all-cause mortality among Medicare beneficiaries with a history of kidney transplantation. That gout in a subset of beneficiaries without baseline comorbidities was a predictor may suggest that gout serves as an early indicator of declining health in the larger prevalent kidney transplant population. Further research is needed to understand the relationship of gout and mortality in the kidney transplant population.

SAT0431 RED GINSENG EXTRACTS SUPPRESS MONOSODIUM URATE CRYSTAL INDUCED NLRP3 ACTIVATION

Jennifer Lee, Moon Young Kim, Sung-Hwan Park. Seoul St Mary’s hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: It is well known that red ginseng extracts (RGE) has anti-inflammatory properties.

Objectives: We aimed to investigate if RGE could suppress monosodium urate crystal (MSU) - induced NLRP3 activation and thus could be a potential therapeutic for gout.

Methods: Acute air-pouch model was used to investigate in vivo effect on acute gouty inflammation of RGE in mice. Human monocyte cell line –THP-1 was stimulated with MSU in the presence of RGE and expression of NLRP3, ASC, caspase-1, IL-1β was measured by PCR, immuno-blotted and ELISA. Twenty four gout patients in intercritical period were randomized either to red ginseng tablet or placebo receiving group in a double-blind manner. After 3 months of taking red ginseng tablets (RGT)/ placebo, expression of NLRP3 and inflammatory cytokines of peripheral blood mononuclear cell was addressed by PCR.

Results: RGE sufficiently inhibited acute gouty inflammation in air-pouch mouse model, represented by reduced number of white blood cells in air pouch lavage fluid. In vitro, RGE dose-dependently suppressed MSU-induced IL-1β production of THP-1 cells. RGE did not affect NLRP3 or pro IL-1β expression. However, ASC oligomerization was inhibited and suppressed NLRP3 inflammasome assembly. Patients taking RGT for 3 months showed significantly reduced NLRP3 expression compared to baseline, which was not observed in the control group.
Conclusion: RGE successfully suppressed MSU-induced acute inflammation in mouse model. Also, RGT reduced NLRP3 expression in intercritical gout patients. These results suggest that red ginseng can be implicated as a therapeutic agent for gout.

SAT0432 GOUTY ARTHRITIS AND DRUG-INDUCED LIVER INJURY AFTER THE TREATMENT WITH NSAIDS
Eleanora Mikhnevich1, Tatiana Rayevyna2, Ekaterina Leonchik3, 1Belarusian State Medical University, Internal Medicine, Rheumatology, Minsk, Belarus; 2Belarusian State Medical University, Internal Medicine, Gastroenterology, Minsk, Belarus; 3City Clinical Hospital № 5, Minsk, Belarus

Background: In order to relieve the pain during acute gout attacks, most patients take high doses of nonsteroidal anti-inflammatory drugs (NSAIDs), which can provoke the hepatotoxicity, or DILI (drug-induced liver injury).

Objectives: To define the timing of DILI formation after the treatment with NSAIDs and its severity in patients with gouty arthritis (GA).

Methods: 738 patients with GA from our database who meet the criteria of the ACR (1977) were included into the study. NSAIDs-induced liver damage is known to be mainly hepatocellular. The dynamic ALT concentration in blood before the start of NSAIDs and during the treatment has been assessed. Hepatocellular toxicity was determined according to the DILI classification criteria based on the blood ALT level increased > 2 times to the upper limit of norm (42 U/l for men and 35 U/l for women). Inclusion criteria for the study group (n = 88): normal ALT before the treatment with NSAIDs, its increase during the treatment and return to the norm after the treatment. Exclusion criteria: chronic hepatitis of any etiology, the comparison group (n = 650) consisted of patients with normal blood ALT level throughout the treatment.

Results: Among 738 patients with GA, 11.9% (n = 88) developed the hepatotoxicity following the NSAIDs therapy. No significant differences in age (54 (59.5) and 57 (52-63) years; p> 0.05) and gender (men 93.3% and 87.6%; p > 0.5) between the study and comparison groups were found. In the study group, the duration of NSAIDs administration was 10 (6-14) days, which did not differ from that in the comparison group — 9.5 (7-12) days (p>0.05).

In patients with DILI, the elevated ALT was observed as follows: 2-3 times in 74 patients (84.1%); 3 to 5 times in 10 (11.4%); more than 5 times in 4 patients (4.5%). So, minimal cytolysis was presented more frequently than more severe forms (p < 0.05).

In the subgroup with the ALT concentration > 5 times (n = 10), 6 patients received Diclofenac in high doses, 2 patients were treated with Nimesulide, 1 patient with Etodolac and 1 with Dexamgion during the observation period. The elevation of ALT concentration 5 times was observed in 3 patients taking Diclofenac i/m and Nimesulide per os, simultaneously, and in 1 patient taking Diclofenac in high doses.

Patients with DILI were taking the following medications: Diclofenac 48.9% (n = 43); Nimesulide 18.2% (n = 16); Meloxicam 5.7% (n = 5), the combination of NSAIDs 20.5% (n = 18) without statistical differences (p > 0.05).

The number of patients who abused alcohol in DILI and control groups did not differ significantly — 53.4% and 48.2%, respectively (p>0.05).

Conclusion: In patients with GA, the hepatocellular DILI was observed in 11.9% cases after the treatment with NSAIDs during 10 days (from 6 to 14 days). Among patients with DILI, 84.1% (n = 74) had NSAIDs-induced hepatitis with minimal cytolysis. Mild cytolysis was seen in 10 (11.4%), moderate in 4 patients (4.5%). In our study, no severe or fatal DILI has been noted. No significant differences for particular drugs in the hepatotoxicity incidence have been found (p > 0.05).

SAT0433 AN ANALYSIS OF PRESCRIPTION RECORDS OF GOUT PATIENTS IN EUROPE: EVIDENCE OF SUBOPTIMAL MANAGEMENT AND CLINICAL INERTIA
Frederic Liote1, Ravi Karra2, Prashanth Kandaswamy3, Abhishek Abhishek3, Carlo Alberto Scire1, Fernando Perez-Ruiz2, 1AHP-H (Hiptat Laboxioane) and Inserm and University Paris Diderot, University of Paris, Rheumatology department; PARIS CEDEX 10, France; 2Grunenthal GmbH, Medical department, Aachen, Germany; 3University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom; 4University of Ferrara, Department of Medical Sciences, Ferrara, Italy; 5Cruces Hospital and University of the Basque Country, Division of Rheumatology, Baracaldo, Spain

Background: Urate-lowering therapy (ULT) should be prescribed to people with recurrent gout flares and tophi, and offered to people with first-onset gout. Despite effective drugs, gout flares are common. Reasons for this include lack of prescription of ULT, under-dosing of ULT by physicians (clinical inertia), and poor adherence to ULT.

Objectives: To ascertain the quality of gout care delivered by general practitioners (GPs), prescribing patterns for ULT were analysed in 4 western European countries.

Methods: Data for this retrospective study were obtained from IQVIA’s Real-World Data Longitudinal Prescription databases of GPs from France, Italy, Spain and United Kingdom (UK). The databases contain anonymised patient prescription records, including demographics, dispensing details (pharmacy, prescription date), and medication (name, dose, therapy duration). Data for patients with gout with or w/o ULT were analysed from July 2015 to June 2016.

Results: Crude prevalence of gout was 0.7% (UK) to 1.1% (France, Italy, and Spain) (Table 1). Only about half (France, Italy, UK) to 1/3 (Spain) of diagnosed patients were on ULT. Between 19.9% (France) and 56.4% (Spain) of patients on ULT had serum urate (sUA) measurements recorded within the year. Only 26.6% (Italy) to 45.6% (France) of patients with a recorded sUA level at target (<6.0 mg/dL). The most common 1st-line treatment was allopurinol (ALLO), almost always at a dose ≥300 mg/d. Febuxostat (FBX) was prescribed as a 1st-line alternative in France and Italy. Switch to 2nd-line ULT, such as FBX, was uncommon, especially in Spain and UK. Uricosurics in monotherapy were not used. Average time on ULT ranged from 57.3% (Italy) to 72.6% (France) of the assessment year. At least one comorbidity (CM) was present in >78% of patients, the most common being hypertension, dyslipidemia, diabetes, chronic kidney disease, and obesity.

Conclusion: In the study period, management of patients with gout in 4 EU countries was suboptimal. Nearly half of diagnosed patients were not prescribed ULT. sUA levels were not being monitored regularly and mean sUA levels were above target. ALLO as the most common 1st-line ULT was generally prescribed at sub-therapeutic doses. Initiation of 2nd-line therapy was infrequent indicating a status quo and/or other reasons and medication adherence was poor indicating low patient self-management.

SAT0434 A TRANSIENT DECREASE IN SERUM URATE CHANGES THE CLINICAL TRAJECTORY OF SUBJECTS WITH ADVANCED GOUT

Michael H. Pillinger1, Theodore Fields2, Anthony Yeo3, Peter Lipsky4. 1NYU Langone Medical Center, New York, United States of America; 2Hospital for Special Surgery, New York, United States of America; 3Horizon Pharma, Lake Forest, United States of America; 4AMPEL BioSolutions, LLC, Charlottesville, United States of America

Background: The standard approach to monitor subjects with gout is to measure serum urate. The assumption is that the signs and symptoms of disease will improve if serum urate is maintained below the target level of 6 mg/dL. However, there has been little emphasis on whether lowering urate transiently would have a prolonged impact on the clinical manifestations of advanced gout.

Objectives: Assess the clinical benefit in patients with advanced gout who had transient lowering of serum urate resulting from treatment with pegloticase, a pegylated recombinant uricase.

Methods: A post hoc analysis was carried out using the results from two randomized controlled trials (RCTs) of 6 months duration to assess the efficacy of treatment with 8 mg of pegloticase every 2 weeks (q2w). Serum urate was measured before each infusion and the serum urate area under the curve (AUC) was calculated as described2 for the first and second three-month periods of time in the RCTs. The following clinical outcomes were assessed: gout flares, tophus reduction, patient global assessment (PGA), tender and swollen joints (TJC and SJC), pain measured with a 100-mm visual analog scale (VAS) and a variety of patient-reported outcomes (36-item Short Form Health Survey [SF-36] Physical Component Score [PCS] and Arthritis-Specific Health Index Score [ASHIS]).

Results: The analysis included 85 subjects treated with q2w pegloticase and 43 patients who received placebo. Of the 85 pegloticase-treated subjects, 49 had only a transient decrease in serum urate owing to the development of anti-pegloticase antibodies. The mean length of time these subjects experienced a serum urate <6 mg/dL was approximately 6 weeks.3 Despite the transient reduction in serum urate, the serum urate AUC for the first and second 3 months of the RCTs was significantly (p=0.008) decreased compared to placebo-treated subjects. However, it was significantly (p<0.0001) less reduced compared with those with persistent urate lowering throughout the 6 month RCTs (Table 1). Results for both the subjects with persistent and transient lowering of serum urate to <6 mg/dL indicated significant reduction in tophi and improvements from baseline in PGA, TJC, SJC, pain, and ASHIS after 6 months of the RCT. No significant improvements were observed in the patients who received placebo.

Conclusion: A transient reduction in serum urate resulting from pegloticase therapy can result in significant clinical benefit lasting through the 6 months of the RCTs. These results suggest that transient lowering of urate can alter the trajectory of the clinical manifestations of advanced gout. Moreover, estimates of serum urate AUC may be more helpful in assessing the impact of urate lowering therapy than individual measurements of serum urate.

SAT0435 MANAGEMENT OF ADVANCED GOUT: A CLAIMS-BASED ANALYSIS FROM THE UNITED STATES

N. Lawrence Edwards1, Naomi Schlesinger2, Sanders Clark3, and Alexandra Amr4,5.
1University of Florida, Gainesville, United States of America; 2Rutgers Robert Wood Johnson Medical School, New Brunswick, United States of America; 3AMPEL BioSolutions, LLC, Charlottesville, United States of America

Background: Gout is one of the most common inflammatory arthropathies. Despite available urate lowering therapies (ULT), many patients progress to chronic or advanced gout, characterized by the development of tophi, chronic inflammatory arthritis, and other manifestations resulting from persistent urate depositions. While numerous guidelines exist for the management of gout, there is little information on the frequency of their implementation, especially in patients with advanced gout.

Objectives: To evaluate the real-world practice patterns in patients diagnosed with advanced gout using a large administrative claims database from the United States.

Disclosure of Interests: Peter Lipsky Consultant for: Consult-
Methods: We carried out a retrospective analysis of the Symphony Integrated Dataverse to identify patients with advanced gout over an approximately 6-year period from October 2012 to August 2018. Patients were identified as having advanced gout if they were >18 years of age and had at least two medical claims for the diagnosis of gout on different days, separated by at least 3 months. Patients with advanced gout were identified and stratified based on their diagnosis as either chronic gout (ICD-9: 274.02, 274.03, ICD-10: M1A.x.x) or tophaceous gout (ICD-9: 274.03, 274.81, 274.82, ICD-10: M1A.xxx.x). A third category designated "uncontrolled gout" was clinically defined as any patient with at least three primary diagnoses of idiopathic gout (ICD-10: M10.0.x, M1A.0x) along with at least three urate tests (CPT 84550, 84560). Percent and frequency of urate testing, rheumatology specialist visits, and administration of ULT (allopurinol, febuxostat, probenecid, and lesinurad) were evaluated for each diagnostic group.

Results: We identified 191,097 advanced gout patients, including 177,610 (93%) with chronic gout, 31,475 (16.5%) with tophaceous gout, and 20,943 (11%) with uncontrolled gout. 35,992(18.8%) were coded in more than 1 diagnostic category. The median age was 67 (range: 19-80), 24.7% were female and 75.3% male, with an average of 5.4 years of claims history in the database. As shown in Tables 1 and 2, despite the diagnosis of advanced gout, urate testing, rheumatology, and ULT were inconsistent. Urate testing was definitional for uncontrolled advanced gout patients, but was done in less than 65% of patients with the diagnosis of chronic or tophaceous gout and then less than once per year. Similarly, less than 60% of subjects with advanced gout received care by a rheumatologist and less than 80% received ULT and for less than 50% of the year.

</tbody>
</table>

*Urate lowering therapies

Conclusion: The subset of patients with advanced gout, identified either as chronic, tophaceous or uncontrolled, received suboptimal care compared to current guidelines. As this group of advanced gout patients is the most affected by urate deposition, added attention should be paid to optimizing their care.

CROWNED-dens syndrome: a recent case series in a single centre in the United Kingdom

Background: The crowned dens syndrome is a rare presentation of calcium pyrophosphate deposition disease. It is characterised by severe acute or recurrent neck pain associated with headache, fever and elevated inflammatory markers. CT usually demonstrates calcium pyrophosphate crystal deposition in the suspensory ligaments adjacent to the atlanto-axial joint. We are reporting a series of four patients presenting with sudden onset of neck pain and increased inflammatory markers over a 9 month period.

Objectives: To raise awareness of crowned-dens syndrome, its clinical presentation, radiographic findings and management.

Methods: Four patients’ electronic patient records including history, clinical findings and treatment were reviewed. Imaging was discussed at a rheumatology/radiology multi-disciplinary meeting.

Results: Four patients (2 female, 2 male) aged between 64 and 86 years presented with severe neck pain and stiffness. In all cases the onset of symptoms was less than a week prior to presentation and was associated with a restricted neck movement. 2 patients had associated headache, arthralgia and myalgia. All patients had normal tone, power, reflexes and sensation on neurological examination. There was no pyrexia. Inflammatory markers were markedly raised with CRP ranging from 90-343 mg/L at presentation (Table 1). One patient had a neutrophilia. CT scan of the head was performed in each case and showed no evidence of subarachnoid haemorrhage, space occupying lesion or meningeal enhancement. PET-CT scan in all patients showed intense uptake around the atlanto-axial joint as well as calcification of the ligaments. All patients were commenced on a reducing regime of prednisolone starting at 40mg daily, tapering to 0mg over 6 weeks. Symptoms and inflammatory markers reduced on induction of steroids. Two patients suffered a relapse on reducing steroids and required further higher doses of steroid.

Figure 1. Image from PET-CT scan of Patient 4 showing increased tracer uptake around the odontoid peg (arrow)

Conclusion: Patients presenting with acute neck pain, headache and raised inflammatory markers require evaluation for an infective aetiology. Pyrophosphate disease of the atlanto-axial joint however, appears to be an increasingly recognised cause of this presentation. Awareness by acute physicians, rheumatologists and radiology colleagues is important, as the condition can be misdiagnosed as Giant Cell Arteritis, Polymyalgia Rheumatica or meningitis; in order to avoid unnecessary investigations and delay in initiating the appropriate treatment. The condition is steroid responsive.

SAT0437 ABSTRACT WITHDRAWN

SAT0438 TO SCREEN OR “WAIT AND SEE” – CAN HLA GENE TESTING PREVENT ALLOPURINOL RELATED SEVERE CUTANEOUS ADVERSE REACTION? AND WHO ARE AT RISK?

Pui Shan Julia Chan, Sin Nga Ng, Moon Ho Leung. Hong Kong, Department of Medicine, Queen Elizabeth Hospital, Hong Kong, Hong Kong (SAR)

Background: Allopurinol is one of the most common causes of drug-induced severe cutaneous adverse reaction (SCAR). HLA-B*58:01 gene positivity is shown to be the strongest risk factor. However, local data on HLA-B*58:01 test and allopurinol-related SCAR is scanty. Moreover, there is no consensus on routine checking of HLA-B*58:01 before starting allopurinol in Hong Kong and this test is performed according to physicians’ clinical judgement.

Objectives: This study review the use of HLA-B*58:01 in daily practice, included the clinical characteristics and its implications in patients who developed allopurinol allergy in a tertiary internal medicine and rheumatology referral center.

Methods: This is a retrospective study of patients who had HLA-B*58:01 checked in Queen Elizabeth Hospital from January 2008 to December 2017. Patients’ demographic data, clinical characteristics, laboratory findings, gene profile, drug allergy records were retrieved from Clinical Data Analysis and Reporting System and outcomes were reviewed.

Results: Within 10 years, 432 patients had HLA-B*58:01 checked - 23% (N=99) were positive (Figure 1). Among patients who were HLA-B*58:01 positive, 86% had clinical and/or crystal proven gout and 68% were male (M:F=67:32). Gene testing was performed as screening in 56% (57/99) and after skin reaction in 42% (42/99). Alternative urate lowering therapy was considered for patients who screened positive for HLA-B*58:01 and none developed SCAR (Febuxostat 16 patients, probenecid 3 patients). For those who reported skin reaction after allopurinol, 50% had minor rash while 50% (each 21 patients) developed SCAR. In SCAR-group, 52% was male, 76% were chronic kidney disease (CKD) stage 3 or older, 60 years, with mean age 71.2±14.2 and mean estimated glomerular filtration rate 57.1±30.7 mL/min/1.73m² (Figure 2 and table 1). The mean time interval to SCAR was 44.8±52.1 days and the mean starting dose of allopurinol was 154.6±90.7 mg/day. SCAR was associated with substantial morbidity and mortality: 71% (15/21) required steroid and/or intravenous gammaglobulin in addition to supportive care and 17% (4/21) died in the same admission due to sepsis including pneumonia. For patients who were tested negative for HLA-B*58:01, although 12% reported skin reaction, these were self-limiting and all recovered after allopurinol was stopped. Renal impairment was less pronounced in this group, yet 38% were CKD stage 3.

Conclusion: In our cohort, HLA-B*58:01 can identify most of the high risk patients who prompt to develop SCAR. Thus in routine practice, clinicians should consider screening HLA-B*58:01, especially in patients with CKD stage 3 or age ≥60 year, before starting allopurinol, and consider alternatives if positive, to prevent allopurinol-related SCAR.

REFERENCES

Objectives: To assess the effect of XO1 therapy in gouty patients with moderate CKD, in terms of eGFR changes.

Methods: In this multicenter, retrospective study, we included patients from 4 centers diagnosed with gout (EULAR/ACR criteria) and stage-3 CKD according to Cockroft-Gault formula (eGFR 30-59 ml/min/m²) who from 4 centers diagnosed with gout (EULAR/ACR criteria) and stage-3 CKD according to Cockroft-Gault formula (eGFR 30-59 ml/min/m²) who have been in treatment with XOI for at least 6 months. Within the adjusted model we obtained significant differences in eGFR between baseline and 6 months (p=0.0081), and between baseline and 12 months (p=0.0028). eGFR decreased significantly between baseline and 6 months (p=0.0161) and 12 months (p=0.0188).

Conclusion: Reduction of sUA levels in gouty patients with XO1 therapy is significant different between eGFRs in stage-3 CKD. These findings suggest that the response to urate lowering therapy take place in the first 6 months, leading to an improvement in eGFR in this period. From 6 months to 1 year, sUA levels are stabilized and so is eGFR. Conclusion: There is an expected increased electron density (μe) in monosodium urate (MSU) crystal deposition in gout patients with MSU deposition, even though DECT measures do not reach statistical significance. Partial attention will be given to patients with high MU burden (large DC signs on US).

CALCIUM PYROPHOSPHATE CRYSTAL ARTHRITIS DURING HOSPITALIZATIONS: A PROSPECTIVE, CRYSTAL-PROVEN CASE SERIES

Laura Rantet, Francisca Sivera, Mariano Andrés, Alicante, Hospital General Universitario, Alicante, Spain

Background: Despite having passed more than fifty years after its initial description, essential questions for calcium pyrophosphate (CPP) crystal disease, such as clinical spectrum, diagnosis or management schemes, remain unsolved. Acute flares often occurred during hospitalizations. Scant reports have addressed this common setting for CPP crystal disease, and whether these patients behave similarly to ambulatory cases is unknown.

Objectives: The aim of this work was to describe in a prospective way a crystal-proven case series of patients developing acute CPP crystal arthritis during hospitalizations for another conditions.

Methods: An observational, cross sectional descriptive study was conducted in two Spanish centers from November 2013 to December 2018. A prospective convenience sampling was employed to select patients with crystal-proven CPP acute arthritis seen during hospital admissions. Demographic, clinical and CPP-related variables were collected, and X-rays (pelvis, knees, hands, affected joint when different) and laboratory tests (to rule out associated metabolic conditions) were systematically requested. A descriptive analysis is present.

Results: 90 episodes of acute CPP arthritis in 87 patients were seen in the study period, with an average age of 81.8 years (SD 7.7). 50.6% of them men. Approximately 26% of patients reported prior episodes of arthritis, most of them (68.4%) as outpatients. Only three patients were on preventive treatment for CPP arthritis (two on colchicine and one on low dose glucocorticoids). Regarding the acute CPP arthritis during admissions, they were predominantly monoarticular (81.0%) and the main involved joints were knee (46.0%), wrist (13.8%) and ankles (6.9%). The reasons for admission were diverse, with a mean of 7.7 days (SD 9.1) from admission to flare. About X-rays, 23.8% showed no chondrocalcinosis (CC) in the evaluated joints [61/80]. In 57.1% of patients there was chondrocalcinosis in the affected joint [44/77] and regarding usual joints: 74.3% in knees [55/74], 51.5% in triangular carpal ligament [34/66], 25.4% in metacarpophalangeal joints [17/67], 20% in public symphysis [14/70] and 17.6% in coxofemoral joints [12/68]. A secondary form of osteoarthritis was only seen in 10 patients (12.5%). About associated metabolic diseases, one case of primary hyperparathyroidism-related hypercalcemia and five cases of hypomagnesemia at the time of the flare were detected. In all six patients with a polyarticular presentation, laboratory tests for rheumatoid factor and ACPA were negative.

Conclusion: From the findings of this prospective, crystal-proven series of CPP crystal arthritis in an intrahospital setting, we can remark:

- 1. The low numbers of previous ambulatory flares may suggest a different clinical entity of CPP disease.
- 2. Radiological CC was absent in around a quarter of patients despite a extensive assessment, so synovial fluid analysis remains essential for diagnosis.
- 3. The rarity of associated metabolic diseases seen runs against ruling out secondary causes of CPP disease in this setting.

SA70443 RECONCILIATION OF URATE LOWERING THERAPIES DURING HOSPITALIZATION AND THE IMPACT OF RHEUMATOLOGIC CONSULTATION ON MANAGEMENT OF INPATIENT GOUT FLARES

Maia Seg, Emory University, Rheumatology, Atlanta, United States of America

Background: Hospitalizations complicated by gout flares may have an impact on patient care. Delayed diagnosis and suboptimal management can lead to prolonged discomfort, impair chronic outcomes of the disease and lengthen the hospitalization. Patients on urate lowering therapy (ULT) are frequently admitted to the hospital for unrelated causes but there is variability in inpatient medication management of the urate lowering agent and acute management of the flare.

Objectives: In this descriptive study, we analyse the variability of reconciliation of ULT on admission and discharge and the impact of rheumatologic consultation on acute and chronic management of gout.

Methods: Patients- above the age of 18- admitted to our tertiary care hospital from 01/01/2010 to 01/01/2016 with an ICD-9 or an ICD-10 diagnosis of gout were reviewed. The first 200 patients underwent a retrospective chart review as a pilot study for an ongoing project. We reviewed patient demographics, laboratory testing, and co-morbid conditions; medications on admission and discharge, incidence of gout flare diagnosis and management during hospitalization, rheumatology consultation and discharge plan for these patients.

Results: Of the 200 patients reviewed, 2.69 admissions per person. We further described the patients who had a gout flare during hospitalization (n =54, 27%). 66% of these patients were males, mean age 69.8 years and BMI 31.78kg/m². A majority of patients had hypertension, renal disease, and dyslipidemia (Table 1). 70% of the patients were on chronic medications for gout (Table 2). 29.6% of these patients were continued on these agents upon admission and only 64.8% of these patient was eventually discharged on these drugs.

Rheumatology consulted for 68.5% of the patients. Arthrocentesis was more frequently performed when rheumatology was consulted (70% vs.17.6%; p<0.001). Rheumatology consultation did not decrease length of stay in the hospital. 78.5% of the patients managed by primary team were discharged on a ULT or colchicine compared to 100% in the group managed by rheumatology consult team (100% vs 78.5%; p=0.0431). Outpatient rheumatology follow up was documented in discharge papers for 62% of the patients managed with rheumatology consult compared to 11.7% in the comparison group. (62% vs.11.7%; p=0.002).

Conclusion: Rheumatology consultation improved adherence to guidelines in diagnosis and management of gout flare and improved the discharge planning and follow up.

SAT0445 ADEQUATE URATE LOWERING THERAPY FOR GOUT IS RARE IN CLINICAL PRACTICE BUT PRESERVES RENAL FUNCTION WHEN EFFECTED

Valgerdur Sigurdardottir1,2, Lena T.H. Jacobsson3, Anna Svärd4, Mats Dehlin2.
1Center for Clinical Research (CKF) Dalarna, Uppsala University, Falun, Sweden;
2Salghirka Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: Optimal urate lowering therapy (ULT) as defined by most guidelines requires monitoring of serum urate (SU) and titration of the medication dose to achieve a target level of SU. In Sweden, allopurinol is the most widely used ULT and most patients with gout are managed in primary care. As a first step towards implementation of gout treatment guidelines in the Swedish region of Dalarna, we undertook a register study to assess how allopurinol is prescribed and to what extent monitoring of SU takes place.

Objectives: To determine the proportion of patients with gout that receive a) ULT and b) adequate ULT and to determine to what extent SU is monitored. A secondary aim was to explore the effects of adequate ULT on SU and estimated glomerular filtration rate (eGFR) over time.

Methods: Data was retrieved from the electronic healthcare record database of the region. The database holds records of all diagnoses at visits to physicians, prescriptions made in primary care as well as results of laboratory tests. We searched the database from 1997-2012 for individuals with a first diagnosis of gout during 2000-2012 and retrieved data for all prescriptions of allopurinol for the identified patients. Results and dates of SU and creatinine measurements after gout diagnosis were retrieved. MDRD eGFR was calculated from s-creatinine, sex and the age of the patient at the time of measurement. The value nearest in time before initiation of ULT was defined as the baseline measurement for both urate and creatinine. Duration of therapy was defined as number of days from first to last prescription adding 365 days (the usual period for which chronic medication is prescribed in Sweden). The mean daily dose of allopurinol was estimated from prescription data.

Disclosure of Interests: None declared
Adequate ULT was defined as a mean daily dose of at least 300 mg of allopurinol and a duration of therapy of at least 2 years. Patients that had received adequate ULT were matched using propensity score on the basis of baseline eGFR and length of follow-up time to patients that received non-adequate ULT. Change from baseline in SU and eGFR was calculated and compared between groups.

Results: We identified 5433 patients with an incident gout diagnosis during 2000-2012 (and no gout diagnosis or prescription for ULT during 1997-1999). Of these, 2393 (44%) received at least one prescription for allopurinol. SU was measured at some time point after initiation of ULT in 58% of patients. Adequate ULT as defined above was prescribed for 154 patients (3%), of these, 112 (73%) had a SU measurement at some time point after initiation of therapy and 35 (23%) had such a measurement done within 6 weeks of starting treatment. Matched controls could be identified for 109 of the patients with adequate ULT. Mean urate and eGFR at the start of therapy and end of follow up for the group with adequate ULT treatment and the controls are shown in table 1.

Conclusion: ULT was prescribed to less than half of the patients identified. Adequate ULT was rare in clinical practice during the time period studied. Urate monitoring occurred in less than half of ULT-treated patients. The patients with adequate ULT achieved greater lowering of serum urate than matched controls and were more likely to maintain unchanged renal function over time.

Disclosure of Interests: Valgerdur Sigurdardottir: None declared, Lennart T.H. Jacobsson Consultant for: LJ has received lecture and consulting fees from Pfizer, Abbvie, Novartis, Eli-Lilly and Janssen, Anna Svärd: None declared, Mats Dehlin: None declared

Methods: Audit criteria were derived from the latest BSR gout guideline (Hui et al; 2017). A randomised sample of adult patients with a read code for the diagnosis of gout from Jan 2006-Jan 2018 was chosen from six large general practices in Leicestershire County of the United Kingdom. The data collected included demographics, provision of patient information, management of acute attacks and prophylactic treatment, screening of appropriate co-morbidities, dosing of urate-lowering therapy (ULT) and titration of doses against measurement of uric acid levels.

Results: Data was obtained for 861 patients. The mean age was 60 years and 91% were male. 21.5% were recorded as being provided with written information about gout and 65.0% of patients were treated with NSAIDs and COXIBs for acute attacks of gout. When colchicine was prescribed to patients, 71% had no dose recorded in their clinical records. 323 (37.5%) of patients were prescribed a ULT and the recorded starting dose of allopurinol was 100mg daily for 73.8%. Titration of subsequent allopurinol doses was recorded in only 21% of patients. 539 patients (62.6%) had no record of a serum urate level check after starting ULT.

Conclusion: Clinical records indicate that the management of gout in UK General Practitioners in Primary Care is suboptimal in concordance with the BSR guidelines. It was clear that general practices did not employ the treat to target strategy. There is a clear need for increased GP awareness and adherence to the BSR guidelines in order to optimise deficient areas of care, particularly in patient education, initiation and titration of ULT and monitoring of serum urate levels in gout patients. Appropriate patient recording templates are needed so that key information is captured during a patient consultation in order to enable medicines optimisation for those with gout. Most aspects of gout management in primary care did not concord well with published BSR guidelines.

Sensitivity of Dual-Energy CT Scanning, Ultrasond, and X-Ray for Crystal-Proven Pseudogout

Sara Tedeschi¹, Daniel Solomon¹, Kathleen Vannì¹, Neal Suh¹, Stacy Smith²
¹Brigham and Women’s Hospital, Rheumatology, Boston, United States of America; ²Brigham and Women’s Hospital, Musculoskeletal Radiology, Boston, United States of America

Background: Advanced imaging modalities such as ultrasound (US) and dual-energy CT (DECT) can help diagnose crystalline arthritis. DECT is highly sensitive and specific in gout and has not been well studied in pseudogout.

Objectives: To compare the sensitivity of DECT, US, and x-ray (XR) in pseudogout.

Methods: We prospectively enrolled patients with crystal-proven pseudogout at a tertiary care center, 3/2018-11/2018. We searched the electronic medical record for synovial fluid crystal lab orders and reviewed the record to identify candidates. Eligible patients were 18 years old with acute monoarthritis, joint aspiration, and synovial fluid calcium pyrophosphate (CPP) crystals on polarized microscopy. Patients with both monosodium urate and CPP crystals were excluded. Subjects provided informed consent and underwent DECT, US, and XR of the aspirated joint and standardized joint (right wrist). All images were interpreted by a musculoskeletal radiologist and a rheumatologist trained in US; consensus was reached on each image. DECT images were post-processed using Siemens Syngo.via software, applying color-coded overlay indicating volume and location of CPP deposits. We considered two volume thresholds to identify candidates. Eligible patients were 18 years old with synovial fluid CPP crystals as the gold standard. Larger studies testing DECT sensitivity and specificity in pseudogout vs. other arthritis and establishing a volume threshold are needed.

Gout Flares Become Infrequent During a Treat-to-Target Strategy Over One Year: Data from the Nor-Gout Study

Till Uhlig, Lars Fridjip, Karolussels, Espen A. Haavardsholm, Tore K. Kven, Hilde Berner Hammer, Dønkerhenmøet Hospital, Rheumatology, Oslo, Norway

Background: Urate lowering therapy (ULT) is expected to prevent new gout flares. Treat-to-target ULT is however often not performed, and we need more evidence on how often patient become flare-free during ULT.

Objectives: Urate lowering therapy (ULT) is expected to prevent new gout flares. Treat-to-target ULT is however often not performed, and we need more evidence on how often patient become flare-free during ULT.

Methods: In a prospective observational study, patients with crystal-proven gout with a recent gout attack and insufficiently treated serum urate (sUA) level (>360 µmol/L/4 mg/dl) were included. They received ULT with drug escalation during monthly follow-up until the target sUA level was met (sUA <360 µmol/L, or <300 µmol/L if clinical tophi). Assessment in this ongoing data collection included demographic and clinical variables, serum urate levels, previous medication with allopurinol, colchicine and NSAIDs, co-morbidities, and health related quality of life (SF-36). Flares during the last six months of one year with “treat-to-target” were recorded. Bivariate analyses and logistic regression analyses examined factors associated with and prediction (odds ratio with 95% confidence intervals) of a flare-free period during months 6-12.

VITAMIN D INSUFFICIENCY AND DEFICIENCY ARE ASSOCIATED WITH A HIGHER LEVEL OF SERUM URIC ACID: A SYSTEMATIC REVIEW AND META-ANALYSIS

Niph Charoengnam1, Ben Ponvilawan2, Patoompong Ungprasert2, 1Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, 2Faculty of Medicine Siriraj Hospital, Mahidol University, Clinical epidemiology unit, Bangkok, Thailand

Background: Several studies have revealed a relationship between vitamin D deficiency and a number of non-skeletal health conditions such as insulin resistance, metabolic syndrome, cardiovascular diseases, inflammatory diseases, infection and malignancy. The interaction between serum uric acid and vitamin D has also been observed. A study found that uric acid can suppress 1-alpha-hydroxylase in vitro and in vivo, leading to the reduction in the conversion of the storage form of 25-hydroxyvitamin D into the active form of 1,25-dihydroxyvitamin D [1]. In fact, several epidemiological studies have suggested that patients with vitamin D insufficiency and deficiency tend to have a higher level of serum uric acid compared to those with adequate vitamin D level although the results were inconsistent across the studies.

Objectives: To compare serum uric acid level between individuals with normal vitamin D level versus patients with vitamin D deficiency and vitamin D insufficiency.

Methods: A systematic review was conducted using MEDLINE and EMBASE database from inception to October 2018 to identify all studies that compared the level of serum uric acid between individuals with normal vitamin D level and patients with vitamin D insufficiency/deficiency. Eligible studies must be cohort or cross-sectional studies that consisted of two groups of adult participants, one with normal level of vitamin D (vitamin D level >30 ng/ml) and one with vitamin D insufficiency (vitamin D level 20-30 ng/ml) or vitamin D deficiency (vitamin D level <20 ng/ml). Mean serum uric acid level and standard deviation of participants in each group were extracted from each study to calculate mean difference (MD) between the groups. Pooled MD was then calculated by combining MDs of each study using random-effects model.

Results: A total of seven cross-sectional studies were eligible for the meta-analyses. Individuals with normal vitamin D level had a significantly lower serum uric acid level than patients with vitamin D insufficiency with the pooled MD of -0.33 mg/dL (95% CI, -0.61,-0.04) (figure 1) and also had a significantly lower serum uric acid level than patients with vitamin D deficiency with the pooled MD of -0.45 mg/dL (95% CI, -0.82,-0.08) (figure 2). The funnel plots had a certain degree of asymmetry. Funnel plots both meta-analyses were fairly symmetric which did not suggest the presence of publication bias.

Conclusion: Both patients with vitamin D insufficiency and patients with vitamin D deficiency had a significantly higher level of serum uric acid compared to individuals with normal vitamin D level.

Infection-related rheumatic diseases

JONI MANIFESTATIONS OF WHIPPLE’S DISEASE: CLINICAL AND RADIOLOGICAL PRESENTATION OF 19 PATIENTS

Marie Desmurs1, Hélène Petit2, Jacques-Eric Gottenberg3, 1Hôpital Émilie Muller, Mulhouse, France, 2Centre hospitalier René Pleven, Dinan, France, 3Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Background: Whipple’s disease (WD) is a rare chronic systemic bacterial infection caused by Tropheryma whippelii. It affects middle-aged men with diarrhea, weight loss, fever and joint manifestations. It usually develops as oligoarthritis or polyarthritis of large joints. WD may mimic chronic inflammatory rheumatisms. Some studies and case reports show that immunosuppressive treatment can worsen WD.

Objectives: Clinical and radiological (radiograph, ultrasound (US), MRI) presentation of joint manifestations of WD.

Methods: This retrospective monocentric observational study was led in Strasbourg University Hospital, Reference Center for Rare Diseases and included patients with WD diagnosed between 2006 and 2017. Patients were included if they had joint manifestations, positive T. whippelii polymerase chain reaction in stools or/and saliva, positive T. whippelii polymerase chain reaction on duodenal biopsy and/or positive periodic acid-Schiff performed on duodenal biopsy and good evolution with antibiotics.

Results: Nineteen patients including fifteen men were included. The median age at diagnosis was 57. The median time from first symptoms to diagnosis was 60 months. Before the diagnosis of WD, 13 patients had immunosuppressive therapies.

Clinical presentation of joint manifestations: 11 polyarthritis, 3 oligoarthritis, 1 monoarthritis and 4 inflammatory polyarthritis including 3 with axial pain. Wrists (15/19), ankles (11/19) and knees (10/19) were the most affected. The metacarpophalangeal joints were affected in 8 patients. Eight patients had diarrhoea and weight loss.
Its principal clinical significance is causing carditis at the acute phase of the disease, and valvular impairment, leading to a significant hemodynamic disturbance, as a late sequela.

Despite being a completely preventable disease, Rheumatic fever continues to be the most common cause of acquired heart disease among children in developing countries. In developed countries, a sharp decline in ARF was seen in the last decades.

**Objectives:** To examine the number of cases of Rheumatic fever in Schneider Children’s medical center, and to find whether it has declined during the years of its existence. In addition, to characterize the patient population during that period, determine the clinical characteristics of ARF. Its risk factors and assess the course of the disease and its treatment. In addition, we will address the relapse rates, with an emphasis on cardiac relapses, with a correlation to preventive treatment.

**Methods:** A retrospective cohort study was conducted, by collecting data from medical records of patients with rheumatic fever who were admitted to the Schneider Medical Center from 1993 to 2017. A database was built based on these medical records in order to assess the incidence of rheumatic fever and rheumatic heart disease, and the relapse rates, by use of descriptive and survival analysis.

**Results:** A 402 cases with relevant diagnostic codes were examined during the follow-up period, of which 307 patients met the inclusion criteria. During the acute phase, 197 of the patients (64%) presented with arthritis, 159 patients (52%) with carditis, 47 patients (15%) with chorea, 16 patients (5.2%) with erythema marginatum, and 2 patients (0.7%) with subcutaneous nodules. Carditis was found in higher rates among Jewish patients than among Arabs. 31 patients (19.5%) developed severe carditis, 21 patients (13.2%) of whom developed heart failure signs, 5 were hospitalized in intensive care, and one died. There was a decrease in incidence of rheumatic fever and rheumatic heart disease during the study period. Thirty-two patients (12% of all patients with rheumatic fever) developed a relapse of the disease and 11 of whom (4% of all patients) developed a cardiac relapse.

Median follow-up time was 49 months, and relapse rate was 13.9% after 5 years of follow-up. 15% of the patients who received oral prophylaxis experienced relapse, compared to 9% of those who received intramuscular injection therapy.

The rate of recurrence among all patients with rheumatic fever was 2.8% after 2 years of follow-up, 8% after 5 years of follow-up, and about 7% after 8 years of follow-up. 10 (90.9%) of the 11 patients with cardiac recurrence were present with carditis during the initial disease, with 7 of them (63.6% of patients with cardiac recurrence) having isolated carditis and 3 of them had a combined involvement of arthritis and carditis (27.3% of Cardiac relapses). Only in one case (9.1% of patients with cardiac recurrence) was an isolated occurrence of arthritis in the initial presentation. It was found that chorea is more common among females.

**Conclusion:** Despite the reduction in incidence of rheumatic fever and rheumatic heart disease during the study period, the disease remains a significant cause of general and cardiac morbidity among children despite being completely preventable, therefore. It should remain in the mind of every doctor, pediatricians in particular.

**Disclosure of Interests:** None declared. DOI: 10.1136/annrheumdis-2019-eular.4981

---

Simultaneously, we introduced staff education sessions, point-of-care paper “Arthritis and Infection Worksheets” and “Vaccination Advice Letters”. In 2018, the clinic was re-assessed.

**Results:** 163 patients met inclusion criteria in 2017 and 262 in 2018. Patients were typical of an IA clinic (74% women, 45.4%;60 years old, 72.7% had RA, 61.1% on cDMARDs, 53.6% on methotrexate, 46.6% on bDMARDs, 23.1% on CDMA RD plus bDMARD).

In 2017, 104 (65.4%) knew of the increased infectious risk of IA. In 2018, 168 (65.6%) were aware. Awareness of infection risk with medications increased from 111 (69.8%) to 172 (66.9%).

Table 1 shows vaccination rates. PPSV23 rates increased from 41.0% to 47.2% (P value=0.29, Pearson Chi squared), and influenza from 61.8% to 62.1% (P value=0.95, Pearson Chi squared).

**Conclusion:** This study shows suboptimal vaccination awareness and uptake. Our interventions increased PPSV23 and influenza vaccination rates. There is debate about who is responsible for vaccinations. Guidelines advocate specialists sharing responsibility with GPs. 57% of rheumatologists considered GPs responsible (2). Perhaps, we should take a more active approach.

In areas where Lone Star ticks are present, and in patients with risk factors for tick exposure, alpha gal IgE reactivity should be considered and tested for as part of a “tick panel” in patients who present with symptoms of potential rheumatologic diseases.

with CHIKV IgM positive. In the EQ-5D (Figure 1), between 72% and 92% of patients didn’t report problems on the mobility, self-care, usual activities, anxiety and depression dimensions. In contrast pain and discomfort dimensions were affected from moderate to extreme (44.7% and 86.6%). There weren’t significant differences between true positives, true false, false negative within all the variables, except on the anxiety and depression dimensions where the false positives had a higher significant score in comparison to the other groups (n: 10, 38.5%; p=0.00; OR:4.17, IC:1.8-9.57). In the EQ-5D-VAS, media for VAS was 75.56 (SD±21.18) where the highest scores of VAS were found on the false negatives. In pain VAS, false positives as well as the duration greater than 7 weeks where associated with several pain (n: 10, 2.9%; OR: 0.2; IC 1.25-6.33; y n: 27, 21.3%; p=0.016; OR 2.02, IC 1.12-3.66 respectively).

Conclusion: In general, the disability of CHIKV infected patients was mild to moderate, finding the most affected dimensions to be pain, discomfort, anxiety and depression. The false positives and the population with anxiety and depression are related with higher score of disability.

SAT0459 DIAGNOSIS AND MANAGEMENT OF ACUTE HOT JOINTS AT A TERTIARY RHEUMATOLOGY CENTRE OVER A 7-MONTH PERIOD
Mrinalini Dey1, Pankaj Lal2, Robert N. Thompson1, Nicola Goodson1. 1Aintree University Hospital, Rheumatology, Liverpool, United Kingdom; 2Aintree University Hospital, Microbiology, Liverpool, United Kingdom

Background: The acute hot joint presentation is common in clinical practice, often due to crystal arthritis or non-inflammatory conditions. The most serious diagnosis is septic arthritis (SA), which can destroy cartilage within days, and therefore must be promptly diagnosed or excluded. The mortality rate for SA is 7-15%, despite antibiotic use [1]. Crystal arthropathies and SA are difficult to distinguish clinically, requiring arthrocentesis and synovial fluid (SF) analysis, in keeping with national guidelines.

Objectives: 1. Quantity number of acute hot joint presentations to our hospital over 7 months, including incidence of SA and crystal arthropathy. 2. Determine clinical features and outcomes (including morbidity/mortality) in SA. 3. Compare clinician diagnosis with laboratory diagnosis (gold-standard diagnostic test; crystal microscopy and culture). 4. Determine the correlation between WCC and crystal arthropathy or SA.

Methods: We retrospectively analysed laboratory diagnostic data and electronic clinical records, for patients presenting to a tertiary rheumatology centre in Northwest England with an acute hot joint, February-August 2018. For crystal arthropathy and SA, sensitivity, specificity, likelihood ratio. In the EQ-5D-VAS, media for VAS was 75.56 (SD±21.18) where the highest scores of VAS were found on the false negatives. In pain VAS, false positives as well as the duration greater than 7 weeks where associated with several pain (n: 10, 2.9%; OR: 0.2; IC 1.25-6.33; y n: 27, 21.3%; p=0.016; OR 2.02, IC 1.12-3.66 respectively).

Conclusion: In general, the disability of CHIKV infected patients was mild to moderate, finding the most affected dimensions to be pain, discomfort, anxiety and depression. The false positives and the population with anxiety and depression are related with higher score of disability.

SAT0460 HCV-RELATED MIXED CRYOglobulinemia in the DIRECT-antiviral agents era: is there Advantage in Sequential Therapy with Rituximab?
Maria Di Cicco1, Davide Antonio Filipini2, Federica Filippini2, Laura Bellot1, Valeria Camparella1, Cinzia Casu1, Michel Chevallard3, Marina Muscarà1, Mariaveta Romano1, Emanuela Schito1, Elisa Verducc1, Massimo Puoti2, Maria Vinc2, Oscar Massimiliano Epis1, Grande Ospedale Metropolitano Niguarda, Rheumatology, Milano, Italy; 1Università Politecnica, Mathematics, Milano, Italy; 2Università Politecnica, Mathematics, Milano, Italy; 3Università Politecnica, Mathematics, Milano, Italy

Background: Mixed Cryoglobulinemia (MC) is a small vessel vasculitis characterized by the presence of a monoclonal rheumatoid factor (RF) and polyclonal immunoglobulins that precipitate at cold temperature, with a large spectrum of clinical manifestations. MC is strongly associated with hepatitis C (HCV) infection. 90% of the direct-acting antivirals (DAA) against HCV, which can eradicate the virus in >95% of patients, are supposed to have benefits on clinical manifestations of MC, nonetheless the amount of data is still limited. Patients with severe vasculitis may require anti-CD20 agent Rituximab (RTX) over DAA. However, despite the strong rationale, the advantage of dual therapy is still debated and the optimal therapeutic schedule unknown.

Objectives: To investigate the impact of DAA treatment on clinical manifestations and biochemical parameters of disease activity in HCV-related MC patients who reached complete viral eradication, and if pre-treatment with RTX was able to define a subset of patients with a different prognosis.

Methods: Data was collected from 31 patients with MC, mean age 68 yrs, female 80%, mean disease duration 10 yrs who were treated with
Vertebral Osteomyelitis (VO) is an infectious disease that requires specific treatment management. The treatment includes long-term antibiotic therapy, which can be guided by imaging studies. The objectives of this study were to evaluate the interest of follow-up imaging examinations in patients with pyogenic vertebral osteomyelitis (PVO) in order to improve the clinical and biological follow-up and the management of these patients. We conducted a retrospective cohort analysis of patients with PVO who had both baseline and follow-up imaging results available in a French university hospital during the period of 2010-2018. We identified the follow-up images into two groups, improvement/stability and deterioration, compared with the baseline findings. For each patient, we compared their imaging follow-up to their clinical-biological condition assessed at the same time.

Results: We have collected 80 patients. The median age was 71 years (32-89), 46 men, 13 patients had a history of spinal surgery. The most frequently reported germ was methicillin-sensitive staphylococci and the level of spinal involvement was predominantly lumbar. A Computerized Tomography (CT) was performed in 64% and a Magnetic Resonance Imaging (MRI) in 85% at the time of diagnosis. We identified 89 follow-up images, 58 MRIs, 31 CTs. The median delay of realisation was 85 days [11-364]. Soft tissue infiltration was observed in 50 patients compared to 26 on follow-up images but 3 were new. Similarly, 24% of the initial images had epiduritis compared to 16% during follow-up, 3% had compression (61.11% versus 26.92% respectively, p=0.05). Fifteen patients underwent CT-guided biopsy (83.33%) with prior antibiotic exposure in 11 of them. Median exposure was 4.5 days (3, 8.75). Delay from admission to procedure had a median value of 6 days (3.5, 9). Culture was positive in 53.33% of cases. In 10 patients, the picture was attributed to Gram+ (55.56%), in other 2 cases Gram- (11.11) and 1 case of tuberculosis (5.56). In 5 cases (7.88%) final pathogen was unknown. Four patients (22.22%) required further surgical surgery and 2 patients (11.11) died, similar than non-IS group, 11.54%.

Conclusion: In general terms, data about imaging is worse in IS patients and higher proportion of cervical spine involvement was also noted. Although, early intervention (diagnosis, puncture guided biopsy and treatment) seems to be protective against a bad outcome, since IS patients showed similar prognosis (further surgical procedures and death) than non IS patients. To sum up, new onset back pain in a IS patient, should be thoroughly studied so as to consider a VO as soon as possible.

Disclosure of Interests: None declared

SAT0462 INTEREST OF FOLLOW-UP IMAGING EXAMINATIONS IN PATIENTS WITH PYOGENIC VERTEBRAL OSTEOMYELITIS: A RETROSPECTIVE STUDY

Sophie Hequeuot, Kevin Boullier, Frank Verhoeven, Clément Prat, Daniel Wendling, Catherine Chirouze, Centre hospitalier régional universitaire de Besançon, Besançon, France

Background: Systematic follow-up imaging in patients with pyogenic vertebral osteomyelitis (PVO) is widespread. However, it is discussed, and there is no recommendation.

Objectives: Evaluate the interest of follow-up imaging examinations in patients with pyogenic vertebral osteomyelitis

Methods: We conducted a retrospective cohort analysis of patients with PVO who had both baseline and follow-up imaging results available in a French university hospital during the period of 2010-2018. We have classified the follow-up images into two groups, improvement/stability and deterioration, compared with the baseline findings. For each patient, we compared their imaging follow-up to their clinical-biological condition assessed at the same time.

Results: We have collected 80 patients. The median age was 71 years (32-89), 46 men, 13 patients had a history of spinal surgery. The most frequently reported germ was methicillin-sensitive staphylococci and the level of spinal involvement was predominantly lumbar. A Computerized Tomography (CT) was performed in 64% and a Magnetic Resonance Imaging (MRI) in 85% at the time of diagnosis. We identified 89 follow-up images, 58 MRIs, 31 CTs. The median delay of realisation was 85 days [11-364]. Soft tissue infiltration was observed in 50 patients compared to 26 on follow-up images but 3 were new. Similarly, 24% of the initial images had epiduritis compared to 16% during follow-up, 3% had appeared secondarily. There were 12 initial erosions described compared to 25 at follow-up. Of the 33 patients with clinical and biological recovery, 67% of follow-up images were classified as improving/stable and 13% as worsening (new abscesses (n=3), extension of soft tissue infiltration (n=2) and/or epiduritis (n=2) or appearance of new locations (n=2)). Among the 37 patients considered as unhealed, 87% of follow-up images were classified as improving/stable and 13% as worsening (new abscesses (n=1), extension of soft tissue infiltration (n=1) and/or epiduritis (n=1) or appearance of new locations (n=1)).
Conclusion: Our study showed that there was no correlation between the clinical condition of patients and their follow-up imaging in the context of PVO. Clinical and biological evaluation seems sufficient to determine whether or not the patient is cured. Many images are made during the follow-up with a questionable cost/effectiveness ratio. A standard radiograph may be sufficient to provide a basic structural condition at the end of antibiotic therapy.

Disclosure of Interests: None declared

SAT0463 BRUCELLAR SPONDYLODISCITIS: CLINICAL, RADIOLOGICAL AND THERAPEUTIC FEATURES

Aïcha Ben Tekaya1, Khouloua Zouaouli1, Ines Mahmoud1, Olfa Saida1, Mohamed Ben Hammamia2, Rawdha Tekaya1, Leïla Abdelmoula1,1. Charles Nicole Hospital, Tunis, Tunisia;2 la rabta hospital, Tunis, Tunisia

Background: Brucellosis is an endemic disease around the Mediterranean and especially in Tunisia and Brucellar spondylodiscitis is the most common systemic manifestation of the disease in our reality.

Methods: It is a retrospective descriptive study, conducted over 20 years (1999-2019) at a Rheumatology Department. We collected cases of Brucellar spondylodiscitis. We studied the clinical, radiological features and therapeutic outcomes.

Results: We included 23 patients, 15 men and 8 women, with a mean age of 53.21 years [31.79]. Contact with livestock or consumption of raw milk was noted in 16 cases. The diagnosis time was, on average, 3.8 months [1.9]. Spiné pain was present in all cases, with lumbar seat in 16 cases and was inflammatory in 20 cases. At the examination, 19 patients had a limitation of spinal mobility and 4 had neurological abnormalities. A motor deficit with a horsetail syndrome was objectified in one case. We noted a biological inflammatory syndrome in 19 cases. Wright’s serology was positive in 21 cases. Standard radiographs showed disc narrowing in 10 cases. 21 patients had spinal magnetic resonance imaging showing the abnormalities of the disc and adjacent vertebrae. We found abscess in four patients and epiduritis associated with the abscess in six patients. MRI showed spinal compression in 2 patients. Disco-vertebral biopsy was performed in 11 cases and helped to make the diagnosis in 3 cases. The patients had received antibiotic therapy with a combination of doxycyclin and rifampicin with a mean total duration of 4.9 months [2.12]. Evolution was favorable in 19 cases. Complications were mainly neurological (n=3) or related to the toxicity of the treatment(n=3).

Conclusion: Brucellar spondylodiscitis can be serious because of the neurological complications that it can cause. At the slightest diagnostic doubt, we should perform an MRI. And antibiotic treatment must be urgent and well-adapted with careful monitoring of patients.

Disclosure of Interests: None declared

SAT0466 HEPATITIS SAFETY OF ANTI-TUBERCULOUS TREATMENT IN SPONDYLODISCITIS

Aïcha Ben Tekaya1, Khouloua Zouaouli1, Rawdha Tekaya1, Olfa Saida1, Mohamed Ben Hammamia2, Ines Mahmoud1,1. Charles Nicole Hospital, Tunis, Tunisia;2 la rabta hospital, Tunis, Tunisia

Background: Tunisia is considered as a country with high tuberculosis endemicity. The anti-tuberculous treatment is quite long and binding and requires close hepatic monitoring.

Objectives: The purpose of this study was to highlight the hepatic safety of anti-tuberculosis treatment in tuberculous spondylodiscitis.

Methods: This is a retrospective descriptive study, over 20 years (1999-2019) collating cases of tuberculous spondylodiscitis in a rheumatology department. We studied the epidemiological, clinical, radiological and therapeutic aspects.

Results: Our study included 62 patients, 35 women and 27 men. Mean age was 56 years [16-86]. The diagnosis delay averaged 5.59 months [0.23-24]. Tuberculous contact was noted in 11.3% of the cases. Neurological abnormalities were noted in 16.1% of cases with spine compression in 3.2%. The tuberculosis skin test was positive in 29 cases and the Koch bacillus investigations in the sputum and the urine were positive in only 3 patients. Magnetic resonance imaging was performed in 71% of the patients, and mainly showed images of disc destruction with images of abscess, epiduritis and epidural extension. Infectious spondylodiscitis affected the lumbar spine in 66.1% of the cases, the dorsal spine in 14.51% of the cases and the cervical spine in 6.55% of the cases. It was bi-staged in 19.35% of the cases and bifocal in 17.74% of the cases.

Conclusion: Brucellar spondylodiscitis can be serious because of the neuropathy it can cause. The diagnosis delay averaged 5.59 months. Following the initial 4-drug regimen, most patients continued to receive a two-drug regimen with RMP and INH for a mean duration of nine months. Hepatotoxicity was seen in 13%: 11.4% of the patients had a history of cholestasis due to TB treatment, Only 2% of the patients had cytolysis. We needed to modify the treatment in 3.22%, and switch to triple anti-TB therapy based on Isoniazid, Rifampicin and ethambutol with a favorable evolution. No cases of hepatic insufficiency were noted.

SAT0465 VALUE OF SERUM PROCALCITONIN FOR THE DIAGNOSIS OF BACTERIAL SEPTIC ARTHRITIS IN DAILY PRACTICE IN RHEUMATOLOGY

Mickael Chouk1, Frank Verhoeven1, Maxime Sondag1, Xavier Guilhot2, Clément Pral1, Daniel Wendling1, 1Centre hospitalier régional universitaire de Besançon; Besançon, France;2Hospital Center Félix Guyon, Saint-Denis, Reunion Island

Background: Septic arthritis is a diagnostic and therapeutic emergency because of a high morbidity and mortality. Nevertheless, the etiologic diagnosis is often difficult.

Objectives: The aim of our study was to determine if serum procalcitonin was a discriminatory biomarker in case of arthritis of undetermined etiology.

Methods: Patients were separated in 5 groups: gouty arthritis, calcium pyrophosphate deposition arthritis, osteoarthritis or post-traumatic arthritis (“mechanical” arthritis), chronic inflammatory rheumatic arthritis, and septic arthritis. Levels of serum with blood cells, C-Reactive Protein and procalcitonin were measured.

Results: 98 patients were included: 18 in the “gout” group, 26 in the “calcium pyrophosphate deposition arthritis” group, 16 in the “mechanical” group, 18 in the “chronic inflammatory rheumatic” group and 20 in the “septic” group. The area under the receiver operating characteristic curve of with blood cells, C-Reactive Protein and procalcitonin levels to diagnose a septic arthritis were 0.69 (IC95% 0.55-0.83), 0.82 (IC95% 0.73-0.91), and 0.87 (IC95% 0.76-0.98) respectively. For a cut-off of 0.5 ng/ml, procalcitonin sensitivity, specificity, positive predictive value, negative predictive value, positive likelihood ratio and negative likelihood ratio were 65%, 91%, 65%, 91%, 7.2 and 0.4, respectively. Serum C-Reactive Protein and procalcitonin levels were correlated, were not different in septic arthritis with poly-arthritis than with mono-arthritis (p=0.05).

Conclusion: Serum procalcitonin is a useful biomarker in arthritis management with diagnosis performances higher than those of other biomarkers (with blood cells, C-Reactive Protein).

Disclosure of Interests: None declared

SAT0466 PNEUMOCCOCAL CELLULITIS AND FASCIITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW

Martin Greci1, Iligo Rua-Figueroa1, Antonio Narango1, Sabrina Ghiglione2, Maria Celia Erausquin1, Juan Carlos Quevedo-Abeldeo1, Carlos Rodriguez-Lozano1, Cristina Almeida1, Paola Leon1, Estibaliz Loza2; 1Hospital Universitario de Gran Canaria Dr. Negrín., Las Palmas, Spain;2Complejo Hospitalario Universitario de Jaén - Materno Infantil – CHUIM. Las Palmas, Spain;3Instituto de Salud Musculoesquelética Innusac, Madrid, Spain

Background: Streptococcus pneumoniae (SPN) is an encapsulated gram-positive bacterium that can be found in the nasopharynx as part of the normal flora. However, it is the most common cause of community-acquired pneumonia in adults and can also cause invasive diseases such as bacterial meningitis, and otitis media. Pneumococcocal cellulitis and fasciitis...
are uncommon. Several factors are associated with a predisposition to infections in patients with Systemic Lupus Erythematosus (SLE).

**Objectives:** To describe and analyze all documented cases of cellulitis or fasciitis caused by SPN in SLE patients.

**Methods:** In the framework of the study of a 24-years-old woman that during the SLE onset presented left tight cellulitis and fasciitis caused by SPN, a systematic review was conducted (until September 2018). The search included terms to identify any SPN infection in SLE patients and all those articles that reported cellulitis or fasciitis were selected (Table 1).

Table 1. Flow chart.

| Total searched articles: 313 | - Medline 72, Embase 241, Cochrane 0. |
| - Selected: 8 | - Selected: 8 |
| Manual included articles: 1. |

**Results:** A total of 313 articles were obtained. Eight of them (1-8) and 1 article identified in a manual search (9) described a total of 15 cases presenting SLE and cellulitis or necrotizing fasciitis caused by SPN; our case is the 16th described.

Documented infections (n=16):

- Cellulitis (n=8): neck, face or chest (n=5, 62.5%); extremities (foot or hand) (n=2, 25%); breast (n=1, 12.5%).
- Fasciitis (n=8): neck, face or chest (n=5, 62.5%); tights (n=3, 37.5%).

**Description of the documented cases:**

- Demographic characteristics (n=13): female sex (n=11, 85%); <30 years of age at the moment of the infection (n=11, 85%).
- Time of SLE evolution at the moment of the infection (n=9): ≤ 1 month (n=3, 33.3%); ≤ 3 years (n=3, 33.3%); ≤ 8 years (n=3, 33.3%).
- Associated conditions (n=12): previous high doses of prednisone (n=5, 45%); recent respiratory symptoms (n=4, 33.3%); renal insufficiency (n=2, 16.6%); previous SPN infections (n=1, 8.3%); recent surgery in the affected area (n=1, 8.3%).
- Microbiological diagnosis (n=12): blood cultures (n=11, 91.6%); other cultures (n=1, 8.3%).
- Treatment (n=12): beta-lactams (n=12, 100%); intensive care support (n=6, 50%); surgical debridement (n=5, 41.6%).
- Outcome (n=15): death (n=3, 20%); recurrent SPN infections (n=2, 13.3%).

**Conclusion:** * - Pneumococcal cellulitis and fasciitis in SLE were predominantly presented in young women and in a high rate of cases during the disease onset.
- Almost half of the cases were previously treated with high doses of steroids. Nevertheless, no other potential predictors of pneumococcal cellulitis or fasciitis were identified; in addition, only one patient presented a previous surgery in the affected anatomical area, previous trauma were not described in any case, and a low number of cases reported associated respiratory symptoms. This supports the importance of the intrinsic immune dysregulation in SLE patients.
- Pneumococcal cellulitis and fasciitis in SLE patients present poor prognosis, requiring intensive care support and surgical debridement in a high rate of cases, and presenting a fatal outcome in a fifth of them.

**SAT0468** INFECTIOUS SPONDYLODISCITIS IN A SPANISH REGIONAL HOSPITAL BETWEEN 2000 AND 2018: 66 CASES

Isla Morante Bolado1, Montserrat Santos Gómez2, Ignacio Villa-Blanco1, Leyre Riancho Zarrabeitia1, Elena Aurecoechea3, Teresa Ruiz Jimeno3, Jaime Calvo4, 1Síerrallana Hospital, Torrelavega, Spain; 2Síerrallana Hospital, Torrelavega, Spain; 3Universitary Hospital of Valdecilla, Santander, Spain; 4Universitary Hospital of Araba, Vitoria, Spain

**Background:** Spondylodiscitis have a large spectrum of clinical manifestations. The early diagnosis and treatment of this condition are essential to give the patient the best chance of a good outcome.

**Objectives:** To analyze the clinical characteristics, most frequent diagnostic methods and different treatments used in spondylodiscitis (SD) in our sanitary area.

**Methods:** Descriptive and retrospective study of patients with the diagnosis of infectious SD (clinical or microbiological) from 2000 to 2018. In each case we studied the presence of underlying diseases, an episode of infection in the previous 6 months, way of presentation, location, diagnostic methods, treatment and evolution, comparing among different etiologies.

**Results:** 66 patients were diagnosed of spondylodiscitis, 44 men (24-90 years: mean 71.7). 62 were pyogenic, 3 tuberculous (TBC) SD, and 1 candida. The patients with TBC were younger (mean age: 45.3; <0.05). An underlying disease was observed in 51 patients, specially Diabetes Mellitus (DM) (53% of SD). 4 patients were Rheumatoid Arthritis patients. A previous episode of bacteremia or a primary source of infection was identified in a 34.8% of the cases, obtaining a microbiological isolation in 50/66 (75.7%) SD (46 bacterial, 3 TBC and 1 Candida). The most frequent pathogens were Gram + (G+) (51% of the total SD) being S. aureus and S epidermidis responsible of 23/66 cases (34.8%). In the 94% of SD caused by G+, hemocultures positive were obtained, in comparison to a 55% of SD caused by G- (p=0.016).

The most frequent presentation symptoms were: lumbar pain (90%), fever (53%) and neurological deficit (19%). Leucocytosis was present in only a third of the SD, observing an increase of ESR and CRP in the pyogenic etiology (p no significative for low number of patients in SD group caused by TBC) and lower levels of hemoglobin, cholesterol and albumin. Lumbar area was affected in the 75.7% of SD (77% in G+ and 50% in G-). In a 13.6% of patients, more than one intersomatic space was affected, being visible the presence of an abscess in 47/66 cases (71.2%). It was necessary surgical treatment in 10/47 (21.2%). 5 patients died due to pathology related to SD (7.5%), without any correlation with a risk factor and other 5 presented a relapse in the subsequent months.

**Conclusion:** - The bacterial SD are the predominant group, being DM the most frequent risk factor.
  - The incidence of SD due to TBC and fungi is scarce in our environment, being absent the Brucella etiology.
  - The G+ SD usually have a previous associated bacteremia.
  - The majority of the patients had pain in the presentation, but only half of them had associated fever.
  - The most frequent location of SD was lumbar.
  - We established a 7.5% of mortality rate in our sanitary area.

**SAT0469** THE IMPACT OF CHIKUNGUNYA VIRUS INFECTION ON QUALITY OF LIFE, FUNCTIONAL STATUS AND WORK ABILITY

Marina Porangabh1, André M. Siqueira1, Genaldo Castelar1, 1Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil; 2Fundação Oswaldo Cruz – Fiocruz, Rio de Janeiro, Brazil

**Background:** Chikungunya virus (CHIKV) is a re-emergent arbovirus from the Alphavirus genus transmitted by Aedes species mosquitoes. The frequent feature of CHIKV disease is severe polyarthralgia, which is reported in more than 90% of cases. Musculoskeletal symptoms may persist in the subacute (> 3 weeks) and chronic (> 12 weeks) phases, causing critical physical impairment and significantly impacting the quality of life of patients.

**Objectives:** To assess the impact of CHIKV on pain, functional status, work ability and health-related quality of life (HRQoL) in the subacute and chronic phases of the disease.

**Methods:** Patients with a diagnosis of CHIKV disease (confirmed by PCR or serology) with persistent musculoskeletal symptoms after 4 weeks were referred to the Rheumatology outpatient clinic and followed up from April 2018 to January 2019. Evaluation questionnaires of pain (visual analogue scale – VAS), disability (Health Assessment Questionnaire – HAQ), HRQOL (Short-form 12 – SF-12) and work ability (Work Productivity and Activity Impairment-WPAI) were applied. The assessments were divided into 3 stages according to the time of disease: subacute from 4 to 12 weeks, chronic from 12 to 24 weeks and chronic with more than 24 weeks.

**Results:** Of the 69 patients analyzed, 76.81% were women, mean age 49.78 ± 14.24 years, 49.27% had some comorbidity (such as hypertension and diabetes), 26 were obese and 37.68% presented a previous musculoskeletal condition. Fifty-eight patients initiated follow-up in the subacute phase, in which the average pain was 6.84±1.9, mean HAQ of 1.59±0.57, mean Physical Health Composite Scale Score (PCS) of 26.81 ±14.3 and Mental Health Composite Scale Score (MCS) of 36.77±15.9. Of the 58 patients, 35 were employed and of these, 54.25% were absent from work during the previous week. Women presented higher scores in the mental component of SF-12 (<p=0.0215) and the presence of comorbidity related to higher values reported in the pain VAS (p = 0.026).

In the chronic phase of 12-24 weeks, 50 patients were evaluated, with mean pain 5.27 ± 2.22, HAQ 1.16 ± 0.81, PCS of 38.82±17.26 and MCS 43.72±17.13. Thirty-two patients were employed, of which 25% were absent the previous week. During this stage, women presented lower values of MCS (<p = 0.0245) and the presence of obesity was related to higher values in HAQ (p=0.0157). Finally, in the evaluation of the chronic phase after 24 weeks of evolution, we included 25 patients with the mean of pain 5.64 ± 2.3, HAQ 1.11 ± 0.49, PCS 36.72±19 and MCS 41.56±17.74. Fifteen of the 25 patients were employed and 33% were absent from work as the previous week. There was no significant difference between the groups evaluated after 6 months of evolution.

**Conclusion:** In this study, we demonstrated that the impact of chikungunya persist after 1 month of evolution in a large number of patients. The incapacity for work caused by the disease, represented by persistent rates of absenteeism at work in an economically active age group, further aggravates the magnitude of the problem.

**SAT0470** RISK OF HOSPITAL ADMISSION DUE TO INFECTION IN PATIENTS UNDERGOING TREATMENT WITH BIOLOGICAL THERAPY: CASE-CONTROL STUDY

Jose Rosas1, Ana Pons1, José Alberto Garcia-Gómez2, José Miguel Senabre-Gallego1, Gregorio Santos Soler1, Esteban Salas-Heredia1, José Antonio Bernal-Vidal1, Catalina Cano3, Estibaliz Ivars1, Xavier Barber3, AIRE-MB. 1Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain; 2Fundación General Hospital, Infectious Diseases, Elche (Alicante), Spain; 3University General Hospital, Statistics, Elche (Alicante), Spain

**Objectives:** To know risk of admission due to infection in patients treated with biological drugs (DMARDs).

**Methods:** Case-control study, in patients admitted for infection, treated with DMARDs, from 2000-2018. As a control group, patients included, in treatment with conventional synthetic DMARDs (DMARDcs). General data (age, gender), disease (diagnosis, time evolution, DMARD, time in DMARDs, DMARDcs); and infection (time in DMARDs to infection, location of infection, more than one admission).

**Results:** Of 384 patients, 48 (13%) had DMARDcs. 51% had DMARDs and 49% had infection. Absent of SD, 4 patients, 48 (13%) and 32 (9%) treated with DMARDs and DMARDcs alone. When comparing patients admitted vs who do not, RA predominates and no differences in the treatment with DMARDs and/or DMARDcs, corticosteroids, type of DMARD or the infection.

SAT0471 HIGH-RESOLUTION MELTING CURVE ANALYSIS: A RAPID AND PRAGMATIC APPROACH FOR SCREENING OF MULTIDRUG RESISTANT OSTEOARTICULAR TUBERCULOSIS (OATB)

Kusum Sharma1, Aman Sharm2, Mandep Phillon3. 1Post Graduate Institute of Medical Education and Research, Chandigarh, 2Chandigarh, 3Medical Microbiology, Chandigarh, India; 1Post Graduate Institute of Medical Education and Research, Chandigarh, Internal Medicine, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Orthopaedics, Chandigarh, India

Background: Emergence of MDR in extrapolummary tuberculosis (EPTB) is a major concern in endemic areas. Timely diagnosis and screening of multidrug resistance in patients of Osteoarticular Tuberculosis (OATB) is a challenge.

Objectives: To evaluate the rpoB gene real time PCR (RT PCR) in synovial fluid/pus samples and its comparison with MPB64 and IS6110 RT PCR for diagnosis of OATB.

Methods: Real time PCR using IS6110, MPB64 and rpoB genes was carried out in 150 cases of OATB and in100 non TB control group. Out of these, 20 OATB cases were culture confirmed and 130 were clinically suspected cases. Phenotypic susceptibility testing for culture isolates was performed by standard proportion method. DNA extracted from samples of the culture confirmed cases and the suspected OATB cases confirmed by RT PCR were subjected to rpoB and katG HRM analysis for screening of MDR.

Results: The sensitivity of rpoB RT PCR, MPB64 RT PCR and IS6110 RT PCR was 86.5%, 86.5% and 76.5% respectively. All RT PCR were negative in the control group thus the specificity was 100%. HRM analysis detected rifampicin resistance in 10 cases of which, 8 (80%) were MDR while 2 (20%) were isolated rifampicin resistance. Of the 13 cases of isoniazid resistance detected by HRM analysis, 8(61.5%) were MDR while 5(38.46%) were isolated isoniazid resistant. HRM analysis detected an additional 4 MDR cases directly from the samples which were negative by culture. Subsequently, results of HRM analysis were confirmed by rpoB sequencing and mutation were observed at codon 531 (60%); 533 (16%); 516 (12%) and 526 (12%). KatG sequencing revealed mutation at codon 315(100%). There was 100% concordance in the results of phenotypic DST, sequencing results and HRM analysis.

Conclusion: rpoB and katG HRM analysis is a promising method in reliable and rapid screening of drug resistance in OATB cases in 90 minutes.

Disclosure of Interests: None declared

SAT0472 THE CONTRIBUTION OF MRI IN THE DIAGNOSIS OF INFECTIOUS SPONDYLODISCITIS

Rawdha Tekaya1, Khelaoua Zouaoui, Aicha Ben Tekaya, Lobna Ben Ammar, Olfa Saidaane, Ines Mahmoud, Leila Abdelmoula. Charles Nicolle Hospital, Tunis, Tunisia

Background: Infectious spondylodiscitis is a diagnostic and therapeutic emergency, and if there is any doubt, an MRI should be performed to support the diagnosis.

Objectives: The aim of our study is to highlight the role of MRI in the diagnosis of infectious spondylodiscitis.

Methods: This is a 20-year retrospective study (1999-2019) performed at a rheumatology department, collecting cases of infectious spondylodiscitis. We have identified the epidemiological, clinical, and radiological characteristics.

Results: Our study included 106 patients, 57 men and 49 women. The average age was 55 [16; 86]. Mean disease duration averaged 4.54 months [0.23; 24]. All patients had spinal pain: lumbar in 65.09% of cases, dorsal in 17% of cases and cervical in 6% of cases. Standard X-rays showed abnormalities suggestive of spondylodiscitis in 88.67% of cases. Magnetic resonance imaging was then performed in 76.41% patients and was pathological in all cases. The abnormalities found were paravertebral abscess in 23.58% of cases, epiduritis in 10.37% of cases and association of abscess and epiduritis in 32.07% of cases. The rest of the abnormalities noted were vertebral osteolysis (8.49%), spinal cord compression (9.43%) abnormalities of the intervertebral disc with narrowing and/or signal modification (4%). The abnormalities were monofocal in 82.07% of cases and bilocular in 13.2% of cases. 78.57% of bilocular lesions were objectified in tuberculosis spondylodiscitis. 82.07% of the spinal injuries were single-stage and 15.09% were bi-staged. 75% of these were of tuberculous origin. There were 2.63% of spondylodiscitises up to 3 stages and all were tuberculous.

Conclusion: MRI is a great diagnostic aid during infectious spondylodiscitis. It also allows to orient towards the etiological diagnosis.

SAT0473 MUSCULOSKELETAL STIFFNESS IN CHIKUNGUNYA DISEASE: DISTINCT FROM PAIN AND RELEVANT TO QUALITY OF LIFE

Hugh Watson1, Sarah Tritsch2, Liliana Encinales3, Andres Cadera4, Carlos Cure5, Alexandra Porras6, Alejandro Rico Mendoza7, Aileen Chang4, 1Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 2The George Washington University, School of Medicine and Health Sciences, Washington, United States of America; 3Alfred Research Society LLC, Barranquilla, Atlantico, Colombia; 4Clinical de La Costa Ltda, Barranquilla, Atlantico, Colombia; 5Biomelab, Barranquilla, Atlantico, Colombia; 6Universidad El Bosque, Grupo de Medicina Comunitaria y Salud Colectiva, Bogota, Colombia

Background: Musculoskeletal stiffness is reported to be frequent following chikungunya infection and can persist for many months after infection. However, stiffness severity and its impact is not well characterised in this disease. A stiffness patient reported outcome instrument has been developed for use in rheumatoid arthritis.

Objectives: Our objective was to assess the use of this questionnaire and importance of musculoskeletal stiffness in a cohort of chikungunya patients.
patients with chronic joint symptoms in the Atlántico Department of Colombia.

Methods: Sixty-seven patients with chronic arthralgia and 15 patients without arthralgia were followed up a mean of 40 months after chikungunya infection. The patients came from a larger cohort of 500 patients previously followed up 20 months after infection. Those consenting to a 40-month in-person follow-up were included here. Tender joint counts, a pain intensity visual analogue scale (VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI) and the EuroQol overall health VAS (EQ-VAS) were completed. A 21-item musculoskeletal stiffness questionnaire (MSQ) was completed and summarized as percentage scores for overall stiffness and its components: stiffness severity, physical impact and psychosocial impact.

Results: The 82 patients (12 male and 70 female) had a mean age 51±14 years. Forty-two out of sixty-seven patients with arthralgia and 3/15 patients without arthralgia reported musculoskeletal stiffness. Stiffness in those patients had a median severity of 28% (IQR 0–42). An impact of their stiffness on physical activities was reported by 39/45 patients (87%) and psychosocial impact by 32/45 patients (71%). Overall MSQ score was a median of 16% (IQR 0–34). Mean tender joint count in patients reporting arthralgia was 6.2±7.1, mean pain intensity 65±20 out of 100, mean HAQ-DI = 0.54±0.52, and a mean EQ-VAS = 61±26 out of 100. Overall stiffness scores were poorly correlated with tender joint counts (r²=0.17) and pain intensity (r²=0.22). Stiffness scores were more strongly associated than arthralgia with overall health and disability indicators in patients with chikungunya disease. The MSQ is a potentially useful instrument for assessing symptoms in chronic chikungunya disease.

Conclusion: Musculoskeletal stiffness following chikungunya infection is distinct from the persistent arthralgia usually reported. It does not necessarily occur in the same patients and is poorly correlated with joint pain severity. Stiffness, as measured by this questionnaire, may be more strongly associated than arthralgia with overall health and disability indices in patients with chikungunya disease. The MSQ is a potentially useful instrument for assessing symptoms in chronic chikungunya disease.

SEPARATE POLICY STATEMENT

Echinococcosis and Auto-Immune Inflammatory Arthritis; Report of 8 Cases AND REVIEW OF THE LITERATURE

Pascal Zuflyer1, Zambaz Camille1, Rudiger Muller2, Boilat-Blanco Noémie2, Thomas Huegle1, Hasler Paul2, Peter Villiger3. 1JHU, DAL/CHUV, Lausanne, Switzerland; 2rheumatology, Medizinische Universitätsklinik kantonsspital, Aarau, Switzerland; 3rheumatology, Medizinische Universitätsklinik kantonsspital, Aarau, Switzerland. *rheumatology, Medizinische Universitätsklinik kantonsspital, Aarau, Switzerland.

Background: The prevalence of Echinococcosis in Western Europe and Switzerland has been rising in the past 20 years: <30 cases per year have been reported since 2005 (1). A few case reports (2) and some experimental animal studies (3) have suggested that the immunosuppression linked to inflammatory arthritis and their treatments could favor the development and the growth of parasitic lesions. On the other hand, a recent French study (4) has shown that the prevalence of Echinococcosis in arthritis patients was closer to the normal population. The characteristics of the parasitic disease were quite similar whether inflammatory arthritis was present or not.

Objectives: To evaluate the yearly recent incidence of this disease among patients with inflammatory arthritis in Switzerland and to search

SAT0474 AUTOIMMUNE MANIFESTATIONS OF VISCERAL LEISHMANIASIS IN CHINESE PATIENTS

Xiei Chen, Qiao Zhou, Rui Wu, Jia Cheng, Jian Liu, Bin Zhou, Li Long. Sichuan Provincial People’s Hospital, Rheumatology, Chengdu, China

Background: Visceral leishmaniasis (VL), caused by the protozoan Leishmania species, is the most severe form of leishmaniasis. The parasite migrates to the internal organs such as the liver, spleen, and bone marrow, and if left untreated, will almost always cause the host to die [1]. Due to polyclonal B cells activation, VL may present signs and symptoms resembling those of rheumatic diseases, especially systemic lupus erythematosus (SLE) [2–4]. This can sometimes lead to mis-diagnosis and treatment of corticosteroids.

Objectives: To analyze 27 Chinese VL patients retrospectively and focused on their autoimmune findings that could help clinicians to differentiate VL from SLE.

Methods: 27 in-hospitalized VL patients in our hospital from 2006 to 2015 were analyzed. VL was diagnosed by the presence of high titers of parasitic disease were quite similar whether inflammatory arthritis was present or not.

RESULTS: The basic characteristics and laboratory findings of the 27 patients were summarized in Table 1. All patients had hepatitis and the liver was more than 130%.

All of the patients had positive anti-Sm antibody and only 1 had anti-dsDNA antibody. 85.5% had increased IgG level and none had decreased C3 or C4.

All patients were cured with sodium stibogluconate, and ANA titers decreased C3 or C4.

None of the patients had positive anti-Sm antibody and only 1 had anti-dsDNA antibody. 89.5% had increased IgG level and none had decreased C3 or C4.

None of the patients had positive anti-Sm antibody and only 1 had anti-dsDNA antibody. 89.5% had increased IgG level and none had decreased C3 or C4.
for any interaction between arthritis, the treatment of arthritis and development and evolution of the echinococcosis.

Methods: We collected all the cases with the diagnosis of echinococcosis among the patients regularly followed and treated for inflammatory arthritis in three different tertiary rheumatology centers of Westen Switzerland (1.7 million inhabitants, 5000 arthritis pts).

Results: Between 2012 and 2018, 8 cases of echinococcosis (1.3 case/year/5000pts) could be found. The estimated yearly incidence among this arthritis population appears therefore to be significantly higher (p=0.0001) than the one reported in the general population in Switzerland (30/8000000 inhabitants). Figure summarized the relation between the parasitic and the inflammatory disease. Different types of inflammatory arthritis were implicated. Previous and ongoing arthritis treatments comprised also different types of biologics. In 6/8 cases, the parasitic disease was asymptomatic and limited to a single organ, a proportion much higher than what is usually found in the general population. In 2 of them, the discovery was very close in time to the diagnosis of arthritis and treatment initiation (<8 months), 4 pts could be treated by surgery alone. 6 continued their treatments for arthritis. No evidence of relapses after surgery (4 pts) or progression under albendazole (4 pts, median follow-up: 44 months) was found.

Conclusion: The incidence of echinococcosis in autoimmune arthritis appears to be higher than in general population but remains very low. Outcome seems not to be affected by inflammatory arthritis and their treatments but the long-time effects of the combination between arthritis treatments and albendazole need to be further evaluated.

Paediatric rheumatology

SAT0476 JUVENILE IDIOPATHIC ARTHRITIS IN SINGAPORE: A 10-YEAR CLINICAL EXPERIENCE

Poh Lin Pauline Chng Na1, Pei Ling Ooi2, Elizabeth Ang1, Lee Keen Lin3, Sook Fun Hoh4, Lena Das5, Yen Xin Book6, Thaschawee Arkachaisri2,3, Kho Teck Puat National University Children’s Medical Institute, National University Hospital, Singapore, Singapore; 1KK Women’s and Children’s Hospital, Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Graduate Medical School, Singapore, Singapore

Background: Juvenile Idiopathic Arthritis (JIA) is the commonest inflammatory arthritis of childhood worldwide.

Objectives: To describe the incidence, clinical characteristics and experiences with JIA in Singapore over a 10-year period.

Methods: A prospective study was conducted in KK Women’s & Children’s Hospital and National University Hospital, Singapore from Jan 2009-Dec 2018. JIA was defined and classified according to ILAR criteria1. Demographics and clinical information were collected for every patient diagnosed with JIA.

Results: 379 children were diagnosed with JIA (60.2% male, 71.2% Chinese). Average estimated incidence was 5.8 per 100000yr. Clinical characteristics and treatment used are summarized in Table 1. Table 1, “Median (IQR), Rest expressed in (%).

Disease modifying anti-rheumatic drugs (DMARD) were used in 67.8%, and younger age of diagnosis (p=0.002), longer lag time (p=0.004), males (p=0.018) and ERA (p=0.043) predicted their use. 36.3% required biologics, and males (p=0.047), longer lag time (p=0.037) and HLA-B27 positivity (p=0.030) were associated with their use. Uveitis incidence was 2.9%; 54.5% had oligoarthritis, 36.4% ERA, 9.1% polyarthritis (RF+). Younger age at JIA diagnosis was associated with uveitis (p=0.030).

Conclusion: ERA is the commonest subtype of JIA in our cohort, explaining the male predominance and higher HLA-B27 positivity as compared to the West2. Longer lag time was associated with DMARD and biologic use, likely due to more severe disease at presentation. HLA-B27 association with biologic use may predict ineffectiveness of DMARD. Uveitis incidence was low as compared to Western literature that cites a prevalence of 11-30%3,4. Young age at diagnosis is a risk factor for uveitis. Interestingly, ANA-positivity and female gender were not associated with uveitis cases.

SAT0477 QUALITY OF LIFE IN SUBJECTS WITH PRE-PUBERTAL ONSET SYSTEMIC LUPUS ERYthematosus

Brand Stevens, Martha Rodriguez, Amy Rakeshw, Kathleen O’Neil. Indiana University Health, Pediatrics, Indianapolis, United States of America

Background: Systemic Lupus Erythematosus (SLE) can be a severe disease, especially when diagnosed in childhood. Onset prior to puberty (Tanner stage II) is rare, and less is known about the impact SLE has on this pediatric population. We assessed clinical and quality of life (QOL) measures in a prepuberal SLE onset cohort to better globally understand the burden of this disease in this group.

SAT0478

School functioning domain had the worst QOL measure with the greatest number of children impacted (Table). Active arthritis was associated with lower mean scores in Physical health (p=0.007), PedsQL Core total (p=0.048), Pain and Hurt (p=0.002), Daily Activities (p=0.003), Treatment (p=0.002), Worry (p=0.036), and PedsQL Rheumatology total (p=0.001). There was no association with QOL measures for rash, alopecia, or laboratory markers. Disease damage on SLICC/ACR DI was associated with greater impact on the Worry domain (mean 64.3 vs 88.1, p=0.02).

Conclusion: Children with pre-pubertal SLE onset report significant impacts on QOL regarding school. The disease manifestation affecting the most QOL domains was arthritis, whereas skin manifestations, while common, did not demonstrate an impact on QOL. This is the first study to specifically address quality of life for children who develop SLE prior to pubertal development.

**UPDATE FROM THE JUVENILE SCLERODERMA CHRONIC KIDNEY DISEASE IN PATIENTS WITH**

Anjali Patwardhan, Yosef Uziel, Nicola Helmus, Kathryn Torok, Valda Stanevicha, Filivio R. Sztajnbok, Maria T. Teren, Ekaterina Alexeeva, Jordi Anton, Maria Katsiks, Vanessa Smith, Tadej Avcin, Rolando Cinaz, Mikhail Kostik, Thomas Lehman, Walter Alberto Silveutenes-Giraldo, Simon Appenzeller, Mahesh Janarthanan, Monika Molf, Dana Nemcova, Maria Jose Santos, Dienneke Schonenberg, Cristina Battagliotti, Lillemor Bernstoff, Blanca Bica, Juergen Brunner, Patricia Costa Reis, Despina Eleftheriou, Lora Harel, Gerd Horneff, Tilmann Kallinich, Dragana Lazarevic, Kirsten Minden, Susan Nieman, Farzana Nuruzzaman, Anjali Palwardhan, Yosef Uziel, Nicola Helmus, Hamburger Zentrum für Kinder-und-Jugendrheumatologie, Hamburg, Germany, Deutsches Rheuma-Forschungszentrum (DRFZ), Berlin, Germany, JSSc Collaborative Group, Hamburg, Germany

**Background:** Juvenile systemic sclerosis (JSSc) is an orphan disease with a prevalence of 3 in 1,000,000 children. There are limited data regarding the clinical presentation of JSSc. The Juvenile Systemic Sclerosis Inception Cohort (JSSIC) is a multinational registry that prospectively collects information regarding patients with this disease in a standardized manner.

**Objectives:** Evaluation of the JSSc patients at the time of inclusion in the JSSIC.

**Methods:** Patients were included in the JSSIC if they fulfilled the adulthood classification criteria, if they presented the first non Raynaud symptom before 16 years old and if they were younger than 18 years old at the time of inclusion. Patients’ characteristics at time of inclusion were evaluated.

**Results:** Currently, the cohort includes 120 patients, being 89% Caucasian and 80% female. The majority had diffuse subtype (74%) and 18% had overlap features. The mean age of onset of Raynaud phenomenon was 9.7 years in the diffuse subtype (dJSSc) and 10.7 years in the limited subtype (lJSSc). The mean age of non-Raynaud's symptoms was 10.0 years in the dJSSc and 11.4 years in the lJSSc. Mean disease duration time of inclusion was 3.4 years in the dJSSc and 2.4 years in the lJSSc group. Mean Modified Rodnan skin score was 17.5 in the dJSSc and 7.3 in the lJSSc (p=0.002). Gotton papulea were significantly more common in the dJSSc compared to lJSSc group (29% vs 6%, respectively) (p=0.011). History of ulceration was significantly more common in the dJSSc than in the lJSSc group (57% vs 30%, respectively) (p=0.004). FVC<80% occurred in 31% in the dJSSc and 24% in the lJSSc group (p=0.55). Pulmonary hypertension assessed by echocardiogram occurred around 7% in both groups. No systemic hypertension or renal crisis was reported. Gastrentestinal involvement occurred in 39% in the dJSSc and in 26% in the lJSSc (p=0.176). Number of joints with decreased range of motion was observed in approximately half of patients in both groups. Muscle weakness with joint contractures was present in 18% in the dJSSc and 38% in the lJSSc group (p=0.271). Tendon friction rub was present in 11% in dJSSc and 4% in the lJSSc group. dJSSc patients had significantly worse scores for physician global disease activity (VAS 0-100) (41 vs 30) (p=0.020) and for physician global disease damage (VAS 0-100) (37 vs 18) (p=0.001). Patient judgment of disease activity and damage was similar in both subtypes. ANA positivity was 88% in both groups. Anti-Scl70 was positive in 33% in dJSSc and 37% in the lJSSc group. Anticentromere positivity occurred in 3% in the dJSSc and 10% in the lJSSc group. ESR was elevated in 30% in dJSSc compared to 18% in the lJSSc group. DMARDs were used in 86% of the patients.

**Conclusion:** In this large cohort of JSSc patients there were surprisingly not many significant differences between dJSSc and lJSSc. According to the physician global scores the dJSSc patients have a significantly more severe disease.

**SAT0480 CHRONIC KIDNEY DISEASE IN PATIENTS WITH JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS: EVIDENCE FROM A SINGLE CENTRE**

Yasmin Mahouz, Anastasia-Vasiliki Madenidou, Coiziana Citru, UCL, Arthritis Research UK Centre for Adolescent Rheumatology, London, United Kingdom, UCL, Medical School, London, United Kingdom

**Background:** Estimated 10–20% of all patients with systemic lupus erythematosus (SLE) develop clinical disease before the age of 18 years and are therefore classified as juvenile-onset SLE (JSLE). JSLE is characterised by a higher prevalence of lupus nephritis, compared to adult-onset SLE (1). Chronic kidney disease (CKD) refers to a state of irreversible kidney damage and/or reduction of kidney function that is associated with progressive loss of function over time. Lupus nephritis does not always lead to CKD. However, when it does it is associated with increased morbidity and mortality (2).

**Objectives:** We aimed to identify clinical and laboratory predictors of CKD development in JSLE patients by comparing the baseline characteristics of JSLE patients with and without CKD to ascertain if there are any significant differences between the two groups.

**Methods:** This is a single-centre retrospective study, who included patients reviewed in our young adult and adolescent clinics. All data were analyzed descriptively. Mann-Whitney U or Chi-square test were performed to compare the characteristics between the patients with and without CKD. We used the Pearson’s (r) or Kendall’s τ (tau) correlation to examine if there is any association between the CKD and the baseline characteristics.

**Results:** We identified 44 JSLE patients, out of which 17 (39%) fulfilled the diagnostic criteria for CKD at their last clinical review. The stages of CKD varied from 2 to 5. All patients with CKD also had lupus nephritis, compared to patients without CKD. The baseline characteristics are detailed in the table below. There were statistically significant differences in the treatments used for patients with and without CKD. As expected, the highest dsDNA levels were higher in patients with CKD (p=0.03). There was also a positive correlation between raised levels of dsDNA and the development of CKD (p=0.008). We also found a negative moderate correlation (r=-0.439) between the presence of RF and CKD (p=0.04).

**Conclusion:** Acknowledging the limitations posed by this small study, we identified a negative moderate correlation between the presence of RF and CKD, which has also been reported in the literature before (3). We cannot conclude that RF exerts a protective effect against renal disease in SLE, because of the many confounders that might account for a decreased RF in JSLE. Further research using a large JSLE cohort enabling multivariate logistic regression is recommended. dsDNA antibody levels are a measure of disease activity in lupus nephritis and therefore this might explain why patients who developed CKD were noted to have higher anti-dsDNA levels, in comparison with the patients who did not develop CKD.

SAT0482 TREAT-TO-TARGET STUDY FOR IMPROVED OUTCOME IN POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS
Gerd Hornett, Joachim Peitz, Ivan Foeldvari, Ralf Trauzeddel, Toni Hospach, Tilmann Kallnich, Frank Welter-Heinemann, Ariane Klein, Kirsten Minden, BIKER-Registry, Sankt Augustin, Germany

Background: Evidence suggests that early effective treatment is important to minimize the burden of Juvenile idiopathic arthritis (JIA). We hypothesize that a guided-treat to target (T2T) approach as recommended by the German Society for Pediatric Rheumatology (1) is superior to routine care in polyarticular JIA (pJIA) in terms of reaching minimal disease activity and remission after 12 months of treatment.

Objectives: To assess the clinical benefit in subjects with pJIA treated in compliance with national recommendations measured by rates of patients reaching JADAS remission (<1), JADAS minimal disease activity (MDA) (<3.8), JADAS acceptable disease status (<5.4).

Methods: After informed consent, patients with early disease (diagnosis ≤12 months) and active (JADAS ≥3) pJIA were enrolled. Initially, all patients received methotrexate (MTX). Targets for treatment were defined by the level of improvement and are progressively more rigorous with ongoing treatment. Failure to meet a defined target required treatment modification of specified intervals. The choice of biologic was made by shared decision between the investigator and the patient/parent and not influenced by the protocol. Minimal treatment target defined as recognizable improvement of disease activity (2) was demanded after 3 months, JADAS acceptable disease status at month 6, JADAS MDA at month 9 and JADAS-remission at month 12. T2T Patients were 1:4 matched to a pJIA cohort with unguided therapy documented by the BIKER-registry.

Results: Altogether 62 patients (16 males, 26% with non-systemic JIA (46/9 RF negative/positive polyarthritis, 3 extended Oligoarthritis, 1 ERA, 1 PsA) were included (mean age 9.4±4.8 years, disease duration 0.5+/−0.6 years). At month 3; 49 (79%) patients showed JADAS improvement. In 13 (21%) treatment with a biologic was started. At month 6, 45/56 (80%) reached JADAS acceptable disease. In 6 (11%) a biologic agent was started. At month 9, 41/48 (85%) reached JADAS acceptable disease and 38/48 (79%) reached JADAS MDA. In 4 (10.6%) a biologic agent was started and the two patients switched biologics.

So far, 52 patients completed 12 months of observation. 4 patients did not start a biologic although mandatory according to protocol and were excluded. JADAS MDA was reached by 39/48 (81%) and JADAS remission was reached by 22/48 (46%). Compared to the matched control cohort, upon T2T guidance significant more patients reached JADAS MDA (81% vs. 60%; odds 2.9[1.3-6.3]; p=0.0006) and more patients reached JADAS remission (46% vs. 34%; odds 1.6[0.9-3.0]; p=0.15). During the first 12 months of treatment, the T2T approach lead to a significant increase of use of biologics (46% vs. 21%; odds 3.2[1.7-6.3]; p=0.004).

Disclosure of Interests: None declared
remission after 12 months of treatment. Interestingly, about half of patients did not need to be treated with a biologic to reach predefined T2T (2). Thus, the early treatment escalation seems advantageous indicating a window of opportunity to successfully treat polyarticular JIA.

SAT0483
COMPARISON OF THE CLINICAL DIAGNOSTIC CRITERIA AND RESULTS OF THE NEXT GENERATION SEQUENCE GENE PANEL IN PATIENTS WITH PERIODIC FEVER

Ferhat Demir1, Yasemin Kendir Demirkol2, Zeynep Acgon Dogan2, Sazin Canbek3, Kubra Emir Teklu3, Nurye Aktay Ayaz4, Levent Doganay4, Bethil Sören5
1University of Health Sciences, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 2University of Health Sciences, Umraniye Training and Research Hospital, Pediatric Genetics, Istanbul, Turkey; 3University of Health Sciences, Umraniye Training and Research Hospital, Medical genetics, Istanbul, Turkey; 4University of Health Sciences, Karuni Sultan Suleyman Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 5University of Health Sciences, Umraniye Training and Research Hospital, Genomic Laboratory (GLAB), Health Directorate of Istanbul, Istanbul, Turkey

Background: Autoinflammatory diseases (AID) are a group of hereditary diseases characterised by inflammation periods accompanied with clinical findings such as fever, skin rash, lymphadenopathy, abdominal pain, musculoskeletal symptoms, and with sign of inflammation in the blood. Each disease has own typical clinical findings and they are associated with mutations in specific genes such as in MEFV gene in familial Mediterranean fever (FMF), MVK gene in mevalonate kinase deficiency (MKD), TNFRSF1A gene in TRAPS and NLRP3 gene in cryopyrin associated periodic fever syndrome (CAPS). There are also patients exhibit the incomplete phenotype of a disease or overlap signs of more than one AID. The diagnosis of these patients have difficult and may not be possible by a single target gene analysis. Screening of the periodic fever syndromes (PFS) genetic panel including various AID genes may be beneficial to define the atypical cases.

Objectives: The aim of this study was to compare the phenotypic diagnoses of the genotypic results obtained from the PFS genetic panel, which studied in patients with phenotypic findings of AIDs except the FMF, such as MKD, TRAPS and CAPS.

Methods: This is a prospective study and conducted between June 2016 and December 2018. Patients who met ‘The Eurofever clinical diagnostic classification criteria’ for MKD, TRAPS and CAPS were included in the study. Next-generation sequencing (NGS) analysis was performed including 8 genes (MEFV, MVK, NLRP3, NLRP12, TNFRSF1A, TNFRSF1A1, LPIN2 and PSTPIP1) in 37 patients with phenotypic findings of MKD, TRAPS or CAPS. The patients phenotypic preliminary diagnoses and genotypic results were compared.

Results: Thirty seven patient included in the study who met the clinical diagnostic criteria for MKD, TRAPS or CAPS. As a result of clinical signs: 19 patients were diagnosed with MKD, 10 were TRAPS and 8 were CAPS.

In the PFS genetic screening panel of 19 patients with phenotypic diagnosis of MKD, disease causing mutation was found in 8 patients in MVK gene, in 3 patients in MEFV gene, in 2 patients in NLRP12 gene and in 1 patient in TNFRSF1A gene. No pathogenic mutation was shown in 3 patients and genetic variants of uncertain significance (VUS) in different genes were shown in two patient.

In the result of PFS panel of 10 patients with phenotypic diagnosis of TRAPS, disease causing mutation was found in 5 patients in MEFV gene and in 2 patients in TRAPS gene. No pathogenic mutation was identified in 3 patients. In 8 patients who were diagnosed phenotypically as CAPS; disease causing mutation was found in 3 patients in NLRP3 gene, in 2 patients in NLRP12 and in one patient in MEFV. No mutation was detected in remaining two patient.

The final diagnosis was made by both phenotypic and genotypic data. In 37 patients (phenotypically 19 MKD, 10 TRAPS, 8 CAPS), respectively; 8 had MKD, 9 had FMF, 3 had CAPS, 3 had TRAPS, 4 had FCAS2 and 10 had undifferentiated PFS.

Conclusion: In our study, we have shown that clinical diagnostic criteria may not always be sufficient to establish the correct diagnosis. In case of clinical suspicion or in the presence of more than one autoinflammatory disease findings, NGS analysis may help to determine the diagnosis.

Disclosure of Interests: We are grateful to all participating children and their families. Ethics committee approval was received from the Institutional Review Board of Umraniye Training and Research Hospital. All the participants and their legal guardians were informed, and their written consent was obtained. Disclosure of Interest: None Declared

SAT0484
QUALITY OF LIFE IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS ASSOCIATED UVEITIS: DO WE NEED A NEW ASSESSMENT QUESTIONNAIRE?

Mario Sestan1, Danica Grguric1, Maja Sedmak1, Nastasia Kifer1, Marijan Frkovic1, Sanja Peric1, Kristina Potocki1, Nenad Vukovic1, Marija Jelusic1
1University Hospital Centre Zagreb, University of Zagreb School of Medicine, Department of Paediatrics, Zagreb, Croatia; 2University Hospital Centre Zagreb, University of Zagreb School of Medicine, Department of Ophthalmology, Zagreb, Croatia; 3University Hospital Centre Zagreb, University of Zagreb School of Medicine, Department of Radiology, Zagreb, Croatia

Background: Uveitis, the most common extra-articular manifestation in juvenile idiopathic arthritis (JIA), occurs in 10-20% of patients. Although presence of uveitis within JIA-U (JIA-U) improved, complications still cause severe impairment of visual function in 25-33% of children that affects their psychophysical and psychosocial development and quality of life (QoL).

Objectives: To study the QoL and its dimensions in children suffering from JIA-U as well as to investigate is there any difference in childhood’s and parent’s perception of disease between the group of children with JIA-U and children with JIA without uveitis.

Methods: The study included 42 children with JIA and their parents. Patients were divided into two groups. The first consisted of 21 children with JIA-U and the second of 21 children with JIA and no uveitis. Both groups of patients and their parents filled the Juvenile Arthritis Multidimensional Assessment Report questionnaire (JAMAR) for monitoring and assessing the health status of children with JIA. The variables used to test differences were: QoL, functional ability, pain level, disease activity estimation, and current emotional state of the child. The significance of differences between groups of children and parents was verified by the independent-samples t-test. The Pearson correlation coefficient was used for measurement of the strength of the linear relationship between variables.

Results: There were no statistically significant differences in the JIA-U group and the control group in either of the examined variables. Although there is a tendency of higher scores in children with JIA-U, which indicates their worse functioning, higher pain intensity and worse current emotional state, these differences were not statistically significant. Two groups did not differ significantly in the assessment of their own overall functional ability, which was associated with experienced pain intensity. Stronger pain intensity was associated with dysfunction (r = 0.642, p
<0.01) while a lower level of QoL was associated with more intense pain (r = 0.542, p <0.01) and poor current emotional state (r = 0.401, p <0.05). The activity of the disease in children was not significantly related to any determinant of the QoL. In contrast to children, parents of children with JIA estimated current emotional state of their children significantly worse (t = 2.05, p <0.05) and the overall level of functioning significantly lower than parents whose children did not have uveitis (t = 2.03, p <0.05).

Conclusion: Since children with JIA evaluated the QoL equally well, whether they had uveitis or not, we can conclude that they are psychologically well adapted to their health status and cope well with different levels of pain. Unlike children with uveitis, their parents evaluated the current emotional state and overall functionality significantly worse compared to parents of children who did not have uveitis. These results support a need for the development of new uveitis specific questionnaires that will enable us better identification of patient’s requirements. It is necessary to implement a holistic and multidisciplinary approach to assess the emotional functioning of the children and their families, and to devise appropriate psychosocial interventions for continuing support for ill children and their families.

Disclosure of Interests: None declared
treatment of systemic-onset and polyarticular course juvenile idiopathic arthritis (JIA), and is used off-label in other treatment refractory inflammatory diseases. Real-world data regarding tolerance of TCZ in children are scarce.

**Objectives:** To assess the incidence rate and type of serious adverse events in children treated with TCZ.

**Methods:** A single-center retrospective review of all consecutive patients receiving TCZ in the pediatric rheumatology division from 01/2007 to 12/2018 was performed. Inclusion criteria were a diagnosis of inflammatory rheumatic disease and treatment with at least one dose of TCZ. Patients with missing data were excluded. Serious adverse events (SAE) were defined as a life-threatening event and/or an event requiring hospital admission, leading to permanent disability or treatment discontinuation.

**Results:** A total of 70 children (39 females) were included. Thirty children had systemic JIA, 25 polyarticular course JIA, 14 systemic inflammatory disorders such as autoinflammatory syndromes and one patient severe refractory idiopathic uveitis. Median age at diagnosis was 4.2 years (IQR 2.9 – 7.3). The majority of children had received prednisone (n=56), and/or at least one biologic agent (n=63) prior to TCZ initiation. At TCZ start, children had a median age of 8.9 years (IQR 4.9 – 12.3) and disease duration of 3.2 years (IQR 0.9 – 7.4). TCZ was initiated at a 2-week interval in 44 children, 28 children received TCZ every 4 weeks. Fifty-eight children received concomitantly another immunosuppressive agent (prednisone (n=47) and/or methotrexate (n=20) and/or various other drugs (n=5)). A median of 26 TCZ doses were given per child (IQR 7 – 48). TCZ exposure was 146.8 patient years. Twenty-two SAE were observed in 18 (26%) children (SAE 14.9/100 patient years): 8 severe infusion reactions, 7 serious infections, 3 cutaneous reactions (toxic epidermal necrolysis, cutaneous vasculitis, scleroderma-like skin thickening with fasciitis), two macrophage activation syndromes, and one abnormal hepatic function and severe dizziness each. Infusion reactions occurred most frequently during the first few infusions (median during 4th infusion, IQR 3 – 5). All patients with infusion reactions had either systemic JIA (n=4) or another autoinflammatory disease (n=4). At time of infusion reaction, all children (8/8) had active disease, 7/8 had a concomitant treatment with prednisone and 2/8 additionally with cyclosporine. At last follow up, 35 (50%) children were still on TCZ, the other 35 had discontinued TCZ: 4 for remission, 13 because of inefficacy, 12 because of side effects, 3 because of both inefficacy and side effects, and 3 for other reasons. No death occurred during TCZ treatment; two patients with systemic inflammatory disease, in whom TCZ had been inefficient, died from uncontrollable disease 13 and 15 months after TCZ discontinuation, respectively.

**Conclusion:** In this cohort, serious adverse events were observed in a quarter of children with half of them having severe infusion reactions. Higher incidence rates of severe infusion reactions were observed in children with systemic JIA or autoinflammatory diseases. Ongoing careful monitoring of patients treated with TCZ, especially those with important systemic inflammation is required.

Background: Castleman disease (CD) is a very rare non-malignant lymphoproliferation of undetermined origin. CD diagnosis is difficult and often delayed because of insidious onset, low awareness and clinical heterogeneity. Two major disease phenotypes can be distinguished: unicentric CD (UCD) and multicentric CD (MCD). Diagnosis confirmation is based on histopathological findings on an involved lymph node.

Objectives: We attempted to survey all cases of paediatric CD identified in France so far, in order to set up a national registry aimed to improve CD early recognition, treatment and follow-up, within the context of a new reference centre (http://www.castleman.fr).

Methods: In 2016, we e-mailed a questionnaire to members of the French paediatric immuno-haematology society, the French paediatric rheumatology society and the French Reference Centre for Castleman Disease to retrospectively collect cases of paediatric CD (first symptoms before age 18 years). Anatomopathological confirmation was mandatory.

Results: We identified 23 patients (12 girls and 11 boys) diagnosed with CD before age 18 years). Anatomopathological confirmation was mandatory. Two major disease phenotypes can be distinguished: unicentric CD (UCD) and multicentric CD (MCD). Diagnosis confirmation is based on histopathological findings on an involved lymph node.

SAI0489 PREVALENCE OF AUTOIMMUNE DISEASES IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Daniel J. Lovell1, Bin Huang1, Chen Chen1, Sheila Angeles-Han1, Teresa Simon2, Hermine Brunner1, CHMC Cincinnati, Cincinnati, Cincinnati, United States of America;

1CHMC Cincinnati, Cincinnati, United States of America; 2Bristol-Myers Squibb, Princeton, United States of America

Background: Juvenile idiopathic arthritis (JIA) is one of at least 80 different types of autoimmune diseases, and is the most common paediatric rheumatic disease. After cancer and heart disease, autoimmune diseases are the most common type of disease in the US. The estimated prevalence of autoimmune diseases is 3.2% and 5.9% in the US and Europe, respectively, with a corresponding increase in mortality. Many autoimmune diseases share a common pathogenic mechanism. There are few published studies quantifying the occurrence of other autoimmune diseases in patients with JIA.

Objectives: To estimate and compare the prevalence of 38 co-existing autoimmune diseases in patients with JIA and in a general paediatric population.

Methods: This was a retrospective cohort study conducted using registry data from the Cincinnati Children’s Hospital Medical Center (CHMC; Cincinnati, OH, USA) from Jan 2010 to Oct 2018. Patients <21 years old who had at least one clinic visit at the CHCMC were included in the general patient (GP) cohort, excluding pts with JIA. The JIA cohort consisted of patients <21 years old who had one of the International Classification of Diseases (ICD)-9 or ICD-10 diagnosis codes for JIA. No exclusion criteria were applied. Cases for each of 38 autoimmune conditions (AICs) were identified using ICD9/10 codes. Comparisons were made between the JIA and the GP cohorts for each of the 38 AICs in crude prevalence (reported as X cases per patient-year) for each year up to the end of the study period. A Bayesian Poisson regression model was used for estimating and comparing prevalence rates for the JIA and GP cohorts at the end of study period. The rate and corresponding 95% confidence limits of the two cohorts on their prevalence rates are reported.

Results: There were 2,026 and 41,572 patients included in the JIA and GP cohorts, respectively. Out of 38 AICs, 26 showed significantly higher prevalence in the JIA cohort compared with the GP cohort (Figure). Of the 38 ICD9/10 codes assessed, 14 (36.8%) showed a more than 20-fold greater prevalence in the JIA cohort than in the GP cohort. There

Figure: Significant results from Bayesian Poisson analysis on point prevalence comparisons: JIA cohort vs GP cohort

National Arthritis Foundation of Singapore

Consultant for: SOBI, Novartis, Pfizer, Abbvie, UCB, CHUGAI, ROCHE, Caroline Galeotti: None declared.

were statistically significant differences in 26 conditions (Figure), with the most striking differences comparing the GP cohort with the JIA cohort in: serum amyloid A (0.001% vs 0.98%), psoriatic arthritis (0.01% vs 4.4%), systemic sclerosis/scleroderma (0.004% vs 0.6%), uveitis (0.07% vs 7.82%) and sarcoidosis (0.003% vs 0.3%). Only alopecia areata was more frequent in the GP cohort than in patients with JIA (4.5% vs 0.2%).

Conclusion: Patients with JIA have more pronounced autoimmune prevalence than the general paediatric population, especially for ankylosing spondylitis, psoriatic arthritis, uveitis, systemic sclerosis/scleroderma and sarcoidosis.

Lipoprotein lipase is a key enzyme in lipid metabolism, ensuring the hydrolysis of plasma triglycerides found in chylomicrons and very low density lipoproteins. An increase in the catalytic activity of lipoprotein lipase leads to a decrease in the level of TG and an increase in the level of HDL in the blood. According to the results of the survey in children with JIA, the concentration of lipoprotein lipase was 13.9 [7.1; 25.3] μg/l, with obesity 27.5 [9.9; 47.8] μg/l. A direct relationship was established between its content in blood serum and the concentration of LDL (r = 0.37; p < 0.05) and the inverse with the level of LDL (r = -0.4; p < 0.05). There was a significant difference (p < 0.05) by gender: the level of lipoprotein lipase in the blood serum in girls was 25.8 [16.7 - 54.4] μg/l, in boys - 15.6 [7.8 - 29.0] μg/l. A correlation was also established between the level of lipoprotein lipase and body mass index (r = 0.35; p < 0.05).

According to the results of the study, a significant (p < 0.05) increase in the level of primary (DK233) and secondary (DK278 and MDA) LPO products in the blood serum of children with JIA was found in comparison with the control group. During the correlation analysis, a positive correlation was established between the levels of DK233, DK278 in serum and ESR (r = 0.587, p < 0.01). The results obtained indicate the intensification of lipid peroxidation processes. A significant (p < 0.05-0.01) decrease in the content of water-soluble (ACW) and fat-soluble (ACL) antioxidant capacities of substances in the blood serum of children with JIA was found when compared with similar indicators in the control group. During the correlation analysis, a negative correlation was established between the level of CRP and the content of ACL in serum (r = -0.346, p < 0.05), between the content of ACW and CRP in serum (r = 0.54, p < 0.01).

Conclusion: It can be concluded that the activation of lipid peroxidation and the failure of the antioxidant system play a significant role in the development and progression of JIA in the examined children, as well as in the formation of attherosclerotic disorders by the lipid peroxidation mechanism. In addition, children with JIA have abnormalities in the lipid spectrum, acquiring an atherogenic orientation, which, together with hemostatological changes, can be regarded as a risk factor for attherosclerosis.

Disclosure of Interests: None declared

GASTROINTESTINAL MANIFESTATIONS IN CHILDHOOD BEHÇET’S DISEASE

Fatih Demir1, Nergin Gererli2, Seval Sismeke1, Belgül Sözen1. University of Health Sciences, Ümraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 1University of Health Sciences, Ümraniye Training and Research Hospital, Pediatric Gastroenterology, Istanbul, Turkey

Background: Behçet’s disease (BD) is an idiopathic, chronic, inflammatory systemic vasculitis characterized by recurrent oral and genital aphthous ulcers, skin lesions, and ocular involvement. It can also affect multiple visceral organs and system such as heart, lung, blood vessels, gastrointestinal (GI) system, and central nervous system (1). The etiology of the disease is still unknown. New diagnostic criteria for pediatric Behçet’s disease (2). Two major disturbances in the examined children, as well as in the formation of attherosclerotic disorders by the lipid peroxidation mechanism. In addition, children with JIA have abnormalities in the lipid spectrum, acquiring an atherogenic orientation, which, together with hemostatological changes, can be regarded as a risk factor for atherosclerosis.

SAT0493

THE CHALLENGE OF TREATING PULMONARY VASCULITIS IN BEHÇET’S DISEASE: TWO PEDIATRIC CASES

Selcan Demir1, Erdal Sag1, Ummesen Kaya Akca1, Tuncay Haziholan2, Yelda Bilgili1, Seza Özen1, 1Hacettepe University Faculty of Medicine, Pediatric Rheumatology, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Radiology, Ankara, Turkey

Background: Behçet’s Disease (BD) is a multisystemic autoinflammatory disease and the most severe complication of BD is pulmonary artery involvement (PAI). Data regarding treatment and outcomes of pediatric patients with PAI is very limited.

Objectives: Herein, we report two pediatric patients with BD presenting with PAI and treated successfully with aggressive immunosuppressive treatment.

Methods: Demographic data, clinical manifestations, laboratory and radiological findings, and treatments of patients were documented from patient charts retrospectively.

Results:

Case 1: A 15-year-old boy was admitted with abdominal pain and fever. An abdominal Doppler ultrasonography (USG) showed stenosis of vena cava inferior (VCI) with a thrombus. Transesophageal echocardiography (TEE) detected that the thrombus extended from VCI to the right atrium. When he started to have hemoptysis, he was referred to our hospital. TTE showed a mass in RV. The computed chest and abdominal tomography angiography (CTA) showed bilateral aneurysmatic dilatation with thrombi in the pulmonary arteries and thrombosis in vena hepatica. The paternity test was negative and the HLA B5 was negative. According to the ICBJD, the patient had been diagnosed as BD due to genital ulcers and vascular involvement. He was given pulse methylprednisolone (MP) 500 mg 3 days along and followed by oral prednisolone 1 mg/kg/day, intravenous cyclophosphamide at a dose of 15 mg/kg every 3 weeks for a total of 6 cycles, and Interferon-02a (IFN-02a) 3 times a week. Within one month, hemoptysis and fever disappeared, and CRP values normalized. After a three-month treatment, TTE and CTA revealed that thrombi shrank significantly. The dosage of prednisolone was tapered gradually and stopped 2 years later. Immunosuppressive treatment was continued with adalimumab. The patient has been followed in remission for nearly 6 years.

Case 2: A fifteen-year-old boy was referred to our hospital for the evaluation of fever for over 4 months and a thrombus in his right ventricle. He had a medical history with cough, fever, intermittent hemoptysis and weight loss for the past 3 months. Physical examination revealed acene-like rashes over face and back, oral ulcers. A CTA confirmed the inflammation. The endoscopic findings shown in the patients are: gastric inflammation in 100% (7/7), esophageal inflammation in 57% (4/7), duodenal inflammation in 42% (3/7), colonic erythema and inflammation in 83% (5/6), polyps in 50% (3/6), ulceration in 66% (4/6), and hemorrhoids in 16% (1/6). Upper GI ulceration was not observed. Pathology specimens were taken in 7 upper endoscopies and 6 colonoscopies within our patients. The findings of pathology specimens were vascular congestion and inflammation in 100% (7/7) of upper GI biopsies and 83% (5/6) of colonic biopsies, cryptitis in 66% (4/6) of colonic biopsies. Acute colitis in pathology specimens was shown in 83% (5/6) of the patients. Three of the patients with colitis had punch ulcers, and these patients were evaluated as BD-associated colitis. The other two patients were diagnosed and treated as Crohn’s colitis accompanying BD.

Conclusion: The GI system is one of the most frequently affected organ by the BD. It may cause the inflammation and ulceration in the GI tract. Inflammatorily bowel diseases can also cause GI inflammation similar to BD. In patients with symptoms of GI inflammation, upper and lower GI endoscopic examination and pathological analysis may be helpful in determining the underlying etiology.

Acknowledgement: We are grateful to all participating children and their families.

Disclosure of Interest: None Declared

thrombus in RV and showed bilateral multiple aneurysms along the pulmo-
mary artery and its branches. According to ICBD, the patient was diag-
nosed with BD due to having aphthous ulcers, pseudofolliculitis, and vascular involvement. IV MP (500 mg/day) for 3 days was followed by oral prednisolone 1 mg/kg/day, which was subsequently tapered. IV cyclo-
phosphamide at a dose of 500 mg was also given every 3 weeks for a total of 6 cycles, followed by oral azathioprine (AZA). Concomitant sub-
taneous IFN-α2a was given two times per week for 6 months. Within two weeks, cough and fever disappeared, CRP values normalized. After 1 year the pulmonary artery aneurysm disappeared and cardiac thrombo-
sis resolved. We have been following the patient with AZA for four years without recurrence.

Conclusion: We present two pediatric patients with pulmonary involvement of BD. PAI is a life-threatening condition and should be managed with more aggressive medical therapy. Early diagnosis and aggressive immu-
nosuppressive treatment are very important in PAI. We strengthened our treatment with IFN-α2a. There is no data in the literature regarding the use of IFN-α2a in PAI treatment along with low dose cyclophosphamide. There were no mortality or recurrences within the 6 and 4 years follow up period. An aggressive immunosuppressive therapy leads to better prognosis in this most dreadful complication of BD.

SAT0494 HOME MONITORING OF INACTIVE DISEASE IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: PREDICTIVE VALUE OF EQ-5D-5L-Y

Martin J.H. Doeleman1, Sytze De Roocok1, Nathan Buijsse1, Mark Klein1, Gouke J. Bonsel2, V. Seyfert3, Nico Wulffraat1, Joost F. Swart1.

1University Medical Center Utrecht, Pediatric Rheumatology, Utrecht, Netherlands; 2University Medical Center Utrecht, Obstetrics and Gynaecology, Utrecht, Netherlands; 3MyOwnMed, Bethesda, United States of America

Background: In recent years, juvenile idiopathic arthritis (JIA) research has shifted towards treat-to-target therapy based on clinical assessments and patient-reported outcomes (1). A well-known measurement of quality of life is the EQ-5D-5L (2). Herewith, we report preliminary results of a retrospective study using the child-friendly ‘EQ-5D-5L-Y’ with an E-health application (Reuma2GO) to monitor children with JIA in an outpatient setting.

Objectives: To assess the relationship between dimensions of the health-related quality of life ‘EQ-5D-5L-Y’ questionnaire and conventional assessments for children with JIA, including the Juvenile Arthritis Multidimensional Assessment Report (JAMAR) and active joint count (AJC), and to investigate the potential of the EQ-5D-5L-Y score as instrument for outpatient management.

Methods: The study was designed as a monocentric retrospective cohort study. Data from October 2017 to January 2019 were available for 70 patients with JIA. The relationships between individual dimensions of the EQ-5D-5L-Y, JAMAR and several clinical assessments were investigated. Furthermore, dimensions of the EQ-5D-5L-Y were investigated as possible predictors for binary disease activity using AJC > 0 as reference standard for active disease.

Results: Seventy patients with JIA completed 115 EQ-5D-5L-Y and JAMAR questionnaires within two weeks before a clinical visit. Moderate to high correlations were found between the EQ-5D-5L-Y and JAMAR. Moreover, the best possible EQ-5D-5L-Y score, with and without health-related visual analogue scale (EQ-VAS), demonstrated high sensitivity (81.1%) and negative predictive value (84.8%) for active disease (Table 1). The few patients who were incorrectly classified as having inactive disease (false-negatives) did not have their medication changed at the clinical visit and experienced little to no impact of disease activity on their quality of life, as indicated by the JAMAR questionnaire.

CONCLUSION: The results indicate the potential of ‘EQ-5D-5L-Y’ as an instrument for outpatient management with an E-health application. The EQ-5D-5L-Y score could be a valuable tool in monitoring children with JIA in an outpatient setting which could aid physicians with deciding whether a clinical visit is necessary or not.

PPV: positive predictive value; NPV: negative predictive value.

PPV: positive predictive value; NPV: negative predictive value.

Conclusion: These results demonstrate the discriminatory value of the EQ-5D-5L-Y between active and inactive disease in our cohort of patients with JIA. High negative predictive value was found for the total EQ-5D-5L-Y score, with and without EQ-VAS. In conclusion, the EQ-5D-5L-Y could be a valuable instrument for monitoring children with JIA in an outpatient setting which could aid physicians with deciding whether a clinical visit is necessary or not.

SAT0495 PHENOTYPE OF PATIENTS WITH JUVENILE DERMATOMYOSITIS ASSOCIATED WITH ANTI-FACTOR H AUTO-ANTIBODY: A SEVERITY FACTOR?

Cécile Dumaine1, Isabelle Mekli1, Brigitte Bader-Meunier2, Cyril Giliat2, Marie-Agnes Durey3, Hôpital Robert-Debré Ap-Hp, Paris, France; 3Hôpital Necker, Paris, France; 4Hopital European Georges-Pompidou Ap-Hp, Paris, France

Background: Juvenile Dermatomyositis (JDM) is a rare, autoimmune and highly heterogeneous paediatric-onset myopathy, characterized by skin and muscles inflammation. Development of vasculopathy is associated with the severe extra-muscular manifestations of JDM, and portends a poor prognosis. Impaired function of JDM vasculature includes immune complex and complement deposition.

Objectives: The aim of our study is to describe the clinical and paraclinical phenotype of patients with anti-factor H autoantibody (Ab) associated with JDM and overlap myositis.

Methods: Patients with a diagnosis of JDM or overlap myositis and presence of anti-FH auto-antibody, followed in two Parisian tertiary centers over the last twelve years, were retrospectively selected. Besides demographic data, clinical features (cutaneous lesions, severity of muscle involvement, extra-muscular manifestations), treatment options and their outcome were retrieved for each patient. Biological data and presence of myositis-specific autoantibodies were collected, muscle MRI were examined, and data from muscle biopsies were assessed using a validated score tool when available.

Results: Eleven female patients were included in the study, with a median age at diagnosis of 8.8 years [2.8 – 13.1], and a median follow-
up of 3 years [1 – 11.7]. Apart typical cutaneo-muscular presentation, seven developed calcinosis, and six presented with subcutaneous oedema (of which 5 were anti-NXP2 positive). Median CMAS was 24/52 [1 – 47], and median MMT was 52/80 [2 -76]. Gastro-intestinal involvement was found in 10 patients (91%), 4 presented a pulmonary impairment, and 3 girls had psychiatric symptoms. Six patients had a severe form (54%), one of them led to death (after 2.8 years of evolution).

MSA were found in 9 patients (anti-NXP2 = 1, anti-fibrillarine = 2, anti-MDA5 = 1 and anti-TIF1γ = 1). IFN-signature was positive in 9 patients. Complement exploration was normal in all patients, and median positive rate of Anti-Factor H Ab was 260 U/L [115 – 2800]. Muscle biopsy was performed in all patients but one with a median total score severity of 20. All patients received corticosteroids, and one to six other lines of treatment to achieve remission, obtained in 8 patients, with a median time to remission of 2 years [0.5; 4.8]. Use of plasmapheresis/immunoabsorption and/or Ruxolitinib was necessary in 3 of them (27%).

Conclusion: Presence of anti-factor H auto-antibodies in JDM or overlap myositis patients seems associated with more frequent gastro-intestinal involvement, and a more severe phenotype, requiring more aggressive treatment.

SAT0495

THE FREQUENCY OF JOINT HYPERMOBILITY IN TURKISH SCHOOLCHILDREN: EFFECTS TO PHYSICAL ACTIVITY, BALANCE, PAIN AND QUALITY OF LIFE

Zahide Ekici Tekin1, Gulin Otar Yener2, Bilge Başağaç Çiçek3, Selçuk Yuksel4, 1Pamukkale University Faculty of Medicine, Pediatric Rheumatology, Denizli, Turkey; 2Pamukkale University School of Health Sciences, Physical Therapy and Rehabilitation, Denizli, Turkey

Background: Recent studies have focused on the joint hypermobility (JH) to show the association with musculoskeletal pain, functional disability, motor development and psychological distress (1). In contrast, in some publications, the negative effects of JH in childhood were not observed (2).

Objectives: The aim of this study was mainly to determine the frequency of JH in Turkish schoolchildren and to investigate whether relationship between JH and pain, physical activity level and the balance. In addition, the study aimed whether JH has an impact on the quality of life.

Methods: This cross-sectional school-based study evaluated 737 children (52.5% girls) from 8 to 14 years of age, and the data were collected in 2018 in the city of Denizli, Turkey. Firstly, each of the participants was individual assessed by a clinician on the Flamingo Balance Test for stability and Brighton for the diagnosis of JH. According to Brighton, children who scored ≥5 were accepted as hypermobile. Secondly, all participants completed the self-reported measures for the screening of physical activity level and quality of life. The Physical Activity Questionnaire (PAQ) and the Pediatric Quality of Life Inventory (PedsQL) tests were used to determine the level of physical activity and the quality of life. Also, pain severity was quantified by the Visual Analogue Scale (VAS) that is ranging from no pain (score: 0 mm) to worst pain (score: 100 mm) in the last month.

Results: The prevalence of JH in schoolchildren was 19.7% in Turkish population (Table 1). The mean pain severity was 1.29±2.024 in all children. Significant differences were found between hypermobile and non-hypermobile groups in social and school functioning (p<0.05), but no significant differences were found in pain, physical activity level (p>0.05) (Table 2). Brighton score was not significant correlated with pain severity, physical activity, quality of life and balance in childhood (p>0.515, p>0.986, p>0.512, p=0.362 respectively).

Conclusion: As a result, the existence of hypermobility in children had an impact on school and social functions. However, it has been observed that hypermobility does not have a negative effect on these children’s pain, balance, physical activity level, and physical and emotional functions.

SAT0497

CLINICAL PICTURE OF 7 PAPA PATIENTS FOLLOWED IN A SINGLE PEDIATRIC RHEUMATOLOGIC CENTER

Silvia Federici1, Camilla Celesti1, Virginia Messia1, Giulia Marucci1, Christoph Kees2, Fabrizio de Benedetti3, Antonella Insalaco1, 1IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy; 2Medical center, Department of pediatric Rheumatology and immunology, Muenster, Germany

Background: Pyogenic sterile arthritis, pyoderma and acne (PAPA) syndrome is an autosomal dominant inflammatory disorder caused by mutations in the PSTPIP1 gene primarily affecting joints and skin. The E250K mutation cause the hyperzincaemia/hypercalprotectinemia syndrome termed PSTPIP1-associated-related proteinemia inflammatory (PAMI) syndrome in which a bone marrow involvement is reported

Objectives: To describe the clinical presentation of 7 PAPA patients followed at a single pediatric rheumatology center.

Methods: For each patient clinical and laboratory data were collected from medical charts. PSTPIP1 was sequenced through Sanger Sequencing or targeted resequencing using a customized panel, and analyzed with the NextSeq® platform (Illumina).

Results: We describe 7 patients from 4 unrelated families with the E250K mutation in a mother and 2 siblings, the A230T variant in a father and his son and the R405C and D266N respectively in the last 2 unrelated patients. Disease onset occurred within the 7th year of life in all patients. Patients 3 and 4 (Table) presented since the 1st year of life recurrent episodes of fever without any cutaneous or articular symptoms. In both patients inflammatory markers were elevated during fever episodes, but persistently negative during wellbeing not requiring any therapy. The variants described in these patients were not previously reported. However their pathogenic role is supported by the detection of markedly high serum calprotectin levels (>10.000 microg/ml). The predominant feature of patients 1 and 2 was articular involvement with recurrent episodes of arthritis associated to acne. Patient 1 was initially treated
with prednisone with good clinical response but relapse of arthritis at discontinuation followed by the development of a sterile muscle abscess. An anti-TNF drug was started in both patients with complete clinical response. Patient 5 reported severe acne and psoriasis, and recurrent epistaxis and a sterile arthritis. She presented a persistent elevation of acute phase reactants with severe anemia and leukopenia not resolving after splenectomy. Her son (pts 6) presented with recurrent episodes of sterile arthritis, hepato-splenomegaly, anemia and neutropenia. Zinc and ciprofloxacin serum levels resulted respectively 728 microg/ml and 2600 microg/ml. IL-1 inhibition determined a complete normalization of inflammatory parameters with no effects on anemia and neutropenia. In patient 6 zinc decreased to almost normal value after 4 months of therapy. Patient 7 presented at the age of 4 years a sterile lymphnode abscess. She also presented with splenomegaly and neutropenia with persistent elevation of acute phase reactants. Anakirna was proposed but not administered for poor compliance.

**Conclusion:** The clinical picture of patients carrying PSTPIP1 mutation may be heterogeneous. In our cohort TNF-inhibitors were successfully used in PAPA patients preventing new arthritis episodes and resolving cutaneous manifestation where present. In 2 patients the clinical picture was mild not requiring continuous treatment. One PAMI patient had a good response to IL-1 inhibition, which however, had no effect on hematological manifestations.

**Disclosure of Interests:** Silvia Federici: None declared, Camilla Celani: None declared, Christoph Kessel: None declared, Fabrizio De Benedetti Grant/research support from: Abbvie, SOBI, Novimmune, Roche, Novartis, Sanofi, Pfizer, Antoinella Insalaco: None declared DOI: 10.1136/annrheumdis-2019-2019.eular.6176

**SAT0499**

**THE IMPACT OF OVERWEIGHT ON THE OUTCOME OF JUVENILE IDIOPATHIC ARTHRITIS**

Juliane Riess1, Ivan Foeldvari1, 2Slemmelsveis University, Asklepios Campus Hamburg, Hamburg, Germany; 2Hamburger Zentrum für Kinder- und Jugendrheumatologie, Hamburg, Germany

**Background:** Overweight and obesity are considered to have a negative impact on Rheumatoid Arthritis in adults and there is less information regarding the correlation in juvenile idiopathic arthritis (JIA).

**Objectives:** To assess the effect of overweight on the activity of JIA as well as the stability and ability to achieve a remission using the cJADAS10 score.

**Methods:** This is a longitudinal retrospective study design. We collected data of 164 patients suffering from JIA from three consecutive visits. Treatment was conducted between 2012 and 2015 at our centre in accordance to current guidelines. Remission was defined by cJADAS10 score ≤0.5 in Oligoarthritis and ≤0.7 in Polyarthritis. Patients were categorized by weight-for-age percentiles as heavily underweight (less than 3rd percentile), underweight (4th up to 10th percentile) healthy (11th up to 90th percentile) overweight (91st up to 96th percentile) and obese (97th up to 100th percentile). We compared the cJADAS10 of normal-weighted children with the cJADAS10 of the overweight and the obese patients, respectively.

**Results:** Of all patients, 13 were "underweight" (7.9%), 109 were defined as "normal weight" (66.5%) and 42 patients were categorized as "overweight" (25.6%) of which 16 children (9.8%) were 'obese'. 95 (57.9%) reached a remission during follow-up visits. Overweight was associated with higher disease activity compared to healthy weight children at the first visit (mean 9.5 vs. 8.5) and a wider range of the cJADAS10 score (0-22 vs.0-20.5). Results from the 3-months-follow-up revealed an overall good response to the prescribed medication. At 6-months-follow-up, overweight children couldn’t stabilize the improvement since cJADAS10 range rises while it stays stable in healthy weight children. At the same time, while interpreting the disease activity of "overweight" and "obese" children separately, obese children show significantly less disease activity than overweight children, especially at the 3- and 6-months-follow-ups.

**Conclusion:** Overweight seems to have a negative influence on the disease activity and remission of JIA patients but it is most likely not the only influencing factor since obese patients show a better result regarding the cJADAS10 score than overweight patients. In the future, factors like socioeconomic status, BMI of the parents or physical activity level of the patient should be included in the evaluation. Also, the 7 subtypes of JIA should be analyzed individually since they show heterogeneous etiology, phenotype and prognosis.

---

**ORAL MICROBIOME IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS RELATION TO DISEASE STATUS, TEMPOROMANDIBULAR JOINT ARTHRITIS AND MEDICATION: A NORWEGIAN 2-YEAR PROSPECTIVE STUDY**

Paula Frid1, Josefine Habbig2, Divyashri Baraniya3, Veronika Rydafi4, Nils Thomas Sangstad5, Anriika Rosen6, Johanna Rykke7, Bent Fiala8, Tuule Chen9, Nezar Noor Al-Hebshi10, Ellen Nordal11, Mohammad Al-Harbi11,12, Norwegian multicenter NorJIA cohort study, 1UIT The Arctic University of Norway, Tromsø, Norway, Department of Otohinolaryngology, Division of Oral and Maxillofacial Surgery, University Hospital North Norway and Public Dental Service Competence Centre North Norway and Department of Clinical Medicine, Tromsø, Norway, 2UIT The Arctic University of Norway, Tromsø, Norway, Public Dental Service Competence Centre North of Norway and Department of Clinical Dentistry, Tromsø, Norway, 3Temple University, Philadelphia, PA, USA, Oral Microbiome Research Laboratory, Maurice H. Kornberg School of Dentistry, Philadelphia, United States of America, 4UIT The Arctic University of Norway, Tromsø, Norway, Department of Clinical Medicine and Department of Pediatrics, Tromsø, Norway, 5UIT The Arctic University of Norway, Tromsø, Norway, 6University of Bergen, Department of Clinical Dentistry and Haukeland University Hospital, Bergen, Bergen, Norway, 7University of Oslo, Department of ENT and Oral and Maxillofacial Surgery, Oslo University Hospital, Oslo, Oslo, Norway, Oslo, 8University of Oslo, Department of Rheumatology, Oslo University Hospital, Oslo, Norway, Oslo, Norway, 9Forsyth Institute, Cambridge, USA, Department of Microbiology, Cambridge, United States of America, 10Temple University, Philadelphia, PA, USA, Oral Microbiome Research Laboratory, Maurice H. Kornberg School of Dentistry, Philadelphia, United States of America, 11UIT The Arctic University of Norway, Tromsø, Norway, Department of Clinical Dentistry, Tromsø, Norway

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children, with an annual incidence of 1-2 per 1000 children. The temporomandibular joint (TMJ) is involved in 40-70%. The human microbiome might be a potential contributing factor to the development of JIA.

**Objectives:** To describe the oral salivary microbiome in children with JIA and relate this to disease activity, TMJ arthritis, and systemic medications.

**Methods:** 83 children: JIA (n=59), Healthy (n=34) were recruited. Demographics, disease activity, presence of TMJ-arthritis and type of medication was collected in this Norwegian prospective study (www.norjia.com). 116 saliva samples were analyzed using Next Generation Sequencing, V1-3 region of the 16S rRNA gene, coupled with BLASTn-based, species-level taxonomy assignment algorithm. Downstream bioinformatics analysis was performed with QIIME and LEfSe.

**Results:** Mean age for healthy group (n=34; 27 females) is 12.3 ±3.0 years while for the JIA group (n=59; 43 females) the mean age is 12.6 ±2.7 years. A total of 541 bacterial species belonging to 111 genus and 10 phyla were identified, with Prevotella, Streptococcus, Actinomyces, Rothia Haemophilus and Veillonella accounting for the bulk of the average microbiome. There were no significant difference between JIA and healthy subjects in species richness and alpha diversity. However, differ- entially abundant analysis revealed genera TM7-G1, Solobacterium and Mogibacterium to be associated with JIA, while Haemophilus and Lactobacillus to be overabundant in healthy subjects.

**Conclusion:** It seems that taxa associated with chronic inflammation were found to be enriched in the saliva of JIA patients.
JUVENILE RECURRENT PAROTITIS: A RARE MANIFESTATION OF RHEUMATIC IMMUNE-MEDIATED DISEASES

Sara Ganhão1, Francisca Aguiar2, Ana Rodrigues2, Ana Maia1, Iva Brito1,2,4
1Centro Hospitalar e Universitário de São João, Department of Rheumatology, Oporto, Portugal; 2Centro Hospitalar e Universitário de São João, Pediatric Rheumatology Unit, Oporto, Portugal; 3Centro Hospitalar e Universitário de São João, Pediatrics Department, Oporto, Portugal; 4Faculty of Medicine of Oporto University, Oporto, Portugal

Background: Juvenile recurrent parotitis (JRP) is the second most common childhood disease of the salivary glands after mumps and mainly affects children between the ages of 3 and 6. There is a male predominance, often with spontaneous resolution at puberty. However, in some cases, it can be the first manifestation of a rheumatic immune-mediated disease.

Objectives: To analyze the clinical, laboratory and imaging profile of children with JRP and investigate the prevalence of rheumatic immune-mediated diseases in these patients.

Methods: Retrospective study from 2008 to 2018 including all cases of recurrent parotitis with juvenile onset at our center. Parameters evaluated included gender, age, laterality, number of recurrences, symptoms of presentation, associated conditions, imaging details, blood tests, treatment, outcome and follow-up.

Results: 40 patients were identified over a 10-year period, with a female to male ratio of 5:3; 62.5% females. The youngest child was nine months old and the eldest was 16 years old with median age at presentation of 5 years. The median (min-max) follow-up period was 3 (0.04-33) years. 29 children (72.5%) only ever reported unilateral symptoms, while the rest had both glands affected, although not usually at the same time. Pain and swelling were the most common presenting symptoms, seen in all cases. Fever in 15 (37.5%) and whitish discharge from Stenson’s duct in one (2.5%), 14 (35%) had palpable cervical lymphadenopathy and 4 (10%) had dental caries. The average reported frequency was 1.25 episodes per year, with a range of 0.43-5 episodes. Numbers of recurrences were in range of one to 15 with average of 3 times. Younger age at first episode didn’t increase the likelihood of recurrences in our sample (p=0.123). Sonography was performed in 34 cases as primary investigation. Reports showed multiple hypoechoic lesions with enlarged intraglandular lymph nodes and enlarged gland. MRI was performed in 10, CT in 4, scintigraphy in 2 and biopsy of minor salivary glands in 1.

The median level of C-reactive protein and erythrocyte sedimentation rate measured, 6 of them having hypergammaglobulinaemia. One patient had a marginally low serum Immunoglobulin A (50; normal variation 55-210).

Conclusion: The clinical, laboratory and imaging profile of our sample is in accord with the literature, except for sex predilection. Although recurrent juvenile parotitis is more common, primary juvenile SS should be considered. A high suspicion is crucial mainly because of a lower incidence of xerostomia and xerophthalmia in this population.
Efficacy and Safety of Adalimumab in Juvenile Idiopathic Arthritis – 10 Year Experience Using Data of the BIKER Registry

Gerd Horneff1,2, Kirsten Minden3, Toni Hospach1, Ivan Foeldvari1, Peter Haas3, Angelika Thorn1, Belina Rogalski1, Gerd Ganser1, Frank Weller-Heinemann1, Andreas Urban1, Markus Hufnagel1, Prasad Oommen1, Ariane Klein1,1 BIKER Registry, Sankt Augustin, Germany; 2Paediatric Rheumatology Centre, General Paediatrics, Sankt Augustin, Germany

Background: Since 2008, Adalimumab is approved for polyarticular juvenile idiopathic arthritis (JIA) and approval has been extended to other JIA categories and for uveitis.

Objectives: To evaluate efficacy and safety of Adalimumab in clinical practice in JIA patients in comparison to a biologic-naïve JIA cohort using the German Biologics registry (BIKER). Methods: Baseline demographics and disease activity parameters have been documented. Efficacy was determined using the JADAS10. Safety assessments were based on adverse events (AE) reports processed according to MedDRA.

Results: Until October 1, 2018, 951 JIA patients treated with Adalimumab were registered in BIKER, representing 1519 patient-years (PY) of exposure. The total observation time (from date of first dose until last follow-up, censored, if another biologic was started) was calculated with 1709 PY. At baseline, the cohort treated with Adalimumab had experienced disease with a disease duration of 5.4–3.9 years (mean±SD). 849 patients (89.3%) were pretreated with methotrexate, 525 (54.2%) with Etanercept. Concomitantly, 584 (61.4%) received methotrexate, 529 (55.5%) NSAIDs and 255 (26.8%) systemic corticosteroids. In the control cohort, 1517 biologic naïve JIA patients started methotrexate.

Upon treatment, the median (IQR1-3) JADAS10 score decreased from 9.8 (4.7-15.5) to baseline at 3.9 (0.9-9.7) at the last follow-up. With respect to patients with ongoing treatment, approximately 43% achieved a JADAS defined minimal disease activity while 2.2% reached a JADAS defined remission at last follow-up.

904 AE have been observed during exposure or up to 90 days follow-up (58.4/100 exposure years (EY) [95% CI 54.7-62.3]). 66 qualified as serious AE (SAE) [4.3/100 EY [3.3-5.4]]. These figures were compared to 1294 AE reported in the control cohort (34.8/year [32.9-36.8]) and 52 SAE (1.4/100 EY [1.1-1.8]). Adverse events of special interest were serious/medically important infection (n=33), opportunistic infection (n=6), all H. cesteri, malignancy (n=2), anaphylaxis/hypersensitivities (n=3), thrombotic disorders (n=2), autoimmune diseases (n=91, including 12 cases with psoriasis and 53 reports of uveitis), bleeding (n=3), cytopenias (n=4), pregnancies (n=2). Macrophage activation syndrome, demyelination, cardiac or cerebral infarction, or death were not observed. However, 2 malignancies were reported in patients who had ever been exposed to Adalimumab before. Both events were judged as unrelated.

A total of 449 patients (48.5%) discontinued Adalimumab, 188 (19.8%) due to lack of efficacy, 111 (11.7%) due to remission and 76 (8.2%) because of intolerance.

Conclusion: The current analysis adds to the established safety profile of Adalimumab and demonstrates that the rate of SAEs was comparable and consistent with the overall AE profile in paediatric patients. As expected, infections were the most frequent SAE. Uveitis, as well as psoriasis, are likely associated with JIA. Of notice, only one patient developed a chronic inflammatory bowel disease. No new safety signals specific to the paediatric population were identified in this large cohort of JIA patients.

Development of Malignancies in JIA Patients Exposed to Biologic Agents: A Single Centre Retrospective Study

Oya Koker1, Sezgin Sahin1, Amra Adrovic1, Mehmet Yildiz2, Kenan Barut1, Rukyie Eker Onoreoglu2, Cagür Kasapoglu1, Istanbul University-Cerrahpaşa, Cerrahpasa Medical School, Pediatric Rheumatology, Istanbul, Turkey; Istanbul University, Istanbul School of Medicine, Pediatric Rheumatology, Istanbul, Turkey

Background: Over the last two decades, the usage of biological agents in the treatment of Juvenile Idiopathic Arthritis (JIA) has been a successful and promising approach in controlling the disease activity and preventing chronic sequelae. However, since Food and Drug Administration (FDA) has drawn attention to the possible association between the use of biological agents and the development of malignancy in 2008, there are ongoing concerns about the long-term safety data and side effect profile of the drugs with the contradictory study results.

Objectives: We aimed to present preliminary data on the incidence of malignancy in patients with JIA treated with biological agents versus the general population rates in Turkey.

1340 Saturday, 15 June 2019

Scientific Abstracts
Methods: A retrospective single-center hospital-based cohort study was performed to analyse cancer occurrence among JIA patients treated with biologic agents over the observation period between January 2004 and January 2018. The medical patient records were reviewed to obtain information about the clinical follow-up. As reference data for direct standardization; age, sex, and calendar-year-specific incidence rates from Turkish cancer registry were used. The standardized incidence ratio (SIR, ratio of cancers observed to expected) was generated, with 95% confidence intervals.

Results: The study sample consisted of 504 JIA patients, who had been started their first biologic treatment between 2004 and 2018. Mean age was 17.1 years (SD 5.6) with 56% of female proportion. The mean disease duration was 10.3±5.1 years. Median time from baseline to start of the first biological was 17.5 (IQR:43) months. Mean age of initiation of biologic treatment was 9.8 ± 4.2 years. Etanercept was most commonly preferred drug to initiate as first-line biologic treatment (n=361,72%). 172 (34.1%) patients in the cohort required a switch to a second biologic agent. Main reason for switching to another biologic agent was due to lack of response (16.6%). Median duration of biologic use was 35 (IQR:41) months. One cancer occurred within observation period, compared with 0.095 expected (SIR:10.53, 95% CI 0.526 to 51.91). The patient was a 18-year-old male, who had previously received etanercept and tocilizumab up until diagnosis of the hematological malignancy.

Conclusion: In our JIA cohort, patients treated with biologic agents appeared to have an increased rate of incident malignancy compared to children and age group in the population in Turkey. However, before mentioning a clear causal relationship, other potential contributing factors such as inflammatory process of the underlying disease itself and the use of concomitant immunosuppressants should be taken into consideration. Additional long-term studies with larger populations are needed to be able to draw definite conclusions.

SA10504 IG4 RELATED DISEASE IN CHILDREN: A SINGLE CENTRE EXPERIENCE FROM NORTH-WEST INDIA

KUMAR RAKESH1, Amit Rawat1, Anam Gupta1, Sandesh Galeria1, Johnson Nameziekparp1, Deepali Suni2, Anju Gupta1, Ritambaha Nada1, Sujit Singh1. 1Post Graduate Institute of Medical Education and Research, Chandigarh. 2Allergy Immunology Unit, Department of Pediatrics, Chandigarh, India.

Background: Immunoglobulin G4 related disease (IgG4RD) is a multisystemic disorder characterized by elevated serum IgG4 levels and infiltration of IgG4 positive plasma cells accompanied by fibrosis. It is mostly considered a disease of adults and elderly people. There is paucity of literature on pediatric IgG4RD. A recent systematic review has found only 25 pediatric cases.

Objectives: To report broad patterns of organ involvement in IgG4RD in children and also to create awareness among treating pediatricians about this new entity.

Methods: The study is based on a review of the hospital records of children with IgG4RD at tertiary centre from North-West India. Diagnosis was based on clinical features, IgG4 levels and characteristic histopathology findings.

Results: Six patients had IgG4RD. Pt-1: 10-year-old boy presented with fever for 3 months and significant hepatomegaly. Investigations showed anemia, thrombocytopenia, elevated erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP). Ultrasonography (USG) revealed a hepatic mass (10x5x6 cm) that was confirmed on computed tomography. Liver biopsy showed increased plasma cells (>50 IgG4 positive plasma cells/HPF) and perisinusoidal fibrosis suggestive of IgG4 related hepatic mass. Serum IgG4 level was 420 mg/dl (N: 5-28). Pt-2: 12-year-old girl presented with an abdominal lump. Upper gastrointestinal endoscopy showed an intragastric mass with exophytic component. Histopathology of abdominal mass was consistent with IgG4RD. Serum IgG4 level was > 170 mg/dl (N: 6-28). Pt-3: 21-year-old male symptomatic since age of 14 years with recurrent erythematous swellings over dorsum of the left hand, forearm and chest. Investigations showed anemia, elevated ESR, CRP, and hypergammaglobulinemia. IgG4 levels were 211 mg/ml (N: 7-57). Histopathology from left hand showed lymphoplasmacytic infiltrates, storiform fibrosis, obliterative phlebitis and increased IgG4 plasma cells (>50/HPF). Pt-4: 18-year-old girl presented with fever and weight loss. She had anemia, thrombocytosis, elevated ESR and CRP. USG abdomen showed omental thickening. Serum IgG4 level was 215 mg/ml (N: 7-57). Peritoneal and omental biopsy showed fibrosing stage of IgG4RD. Pt-5: 7-year-old girl presented with fever, oliguria, and anasarca. Investigations revealed anemia, elevated CRP, ESR, deranged renal functions and nephrotic proteinuria. Renal biopsy showed plasma cell infiltrate, storiform fibrosis, and 10-16 IgG4 plasma cells/HPF; consistent with IgG4 related tubulointerstitial nephritis. Serum IgG4 was 68 mg/dl (N: 7-26). Pt-6: 14-year-old, boy presented with painful protrusion of right eye for 8 months. MRI orbit showed bulky and enhancing extra-ocular muscles of the right eye with lacrimal gland involvement. Serum IgG4 was 119 mg/ml (N: 7-26). Histopathology of mass showed extensive fibrosis, obliterative phlebitis and lymphoplasmacytic cells infiltrate with IgG4 plasma cells >30/HPF, consistent with IgG4RD. All patients showed good clinical response to oral prednisolone (1-2 mg/kg/day and subsequently tapered). Four patients required maintenance therapy with azathioprine.

Conclusion: We report 6 cases of pediatric IgG4RD with varied organ involvement and clinical manifestations. Some of the cases presented as space-occupying lesions that can sometimes be confused with neoplastic lesions. It is important to suspect these disorders early and start immunosuppressive therapy promptly to halt end-organ damage due to fibrosis.

Disclosure of Interests: None declared

polyomavirus rash was in 244 pts (91.4%), conjunctivitis in 229 (85.8%), mucositis in 224 (83.9%), extremities abnormalities in 196 (73.4%) and lymphadenopathies in 165 (61.8%). The average duration of fever was 7 days (range 1-25 days), CAL were detected in 73 pts (20.2%); 58% (16) had CE, 15 (4.1%) had CAn. Median long-term follow-up was 10 years and 2 months (range 1 year – 36 years). The variance analysis in the different groups of CAL showed a significant difference as regard age at disease onset (F= 2.77, p= 0.025), duration of fever (F=16.32, p=0.0001), CRP value (F=6.94, p=0.001) and day of first administration of IVIG (F=7.963 p<0.001) (Table). A significant correlation between CAL and disease onset at <6 months (p=0.137, p=0.009), the need to administer 2 IVIG doses (p=0.305, p< 0.001), and male (p=0.109, p=0.038) has been highlighted. At the last follow-up, in the group of no-CAL (261 pts), cardiological visit, echocardiography and ergometric test (performed 177/261 pts) were normal in all pts. At the last available follow-up, 53 pts with CE had normal cardiological visit, echocardiography and ergometric test (performed 39/53 pts). Conversely, all 13 pts with CAn showed a normal cardiological visit, whilst ECG was abnormal in 1 patient (7.69%) and echocardiography showed persistent CAn in 8 (61.53%). Ergometric test was performed in 9/13 pts showing abnormal results in one pt (11.11%).

Conclusion: Our long-term follow-up in a large, even monocentric, cohort reports possible risk factor of CAL according to current literature. Our long-term follow-up assesses, in real life, the benign course of KS in children without CAL after 6-8 weeks from onset. According to recent guidelines, stopping cardiologic assessment in no risk pts results economically advantageous, timesaving and able to reduce emotional discomfort in children and their families.

KAWASAKI DISEASE AND CARDIOVASCULAR OUTCOMES IN THE LAST 25 YEARS. STUDY OF 55 PATIENTS FROM A REFERAL HOSPITAL IN THE NORTH OF SPAIN

José Luis Martín-Velázquez1, D. Prieto-Peres2, Lara Sánchez Bilbao3, Evg Peña Sainz-Pardo2, Bélen Atienza-Mateo1, Monica Calderón-Goercke1, Iñigo González-Mazoñ1, Natalia Palmou-Fontana1, María Teresa Valderr Ubierna3, María Jesús Cabero4, Miguel A. González-Gay1, Ricardo Blanco1.

Background: Kawasaki disease (KD) or “mucocutaneous lymph node syndrome” is a systemic vasculitis in children that involve medium-sized vessels with predilection for coronary arteries. Due to the high probability of cardiovascular complications, an early diagnosis and treatment is required.

Objectives: A) To describe demographic, clinical and analytical features in a cohort of patients with KD diagnosis from northern Spain. B) To assess the rate of long-term cardiovascular outcomes.

Methods: We set up an observational study of patients with KD in a University Hospital between Jan-94 and Dec-18. Classic classification criteria were used for diagnosis. Diagnosis of aneurysms was made by serial echocardiography and/or coronary-CT. Results are expressed as mean±SD or as median and interquartile range (IQR) as appropriate.

Results: 55 patients (28 women/27 men), with a mean age at diagnosis of 3.6±2.8 years, 60% presented a previous infection prior to administration of any antiinflammatory doses. 2 required endovenous corticosteroid, and in 1, an anti-TNF drug (infliximab) was needed. At the last follow-up of 13.9±7.0 months, only 1 of them maintained coronary involvement. 98.2% received intravenous immunoglobulin (IVIG) according to international recommendations (2 g/kg). All patients received anti-inflammatory doses of acetylsalicylic acid at diagnosis and subsequently antiplatelet doses.

Conclusions: Although the incidence of KD in our population is lower than other territories, it is still the most frequent cause of acquired heart disease in childhood. Early recognition and treatment with IVIG improve prognosis leading to a decrease in the rate of long-term cardiovascular outcomes.

EVALUATION OF THE NEW CLASSIFICATION CRITERIA FOR PFAPA SYNDROME

Fabio Crimi1, Manel Mejbri2, Véronique Henriksen2, Glory Dingulu2, Isabelle Koné-Paule2, Sophie Georgin-Lavalette3, Pascal Pilliet4, Michael Hofer4, JIRCochort5, 1Pediatric Rheumatology, Lausanne, Switzerland; 2Pediatrics, Versailles, France; 3Pediatric rheumatology, Lausanne, Switzerland, 4Pediatrics, Versailles, France; 5Pediatric rheumatology, Bordeaux, France

Background: Modified Marshall criteria used for PFAPA syndrome have never been validated and are little used by the experts because the symptoms of monogenic fevers often overlap with PFAPA ones. A new set of classification criteria based on an international survey and a consensus conference in Genoa was developed in 2017.

Objectives: Evaluate the performance of the new criteria in a real-life setting.

Methods: This is a multicentric, prospective and descriptive cohort study, through the recurrent fever module of the JIRCochort platform. 417 patients diagnosed with PFAPA (187), monogenic fever syndromes (167) or unclassified recurrent fever syndrome (UPF=63) from Swiss and French centers were enrolled in the study. The new classification criteria were applied to this cohort and we calculated their performance. We then analyzed which of the criteria performed the less well.

Results: One hundred fourteen from 187 (61%) PFAPA patients met the new criteria, as well as 20/230 non-PFAPA patients (FMF: 3, MKD: 4, other: 13); 73 PFAPA patients did not meet the criteria. We calculated a specificity of 91.3% and a sensitivity of 60.9%. The least satisfied criterion among PFAPA patients not meeting the criteria was “absence of skin rash”. By removing this criterion, the sensitivity improved (81.2%), but the specificity decreased slightly to 86%.

Conclusion: Genoa 2017 classification criteria for PFAPA syndrome showed a good specificity but an insufficient sensitivity. Excluding the less satisfied criterion, the set reaches a sensitivity and specificity around 80% which could be a fair compromise for PFAPA classification criteria. Our study highlights the difficulty in establishing classification criteria due to the lack of gold standard for PFAPA diagnosis.

AN INTERNATIONAL SURVEY ON APPROACHES TOWARDS IMMUNISATION IN CHILDREN WITH RHEUMATIC DISEASES: A REPORT OF THE PRES VACCINATIONS WORKING GROUP

Elena Morallès1, O Mariliß2, Yoshit Uziel3, Geocimara Salvato Pfeffer4, Raju Khubchandani5, Marc Jansen6, Nico Wulffraat6, Nabasa Toplak1, 1GOSH, London, United Kingdom; 2NKUA, Athens, Greece; 3MMC, Kfar Saba, Israel; 4FACISB, Barreiros, Brazil; 5SRRCC, Mumbai, India; 6UMC, Utrecht, Netherlands; 7UMC, Lubljana, Slovenia

Background: Data on immunisation practices in Paediatric Rheumatology are scarce. EULAR recommendations for vaccination in paediatric patients with rheumatic disease (RD) were published in 2011. In some countries national recommendations for vaccination of immunocompromised patients are available.

Objectives: To ascertain the opinion and current practices of paediatric rheumatologists with regards to immunisation of children with rheumatic diseases (RD), and to establish their confidence to immunise the patients with RD on immunosuppressive medication with live vaccines in light of the evidence available.

Methods: An online survey of practices and opinions towards immunisation of patients on lower grade immunosuppression with MMR or varicella vaccines was conducted with a focus on immunisation of the immunocompromised child with RD was distributed to paediatric rheumatologists across the globe. Responses were collected via SurveyMonkey and descriptive analysis was performed. Responses were anonymous with the exception of identification of the country and length of practice.

Results: 289 responses were received from 53 countries in Europe, North and South America, Australia and Asia. 35% of the responders had over 15 years of practice in Paediatric Rheumatology, while 42% had 5-15 years.

57% responded that all immunisations or at least part of them are given in their paediatric rheumatology unit, and 60% that the vaccinations are mandatory in their country. 93% of responders support the immunisation of paediatric patients with RD, 6.9% responded that they are either not supportive/not sure/support only vaccinations with inactivated vaccines.

53% reported that national recommendations for immunisations of immunosuppressed child are available but not specific to Paediatric Rheumatology. 41% of responders inform their practice on immunisation of patients with RD based exclusively on the EULAR recommendations, 37.5% based on national guidelines, 8.5% on local guidelines and 10% on combinations of the above. 48% of clinicians would postpone vaccinations in all cases if disease is active.

In terms of immunisations with live vaccines of patients with JIA on immunosuppressive treatment, 41% of responders would recommend the first dose of MMR or Varicella vaccines to patients with stable disease on Prednisolone < 1 mg/kg/day (maximum 20 mg) for less than 1 month or higher dose up to 2 mg/kg/day for less than 14 days, 14% would also recommend these vaccines if the above steroid dose was given in combination with Methotrexate (MTX) < 15mg/kg/week, 30% would recommend these vaccines if the patient was on MTX monotherapy. Comparably percentages reported confidence to also recommend booster doses of the two vaccines for the above drug combinations (45%, 15.7%, 37%, respectively), whilst up 10% of respondents would recommend them to patients on anti-TNF agent alone, and up to 7% for other biologics. For patients with SLE and quiescent disease on similar medications as above, 41%, 15%, 31%, respectively, of clinicians reported confidence to recommend MMR or Varicella booster doses.

48% of the respondents identified the reluctance of other health professionals involved in the process of immunisations as the main reason hampering the vaccination of paediatric patients with RD, whilst 22% indicated parental refusal or hesitancy.

Conclusion: There is variation in practice and opinions worldwide with regards to immunisations in paediatric patients with RD, and this likely reflects the discrepancies between national guidelines for immunisation of immunosuppressed child and also national policies. More studies are required, but there is an increasing vote of confidence towards immunisation of patients on lower grade immunosuppression with MMR or varicella vaccines.

BODY MASS INDEX AND DISEASE ACTIVITY IN PORTUGUESE AND BRAZILIAN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS: RESULTS FROM RHEUMATIC DISEASES PORTUGUESE REGISTER – REUMA.PT

Background: The influence of body mass index (BMI) on Juvenile Idiopathic Arthritis (JIA) disease activity is poorly understood. In adults with Rheumatoid Arthritis, obesity has been associated with higher disease activity, while in JIA patients, a previous study has failed to find any association.

Objectives: To investigate the relationship between BMI and JIA disease activity.

Methods: This is an international, multicenter, observational, cross-sectional study. JIA patients (according to ILAR criteria) aged < 18 years, registered at Reuma.pt in Portugal and Brazil were included. Data was analysed upon records from the first registered visit. Age- and sex-specific BMI percentiles (P) were calculated based on WHO growth standard charts and categorized into underweight (P≤85), normal weight (85<P<97) and obesity (P≥97). Disease activity was assessed by Juvenile Arthritis Disease Activity Score (JADAS-27). Univariate linear regression was used to examine the association of JADAS-27 with BMI categories. Two multivariate regression models were performed a) adjusting for age, gender, race, country, disease duration and JIA category (model 1); b) adjusting for those covariates plus use of DMARDs (model 2).

Results: 255 patients included, mean age 10.1±4.7 years, mean disease duration 6.3±4.9 years; 62% female; 85% Caucasian. Thirty-two percent were persistent oligoarticular, 9% extended oligoarticular, 34% polyarticular RF+, 6% systemic, 13% enthesitis-related arthritis, 5% psoriatic arthritis. The influence of body mass index (BMI) on Juvenile Idiopathic Arthritis (JIA) disease activity is poorly understood. In adults with Rheumatoid Arthritis, obesity has been associated with higher disease activity, while in JIA patients, a previous study has failed to find any association.

Conclusion: Importantly, these results suggest that active disease can impair child’s weight gain. Further studies are needed to confirm these findings and understand the underlying mechanisms of this association.

NON-BACTERIAL OSTEITIS IN CHILDREN: PROGNOSTIC FACTORS

Nuria Heredia Torres1,2, Esmeralda Núñez Cuadros1,2, Rocío Galindo Zavala3, Gisela Díaz-Cordero4, Laura Martín Pedraz5, Antonio Urra Cardona6,1, Hospital Regional Universitario de Málaga, Pediatrics, Málaga, Spain, 2Hospital Universitario Reina Sofía, Málaga, Spain, 3Hospital Regional Universitario de Málaga, Pediatric Rheumatology Unit, Málaga, Spain, 4Hospital Regional Universitario de Málaga, Pediatrics, Málaga, Spain, 5Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain

Background: The incidence of non-bacterial osteitis (NBO), a rare autoinflammatory disease in childhood, has increased over the past few years. Early diagnosis and treatment, as well as an adequate follow-up, are necessary to prevent sequelae and complications. However, prognostic factors of the disease are unknown.

Objectives: To establish the prognostic factors of NBO.

Methods: A retrospective study of NBO, according to Jansson criteria, in children (<14 years) at a tertiary hospital from 2009 to 2018. Descriptive statistics were performed to examine clinical features, diagnoses, treatments and progress of the disease. Furthermore, bivariate analysis was performed in order to investigate factors involved in the remission of the disease (without treatment), the number of relapses and sequelae. We considered p<0.1 as significance level due to the small sample size.

Results: We reviewed 15 cases. Table shows the descriptive data. The likelihood of remission was found to be associated with the presence of X-ray findings apart from sclerosis/lysis. (80% vs 40%, p=0.07), a high white blood cell count (mm3) (11988.7 ± 3004.9 vs 8915.7 ± 3310.3, p=0.08) and ESR (mm) (58.3 ± 36.3 vs 26.8 ± 17.4, p=0.05) at diagnosis

Sequelae, n (%) | Localized deformation | 2 (13.3) |
and a longer duration of disease (months) (5.7 ± 1.6 vs 3 ± 1.2, p = 0.06). In addition, fewer relapses were found among patients with peroneal involvement a 0 (0-5) v 5 (1-6.7), p = 0.05, a high white blood cell count at diagnosis (r = 0.569, p = 0.02) and those who were not treated with pamidronate at diagnosis (r = 0.5) v 5 (1.2-6.7), p = 0.07. Finally, the lack of sequelae was related to the administration of pamidronate (100% vs 57.1%, p = 0.07), younger age at diagnosis (years) (9.08 ± 1.4 vs 11 ± 2, p = 0.07) and lesser CRP level at diagnosis (mg/L) [2.9 (2.9-2.9) vs 3.8 (2.9-3.8), p = 0.005].

Conclusion: Advanced cases of NBO, without radiological signs of sclerosis or lysis, were more likely to achieve remission. Elevation of acute phase reactants was related to a better response to treatment and a lower relapse rates, but with a greater probability of sequelae. As described in the literature, bisphosphonates achieve higher rates of clinical and radiological remission. In our study, they are also associated with a lower relapse rates and the lack of sequelae. The last is the main reason to be considered the first treatment choice in NBO.

SAT0511 CANAKINUMAB IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS: CLINICAL INACTIVE DISEASE RATE AND SAFETY IN ITALIAN PATIENTS

Manuela Pardeo1, Claudia Bracca1, Anna Lucia Piscitelli1, Arianna De Matteis1, Jessica Tibaldi2, Maria Alessio1, Silvana Martino1, Giovanni Filocamo1, Francesca Orlando2, Silvana Martino2, Rolando Cimaz2, Giovanna Pardeo1, Claudia Bracca1, Anna Lucia Piscitelli1, Arianna De Matteis2,

Background: Systemic juvenile idiopathic arthritis (sJIA) is a polygenic autoimmune inflammatory disease. The innate immune mechanisms play a central role with overproduction of inflammatory cytokines. The increased knowledge on the role of these cytokines has provided a change in the natural history of the disease with the introduction of the targeted treatments. Remarkable results has been observed with canakinumab, an anti-interleukin-1β monoclonal antibody, in two clinical trials but little information are recorded in our population.

Objectives: To evaluate clinical inactive disease rate and safety of canakinumab in Italian patients with sJIA.

Methods: We have collected retrospectively clinical and laboratory data of patients with sJIA treated with canakinumab in 9 Italian Pediatric Rheumatology centers. Clinically inactive disease (CID) at 6 months was defined according to Wallace criteria. We analyzed the effect of canakinumab on fever, rash, number of active joints, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and physician’s global assessment of disease activity score.

Results: Forty seven patients (26 F) were included in the analyses. The median age (range) at the beginning of treatment with canakinumab was 7.6 (1.1-4.7) and 10.2 (1.7-22.2) years, respectively. Twenty seven patients (57.4%) had been previously treated with other biologic agents (18 with anakinra, 1 with tocilizumab, 6 with both and 2 with etanercept), withdrawn for inefficacy in 15/27 (55.5%). Thirty patients (63.8%) were receiving concomitant treatment with glucocorticoids at the median dose (range) of 0.69 (0.02-2.75) mg/kg/die. Thirty nine of 47 patients had > 6 months of follow-up. Among these 39 patients, 27 (69.2%) achieved CID at 6 months and 5/27 (18.5%) were still on glucocorticoids. Of the 30 patients who received concomitant glucocorticoids at baseline, 24 achieved 6 months of follow-up and 12 (50%) of these were able to withdraw glucocorticoids. Minor adverse events were reported in 5/30 (16.6%) patients: upper respiratory tract infections in 4 and transient injection site reaction in 1. No cases of macrophage activation syndrome was reported.

Conclusion: Our results provide initial real world evidence of the efficacy of treatment with canakinumab in patients with sJIA. In our study the median age of patients at the end of 27 months treatment (69.2%) than reported at the end (from 3 months to one year) of the 2 published randomized trials (60%). No serious adverse events were recorded in our population.

SAT0512 LONG-TERM FOLLOW-UP OF CARDIOVASCULAR OUTCOMES IN KAWASAKI DISEASE. OBSERVATIONAL STUDY FROM A SINGLE CENTER

D. Pijo-Peña, José Luis Martín-Varillas, Lara Sánchez Bilbao, Eva Peña Sainz-Pardo, Monica Calderón-Goerke, Natalia Palmou-Fontana, María Teresa Viadero, María Jesús Cabero, Miguel A. González-Gay, Ricardo Blanco, Marqués de Valdecilla University Hospital, Santander, Spain

Background: Kawasaki disease (KD) is an acute systemic vasculitis of unknown aetiology which can lead to coronary aneurysm (CA) formation in 15-20% of patients. Long-term rates of adverse cardiac events are not well-known.

Objectives: a) to compare demographic, clinical and laboratory features of patients who developed coronary aneurysm with patients who did not. b) to assess long-term cardiovascular outcomes in the subgroup of patients who developed cardiac aneurysms.

Methods: Single center study of 55 patients with KD who were diagnosed between 1994-2009. KD diagnosis was based on the classic criteria2. We considered two groups: a) patients who presented CA at diagnosis, b) patients who did not present CA. Statistical analysis was performed with SPSS. Student’s t test or Mann-Whitney U test was used to compare continuous variables, and Chi-squared test or Fisher’s exact test for categorical variables as appropriate.

Results: Out of 55 patients with KD, 8 patients (3 men/5 women) presented CA at diagnosis. Differences between the two groups mentioned above are shown in Table 1. Mean age at diagnosis was lower in patients who presented CA (1.74 vs 3.88 years; p = 0.04). The duration of symptoms was longer in patients with CA vs 14.1 vs 9.20 days; p = 0.015, however there were no qualitative differences in the symptomatology. Regarding laboratory markers, C- reactive protein (CRP) levels were significantly higher in patients who developed CA (17.0 vs 10.8 mg/L; p = 0.047). There was also a tendency to higher levels of erythrocyte sedimentation rate (ERS) and higher platelet count. All patients received intravenous immunoglobulin (IVIG) and antiplatelet agents at the time of...
**THERAPEUTIC APPROACH IN JUVENILE IDIOPATHIC ARTHRITIS: EMPIRICAL PAIN MEDICATION AND NEWLY INITIATED DISEASE MODIFYING ANTI-RHEUMATIC DRUGS**

Katarina Rebane1, Kristiina Aalto1, Maji Häapasää2, Kari Puolakkia3, Lauri Virta4, Hannu Kautiainen5, Heini Pohjankoski6.

1Children’s Hospital, Helsinki University Hospital, Helsinki, Finland
2National Pensions Insurance Company, Helsinki, Finland
3South Karelia Central Hospital, Lappeenranta, Finland
4Social Insurance Institution of Finland, Turku, Finland
5Department of General Practice and Unit of Primary Health Care, University of Helsinki and Helsinki University Hospital, Helsinki, Finland
6Päijät-Häme Central Hospital, Lahti, Finland

**Background:** Pain relief remains an important aspect in treating patients with juvenile idiopathic arthritis (JIA) despite of the new advanced therapeutic options. Nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended providing symptomatic relief in JIA1. There is evidence of increased opioid use in adults with rheumatoid arthritis2, the use of opioids in children with JIA is poorly studied.

**Objectives:** Aim of the study was to describe patterns in using of pain medication and newly initiated anti-rheumatic drugs in outpatients with JIA. Methods: Data on 1507 patients (<16 years) with newly diagnosed JIA from 1 Jan 2010 to 31 Dec 2014 were collected from the register of the Finnish Social Insurance Institution. The index day was the date when reimbursement for JIA medication was admitted. The study period included 12 months pre- and post-index date. All patients were without disease modifying anti-rheumatic drugs (DMARDs) before the index day. For each patient three age-, gender- and residence-matched controls (altogether 4511) were identified from the National Centre for Population. Drug purchases were assessed in 3-month periods. Co-morbidities were evaluated.

**Results:** 20-fold more JIA patients purchased NSAIDs, 10-fold more paracetamol, and 10-fold more opioids (mostly tramadol and codeine) compared to controls. 648 patients (43%) purchased NSAIDs during 0-3 months before and after the index day, and 165 patients (11%) 10-12 months after the index day.

28 patients (2%) purchased opioids 12 months before the index-day, and 14 patients (1%) 12 months after. Paracetamol was purchased by 83 patients (5.1%) and by 59 patients (3.9%), respectively. Methotrexate (n = 1361 (90.3%)) was most commonly prescribed conventional DMARD, followed by prednisolone (n = 368 (24.4%)), hydroxychloroquine (n = 194 (12.9%)), sulfasalazine (n = 107 (1.9%)), and biological DMARDs (n = 41 (2.7%)). 26 patients (1.7%) were without antirheumatic treatment at 3-months after index-day.

JIA patients had significantly more comorbidities and traumas (p<0.001), compared to controls. 648 patients (43%) purchased NSAIDs during 0-3 months before and after the index day, and 165 patients (11%) 10-12 months after the index day.

**Conclusion:** Purchases of pain medication reduced after DMARDs were started. Only small proportion of JIA patients purchased opioids, despite of having more traumas and surgical procedures.

Background: Therapeutic patient education (TPE) is widely recommended in the health care pathway of patients with chronic inflammatory rheumatism (CIR) but few pediatric programs are currently available. MIRAJE is a program for children and adolescents with CIR. It has been developed within a French health network (RESRIP (Réseau Rhumatismes Inflammatoires Pédiatriques)) to improve patient care for paediatric patients with CIR living in the Ile de France region.

The originality of the program was to design cross-cutting TPE using common issues to different pathologies: the experience of chronic illness, the management of daily life, inflammatory attacks, long-term treatments, physical activity.

Objectives: Assessment of acquisition of coping, self-care and safety skills.

Methods: After signing a written consent, an educational assessment is conducted in an individual interview with the patients and/or parents (for children under 6 years old), by a member of the multidisciplinary team. Five group sessions and one self-injection session are offered to patients. During the collective sessions, patients and parents are reappointed according to 4 groups: the group of parents, that of adolescents (12-18 years), that of children (6-11 years) and that of toddlers (<6 years).

To investigate the cognitive and behavioral impact of TPE on our patients and parents, a pre-post assessment was performed using a skill/knowledge questionnaire, based on three educational objectives: adaptation (8 skills), self-care (5 skills) and safety (1 skill), before and after the intervention.

Results: We present the results of the first year of implementation of our TPE program (2017). Nineteen children and 20 parents attended at least one group session. Ten participants (6 children aged 6 to 17 and 4 parents) completed the TPE program. The diseases covered were juvenile idiopathic arthritis (7), systemic lupus (2) and mevalonate kinase deficiency (1). All participants improved their knowledge and skills following TPE with greatest improvement in management of inflammatory attacks (self-care) (4 skills), self-care (5 skills) and safety (1 skill) before and after the intervention.

Conclusions: MIRAJE is the first French cross-cutting TPE program for children suffering from CIR and their parents. Although the number of participants having benefited from a full TPE program is relatively low, the first results are very encouraging. Indeed, TPE has allowed improving coping skills (6.8 versus 2.6 skills) and 8 security skills. Regarding self-injection workshop, most patients (4/5) have acquired skills in subcutaneous self-injection.

Background: TPE allows a better acceptance of the disease and fosters patient knowledge and skills for most children and parents.

The originality of the program was to design cross-cutting TPE using common issues to different pathologies: the experience of chronic illness, the management of daily life, inflammatory attacks, long-term treatments, physical activity.

Objectives: Assessment of acquisition of coping, self-care and safety skills.

Acute Rheumatic Fever (ARF) and Post-streptococcal reactive arthritis (PSRA) are well known as post-streptococcal syndromes with arthritis in children. ARF have been declining in developed nations and it is generally thought to be a disease of the past. Despite decreasing incidence between 2010 and 2018 in Japan, focal outbreaks have been reported in developed nations.

The aims of this study were to assess ARF and PSRA incidence, the ratio was 13/21. Manifestations including; carditis, 26 (78.8%); arthritis, 26 (78.8%). The mean age of ARF was 8.0 years (3-15 years), and female/male ratio was 13/21.

Results:

From a total of 63 hospitals (58% response rate), 34 cases of ARF and 32 cases of PSRA were reported. For the research activities of the hospital in fully independent manners the industries listed in this section. This money has been reinvested for drug trials supported by Bristol-Myers Squibb, Pfizer, Novartis, Genentech, Roche, and AbbVie. I have received research support from Janssen. All of the support for these studies was paid to my institution, the University of Utah, and not directly to me.

Acknowledgement:

Professional medical writing: Lola Parfitt, MRes, Caudex; funding: Bristol-Myers Squibb.

Disclosure of Interests: Nicolinor Ruperto Grant/research support from: The Gaslini Institute for the research activities of the hospital in fully independent manners besides any commitment with third parties.

The money received for these activities are directly transferred to the Gaslini Institute’s bank account. Before March 2016, I was the head of the Pediatric Rheumatology Department at the G. Gaslini Hospital, where the PRINTO Coordinating Centre is located. For the coordination activity of the PRINTO network, the Gaslini Hospital received contributions from the industries listed in this section. This money has been reinvested for the research activities of the hospital in fully independent manners besides any commitment with third parties.

Background: Acute Rheumatic Fever (ARF) and Post-streptococcal reactive arthritis (PSRA) are well known as post-streptococcal syndromes with arthritis in children. ARF have been declining in developed nations and it is generally thought to be a disease of the past. Despite decreasing incidence, focal outbreaks have been reported in developed nations. Despite its importance, ARF and PSRA epidemiology has not been reviewed recently.

Objectives: The aims of this study were to assess ARF and PSRA incidence between 2010 and 2018 in Japan.

Methods: This retrospective Study examined ARF and PSRA incidence in 2010-2018, using medical record included in a total of 108 hospitals.

Results: From a total of 63 hospitals (58% response rate), 34 cases of ARF and 32 cases of PSRA were reported.

The mean age of ARF was 8.0 years (3-15 years), and female/male ratio was 13/21. Manifestations including: carditis, 26 (78.8%); arthritis, 26 (78.8%).

REFERENCES

(78.8%); Erythema marginatum in 7 (21.2%); Sydenham chorea, 4 (12.1%); Subcutaneous nodules, 2 (6.1%), respectively. And minor criteria were; fever, 27 (81.8%); first degree heart block, 7 (21.2%); elevated inflammatory markers (ESR, CRP), 30 (90.9%). ARF patients were treated with antimicrobial agent prophylaxis. On the other hand, the mean age of PSRA was 8.0 years (3-14 years), and female/male ratio was 17:14. Three patients (9.4%) had monoarthritis, 15 patients (46.9%) had oligoarthritis, and 14 patients (43.6%) had polyarthritis. Two patients had arthritis and enthesitis. And fever in 24 (75.0%) and Elevated inflammatory markers in 29 (90.6%). PSRA patients were treated with antimicrobial agent therapy 25 (78.1%); NSAIDs 27 (84.4%); and glucocorticoids therapy 3 (9.4%). During the follow up, there was no patient with carditis. 18 (56.3%) patients with PSRA were prescribed with antimicrobial agent prophylaxis.

Conclusion: In this study, ARF is rare in the Japanese pediatic population, but ARF has not yet disappeared. We observed high incidence of arthritis, carditis and erythema marginatum. No PSRA case was complicated with carditis. General pediatrician need to have updated information about ARF and PSRA even in industrialized countries.

SAT0517 MANAGEMENT OF RISK OF VARICELLA INFECTION IN IMMUNOCOMPROMISED CHILDREN: WHAT IS THE EVIDENCE?

Maria Seago 1, Kate Armon 2, 1 Cambridge University, School of Clinical Medicine, Cambridge, United Kingdom; 2 Addenbrookes Hospital, Department of Paediatrics, Cambridge, United Kingdom

Background: Varicella-naive children on methotrexate are at risk of severe infection if they encounter varicella. Current guidance advises that management of children on higher doses or combination immunosuppression is challenging as there is no consensus about their management. Acyclovir and varicella-zoster immune globulin (VZIG) are commonly used as post-exposure prophylaxis (PEP).

Objectives: Assess the evidence for use of acyclovir and/or VZIG as PEP in the management of varicella exposure in susceptible children taking methotrexate.

Methods: A literature search using PubMed, the Cochrane Library and EMBASE was conducted from November to December 2017, using the terms methotrexate, immunocompromised, varicella, child, prophylaxis, acyclovir, VZIG and their variations. Only full papers, in English language, studying children were analysed (63 abstracts read for relevance, 28 papers obtained, 11 papers included).

Results: There have been no randomised controlled trials (RCTs) analysing the effectiveness of acyclovir and/or VZIG as PEP in immunocompromised children. The studies that do exist (see table for key publications) are small and uncontrolled and have largely been carried out in oncology rather than rheumatology patients. While they suggest that acyclovir and VZIG are effective at reducing historical infection rates of >70%, a significant proportion of recipients still get varicella.

Conclusion: There is only level 3 evidence for the use of acyclovir and/or VZIG as PEP in susceptible children on methotrexate. The literature indicates acyclovir is more effective, but this is a grade 3 recommendation only. A RCT to compare the effectiveness and acceptability of VZIG and acyclovir is needed, however the difficulty of randomising a cohort of similarly immunocompromised patients should not be underestimated.

SAT0518 READINESS FOR TRANSITION – CROATIAN VERSION AND PILOT EVALUATION OF THE TRANSITION READINESS ASSESSMENT QUESTIONNAIRE (TRAQ) IN RHEUMATOLOGIC PATIENTS

Marina Šeršnik Perica 1, Miroslav Mayer 2, Lana T. Bukovac 3, 1 Srebrnjak Childrens Hospital, Department of Pediatric and Adolescent Rheumatology, Zagreb, Croatia; 2 University Hospital Centre Zagreb, University of Zagreb School of Medicine, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, Zagreb, Croatia; 3 Srebrnjak Childrens Hospital, Department of Pediatric and Adolescent Rheumatology, Zagreb, Croatia

Background: Rheumatic diseases of childhood extend to adulthood as an active disease in 30-70% of patients, which is the reason for requiring transition of rheumatologic care into adulthood. Transition should be individualized based on patient’s readiness, and good transition readiness analysis tools should be available at the time of transition.

Objectives: As systematic review of the available assessment tools for transitional readiness in adolescents with chronic diseases has shown that only the Transition Readiness Assessment Questionnaire (TRAQ) has proven reliability in its key measurement components, we have decided to use the TRAQ in pediatric rheumatology patients.

Methods: English version of TRAQ was translated to Croatian, afterwards a back-translation to English was done. Due to difference in the insurance policy in Croatia (health care is free for children under 18 years of age), question 9 was modified into: “Are you aware of the fact that after 18 years of age you have to start paying for the additional health insurance?”

A pilot study was performed in order to validate translated TRAQ by applying questionnaire to pediatric rheumatology patients at the time of transition.

Results: A total of 41 patients at the median age of 18.25 years (range 17.8-21.1 years) were enrolled, 28 female and 13 male patients. Most of them were under 18 years of age. The mean age of patients was 17.6 years (range 13-21 years), 56% female and 44% male. Most of the patients (85%) were on methotrexate treatment. 32 patients (78%) had history of immunosuppressive treatment.

SAT0519

CLINICAL CHARACTERISTICS, TREATMENT AND OUTCOMES OF ENTHESIS-RELATED ARTHRITIS IN TAIWAN

Yang-Jen Shih1,2, Yao-Hsu Yang1, Bor-Luen Chiang1. 1National Taiwan University Hospital, Pediatric, Taipei, Taiwan, Republic of China; 2Taipei City Hospital Heping Branch, Pediatric, Taipei, Taiwan, Republic of China

Background: Juvenile idiopathic arthritis (JIA) has been categorized into seven different subtypes according to International League of Associations for Rheumatology system (ILAR) criteria [1]. Enthesitis-related arthritis (ERA) has represented the largest subtype in Taiwanese cohort study [2].

Objectives: The aim was to compare the clinical characteristics, treatments and outcomes of ERA in one of tertiary medical center in Taiwan to other subtypes of JIA. Further, to determine patients’ characteristics and risk factors help to predict the development of active and non-active treatment outcomes in ERA.

Methods: Retrospective review of patients diagnosed with JIA between March 1993 and December 2018 at a pediatric rheumatology clinic in National Taiwan University Hospital (NTUH), Taipei, Taiwan were enrolled. The outcome assessments were based on Wallace criteria to categorize patient into active and non-active (inactive, remission on medication and remission off medication) group.

Results: One hundred and eighty-three patients were included for 8 years mean follow up duration. Distribution of JIA subtypes in Figure 1 showed ERA was the single largest category of JIA (39.8%) in Taiwan. The demographic details of ERA patients in Table 1 revealed: male predominated (86%), late onset age (11.1±3.2 yrs), majority with HLA-B27 positive (92%), sacroiliac join or lumbosacral involvement (16%) and anterior uveitis (10%). Category specific outcomes in Table 2 showed ERA and extensive oligoarthritides were less likely to achieve non-active treatment response compared to persistent oligoarthritides. Among risk factors contributed to poorer treatment response in ERA were any clinical signs of sacroiliitis with P value of significant (0.0057).

Disclosure of Interests: None declared

*Comparison to Persistent Oligoarthritides. **P<0.05 with significant

Conclusion: ERA has represented the most common subtype of JIA in Taiwanese cohort study and has poorer treatment responses when compared to other JIA subtypes. To identify risk factors that contributing to poorer ERA treatment response might help more aggressive therapeutic strategy and improve outcome of ERA.

DEFINING OUTCOME MEASURES IN JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED UVEITIS BY A SYSTEMATIC REVIEW ANALYSIS. DO WE NEED A CONSSENSUS?

Greta Mastrangelo1, Ivan Foeldvari2, Jordi Anton3, Gabriele Simonini1

1Rheumatology Unit-Pediatric Section NEUROFARBA Department AOU A.Meyer University of Florence, Firenze, Italy; 2Centre for Pediatric and Adolescence Rheumatology, An der Schön Klinik, Hamburg Elbæk, Hamburg, Germany; 3Pediatric Rheumatology, Hospital Sant Joan de Déu, Barcelona, Spain

Background: Juvenile Idiopathic Arthritis associated Uveitis (JIA-U) represents its most frequent extra-articular manifestation and the main cause of childhood uveitis in in developed countries. The broad variety of outcome measures utilized makes the comparison of the disease course risk for complications, impairment in visual function, and responses to treatment quite difficult.

Objectives: Our aim was to define related and unified outcome measures in JIA-U.

Methods: A systematic review between January 2000 and December 2018 was performed to identify studies investigating outcome measures used in JIA-U.

Results: The initial search identified 8252 articles of which 29 were potentially eligible. Eighteen eligible articles remained in the analysis. A total of 27 studies, including 2 RCTs, were included. Among these studies 12 outcome measures for JIA-U use have been identified (grade of cells in the AC, grade of flare in the AC, VA, amblyopia, structural complications, use and sparing of oral corticosteroids and immunosuppressive drugs, surgery requirement, biomarkers, bilateral disease, JIA persistence, quality of life assessments, uveitis subtype). As regards primary outcome measures, 44% among studies included one or more variables related to disease activity (i.e. grade of flare, grade of cells); 56% included visual function performance (i.e. visual acuity); 68% (17/25) included one or more variables of disease-associated tissue damage or complications (i.e. cataract, amblyopia); 24% included disease features (i.e. bilateral disease; uveitis subtype); 44% included laboratory features (i.e. biomarkers); 8% included JIA features (i.e. persistence of disease); 12% included quality of life (i.e. EYE-Q); 44% included management (i.e. use and sparing of oral corticosteroids and other immunosuppressive drugs; surgery requirement).

Conclusion: Our systematic review surveys the heterogeneity around outcome measures related to JIA-U in children, even in RCTs. It does not provide the solution to overcome the heterogeneity in uveitis studies, but it does provide an estimate of the scale of the problems and provides data to inform this important debate; highlighting the requirement to obtain a new consensus regarding a common approach to identify suitable and efficient outcome measures in JIA-U.

Comparison of Children Carrying E148Q Variant with Children Carrying Homozygous Pathogenic Variants

Ayse Tanatık, Seife Göli Karadağ, Halize Emine Sonmez, Mustafa Çañkan, Nuray Aktyay Ayaz. University of Health Science, Karuni Sultan Suleyman Research and Training Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: Familial Mediterranean Fever (FMF) is the most frequent autoinflammatory disease. Nearly 300 MEFV variants have been reported and recorded in INFEVERS database. The most common disease-associated variants are mapped on exons 2 and 10 of chromosome 16. Although E148Q variant is the most common one among carriers, its role as a disease causing mutation is still debate (1).

Objectives: The aim of our study was to evaluate and compare the demographic, clinical data, features and severity scores of children carrying only E148Q variant with the patients homozygous for pathogenic MEFV mutations (M694V, M694I, M680I, V726A). One of our objective was to test and compare these two groups for the diagnostic utility of 2 adults and 1 pediatric MEFV diagnostic criteria (Tel Hashomer, Livneh and Pediatric Rheumatology) (2-4).

Methods: The medical records of 1685 children diagnosed and followed up as FMF were reviewed retrospectively. The demographic, clinical and genetic data of children carrying only E148Q variant (either heterozygous or homozygous carriers) (group 1) and children with pathogenic mutations (M694V, M694I, M680I, V726A) (group 2) were collected. All patients were evaluated for three diagnostic criteria.

Results: Children with E148Q variant were 128 and children with pathogenic homozygous variants were 429. Male to female ratio was 1.13 in group 1 and 1.15 in group 2 (p>0.05). The mean age of patients in group 1 was 12±1.5 years, in group 2 14±5.9 (p<0.001). The mean age of symptom onset was 5.4±4.1 in group 1, 4.3±3.6 in group 2 (p<0.01). Consanguinity was significantly higher in group 2 (29% vs 53%, p<0.01). In group 1 17.9% had a sibling with FMF, while in group 2 27% had a sibling with FMF (p=0.03). Clinical features like pleuritis, synovitis, recurrent fever, erysipelas-like erythema and monoarthritis were significantly more common in group 2 than group 1 (31.7% vs 9%; p<0.001, 55.9% vs 32%; p<0.001, 86.9% vs 78.9%; p<0.03, 31.2% vs 7%; p<0.001, 51.7% vs 28.1%; p<0.01, respectively). Incomplete attacks were significantly more common in group 1 than group 2 (16.4% vs 7.4%; p<0.005). Moderate and severe PRAS scores were significantly higher in group 2 (93.9% vs 71.9%; p<0.001). Laboratory values like C-reactive protein, erythrocyte sedimentation rate, serum amyloid A were found significantly higher in group 2 than group 1 (3.6±6.3 vs 0.8±1.2; p<0.001, 13±10 vs 7.3±6; p<0.001, 6.9±22.5 vs 2.9±2.2; p<0.007, respectively). The percentage of children diagnosed according two Tel Hashomer and pediatric criteria was significantly higher in group 2 than group 1 (88.5% vs 77.3%; p=0.002, 95.3% vs 84.3%; p<0.001, respectively). But both groups show similar diagnostic utility according to Livneh criteria.

Conclusion: Although children carrying E148Q variants meet the three validated diagnostic criteria of FMF. They had milder course of disease than children homozygous for pathogenic MEFV variants both clinically and in laboratory means.

Evaluation of Coexisting Diseases in Children with Familial Mediterranean Fever

Vildiz Mehmet, Amna Adrovic, Emre Tadesmir, Khamin Baba-Zada, Muhammed Aydin, Oya Koker, Sezgin Sahin, Kenan Barut, Ozgur Kasapcopur. Cerrahpasa Medical School, Istanbul University Cerrahpasa, Department of Pediatric Rheumatology, Istanbul, Turkey

Background: Familial Mediterranean Fever (FMF) is the most common periodic fever syndrome in childhood. It is characterized by fever attacks, abdominal pain lasting between 6 - 72 hours, serositis and erysipelas like erythema. Since FMF is inherited in autosomal recessive manner, it has higher frequency in populations that have higher rate of consanguineous marriages. As it is a lifelong chronic disorder, it is important to understand its clinical course for preventive medicine. Despite the higher incidence of variety of disorders showed studies among adult FMF patient, there is not enough data from pediatric populations.

Objectives: The objective of the study is to evaluate the comorbidity disorders in a large pediatric familial Mediterranean fever cohort.

Methods: Six hundred and eighty-six children with FMF were interviewed by the same investigator between October 2018 and January 2019 in our pediatric rheumatology department. Demographic features and MEFV gene mutations were recorded from patients charts. Patients and/or their parents were asked about characteristics of their fever episodes, presence of arthralgia, arthritis, abdominal pain, chest pain in the course of fever attack and coexistence of any other disease confirmed by a physician.

Results: Female-male ratio of our cohort was 0.85. Mean age of the patients was 12.8 ± 7.4 years. Mean age of patients at disease onset and at the time of diagnosis was 4.38 ± 3.46 years and 6.55 ± 3.67 years, respectively. Sixty-five and a half percent of patients had family history of FMF. Consanguineous marriage rate was 29.8%. Most common MEFV mutations were: M694V homozygotes (18.8%), M694V heterozygotes (17.7%), R202Q heterozygotes (13.1%), R202Q homozygotes (5.5%) and V726A homozygotes (4.9%), respectively. Resistance to colchicine treatment was present in 43 (6.2%) patients. Number of patients that underwent tonsillectomy were 9 (1.3%) and number of patients that had appendectomy was 11 (1.6%). Detected coexisting diseases are listed in Table 1.

Conclusion: In this study, we have reported increased frequency of juvenile idiopathic arthritis, asthma- reactive airway disease, Henoch Schonlein purpura, uveitis, inflammatory bowel disease, PFAPA syndrome and acute rheumatic fever in a large pediatric FMF cohort. Those findings consistent with data from literature. It is important to be alert about these diseases that may develop in patients with FMF for preventing them from the potential morbidities.

THE ROLE OF MEFV GENE SEQUENCING ON PREDICTING THE RISK AND DISEASE SEVERITY OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

Linqing Zhong, Hongmei Song. Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Genetically susceptibility was essential in pathogenesis of systemic juvenile idiopathic arthritis (SJIA). Objectives: To find out whether MEFV mutations contributed to the occurrence of SJIA and study the association of MEFV mutations with systemic juvenile idiopathic arthritis (SJIA) patients’ disease severity. Methods: SJIA children diagnosed based on the ILAR criteria and followed up for at least 6 months between January 2011 and July 2016 were enrolled. Meta-analysis was performed to evaluate the contribution of MEFV mutations to SJIA susceptibility. All included children were divided into three groups by presence and number of MEFV mutations, namely, those without MEFV mutation, the one mutation group, and those with more than one mutation. Demographic and clinical characteristics, as well as disease severity were compared among these groups. Disease severity was evaluated with the following three items, i.e., average duration of use of each drug, the proportion of disease activity duration and relative relapse rate. Kaplan-Meier curves and log rank test were used to estimate the probability of the first relapse.

Results: Eighty-nine patients met the ILAR criteria, among which 55 patients were eligible for further analysis. The MEFV mutations of our subjects primarily existed in exons 2 and 3. No significant difference were found in frequency of each mutation between SJIA children and healthy controls. Meta-analysis demonstrated that M694V was a risk factor for SJIA (pooled OR: 7.13, 95% CI: 3.01-16.89). Comparing with the one mutation group, biologics were used more frequently in those without or with more than one mutation in MEFV (p<0.017). Moreover, the proportion of disease activity duration was significantly lower in the one mutation group than the other two groups (p=0.028 and 0.002 respectively).

Conclusion: The mutation M694V in MEFV contributed to occurrence of SJIA. SJIA patients carrying one heterozygous mutation in MEFV tend to be less severe, which might be attributed to E148Q.

THE HETEROGENEITY OF JUVENILE PSORIATIC ARTHRITIS: EVIDENCE FROM A LARGE MULTINATIONAL COHORT

Hala Etyar1, Arūne Rama-naukiene2, Alessandra Alongi3, Yaryna Boyko4, Yosef Uziel5, Tadej Avcina6, Pierrot Quartier7, Nicoline Ruperto8, Angelo Ravelli9, Alessandro Consolaro10, Tripoli Children Hospital, Pediatric Rheumatology, Tripoli, Libya; 2Research Council, University of Lithuania, Kaunas, Lithuania; 3Instituto Gianna Gaslini, Pediatrica Rheumatologia, Genoa, Italy; 4Western Ukrainian Specialised Children’s Medical Centre, Pediatric Rheumatology, Lviv, Ukraine; 5Meir Medical Center, Kefar Sava, Israel; 6Necker-Enfants Malades Hospital, Pediatric Rheumatology, Paris, France

Background: Despite being considered as a distinct diagnostic category in the current ILAR classification criteria, Juvenile Psoriatic Arthritis (JPsA) is known to be a heterogeneous clinical entity, with growing evidence suggesting at least two age-based distinct subgroups (1)

Objectives: To identify and characterize subgroups of patients classified as JPsA according to the ILAR criteria and their possible differences in laboratory features at onset and outcomes measures collected at visit, namely JADAS scores, VAS-measured Pain, Overall Well-Being (PGA) Pediatric Rheumatology Quality of Life Scale (PROLL). In patients with disease duration more than 2 years (n=233), the relation with Articular and Extraarticular Juvenile Arthritis Damage Index (JADI) was also assessed.

Results: LCA revealed 5 classes: 1) late-onset patients with psoriasis, characterized by higher frequency of axial involvement at visit (n = 121); 2) early-onset patients with psoriasis, more likely to be ANA-negative (n = 66); 3) young females with dactylitis at onset and family history of psoriasis, more likely to present with symmetric joint involvement (n = 62); 4) subjects with nail changes and family history of psoriasis (n=34); 5) group of patients exhibiting dactylitis and nail changes at onset, mostly males, with higher rates of HLA-B27 positivity, small joint involvement and enthesis at visit (n = 25). Class 1 is associated with higher scores of JADAS10, pain, PGA and J2; these group also shows higher JADI-A than Class 3. Extraarticular damage is worst for Class 2 subjects.

Conclusion: The data driven clustering approach revealed several subgroups, confirming the heterogeneity of JPSA in a multinational cohort. Later-onset subjects with psoriasis have more aggressive disease, being clearly distinct from early-onset ANA-positive patients with psoriasis. The results suggest the need to revise the current classification in order to identify groups that may benefit from different therapeutic choices.

IMMUNOSCINTIGRAPHY OF SACROILIAC JOINTS SHOWS VERY GOOD AGREEMENT WITH INFLAMMATION ON MRI IN AXIAL SPONDYLOARTHRITIS PATIENTS

Philipp Carron1,2, Manouk de Hooge1,3, Thomas Renson1,2, Filip van den Bosch1,2, Kathia De Man1, Dirk Elewaut1,2, Philippe Carron1,2, Manouk de Hooge1,3, Thomas Renson1,2, Filip van den Bosch1,2, Ghent University Hospital, Rheumatology, Gent, Belgium; 2VIB Inflammation Research Center, Gent, Belgium; 3Ghent University Hospital, Nuclear Medicine, Gent, Belgium

Background: Currently MRI is the preferred imaging method to detect bone marrow edema (BME), the hallmark of sacroiliitis. MRI plays an important role in the early diagnosis of axial Spondyloarthritis (axSpA). Biological disease-modifying anti-rheumatic treatment has revolutionized the therapeutic armamentarium of axSpA. With drugs targeting TNF, 50% of axSpA patients achieve a clinically important response. Therefore, we hypothesized that if we would be able to demonstrate in vivo expression of TNF in sacroiliac joints by scintigraphy with 99mTc-radiolabeled certolizumab pegol (99mTc-CZP), this might lead to more evidence-based biological therapy.

Objectives: To investigate the agreement between BME on MRI-SIJ and tracer uptake on immunoscintigraphy with 99mTc-CZP in the same location in patients with axSpA.

Methods: CZP was conjugated with S-HYNIC and subsequently radiolabeled with approximately 740 MBq Tc99m and injected intravenously. Static images with single photon emission tomography (SPECT)/computed tomography (CT) of SIJ were acquired 4-6h post injection. Uptake of the tracer was scored semi-quantitatively, per quadrant of the SIJ: 0=no uptake, 1=faint uptake or 2=clear uptake. BME on MRI was scored per quadrant over 6 slices as absent or present, providing a maximum score of 6 per quadrant. Agreement between MRI-SIJ and immunoscintigraphy was calculated (kappa; percentage agreement) for all quadrants separately. To calculate the agreement a cut-off of ≥1 was used for MRI scores as well as immunoscintigraphy scores. In addition, depth and intensity of BME lesions on MRI-SIJ (as defined in the Spondyloarthritis Research Consortium of Canada (SPARCC) method) were assessed per slice per SIJ.

Results: 7 axSpA patients (mean age 36±5.7 years) had both MRI-SIJ and immunoscintigraphy available. The mean score for BME lesions seen on MRI was 12.9±7.9 and 4.8±5.4 for tracer uptake observed on the immunoscintigraphy. In 2 out of the 7 patients there was no BME on MRI and in the same 2 patients there was no tracer uptake seen on scintigraphy. In table 1 kappa coefficients and percentage agreement for every quadrant are shown. The mean and median of agreement for all quadrants was k=0.80 and k=0.86, respectively. Clear tracer uptake (score 2) was correlated to deep BME lesions on MRI-SIJ (extending over the depth of at least 1cm from the articular surface); the observed Spearman’s rho correlations were 0.986 (p<0.00) and 0.956 (p<0.00) for left and right SIJs, respectively. Regarding intensity, no significant correlation with clear tracer uptake was found. Interestingly, in one additional patient with complete ankylosis of the SIJs on radiographs no tracer uptake could be detected, suggesting that in vivo detection of TNF does not correlate with bone formation.

Table 1. Agreement on presence of BME on MRI-SIJ in a quadrant and tracer uptake on the immunoscintigraphy in that same quadrant.

</table>

Conclusion: Inflammation on MRI-SIJ can be detected with immunoscintigraphy with 99mTc-CZP. The immunoscintigraphy showed good correlation with BME lesions on MRI in patients with axSpA. Deep lesions, considered specific for axSpA, showed an almost perfect correlation.

THE COURSE OF ABERRANT FINDINGS ON MRI OF THE SACROILIAC JOINTS OVER 6 MONTHS IN POSTPARTUM WOMEN

Anais Depecic1, Thomas Renson1,2, Ann-Sophie De Craene1,2, Manouk de Hooge1,3, Thomas Renson1,2, Filip van den Bosch1,2, Ghent University Hospital, Rheumatology, Gent, Belgium; 2Ghent University Hospital, VIB Inflammation Research Center, Gent, Belgium; 3Ghent University Hospital, Obstetrics, Gent, Belgium

Background: Sacroiliac bone marrow oedema (BME) on magnetic resonance imaging (MRI) can have different causes. Besides spondyloarthritis (SpA), other more rare causes as stress fractures, mechanical stress, infections or malignancies can be identified. There are limited data regarding the specificity of MRI lesions in a non-SpA population. Prenancy and vaginal delivery might induce the presence of inflammatory and/or structural MRI lesions by mechanical stress.

Objectives: To assess aberrant findings on MRI features of the sacroiliac joints (SIJ) in postpartum women and describe the course after a 6 month time period.

Methods: Twenty-five women underwent an MRI of the SIJ within 10 days after childbirth; delivery by caesarean section was excluded. The scan was repeated after 6 months. One subject was lost to follow-up. Three trained readers systematically scored inflammatory and structural SpA-like lesions (not reported here) and qualitatively described other aberrant findings. Both time points were scored on T1-weighted and short tau inversion recovery (STIR) MRI images. Readers were blinded for time sequence and clinical and demographic information on the subjects.

Results: In 16 out of 25 (64%) subjects there were aberrant MRI findings at baseline. Thirteen out of 25 (52%) showed BME at the symphysis pubis on the baseline MRI (fig. 1). After 6 months, 6 out of 24 (25%) subjects still showed BME; in 1 subject BME of the symphysis pubis was increased at 6 months. Two out of 25 (8%) displayed a sacral fracture on the baseline MRI. Both these fractures were asymptomatic and resolved completely after 6 months (fig. 2). One out of 25 subjects (4%) showed degenerative disc disease at level L5-S1 in the form of Modic type 2; vertebral and endplate related replacement of bone marrow with fat deposition. As expected, the presence of Modic type 2 did not decrease at follow-up. No other aberrant findings were seen.

Figure 1. BME of the symphysis pubis on STIR sequence.
**SA70527**

**DOPPLER IN ENTHESIES: A POTENTIAL USEFUL OUTCOME IN ACTIVE SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS**

Juan Molina Collada1, Cristina Macía-Villa1, Chaimada Plasencia1, Diana Peiteado1, Laura Nuño1, Irene Moro1, Alejandro Villalva1, Carolina Tornero1, Patricia Bogas1, Luis Coronel1, Gabriela González1, Diego Benavent1, Elisa Fernández1, Pablo Rodríguez-Merlos1, Gerardo Napky1, Alejandro Balsa1, Eugenio de Miguel1, Hospital Universitario La Paz, Madrid, Spain; Hospital Universitario Severo Ochoa, Madrid, Spain; Hospital Universitario Nuestra Señora de la Candelaria, Tenerife, Tenerife, Spain

**Background:** The assessment of activity in spondyloarthritis (SpA) and psoriatic arthritis (PsA) involves several domains, including entheses. Clinical enthesitis has shown low sensitivity, specificity and reliability. The inclusion of ultrasound (US) could be an objective outcome in the assessment of the disease.

**Objectives:** To assess the prevalence of peripheral US enthesitis using an US score, at patient level, among active SpA and PsA patients.

**Methods:** A cross-sectional study in patients with SpA and PsA active disease, are observed when assessing MRI-SIJ of postpartum women for SpA-like lesions. BME at the symphysis pubis was often seen shortly after birth and half of those lesions persisted at follow-up after 6 months.

**Disclosure of Interests:**: None declared.

**Conclusion:** Aberrant findings, like sacral fractures and degenerative disc disease, are observed independently of SpA subtype and activity. Presence of PD enthesitis is found in 80% of patients with active SpA and PsA. This finding is independent of SpA subtype and support the usefulness of PD US in the assessment of enthesitis.

**Table 1. Baseline characteristics of active SpA patients**

**DETECTION OF FACET JOINT ANKYLOSIS ON WHOLE SPINE LOW-DOSE CT IN RADILOGraphic AXIAL SPONDYLOARTHRITIS: DATA FROM THE SENSITIVE IMAGING OF AXIAL SPONDYLOARTHRITIS (SIAS) COHORT**

Rosalinde Stal1, Floris A. van Gaalen1, Désirée van der Heijde1, Xenofon Baraliakos2, Rosalinde Stal1, Désirée van der Heijde1, Xenofon Baraliakos2, LUMC, Leiden, Netherlands; Rheumazentrum Ruhrgebiet, Herne, Germany

**Background:** In radiographic axial spondyloarthritis (r-axSpA), whole spine low-dose CT (ldCT) is superior in detecting syndesmophytes to conventional radiography (CR), which is limited to the lumbar and cervical spine. As facet joints are difficult to visualize on CR, CT has been used to study facet joint ankylosis in r-axSpA in parts of the spine. However, facet joints in the whole spine have never been studied.

**Objectives:** To assess visibility and interreader reliability of facet joint ankylosis as detected by whole spine ldCT and to describe the prevalence of facet joint ankylosis in patients with r-axSpA.

**Methods:** In an observational cohort, 60 r-axSpA patients with 1-18 syn- desmophytes on CR and at least one inflammatory lesion on spinal MRI, underwent ldCT (approximately 4 mSV) of the whole spine. Images were assessed independently by two trained readers and left and right C2-C3 to L5-S1 facet joints were scored as ankylosis present (1) or absent (0). The percentages of missing joint scores per reader were calculated.

**Disclosure of Interests:** Juan Molina Collada: None declared, Cristina Macía-Villa: None declared, Chaimada Plasencia Speakers bureau: Pfizer, MSD, MD, Diego Benavent: None declared, Laura Nuño: None declared, Irene Moro: None declared, Alejandro Villalva: None declared, Carolina Tornero: None declared, Patricia Bogas: Grant/research support from: non restricted grant from Sanofi, Luis Coronel: None declared, Gabriela González: None declared, Diego Benavent: None declared, Elisa Fernández: None declared, Pablo Rodríguez-Merlos: None declared, Gerardo Napky: None declared, Alejandro Balsa: Grant/research support from: Abbvie, Pfizer, Novartis, BMS, Nordic, Sanofi, Consultant for: Abbie, Pfizer, Novartis, BMS, Nordic, Sanofi, Consultant for: Pfizer, Speakers bureau: Pfizer, Novartis, UCB, Nordic, Sanofi, Sandoz, Lilly, Paid instructor for: Pfizer, Speakers bureau: Pfizer, Novartis, UCB, Nordic, Sanofi, Sandoz, Lilly, Eugenio de Miguel: None declared

Facet joint ankylosis progression in patients with radiographic axial spondyloarthritis (r-axSpA).

**Objectives:** To study facet joint ankylosis progression in the whole spine and per segment.

**Methods:**
- In an observational cohort, r-axSpA patients who had between 1-18 syndesmophytes on CR and ≥1 inflammatory lesion on spinal MRI underwent lCT of the whole spine (approximately 4 mSv) with a repeated lCT after two years. Paired lCTs were assessed by two trained readers independently blinded to chronology. Left and right C2-C3 to L5-S1 facet joints were scored as ankylosis present (1) or absent (0).
- Change scores, intraclass correlation coefficients (ICCs; two-way average, absolute agreement) and smallest detectable change (SDC) were calculated for the whole spine and per segment. Joints C2-C3 to L5-S1 were included in the analysis, with the exception of the cervicothoracic junction.

**Results:**
- 60 r-axSpA patients were analyzed (mean age 47.7 years, 85% male, 80% HLA-B27+). Reader 1 had between 0% and 18.3% missings per joint, reader 2 had between 0% and 51.7% missings per joint (figure). Most missings occurred in the cervicothoracic junction for both readers and mostly at both left and right facet joints of the same level. Means (SD) of sum-scores for the whole spine and cervical, thoracic and lumbar segments for both readers as well as ICCs are presented in the table. The lowest ICC was found in the cervical segment. After excluding facet joints with more than 15% missings (C5-C6 to T1-T2), ICCs were 0.93, 0.84 and 0.91 for the whole spine and cervical and thoracic segments, respectively. A striking finding was that while patients with >18 syndesmophytes were excluded from our study, very high scores of ankylosis were reported, suggesting that facet joint ankylosis may occur without syndesmophytes at the same level.

**Conclusion:**
- In patients with r-axSpA and at least one syndesmophyte, facet joint ankylosis was detected in all spinal segments. Facet joints around the cervicothoracic junction were difficult to score in a relatively high percentage of patients. The interreader reliability of the remaining levels was good to excellent. These results show that lCT can be used to study facet joint ankylosis in r-axSpA in all segments of the spine except the cervicothoracic junction.

**SAT0529**

**TWO-YEAR PROGRESSION OF FACET JOINT ANKYLOSIS ON WHOLE SPINE LOW-DOSE CT IN PATIENTS WITH RADIOPHGRAPHIC AXIAL SPONDYLOARTHRITIS: DATA FROM THE SENSITIVE IMAGING OF AXIAL SPONDYLOARTHRITIS (SIAS) COHORT**

Rosalinde Stal1, Floris A. van Gaalen1, Alexandre Sepriano1, Juergen Braun2, Monique Reinijerse1, Désirée van de Heijde1, Xerofon Baraliakos1, LUMC, Leiden, Netherlands; 2Rheumazentrum Ruhrgebiet, Herne, Germany.

**Background:** Facet joints are difficult to visualize on conventional radiography (CR). As an alternative, CT has been used to study facet joint ankylosis in radiographic axial spondyloarthritids (r-axSpA) of the spine. In the SIAS study we have shown that, with the exception of the cervicothoracic junction, which is difficult to visualize, low-dose CT (lCT) can be used to study facet joint ankylosis in the whole spine.

**Objectives:** To study facet joint ankylosis progression in the whole spine over two years in patients with r-axSpA.

**Methods:** In an observational cohort, r-axSpA patients who had between 1-18 syndesmophytes on CR and ≥1 inflammatory lesion on spinal MRI underwent lCT of the whole spine (approximately 4 mSv) with a repeated lCT after two years. Paired lCTs were assessed by two trained readers independently blinded to chronology. Left and right C2-C3 to L5-S1 facet joints were scored as ankylosis present (1) or absent (0).

**Change scores, intraclass correlation coefficients (ICCs; two-way average, absolute agreement) and smallest detectable change (SDC) were calculated for the whole spine and per segment. Joints C2-C3 to L5-S1 were included in the analysis, with the exception of the cervicothoracic junction, which were excluded in all patients due to high levels of missing joint scores as previously reported. For change score calculations, segments of individual patients with >25% missings were excluded. Remaining missings were imputed with the segment change score mean. Total scores were calculated using only patients with no excluded segments.**

**Results:** Baseline and 2-year follow up lCT were available in 53 r-axSpA patients (mean age 48.3, 85% male, 79% HLA-B27+). For reader 1, 17%, 5.7% and 3.8% of segments were excluded from the cervical, thoracic and lumbar spine for change score analysis, respectively, and 20.7% of patients were excluded for the whole spine change score analysis. For reader 2 the percentages were 15.1%, 1.9% and 1.9% and 17%, respectively. Therefore, the numbers of patients differed per reader and segment. Mean scores for baseline and follow up, mean change scores,
SDCs and ICCs are presented in Table 1. ICCs for mean status scores are good to excellent, with the lowest ICCs occurring in the cervical segment. ICCs for change scores vary greatly, the lowest ICCs being in the lumbar segment where little progression was seen. Over two years, a fair number of patients had progression of facet joint ankylosis with most progression occurring in the thoracic spine. These results show that using whole spine IDCT, progression of facet joint ankylosis can be studied in r-axSpA patients.

**Disclosure of Interests:** Rosalinde Stal: None declared, Floris A. van Gaalen: None declared, Alexandre Sepriano: None declared, Juergen Braun Shareholder of: AbbVie, Pfizer, UCB, Consultant for: AbbVie, BMS, Celgene, Chugai, Hexal, Janssen, Lilly, Medac, MSD, Pfizer, UCB, Speakers bureau: AbbVie, BMS, Celgene, Chugai, Merck, Novartis, Pfizer, UCB, Monique Reijnierse Grant/research support from: Funding from the Dutch Arthritis Foundation.

The funding source had no role in the design and conduct of the study. Désirée van der Heijde Consultant for: AbbVie, Amgen, Astellas, AstraZeneca, Bristol-Myers Squibb, Boehringer Ingelheim, Celgene, Daiichi, Eli-Lilly, Galapagos, Gilead, GlaxoSmithKline, Janssen, Merck, Novartis, Pfizer, Regeneron, Roche, Sanofi, Takeda, Union Chimique Belge, Xenoanon Baraliakos Grant/research support from: AbbVie, Boehringer Ingelheim, Bristol-Myers Squibb, Celgene, Centocor, Chugai, Janssen, Lilly, Medac, MSD, Pfizer, UCB, Speakers bureau: AbbVie, BMS, Celgene, Chugai, Merck, Novartis, Pfizer, UCB, Monique Reijnierse Grant/research support from: Funding from the Dutch Arthritis Foundation.

**Background:** Standardized imaging scores in MRI are barley used in daily clinical practice whereby the high expenditure (in terms of time and staff) is often given as a reason.

**Objectives:** To develop and evaluate a simplified version of the OMERACT Psoriatic Arthritis Magnetic Resonance Imaging Score (PsAMRIS).

**Methods:** 19 patients with PsA according to CASPAR classification criteria with inadequate methotrexate response received anti-TNF treatment and were assessed by 3T MRI of the clinically dominant hand at baseline and after 6 months. Scoring was according to PsAMRIS. Items were reduced based on standard response mean (SRM) resulting in sPsAMRIS, which was compared to PsAMRIS by calculation of the total SRM and relative efficiency (RE) after bootstrapping.

**Results:** PsAMRIS subscore of MCP3, 4, and PIP4 resulted in the highest SRM (-0.07 each) and were therefore included in sPsAMRIS. sPsAMRIS had higher SRM compared to PsAMRIS (-0.13 vs. -0.02) and a higher RE (29.46). PsAMRIS and sPsAMRIS highly correlated at baseline (r = 0.75; p < 0.01) and follow-up (r = 0.64; p = 0.01). Evaluation time was reduced from 471 to 142 seconds at baseline and from 478 to 133 seconds at follow-up (p < 0.001).

**Conclusion:** The abbreviated MRI scoring system for PsA-related changes in hands, sPsAMRIS, showed a strong correlation with the well-evaluated PsAMRIS. Hence, sPsAMRIS can be considered as a time and resource saving alternative for detection and monitoring of disease-related joint changes.
COLLAGEN IMAGING USING DUAL-ENERGY COMPUTED TOMOGRAPHY CAN DETECT SOFT-TISSUE INVOLVEMENT OF THE INTERVERTEBRAL DISC IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Torsten Diekhoff1, Kay-Geert Hermann1, Fabian Prof1, Mikhail Protopyopov2, Marcus R. Makowski1, Denis Podubryny2, Arthritis Imaging Research Group - Berlin, 1Charité – Universitätsmedizin Berlin, Department of Radiology, CCM, Berlin, Germany; 2Charité – Universitätsmedizin Berlin, Department of Rheumatology, CBF, Berlin, Germany

Background: Based on the unique physical properties of collagen, dual-energy computed tomography (DECT) is able to detect pathological changes in fibrous structures. This has been demonstrated for the Achilles tendon (1) and traumatic disc injury in elderly patients (2).

Objectives: The purpose of this study was to assess the diagnostic potential of DECT collagen imaging for the detection of intervertebral disc involvement in patients with axial spondyloarthritis (axSpA) in correlation with osseous lesions in MRI.

Methods: Sixteen patients with suspicion of or known axSpA and back pain were included. All patients underwent a 1.5-Tesla-MRI including T1 and STIR sequences and an ultra-low-dose DECT of the spine using two sequential helical acquisitions. DECT images were reconstructed in 120 kV-equivalent standard CT images and collagen maps with 1.0 mm slice thickness in sagittal reconstructions. MRI and CT images (D1 to S1) were scored for transdiscal ankylosis, Andersson lesions, syndesmophytes, spondylitis anterior and fatty corner lesions (when applicable) as well as for degenerative findings. DECT images were scored for a loss of collagen density affecting the nucleus pulposus or the annulus fibrosus. Sensitivity (SE) and specificity (SP) values were calculated. All analyses were performed on the level of the disco vertebral units.

Results: Twelve male and four female patients with a mean age of 46.6 ± 11.6 years were included. Eleven were finally diagnosed with axSpA, 3 with degenerative spine disease and 2 with diffuse idiopathic skeletal hyperostosis (DISH). MRI detected 73 lesions in 274 discovertebral units (61 SpA related, 12 degenerative; 26 affecting the disc and 35 affecting the vertebral corner) and CT 68, whereas DECT identified pathologically decreased collagen content in 60 discs (35 in the nucleus and 25 in the annulus). DECT showed high diagnostic accuracy when compared to SpA-related and degenerative changes (MRI and CT combined; SE: 67%; SP: 99.5%) and for SpA-lesions only (SE: 72%; SP: 94.2%), however, was less susceptible for degeneration (SE 60%; SP 81.9%). When comparing disc lesions in SpA as detected by MRI (transdiscal ankylosis and Andersson lesions) with nucleus-pulposus changes in DECT, it showed an SE of 88.5% and an SP of 95.1%. However, the diagnostic accuracy was inferior when comparing anterior spondylitis and fatty corner lesions in MRI with annulus fibrosus changes in DECT (SE 51.4% and SP 97%), although the SE was markedly higher for active inflammatory corner lesion (92.3%) than for fatty marrow lesions (23.3%). The mean radiation exposure was 8.1 ± 3.4 mSv.

Conclusion: DECT is able to demonstrate soft-tissue involvement of the disc, especially for transdiscal ankylosis, Andersson lesions and active anterior spondylitis. This can be achieved with considerably low radiation exposure. While measuring the collagen density, it provides additional information to conventional CT and MR images. Thus, it has high potential to develop into a useful tool to further enhance our understanding of pathological soft-tissue changes in axSpA patients outside the bone and bone marrow.
MRI ASSESSMENT OF HIP JOINTS INVOLVEMENT IN EARLY AXIAL SPONDYLARTHROPATHY PATIENTS

Ekaterina Agafonova, Tatiana Dubinina, Daria Rumiantceva, Anastasiya Demina, Shandor Erdes.

Background: Based on available data from epidemiological studies in Russia different degree of hip involvement was found in 46% of ankylosing spondylitis (AS) patients, but only 7% of all cases resulted in total hip replacement procedures.

Objectives: To describe whether cartilage defects, bone marrow lesions (BMLs), effusion-synovitis, and meniscal pathologies at baseline are associated with TKR over 13 years and to estimate the additive effect of these measures for risk prediction of TKR. To compare the ultrasound (US) manifestations of hip arthritis (coxitis) with the results of magnetic resonance imaging (MRI) of the hip joints (HJ) in patients with early axial spondyloarthritis (AxSpa).

Methods: We examined 59 patients (mean age 28 ± 5.92 years) with a diagnosis of AxSpa (ASAS criteria 2009), with prescription inflammatory spondylitis (AS) patients, but only 7% of all cases resulted in total hip replacement procedures.

Results: All patients in addition to ultrasound signs of coxitis had MRI signs of inflammation of the HJ. Pain in the HJ was determined in 33 (5%). In 15% of cases, coxitis is asymptomatic at early stages, which requires a thorough examination of patients with AxSpa. In addition to clinical and radiological examination, all patients were subjected to MRI with T1 and T2 images. An increase in cervical-capsular distance (CCD) more than 7 mm. Pain in the HJ was determined in 33 (5%).

Conclusion: Ultrasound allows you to detect changes in H in the early stages of the disease. It is possible to use ultrasound as a screening method to determine the presence of synovitis in the TBS. MRI HJ with AxSpa, allows to determine whether the patient has inflammatory changes, including in the absence of radiological changes in these joints. In 15% of cases, coxitis is asymptomatic at early stages, which requires a thorough examination of patients with AxSpa. In addition to clinical and radiological examination, all patients were subjected to MRI with T1 and T2 images.

Disclosure of Interests: Ekaterina Agafonova: None declared, Tatiana Dubinina: None declared, Daria Rumiantceva: None declared, Anastasiya Demina: None declared, Shandor Erdes: Consultant for: Development of research concepts, Speakers bureau: Educational meetings organized or supported by companies.

Figure 1. Planter fascia (A & B) and Achilles tendon (C & D) with increased T2 signal reflecting edema (arrowhead) and contrast enhancement (arrow) around the enthesis.
Semi-quantitative MRI measures such as cartilage defects significantly improve the model performance for prediction of TKR over 13 years, and hence could be utilized in prediction/decision making of TKR.

**SAT0535**

**ANTI-CARBAMYLATED ANTIBODIES IN DISCRIMINATION BETWEEN RHEUMATOID ARTHRITIS AND CHRONIC HEPATITIS C INDUCED ARTHROPATHY PATIENTS**

Asmaa Beltagy1, Ragaa Mahmoud1, Ibtessam Abd-Elhamid1, Akram Deghady2, Nevine Mohannad3.

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease presenting by chronic joint inflammation. Early diagnosis and therapy of RA are crucial for avoiding joint damage and functional disability. HCV related arthropathy (HCVA) is one of the RA mimics that is detected in around 52.2% of HCV patients. The discrimination between HCVA and RA is a challenge especially in early onset RA because of their similar manifestations. Detection of certain serologic markers in sera of arthritis patients could be helpful to differentiate between both types of arthritis. Besides RF and ACPA, anti-Carbamylated Protein (anti-CarP) antibodies were described for their role in early identification of RA. Antibodies were described for their role in early identification of RA. They can be found in up to 45% of early RA patients. Moreover, they can be detected in around 52.2% of HCV patients. The discrimination between HCVA and RA is a challenge especially in early onset RA because of their similar manifestations. Detection of certain serologic markers in sera of arthritis patients could be helpful to differentiate between both types of arthritis. Besides RF and ACPA, anti-Carbamylated Protein (anti-CarP) antibodies were described for their role in early identification of RA.

**Objectives:** To determine the role of anti-CarP antibodies in the differentiation between RA and HCVA.

**Methods:** This study was carried out on 4 groups:

- **Group I:** 20 Patients with chronic HCV infection, **group II:** 20 Patients with HCVA, **group III:** 20 Patients with RA fulfilling the 2010 (ACR/EULAR) classification criteria and **group IV:** 20 Patients with both chronic HCV infection and RA.

All patients were subjected to detailed history taking and musculoskeletal examination. Routine laboratory investigations were done for all patients in addition to ESR, CRP, RF, ACPA and anti-CarP antibodies. Plain X-ray hands and feet were performed to all patients with arthritis.

**Results:**

- **Anti-CarP antibodies were detected in the sera of 12.5% of HCV patients (10% with and 15% without arthritic symptoms) in comparison to 75% of RA patients. The difference between the two groups was statistically significant (p<0.001).**

- **ACPA were detected at low titers in 15% of HCV patients (with and without articular involvement).**

- There was a significant positive correlation between RF and anti-CarP antibodies (r=0.386) and between ACPA and anti-CarP antibodies in the total sample studied (r=0.393).

**Conclusion:** The presence of anti-CarP antibodies together with clinical features could discriminate RA patients from HCVA patients. The detection of ACPA and anti-CarP antibodies in few HCV patients should be interpreted with caution. Simultaneous detection of both anti-CCP and anti-CarP antibodies could be of great value in differentiating RA from other mimicking conditions like HCVA.

SAT0537  THE REMS TECHNIQUE IS NOT AFFECTED BY ARTHROSIIS ARTIFACT, WHICH CAN HINDER THE DENSITOMETRIC RECOGNITION OF OSTEOPOROSIS

Loredana Cavalli1, Fiorella Anna Lombardi1, Daniele Perrone1, Maria Luisa Brandi2. 1Institute of Clinical Physiology – National Research Council, IFCC-CNRC, Lecce, Italy; 2Unit of Diseases of Mineral and Bone Metabolism, CTO, AOU-Careggi, Florence, Italy, Firenze, Italy

Background: the measurement of bone mineral density (BMD) with dual-energy X-ray absorptiometry (DXA) is the current “gold standard” for diagnosing and monitoring osteoporosis, any errors in demographic information, improper patient positioning, incorrect scan analysis or interpretation can lead to erroneous results and decisions [1]. Moreover, a common condition represented by osteoarthritis, by modifying the joint soft tissues composition, can alter the values of BMD [2]. In patients affected by discarthrosis, in fact, osteoporotic T-score values at femoral neck can lead to erroneous results and decisions [1].

Objectives: To evaluate the predictive value of an innovative densitometric technique, the Radiofrequency Echographic Multi Spectrometry (REMS) [3], in detecting bone fragility in patients affected by osteoarthritis.

Methods: The T-score values of 35 postmenopausal women with clinical and/or radiological signs of osteoarthritis (mean age 71 years, average BMI 24.2) obtained by DXA at lumbar spine and femoral neck were compared with those obtained by REMS technique performed in the same bony sites.

Results: In all the subjects, LS T-score resulted significantly higher than the FN one according to DXA measurement. However, REMS outcomes in both the sites were significantly lower than the corresponding DXA measurement (significant difference between DXA and REMS T-score for both LS (p = 0.006) and FN (p = 0.010), and spinal REMS T-scores resulted more similar to femoral REMS (average REMS T-score LS: -2.6 ± 1.6 vs T-score FN: -2.4 ± 0.6) and to femoral DXA values.

Conclusion: These preliminary data suggest that REMS technique, which has been shown to have high sensitivity, specificity and accuracy when compared with DXA in diagnosing and monitoring osteoporosis [3], is not affected by the presence of altered soft tissues composition. It would therefore be particularly useful for the evaluation of bone fragility in subjects at risk of osteoarthritis.

DUAL ENERGY CT FINDINGS IN GOUT WITH RAPID KILOVOLTAGE-SWITCHING SOURCE WITH GEMSTONE SPECTRAL IMAGING

Elin Svensson1, Yva Aurell2, Lennart T.H. Jacobsson2, Anton Landgren2, Hassan Bassiouoni1, Khaled Zaky2, Harry Edén3, Ibrahim Elsakka1, Al-Azhar, Cairo, Egypt; Al-Azhar University, Rheumatology, Cairo, Egypt

Background: The gold standard for diagnosis of gout is the demonstration of monosodium urate(MSU) crystals in the synovial fluid or in tophi. However, joint aspiration is seldom performed and most patients do not have visible tophi. Dual energy CT( DECT) has been shown capable of detecting MSU crystals with high precision in many studies but the vast majority of these studies were performed using CT scanners with two X-ray tubes(dual source) while the performance of other technical CT solutions are much less investigated.

Methods: Patients with incident/prevalent gout who had been examined with DECT with rapid kilovoltage-switching source with Gemstone Spectral Imaging(GSI) to identify MSU crystals and validate these results only were seen in 31% (table 1). Beam hardening was only found in the MTP-joints but also present in ankle/midfoot joints and tendons(table 1). The total urate deposit score was significantly higher in the presence of clinically identified tophi(Wilcoxon Mann-Whitney, p=0.0005) and correlated strongly to disease duration(Spearman corr. coefficient 0.64, p<0.0001) while no association or correlation was seen to age, sex, erosive disease, urate levels, BMI, diuretic or ULT use or renal function. The majority of patients displayed nail artefacts while skin artefacts only were seen in 31% (table 1). Beam hardening was only found in one patient and noise was not seen at all(table 1).

SAT0540 CLINICAL AND ULTRASONOGRAPHIC ASSESSMENT OF STERNOCLAVICULAR JOINT IN PATIENTS WITH RA

Hassan Bassiouoni1, Khhaled Zaky2, Harry Edén3, Ibrahim Elsakka1, Al-Azhar, Cairo, Egypt; Al-Azhar University, Rheumatology, Cairo, Egypt

Background: The sternoclavicular (SC) joint is a real diarthrodial joint that can be affected during the route of RA; but, its scientific implications appear to remain underestimated through the rheumatology network, (1) ultrasound (US) is right extensively common imaging approach in each clinical exercise and in rheumatology studies to visualize joints and tendon tissues. To date, there is a regular frame of evidence assisting its validity, reliability, and feasibility inside the evaluation of persistent inflammatory arthritis and its higher sensitivity than scientific exam in the analysis of synovitis, enthesitis, and tenosynovitis in these patients (2).

Objectives: To describe the prevalence of sternoclavicular (SC) joint involvement and the relationship between clinical and ultrasound (US) findings in patients with rheumatoid arthritis.

Methods: 120 subjects with age range from 20 to 50 years were recruited from Physical Medicine, Rheumatology and Rehabilitation department of Sayed Galal and Al-Hussein Al-Azhar University Hospitals, during the period from April 2018 to October 2018. All the patients were informed about the study and signed an informed consent.

Subjects were divided into two groups: Group A: 60 patient known as RA fulfilling ACR criteria for classification of rheumatoid arthritis (1987) (3). Group B: 60 normal control subjects. All subjects have been clinically evaluated and t blinded US examinations of the SC joint were performed bilaterally in both groups. The presence of gray-scale synovitis, erosions, and intraarticular power Doppler (PD) was recorded.

Results: A total of 240 SC joints were evaluated: 120 from patients with RA and 120 from healthy controls. In the RA group, 21 joints (17.5%) were found to be clinically involved (pain/swelling), in contrast to only 6
(5%) in the control group (P = 0.002). In the RA group, US abnormalities were recorded in 62 SC joints (51%) compared with 3 (2.5%) in the healthy control group (P = 0.0001), comprising synovitis in 28 (23.3%) versus 3 (2.5%) (P < 0.001), erosions in 27 (22.5%) versus none (P < 0.001), and intraarticular PD in 7 (5.8%) versus none (P = 0.031). Furthermore, a correlation between the presence of US synovitis (P < 0.001) and intraarticular PD (P < 0.0001) with a higher Disease Activity Score in 28 joints (DAS28) was found.

Figure (1) showing erosions of clavicular head of sternoclavicular joint.

Conclusion: US is extra sensitive than medical examination for detecting SC joint involvement in RA. The correlation amongst US synovitis, intraarticular PD, and the DAS28 show that SC joints actively participate within the systemic inflammatory manner of RA. The precise position of US within the assessment of the SC joint in suffers with RA is but to be mounted firmly in the rheumatologic examination.

SAT0541 MULTIDRUG TRANSPORTERS OF PERIPHERAL LYMPHOCYTES SERVE AS BIOMARKERS TO BDMARD RESPONSE IN RHEUMATOID ARTHRITIS (RA)

Gergely Toldi1, Peter Kraics2, Peter Szeremy1, Kata Filter1, 1MDQuest Ltd., Szeged, Hungary; 2QOL-VO Biotechnology, Szeged, Hungary

Background: Multidrug resistance transporters (MDR-ABC transporters, namely MDR1, MRP1 and BCRP) play essential role in the homeostasis of a variety of endogenous molecules, proinflammatory mediators among them [1]. When the regulation of this phenomenon is disturbed, cell migration, proliferation and inflammatory processes are over activated which finally results in the pathogenesis of RA. Moreover, enhanced function of MDR proteins leads to multidrug resistance [2].

Objectives: In our multicenter, multinational clinical trial we aimed to assess the predictive value of flow cytometry-based multidrug resistance activity measurement of the previously mentioned MDR proteins for bDMARD response in RA in CD3+ and CD19+ lymphocytes before and as well as 4 to 6 and 12 weeks after initiation of bDMARD therapy.

Methods: Peripheral blood samples were collected from 27 bDMARD responders and 12 non-responders RA patients at the indicated time points. Multidrug activity factors (MAFs) were measured from CD3+ and CD19+ lymphocytes by using SOLVO MDQ kit™. Cut-off values were determined by using ROC curve analysis.

Results: Before starting bDMARD therapy, MAFCD3 and MAFCD19 values of CD3+ cells were higher in non-responders as compared with responders. Six weeks after starting therapy, the same pattern was detected in case of MAFCD3, MAFMRP1, and MAFBCRP in both investigated cell types. ROC analysis revealed that when MAFCD3 value is higher than 21.3 in CD3+ cells before starting bDMARD therapy are likely to be non-responders. At later time points, MAFCD3 values above 20.3 and MAFMRP1 above 6.0 and MAFBCRP values above 13.9 in CD3+ cells also predict unfavourable treatment response. Of note, these cut-off values are all below the respective reference ranges in healthy individuals established in our earlier study [3].

Conclusion: Importantly, little is known about the relation of MDR activities and therapeutic success to bDMARDs. Proinflammatory mediators and cytokines may serve as an interface between pharmacological activity of bDMARDS and MDR transporters [4-6].

SAT0542 DETECTION OF SUBCLINICAL LV MYOCARDIAL DYSFUNCTION IN RHEUMATOID ARTHRITIS PATIENTS BY SPECKLE TRACKING ECHOCARDIOGRAPHY

Yasser gazar1, Mohammed Nawar2, Abdelhamid tuma3, 1Faculty of medicine, Al-Azhar university, Rheumatology, Cairo, Egypt; 2Faculty of medicine, Al-Azhar university, cardiology, Cairo, Egypt

Background: Patients with rheumatoid arthritis (RA) have shorter life expectancy and their risk of cardiovascular (CV) death is more than 50% higher than the rest of the population. Early myocardial dysfunction may be detectable more precisely and sooner using speckle tracking echocardiography.

Objectives: This study was designed to assess myocardial (LV) systolic function by STE (speckletracking) Echocardiography) strain imaging in patients with RA and to correlate the findings with characters of the disease.

Methods: Cross-sectional observational study enrolled 60 patients with RA (mean age 46.22 ± 8.14 years) without known CVD and 20 healthy controls. All subjects underwent a standard echocardiographic examination as well as the speckle tracking assessment of left ventricle strains.

Results: Speckle-tracking assessment of LV systolic function revealed decreased GLS among the patients group (-16.80% vs. -22.35%, P < 0.001). There was a negative correlation between the duration of RA and the GLS (r = - 0.301). Receiver operating characteristics (ROC) curve was used to define the best cut off value of GLS which was -20, with sensitivity of 76.7%, specificity of 80%, positive predictive value of 92%, negative predictive value of 63% with diagnostic accuracy of 83.9%.

Conclusion: The speckletracking method for myocardial strain analysis showed unambiguously systolic impairment of longitudinal strain parameters. So, patients with RA should undergo a full comprehensive echocardiographic study for assessment of LV systolic function.

Background: Artificial intelligence (AI) techniques including deep learning have been rapidly evolving and have yielded appreciable benefits in many fields in recent years. In rheumatology field, however, these techniques have not been used often.

Objectives: In an early phase of development of an AI-based automatic radiographic evaluating system for bone destruction, we aimed to develop learning-based models to automatically detect hand joint region, ankylosis and subluxation in radiographic images.

Methods: A total of 130 radiographic image sets of both hands were randomly obtained from rheumatoid arthritis patients who had visited our division at Keio University Hospital in 2015. Well-trained rheumatologists determined the boundaries of regions of MP and PIP/IP joints and evaluated the presence of ankylosis and subluxation of each joint in radiographs. These evaluations of hand joints were performed using our developed annotation software tool [1].

In learning phase, joint images were randomly divided into five sets for 5-fold cross validation. As deep learning models, we utilized Single Shot Multibox Detector (SSD) method [2] with ensemble learning for detecting ankylosis and subluxation of MP and PIP/IP joint regions.

Results: Our model showed 100% detection rate of MP and PIP/IP joint regions. As a performance of detecting hand joint ankylosis and subluxation, our model presented precision values of 0.85 and 0.73, recall values of 0.94 and 0.79, and F-measure values of 0.90 and 0.76, respectively.

Conclusion: Deep learning-based models to automatically detect hand joint region, ankylosis and subluxation in radiographic images were developed with relatively small samples, which suggests that the predictive performance may increase by collecting more training dataset. Next, we are elaborating a plan for a deep learning-based evaluating system for erosion and joint space narrowing.

Coronary Plaque Progression in Rheumatoid Arthritis: Role of Inflammation, Cardiovascular Risk Factors, Medications and Impact on Event Risk

George Karpouzas1, Sarah Ormseth, Elizabeth Hernandez, Matthew Budoff2,1 Harbor UCLA Medical Center, West Carson, United States of America, 2 Harbor UCLA Medical Center Cardiology, Torrance, United States of America

Background: Patients with Rheumatoid Arthritis (RA) exhibit higher prevalence, burden and different composition of occult coronary plaque compared with age and gender-matched controls. More specifically, plaque burden on coronary computed tomography angiography (CCTA) predicted long-term cardiovascular events (CCE) in RA beyond cardiac risk factors or scores.

Objectives: To evaluate change in coronary plaque burden and composition, predictors thereof and its impact on CCE risk in RA.

Methods: One hundred-one participants with a baseline CCTA underwent a follow-up evaluation in 83±3.6 months. Plaque load was reported as segment involvement score (SIS-number of segments with plaque); segment stenosis score (SSS-cumulative stenosis over all evaluable segments) and total plaque score (TPS-collective plaque amount over all segments). Plaque composition was defined as non-calcified (NCP), mixed (MP) or calcified (CP). Coronal artery calcium (CAC) was quantified by the Agatston method. Robust regression was used to evaluate predictors of increased plaque burden compared to non-progression.
A COMPARATIVE STUDY OF NAILFOLD IL-17A IS UPREGULATED IN SYSTEMIC SCLEROSIS

Rheumatology and Clinical immunology, New Delhi, India

Objective: To study the various patterns on Nailfold Capillaroscopy in microvascular changes in patients with ILD.

Methods: A comparative study was conducted on 50 patients each of IIP and IPAF who fulfilled ERS/JRS/ALAT 2011 revised diagnostic criteria for IIP demonstrating a higher frequencies of abnormalities (microhemor-

Results: Total plaque burden increased in 42% of patients; progression was predicted by older age, higher cumulative inflammation (TA-CRP) and higher total prednisone dose (table 1).

Discussion: The study showed that Nailfold Capillaroscopy is a useful tool in the diagnosis and follow-up monitoring of patients with IPAF.

Conclusion: This study provides valuable insights into the role of nailfold capillaroscopy in the evaluation of microvascular changes and disease progression in IPAF patients.

IL-17A IS UPREGULATED IN SYSTEMIC SCLEROSIS PATIENTS WITH MIXED ANA IMMUNOFLUORESCENT PATTERN AND MORE THAN ONE POSITIVE ANTINUCLEAR ANTIBODY TO THE SERUM

Ekatierina Kupteva1,2, Ekaterina Ivanova-Todorova2,3, Kalina Tumangaleva-Yuzevi2,

Methods: We enrolled 31 patients who fulfilled the 2013 ACR/EULAR Classification Criteria for SSc at mean age of 47±3 were recruited in the study. 17 with diffuse SSC and 14 patients with localized SSC, respectively.

Results: Our study consisted of 23 (46%) female patients and 27 (54%) male patients for IPAF group and 19 (38%) female patients and 31 (62%) male patients for IIP group. The mean capillary density was significantly reduced in IPAF group and also had presence of abnormal capillary morphologic patterns (microhemorrhages, neangiogenesis and megacapillaries).

Conclusion: This single centre study found that Nailfold Capillaroscopy (NFC) is an important adjunct to differentiate between patients of IPAF and IIP demonstrating a higher frequencies of abnormalities (microhemor-

A COMPARATIVE STUDY OF NAILFOLD CAPILLAROSCOPY CHANGES IN IDIOPATHIC INTERSTITIAL PNEUMONIA WITH IDIOPATHIC INTERSTITIAL PNEUMONIA AUTOMMUNE FEATURES

Kurali Kishore1, Vivek Vasudev2, 3Army hospital research and Referral, Rheumatology and Clinical immunology, New Delhi, India; 4Army Hospital Research and Referral, Rheumatology and Clinical Immunology, New Delhi, India

Background: Lung involvement especially interstitial lung disease (ILD), can be the first manifestation of an underlying connective tissue disorder (CTD). About 25% of ILD occurs in the context of an "undiagnosed" CTD, characterized by signs and symptoms that are not specific for any of the described CTD entities, now known as IPAF. Nailfold capillaroscopy (NFC) is an important tool, which helps us in early recognition of microvascular changes in patients with ILD.

Objectives: To study the various patterns on Nailfold Capillaroscopy in patients of Interstitial Pneumonia with autoimmune features (IPAF) and compare them with those having idiopathic Interstitial Pneumonia (IIP).

Methods: The study population consisted of 50 patients each of IIP and IPAF who fulfilled ERS/JRS/ALAT 2011 revised diagnostic criteria for IIP and ERSATS classification criteria for Interstitial pneumonia with autoimmune features respectively. The study also included 50 age and sex matched controls, having normal respiratory examination clinically, normal CXR and normal PFTs. All patients underwent NFC at room temperature and the following parameters were recorded: capillary density, presence of megacapillaries, tortuosity, avascular areas, disarrangement and neoangiogenesis.

Results: Our study consisted of 23 (46%) female patients and 27 (54%) male patients for IPAF group and 19 (38%) female patients and 31 (62%) male patients for IIP group. The mean capillary density was significantly reduced in IPAF group and also had presence of abnormal capillary morphologic patterns (microhemorrhages, neangiogenesis and megacapillaries).

Conclusion: This single centre study found that Nailfold Capillaroscopy (NFC) is an important adjunct to differentiate between patients of IPAF and IIP demonstrating a higher frequencies of abnormalities (microhemor-

Scientific Abstracts

Saturday, 15 June 2019 1365
sena with mixed AC pattern. Regarding the Tregs and Th17 cells, we identified a reduced percentage of the CD25+Tregs at a marginal trend toward significance in the patients with mixed AC pattern versus the group with simple AC pattern [5.9 [3.2 – 10.6] vs 11.2 [6.1 – 14.3], p = 0.06].

Conclusion: Although the pathogenetic contribution of ANA in SSc remains unclear, ANA play an important role in the differential diagnosis, risk stratification and assessment of disease activity in SSc. Further research is warranted to clarify the interconnection between the disregulated Th17/Tregs axis and the production of high-high-titer specific ANA in SSc. In the future, rheumatologists could benefit from ANA in order to apply the most accurate therapeutic strategy for each patient.

SAT0547

ULTRASONOGRAPHIC FOLLOW UP OF ENTHESOPHYTE GROWTH IN A CONSECUTIVE SERIES OF IBD PATIENTS

Pierkulk Macchioni1, Federica Martinis2, Giorgia Citriniti3, Carlo Salvarani1

1Arcispedale S Maria Nuova, RCCS, Reggio Emilia, Italy; 2Policlinico GB Rossi, University of Verona, Verona, Italy; 3University of Modena and Reggio Emilia, Modena, Italy

Background: Previous studies have found an interconnection between inflammatory intestinal diseases (IBD), particularly Crohn disease (CD) and Ulcerative Colitis (UC), and spondyloarthritides.

Objectives: We prospectively evaluate the pattern and predictive factors of enthesophyte growth in a cohort of patients with IBD.

Methods: A total of 68 IBD consecutive patients (31 CD, 36 UC, 1 ID, M/F 37/31, mean age 40.2 ± 13.2 years, mean disease duration 107.5 ± 129 months) were enrolled. Rheumatological examination included 66 peripheral joint count, MASES and Leides entheseal indexes, BASDAI, BASFI and evaluation of spine mobility. US examination was done at baseline and at 24 months using an Esaote MyLabClass, 18-6 MHz linear multifrequency transducer both in B-mode and PD-mode. The follow-up sites were blindly evaluated bilaterally: lateral epicondylear of the humerus, distal quadrupital insertion at the patella, superior and inferior pole of the patella, Achilles tendon insertion, and plantar aponeurosis insertion. Quadriceps, patellar, Achilles and plantar fascia entheses were scored according to the 0-36 Glasgow Ultrasound Enthesitis Scoring System (GUESS) and power Doppler (PD). The presence of enthesophytes were scored dichotomously as present (=1) or absent (=0) for each site and summed up to generate the ARE score (ARES). Enthesophytes was also scored semiquantitatively in a 0-3 scale (0 = absent, 1 = minimal, 2 = discrete, 3 = massive) for each site and summed up to generate RES score (RESS).

Results: Eighteen patients showed no increase of the RESS, 13 pts had 1 point increase, 12 pts less than 4 and 25 pts more than 4 points increase of the RESS at the end of follow-up. Baseline factors associated with RESS progression were age > 50 years, male sex, BMI ≥ 25, CRP > 0.50 mg/dl, and alcohol consumption. As far as the number of sites involved only 8 patients showed no increase of ARES, while 25 pts had ARES increased more than 4. Baseline factors predicting ARES increase were pre-existing presence of enthesophytes at quadriceps tendon insertion at superior patellar pole, age > 50 years, male sex, and alcohol consumption. Progression of ARES and RESS was not associated with type of IBD, use of corticosteroid, biological agents or immunosuppressive drugs nor with the concomitant presence of cutaneous psoriasis smoke habit, diabetes, dyslipidemia.

Conclusion: US examination of selected entheseal area demonstrates the increase of number and size of enthesophytes during a 2 years follow-up of IBD patients. Alcohol consumption and the presence at baseline of enthesophytes are the most important predictive factors for RESS and ARES progression respectively.

SAT0548

TRACKING RESIDUAL INFLAMMATION USING ULTRASOUND IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL REMISSION

Saoussen Miledi, Myriam Moalla, Alia Fazaa, Kmar Gueniche, Leila Souabni, Selma Kassab, Selma Chekli, Zakraoui Leith, Kawther Ben Abdelghani, Ahmed Laatar. Mongi Slim Hospital, Rheumatology department, Tunis, Tunisia

Background: With current treatment strategies, achieving a state of remission has become a realistic goal in rheumatoid arthritis (RA). Several composite scores and indices are available to assess remission based on clinical and biological parameters. None of the European League Against Rheumatism or American College of Rheumatology current recommendations include ultrasonography (US) findings as a parameter to define whether or not a patient is in remission.

Objectives: Describe and compare clinical and ultrasonographic findings in RA patients in clinical remission.

Methods: We included RA patients who were in clinical remission by the Disease Activity Score (DAS28-cv2.6) for at least three months. B mode and Power Doppler (PD) US examination were performed by an experienced rheumatologist, blinded to clinical data. Twenty-two joints of both hands (wrist, metacarpophalangeal (MCP) and proximal interphalangeal joints (PIP)) were assessed. A binary score (absence or presence) of synovial hypertrophy/effusion (SH) and power Doppler (PD) signals was applied for each joint. The sonographic Remission was defined by the absence of PD signals.

Results: Thirty patients were recruited (25 female and 5 male). The mean age of our population was 48 ± 8.98 years-old. All patients were in remission according to DAS28. The mean DAS28 was 2.03 ± 0.40 ranged from 1.13 to 2.6. Average length of remission was 16 months [3-72 months]. On clinical examination, nine swollen joints were identified, represented by wrists in all cases. On B mode, synovial hypertrophy was detected in 80% of patients. Among the 660 joints examined, synovitis was identified in 89 cases. A wrist synovitis was detected in 55% of cases (33 out of 60 wrists studied) making it the most affected joint, followed by the second and third PIP in 14 and 12 cases out of 60 studied, respectively. PD signal, as a sign of active disease, was observed in 78% of patients and detected in 43% of the total wrists examined (26/60) [Table 1]. Among the swollen joints found on clinical examination, only one had no synovial hypertrophy in B mode. However, subclinical synovitis was detected in 81 joints (12% of total joints) with prediction for PIP joints (47% of subclinical synovitis). In PD mode and subclinical synovitis, PD signals were found in 38 joints (47%). Thus, the sensitivity of the clinical examination to identify swollen joints compared to US was 9%, its specificity of 99%, its PPV of 89% and its VPN of 88%.

Conclusion: Subclinical joint inflammation detected by US might explain the structural deterioration in RA patients despite clinical remission. Our findings support the use of US for the accurate evaluation of disease status before concluding to remission or otherwise to adjust treatment.

SARCOPENIA IN RHEUMATOID ARTHRITIS FEMALE  
THROMBIN GENERATION ASSAY AND GLOBAL  
TRABECULAR BONE SCORE

Andrea Casabella1, Barbara Ruaro1, Chiara Seriolo2, Luigi Molfetta2,  
Elisa Alessandri1, Carmen Pizzorni1, Alberto Sulii1, Maurizio Cutolo1,  
Sabrina Paolino1,1 Research Laboratory and Academic Division of Rheumatology,  
Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy, Genova, Italy;  
Osteoporosis, Bone and Joint Disease Research Center, CROPO, Department of Internal Medicine, University of Genova, Italy, Genova, Italy

Background: Rheumatoid arthritis (RA) is associated with muscle loss, osteoporosis and an increased risk of fractures. Sarcopenia is a syndrome in which muscle mass loss is linked to functional loss. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) that provides an indirect measurement of bone microarchitecture and allows to get information about bone quality [1-3].

Objectives: The aims of this study were to examine associations between bone mineral density, bone quality, fat mass and lean mass in the whole body in female patients with RA and healthy controls (CNT).

Methods: 55 female patients (mean age 58±12 years) affected by RA and 55 CNT (mean age 52±16 years) were enrolled. Bone Mineral Density (BMD, g/cm²) of the lumbar spine (L1-L4) and whole body and the Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) that provides an indirect measurement of bone axial microarchitecture and allows to get information about bone quality [1-3].

Results: The mean BMI±SD compared by RA and CNT was 26.1 ± 3.92 kg/m2 and 5.94 ± 0.42 kg/m2 respectively, compared by CNT (23.7±5.5 kg/m2 and 5.5 kg/m2 on women.

Discussion: In this study 55 female patients (mean age 58±12 years) affected by RA and 55 CNT (mean age 52±16 years) were enrolled. Bone Mineral Density (BMD, g/cm²) of the lumbar spine (L1-L4) and whole body expressed by Relative skeletal mass index (RSMI) was analyzed using a DXA scan (GE, Lunar Prodigy). Lumbar spine TBS was derived for each patient with APS compared to patients treated with warfarin and no APS, APS patients had significantly lower ILag (13.3 ±5.9 min; p= 0.003; p= 0.008, respectively) and TPeak (21.3 ±9.2 min; p= 0.006; p= 0.014, respectively) with lower Peak (99.1 ±71.8 nM; p< 0.001; p= 0.005, respectively) and AUC (1150.5 ±637.4 nM; p< 0.001; p= 0.004, respectively).

Conclusion: This study show that sarcopenia is frequent in RA patients, mostly on those classified as normal or overweight according to BMI. Therefore TBS and BMD values, as demonstrated could have a key role in a bone-muscle feedback in chronic systemic inflammatory rheumatic diseases, such as RA.

THROMBIN GENERATION ASSAY AND GLOBAL ANTIPHOSPHOLIPID SCORE (GAPSS) FOR RISK STRATIFICATION IN ANTIPHOSPHOLIPID SYNDROME

Massimo Radici, Irene Cecchi, Elena Rubini, Silvia Graziella Foddai, Savino Sciascia, Darío Roccatello. University of Turin, Turin, Italy

Background: Thrombin generation assay (TGA) is a simple and reproducible technique, that could potentially be used in coagulation laboratories, that measures the concentration of generated thrombin after plasma recalcification. The clinical usefulness of TGAs in assessing thrombotic risk has been a matter of growing interest, however, it has not been applied on a large scale to a large cohort of patients with antiphospholipid syndrome (APS).

Objectives: The aim of our study was to assess the potential use of TGA in monitoring the pro-coagulant state in APS patients and its role in predicting the relative risk score in developing APS clinical manifestations, by comparing its parameters to the validated global antiphospholipid score (GAPSS).

Methods: After chart-reviewing all APS patients that presented at San Giovanni Bosco Hospital in the last 5 years, we enrolled 4 groups of patients for the sake of this study, matched for age and sex. Clinical and laboratory characteristics were retrospectively collected. Inclusion criteria were as follows:

Group A) Fulfilled the diagnosis of Thrombotic APS defined as per Sidney criteria [1]: 60.
Group B) Patients with aPL positivity, but with no clinical manifestations of APS defined as per Sidney criteria [1]: 30.
Group C) Patients treated with Warfarin (target INR 2-3), negative for aPL and other autoimmune conditions: 60.
Group D) Healthy Controls: 60.

Results: Figure 1 resumes the representative TGA profiles between groups. Healthy controls and patients with aPL positivity, but no APS clinical manifestations, had similar TGA profiles [mean ILag (min) 9.6 ±2.9 v.s. 8.6 ±3.2; mean TPeak (min) 16.2 ±4.7 v.s. 13.7 ±5.8; mean Peak (nM) 209.2 ±103.8 v.s. 265.4 ±106.2; mean AUC (nM) 2057.1 ±571.8, respectively).

When analyzing the TGA profile of the patient with APS compared with healthy controls and aPL positive patients with no clinical manifestations of APS, we observed a statistically significant higher ILag (13.3 ±5.9 min; p= 0.003; p= 0.008, respectively) and TPeak (21.3 ±9.2 min; p= 0.006; p= 0.014, respectively) with lower Peak (99.1 ±71.8 nM; p< 0.001; p= 0.005, respectively) and AUC (1150.5 ±637.4 nM; p< 0.001; p= 0.004, respectively).

Furthermore, also when analyzing the TGA profile of APS patients compared to patients treated with warfarin and no APS, APS patients had significant higher ILag (13.3 ±5.9 min v.s. 8.2 ±2.1; p= 0.001), TPeak (21.3 ±9.2 min v.s. 13 ±2.8; p= 0.001), Peak (99.1 ±71.8 nM v.s. 62.3 ±21.5; p= 0.018) and AUC (1150.5 ±637.4 nM v.s. 605 ±148.8; p< 0.001).

When analyzing a correlation model between GAPSS and TGA parameters, we observed a statistically significant correlation for ILag (Pearson
INCIDENTAL FINDINGS OF TEMPOROMANDIBULAR
JOINT DISORDERS ON STANDARD BRAIN MRIS: A CROSS-SECTIONAL STUDY

Tatiana Reitblat1, Azaria Simonovich2, Svetlana Kolontaevsky3, Leonid Kalichman4.

Background: The temporomandibular joints (TMJ) changes is quite often ignored as a differential diagnosis in the evaluation of patients with suspicion on rheumatic and musculoskeletal disease such as temporal arteritis, fibromyalgia, rheumatoid arthritis. To understand whether TMJ changes have to be included in routine workup of patient’s evaluation with the suspect to rheumatic disease, we assessed the prevalence of TMG changes incidental findings in standard brain MRI scan. In our experience, numerous incidental findings are found on a standard brain MRI scan, especially the elderly. A literature search revealed that no studies have reported the prevalence of these findings and their clinical relevance.

Objectives: To evaluate the prevalence of incidental TMJ findings on standard brain magnetic resonance imaging scans and assess if these findings are associated with symptoms.

Methods: Our sample comprised 65 males (47.1%) and 75 females (52.9%), mean age 54.75±17.45 (range: 18-87). Data collected from each TMJ included articular displacement, articular effusion, condyle flattening, condyle erosions, capsule enhancement, and bone marrow edema. Dichotomous data as to TMJ-related symptoms such as headaches, earaches, dizziness, clicking or grating sound, pain or soreness of the joint, limited mouth opening, locking of the jaw, facial muscle pain, unexplained teeth pain, neck pain or stiffness and difficulty swallowing, were acquired during telephone interviews.

Results: The most frequent finding was disc displacement (39.9% on the right side and 47.8% on the left), followed by condyle flattening (33.3% on the right side and 44.2% on the left). All findings, except bone marrow edema, were significantly more frequent on the left side than the right (Table 1). Significant associations were found between incidental findings in the TMJ and earaches (odds ratio 2.759, P=0.043), dizziness, clicking or grating sound, pain or soreness of the joint, limited mouth opening, locking of the jaw, facial muscle pain, unexplained teeth pain, neck pain or stiffness and difficulty swallowing, were acquired during telephone interviews.

Conclusion: Incidental findings of TMJ degenerative features were commonly found on standard brain magnetic resonance imaging. The high frequency of the findings and strong association with facial pain requires performing TMJ assessment in all patients who undergo medical inquiry for suspected rheumatic and musculoskeletal disease.

INCIDENTAL FINDINGS OF TEMPOROMANDIBULAR JOINT DISORDERS ON STANDARD BRAIN MRIS: A CROSS-SECTIONAL STUDY

Tatiana Reitblat1, Azaria Simonovich2, Svetlana Kolontaevsky3, Leonid Kalichman4.

Objectives:

1. To describe lacrimal gland biopsy results in children, Ophthalmology, London, United Kingdom
2. To describe the largest paediatric cohort of biopsy proven non-infectious dacryoadenitis (4,5).

Methods: We identified 72 children who had lacrimal gland biopsy at GOSH between 25/09/2000 and 12/04/2018 using two key-words: “lacrimal” and “dacryoadenitis”. We excluded patients with infectious dacryoadenitis, benign tumors or malignancy. We retrospectively reviewed the medical notes, laboratory and histopathology results.

Results: Twenty six patients had non-infectious dacryoadenitis with or without soft tissue involvement. All cases manifested as upper lid swelling. 19 (73.1%) patients had unilateral involvement. 12 (46.2%) patients were male. Mean age at time of biopsy was 10.5 years and median 13 years (range 1 – 17.7).

Four patients had GPA (granulomatous polyangiitis), 4 patients sarcoidosis, 1 patient IgG4-related disease, 1 patient Sjögren with secondary anti-phospholipid syndrome and 16 patients non-specific chronic inflammation (NSCI). 2/4 patients with sarcoidosis had extra-ocular involvement. One patient with sarcoidosis had NO2 mutation without Blau phenotype. One patient with GPA had extra-ocular involvement.

4/13 children tested had raised ACE including 2 sarcoidosis and 2 NSCI. 7/17 had raised amylase (2 sarcoidosis, 1 Sjögren, 4 NSCI). 7/20 had elevated CRP and 4/20 had raised ESR. 22/24 had raised IgG (range 0.6-3.3 g/L). 7/20 had raised IgA (range 0.2-1.8 g/L).

We describe the largest paediatric cohort of biopsy proven non-infectious dacryoadenitis (4,5).

Objectives: 1. To describe lacrimal gland biopsy results
2. To report associated clinical, laboratory features and treatment

SAT0552

PAEDIATRIC NON-INFECTIONOUS DACRYOADENITIS: THE GOSH EXPERIENCE

Joana Silva-Diniz1, Ameenat Lola Solèbo2, Yasirr Abou-Rayyah1, Sandrine Compeyrot-Lacassagne1, Great Ormond Street Hospital for Children, Rheumatology, London, United Kingdom
2Great Ormond Street Hospital for Children, Ophthalmology, London, United Kingdom

Background: Dacryoadenitis is an inflammatory enlargement of the lacrimal gland and the most common orbital inflammatory condition in the paediatric population, although only 6 to 17% of orbital inflammatory disorders occur in children (1-4). Dacryoadenitis may be idiopathic or associated with infections or inflammatory diseases. Systematic inflammatory disorders are more typically associated with chronic than acute dacryoadenitis (3).

We describe the largest paediatric cohort of biopsy proven non-infectious dacryoadenitis (4,5).

Table 1: Frequencies of incidental findings in TMJs on standard brain MRI (n=138).

SAT0553  HIGH FEASIBILITY AND ACCEPTANCE OF A MUSCULOSKELETAL ULTRASOUND PROGRAM TO IMPROVE DMARDs ADHERENCE IN RHEUMATOID ARTHRITIS

York Kit Tan1,2,3, Julian Thumboo2. 1Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore; 3Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background: Disease modifying anti-rheumatic drugs (DMARDs) non-adherence is a widespread issue in rheumatoid arthritis (RA) which needs to be urgently addressed as it can lead to suboptimal therapy with poor disease outcomes. The subsequent need for more aggressive therapy, treatment of disease related complications and increased consultations can translate into increased healthcare utilization and costs.

Objectives: To describe the feasibility and patient’s acceptance of a Musculoskeletal Ultrasound Program (MUSP) developed to improve DMARDs adherence in RA patients who are non-compliant to their conventional DMARDs (Methotrexate, Leflunomide, Sulfasalazine and/or Hydroxychloroquine) therapy.

Methods: The MUSP is a standardized approach (i.e. each patient given the same standardized intervention) which synergises (1) the patients’ direct visualization of their joint pathologies (inflammation and/or erosions) using real-time ultrasonography and (2) a Rheumatologist’s simultaneous reinforcement of the need for medication adherence, thereby improving patient’s understanding of their joint disease and motivating them to adhere to their DMARDs therapy. Joints utilized to demonstrate joint pathologies real-time using ultrasonography.

Results: 62 RA patients (baseline characteristics: majority Chinese, 40/62 (64.5%); 55/62 (88.7%) female; mean (SD) age, 49.2 (12.0), mean (SD) DAS28, 3.27 (1.39); mean (SD) disease duration, 6.1 (5.4) years) completed the MUSP. The mean (SD) time taken to complete the MUSP was 18 (8.7) minutes. All patients had at least one joint pathology demonstrable to them on real-time ultrasonography. Specifically, 62/62 (100%), 14/62(22.6%) and 25/62 (40.3%) had demonstrable synovial hypertrophy, power Doppler synovial vascularity and bone erosions, respectively. Figure 1 shows the frequency distribution of the joint sites utilized to demonstrate joint pathologies real-time using ultrasonography. The majority of patients reported that the MUSP had moderately or very much improved their understanding of their underlying joint condition (i.e. 44/62 (71.0%) patients) and the importance of regularly taking their RA medication (i.e. 49/62 (79.0%) patients) (figure 2). Most patients (i.e. 56/62 (90.3%) patients) will also recommend the MUSP to another RA patient.

Conclusion: Our results demonstrated high feasibility and acceptance of a MUSP developed to improve DMARDs adherence in RA patients. Further studies are required to establish the clinical impact and cost-effectiveness of the MUSP in this population.

Disclosure of Interests: None declared

Objectives: To retrospectively summarize 50 cases of mesenteric panniculitis/MP diagnosed by CT to improve the clinicians’ understanding of the disease.

Methods: The patients with MP diagnosed by abdominal CT were collected from the hospital of Shari Medical University from January 2013 to May 2017. The demographic characteristics, clinical features, auxiliary examination, treatment and prognosis were analyzed and summarized.

Results: The proportion of men and women was 1:0.92, the age of onset was 25 - 85 years old, the average age was (59.1±14.0) years old. Most of the patients presented with abdominal pain, fever, hematuria, and lymphadenopathy. 22 cases with tumor, the most common type is lymphoma, 16 cases with abdominal surgery history. There were no special laboratory tests, no patients had mesenteric pathologic biopsy. 6 cases had abdominal CT review. 1 case of who used hormone treatment showed the lesion was significantly absorbed, the remaining 5 cases no significant changes.

Conclusion: MP is common in the elderly, the clinical manifestations are diverse, easy to merge tumor, lymphoma more common, abdominal CT is its most important diagnostic means, when found MP, should pay attention to whether the merger with malignant tumors.

SAT0555 LOSING FOLLOW-UP IN REGISTRIES OF RHEUMATIC PATIENTS TREATED WITH BIOLOGICS: A POTENTIALLY VALUABLE HIDDEN REAL-WORLD DATA THAT IS BEING OVERLOOKED?

Ana Valido1,2, Joana Silva-Dias1,2, Maria João Gonçalves2, Vasco Romão1,2, Maria João Saavedra2, João Euriro Fonseca1,2, Hospital Santa Maria, Serviço de Reumatologia e Doenças Osteo-Metabólicas, Hospital de Santa Maria, CHULN; Lisboa, Portugal, Portugal, Lisbon, Portugal, Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa; Lisboa, Portugal, Portugal, Centro Académico de Medicina de Lisboa, Portugal, Lisboa, Portugal;
Hospital Egas Moniz, Serviço Reumatologia, Centro Hospitalar de Lisboa Ocidental, Lisboa, Portugal

Background: The information associated with loss to follow-up (LFU) patients (Pts) may affect a real-world data evaluation of the use of biologics (Bio) that is not being adequately captured in registries.

Objectives: To identify the reasons for LFU in rheumatic patients treated with biologics in our center.

Methods: We identified all Pts treated with Bio in our center who had no registered visits in Reuma.pt for more than 6 months. We retrieved baseline information from Reuma.pt and from the hospital electronic clinical record. We then performed a telephonic interview to characterize the reasons for LFU up at our day care unit. For Pts unable to be contacted by telephone a letter of invitation to an appointment at the hospital was sent.

Results: From a total of 790 Pts registered in Reuma.pt at our centre with active Bio therapy (BioTx) 227 did not have any information registered in last 6 months. Of this, 36 Pts were on BioTx prescribed by other Department (Dermatology, GEA) and maintain follow-up in these departments. 102 Pts had suspended BioTx by medical indication, and this information was registered in the hospital electronic clinical records but not updated in Reuma.pt. For 89 Pts (47%) no information could be retrieved from either the hospital electronic clinical record or Reuma.pt and we classified these Pts as true LFU. Reasons of LFU were: being followed in other Rheumatology centres (n=28; 31.4%), death (n=26; 29.2%), adverse effects (AE) (n=11; 12.4%), other (n=5, 5.6%) and clinical remission (n=4; 4.5%). 15 Pts (16.9%) could not reach us by telephone or attend the appointment.

28 of these LFU Pts were being followed up in another Rheumatology center. The most frequent reasons for this change were: 15 (16.9%) decided to move the follow-up to a newly created and closer Rheumatology Department; 6 (6.7%) moved to another city; 5 patients (5.6%) had administrative problems related to our Department/Hospital and 2 (2.3%) patients referred socio-economic reasons that were interfering with travelling.

26 of the LFU Pts died, at a mean age of 66.3 years. The mean disease duration was 14.3 years and 20 Pts (76.9%) had RA. The mean duration of Bio was 5.9 years and 53.8% were under anti-TNF therapy, 16% under Anti-CD20 therapy and 12% under interleukin-6R inhibitors. Cause of death was identified in only 3 patients: 1 had a myocardial infarction, 2 had surgery complications. None of these Pts was on BioTx at the moment of death.

11 Pts of the LFU had stopped BioTx and abandoned follow-up by their own decision after suffering AE attributed by the patient to the use of Bio. 6 patients (6.7%) had infections: cutaneous (n=3, 3.4%) or urinary tract related (n=3, 3.4%), with need of hospital admission in 2 of the cases (2.2%). The remaining Pts stopped the drug because of cutaneous reactions (n=5, 5.6%).

4 Pts of the LFU were in remission and decided to stop the drug and the medical follow up. All of them believed that the disease was inactive without the need of medical drugs.

Conclusion: Identifying LFU Pts and clarifying the reason for the loss of data in a register contributes to a better knowledge on strategies to discontinue Bio in stable Pts, to a better pharmacovigilance of adverse effects and to more efficiency in data capture by registries. The authors of this study are now making additional efforts to contact the 15 still missing Pts and obtaining access to death certificates in order to further clarify the cause of death of 23 Pts.

SAT0556 EVALUATING RESEARCH PARTICIPANT EXPERIENCE IN A RHEUMATOID ARTHRITIS OBSERVATIONAL STUDY

Siena Menegatti1, James Anderson1, Claire Plannert2, Caroline Sanders2, Suzanne Verstappen2, Jamie Sergeant2.

1The University of Manchester, School of Medicine, Manchester, United Kingdom; 2The University of Manchester, Manchester, United Kingdom

Background: Patient and public involvement (PPI) in research is increasingly common (1), but the experience of research participants is rarely evaluated, missing opportunities to gain insights for improving future studies. (2) Observational studies are often used to study natural progression and treatment response in chronic diseases like rheumatoid arthritis (RA).

Objectives: We aimed to pilot a participant experience questionnaire in an observational study of RA patients, to gain feedback on the study and evaluate the questionnaire as a feedback tool.

Methods: The Rheumatoid Arthritis Medication Study (RAMS) is a large UK prospective observational study of patients with RA or undifferentiated polyarthritis starting methotrexate (MTX) for the first time. Participants were recruited prior to initiation of MTX and followed-up at 3, 6 and 12 months. At visits, disease activity is measured and participants complete a study questionnaire including patient reported outcomes. Participants also complete a weekly diary about their MTX use. (3) A subset of RAMS participants were given a feedback questionnaire at their final visit. The questionnaire was designed by researchers and study coordinators with feedback from patients. Questions addressed the value of participation, study conduct and priorities for future research. Multiple-choice question responses were summarised and key themes were identified in the free-text responses.
OUTPATIENT READMISSION IN RHEUMATOLOGY: A MACHINE LEARNING PREDICTIVE MODEL OF PATIENT’S RETURN TO THE CLINIC

Luis Rodriguez Rodríguez, Alfredo Madrid García, Judit Font-Urgelles, Dalifer Freites, Cristina Lajas, Esperanza Pato, J Ángel Jover, Benjamin Fernandez, Lydia Abasolo. Hospital Clínico Universitario San Carlos, Rheumatology, Madrid, Spain

Background: Readmissions can be defined as the return of a patient to a healthcare setting after a discharged. Attention has been mainly focused on readmissions following inpatient hospitalizations. In the outpatient setting, readmissions have been far less studied. Premature outpatient discharges can have negative impacts at multiple levels, as they may prolong disability, and increase the chance of disease chronification, the demands to the immediate patient’s support system, and healthcare resources utilization. As the first step in preventing outpatient readmission, the assessment of the individual patient’s risk could be useful to help identify those subjects at greatest risk, so, in a further step we could focus the delivery of an intervention in those patients to reduce their risk.

Methods: Patients stored in a departmental electronic health record from April 1st, 2007 to November 30th, 2016, and followed-up until November 30th, 2017, were included in this study. Only readmissions taking place between 3 and 12 months after discharge were analyzed. Discharge episodes were split into training, validation and test datasets. Clinical and demographic variables, including diagnoses, treatments, quality of life, and comorbidities, were used as predictors. Models were developed using Random Forest.

Results: 17,473 patients (18,117 discharges episodes) were analyzed and 1,960 (10.8%) discharges episodes were classified as outpatient readmissions. 46,654 models were finally developed. The best final model showed an AUC-ROC of 0.674 a sensitivity of 0.330 and a specificity of 0.867. The most relevant variables in the model were the number of diagnoses given at discharge, follow-up duration, age, number of previous discharges, previous corticosteroids use and disability.

Conclusion: We have developed a predictive model for outpatient readmission in a rheumatology setting. Clinical, demographical characteristics as well as medication and disability were the most important predictors.

SAT0560 A QUALITATIVE STUDY EVALUATING NEAR-PATIENT TOOLS INCLUDING A MOBILE APPLICATION FOR EARLIER RA REFERRAL; POTENTIAL TO REDUCE CHRONIC DISEASE BURDEN

Norma Bin, Simran Chahal, Augurex Life Sciences Corp., Vancouver, Canada

Background: Rheumatoid arthritis (RA) is a chronic, debilitating autoimmune disease. Patients who are treated with disease modifying therapy within 6-12 weeks of symptom onset have better outcomes which leads to a reduced economic burden of disease. 1 Technology that enables near-patient blood testing coupled with digital health applications may increase the proportion of patients treated within this window. Objectives: This study aimed to assess the perceived unmet need for early treatment amongst clinicians and patients as well as their perceptions of a near-patient blood test and digital health mobile application. Methods: 74 participants, approximately half from each of Canada (n=18) and the US (n=20) participated in a combination of in-depth interviews and surveys for 40-50 minutes. 38 of the 74 subjects, consisted of 16 rheumatologists, 14 primary care physicians (PCPs) and 8 RA patients. To supplement the patient study-sample, 36 additional patients completed an online survey of quantitative and open-ended questions focused on diagnosis and perspectives of a described near-patient blood test and mobile application. Rheumatologists who were in full-time practice and PCPs who see at least 15 RA patients a month were included. Patients were between 18 and 60 years old, had an RA diagnosis and experience using apps for health management. Results: Almost all Rheumatologists and PCPs indicated that the time between symptom onset and treatment initiation (currently 6-18 months) could be improved and agreed that difficulty diagnosing is still one of the biggest unmet needs. Referrals to a Rheumatologist range from 6 weeks to 3 months. Patients indicated that it took 8 months to 2 years before treatment initiation. Most Rheumatologists said the longest delay is due to inconclusive PCP clinical exacerbations and blood work, leading to repeated visits before patients are referred. Most clinicians and patients welcomed new tools with 33% of patients willing to pay for the near-patient blood test and mobile application. Clinicians had few concerns about a near-patient blood test and indicated that it should be available in the clinic, not the pharmacy. Patients reported the appeal of an easy to use near-
patient blood test that could have meant an earlier diagnosis over a traditional laboratory blood test.

Conclusion: RA is difficult for PCPs to identify for early referral and treatment within 6-12 weeks of symptom onset. The clinicians and patients we surveyed reported positive perspectives regarding near-patient blood tests and mobile applications and welcome their use to assist with earlier referral and treatment.

With the emergence of innovative near-patient technologies, opportunities exist to intervene earlier and potentially reduce the social and economic burden of chronic diseases.

Acknowledgements: The authors would like to acknowledge B2 Consulting for their assistance with this project. This project was funded by the National Research Council – Industry Research Assistance Program (NRC-IRAP).

SAT0561 DIAGNOSTIC ACCURACY OF GOUT IN ELECTRONIC HEALTH RECORDS AND THE ROLE OF RHEUMATOLOGY ELECTRONIC CONSULTS

Juliana Chang1,2, Jonathan Tsui3, Maida Wong1,2, 1Tibor Rubin VA Medical Center, Rheumatology, Long Beach, United States of America; 2University of California, Irvine, Rheumatology, Orange, United States of America; 3Geisinger Medical Center, Danville, United States of America

Background: Gout is the most prevalent inflammatory arthritis globally. Despite treatment advances, it still has a significant effect on quality of life and healthcare costs. There have been inconsistent studies on administrative coding as an accurate marker of true diagnosis. Although gout can be solely managed by primary care physicians (PCPs), complex cases often require rheumatology consultation. The wait time for an initial rheumatology clinic visit ranges from 38 days to 47 weeks. However, electronic consults (e-consults) allow for swift two-way communication between PCPs and rheumatologists (pre-consult exchange) to facilitate coordination of care among providers.

Objectives: To determine the accuracy of gout diagnosis based on ICD 9 and 10 coding, and the differences in gout outcomes based on PCP management, e-consult or rheumatology clinic visits at two Veterans Affairs Medical Centers.

Methods: A retrospective cohort study was created from 2009-2014 including 101 e-consult patients and a control group of 176 patients. In the e-consult group, 76 patients were ICD 9 or 10 coded for gout; in the control group, 116 were ICD 9 or 10 coded for gout. A blinded abstractor determined the accuracy of gout coding based on chart review and EULAR criteria.

A second random sample of 183 gout patients from 2009-2014 was identified and stratified to 3 modes of management: PCP only (48), e-consult (68), and rheumatology clinic visit (67). Data was reviewed for 24 months following initial gout diagnosis or e-consult. Management was evaluated based on frequency of flares and related ED visits, creatinine clearance, and serum uric acid levels (sUA).

Results: The sensitivity and specificity of ICD coding for accurate gout diagnosis was 94% and 79% in the control (PPV 88%, NPV 90%). For e-consult patients, the sensitivity and specificity was 100% and 70% (PPV 87%, NPV 100%). E-consult patients were more accurately diagnosed with gout by PCPs than in the control group (p=0.03). 83% of e-consults were resolved electronically and 17% were converted to rheumatology clinic visits. The mean wait time for e-consult recommendations was 1.8 days. The mean clinic visit wait after pre-consult exchange was 22.9 days compared to an average of 43.1 days for direct rheumatology clinic visits. Both e-consult and rheumatology clinic patients had more gout flares and related ED visits at diagnosis compared to PCP care; however, at 12 months, both groups had significantly fewer gout-related ED visits, decreased sUA, and improved creatinine clearance (p<0.05).

Conclusion: VA databases are an accurate source of gout patients based on ICD coding. When viewing e-consults, rheumatologists can rely on accurate PCP gout diagnoses, confidently answer clinical questions, and triage more efficiently. E-consult serves as an effective alternative in managing gout with shorter wait times for recommendations and appointments while still reimbursing physicians at a reasonable rate. Therefore, complex gout management can be enhanced by e-consults to improve clinical outcomes, decrease gaps in care and optimize healthcare resources.

SAT0562 BURDEN OF RHEUMATIC DISEASE AMONG KOREAN WOMEN IN CHILDBEARING YEARS BASED ON THE NATIONAL HEALTH INSURANCE SERVICE

Min Kyung Chung1, Jin Su Park2, Hyun Sun Lim3, Chan Hee Lee6, Jasco Lee6

1Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Rep. of (South Korea); 2Division of Rheumatology, Department of Internal Medicine, National Health Insurance Service Ilsan, Seoul, Korea, Rep. of (South Korea)

Background: Many rheumatic diseases (RDs) predominantly affect women in their reproductive years, and have a significant impact on childbearing, but its burden remains incompletely understood.

Objectives: The study aimed to identify the prevalence and incidence of RDs among Korean women in childbearing years, and the effect of the diseases on prevalence of comorbidities, medication use, and pregnancy rate.

Methods: From National Health Insurance Service data during 2009-2016, we identified 9,217,119 women aged between 20-44 years. Among these women, we estimated the prevalence and incidence of RDs including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and ankylosing spondylitis (AS). Prevalence of chronic diseases such as cancer (Ca), hypertension (HT), hyperlipidemia (HLD), and diabetes mellitus (DM) was compared in women with or without RDs. The prescription prevalence of medications including NSAIDs and corticosteroids were compared according to the presence of RDs. We also investigated pregnancy rate in women with rheumatic or chronic diseases, and control subjects without rheumatic or chronic diseases.

Results: Overall prevalence of RDs was 56.3 per 100,000 20-44 aged females, and overall incidence was 7.68 cases per 100,000 person-years. Women with RDs had increased risk for overall chronic diseases (OR 1.90, 3.0, and for Ca (OR 1.3), HT (OR 1.4), HLD (OR 2.9), and DM (OR 2.8), respectively (p<0.0001). The prescription of NSAIDs and steroids was significantly more frequent in women with RDs than those without (81.62% vs 21.79% in NSAIDs, 77.83% vs 4.28% in steroids, p<0.0001). Pregnancy rate was significantly lower in women with RDs compared with the controls (15.92% vs 19.30%, p<0.0001). Among women with RDs, women with RA were less likely to become pregnant (OR 0.80, p<0.0001), whereas women with SLE and AS showed no significant difference in pregnancy rate compared with the normal controls.

Conclusion: RDs are a significant burden for women in childbearing years causing increased co-morbidities and medication use and causing reduced pregnancy rate.

Efficacy of Etanercept over a Period of 12 Months in the Routine Treatment of Patients with RA, AxSpA, PsA or Pso: Final Results of a German Non-Interventional, Prospective, Multi-Center Study (Adequate)

Eugen Feist1, Xenofon Baraliakos2, Frank Behrens3, Diamant Thaçi1, Anja Plenske1, Lisa Kristina Blindzeline6, Thomas Meng4, Peter Andreas Lüschnann4, Charlotte Berlin University Medical Center, Berlin, Germany; 2Rheumaklinik München, Munich, Germany; 3Charité Universitätsmedizin Berlin, Berlin, Germany; 4Schilling-Holstein University Hospital, Luebeck, Germany; 5Rheumaklinik Neubrandenburg, Germany; 6Pfizer Pharma GmbH, Berlin, Germany

Background: Patients with chronic autoimmune diseases such as rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA) or plaque psoriasis (PsO), the treat-to-target concept requires attaining remission or at least low disease activity and is defined by the corresponding guidelines. The achievement of these targets affects radiological progression and functional measures. If treat-to-target has not been achieved after 3 months, current treatment could either be continued with an expected increased response over time or could be switched to another treatment option.

Objectives: The primary goal of this non-interventional study was to determine the proportion of patients achieving the treat-to-target criteria with Etanercept at month 3, 6 and 12 in a real-life setting. Secondly, the proportion of patients achieving the treat-to-target criteria at month 6, even if it has not yet been fully attained until month 3, was determined.

Methods: Into this German non-interventional, prospective, multi-center cohort study, adult patients with confirmed diagnosis of RA, axSpA, PsA or Pso without prior Etanercept treatment were included. Planned recruitment number was 2,100 RA patients, and 300 patients each with axSpA, PsA or Pso. Criteria for remission and minimal clinical efficacy were defined according to recommendations of the respective treatment guidelines and the study protocol. The analyses were based on the number of patients completing the respective study period (3, 6 and 12 months).

Results: Overall, 1,465 patients were included (treated set), i.e. 901 females (61.5%) and 564 males (38.5%); patients mean ± SD age was 54.9 ± 14.5 years. Patients’ median disease duration ranged across the rheumatic indications from 3.4 years in PsA to 5.5 years in RA, and was markedly longer in Pso (median: 15.3 years). At week 12, the proportion of patients reached remission was 24.4% in RA, 19.0% in axSpA, 38.3% in PsA and 7.1% in Pso. Further increases were seen up to week 24 in RA (30.6%), PsA (50.7%) and Pso (18.6%), while axSpA rates remained similar (18.4%). In all indications, these proportions continued to increase from week 24. At the end of the observational period, a total of 702 patients (47.9%) experienced at least one treatment emergent adverse event (TEAE). However, serious drug-related AEs were only reported in 41 patients (2.8%).

Conclusion: A considerable proportion of patients attained the target of remission or low disease activity at week 12 under daily routine practice conditions, proving a reliable protective therapeutic effect of Etanercept in a real life setting. These percentages further increased up to week 24 except for axSpA patients. With regard to the safety profile of Etanercept, the incidence numbers and types of AEs were in an expected range and in-line with documented safety profile according to the SmPC.

SAT0565  COST EVOLUTION OF BIOLOGICAL AGENTS FOR THE TREATMENT OF RHEUMATOID ARTHRITIS IN A TERTIARY HOSPITAL INFLUENTIAL FACTORS IN PRICE

Mª Angéles González-Fernández1, Elena Villamañán Bueno2, Irmaculada Jiménez-Nácher3, Chamaida Plasencia3, Alicia Herreño Ambrosio4. La Paz University Hospital, Madrid, Spain, Pharmacy Department, Madrid, Spain; La Paz University Hospital, Pharmacy Department, Madrid, Spain; La Paz University Hospital, Rheumatology Department, Madrid, Spain.

Background: The availability of biological therapy has changed the approach to treating rheumatoid arthritis. Spending on biological agents has risen due to the drugs' high cost and the increased prevalence of rheumatoid arthritis.

Objectives: To evaluate the annual cost-per-patient and cost for each biological drug for in patients with rheumatoid arthritis from 2009 to 2017, and to calculate factors that affect at treatment cost, such as optimized therapies by monitoring drug serum levels, the use of biosimilars-TNF inhibitors, and discounts or negotiated rebates in biologicals acquired by pharmacy department.

Methods: Retrospective, observational study in a Spanish tertiary hospital. Main outcome: Annual cost-per-patient and per drug. Influential factors that affected the costs and demographic parameters and disease activity were also analyzed.

Results: A total of 320, 270, and 389 patients were treated in 2009, 2013, and 2017, respectively. Annual cost-per-patient decreased: € 10,798 in 2009, € 7,491 in 2013 to € 7,116 in 2017. The introduction of new drugs drives economic competition leading to discount savings from original infliximab, etanercept, adalimumab, certolizumab, golimumab and tocilizumab respectively, while rebates for biosimilar-infliximab reached 43.1% in 2017. Patients with optimized therapies reached 35.2% in 2017, which lead in cost savings of € 458,535 and savings from optimized therapies of € 830,000 in 2017.

Conclusion: The cost of biological treatments declined after official discounts, negotiated rebates, and optimized therapies, leading to a significant decrease in the annual cost per patient. The greatest contribution to economic savings in biological therapy according to our study was biological therapy optimization.

SAT0566  LIVING WITH CHRONIC INFLAMMATORY AUTOIMMUNE DISEASE IN BRAZIL: THE PATIENT’S PERSPECTIVE

Wanda Heloísa Ferreira1, Nilma Rodrigues de Oliveira2, Gládis Lima3, Mateus Rodrigues Alves4, Mayara Elka Isaura5. 1Instituto UCB PARU-PETRÓPOLIS, Petrópolis, RJ, Brazil; 2ARUR, Uberlândia, MG, Brazil; 3Pfizer Brasil, Porto Alegre, RS, Brazil; 4UCB Biopharma, São Paulo, SP, Brazil.

Background: The patient’s journey is a complex phenomenon. It includes all the stages, perceptions, and experiences that the patient goes through since the identification of the first symptoms of a given disease. Therefore, it is crucial to understand this journey as it may help to optimize the patient’s quality of life, especially for those who live with chronic inflammatory autoimmune diseases such as Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Axial Spondyloarthritis (axSpA).

Objectives: The aim of this study was to understand the journey of people living with rheumatic disease in Brazil and its impact on several different areas of the patient’s life, including family planning, use of medications, and access to health care services and professionals.

Methods: The data were extracted from an exploratory, descriptive and quantitative research, with primary data collection. It was performed between May 09, 2018 and August 01, 2018. The survey had 58 questions and it was available online for public participation through the GRU-PARU PETRÔPOLIS website.

Results: The survey was accessed by 1223 participants. The proportion of patients with RA, PsA, and axSpA were 70.97%, 17.42% and 11.61%, respectively. Most participants were female (87.64%) and 59.21% of all attendees were between 18 and 54 years old. Only 38.72% of the participants declared that they were working, while 32.34% admitted to being retired or on sick leave. About 60% of the attendees have taken more than a year to visit a rheumatologist and 48.08% received their diagnosis after at least one year of the first symptoms. Nevertheless, once they started to visit a rheumatologist, more than two thirds do not have difficulty to schedule a visit with this specialist. In addition, participants are satisfied with the health care they receive and feel well informed about their treatment. At least half of the attendees used synthetic disease-modifying antirheumatic drugs to control their disease, 41.73% also used corticoids and 33.87% are on biologic drugs. Nevertheless, 37.24% and 17.35% of the participants classified their disease activity as moderate or high, respectively, thus not achieving the target of treatment from their own perspective. This may affect the patient’s quality of life as reflected in the percentage of respondents suffering from emotional problems (46.62%) as well as in the proportion of patients having some or many difficulties to do daily activities. This scenario is impacted by the fact that more than half of the participants do not have access to another health care provider other than the rheumatologist to help manage their condition. This survey has also delved on the topic of family planning. With regards family planning, 50% of the women indicated an unplanned pregnancy (n=142). Moreover, 48.59% (n=69) of these women had never discussed with their rheumatologist about the desire to be pregnant. Furthermore only 13.38% (n=19) affirmed that their treatment during pregnancy was discussed between the rheumatologist and the gynecologist/ obstetrician.

Conclusion: Although most of the participants in this survey indicated a good level of satisfaction with the health care they receive, data also indicate opportunities for improving the patient’s quality of life. Patients are satisfied with the access to the rheumatologist, drug treatment as well as the information they receive on physician’s appointments. This work illustrates the complexity of these chronic inflammatory autoimmune disease and the importance of multidisciplinary treatment to manage it to impact positively the patient journey.

Acknowledgement: This study was sponsored by UCB Biopharma (Brazil).

Disclosure of Interests: Wanda Heloísa Ferreira Grant/research support from: UCB Biopharma, Nilma Rodrigues de Oliveira Grant/research support from: UCB Biopharma, Gládis Lima Grant/research support from: Satif 2019.
Background: As part of the IOF recommendations and the “Capture the fracture” program a Multidisciplinary and focused on Primary Medicine Fracture Liaison Prevention Unit (FLS) was created in May of 2018 in the Hospital Universitario Virgen Macarena, in Seville, Spain. In previous reports, the rate of osteoporosis treatment prescription after the fragility fracture was as low as 20%, with a poor communication between the medical specialties involved in the attention of this patients.

Objectives: To improve the medical attention and treatment of patients with a FF. To create a multidisciplinary FLS with the collaboration of Primary Care Medicine, Internal Medicine, traumatology, Emergency Room, Rheumatology, Rehabilitation Service and the Medicine Department of the Seville University.

Design: A prospective, observational study in the setting of usual clinical practice and with approval of the local ethics committee. The Multidisciplinary FLS started to work at may, 2018 connecting primary care with medical specialties. The FLS has 3 weekly consultations (11 first visits, 4 second visits and email consultation, each day) attended by 2 internal medicine physicians, one Rheumatologist and one nurse. All medical specialties involved in the attention of patients with FF can refer patients and the inclusion criteria is the history of a FF in the past 18 months. In a single medical visit, the doctor and the nurse make a clinical history, assesses the risk of FF according to FRAX, the risk of falls (J.H. Downton scale), they evaluate malnutrition (Mini Nutritional Assessment Elderly) and sarcopenia (hands dynamometry and Short Physical Performance Battery). Complete blood count and blood and urine biochemistry in order to evaluate secondary causes of osteoporosis and vertebral radiographs are done. A treatment plan agreed and discussed with patient is started. The plan advice on diet and exercises, drugs, and a written report and medical prescription. And a phone follow-up is programmed. The data are entered and stored in a database (OpenClinica) real time.

Results: From May to October of 2018, 170 patients have been included: 135 (89%) women. The mean (standard deviation) age was 73 ± 11.8 years old; 25% of them with ages between 83 to 94 years. The patients were defined by a series of screening questions in the CCHS-MH and included all rheumatic diseases. The rate of receiving adequate treatment for their comorbid mental disorders. The outcome of interest was utilization of mental health treatments in the previous 12 months, including: 1) medications; 2) professional services (e.g. physician, psychiatrist, nurse); or 3) non-professional services (e.g. family, self-help group, internet). The explanatory variable was self-reported doctor-diagnosed arthritis and included all rheumatic diseases. Multivariable binomial logistic regression was used to evaluate utilization of mental health treatment differs among those with and without arthritis, adjusting for the confounding factors of age, sex, race/ethnicity, and household income.

Methods: We used nationally representative data from the 2012 Canadian Community Health Survey – Mental Health (CCHS-MH) to draw a sample of 1,810 participants with depression, anxiety, or bipolar disorder. Depression, anxiety, and bipolar disorder (bipolar I, bipolar II, or hypomania) were defined by a series of screening questions in the CCHS-MH derived from the World Health Organization version of the Composite International Diagnostic Interview. The outcome of interest was utilization of mental health treatments in the previous 12 months, including: 1) medications; 2) professional services (e.g. physician, psychiatrist, nurse); or 3) non-professional services (e.g. family, self-help group, internet). The explanatory variable was self-reported doctor-diagnosed arthritis and included all rheumatic diseases. Multivariable binomial logistic regression was used to evaluate utilization of mental health treatment differs among those with and without arthritis, adjusting for the confounding factors of age, sex, race/ethnicity, and household income.

Results: A total of 447 (20.5%) participants from our study sample reported having arthritis (66.9% female). Utilization of mental health treatments in the previous 12 months was reported by 82.4% individuals with arthritis and 79.5% without arthritis. The most common treatment utilized by those with arthritis was professional services (66.5%), followed by medication (61.8%) and non-professional services (51.5%). Participants without arthritis most often received mental health treatment in the form of non-professional services (67.3%), followed by professional services (58.1%) and medication (45.6%). The point estimate of the adjusted analysis suggested a positive association between arthritis and utilization of at least one type mental health treatment (odds ratio [OR] 1.41, 95% confidence interval [CI] 0.85, 2.34), though not statistically significant. In the sub-analysis, the ORs for the association between arthritis and specific mental health treatments were: medication (OR 1.30, 95% CI 0.86, 1.99) and for professional services (OR 1.27, 95% CI 0.83, 1.93), but decreased for non-professional services (OR 0.81, 95% CI 0.52, 1.27).

Conclusion: These nationally representative data show that a high proportion of individuals with arthritis seek treatment for their comorbid mental disorders. Findings of this study may also suggest a positive association between having arthritis and seeking care for comorbid mental disorders, which may be explained by an already established connection with the healthcare system to manage arthritis. Opportunities to improve mental health treatment among those with arthritis include optimizing access to non-professional services.
Objectives: We sought to: (i) describe trends of prescribed opioids for non-cancer pain in the UK primary care setting over a 10-year period (ii) assess the sequential transition of opioid strength from index date over a 2-year period.

Methods: We conducted a retrospective observational study over a 10-year period from 1/1/2006 to 31/12/2015 using the Clinical Practice Research Datalink (CPRD). CPRD collects de-identified patient data from a network of GP practices across the UK. New users of opioids, 18 years or over, without cancer in the 2 years prior to index date were included. The number of prescriptions for each drug were calculated by each calendar year accounting for the number of eligible patients registered in CPRD for that year. Sunburst plots were created to evaluate the sequential transition of opioids over time. A 4-state hidden Markov model was used to estimate the transition probability for individuals escalating to more potent opioids over a 2-year period. States were defined as (i) no drug (ii) weak opioid (codeine, dihydrocodeine) (iii) moderate opioid (tramadol) (iv) strong opioid (all others in CPRD). Methadone prescriptions were excluded for the purposes of this analysis.

Results: 1,026,955 opioid users were included: mean age (SD) was 55 (18) years; 58% being female. New users of opioids were most commonly prescribed codeine (n=723,102; 70.8%), followed by dihydrocodeine (n=179,831; 17.6%), tramadol (n=93,338; 9.1%) with n=94,808 (2.4%) strong opioid prescriptions. The rate of prescribing strong opioids/10,000 population increased 12 fold from 2006-2013, followed by a gradual decline till 2015 (Figure 1). This trend was most marked with certain opioids: morphine, oxycodone, buprenorphine and fentanyl (28.5 prescriptions per 10,000 population to a peak of 353.0 prescriptions per 10,000 population in 2013 and 303.1 prescriptions per 10,000 population in 2015). Using sunburst plots, of the new users prescribed weak opioids as their first prescription at index date, 5.5% transitioned to moderate opioids, 4.1% to strong opioids over 2 years (Figure 2). Transition probability of staying on a strong opioid (if first prescription at 2 years remained high if prescribed first as a new user.

SAT0571 IDENTIFYING DETERMINANTS OF PRESENTEEISM IN WORKERS WITH INFLAMMATORY ARTHRITIS
André Luquini1,2, Diane Lacaille1,2, Eric C. Sayre2, Rebecca Schnurr-Howsam2.
1The University of British Columbia, Vancouver, Canada; 2Arthritis Research Canada, Richmond, Canada

Background: Work disability (WD) and presenteeism (decreased at-work productivity) are often caused by arthritis, leading to major impact on individuals’ quality of life and cost to society.

Objectives: Our study objective was to identify the determinants of presenteeism in workers with inflammatory arthritis.

Methods: Baseline data from the randomized controlled trial of an employment intervention, the Making-it-WORK program, were used. Participants were recruited from British Columbia, Alberta and Ontario. Inclusion criteria: diagnosis of inflammatory arthritis, currently employed, age 18-59, and having concerns about arthritis affecting ability to work. The primary outcome, presenteeism, was assessed using the ‘In’ impaired while at work, importance of working. Variables correlated with WPAI-SHP were selected for inclusion. The independent variables included: 1) sociodemographic variables: age, gender, ethnicity, marital status, education, children under age 19; 2) disease variables: IA diagnosis, disease duration, number of limiting comorbidities, global assessment of disease activity (VAS), joint pain (VAS), Disease activity [Rheumatoid Arthritis Disease Activity Index (RADAI)], physical function (HAQ II), Fatigue [VAS, Global Fatigue Index from the Multidimensional Assessment of Fatigue (MAF)], Sleep quality [Insomnia Severity Index (ISI)], Depression [Patient Health Questionnaire – PHQ-9]; 3) work variables: physical demand, job autonomy, difficulty commuting to/from work, job spillover, job strain, psycho-social work characteristics [Job Content Questionnaire (JCC) decision latitude, physical and psychological job demands, social support at work], self-employment, family support of decision to work, economic situation of working. Variables correlated with WPAI-SHP at p ≤ 0.20 were selected for inclusion in the multivariable linear regression analysis, using stepwise selection with alpha of 0.15.

Results: The sample included 585 participants [49% with RA, 17% PsA, 14% SLE, 20% AS] with median (IQR) arthritis duration of 7(3-15) years, mean (SD) age 45.6 (10) years; 43% were 50 years or older; 78% were females; 76% had completed post secondary education; 17% were self-employed. Multivariable linear regression analyses revealed that age < 30 (vs.age 30-49, p=0.067; vs. age ≥ 50, p=0.266), having more fatigue (GFI-MAP) (p<0.001), job strain (p=0.011), job spill over (p=0.002), disease activity (RADAI) (p=0.001), poor family support for working (p=0.049), poor physical function (HAQ II) (p=0.077) and commuting difficulty (p=0.081) were associated with greater impairment in work productivity.

Conclusion: This study identified important sociodemographic, disease and work-related factors associated with reduced productivity at work in people with inflammatory arthritis. These results provide useful information to health professionals counselling patients on dealing with employment issues.

SAT0572 ANTI NUCLEAR ANTIBODIES IN PRIMARY CARE SETTING: IS IT WORTH IT?
Mariana Luís, Luisa Bites, Ana Rita Prata, Tânia Santiago, José Antonio P. Da Silva, Catia Duarte. Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal

Background: Antinuclear antibodies (ANA) are the most frequently used screening tests for connective tissue diseases. However, their diagnostic value depends on the pre-test probability of such conditions.

Objectives: To evaluate the usefulness, clinical correlates and associated direct costs of ANA testing in the primary care setting in an Early Arthritis Clinic (EAC) referral cohort.

Methods: A retrospective study of consecutive patients referred to the EAC between 2011 and 2018 was conducted. Referral is based on the fulfillment of specific criteria: presence of arthritis or clinically suspected arthralgia beginning in the previous 12 months, plus suggestive laboratoro abnormalities (rheumatoid factor, C-reactive protein or erythrocyte sedimentation rate). Many general practitioners also performed ANA testing (ANA-GP) and all patients underwent ANA testing, per protocol, in EAC (ANA-EAC). All patients having these 2 separated ANA results were included in the analysis. ANA-GP titers and pattern were assessed by indirect immunofluorescence (Hep2, positive–fitter≥1:160). Direct associated costs of ANA-GP were calculated, based on the mean charge of 3 different local labs. Positive (PVV) and negative predictive values (NPV) of ANA-GP for the diagnosis of inflammatory rheumatic disease, ANA-related rheumatic disease (ARD) and for the presence of ANA-EAC were estimated.

Results: 207 patients were referred to the EAC Clinic during this period (84.3% female, aged 53.9 ± 18.2 years-old). Fifty eight percent of these patients (n=120) had their ANA previously determined in primary care setting. Of the 18% (n=11) patients testing positive in both settings, 2 had no rheumatic disease, 2 had an ARD and 4 had another type of inflammatory rheumatic disease.

Disclosure of Interests: André Luquini: None declared, Diane Lacaille Grant/research support from: Bristol-Myers Squibb and Eli Lilly Canada, Eric C. Sayre: None declared, Rebecca Schnurr-Howsam: None declared

Scientific Abstracts
ANA-GP PPV and NPV were: i) 18.2% and 92.7% (LR 2.44) for ARD.; ii) 63.6% and 27.5% (LR 0.74) for inflammatory rheumatic disease and 72.7% and 23.9% (LR 0.124) for a positive ANA-EAC result. The referral criteria with the highest PPV for the diagnosis of inflammatory rheumatic disease were: positive rheumatoid factor (76.2%), high erythrocyte sedimentation rate (71.6%) and clinical signs of arthritis (70.8%). The direct cost associated with duplicate ANA testing was estimated in 2.160 €.

Conclusion: ANA testing in the primary care setting had a poor predictive value in this cohort, which can be explained by its application in patients with low pretest probabilities for ARD. Although the direct costs may not seem impressive, we speculate the real cost to be much higher since ANA test rarely is requested solo but, instead, along with a lot of other autoantibodies in a “trawl fishing” attempt to diagnosis. ANA evaluations are not recommended for the study of putative arthritis cases in primary care and local campaigns should be promoted in order to improve referral quality avoiding unnecessary, costly and lengthy lab tests as ANA.

SAT0573 HEALTHCARE RESOURCE UTILISATION AMONG PATIENTS DIAGNOSED WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE IN ENGLAND

Alicia Gaye1, Nils Schoof2, Margarida Alves3, Deborah Clarke1, Christina Raabe3, Prithwiraj Das4, Toby Maher5, Boehringer Ingelheim Ltd, Bracknell, United Kingdom; 2Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany; 3National Heart and Lung Institute, Imperial College and Interstitial Lung Disease Unit, Royal Brompton Hospital, London, United Kingdom

Background: Systemic sclerosis-associated interstitial lung disease (SSc-ILD) is a substantial burden on patients and on healthcare services. Despite this, assessments of healthcare resource utilisation and costs incurred during the management of SSc-ILD are limited.

Objectives: To assess healthcare resource utilisation and costs among patients with SSc-ILD compared with SSc overall and patients with SSc and other organ involvement (SSc-OI).

Methods: This was a population-based cohort study. Routinely collected healthcare data were extracted from medical records (dated 1 January 2005 to 31 March 2016) in the Clinical Practice Research Datalink (CPRD) and the Hospital Episode Statistics (HES) databases. Patients with SSc, with or without ILD and/or OOI, were identified from primary and secondary care records in combination with modified European League Against Rheumatism (EULAR) classification criteria. Patients were included in the OI cohort if their SSc affected cardiac, gastrointestinal, renal or oral function. Eligible patients were aged at least 18 years at first diagnosis, were diagnosed within the study period, and had at least 12 months of available data in CPRD/HES before and after diagnosis. All-cause healthcare resource utilisation (inpatient stays; A&E attendances; outpatient visits, A&E attendances, and general practitioner visits per patient per year). Each patient with SSc-ILD had, on average, 10 outpatient visits, A&E attendances, and general practitioner visits per year. Inpatient stays alone accounted for >60% of the total healthcare costs among SSc patients with ILD (median cost >€3,600 per patient per year). Each patient with SSc-ILD had, on average, 10 outpatient visits per year, at a total yearly median cost of >€840. In comparison, patients with SSc-OI averaged 7 outpatient visits at a total yearly median cost of €915. Characteristics significantly associated with higher yearly healthcare costs among SSc patients were: older age at diagnosis, diagnosis of anaemia, and number of comorbid diseases.

Conclusion: The annual healthcare cost for a patient with SSc-ILD is substantial (€2,986–13,905), with inpatient stays the major cause of costs, and is much higher than for patients with SSc-OI (without ILD). Healthcare costs are also higher among older SSc patients and those with more comorbidities. These results highlight the economic burden of SSc-ILD in a real-world setting, which will be useful when evaluating the cost-effectiveness of new treatment options for SSc-ILD. There is an unmet need for effective therapies for SSc-ILD.

SAT0574 A SYSTEMATIC LITERATURE REVIEW OF HEALTHCARE BURDEN IN PATIENTS WITH BEHÇET’S DISEASE

Oriol Sola-Mongès1, Shields Nahta2, Sarah Ronnebaum2, Dipen Patel3, Tara Nazareth4, Angela Paduk4, 5Health Institute for Technology Transfer (HITT), Barcelona, Spain; 2Celgene Corporation, Summit, United States of America; 3Pharmint International, LP, Bethesda, United States of America; 4Pharmint International, Bethesda, United States of America; 5Celgene Corporation, Summit, United States of America; 6San Carlo Hospital of Potenza, Rheumatology Department of Lucania, Potenza, Italy; 7Madonna delle Grazie Hospital of Matera, Potenza, Italy

Background: Behcet’s disease (BD) is a chronic, multisystem, inflammatory disorder primarily characterized by recurrent oral ulcers (OU) and other key features, such as genital ulcers, skin lesions and articular and ocular inflammation. The prevalence of BD is typically reported as higher in Silk Road countries (e.g., Turkey, Jordan); however, it has increased in developed countries (e.g. Europe), likely due to migration. Given the diagnoses across geographic regions, we sought to understand the prevalence of BD manifestations, related symptoms and the impact on comorbidities, treatments, and quality of life (QoL).

Objectives: To understand the clinical and humanistic burden among patients (pts) with BD based on a systematic literature review (SLR).

Methods: An SLR was performed to identify real-world BD studies reported between 2005 and 2016. BD studies were selected if they were published in English, published from January 2005 to 2016, and were included in the Embase/MEDLINE databases. Studies were excluded if they did not report on the prevalence of BD, or if they were not published in English, or if they were not published in English. The following key terms were used: BD, Behcet's disease, BD prevalence, BD manifestations, BD symptoms, BD QoL. The inclusion criteria were: publications published from January 2005 to 2016, and were included in the Embase/MEDLINE databases. Studies were excluded if they did not report on the prevalence of BD, or if they were not published in English, or if they were not published in English. The following key terms were used: BD, Behcet's disease, BD prevalence, BD manifestations, BD symptoms, BD QoL.

Results: A total of 2146 citations were identified, of which 66 citations (55 manuscripts; 11 abstracts) describing >21,000 pts with BD were included. For categorical outcomes, the number (#) of studies, median, interquartile range (IQR) and/or min-max range of prevalence are reported; for continuous outcomes, the # of comparisons with significance (P<0.05) are reported.

Results: A total of 2656 citations were identified, of which 66 citations (55 manuscripts; 11 abstracts) describing >21,000 pts with BD were reviewed. The most common manifestation was OU, with 19 of 27 studies reporting 100% prevalence (IQR: 84%-100%). One study reported an average of 12.7 OU per patient per year; in another study, OU were the only manifestation currently or previously experienced by all pts. Frequently reported symptoms included fatigue/sleep-related issues (7; 70%), pain (4; 59%), and headache (5; 58%); skin lesions were also common (19; 58%). Several comorbidities, e.g. emotional issues (4; 24%-44%), fibromyalgia (4; 8%-24%), hearing loss (3; 10%-59%), etc. were significantly
RACIAL DIFFERENCES IN PRESCRIPTION PATTERNS OF DISEASE MODIFYING ANTI-RHEUMATIC DRUGS, NARCOTICS AND GLUCOCORTICOIDS AMONG MIDDLE-AGED PATIENTS WITH DISABILITY AND RHEUMATOID ARTHRITIS

Iris Navarro-Millan1,2, Mangala Rajan3, Gayanne Liu4, Lisa Kern1, Laura Pinheiro1, Monika Safford1, Jeffrey Curtis2, Well Connell Medicine, New York, United States of America, 2Hospital for Special Surgery, New York, United States of America; 3University of Alabama at Birmingham, Birmingham, United States of America.

Background: Many patients with rheumatoid arthritis (RA) become disabled. While racial/ethnic differences in RA treatment have been described in RA patients without disability, less is known about racial/ethnic differences in RA treatment among middle-aged individuals with RA receiving disability benefits.

Objectives: To determine if racial/ethnic differences exist in the prescription patterns of conventional synthetic (CS) and biologic (B) disease modifying anti-rheumatic drug medications (DMARD), glucocorticoids, and opioids.

Methods: We conducted cross-sectional analyses in the calendar year 2014 using Medicare and Medicaid claims data of individuals receiving Social Security Disability Insurance (SSDI). To be included, patients had to be continuously enrolled over one year, aged <65 years, eligible for both Medicare and Medicaid, and have RA, defined as: 1) two RA diagnoses (ICD9-714.xx) by a rheumatologist between 7 to 365 days apart; or 2) one RA diagnosis by a rheumatologist and at least 1 prescription for a DMARD. We examined the proportion of patients with CS-DMARD, B-DMARD, glucocorticoid (>7.5 mg prednisone daily for >30 days), or opioid (either a prescription for opioids with 3 refills or at least one 90 day supply) prescriptions in each year by race/ethnicity. Generalized estimating equation (GEE) models were used to report adjusted differences in prescription rates for Blacks, Hispanics, and Other using Whites as the reference group, adjusting for age, gender, and medical comorbidities.

Results: The were 9,265 patients in 2014 out of which 60% were White, 21% were Black, 15% were Hispanic, and 5% were Other race. The proportion of female patients by race/ethnicity was >75% for each group. Hispanics had a 6.6% point higher rate of B-DMARD prescriptions and a 10.7% point lower rate of opioid prescriptions compared to Whites. Blacks had a 3.4% point higher rate of glucocorticoid prescriptions, and a 3.3% point lower rate of opioids prescriptions compared to Whites.

Conclusion: We observed racial differences in arthritis-related treatment patterns, among disabled RA patients, with Blacks receiving less biologic treatment and Whites receiving more opioids. Hispanics received the highest prescription rates of biologics and the Other race received lowest prescription rates of opioids among the three racial/ethnic groups. Further studies are needed to examine the reasons for such differences.

SAT0576  ETANERCEPT BIOSIMILAR SWITCH: CAN IT BE SUCCESSFUL WITHOUT CLINIC REVIEW?

Muhammad Khurram Nisar, Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom

Background: Since the introduction of anti-TNF biosimilars in routine clinical practice, there has been a drive to implement the switch program for all biosimilars at the point of availability. Etanercept biosimilar (SB4) was granted marketing authorisation by the EMA in January 2016. Our Trust was one of the leading centres to switch all patients within one year of the drug’s availability. The aim of the non-medical switch was to obtain significant savings for the NHS whilst achieving similar clinical outcomes.

Objectives: We report patient experience after a year of completing the switch program.

Methods: A list of all patients prescribed etanercept was extracted through our database. The original strategy included a ‘switch’ letter sent to all patients including SB4 information sheet. Patients were given the opportunity to contact nurse helpline for information or if disease control worsened/adverse effects developed. We reviewed all relevant records and collected data on any adverse events and disease outcome on either side of the switch.

Results: 84 patients were prescribed reference etanercept. 41 (49%) had RA, 17 (20%) had PsA, 18 (21%) had AS and remaining eight had JIA. 84 patients were prescribed reference etanercept. 41 (49%) had RA, 17 (20%) had PsA, 18 (21%) had AS and remaining eight had JIA.

Conclusion: Overall patient experience following etanercept biosimilar switch has been positive. 90% continue with SB4 originator a year later with no adverse outcomes. All were happy to switch after receiving a
letter and having the opportunity to contact if necessary. This made the process quite smooth, easy to administer and avoided costs associated with face-to-face review. Substantial annual cost savings of nearly £100,000 were achieved once the switch process completed. Only six patients (7%) encountered adverse effects, two of whom had uncontrolled disease despite switching back to the originator. We support the routine switching from originator to biosimilar etanercept in view of good patient experience and disease outcomes. This can be achieved with minimal contact in a cost-efficient manner.

Disclosure of Interests: : Muhammad Khurram Nisar Grant/research support from Roche, Chugai, MSD, Abbvie, Pfizer, BMS, Novartis, Celgene, Mallinckrodt, UCBB and Lilly. Consultant for: Muhammad Khurram Nisar undertakes clinical trials and received support (including attendance at conferences, speaker fees and honoraria) from Roche, Chugai, MSD, Abbvie, Pfizer, BMS, Novartis, Celgene, Mallinckrodt, UCB and Lilly. Disclosure of Interests: None declared

others are dedicated to primary immunodeficiencies and autoinflammatory diseases (respectively 15 registries, 28%, and 12 registries, 23%). Fifteen registries (28%) enrolled patients with a single specific disorder; in particular, three registries are devoted to systemic lupus erythematosus, two registries to Kawasaki disease or Behcet disease, and single registry to juvenile dermatomyositis, juvenile systemic sclerosis, juvenile idiopathic arthritis (JIA)-related uveitis, systemic JIA, Blau syndrome, sarcoidosis, Guillain-Barre syndrome, and myasthenia gravis. More than 55000 patients with RID are enrolled. The majority of registries (36; 68%) enrol only patients from national territories. Among the international, six collect data on autoimmune disorders (Pharmachild, BrainWorks, EuroMyoBis, EULAR web library, UKIVAS registry and JIR cohort), five on primary immunodeficiencies (ESID, EBMT, SCETIDE, PCID and HLH registry), and three are devoted to autoinflammatory diseases (Eurofever, Infevers, and ImmuN.AI), despite also ESID registry and JIR cohort collect data on autoinflammatory diseases. Data usually collected in these registries are demography, diagnosis, clinical manifestations, laboratory tests and treatment, while genetic and imaging data are less frequently reported (respectively in 38% and 9% of registries). A treatment safety profile is reported in 29 registries (55%). Collectively, fifteen biobanks are counted.

Conclusion: The survey highlighted the pivotal role of national and international registries in Europe to collect and organize clinical data on immune diseases, allowing the rapidly growing knowledge on these rare disorders, creating research networks and providing significant numbers of data to support new discoveries in the field. RITA network could improve the coordination of these numerous entities, supporting initiatives of collaboration. As a first attempt, the present survey revealed that the collection of key parameters about patient safety, as well as outcome data and quality of life measures should be improved among the registries of RITA network.

SAT0579

AN ELECTRONIC MDHAQ (MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE) GIVES SIMILAR RESULTS TO A PAPER VERSION

Mariam Riad, Elena Obreja, Isabel Castrejon, Theodore Picouc, Rush University Medical Center, Chicago, United States of America

Background: A self-report multi-dimensional health assessment questionnaire (MDHAQ) is used in many routine care rheumatology settings as a pragmatic tool to recognize efficacy and adverse events. The MDHAQ is available in all rheumatic diseases in which it has been studied. An electronic version of the MDHAQ (eMDHAQ) could offer several advantages, including completion at home rather than in the waiting area and completion from any site between visits to report possible change in status and/or adverse events of a medication. Furthermore, the 4-page-“new patient” eMDHAQ can allow a patient to store a full medical history at a password-protected, secure website. Reports of the patient history can be available for an electronic medical record (EMR) without dictation or typing by the doctor, although interaction with the EMR vendor is required, which often has proven difficult. Implementation of eMDHAQ software requires documentation that eMDHAQ responses are similar to responses on a paper MDHAQ.

Objectives: To compare scores on an eMDHAQ vs paper version of MDHAQ.

Methods: All patients with all diagnoses complete a paper MDHAQ at all visits in the waiting area and part of routine clinical care in one setting. Consecutive patients completed MDHAQ in paper and in an iPad at the same visit. The MDHAQ includes 0-10 scores for physical function, pain and patient global visual analog scales (VAS), compiled into 0–30 Rapid3, as well as a 0–48 self-report painful joint count, and 0–20 symptom checklist. For this study, at the conclusion of the visit, the rheumatologist asked a patient if she/he would volunteer to complete an eMDHAQ on an iPad indicating no problem if a patient declined for any reason. Patients who agreed to participate completed the an eMDHAQ, with identical content to the paper MDHAQ. The patient also completed a 3-query questionnaire, with 2 VAS concerning the value of the MDHAQ to the patient or the doctor (0= no value, 10= great value), and a query of her/his preference for the eMDHAQ vs paper MDHAQ or no preference. Test-retest reliability was examined by intraclass correlation coefficients (ICC).

Results: 65 patients completed the study. The ICC for physical function, patient global VAS, and RAPID3 was >0.9 indicating excellent reliability between the electronic and paper versions, while the ICC for pain, self-report painful joint count, and symptom checklist was >0.75, indicating good reliability. Differences between the 2 versions were within variation on the paper questionnaire. The mean rating for the value of MDHAQ was 8.8±10 to the patient, 8.8±10 to the doctor. Among the 65 patients, 43 (66%) indicated a preference for the eMDHAQ, 7 (11%) for the paper MDHAQ, and 15 (23%) indicated no preference.

Conclusion: An eMDHAQ appears to have similar performance compared to a paper MDHAQ version. A high percentage of patients prefer the digital version to paper, although about 20% of patients are likely to require a paper MDHAQ. An eMDHAQ offers remote completion at home, before and/or between visits, to report issues concerning efficacy and adverse events. Expanded eMDHAQ software can allow a doctor to develop flow-sheets and a database for all patients, a full patient medical history, and interfacing with any electronic medical record (EMR), although that requires interaction with the EMR vendor, which is often difficult. The eMDHAQ appears useful independent of the EMR.

SAT0580

HEALTHCARE BURDEN AND COST OF ILLNESS OF GIANT CELL ARTERITIS IN THE ITALIAN REGION OF FRIULI VENEZIA GIULIA: A 17-YEAR INTEGRATIVE ANALYSIS OF DIGITAL ADMINISTRATIVE DATABASES

Luca Quattrocchi1, Milena Bond1, Elena Cavallaro1, Annarita Tolló2, Bruno Bembi2, Christian Dejaco3, Salvatore De Vita1, Francesca Valent1. 1Rheumatology Clinic, Udine, Italy; 2Institute of Epidemiology, Udine, Italy; 3Regional Centre for Rare Diseases, Udine, Italy; 4Rheumatology Unit, Brunico, Italy

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in persons aged 50 and above (1). Data on incidence and prevalence of GCA are welcomed. Further information is also needed on the healthcare burden and resource consumption. The use of multiple digital administrative databases with the integration of clinical data from a formalized network of specialists is needed.

Objectives: To estimate incidence, prevalence and costs of GCA by an integrative analysis of multiple administrative databases of the healthcare system of the Italian Region of Friuli Venezia Giulia (about 1.2 millions of inhabitants), cooperating with the existing local Rheumatology Network.

Methods: A 17-year retrospective study was conducted through the following administrative health regional digital databases of the Friuli Venezia Giulia Regional Health Services, the Friuli Venezia Giulia Regional Health Services, and the Friuli Venezia Giulia Regional Health Services.
Giulia Region: the Database of Regional Potential health Care Beneficia-
ries, the Hospital Discharge Database, the Ambulatory Care Database, the
Pharmaceutical Prescription Database, the Emergency Department
Database, the Mortality Database, the Anatomical Pathology Database, the
Database of Exemptions from Medical Charges, and the Regional
Rare Disease Registry. All the databases were integrated at the individual
patient level using a univocal stochastic key.

Results: From 2001 to 2017, 208 patients with GCA were registered.
The crude identification rate of patients identified with GCA until 2017 in
the population >45 years of age was 3.8/100,000 person-years (95%CI:
2.5-5.5). The maximum incidence rate was observed in the age group
70-74 years. The prevalence of GCA in the population >45 years of age
as of December 31st, 2017 was 27.2/100,000 (95%CI 23.5-31.4). The
mean medical observation was 4.5±3.6 years per patient, totaling
940.8 years of observation.

192 patients had at least one ambulatory specialist visit, resulting in a
total of 3162 specialist visits (338 per 100 patient-years). The most fre-
quent medical specialties involved were Rheumatology (N=610, 19.2%),
Internal Medicine (N=564, 17.7%), Ophthalmology (N=292, 9.2%), and
Orthopedics (N=191, 6%). 108 (52%) patients had at least one hospitalization, resulting in 287 hos-
apitalizations (30 per 100 patient-years). Circulatory Cardiovascular diseases
were the most common discharge diagnoses, followed by musculoskeletal
conditions.

199 subjects were prescribed medications for a total of 9588 prescriptions
(91 per 100 patient-years). Notably, an immunosuppressive drug, usu-
ally methotrexate, was prescribed in more than half of the patients. Car-
diovascular medications were prescribed to 154 (74%) patients; bisphosphonates or other anti-osteoartropenic drugs to 123 patients (59%).
The average annual direct cost of GCA was 2374 Euros per patient-year
(81 for outpatient visits, 1661 for hospitalizations, 312 for prescribed med-
ications and 340 for medications directly dispensed by the hospital phar-
cacies). The overall estimated direct healthcare cost for 940.8 patient-
years was 2,234,070 Euros.

Conclusions: Novel epidemiologic data in GCA are reported after a very
long-term observation, and by integrating data from multiple databases
with clinical data from a Regional network of specialists (Rheumatology
being the major contributor to disease clinical follow-up).

Cost of illness is high in GCA. Both the diseases itself and cardiovascu-
lar manifestations, and, possibly, the complications of glucocorticoids, may
contribute to the healthcare burden of GCA. Despite a high use of
immunosuppressors in our region, new drugs (2) and novel treatment strategies are required.

5University of Alabama at Birmingham, Birmingham, United States of America; 6Universidad Peruana Cayetano Heredia, Lima, Peru

Background: Because most patients with SLE are in their productive-age
years, the ability to maintain a gainful employment is fundamental for both
the patient and society at large. It is thus quite important to
determine the work and non-work factors that are associated with work
productivity impairment in these patients.

Objectives: To determine the factors associated with absenteeism (per-
centage of the time missed from scheduled work-time over the preceding
7 days, due to SLE), presenteeism (percentage of time from scheduled
work-time where productivity was impaired while patient was at work,
over the preceding 7 days, due to SLE) and overall work impairment
(combination of absenteeism and presenteeism) in patients with SLE.

Methods: The study included a cohort of 133 consecutive (1997 American College of Rheuma-
tology (ACR) criteria) working patients with SLE were assessed between
October 2017 and December 2018, using a standardized data collection
form. Sociodemographic, disease and work-related variables were col-
lected. Disease activity was assessed with the Systemic Lupus Erythe-
matosus Disease Activity Index (SLEDAI); disease damage with the
Systemic Lupus International Collaborating Clinics/ACR Damage Index
(SDII); health-related quality of life was assessed with the LupusQol and
fatigue with the FACIT-Fatigue (Functional Assessment of Chronic Illness
Therapy-Fatigue). Work Productivity and Activity Impairment (WPAI) was
assessed with the respective questionnaire; absenteeism and presentee-
ism due to overall health and symptoms during the past 7 days were
scored. Linear regression models were performed to determine the factors
associated with absenteeism, presenteeism, and overall work impairment.
Potential factors included were age at diagnosis, gender, socioeconomic
status, educational level, SLEDAI, SDII, FACIT- Fatigue and the compo-
nents of the LupusQol.

Results: The mean age at diagnosis was 32.2 years (11.8); 121 (91.7%)
were female. Nearly all patients were Mestizo. Mean years of education
was 14.1 (2.6). The mean disease duration was 11.9 (7.5) years. Mean
SLEDAI was 2.9 (4.0), and mean SDII was 1 (1.4). The mean percent of
time for absenteeism was 5.0 (12.9), it was 28.5 (26.4) for presenteeism,
and it was 31.3 (27.2) for overall work impairment. In the multiple regres-
sion analysis, factors associated with absenteeism were disease duration
(B=-0.34; p<0.001), daytime sleepiness (B=0.14; p=0.007) and pain (B=0.14;
p<0.001); night-time sleepiness (B=0.14; p=0.006), presenteeism were physical health (B=-0.43;
p=0.002) and FACIT (B=0.87; p<0.001) and with overall work impairment were pain (B=0.40;
p=0.001) and FACIT (B=0.74; p<0.001) and presenteeism were physical health associated with a higher percentage of absenteeism, presenteeism and overall work
impairment in SLE patients. Addressing the factors related to HRQol and Fatigue may have significant impact on work performance among SLE patients.

SA2575 THE LATIN AMERICAN RHEUMATOLOGY SURVEY: LARS STUDY

Genesio Maldonado1, Enrique Soriano2, Letty Moreno3, Carlos Pizar1,3,1Espitali
Santo University, Guayaquil, Ecuador; 2Hospital Italiano de Buenos Aires,
Rheumatology, Buenos Aires, Argentina; 3Centro de Reumatología y
Rehabilitación, Rheumatology, Guayaquil, Ecuador

Background: Currently, Latin America does not have detailed information
of rheumatologists in the region based on: education, working conditions,
productivity, distribution of time between work activities and job
satisfaction.

Objectives: The purpose of this survey was to provide more information
on the rheumatology community in Latin America

Methods: A digital survey was created using the Google Forms platform,
it was approved and endorsed by the scientific committee of PANLAR
and later sent to the different rheumatology associations of the region.
The data was analyzed in the statistical programSPSS v.23.

Results: 456 surveys of rheumatologists from 23 countries were received.
The majority were females (64%). The mean age was 47.18 ± 11.79 [20-78] years, with a majority of mixed race 58%, 63% are married, 23% are single, 8% are divorced, 5% in free union and 2% are widowed. The mean number of children was 2 [0-7]. Birthplaces included Argentina (27%), Brazil (16%). The selection of the professional practice after obtain-
ing the title of specialists was: public hospital (35%), private (25%), pri-
ivate/teaching in a university hospital (12%), public/teaching in a university
hospital (14%), and industry (1%). The main place of work was in public/
government hospitals by 30% followed by private practice 31%, private
hospital 23%, university hospital 15% and nonprofit organization of Rheu-
matics. The average of weekly working hours was 39.12 ± 27.53, 89% of the sample
practices adult rheumatology, 17% pediatric rheumatology, 2% immunology

and 3% another specialty. 30% had an early arthritis care center at their workplace, 71% had an infusion unit, 17% had ultrasound, 23% had a densitometer, 17% had a resonator and 9% had X-rays, however, most work in collaboration. 30% have training in ultrasound and 9% are in training period. 75% have training in reading densitometry and 2% in training period. 54% have training in resonance reading and 11% in training period. The average satisfaction with practice as a rheumatologist was 5/7, career options/professional growth 4/7, geographic location 5/7, income 4/7, security 4/7, colleagues and co-workers 5/7. 33% had an annual compensation of <19,000 US dollars. Only 58% have malpractice insurance and 87% have medical insurance. 40% present at least one clinical comorbidity.

Conclusion: The majority of rheumatologists in the region who responded were female and felt satisfied with their clinical practice. This survey shows a low level of income for the region, however, more data should be obtained. This is the first study of its kind in Latin America, being an initiative for similar projects.

DEVeLOPMENT AND TESTING OF A SMARTPHONE APPLICATION TO SELF-MONITOR DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

Bart Seppen1, Merel J. L’am1, Sharon Rico2, Marieke Ter Wee2, Frank Timmstra1, Leo D. Roorda3, Fabio Catarinella4, Dirkjan van Schaardenburg3, Michael Nummohamed3, Maarten Boers3, W.H. Bos1, 1ARC / Reade, Rheumatology, Amsterdam, Netherlands; 2VUMC / Amsterdam UMC, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands; 3ARC / Reade, Rehabilitation, Amsterdam, Netherlands; 4Brightline B.V., Hoofddorp, Netherlands

Background: Several mobile applications (apps) exist to monitor symptoms of rheumatoid arthritis (RA), but high-quality apps are lacking.1 We developed an app with patients, following the Medical Research Council (MRC) sub-model.2 It focused on self-monitoring and self-initiated care.

Objectives: To evaluate the users' satisfaction, usability and engagement of the app, as a first and preparatory step toward the ultimate goal of telemonitoring and self-initiated care.

Methods: In a first, one month pilot study 42 RA patients used the app. User's satisfaction was measured using an 11-point Likert scale. Usability was measured using the three concepts of the Technology Acceptance Model (TAM).3 According to TAM, perceived usefulness (PU), perceived ease of use (PEOU), (behavioral) intention to use (ITU) predict how and when a product will be used. The PU and PEOU were measured using the system usability scale (0-100). A score of 68, or higher, indicates sufficient system usability.4 The ITU was measured on a 11-point Likert scale. Engagement was measured by the percentage of patients completing all weekly questionnaires. General feedback was collected and implemented.

In a second, one month pilot study, the improved app was evaluated in 24 RA patients using 5 themes derived from the Mobile App Rating Score5: 'engagement', 'functionality', 'aesthetics', 'information' and 'subjective quality.' Participants rated the questions on a 5 - point Likert scale. All responses were categorized into three categories: negative (1-2), neutral (3) and positive (4-5). Afterwards, nine participants (three users, three dropout users, and three non-users) agreed to participate in a semi-structured interview to get feedback on the App.

Results: In the first study, the ReumaMeter scored an overall median score of 8.0 (interquartile range (IQR) 7.0-9.0), a mean system usability score of 76 (SD 14.8) and participants intended to keep using the ReumaMeter in the future (median 7.0, IQR 5.0-9.0). Engagement decreased to 61% in week 4. During the second study, the number of positive responses for each category was at least twice as high as the number of negative responses (Figure 1). Feedback that emerged during the interviews matched these responses. In addition, several participants stated that app usage declined due to low disease activity.

Conclusion: The participants' overall feedback was positive in terms of users' satisfaction and usability. Engagement dropped, which may be due to lack of internal triggers to measure disease activity when patients are in remission. To assess the overall impact of the app on RA patient care, a randomized controlled trial is planned.

PATIENTS WITH LUPUS

jasvinder singh*, John Cleveland, University of Alabama at Birmingham, Birmingham, United States of America

Background: Hip osteonecrosis and hip osteoarthritis are common causes of severe hip disease in lupus (1), both treated successfully with a total hip arthroplasty (THA). A recent systematic review of arthroplasty outcomes reported that the risk of overall complications post-THA was higher than in patients with lupus compared to those without lupus (2). However, no analyses were provided for specific outcomes such as infection, revision or associated health care utilization.

Objectives: To assess the risk of specific post-THA outcomes, i.e., infection, transfusion, revision and mortality and associated health care utilization, associated with lupus.

Methods: We used the 1998-2014 U.S. National Inpatient Sample data. Multivariable-adjusted separate Cox proportional hazard regression models assessed the association of lupus with post-operative complications (infection, transfusion, THA revision and mortality) and health care utilization outcomes (total hospital charges, discharge to inpatient facility, length of hospital stay) post-THA, adjusting for demographics, underlying diagnosis, comorbidity, insurance payer, and hospital characteristics, using hazard ratios (HR) and 95% confidence intervals (CI).

Results: Among 4,116,485 primary THA hospitalizations, 22,557 (0.5%) were in lupus patients. Patients with lupus were younger, more likely to be female, African-American or Hispanic and, have higher comorbidity, Medicaid insurance payer, lower income, or living in the South. In multi-variable-adjusted analyses, lupus was associated with a significantly higher risk of infection, transfusion, hospital charges above the median

POORER OUTCOMES AND HIGHER HEALTHCARE UTILIZATION AFTER TOTAL HIP ARTHROPLASTY IN PATIENTS WITH LUPUS

Scientific Abstracts
Knee osteoarthritis (OA) is a painful, disabling condition with increasing prevalence. The concept of spondyloarthritis (SpA) comprises several chronic inflammatory joint diseases. SpA patients can be distinguished as having SpA with predominantly peripheral SpA (pSpA) or with predominantly axial SpA (axSpA) according to their clinical presentation. AxSpA primarily affects the axial skeleton and the sacroiliac joints. Within axSpA patients, a subdivision based on the radiographic changes of the sacroiliac joints can be made: radiographic axSpA, which corresponds to ankylosing spondylitis (AS), and non-radiographic axSpA (nr-axSpA). SpA occurs typically in young and professionally active patients. Since 2000, important improvements have been made in the management of SpA, both on a pharmacological (introduction of biological disease-modifying antirheumatic drugs (bDMARD)) and a non-pharmacological (holistic approach) level. As a result of early diagnosis followed by adequate treatment, the majority of patients achieve a state of clinical remission allowing them to function without significant problems. However, many of these persons still experience problems such as exclusion clauses, additional premiums and even contract refusals when contracting private insurances because mostly risk contracts refusals when contracting private insurances because mostly risk contract refusals when contracting private insurances because mostly risk

**SAT0586 THE INFLUENCE OF THE NEW PHARMACOLOGICAL AND NON-PHARMACOLOGICAL TREATMENTS IN AXIAL SPONDYLOARTHRITIS ON WORK PARTICIPATION: A SYSTEMATIC REVIEW**

**Background:** The concept of spondyloarthritis (SpA) comprises several chronic inflammatory joint diseases. SpA patients can be distinguished as having SpA with predominantly peripheral SpA (pSpA) or with predominantly axial SpA (axSpA) according to their clinical presentation. AxSpA primarily affects the axial skeleton and the sacroiliac joints. Within axSpA patients, a subdivision based on the radiographic changes of the sacroiliac joints can be made: radiographic axSpA, which corresponds to ankylosing spondylitis (AS), and non-radiographic axSpA (nr-axSpA). SpA occurs typically in young and professionally active patients. Since 2000, important improvements have been made in the management of SpA, both on a pharmacological (introduction of biological disease-modifying antirheumatic drugs (bDMARD)) and a non-pharmacological (holistic approach) level. As a result of early diagnosis followed by adequate treatment, the majority of patients achieve a state of clinical remission allowing them to function without significant problems. However, many of these persons still experience problems such as exclusion clauses, additional premiums and even contract refusals when contracting private insurances because mostly risk assessments are solely based on historical data.

**Objectives:** The aim of this systematic literature review was to investigate whether the work participation in patients with axSpA has improved since the introduction of the bDMARD and the non-pharmacological treatment modalities. This would provide arguments for a more accurate and updated risk assessment of the expected personal and economic incapacity of axSpA patients by private insurance companies.

**Methods:** A systematic literature review from January 1997 until November 2017 was performed using Pubmed, Embase and Web of Science. Different search terms were used in each database: absenteeism, presenteeism, employment, sick leave, work disability and work participation. All studies assessing one of the search terms were analysed.

**Results:** In total, 33 studies out of 603 retrieved citations were included. Overall, the results were highly heterogeneous because of the different study designs and different use of definitions regarding work outcomes. Patients with AS were significantly confronted with restrictions on work participation compared to the general population before the availability of bDMARD. In addition, our literature review showed that, since the introduction of the bDMARD and other non-pharmacological treatments, there is no evident improvement in work disability in AS patients. In contrast, a significant improvement could be observed on absenteeism, presenteeism and work productivity. Only 6 studies included patients with nr-axSpA. In most of these studies a positive tendency towards work productivity was detected. In addition, contextual factors such as the type of job, support from employers and colleagues, adjustments in workplace, and so forth were also considered. Further research into treatment patterns and characteristics of knee OA patients treated by rheumatologists is warranted.
Epidemiology, risk factors for disease or disease progression

SAT0587 THE ART OF IMPUTING MISSING DATA OF DISEASE AND FUNCTION ACTIVITY IN RHEUMATOID ARTHRITIS REGISTRIES

Denis Mongin1, Kim Lauper1, Carl Turesson1,2,3, Merete L. Hetland4,\nFlorenzo Iannone5, Axel Finckh1, Delphine Courvoisier1,\nErik Kristianslund6, Tone K. Kvien7, Maria Jose Santos8, Karel Pavelka9,\nDreauzio Lannone10, Axel Finckh1, Delphine Courvoisier1,\nFlorenzo Iannone8, Axel Finckh1, Delphine Courvoisier1.

Background: Large observational studies become more common in rheumatoid arthritis (RA). Disease registers [1] allow to analyse the effectiveness and safety of RA treatments in real-world populations, but observational studies suffer from missing data. To minimise bias, it has been shown that imputing missing data is superior to the use of complete case analysis [2]. Although some imputation methods have been studied in clinical trials of rheumatic diseases [3] and in small registers [4], the various imputation techniques have never been systematically compared in large registers.

Objectives: To compare the effects of available imputation methods on the estimated values and on RA remission rate for missing disease activity measures in large registers.

Methods: We used 1000 patients with complete data for disease activity (Disease Activity Score (DAS28) and Clinical Disease Activity Index (CDAI)) at baseline (treatment initiation), 6, 12, and 24 months after initiation of abatacept or a tumor-necrosis factor inhibitor (TNFi) from an existing register collaboration (PANABA). Simulation procedure: Values were deleted randomly and imputed with three types of imputation methods: (1) methods imputing forward in time, such as Last Observation Carried Forward (LOCF) or Linear Forward Extrapolation (LFE); (2) methods considering data both forward and backward in time, such as Nearest Available Observation (NAO), Linear Extrapolation (LE) or Polynomial Extrapolation (PE); and (3) methods using computer-intensive multi-individual imputations, such as Linear Mixed Effects cubic regression (LME3) and Multiple Imputation by Chained Equation (MICE).

We conducted a simulation study by performing this procedure 1000 time and computing the mean difference between the true and the imputed values, and between the true remission rate (CDAI and DAS28) and the imputed ones.

Results: Results are summarised in Fig. 1. At baseline, all methods underestimated the true values by up to 20%. Despite this, LME3 and MICE were able to provide estimates of baseline remission rates with less than 15% of error. For follow-up data, missingness at 6, 12, or 24 months, NAO, LE and PE led to relative bias of the mean values ≤15% and almost unbiased remission rate. LOCF and LFE respectively over- and underestimated the mean imputed values up to 20%, leading respectively to a non-negligible under- and over-estimation of the remission rate. Although LME3 and MICE had low bias in estimating the mean values, they narrowed the distribution of the imputed values and thus strongly underestimated remission rate.

Conclusion: When imputing disease activity in rheumatoid arthritis register data, researchers should prefer Linear Mixed Effects cubic regression (LME3) for baseline and nearest available observation (NAO) for follow-up data.

SAT0588 COMPARATIVE EFFECTIVENESS RESEARCH IN OBSERVATIONAL SETTINGS: EVALUATING TWO NEW METHODS TO ANALYSE RESPONSE RATES

Kim Lauper, Denis Mongin, Cem Gabay, Axel Finckh, Delphine Courvoisier.
Geneva University Hospitals, Geneva, Switzerland

Background: Researchers typically report the proportion of patients reaching a defined clinical threshold (e.g. EULAR response, low disease activity (LDA) rates) after a set time. Comparing response rates (%rr) in observational settings is hampered by two major threats. 1. Confounding: Patient, disease, and treatment characteristics often differ for each drug. 2. Attrition bias: Assessing %rr after a set time excludes patients who discontinued their treatment, which may overestimate drug effectiveness. Currently, no proposed method accounts for both confounding and attrition.

Conclusion: Most of the patients included in the selected studies had longstanding AS with significant structural damage. The great heterogeneity between the studies in patient populations, study design and evaluation methods impeded the formation of a uniform conclusion. However, since the introduction of the new treatment modalities, a positive tendency in work productivity in AS and nr-axSpA patients could be observed. More observational, cross-sectional and prospective studies are needed - especially in nr-axSpA patients - to evaluate the effect of both pharmacological and non-pharmaceutical treatment on the work outcome in SpA patients.

Disclosure of Interests: None declared
Objectives: To propose two new methods (3 and 4) to adequately compare %rr in patients with different baseline characteristics, while accounting for attrition and compare them to established methods (1 and 2).

Methods: 1. Complete case (CC) for attrition and compare them to established methods (1 and 2).

1. LUNDEX: %rr is computed as the percentage of responders on total patients still on treatment at the given time point.

2. PSM LUNDEX: Propensity Score (PS) Matching LUNDEX

Step A: Select patients in both exposure groups using propensity score matching.

Step B: Use the LUNDEX to compute the %rr.

3. CARRAC: Confounder-Adjusted Response Rate with Attrition Correction by reason for drug discontinuation.

Step A: Compute estimates of drug survival for the main reasons of drug discontinuation (e.g., ineffectiveness, adverse events, remission, other reasons).

Step B: Estimate %rr using random effect IPD meta-analysis with estimates for each reason of drug discontinuation.

Step C: Combine %rr estimates using weights of step A.

The methods will be illustrated using CDAI LDA (%10) rates in data from a collaboration of registries.

Results: We used 3,448 patients treated by a biologic, either intravenously (IV: n=2,414) or subcutaneously (SC: n=1,034). Before matching, the population differed in terms of body mass index, function (Health Assessment Questionnaire, HAQ), concomitant treatments and erythrocyte sedimentation rate (ESR). Adjustment was done using these potential confounders. For PSM LUNDEX, PS matching was done on a 1:1 basis, yielding 561 patients in each group with similar characteristics. Estimated %rr differed by more than 20%, depending on the method used (Figure). Compared to CC %rr, both PSM LUNDEX and LUNDEX methods yielded much lower %rr, while the CARRAC method estimated %rr was in between these estimates.

Conclusion: Both LUNDEX methods certain underestimate the true response rates by considering all patients stopping treatment as non-responders, while complete case method certainly overestimates the %rr by considering patients stopping as having a similar %rr to patients continuing treatment. As expected, the CARRAC method, which accounts for attrition by reason for drug discontinuation, obtained %rr estimates in between complete-case and LUNDEX corrections. Simulation studies are needed to assess the most accurate estimation method.
PPV>=0.90 for all medication except golimumab, which had a low prevalence in our dataset.

**Conclusion:** We developed and validated an algorithm enabling a highly accurate automated extraction of RA medication from format-free fields of Electronic Medical Records.

**SAT0590** AUTOMATED DIAGNOSIS EXTRACTION FROM ELECTRONIC MEDICAL RECORDS WITH MACHINE LEARNING CLASSIFIERS

Tjardo Maarseveen1,2, Thomas Huizinga3, Marcel Reinders2,3, Erik van den Akker4, Rachel Knevel3,7, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2 Leiden University Medical Center (LUMC), Molecular Epidemiology, Leiden, Netherlands; 3 Leiden University Medical Center (LUMC), Leiden Computational Biology Center, Leiden, Netherlands; 4 Brigham and Women’s Hospital, Rheumatology, Boston, United States of America

**Background:** While Electronic Medical Records (EMR) constitute a rich resource for research into various diseases, their unstructured format often poses practical challenges. For instance, retrieval of the records belonging to all patients with a particular outcome is often accomplished with naive methods such as exact word matching. A more advanced alternative is to employ methods of Machine Learning (ML) for text classification. Rather than requiring a set of rules, an ML-model extracts these rules by itself given sufficient example records with known annotations.

**Objectives:** To build a reliable classifier with machine learning techniques that can identify Rheumatoid Arthritis (RA) cases in provided EMR entries.

**Methods:** Data was acquired from the HI-X-EMR database consisting of 2,771 patients that visited the rheumatology outpatient clinic of the Leiden University Medical Centre between 2007 and 2018. This database featured a total of 38,216 entries. The first visit entry (if available) was selected per patient for annotation, resulting in a total of 1,361 entries.

The annotated sample was then randomly split into an equally sized training and test set. Both sets were preprocessed and then classified with the following methods: Exact word-matching, Naive Bayes (NB), Decision Tree, Gradient Boosting (GB), Neural Networks and Support Vector Machines (SVM), see table 1 for more information. Classification of the naive word-matching model was based on the presence of the Dutch RA-defining terms ‘Reumatoïde Artritis’ and ‘RA’. Default Scikit-learn implementations [1] were used to create the ML-models. Finally, the performance of the models was evaluated with a receiver operating characteristic (ROC) curve analysis via the pROC R-package [2]. The Delong test was used to assess the 95% confidence intervals (CI) and to determine the difference in performance between the word-matching method and the ML-models.

**Results:** The exact word-matching approach resulted in an area under the curve (AUC) of 0.76 (CI: 0.7265-0.7783), see figure. Likewise, the ML-models resulted in relatively high AUC-scores (CI) as well: NB =0.83 (0.80-0.86), SVM=0.91 (0.89-0.93), Neural Networks=0.92 (0.90-0.94) and the GB-method with a 0.94 (0.92-0.96). The Decision Tree showed the worst performance with an AUC-ROC of only 0.51 (0.49-0.56). In comparison to the exact word-matching ROC-curve, all the ML-models showed a significant difference: Decision Tree (p<2.2e-16), NB (p= 0.004), Neural Networks (p<2.2e-16), GB (p<2.2e-16) and the SVM (p<4.0e-16).

**Conclusion:** The Gradient Boosting, Neural Networks, SVM and Naive Bayes models all showcased a significantly better performance than a naive exact word matching, which establishes these ML-methods as an efficient approach for data extraction from EMR.

A CLINICAL TOOL FOR AUTOMATED PREDICTION OF HIP AND MAJOR OSTEOPOROTIC FRACTURES USING ELECTRONIC MEDICAL RECORDS DATA: THE EPIC STUDY

Cristian Tebé1, Natalia Pallarés1, Cristina Carbonell-Abella1, Carlen Reyes2, Xavier Negues3, Adolfo Diez-Perez3, Daniel Martinez-Laguna4, Daniel Prieto-Alhambra1. GREMPAL, IDIAP Jordi Gol. CIBERFES.

Background: With increasing availability of patient data in healthcare, there is an unprecedented opportunity for prediction tools that can be automatically implemented in electronic medical records systems.

Objectives: We aimed to develop and validate a fracture prediction tool that leverages patient data as routinely available in primary care computerized records.

Methods: We conducted a population-based cohort study. Data was extracted from all subjects registered in the SIDIAP database on 1/1/2012, with data for 1+ years, and aged 50 years or older on that date. SIDIAP contains primary care records linked to pharmacy dispensations for >6 million people, equivalent to >80% of the population of Catalonia. Participants were followed up until the earliest of death, transfer out/immigration, or end of 2017. Two models were developed to predict hip fracture (main outcome) and major osteoporotic (hip, clinical vertebral, wrist/forearm, and proximal humerus) fracture risk over 5 years. Potential predictors were pre-specified based on previous literature and combined in Cox models to derive prediction tools. Internal validation was performed using c-statistic for discrimination, and observed vs predicted plots for calibration. Multiple imputation with chained equations was used to minimize the impact of missing data on body mass index, smoking, and alcohol consumption. Bootstrapping methods were used to select key predictors to be combined in the final resulting models.

Results: A total of 1.76 million people (9.76 million person-years) were included, 50.7% women, of average age 65.4 years old. A 10.1% and 7.4% were lost to follow-up over 5 years due to mortality and migration respectively.

Fracture rates were 3.57/1000 person-years [95% CI 3.53-3.60] for hip and 11.61 [11.54-11.68] for major fracture. Key predictors of increased fracture risk included age, female gender, history of falls or previous fractures, specific medication/s use (insulin, GnRH inhibitors, anticonvulsants, sedatives, SSRI, antipsychotics), and a history of diabetes mellitus (type 1/type 2), cerebrovascular disease, ischemic heart disease, COPD and anorexia nervosa. Variables associated with lower fracture risk included use of statins, thiazidic diuretics, and overweight/obesity. Combined, these resulted in a c-statistic of 0.84.9% for hip and 72.9% for major fracture. Calibration was excellent for both outcomes.

Conclusion: We have developed and validated a clinical prediction tool for 5-year hip and major osteoporotic fracture risks. The algorithm has excellent performance and can be installed in electronic primary care record systems for automated risk calculations at the population level. More research is needed on the transportability and external validity of this prediction tool.

and all of them are associated with a high burden of comorbidities. Incidence of these diseases and of their comorbidities are unknown in Belgium.

**Objectives:** To determine incidences of disease and comorbidities in patient populations of RA, PSA and SPA in a General Practitioners (GP) setting.

**Methods:** Data were obtained from Intego over a 13-year time interval from 1999 to 2012. Intego is a Flemish GP-based morbidity registration network hosted at the Academic Center for General Practice of KU Leuven, covering 2% of the Flemish general population. Patients classified under the International Classification of Primary Care codes L88 (rheumatoid/seropositive arthritis) and L99 (musculoskeletal disease other) were selected for this study. Experienced rheumatologists verified if the keywords mapped to these codes corresponded to a diagnosis of RA/SPA/PSA. The entry date of these diagnoses in Intego was considered "baseline". Yearly disease incidence and comorbidity incidence over 3 years are presented. The following comorbidities with high impact on outcomes like disability, costs, hospitalization and death were considered: lung disease, cardiovascular disease including myocardial infarction, stroke or other heart condition, hypertension, fracture of the spine/hip/leg, depression, diabetes mellitus, digestive disease including ulcers and stomach disorders and malignancies [1].

**Results:** Over a 13-year period, 817, 258 and 190 patients were included with a diagnosis of RA, SPA or PSA, respectively. The average incidence of RA was 0.47, of SPA 0.15 and of PSA 0.11 per 1000 person years. Fig1 gives the yearly incidence per disease. The RA cohort had a mean(SD) age of 57.7(17.2) with 68% being women. The SPA cohort had a mean(SD) age of 40.6(15.1) with 50% being women. The SPA cohort had a mean(SD) age of 47(13.2) with 48% being women.

The comorbidity with the highest prevalence (23%) and incidence (29.6/1000 person years) in RA was hypertension. In the SPA cohort, digestive disease was most common at baseline (14%) and during follow-up (21.0/1000 person years) in RA was hypertension. In the SPA cohort, digestive disease was most common at baseline (14%) and during follow-up (21.0/1000 person years) in RA was hypertension. In the SPA cohort, digestive disease was most common at baseline (14%) and during follow-up (21.0/1000 person years).

**Conclusion:** The incidence of RA appears to remain stable while incidence of PSA - and to a lower extent SPA - seem to increase over a 13-year interval. A control cohort will be formed to improve comparability of comorbidity presence, yet from these preliminary results we can determine that an important subgroup of patients with rheumatic diseases already presents with significant comorbidities at baseline, or during 3-year follow-up. This study highlights the growing issue of multimorbidity in patients with musculoskeletal diseases and the importance of a holistic approach to manage these patients.

**References**
with IAEs, for which immunotherapy was not suppressed. However, the medication was suppressed in the remaining 40% of the cases. Exceptionally, one patient underwent a severe IAE (pneumonitis) that resulted in death. In terms of the occurrence of IAEs, there was no difference between sexes (men 6.3%, women 6.4%). The rheumatic IAEs responded well to treatment with corticosteroids without further biological treatments or DMARDs.

**Conclusion:** Immunotherapy is changing the typology of side effects in cancer patients, including IAEs. The cases analysed showed a relatively small number of rheumatic events that were easily solved with corticosteroids (nor the immunotherapy treatment was suppressed or immunosuppressive treatment was necessary). The study highlights the benefits of involving multidisciplinary medical teams to manage oncologic patients treated with immunotherapy towards the early detection and treatment of IAEs.

**DIRECT COMPARISON OF CERTOLIZUMAB PEGOL, ABATACEPT AND BIOSIMILAR INFlixIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED IN ROUTINE CARE. OBSERVATIONAL DATA FROM THE DANISH DANBIO REGISTRY ANALYZED LIKE A RANDOMIZED CLINICAL TRIAL.**

**Kathrine Gøn1, Bente Glinthøj1, Mette Nørgaard2, Frank Mehnert2, Mikkel Stergaard1, Lene Dreyer1, Niels Steen Krog1, Jakob B. Bjørner3, Merete L. Hetland1,2, DANBIO and the Danish Departments of Rheumatology, Copenhagen, Denmark; 2Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; 3Department of Public Health, University of Copenhagen, Copenhagen, Denmark**

**Background:** Nationwide Danish guidelines regarding RA patients (pts) initiating bDMARDs are issued approximately annually. For bio-naïve pts on concomitant methotrexate (MTX) the recommended drugs (year, recommended compliance) were: certolizumab pegol (CTZ) (2013-2014, 80%)/abatacept (ABA) (2014-2015, 80%)/biosimilar infliximab (CT-P13) (2015-2016, 50%). We hypothesized that the guidelines could be perceived as a surrogate randomization tool where calendar-time rather than patient-specific factors defined choice of bDMARD.

**Objectives:** To assess compliance to guidelines (justifying the assumption of surrogate randomization) and compare effectiveness of CTZ/ABA/CT-P13 in Danish RA patients treated according to guidelines.

**Methods:** Observational cohort study analyzed like a randomized clinical trial (RCT, intention-to-treat). RA patients were identified in DANBIO. Compliance in each calendar period was defined as number of pts adherent to guideline/numbers of all bio-naïve pts initiating bDMARD + MTX. Outcomes were DAS28-remission-rates (at 6 and 12-months) and one-year retention rates, compared across treatments (confounder-adjusted multivariable logistic and Cox regression analyses).

**Results:** Compliance to guidelines was 70%/85%/59%, and 776 patients were included (CTZ/ABA/CT-P13: 336/215/225). Baseline characteristics were similar across drugs. DAS28-remission-rates after 6 and 12 months were: 37%/34%/44% and 37%/33%/36%, respectively. Adjusted odd ratios for achieving DAS28 remission were at 6 months: 0.96 (95% CI: 0.6;1.5) for ABA and 1.38 (0.9;2.1) for CT-P13; 12 months: 0.74 (0.5;1.2) and 0.96 (0.6;1.5), CTZ reference drug (figure). The adjusted hazard ratios for withdrawal were 1.16 (95% CI: 0.84;1.60) for ABA and 0.83 for CT-P13 (0.59;1.17) (table).

**Table.** RA patients starting first bDMARD according to Danish national guidelines during the three calendar periods. Baseline characteristics and adjusted hazard ratios (HR) for withdrawal during the first year of treatment (Cox regression analyses).

*Variables are median (IQR) unless otherwise mentioned. *age, gender, DAS28, HAQ, smoking, CCI Abbreviations: CCI: Charlson Comorbidity Index; CI: confidence intervals; DAS28: Disease Activity Score of 28 joints, HAQ: Health assessment questionnaire

**Conclusion:** Compliance to guidelines was high. Direct comparison showed that remission and retention rates were highest for CT-P13, intermediate for certolizumab and lowest for abatacept. Results should, however, be interpreted with caution due to wide CIs and risk of residual confounding.

SAT0596

RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS AND A LOW-INTERMEDIATE A PRIORI RISK OF CORONARY ARTERY DISEASE AFTER INITIAL CT-BASED DIAGNOSIS AND TREATMENT A REGISTRY-BASED FOLLOW-UP STUDY USING DATA FROM THE WESTERN DENMARK HEART REGISTRY

Annette de Thauril1,2, Ina Tolle Andersen1, Andreas Buegge Tingsgaard3, Anders Hammertch Rits4, Josephine Therkildsen1, Hans Erik Beker5, Morten Böttcher5, Ellen Margrethe Hauge1,2, Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark; Hospital Unit West, Herning, Department of Cardiology, Herning, Denmark; Aarhus University Hospital, Department of Cardiology, Aarhus, Denmark

Background: Rheumatoid arthritis (RA) is a known risk factor for developing coronary artery disease (CAD). The influence of RA on the prognosis after initial diagnosis and treatment of CAD is however largely unknown.

Objectives: To examined the risk of major cardiovascular events among RA and non-RA patients with chest pain referred to cardiac computed tomography (CCT).

Methods: This was a follow-up study, using data from the Western Denmark Heart Registry[1]. Information on RA diagnosis and co-variables were identified through nationwide administrative registers. The primary outcome was a combined outcome including myocardial infarction, ischemic or unspecified stroke, coronary artery bypass grafting, percutaneous coronary intervention, and all-cause mortality. In the studied region, RA-fares are controlled through escalation of disease modifying drugs and intra-articular or intramuscular glucocorticoid injections (GGI). Hence, the number of times a patient had received GCS 3 years prior to the CCT were used as a surrogate marker of disease activity. Analyses were performed for overall RA and the serological subtypes: ‘seropositive RA (ICD-10: M05) and ‘other RA (ICD-10: M06).

Median time until events or censoring was 3.5 years (min/max: 0.0-9.2). Cox proportional hazard models were used to examine the association between RA/non-RA patients and outcomes.

Results: Among 42,257 patients, referred from 2008 and 2016, we identified 358 (0.8%) with RA. An increased risk was seen in RA compared to non-RA (adjusted hazard ratio (HR) 1.35 (95% CI: 0.93; 1.36)). An additional risk was found among patients who had received flare treatment more than once prior to CCT (adjusted HR 1.80 (95% CI: 1.08; 3.00)), and in patients with sero-positive RA (adjusted HR: 1.42 (95% CI: 0.93; 2.16)).

Conclusion: In patients with low-intermediate a priori risk of CAD, we found an association between RA and the combined primary outcome, supporting that RA per se, but in particular sero-positive and active RA, increase the risk of cardiovascular events even after initial CAD diagnosis and treatment.

RISK OF HEART FAILURE FOLLOWING EXPOSURE TO NON-TNFİ COMPARED TO TNFİ BIOLOGICS IN US PATIENTS WITH RHEUMATOID ARTHRITIS

Thomas Bo Jensen1,2, Nicole Tsao3,4, Ajinkya Pawar2, Rishi J. Desai2,3, Seoyeong Kim3,4, Copenhagen University Hospital Bispebjerg, Department of Clinical Pharmacology, Copenhagen, Denmark; Brigham and Women’s Hospital, Division of Pharmacoeconomics and Pharmacoeconomics, Boston, United States of America; Harvard Medical School, Boston, United States of America

Background: Biologic disease modifying drugs including TNF inhibitor (TNFi) and non-TNFi agents have become cornerstone of rheumatoid arthritis (RA) management. Case reports on new-onset heart failure (HF) following TNFi initiation led to an FDA black box warning released in October 2001. Subsequent observational studies have shown no association or even a protective effect of TNFi for HF, but the black box warning is still in place. There is a lack of knowledge regarding the risk of HF following exposure to the newer non-TNFi biologics.

Objectives: We aimed to assess the risk of incident HF following exposure to non-TNFi compared to TNFi biologics.

Methods: Using US claims data from Truven MarketScan (2004-2016), we conducted a cohort study of RA patients who initiated a ‘TNFi (adalimumab, certolizumab pegol, etanercept, golimumab, infliximab), or non-TNFi biologic or targeted synthetic DMARD (abatacept, anakinra, tocilizumab, tofacitinib). Patients were excluded if they were <18 years old, had previous HF, an implantable cardiologic device, or a loop-diuretics prescription. Patients were followed from the day after treatment initiation until the earliest event of the following: death, insurance disenrollment, treatment switching or discontinuation. The primary outcome of incident HF was defined based on primary inpatient diagnosis. Cox proportional hazards regression compared risk of HF among new users of non-TNFi compared to TNFi. To control for confounding, we used multivariable adjustment as well as propensity score (PS) adjustment by decile with trimming.

Results: A total of 13,290 non-TNFi patients were included, primarily consisting of abatacept (65%), tocilizumab (17%), and tocilizumab (15%). For the TNFi group, we identified 67,892 patients, primarily consisting of etanercept (42%), adalimumab (37%), and infliximab (15%). More patients treated with non-TNFi were female, older, had higher proportion of comorbidities and number of rheumatologist visits; lower proportion of NSAID/Coxib use. Table 1. The crude hazard ratio (HR) of HF after initiating a non-TNFi was 1.28 (95%CI 0.75-2.18) versus TNFi. After confounding adjustment in a multivariable model, the HR was attenuated to 1.08 (95%CI 0.57-2.05). The PS adjusted analysis showed consistent results (Table 2).

Conclusion: In this large US-based cohort of 81,182 RA patients, we found no difference in the risk of incident HF after initiation of non-TNFi biologic or targeted synthetic DMARD versus TNFi.

RHEUMATIC IMMUNE RELATED ADVERSE EVENTS ASSOCIATED WITH CANCER IMMUNOTHERAPY: A NATIONWIDE MULTI-CENTER CANADIAN COHORT FROM THE CANADIAN RESEARCH GROUP OF RHEUMATOLOGY IN IMMUNO-ONCOLOGY (CANRIO)

Daniel Ennis1, Shahin Jamali2, Marie Hudson2, Carrie Ye3, Alexandra Saltman1, Meghan Himmel1, Janet Pope4, Sabrina Hoa5, Annalise Tisseverasinghe1,2, Aurore Fill-Mah1, Nancy Maltez1, Janet Roberts1, CanRIO. 1University of Toronto, Toronto, Canada; 2University of British Columbia, Vancouver, Canada; 3McGill University, Montreal, Canada; 4University of Alberta, Edmonton, Canada; 5University of Western Ontario, London, Canada; 6University of Montreal, Montreal, Canada; 7University of Manitoba, Winnipeg, Canada; 8University of Calgary, Calgary, Canada; 9University of Ottawa, Ottawa, Canada; 10Dalhousie University, Halifax, Canada

Background: Immune checkpoint inhibitors (ICI) have revolutionized cancer therapy by harnessing the immune system to fight cancer. As the indications for ICI continue to expand, their success in advanced stage malignancies is tempered by the development of autoimmune toxicities, referred to as immune-related adverse events (irAE). Rheumatic irAE (Rh-irAE), particularly arthralgias and arthritis are common and optimal management remains unknown.

Objectives: The Canadian Research Group of Rheumatology in Immun-oncology (CanRIO) is an emerging network of Canadian rheumatologists with an interest in Rh-irAE secondary to ICI. We describe the clinical presentation and management of Rh-irAE associated with ICI in patients seen at 9 CanRIO sites.

Methods: Patients presenting with rheumatic symptoms associated with ICI therapy between 2013 and January 2019 at participating CanRIO sites were identified. Cases were stratified based on the presence or absence of pre-existing autoimmune disease (PAD). Standardized data were extracted by chart review. The data were pooled and analyzed descriptively.

Results: 118 patients without PAD who developed 140 Rh-irAE were identified, 59% were male with a mean age of 62 years. Common indications for ICI were melanoma (n=57, 43.8%), lung (n=30, 23.4%), and genitourinary cancer (n=19, 16.1%). ICI included nivolumab (n=30, 25.6%), pembrolizumab (n=38, 32.5%), ipilimumab (n=1, 0.9%), durvalumab (n=3, 2.6%), atezolizumab (n=4, 3.4%) or combination therapy (n=29, 24.8%). Common Rh-irAE included symmetric polyarthritis (n=45, 32%), arthralgias/myalgias or acute flare of osteoarthritis (n=20, 14.3%), polymyalgia rheumatica-like presentation (n=17, 12%), tenosynovitis/enthesitis (n=17, 12%), sicca syndrome (n=11, 7.9%) and myositis (n=5, 6.4%). 20 patients with PAD were identified, 70% of whom were in remission prior to starting ICI. 50% (n=10) had flares, 15% (n=3) developed a new Rh-irAE and 20% (n=6) developed O-irAE. 53% experienced at least one other non-rheumatic irAE (O-irAE) (n=63). Mean time from first ICI exposure to onset of Rh-irAE was 6.8 months. In 65% ICI was held or discontinued (n=77). Despite this, 68.6% (n=81) had favorable tumor response, while 12% (n=14) had tumor progression. There were no deaths related to Rh-irAE. The majority of patients without PAD had partial or complete response to mono or combination therapy with oral prednisone (n=77; maximum dose 60 mg/d), nonsteroidal anti-inflammatories (NSAID; n=52), intra-articular corticosteroids (n=29), hydroxychloroquine (n=26), methotrexate (n=17), or tumor necrosis factor alpha inhibitors (n=8).

Conclusion: This is the largest multi-centered cohort of Rh-irAE described to date. Seronegative inflammatory irAE was the most common Rh-irAE although a broad range of conditions were identified. The most common first-line treatment was systemic corticosteroids followed by NSAID and intra-articular steroid injections. Prednisone was effective, however higher doses were required. Disease-modifying anti-rheumatic drugs (DMARD) and biologic therapy were well tolerated and effective, with hydroxychloroquine being the most commonly used DMARD. Despite moderate to high doses of immunosuppression, the majority of patients had favorable tumor responses.

Disclosure of Interests: Daniel Ennis: None declared, Shahin Jamali Consultant for: Consultant for Abbvie, Amgen, BMS, Eli Lilly, Pfizer, Janssen, Merck, UCB, Marie Hudson Grant/research support from: Unrestricted research funds from Bristol-Myers Squibb, Carrie Ye: None declared, Alexandra Saltman: None declared, Meghan Himmel: None declared, Janet Pope Consultant for: Eli Lilly and Company, Sabrina Hoa: None declared, Annalise Tisseverasinghe: None declared, Aurore Fill-Mah Grant/research support from: Roche, Abbvie, Janssen, BMS, Speakers bureau: Roche, Abbvie, Janssen, BMS, Pfizer, Nancy Maltez: None declared, Janet Roberts: None declared

controlled, longer RA duration) sustained the lowest mean SJC throughout follow-up. Cluster 4 patients ("health low, moderate, moderate RA") exhibited the highest improvement in mental health (FSMHI; Figure). Cluster 5 patients ("health low, RA uncontrolled, longer RA duration") exhibited the highest CDAI scores (Figure) and maintained baseline line of therapy the longest.

Conclusion: Five patient clusters identified by data-driven PC analysis of the BRASS registry exhibited distinct patterns of clinical outcome and management over a 4-year follow-up period. The clinical outcomes data suggest the clusters represent clinically meaningful categories of RA and illustrate the potential of data-driven patient profiling as a tool to support personalized medicine in RA. Validation in an independent dataset is ongoing.

**COMPARATIVE CARDIOVASCULAR SAFETY OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS) IN PATIENTS WITH OSTEOARTHRITIS: FINDINGS FROM PROVINCIAL PRESCRIPTION CLAIM RECORDS IN BRITISH COLUMBIA, CANADA**

Mohammed Atiquzzaman1,2, Ehsan Karim1, Hubert Wong3, Jacek Kope3,2, Mary De Vera3,4, Aslam Anis2,3, University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada. 1Arthritis Research Canada, Richmond, Canada. 2University of British Columbia, School of population and public health, Vancouver, Canada.

**Background:** Osteoarthritis (OA) has been reported as an independent risk factor for cardiovascular diseases (CVD) (1). Furthermore, mediating role of NSAIDs in the observed OA-CVD association has also been noted (2). Thus, a substantial proportion of the total risk of CVD among OA patients compared to non-OA controls was attributable to NSAIs use (1). This is particularly worrisome as there is no cure for OA, and NSAIDs are the mainstay of treatment in controlling the primary symptoms of pain and inflammation among OA patients. However, only a handful of observational studies evaluated the risk of a specific NSAID among OA patients for a specific CVD event such as myocardial infarction (MI) (3). The overall cardiovascular safety of NSAIDs used in treating OA in the real-world therefore remains unknown.

**Objectives:** To evaluate the comparative safety of various NSAIDs against CVD when treating patients with OA.

**Methods:** We used linked health administrative data (HAD) of a previ- ously assembled, population-based cohort of 720,055 British Columbians from Canada. We identified individuals with OA who received at least one NSAID prescription from January 1996 to December 2013. Eligible study subjects were at least 20 years old, did not have CVD and had not received an NSAID prescription within the last 90 days from their OA diagnosis date. We defined composite CVD outcome from hospital discharge abstract database, payment information file of Medical Services Plan and vital statistics deaths data file using ICD-9 or ICD-10 codes. We created an NSAID exposure variable in a time-dependent fashion in which individuals were considered at risk for the duration of NSAID pre- scriptions. We used time-dependent Cox regression analysis to estimate CVD risk associated with NSAID use overall as well as four unique groups of NSAIDs, i.e., coxibs, naproxen, ibuprofen and other conven- tional NSAIDs.

**Results:** Our cohort included 3,806 OA individuals. There were 1,147 CVD events. After adjusting for age, sex, SES, COPD, diabetes, hyper- tension, hyperlipidemia, peptic ulcer disease and Romano comorbidity score, the hazard ratio (HR) and 95% confidence interval (CI) from the time-dependent Cox regression model was 1.48 (1.27, 1.73). When expo- sure to different groups of NSAID was compared with unexposed person- time, CVD risk were similar among coxibs and naproxen followed by other conventional NSAIDs and ibuprofen, adjusted HR (95% CI) were 1.58 (1.24, 2.00), 1.58 (1.11, 2.24), 1.39 (1.10, 1.75) and 1.36 (0.75, 2.47), respectively.

**Conclusion:** Our study is the first retrospective cohort study using BC HAD that looked at the overall CVD risk of NSAID use in treating OA in a real-world setting. After modelling exposure to NSAIDs as time-depend- ent, we found that exposure to NSAIDs substantially increased overall CVD risk compared to non-exposed periods. We also found that coxibs and naproxen may increase CVD risk more than conventional NSAIDs including ibuprofen.

**MORTALITY RATE IN PATIENTS TREATED WITH BIOLOGICS: DATA FROM THE ROMANIAN REGISTRY OF RHEUMATIC DISEASES**

Catalin Codreanu1, Corina Mogosan2, Denisar Predeteanu3, Simona Rednic4, Magda Parvu5, Elena Rezus6, Ruxandra Ionescu, Romanian Registry of Rheumatic Diseases. 1Clinical Center of Rheumatic Diseases “Dr. Ion Stoia”, Bucharest, Romania. 2Clinical Center of Rheumatic Diseases “Dr. Ion Stoia”, Bucharest, Romania. 3Clinical Center of Rheumatic Diseases “Stiinta Maria” Hospital, Bucharest, Romania. 4Clinical Center of Rheumatic Diseases “Stiinta Maria” Hospital, Bucharest, Romania. 5County Emergency Hospital, Bucharest, Romania. 6Clinical Hospital “Cotleni”; Bucharest, Romania. 7Clinical Rehabilitation Hospital, Bucharest, Romania. 8University of Medicine and Pharmaceutical Sciences, Iasi, Romania. 9“Stiinta Maria” Hospital, Bucharest, Romania.

**Background:** Rheumatoid arthritis (RA) is associated with increased mor- tality, with longitudinal studies averaging a standardised mortality ratio of
1.5 (95%CI 1.2 to 1.8) for RA patients compared to the general population [1]. In contrast, information on mortality in ankylosing spondylitis (AS) is scarce, whereas there are conflicting reports of the mortality risk among patients with psoriatic arthritis (PsA), but it is accepted that patients with PsA do not have a significantly elevated risk of mortality [2].

Objectives: To estimate the Mortality Rate in RA, SA and PsA for patients (pts) treated with biologics in Romania.

Methods: Data were gathered from the Romanian Registry of Rheumatic Diseases (RRRB), which comprises all patients treated with biologics in Romania for RA, AS and PsA. We have studied demographic data, disease duration, exposure to biologics in person-years (PY), and all-cause mortality until 01.07.2018.

Results: The cohort included 9577 pts (35596.83 PY) as following: 5224 RA pts (18676.75PY), 3469 AS pts (12680.63PY) and 884 PsA pts (4212.45PY). The mean age of the cohort was 54.86 yrs (62.87 yrs for RA pts, 56.54 yrs for AS, 56.18 yrs for PsA); 3196 pts (33.57%) were men: 79 (1.5%) RA pts, 2681 (77.28%) AS pts and 436 (49.3%) PsA pts. Mean disease duration for the cohort was 16.46 yrs for RA, 11.46 yrs for AS and 10.99 yrs for PsA. The number of all-cause deaths was 89 (74 deaths in RA, 11 in AS and 4 in PsA group). The mortality rate for the entire cohort was 0.25/100PY, and the rate varied across the diseases: 0.39/100PY in RA pts, 0.08/100PY in AS pts and 0.09/100PY in PsA. Infections were the major mortality cause in RA (0.09/100PY) and AS (0.04/100PY). Cardiovascular fatal events occurred in 0.06/100PY in RA population, significantly higher than 0.007/100PY in AS pts. Rate of solid neoplasm death in RA cohort was 0.04/100PY, compared to 0.007/100PY in AS; non-Hodgkin lymphoma was recorded only in RA pts (0.005/100PY). All deaths reported in PsA cohort (4 deaths) were of unknown cause.

Conclusion: This is the first report on mortality rate in biological treated patients in Romania. These data support data from the literature, showing that RA patients have a higher mortality risk compared to AS and PsA.

SAT0602 SHOULD ALL PATIENTS WITH ANTI-CENTROMERE ANTIBODIES BE REFERRED FOR A RHEUMATOLOGY ASSESSMENT?

Hoda Alkoty, Mark Lazarus. Southend University Hospital, Rheumatology, London, United Kingdom

Background: Anti-centromere antibodies (ACA) are commonly associated with systemic sclerosis (SSc). The presence of ACAs in patients with SSC is known to increase the likelihood of developing Pulmonary Hypertension, which has a high mortality rate. ACAs are also seen in patients with other connective tissue diseases (CTD) and can sometimes be identified after testing for antinuclear antibodies in patients who have not reported any rheumatological symptoms. It is possible that connective tissue diseases are being under diagnosed due to a lack of awareness by physicians of the clinical significance of ACAs.

Objectives: To investigate whether patients with ACAs are being appropriately referred to the Rheumatology service.

Methods: All patients who were positive for ACAs in Southend university hospital between April 2016 and October 2018 were included in this single centre retrospective observational study. We identified patients’ demographics, diagnosis, ANA titre, additional diagnosis and immunosuppressive therapy. We also captured their monitoring with pulmonary function testing and echocardiography.

Results: A total of 75 patients were identified with ACAs. The average age was 65 years, 61 females, 14 Male. Fifty-six patients were referred to rheumatology team and were found to have the following diagnosis. LCsSc (21), Sjogren’s syndrome (SS) (10), undifferentiated connective tissue disease (UCTD) (6), Rheumatoid arthritis (RA) (5), ANA associated vasculitis (AAV) (3), Raynaud’s phenomenon (3), Lupus (2), Antiphospholipid syndrome (APS) (1), Primary biliary cirrhosis with Sjogren’s syndrome (SS) (1), Autoimmune hepatitis (1) and osteoarthritis (1). Of those 33 patients had a routine screening with an Echocardiogram and 26 had pulmonary function tests. One patient with lqScs developed pulmonary hypertension. The remaining 19 patients were not referred and did not have the appropriate screening for pulmonary hypertension. ANA titre was 1:30 in one patient, 1:320 for 4 patients, unknown for three and 1:640 for the remaining 67. 11 patients were treated with Hydroxchloroquine (4 SS, 4 UCTD, 1 lupus, 1 APS and 1 lc SSc), 5 on Methotrexate (4 RA and 1 AS), 2 on MMF and steroid (AAV).

Conclusion: Nearly all patients with ACAs that were seen in the Rheumatology clinic had an autoimmune rheumatic disease. However, we found that 25% of people with ACAs were not referred to the Rheumatology service. The reasons for this are unclear. It is possible that patients did not report symptoms that would have prompted a referral. Some of the CTDs in which ACAs are typically found (lqScs and SS) are associated with symptoms that can be mild and might not be reported by the patients or general physicians do not associate them with rheumatological disorders (e.g. sicca symptoms, gastro-oesophageal reflux and Raynaud’s phenomenon). Early diagnosis might enable earlier treatment and prevent complications from these diseases. General physicians should therefore be made aware of these antibodies and the disorders that they can be associated with.

Disclosure of Interests: None declared

SAT0603 SENSITIVITY TO PHENYLTHIOCARBAMIDE IN RHEUMATOID ARTHRITIS PATIENTS

Natalia Dostanko¹, Viktor Yagui², Tatiana Zybalkova³, Valery Andreashov¹, Viktoria Dostanko². Belarusian State Medical University, 2nd Department of Internal Medicine, Minsk, Belarus; ²PMUE Infomed, Minsk, Belarus

Background: Sensitivity to phenylthiocarbamide (PTC) as the ability to taste this bitter compound is a genetic marker ranked alongside eye color and blood groups [1,2]. Almost 90 years have passed since the first publication of A.L. Fox on the relationship of the “chemical constitutio- tion” and sensitivity to PTC [3] and 35 years later, J. Stepan et al. (1965) analyzed the sensitivity to PTK in patients with joint diseases. According to the literature [4,5] sensitivity to PTK is associated with the peculiarities of clinical manifestation and the course of these diseases.

Objectives: To estimate the sensitivity to PTC in RA patients and its influence on the prognosis of the disease.

Methods: The physiological parameter of sensitivity to PTC was determined by H. Harris et al. [8]. The total number of dilution thresholds was 15 (PTC<1), Patients were considered as non-tasters (not able to taste PTC) in the case of PTC<4 sensitivity thresholds and as tasters in the case of PTC≥4 sensitivity thresholds. Sensitivity to PTC was assessed in 140 RA patients, 110 women and 30 men, at Minsk clinical hospital No9 and we used the data on the PTC sensitivity of the mixed population of Minsk as a control [7].

Results: The frequencies of tasters (PTC+) and non-tasters (PTC-) as well as allele frequencies (T and t) of the PTC sensitivity gene among RA patients and controls are presented in the table.

<table>
<thead>
<tr>
<th>Group</th>
<th>n</th>
<th>Phenotypes</th>
<th>Allele frequencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RA, t</td>
<td>110</td>
<td>32</td>

<td>40</td>
<td>90</td>
</tr>
<tr>
<td>Control, T</td>
<td>119</td>
<td>41</td>
<td>78</td>
</tr>
</tbody>
</table>

There were no significant differences between general groups of PTC tasters and non-tasters among RA patients and the controls (two-way Fisher exact test, two-way FET, p<0.01) while the sensitivity threshold of PTC<4 was revealed 2 times less in RA patients than in the control group 10.7% and 22.1%, respectively (two-way FET, p=0.0057). Operating characteristics of PTC<4 are the following: OR=0.43 Cl95:0.23-0.78, LR+=0.49 Cl95:28-0.81, LR−<1.15 Cl95:0.95-1.23, that means that a taste threshold of PTC<4 decreases the chance of RA by 2.0 times.

Seronegative RA was significantly more common in non-tasters vs tasters in the case of PTC<4 sensitivity thresholds and as tasters in the case of PTC≥4 sensitivity thresholds. Sensitivity to PTC was assessed in 140 RA patients, 110 women and 30 men, at Minsk clinical hospital No9 and we used the data on the PTC sensitivity of the mixed population of Minsk as a control [7].

Results: The frequencies of tasters (PTC+) and non-tasters (PTC−), as well as allele frequencies (T and t) of the PTC sensitivity gene among RA patients and controls are presented in the table.

advanced stages of RA (3-4 stages by O. Steinbrocker) (two-way FET, p=0.0024) with the same duration of RA.

Conclusion: The taste threshold of PCTC decreased the chances of RA by 2.0 times and non-sensitivity to PCTC was associated with seronegative RA, especially in men, and more benign course of the disease.

SAT0604 ANALYSIS OF INFECTIOUS SPONDYLODISCITIS: 20-YEARS DATA: EPIDEMIOLOGY, CLINICAL FEATURES, DIAGNOSIS AND TREATMENT

Llobna Ben Ammar, Ines Mahmoud, Aicha Ben Tekaya, Olla Saidane, Rawdha Tekaya, Leila Abdelmoula. Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia

Background: Infectious spondylodiscitis is defined as an infectious disease involving intervertebral disks and adjacent vertebral bodies. It is rare and difficult to diagnose due to its non-specific clinical features.

Objectives: To study the clinical, microbiological, radiological, therapeutic and evolving of infectious spondylodiscitis.

Methods: Retrospective monocentric study including patients diagnosed as spondylodiscitis and hospitalized in our department between January 1999 and December 2018. The diagnosis was based on clinical, biological, radiological and bacteriological data.

Results: We included 107 patients. There were 58 men (54.2%) and 49 women (45.8%) with a mean age of 55 years [16-86]. Predisposing factors were found in 59 patients (55.1%). This was diabetes in 21.49% of cases, spinal cord compression in 9.3% and vertebral ostelysis in 8.4% of cases. The lumbar spine was most affected (54.2%), followed by the dorsal spines in 31.7%.

Conclusion: Early diagnosis is needed to avoid neurological complications and to reduce the duration of antibiotic treatment. Early diagnosis is needed to avoid neurological complications and to reduce the duration of antibiotic treatment.

SAT0605 BODY MASS INDEX AND SYSTEMIC CORTICOSTEROID USE AS INDICATORS OF DISEASE BURDEN AND THEIR INFLUENCE ON THE SAFETY PROFILE OF CERTOLIZUMAB PEGOL ACROSS INDICATIONS

Vivian Bykerk1, Andrew Braun2, Jeffrey Curtis3, Cecile Gaujoux-Viala4, Tore K. Kvien5, William Sandstrom6, Kevin Winthrop7, Christina Popova8, Xavier Mar LTE9, 1Hospital for Special Surgery, New York, United States of America; 2Oregon Medical Research Center, Portland, United States of America; 3University of Alabama at Birmingham, Birmingham, United States of America; 4Nimes University Hospital, Nimes, France; 5Diakonhjemmet Hospital, Oslo, Norway; 6University of California, La Jolla, United States of America; 7Oregon Health and Science University, Portland, United States of America; 8UCB Pharma, Brussels, Belgium; 9Université Paris-Sud, Paris, France

Background: Certolizumab pegol (CZP) is an anti-TNF drug approved for rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA), ankylosing spondylitis (AS) and Crohn’s disease (CD). Older age, comorbidity burden and corticosteroid (CS) use have been linked to increased risk of serious infectious events (SIEs) in CZP-treated patients (pts) with RA. However, the impact of overall disease burden on the risk of serious adverse events (SAEs) has not been fully examined for other CZP indications. High body mass index (BMI) has been associated with systemic inflammation and greater comorbidity risk. Greater disease burden in these pts may lead to increased CS use – a known risk factor for SAEs.

Objectives: To examine the contribution of BMI and CS use to the risk of SIEs, malignancies and major adverse cardiovascular events (MACE) in CZP-treated pts across indications.

Methods: Safety data were pooled across 49 CZP clinical trials (27 RA, 1 axSpA, 1 PsA, 5 PSU, 15 CD). SAEs of potential concern were medically reviewed by an external expert committee using predefined case rules. Incidence rates (IR) were calculated per 100 pt-years (PY). Multivariate Cox modeling was used to estimate relative risk (hazard ratio [HR]) of time to first SIE, malignancy or MACE by baseline BMI (<18.5, 18.5–25, 25–30, >30 kg/m²) and CS use (yes, no). The model was adjusted for baseline age, sex, disease duration, methotrexate (MTX) use, prior anti-TNF drug use, and CZP indication.

Results: Across indications, 11,317 pts received CZP (21,695 PY total exposure; max: 7.8 years [yrs]; exposure for RA: 13,542 PY; axSpA: 978 PY; PsA: 1,316 PY; PSU: 1,481 PY; CD: 4,378 PY). Mean BMI was 27.8 kg/m² in RA, 27.6 kg/m² in axSpA, 29.8 kg/m² in PsA, 30.1 kg/m² in PSU, and 24.0 kg/m² in CD. Overall, 4,132 pts (37%) took CS at baseline, more so in RA (46%) and axSpA (51%). Across indications, IRs were 0.82/100 PY for all malignancies (IR for malignancies excluding non-melanoma skin cancer [NMSC] was 0.66/100 PY), 0.47/100 PY for serious infectious events, and 0.70/100 PY for major adverse cardiovascular events.
MACE, and 3.6/2/100 PY for SLEs. According to the Cox model, age ≥45 yrs, disease duration <1 yr (compared with ≥5 yrs), and no MTX use were risk factors for malignancies (including NMSCs); BMI and CS use did not have a detectable impact (Table). MACE risk was higher in RA and PsA; BMI >30 kg/m² was a risk factor for MACE, in addition to age ≥45 yrs and male sex (Table). Compared with RA, SIE risk was higher in CD and lower in PSO and PsA; key risk factors included age ≥65 yrs, disease duration ≥10 yrs and CS use. Without CS use, BMI did not impact SIE risk, but among CS users, SIE risk was higher for obese pts (Table).

Conclusion: In CZP-treated pts across indications, malignancy risk was not influenced by BMI or CS use. As expected, obesity and CS use increased the risk of MACE. The SIE risk associated with CS use was compounded in obese pts, which may reflect the contribution of comorbidity, disease activity or other factors not examined here.

INCIDENCE AND SEVERITY OF FRACTURE FRAILTY

Bernard Cortet1, Pierre Chauvin2, Jean-Marc Feron3, Laurent Grange4, Alan Coulomb5, Robert Lauonis6, Francoise Alliot Launois7, Rahima Sellami8, Chantal Touboul9, Benoit Vincent9, Jean-Michel Joubert9, Karine Briot10.

Background: Certain fragility fractures (for example of the hip and femur) are the most frequent falling-related injuries in the elderly and are considered major since they are associated with increased mortality and morbidity.1

Objectives: To describe the characteristics of adults aged ≥50 years in France experiencing fragility fractures according to the site of fracture.

Methods: A postal questionnaire was sent to 15,000 individuals aged ≥50 years in order to identify and characterise subjects with a history of fragility fracture. Subjects were asked whether they had experienced a fracture in the previous 3 years and, if so, how many. Fractures were classified according to site into major (shoulder, vertebrae, pelvis, hip or femur and ≥3 ribs) or minor (other sites).1

Results: Of the 13,914 subjects returning the questionnaire, 425 (3%) reported ≥1 fragility fracture. The fracture rate history in the previous year was 1.4% [95%CI: 1.2–1.6], this rate was higher in women (2.0%) than in men (0.7%) and increased with age. 147 subjects reported major fractures and 287 subjects minor fractures. Most fractures (82.4%) resulted from falling over. The most frequent major fracture sites were the humerus (10.6% of all fractures), vertebra (8.1%) and hip (7.1%). The most frequent minor fracture sites were the forearm/wrist (24.7%) and ankle (17.7%). 25 subjects reported ≥1 fractures and were excluded from further analyses. Subjects with a history of major fractures were older (<p>0.01) than those with minor fractures (72:61±13 vs. 67:1±10.6 years; <p>0.01). Distribution of gender, body mass index and comorbidities did not differ between fracture type groups. Current obesity was, however, associated with a higher rate of previous fracture of the lower limb. Subjects with a history of major fractures reported a significantly greater loss in height since the age of 20 (p<0.01) than those with a history of minor fractures (-3.9±2.35 vs. -2.7±2.02 cm). Subjects who reported lifetime corticosteroid use for ≥3 months more frequently reported major fractures than minor fractures (odds ratio: 1.90 [1.13;3.18], as did post-menopausal women (odds ratio: 4.64[1.06;20.43]) and women using oestrogen-based hormone replacement therapy (odds ratio: 1.86 [1.06;3.29]). Parental fracture history, a history of falls, excess alcohol consumption or active smoking, and use of drugs that may increase risk of falls (antidepressants, antiepileptic drugs) were not associated with the type of fracture.

Conclusion: Extrapolated to the total French population, >340,000 people aged ≥50 years would be expected to experience a fragility fracture each year. One third of these fractures are major. Characteristics found to be associated with the severity of the prior fracture were older age, corticosteroid use, post-menopausal status and use of oestrogens. Limitations of the study include retrospective data collection, risk of recall bias, lack of ascertainment of fracture history and failure to capture subjects in residential care or who had died since the fracture.

THE PREVALENCE OF RHEUMATOID ARTHRITIS IN CHILE, A STUDY PERFORMED AS PART OF THE NATIONAL SURVEY HEALTH (ENS 2016-17)

Joselina Duran1, Loreto Massaró2, Carolina Llanos3, Sergio Iacobelli4, Paula Burgos5, Raquel Arquilla6, Maria Eugenia Martinez7, Natalia Cristostomo7, Alvaro Cisternas3, Paula Margozzini8, ENS2017, Pontificia Universidad Católica de Chile, Santiago, Chile; Universidad San Basilio, Santiago, Chile; Pontificia Universidad Católica de Chile, Santiago, Chile; Clínica Santa María, Santiago, Chile; Universidad de la Frontera, Temuco, Chile.

Background: Genetic and environmental backgrounds influence the development of rheumatoid arthritis (RA) and its frequency has regional variations. In Latin America epidemiologic data are scarce.

Objectives: We aimed to determine the prevalence of RA in Chile as part of the National Health Survey (ENS, Encuesta Nacional de Salud).

Methods: ENS was a cross-sectional household survey with a stratified multistage probability sample of 6,233 participants performed between August 2016 and March 2017. A screening instrument for RA was applied to a random sample of 3,700 subjects >30 years old.1 Positive screening was defined by at least one of the following: (i) 2 swollen joints for at least 4 consecutive weeks (past or present) and/or (ii) a diagnosis of arthritis in the past. Individuals with positive screening had Rheumatoid Factor, Anti-citrullinated protein antibodies, and C-reactive protein measured and clinical examination was performed by a rheumatologist. Self-report of doctor-diagnosed RA was also performed.

Results: The screening questionnaire was applied to 2,998 subjects. Seven hundred and thirty-eight (22.1%) had a positive screening. Among the subjects with a positive screening 493 (66%) had consulted a rheumatologist. Thirty-one subjects had RA according to the ACR/EULAR 2010 classification criteria, which corresponds to 0.6% (95%CI 0.3, 1.2). Two point three per cent reported having RA. Prevalence was higher in women and in high SES.

Conclusion: According to this national population-based study RA prevalence in Chile is 0.6% (0.3, 1.2). This is similar to the prevalence previously reported in developed countries, which is noteworthy given the differences in sociodemographic characteristics which exist compared to Chile. Self-reporting leads to an important overestimation of RA. Our study suggests there is a higher risk of RA in subjects with high SES in this region.

SAT0609 WOMEN WITH METABOLIC SYNDROME AND GENERAL OBESITY ARE AT HIGHER RISK FOR SIGNIFICANT HYPERURICEMIA THAN MEN: RESULTS FROM THE 2016 KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY

Yeonghee Eun1, In-Yeong Kim2, Eun-Jung Park3, Ji-Yeong Choi4, Kyung-Do Han2, Hoon-Suk Cha1, Eun-Mi Koh1, Hyung Jin Kim1, Jangjeon Lee1. 1Sungkyunkwan University College of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 2National Police Hospital, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 3Seoul Medical Center, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 4Bundang Jesaeng Hospital, Department of Medicine, Seongnam, Korea, Rep. of (South Korea); 5College of Medicine, The Catholic University of Korea, Department of Biostatistics, Seoul, Korea, Rep. of (South Korea)

Background: Hyperuricemia is emerging as a potential biomarker and a predictor for metabolic syndrome (MetS) and its related complications.

Objectives: We aimed this study to investigate the risk factors of hyperuricemia, particularly, the association of hyperuricemia with MetS and general obesity.

Methods: We performed multivariate logistic regression analyses using the 2016 Korea National Health and Nutrition Examination Survey (KNHANES) data collected in a representative sample of Korean adults. Hyperuricemia was defined by serum uric acid level >7.0 mg/dl for men and >6.0 mg/dl for women. General obesity was based on body mass index (BMI) >25 kg/m².

Results: Among a total of 5,591 Korean adult participants, 685 (12.3%) individuals were classified as having hyperuricemia. Hyperuricemia was significantly associated with MetS in men (Odd ratio (OR): 1.74, 95% CI: 1.29-2.34) and women (OR: 2.47, 95% CI: 1.55-3.93) after adjustments for age, sex, smoking, alcohol, exercise, BMI and estimated glomerular filtration rate (eGFR). General obesity was also independently related to hyperuricemia in both sex (OR: 1.70, 95% CI: 1.31-2.19 in men, OR: 3.73, 95% CI: 2.57-5.41 in women). Among the components of MetS, elevated blood pressure, elevated triglyceride and reduced HDL-cholesterol in men, and increased waist circumference, hyperglycemia, elevated triglyceride in women were risk factors for hyperuricemia. In subgroup analyses, the presence of concomitant MetS and general obesity posed strikingly higher risk for hyperuricemia among women (OR: 7.24, 95% CI: 4.56-11.50 in women, versus, OR: 2.90, 95% CI: 2.12-3.96 in men) when compared to individuals free of neither conditions (OR: 1.00, referent). In addition, the risk of hyperuricemia has increased up to 6-fold by the presence of MetS and general obesity among young adults aged less than 40 years old.

Conclusion: Hyperuricemia was independently associated with MetS and general obesity, regardless of sex. These increases in risk of hyperuricemia were more prominent in women. Among women, those who had both MetS and general obesity were at nearly 7-fold increased risk for hyperuricemia compared to those without both conditions. It may be considered to incorporate hyperuricemia as one of the components of MetS.

SAT0610 THE DELPHI METHOD IN RHEUMATOLOGY RESEARCH: ARE WE DOING WELL?

Daniel G. Fernandez-Julva1, Maria Rojas2, Diego Rosello1. 1Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Internal Medicine – Rheumatology, Bogota, Colombia; 2Pontificia Universidad Javeriana, Clinical Epidemiology and Biostatistics, Bogotá, Colombia

Background: Delphi method is an iterative process, designed to combine the opinion of a group of experts within a consensus. It is a structured methodology to systematically collect expert judgments about a problem, process the information and finally build a general group agreement. It has 4 defining characteristics: iterative, anonymous process, generates feedback and generates a consensus.

Objectives: To evaluate the methodology and application of the Delphi method in rheumatology research.

Methods: Search of the literature was performed in the MEDLINE, EMBASE, Clinical key and Scielo databases. MESH terms “Delphi Technique”, “Rheumatology” and “Rheumatoid arthritis” were used, finding 404 articles. A total of the abstracts of these studies was read, discarding duplicates, articles of consensus methodology different from the Delphi technique and articles from studies of other specialties. The consultation was held on 30-10-18.

Results: 109 articles were found. Journal with highest number of publications was Clinical Rheumatology (30 articles), followed by Journal of Rheumatology (11 articles), Rheumatoid arthritis was the first rheumatic diseases studied in 21.1% (n=23), followed by psoriatic arthritis in 11% (n=12). Only 16.5% (n=18) of the studies met the 4 characteristics of the Delphi method, 31.2% (n=34) met 3 characteristics, 18.3% (n=20) met 2 characteristics and 39.9% (n=37) meets only one of the defining characteristics of the method. Feedback was made in 43.1% (n=47) of the studies. Process was iterative in 64.2% (n=70) of papers. The coordinating group of the exercise was only reported in 27.5% (n=30), with an average of 8 (± 3.14) coordinators for each study. The group of experts was reported in 90.6% (n=102) of the studies, with a median of 28 (interquartile range: 54) experts per study. In 30.4% (n = 45) of the studies, the way in which communication with the group of experts was established was not reported. The modification of the Delphi technique was declared in 14.9% (n = 22) of the studies, however, in 18 of these studies it is not explained what was the modification of the technique; in 4 studies, the modification consisted of holding a face-to-face meeting of the group of experts after the consultation rounds; one of the studies clarifies having made a "RAND/UCLA" method without explaining in more detail what this method consists of. To refer to the modified versions of the method, terms such as "informal Delphi" or "Delphi like study" are coined, without further considerations or clarifications to what these mean.

Conclusion: Use of Delphi technique in rheumatology has not been carried out following the original methodology in most of the evaluated works, which puts at risk the validity of the results of these studies. Propening for the correct use of the technique, will improve the validity of the results obtained with this type of qualitative research. It is necessary to establish and validate minimum compliance criteria, so that an expert consensus exercise through the Delphi method achieves its purpose in a valid way. This context allows to open a line of methodological research in evaluation of the application of the Delphi methodology in the health area.

SAT0611 PREVALENCE OF HYPOTHYROIDISM WITH THERAPEUTIC INDICATION IN PATIENTS WITH RHEUMATOLOGICAL DISEASES

Sho Fukugi, Yukihiko Ikeda, Haruki Sawada, Mitsuhiro Watanabe, Ayako Kido, Rui Imai, Masei Suda, Haruyuki Yanaska, Hisanori Shimizu, Ryo Rokutanda, Hiroshi Tamaki, Tokutaru Tsuda, Kenichi Yamaguchi, Mitsumasa Kishimoto, Masato Okada. St. Luke’s International Hospital, Immuno-Rheumatology Center, TOKYO, Japan

Background: Hypothyroidism is known as a common complication of rheumatological diseases(RD). Thyroid hormone supplementation is important not only in clinical hypothyroidism but subclinical one for cardiovascular events in the future. But the data about prevalence of hypothyroidism requiring treatment and it’s changes with follow up in patients with RD is limited.

Objectives: To reveal the prevalence and risk factors of hypothyroidism, especially which requires thyroid hormone supplementation, in patients with RD and compare it with that of general population.

Methods: We retrospectively reviewed charts of RD patients and healthy controls in preventive medicine center, at St. Luke’s International Hospital from January 2004 to July 2018. We investigated basic demographics, underlying diseases, blood tests including thyroid functions and treatment with thyroid hormones. We compared the number of hypothyroidism requiring treatment (Thyroid stimulating hormone: TSH ≥10 μIU/mL or physician started treatment) and it’s changes in follow up using univariate analysis and Kaplan–Meier method with log rank test. Cox proportional hazard model was performed for evaluating the risk of hypothyroidism which needs treatments in all patient and only RD patients.

Results: 2307 RD patients and 78251 controls without past medical history of hypothyroidism with therapeutic indications are included. Newly-detected hypothyroidisms requiring treatments are significantly frequent in

</tbody>
</table>

Conclusion: Hypothyroidism with therapeutic indication is more frequent in RD patients, even if screening TSH is within normal range. We encourage active routine measurement of thyroid function tests in patients with RD, especially with above risk factors.

FREQUENCY OF POLYAUTOIMMUNITY IN A TERTIARY HOSPITAL

Elena Grau García, Jose Ivorra Cortés, Jorge Juan Frago-Gil, Roxana González Mazzaro, Marta De la Rubia Navarro, Cristobal Pávez Perales, Paloma Valentina Castillo Dayer, Cristina Alcañiz Escardellí, Inmaculada Chalmeta Verdejo, Luis González Puig, Isabel Martínez Cordelá, rosa Negueruelos Albuixech, Jose Eloy Oller Rodriguez, Francisco Miguel Ortiz Sanjuan1, Elvira Vicens Bernabeu, Carmen Nájera Herranz2, Inés Cánovas Olmos3, Borja García Sousa4, Jose Andrés Román Ivorra5,6,7,8,9,10 Rheumatology Department, HUP La Fe, Valencia, Spain, 5Medical School, UCV, Valencia, Spain, 6Rheumatology Department. H. Virgen de la Arrixaca, Murcia, Spain

Background: Polyautoimmunity (PAI) is the presence of more than one Autoimmune Disease (AID) in one patient. PAI have been reported in different AIDs as systemic lupus erythematosus (SLE) (33-45%), rheumatoid arthritis (RA) (13-23%), systemic sclerosis (SSc) (10-43%) or Sjögren Syndrome (SS) (32-52%). On the other hand, Multiple Autoimmune Syndrome (MAS) where three or more AIDs coexisting in one patient has been reported.

Objectives: To determine PAI frequency in the context of AIDs reported in a tertiary hospital.

Methods: Cross-sectional observational study with systematic revision of patients’ electronic clinical records with AIDs (from 2014 to 2018). We selected those patients who had two or more diagnosis of AIDs. Demographic, clinical and immunological data were collected.

Results: Of 1854 patients with AIDs, 96 (5.17%) had PAI. Mean age was 56±15 years and 93.75% were female. 7 patients from the 96 (0.4%) also had MAS.

The mean age at diagnosis of the first AID was 39.03±15.93 years and median age at diagnosis of the second AID was 48.16±15.04 years. A mean difference of 9.17±10.18 years between first and second AIDs debut was observed.

The most frequent AIDs registered are shown in table 1.

Table 3. Frequency of Polyautoimmunity by diseases

Conclusion: A 5.17% frequency of patients with PAI in our group of AID diseases in PAI cases were RA-SS, APS-SLE and SS-SLE. We also observed the coexistence of a MAS in 0.4% of patients.

REFERENCES
found a rather lower frequency compared with those published in the literature, possibly due to the putative bias of retrospective studies and the geographical differences of PAI patients.

SAT0613 CHANGING TREATMENTS AND OUTCOMES FOR JUVENILE IDIOPATHIC ARTHRITIS: INITIAL FINDINGS FROM A NEW CANADIAN INCEPTION COHORT
Jaime Guzman, Michelle Battish, Roberta Berard, Roxana Bolaria, David Cabral, Gaëlle Chédeville, Ciaran Duffy, Kerstin Gerhold, Tommy Gerschman, Adam Huber, Jean-Philippe Proulx-Gauthier, Alan Rosenberg, Dax Rumsey, Heinrike Schmeling, Natalie Shiff, Gordon Soon, Lori Tucker. Canadian Alliance of Pediatric Rheumatology Investigators, Vancouver, Canada

Background: Treatments for juvenile idiopathic arthritis (JIA) are changing rapidly. Healthcare providers and families require up-to-date knowledge of current treatment practices and expected outcomes to inform their decisions.

Methods: A new investigator-driven Canadian Alliance of Pediatric Rheumatology Investigators (CAPRI) JIA Registry was started in February 2017 to prospectively collect information on children enrolled within 3 months of JIA diagnosis. Information about disease activity, treatments, outcomes and adverse events is collected at all clinic visits. Registry data were extracted in October 2018 and clinical characteristics at presentation, use of anti-rheumatic medications, attainment of inactive disease, cJADAS10 scores and adverse events were described. Selected findings were compared to those observed in the ReACCh-Out cohort. The proportion of patients (cumulative incidence) receiving various treatments and their outcomes were estimated with Kaplan Meier survival methods.

Results: A total of 166 patients enrolled a median of 6 weeks after diagnosis at 10 centres were included. Median age at diagnosis was 9 years (IQR 3, 13), 61% were female and 51% had oligoarthritis. At enrolment, subjects had a median of 2 active joints (IQR 1, 3), a Physician Global Assessment of 3 (1.5, 4) and a Parent Global Assessment of 1 (0, 3). The median cJADAS10 score was 6.5 (4, 10). Table 1 compares baseline characteristics and the cumulative incidence of medication use and inactive disease at one year after diagnosis with those observed in the ReACCh-Out cohort, diagnosed on average 10 years earlier. Figure 1 shows the Kaplan Meier curves for attainment of inactive disease.

Conclusion: In Canada, treatments for newly diagnosed patients with JIA have intensified in the last 10 years, and 35% will now start their first biologic within 1 year of diagnosis. Short-term outcomes have improved, 81% of current patients now attaining inactive disease within one year of diagnosis. Funding: The Arthritis Society, Canada.

Background: Tumour necrosis factor inhibitors (TNFi) are efficacious in patients with psoriatic arthritis (PsA), but some patients switch to a different TNFi because of adverse events (AE) or lack of effect (LDE). The EuroSpA Collaboration has previously demonstrated a 1-year retention rate of 77% and 6 months LUNDEX adjusted 28-joint count Disease Activity Score (DAS28) remission rates of 45% in patients with PsA initiating the first TNFi treatment. Little is known about the effectiveness of switching to a second and third TNFi in patients with PsA.

Objectives: Firstly, to investigate retention and remission rates at 6, 12 and 24 months in patients with PsA initiating the 2nd and 3rd TNFi in clinical practice across Europe. Secondly, to investigate whether the outcomes are associated with the reason for withdrawal (AE or LDE) from the previous TNFi-treatment.

Methods: Prospectively collected data on PsA patients in routine care from 12 European registries were included. Kaplan-Meier estimation was used to investigate TNFi retention rates. LUNDEX adjusted remission rates were calculated for DAS28<2.6 and 28 joint Disease Activity index

Heiland: None declared.

The overall retention rates for 2nd and 3rd TNFi at 12 months were 69% (67-70%) and 66% (64-68%), (2nd vs 3rd p=0.053), respectively (Figure). Corresponding retention rates for the individual registries ranged from 48-100% and 49-91%, respectively. If patients had stopped the 1st TNFi due to AE or LOE, 12-month retention rates for the 2nd TNFi treatment were 66% and 65%, respectively. In patients who stopped the 2nd TNFi due to AE or LOE, 12-month retention rates for the 3rd TNFi treatment were 65% and 63%, respectively.

For the 2nd and 3rd TNFi, 6 months LUNDEX adjusted DAS28 remission rates were 35% and 27% (p<0.001), respectively, and for DAPSA28 remission 14% and 10% (p=0.008) (Table).

Conclusion: The EuroSpA Collaboration demonstrated decreasing retention and remission rates with increasing number of previous TNFi, although with only minor difference between 2nd and 3rd. Patients who had withdrawn from the previous TNFi due to LOE had retention rates and remission rates similar to those who had withdrawn due to AE.

Background: In rheumatoid arthritis (RA), cigarette smoking affects both rheumatoid factor (RF) and anti-citrullinated cyclic peptide/protein antibody (ACPA) formation, but its association related to HLA-DRB1 alleles, especially shared epitope (SE) alleles, have been controversial among different races. Furthermore, the impact of cigarette smoking and its cessation on levels of RF and ACPA have not been well documented.

Methods: A total of 6,239 subjects from two independent Japanese cohorts were enrolled. Their precise smoking histories both before and after the onset of RA were collected in questionnaires. The latest RF and ACPA levels were used (mean disease duration 15.6 years). We defined top quadrant of levels of RF or ACPA as high levels. Associations between smoking status and positivities or high levels of ACPA or RF as well as effects of HLA-DRB1 alleles on the associations were investigated by multiple logistic regression models.

Results: Smoking at onset was an independent risk factor of not only RF and ACPA, odds ratios (OR) 1.31, 95% CI 1.22-1.41, but also high levels of these autoantibodies, especially RF (OR 2.06, 95% CI 1.26-1.85, p = 1.8 x 10^-5; ACPA, OR 1.39, 95% CI 1.09-1.76, p = 6.8 x 10^-3), but their odds ratios decreased over time. The risk of RF positivity and its high level was apparent only in the presence of SE alleles (Table below).

Conclusion: Cigarette smoking especially at RA onset is a significant risk factor of future high levels of ACPA and RF preferentially in males, and RF is more sensitive to smoking status than ACPA. The effect of cigarette smoking was significantly larger in males than in females. The patients who quit smoking before onset had no longer significant risks of high autoantibody levels compared to subjects who had never smoked (RF, OR 1.33, p = 0.059; ACPA, OR 1.19, p = 0.013) and the risk was gradually attenuated depending on cessation years (RF, 0-10 years OR 1.34, 10-20 years OR 1.21, > 20 years OR 1.06; ACPA, 0-10 years OR 1.38, 10-20 years OR 1.01, > 20 years OR 1.12). The effect of smoking on ACPA positivity and its high level was apparent only in the presence of SE alleles, while the effect on RF positivity and its high level was apparent despite the presence of SE alleles (Table below).

DIETARY HABITS OF SIX AUTOIMMUNE DISEASES IN THE SPANISH POPULATION: A CROSS-SECTIONAL STUDY

Background: In the last years multiple genetic variants have been associated with autoimmune disease (AD) risk. However, much less is known about the association with important environmental factors like diet.

Objectives: The objective of the present study is to characterize the dietary patterns of six prevalent ADs, including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE).

Methods: A cross-sectional cohort of 11,621 individuals from Spain encompassing 1,949 RA, 2,186 Psoriasis (PS), 1,437 PsA, 699 SLE, 1,415 ulcerative colitis (UC), 1,952 Crohn’s disease (CD) and 1,983 atopic dermatitis (AD) cases were recruited. Together with presenting demographic data, lifestyle factors and smoking status, lifestyle factors were grouped into comprehensive dietary patterns using a novel approach combining multiple linear regression analyses to identify a few groups among 116 available dietary variables. The resulting dietary patterns were tested for association with disease status using multivariate linear models.

Results: Patients with AD targeting the digestive system showed the largest differences in comparison to controls. In the rheumatic ADs several food categories were also found to be consumed differently compared to controls. In PsA the dietary pattern differences with controls

PROGRESSION IN RHEUMATOID ARTHRITIS INFLAMMATORY BURDEN ON CORONARY PLAQUE ANTIBODIES MODERATES THE EFFECT OF

Antonio Julià1, Sergio Hilario Marín2, Marc'el Reinert3, Daniel Roig4, Carmen Gómez1, Ana Bolaños5, Miguel A. Carrasco1, Antonio Julià1, Sergio Hilario Marín2, Marc’el Reinert3, Daniel Roig4, Carmen Gómez1, Ana Bolaños5, Miguel A. Carrasco1

Background: Beta2-glycoprotein-1 (b2GPI), an apolipoprotein abundant in human plasma, is readily expressed in human atherosclerotic plaques. High frequencies of anti-b2GPI-IgA antibodies have been previously reported in both Rheumatoid arthritis (RA) patients and controls; their presence has been independently predictive of cardiovascular events in general populations.

Objectives: We explored the role of a-b2GPI-IgA presence and their interaction with inflammatory load on occult coronary plaque progression in patients with RA.

Methods: One hundred-one participants with a baseline plaque evaluation with coronary computed tomography angiography (CCTA) underwent follow-up assessment within 23±3.6 months. Coronary artery calcium (CAC) was quantified by the Agatston method. Subclasses (IgG, IgM, and IgA) of a-b2GPI Ab, antiradiliprotein-Ab (ACL) and lupus anticoagulant (LA) were assessed on the day of baseline CCTA and reconfirmed 12 weeks later, if positive. Serum interleukin-6 (IL-6) was measured at baseline scan, while CRP was assessed on every clinic visit from baseline through follow-up scan. Multivariate linear regression models evaluated predictors of CAC progression; predictors entered as continuous variables included baseline CAC, age, waist-to-height ratio (obesity index), cumulative prednisone dose, years exposure to bDMARDs, statins and baseline IL-6 or time-averaged CRP. Gender, diabetes, hypertension, dyslipidemia, and a-b2GPI-IgA positivity were entered as dichotomous independent variables. Specific interactions between a-b2GPI-IgA presence (predictor) and time-averaged CRP or baseline IL-6 (moderator) where explored; the conditional effects of the predictor at values of the moderator and significant CAC regions were defined with the John-Neyman test.

Results: A-b2GPI-IgA antibodies were highly prevalent (34.7%) in contrast to other antiphospholipid-Ab subclasses (<4%). A-b2GPI-IgA presence predicted incident CAC [OR=3.69 (1.02-13.32), p=0.046] as well as greater CAC change from baseline, after adjustments for age, baseline CAC score and significant covariates [mean change (95%CI) = 93.2 (69.8-116.6) vs. 56.0 (39.0-73.0) units, p=0.012]. A significant interaction between a-b2GPI-IgA positivity and time-averaged CRP as well as baseline IL-6 on CAC progression was observed [beta=-0.19, p=0.048 for time-averaged CRP and beta=-0.26, p=0.029 for IL-6 respectively]; higher baseline IL-6 and time-averaged CRP associated with significant CAC progression exclusively in a-b2GPI-IgA positive patients but not in negative ones (figure 1).

Conclusion: A-b2GPI-IgA antibodies independently contributed to occult coronary plaque progression in RA and specifically moderated the effect of inflammation on progression of atherosclerotic burden. Tight control of inflammation may be particularly important in Ab positive patients in order to prevent coronary plaque progression; additionally, a-b2GPI-IgA presence may serve as a predictive biomarker for atherosclerosis progression, especially in the context of higher inflammatory state.

SA0618 BASELINE CHARACTERISTICS AND TREATMENTS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: THE CREDIT STUDY IN CHINA, 2016-2018

Nan Jiang1, Mengtao Li*, Yanhong Wang1, Jiuliang Zhao1, Qiawang Wang1, Xinping Tian1, Hanjun Wu3, Max Xiao2, Lujing Zhan2, Xiaofeng Zeng1, Nan Jiang1, Mengtao Li*, Yanhong Wang1, Jiuliang Zhao1, Qiawang Wang1, Xinping Tian1, Hanjun Wu3, Max Xiao2, Lujing Zhan2, Xiaofeng Zeng1

Background: Rheumatoid Arthritis (RA) has been a huge public health issue among the Chinese population, but little is known about the current treatments among RA patients, especially with different disease activity levels.

Objectives: To describe the baseline characteristics among all RA patients registered in the Chinese Registry of rhEumatoID arthritis (CRedit) and the treatment patterns by patients’ disease status.

Methods: A total of 25,191 RA patients registered in CREDIT from Nov, 2016 to Apr, 2018 were enrolled. Patients’ baseline characteristics of demographics, disease characteristics, comorbidities, as well as treatment agents for RA were abstracted for analysis.

Results: The mean age of patients was 53.0 years and 79.9% of them were female. The median disease duration from diagnosis was 2.0 years. The proportions of moderate/high disease activity according to the Disease Activity Score 28 (DAS28-CRP<3.2) and Clinical Disease Activity Index (CDAI>10) were 76.1% and 87.1%, respectively. Among those patients with treatment records, a similar conventional systematic disease-modifying antirheumatic drugs (cDMARDs) usage was observed in remission/low activity patients and

SAT0619 ATTITUDES AND PERCEPTIONS OF PHYSICAL ACTIVITY IN PATIENTS WITH SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW

Stephen Morsia1, Shao-Hsien Liua2, Kate Lapane2, Jonathan Kaya1

1UMass Memorial Medical Center and University of Massachusetts Medical School, Division of Rheumatology, Department of Medicine, Worcester, United States of America; 2University of Massachusetts Medical School, Population and Quantitative Health Sciences, Worcester, United States of America

Background: Patients with arthritis are less likely to adhere to physical activity recommendations than are individuals in the general population. In contrast to rheumatoid arthritis (RA), which affects predominantly peripheral joints, axial spondyloarthritis (axSpA) affects predominantly the axial skeleton and may result in restricted spinal mobility. Both RA and axSpA are associated with an increased risk of cardiovascular disease, the development of physical disability, and decreased levels of physical activity. However, the extent to which the distinct joint distributions in these forms of inflammatory arthritis might differentially affect physical activity behaviors is not known. Several studies have addressed the relationship between “physical activity behavior” and “disease-specific outcomes” among patients with RA, but information about this among patients with axSpA is more limited.

Objectives: To review systematically and synthesize qualitatively the literature about perceived facilitators and barriers to physical activity in patients with axSpA and identify the types of physical activity preferred by these patients.

Methods: PubMed and Scopus and reference lists were searched for quantitative and qualitative studies reporting on beliefs towards exercise activity among patients with axSpA. Searches were limited to studies published from 2000 through 2018. The PRISMA guidelines were followed. Systematic searches identified 125 publications which underwent a title, abstract, or full-text review. Studies were excluded if articles were not in English or did not include original data. We summarized the methodologic quality using modified criteria for quantitative and qualitative studies.

Results: Eight quantitative and three qualitative studies met eligibility criteria, with variable study quality. Based on self-reported data, 50% to 68% of patients with axSpA have engaged in swimming or water exercise, while most common forms reported, intrinsic factors such as motivation and improvement in symptoms and health were commonly reported as facilitators associated with physical activity/exercise. Barriers included lack of time, fatigue, and symptoms such as pain.

Conclusion: Up to half of patients with axSpA do not meet established physical activity recommendations. Given the potential for regular physical activity to reduce symptom burden in this patient population and the recent 2018 EULAR recommendations for regular physical activity as part of the management of these patients, more rigorous studies of physical activity behaviors and attitudes will be useful to inform interventions and promote exercise among individuals with axSpA.

SAT0620 INCIDENCE AND TREND OF HIP FRACTURE IN SPAIN, FACTORS ASSOCIATED WITH THE VARIABILITY OBSERVED

Ramón Mazcuñach,1 Elia Perez-Fernandez2, Miguel Angel Tejedor3, Javier Quintaín,4 Natalia Crespi-Villarías,5 Alberto García-Vadillo6, Raquel Almudovar1, Pedro Zarco-Montepé1,2,2Hospital Universitario Fundación Alcorcón, Rheumatology, Alcorcón, Spain; 3Hospital Universitario Fundación Alcorcón, Clinical Investigation Unit, Alcorcón, Spain; 4Hospital Universitario Fundación Alcorcón, Allergy, Alcorcón, Madrid, Spain; 5Health Center Rivolta, Alcorcón, Spain; 6Hospital de La Princesa, Rheumatology, Madrid, Spain

Background: It is known that in Spain there is a great variability between Autonomous Communities (CCAA) in the incidence and trend of hip fracture, with rates in certain regions that can double those of others. Although it is speculated with different hypotheses that explain it, there are no studies that demonstrate the reasons for this variability.

Objectives: 1.- To analyze the incidence and trend of hospital admissions for hip fracture, in Spain, during the period between 1999 and 2015. 2.- Analyze factors/risk markers (genetic, demographic, level and living conditions, health indicators, cohort effect centered on the period of the civil war, climatology and environment) that could explain the variability in incidences and trend between different CCAA.

Methods: Part 1: retrospective observational study, nationwide, based on the exploitation of an administrative database (MBDS) that collects hospital admissions from 1/1/1999 to 12/31/2015. Hip fractures were identified through the presence of ICD-9-CM 820.0 to 820.9 as primary or secondary diagnosis. Only those that the patient was 50 or older were selected. The crude rates and adjusted for age of incidence of hip fracture were calculated, by sex, age groups and by CCAA. The population census issued by the National Institute of Statistics (INE) was used to calculate this rate. The trend over the 17 years covered in the study was analyzed using Poisson regression and negative binomial models.

Part 2: ecological study, based on the analysis of the results obtained in part 1, with different risk markers obtained from the INE (except the 4), by CCAA. The analyzed factors were: 1.- Genetic; 2.- Demographic; 3.- Level and conditions of life; 4.- Health; 5. Impact of the civil war. 6.- Environment; 7.- Climatological. This analysis was performed using bivariate correlations and univariate and multivariate linear regression.

Results: There were 744,848 patients diagnosed with hip fracture: 182,205 (24.4%) men and 562,643 (75.5%) women p <0.001. (Ratio M: V of 3.07). The mean age was 81.7 years (SD 8.9), 79.3 years (SD 10.3) in men and 82.5 years (SD 8.2) (p <0.001). In-hospital mortality was 27%. The average of the Charlson Index was 0.71 (SD1.14). The rate adjusted for the age of incidence of global hip fracture at the national level was 315.38/100,000 inhabitants * year (95% CI 312.36-317.45), 196.59 (95% CI 166.26-172.39) in men and 434.89 (95% CI 430.66-438.17) in women. By CCAA the incidence of hip fx varied from 213.97 in the Canary Islands to 363.13 in Comunidad Valenciana and Cataluña.

The trend for both sexes was -0.67% (95% CI 0.9990-0.9957) (p <0.001); in men it was -0.06% (95% CI 0.9975-1.0013) (p = 0.537) and
Impact of hindfoot coronal/sagittal alignment on metatarsus primus elevatus in rheumatoid foot deformities

Shinichi Mizuki1, Matsuyama Red Cross Hospital, The Center for Rheumatic Diseases, Matsuyama, Japan

Background: Typical foot deformity patterns of patients with rheumatoid arthritis (RA) include hallux valgus, claw toes, splay foot, flat foot, and hindfoot valgus deformities. However, some patients show deformities different from a typical pattern, including metatarsus primus elevatus, described as dorsal elevation of the first metatarsal in relation to the lesser metatarsals, as we reported previously. In the report, we speculated that metatarsus primus elevatus might be associated with calcaneal inclination and hindfoot varus alignment. However, there are no studies on the association of hindfoot alignment with metatarsus primus elevatus in patients with RA.

Objectives: To elucidate the impact of hindfoot coronal/sagittal alignment on metatarsus primus elevatus in patients with RA.

Methods: A retrospective study was performed of standing anteroposterior and lateral radiographs of 81 feet in 53 patients who underwent surgical treatment for metatarsalgia in our hospital. The distance between the dorsal cortical bones of the first and second metatarsals (MPE) was measured using a two-dimensional coordinate system on the lateral radiographs of 81 feet in 53 patients who underwent surgical treatment for metatarsalgia in our hospital. The distance between the dorsal cortical bones of the first and second metatarsals (MPE) was measured.

Results: Median MPE was 1.7 mm (interquartile range: 0-5.2 mm). The first metatarsal head, first metatarsal-cuneiform and posterior talocalcaneal joint were shifted dorsally (r=0.70, p<0.01; r=0.57, p=0.01; r=0.42, p=0.01, respectively). No correlation MPE with HVA and M1M5A were observed (r=-0.26, p=0.05; r=-0.25, p=0.07, respectively), however, M1M2A showed correlation with MPE (r=0.52, P<0.01). On the other hand, MPE showed a high degree of correlation with talar declination angle, calcaneal pitch, and NC overlap ratio (r=0.45, p<0.01; r=0.35, p=0.01; r=-0.45, p=0.01, respectively).

Conclusion: In patients with RA, the hindfoot joints shifted dorsally in metatarsus primus elevatus. Moreover, hindfoot varus alignment and high-arched foot affect metatarsus primus elevatus. The results of the present study suggest the importance of evaluating hindfoot alignment when determining surgical treatment procedures for rheumatoid foot deformities.

SERUM URIC ACID LEVELS WERE INDEPENDENTLY ASSOCIATED WITH AORTIC ARCH CALCIFICATION IN MIDDLE-AGED AND ELDERLY CHINESE POPULATION

Wei Yan1, Aishu Luo1, Shiyu Lin1, Jiayang Li1, Fang Wang2, Vittorio Grosso: University, Nanjing, China

Disclosure of Interests: None declared, Carlomaurizio Montecucco Speakers bureau: AbbVie, Bristol-Myers Squibb, Celgene, Roche, Genzyme, Lilly, MSD, Pfizer. UCB, Vittorio Grosso: None declared, Barbara Vitolo: None declared, Silvana Quaglini: None declared, Carlon-switzerland Montecucco Speakers bureau: AbbVie, Bristol-Myers Squibb, Celgene, Roche, Genzyme, Lilly, MSD. Pfizer. UCB, Vittorio Grosso: None declared.

Background: Aorta calcification are considered markers of subclinical atherosclerotic disease that are independent predictors of subsequent cardiovascular events. A growing number of studies have shown that serum uric acid is associated with the development of cardiovascular diseases.

Objectives: The main purpose of this study was to investigate the prevalence of aortic calcification and to determine the relationship between the levels of serum uric acid and aorta calcification in the middle-aged and elderly population.

Methods: From Jan 2018 to Dec 2018, totally 6152 consecutive participants aged ≥50 years old underwent annual health survey were included in this study. Detailed physical examination was performed as well as a thorough review from structured questionnaires, which in baseline demographics and medical history including alcohol consumption, smoking and physical activity status, BMI, blood pressure, blood glucose and serum lipid were all collected and recorded. Aortic calcification was analyzed by chest X-ray. All data were analyzed retrospectively.

Results: The prevalence of aortic arch calcification was 13.9% in these 6152 participants with age >50 years and was equally common in men and women. Aortic arch calcification prevalence was significantly increased in populations with hyperuricemia (defined as serum uric acid ≥ 420 umol/L), as compared with populations with normal serum uric acid levels (defined as serum uric acid ≤ 420 umol/L) (83.39% vs. 16.61%, p < 0.001). Participants were divided into three groups according to their uric acid levels: A more prevalent aortic arch calcification was identified in high uric acid level group than those in middle or low uric acid level group (p < 0.05). On logistic regression analysis, serum uric acid levels were found to be independently associated with aortic calcification (OR=1.469, 95%CI: 1.199-1.800, P<0.01) in these participants.

Conclusion: Serum uric acid levels were independently associated with aortic arch calcification in middle-aged and elderly Chinese population. These results may suggest the need for more aggressive actions for urate lowering therapy in middle-aged and elderly hyperuricemia patients, especially in patients coexist with other cardiovascular disease risks.

SAT0624 VALIDATION PROCESS OF CASES OF RHEUMATOID ARTHRITIS IN A LARGE PROSPECTIVE COHORT OF FRENCH ADULT WOMEN: THE E3N COHORT

Yann Nguyen1,2, Carine Salitt1,3, Gaëlle Gusto1, Elise Descamps1, Xavier Mariette1,4, Marie-Christine Boutron-Ruault1, Raphaëlle Seror1,2,4. 1Center for Research in Epidemiology and Population Health – INSERM U1018 – Université Paris Sud, Villejuif, France; 2AP-HP Hôpital Bicêtre, Rheumatology, Le Kremlin-Bicêtre, France; 3Centre Hospitalier Régional d’Orléans, Rheumatology, Orléans, France; 4Université Paris-Sud, Center for Immunology of Viral Infections and Auto-immune Diseases (IMVA), INSERM UMR 1184, Université Paris-Orléans, Le Kremlin-Bicêtre, France

Background: Rheumatoid arthritis (RA) is a complex multifactorial autoimmune disease in which genetic and environmental factors interact in the pathogenesis of the disease to trigger autoimmunity. Except for tobacco smoking, the role of environmental factors has been suggested yet poorly investigated, and results were rarely reproducible. More observational studies are requested to address the question. Cohort studies offer the advantage over case-control studies of having a prospective collection of environmental factors before disease onset, thus avoiding recall bias. However, collected information about disease phenotypes is usually limited, and a rigorous process of case validation is needed.

Objectives: To detect RA cases in a large prospective cohort of healthy French adult women and to assess the performance of the validation methods.

Methods: The French E3N cohort included 98,995 healthy women prospectively followed since 1990. Self-administered questionnaires were sent every 2–3 years to collect medical events, and general, lifestyle, and environmental characteristics. Potential cases of inflammatory rheumatic diseases (IRD), including RA cases, were identified through self-reports in three consecutive questionnaires. Self-reported RA cases were validated with two methods including sending of a specific validation questionnaire and the use of the reimbursement database. The sensitivities and specificities of each method were calculated using as a reference the analysis of available medical records reviewed by a panel of expert rheumatologists.

Results: Among the 3,192 identified potential IRD cases, 964 RA cases were validated, including 698 incident cases and 266 prevalent cases. Of them, 314 (32.6%) had unknown antibody status. Mean age at diagnosis was 57.4 ± 13.9 years (40.9 ± 10.4 years for prevalent cases, and 63.8 ± 9.0 for incident cases). Sensitivities and specificities of the validation methods were 92.2 and 83.7% for the specific validation questionnaire and 69.8 and 97.0% for the reimbursement database.

Conclusion: This study enabled us to detect a large number of RA cases in a large general population prospective cohort of women with acceptable sensitivity and specificity. This will allow investigating a large number of potential endogenous and exogenous risk factors of RA in women.

1EuroSpA Research Collaboration, On behalf of the DANBIO (Denmark), ARTIS (Sweden), SCOM (Switzerland), NOR-DMARD (Norway), ATTRA (Czech Republic), Reuma.pt (Portugal), BIOBADASER (Spain), ROB-FIN (Finland), biorx.si (Slovenia), ICEBIO (Iceland), TURKBIO (Turkey), RBBR (Romania), ARC (Netherlands), BSRBR-AS (United Kingdom), GISEA (Italy), Denmark

Background: The efficacy of Tumour Necrosis Factor Inhibitor (TNFi) in patients with axial spondyloarthritis (axSpA) has been investigated in randomized controlled trials (RCTs) with strict inclusion and exclusion criteria. Patients treated in routine care are more heterogeneous and only ~20-30% of patients receiving TNFi in routine care would have been eligible to be enrolled in the RCTs. This emphasizes the need for real-world observational data as a valuable supplement to RCTs. Studying large patient groups from several European countries would increase the external validity of the results. Particularly, large data sets from patients with non-radiographic axSpA (nr-axSpA) are lacking.

Objectives: To investigate TNFi retention rates at 12 months (primary objective), 6 and 24 months, and response rates at the same time-points in biologic-naïve patients with axSpA from the EuroSpA Research Collaboration. Furthermore, to investigate if findings vary between patients with nr-axSpA and ankylosing spondylitis (AS).

Methods: Data from 12 European quality registries in rheumatology, prospectively collected in routine care, were anonymized and uploaded through the secure Virtual Private Network pipelines to the EuroSpA server. Baseline characteristics were investigated with non-parametric descriptive statistics. TNfi retention rates (Kaplan-Meier statistics), and Ankylosing Spondylitis Disease Activity Score (ASDAS) Inactive disease (<1.3) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) ≤4 were assessed, including LUNDEX adjustment1. For patients initiating 1st TNFi after January 1st 2009, the following sub-cohorts were also included: patients starting 1st TNFi after January 1st 2009, patients starting 1st TNFi after 2009, patients receiving TNFi after 2009, patients with nr-axSpA and AS, patients with nr-axSpA and AS, and patients with nr-axSpA and AS.

Results: Among the 23,956 biologic-naïve patients, 1,492 patients with nr-axSpA and 22,464 patients with AS were included in the analysis. The efficacy of TNFi in axSpA and AS was comparable. However, patients with nr-axSpA had a lower retention rate compared to AS. Retention rates for AS patients were ~70% at 12 months, ~55% at 6 months, and ~45% at 24 months. In contrast, retention rates for nr-axSpA patients were ~60% at 12 months, ~45% at 6 months, and ~35% at 24 months.

Conclusion: TNFi retention rates in biologic-naïve patients with axSpA are lower compared to AS. Further research is needed to investigate factors influencing TNFi retention in nr-axSpA.

studied: patients fulfilling the ASAS criteria for axSpA, the modified New York criteria for AS and ASAS criteria for nr-axSpA.

Results: First TNFi treatment was initiated in 23,956 axSpA patients. Baseline characteristics of the pooled population are shown in the Table. The 12-month retention rate was 83.2% (95%CI: 81.5%-84.7%) across registries (Figure). At 6 months, overall ASAS Inactive disease/ BASDAI<4 scores were: 35% (LUNDEX adjusted: 27%-59%). Percentage of patients initiating 1st TNFi after 2009 and registered with fulfillment of axSpA (ASAS) was 6,087. Ankylosing Spondylitis (modified New York Criteria) was 2,935 and non-radiographic axSpA (nr-axSpA) was 1,178. We observed lower retention rate and marginally lower LUNDEX adjusted response rates in nr-axSpA patients (Table).

Table: Baseline characteristics, treatment and response status of all patients in the axial subgroup (ASAS criteria, modified New York criteria and nr-axSpA).

Conclusion: In routine care ~1/3 of patients with axSpA initiating 1st TNFi treatment were in ASAS inactive disease after 6 months, while 1/3 achieved BASDAI<4. Four out of five patients continued treatment after 1 year. Results were slightly inferior in nr-axSpA as compared to AS.

The influence of Mediterranean diet in rheumatoid arthritis: a monocenter cross-sectional study

Tommaso Schioppo1, Isabella Scotti1, Giuseppe Marano2,3, Patrizia Boracchi2,3, Orazio De Lucia1, Antonella Murgio1, Francesca Ingegno1,2, ASST Pini-CTO, Division of Clinical Rheumatology, Milano, Italy; 2Università degli Studi di Milano, Department of Clinical and Community Health, Milano, Italy; 3Università degli Studi di Milano, Labor of Medical Statistics, Epidemiology and Biometry GA Maccacaro, Milano, Italy

Background: Mediterranean diet (MD) is considered a well-balanced and potentially anti-inflammatory diet characterized by high consumption of olive oil, unrefined cereals, fresh or dried fruit and vegetables, fish, dairy, meat and with a moderate amount of red wine. Currently, there is conflicting data for the benefits of MD in RA, and no enough evidence to support a role of MD in the prevention and treatment of rheumatoid arthritis (RA) [1].

Objectives: The aim of our study was to evaluate the association between MD adherence and disease activity, general health (GH) and comorbidities in patients with RA.

Methods: Consecutive patients with RA (ACR/EULAR Criteria 2010) were enrolled in this cross-sectional study. For each patient, Disease Activity Score on 28 joints (DAS28), Simple Disease Activity Index (SDAI), patient GH and a self-reported questionnaire called MD score [2] were recorded. The association between MD score and the above mentioned variables was assessed through univariate regression models (MD score as response variable and the variables of interest as independent variables).

Results: From each model were reported in terms of: 1) test of association (Likelihood Ratio test, with a Chi-square distribution); 2) for categorical independent variables, estimated differences of mean MD score between groups, with respective 95% CI; 3) for numerical independent variables, estimate of correlation coefficient and regression slope coefficient, with respective 95% CI. All analyses were performed using the R software.

Results: 205 patients (197 Italian) were enrolled: median age at visit 53 (IQR 47-61); age at onset of disease 38 (IQR 31-45); disease duration 12 (IQR 8-17). A high proportion of patients had a low MD score (41% had a MD score <15). Patients with a lower MD score had a significantly higher disease activity (DAS28 >5.1; p=0.007). A significantly lower DAS28 and SDAI were observed in the highest tertile of MD score (p=0.029). Moreover, a significant negative correlation was observed between MD score and DAS28 (r=-0.2; p=0.05). A significant positive correlation was observed between MD score and patient GH (r=0.23; p=0.02). A significant positive correlation was observed between MD score and a self-reported questionnaire called MD score [2] (r=0.22; p=0.03).

Conclusion: Mediterranean diet (MD) is considered a well-balanced and potentially anti-inflammatory diet characterized by high consumption of olive oil, unrefined cereals, fresh or dried fruit and vegetables, fish, dairy, meat and with a moderate amount of red wine. Currently, there is conflicting data for the benefits of MD in RA, and no enough evidence to support a role of MD in the prevention and treatment of rheumatoid arthritis (RA) [1].

**Table 1:** presents the number and percentage of patients with rheumatic diseases accompanied by anxiety or depression. The ratio of probable anxiety was 12% in RA, 14% in SLE, 15% in SS, 16% in AS, 10% in Gout, 11% in OA, 12% in MCTD, 14% in UCTD and 10% in PM/DM. The prevalence of probable depression was 19% in RA, 21% in SLE, 20% in SS, 21% in AS, 17% in Gout, 19% in OA, 21% in MCTD, 18% in UCTD and 16% in PM/DM.

**Conclusion:** SSDM can be used for HADS self-assessments by patients with rheumatic diseases. RA was recorded as the most prevalent condition, followed by SLE. 10% to 20% patients could be classified as probable case of anxiety or depression according to HADS scores. The prevalence of anxiety was usually lower than that of depression in patients with rheumatic diseases in this study.

**Background:** Models predicting outcome in juvenile idiopathic arthritis (JIA) have recently been proposed by Guzman et al. and Rydal et al. Guzman et al. constructed a model for predicting severe disease course derived from the ReACCh-Out study, and Rydal et al. constructed models for prediction of non-remission, functional disability and joint damage.

**Objectives:** To validate methods for prediction of long-term outcome in JIA by testing the ability of Guzman’s model and Rydal’s model to predict severe disease course (the ReACCh-Out outcome) in the Nordic cohort.

**Methods:** The Nordic cohort is a prospective longitudinal multicenter cohort from defined geographical areas of 4 Nordic countries. Children with a baseline and an 8-year study visit were included. Missing data were imputed using low rank matrix factorization3 and a K-medoids algorithm4 was used to identify clusters corresponding to severe disease course in the ReACCh-Out study. With this outcome, the prediction model of Guzman et al. was tested with no re-estimation of parameters. A Receiver operating characteristic (ROC) curve and the corresponding area

**Background:** The patients with chronic diseases such as rheumatic diseases suffer from physical pain and/or disability. In addition, psychological morbidities have also been found in patients with rheumatic diseases. Hospital Anxiety and Depression Scale (HADS) is commonly applied to assess the mental health of patients with rheumatic disease. A Smart System of Disease Management (SSDM) is a mobile application which has two application systems for both patients and doctors for rheumatic diseases management. The patient application system provides functions including self-assessment, medication management, adverse events management and laboratory records. After input by patients, all the data will be synchronized to the mobile terminal for further analysis. The HADS self-assessment data could be extracted from the mobile terminal for further analysis. The HADS self-assessment results can be shared with the rheumatologists. Based on these data, rheumatologists can evaluate and follow up with their patients and provide consultation service through SSDM in text or voice method. The rheumatologists can also adjust therapeutic regimens based on patients’ profiles.

**Objectives:** The purpose of this study is to explore the profile of psychological morbidities in patients with rheumatic diseases.

**Methods:** The patients were educated and trained to perform HADS assessments using SSDM by the rheumatologists. The HADS self-assessments data could be extracted from the mobile terminal for further analysis. The HADS scale consists of two subscales for anxiety (HADS-A) and depression (HADS-D) which have 7 items, respectively. Both subscales range from 0 to 21, with higher scores indicating greater anxiety and depression. A score between 11 and 21 indicates a probable case of anxiety or depression according to HADS scores.
under the curve (AUC) were computed. For the same outcome, prediction models were built using the method of Rydhal et al. on randomly sampled training sets, and tested on disjoint validation sets.

Results: In the Nordic cohort 98/440 (22%) patients were identified with a severe disease course. This ratio is similar to the 125/610 (20%) found in the ReACCh-Out study. Characteristics of groups of patients with severe and non-severe disease course are similar in the two cohorts. The model of Guzman et al. had an AUC of 0.85 for prediction of severe disease course and an AUC of 0.66 for predicting remission off medication. In repeated cross-validations, the model of Rydhal et al. had a median AUC of 0.90 (IQR 0.86-0.92) for prediction of severe disease course, and a median AUC of 0.78 (IQR 0.72-0.82) for remission off medication.

Conclusion: Tests in the Nordic cohort validate the ability of the model of Guzman et al. to predict severe disease course. Repeated cross-validations of the model of Rydhal et al. indicate that validation results are highly dependent of the chosen outcome, and that prediction of long-term remission status is more challenging than prediction of a severe disease course.
