EULAR European Congress of Rheumatology

EULAR 2023
31 May–3 June 2023

Abstracts

The EULAR Journal
Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome.

Editorial Board
- Daniel Aletaha (Austria)
- Johan Askling (Sweden)
- Sang-Choon Baek (Korea)
- Xenofon Baraliakos (Germany)
- Anne Barton (UK)
- Maarten Boers (The Netherlands)
- Maxime Breban (France)
- Matthew Brown (Australia)
- Maya Buch (UK)
- Frank Buttgereit (Germany)
- Loreto Carmona (Spain)
- Carlo Chizzolini (Switzerland)
- Bernard Combe (France)
- Philip Conaghan (UK)
- Maurizio Cutolo (Italy)
- Nicola Dalbeth (Australia)
- Christian Dejaco (Italy)
- Oliver Distler (Switzerland)
- Thomas Dörner (Germany)
- Dirk Elewaut (Belgium)
- Axel Finckh (Switzerland)
- Rebecca Fischer-Betz (Germany)
- Roy Fleischmann (USA)
- Mary Goldring (USA)
- Laure Gossec (France)
- Walter Grassi (Italy)
- Ahmet Gül (Turkey)
- Frederic Houssein (Belgium)
- Tom Huizinga (The Netherlands)
- Arthur Kavanaugh (USA)
- Margreet Kloppenburg (The Netherlands)
- Robert Landewé (Netherlands)
- Zhan-Gou Li (China)

Chairman of Advisory Committee
Johannes Bijlsma
(The Netherlands)

Advisory Committee
- Ferry Bredveld (The Netherlands)
- Michael Doherty (UK)
- Maxime Dougdas (France)
- Paul Emery (UK)
- Daniel Furst (USA)
- Steffen Gay (Switzerland)
- Marc Hochberg (USA)
- Edward Keystone (Canada)
- Lars Klareskog (Sweden)
- Tore Krivin (Norway)
- Peter Lipsky (USA)
- Sir Ravinder Maini (UK)
- Emilio Martin-Mola (Spain)
- Haralampos Moutsopoulos (Greece)
- Karel Pleva (Czech Republic)
- Yehuda Shoenfeld (Israel)
- Leo van de Putte (The Netherlands)
- Frank Wollheim (Sweden)
- Anthony Woolf (UK)

Rik Lories (Belgium)
Ingrid Lundberg (Sweden)
Gary MacFarlane (UK)
Xavier Mariette (France)
Alberto Martini (Italy)
Marco Mattiucci Cerinic (Italy)
Dennis McGonagle (UK)
Fred Miller (USA)
Peter Nash (Australia)
Michael Nurmohamed (The Netherlands)
Caroline Ospelt (Switzerland)
Monika Östensen (Norway)
Constatino Pitzalis (UK)
Jane Salmon (USA)
Georg Schett (Germany)
Philipp Severin (Germany)
José da Silva (Portugal)
Hendrik Schulze-Koops (Germany)
Nan Shen (China)
Gegg Silverman (USA)
Alexander So (Switzerland)
Hiroshi Takayanagi (Japan)
Tsuchi Takeuchi (Japan)
Yoshiya Tanaka (Japan)
Dimitrios Vassilopoulos (Greece)
Douglas Veale (Ireland)
Jiri Vencovsky (Czech Republic)
Ronald van Vollenhoven (Netherlands)
Erwin Wagner (Spain)
Michael Ward (USA)
Kevin Winthrop (USA)
Huij Xu (China)

Subscription Information
ARD is published monthly; subscribers receive all supplements
ISSN 0003-4987 (print); 1468-2060 (online)

**DECONVOLUTING IMMUNOLOGICAL AND CLINICAL HETEROGENEITY ACROSS AUTOIMMUNE RHEUMATIC DISEASES BY COHORT-WIDE IMMUNO-PHENOTYPING**

**Keywords:** Systemic lupus erythematosus, Genetics/Epigenetics, Rheumatoid arthritis

H. Tanaka 1, 2, Y. Okada 2, 3, 4, S. Nakayama 1, Y. Miyazaki 1, S. Namba 2, K. Sonehara 3, 5, Y. Shira 5, K. Yamamoto 3, K. Sonomoto 5, Y. Tanaka 1, University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; 2Osaka University Graduate School of Medicine, Department of Statistical Genetics, Suita, Japan; 3Graduate School of Medicine, the University of Tokyo, Department of Genome Informatics, Bunkyo City, Japan; 5RIKEN Center for Integrative Medical Sciences, Laboratory for Systems Genetics, Yokohama, Japan

**Background:** Autoimmune rheumatic diseases (AIRDs) are systemic but heterogeneous diseases characterized by orchestration of disrupted self-tolerance of immune systems. We face a challenge in characterizing clinical immune features and selecting best treatment strategy of the AIRD patients.

**Objectives:** Deconvolution of immunological and clinical heterogeneity within and across AIRDs is an essential step towards implementation of personalized medicine. Immuno-phenotypes, immune-related cell types in peripheral blood mononuclear cells quantified by flow-cytometry analysis, can less invasively describe immune profiles of individuals and is considered as a promising technique.

**Methods:** We conducted large-scale and cohort-wide immunophenotyping of 46 peripheral immune cells using the Human Immunology Protocol of comprehensive 8-color flow cytometric analysis. The dataset consisted of >1,000 Japanese patients of 11 AIRDs and controls with deep clinical information registered at the FLOW study, including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc), ANCA related vasculitis (AAV), idiopathic inflammatory myopathy (IIM), psoriasis, IgG4 related disease (IgG4RD), mixed connective tissue disease (MCTD), ankylosing spondylitis (AS), Sjogren’s syndrome (SS), and giant cell arteritis (GCA). In depth and longitudinal clinical analysis was conducted for the identified RA patient clusters registered at the FIRST registry. Inborn human genetics represented by genome-wide polygenic risk score (PRS) were estimated for the RA patients.

**Results:** Multimodal clustering of immuno-phenotypes deciphered underlying disease-cell type network, providing immune cell type specificity shared or distinctly expressed across AIRDs, such as close immunological network of MCTD with SLE rather than with SSc. Individual patient-level clustering deconvoluted the AIRD patients into several clusters with different immunological features (Figure 1A). Of these, RA- or SLE-like clusters were exclusively dominant, showing immunological polarization between RA and SLE across AIRDs (the patient clusters 4-6 and 1-3 for RA and SLE, respectively; Figure 1B). In depth and longitudinal clinical analysis of RA revealed that such patient clusters differentially defined clinical heterogeneity in disease activity and treatment responses, which were supported by immune cell-type specificity (e.g., decreased regulatory T cells associated with treatment resistance in the RA patients with SLE-like imuno-phenotypes), PRS based on RA case-control genome-wide association study (GWAS) and within-case stratified RA GWAS were associated with patient characteristics, disease activity, and immuno-phenotypes of the RA patients, such as dendritic cells for RA-intestinal lung disease.

**Conclusion:** Our study demonstrated a value of cohort-wide and cross-disease immuno-phenotyping to elucidate clinically heterogenous patient subtypes existing within the single disease in an immune cell type-specific manner.

**OP0002  
EXPLORING THE USE OF ARTIFICIAL INTELLIGENCE IN PREDICTING RHEUMATOID ARTHRITIS, BASED ON EXTREMITY MR SCANS IN EARLY ARTHRITIS AND CLINICALLY SUSPECT ARTHRALGIA PATIENTS**

**Keywords:** Imaging, Rheumatoid arthritis, Artificial Intelligence

Y. Li 1, D. Shamonin 1, T. Hassanazadeh 1, M. Reijnierse 2, A. Van der Helm van Mi 2, B. Stoebl 1, Leiden University Medical Center, Division of Image Processing, Department of Radiology, Leiden, Netherlands; 2Leiden University Medical Center, Department of Radiology, Leiden, Netherlands; 2Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands

**Background:** Predicting early rheumatoid arthritis (RA) from extremity MRI facilitates timely treatment, possibly preventing chronicity. Image interpretation by Artificial Intelligence (AI) may provide more accurate predictions than visual scoring.

**Objectives:** We developed a deep learning AI-method that automatically analyzes extremity MRI scans by pre- and post-processing images, in order to predict RA at an early stage.

**Methods:** MRI scans of the hands and feet from a total of 1974 patients were collected, consisting of 1247 early onset arthritis (EAC) patients, of whom 538 developed RA in two years, and 727 clinically suspect arthralgia (CSA) patients, of whom 113 developed RA. MRI scans were preprocessed automatically through background removal, slice-by-slice normalization and central slice selection. Subsequently, a self-supervised deep learning model was pre-trained to fill-in parts of the image that have been blinded by square patches (Figure 1(a), top row). Finally, after transferring the resulting weights, the model was fine-tuned to predict RA development (see Figure 1 (a) bottom row). The model was evaluated through 5-fold cross-validation and in a held-out test set (n=312 for EAC and n=146 for CSA). The model’s accuracy was evaluated with the area under the receiver operator curve (AUC). An improved class activation map was developed and applied to indicate, which areas were most important to the AI decision.

**Results:** On the test set, the proposed model obtained a mean AUC of 0.683 in the EAC group, and 0.727 in the CSA group, using MR scans of the hands (wrist and metacarpophalangeal joints). Models trained separately on the wrists, MCPs and feet, received a mean AUC of 0.679, 0.647, 0.664, and 0.688, 0.669, 0.715, for the EAC and CSA group, respectively (see Table 1). These accuracies were close to the expert-level using RAMRIS, with reported AUCs of 0.74 and 0.69 in predicting RA in CSA [1]. According to the proposed visualization method,
the deep learning models predict RA, based on very similar patterns of known (teno-)synovial inflammation and bone marrow edema (see Figure 1 (b)).

Figure 1. The overall workflow of the AI model and visualization examples from correctly-predicted samples.

Conclusion: Automatic RA prediction is feasible, using AI interpretation of MRI scans. AI performed close to the level of human experts, including MRI data from healthy controls, as used in RAMRIS-based prediction [1], will probably improve the AI prediction further. The new visualization method not only confirms the significance of known inflammatory features but may also point to new imaging biomarkers, giving a different perspective of understanding RA.

A. Polster1, L. Ashpah2, A. T. Tvedt3, K. Bergsmark1, B. Christensen3, I. K. Haugen4, M. Hermann-Eriksen5, Å. Hove5, A. Praven6, T. Hennig7, T. A. Sjøvold8, I. Kjeken9, Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; 2Oslo University Hospital, Health Economics, Oslo, Norway; 3Diakonhjemmet Hospital, Department for Rheumatology and Research, Oslo, Norway; 4Diakonhjemmet Hospital, Division of Clinical Service, Oslo, Norway; 5Martina Hansen Hospital, Sandvika, Norway

Background: Hand-osteoarthritis (HOA) is a prevalent rheumatic joint disease that significantly reduces quality of life. In Norway, HOA should mainly be managed in primary care, but patients often have insufficient access to recommended treatment options there and are instead frequently referred to rheumatologists. This leads to high healthcare costs and reduces the access to rheumatologists for patients with inflammatory rheumatic diseases, for whom early diagnosis, disease modifying medication and tight controls may induce remission and prevent irreversible joint damage and long-term disability. Delegating the healthcare management and treatment of HOA to allied health professions such as occupational therapists may therefore free scarce healthcare resources and improve overall health economics.

Objectives: In this study we evaluated a new model of care in specialist healthcare, where HOA patients receive their first consultation by occupational therapists instead of rheumatologists. The objective was to test the non-inferiority of occupational therapist-led care (OTC) compared to rheumatologist-led care (RC) with regards to effectiveness defined as proportion of responders (based on OMERACT/OARSI criteria) and safety. In addition, we conducted a health economics evaluation comparing Quality-adjusted life years (QUALY’s) and treatment costs between the treatment groups and conducted a cost-economics analysis.

Methods: We conducted a randomized controlled multicentre parallel group trial in which we recruited 400 patients with symptomatic HOA and no signs of possible inflammatory rheumatic disease at two Norwegian hospitals. Participants were randomized (1:1, computer-based) to either OTC (n=200) or RC (n=200). Various demographic and clinical parameters were registered at baseline. Disease activity (numeric rating scale, NRS, 0-10, 0=no disease activity, pain (NRS, 0-10, 0=no pain) and function (using the MAP-hand questionnaire, 18 items averaged to a 1-4 score, 1=no problems) were registered at baseline and 6 months post-intervention, and the delta was used to determine if patients were responders/non-responders based on OMERACT/OARSI criteria. Chi2-test and logistic regression were used to compare the proportion of responders/non-responders per treatment arm, and to analyse the relationship between response status (as dependent variable) and treatment arm (as independent variables). Results of the logistic regression are presented as odds ratio (OR) with 95% confidence interval (CI). Safety analysis was conducted by screening healthcare journals 12 months post-baseline for new diagnoses and adverse events related to musculoskeletal diseases. QUALY’s were calculated using data from EQ-5D weighted with preference weights from the general population. To evaluate cost-effectiveness, we calculated and compared the incremental cost-effectiveness ratio (ICER).

Results: Mean age was 63.6 years (SD=10.01), 80.8 % were female. No statistical difference between the treatment arms was found in any baseline variables. In the RC group, 48 patients (25.8%) met the primary outcome criteria for treatment response. In the OTC group, also 48 (25.4%) were classified as responders. The proportion of responders did not differ by treatment group (X2 (1, N = 337) = 0.0002, p = 0.97). Treatment group did not significantly predict response status (OR=0.99, CI=0.62-1.59, p = 0.97). No notable safety-related events were found in either group. No statistically significant differences were found regarding QUALY’s and overall treatment costs, and cost-effectiveness was marginal.

Conclusion: We found no statistically significant difference regarding proportion of treatment responders between the two treatment arms, suggesting non-interiority of OTC compared to RC with regards to effectiveness and safety. While the cost-effectiveness analysis showed no clear benefit for either of the treatment options, delegating HOA treatment to OT’s may free RT time and improve health-care accessibility for urgent diagnoses, and thus prove a valuable opportunity to optimize future healthcare allocation.

Keywords: Patient information and education, Systemic lupus erythematosus, Self-management

Z. Karakalliga-Mitsakou1, A. Cornell1, J. D. Povilaitis2, M. Olsen2, K. Blomkvist Sporre3, N. Z. Serrano4, M. Misuno5, 1Lupus Europe, PAN, London, United Kingdom; 2Lupus Europe, EQ, Brussels, Belgium; 3Lupus Europe, PAN, Vilnius, Lithuania; 4Lupus Europe, PAN, Reykjavik, Iceland; 5Lupus Europe, PAN, Stockholm, Sweden; 6Lupus Europe, PAN, Dubai, United Arab Emirates; 7Lupus Europe, PAN, Krakow, Poland

Background: Quality of information on lupus on the internet is a real issue. “Word of mouth”, rumors, unchecked data, or unconfirmed research increase
confusion, create anxiety and can lead to incorrect actions. Patients need access to quality information about lupus. Therapeutic Patient Education (TPE) is a key part of the self-management of chronic conditions; an essential component of TPE is access to quality information. Most patients in Europe prefer printed and digital information.

**Objectives:** To provide access to quality information on lupus online, in the native language of 95%+ of the European population.

**Methods:** The first step was to get the project endorsed by specialised lupus doctors, ERN ReCONNET. The French book “lupus en 100 questions” (initiated by FAI2R) was used as a starting point. Patients from the Lupus Europe Patient Advisory Network (PAN) and doctors worked together to create the English version. The least internationally relevant questions were removed to make space for new questions suggested by Lupus Europe’s PAN. Answers for the new questions were constructed collaboratively between patients and doctors. The other questions were translated to English, updated where needed and adapted for international use. The resulting English document was distributed to ERN ReCONNET SLE working group doctors and to all PAN members, and feedback was incorporated. This master version was then put online and served as starting point for an ambitious multilingual translation. The translation process included generating an initial draft translation through DeepL Pro, and then upgrading this by a Doctor-Patient native speaker team. In parallel, a process has been established to collect comments and suggestions so that content can be maintained and updated on a continuous basis while keeping all language versions synchronised.

**Results:** lupus100.org in English was launched at the European Lupus Meeting in October 2022 and has to date received 8,900 visits. 18 translations have been completed and 10 of them are under final validation. The international launch of the multilingual website will take place on May 10, World Lupus day.

**Conclusion:** The website will provide access to information about lupus to 95% of European lupus patients in their own language, eliminating a big barrier to quality information. Thanks to the effective collaboration between patients and doctors, quality of information can be guaranteed and information truly answers the patient concerns. Both national groups and the ERN network of doctors will ensure effective dissemination, so patients in all European countries are aware of the initiative.

**Background:** Unacceptable diagnostic delay in axial Spondyloarthritis (axSpA) remains an issue. In 2009, the longitudinal SPondyloArthritis Caught Early (SPACE)-cohort started to assess the prevalence of axSpA and the reliability of an early diagnosis in patients with chronic back (CBP) of unknown origin. Here we present one of the main outcomes of SPACE.

**Objectives:** To assess the two-year (2y) prevalence of an axSpA diagnosis among patients with recent onset CBP referred to the rheumatologist; To investigate the sustainability of a baseline (BL) diagnosis of axSpA when reviewed after 2y; And to explore patient-differences between BL and 2y, in those with and without an axSpA diagnosis.

**Methods:** We analysed the 2y data from SPACE, a European inception cohort of patients (age <45y) with CBP of recent onset (≥3 months, ≤2y) and unknown origin. The full diagnostic work-up included all clinical SpA-features, acute phase reactants, HLA-B27, radiographs and MRI of the sacroiliac joints (SI-CR and SI-MRI) and spine (data not shown). Patients with increased likelihood of having axSpA (≥1 major or ≥2 minor prespecified SpA-features) were eligible for follow-up with the remaining patients excluded per protocol. The clinical diagnosis at 2y was the main outcome of this study. At each visit, the treating rheumatologist judged on the presence or absence of axSpA (axSpA or no-axSpA) with a level of confidence (LoC) on a numeric rating scale (0, not confident at all to 10, very confident). The main outcome was the presence of ‘definite axSpA at 2y’ defined as a clinical diagnosis of axSpA with a LoC ≥7 (complete follow-up) or at the two last available visits if 2y visit was missing. ‘No axSpA was defined as not having axSpA at 2y (with LoC ≤7; or if LoC <7, plus an alternative diagnosis for CBP reported). All other patients were considered having an ‘uncertain’ diagnosis. The ASAS classification criteria were computed using sacroilitis central reading results in definite axSpA patients. We assessed the prevalence of definite axSpA at 2y as well as changes in diagnosis over time, and descriptively summarised BL characteristics.

**Results:** A total of 555 CBP patients were included (Leiden n=383, Oslo n=97, Amsterdam n=48, and Gouda n=27). A diagnosis of definite axSpA was given to 175 (32%) patients at BL and 166 (30%) at 2y (Figure 1). The mean (SD) LoC’s were 8.1 (2.0) and 8.7 (1.0), with 155/175 (89%) and 145/166 (87%) fulfilling ASAS classification criteria, respectively. BL diagnostic judgments were relatively unconfident and remained rather stable: At 2y, 6% of the BL diagnoses of definite axSpA were refuted; and -vice versa: 9% of those who did not obtain a BL diagnosis of axSpA ‘gained’ one at 2y. Residual diagnostic uncertainty remained in the 2y definitive axSpA group (Table 1). The presence or absence of imaging-detected sacroilitis at BL appeared the best discriminator between axSpA and no axSpA at 2y.

**Conclusion:** One third of patients with CBP of recent onset referred to the rheumatologist has definite axSpA. Most of these patients can be unequivocally and reliably diagnosed at their first assessment. None of the many SpA-features suffices alone, but imaging discriminates best.

**Background:** Interstitial lung disease (ILD) is a common (extra-articular) pulmonary manifestation of rheumatoid arthritis (RA). In RA, use of biologic or targeted synthetic disease-modifying drugs (b/tsDMARDs) have been linked to ILD, whereas the risk attributable to MTX use remains unclear. In psoriatic arthritis (PsA), few studies have investigated the risk of ILD, let alone in relation to use of MTX and b/tsDMARDs.

**Objectives:** To assess the incidence of ILD in patients with RA in RA or PsA initiating a b/tsDMARD (vs. the general population), compare the risk of ILDs across b/tsDMARDs and investigate the role of MTX co-medication.

**Methods:** Patients with RA or PsA initiating a b/tsDMARD were identified in rheumatology registers from Denmark, Finland, Iceland, Norway and Sweden. Details of b/tsDMARD treatment, MTX co-medication, and disease activity at treatment initiation were retrieved. Gender and age-matched general population subjects were available from four countries. The incidence of ILD was assessed through linkages to national hospital and death registers with cases defined as patients who had been given an ILD diagnoses on more than one occasions. Subjects with a history of ILD prior to b/tsDMARD initiation were excluded. In multivariable models, we calculated the hazard ratios (HR) for ILD in individual patients starting b/tsDMARDs vs. population subjects, following each patient from treatment start until the first of ILD event, end of, death, or five years of follow-up. In separate on-treatment analyses we compared the risk of ILD between b/tsDMARD initiations using etanercept treatment as a reference, and between those using vs. not using MTX (reference) as co-medication. Follow-up in on-treatment analyses was defined as time to first of ILD event, end of treatment plus 29 days, death or five years. For these analyses one patient could have several treatment courses in a time-split co-regression analyses.

**Results:** 37010 patients with RA, 12,341 patients with PsA and 569,451 population subjects, were identified, contributing 300, 30 and 400 ILD cases during follow-up, respectively, HR for ILD (vs. the general population) was 10.1 (95% CI 8.6 to 11.9) in RA and 5.0 (3.4 to 7.4) in PsA patients initiating a b/tsDMARD. In on-treatment analyses 69,808/21,340 b/tsDMARD treatment-courses were identified in RA/PsA patients with 558 and 46 ILD events during follow-up, respectively. Among patients with RA a significantly increased HR (vs. etanercept) was only noted for rituximab 1.7 (1.2 to 2.4). No b/tsDMARD increased the risk of ILD in patients with PsA. MTX co-medication was used in 51.3%/42.2% of RA/PsA patients but did not give an increased risk of ILD compared to no use of MTX-co-medication (Figure 1 shows details of results for RA populations).

**Conclusion:** Among RA and PsA patients initiating b/tsDMARDs, the risk of ILD was higher than in the general population, and the risk of ILD in RA was approximatively twice that of PsA patients. In these preliminary analyses, the increased risk of ILD in RA patients initiating treatment with rituximab may indicated a channel bias. When used in clinical practice, MTX co-medication is not a risk factor for ILD in RA/PsA patients initiating b/tsDMARD therapy.

**Figure 1. Risk of ILD across b/tsDMARD treatment and methotrexate co-medication in patients with rheumatoid arthritis. (Hazard ratios (95% CI). Etanercept 21.079 patients, adalimumab 12.018, abatacept 4.973, infliximab 12.636, Other TNFis 5.424, other bDMARDs 244 (not shown, no events) Rituximab 6.917, bDMARDs 1.248 (not shown, no events), Tocilizumab 5.067.

INCIDENCE, PREVALENT AND CO-OCCURRENCE OF AUTOIMMUNE DISORDERS, TRENDS OVER TIME AND BY AGE, SEX AND SOCIOECONOMIC STATUS. A POPULATION-BASED STUDY IN 22 MILLION INDIVIDUALS.

Keywords: Real-world evidence, Gender/diversity issues, Epidemiology

Methods: We used linked primary and secondary electronic health records of 22 million individuals from the Clinical Practice Research Datalink (CPRD), a cohort that is representative of the UK population in terms of age and sex. We calculated incidence and prevalence of 19 autoimmune disorders from 2000 to 2019 and used negative binomial regression models to investigate temporal trends and variation by age, sex, socioeconomic status, season of onset and region. To characterise co-occurrence of autoimmune diseases, we calculated incidence rate ratios, comparing incidence rates of comorbid autoimmune disease among patients with a first autoimmune disease with incidence rates in the general population, using negative binomial regression models, adjusted for age and sex.

Results: Among the 22,009,375 individuals included in the study, we identified a total of 978,872 patients with at least one diagnosis of at least one autoimmune disease between 2000 and 2019 (mean (SD) age: 54.0 (21.4) years, 64% women). Over the study period, age-standardised incidence rates of autoimmune diseases increased by 4%, similarly for men and women. The largest increases were seen in Graves' disease, coeliac disease and Sjogren's syndrome, for which incidences have doubled over the past two decades. Two conditions exhibited a significant decrease in incidence (Hashimoto's thyroiditis and pernicious anaemia), taken together the 19 autoimmune disorders examined affected 10.2% of the population over the study period (13.1% of women, 7.4% of men). A socioeconomic gradient was evident across several diseases, including Graves' disease, pernicious anaemia, rheumatoid arthritis, and systemic lupus erythematosus. Seasonal variations were observed for type 1 diabetes (more commonly diagnosed in winter) and vitiligo (more commonly diagnosed in summer), and regional variations were observed for a range of conditions. Autoimmune disorders were commonly associated with each other, particularly Sjogren's, systemic lupus erythematosus and systemic sclerosis. Patients with type 1 diabetes also had significantly higher rates of Addison's, coeliac, and thyroid diseases, and multiple sclerosis stood out as having low rates of co-occurrence with other autoimmune diseases.

Conclusion: Autoimmune diseases affect about one in ten individuals. Their burden continues to increase over time, albeit at varying rates across individual diseases. The socioeconomic, seasonal, and regional disparities observed among several autoimmune disorders, implicate environmental factors in disease pathogenesis. The interrelations between autoimmune diseases are commensurate with shared pathogenetic mechanisms or predisposing factors, particularly among connective tissue diseases and among endocrine diseases.
Background: The multifaceted clinical presentation in crystal-induced arthropathies (CiA) poses challenges to imaging.

Objectives: To formulate evidence-based recommendations on the use of imaging in the diagnosis and management of CiA.

Methods: Following EULAR standard operating procedures a task force of 25 stakeholders from 11 countries was created. Four systematic literature searches were performed in MEDLINE, EMBASE and CENTRAL to guide task force decisions, answering 14 research questions on the role of imaging in gout, calcium pyrophosphate and basic calcium phosphate deposition disease. Level of agreement (LoA) with each overarching principle and recommendation was assessed by numerical rating scale (0-10).

Results: Five overarching principles and 10 recommendations were produced on the role of imaging in making a diagnosis, monitoring, predicting, guiding intervention, and patient education in CiA (Table 1). Overall, the LoA for the recommendations was very high (8.5-9.9).

Conclusion: These are the first recommendations that encompass all common forms of CiA and guide the use of established imaging modalities in this disease group.

Table 1. EULAR recommendations for the use of imaging in CiA in clinical practice

Recommendations
1. When performing imaging in CiA, both symptomatic areas and disease-spe-9.7 (0.5) ific target sites (i.e. MTP1 in gout, wrist and knee in CPPD, shoulder in BCPD) should be considered.
2. In the diagnostic assessment of gout, US and DECT are both recom-9.7 (0.6) mended imaging modalities.
3. When characteristic features of MSU crystal deposition on US (i.e. double contour sign or tophi) or on DECT if identified, synovial fluid analysis is not needed to confirm a diagnosis of gout.
4. In the diagnostic assessment of CPPD, CR or US (or CT if axial involve-9.6 (0.9) ment is suspected) are recommended imaging modalities.
5. In the diagnostic assessment of BCPD, Imaging is necessary; CR or US9.1 (1.7) are the recommended modalities.
6. In gout, US and DECT can be used to monitor crystal deposition and9.3 (1.2) in case of US, also inflammation. Both modalities provide additional information on top of clinical and biochemical assessment. In case US/DECT are not available, CR can be used to assess structural damage due to gout. The decision on when to repeat imaging depends on the clinical circumstances.
7. In CPPD and BCPD serial imaging is not recommended, unless there is an9.4 (1.2) unexpected change in clinical characteristics.
8. In gout, assessing the amount of MSU crystal deposition by US or DECT8.5 (1.7) may be used to predict future flares.
9. If synovial fluid analysis is required in the assessment of CiA, US-guidance 9.7 (0.5) should be used in cases where aspiration based on anatomical landmarks is challenging.
10. Show and explaining imaging findings of CiA to people with such condi-9.4 (0.9) tions may help them understand their condition and improve treatment adherence in gout. BCPD: basic calcium phosphate deposition disease; CiA: crystal-induced arthropathies; CPPD: calcium pyrophosphate deposition disease; CR: conventional radiography; CT: computed tomography; DECT: dual-energy computed tomography; MSU: monosodium urate; MTP: metatarsophalangeal joint; US: ultrasound.

"Buy one - get 4 free" - RMDs and comorbidities

**Keywords:** Mental health, Pain, Patient information and education

**Background:** As many as 1-in-5 people are living with chronic pain (pain for three or more months) in the UK. Living with a long-term health condition can increase the likelihood of experiencing poor mental health. Having access to high-quality resources to raise mental health awareness and support good mental health among this population is crucial. Co-production of patient-facing resources with people with lived experience of health conditions (experts by experience) has been acknowledged as an important way of achieving impact and engagement.

**Objectives:** To describe how branding and design expertise was used to co-produce with experts by experience evidence-based, patient-facing animations to support the mental health needs of people with chronic pain.

**Methods:** A task and finish group (n=10) met virtually six times over 12 months from March 2020. The group included patients, public, representatives of charities, hospital volunteers, researchers and design experts. The group started with a blank canvas and worked together to decide which evidence-based messages to include in the resources, their format and style, and where and how they would be implemented. The group decided to create one website to host branded resources:

- A positive and informative animation and social media content
- Free online training for healthcare professionals, public and volunteers to improve awareness of the links between pain and mental health
- A library of local support resources

The marketing and design experts facilitated collaborative working to develop clinical (physiotherapist, general practitioner) and patient (retired, volunteer, carer) personas to better understand the intended resource end-users. The group explored in-depth the emotions, thoughts and actions conveyed by the resources through word clouds and brainstorming. This helped the group to create a brand, the central character and provided vision for the style of the resources. Through facilitated discussion with design experts, the group co-produced animation storyboards, the plain language text on the website, training package, animation and local support library, and the final overall brand by choosing logos, colour schemes, fonts and images.

**Results:** The group chose Support, Progression and Freedom through ‘Mind and Movement’ as the key words on which to base the resources. Patients and the public suggested that a human character would not represent all people living with chronic pain; so, a bee was chosen to be the central character. It was agreed that the bee personified the key words whilst generating an engaging theme. The group agreed to name the resource package ‘BeeFree’ with the website slogan ‘a support hive for mind and movement’ and go live in 2021. Patients and the public championed the resources and facilitated the launch. Challenges for the clinical group members included negotiating time and commitment to the work amidst multiple pandemic-related NHS pressures, and for the public group members there were difficulties adapting to working collaboratively online.

Figure 1.

**Conclusion:** Co-creating a positive, recognisable brand with patients and the public can facilitate the promotion and impact of evidence-based messages into healthcare. In the pandemic online co-production approaches offered creative adaptations to bring together stakeholders. Designing expertise and taking time to build and nurture relationships with patients and the public resulted in a valuable and insightful co-production and consequently highly accessible and engaging resources.

---

**Keywords:** Self-management, Work-related issues, Telemedicine

**Background:** A Fatigue and Activity Management Education in Work (FAME-W) programme was developed for individuals with inflammatory arthritis to manage fatigue in work (McCormick, 2018). FAME-W was designed as an in-person programme; however, due to COVID-19 pandemic it was modified to be an online group-based self-management intervention.

**Objectives:** This study tested the effectiveness of an online format of FAME-W for future use by occupational therapist to help individuals with inflammatory arthritis to stay in work.

**Methods:** Participants were randomly allocated to intervention or control groups. Participants in the intervention group received the online four-week FAME-W and the control group participants received a FAME-W handbook. Participants in the intervention group attended a focus group immediately after the completion of the online FAME-W programme. A qualitative descriptive design was used with semi-structured focus groups. Data were analysed by thematic analysis (Braun and Clarke, 2021).

**Results:** Twenty-six individuals took part in five separate focus groups. The average number of participants per group was 5 individuals with the largest group having 8 and smallest having 3 participants. The majority of participants were female, working full time and had Rheumatoid Arthritis. The four themes emerging from the focus groups were: ‘content and delivery of the programme’ where participants discussed the relevance of the content to their symptoms and the online delivery format of FAME-W. In the second theme, participants discussed “understanding the impacts of symptoms on their own and combined” and how symptoms effect mood, work, cognitive and physical abilities. In the third theme, “implementing the knowledge gained from the programme” through goal setting and practicality of the self-management strategies provided were discussed. Final theme “impact of the FAME-W on symptoms and work” including reassurance of normalising symptoms, change in mindset and approach to their condition were discussed.
Conclusion: Preliminary results show that participants found the online FAME-W to be effective, relevant, reassuring, and helpful. These results suggest that work-related self-management skills are essential in assisting participants with symptom management in the workplace. Furthermore, these preliminary results suggest that the online format of FAME-W may be helpful for individuals with inflammatory arthritis to stay in work and it may become a standard part of clinical care for occupational therapists.

**Keywords:** Systemic lupus erythematosus, Genetics/Epigeneics, Innate immunity

A. Banaz1, A. Kloetgen2, K. Katsiki3, A. Filia4, D. Nikolopoulos1,5,6, A. Tsirigos5,6, D. Bournias1,3, 1Biomedical Research Foundation Academy of Athens, Laboratory of Autoimmunity and Inflammation, Center of Clinical, Experimental Surgery and Translational Research, Athens, Greece; 2Applied Bioinformatics Laboratories and Department of Pathology, New York University School of Medicine, New York, United States of America; 3Medical School, National and Kapodistrian University of Athens Medical School, 4th Department of Internal Medicine, Attikon University Hospital, Athens, Greece

**Background:** Monocytes are key effector cells in human systemic lupus erythematosus (SLE). Cytokine production, antigen presentation and initiation/amplification of tissue inflammation[1] represent some of output functions of transcriptional rewiring within the inflammatory milieu of the disease. Epi-transcriptomes include all functionally relevant changes to the RNA level (transcriptome), reforming RNA metabolism and fine-tuning gene expression[2].

**Objectives:** To construct the transcriptional map of monocytes in lupus patients and impose the A-to-I base editing events as co-factor of the disease pathogenesis.

**Methods:** A cohort of 8 SLE patients (SLEDAI(≤8) and 5 age/sex matched healthy volunteers was used for this study. PBMCs were obtained through Ficoll centrifugation and monocytes were isolated with CD14+ magnetic bead selection. Total RNA was extracted and miRNA libraries were generated. Single-end 75-bp mRNA sequencing was performed on Illumina NextSeq 500. Differential expression analysis was performed using edgeR package. Genes with a false discovery rate of ≤0.05 and fold change of >1.5 were considered statistically significantly deregulated. Significant differentially expressed genes (DEGs) were used for pathway and gene ontology (GO) analysis using gProfiler web-server[3]. For base editing events, JACUSA2 was utilized for base calling and list refinement was performed by the following criteria: (a) known editing sites based on REDportal, (b) the number of reads with “G” at the putative editing site is at least 10 and (b) the editing level per sample, defined as 100 nG/[nA+nG]), is at least 20%, (c) JACUSA2 call-2 score for differential editing between SLE and healthy was 1.5.

**Results:** Differential gene expression analysis produced a list of 764 statistically significant genes, 492 of which are upregulated and 272 downregulated. Gene enrichment analysis concluded that DEGs are participating in transcription regulation, signal transduction, regulation of immune processes and apoptosis/cell death. IL-17 signaling pathway and RNA metabolic process are part of the pathogenic profile of lupus monocytes. Interestingly, ADARB1, key regulator of RNA editing, is upregulated (logFC=0.76, pval=0.018). A-to-I editing events found to be significant, contain among others GDI2 (UTR3 region/signaling mediator), ARPC2 (Alu region/actin polymerization) and CERK (UTR3 region/inflammation) regulatory regions. A complex network of transcriptional and epi-transcriptomic alterations embeds immune-related genes and affects multiple cellular processes.

**Conclusion:** Transcriptional machinery and signal transduction molecules exhibit abnormal expression during transcriptional rewiring in monocytes of lupus patients. Our data support RNA editing as an additional player of immune-related epigenetic memory of monocytes, further integrating inflammatory cues and enhancing autoimmune identity of the disease.

Salaffi2. 1Division of Rheumatology, Academic Hospital “Santa Maria della Misericordia”, ASUFC, University of Udine, Department of Medicine (DAME), Udine, Italy; 2Rheumatology Unit, Sapienza Università di Roma, Dipartimento di Scienze Cliniche Internistiche, Anestesiolgeiche e Cardiovasculari-Reumatologia, Roma, Italy; 3Rheumatology Clinic, Università Politecnica delle Marche, Department of Clinical and Molecular Sciences, Jesi, Italy; 4U.O. Reumatologia e Immunologia Clinica, ASST Spedali Civili di Brescia, Brescia, Italy; 5SODc Reumatologia, Dipartimento di Medicina Sperimentale e Clinica Azienda Ospedaliero Universitaria Careggi, Firenze, Italy; 6Rheumatology Unit, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy; 7Unità Operativa di Reumatologia, Dipartimento di Medicina di precisione, Università degli Studi della Campania, Napoli, Italy; 8Rheumatology Unit - Siena University Hospital, Department of Medicine, Surgery and Neurosciences, Siena, Italy; 9Division of Clinical Immunology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy

**Background:** Central sensitization (CS) assessed with Central sensitization Inventory (CSI) is significantly associated with functional disability and frailty in patients with rheumatoid arthritis (RA). Frailty is common in RA and associated with hospitalization and mortality. Frailty is also a dynamic area, for some, may be ameliorated through controlling disease activity and functional disability.

**Objectives:** Our aim was to investigate the prevalence of CS in patients with RA and its association with measures of disease activity, functional disability, and frailty.

**Methods:** We administered to all the subjects in the study the CS inventory (CSI), a questionnaire that has been used for the diagnosis of CS. Demographic and clinical characteristics of all patients and the principal sociodemographic and health-related quality of life (RAID), functional disability (ROAD) and Kihon Checklist (KCL) screening tool to identify community-dwelling adults vulnerable to frailty potentially at risk of becoming dependent. Patients with fibromyalgia were excluded from the study.

**Results:** Of the 192 included RA patients, mean CSI score was 36.7 ±15.5 and 36.5% scored >40, which indicates a high probability of CS. Mean CDAI score was 16.8 ± 12.4 and mean RAID 5.0 ± 2.0. A CSI score >40 was significantly associated with higher RAID (mean 5.7 vs. 4.6; F-ratio 12.28; p<0.001), higher
ROAD (mean 4.3 vs. 3.0; F-ratio 17.37; p<0.001) and higher Kihon score (mean 9.1 vs. 5.7; F-ratio 29.88; p<0.001).

Conclusion: CS is strongly related to patient-reported disease activity; functional disability and frailty in patients with RA independently from other patient-and disease-related aspects. CS is an important determinant of functional disability in patients with chronic inflammatory arthritides. Therefore, special attention should be paid to RA patients, in whom the concomitant diagnosis of CS should be routinely ruled out.

Precision medicine in SLE: where are we?

OP0013

APPLYING STANDARD CLASSIFICATION CRITERIA EXCLUDES UP TO A HALF OF ALL PATIENTS FROM CONNECTIVE TISSUE DISEASES (CTD) CLINICAL TRIALS

Keywords: Sjögren syndrome, Systemic sclerosis, Systemic lupus erythematosus

S. Dyball1, M. Rodziewicz1, A. V. Madenidou1, J. Reynolds2,3, A. Herrick4,5, S. Haque6, H. Chinyo7,8, E. Bruce7, B. Parker1, I. N. Bruce1,7,9,10
1 The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2 University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, Birmingham, United Kingdom; 3 Sandwell and West Birmingham NHS Trust, Rheumatology Department, Birmingham, United Kingdom; 4 Northern Care Alliance NHS Foundation Trust, Department of Rheumatology, Salford Royal Hospital, Salford, United Kingdom; 5 Manchester NHS Foundation Trust, Rheumatology Department, University Hospital of South Manchester, Manchester University Hospitals NHS Foundation Trust, The Kellgren Centre of Rheumatology, Manchester United Kingdom; 6 NIHR Manchester Biomedical Research Unit, The University of Manchester, Manchester, United Kingdom

Background: Classification criteria aim to identify a homogeneous population of patients with a high specificity for clinical research.

Objectives: To determine how connective tissue disease (CTD) phase III trials utilise classification criteria within their inclusion and exclusion criteria. We then applied the most commonly used classification criteria to a large cohort of patients with an existing CTD diagnosis to explore which patients would be included and excluded from trials.

Methods: A comprehensive review of all major published phase III trials in CTDs was performed using clinicaltrials.gov (Nov 22). We included trials of biological or DMARD therapy, and excluded open label trials and long-term extensions. Adult patients (May 14 - July 22) were recruited from five rheumatology centres in North West England into the LEAP cohort. Patients were eligible for inclusion if they had ≥1 clinical feature of a CTD and ≥1 antibody within the ANA spectrum. The physician (rheumatologist) diagnosis at time of recruitment was used as the primary classifier of patients. Classification criteria utilised in the majority of clinical trials were systematically applied to this cohort, irrespective of clinical diagnosis.

Results: There were 49 trials in CTDs identified from 1909 records: systemic lupus erythematosus (SLE)=29, systemic sclerosis (SSc)=7, idiopathic inflammatory myopathy (IIM)=7 and primary Sjögren’s syndrome (pSS)=6. There were no trials in MCTD or UCTD. The majority of trials (N=47, 95.9%) required patients to meet classification criteria for their respective disease. The ACR-1997 for SLE, 2002 American European Consensus Criteria (AECG) criteria for pSS, ACR criteria for SSc 1980, and Bohan and Peter for IIM were the most commonly employed criteria. The majority of pSS (N=5= 83.3%) and SSc (N=4, 57.1%) trials excluded patients with other overlapping CTDs, whereas only a minority of IIM (N=1, 14.3%) and SLE (N=2, 6.9%) trials mandated this. A further 2 (28.8%) IIM and 2 (6.9%) SLE trials excluded CTD patients with specific overlapping features, e.g. SSc with significant pulmonary hypertension. 15 trials (30.6%) allowed exclusion of significant coexisting diseases at the investigators’ discretion and 18 (36.7%) made no reference. 391 patients were recruited to the LEAP cohort (Female: 352 [90.0%], median [IQR] age: 52 [40-59] years, median [IQR] disease duration: 6.1 [2.9-13.2] years). 254 (65.0%) patients met classification criteria for at least one CTD (Table 1). 22 (74.0%) patients with pSS, SLE, SSc or IIM met the classification criteria for their respective diagnosis. Of these, 26/22 (6.7%) met criteria for >1 CTD. In total, 196/391 (50.1%) would be eligible, and 195/391 (49.9%) ineligible for recruitment to a phase III trial, based upon their physician diagnosis, and trial eligibility criteria. Patients eligible to participate were similar in age (p=0.882), gender (p=0.607) and ethnic background (p= 0.822) but had longer median disease duration (7.5 vs 5.2 years, p=0.024) to those ineligible.

Conclusion: Clinical trial recruitment is challenging, in part due to due to strict eligibility criteria. In an unselected, real-world cohort of CTD patients, up to a half would be excluded due to classification criteria, overlapping features or a lack of trials within their disease. Directly targeting molecular pathology in biomarker driven basket trials could potentially revolutionise drug development by benefitting those with an undifferentiated or overlap condition who would be traditionally excluded from clinical trials.

**Background:** Aging is associated with an increased incidence of cancers and autoimmune diseases, which share pathophysiological mechanisms. Understanding these common pathways would make it possible to better define a certain risk linked to the disease or their treatment and to decipher new therapeutical targets in autoimmunity. Using an original individual approach to constitutive genetics at low penetrance, our team identified a constitutional mutation pR988C, c2962C> T of MET gene (tyrosine kinase receptor MET) in the patient with autoimmune diseases and malignant tumors. This mutation results in the constitutive activation of MET receptor and to the expression of an autoimmune phenotype associating a diffuse Sjögren disease with histological synovitis in transgenic MET mice [1]. The MET receptor (hepatocyte growth factor, HGF) participates in the regulation of physiological defensive responses following organs inflammation in tissues. Studying apoptosis phenotype, we observed a shift in cell death pathways that could be the relying mechanism of autoimmune prone phenotype linked to the MET mutation.

**Conclusion:** The model of transgenic mice appears ideal for studying the transition phenotype of autoreactivity versus autoimmune disease and the functional involvement of dendritic cells. We confirmed the direct involvement of the MET gene in autoimmunity. For the first time, we showed that the change in cell death pathways could be the direct origin of the emergence of autoimmunity. These preliminary results, for which additional experiments are underway, open up physiopathological and therapeutic perspectives.

**Background:** Immune checkpoint inhibitor (ICI) therapies used to treat cancer, such as anti-PD1 antibodies, can induce autoimmune conditions. The T cells responsible for mediating such iatrogenic autoimmunity, their activation profiles and characteristics remain unclear.

**Objectives:** To investigate the transcriptomic and clonotypic features, activation, and role of infiltrating T cells in patient joints affected by ICI-induced inflammatory arthritis (ICI-arthritis).

**Methods:** Paired TCR and scRNA-seq was performed on synovial fluid (SF) CD8 T cells from ICI-arthritis (ICI-A) to determine their transcriptomic and clonotypic features. Detailed immunophenotyping was performed on SF mononuclear cells using mass cytometry and flow cytometry to identify significantly altered populations in ICI-A compared to seropositive rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Further, bulk TCR-seq was performed on altered SF bulk RNA-seq cell subsets from the three arthritides to investigate differences in activation profiles and immune pathways enriched. In vitro cytotoxicity assays were performed by measuring annexin staining in fibroblasts co-cultured with various CD8 subsets from synovial fluid and blood. Mass cytometry was performed on PBMCs from melanoma patients to assess changes before and after checkpoint blockade and bulk TCR-seq of ICI-bound (IgG4+/-) non-naive CD8 T cells was used to analyze TCRs enriched in blood and synovial fluid of ICI-arthritis patients.

**Results:** Single cell transcriptomic and antigen receptor repertoire analyses highlighted clonal expansion of an activated effector CD8 T cell population in the joints and blood of ICI-arthritis patients (n = 6). These CD8 T cells, identified as CD38hiCD127low, were uniquely enriched in ICI-arthritis joints compared to RA and PsA and displayed an elevated interferon signature. In vitro, type I interferon induced CD8 T cells to acquire the ICI-associated CD38hi phenotype and boosted cytotoxic function in a novel cytotoxicity assay. In a cohort of patients with advanced melanoma, anti-PD-1 and anti-CTLA-4 therapy dramatically expanded circulating CD8hiCD127low T cells more so than any other T cell
population. CD38^hiCD127^+ T cells were Ki67+ and were frequently bound by the therapeutic anti-CD1-2 drug. In ICI-arthritis patients, anti-CD1-2 drug-bound CD8 T cells in circulation showed marked clonal overlap with drug-bound CD8 T cells from synovial fluid, but almost no overlap was observed between drug-bound cells in the synovial fluid and non-drug-bound cells in blood (Figure 1).

**Conclusion:** These results suggest that ICI therapy directly targets CD8 T cells in patients with ICI-arthritis to induce a novel autoimmune pathology that is distinct from the prototypical spontaneous autoimmune arthritides.

**ABATACEPT TO SILENCE ANTI-CITRULLINATED PROTEIN ANTIBODY-EXPRESSING B CELLS IN RHEUMATOID ARTHRITIS: THE ASCARA TRIAL**

**Keywords:** Rheumatoid arthritis, Randomized controlled trial, Biomarkers

N. Blomberg^1, J. Kwiekkeboom^1, S. Böringer^2, T. Huizinga^1, R. Toes^1, H. U. Scherer^1, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands;^2Leiden University Medical Center (LUMC), Biomedical Data Sciences, Leiden, Netherlands

**Background:** Rheumatoid arthritis (RA) is one of the most prevalent systemic autoimmune diseases. Despite clinically effective drugs, RA remains a chronic disease with frequent disease flares upon drug tapering. Patients harbouring anti-citrullinated protein antibodies (ACPA) most frequently relapse and rarely achieve drug-free remission. We observed that in established RA, ACPA-expressing memory B cells (mBC) are highly activated, proliferate, secrete pro-inflammatory cytokines and differentiate into plasmablasts [1]. This phenotype points to continuous, T helper cell-driven stimulation of the ACPA B cell response and persists in patients in clinical remission induced by conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), suggesting ongoing immunological disease activity (IDA) despite clinically quiescent disease. Persistent IDA may be responsible for disease flares, making immunological remission a potential treatment target required for cure.

**Objectives:** To test the hypothesis that CTLA4-Ig (abatacept), a biological DMARD that blocks co-stimulatory signals such as those provided by helper T cells to B cells, can impact on IDA, as evidenced by the induction of a silent, non-proliferative phenotype of ACPA-expressing mBC.

**Methods:** We conducted a single-center, randomized, open-label clinical trial in which patients with newly diagnosed, untreated RA (n=42) were treated with either methotrexate (MTX, n=21) or abatacept/MTX combination (n=21) for 6 months. Frequency and phenotypic characteristics of peripheral blood ACPA-expressing B cells were assessed directly ex-vivo by flow-cytometry at baseline (BL), 3 months (V2) and 6 months (V3). The expression of Ki-67 (primary endpoint), CD80, CD86 and HLA-DR were used to determine the activation state of the B cells in either group, next to B cell lineage and differentiation markers. Tetanus-toxoid (TT) specific B cells served as antigen-specific controls. Clinical disease characteristics as well as serum parameters were assessed in parallel. Differences between treatment groups were statistically analyzed using a mixed effect model with random slope and intercept.

**Results:** Of patients receiving treatment, n=14 in the ABA/MTX and n=16 in the MTX monotherapy arm harboured ACPA-expressing mBC in the circulation at sufficient frequency for phenotypic analysis. Patients with untreated RA exhibited a highly active ACPA mBC response, in line with previous results [1]. Both MTX and ABA/MTX reduced clinical disease activity at 6 months to a similar extent (p=0.33). The frequency of circulating ACPA-expressing mBC remained unaffected in either group. However, while ACPA-expressing mBC maintained their highly active phenotype in the MTX group, ABA/MTX impacted on the ACPA mBC response by significantly reducing the expression of Ki-67; CD86 and CD80. The expression of HLA-DR did not change upon treatment.

**Conclusion:** The ASCARA study provides first evidence that the activation of ACPA-expressing mBC can be therapeutically modulated towards a phenotype compatible with immunological remission. ABA/MTX, but not MTX alone had this modulatory effect, indicating that potentially important immunological drivers of RA disease processes are resistant to MTX-mediated effects. Interestingly, the phenotype induced by ABA/MTX resembles that observed in patients in sustained drug-free remission as well as in individuals with clinically suspect arthralgia that do not convert to RA (long-term non-converters, (1)). Follow-up analysis of the ASCARA study with ABA discontinuation beyond V3 will elucidate the stability of this effect and its relation to clinical disease characteristics.

**ACTIVE LUPUS NEPHRITIS PATIENTS DISPLAY AN INCREASED PROPORTION OF RECENTLY ACTIVATED NAÏVE DNA-REACTIVE B CELLS**

**Keywords:** Adaptive immunity, Kidneys, Systemic lupus erythematosus

K. Wangnatiask1,2, F. Faustimo2,3, R. Kumar2,4, C. De Vries6,4, P. Piiltikun6, P. Chootong1, V. Malmström2,4, I. Gunnarsson2,4. 1Faculty of Medical Technology, Mahidol University, Department of Clinical Microbiology and Applied Technology, Nakonpathom, Thailand; 2Karolinska Institutet, Department of Medicine, Division of Rheumatology, Stockholm, Sweden; 3Karolinska University Hospital, Unit of Rheumatology, Stockholm, Sweden; 4Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden; 5Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Department of Medicine, Division of Allergy, Immunology and Rheumatology, Bangkok, Thailand

**Background:** Altered composition of B cell compartments is known in patients with systemic lupus erythematosus (SLE). However, similar characterisation of the disease-associated autoreactive B cells remains scarce. Elucidating the autoreactive B cell subsets and their association to lupus manifestations may provide tools for monitoring, biomarkers and even identifying possible targets for future therapeutic intervention.

**Objectives:** To investigate phenotypic characteristics of extrafollicular B cell subsets in a cohort of SLE patients.
Methods: Twelve SLE patients, including nine with positive anti-dsDNA antibodies (75%), and ten healthy controls (HCs) were recruited for this study. Data was represented as median and interquartile range (IQR). To identify DNA-reactive B cells, surrogate peptide (DWEYSVWLSN) that serves as dsDNA mimotope was used, as previously shown (1, 2). The phenotype of peripheral B cell subsets and DNA-reactive B cells was analyzed by spectral flow cytometric analysis. The correlations between different B cell populations and Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) scores, clinical manifestations and laboratory data were assessed.

Results: In SLE patients, median SLEDAI-2K score was 14.5 (4.5-19.5), median age and disease duration were 32 (29-48.5) and 10 (1-13) years, respectively. Eight patients presented with lupus nephritis (LN), with proliferative (class III/V, n = 2), membranous (class V, n = 1) and mixed histological pattern (class III & V, n = 3 and class IV & V, n = 2). Phenotypic analysis showed an expansion of recently activated, so-called activated naïve (aNAV; CD11c+CXCR5+CD21-CD27-IgD-, p = 0.0005), double negative 2 B cells (DN2; CD11c+CXCR5-CD21+CD27-IgD+, p = 0.0001) and negative 3 B cells (DN3; CD11c+CXCR5+CD21+CD27-IgD+, p = 0.005) in the blood of the total SLE patient group compared to HC, with aNAV B cells frequency being higher in LN patients (Figure 1). DNA-reactive B cells were mostly represented by an aNAV phenotype (CD11c+CXCR5+CD21+CD27-IgD-) which overexpressed CD11c and CD80. Moreover, a significantly increased percentage of such autoreactive B cells was observed in LN patients (median (IQR) 0.13% (0.095-0.160) compared with non-LN patients (median (IQR) 0.056% (0.042-0.070), p = 0.0357). The percentage of aNAV B cells was positively correlated with disease activity measured as SLEDAI-2K index (r = 0.619, p = 0.036). These aNAV B cells also had a positive correlation with DN2 (r = 0.578, p = 0.049) and plasmablasts (r = -0.420, p = 0.041).

Conclusion: Our data show that aNAV B cells are expanded in SLE and display autoreactivity to dsDNA. The association between the frequency of aNAV B cells and disease activity, and with lupus nephritis suggests that these cells may be used as a monitoring biomarker in the disease.

Conclusion: We observed premature aging of lymphoid stroma in RA patients and to lesser extent already in individuals at risk of developing RA, which could partly be restored by dasatinib treatment. Premature aging of LNSCs may negatively impact the local niche by inducing inflammation and senescence in nearby cells. However, consequences of prematurely aged lymphoid stroma remain inconclusive providing a rationale for investigating the effect on immune cell responses.

OP0020
THE CELLULAR METABOLISM OF SLE NK CELLS IS PRIMARILY ALTERED AT THE LEVEL OF MITOCHONDRIAL HOMEOSTASIS

Keywords: Systemic lupus erythematosus, Innate immunity, Cell biology

BACKGROUND: Systemic lupus erythematosus (SLE) is a multi-systemic inflammatory disease, of unknown etiology, which involves the development of autoreactive cells and a loss of tolerance to self. Natural Killer (NK) cells represent a group of innate immune cells that play a pivotal role in the interaction between the innate and adaptive immune system. In patients with SLE, NK cells are decreased in the peripheral blood, exhibit reduced cytotoxicity, and impaired cytokine production. (1, 2) To date, few studies have explored the molecular mechanisms underlying NK cell dysfunction in SLE.

OBJECTIVES: To characterize the immunometabolic alterations of NK cells from patients with SLE.

METHODS: SLE and healthy NK cells were isolated from human PBMCs. Glycolysis and mitochondrial respiration (OXPHOS) were measured using Seahorse real-time metabolic assay. Mitochondrial function (membrane potential, mitochondrial mass), superoxide levels and lysosomes acidification were assessed by flow cytometry. Mitochondrial membrane potential and mass were analyzed by confocal microscopy (CM). Mitochondrial DNA was quantified by qPCR. Mitochondrial structure was examined by transmission electron microscopy (EM). Functional (cytokine production, degranulation) assays were performed in parallel with mitochondrial mass measurement by flow cytometry. Quantitative proteomic analysis was conducted focusing on the expression of proteins involved in mitochondrial homeostasis.

RESULTS: We first examined the cellular metabolism of SLE NK cells in comparison to healthy NK cells. We observed that OXPHOS is significantly increased in SLE NK cells, while glycolysis is similar to healthy controls. Due to this alteration in oxidative phosphorylation, we conducted experiments to examine the mitochondrial fitness of SLE NK cells. We showed that mitochondrial mass is increased, while mitochondrial activity is decreased in SLE NK cells, suggesting an accumulation of dysfunctional mitochondria. SLE NK cell mitochondria displayed increased superoxide levels and elevated lysosomal acidification, compared to healthy NK cells. qPCR analysis showed no significant difference, in mitochondrial DNA between SLE NK cells and healthy controls suggesting that the size of mitochondria is increased but not their number in SLE NK cells. Examination of the mitochondrial structure in SLE NK cells by TEM, showed cristae disorganization. Quantitative proteomic analysis showed that SLE NK cells express high levels of proteins associated with mitochondrial synthesis (mitochondrial import receptor TOM6) and OXPHOS (ATP synthase F(0), NADH dehydrogenase 1 C1). In parallel, we observed a reduction in proteins key for mitochondrial clearance such as E3 ubiquitin ligases (RNF181, MARCHF5), as well as lysosomal acidification (Proton-transporting V-Type ATPase), in SLE NK cells.

Conclusion: SLE NK cells exhibit impaired mitochondrial respiration, which is linked to an accumulation of large mitochondria with cristae disorganization. These results suggest an alteration in mitochondrial degradation in SLE NK cells related to dysfunctional mitochondy. Taken together, these data suggest that impaired mitochondrial function and homeostasis represent a major feature of SLE pathogenesis.

STRATIFICATION OF PATIENTS WITH SJÖGREN’S SYNDROME BY JOINT MULTI-MODAL ANALYSIS OF CIRCULATING B CELLS

Keywords: Sjögren syndrome, Adaptive immunity, Autoantibodies

BACKGROUND: B cells are important in the pathogenesis of primary Sjögren’s syndrome (pSS) with hypergammaglobulinemia, SSA/SSB autoantibodies and an increased risk of B cell lymphoma. (1) Patients with pSS positive for SSA/SSB autoantibodies are more prone to systemic disease manifestations and adverse outcomes. Only few studies have investigated peripheral blood mononuclear cells at single cell resolution and primarily reported differences in the T cell compartment while the B cells were only briefly considered. (2,3). We aimed to determine the role of peripheral B cell subtype composition, gene expression and B cell receptor (BCR) usage in patients with pSS stratified for SSA/SSB antibodies.

METHODS: Over 230 000 B cells were isolated by negative selection from peripheral blood of 24 pSS patients (n=6 SSA+, n=8 SSA- and n=10 SSA and SSB+ (SSAB)) and four healthy controls. Single cell gene expression and targeted BCR libraries were generated and processed for RNA and VDJ sequencing.

RESULTS: Gene expression-based clustering and cell annotation defined 16 B cell subsets. We show that pSS patients have a heterogeneous circulating B cell population while the B cells were only briefly considered. (2,3). The most notable difference was in memory B cells from SSAB patients displayed a higher proportion of naïve and memory B cells, respectively. Interferon-induced genes were upregulated across all B cell subtypes with the highest levels in the SSAB group. Differential usage of Immunoglobulin Heavy Chain (IGH) genes, showed that memory B cells from SSAB patients displayed a higher proportion of IGHV4-69 expressing cells and cells with unmutated VDJ transcripts, including IGHV4-69 and IGHV4-34, compared to other pSS patient groups and controls, indicating altered somatic hypermutation and class switching processes. Comparison with
Comorbidities in RMD...
Conclusion: Comorbidities impact treatment outcomes in patients with PsA. The retention and effectiveness of JAK and TNF inhibitors are similar in patients with (but not in patients without) at least one pre-existing comorbidity. Further analyses exploring impact of the number of comorbidities and of specific comorbidities are planned.

Objectives: This study aimed to: 1) Analyze the circulating inflammatory profile of Rheumatoid Arthritis (RA) patients, in order to recognize distinctive clinical phenotypes associated with CV risk; 2) Evaluate inflammatory profile mimicked that found in C1, supporting the association of RA-patients conforming C3 showed the lowest inflammatory profile and the lowest CV-risk score. Lastly, C2 characterized an intermediate phenotype. Comparative analyses with a cohort of 98 RA patients presenting previous CV events, demonstrated that their inflammatory profile mimicked that found in C1, supporting the association of this altered shape with the CV status. In vivo, both biological and targeted-synthetic DMARDs therapy reduced DAS28-score and re-established normal levels of several altered biomolecules, reflecting a key role in the CV-risk control. In vitro, RA patients’ serum pool from cluster 1 promoted in cultured ECs increased expression of several CV-related proteins, further prevented-albeit in an specific way- by the pre-incubation with TNFi (Etanercept), JAKinibs (Baricitinib) and anti-IL6R (Tocilizumab).

CONCLUSION: 1. The systemic inflammatory profile of RA identified patients’ subgroups with enhanced CV-risk, not associated with their disease activity status. 2. Both biological and targeted-synthetic DMARDs re-established normal levels of circulating inflammatory biomolecules, reducing the CV-risk in RA. 3. In vitro studies revealed that RA-serum inflammatory mediators directly enhanced endothelial damage which might be prevented by effect of both, biological and targeted-synthetic DMARDs therapy.

Thus, the analysis of the RA patients circulating molecular profile might contribute to improve the personalized clinical management of these patients and their CV risk. OP0024 DOES ANTIINFLAMMATORY THERAPY OF RHEUMATOID ARTHRITIS AFFECT SURVIVAL AFTER FIRST ACUTE MYOCARDIAL INFARCTION

Keywords: Comorbidities, Disease-modifying drugs (DMARDs), Cardiovascular disease

M. Skjetne1, L. Soderstrom2, S. Rantapaa-Dahlqvist3, A. Sodergren1, T. Moe2, 1Umea University, Public health and Clinical Medicine/Rheumatology, Umea, Sweden; 2Östersund Hospital, Unit of Research, Östersund, Sweden; 3Umea University, Public health and Clinical Medicine, Östersund, Sweden

Background: Our previous study showed that rheumatoid arthritis (RA) was associated with higher one-year mortality after first acute myocardial infarction (AMI). Studies have shown increased mortality already within 30 days after cardiovascular events (AMI or stroke) in RA patients compared to non-RA patients. Objectives: We aimed to study if antiinflammatory medical treatment affected survival within 30 days after a first AMI in patients with RA versus non-RA patients. Methods: Data for 198944 patients with a first AMI were drawn from the Swedish Register of Information and Knowledge about Swedish Heart Intensive Care Admissions for 2006-2017. We used the National Patient Register to identify RA patients with AMI. RA was defined as ≥2 visits to a Rheumatology or Internal Medicine department with a diagnosis of RA, 3725 patients were diagnosed. Antirheumatic medical treatment prescribed during six months prior to the first AMI in RA and non-RA patients was obtained from the National Prescribed Drug Register. The drugs and all their combinations were divided into five groups: Corticosteroids, NSAID (Non-steroidal anti-inflammatory drug), csDMARD (conventional synthetic Disease-modifying antirheumatic drug), anti-TNF (anti-Tumor Necrosis Factor), BDMDARD (biologic Disease-modifying antirheumatic drug). Logistic regression analysis was used to identify variables associated with increased mortality within 30 days after first AMI in each treatment group. Results: Increased risk of death was found in the corticosteroid group in both non-RA and RA groups (OR 1.61 and 1.66). Treatment with csDMARD and anti-TNF in the RA group were associated with increased survival (OR 0.81 and 0.72), Table 1. Conclusion: We showed that patients treated with corticosteroids had an increased risk of death after first AMI. RA patients treated with csDMARD and anti-TNF had a lower risk of death which could explain that high inflammatory activity in RA patients may be part of the explanation of the increased mortality after first AMI.

OP0025

MORTALITY AND MAJOR ADVERSE CARDIOVASCULAR EVENTS AFTER GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONIST INITIATION IN PATIENTS WITH AUTOIMMUNE DISEASES AND TYPE 2 DIABETES: A POPULATION-BASED STUDY

Keywords: Cardiovascular disease, Comorbidities, Epidemiology

D. Karacabeyli1, N. Lu2,3, N. MCCormick3, H. Choi1,3, D. Lalacille1,2, J. A. Aviña-Zubieta1,3,4, A. The University of British Columbia, Medicine (Division of Rheumatology), Vancouver, Canada; Arthritis Research Canada, Rheumatology, Vancouver Canada; Massachusetts General Hospital, Medicine (Division of Rheumatology, Allergy, and Immunology), Boston, United States of America

Background: Patients with autoimmune rheumatic diseases are at higher risk of cardiovascular complications and premature mortality [1,2], possibly related to chronic inflammation. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are used to treat type 2 diabetes and obesity (two pro-inflammatory states associated with systemic autoimmune diseases) and have anti-inflammatory properties [4], but their clinical effects on cardiovascular outcomes and mortality in patients with autoimmune diseases remain unknown.

Objectives: To assess the risk of all-cause mortality and major adverse cardiovascular events (MACE) in patients with autoimmune diseases and type 2 diabetes initiating GLP-1 RAs versus dipeptidyl peptidase-4 inhibitors (DPP-4 ias).

Methods: We performed a sequential propensity score (PS) overlap weighted population-based cohort study using administrative health data from British Columbia. Data included diagnostic codes from physician visits and hospitalizations in a universal health care system, all pharmacy-dispensed medications, and vital statistics from January 1, 2010, to December 31, 2021. All patients with an autoimmune disease (i.e., rheumatoid arthritis, psoriatic disease, ankylosing spondylitis, inflammatory bowel disease, or a systemic autoimmune rheumatic disease) and type 2 diabetes who newly initiated a GLP-1 RA or DPP-4i were identified using ICD-9/10 codes. The primary outcome of interest was all-cause mortality. The secondary outcome was MACE (composite of cardiovascular death, myocardial infarction, and ischemic stroke). Herpes zoster reactivation was assessed as a negative control outcome. Cox proportional hazard regression models with PS overlap weighting were used.

Results: We identified 10,855 patients with autoimmune diseases and type 2 diabetes who newly initiated a GLP-1 RA or DPP-4i. All-cause mortality rate was lower among initiators of GLP-1 RAs compared to initiators of DPP-4 ias, with a weighted hazard ratio (HR) of 0.48 (95% CI, 0.31-0.75) and rate difference (RD) of -9.4 (95% CI, -16.0 to -2.7) per 1000 person-years (Table 1). Rates of MACE were also lower with GLP-1 RA versus DPP-4i exposure (HR 0.66 CI, 0.50-0.88, RD -10.5 [CI, -20.4 to -0.8]). There was no difference in the risk of herpes zoster reactivation (HR 0.98 CI, 0.65-1.43).

Conclusion: In patients with autoimmune diseases and type 2 diabetes, GLP-1 RA exposure is associated with a lower risk of all-cause mortality and MACE compared to DPP-4i exposure. Further research is needed to explore potential adipo-ceptivity-dependent and independent mechanisms through which GLP-1 RAs may reduce cardiovascular risk for patients with autoimmune rheumatic diseases.

OP0026

INCREASED VASCULAR INFLAMMATION ON PET-CT IN PSORIATIC ARTHRITIS PATIENTS IN COMPARISON WITH HEALTHY CONTROLS

Keywords: Psoriatic arthritis, Cardiovascular disease, Imaging

N. J. Kleineinsins1,2, W. Poppen2, N. Sedding2, H. Vonkeman3, K. Sjuijkerbuijk4, M. Jansen1, P. De Jong2, M. W. Heijstek1, J. Spierings1, 1UMC Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands; 2UMC Utrecht, Department of Radiology, Utrecht, Netherlands; 3Medisch Spectrum Twente, Department of Rheumatology, Enschede, Netherlands, 4UMC Utrecht, Department of Medical Oncology, Utrecht, Netherlands

Background: Patients with psoriatic arthritis (PsA) have an increased risk of cardiovascular disease, possibly due to a chronic inflammatory state.
Independent Samples t-test

**Objective:** The main objective of this study was to investigate whether vascular inflammation, measured with 18-fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT), is elevated in PsA patients.

**Methods:** We included 75 PsA patients with active peripheral arthritis (≥2 tender and swollen joints) from an ongoing clinical trial (EudraCT 2017-003900-28), and a retrospective group of 40 controls with melanoma, without distant metastases and not receiving immunotherapy. Both PsA patients and controls were aged 18-75 years. The main outcome measure was aortic vascular inflammation, which was measured using target-to-background-ratios (TBR) on PET/CT. Clinical disease activity in PsA was assessed with the TBR, body surface area and the composite measure Disease Activity index for PsA. Laboratory assessments included the inflammatory parameters C-reactive protein and Erythrocyte Sedimentation Rate. Vascular inflammation was compared between PsA patients and controls in univariate analysis with an unpaired t-test with equal variances. A multiple linear regression analysis was performed to adjust for age, gender, body mass index and mean arterial pressure (MAP). Associations of clinical parameters of disease activity in PsA with vascular inflammation were assessed using Spearman’s correlation coefficient.

**Results:** Vascular inflammation was increased in PsA patients in comparison with controls (mean TBR for entire aorta respectively 1.53±0.15 and 1.42±0.13; P<0.001; Figure 1). This association remained significant after adjusting for gender, age, body mass index and mean arterial pressure (P=0.002). In individuals with PsA, vascular inflammation was not associated with disease-related parameters. There were no significant differences between PsA patients and controls regarding age, mean arterial pressure (MAP) and history of CVD. PsA patients had a higher BMI in comparison with healthy controls (Table 1).

**Conclusion:** Aortic vascular inflammation was increased in patients with active PsA compared with controls. This evidence suggests that inflammation in PsA is not limited to skin and joints, but also involves the cardiovascular system.

**Background:** Rheumatoid arthritis (RA) patients are at high risk for atherosclerotic cardiovascular disease (CVD) and mortality, and dyslipidemia represents a modifiable CV risk factor significantly contributing to the increased risk. However, dyslipidemia is frequently underestimated and inadequately managed in rheumatologic clinical practice.

**Objectives:** The aim of the present study was to investigate how dyslipidemia in RA patients is managed in a real-life setting for primary prevention strategies.

**Methods:** A cross-sectional study of RA patients of the Cardiovascular Obesity and Rheumatic DiSeases (CORDIS) cohort [1], with no previous CVD and with available lipid levels was performed. All patients were stratified by the Systematic COronary Risk Evaluation (SCORE) algorithm for CV risk [2] and the application of primary preventive strategy was assessed in accordance with the 2019 European Society of Cardiology (ESC)/European Atherosclerosis Society (EAS) guidelines for the management of dyslipidemias [3].

**Results:** A total of 1296 RA patients (79% females) with a mean age of 59±12 years were included. According to the SCORE algorithm, 457 (35.5%) patients were at moderate CV risk (1-5%), 455 (35.1%) at high CV risk (5-10%), and 384 (29.6%) at very high (>10%) CV risk. None was at low CV risk (<1%). Eighty percent of the whole cohort was eligible for statin therapy, but only 22.3% was on treatment at inclusion, and 39.7% presented lipid levels on target. Among patients at high and/or very-high SCORE risk, 70% were not on statin treatment even if recommended and 26.7% were not at lipid target even if under statin use. Among patients at moderate SCORE risk, 208 (45.5%) were at lipid target and 31(14.9%) of them were on statin therapy. Globally 565 (43.6%) patients were not on treatment for dyslipidemia even if recommended according to ESC/EAS guidelines (Figure 1). Of note, about 80% of RA patients at high or very high CV risk were on anti-hypertensive and/or antiaggregant treatment.

**Conclusion:** Statin therapy prescription is suboptimal in RA despite a relevant proportion of patients meeting indications according to LDL thresholds and/or
SCORE algorithm. Preventive CV strategies seem mainly focused on anti-hypertensive or antiplatelet therapy. Rheumatologists should pay close attention to lipid levels and preventive therapeutic interventions to reduce the CV risk of RA patients.

Conclusion: In this largest study to date of patients with pre-existing RA initiating ICI, 46% flared, often after initial ICI infusion, but were mostly mild and managed with typical therapies. A minority had severe RA flares requiring disruption of ICI, but RA flares were not associated with mortality. These results reiterate that pre-existing RA should not be considered a contraindication to ICI treatment for cancer.

Background: Despite advances in the understanding of juvenile idiopathic arthritis (JIA) pathophysiology, personalized treatments informed by gene transcriptomic profiles remain elusive.

Objectives: To examine the relationship between changes in gene expression and treatment response in patients with JIA treated with tofacitinib.

Methods: Whole blood samples from patients with JIA were collected using Paxgene tubes at baseline (BL) and again at week (wk) 18 of treatment with tofacitinib as part of a clinical trial (NCT02592434) [1]. Patients were classified as treatment responders (TR) if they achieved at least a JIA-American College of Rheumatology score of (JIA-ACR70) or above (NTR = 47; NTR = 58); and non-responders (NR) improvement was no more than a JIA-ACR30 response (NTR = 20; NNR = 8). Bulk RNA was isolated, subjected to globin/rRNA deple- tion, and used for generation of cDNA libraries for subsequent sequencing. RNA sequencing via Illumina Nova-seq generated 50 million reads per sample. Gene expression was compared in TR and NR (BL, wk18; change BL to wk18). Kallisto 0.48.0 was used for pseudo-quantification (GRCh38 release 94 index). Differential expression and Gene Ontology (GO) over-representation analyses were performed with dseep 0.34.0.

Results: Significant differential expression (FDR<0.05) was observed in 10,138 genes between BL and wk18. GO over-representation analysis was performed separately for up- and down-regulated genes with FDR<0.05 and absolute logFC>0.8 (n=231). For genes down-regulated with treatment (BL-wk18), ontologies related to negative regulation of gene expression, type I and type II interferon pathways were significantly over-represented (FDR<0.05), while ontologies for synapse organization and activity were over-represented among up-regulated genes (Figure 1). The latter might reflect the normalization of the immunological synapse leading to improved cytotoxic NK and T cell functions, the impairment of which has been proposed to escalate the production of IFN-γ and other proinflammatory cytokines [2]. There were no significantly differentially expressed genes (FDR < 0.05) between TR vs. NR at BL or wk18. Exploratory GO analysis in NR vs. TR at baseline (FDR<0.13, n=76 genes) suggests up-regulation of genes in ontologies related to the activation of MAP kinase activity.

Conclusion: Tofacitinib treatment in JIA patients leads to widespread changes in whole blood transcriptional profiles. The most significant transcriptional changes observed included the down-regulation of genes associated with type I and type II interferon pathways, and the up-regulation of genes involved in synapse organization and activity. Potential association of MAP-kinase activation in NR at baseline needs to be further explored. MAP-kinase is one of the signalling pathways in inflammatory arthritids that can be targeted by small molecules other than JAK inhibitors. Thus, patients with a predominantly active MAP-kinase pathway could be less likely to respond to tofacitinib. If confirmed, these findings might be useful to personalize JIA treatment in the future.

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children. Our group has recently demonstrated that extended oligoarticular and polyarticular JIA mostly evolve to a rheumatoid arthritis (RA)-like phenotype in adulthood. Disturbances in B cells, T follicular helper (ThF) and T follicular regulatory (TfR) cell immune responses are associated with RA pathogenesis, but their exact role in JIA development is poorly understood.

Objectives: The main goal of this study was to characterize the frequency and phenotype of B, ThF and TfR cells in peripheral blood and the cytokine envi- ronment present in circulation in children with with extended oligoarticular JIA (eOJIA) and polyarticular arthritis (pJIA) when compared to healthy controls, children with persistent oligoarticular JIA (pOJIA) and adult JIA patients.

Methods: Blood samples were collected from 105 JIA patients (children and adults) and 50 age- and gender-matched healthy individuals. Peripheral blood mononuclear

Methods: Blood samples were collected from 105 JIA patients (children and adults) and 50 age- and gender-matched healthy individuals. Peripheral blood mononuclear
cell-mediated inflammation.

The frequency of B and Tfh cell subsets, but not in Tfr cells, were found in peripheral blood of children with eoJIA and pJIA when compared to controls. Our results suggest a potential role and/or activation profile of B and Tfh cells were isolated and the frequency and phenotype of B, Tfh and Tfr cells were measured by multiplex bead-based immunoassay and/or ELISA in all groups included. 

**Results:** The frequency of B, Tfh and Tfr cells was similar between JIA controls. Our results suggest a potential role and/or activation profile of B and Tfh cells were isolated and the frequency and phenotype of B, Tfh and Tfr cells were measured by multiplex bead-based immunoassay and/or ELISA in all groups included.

**Conclusion:** In ERA, the immune architecture of the inflamed synovium is profoundly perturbed, whereby Th1 and Th17 cells are the main CD4+ T cell drivers of disease. CXCR3+CXCR6+ CD4+ Tffs are possible precursors of Th1- and Th17-mediated synovial inflammation, and may be inadequately regulated during disease. The results provide mechanistic support for therapeutic targeting of the Th1 and Th17 pathways, as well as CXCR3 and CXCR6 signalling to curb T cell-mediated inflammation.

Albani3,4,1 Duke-NUS Medical School, MD-PhD Programme, Singapore, Singapore; 2Translational Immunology Institute, SingHealth Duke-NUS Academic Centre, Singapore, Singapore; 3Duke-NUS Medical School, SingHealth Duke-NUS Paediatrics ACR, Singapore, Singapore; 4KK Women’s and Children’s Hospital, Division of Medicine, Singapore, Singapore

**Background:** Enthesitis-related arthritis (ERA), a common subtype of juvenile idiopathic arthritis (JIA), carries a poor prognosis. Current therapies, including anti-TNF agents, are limited in controlling disease. There is a poor understanding of ERA immunopathogenesis, especially the ontogeny of synovial pro-inflammatory T cells, which limits prognostic and therapeutic targets.

**Objectives:** We aim to compare, using a high-dimensional approach, the synovial and circulatory immune architectures of active ERA patients. Through this, we aim to identify CD4+ T cell subsets strongly associated with synovial inflammation in active ERA patients. We also aim to assess differentiation, cytokine production and regulation of candidate CD4+ T cell subsets.

**Methods:** We interrogated, using mass cytometry, CD4+ immune cells from the synovium (n=10) and circulation (n=30) of ERA patients with active joint inflammation, as well from blood of healthy paediatric controls (n=30). FlowSOM clustering were performed with functionally and phenotypically important immune markers. Multiple Mann-Whitney U tests with Holm-Sidak correction identified significantly different cluster frequencies. Significant clusters were validated with supervised gating on FlowJo. To evaluate CXCR3+CXCR6+ CD4+ T cells, we sorted CXCR3+CXCR6+ Tffs and Tregs from active ERA SFMCs and PBMCs with FACs. We then conducted in-vitro maturation and Treg suppression assays on sorted cells.

**Results:** The ERA synovium has a deranged immune architecture that is distinct from the circulation, and this involves innate and adaptive immune perturbations. The ERA synovium is enriched with CD4+ Effector memory cells (median: 68.45% vs. 23.85% of total CD4+ T cells; p<0.0001), of which IFNγ+ (44.85% vs. 4.08% of total CD4+ T cells; p<0.0001), and TNFα+ (10.64% vs. 2.52% of total CD4+ T cells; p<0.0001) producers dominate. The ERA synovium is also enriched with CXCR3+CXCR6+ CD4+ T cells, which are present at lower numbers and activation status in the ERA circulation (6.64% vs. 2% of total CD4+ T cells; p<0.0001). Under in-vitro TCR stimulation, synovial CXCR3+CXCR6+ CD4+ Tffs mature into IFNγ+ IL-17A, and dual IFNγ+IL-17A producers. Synovial CXCR3+CXCR6+ CD4+ Tregs are bona fide Tregs that suppress their Teff counterparts. However, CXCR3+CXCR6+ CD4+ Tregs are not proportionally expanded relative to CXCR3+CXCR6+ CD4+ Tffs in the ERA synovium.

**Conclusion:** In ERA, the immune architecture of the inflamed synovium is profoundly perturbed, whereby Th1 and Th17 cells are the main CD4+ T cell drivers of disease. CXCR3+CXCR6+ CD4+ Tffs are possible precursors of Th1- and Th17-mediated synovial inflammation, and may be inadequately regulated during disease. The results provide mechanistic support for therapeutic targeting of the Th1 and Th17 pathways, as well as CXCR3 and CXCR6 signalling to curb T cell-mediated inflammation.

**ANALYSIS OF B CELL SUBSETS AND B CELL CYTOKINES IN PEDIATRIC SJÖGREN’S SYNDROME.

**Keywords:** Sjögren syndrome, Cell biology, Adaptive immunity

P. Nicolai1, C. Bracaglia1, A. Boni1, I. Caiello1, D. Pires Marafon1, F. De Benedetti1, E. Marasco1,2 Bambino Gesù Children Hospital, Unit of Rheumatology, Rome, Italy

**Background:** Pediatric Sjögren’s syndrome (pSS) is a rare disorder that is often diagnosed late due to the lack of validated diagnostic criteria and validated biomarkers. The pathogenesis is largely unknown, but there is evidence of involvement of both the innate and adaptive branch of the immune system. Immunological overactivity is central in the pathogenesis of pSS. Several studies showed the presence of B cells abnormalities in patients with SS with an expansion of naïve B cells and a decrease in the frequency of memory B cells.

**Objectives:** We set out to investigate the distribution of B cell subsets and B cell cytokines in patients with pSS at disease onset and at follow up visits.

**Methods:** A monocentric retrospective cohort study was conducted on 23 patients with pSS enrolled at the department of Rheumatology of Bambino Gesù Children’s Hospital. Serum levels of CXCL13 and BAFF were analyzed by ELISA. B cell phenotype was assessed on peripheral blood mononuclear cells (PBMCs) by flow cytometry. Systemic disease activity was evaluated by ESSDAI (EULAR Sjögren’s syndrome disease activity index) and Clinical-ESSDAI score (Clin-ESSDAI), according to 2020 EULAR recommendations; active disease was defined by Clin-ESSDAI ≥1 and remission by ClinESSDAI=0. As controls we selected age-matched people with no diagnosis of pSS or any other systemic autoimmune disease.

**Results:** Serum levels of CXCL13 and BAFF were significantly higher in patients with pSS than the control group (p<0.05) (Figure 1A). We correlated levels of biomarkers with clinical and laboratory parameters: we observed a positive correlation between hypergammaglobulinemia and BAFF (rho=0.80). Analysis of B-cell subsets at disease onset revealed the expansion of a population of atypical memory B cells (p=0,00049) and a reduction in IgM memory B cells (p=0.0034) compared to the control group (Figure 1B). We then compared the distribution of B cell subpopulations at disease onset (pre) with samples obtained at follow-up (post) for each patient no significant differences were observed (Figure 1B). We also investigated the distribution of Th17 cells in patients with pSS and we observed a significant expansion of CXCR5PD1+ Tffs (Figure 1B).

**Conclusion:** Patients with pSS showed high levels of CXCL13 and BAFF at disease onset. Alteration in B cell subsets are present in patients in pSS compared to controls, with an expansion of atypical memory B cells and Tffs. The B cell abnormalities are not affected by treatment. Our data confirm a hyperactivation of the humoral immune system in patients with pSS and provide evidence for their development as biomarkers and to develop new therapeutic strategies aimed at controlling B cell hyperactivation in pediatric patients with SS.

Background: Differential diagnosis in children with signs of unprovoked inflammation can be challenging. In particular, differentiating systemic-onset juvenile idiopathic arthritis (SJIA) from other diagnoses is difficult in individuals presenting with fever of unknown origin. We have recently validated myeloid-related protein 8/14 (MRP8/14, S100A8/A9, calprotectin) serum analyses as a helpful tool supporting the diagnosis of SJIA. The results could be confirmed with a commercial ELISA. However, further optimization of the analytical technology will be important to enable large-scale use in routine laboratory settings.

Objectives: To evaluate the accuracy in identifying children with SJIA, the performance of an immunoturbidimetric assay for measurements of serum-calprotectin (BÜHLMANN sCAL turbo) on an automated laboratory instrument was tested in serum samples of children with various conditions.

Methods: Samples from 650 children were available with diagnoses SJIA (n=99), non-systemic JIA (n=169), infections (n=51), other inflammatory diseases (n=161), and acute lymphatic leukemia (ALL, n=147). In addition, samples from 23 healthy controls were included. The patients with systemic inflammatory diseases were collected at Muenster University as reported before.[1] Patients with non-systemic JIA were from the Nordic JIA cohort as previously described in detail.[2] The ALL cohort included consecutive cases from Aalborg and Aarhus University Hospitals.[3] The BÜHLMANN sCAL turbo test is a particle enhanced immuno-turbidimetric assay (PETIA) and was compared to the established MRP8/14 ELISA from BÜHLMANN (EK-MRP8/14). The sCAL PETIA has a range of 230-15,000 ng/mL (extended range up to 225,000 ng/mL by dilution of 1:15) in sample volumes of only 2-3 µl and was implemented into the automated laboratory setting at the central clinical laboratory of the University Hospital Muenster as a rapid test available on demand.

Results: The sCAL turbo assay showed an excellent correlation to the MRP8/14 ELISA used in the previous validation studies (r=0.99, p<0.001). It could reliably differentiate SJIA from all other diagnoses with significant accuracy (cut-off at 9,100 ng/mL, sensitivity 93%, specificity 87%, ROC area under curve 0.961, p<0.001). Results are shown in Table 1 and Figure 1.

Conclusion: MRP8/14 (S100A8/A9, calprotectin) serum analyses have been validated as a helpful tool supporting the diagnosis of SJIA in children with prolonged fever or inflammatory disease. Here we show that an immunoturbidimetric assay for detection of serum-calprotectin on an automated laboratory instrument can be implemented in clinical laboratory settings to facilitate its use as a diagnostic routine test in clinical practice.

ADHERENCE TO URATE-LOWERING THERAPY AFFECTS THE RISK OF CARDIOVASCULAR EVENTS IN PATIENTS WITH GOUT

Keywords: Cardiovascular disease, Real-world evidence, Gout

1. Seoul Metropolitan Government–Seoul National University Hospital Boramare Medical Center, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2. Seoul Metropolitan Government–Seoul National University Hospital Boramare Medical Center, Medical Research Collaborating Center, Seoul, Korea, Rep. of (South Korea); 3. Kangwon National University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Chuncheon, Korea, Rep. of (South Korea)
Background: The benefit of urate-lowering therapy (ULT) on cardiovascular disease is still controversial. One confounding factor of its association is the adherence to ULT. The impact of adherence to ULT on major adverse cardiovascular events (MACE) has not yet been characterized.

Objectives: We aimed to investigate the patterns of adherence to ULT and their long-term effects on the risk of MACE in patients with gout.

Methods: Using the Korean national health insurance database, we identified 48,600 patients with gout who were 40 years-old or older and started ULT (allopurinol or febuxostat) in 2013-2014. Patient groups were determined based on ULT adherence at 1 and 3 years after its initiation. Non-adherence was defined by the ratio (<80%) of the proportion days covered during the reference period. Patients were divided into 4 groups: persistently adherent (n=11,087), first adherent/ later non-adherent (n=4,492), first non-adherent/ later adherent (n=5,486), and persistently non-adherent (n=27,535). The primary outcome was the occurrence of MACE (a composite of acute myocardial infarction, revascularization, or acute ischemic stroke) identified in the claims database. The hazard ratio (HR) derived by Cox proportional hazards models was calculated adjusting for age, sex, and comorbidities.

Results: The median follow-up period was 5.2 (interquartile range, 4.6-5.6) years. The persistently non-adherent group had a significantly higher risk of MACE than the persistently adherent group (adjusted HR, 1.14 [95% CI, 1.05-1.24]). The first non-adherent/ later adherent group had a significantly lower risk of MACE than the persistently adherent group (adjusted HR, 0.85 [95% CI, 0.76-0.96]). The risk of MACE was comparable between the persistently adherent group and the first non-adherent/ later non-adherent group (adjusted HR, 1.03 [95% CI, 0.91-1.17]).

Conclusion: Sustained non-adherent to ULT significantly increases the risk of MACE in patients with gout. Regained adherence to ULT was associated with a lower risk of MACE compared with sustained non-adherence.

Introduction.

Weight gain is one of the most feared patient-reported adverse event of glucocorticoids, however the effect of low-dose prednisolone on body weight and composition in RA still has to be unraveled.

Objectives: Current study is a substudy of the GLORIA trial.[1] We report changes in body weight of the whole study population, and relate these to changes in disease activity, and changes in body composition in a subgroup of patients.

Methods: The GLORIA trial, a pragmatic, placebo-controlled, double-blind, randomised controlled trial investigated the balance of benefit and harm of 2 years of prednisolone 5 mg/day added to standard care in 451 patients with active RA aged 65+.[1] In current study 449 patients were included, and body weight and disease activity score of 28 joints (DAS28) were measured at baseline and after 2 years with dual-energy X-ray absorptiometry. Data were analysed with longitudinal mixed models, and log-ratio analysis to evaluate the mutual changes in body composition, given as the proportions total lean mass, total fat mass, and total bone mass.

Results: Body weight changed by mean (95% CI) 0.9 (0.3;1.6) kg on prednisolone after 2 years, versus −0.4 (~1.1;0.2) kg on placebo, with a difference between treatment groups of 1.3 (0.5;2.2) kg (p<0.01). In multivariable regression analysis, the effect of AUC DAS28 0–2 years was not significantly associated with weight change (p=0.18). The change in body composition after 2 years was different in...
prednisolone compared to placebo patients (log-ratio analysis, p=0.02; Table 1). Prednisolone patients showed small but favorable changes in body composition, i.e. lean mass increases exceeding fat mass increases, with trends in differences for total lean mass and lean mass index, and even significant differences for appendicular lean mass (p=0.02), and its corresponding index (p<0.01). No differences in change were seen in total fat mass, nor in fat distribution over the body, i.e. trunk, extremities and head (log-ratio analysis, p=0.93).

Conclusion: Patients with active RA aged 65+ treated with prednisolone 5 mg/ day for 2 years gained about 1 kg in weight, compared to non-significant weight loss on placebo. This weight gain is a direct effect of the glucocorticoid treatment, and not significantly dependent of decrease in disease activity. The small increase in weight is mostly (appendicular) lean mass, rather than increase or redistribution of fat mass traditionally associated with glucocorticoid treatment.

VACCINATION RATE, ADVERSE REACTIONS, AND REASONS FOR NONVACCINATION OF COVID-19 VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A JAPANESE REAL-WORLD CLINICAL PRACTICE

Keywords: Rheumatoid arthritis, COVID, Vaccination/Immunization

Y. Hirano1, Y. Saito1, 1Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan

Background: The first coronavirus infection was confirmed in Wuhan City, People’s Republic of China, in December 2019. On January 30, 2020, the World Health Organization declared the novel coronavirus disease a public health emergency of international concern. On March 11, 2020, World Health Organization announced that the new coronavirus infection can be regarded as a pandemic because of the global spread of the infection. The world’s first authorization announced that the new coronavirus infection can be regarded as an emergency of international concern. On March 11, 2020, World Health Organization, in December 2019. On January 30, 2020, the World Health Organization, in December 2019.

Conclusion: This study provides a comprehensive long-term picture of the rate and pattern of accumulation of multimorbidity in RA over the disease course. MLT involved most patients with RA over time. Smoking, obesity and the use of disease modifying drugs were all found to influence the rate of MLTCA accumulation across a range of organ systems. The data suggest that sustained control of inflammation in RA, both through drug interventions and lifestyle management is an important part of limiting the risk of MLTC development throughout the disease course.

IMPACT OF CARDIOVASCULAR COMORBIDITIES ON EFFICACY OF TOFACITINIB VS TNFI IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Cardiovascular disease, Comorbidities

M. H. Buch1, M. Mortezavi2, J. Giles3, C. Charles-Schoeman4, G. Karpuzas5, H. Jo6, K. Kwok6, E. Nagy7, J. L. Rivas8, A. Yndestad9, 1NHR Manchester Biomedical Research Centre and University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; 2Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America; 3Columbia University, Vagelos College of Physicians & Surgeons, Department of Medicine, Division of Rheumatology, New York, NY, United States of America; 4University of California Los Angeles, Department of Medicine, Division of Rheumatology, Los Angeles, CA, United States of America; 5Harbor-UCLA Medical Center, Department of Internal Medicine, Division of Rheumatology and the Lundoquist Institute, Torrance, CA, United States of America; 6Pfizer Inc, Statistics, New York, NY, United States of America; 7Pfizer Ltd, Safety Surveillance and Risk Management, Tedworth, United Kingdom; 8Pfizer SLU, Inflammation and Immunology, Madrid, Spain; 9Pfizer Inc, Inflammation and Immunology, Oslo, Norway

Background: Patients (pts) with rheumatoid arthritis (RA) and a history of atherosclerotic cardiovascular (CV) disease (HxASCVD) have a higher risk of major adverse CV events (MACE) with tofacitinib vs tumour necrosis factor inhibitors (TNFi), whereas risk difference is not detected in pts with no HxASCVD.[1]

Objectives: To further explore the benefit/risk profile of tofacitinib by assessing efficacy in pts with RA with and without HxASCVD.

Methods: ORAL Surveillance (NCT02092467) was an open-label, post-authorisation safety study that included pts with active RA despite methotrexate treatment, aged ≥50 years and with ≥1 additional CV risk factor.[2] Pts were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or TNFi. In this post hoc analysis, pts were categorised by HxASCVD; for pts with no HxASCVD, 10-year risk of ASCVD was determined using the pooled cohort equations calculator[3] with a 1.5x multiplier applied per EULAR guidelines.[4] Odds ratios (ORs) were presented to compare tofacitinib vs TNFi in achieving remission (Clinical Disease Activity Index [CDAI] ≤2.8) or low disease activity (LDA; CDAI ≤10) at Month 6. ORs and adjusted rates of remission and LDA were obtained from a Generalised Estimating Equation repeated measures model, including baseline (BL) value, visit, treatment, treatment × visit and disease duration.

Results: Of 4362 pts, 640 had a HxASCVD, and 3722 had no HxASCVD, of which 3672 had BL CV scores calculated. Full pt demographics and BL disease characteristics have been published.[1,2] Mean BL CDAI scores across
treatment groups ranged from 37.6–41.0 for pts with a HxASCVD or non-missing BL CV scores. ORs and the percentage of pts achieving remission and LDA with tofacitinib vs TNFi at Month 6 are shown in the Table 1 and Figure 1, respectively. ORs were greater for pts receiving tofacitinib vs TNFi in the Overall population, and in pts with no HxASCVD, and were similar in pts with a HxASCVD. Pts with high or intermediate CV risk scores tended to be more likely to reach remission or LDA with tofacitinib vs TNFi, as were pts with low–borderline risk scores who received tofacitinib 10 mg BID.

</tbody>
</table>

For pts randomised to tofacitinib 10 mg BID who had their dose reduced to 5 mg BID due to a protocol amendment in 2019, data collected after pts were switched to 5 mg BID were counted in the tofacitinib 10 mg BID group CI, confidence interval; N, number of evaluable pts.

Conclusion: In pts with no HxASCVD, the efficacy of tofacitinib is at least as good as TNFi, and risk of MACE is comparable.[1] In pts with HxASCVD, clinicians should consider that risk of MACE with tofacitinib is higher vs TNFi,[1] while efficacy is similar. Overall, our findings further characterise the benefit/risk of tofacitinib by risk category, and provide a means to risk-stratify pts such that tofacitinib can be considered an effective treatment option where appropriate.

OP0044

DOES RHEUMATOID ARTHRITIS PATIENTS’ RISK OF OVERALL AND SITE SPECIFIC MALIGNANCIES DIFFER FROM THE GENERAL POPULATION? A NATIONAL CLAIMS DATABASE COHORT STUDY IN THE ERA OF BIOLOGICAL TREATMENTS

Keywords: Rheumatoid arthritis, Epidemiology, Comorbidities

M. Beydoun1, S. Pinto1, Y. De-Flyck2, B. Faureit3, X. Mariette4, R. Sero4, F. Tubach4. 1Institut Pasteur Louis Epidemiology and Public Health, Public Health, Paris, France; 2Institute Pierre Louis Epidemiology and Public Health, Cephepi CIC-1901, Paris, France; 3University Hospitals Pitié Salpêtrière - Charles Foix, Rheumatology, Paris, France; 4Bicêtre Hospital, Viral infection and immunology, INSERM U1184, Le Kremlin-Bicêtre, France

Background: Earlier studies, before the era of biologics, showed that rheumatoid arthritis (RA) patients were at higher risk of overall malignancies, with an excess relative risk of 28% compared to the general population. This risk is mostly carried by specific cancers such as lung cancer, lymphomas along with skin cancers. An update of cancer incidence is warranted in order to explore whether cancer risk has been modified in the era of biological and targeted DMARDs.

Objectives: To estimate the risk of cancer in patients with rheumatoid arthritis compared to the general population.

Methods: We conducted a nationwide population-based study within the French national claim database “Système National des Données de Santé” (SNDS) between January 1st 2010 and December 31st 2020. We estimated the site-specific and hematologic malignancies of RA patients, with the French population as reference, by use of the French Network of Population-Based Cancer Registries (FRANCIM). SIR were estimated with Poisson regression models.

Results: During the study period, 257,075 patients met the eligibility criteria, who contributed to a total of 1,906,742 person-years for the main analysis. RA patients had an increased risk of overall malignancy (SIR 1.20 [1.17-1.23]), particularly lung (SIR 1.41 [1.36-1.46], bladder (SIR 2.38 [2.25-2.51]), ears-nose-throat (SIR 1.40 [1.31-1.50]), cervix (SIR 1.80 [1.62-2.01]), prostate (SIR 1.08 [1.04, 1.13]), melanoma (SIR 1.37 [1.29-1.46]) cancers, marginal zone (SIR 1.22 [1.06-1.42]), diffuse large b cell (SIR 1.79 [1.63-1.96]), and Hodgkin (SIR 2.68 [2.33-3.18]) lymphomas, and multiple myeloma (SIR 1.50 [1.36-1.65]). Of note, some cancers were less frequent than in the general population such as pancreatic cancer (SIR 0.90, [0.83-0.97]) as well as breast and uterine body cancers (SIR 0.91 [0.88-0.94] and SIR 0.77 [0.70-0.84] respectively). Subgroup analyses revealed that the risk of overall malignancy was significantly less increased in women (SIR 1.08 [1.06-1.10] than in men (SIR 1.34 [1.31-1.36]) (between group difference p < 0.001). Whereas, the risk of pancreatic cancer was only decreased in men but not in women (SIR 0.83 [0.75-0.91] vs SIR 1.04 [0.93-1.17] respectively, p < 0.001). Full details are presented in the Figure 1 below. Overall risk of cancer
In the era of biologics, RA patients remain at greater risk of overall malignancy and some site-specific cancers, not only lung cancer and lymphoma. This higher incidence of overall malignancy was observed in RA patients treated with almost all type of DMARD or bDMARD. However, no causal relationship between treatments and cancer incidence can be drawn as indication bias was not taken into account. Of note, we observed a lower incidence of breast, pancreatic and uterine body cancers than the general population.

(RhZM), Department of Rheumatology, München, Germany; 21Hospital Universitari Son Espases, Rheumatology Department, Palma, Spain; 22University of Leeds, Department of Rheumatology, Leeds, United Kingdom; 23Hôpital de Hautepierre - Hôpitaux Universitaires de Strasbourg, Department of Rheumatology, Strasbourg, France

Background: Potential associations between targeted therapies and a new cancer in patients with an inflammatory arthritis (IA) and a history of malignant disease are a frequent concern in daily rheumatology practice. IA and/or immunomodulatory drugs might confer a specific risk of malignancy. No evidence-based framework has been proposed to guide clinicians on the benefit/risk balance when initiating or re-initiating a targeted therapy (bDMARDs and bDMARDs) in this context.

Objectives: This initiative aimed to develop points to consider (PTC) to assist rheumatologists when initiating/re-initiating a targeted therapy in the context of a previous malignancy.

Methods: Following EULAR standardised operating procedures, a task force of 2 patient representatives, and 25 experts (comprising 2 methodologists, 2 EMEUNET members, 1 oncologist, and 20 rheumatologists) first met to define the research questions for a systematic literature review concerning patients with IA and a history of cancer and other relevant information for consideration including: incidence of cancer in targeted therapy-treated patients and no history of cancer, traditional research in concomitant malignancy, management with targeted therapy, immune-related adverse events of checkpoint inhibitors. In a second meeting, the task force formulated the overarching principles and the PTC.

Results: The group formulated 5 overarching principles and 8 PTC relevant to the initiation of targeted therapies in patients with IA and a history of cancer. Major themes included a) the need to assess the individualized risk of cancer recurrence based on the characteristics of the patient, the cancer and the underlying disease; b) the importance of engaging with specialists caring for the cancer and, to define treatment based on a shared decision between the patient and the rheumatologist; c) the possibility to initiate without delay an appropriate targeted therapy for the treatment of the IA in patients in remission of their cancer; d) the proposal to prefer anti-cytokine bDMARDs over other treatment options in patients with history of solid cancer and to prefer B cell depleting therapy in patients with a history of lymphoma; e) the proposal to use JAK inhibitors and abatacept with caution, and only in the absence of therapeutic alternatives, based on the significant increase in cancer incidence in patients without a history of cancer, with tofacitinib compared to anti-TNF in a randomized clinical trial, and a modest but significant increase. with abatacept compared to other bDMARDs in some observational studies.

Conclusion: The 2023 EULAR Points to Consider provide guidance on the management of targeted therapies. in patients with IA and a history of cancer. The research agenda highlights the need for studies, to evaluate targeted therapies other than TNF inhibitors and anti-CD20 to address the evidence gaps in this setting.

**Background:** The daily dose of oral glucocorticoids (OCS) is associated with damage in Systemic Lupus Erythematosus (SLE), and OCS reduction is a major goal of SLE care. However, evidence regarding the real-world use of OCS in nation-wide populations are currently lacking.

**Objectives:** The aim of this study was to analyze the use of OCS in French patients with SLE, at the national level, using medicoadministrative data.

**Methods:** This study used the French health-insurance claims database (SNDIS), which contains pseudonymized individual data for over 66 million people. SLE patients were identified with the ICD-10 diagnosis code for SLE (M32), documented as a chronic condition or associated to hospital stay. Included SLE patients were defined as patients alive on January 1st 2020 whenever the SLE diagnosis occurred. SLE comorbidities and OCS complications were identified through validated algorithms. Real-world use of treatments was identified through drug deliveries in pharmacies and daily OCS doses (expressed in prednisone-equivalent) were calculated for the year 2019. Comparisons were made to age- and gender-matched controls without SLE from the general population.

**Results:** A total of 32,173 patients with SLE (mean age 49.9 ± 16.0 years; 86.1% women) were alive on January 1st 2020, with a mean disease duration of 7.1 ± 6.2 years. Among these prevalent SLE patients, 48.2% were treated with OCS. The mean daily dose of OCS was below 5 mg/day in 35.7%, between 5 and 7.5 mg/day in 64.4% and above 7.5 mg/day in 61.1%. OCS use was significantly more frequent in women, in patients with CMJC (specific health coverage for low income patients) and decreased with age (p <0.0001, for all). SLE-specific comorbidities, including glomerular disease, skin involvement, polyarthritis, pleurisy, pericarditis, and thrombocytopenia, were significantly increased in patients with higher doses of OCS (p <0.0001, for all). Use of SLE treatments other than OCS was significantly increased in patients with higher doses of OCS (p <0.0001, for all) (Table 1). Strikingly, 14.6% of patients receiving 5 to 7.5 mg of OCS per day and 14.2% of those receiving more than 7.5 mg per day were not treated with antimalarial drugs, immunosuppressives or other biologic treatments for SLE. Complications of OCS, including cardiovascular diseases, infections, osteoporosis, and obesity, were significantly increased in SLE patients receiving ≥ 5 mg per day of OCS (p <0.0001 for all). The overall annual mean cost of healthcare consumptions from a societal perspective in 2019 was €6,048 for prevalent SLE patients and €2,610 for matched controls (p <0.0001). Among prevalent SLE patients, the cost increased significantly according to the OCS daily dose: 3,683€ for patients without OCS, 6,383€ (daily dose of 0-5 mg/day), 9,815€ (5-7.5 mg/day) and 13,861€ (above 7.5 mg/day).

**Conclusion:** To the best of our knowledge, this is the first nation-wide study reporting on real-life use of OCS in patients with SLE. The proportion of patients treated with high-dose OCS ≥ 7.5mg/day remains unacceptable high and associated with increased comorbidities, OCS complications and significantly increased healthcare costs. Also, over 14% of patients receiving OCS doses ≥ 5 mg/day were not treated with antimalarial drugs, immunosuppressives or other biologic treatments for SLE. These results highlight the need for tight disease control and implementation of robust OCS-sparing strategies in SLE.

WITHDRAWAL OF MAINTENANCE GLUCOCORTICOID VERSUS OTHER IMMUNOSUPPRESSANTS AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN LONG TERM CLINICAL REMISSION: INTERIM ANALYSIS OF A NON-INFERIORITY RANDOMISED CONTROLLED TRIAL

**Keywords:** Randomized control trial, Tapering, Systemic lupus erythematosus

**Background:** Attempts to stop glucocorticoids (GC) among lupus patients in long term remission have been successful. Continuing other immunosuppressive (IS) agents indefinitely is currently the norm and this approach results in significant infectious, psychological and economic burden on patients. Moreover, there is no pathophysiological basis to withdraw GC over the other IS agents, except for the indirect evidence of higher adverse effects with continued low dose GC use. Hence, there is a need to assess, if the approach to taper steroids first is the right way in lupus.

**Objectives:** To compare the outcome of glucocorticoid withdrawal versus immunosuppressant withdrawal in patients of SLE in clinical remission.

**Methods:** This is a single centre, non-inferiority, open-label stratified randomized (1:1) controlled trial. Patients with SLE who were on IS for at least 3 years, in DORIS remission for a minimum of 1-year preceding screening and were on stable prednisolone dose of ≤7.5 mg/day plus a maintenance non biological IS were included. Stratification was done based on duration of IS use (<3 years and ≥3 years), and presence of proliferative lupus nephritis. All patients continued HCO during the study. Prednisolone or IS was tapered gradually over 3 months after randomisation. Primary end point was proportion experiencing a flare [SELENA-SLEDAI flare index (SFI)] and BILAG index at 52 weeks. Secondary end points were time to flare and severity of flare. Non-inferiority margin considered was 10%. For this abstract, data of maximum available follow up period for each patient was used.

**Results:** A total of 117 patients were randomised into steroid withdrawal (n=58) and IS withdrawal (n=59). Overall, 72% of the patients were in prolonged remission (DORIS remission on treatment >5 years). Median duration of available follow up is 46 weeks. There was a total of 23 flares of which 20 were mild-moderate and 3 were severe flares (SFI). Proportion of patients experiencing a flare was numerically higher in the steroid withdrawal group (15 vs 8 patients, RR 1.91 (0.88-4.15), p<0.09). (Table 1). Time to first flare was 27 days and 18 days following intervention in steroid and IS arm respectively. Severity of flare and time of first flare were not significantly different between the two groups (HR=0.49, 95%CI (0.20-1.15), p=0.096) (Figure 1). Severe flares were 2(3.4%) vs 1(1.7%) and mild-moderate flares were 13(22.4%) and 7(11.9%) in the steroid versus IS withdrawal arm respectively. There was one death due to MI secondary to SLE in patients on IS withdrawal.

**Conclusion:** Immunosuppressant withdrawal is noninferior to steroid withdrawal in patients with SLE in long term clinical remission. Identifying the individuals who are likely to flare is of utmost importance which can pave the way for a more personalised drug withdrawal approach.

HRs (95% CIs): per unit decrease in prednisolone dosages (1mg/day) were calculated using Cox proportional hazard model and adjusted by initial prednisolone dosage, antimalarial, immunosuppressive, disease duration, SLEDAI-2K, age at visit, gender, and ethnicity.
Conclusion: Tapering prednisolone was not significantly associated with subsequent flare in SLE patients who were SACQ. Antiinflammatory and immunosuppressive use was associated with reduced risk of flares in SACQ patients. Tapering prednisolone was associated with reduced risk of damage accrual in SACQ patients treated with more than 5 mg/day of prednisolone. These findings suggest glucocorticoid tapering is safe and protective in SLE patients in SACQ.

Background: Glucocorticoids (GC) (aka corticosteroids) are a class of drugs with broad range anti-inflammatory and immunosuppressive activities making them the most potent anti-inflammatory drugs. However, chronic or high dose systemic exposure consistently leads togethe with reduced risk of damage accrual in SACQ patients treated with more than 5 mg/day of prednisolone. These findings suggest glucocorticoid tapering is safe and protective in SLE patients in SACQ.

Methods: We have achieved specific targeting of GC to the immune system with INX200, an antibody-drug conjugate (ADC). INX200 is a fully humanized immune-targeting monoclonal antibody with silent Fc domain and conjugated through a cleavable linker to budesonide. Validation experiments were conducted using human target knock-in mice, mouse surrogate antibodies and non-human primates in various inflammation and chronic disease models.

Results: We show that INX200 targets both lymphoid and myeloid cells with minimal off-target activity outside the immune compartment. This translates to reduced toxicity when compared to free GC as measured by the lack of impact on the Hypothalamic-Pituitary-Adrenal axis (no changes in corticosterone levels) and bones (no changes in GC- activated transcription) both in mice and non-human primates. INX200 rapidly internalizes allowing for robust and efficient uptake of the ADC thereby providing superior loading of GC into immune cells which results in therapeutic equivalence to free GC at 1/10th of the dose. One dose of INX200 also leads to substantially longer exposure (>3 weeks) when compared to free GC (<24h) both in mice and non-human primates. Additionally, we show that in both acute and chronic inflammation models (Figure 1), INX200 is therapeutically as broadly efficacious as free GC demonstrating that GC targeting to immune cells is sufficient for full GC anti-inflammatory efficacy. Finally, developability studies show that INX200 is stable at high concentration and as such suitable for subcutaneous administration.

Figure 1. INX200 has equivalent efficacy to free GC at <1/10th of the dose in controlling disease development in the type 1 diabetes NOD mouse model. NOD mice were enrolled at 12-week old; INX200 (red) was dosed once a week at 10 mg/kg (~0.2 mg/kg of GC payload) and free GC (blue) in water at 2 mg/kg per day. Left graph shows blood glucose levels over time of treatment, the dashed line indicating diabetic glucose levels as >250 mg/dL. Right graph shows the % of diseased mice over time (n=10 mice, experiment repeated twice).

Conclusion: INX200 retains all the efficacy/potent therapeutic activities of GC but with little to no side effects. The successful targeting of GC to the immune system with the sparing of non-hematopoietic toxicities, offers a transformative advance in GC-based drugs for the treatment of severe, chronic inflammatory diseases such as IBD, lupus and asthma.

Acknowledgement: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease that leads to significant worsening of quality of life and mortality. The
enormous molecular heterogeneity of SLE is reflected in different clinical manifestations, disease progression and also in a different drug efficacy across patients.[1] Lupus nephritis (LN) is the most severe SLE manifestation with the potential of rapidly evolving into irreversible chronic kidney disease and kidney failure if not adequately followed and treated. Mycophenolate mofetil (MMF) is the most widely used first-line treatment for LN, being ineffective or partially effective in 15-30 percent of the patients.[2] Reasons for non-response are still unknown and low or moderate drug efficacy may lead to aggravation of the disease. Treat-to-target approaches where personalized molecular patterns guide therapeutic decisions, are rapidly growing in medical fields such as oncology, but remain unmet within clinical rheumatology.[3]. In addition, pathological molecular dysregulation behind SLE fluctuates within a non-linear clinical course and unpredictable patterns of flares and remissions, hindering the development of effective and robust predictive biomarkers for both diagnosis and drug responsiveness.[4] Objectives: The development of new, more effective therapies to treat LN is an urgent unmet need. The objective of this work is to define the cellular and molecular immune landscape behind non-response to MMF to finally apply this knowledge within routine clinical practice.

Methods: A longitudinal cohort comprising gene-expression and clinical data of 97 MMF responder and 28 non-responder blood samples was retrospectively analyzed. Differential gene expression and functional analysis were performed. Response rate was measured based on blood cell proportions. Single-cell RNA sequencing data was analyzed to identify the cell subtypes influencing non-response and their contributing genes and regulation mechanisms.

Results: A robust signature comprising 41 differentially expressed genes defined non-response to MMF and cellular profiles that favor the response to the drug in the patients were revealed. The response rate to MMF increases the lower the B cell cell ratio. Single-cell RNA sequencing showed that overexpression of the IFITM-family of genes in age-associated B cells, plasma cells, myeloid dendritic cells and macrophages was behind the non-response signature.

Conclusion: Blood cell subtypes and genes mediating non-response to MMF were revealed, opening a new scenario for the development of new therapeutic strategies for LN.

LUPUS LOW DISEASE ACTIVITY STATE ATTAINMENT IN THE PHASE 3 PLACEBO-CONTROLLED TULIP LONG-TERM EXTENSION TRIAL OF ANIFROLUB

Keywords: Treat to target, Systemic lupus erythematosus, Clinical Trials

Background: The Lupus Low Disease Activity State (LLDAS) has been prospectively validated as protective from flares, damage accrual, and mortality and is an important treatment goal in patients with SLE.[1] Recent analysis of pooled data from 2 phase 3 trials (TULIP-1 and TULIP-2) found that LLDAS attainment was achieved earlier, more frequently, and for a more sustained period with anifrolub vs placebo in patients with moderate to severe SLE.[2] Objectives: We investigated the long-term impact of anifrolub compared with placebo on LLDAS attainment over the 1 year TULIP-1/TULIP-2 and 3 year long-term extension (LTE) study period.

Methods: TULIP-1 and TULIP-2 (NCT02446912, NCT02446899) were randomized, placebo-controlled, 52-week trials of IV anifrolub (Q4W, 48 weeks) in patients with moderate to severe SLE despite standard therapy. Following the double-blind treatment period of the TULIP trials, patients could consent to participate in the 3-year, randomized, blinded, placebo-controlled LTE study (NCT02794288).[3] Here, data were analyzed by timepoint from TULIP baseline through the end of the LTE (Week 208) for patients who were assigned and received the same study drug (anifrolub 300 mg or placebo) during the TULIP-LTE periods. LLDAS attainment was defined as all of the following: SLE-DAI ≤2, ≤4 without major organ activity, no new disease activity, Physician’s Global Assessment [≤3], ≤1, prednisone or equivalent ≤7.5 mg/day, standard immunosuppressant dosing, no use of restricted medications (considered only during the pooled TULIP-1/TULIP-2 period but not during the LTE period), and no investigational product (IP) discontinuation. LLDAS percentages and cumulative time in LLDAS were compared using a Cochran–Mantel–Haenszel approach, and response rates were compared using logistic regression. Last observation carried forward was used to impute missing data for TULIP-1/TULIP-2, not for data captured in the LTE. All P-values are nominal.

Results: Data from 369 patients (anifrolub 300 mg, n=257; placebo, n=112) were evaluable for the 4-year TULIP-LTE study period. At the last TULIP visit (Week 52), 39.3% of the anifrolub group and 27.9% of the placebo group were in LLDAS (odds ratio [OR] 1.6, 95% CI 1.0–2.7, P=0.049). At the first visit of the LTE (Week 64), 33.5% of the anifrolub group and 22.8% of the placebo group were in LLDAS (OR 1.7, 95% CI 1.0–2.9, P=0.038). LLDAS attainment was relatively stable for the first 3 years (up to Week 156) and declined slightly in Year 4; this decrease likely reflects the proportions of patients who discontinued IP over time (Figure 1). However, attainment of LLDAS favored anifrolub vs placebo at all timepoints up to Week 208 (OR 2.7, 95% CI 1.3–5.6, P=0.007). For the combined 4-year TULIP-LTE period, greater cumulative time (P=0.001) and percentage of time (P=0.006) was spent in LLDAS by patients receiving anifrolub compared with placebo. Cumulative time in LLDAS at a threshold of ≥80% also favored anifrolub (OR 2.2, 95% CI 1.4–3.5, P<0.001); a similar trend was seen with a threshold of ≥50%, although this did not reach statistical significance (OR 1.4, 95% CI 0.8–2.4, P=0.217). Compared with placebo, patients treated with anifrolub were more likely to be in sustained LLDAS for ≥3 consecutive visits (49.4% vs 35.1%; OR 1.8, 95% CI 1.1–2.8, P=0.018), ≥5 consecutive visits (32.6% vs 20.1%; OR 1.8, 95% CI 1.0–3.1, P=0.033), or ≥7 consecutive visits (22.2% vs 11.6%; OR 2.1, 95% CI 1.1–4.1, P=0.028).

Conclusion: Anifrolub 300 mg treatment was associated with more frequent, prolonged, and sustained LLDAS compared with placebo during the 4-year TULIP-LTE period.

**PREDECTORS OF RENAL FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS: A POST-HOC ANALYSIS OF FOUR PHASE III CLINICAL TRIALS OF BELIMUMAB**

**Keywords:** Systemic lupus erythematosus, Kidneys, Biomarkers

S. Jägerback, A. Gomez, I. Parodis, 1 Karolinska Institutet and Karolinska University Hospital, Stockholm, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden; 2 Danderyd University Hospital, Division of Rheumatology, Danderyd, Sweden; Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden

**Background:** In patients with systemic lupus erythematosus (SLE), renal involvement is associated with high morbidity, and renal flares are major contributors to poor long-term prognosis. Identification of patients at risk of developing renal flares despite immunosuppressive therapy is imperative to optimize management.

**Objectives:** To identify predictors of renal flares in patients receiving treatment for active extra-renal SLE.

**Methods:** Data from BLISS-52 (NCT00424476), BLISS-76 (NCT00410384), BLISS Northeast Asia (NEA; NCT01345253), and BLISS-SC (NCT01484498) were used (N=3218). The trials included patients with active, seropositive SLE and excluded active severe renal SLE. Participants were assigned to belimumab or placebo, on top of non-biologic standard therapy. We investigated anti-dsDNA, anti-Sm, anti-ribosomal P, and anti-cardiolipin (aCL) antibodies, low C3 and low C4 levels, B cell activating factor (BAFF), serum albumin, serum creatinine, and proteinuria at baseline as potential predictors of renal flares during a 52-week follow-up. We used Cox regression models to evaluate traditional disease features as predictors of renal flares in the pooled trial population. We also performed subgroup analysis of belimumab and placebo recipients. Covariates in the adjusted models included age, sex, ethnicity, body mass index, organ damage, baseline extra-renal activity (SLEDAI-2K score excluding renal and immunological descriptors), current or former renal SLE history (renal BILAG A–D), baseline use of glucocorticoids, antimalarials, and immunosuppressants, and use of belimumab.

**Results:** The mean age of the study population was 36.7 years, 94% were women, 54.6% had current or former renal involvement at baseline, and 192 developed a renal flare after a median follow-up time of 197 (IQR: 85–330) days from baseline. Patients with current or former renal involvement at baseline displayed a >9-fold increased hazard to develop a new renal flare (HR: 9.4; 95% CI: 5.0–17.7; P<0.001). In the pooled study population, baseline serum albumin (adjusted HR 0.9; 95% CI: 0.9–0.9; P<0.001), proteinuria (adjusted HR: 1.3; 95% CI: 1.2–1.4; P<0.001), and low C3 levels (adjusted HR: 1.8; 95% CI: 1.3–2.5; P<0.001) were robust determinants of subsequent renal flare occurrence; similar associations were found in the belimumab and placebo subgroup analyses. Furthermore, we observed an association between anti-dsDNA positivity and renal flare development in univariable models (HR: 2.1; 95% CI: 1.4–3.2; P<0.001 in the pooled population), which attenuated in multivariable models (Figure 1). Positive levels of anti-Sm antibodies were associated with renal flare occurrence in the placebo (adjusted HR: 2.9; 95% CI: 1.5–5.6; P=0.002) but not in the belimumab subgroup, whereas anti-ribosomal P antibodies were associated with renal flare development in belimumab-treated (HR: 2.8; 95% CI: 1.5–5.0; P=0.001) but not in placebo-treated patients. Finally, positive levels of aCL antibodies (any isotype) predicted renal flare development in the belimumab group (adjusted HR: 1.8; 95% CI: 1.1–2.8; P=0.020) but yielded a negative association in the placebo group (adjusted HR: 0.4; 95% CI: 0.2–0.9; P=0.028).

**Conclusion:** Current or former renal involvement, baseline proteinuria levels, hypoalbuminemia, and C3 consumption were robust determinants of imminent renal flares. Beyond anti-dsDNA, anti-ribosomal P and aCL antibody positivity may prove valuable early signals of imminent renal flares in patients treated with belimumab. Anti-Sm positivity predicted imminent renal flares in patients treated with non-biological standard therapy, but not in belimumab-treated patients, assumably due to benefit conferred from belimumab in anti-Sm positive individuals, as shown previously [1].

**Background:** Baricitinib a selective Janus kinase (JAK) inhibitors 182 have been recognized as a potential therapeutic option in systemic lupus (SLE), also known Baricitinib, a JAK inhibitor, has demonstrated efficacy and safety in the treatment of dermatitis and arthritis 1; however, no JAK inhibitor studies have been conducted in lupus nephritis (LN) to date.

**Objectives:** To assess the efficacy and safety of Baricitinib in patients (pts) with active LN.

**Methods:** The study is a randomized, double-blind, active comparator (cyclophosphamide)-controlled, phase 3 trial registered on clinicaltrials.com (NCT015432531), enrolled adults ≥18 years with a clinical diagnosis of LN (who also fulfilled classification criteria for LN grade III & IV), who had objective signs of active nephritis consistent with persistent proteinuria≥0.5 g/day and/or cellular casts at screening, and who had SLEDAI-2K ≥ 4 and patient assessment of anti-dsDNA and C3 serum levels at study entry. Pts were randomized 1:1 to receive Group 1: oral Baricitinib 4mg once daily and PBO saline infusion monthly, Group 2: oral PBO tablet and cyclophosphamide (0.7mg/kg2) infusion monthly during a 6-months double-blind treatment period. The primary endpoint was proteinuria, response at week 12 and 24. Multiplicity-controlled secondary endpoints assessed at week 12 &24 included C3, anti-ds-DNA and SLEDAI-2K, and their changes from baseline. Treatment adverse events was recorded.

**Results:** Of 65 pts randomized at baseline, 60 enrolled in the study (Baricitinib 4mg, n=30; cyclophosphamide, n=30) and 100% received study drug through week 24. Baseline demographic and disease characteristics were balanced across treatment groups and consistent with an active LN population, all were females, 58% LN grade III; mean age 32.4 years; mean SLEDAI-2K 6.9; mean C3 12.1mg/L). A significantly reduction in proteinuria response rate at week 12 was achieved in group 1 vs group 2 (70% vs 43%; P<0.0001). Statistical significance was also achieved in the first 12 of the 24 multiplicity-controlled secondary endpoints (C3 and SLEDAI-2K) at week 12 in group 1 compared with group 2 (P<0.01). The proportion of pts who experienced adverse events was similar between treatment groups (group 1, 48%; group 2, 46%). Serious adverse events leading to discontinuation were reported in 2 (6.6%) pts treated with Baricitinib and 1 (3.3%) pts treated with cyclophosphamide, respectively (serious infection or herpes zoster), major adverse cardiovascular events, venous thromboembolic events, were not reported in the study.

**Conclusion:** Baricitinib 4mg once daily demonstrated significantly good improvements in disease activity, proteinuria, C3, anti-ds-DNA, than cyclophosphamide after 12 &24 weeks of treatment in pts with active LN. The safety profile of Baricitinib 4mg was consistent with what has been observed with other inflammatory musculoskeletal diseases, and no new risks were identified. These results support the potential use of Baricitinib 4mg in pts with active LN.
Clinical aspects and Treatment of axSpA: effects and predictors of effects

Keywords: Real-world evidence, Diagnostic Tests, Spondyloarthritis

Background: We have shown in the SPACE cohort that a diagnosis of early axial spondyloarthritis (axSpA) can be made in patients with chronic back pain (CBP) of less than two years (2y). However, diagnostic uncertainty can be an obstacle towards initiating disease-modifying treatment. The value of repeated assessments of SpA features over time.

Methods: We used the 2y data from the SPACE cohort. A European multicentre inception cohort of patients (age <45y) with CBP of recent onset (≥3 months, ≤2y) included from 2009 to 2016. The diagnostic work-up consisted of patient history, physical examination, acute phase reactants (APR), and HLA-B27 testing, radiographs and MRI of the sacroiliac joints (SI-CR and SI-MRI) and spine.

Results: We included 552 patients. Definite axSpA was attributed to 175 (32%) patients at BL and 166 (30%) at 2y (Figure 1). 155/175 (89%) and 145/166 (87%) fulfilled ASAS classification criteria, respectively. Of the 175 patients with definite axSpA at BL, 133 retained the diagnosis, and only 13 changed to no axSpA at 2y. Among the 175 patients with definite axSpA at BL, 133 retained the diagnosis, and only 13 changed to no axSpA at 2y. Most SpA features were already present at BL, with imaging findings and response to NSAIDs appearing as frequent incident SpA features potentially adding to a definite axSpA diagnosis over time.

Conclusion: The yield of repeated assessments of SpA features in patients with CBP suspected of axSpA was modest for the new definite axSpA diagnosis at 2y.

DOI: 10.1136/annrheumdis-2023-eular.560
Background: There is a growing interest in understanding the early disease stages of axial and peripheral SpA (axSpA and pSpA). In order to facilitate this, standardized definitions are needed for research purposes.

Objectives: To develop a consensus definition for the terms “early axSpA” and “early pSpA” in the research setting under the auspices of the Assessment of SpondyloArthritis international Society (ASAS).

Methods: The ASAS-SPEAR (SPondyloarthritis EARly definition) steering committee convened an international working group (WG). Five consecutive steps were followed: i) Systematic literature review (SLR) to identify existing definitions of early axSpA and pSpA and to summarize the evidence on the relationship between early treatment and clinical response in SpA[1,2]; ii) Discussion of SLR results within the WG and ASAS community (2022 annual meeting); iii) A three-round Delphi survey (Apr-Nov 2022) inviting all ASAS members to select the items that should be considered for the definition of the terms (using a Likert scale 1-9). In total, 20 items relating to different aspects (axial symptoms, duration of symptoms and radiographic damage involvement) were voted on. Consensus was defined as acceptance or rejection if ≥70% of responses fell within 1-3 or 7-9 on the Likert scale, respectively; iv) Presentation of Delphi survey results to the WG and later to the ASAS community; v) Final discussion, voting and endorsement by the ASAS community with 88% full ASAS members voting in favor (step v).

Results: After discussing the results of the SLR[1,2] (step i) with the ASAS community, consensus was to proceed with an expert-based consensus definition for early axSpA (81% full ASAS members voted in favor) but not for pSpA (54% voted against) (step ii). Importantly, it was decided that the definition should be based on the symptom duration (91% in favor) taking solely axial symptoms into account (77% in favor). A total of 151-164/205 (72-78%) ASAS members participated in the Delphi survey rounds (step iii). Consensus was achieved to define early axSpA as a duration of symptoms ≤2 years. Relating to axial symptoms, consensus was reached for acceptance of 6 items (axial symptoms should include cervical pain, thoracic pain, back pain, buttock pain and morning stiffness and be defined by a rheumatologist) and rejection of 2 items (should not include shoulder pain and hip pain). In addition, consensus was achieved to define early axSpA regardless of the presence/absence of radiographic damage (Table 1). Following the discussion of the Delphi survey results the WG agreed that in patients with a diagnosis of axSpA “early axSpA” should be defined as a duration of ≤2 years of axial symptoms. Axial symptoms should include spinal/buttock pain or morning stiffness and should be considered by a rheumatologist as related to axSpA, Figure 1. The WG proposal was discussed and endorsed by the ASAS community with 88% full ASAS members voting in favor (step v).

Conclusion: Early axSpA has for the first time been defined based on expert consensus. This ASAS definition should be used in research studies addressing early axSpA.

A patient with axSpA with axial symptoms ≤2 years has early axSpA regard less of the presence or absence of radiographic damage of the SIJ 78%
A patient with axSpA with axial symptoms ≤2 years has early axSpA regardless of the presence or absence of syndesmophytes on x-rays of the spine 70%
Background: The change over time of the structural damage of axial spondyloarthritis (axSpA) is important to consider since it may reflect the severity of the disease. In axSpA this structural damage can be evaluated either at the sacroiliac joints (SIJ) or spine level, and also either on conventional radiographs or Magnetic Resonance Imaging (MRI).

Objectives: To evaluate the sensitivity to change of different structural imaging outcomes over 10 years of follow-up in patients with early axSpA.

Methods: Patients with early onset (<3 years) axSpA (according to the treating rheumatologist) from the DESIR cohort were included. Radiographs and MRI of the SIJ and spine were obtained at baseline, 1, 2, 5 and 10 years in 4 separate reading waves. Images were scored by 3 trained central readers (wave 1 only 2 readers with one adjudicator) unaware of chronological order. The yearly rate of change (ROC) of each outcome was analyzed using generalized estimation equations (GEEs) including all patients with ≥1 score from ≥1 reader from ≥1 wave and using time (years) as explanatory variable. All outcomes (see the list on Table 1) were standardized (difference between the individual’s value and the population mean divided by the population SD). In addition, the relative standardized ROC (i.e., the standardized yearly ROC of an outcome divided by the corresponding rate of a reference imaging outcome) was calculated, with a value > 1 reflecting larger sensitivity, and < 1 lower sensitivity compared to the reference. Finally, the relative standardized ROC per anatomic site was calculated.

Results: Among all locations and modalities, the change in ≥3 fatty lesions was the outcome with the highest sensitivity to change (standardized ROC 0.073 per year). Considering as reference the modified New York criteria (mNY), the two most sensitive to change in outcomes in SpA (taking into account both MRI and radiographs) were ≥3 fatty lesions and the absolute number of fatty lesions on MRI (relative standardized ROC per year 4.867 and 4.130, respectively). Similarly, the most sensitive to change lesion in the spine (both MRI and radiographs) was the mSASSS score (relative standardized ROC per year 1.778) considering ≥1 syndesmophyte as the reference.

Conclusion: MRI structural outcomes in the SIJ, in particular fatty lesions, are more sensitive to change than radiographic outcomes. On the other hand, mSASSS remains the most sensitive method, even if compared to MRI of the spine.

Figure 1: Multivariable GEE analyses show associations between parameters and outcomes
A) DAPSA, B) ASDAS, and C) Clinical remission.

Figure 2. Predictive models for low disease activity in patients with ankylosing spondylitis treated with secukinumab in real-world – data from the German AQUILA study.

Main results:
A: Main predictors at baseline and their direction of influence based on Shapley values [3].
B: Explanation of patient-individual influence based on Shapley values [3].

Methods: Data of 580 AS patients from the AQUILA study were used. Thirty-two demographic, clinical, and treatment parameters at baseline (BL) served as input to develop prediction models. LDA was defined as Bath ankylosing spondylitis disease activity index (BASDAI) ≤ 2.0 at week (w) 16 (+/- 6 w). Samples were divided into training (70%) and validation (30%) cohorts. Ten different prediction models were applied and compared. Model performance was measured using area under the receiver operating characteristic curve (AUROC) which represents the probability that a randomly selected patient with LDA will have higher BASDAI than a randomly selected patient without LDA.

Acknowledgements: GESPIC has been financially supported by the German Federal Ministry of Education and Research (Bundesministerium für Bildung und Forschung-BMBF). As funding by BMBF was reduced according to schedule in 2005 and stopped in 2007, complementary financial support has been obtained also from Abbott/AbbVie, Amgen, Centocor, Schering-Plough, and Wyeth.

Background: Secukinumab (SEC) proved to be an effective treatment for patients suffering from ankylosing spondylitis (AS) in randomized clinical trials [1]. There is only limited knowledge on prediction of low disease activity (LDA) and treatment strategy in AS patients under SEC treatment in routine clinical care.

Objectives: Using real-world data from the German non-interventional study AQUILA [2], the main objectives were (1) to predict LDA in individual AS patients treated with SEC through machine learning methods and (2) to identify the most important predictors and their influence on the prediction using explainable artificial intelligence (XAI).

Methods: Data of 580 AS patients from the AQUILA study were used. Thirty-two demographic, clinical, and treatment parameters at baseline (BL) served as input to develop prediction models. LDA was defined as Bath ankylosing spondylitis disease activity index (BASDAI) ≤ 2.0 at week (w) 16 (+/- 6 w). Samples were divided into training (70%) and validation (30%) cohorts. Ten different prediction models were applied and compared. Model performance was measured using area under the receiver operating characteristic curve (AUROC) which represents the probability that a randomly selected patient with LDA will have higher prediction to achieve LDA than a patient with moderate/high disease activity. Additionally, sensitivity and specificity of the prediction model were computed and express the proportion of correctly identified patients who reach or don't reach LDA at w16, respectively. Shapley XAI estimated importance and impact of each predictor based on how it affected the change in individual prediction [3].

Results: The most influencing predictor was BASDAI at BL, followed by the number of pretreatments with biologics, C-reactive protein (CRP), assessment of spondyloarthrits international society health index (ASAS-HI) and patient height (Figure 1 A). AUROC of the best performing prediction model was 0.84. Sensitivity and specificity were 0.87 and 0.67, respectively. Applied XAI approach showed that the lower the BL values of BASDAI, ASAS-HI and number of pretreatments with biologics were, the higher the probability of reaching LDA at w16 was. The opposite was the case for BL values of CRP and body height (Figure 1 A). The approach also provided visual explanations of patient-individual predictions: Variables with values shown in green color increased probability of achieving LDA at w16, whereas red ones showed the opposite effect (Figure 1 B).

Conclusion: A promising prediction model accuracy of LDA in AS patients treated with SEC could be reached and validated. Identified main predictors at BL, such as BASDAI and number of pretreatments with biologics, and their direction of influence on the prediction of LDA mostly match the existing clinical knowledge [4]. The analysis showed that XAI can provide useful clinical insights into patient-individual predictions, potentially guiding AS treatment decisions in future.

REFERENCES:
Background: Limited data exist on the effect of biologics in slowing radiographic progression in patients (pts) with radiographic axial spondyloarthritis (r-axSpA).

Two-year data from MEASURE 1 showed low radiographic progression with secukinumab (SEC)[1]

Objectives: To compare the effect of SEC vs adalimumab biosimilar (SDZ-ADL) on spinal radiographic progression from SURPASS[2,3] the first head-to-head study in r-axSpA.

Methods: In this phase IIIb study, bio-naïve pts with active r-axSpA with a BASDAI ≥2, spinal pain score ≥2 (range 0–10), total back pain score ≥40 (range 0–100), and with hs-CRP ≥5 mg/L or ≥1 syndesmophytes(s) on spinal radiograph were randomised (1:1:1) to SEC (150 mg or 300 mg) or SDZ-ADL (40 mg; open label). Radiographs and MRIs were reviewed by 3 independent central readers (no adjudication performed) blinded to treatment and chronology of images. Primary endpoint was the proportion of pts with no radiographic progression (change from baseline [CBF] in modified Stoke AS Spinal Score [mSASSS] ≤0.5) on SEC vs SDZ-ADL at week (wk) 104 (superiority testing).

Secondary endpoints included CBF-mSASSS at wk 104, proportion of pts with ≥1 syndesmophyte(s) at baseline (BSL) with no new syndesmophytes(s) at wk 104, CBF-MRI Berlin sacroliac joint (SJU) inflammation score, CBF-AS Spine MRI-activity (ASpMIR-A) Berlin modification score, and safety.

Results: Overall, 855 pts received SEC 150 mg (n=287), 300 mg (n=286), or SDZ-ADL (n=282). With 78.5% male, age mean 42.1 years, mSASSS 16.6, BASDAI 7.1, hs-CRP 20.4 mg/L, and 73% with ≥1 syndesmophyte(s), this population had high risk of radiographic progression. At wk 104, cumulative distribution of CBF-mSASSS was similar across arms (Figure 1). Proportion of pts with no radiographic progression was 66.1%, 66.9%, and 65.6% (P=ns, both SEC groups) while mean CBF-mSASSS was 0.54, 0.55, and 0.72 with SEC 150 mg, 300 mg, and SDZ-ADL Overall, 56.9%, 53.8%, and 53.3% of pts in SEC 150 mg, 300 mg, and SDZ-ADL arms, with a BSL ≥1 syndesmophyte(s) did not develop new syndesmophytes(s) by wk 104 (Table 1). In the MRI sub-set (N=148), mean SJU scores at BSL and wk 16 were 2.54 and 0.98 (SEC 150 mg), 1.96 and 0.92 (SEC 300 mg), and 1.59 and 0.38 (SDZ-ADL); corresponding spine scores were 3.50 and 1.79, 2.56 and 1.25, and 3.00 and 0.71.

Conclusion: Spinal radiographic progression over 2 years was low with no significant difference between SEC and SDZ-ADL arms. No new safety signals were identified.

CLINICAL CONSEQUENCES OF INFILXIMAB IMMUNOGENICITY AND THE IMPACT OF THERAPEUTIC DRUG MONITORING: SECONDARY ANALYSES OF A RANDOMISED CLINICAL TRIAL

Keywords: Rheumatoid arthritis, bDMARD, Spondyloarthritis

M. K. Brun1,2, K. H. Bjertläke2,3, J. E. Gehin4, D. J. Warren5, R. A. Klaasen6, J. Sexton2, O. Sandanger2, T. K. Kvi61, C. Mork2, J. Jahnsen2,3, N. Bolstad7, K. K. Jørgensen2, E. A. Haavardsholm1,2, G. L. Goll7, S. W. Syversen1, Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; 1University of Oslo, Institute of Clinical Medicine, Oslo, Norway; 2Akershus University Hospital, Department of Gastroenterology, Lørenskog, Norway; 3Norwegian Radium Hospital, Department of Medical Biochemistry, Oslo, Norway; 4Oslo universitetssykehus HF, Rikshospitalet, Section of Dermatology, Oslo, Norway; 5Akershus Dermatologist Center, Akershus Dermatologist Center, Akershus, Norway

Background: Neutralising anti-drug antibodies (ADAb) are a problem in treatment with TNF-inhibitors (TNFi). Prospective data are needed to better understand how ADAb formation impacts safety and treatment outcomes of TNFi. Proactive therapeutic drug monitoring (TDM) allows for timely detection of ADAb and this strategy may have a role in reducing the negative clinical consequences of ADAb.

Objectives: To explore the temporal relation between anti-infliximab antibody formation and treatment outcomes and adverse events, and to assess the impact of TDM as a strategy to reduce these consequences.

Methods: Patients with immune mediated inflammatory diseases on infliximab therapy (n=615; 181 spondyloarthritis, 120 rheumatoid arthritis, 72 psoriatic arthritis, 114 ulcerative colitis, 83 Crohn’s disease and 45 psoriasis) were included in the Norwegian Drug Monitoring (NOR-DRUM) trials (1, 2) and randomised to TDM or standard infliximab therapy. Patients were followed for 52 weeks in the NOR-DRUM (induction therapy) and NOR-DRUM B (maintenance therapy) trials, respectively. Neutralising ADAb were assessed with a drug sensitive automated fluorescence assay at each infusion. In this sub-study, we assessed the risk of: failure to achieve remission (analysis A), disease worsening during maintenance therapy (analysis B), treatment discontinuation (analysis C) and adverse events (analysis D) in patients developing ADAb compared to patients without ADAb using logistic- or cox regression and Kaplan-Meier survival analyses, stratified by TDM or standard therapy. Regression analyses were adjusted for potential confounders (Table 1). Remission and disease worsening were defined by disease specific composite scores (1, 2).

Results: ADAb were detected in 147/615 (24 %) patients. Patients with ADAb had higher risk of not achieving remission 30 weeks after initiating infliximab therapy (odds ratio (OR) 2.4, 95 % confidence interval (CI) 1.3-4.2, P<0.01) (Table 1, Figure 1A) and of having a disease worsening during 52 weeks of infliximab maintenance therapy (hazard ratio (HR) 2.1, CI 1.4-3.3, P<0.001) (Figure 1B). ADAb formation was not significantly associated with adverse events in general, but the risk of infusion reactions was highly increased in patients with ADAb (HR 6.5, CI 4.7-8.9, P<0.001). Patients developing ADAb in the TDM group had lower risk of disease worsening or an infusion reaction than patients with ADAb in the standard infliximab therapy group (Table 1, Figure 1B and C). Patients with ADAb discontinued infliximab treatment more often in the TDM group than in the control group (Table 1, Figure 1D).

Conclusion: Formation of ADAb led to poorer clinical outcomes both during induction and maintenance therapy with infliximab and increased the risk of infusion reactions. Early detection of ADAb by proactive TDM reduced the negative consequences of ADAb, both on infliximab effectiveness and safety, highlighting the role of proactive TDM in optimising TNFi therapy.

Results from multivariable logistic (A)- or cox (B-D) regression models including the covariates: ADAb, TDM, age, sex, diagnosis, comorbidities. Results shown in table are risk of A) non-remission week 30, B) disease worsening during 52 weeks of maintenance therapy, C) infusion reactions and D) infliximab treatment discontinuation for patients developing ADAb and for patients in the TDM group.
Background: Extra-musculoskeletal manifestations (EMMs) are common in patients with spondyloarthritis (SpA), but there are limited data on the impact of upadacitinib (UPA), an oral JAK inhibitor, on EMMs in SpA patients.

Objectives: To assess the development of EMMs among patients with PsA, AS, or non-radiographic axial spondyloarthritis (nr-axSpA) treated with UPA 15 mg (UPA15) or placebo (PBO) in the SELECT clinical trial program.

Methods: This analysis includes safety data from UPA trials in PsA (2 trials),[1,2] AS (2 trials),[3,4] and nr-axSpA (1 trial).[5] All trials were designed with initial randomization to UPA or PBO for a pre-specified number of weeks, followed by a second open-label extension where PBO-treated patients were switched to UPA. Treatment-emergent adverse events (TEAEs) of EMMs, including uveitis, inflammatory bowel disease (IBD), and psoriasis, were assessed; as psoriasis is considered a core manifestation of PsA, it was only evaluated as an EMM in AS and nr-axSpA.[6] TEAEs were defined as an AE with onset on or after first dose of study drug and ≤30 days after last dose and summarized for PBO (pooled PBO to week 24 and pooled UPA15 to data cut-off), AS (pooled PBO to week 14 and pooled UPA15 to data cut-off), and nr-axSpA (PBO to week 52 and UPA15 to data cut-off). EMMs are reported as exposure-adjusted event rates (EAEERs; events/100 patient years [E/100 PY]) and are stratified by patients with or without a reported history (flare) of the respective EMM vs those without a history (new onset).

Results: The vast majority (92-99%) of patients across PsA, AS, and nr-axSpA did not have a prior history of EMMs at baseline (Table 1). In PsA, development of uveitis and IBD was low regardless of treatment or prior history (Figure 1). In AS, development of uveitis was numerically higher (E/100 PY [95% CI]) in patients treated with PBO (total: 75 [2.7, 16.3] vs UPA15 (total: 2.8 [18, 4.1]) and in patients with a prior history of uveitis (PBO: 6.2 [2.0, 14.5], UPA15: 2.1 [1.3, 3.3]) vs no prior history (PBO: 1.2 [0.6, 0.9], UPA15: 0.6 [0.2, 1.4]); occurrence of IBD and psoriasis were low regardless of treatment or prior history. In nr-axSpA, development of uveitis was low regardless of prior history, while the total rate was numerically higher in patients treated with PBO (2.1 [0.4, 6.3]) vs UPA15 (0.9 [0.2, 2.7]); occurrence of IBD and psoriasis were low or absent.

Conclusion: Data from this post-hoc analysis describe adverse events of relevant EMMs in the SELECT program and should be interpreted with caution as the efficacy of UPA in patients with specific EMMs was not systematically evaluated, as well as the overall low number of events observed. Development of EMMs in patients treated with UPA15 was generally low across PsA, AS, and nr-axSpA. Uveitis was numerically higher in patients treated with PBO vs UPA, and particularly in patients with AS. A better understanding of the impact of UPA across EMMs in SpA, and subsequent follow-up analyses, may help clinicians make informed treatment decisions and guide future treatment recommendations.

Background: The transition from psoriasis (PsO) to PsA is of considerable interest for potential prevention and interception of PsA.

Objectives: To formulate EULAR points to consider (PIC) for the development of data-driven guidance and consensus for clinical trials and clinical practice in the field of prevention/interception of PsA.

Methods: A multidisciplinary EULAR task force of 30 European members was established and the EULAR standardized operating procedures were followed.

Results: Nomenclature was proposed for 3 stages towards PsA development: i) PsO patients at higher risk of PsA (i.e., nail disease, obesity, severe PsO); ii) subclinical PsA (those at more imminent risk of PsA for arthralgia and imaging abnormalities) and iii) clinical PsA that most typically manifests as synovitis (Figure 1). For the purpose of prevention, our SLR showed that the vast majority of new PsA presented with synovitis. Thus, the presence of synovitis in PsO could be used as an outcome for prevention trials. Five overarching principles (OAPs) addressed the nature of PsA at its onset and underline the importance of collaboration between rheumatologists and dermatologists (Table 1). The 10 PIC highlight arthralgia plus imaging abnormalities as key elements of subclinical PsA that can be used as potential short-term predictors of PsA development and useful criteria to design trials for PsA interception (Table 1).

Conclusion: These PIC are helpful to define the features of PsO patients suspicious for progression to PsA. This information may ultimately facilitate identification of those who could benefit from a therapeutic intervention to attenuate, delay, or prevent PsA development.

Points to Consider

1. Arthralgia in PsO patients should be considered as a risk factor for PsA, taking into account alternative diagnoses such as osteoarthritis and fibromyalgia.

2. In PsO patients, joint and enthesal pain and functional limitation should be enquired about regularly and, if present, referral to a rheumatologist should be considered.

3. Imaging in PsO could be used to help identify those at risk for PsA in particular to detect synovio-entheseal involvement/abnormalities.

4. Imaging abnormalities in the absence of musculoskeletal symptoms should be considered carefully in order to avoid the risk of inappropriate treatment.

5. The combination of musculoskeletal symptoms and imaging abnormalities in PsO, without a diagnosis of PsA, should be considered as an entry criterion for clinical trials to prevent the transition to PsA.

6. In the context of clinical trials, patients with PsO and clinically evident synovitis should be considered to have PsA when alternative diagnoses have been excluded.

7. In PsO patients that require systemic treatment, the risk of transition to PsA should be taken into account in the choice of treatment.

8. PsO patients with obesity, nail disease and/or extensive PsO should be considered at increased risk for PsA over the longer term.

9. PsO patients should be informed about the risk of developing PsA and prompted to report their symptoms to facilitate early PsA recognition.

10. In PsO patients, risk factors for PsA development should be regularly assessed over time.

Patient satisfaction with the treatment, n (%) | 290 (43) | 149 (52) | 409 (46) |

Patient satisfaction with the tolerability of the current treatment, n (%) | 349 (60) | 217 (76) | 566 (66) |

Drug retention rates did not differ between the two groups (p=0.19; Figure 1). After 6 months, 62% of patients with combination and 58% of those receiving bDMARDs/ tsDMARDs as monotherapy were still on their respective treatment.

Conclusion: Baseline clinical parameters did not differ whether a PsA patient was started on bDMARD/tsDMARDs monotherapy or MTX-bDMARD/tsDMARDs combination. Especially parameters usually taken into account for GRAPPA or EULAR treatment recommendations, such as the number of swollen or tender joints, the number of involved enthesial sites and the severity of affected skin did not differ between the two treatment groups. Also drug retention rates were very similar. It seems that in routine care, the decision to continue or stop MTX at escalation to bDMARD/tsDMARD treatment mostly depends on the subjective tolerability of the ongoing MTX treatment.

Figure 1. Drug retention rates
OBESITY IN PSORIATIC ARTHRITIS IS INCREASINGLY AFFECTING MEN AND APPEARS LESS DEPENDENT OF SOCIOECONOMIC STATUS THAN IN THE GENERAL POPULATION

Keywords: Epidemiology, Psoriatic arthritis, Comorbidities

1 University of Zurich, University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland; 2 University of Zurich, University Hospital Zurich, Department of Dermatology and Venereology, Zurich, Switzerland; 3 ETH Zurich, Institute of Pharmaceutical Sciences, Department of Chemistry and Applied Biosciences, Zurich, Switzerland; 4 Inselhospital University Hospital Bern, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland; 5 Geneva University Hospitals, Division of Rheumatology, Geneva, Switzerland; 6 Swiss Clinical Quality Management Foundation, Statistics Group, Zurich, Switzerland

Background: Obesity in psoriatic arthritis (PsA) is associated with an elevated cardiovascular risk and higher disease activity. It represents a negative prognostic marker with a lower probability of remission on biologic therapy. Furthermore, obese patients with psoriasis have an increased risk of developing PsA. However, the prevalence of obesity in PsA compared with the general population and associated socioeconomic factors that would allow interventions targeted at these individuals are unknown.

Objectives: This study aimed to compare the prevalence of obesity in PsA patients and individuals from the general population at several time points and within those time points and find socioeconomic characteristics for obesity in PsA patients.

Methods: We compared the distribution of different body mass index (BMI) groups between patients with PsA from the Swiss Clinical Quality Management (SCQM) cohort and individuals from the general Swiss population using publicly available data from the Federal Statistical Office collected in 2007, 2012, and 2017. Patients were grouped into four BMI categories: underweight (BMI <18.5), normal weight (BMI 18.5 to <25), overweight (BMI 25 to <30) and obese (BMI ≥30). A comparison of BMI categories between the general Swiss population and PsA patients was performed by sex and level of education using the Chi-Squared test for categorical variables.

Results: The PsA population recruited to the SCQM registry increased from 517 patients in 2007 (54.5% male, mean (SD) age 47.9 (22.7) years) to 1245 patients in 2017 (51.7% male, mean (SD) age 53.1 (23.9) years). Within this timeline the mean (SD) BMI of 26.6 (10.0) in 2007 raised to 27.5 (10.6) in 2017, representing a significant change (p<0.001). Compared to the general Swiss population, the proportions of obese and overweight individuals were significantly higher in PsA patients at all collected time points (e.g., in 2017: 27.2% being obese and 36.6% being overweight in PsA patients compared to 11.3% being obese and 30.6% being overweight in the general Swiss population) (Figure 1A). In male PsA patients, the proportion of obesity increased, while female PsA patients had a slightly lower proportion of obese patients in 2017 than in 2012 (proportions of obese PsA patients in 2007, 2012 and 2017: 17.9%, 23.0%, and 27.3% in males compared to 22.4%, 26.8%, and 27.1% in females, respectively) (Figure 1B). Compared to the general Swiss population, the proportion of obese and overweight PsA patients was higher in both sexes at all three time points. Higher socioeconomic status represented by a higher level of education was associated with lower proportions of obesity and overweight in the general Swiss population at all three time points. However, patients with PsA lacked those differences in 2007. A decrease of obesity and overweight proportions in PsA associated patients exists only between secondary to tertiary education in 2012 and 2017. Between mandatory and secondary education, the proportions stay similar (Figure 1C shows the distribution of the BMI groups within education levels using data from 2017). In addition, PsA patients who worked in physically demanding occupations (e.g., transport, manufacturing or agriculture) had a comparable proportion of overweight and obesity as patients who worked in less physically demanding occupations (e.g., office workers, homemakers, teachers) (p<0.13).

Conclusion: Overweight and obesity are much more prevalent in patients with PsA than in the general population. Men have shown an increasing trend of obesity in recent years, and our data suggest that it is not only the socially disadvantaged who are at risk. There is an urgent need to address the expanding obesity epidemic in PsA with future public health initiatives that should consider our findings.

THE DETERMINANTS OF RADIOGRAPHIC PROGRESSION IN EARLY PSA PATIENTS

Keywords: Outcome measures, Imaging, Psoriatic arthritis

G. H. Koc1, M. R. Kok2, J. Luijmen1, I. Tchetverikov1, F. R. Kassem1, K. Wervens1, Y. Goekeop-Ruiterman1, L. A. Korswagen1, F. Fedd1, M. Van Oosterhout2, N. H. A. M. Denissen1, R. Dolhain1, M. Vis1. 1 Erasmus MC, Rheumatology, Rotterdam, Netherlands; 2 Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; 3 Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands; 4 Haga Hospital, Rheumatology, Zuid-holland, Netherlands; 5 Franciscus Gasthuis & Vlekken, Rheumatology, Rotterdam, Netherlands; 6 ReumaZorg Zuid West Nederland, Rheumatology, Roosendaal, Netherlands; 7 Groene Hart Ziekenhuis, Rheumatology, Gouda, Netherlands; 8 Amphia Hospital, Rheumatology, North Brabant, Netherlands

Background: Psoriatic arthritis (PsA) is inflammatory arthritis associated with a progressive erosive disease which had been reported in more than one-half of patients with PsA and is often associated with functional impairment [1]. Despite advances in diagnosis and therapy, radiographic structural damage is still prevalent in PsA. To shed light on this topic, we studied which clinical characteristics determine radiographic progression using conventional radiography.

Objectives: Our aim is to assess baseline clinical parameters as determinants for radiographic progression in early PsA patients at 2-year follow-up.

Methods: The study population consisted of 358 PsA patients from the DEPAR study which consists of PsA patients who were newly diagnosed from 11 centers in the Netherlands. Radiographic progression was measured with the modified Total Sharp Score (mTSS). The proportion of patients with radiographic progression was defined as a change in (ΔmTSS)>1.97 (the smallest detectable change) over 2 years of follow-up. Baseline clinical parameters comparisons between groups at diagnosis were made by Student’s t-test, chi-squared test, ANCOVA (age, gender baseline CRP and baseline mTSS were used as confounders).

All clinical data are observed, without imputation; except for the mTSS values, which were imputed using the linear interpolation approach.

Results: Of the 358 early PsA patients, change in mTSS (mean(SD)) was found 123±(52), and 42 were in the radiographic progression group at follow-up 2-year(12%). At diagnosis, the mean age of the progression group was older than the non-progression group (57 ± 14 vs 50 ± 14). Patients who had a radiographic progression in 2 years had significantly higher median scores in mTSS(22, IQR =4–48 vs 0, IQR = 0–1) at diagnosis. The erosion score in progressors followed poorer results compared to non-progressors but there was no significance. In addition, the patients with progressive mTSS had a significantly higher prevalence of erosive disease at baseline(57% versus 18%). The progression group had higher swollen joint counts (median(IQR)) but was no difference in statistics. However, the percentage of the presence of swollen joints was significantly greater in the progression group at baseline(93% vs 78%)(Figure 1). Baseline CRP levels were higher in progressions than non-progressions, but there was no difference between groups as a continuous measure(12.3(18.4) vs 8.5(13.6)). Furthermore, the progression group had a significantly higher percentage of patients with CRP levels of more than 1 mg/dl(88% vs. 74%). Meanwhile, DAPSA, ESR, and the baseline presence of dactylitis/enthesis did not differ between the groups. We also observed a difference in initial treatments between progressors and non-progressors.

Conclusion: According to this real-world longitudinal cohort, early PsA patients have low radiographic progressions with the current treatment protocols. Baseline clinical determinants for radiographic progression at follow-up 2 years are older age, swollen joints, erosive disease, JSN score, and baseline CRP levels (>1 mg/dl).
The rate of hyperuricemia and depression were higher proportion of smokers than PsA group and controls. Number of patients had above normal BMI, higher than matched controls. RA group had a higher rate of hyperuricemia and depression were significantly higher in PsA than in RA and controls. The rate of obesity, type 2 diabetes mellitus, arterial hypertension, COPD, gout, malignancy was similar in PsA and RA but higher than in controls. Patients with PsA had higher Charlson comorbidity index and higher rate of cardiovascular disease as compared to RA and control group (p=0.005).

**Conclusion:** In conclusion, patients with PsA have a high cardiovascular and metabolic burden already at early stages of the disease. They have higher rate of multiple comorbidities and higher of cardiovascular morbidity as compared to age-matched early RA patients despite comparable BMI and similar rates of obesity. This suggests that metabolic disturbances, present at early stages of PsA might be linked to PsA at a pathophysiological level.

Percentages/binomial tests of the final global data were adjusted for size of each country’s adult population. Statistically significant differences (p<0.05) were described as more/higher.

Results: Eighty-two percent of pts were female; 24% from Europe (France/Spain/UK). Mean age of females/males (41.3/41.0 years) and time since diagnosis (9.2/8.8 years) were similar. More females had anxiety (32% vs 24%), osteoarthritis (17% vs 9%), had taken a steroid (57% vs 43%) and were taking any DMARD (biologic and oral DMARDs; 20% vs 15%). More females vs males reported a major/moderate negative PsA impact on physical activity (81% vs 75%) and emotional/mental wellbeing (73% vs 65%); major/moderate impact on other life aspects, such as work productivity, was similar between sexes (Figure 1). More females vs males reported the following because of PsA: emotional distress (65% vs 50%), stopped social activities (49% vs 41%) and went on permanent work disability (14% vs 9%); more males vs females reported lower work productivity (47% vs 38%) because of PsA. Switching treatment due to joint symptoms (41% vs 28%) and side effects (35% vs 22%) were higher in females vs males; switching due to potential serious side effect concerns (29% vs 16%) and symptoms being under control (18% vs 9%) were higher in males vs females. More females vs males were very satisfied with their rheumatologist’s communication (60% vs 51%), and discussed treatment goals (83% vs 78%), impact on ability to conduct daily activities (82% vs 73%) and response to and/or satisfaction with treatment regimen (81% vs 72%; Table 1). Pt ability to describe their PsA diagnosis/recall symptoms may limit the study.

Conclusion: More women vs men reported a major/moderate PsA impact on physical and emotional/mental well-being. More women were very satisfied with communication and discussed treatment goals with their rheumatologist. It is important to consider how sex impacts a pt’s experience with PsA.

DOI: 10.1136/annrheumdis-2023-eular.2083
Background: Rheumatic diseases result in joint destruction and impaired physiological function [1]. We recently showed that hand function based on objective tests may serve as a biomarker representing subclinical inflammation in psoriasis (PsO) patients and thus could support the early detection of psoriatic arthritis (PsA) onset [2]. Hand function tests are relevant for objective assessment of musculoskeletal function in relation to disease activity in PsA [3]. However, the relationship of hand function with the synovitis and tenosynovitis detected by ultrasound (US) in PsA and PsO patients has not been well studied.

Objectives: To investigate the association of synovitis and tenosynovitis detected by US in grey scale (GS) and power doppler (PD) activity with grip strength and fine motor skills in patients with PsA and PsO.

Methods: PsA and PsO patients were recruited from the Rheumatology Department at the University Hospital Erlangen, for this cross-sectional study. After giving written informed consent, subject characteristics were recorded and study participants underwent bilateral US of the wrists, metacarpophalangeal (MCP) joints, and flexor tendons of all fingers. Each joint was examined by GS (0-3), PD (0-3) and finally a combined score (PDUS: PD + GS) was calculated (0-3) [4]. The flexor tendon was scanned in GS (0’1) and with PD [0-3], US activity considered either a synovitis or tenosynovitis score ≥1. Activity in tender joint count (TJC) and swollen joint count (SJC) 68/66 was considered ≥1 tender or ≥1 swollen joint. Hand function was assessed by a visiometric grip strength (bf) and the fine motor skill MPUT (Moberg pick-up test). For the analysis, patients’ hands were either divided in dominant/non-dominant or patient reported affected/non-affected hand. A correlation matrix was applied to measure the linear relation between the pairs of synovitis and tenosynovitis scores, grip strength and MPUT for both hands, using the Spearman correlation method.

Results: 106 patients (40 PsA, 66 PsO) participated in this study. Subject characteristics and general outcomes are summarized in Table 1. While grip strength was higher in the dominant hand (p<0.001), MPUT times are comparable between the dominant vs. non-dominant hands (p=0.056) but was faster in the non-affected hand (p=0.008). Low to moderate positive correlations were observed between overall GS synovitis score (MCP 2-5 + wrist) (r=0.24, p<0.05), and PDUS (r=0.23, p<0.05) with MPUT. In US active patients, a high correlation between grip strength and GS tenosynovitis score in digit 2 (r=-0.566, p=0.028) was detected. When considering patients with US in addition to SJC/TJC activity, imaging modalities did not correlate with hand function.

Conclusion: These findings indicate that the synovitis detected by grey scale is related with fine motor skills and tenosynovitis scores in grey scale with grip strength. This suggests, that chronic tenosynovitis has a greater impact on hand function than the acute inflammatory phase. When considering patients with TJC68/SJC66 ≥1 this relation is not present, suggesting that clinically assessed joint count, unlike ultrasonography, does not correlate with hand function impairment.

Emerging a New Era in Osteoarthritis Therapies

METHODS - A RANDOMIZED CONTROLLED TRIAL OF METHOTREXATE TO TREAT HAND OSTEOARTHRITIS WITH SYNOVITIS

Keywords: Disease-modifying drugs (DMARDs), Randomized controlled trial, Osteoarthritis

Y. Wang1, G. Jones2, H. Keen2, C. Hill3, A. Wluka1, J. Kasza1, A. Teichtahl2, R. O’Sullivan5, F. Cicuttini1,1; Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; 2; University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; 3; University of Western Australia, School of Medicine, Perth, Australia; 4; University of Adelaide, Department of Medicine, Adelaide, Australia; 5; Alfred Hospital, Rheumatology, Melbourne, Australia; 6; Lumus Imaging, Lumus Imaging, Melbourne, Australia

Background: Hand osteoarthritis (OA) with synovitis is a common clinically identifiable phenotype which is associated with pain and disease progression. Methotrexate is a low-cost, well-established and effective treatment for inflammatory arthritis with a well-described safety profile. A previous randomized controlled trial showed no superiority of 10 mg methotrexate over placebo in pain relief at 3 or 12 months in patients with erosive hand OA [1]. No study has examined methotrexate in hand OA with inflammatory phenotype.

Objectives: To examine whether methotrexate reduced pain and improved function over 6 months in patients with hand OA and synovitis.

Methods: In a multicentre, randomized, double-blind, placebo-controlled trial, patients with symptomatic hand OA and MRI-detected synovitis were recruited and randomly assigned in a 1:1 ratio to receive methotrexate 20 mg (n=50) or identical placebo (n=47) once weekly for 6 months. The primary outcome was pain reduction (assessed by 100mm visual analogue scale, VAS) at 6 months. Secondary outcomes included changes in physical function and quality of life assessed using Australian Canadian Osteoarthritis Hand Index (AUSCAN), Functional Index for Hand Osteoarthritis (FIHOA), Health Assessment Questionnaire (HAQ), and Michigan Hand Outcomes Questionnaire (MHQ). Adverse events were recorded. The primary analysis was by intention to treat, including all participants in their randomized groups. Mixed linear regression models were fit to continuous outcomes, adjusting for baseline values of outcome, sex and site, and the clustering of measurements within participants.

Results: Of 97 patients [mean age 61.6 (SD 6.7) years, 68 (70.1%) female], 84 (86.5%) provided the 6-month primary outcome. At 6 months, the methotrexate group had greater reduction in VAS pain (-15.2 vs -7.7, difference -9.9, 95% CI -19.3 to -0.6) (Figure 1), AUSCAN pain (-55.3 vs -13.5, diff -47.0, 95% CI -91.5 to -2.5) and stiffness (-14.5 vs -2.9, diff -11.9, 95% CI -20.8 to -2.0) than the placebo group (Table 1). The between-group differences were not clinically meaningful for change in AUSCAN function [-52.7 (+1273 to 219.9)], FIHOA [-0.9 (-3.3 to 1.7)], HAQ [-0.0 (-2.0 to 0.2)], or MHQ [5.5 (-0.3 to 11.3)]. Incidence of adverse events was 62.0% in methotrexate and 59.6% in placebo group.

Conclusion: This study provides high-quality evidence for the effect of methotrexate (20 mg once weekly) on reducing pain and stiffness over 6 months in patients with hand OA and synovitis. The results have the potential to inform clinical practice guidelines for the management of hand OA with the inflammatory phenotype.

OBJECTIVE

EFFECTION OF DENOSUMAB ON STRUCTURE MODIFICATION IN EROSIIVE HAND OSTEOARTHRITIS: RESULTS OF A 48-WEEKS, MONOCENTRIC, RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE-BLIND PHASE 2 STUDY AND OPEN LABEL EXTENSION PHASE

Keywords: Clinical Trials, Osteoarthritis

R. Wittekoek 1, G. Verbruggen 1, T. Vanhaverbeke 2, D. Elewaett 1, Gent University, Rheumatology, Gent, Belgium

Background: Erosive hand osteoarthritis (OA) is a disabling disease with limited therapeutic options. Denosumab, a Receptor Activator of Nuclear Factor kappa-β Ligand inhibitor affects bone resorption and osteoclast activity.

Objectives: The purpose of this clinical trial was to study the structure modifying effect of denosumab in patients with erosive hand OA, and to explore the clinical benefits and safety of subcutaneous denosumab 60 mg every 3 months versus placebo.

Methods: One hundred patients with erosive hand OA were randomly allocated to placebo or denosumab in a monocentric clinical trial during 48 weeks, followed by an open-label extension phase through week 96. The primary radiographic endpoint was change in total Ghent University Scoring System (GUSS) score at week 24. GUSS (0-300) is a semi-quantitative scoring system specifically developed to combine scoring of both aspects of radiographic changes in erosive hand OA, being erosive progression (decrease of score) and signs of repair (increase of score) (1) and able to detect changes on short term [2]. The secondary endpoint was the percentage of new erosive joints at week 48. Exploratory clinical outcomes (e.g., pain, tender joint count, swollen joint count, grip strength, the Australian-Canadian Hand Osteoarthritis Index and the Functional Index for Hand Osteoarthritis) were assessed. Radiographic and clinical changes after 96 weeks of treatments were measured. Safety outcomes including (serious) adverse events, laboratory changes and changes in bone mineral density by dual-energy X-ray absorptiometry were registry. Primary efficacy analyses were performed in an intention-to-treat approach. Changes in GUSS were analysed at joint level with generalized estimating equations, accounting for within-patient clustering. Robust standard errors were used and the working correlation structure specified exchangeable.

Trial registration number: EU/DRCT CT-2015-003223-53.

Results: 51 and 49 patients received subcutaneous administration of denosumab and placebo respectively. Total change GUSS was found statistically higher in denosumab compared to placebo at week 24 (mean change GUSS = 8.9 (95% CI: 1.0 - 16.9; p = 0.024)) (Figure 1A). This difference further increased at week 48 (ΔGUSS = 14.3 (95% CI: 4.6 - 24.0; p = 0.003)). Development of new erosive joints was significantly lower in denosumab (1.8%) compared to placebo (7.0%) at week 48 (OR = 0.23 (95% CI: 0.10 to 0.50; p < 0.001)) (Figure 1B). After open-label treatment through week 96, both groups continued remodelling and both pain and function significantly improved compared to baseline. Equal numbers of adverse events occurred in both groups.

Conclusion: Denosumab has clear structure modifying effects in erosive hand OA compared to placebo: significantly less erosive progression occurs after 24 weeks treatment, and the treatment effect enhances after 48 weeks. Symptom improvement was observed after sustained treatment.

REFERENCES:

Methods: We performed a post-hoc analysis of data collected in the LoDoCo2 trial to determine the time to first knee or hip replacement. A Cox proportional hazard model was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for colchicine 0.5 mg once daily as compared to placebo. Sensitivity analyses were performed by excluding patients known with gout at baseline (to avoid possible carry-over effects as colchicine is used to prevent gout attacks) or by excluding the patients who had joint surgery within the first 3 months after randomization (to avoid any bias related to planned joint surgery prior to randomization). All analyses were performed on an intention-to-treat basis.

Results: Among the 5522 randomized LoDoCo2 trial participants, 2762 received colchicine and 2760 placebo during a median duration of follow-up of 28.6 months (interquartile range, 20.5 to 44.4). The mean (SD) age was 66 (8.6) years and 846 (15.3%) were female. During the trial, TKR/THR was performed in 68 patients (2.5%) in the colchicine group and in 97 patients (3.5%) in the placebo group (HR, 0.69; 95% CI, 0.51-0.95; p = 0.02) (Table 1 and Figure 1). In a sensitivity analysis that excluded patients with gout similar results were obtained, while omitting joint replacements that took place in the first three months of follow-up yielded in an even larger rate reduction of TKR/THR (Table 1).

TKR/TH= total knee replacement/ total hip replacement

Conclusion: In this post-hoc analysis of the LoDoCo2 trial, use of colchicine 0.5 mg daily was associated with a reduced risk of TKR/THR. Further investigation of long-term therapy with colchicine to slow disease progression in osteoarthritis is warranted.

Background: Colchicine has been suggested as a treatment for osteoarthritis symptoms, but evidence is contradictory.[1]

Objectives: To investigate the clinical efficacy and safety of colchicine compared with placebo in people with hand osteoarthritis.

Methods: In this double-blind, randomised, placebo-controlled trial we recruited and randomly assigned 100 participants: 50 (50%) to colchicine and 50 (50%) to placebo. All participants completed the study. The mean changes from baseline to week 12 in finger pain: -12.4 (2.8) in the colchicine group and -11.2 (2.8) in the placebo group with a between-group difference of 1.2 mm (95% CI -8.3 to 5.9; p = 0.060).

Results: We screened 186 people for eligibility between January 15, 2021 and March 3, 2022 and randomly assigned 100 participants: 50 (50%) to colchicine and 50 (50%) to placebo. All participants completed the study. The mean changes from baseline to week 12 in finger pain were -13.9 mm (SE 2.8) in the colchicine group and -13.5 mm (SE 2.8) in the placebo group with a between-group difference of 0.4 mm (95% CI -7.6 to 6.7; p = 0.90). The efficacy on primary and secondary outcomes is summarized in the Table 1.

Table 1. Changes from baseline to week 12 in finger pain

estimate difference between LOR and PBO on outcomes using the OA-07 baseline. Treatment effect at Month 36 was estimated using marginal comparison from baseline-adjusted ANCOVA to a last PBO observation prior to crossover for LOR only. Concordance between OA-07 baseline-adjusted medial JSW change and pain response was conducted for 36 month completers using logistic regression.

**Results:** 277 subjects (mean age 61.0 ± 8.2 years, BMI 31.8 ± 4.9 kg/m², female 62.8%, KLI 45.5%, 67.1% bilaterally symptomatic, mean baseline medial JSW 2.63 ± 0.69 mm, 68.6% medial JSW < 3 mm) were enrolled. LOR appeared safe and well-tolerated, consistent with its previously observed safety profile. At 24 months, the LOR treatment arm showed reduced medial JSW loss compared to placebo: LOR -0.11 (± 0.05) mm (n=111) vs. PBO -0.20 (± 0.05) mm (n=119) (Δ=0.09mm, 95% CI [-0.06, 0.23], P=0.246). The 36-month LOR completers demonstrated continued improvement with LOR (n=21) medial JSW change of 0.03 (± 0.11) mm vs. PBO (n=28) -0.30 (± 0.09) mm (Δ=0.33mm, 95% CI [0.05, 0.62], P=0.023) at 24 months. At 36 months, LOR median JSW change was -0.19 (± 0.14) mm (n=23), a difference of -0.49 mm (P=0.019) in medial JSW with LOR in comparison to the last PBO measure before crossover at 24 months (Figure 1). Average change from extension baseline to 24 months in Pain NRS was -0.25 (± 0.19) for LOR (n=121) compared to 0.09 (± 0.19) for placebo (n=130) (Δ=-0.34, 95% CI [0.87, 1.19], P=0.207). Similar trends were seen for LOR treatment effect over PBO at 24 months for WOMAC Function ∆=-4.90 (95% CI [-9.92, 0.13], P=0.056) and WOMAC Pain ∆=-5.18 (95% CI [-10.28, -0.08], P=0.047). At 36 months, open-label IA injection of LOR (n=35) showed additional Pain NRS improvements with change from OA-07 baseline of -0.91 (±0.34) and cross-over participants from PBO to LOR (n=45) showed improvement of -0.43 (±0.30). Good concordance was shown between change in medial JSW and at least a 20% improvement in Pain NRS at 36 months (n=20, AUROC=0.719).

### Conclusion
LOR continues to appear safe and well tolerated. A potential benefit of LOR 0.07mg compared with PBO in medial JSW is observed 12 months after comparison in to the last PBO measure before crossover at 24 months (Figure 1). Average change from extension baseline to 24 months in Pain NRS was -0.25 (± 0.19) for LOR (n=121) compared to 0.09 (± 0.19) for placebo (n=130) (Δ=-0.34, 95% CI [0.87, 1.19], P=0.207). Similar trends were seen for LOR treatment effect over PBO at 24 months for WOMAC Function ∆=-4.90 (95% CI [-9.92, 0.13], P=0.056) and WOMAC Pain ∆=-5.18 (95% CI [-10.28, -0.08], P=0.047). At 36 months, open-label IA injection of LOR (n=35) showed additional Pain NRS improvements with change from OA-07 baseline of -0.91 (±0.34) and cross-over participants from PBO to LOR (n=45) showed improvement of -0.43 (±0.30). Good concordance was shown between change in medial JSW and at least a 20% improvement in Pain NRS at 36 months (n=20, AUROC=0.719).

Background: The existing EULAR Recommendations for the non-pharmacological core management of hip and knee osteoarthritis (OA) were published in 2013. A considerable number of new studies on various non-pharmacological treatment modalities have since been published, as well as updates of the Recommendations for the non-pharmacological core management of hip and knee OA.

Objectives: The objective of this project was to perform an updated systematic literature review and to update the 2013 EULAR Recommendations for the non-pharmacological core management of hip and knee osteoarthritis, accordingly.

Methods: The standardised operating procedures for EULAR-endorsed Recommendations [1] were used as a framework for this project. A multi-disciplinary Task Force (TF) including 9 physiotherapists, 6 rheumatologists, 2 orthopaedic surgeons, 2 psychologists, 2 patient research partners, 1 occupational therapist, 1 nurse, 1 general practitioner and 1 nutrition expert from 13 European countries was established. Based on the original search strategy underpinning the original 11 recommendations, 11 updated PICOs (Population, Intervention, Control, Outcome) were agreed upon by the TF members in the first digital meeting in January 2022. Systematic literature searches were conducted from 1st January, 2012 until 27th May, 2022 aiming to identify new evidence related to non-pharmacological core management treatment interventions for hip and knee OA. Evidence was primarily collected from published systematic reviews (SRs) and secondarily, from randomised controlled trials (RCTs) if no relevant, updated SR was available. The retrieved evidence was discussed in 5 digital subgroup meetings and subsequently presented to all TF members in the second plenary digital meeting in November 2022. Here, the recommendations were revised based on the new evidence and discussions and TF members voted on each newly proposed recommendation to reach consensus (more than 75% in favour). After the meeting 10 revised recommendations completed a短短期 survey to ascertain the Level of Agreement (LoA) (0-10, 10=totally agree) with each recommendation and prioritize the order of the recommendations for implementation activities.

Results: Based on evidence from 67 SRs and 31 RCTs, the TF agreed to rephrase and change two of the 11 existing recommendations into two overarching principles; one concerning the initial assessment with a biopsychosocial approach and one on the use of shared decision-making in treatment. The remaining 9 original recommendations were revised into 8 updated recommendations, as the recommendations on footwear and on walking aids and other assistive devices were combined. The 8 updated recommendations concern the application of: 1) an individualised, component management plan; 2) delivery of information, education and self-management strategies; 3) delivery of exercise with adequate dosage and progression; 4) the mode of delivery of exercise; 5) education on maintaining a healthy weight and support with weight loss when indicated; 6) advice on walking aids and assistive devices; 7) work-related advice; and 8) application of behaviour-change techniques to improve lifestyle. The lowest mean LoA for the 8 revised recommendations was 9.2 and the highest 9.8. Recommendation 2) was ranked by the TF as having the highest priority for implementation.

Conclusion: The updated overarching principles and recommendations for the non-pharmacological core management of hip and knee OA based on previous evidence and on new evidence from relevant SRs and RCTs published during the last 10 years and on discussions by a multi-disciplinary TF: A plan for dissemination and implementation will be developed, with emphasis on the recommendation on patient education, with the ultimate aim to improve the quality of care for people with hip and knee OA.

Jansen1. 1University Medical Center Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands; 2Martini Hospital, Department of Orthopedics, Groningen, Netherlands; 3University Medical Center Utrecht, Department of Orthopedic Surgery, Utrecht, Netherlands; 4Amphia Hospital, Department of Orthopedics, Breda, Netherlands; 5Antwerp University Hospital, Department of Orthopedics, Antwerp, Belgium; 6Maastricht University Medical Center, Department of Orthopedics, Joint-Preserving Clinic, Maastricht, Netherlands

**Background:** Knee distraction (KD) treatment for young (<65 years) patients with end-stage knee osteoarthritis (OA) has previously been shown to successfully postpone a knee arthroplasty for years by reducing pain, improving function, and inducing joint tissue repair.[1] During KD treatment, the tibia and femur are separated ~5 mm for ~6 weeks using an external fixation device. The studies performed thus far have used proof-of-concept medical devices intended for other applications than KD. Recently, the first device specifically designed and intended for KD treatment has been developed.

**Objectives:** The purpose of the current study was to evaluate the clinical efficacy of this intended device.

**Methods:** In 5 hospitals, 65 patients with end-stage knee OA, in general practice considered for arthroplasty or high tibial osteotomy, were offered KD treatment. Inclusion criteria included age ≤65 years, BMI ≤35 kg/m² with weight ≤110 kg, sufficient knee stability and physical condition, KL grade ≥2, malalignment ≥10 degrees, no history of inflammatory or septic arthritis. KD was performed according to a standardized protocol. Before and 1 and 2 years after treatment, standardized knee radiographs were performed and patients filled out WOMAC (for pain and function, 0–100, primary clinical outcome) and SF-36 (quality of life, 0–100, secondary outcome) questionnaires. From the radiographs, minimum joint space width (JSW, mm, primary structural outcome) was measured by 1 experienced observer and baseline KL grade was determined. Use of self-reported pain medication (paracetamol, opioids, NSAIDs) and intra-articular injections were registered, as were adverse events. Changes over 2 years were evaluated for statistical significance with paired t-tests for continuous variables and McNemar’s tests for categorical variables. For the WOMAC, clinical significance was evaluated as well, on group level defined as an increase of ≥15 points and on individual level using OARS-OMERACT response criteria. The influence of adverse effects on 2-year changes in primary outcomes was analyzed with independent t-tests.

**Results:** Of the 65 patients (age: 53.3±6.7; BMI: 28.0±3.2; sex: 38 (55%) male; KL grade 0/1/2/3/4: 0 (0%) / 7 (11%) / 26 (40%) / 23 (36%) / 9 (14%), 49 patients completed 2 years follow-up. 1 Patient did not complete treatment, 7 patients received arthroplasty (3 in the 1st year) and 8 patients were lost to follow-up in the 2nd year. The total WOMAC score showed a statistically and clinically significant improvement at 1 and 2 years (+26 and +24 points; Figure 1), as did all subscales (all p<0.001). After 1 year 72% of patients were clinical responders, at 2 years this was reduced to 55%. The minimum radiographic joint space width improved over 1 (+0.5 mm; p<0.001) and 2 (+0.4 mm; p=0.015) years (Figure 1), as did the physical SF-36 (+10 points; p=0.001). The most common adverse event was pin tract infection, experienced by 43 (66%) of patients, in the majority successfully treated with oral antibiotics. In 2 cases hospitalization and/or intravenous antibiotics were needed. 8 Patients experienced device-related complications. None of the complications influenced the 2-year outcomes. Before treatment, 42% of patients used pain medication, which had nearly been halved 1 (23%; p=0.02) and 2 years (29%; p=0.27) post-treatment. In total 12 (18%) patients had received an intra-articular injection before KD treatment, of whom 5 (8%) steroids and 3 (5%) hyaluronic acid. Both in the 1st and 2nd year after treatment, 1 patient (2%) received a injection.

**Conclusion:** Patients treated with the first device intended for KD treatment showed significant clinical and structural improvement after 1 and 2 years. Importantly, the effect was clinically relevant, as a majority of patients were clinical responders and pain medication use decreased. Long-term evaluation will show whether arthroplasty can be postponed successfully as well.

**COVID 19: A pandemic with a long tail**

**Keywords:** Epidemiology, COVID, Inflammatory arthritides

L. Boekel1, S. Atiqi1, M. Leeuwen1, F. Hooijberg2, Y. Besten2, W. Lems3, A. Boonen1, S. Tas3, M. Nurmohamed4, T. Rispens5, G. Wolbink1. 1Reade, Locatie Dr Jan Van Bree menstraat, Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC, locatie VUmc, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 3Aaachts Hospital University Medical Centre +, Rheumatology, Maastricht, Netherlands; 4Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 5Sanquin Research and Landsteiner Laboratory, Department of Immunopathology, Amsterdam, Netherlands

**Background:** Studies on long-term consequences of COVID-19, commonly referred to as long-COVID, in patients with inflammatory rheumatic diseases (IRD) are still scarce, and available data are heterogeneous and largely inconclusive. In addition, it is unknown whether correctly classifying patients with IRD as long-COVID cases is complicated by increased background noise due to the occurrence of persistent symptoms that could be attributed to both long-COVID and IRD.
Objectives: The primary objective was to compare the risk of developing long-COVID after a SARS-CoV-2 infection with the Omicron variant between patients with iRD and age and sex matched healthy controls. A secondary objective was to compare the prevalence of the different persistent symptoms observed in long-COVID between patients with iRD and healthy controls with and without a history of COVID-19.

Methods: We collected data from participants enrolled in a Dutch prospective cohort study that was designed to compare the disease severity of COVID-19 between iRD patients and healthy controls from the start of the pandemic. Demographic and clinical data, including data on the occurrence of SARS-CoV-2 infections, were collected using online questionnaires. On March 10, 2022, all study participants were asked about the occurrence, onset, severity and duration of persistent symptoms during the first two years of the COVID-19 pandemic, independent of their history with COVID-19. Subsequently, we prospectively monitored a subset of the cohort, participants with a PCR or antigen confirmed SARS-CoV-2 Omicron infection, for COVID-19 sequelae. In line with WHO guidelines, long-COVID was defined as participants who reported persistent symptoms that lasted at least 8 weeks, started after the onset and within 3 months of a confirmed SARS-CoV-2 infection, and could not be explained by an alternative diagnosis. Descriptive statistics, logistic regression analyses and Kaplan Meier survival analyses were used for statistical analyses.

Results: A total of 1974 iRD patients and 733 healthy controls participated, of whom 468 (24%) patients and 218 (30%) controls had a SARS-CoV-2 Omicron infection. Of those, 361 (77%) patients and 172 (79%) controls completed COVID-19 sequela questionnaires. More patients compared to controls fulfilled long-COVID criteria: 2.7% vs. 2.3% (OR: 1.15; 95% CI: 0.70–1.87; Table 2). However, the effect attenuated after adjusting for potential confounders (aOR: 0.77; 95% CI: 0.44–1.35; Table 3). Although we found no significant difference in long-COVID between patients with iRD and healthy controls with and without a history of COVID-19, we believe that the observed difference in long-COVID between patients with iRD and healthy controls was explained by age and sex differences.

Conclusion: We found that 21% of iRD patients and 13% of healthy controls met WHO criteria for long-COVID after a SARS-CoV-2 Omicron infection. However, confounding by BMI and severity of the acute infection phase of SARS-CoV-2 attenuated this difference, and the duration of long-COVID was similar between patients and controls. In addition, since more iRD patients than healthy controls had a history of COVID-19 reported symptoms that are also observed in long-COVID, we believe that the observed difference in long-COVID between patients and controls could in part also be explained by clinical manifestations of underlying rheumatic diseases. We therefore conclude that iRD patients are not more susceptible for long-COVID than people from the general population.

Background: Due to geographic isolation and border controls, Aotearoa New Zealand attained high levels of population coronavirus disease-19 (COVID-19) vaccination before widespread community transmission of Omicron variant COVID-19 in early 2022. This provides a unique opportunity to examine outcomes in people with rheumatic diseases immunologically naive to COVID-19.

Objectives: This study aimed to describe the outcomes of people with inflammatory rheumatic disease and COVID-19 infection in people with rheumatic diseases in Aotearoa New Zealand.

Methods: We conducted an observational study of people with inflammatory rheumatic disease and COVID-19 infection from centres in Aotearoa New Zealand between 1 March 2020 to 30 April 2022. Data were collected via the Global Rheumatology Alliance Registry, including demographic and rheumatic disease characteristics and COVID-19 vaccination and outcomes. Multivariable logistic regression was used to examine associations of demographic and clinical factors with COVID-19 hospitalisation and death.

Results: A total of 1599 cases were included, with 98% from three hospitals that systematically identified all patients from rheumatology clinics who had COVID-19 infection. At the time of COVID-19 infection, 1513 cases (94.6%) had received at least two COVID-19 vaccinations. Hospitalisation occurred for 104 (6.5%) cases, and 10 (0.6%) patients died. A lower frequency of hospitalisation was seen in cases who had received at least two vaccinations (5.9%), compared to cases who were unvaccinated (20.6%) or who received a single vaccine dose (10.7%). In multivariable adjusted models, people with gest (OR 2.295% CI 1.02, 4.77) or connective tissue diseases (CTD) (OR 2.73 CI 1.61, 4.80) had increased risk of the combined outcome of hospitalisation and death, compared to people with inflammatory arthritis. Glucocorticoid and rituximab use were associated with 3 to 6 times higher odds of hospitalization and/or death. All cases who died had three or more comorbidities associated with a known higher risk of poor outcomes or were over 60 years old.

Conclusion: In this cohort of people with inflammatory rheumatic diseases with high vaccination rates, severe outcomes from Omicron variant COVID-19 were infrequent. The hospitalisation rate during COVID-19 infection was higher in people who had not completed the primary vaccination course, had at least two infections in hospital, and were unvaccinated or had CTD, and used glucocorticoids. These findings suggest that outcomes of Omicron variant COVID-19 infection among people with rheumatic disease who are vaccinated but immunologically naive to prior COVID-19 variant infections were favorable.

Acknowledgements: There was no specific funding for data collection. Data analysis was supported by the COVID-19 Global Rheumatology Alliance. Background: Patients with immune mediated inflammatory diseases (IMID) on immunosuppressive therapies are known to be at greater risk of severe COVID-19 disease, hospitalisation and death. Protective levels of anti-Spike antibodies following vaccination are yet to be determined.

Objectives: To examine whether post-vaccination anti-Spike antibody levels were predictive of breakthrough infection and the clinical outcome of COVID-19.

Methods: The Nor-vaC study is a prospective cohort study that includes IMID patients on immunosuppressive therapies[1]. In the present analyses we included patients who provided post-vaccination samples and responded to follow-up questionnaires after three vaccine doses. Hospital records and the Norwegian Death Cause Registry provided information on hospital admissions and cause of death. Anti-Spike antibody levels were measured 2 – 4 weeks after vaccination. Analyses were performed using a co-regression with time running from two weeks post 3rd vaccine dose until COVID-19 or a 4th vaccine dose, adjusting for age, sex, diagnosis, medication and comorbidity, with calendar month as a time varying covariate.

Results: A total of 1051 IMID patients (375 rheumatoid arthritis (RA), 148 psoriatic arthritis (PsA), 155 spondyloarthritides (SpA), 215 Crohn’s disease (CD), 158 ulcerative colitis (UC)) on immunosuppressive therapies were included in these analyses, mean age 56 (IQR 43 – 65), and 586 (56%) female, with an observation period spanning from July 7th 2021 to December 14th 2022.

Patients had received either BNT162b2 (61%) or mRNA-1273 (39%) as a 3rd vaccine dose. The presence of comorbidities (HR 1.85, p = 0.001, 95% CI (1.11, 2.35)) increased the risk of breakthrough infections. Post-vaccination anti-Spike antibody levels were not associated with duration of COVID-19 over two weeks.

Conclusion: Patients with the highest post-vaccination anti-Spike levels had a lower risk of COVID-19 infection, supporting the role of repeated vaccination in IMID patients on immunosuppressive therapies. These results also underline the good prognosis of Omicron infections in vaccinated IMID patients. Though patients knowing they had low anti-Spike levels may have shielded during periods of high transmission, the absence of severe infections and deaths in this large cohort indicates that low antibody levels did not greatly increase risk of severe COVID-19.

Background: Global data on COVID-19 breakthrough infections (BI) following COVID-19 vaccination among autoimmune rheumatic diseases (AIRDs) and especially rheumatoid arthritis (RA) is scarce.

Objectives: This study aimed to examine the characteristics of COVID-19 BI among patients with RA and compare them with AIRDs and healthy controls (HCs).

Methods: A global e-survey, January-May 2022, collected data on COVID-19 vaccination, and BI in patients with RA, AIRDs, non-rheumatic autoimmune diseases (nrAIDs), and HCs. BI was defined as an infection after both primary or booster vaccine doses. Severe BI was defined as the need for hospitalization, including intensive unit care, oxygen therapy, or advanced treatment in the form of monoclonal antibodies.

Results: Of the 9595 vaccinated respondents of the e-survey, 3224 (33.6%) reported COVID-19. One BI was reported in 323/1802 (17.9%) patients with RA, 584/3869 (15.0%) patients with other AIRDs, and 467/3435 (13.5%) HCs. Similarly, second BI was reported by 280 (8.6%), 42 (2.3%) among RA, 90 (4.0%) among other AIRDs, and 124 (3.6%) among HCs.

The prevalence of first BI in patients with RA was higher than that in those with AIRDs (OR=1.2; 95%CI=1.1-1.4; p=0.001) and HCs (OR=1.4; 95%CI=1.2-1.6; p<0.001), but similar to nrAIDs (p=0.783). The prevalence of second BI was lower in patients with RA than in HCs (OR=0.6; 95%CI=0.4-0.9; p=0.012) and nrAIDs (OR=0.4; 95%CI=0.2-0.7; p=0.004), but similar to AIRDs (p=0.991). When compared with HCs, patients with RA reported significantly higher joint pain, hospitalizations, and need for advanced treatment at first BI. Patients with RA from very high HDI countries had lower hazard of first BI than from those high HDI countries (HR=0.026; 95%CI=0.001-0.6; p=0.027). Rituximab use predicted more frequent hospitalization (OR=3.4; 95%CI=1.3-11.4; p=0.045) and severe BI (OR=3.0; 95%CI=1.2-7.3; p=0.014).

Conclusion: Nearly one in five patients with RA reported BI. BI prevalence was higher in patients with RA and of higher severity than in HCs. Country HDI was an important determinant of outcomes, suggesting potential impact of environmental dynamics, local vaccination policy, and syndemic constructs that merit further exploration. Rituximab use predicted more frequent hospitalizations and more severe BI.

OP0082

COVID-19 VACCINE SAFETY DURING PREGNANCY AND BREASTFEEDING IN WOMEN WITH AUTOIMMUNE DISEASES: RESULTS FROM THE COVAD STUDY

Keywords: Pregnancy and reproduction, COVID, Vaccination/Immunization

I. Andrie1, D. Linn1, K. Schreiber2, P. Sen3, N. Ravichandran4, I. Parodis5, C. E. Toro Gutierrez6, W. Kachtamant7, P. A. Goo8,9, R. Shumalina10, Q. C. Chibuzo11, T. Velikova12, J. Day13,14,15, M. Josh16, S. Katsuysuki Shinjo17, A. E. Gracia-Ramos18, L. Cavagna19, M. Kwanan20, J. Knitz21, A. Mak22, Y. M. Chen23, C. Study24, H. Chino25,26, V. Agarwal27, R. Aggarwal28, L. Gupta29,30,1, University of Brescia | ASST Spedali Civili, Dept Clinical and Experimental Sciences | Unit of Rheumatology and Clinical Immunology, Brescia, Italy; 1Danish ASHT for Rheumatic Diseases, Rheumatology, Sanderborg, Denmark; 2University...
Background: COVID-19 vaccine hesitancy among pregnant and breastfeeding women with autoimmune diseases (AID) is often attributed to the fear of adverse events (AE) and disease flares (DF). No data are available regarding COVID-19 vaccine safety in this population.

Objectives: We aimed at describing delayed-onset (>7 days) vaccine-related AE (minor and major), DF, and related AID treatment modifications from the COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.

Methods: Among complete responses from 9201 participants as of June 21, 2022, 6787 (73.8%) were women. Six subgroups were identified upon diagnosis with AID vs healthy controls (HC) and their pregnancy/breastfeeding status at the time of the survey and/or at the time of at least one dose of COVID-19 vaccine. Chi squared test: \( p<0.01 \); \( p<0.03 \); \( p<0.01 \).

Results: Forty pregnant and 52 breastfeeding AID patients were identified and their vaccination rates (at least one dose) was 100% and 96.2%, respectively (Table 1). Overall AE, minor AE, and major AE were reported significantly more frequently by pregnant than non-pregnant patients (45% vs. 26%, \( p<0.01 \); 40% vs. 25.9%, \( p=0.03 \); 175% vs. 4.6%, \( p<0.01 \), but no difference was found in comparison with pregnant HC. No difference was observed between breastfeeding patients and HC. Post-vaccination DF were reported by 17.5% of pregnant and 20% of breastfeeding patients, and by 18% of age- and disease-matched control patients (n=2315). All DF in pregnant/breastfeeding patients were managed with glucocorticoids and a fifth of patients required initiation or change in immunosuppressive treatment.

Conclusion: This study provides the first insights into the safety of COVID-19 vaccination during the antenatal period in women with AID. While AEs were more commonly reported by pregnant patients with AID, these were no higher than among pregnant healthy patients without AID. These observations are reassuring, likely to strengthen physician-patient communication and overcome hesitancy as the benefits for the mother and fetus by passive immunization are likely to outweigh the potential risks of AE and DF.

OP0083 ANAKINRA PLUS STANDARD OF CARE FOR THE REDUCTION OF HYPERINFLAMMATORY AND RESPIRATORY DISTRESS IN PATIENTS WITH SARS-COV-2 INFECTION: A MULTICENTRE, RANDOMISED, OPEN-LABEL PHASE 2/3 TRIAL (ANA-COVID-GEAS STUDY)

Keywords: COVID, bDMARD, Randomized control trial

P Fanto1, B Gracia Tello2, E Fonseca3, J Alvarez Troncoso4, A Gonzalez5, S Netto-Gonzalez5, M Freire6, A Argibay7, L Pallares Ferreiras7, J Tado8, M Perez Conesa8, S Bujan Rivas11, B Ibáñez12. 1Hospital Universitario de Navarra, Internal Medicine, Pamplona, Spain; 2Hospital Universitario Clínico Lozano Blesa, Internal Medicine, Zaragoza, Spain; 3Hospital de Cabueñes, Internal Medicine, Cabueñes, Spain; 4Hospital La Paz, Internal Medicine, Madrid, Spain; 5Hospital Ramón y Cajal, Internal Medicine, Madrid, Spain;
Background: COVID-19 pneumonia is often associated with hyperinflammation. The efficacy and security of anakinra in patients with severe COVID-19 pneumonia and hyperinflammation are still unclear.

Objectives: The primary endpoint was the proportion of patients not requiring mechanical ventilation up to 15 days after treatment initiation, assessed on an intention-to-treat-basis.

Methods: A multicentre, randomised, open-label, two-arm phase 2/3 trial was conducted at 12 hospitals in Spain. Adult patients with severe pneumonia were randomly assigned (1:1) to receive either usual standard of care plus anakinra (anakinra group) or usual standard of care alone (SoC group). Anakinra was given at a dose of 100 mg four times a day intravenously. The trial is registered with ClinicalTrials.gov; NCT04443881.

Results: Between 8 May 2020 and 1 March 2021, a total of 179 patients were randomly assigned to the anakinra group (n=92) or to the SoC group (n=87). The proportion of patients not requiring mechanical ventilation up to day 15 was not significantly different between groups (77.1% for Anakinra group vs 85.9% for SoC group, risk ratio 0.89 [95% CI 0.77–1.04]; p=0.16). Anakinra did not result in any difference in time to mechanical ventilation (HR 1.72 [95% CI 0.82–3.62]; p=0.14). There was no significant difference between groups in the proportion of patients not requiring invasive mechanical ventilation up to day 15 (RR 0.99 [95% CI 0.88–1.11]; p=1.00).

Conclusion: Anakinra did not prevent the need for mechanical ventilation or reduce mortality risk compared with standard of care alone in hospitalised patients with severe COVID-19 pneumonia.

OP0084
POSSIBLE ROLE OF PEPTIDE EPOPTIDES OF COVID-19 BNT-162B2 mRNA VACCINE IN FOMENTING AUTOIMMUNITY: AN IN SILICO ANALYSIS

Keywords: Adaptive immunity, Vaccination/Immunization, COVID

R. Talotta1. 1University Hospital “G. Martino”; Clinical and Experimental Medicine, Messina, Italy

Background: Following the launch of the global COVID-19 vaccination campaign, there have been increased reports of autoimmune diseases developing de novo following vaccination. These cases include rheumatoid arthritis, autoimmune hepatitis, immune thrombotic thrombocytopenia, and connective tissue diseases. Nevertheless, COVID-19 vaccines are considered safe for patients with autoimmune diseases and are strongly recommended.

Objectives: The aim of this in silico analysis is to investigate the presence of protein epitopes encoded by the BNT-162b2 mRNA vaccine, one of the most commonly administered COVID-19 vaccines, that could elicit an aberrant immune response in predisposed individuals.

Methods: The FASTA sequence of the protein encoded by the BNT-162b2 vaccine was retrieved from http://genome.ucsc.edu and used as a key input to the Immune Epitope Database and Analysis Resource (www.iedb.org). Linear peptides with 90% BLAST homology were selected, and T-cell, B-cell, and MHC ligand assays without MHC restriction were searched and evaluated. HLA-disease associations were screened on the HLA-SPREAD platform (https://hla-spread.ibg.res.in) by selecting only positive markers.

Results: A total of 183 epitopes were found, corresponding to 178 SARS-CoV-2 and 5 SARS-CoV spike epitopes, respectively. Results were obtained from 22 T-cell assays, 398 B-cell assays, and 2 MHC ligand assays. Complementary receptors included 1080 T-cell receptors and 8 B-cell receptors.

Specifically, the IEDB epitope:1392457 (NATTVVKICKCEFQCNDFDLQGVY) was shown to bind to HLA-DRB1*15:02 and HLA-DRB1*15:03 alleles, whereas the IEDB epitope:1392457 (TKCXLSTFVEKGIYQTSNFRQVPT) was reported to bind to HLA-DRB1*07:01, HLA-DRB1*03:01, HLA-DRB3*01:01, and HLA-DRB4*01:01 alleles. The HLA alleles detected were found to be positively associated with various immunological disorders (Table 1).
breakthrough infection, collecting peripheral blood mononuclear cells (PBMCs) 2-4 weeks after each immunisation. Samples were incubated with SARS-CoV-2 spike, nucleocapside or membrane peptides. The percentage of responding T cells was measured by flow cytometry (2) (%0.01% increase in responding CD4 cells, ≥0.001% increase in responding CD8 cells, compared to baseline).

Results: Between February 2021 and December 2022, 144 patients on TNFi (monotherapy n=86 (60%), combination with methotrexate or azathioprine n=58 (40%)) were included (median age 48 years [IQR 33-57]; 51% women) (Table 1). The proportions of arthritis vs IBD patients with CD4 responses after 2 vaccine doses were 75% (12/16 patients) vs 86% (25/29), and after 3 doses 83% (10/12) vs 93% (28/30). In total, 80% (4/5) of arthritis patients showed further increases in CD4 responses after a 4th vaccine dose. Conversely, 81% (13/16) of arthritis patients vs. 55% (16/29) of IBD patients had CD8 T cell responses after two doses, and 67% (8/12) vs. 62% (18/29) after three doses. A 3rd and 4th dose induced higher CD8 responses compared to the previous dose in 55% (6/11) and 62% (9/14) of arthritis patients, respectively. Arthritis patients had lower T cell responses than IBD patients after the 3rd dose; median CD4 response 0.024% [IQR 0.009-0.036] vs 0.031% [IQR 0.009-0.049], p=0.003 vs 0.024% [IQR 0.009-0.049], p=0.0032 (Figure 1). This difference remained robust after adjusting for age and sex, p<0.001, but was no longer detected after the 4th vaccine dose. Breakthrough infection elicited increased T cell responses across all diagnoses to spike (p<0.0001), and to nucleocapsid (p=0.002) and membrane proteins (p<0.001) compared to unstimulated T cells. Also, Spike-specific T cell responses increased compared to the 3rd dose (median CD4 T cell response 0.18% vs. 0.06%, p=0.003; CD8 T cell response 0.08% vs. 0.01%, p<0.0001), but to a lesser extent compared to the 4th dose (median CD4 response 0.3% vs. 0.12%, p=0.05; CD8 response 0.08% vs. 0.03%, p=0.026). There were no differences in cellular response between patients on TNFi mono- or combination therapy (p=0.93).

Conclusion: Patients on TNFi showed improved cellular responses following each immunisation, with infection generating a strong and broad T cell response. Arthritis patients had significantly lower CD4+ responses compared to IBD patients after three vaccine doses, but with no difference after the 4th dose. These results support giving a 4th vaccine dose to TNFi-treated patients, with particular benefit for arthritis patients.

Moving into better health

OP0086-HPR THE SWEDISH OSTEOARTHRITIS REGISTRY: TRENDS IN SWEDISH OSTEOARTHRITIS HEALTH CARE BETWEEN 2008-2021

Keywords: Patient information and education, Descriptive Studies, Osteoarthritis

K. Wetterling1, T. Jönsson2, M. Mohaddes1. 1Institute of Clinical Science, Department of Orthopaedics, Gothenburg, Sweden; 2Division of Sport Science, Department of Health Science, Lund, Sweden

Background: In 2012 the Swedish national guidelines for osteoarthritis (OA) were published. The guidelines implied that all patients with OA should obtain information and supervised exercise as first-line intervention and that OA is a clinical, not radiological diagnosis. The Swedish OA registry contains data which measure compliance to the guidelines since 2008 [2].

Objectives: To describe the trends over time from 2008 to 2021 for patients who have received first-line interventions for hip and knee OA in Sweden and adherence of the healthcare staff to the national guidelines.

Methods: Descriptive registry-based study including patients with hip or knee OA who participated in first-line interventions including education and exercise. Data were extracted from the Swedish OA registry between January 1st, 2008, and December 31, 2021. The registry contains patient-reported outcomes and physiotherapist-reported outcomes. In this study the following physiotherapist-reported outcomes were described over time: radiological examination before first-line intervention, if the first-line intervention was given the first time the patient seek health care caused of OA, which explanation patients had been given about their disease, intake of painkillers before the start of first-line intervention and the percentage who got supervised exercise >10 times according to the guidelines of OA in Sweden. The following patient-reported outcomes were described over time: mean BMI at the first visit, and mean age at the first visit. To be included in the study, participants had to meet the following criteria: i) clinical diagnosis of OA, with hip or knee OA as the most symptomatic joint, ii) provided 3-month follow-up.

Results: A total of 175 764 participants with hip or knee OA were included in the study. The trends from 2008-2021 showed that the proportion of patients who had a radiological examination before entering the first-line intervention decreased from 97 % to 65 % in men and from 95% to 62 % in women. The proportion of patients who get assessed to first-line intervention the first time they seek for their symptoms increased from 4 % to 10 % both in men and women. People that get the correct information about OA increased from 15% to 40 %, and patients that get the explanation that OA was a tear and wear disease decreased from 30 % to 5%. The mean BMI (28) is unchanged over time. The mean age increased from 64 years to 67 years between 2008-2020 but decreased during the covid-19 pandemic to 64 years. The percentage that was given supervised exercise more than 10 times was constant between 2012-2020 at 30 % but decreased during the covid-19 pandemic to 20%.

Conclusion: The results imply that the implementation of a supported OA self-management program in Sweden has been successful and changed the care given to patients with OA in Sweden. However, the national guidelines for OA have still not been fully implemented. We need to keep implementing the guidelines so all patients with OA get the first-line intervention at the right time.
Background: Despite more effective control of inflammation by improved pharmacological therapies, persistent pain and fatigue are still a major problem among patients with rheumatoid arthritis (RA), which often leads to slower deterioration of function and general health. Objectives: To evaluate the effect of high-intensity exercise on fatigue, pain, and general health in patients with established RA. Methods: Patients with RA (ACR/EULAR 1987/2010 criteria), disease duration > 12 months, were recruited and randomised to either an exercise group or a control group. The exercise program of 12 weeks comprised supervised cardiorespiratory high-intensity interval exercise and strength exercise twice per week plus an additional non-supervised session of the patient’s own choice. The controls received individual information for physical activity according to the general health recommendations and were encouraged to be active on moderate to vigorous intensity. Results: A total of 73 patients median age 49 (86.3% women), median disease duration 5.7 years, median swollen joint count 13 (range = 4 to 28), and disease activity assessed by self-reported 28-tender (TJC, 0-28) and 28-swollen joint count (SJC, 0-28), assessed by the rheumatologist at inclusion and at baseline and 12 weeks post baseline. The exercise intervention had beneficial effects on fatigue, pain, and general health. A significant difference of 2.0 points (95% CI 0.95-3.05, p < 0.001) was observed on the Multidimensional Fatigue Inventory (MFI 20) scale, including five subscales; general fatigue, physical fatigue, mental fatigue, general health recommendations and were encouraged to be active on moderate to vigorous intensity, fatigue and general health during the last week due to the rheumatic disease (0 = no symptom, 100 = worst possible). Variables are presented as median and IQR. MFI Multidimensional Fatigue Inventory, VAS Visual Analog Scale Fatigue, Pain, Global. Delta values were compared using the Mann–Whitney U test. Within-group comparisons were made with Wilcoxon signed rank test. **Significant difference, p < 0.01. ***Significant difference, p < 0.001.

**OP0088-HPR** FACTORS ASSOCIATED WITH MEETING RECOMMENDED PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAVE POOR PHYSICAL FUNCTION

Keywords: Patient reported outcomes, Lifestyles, Rheumatoid arthritis

K. Wibring1,2, S. Bergman4, A. M. Anderson3,5,6,1, Spenshult Reserach and Development Centre,., Halmstad, Sweden;1Capio Movement, Department of Rheumatology, Halmstad, Sweden;1Spenshult Reserach and Development Centre,., Halmstad, Sweden;1University of Gothenburg, The Sahlgrenska Academy, Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden;1Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden;1Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden

Background: Rheumatoid arthritis (RA) is a chronic disease that often leads to a major impact on physical function and quality of life. It is well known that physical activity is an important part of treatment and improve clinical outcome. Objectives: The aim was to study factors associated with meeting recommended level of physical activity in people with RA with poorer physical function. Methods: In 2017, a survey was sent to patients included in the BARFOT (Better Anti-Rheumatic pharmacotherapy) cohort [1]. The questionnaire included questions on age, sex, disease duration, smoking, body mass index (BMI), physical function assessed by health assessment questionnaire (HAQ; 0-3, best to worst), numeric rating scale (NRS) pain (0-10, best to worst), NRS fatigue (0-10, best to worst), disease activity assessed by self-reported 28-tender (TJC, 0-28) and swollen joint count (SJC, 0-28), health-related quality of life assessed by EuroQol 5-dimension 3-level (EQ5D; 0-1, best to worst), empowerment assessed by the Swedish Rheumatic Disease Empowerment Scale (SWE-RES-23; 1-5, worst to best), cardiovascular diseases (CVD), and antirheumatic treatment, corticosteroids (CS), conventional disease-modifying antirheumatic drug (cDMARD), biologic DMARD (bDMARD), 1065 patients (69%) answered the questionnaire and were dichotomized based on the median of HAQ, which was 0.5. The group with the worst physical function, HAQ >0.5, was further dichotomized based on whether they met the World Health Organisation (WHO) recommended level of physical activity (pulse-increasing physical activity with moderate intensity at least 150 minutes/week or at least 75 minutes/week with high intensity) or not. Median and interquartile range (IQR) and Mann-Whitney U test or chi² were used to analyse differences between groups, when appropriate. A logistic regression model adjusting for age and sex was used to study factors associated with fulfilling the recommendations on physical activity. Results: The patients with the worst physical function, meeting the criteria for recommended physical activity (RPA), had less pain, and fatigue, fewer swollen and tender joints, less CVD 48% vs. 64% (p<0.001), and fewer were obese than those who did not meet these recommendations (Not RPA), Table 1. They also had a better quality of life and a higher degree of empowerment, Table 1. Factors associated with fulfilling the recommended level of physical activity in the group with the worst physical function were obesity, BMI ≥30kg/m² (OR 0.51, 95% CI 0.32-0.83), HAQ (OR 0.32, 95% CI 0.21-0.48), pain (OR 0.84, 95% CI 0.77-0.91), NRS fatigue (OR 0.88, 95% CI 0.82-0.95). TJC (OR 0.97, 95% CI 0.93-0.99), EQ5D (OR 0.86, 95% CI 0.74-1.00) and SJC (OR 0.91, 95% CI 0.90-0.92) and EQ5D (OR 0.86, 95% CI 0.74-1.00).

(OR 0.65, 95% CI 0.45-0.95). Medical treatment was not associated with meet-
ing the criteria for physical activity.

Conclusion: The results indicate a complex relationship between various factors that can affect the possibility to be physically active when having RA. Disease-re-
lated factors such as pain, fatigue, and tender and swollen joints are important to address, but also the health-related quality of life and empowerment, to be able to improve physical activity in individuals with RA that have poor physical function.

Keywords: Pain, Fibromyalgia, Non-pharmacological interventions

L. De Araújo Cazotti1, J. Natour1, F. Carvalho1, D. Freitas Pereira1, A. Jones1.
1Universidade Federal de São Paulo, Rheumatology Division, São Paulo, Brazil

Background: Fibromyalgia (FM) is defined as a chronic syndrome characterized by diffuse musculoskeletal pain and several symptoms that reflect on the func-
tional capacity and quality of life of the affected patients. Different types of exer-
cises are recommended in the treatment of FM. Pilates is a method of physical conditioning that has been frequently used in rehabilitation programs, due to the benefits perceived in musculoskeletal disorders, as well as in other conditions.

Objectives: To evaluate the efficacy of Pilates method compared to aerobic exer-
cise in pain, quality of life related to the disease, depression, quality of life in gen-
eral, functional capacity, kinesiophobia, catastrophizing, treatment satisfaction and reduction in the use of medication by women presenting FM.

Methods: Sixty-six female patients diagnosed with FM were included, aging 18 to 65, presenting pain between 3 to 8 in numerical pain scale (NPS). Patients with inflammatory rheumatic diseases, neurological diseases, under psychiatric treatment, who have started or changed physical activities or medication in the last three months, patients with uncontrolled cardiorespiratory and cardiovascular diseases or any condition that may limit the practice of exercises, with non-di-
bates mellitus controlled and other musculoskeletal diseases that could prevent the use of this method were excluded. The selected patients were randomized into two groups: Pilates and Control. The Pilates group (PG) had Pilates sessions three times a week for 12 weeks. The Control patients (CG) used a treadmill three times a week for 12 weeks. The treatment sessions in both groups lasted 50 minutes and the groups were instructed to use acetaminophen750mg each 8 hours in case of pain, but the use was controlled. The evaluations were done by blind assessor at baseline (T0), 45 days (T45), 90 days (T90) and 180 (T180) days after initiation of the study using the following instruments: for pain: NPS; Fibromyalgia Impact Questionnaire (FIQ), to evaluate the quality of life related to disease; Beck Depression Inventory (BDI) for depression; The short form 36 (SF-
36) to evaluate the quality of life in general; the 6-minutes walking test (6MWT) to evaluate the functional capacity; kinesiophobia scale (Tampa) to evaluate the fear of movement; Fear Avoidance Beliefs Questionnaire (FABQ), to evaluate catastrophizing and the Likert scale to evaluate the patient satisfaction towards the treatment.

Results: Thirty four patients were randomized for the GP and 32 for the CG. The groups were homogeneous at baseline. In the comparison between groups over time, we found better results for PG with statistical differences when compared to CG for: pain (p<0,001), disease-related quality of life (p<0,001), psychological status (p=0,026), some domains of SF-36 – pain (p=0,014) and general health status (p=0,044), kinesiophobia scale (p<0,001), reduction in analgesic con-
sumption (p=0,042) and on the Likert scale (p=0,003).

Conclusion: Pilates method is effective in the treatment of women with FM, presenting pain improvement, quality of life related to the disease, psycholog-
ical status, the SF-36 (pain, general health) domains, the kinesiophobia scale, the analgesic consumption reduction and satisfaction with treatment with better results when compared to walking.

ASSOCIATION BETWEEN GRIP AND CORE MUSCLE STRENGTH IN PEOPLE WITH AXIAL SPONDYLOARTHROPATHY (ASXPA) AND HEALTHY CONTROLS

Keywords: Spondyloarthritis, Physical therapy/Physiotherapy

A. K. Rausch Oothof1, M. Bruderer-Hofstetter1, L. Ettlin1, F. Bischofberger1, S. Papritz1, F. Schwab1, F. Weidmann1, J. Niggli2, K. Niedermann Schneider1.
1ZHAW Zurich University of Applied Sciences, School of Health Sciences, Institute for Physiotherapy, Winterthur, Switzerland; 2SVMB, Ankylosing Spondylitis Association Switzerland, Zurich, Switzerland

Background: Regular fitness assessments are part of the group exercise ther-
apy concept for people with axSpA living in Switzerland. Participants ask if their performance is comparable with healthy people, which we cannot answer as no norm data are available. Among others, a test battery measuring the isometric strength endurance of the ventral, lateral, and dorsal core muscle chains (in sec-
onds) is used (Rausch 2020). The core strength endurance test battery (CST) is time-consuming. In contrast, hand grip strength (in kg, Jamar dynamometer) can be tested within a short time and is already used as a substitute for multiple fitness-related tests (Kim 2022).

Objectives: 1) to compare core strength endurance of people with axSpA and healthy controls, and 2) to evaluate if grip strength can be used as a proxy for core strength to reduce the assessment time in people with axSpA.

Methods: Data was collected between April 2021 and December 2022. Data of people with axSpA were taken from the SVMB database of routinely gathered assessment data, and grip strength measurement was added. Further, data of CST and grip strength were collected in healthy controls, recruited from ZHAW staff and local sport clubs. All participants gave written informed consent. To investigate differences between both groups, relevant demographics, core and grip strength measures were compared using Welch Two-sample t-tests and Pearson's Chi² test, if appropriate. The associations between grip and core strength were explored through pairwise Spearman rank correlations (R_s) in both groups and sex-specific subgroups. In addition, we fitted linear regression models to the log-transformed data of people with axSpA.

Results: Data from 160 healthy people (50% male, mean age 59.3 (SD 11.47) years) and 122 people with axSpA (58% male, mean age 57.7 (SD 12.1) years) were included. In people with axSpA, mean years since symptoms were 37.3 (SD 24.9), and since diagnosis 29.4 (SD 27.1). The median BASDAI score was 2.5 (IQR 1.7 – 4.2), and the median ADAS Health index was 3 (IQR 0 – 7). Demographic characteristics (i.e., age, sex, weight, height, BMI, and smoking status) did not differ between groups. However, people with axSpA showed less core strength endurance, measured in seconds: ventral mean difference -28, p < 0.001; lateral mean difference -17.1, p < 0.001; dorsal mean difference -38.5, p < 0.001.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.3961
Pairwise correlations in the two groups and sex-specific subgroups are summarized in Table 1.

The final linear regression model with grip strength as response and core strength, age, and sex as predictors explained 45% of the variability. Significant predictors in the model were ventral core strength endurance, age, and sex, while sex was the predictor with the most considerable effect.

Conclusion: People with axSpA showed lower core muscle strength endurance than healthy individuals. All correlations were small to moderate. The results from the multivariate analysis indicate that core strength endurance measures have only marginal effects on grip strength in people with axSpA. Therefore, grip strength is not appropriate to be used as a proxy for core strength endurance in people with axSpA and healthy people.

**Background:** The Inflammatory Arthritis (IA) patient population is growing, whilst there already is a shortage of health care professionals (HCPs). It is impossible to meet the future demand for care with the current healthcare system. Digital biomarkers are objective, quantifiable, physiological and behavioural data that are collected and measured by means of digital devices [1]. They can support continuous measurements outside the physical confines of the clinical environment and so could help close the gap in healthcare demands.

**Objectives:** To obtain the patients’ insights on disease activity, disease management and care needs; and to empathise with their attitude towards digital biomarkers in order to obtain future directions for digital biomarker development.

**Methods:** A Design Thinking approach is followed for the development of digital biomarkers in rheumatology. It is a human-centered problem-solving approach that leverages empathy and collective idea generation to tackle complex challenges [2]. Semi-structured focus group discussions, based on the Common Sense Model of Self-Regulation [3], were conducted through 60-minute video conferences. All interviews were audio-recorded, transcribed to verbatim and coded. Results were discussed with our patient partners.

**Results:** In total 6 focus groups were organised, with a total of 30 IA patients (22 PsA; 8 RA, age 51 ± 11 years, 48% male, time since diagnosis 7 (3:12,5) years).

The main findings were: **Trial and error:** life after diagnosis is marked by trial and error. They needed to learn how and when to listen to their bodies, uncover potential triggers of inflammation and develop appropriate disease management. They felt an urgency to get advice on lifestyle adjustments, career choices and life adaptations, and discuss these with their HCPs and fellow patients. **Role of the HCPs in care needs:** patients visited their HCP for affirmation, reflection and future directions. They often doubted whether their symptoms were rheumatic. Secondly, they wanted to be assured adverse drug reactions are absent, blood tests brought them peace of mind. Furthermore, consultations were indicated as an obligatory moment of self-reflection. Convening with their HCP was seen as a reality check and a conversation about (new) options. Digital Biomarkers; attitudes towards digital biomarkers varied. Some patients thought it could provide them with deeper insights and reminders before crossing a line. Some patients thought it relevant only for their HCP. They did not want a constant reminder of their disease. Others did not see any additional value as they knew themselves well enough that no device should tell them whether their feelings are true or not.

**Conclusion:** The following problem statement from the patients’ perspective can be formulated: “we suffer from a disease that has turned our lives upside down, we have to cope with it every day. Our learning mechanism is by trial and error. We have to know which activities should be avoided and how to predict the seriousness of a flare. It is difficult to discriminate pain as just pain, from pain as a preceding symptom of flare. The affirmation from our HCPs and our blood results bring us peace of mind. Perhaps, by applying technology, we can speed up our learning process and triggers of flare could be identified. However, one should be mindful of the purpose, the amount of reminders it gives us and the visualisation of our measurements.” In general there is no strong resistance to digital biomarkers. However, for future uptake the recorded data should be of clear benefit for the patient.

Fibroblast activation in rheumatic diseases

Keywords: Synovium, -omics, Rheumatoid arthritis

P. I. Reis Nisa1, C. Mehonry1, C. Smith1, C. D. Buckley2, K. Raza1, A. Filer1, D. Windel1, M. Coles2, A. Croft1, University of Birmingham, Inflammation and Ageing, Birmingham, United Kingdom; University of Oxford, Kennedy Institute for Rheumatology Research, Oxford, United Kingdom

Background: Rheumatoid arthritis (RA) is highly heterogeneous with distinct cellular and molecular tissue pathotypes that associate with disease outcome[1]. The synovial membrane is the primary target tissue and undergoes significant architectural re-modelling in response to inflammation. While fibroblasts are known to shape immune cell compartmentalisation in secondary lymphoid organs, by producing distinct sets of chemokines and remodelling extracellular matrix (ECM)[2], the mechanisms underlying immune cell localisation in the synovium are poorly understood.

Objectives: To define the functional zonation of the inflamed synovium at the single cell and regional tissue level using spatial transcriptomics and multiplex imaging.

Methods: We performed oligonucleotide probe-based spatially resolved transcriptomics on synovial tissue samples obtained by minimally invasive, ultrasound-guided synovial biopsy performed in patients with rheumatoid arthritis (RA) and osteoarthritis (OA) using the 10x Visium platform. A total of 27 tissue biopsies processed sequencing 34170 spot transcriptomes. Each tissue section was composed on 1-8 fragments of synovial tissue from the same donor biopsy sample within each capture area, to maximise tissue representation and account for sampling variability. Cellular deconvolution of spot transcriptomes was performed using single cell reference datasets. Multiplex imaging was obtained to confirm gene profiles and cell types associated with the specific zonation patterns.

Results: We identified six spatially resolved tissue niches (or zones) within synovial membrane defined by gene expression and comprised of distinct populations of stromal and immune cells. Specific patterns of gene expression were observed in each of these sub-synovial tissue zones that link to functions of immune infiltrate recruitment and organisation. This zonation pattern is maintained across pathotypes (Fibroid, Lymphocytic) and spatial gene expression analysis revealed that RA is associated with specific synovial re-modeling and the formation of lymphocytic niches when compared to OA synovial tissue. We next defined zonation areas by manually annotating immune infiltrates (as aggregates) and vasculature, based on histology. From these, we selected fibroblasts specific to immune aggregate zones and peri-vascular zones (Figure 1). We have identified differences in gene expression between these fibroblasts based on their anatomical location. Peri-vascular fibroblasts have gene expression profiles related to myofibroblast differentiation, ECM deposition and modulation (COMP), but also immune cell recruitment (PLA2G2A), cell activation (FOS & FOSB), and lipid metabolism (APOD), also associated with OA synovium. These fibroblasts display either a TGF-β response or NOTCH3 activated[3] gene expression program and are expanded in the fibroblast-pauci-immune) tissue pathotype. Immune interacting (peri-aggregate) fibroblasts in contrast, show specific gene expression profiles linked to ECM regulation (POSTN), degradation (MMP3) and co-ordination of ECM remodelling to recruit immune cells (SPARC), and permit aggregate formation. These fibroblasts display a T-cell interacting[4] and IFN-γ gene expression program and along with IL-1β and TNFα activated lining layer fibroblasts dominate the stromal cell landscape of the lymphoid tissue pathotype.

Conclusion: We demonstrate that cytokine directed fibroblast-immune cell crosstalk, positional identity, and matrix specific, fibroblast gene expression programs are responsible for localising infiltrating immune cells to specific niches within the tissue and defining functional tissue zonation. These data identify novel therapeutically tractable disease pathways that underpin the pathogenicity of synovial tissue fibroblasts in RA.

Autoinflammation – the next chapter

Keywords: Inflammatory arthritides, Gout, Crystal Arthritis

T. W. Chirayath1, M. Kayatekin2, I. Rubera2, N. Pham1, F. Liote1, V. Compani1, F. Rassendren3, C. Duranton4, H. K. Ea1, INSERM, Biocar U1132, Paris, France; LPM - Universite Côte d’Azur - CNRS UMR7370, Laboratoire de PhysioMédecine Moléculaire, NICE, France; INSERM, Institut de Génomique Fonctionnelle, Montpellier, France

Background: Monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals are responsible for interleukin (IL-1) dependent acute arthritis. The release of mature IL-1β is dependent on the NLRP3 inflammasome, which can be activated by other sterile stimuli such as hypo-osmolarity and ATP. During extracellular hypotonic stress, there is cellular swelling secondary to water influx. The cell sets up a defence mechanism, called regulatory volume decrease (RVD), allowing it to return to its initial volume. RVD depends on the anion channel LRRC8/VRAC, a hetero-hexamer composed of members of the LRRC8 family. LRRC8A is the obligatory key protein required to form active VRAC channel. Activation of LRRC8/Vrac channel results in an efflux of anions (mainly chloride) and osmolytes leading to water efflux and cell volume reduction.

Objectives: To evaluate the role of the LRRC8/Vrac channel in cell volume regulation and IL-1β release induced by MSU and CPP crystals.

Methods: In-vitro, primed THP-1 monocytes were stimulated by synthetic sterile MSU and CPP and cytokine production was quantified by ELISA. Cell volume variations were visualized by live video recording and cell surface was measured using ImageJ software. The role of the LRRC8/Vrac channel was evaluated using a pharmacological inhibitor DCPIB or by silencing the LRRC8A subunit (shLRRC8A RNA) in these cells. In vivo, MSU and CPP crystals were injected into air pouches created subcutaneously (mimicking synovial cavity) in wild-type mice and conditional LRRC8A Knock-out mice in the macrophage lineage (Ccr3Cre_Lrcc8aflox/flx). Supernatants and pouch lavages were used to measure cytokine production by ELISA.

Results: MSU and CPP-induced NF-κB activation was reduced in WT THP-1 cells treated with DCPIB and in THP-1 cells where LRRC8A expression was silenced. Similarly, IL-1β production induced by MSU and CPP crystals was substantially decreased in WT THP-1 treated with DCPIB (MSU 5200 vs 1080 pg/ml; CPP 11500 vs 4980, p<0.0001) and in shLRRC8A THP-1 cells compared to crystal-treated WT cells. MSU and CPP crystals exposure induced a biphasic cell volume change characterised by a significant increase followed by a RVD-like phenomenon. These cell volume changes were abolished in the presence of DCPIB and not observed in shLRRC8A THP-1 cells. In vivo, inflammation induced by MSU and CPP crystals assessed in lavage fluid and conventional histology was lower in Ccr3Cre_Lrcc8aflox/flx mice as compared with wild-type mice in terms of IL-1β production and cell infiltrate.

Conclusion: These results suggested that MSU and CPP crystal-induced inflammation involved and cell volume variation regulated by VRAC/LRRC8 channel.

OP0095 IMMUNOPHENOTYPING-BASED TRANSCRIPTOME ANALYSIS ON SYSTEMIC IMMUNE-MEDIATED DISEASES

Keywords: Artificial Intelligence, Genetics/EpiGenetics, -omics

S. Iwaki1, T. Komai1, T. Imamiya1, M. Ota2, S. Yamada1, Y. Nagatuchi1,2, H. Shoda1, K. Matsuki1, K. Yamamoto1, T. Okamura2, K. Fujii1. 1The University of Tokyo, Department of Allergy and Rheumatology, Tokyo, Japan; 2The University of Tokyo, Department of Functional Genomics and Immunological Diseases, Bunkyo City, Japan; 3Chugai Pharmaceutical Co Ltd, Research Division, Kamakura, Kanagawa, Japan; 4The Institute of Physical and Chemical Research (RIKEN), Laboratory for Autoimmune Diseases, Center for Integrative Medical Sciences, Yokohama, Japan

Background: Systemic immune-mediated diseases vary in manifestations and pathogenesis. Currently, disease diagnoses and treatments are generally based on clinical symptoms and some specific serological features. Because the diseases share some clinical and pathological features, it is difficult to comprehend the pathogenesis and manage them appropriately. To date, a limited number of studies tried to stratify such patients into some subgroups using the transcriptomic data and molecular patterns [1]; however, the number of included diseases, patients, and transcriptome data were restricted.

Objectives: To identify the significant immune cells forming the diseases and then stratify all patients accordingly, using immunophenotyping and transcriptome analysis.

Methods: We performed an integrative analysis of immunophenotyping and bulk RNA-seq data (RNA-seq) on peripheral mononuclear blood cells (PBMC) from patients diagnosed with systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD), idiopathic inflammatory myopathy (IIM), systemic sclerosis (SSc), rheumatoid arthritis (RA), and large vessel vasculitis (LlV) in the Immune Cell Gene Expression in Diseases (ImmuneGeneDx) database from the University of Tokyo (ImmuneNet).

Immunophenotyping (27 immune cell subsets) were applied to machine learning approaches, a random forest method, and all patients were stratified by k-means clustering. Then, we conducted a transcriptome analysis, including a differentially expressed gene (DEG) analysis and enrichment analysis (5,484 RNA-sequencing data). Finally, we compared clinical features among the clusters (Figure 1A).

Results: A total of 254 patients with systemic immune-mediated diseases (78 SLE, 63 MCTD, 52 SSc, 20 RA, and 19 LlV) were included. To identify important cells to distinguish the diseases, a random forest algorithm was conducted by applying the immunophenotyping data. Using the top 15 important features, k-means clustering was performed, and all patients were stratified into three clusters (Figure 1B). Naïve CD8+ T cells, memory CD4+ T cells, and non-classical monocytes were predominantly in clusters 1, 2, and 3, respectively (Figure 1C).

Each disease showed skewed distribution in each cluster, such that SLE patients were predominantly in cluster 2 and most of the SSc patients were included in cluster 3 (Figure 1B). Next, we conducted DEG and enrichment analysis on 5,484 RNA-sequencing data of each immune cell and found that the number of DEGs in memory CD4+ T cells in cluster 2, and non-classical monocytes in cluster 3 were increased when compared with other clusters, which were consistent with the cell proportions (Figure 1D).

The gene ontology analysis showed enrichment of genes associated with adaptive immune response in naïve CD8+ T cells in cluster 1, T cell activation response and an innate immune response in memory CD4+ T cells in cluster 2, and vascular process in the circulatory system in non-clas-sical monocytes in cluster 3, suggesting that even the same diseases can be stratified into each cluster based on specific pathogenesis. Uniquely, patients with common clinical features such as arthritis, the positivity of anti-SS-A antibody, and disease spectrums of MCTD were each accumulated in the different, specific cluster.

Conclusion: This large-scale integration of immunophenotyping and transcriptome analysis on the six systemic immune-mediated diseases revealed all patients were classified into three clusters and each one has specific clinical and transcriptomic features. It may enhance the understanding of the pathogenesis of heterogeneous diseases.

OP0097 KAME3-DOMINANT BIVALENT CHROMATIN REGIONS ASSOCIATE WITH IMMUNOPRECIPITATION REMODELLING COMPLEXES IN CD4 CELLS

Keywords: Rheumatoid arthritis, Genetics/EpiGenetics, -omics

V. Chandrasekaran1, M. J. Garcia-Boneta2, N. Oparina2, K. M. Andersson1, M. C. Erlandsson1, A. Damdimopoulos2, E. Malmöhi-Bah1, G. Katona2, M. I. Bokarewa3,4,1 University of Gothenburg, Department of Rheumatology and Immunology Research, Gothenburg, Sweden; 1University of Gothenburg, Department of Chemistry and Molecular Biology, Gothenburg, Sweden; 2Karolinska Institute, Department of Biosciences and Nutrition, Karolinska Institute, Gothenburg, Sweden; 3 Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden

Background: Rheumatoid arthritis (RA) is associated with aberrant epigenomic changes. It obstructs the normal function of CD4 T cells. Bivalent chromatin regions (bVCR), containing histone H3 tail trimethylation at lysine 4 (H3K4me3) and lysine 27 (H3K27me3), act as a major organizer of the 3D nuclear environment required for efficient T cell development. Survivin has gained importance in RA pathogenesis. Survivin is shown to interact with chromatin genome-wide and regulate gene transcription in the IFNg producing CD4 T cells [1].

Objectives: This study investigates survivin cooperation with nucleosome in bVCR and functional effect of this cooperation on CD4 cell phenotype.

Methods: BvCR were identified in CD4 cells by annotation of H3K4me3, H3K27me3 and H3K27ac binding through chromatin immunoprecipitation and sequencing (ChIPseq). Protein binding was quantified through peak score. An overlap of the H3 peaks and Survivin ChIPseq (12 individual CD4 cultures) by at least one bp was identified through R package ChIPeakAnno. Changes in H3 peaks in CD4 cells treated with a survivin inhibitor YM155 were assessed. Tag normalization was applied to enable comparison between different ChIPseq. Tag prevalence within the bVCR defined the dominant H3 group. Changeable BvCR were defined by alteration in the dominant-H3 group after YM155 treatment. TF ChIPseq colocalization analysis was performed through ReMap2022 database. To analyse effect of BvCR changeability on transcriptome, we performed RNA-seq of YM155-treated CD4 cells (n=4). Overlap of BvCR with regulatory elements (RE) was done through GeneHancer database. TF enrichment analysis was performed through GSEA (Broad Institute).
### OP0098

**INFLAMMATORY GENE ENHANCERS ARE SHARED IN SYNOVIAL FIBROBLASTS AND MINOR SALINARY GLAND FIBROBLASTS**

**Keywords:** Cytokines and chemokines, SJögren syndrome, Rheumatoid arthritis

L. Moser1, M. Brunner2,3, M. Houtman1, M. Sprecher1, M. Elhai1, O. Distler1, B. Wintergerst1, C. Ouyang1, W. Klein1, University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland; 2University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland; 3University of Bern, Department of BioMedical Research, Bern, Switzerland

**Results:** Integration of H3K4me3, H3K27me3 and H3K27ac ChiP-seq identified 6199 BvCR, 66% of those contained survivin peaks. Fluorescence imaging of effector T cells validated nuclear colocalization of survivin with histone proteins. Of those 6199 BvCR, 43.8% were dominated by H3K4me3, which had also the highest survivin peak scores. Complexes of histone modifiers COMPASS, responsible for H3K4 methylation, and SWI/SNF, responsible for counteracting PRC2-guided H3K27me3, colocalized with BvCR. YM155-treatment significantly increased deposition of both H3K4me3 and H3K27me3. Changeable BvCR frequently acquired a K4me3-dominated status after YM155 treatment. This indicates that survivin contributes to regulation of methylation of lysines in H3 tail within BvCR. TF enrichment analysis of genes connected to the BvCR revealed the role of histone demethylases KDM7A (FDR=1.03e-32), PHF2 (FDR=3.47e-19), KDM5D (FDR=1.51e-15) in their transcription. Strongest overall enrichment was identified in H3K4me3-dominated BvCR colocalized with survivin. Integration of BvCR with CD4 RNA-seq revealed 2469 protein-coding genes connected through RE to H3K4me3, which sustained transcription activity and 346 of those were differentially expressed (DEG, nom p<0.05) in YM155-treated cells. DEG transcriptionally depend on the TF families of histone modifiers built a strong SWI/SNF-dependent interaction network acting in biological processes of immune system regulation (FDR=1.07e-6, FOXP1, KLF3, FYB1, BCL2), DNA repair (FDR=5.57e-6, MSH6, MGMT, MCM8, UPP1), and RNA polymerase transcription (FDR=1.22e-6, TF3, ATRID, RARA). CD4 cell transcriptomics of randomly selected RA patients demonstrated that a) DEG controlled by the H3K4me3-dominated BvCR were upregulated in survivin-high CD4 cells with proinflammatory Th1 phenotype b) DEG had altered expression in CD4 cells of patients treated with JAK-inhibitors.

**Conclusion:** This study demonstrates that survivin contributes to regulation of histone methylation in H3 tail within BvCR, which coordinates activity of the SWI/SNF complex in chromatin remodelling and transcription. We demonstrate that survivin inhibition affects this coordinated activity, and thereby impinge on CD4 activation in RA.

**UNVEILING THE COMPLEX GENE REGULATORY MECHANISMS OF PSORIATIC ARTHRITIS THROUGH CHROMATIN CONFORMATION, GENE EXPRESSION AND CHROMATIN ACCESSIBILITY ANALYSIS IN PRIMARY CELLS**

**Keywords:** Psoriatic arthritis, Genetics/Epigenetics, -omics

C. Shi1, D. Zhao1, J. Ding1, C. Ferrazzano1, C. Wyn1, A. Frantzese1, R. Hum1, R. Ho2, J. Bowes3,4, A. Barton3,4, M. Ratnay1,5, G. Orozco1,3,4 1The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; 2Manchester Royal Infirmary, Manchester University NHS Foundation Trust, The Keigllren Centre for Rheumatology, Manchester, United Kingdom; 3Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; 4The University of Manchester, Lydia Becker Institute of Immunology and Inflammation, Manchester, United Kingdom; 5The University of Manchester, Division of Informatics, Imaging and Data Sciences, Manchester, United Kingdom

**Background:** GWAS have identified genetic variants associated with many complex diseases. These primarily affect regulatory elements that can affect expression of distal genes through chromatin interaction mechanisms. Previous studies have used functional genomics and chromatin conformation capture techniques to study the functional impact of these genetic variants [1]. However, such studies have predominantly used data generated from cell lines which behave differently from primary cells. Additionally, there is a lack of research in Psoriatic Arthritis (PsA), which is a highly heterogenous disease that has been understudied and for which there are few effective treatments.

**Objectives:** To characterise the activation and regulation of transcriptional inflammatory gene enhancers in RA SF and SGF.

**Methods:** SF were obtained from synovial biopsies of patients with RA undergoing joint replacement surgery. SGF were isolated from minor salivary gland biopsies of patients with SJögren’s syndrome (SJö). Recent transcriptome profiling of synovial fibroblasts (SF) from patients with RA and minor salivary gland-derived fibroblast (SGF) from patients with SJö presented the same set of distal genes that were stably expressed over the time points (eCCL2#2, 3, 4). The same set of distal genes and corresponding coding genes was induced in SGF, indicating that inflammatory gene enhancers are shared in fibroblasts from different localisation and diseases. All inflammatory stimuli induced the expression of eRNAs in SF and SGF. However, we detected some differences regarding the peak of eRNA expression (eCCL2#2, eCCL2#2), which was stably expressed over the time points (eCCL2#2, 3, 4). The same set of eRNAs and corresponding coding genes was induced in SGF, indicating that inflammatory gene enhancers are shared in fibroblasts from different localisation and diseases. All inflammatory stimuli induced the expression of eRNAs in SF and SGF. However, we detected some differences regarding the peak of eRNA expression (eCCL2#2, eCCL2#2), which was stably expressed over the time points (eCCL2#2, 3, 4).

**Conclusion:** SF, similar to RA, respond to different pro-inflammatory stimuli by inducing the expression of transcribed eRNAs and their corresponding coding genes. The expression of some eRNAs is maintained for up to 24h, contradicting previous reports that eRNAs are short-lived. Bromodomain inhibitors are sufficient to prevent the activation of eRNAs.

Background: Psoriasis is a systemic inflammatory disease that primarily affects the skin. Approximately one third of psoriasis patients develop joint involvement and are therefore diagnosed with psoriatic arthritis (PsA). While, in adults, the development of arthritis usually follows skin psoriasis, approximately 15% of patients experience arthritis simultaneously or prior to skin disease. Thus, PsA can be missed, leading to disease progression, damage, and reduced quality of life. Individualized care is complicated by the absence of disease- or outcome-specific biomarkers. While the pathophysiology of psoriasis is incompletely understood, a key role of effector T-cells has been established. Recent studies linked altered DNA methylation with T-cell dysregulation and phenotypical variation between patients.

Objective: This project aimed to identify disease-associated DNA methylation signatures in CD4+ T-cells from psoriasis and PsA patients as compared to healthy controls that may be used as diagnostic and/or prognostic biomarkers and inform future treatment.

Methods: Peripheral blood samples were collected from 9 healthy controls, 11 skin psoriasis and 8 PsA patients. PBMCs were isolated ex vivo, CD4+ T-cells were FACs separated, and genomic DNA was isolated. DNA methylation profiling was performed using the Illumina Human Methylation EPIC 850K platform. Bioinformatic analyses, including gene ontology (GO) and KEGG pathway analysis, were performed using R software (minfi, limma, ChAMP, DMRCrate, clusterProfiler). Flow cytometry datasets were analyzed using FlowJo. To identify genes under the control of interferon (IFN), the Interferome database was consulted. DNA Methylation Scores were calculated for type I and type II interferons following the method suggested by Björk et al. (2020).

Results: Numbers and proportions of CD4+ T-cells did not vary between controls and patients with skin psoriasis or PsA. Furthermore, no differences between controls and patient groups were observed in the proportion of CD4+ T-cell subsets (naïve, central memory, effector memory, CD45RA re-expressing effector memory cells). We detected 820 differentially methylated positions (DMPs) affecting 433 genes in CD4+ T-cells from healthy controls when compared to psoriasis and PsA patients. Based on DMP analyses, groups segregated in principal component (PCA) or partial least-squares discriminant analyses (PLS-DA) (Figure 1). Separation in PLS-DA was centrally influenced by two CGs (cg07021052, cg10687131) localized in QDF7 (Growth and Differentiation factor 7), which affects T-cell regulatory factors FOXP3 and CTLA4. GO analysis of genes with at least one DMP in their promoter region delivered hypomethylation of genes involved in “negative regulation of focal adhesion assembly,” “cell-substrate junction organization” and “regulation of the triglyceride biosynthetic.” DNA methylation profiles (855 DMPs affecting 551 genes) distinguished between skin psoriasis and PsA patients; a high proportion of DMPs associated with interferon-regulated genes (68% total: 8.8% type I, 31% type II, 23.8% type I and II IFN). GO analysis delivered an enrichment of hypomethylated genes affecting “carboxylic ester hydrolase,” “alkyl or aryl group transferase” and “glutathione transferase activity.” Notably, we observed a majority DMPs in IFN-related genes when comparing healthy controls with PsA patients (61.9% total: 9.1% type I, 29% type II, 23.8% type I and II IFN) and controls with skin psoriasis patients (62.7% total, 7.7% type I, 31% type II, 24% type I and II IFN). Moreover, DNA methylation calculated for type I and type II IFN-associated genes significantly differed between healthy controls, skin psoriasis and PsA patients.

Conclusion: DNA methylation profiles in CD4+ T-cells discriminate between controls, skin psoriasis and PsA. As DNA methylation signatures may predict disease progression from psoriasis to PsA, they may be applied for molecular patient stratification towards future individualized treatment and care.
BACKGROUND: Lupus nephritis (LN) is one of the main clinical challenges in systemic lupus erythematosus (SLE) and a cause of significant morbidity and mortality. Genetic contribution to SLE pathogenesis is important, and genetic profiling through polygenic risk scores has been shown useful to stratify SLE patients according to dominating molecular disease mechanism.[1] This has not, however, been investigated for specific disease manifestations.

OBJECTIVES: In this work, we aimed to investigate associations between B cell polygenic risk scores (PRSs) and disease manifestations in SLE.

METHODS: Female patients with SLE (n = 1248) and healthy control individuals (n = 519) were genotyped using Illumina’s Global Screening Array. Two PRSs were calculated[2], one including 20 GWS risk loci for SLE in genes assigned to B-cell related pathways according to the KEGG, GO and Reactome databases, and one including a subset of 12 of these genes limited to B-cell activation pathways. PRSs were defined as high in the highest quartile and low in quartile 1-3. Each group was then divided into two groups based on the patients’ SLE B cell PRSs (highest quartile or quartile 1-3). Prevalence of immunologic disorder according to the ACR -82 criteria (A) and prevalence of dsDNA antibodies (B) was then calculated for all 6 groups.

RESULTS: SLE was more prevalent in individuals with high compared with a low SLE B cell PRS (OR 1.44 (1.08-1.93), p=1.4×10^-2), and OR 1.47 (1.07-2.01), p=1.8×10^-2, for immunologic disorder and dsDNA antibodies, respectively. Also, effect sizes were augmented in patients with HLA risk serotypes HLA-DRB1*03:01 and HLA-DRB1*15:01, with the highest prevalence of dsDNA antibodies (87%) demonstrated in patients with HLA-DRB1*03:01 +/- combined with a low SLE B cell PRS (OR 1.84 (1.06-2.54), p = 0.028, for high vs low PRS), Figure 1. Anti-dsDNA antibodies were associated with a higher prevalence of class III or IV nephritis (OR 4.66 (2.78-7.80), p=5.2×10^-9) and the prevalence of nephritis according to the ACR-82 criteria was higher in patients with a high compared to patients with a low B cell activation PRS (OR 1.32 (1.00-1.74), p = 0.048). Numerically, a higher prevalence of nephritis (ACR-82) was observed for patients with a high compared with a low SLE B cell PRS, but the difference was not statistically significant (OR 1.20 (0.91-1.59), p = 0.19).

CONCLUSION: High genetic burden related to B cell function is associated with dsDNA antibody development and LN. Assessing B cell PRSs may be important in order to determine immunologic pathways influencing SLE and to predict clinical phenotype.

Figure 1. Associations with SLE B cell PRS, immunologic disorder (ACR-82) and anti-dsDNA antibodies in SLE subgroups. Female patients with SLE were stratified into three groups according to HLA-type (positive for HLA-DRB1*03:01 or HLA-DRB1*15:01 (DRB1*03/15 +/- or +/-), positive for both (DRB1*03/15 +/-/+), or negative for both (DRB1*03/15 -/-/+ risk variants). Each group was then divided into two groups based on the patients’ SLE B cell PRSs (highest quartile or quartile 1-3). Prevalence of immunologic disorder according to the ACR -82 criteria (A) and prevalence of dsDNA antibodies (B) was then calculated for all 6 groups.

ACR, American College of Rheumatology; dsDNA, double-stranded DNA; HLA, human leucocyte antigen; SLE, systemic lupus erythematosus; SNP, single nucleotide polymorphism; PRS, polygenic risk score.

Giant cell arteritis (GCA) is a chronic large-vessel vasculitis that affects mainly the aorta and its primary branches, and in Western countries is described within the HLA region and the PLG gene. Additionally, we replicated the associations previously described within the HLA region and the PLG gene, which is also involved in angiogenesis. The results of the functional annotation showed that the GCA-associated loci act as regulatory variants influencing gene expression in vascular tissue and immune cell types. Furthermore, we also found a significant enrichment in histone marks in several immune cell types, especially in natural killer cells. The results of the drug repurposing analysis suggest abciximab, an antagonist of the vitronectin protein and approved for the treatment of acute coronary syndrome, as a potential candidate to treat GCA. Finally, the PRS model was best defined by including 28 genetic variants, being capable of identifying a fraction of individuals with more than three times the risk of developing GCA (OR=3.1 [2.14-7.5], p=1.7E-8).

Conclusion: Through the largest genomic study performed in GCA to date, we identified three genetic regions associated with this vasculitis that were not previously reported. These results also identified new physiological pathways and cell types potentially relevant to the development of the disease. These results allowed us to establish a prediction tool for identifying individuals at high-risk for developing GCA and also to propose further investigation of abiciximab, a drug that could be potentially repurposed for treatment of GCA.

Figure 1.
Innate Immunity in Pathogenesis of RMDs

Objectives:

To determine whether there is a genetic basis underlying protein expression in patients with RA treated with etanercept.

Methods:

Participants were recruited from a UK-based prospective multi-centre study of patients fulfilling either the 1987 ACR or 2010 ACR/EULAR classification criteria for RA, starting etanercept as a first biologic. Quantitative protein expression were performed using Sequential Window Acquisition of all Theoretical fragment ion spectra mass spectrometry (SWATH-MS). Genotyping was carried out using the Illumina Infinium HumanCoreExome 12 BeadChip kit and genotype calling was carried out using GenomeStudio software (both Illumina, San Diego, CA, USA). Following standard genetic QC and imputation, a protein quantitative trait loci (pQTL) analysis was performed using a linear model adjusted for potential confounding variables (age, biological sex, disease duration, concurrent DMARD use, seropositive status). A suggestive significance level of p<1E-05 was set for cis pQTLs; trans pQTLs were not considered due to modest sample size. Significance thresholds were adjusted for false discovery rate and subsequently, any adjusted result with p < 0.05 was considered to be significant. pQTLs were sought at baseline and after 3 months of treatment.

Results:

147 participants were recruited, with a median age of 56.39 years [IQR 49.94-64.73], median disease duration of 6 years [IQR 2-13] and of whom 108 (75.52%) were female. 482 unique proteins were available for analysis following proteinomics and genetics data QC. At baseline (pre-treatment), 2,184 cis pQTLs were identified for 60 proteins (this may reflect many pQTLs in strong linkage disequilibrium with one another). After 3 months of treatment, 1,432 cis pQTLs were identified for 60 proteins (this may reflect many pQTLs in strong linkage disequilibrium with one another). A suggestive significance level of p<1E-05 was set for cis pQTLs; trans pQTLs were not considered due to modest sample size. Significance thresholds were adjusted for false discovery rate and subsequently, any adjusted result with p < 0.05 was considered to be significant. pQTLs were sought at baseline and after 3 months of treatment.

Conclusion: Collectively, our data demonstrate that AIRE expression, as well as the expression of the immunoregulatory molecules IDO and PD-L1 in eTACs and DCs can be induced through CD40 stimulation in a non-canonical NF-κB signaling dependent manner. These findings concerning the regulation of AIRE and immunoregulatory molecule expression may point towards a novel role of eTACs in peripheral tolerance.

SINGLE CELL RNASEQ AND FUNCTIONAL STUDIES SUGGEST A ROLE FOR ENTHESIS MESENCHYMAL STEM CELLS RATHER THAN TREGS IN ENTHESIS SOFT TISSUE AND BONE ANCHORAGE SITE IMMUNOMODULATION

Keywords: Enthesitis, Inflammatory arthritis, Inmate immunity

A. Altaie1,2, D. Simone3, H. Owston1, M. Attar1,2, E. Jones1, C. D. Buckley1, S. Sansom1,2, M. Mcgonagle1,2,1 University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 1University of Leeds, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; 1University of Oxford, Kennedy Institute of Rheumatology, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: The enthesis is a the key target tissue in spondyloarthritids (SpA) with inflammation evident in both the enthesis soft tissue (EST) and the adjacent anchoring peri-enthesal bone (PEB)[1]. The healthy human spinal enthesis harbours, resident mesenchymal stem cells (MSCs), myeloid cells, innate immune cell populations including γδ T cells, innate lymphoid cells (ILCs), conventional T-cells but a lack of FOXP3+ regulatory T cells (Treg) [2, 3]. Given the predominance of stroma in EST and the known immunomodulatory effects of MSCs it is credible that such cells could assume important enthesis location immunomodulatory function.

Objectives: To investigate the single cell RNAseq (scRNAseq) landscape of EST and PEB tissues. Reflecting RNAseq findings we examined immunomodulatory capacity of MSCs derived from EST and PEB in co-cultures with allogeneic CD3/CD28-stimulated CD4+ T cells.

Methods: For scRNAseq, interspinous ligament and spinous process samples from patients undergoing spinal surgery (n=4). Samples were divided into EST and PEB and enzymatically digested. Following viability enrichment, we performed single cell partitioning with 10x Chromium, followed by oligo-barcoded RNA library generation and Illumina sequencing. For the co-culture, EST and PEB were expanded until passage 2 (n=5) using bone marrow MSCs (BM-MSCs) as control standard (n=2). CD4+ CD25+ T-cells from blood were induced to proliferate using CD3/CD28 stimulation with MSCs/CD4+CD25+ cell co-cultured at

Background: Spreading of inflammation from skin to joint is still an unsolved key aspect of psoriatic arthritis (PsA) pathogenesis. Psoriasis (PsO) usually anticipates the joint manifestations, suggesting the existence of a disease mediated skin-joint crosstalk. However, only 30% of the patients with psoriasis develop PsA overtime. To date, it is still obscure why the inflammatory process in some patients with PsO is restrained to the skin, whereas in other patients it spreads to the joints.

Objectives: Using a pre-clinical model of PsA and PsO, we aimed to investigate the skin-joint axis, i.e. the spreading of psoriatic inflammation from the skin to the joints, and to address its role in PsA pathogenesis.

Methods: The IL-23 overexpression (IL-23OE) mouse model of psoriasis was performed in different genetic backgrounds of KAEBE-transgenic mice expressing a photo-convertible fluorescent reporter to assess cell trafficking from inflamed skin to other organs. Psoriatic skin lesions were irradiated with UV light to trigger the photoswitch from KAEBEGREEN to KAEDERED. Migration of immune cells to joints was determined by light sheet fluorescence microscopy (LSFM) and flow cytometry. Imaging flow cytometry was used to determine the phenotypic and functional characteristics of cells migrating from the skin to other organs. The interactome of skin-derived migrating cells in joints was characterized by single-cell RNA-sequencing (scRNAseq) and functional analyses. Data were validated in synovial biopsies from PsO and PsA patients by imaging mass cytometry.

Results: IL-23 induced initiation of inflammation at the joints was dependent on the genetic background of the mice as assessed by MRI scan and histological analysis. However, migration of immune cells from psoriatic skin to the joints was observed in both strains, protected and non-protected mice from arthritis, although other organs such as spleen and lymph nodes showed no model dependent skin-derived migration. ScRNAseq and computational fate mapping with RNA velocity analysis revealed CD2+ MChili monocytes as predominant cell type escaping the inflamed skin and entering the synovial tissue. In the pre-differentiated stage, those monocytes showed similar phenotypes in both, arthritis protected and non-protected animals. However, after entering the synovial tissue further differentiation into macrophages resulted into two different phenotypes, with pro-inflammatory characteristics in mice developing arthritis. Interactome analyses between local differentiated skin-derived macrophages and tissue resident synovial cells revealed major implication of synovial fibroblasts shaping the fate of skin-derived monocytes into a protective or pro-inflammatory phenotype with capacity to initiate the cascade of inflammation. Imaging mass cytometry of synovial biopsies from patients with PsO and PsA identified niches of the synovial membrane that were protected from inflammation by a similar fibroblast fate as observed in the murine setting. Protection from arthritis was associated with significantly increased interactions of those protective fibroblasts with innate lymphoid cells (ILC) type II, inducing pro-survival signals and resulting into activation of pro-resolving ILC2s.

Conclusion: Spreading of inflammation from the skin to the joint can be initiated by skin-derived monocytes. However, the interaction between migrating monocytes and synovial-resident cells is essential to define the fate towards joint inflammation or joint protection in PsA. The data might provide completely new diagnostic opportunities to estimate the risk of PsA patients to develop PsA in the future.

Keywords: Psoriatic arthritis, Animal Models, omics
**Objectives:** Our goal was to understand how neutrophils in the inflamed joint and intestine differ from those in blood and which neutrophil states observed in patients with active inflammatory arthritis in which a joint aspiration was diagnostically or therapeutically required, and colon biopsies from patients with inflammatory bowel disease (IBD) in which endoscopy was diagnostically required. Neutrophils were enriched from blood using ACK lysis and from colon biopsies by collagenase digestion. Synovial fluid was diluted, filtered and lysis was performed on samples with visible blood contamination. Technical validation of lysis and digestion of blood cells were performed to control for the influence of these procedures on marker expression. Flow cytometry was applied on the day of sample acquisition to fresh, surface-stained neutrophils to measure protein expression. A multiplex sandwich assay utilizing fluorescent antibody-conjugated beads was used to quantify inflammatory cytokine abundances.

**Methods:** We prospectively collected healthy donor blood, paired blood and synovial fluid from patients with active inflammatory arthritis in which a joint aspiration was diagnostically required. Neutrophils in colon tissue showed downregulation of CD16, CD62L, ICAM-1, IL-17RA and CXCR2 and upregulation of the aging marker CXCR4. These changes were observed irrespective of disease activity. In addition, neutrophils from colon of patients with active inflammation, but not patients in endoscopic remission, showed a marked increase in expression of CD64 and HLA-DR, and the downregulation of CD26 and CXCR2 was more pronounced. We also identified an expanded population of CCR5+ neutrophils in colon tissue, which was more prominent in inflammatory samples. While observable in both tissues, neutrophils in synovial fluid showed a stronger upregulation of HLA-DR and CXCR4 compared to colon. Upregulation of CCR5 and CD64, as well as the downregulation of CD16 were less pronounced. In contrast, synovial fluid neutrophils showed an upregulation of ICAM-1, while this marker was downregulated in the colon. Additionally, synovial fluid neutrophils showed an upregulation of TNF-R1F, which was absent in blood and colon tissue. In serum, we observed greater abundance of IL-1β, IFN-α/β, IL-33, TNF-R1 and TNF-R2 in endoscopically active IBD patients compared to inactive patients. In contrast, measured IL-10 levels were lower in these patients, underscoring the shift to a pro-inflammatory cytokine environment. Independent of disease activity, measured TNF-α levels were higher in patients with Crohn's disease compared to ulcerative colitis.

**Conclusion:** Tissue infiltrating neutrophils display a range of phenotypes in both inflammatory arthritis and inflammatory bowel disease. These range from mature cells lacking activation markers and resembling circulating neutrophils, to CD64+ HLA-DR+ CXCR4+ CXCR2- CD16low aged and activated cells, as well as CCR5- pro-NEToxic cells, in varying proportion. Elevated serum levels of innate-associated cytokines and an increased activation phenotype during active colitis suggest a strong neutrophil involvement in active IBD. Organ-specific differences in neutrophil effector states may require special approaches for therapeutic intervention.

Methods: PBMCs from 32 subjects (ANA−, ANA+, ILE and SLE) were sorted with Nanocellect Wolf microfluidic flow cytometer to remove dead and dying cells. Viable isolated single cells were used to do a multiomics single-cell analysis using 10x Genomics 5′ scRNA-Seq/137-plex Total-Seq multiomics kit, that also enable BCR and TCR repertoire analysis. Single-cell transcript and proteogenomics library preparation was done on a 10x Chromium X targeting 20,000 cells per channel, each sample encapsulated in a single channel. Normalized, pooled UDI labeled libraries were sequenced on Illumina Nova-Seq S4 flowcell (PE100, depth of 50,000 reads/cell). Data were analyzed for cluster identification, differential gene signatures in Python. Pathway analysis was performed in Ingenuity Pathway Analysis (IPA).

Results: Across all subjects, 9 distinct myeloid clusters (Classical, Non-classical, Intermediate, CCR4+ monocytes) were identified with a community detection algorithm and visualized with Uniform Manifold Approximation Projection (UMAP). The proportion of cells in those clusters varied by disease group. Fractions of non-classical monocytes appear to be higher in ILE, SLE patients than in ANA− and ANA+ subjects. Classical monocytes have increasing cell fractions with disease progression, except ILE subjects that appear to have lower fractions than the other groups. Intermediate monocyte fractions are higher in ANA− controls and lower in the other groups. Pathway analysis revealed further differences within ethnicities (African, European Americans). Upregulation of autophagy related pathways was observed in AA ANA+ compared to ANA− and ILE, however it is downregulated in EA. Oxidative phosphorylation is upregulated in AA SLE compared to ILE and upregulated in AA ANA+ compared to ANA−. On the contrary, that pathway is upregulated in EA ANA+ compared to ANA− and ILE, as well as SLE compared to ILE. Further differences between subpopulations of major monocyte clusters were also observed.

Conclusion: Dysregulation of signaling in monocyte activation appears to be manifesting in either increased oxidative phosphorylation or alteration in cellular apoptotic or autophagy pathway regulation. Alterations in these processes may vary by ancestral background reflected in the heterogeneity one sees in the presentation of lupus or trajectory of disease.

REFERENCES:
Results: In the presence of synovial fibroblasts and TGFβ, macrophages had a gene expression program that increased the proportion of macrophages aligning with those found in lymphocyte-low/myeloid-rich synovial tissue. Specifically, the transition of blood monocyte-derived macrophages from a MERTK- homeostatic, tissue macrophage phenotype into the SPP1+ phenotype. This analysis also showed that macrophages incubated with TGFβ and fibroblasts had higher expression of SPP1+ macrophage cluster marker genes, namely SPP1, CLEC5A, and FN1, as well as genes that contribute to RA pathogenesis, including CCL2 and S100A8.

Conclusion: In conclusion, we have shown that TGFβ and factors derived from synovial stromal cells are sufficient to drive monocytes toward the SPP1+ macrophage phenotype found in myeloid-rich RA synovial tissue. In future experiments, we hope to understand the role these macrophages play in shaping the phenotype of the stromal and endothelial cells they interact with, and whether targeting the generation of these cells represents an effective treatment option for this subset of RA patients.

Pathogenic clues to systemic sclerosis and myositis

Keywords: Systemic sclerosis, Adaptive immune, Treat to target

T. I. Papadimitriou1, P. Singh2, A. Van Caam3, M. Gorris3, B. Walgreen3, E. Vitters1, M. Koenders1, R. Smeets4, M. Vonk1, I. J. M. De Vries3, P. Van der Kraan1, M. Huijnen5, H. Koener5, R. M. Thurlings1, 2Radboudumc, Department of Rheumatology, Nijmegen, Netherlands; 2Radboudumc, Center for Molecular and Biomolecular Informatics, Nijmegen, Netherlands; 3Radboudumc, Department of Tumor Immunology, Nijmegen, Netherlands; 4Radboudumc, Laboratory of Medical Immunology, Department of Laboratory Medicine, Nijmegen, Netherlands

Background: Systemic sclerosis is characterized by vasculopathy, fibrosis and autoimmune inflammation. Adaptive immune and NK cells express co-stimulatory molecules to regulate effector responses in inflammatory conditions. CD7 is a co-stimulatory molecule induced by IFN-γ signaling on T and NK cells that is downregulated upon residency in tissues such as skin [1].

Objectives: Hypothetically, CD7 is upregulated in IFN-γ-driven conditions, allowing targeted depletion of pathogenic cells. In this study, we analyzed expression, regulation and targeting of CD7 in SSC tissues and in a patient treated with anti-CD7 immunotoxin (CD7-IT).

Methods: To identify disease-specific activation markers we compared status of T cell activation in SSC skin compared to blood. To do so, single-cell RNA sequencing datasets containing 60,000 skin and blood immune cells from 109 SSC patients versus 65 healthy donors were analyzed. Twenty-one-color flow cytometry (n=50) and 8-color multiplex skin immunofluorescence staining (n=50) were used for validation and spatial localization. CD7-IT was used to induce subset-specific depletion in vitro, and ex vivo skin explants. Fibroblasts and immune cells were co-cultured in 3D collagen hydrogel to test effect of targeted immune cell depletion on fibroblast contractibility. A single patient was treated with immunotoxin on compassionate use basis.

Results: Sc-RNaseq analysis showed that SSC skin is characterized by increased infiltration of CD7+ cells corresponding to CD68+GZMB and CD68+G-ZMB+ cytotoxic T and NK cells. Immunohistochemistry also showed that SSC lesions express significantly higher infiltration of these CD7+ (T and NK) cells than non-affected skin (Figure 1). Expansion of CD7+ cytotoxic T cells was also observed in SSC blood. A CD7-targeting IT effectively depleted 85% of CD7+ cytotoxic T and NK cells in vitro, and in ex vivo skin. Strikingly, depletion of CD7+ cells prevented fibroblast activation and contraction in a 3D fibroblast-immune cells co-culture assay. Notably, also in vivo administration of CD7-IT significantly eliminated CD7+ cell subsets in patient’s blood and skin.

Conclusion: Together, we show strong presence of CD7+ on SSC immune cells and that targeting this molecule depletes T and NK cell populations with potential disease modifying results. Our results pave the way for a novel approach in halting SSC related fibrosis.
**OP014**  ENDOTHELIAL RESPONSE TO TYPE I INTERFERON CONTRIBUTES TO VASCULOPATHY AND FIBROSIS AND PREDICTS DISEASE PROGRESSION OF SYSTEMIC SCLEROSIS

**Keywords:** Systemic sclerosis, Skin, Cytokines and chemokines

H. Yin¹, Q. Yan¹, L. Lu¹. Renji Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Rheumatology, Shanghai, China

**Background:** Type I interferon (IFN-1) signature is a hallmark of patients with systemic sclerosis (SSc) [1, 2]. However, the meaning of the IFN-1 signature for the pathophysiology and clinical manifestations is less clear, and reported associations are rather weak.

**Objectives:** This study aims to better understand the significance of IFN-1 in SSc clinical stratification and its contribution to disease deterioration.

**Methods:** For hypothesis generation, we performed single-cell RNA sequencing (scRNAseq) on skin biopsies (SSc=1, control =2) using the BD Rhapsody platform. A publicly available dataset (GSE138669) of skin scRNAseq (dcSSc=12, control =10) was used for validation. IFN-1 signature was mapped, functionally investigated in a bleomycin plus IFN-2c-adeno-associated virus (IFN2A-AAV) induced model, and verified in an SSc cohort (n=61).

**Results:** In discovery data, endothelial cells (EC) had the most prominent IFN-1 response among dermal non-immune cells. EC from postcapillary venules, arterioles and capillaries were the major responders of IFN-1. Ascending IFN-1 signature presented in total EC from control, lcSSc, to dcSSc and was still true in the EC subclusters above. Endothelial-to-mesenchymal transition (EndoMT) scores increased in parallel. The validation data confirmed IFN-1 signature and EndoMT elevation in total and subgroups of EC. IFN2A-AAV deteriorated bleomycin-induced dermal fibrosis, EndoMT, and perivascular fibrosis and caused vascular/endothelial cell dysfunction in SSc skin biopsies. In particular BACE1 was increased in the fibroblasts and endothelial cells of the SSc skin. BACE1 was elevated in isolated dermal fibroblasts grown in culture (2.3 fold increase, N=4), BACE1 protein levels were elevated in the bleomycin skin fibrosis model. Interestingly BACE1 mRNA levels were unaffected in cultured SSc fibroblasts, suggesting a post-translational modification led to the elevated protein levels. Inhibition of BACE1 with small molecule inhibitors (that have been proven safe in phase 1 clinical trials for Alzheimer’s) or siRNA blocked pro-fibrotic gene (alpha SMA, Collagen Type 1 and CTGF) expression in SSc fibroblasts. In addition overexpression of BACE1 in healthy fibroblasts resulted in myofibroblast activation (2-fold increase in alpha SMA protein expression). Interestingly overexpression of a BACE1 mutant construct which disrupts the secretase activity of the protein, was unable to induce fibroblast activation. Disruption of BACE1 (with both the inhibitors and siRNA) blocked morphogen-mediated fibroblasts activation. The BACE1 inhibitors and siRNA blocked TGF-β, Wnt-3a and Hedgehog mediated alpha-SMA expression in healthy fibroblasts. Furthermore, we show that BACE1 regulation of dermal fibroblast activation was dependent on the β-catenin and Notch signalling pathways. BACE1 ability to regulate non-canonical Wnt receptors led to elevated β-catenin expression which in turn activated the Notch signalling pathway.

**Conclusion:** This is the first evidence that BACE1 and in particular its secretase activity, plays a role in SSc and fibrosis in general. The ability to regulate SSc fibroblast activation reveals an exciting new therapeutic target in SSc. Several BACE1 inhibitors have been shown to be safe in phase 1 clinical trials for Alzheimer’s disease. Future work includes investigating the role of BACE1 in vascular/endothelial cell dysfunction in SSc.

**OP013**  THE BETA SECRETASE BACE1 DRIVES SYSTEMIC SCLEROSIS FIBROBLASTS ACTIVATION THROUGH β-CATENIN AND NOTCH SIGNALLING

**Keywords:** Skin, Systemic sclerosis, Cell biology

C. Wason¹, E. Clavane², R. Ross¹, G. Migneco³, C. Antinozzi⁴, J. Brown², L. Di Luigi⁴, C. McKimmie⁵, F. Del Galdo¹, P. Meakin².

**Background:** The beta-amyloid precursor protein cleaving enzyme 1 (BACE1) is well known for its role in the development of Alzheimer’s disease via the generation of β-amyloid. Recent publications, including our own, have demonstrated a role for this enzyme in other chronic inflammatory diseases, including type 2 diabetes and cardiovascular disease. However, to date there has been no studies looking into the role of BACE1 in the autoimmune condition Systemic Sclerosis (SSc).

**Objectives:** The aim of this study was to assess the expression profile of BACE1 in SSc patient samples and to investigate the effects of BACE1 inhibitors and siRNA on SSc fibroblast activation.

**Methods:** Patient fibroblasts were obtained from full thickness forearm skin biopsies from healthy and early diffuse SSc patients. BACE1 was inhibited with 2 specific small molecule inhibitors and siRNA specific to BACE1. Morphogen signalling was activated with recombinant TGF-β, Wnt-3a or the smoothend antagonist SAG. A xenotransplant bleomycin mouse model using patient pDC was used to interrogate in vivo expression of BACE1 in fibrosis.

**Results:** Here we show that BACE1 protein levels are elevated in SSc patient skin biopsies. In particular BACE1 was increased in the fibroblasts and endothelial cells of the SSc skin. BACE1 was elevated in isolated dermal fibroblasts grown in culture (2.3 fold increase, N=4), BACE1 protein levels were elevated in the bleomycin skin fibrosis model. Interestingly BACE1 mRNA levels were unaffected in cultured SSc fibroblasts, suggesting a post-translational modification led to the elevated protein levels. Inhibition of BACE1 with small molecule inhibitors (that have been proven safe in phase 1 clinical trials for Alzheimer’s) or siRNA blocked pro-fibrotic gene (alpha SMA, Collagen Type 1 and CTGF) expression in SSc fibroblasts. In addition overexpression of BACE1 in healthy fibroblasts resulted in myofibroblast activation (2-fold increase in alpha SMA protein expression). Interestingly overexpression of a BACE1 mutant construct which disrupts the secretase activity of the protein, was unable to induce fibroblast activation. Disruption of BACE1 (with both the inhibitors and siRNA) blocked morphogen mediated fibroblasts activation. The BACE1 inhibitors and siRNA blocked TGF-β, Wnt-3a and Hedgehog mediated alpha-SMA expression in healthy fibroblasts. Furthermore, we show that BACE1 regulation of dermal fibroblast activation was dependent on the β-catenin and Notch signalling pathways. BACE1 ability to regulate non-canonical Wnt receptors led to elevated β-catenin expression which in turn activated the Notch signalling pathway.

**Conclusion:** This is the first evidence that BACE1 and in particular its secretase activity, plays a role in SSc and fibrosis in general. The ability to regulate SSc fibroblast activation reveals an exciting new therapeutic target in SSc. Several BACE1 inhibitors have been shown to be safe in phase 1 clinical trials for Alzheimer’s disease. Future work includes investigating the role of BACE1 in vascular/endothelial cell dysfunction in SSc.

OBJECTIVES:

1) to analyze if spatial WNT/β-catenin activation is observed in adult healthy human skin and whether it is altered in fibrosing skin disorders such as SSc.

2) to assess whether perturbation of spatial WNT/β-catenin activation correlates with disruption of physiological skin structure in SSc.

3) to analyze whether spatial activation is mimicked in a Wnt-driven murine fibrosis model and can be reverted by overexpression of the endogenous Wnt-antagonist Dkk1.

Background: Disruption of the skin structure is a central hallmark of Systemic Sclerosis (SSc). Healthy adult human dermis is characterized by a papillary dermis. Here we quantitatively describe a marked decrease of number, area and height of papillary structures in SSc compared to healthy controls. Consistently, papillary/reticular marker gene expression is shifted towards a reticular profile in SSc skin compared to controls. Next, we analyzed whether the expression of WNT3A-regulated target genes is enriched in papillary or reticular gene sets of healthy skin. We observed an enrichment of WNT3A-regulated target genes in papillary gene sets of healthy skin. Consistently, we observed a distinct pattern of spatial distribution of β-catenin-expressing fibroblasts in healthy skin that is disturbed in SSc: In healthy skin, β-catenin-positive fibroblasts were predominantly located in the papillary dermis and the relative amount of β-catenin-expressing fibroblasts was reduced in the reticular part. In contrast, in SSc skin, we observed a 2-fold increase of β-catenin-positive fibroblasts throughout the dermis.

A gradient with enrichment of β-catenin-expressing fibroblasts in the papillary layer as observed in healthy skin was no longer detectable in SSc. Confocal imaging suggested increased nuclear accumulation of β-catenin in the reticular dermis compared to the papillary dermis in SSc skin. The loss of spatial WNT activation in SSc was confirmed on a transcriptional level. Interestingly, spatial redistribution of WNT activation is mimicked in Wnt10bgt mice compared to wild-type mice and partially reverted by overexpression of the endogenous Wnt antagonist Dkk1. These results suggest that distinct site-specific activation of WNT/β-catenin signaling with a delicate balance of WNT agonists and antagonists might be necessary to maintain and eventually restore physiological skin integrity in adult human skin.

Conclusion: Our study presents first evidence for a loss of the physiological β-catenin gradient in SSc, associated with a loss of papillary dermal structure. Further analyses of WNT agonists and antagonists spatial distribution and advanced in vitro models mimicking a papillary skin structure will be necessary to better understand mechanisms of skin structure maintenance in healthy adult human skin.

DOI: 10.1136/annrheumdis-2023-eular.2955

Methods: Dermal skin morphology was quantitatively assessed using HE and trichrome staining of skin sections of 40 SSc patients and 18 healthy controls. Enrichment of papillary and reticular marker genes and WNT target genes in healthy and SSc skin transcripts were assessed by gene set enrichment analyses using prepublished datasets [2]. Spatial WNT/β-catenin activation was analyzed by RNAscope-in situ hybridization detection of AXIN2. Immunofluorescence (IF) staining was performed to detect β-catenin distribution. In addition, skin sections of Wnt10bgt and Dkk/Wnt10bgt mice were analyzed.

Results: Here we qualitatively describe a marked decrease of number, area and height of papillary structures in SSc compared to healthy controls. Consistently, papillary/reticular marker gene expression is shifted towards a reticular profile in SSc skin compared to controls. Next, we analyzed whether the expression of WNT3A-regulated target genes is enriched in papillary or reticular gene sets of healthy skin. DOI: 10.1136/annrheumdis-2023-eular.2955
Background: Fibrotic changes in the myocardium and cardiac arrhythmias represent fatal complications in systemic sclerosis (SSc). So far, the underlying mechanisms remain elusive. Mice overexpressing AP-1 family transcription factor Fosl-2 (Fosl-2tg) represent an animal model of SSc.

Objectives: We aimed to identify the mechanisms controlling myocardial fibrosis and arrhythmias in SSc.

Methods: Mice overexpressing activator protein-1 transcription factor component Fos-related antigen-2 (Fos-2tg) and Rag2-2tg Fosl-2tg mice lacking T and B cells were subjected to study myocardial fibrosis, arrhythmias and response to stress using radiography, echocardiography and ex vivo Langendorff-system. Immunohistochemistry/immunofluorescence analyses were used to characterize endomyocardial biopsies (EMBs) of SSc patients with heart failure with or without arrhythmia, and mouse hearts. Cardiac human and mouse fibroblasts were used to evaluate molecular mechanisms using bulk RNA sequencing, qPCR, IF, ELISA, Western blot, Bromodeoxyuridine proliferation assay, senescence associated-ß-Galactosidase assay for cell senescence, Caspase Glo 3/7 assay for cell apoptosis and contraction assay.

Results: Fosl-2tg mice showed interstitial cardiac fibrosis with increased numbers of CD45+CD31+Ter119+gp38+ cardiac fibroblasts, disorganized connexin 43 and 40 in intercalated discs and deregulated expression of genes controlling conduction system (Mesi1, Nfkb, Tbx3, Sox5, Scn10a, Konq1, Scn10a, Nos1ap). Fosl-2tg mice developed higher heart rate (HR), prolonged QT intervals, arrhythmias with prevalence of premature ventricular contractions, ventricular tachycardias and atrio-ventricular blocks second-degree, QT intervals positively correlated with AV blocks, while QT intervals and AV blocks positively correlated with the disease phenotype and collagen deposition. Fosl-2tg mice showed significantly reduced HR variability in long-term ECG recordings (reduced NN intervals, SDNN, RMSSD, NN6, pNN6), indicating autonomic imbalance with a shift towards increased sympathetic activity. Following stimulation with isoproterenol (ISO) Fosl-2tg mice revealed impaired HR response. Similarly, ex vivo Langendorff-system measurement of HR in the iso-nent Fos-related antigen-2 (Fosl-2tg) and Rag2-2tg-Fosl-2tg mice lacking T and B cells revealed that systemic inflammation triggered fibrotic changes in the myocardium and cardiac arrhythmias.

Conclusion: These results demonstrate that under inflammatory and fibrotic conditions Fosl-2 drives myocardial fibrosis, arrhythmias and causes aberrant response to stress. This mechanism might represent a promising target against increased cardiac disease burden in the immunofibrotic cardiac disorders.

Background: Dermatomyositis (DM) is an autoimmune myopathy responsible for muscle weakness associated with decreased quality of life and increased mortality. Current treatments are empirical, partially effective, expose to a risk of side effects and a high rate of relapse upon discontinuation. DM muscular histology is characterized by lesions of perifascicular fibers consisting of atrophy, overexpression of type I interferon-dependent genes and mitochondrial dysfunctions of unknown origin [1].

Objectives: The objective of the study was to identify innovative therapeutic strategies for DM, based on the identification of the molecular pathways underlying perifascicular fibers lesions and the repositioning of drugs already approved in humans.

Methods: To reveal the molecular pathways underlying DM perifascicular fibers lesions, perifascicular and endofascicular fibers from 19 patients with recent and untreated myositis (DM, other myositis) or without myopathy were microdissected by laser, their transcriptome was established by RNA sequencing and analyzed by bioinformatic methods. To identify innovative therapeutic strategies based both on DM pathophysiological mechanisms and on existing drugs, the transcriptomic signature specific to DM perifascicular fibers obtained by microdissection experiments was used for a drug repositioning analysis as described by Karatzas et al. [2]. To validate the predications obtained, the effect of drug candidates already used in humans was tested in in vitro and in vivo preclinical models: in 1) cultured human muscle cells treated with IFN-I and in 2) a mouse model of myositis experimentally induced by immunization against skeletal muscle fast-type C protein.

Results: Transcriptomic analysis of patient’s muscle fibers combined with topographic information (perifascicular VS endofascicular localization) revealed that a proteasome deregulation predominant in the perifascicular fibers is a hallmark of DM. The integration of 3 computer databases of drug repositioning allowed the identification of 9 molecules predicted by at least 2 bases to reverse the pathological signature of the perifascicular fibers of patients with DM. The drug with the highest therapeutic potential was a proteasome inhibitor (ixazomib). A second proteasome inhibitor (MG-132) was also identified. 2 drugs already used for DM (dexamethasone and a JAK inhibitor) was identified with a lower therapeutic score. In the cellular model (human myotubes treated with IFN-I) ixazomib and bortezomib reversed the atrophy and the pathological signature of DM perifascicular fibers identified in the microdissection experiments. In the mouse model of myositis, ixazomib and bortezomib restored muscle strength, decreased blood creatine kinase, and reversed the atrophy of muscle fibers.

Conclusion: Proteasome inhibition could be a new effective therapeutic strategy for DM.

INTEGRATED ANALYSIS OF SINGLE-CELL AND BULK RNA SEQUENCING DATA REVEALS CELLULAR HETEROGENEITY IN THE SKELETAL MUSCLE OF IDIOPATHIC INFLAMMATORY MYOPATHY

Keywords: Cell biology, Myositis

Z. Honglin, L. Hui, X. Yizhi, S. Xie, T. Ding, T. Huang, S. Liu, D. Liu, H. Zhang, Xiangya Hospital, Department of Rheumatology and Immunology, Changsha, China

Background: IIMs-affected muscles showed diverse cellular microenvironments, and specific immune activation is involved in the different types of IIMs. Skeletal muscle cells exhibit immunobiological properties and act as nonprofessional antigen-presenting cells in IIMs.

Objectives: We sought to identify the skeletal muscle cells (SMCs) and immune cell populations in IIMs muscles and understand how alterations in these cell subpopulations lead to muscle damage.

Methods: We performed single-cell RNA-sequencing (scRNA-seq) on muscle tissues from 6 IIMs and 3 normal control (NC), and spatial transcriptomics from 2 IIMs and 1 NC. 76 IIMs and 10 NC were analysed by bulk RNA sequencing.

Results: From the scRNA-seq analysis, remarkable heterogeneity of SMCs and immune cells phenotypes were found and spatially organized in IIMs subgroups. They displayed diverse functions and cell-surface proteins. From the
bulk RNA-seq analysis of 143.9 vs 175.7 ± 7.5 g in PDN-treated strength was still comparable between V-treated EM GRL2/L2 and GR(i) mice. Mice of both lines were treated by prednisone (PDN) from D14 to D20 at the dose inactivation in the former mice only, termed hereafter GR(i)skm-/- mice. Mice thus, tamoxifen treatment from D9 to D13 induced GR negative predictive value of 64% (CI 57 -70). Diagnostic accuracy of 99% (CI 97 -100), a positive predictive value of 89% (CI 74-100) and a specificity of 30% (CI 30-46), a positive predictive value of 51% (CI 43-58) and a negative predictive value of 94% (CI 87-99.7). Diagnostic accuracy for ultrasound assessed tenosynovitis had a sensitivity of 17% (CI 9-24), a specificity of 99% (CI 97-100), a positive predictive value of 89% (CI 74-100) and a negative predictive value of 64% (CI 57-70).

**Background:** Glucocorticoids (GC) are the first line treatment in myositis. GC therapy is empirical. Both GC therapeutic and iatrogenic effects are mediated by the glucocorticoid receptor (GR), which is ubiquitously expressed. Our team has recently shown that muscle fibres immuno-metabolic modifications participate to muscle weakness and perpetuation of the disease[1]. Thus, myofibers could be a therapeutic target of GC.

**Objectives:** To unravel the mechanism of GC therapeutic effect in order to optimize myositis care.

**Methods:** Experimental myositis (EM) was induced in 8 to 10 week-old C57BL/6J mice through the immunization against a polypeptide from skeletal muscle fast-type C protein. In order to investigate whether GC target skeletal muscle fibres to elicit their therapeutic response in EM, we generated mice in which GR can be selectively ablated in skeletal muscle fibres in a temporal manner. To this end, EM was induced at day (D) 0 in HSA-Cre-ERT2(tg0)/GRL2/L2 mice (pre-mutant mice), which express the tamoxifen-dependent CreERT2 recombinaase selectively in skeletal muscle fibres and bear two LoxP-flanked GR alleles, as well as in HSA-Cre-ERT2(tg0)/GRL2/L2 littersmates, which do not express the recombinase (GRL2/L2 mice). Thus, tamoxifen treatment from D9 to D13 induced GR inactivation in the former mice only, termed hereafter GR(i)skm-/- mice. Mice of both lines were treated by prednisone (PDN) from D14 to D20 at the dose of 1 mg/kg/day by gavage. Grip test was performed at D0, before the 1st PDN administration (D14) and the day before sacrifice (D20). Creatine-kinase (CK) activity assay in serum, muscle histology, immune-cell phenotyping using flow cytometry and gastrocnemius transcriptomic analysis were run. Transcriptomic data were validated in independent mice cohorts, in vitro and on human muscle biopsies.

**Results:** In pre-mutant EM mice at D0 as well as in EM GR(i)skm-/- at D14, muscle strength was still comparable to that of EM GRL2/L2 mice. At D20, muscle strength was still comparable between V-treated EM GRL2/L2 and GR(i)skm-/- mice. Conversely, PDN treatment did not induce a regain of muscle strength in EM GR(i)skm-/- mice showed a similar increase in serum CK levels at sacrifice. CK decreased only in GRL2/L2 and not in GR(i)skm-/- mice after PDN treatment (145.6 ± 10.9 vs 234.5 ± 13.8 U/l, p=0.002). Although no major differences in the histological inflammatory infiltrate score among the four experimental groups, at muscle flow cytometry, the percentage of proinflammatory macrophages, F4/80-Ly6c-positive, was greater (76% vs 67%, p<0.05) and that of anti-inflammatory macrophages, F4/80-CD206-positive, was lower (12% vs 17%, p=0.07) in PDN-treated GR(i)smk-/- than GRL2/L2 mice suggesting myofiber GR knockout promotes a proinflammatory phenotype in immune cells infiltrate. Strikingly, PDN induced a 3-fold decrease in the percentage of CD8-positive T cells in EM GRL2/L2 mice compared to V-treated EM GRL2/L2 mice (11% vs 29%, p=0.003). This anti-inflammatory effect of PDN was suppressed in PDN-treated EM GR(i)skm-/- mice. Moreover, CD4-CD8 double negative T cells, that inhibit the immune response by killing effector T cells, slightly increased in PDN-treated EM GRL2/L2 compared to V-treated GR(i)skm-/- mice (35% vs 24%, p=0.02). This effect of PDN was suppressed in PDN-treated EM GR(i)skm-/- mice. Transcriptomic and functional analyses of muscle in vitro and in vivo demonstrated the importance of epinephrine secreted by the myofibre relating the effects of GC. The expression of epinephrine by the myofibre in response to GC has been validated in patients with myositis.

**Conclusion:** Skeletal muscle fibres play a critical role in the GC therapeutic response in myositis through an epinephrine-mediated polarization of inflammatory infiltrate toward an anti-inflammatory phenotype.

SYNOVIAL CELLULAR NICHEs ARE DETERMINANTS OF ARTHRITIS PERSISTENCE VERSUS RESOLUTION IN EARLY UNTREATED ARTHRITIS

Keywords: -omics, Inflammatory arthritides, Rheumatoid arthritis

1University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom; 2University Hospitals Birmingham, Dept of Rheumatology, Birmingham, United Kingdom; 3University of Oxford, The Kennedy Institute Of Rheumatology, Oxford, United Kingdom; 4Sandwell and West Birmingham NHS Trust, Dept of Rheumatology, Birmingham, United Kingdom

Background: Published synovial research largely focuses on persistent clinical syndromes such as RA and PsA. However spontaneously resolving synovitis is a common manifestation of viral infection (parvovirus, influenza), post-bacterial reactive states and metabolic disease such as gout. The study of synovial tissue taken from such patients using advanced single cell methodologies may provide biomarkers of outcome in early disease but is also a valuable resource to understand mechanisms underlying the subversion of healthy mechanisms of resolution resulting in persistent disease.

Objectives: To use single cell RNA sequencing to understand the cellular interactions governing resolution versus persistence of disease in untreated patients with active arthritis.

Methods: Synovial tissue biopsies were obtained using ultrasound guidance from treatment naïve patients in the Birmingham BEACON early arthritis cohort presenting with at least one clinically swollen joint and a joint amenable to ultrasound guided biopsy. Tissue samples from patients who went on to develop RA (n=15) or PsA (n=7) according to ACR criteria or CASPAR criteria at 24-month follow-up, and patients whose arthritis spontaneously resolved (n=5) underwent enzymatic disaggregation and were processed through a multimodal single-cell sequencing approach including the characterisation of the transcriptome and 58 surface-protein-panel profile. Sequenced gene libraries were integrated according to batch and sample using the Harmony integrative algorithm before clustering and annotating cell states using canonical marker genes. Seurat-based automated pipelines were used for variable gene identification and clustering. We used DESeq2 to identify per cell type genes, and weighted gene co-expression network analysis (WGCNA) to identify gene programmes associated with persistence (RA and PsA) versus resolving groups. NAMTI was used to identify unique cellular niches associated with persistence or resolution.

Results: ~90,000 viable cells were sequenced and data normalised, clustered and annotated describing over 80 cellular states across eight main synovial cell types (T, B, Plasma, Plasmacytoid DC, myeloid, fibroblast, mural and vascular). A total of 1945 genes varied significantly with prognosis, distributed unequally across cell types (Table 1).

Persistence of arthritis was associated with (i) the presence of plasma cells per se and (ii) a phenotypic shift in fibroblast, vascular, myeloid, Th, and B-cell populations with enrichment of SPP1+ Myeloid cell populations. Patients with active arthritis destined to resolve exhibited enrichment of Treg cells. Persistent and resolving states were characterised by significant compositional differences in key linning and sublining fibroblast subpopulations including sublining MMP3 positive cells, and by gene expression programmes related to matrix remodelling and fibroblast/macrophage interactions.

DOI: 10.1136/annrheumdis-2023-eular.3703
Background: One of the major challenges in the management of rheumatoid arthritis (RA) is to determine individual treatment and predict the prognosis. On a group level, high disease activity and antibodies specific for citrulline (ACPA) and immunoglobulins (RF) are factors associated with poor prognosis. New alternative biomarkers, which could provide more specific information, are antibodies to disease-related targets in the joints [1].

Objectives: To identify circulating autoantibodies to joint-related proteins (hereafter named JointIDs) that predict disease outcome in patients with new onset RA.

Methods: Sera at diagnosis from BARFOT and TIRA-2 cohorts (n=1986) with new onset RA patients were screened with a bead-based multiplex flow immunoassay to detect IgG autoantibodies against 47 peptides derived from joint proteins (JointIDs) (Lönnblom, under review 2023). Disease outcomes included Boolean remission at 6 and 12 months, swollen joint count (SJC) and radiological progression at 12 months (>8% affected feet joints and >3% affected hand joints) in patients who were without joint damage at inclusion. Multivariate logistic regression and zero-inflated negative binomial models adjusted for clinical factors (age, gender, ACPA, RF, changes in medication at 3 and 6 months) were used to identify JointIDs with the strongest potential to predict prognosis.

Results: Six JointIDs were identified as predictors for these disease outcomes in multivariate analyses. Presence of JointID178 predicted an average decrease in SJC at 6 months with 41% and with 33% at 12 months. Presence of at least 2 of the following factors: JointID178 positive and JointID199 negative at inclusion in combination with male sex identified approx. 40% of the patients in Boolean remission at 6 months with approx. 75% specificity (Table 1). A similar test performance was obtained even for Disease Activity Score 28 remission. The sensitivity, specificity and AUC for the multivariate models for remission at 6 months with approx. 75% specificity (Table 1). A similar test performance was obtained even for Disease Activity Score 28 remission. The sensitivity, specificity and AUC for the multivariate models for remission at 6 months with approx. 75% specificity. The proportion of 'progressors' to IA at 24 months was evaluated by named JointIDs that predict disease outcome in patients with new onset RA.

Conclusion: Autoantibodies to joint-related proteins at RA diagnosis can predict remission with a high specificity at 6 and 12 months. This knowledge is of clinical importance as patients positive or negative for these JointIDs in combination with clinical factors may potentially guide future treatment choices.

A reduced ultrasound scanning protocol of 3 joints bilaterally improves prediction of inflammatory arthritis progression in Anti-CCP positive individuals with musculoskeletal symptoms

Keywords: Prognostic factors, Ultrasound, Autoantibodies

A. Di Matteo1, E. De Lorenzis1, L. Duquenne1, J. Nam1, L. Garcia-Montoya1, K. Harnden1, R. Chowdhury1, P. Emery2, K. Mankila1, 1Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds Teaching Hospital NHS Trust, Leeds, United Kingdom

Background: In anti-CCP positive individuals at-risk of developing rheumatoid arthritis (CCP+ at-risk), ultrasound (US) sub-clinical inflammation and bone erosions (BE) are associated with progression to clinical arthritis[1]. However, the additional value of US in predicting progression to inflammatory arthritis (IA) when compared with routinely available clinical/serological variables has not been well defined. Moreover, and which and how many joints need to be scanned for optimum predictive accuracy remains unanswered, with most studies adopting extensive US protocols which are not feasible in clinical practice[1].

OBJECTIVES:
1. In CCP+ at-risk with musculoskeletal (MSK) symptoms but no clinical synovitis, to investigate the additional value of US over and above clinical/serological variables in the prediction of IA.
2. To define an abbreviated US scanning protocol, suitable for routine clinical use, for predicting IA development in CCP+ at-risk.

Methods: The proportion of “progressors” to IA at 24 months was evaluated in 417 CCP+ “at-risk” with MSK symptoms from the Leeds CCP cohort, who were selected for having an US scan at baseline. The US scanning protocol included 18 joints bilaterally [elbow, wrist, MCP joints 1-5, PIP joints 1-5, knee, ankle, MTP joints 2-5]. US synovitis (grey scale ≥1 and power Doppler signal ≥1) and BE were defined according to the EULAR/OMERACT definitions. Routine demographic/clinical data were collected: age, gender, early morning stiffness (EMS) duration, hands and/or feet tenderness on physical examination, anti-CCP antibodies level and rheumatoid factor (RF) status. Two initial multivariable binary regression models with 10-fold cross-validation for IA development at 24 months included all the clinical/serological variables associated with the outcome (“clinical” model) isolated and in combination with US synovitis and/or BE in any of the 36 joints (“clinical-US full” model). Further models explored the prediction accuracy of the clinical variables and US findings (i.e., synovitis and/or BE) in each single joint to identify the most informative scanning sites according to Akaike Information Criterion (AIC). A final model which included clinical/serological predictors and US assessment of 3 joints bilaterally (“clinical-US short” model) was compared to the “clinical-US full” model. The most predictive joints were included in this “short” model only if determining an improvement in the prediction performance (reduction in AIC>2).

Results: Of the 417 CCP+ at-risk, 92 (22.1%) progressed to IA within 24 months. The following clinical/serological variables were associated with IA development at univariate analysis: age, smoking exposure, EMS duration ≥60 minutes, hands tenderness, RF positivity and high-level anti-CCP antibodies (all p<0.05). Moreover, US synovitis and BE in ≥1 of 36 joints were also associated with IA progression (p<0.01). The “clinical-US full” model (AUC 0.785, AUC 380.15) performed better than the “clinical” model (AUC 0.713, AUC 409.51) (p<0.001) showing an adjusted odds ratio (OR) for IA onset of 3.16 (95% CI 1.79-5.58) for US synovitis and 2.83 (95% CI 1.33-5.93) for BE. The developed “clinical-US short” model that included US assessment of wrists, knees and MTPS joints – performed better than the “clinical” model (p<0.001) and similarly (AUC 0.781, AUC 381.41) to the “clinical-US full” model (ΔAIC<2) (Figure 1).
LIPID MEDIATOR PROFILES ASSOCIATE WITH PROGRESSION TO RA IN ANTI-CITRULLINATED PROTEIN ANTIBODY POSITIVE POPULATIONS

Figure 1

Conclusion: In COP+ at-risk with MSK symptoms, US of only 3 joints bilaterally (wrist, knee and MTP5 joint) improved prediction of IA over and above clinical and serological risk factors, performing similarly to an extended research US protocol. This shortened 6 joint US protocol may offer clinically feasible risk prediction, which could be easily incorporated into routine clinical practice.

*1 SERA subject missing
**Background:** Intestinal lung disease (ILD) is a severe extra-arteriolar manifestation of rheumatoid arthritis (RA). Usual intestinal pneumonia (UIP) is the most frequent and severe ILD pattern in RA, and it has a bad prognosis. Abatacept (ABA) has shown effectiveness in RA-ILD during a 12-month period of treatment [1-2].

**Objectives:** To assess the effectiveness and safety of ABA in RA-ILD patients with radiological pattern of UIP during a long-term follow-up.

**Methods:** From a large observational multicenter study of 392 RA-ILD patients treated with ABA, we selected those with UIP. We analyzed from baseline the following outcomes: a) forced vital capacity (FVC), b) diffusion capacity of the lungs for carbon monoxide (DLCO), c) chest high-resolution computed tomography (HRCT), d) dyspnea (modified Medical Research Council scale) and e) arthritis activity (DAS28-ESR).

**Results:** We included a total of 172 patients with UIP (91 women/81 men; mean age 66.9±10.1 years). Baseline demographic and clinical characteristics are shown in Table 1. The median ILD duration up to ABA initiation was relatively short, with a median of 11 [3-39] months. Mean baseline values of FVC and DLCO were >80% and >60%, respectively. During the follow-up, median of 24 [10-44] months, 70.2% and 66.9% of patients showed an improvement in DLCO and FVC, respectively. Evolution of these parameters along 48 months is displayed in Figure 1. Available chest HRCT images improved in 64.5% of patients. Stabilization or improvement of dyspnea was found in 76% of patients. The majority of patients showed articular remission or low activity (mean DAS28-ESR of 4.3±1.5 at baseline and 2.5±1.5 at 48 months).

ABA was withdrawn in 39 (22.6%) patients due to ILD worsening (17), articular inefficacy (9), serious infections (7) and other causes (n=6, development of malignancy in 3, diagnosis of giant cell arteritis and change to tocilizumab in 1, and 2 deceases).

**Conclusion:** ABA shows a lasting effectiveness and safety in RA-ILD patients with UIP, the most aggressive pattern.

Background: Patients with rheumatoid arthritis (RA) and interstitial lung disease (ILD) have increased mortality compared to the general population and factors capable of predicting RA-ILD long-term clinical outcomes are lacking. In oncology, radiomics allows the quantification of tumour phenotype by analysing the characteristics of medical images [2]. The hypothesis of radiomics is that the distinctive imaging features between disease forms may help make a prognosis and predict the therapeutic response for various conditions, thus providing valuable information for personalised therapy and patient management. Using specific software, it is possible to segment organs on high-resolution computed tomography (HRCT) images and extract many features that may uncover disease characteristics that are not detected by the naked eye.

Objectives: We aimed to investigate whether features from whole lung radiomic analysis of HRCT may alone predict mortality in RA-ILD patients.

Methods: HRCTs of RA patients from January 2012 to March 2022 were analyzed. The time between the first available HRCT and the last follow-up visit or ILD-related death was recorded. We performed a volumetric analysis in 3D Slicer, automatically segmenting the whole lungs and trachea via the Lung CT Analyzer. The PyRadiomics platform (version 3.01) can extract radiomic data from medical imaging, calculate features and return results as continuous variables. In a Python 3.9 environment, we extracted 120 features.

Results: We retrieved the HRCTs of 30 RA-ILD patients. The median survival time (interquartile range) was 48 months (36–120 months). Thirteen out of 30 (43.33%) patients died during the observation period. Demographics and clinical characteristics have been reported in Table 1. Whole lung segmentation was fast and reliable. The model included either the median grey level intensity within the whole lung segmentation (HR 9.35, 95% CI 1.56–v55.86) as a positive predictor of death and the 10th percentile of the number of included voxels (HR 0.20, 95% CI 0.05–0.84), the voxel-based pre-processing information (HR 0.23, 95% CI 0.06–0.82) and the flatness (HR 0.42, 95% CI 0.18–0.98), negatively correlating to mortality. The correlation of grey level values to their respective voxels (HR 1.52 95% CI 0.82–2.83) was also retained as a confounder. We observed that the hazard function followed the 45-degree line very closely except for huge values of time, demonstrating goodness-of-fit (Figure 2, Panel B).

Conclusion: Radiomics may predict RA-ILD patients’ mortality and may promote HRCT as a digital biomarker regardless of the clinical characteristics of the disease.

Background: Concentrations of methotrexate polyglutamates (MTX-PGs) in erythrocytes have been reported to be associated with efficacy and safety in patients with rheumatoid arthritis (RA) treated with MTX. However, little is known about the pharmacokinetics and pharmacodynamics of MTX-PG concentrations and their relationship with disease control and adverse effects in patients treated with MTX and a tumor necrosis factor inhibitor (TNFi), especially in patients whose MTX dose is reduced at TNFi initiation.

Objectives: To clarify the association between the concentrations of MTX-PGs with efficacy and safety of treatment in patients with RA treated with low dose MTX and high dose MTX in combination with adalimumab, a TNFi.

Methods: The MIRACLE study (NCT03505008) was a multinational, randomized study in patients with RA with inadequate response to MTX. Three hundred MTX-naive patients were enrolled in the study and started and increased MTX to the maximum tolerable dose. Patients who did not achieve remission according to simplified disease activity index (SDAI) at week 24 were randomised to the maximum tolerable dose group or the reduced dose group and started subcutaneous adalimumab 40 mg every other week. We measured the concentrations of MTX-PGs in erythrocytes with liquid chromatography mass spectrometry at weeks 0, 4, 8, 12, 24, 36, and 48 and analysed the association between the concentration of MTX-PGs with the efficacy and safety of adalimumab.

**Results:** The previously reported results of the MIRACLE trial showed that the efficacy of adalimumab with reduced dose of concomitant MTX was not inferior to that with maximum tolerable dose of MTX (remission rates at week 48: 44.8 % vs 38.4 %, respectively) with better safety profile (adverse events: 19.7% vs 35.3%, respectively). In the maximum tolerable dose group, MTX dose was 13.5±3.2 mg/week (0.24±0.1 mg/kg/week) at week 24 and maintained the dose through 48 weeks. In the reduced dose group, MTX dose was reduced from 12.6±3.1 mg/week (0.23±0.1 mg/kg/week) to 7.6±0.5 mg/week (0.14±0.0 mg/kg/week) at week 24. The concentration of total MTX-PGs in the maximum tolerable dose group was 109.5±36.7 nmol/mL, 99.9±40.1 nmol/mL, and 96.4±38.3 nmol/mL at weeks 24, 36, and 48, respectively. In the reduced dose group, total MTX-PGs concentration was decreased from 113.5±55.3 nmol/mL at week 24 to 80.7±53.1 nmol/mL at week 36 and 68.9±54.4 nmol/mL at week 48 (Figure 1). The decrease in individual MTX-PG levels were more prominent in long and very long chain MTX-PGs compared with short chains; MTX-PG 1-2, 59.0±44.7 nmol/mL at week 24 to 48.9±34.8 nmol/mL at week 36; MTX PG 3-5, 54.5±28.8 nmol/mL at week 24 to 31.8±18.7 nmol/mL at week 36. In both groups, MTX-PG concentrations at week 48 were not different between patients who achieved SDAI remission and those who did not (91.5 nmol/mL vs 98.6 nmol/mL in the maximum tolerable dose group, p=0.743; 64.3 nmol/mL vs 72.9 nmol/mL in the reduced dose group, p=0.556, respectively). On the other hand, patients in the reduced dose group who experienced adverse events after week 24 tended to have higher concentration of total MTX-PGs than those who did not (140.3 nmol/mL vs 106.9 nmol/mL at week 24, p=0.050; 97.3 nmol/mL vs 63.0 nmol/mL at week 48, p=0.069, respectively).

Conclusion: The MIRACLE randomised study demonstrated that total MTX-PG concentrations were not relevant for SDAI remission achievement by combined treatment with methotrexate and adalimumab while patients who experienced adverse events were exposed to higher MTX-PG concentrations.

The potential advantage of temporary bDMARD use earlier in the T2T setting needs further investigation. **Objectives:** To determine the long-term effectiveness of accelerated access to a temporary course of etanercept compared to addition of leflunomide in patients with early RA who insufficiently respond to initial COBRA-Slim induction therapy. **Methods:** DMARD-naïve patients with a recent diagnosis of RA (≤1 year ago) were included in the 2-year, open-label, multicentre, pragmatic randomised controlled superiority trial Care in Early RA 2020 (CareRA2020). All patients started the COBRA-Slim induction regimen. Patients were classified as insufficient responders if, even despite MTX dose increase, they did not achieve DAS28-CRP ≥3.2 between week 8 and week 32 or if DAS28-CRP was ≥2.6 at week 32 regardless of MTX dose. Insufficient responders were randomised to either Standard COBRA-Slim (addition of leflunomide 10mg/d) or COBRA-Slim Bio-induction (addition of etanercept 50mg/w for 24 weeks). Additional treatment adaptations followed the T2T principle. Primary outcome was the difference in DAS28-CRP over time, determined via a linear mixed model including random intercepts and a random slope for time, adjusting for baseline DAS28-CRP and seropositivity. Missing data were imputed with the Expectation-Maximisation algorithm. **Results:** In total, 276 patients were included, of which 155 (56%) were classified as sufficient and 121 (44%) as insufficient responders. Of the insufficient responders, 9 patients were not randomised by investigator decision, 2 were randomisation errors, 55 were randomised to Standard COBRA-Slim and 55 to COBRA-Slim Bio-Induction. The mean ± SD area under the DAS28-CRP curve over 104 weeks was 232 ± 66 for the initial sufficient responders, 310 ± 82 for the Standard COBRA-Slim group, and 316 ± 73 for the COBRA-Slim Bio-induction group. Both randomisation groups had comparable DAS28-CRP scores over time (β = 0.095, 95% CI (-0.299 to 0.108), p=0.351). At the end of the trial, 82% (127/155), 9% (5/55), and 36% (20/55) of patients were on csDMARD monotherapy in the initial sufficient responders, Standard COBRA-Slim, and COBRA-Slim Bio-induction group, respectively. Moreover, 6% (9/155) sufficient responders, 58% (32/55) in the Standard COBRA-Slim, and 45% (25/55) in the COBRA-Slim Bio-induction group were treated with a b- or tsDMARD. **Conclusion:** More than half of the CareRA2020 participants achieved remission with COBRA-Slim induction therapy. DAS28-CRP over 104 weeks was not superior with COBRA-Slim Bio-induction versus the Standard COBRA-Slim T2T regimen in initial insufficient responders. However, compared to the Standard COBRA-Slim group, more patients in the Bio-induction group were treated with csDMARD monotherapy and less with advanced therapies at the end of the study.
ABACETP IN INDIVIDUALS AT RISK OF DEVELOPING RHEUMATOID ARTHRITIS: RESULTS FROM THE ARTHRITIS PREVENTION IN THE PRE-ClinICAL PHASE OF RA WITH ABACETP (APIPPRA) TRIAL

Background: While genetic and epidemiological factors have been used traditionally to evaluate the risk of developing rheumatoid arthritis (RA), the definition of higher risk states has been refined in more recent years through inclusion of serum autoantibodies and symptom complexes, such as inflammatory joint pain. Data from risk cohort studies have reported rates of progression to RA in excess of 50% over 24 months. These combined features have provided a framework for the design of intercetion studies, aimed at delaying or preventing RA.

Objectives: We evaluated the feasibility, efficacy and acceptability of T-cell co-stimulation modulation with abatacept in individuals at risk of developing RA in the Arthritis Prevention in the Pre-clinical Phase of RA with Abatacept (APIPPRA) study.

Methods: APIPPRA is a Phase IIB randomised, double blind, placebo-controlled trial recruiting ACPA+RF+ or ACPAhi (≥3 x ULN) RF - individuals with arthralgia. Consenting participants were randomised, stratified by gender, smoking status and mode of entry, to receive 52 weekly subcutaneous injections of placebo or 125mg of abatacept, and followed up for a further 52 weeks after stopping treatment. Exclusion criteria included previous episodes of clinical synovitis, prior corticosteroids or DMARDs. The primary endpoint was the time to development of either clinical synovitis in ≥3 joints, or RA according to ACR/EULAR 2010 criteria, whichever was met first, where joint involvement required swelling. Joint synovitis was confirmed by ultrasonography. The study was powered to detect a 50% reduction in disease activity-guided dose adjustments and costs. To reduce these disadvantages, disease activity-guided dose adjustments were no new safety signals.

Acknowledgements: The APIPPRA trial is an Investigator Sponsored Research (ISR) study funded by Bristol Myers Squibb, and jointly sponsored by Guy’s and St Thomas’ NHS Foundation NHS Trust and King’s College London in the UK and Leiden University Medical Center in the Netherlands. Bristol Myers Squibb played no role in data acquisition or analysis.

Conclusion: Therapeutic intervention during the RA at risk phase is feasible, with acceptable safety profiles. T cell co-stimulation modulation with abatacept for 52 weeks showed a reduction in the development of RA over two years. There were no new safety signals.

proportion of patients with a DAGDO attempt, and 4) proportion of patients with a discontinuation attempt and duration of b/tsDMARD discontinuation.  

Methods: Observational follow-up (starting from DRESS baseline) of patients who completed the 3-year DRESS extension. During the DRESS intervention phase (month 0-18), RA patients were randomized to DAGDO or continuation of TNFi (adalimumab or etanercept), but thereafter, DAGDO was allowed for all patients. The DAGDO protocol contained the following steps, displayed as a percentage of the current daily dose to the defined daily dose (DDD): 100%-66%-50%-33%-0% (full discontinuation). The disease activity was operationalized as the mean time-weighted (MTW) DAS28-CRP during the whole period 2.13 (95% CI 2.10-2.16) (Figure 1). The DRESS TNFi dose decreased from 97% at baseline (95% CI 96%-99%) to 49% at year 5 (95% CI 42%-56%) and remained stable thereafter (Figure 1). The dose of any b/tsDMARD was comparable although slightly higher. Of the 161 patients with ≥1 DAGDO attempt of their DRESS TNFi during the study, 119 (74%, 95% CI 66%-80%) tapered until full discontinuation. The median time from discontinuation to restart of the first discontinuation attempt was 8 months (IQR 3 - 45 months), and 25 patients (21%, 95% CI 14%-29%) never had to restart their TNFi or another b/tsDMARD throughout the study.  

Conclusion: In this 10-year TNFi dose optimization study, we found a stable low disease activity and halved TNFi dose. The inclusion of discontinuation in DAGDO does not seem to cause disease deterioration and b/tsDMARD free remission for a relevant period of time is possible in a non-negligible number of patients. Overall, this study shows effectiveness of DAGDO of TNFi in RA up to 10 years.

The risk of overall cancers was similar in patients that were (a) prescribed with JAKi/biologics and csDMARDs, as well as in (b) those who used JAKi and TNFi as the first-line treatment. In addition, there was no difference in the incidence of cancers among (c) those who were treated with only JAKi and TNFi during the follow-up and between (d) JAKi, biologics, and csDMARDs users. JAKi: Janus kinase inhibitors, csDMARD: conventional synthetic disease-modifying anti-rheumatic drug, TNFi: tumour necrosis factor-alpha inhibitor.

DO JAKIS WORK THE BEST AMONG THOSE RA PATIENTS WHERE THEIR SAFETY CONCERNS ARE THE HIGHEST?

**Keywords:** Rheumatoid arthritis, Targeted synthetic drugs, bDMARD

H. Bower, T. Frisell, D. Di Giuseppe, B. Delcoigne, J. Asling, Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; Karolinska University Hospital, Rheumatology, Theme Inflammation and Ageing, Stockholm, Sweden

**Background:** Safety is a driving factor when selecting treatment, but the risks should be balanced against the treatment benefits, relative to alternative treatment options. In JAKis, recent evidence of increased safety risks in older patients with cardiovascular (CV) risk factors, have led to concerns. However, an increased risk among certain patients might still be offset by an increasing benefit in the same patient segment, and vice versa. A full understanding of the JAKi benefit-risk profile thus requires a better understanding of the relative (JAKi vs other treatments) benefits in those patients where their relative safety profile may be worse.

**Objectives:** To observe the assessed and adjusted relative effectiveness (remission and response) of JAKis (and non-TNFi bDMARDs) when compared to TNFi, as used in clinical practice, and to assess whether the predicted effectiveness of either drug class is modified by age and the presence of CV risk factors.

**Methods:** RA patients initiating treatment with a JAKi, non-TNFi, or TNFi 2016-2021 were followed using the Swedish Rheumatology Quality Register. Good EULAR response and remission (CDAI≤2.8) at 6 months were assessed at return visits (within 90 to 270 days after treatment initiation). Non-responder imputation was implemented where treatment ended prior to 210 days after initiation. Crude probabilities of outcomes were presented by age and having ≥1 CV risk factor (1/Y). Linear regression estimated the risk difference (versus TNFi) in age and CV risk groups, adjusted for sex, baseline DAS28 (response) and CDAI (remission), and line of therapy. Probability of outcome was predicted from logistic regression models, fitted to allow effect modification of treatment cohort by age and CV risk score (ERS-RA score), adjusted for sex, baseline DAS28 (response) and CDAI (remission), and line of therapy.

**Results:** 10,309 treatment episodes contributed data on response at 6 months, and 12,016 episodes with data on remission. Overall, 21% achieved good EULAR response and 11% reached CDAI remission (Table 1). Crude observed risks overall indicated superior response and remission with TNFi versus JAKi (Table 1). Adjusted risk differences suggested superior outcomes in JAKi versus TNFi, overall, and in those with no CV risk for CDAI remission. Patterns of predicted response and remission varied across age and CV ERS-RA score (Figure 1), with JAKis having superior effectiveness overall once adjusting for line of therapy.

**Conclusion:** Age and CV risk may modify the absolute and relative effectiveness of JAKis vs. TNFi. Further analyses are planned with the aim of presenting these results at EULAR.

REAL WORLD “POLY-REFRACTORY RA”: A RARE BUT UNMET CLINICAL CHALLENGE

**Keywords:** Rheumatoid arthritis, bDMARD, Ultrasound

P. David, A. Di Matteo, C. Hen, S. Dass, P. Emery, B. Galea, D. Mcgonagle, University Of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; Sheba Medical Center - Tel Hashomer, Internal Medicine B Department, Ramat Gan, Israel; Leeds Teaching Hospitals NHS Trust, National Institute for Health Research Leeds Biomedical Research Centre, Leeds, United Kingdom; Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Rheumatology Unit, Carlo Urbani Hospital, Jesi-Ancona, Italy; Sheba Medical Center - Tel Hashomer, Internal Medicine C Department, Ramat Gan, Israel; Leeds Teaching Hospitals NHS Trust, Rheumatology, Chapel Allerton Hospital, Leeds, United Kingdom

**Background:** In an age of dose optimization and drug tapering due to excellent conventional (c), biological (b) or targeted synthetic (ts) disease-modifying anti-rheumatic drugs (DMARDs), the fact remains that many patients still have active disease, being therapy refractory, sometimes to multiple DMARDs. In 2021, EULAR defined the term “Difficult-to-treat (D2T) Rheumatoid Arthritis” as failure of two or more different classes of b/tsDMARDs post csDMARDs (1) but the rate of failure to all available DMARD classes in the real-world setting (poly-refractory RA) is not established. Moreover, the DAS-28-CPB score can be elevated in patients with either persistent inflammatory RA (PIRR) or non-inflammatory RA (NIRR), where the latter do not benefit from medication change.
These findings highlight a twofold clinical challenge in refractory RA with half of D2T RA, real world poly-refractory RA was present in only 2.5%. Almost half of the poly-refractory RA group had CRP levels within normal ranges despite a DAS-28-CRP score above 3.2 (mean DAS-28-CRP of 5.3). 71 D2T RA patients had recent US of clinically involved joints, including 28 poly-refractory RA cases. 17/28 (64%) poly-refractory were found to have no synovial thickening in US in suspected clinically involved joints. Specifically in the poly-refractory RA group, the CRP levels were within normal ranges in 6/10 (60%) NIRRA patients, while they were further divided into NIRRA and PIRRA, according to the presence/absence of signs of active synovitis as indicated by PDUS (Figure 1).

**Results:** 242/1991 (12.5%) met the EULAR D2T criteria of failing at least 2 b/tsDMARDs. 89/1991 (5.6%) failed 2 classes only, with a mean disease duration (mDD) of 11 years. 60/1991 (3.8%) failed 3 classes (mDD= 18) and 52/1991 (3.3%), 4 classes (mDD= 10.5). However, just 41/1991 (2.5%) had poly-refractory RA having all 5 classes (mDD= 21). Of them, 37/41 (90%) failed multiple drugs within each class. 4/41 (10%) poly-refractory and 45/245 (18.5%) of all EULAR D2T cases were seronegative.

Regarding joint involvement patterns, most had typical small joint RA disease pattern but 26/242 (11%) had a predominant large joint pattern. 18/43 (43%) of the poly-refractory RA group had CRP levels within the normal ranges despite a DAS-28-CRP score above 3.2 (mean DAS-28-CRP of 5.3). 71 D2T RA patients had recent US of clinically involved joints, including 28 poly-refractory RA cases. 18/28 (64%) poly-refractory were considered PIRRA as evidenced by synovial hypertrophy and PDUS positivity in at least one evaluated clinically swollen joint. 32/71 (45%) D2T RA had no signs of active synovitis in PDUS being considered NIRRA. Of them, 17/32 (53%) had no synovial thickening in US in suspected clinically involved joints. Specifically in the poly-refractory group, the CRP levels were within normal ranges in 6/10 (60%) NIRRA patients, while just 7/18 (39%) PIRRA cases had normal CRP levels.

**Conclusion:** Although 15.2% of Leeds RA patients met the EULAR criteria for D2T RA, real world poly-refractory RA was present in only 2.5%. Almost half of these patients had no PDUS changes on US and/or had normal CRP levels. These findings highlight a twofold clinical challenge in refractory RA with half of this group (both D2T and poly-refractory RA) having true inflammation that may need new mechanisms of action, but the other half would not be likely to benefit from new DMARD treatment strategies.

**RISK OF DEMYELINATING EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TUMOUR NECROSIS FACTOR INHIBITORS: A SYSTEMATIC LITERATURE REVIEW**

**Keywords:** bDMARD, Rheumatoid arthritis, Systemic review

I. Castrejon1,2, L. Silva-Fernández2, J. A. Gómez-Puerta2, A. Ortúz2, N. Mena-Vizquez2, J. Tomero Molina2, C. Flascia2, J. M. Alvaro-Gracia1,2, Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain;1Complutense University of Madrid, Department of Medicine, Madrid, Spain;2Hospital Universitari Son Espases, Rheumatology, Palma, Spain;3Hospital Clinic de Barcelona, Rheumatology, Barcelona, Spain;4Hospital de La Princesa, Rheumatology, Madrid, Spain;5Hospital Regional Universitario de Malaga, Rheumatology, Malaga, Spain;6Hospital Universitario de Guadalajara, Rheumatology, Guadalajara, Spain;7La Paz University Hospital, Rheumatology, Madrid, Spain

**Background:** Several case reports published in the 2000s indicated that demyelinating diseases could be a serious adverse event following TNFi inhibitors (TNFi) treatment. However, initial data from biological therapy registries did not bring enough clarification.

**Objectives:** To investigate whether treatment with biologics or targeted synthetic DMARDs is associated with an increased risk of demyelinating events among patients with rheumatoid arthritis (RA).

**Methods:** A systematic search was performed in MEDLINE, EMBASE (up to Oct 2022), and by manual references. Selection criteria: (population) patients with RA; (intervention) treatment with any biologic including TNFi and synthetic DMARDs; (outcome) demyelinating event; (study design) observational studies and randomised clinical trials. Titles and abstracts were screened and data were extracted from the selected studies including quality evaluation, and outcomes of interest.

**Results:** From 368 identified studies, 4 cohorts and 3 nested case-control studies reported risk of demyelinating events following treatment with biologics, mainly TNFi and anakinra, in one study. Most studies included mixed populations of inflammatory arthritis and patients with RA were analysed as a separate subgroup. Two nested case-control reported an increased risk, but in a mixed population, with no analysis of a subgroup of RA. In general, demyelinating events were very uncommon in patients receiving TNFi, with a marginal increased risk in males with RA in 2 studies (Table 1).

Background: Lupus nephritis (LN) is one of the most common severe clinical manifestations of systemic lupus erythematosus (SLE), occurring in 21%–48% of SLE patients.[1] The kidney is the major organ affected in SLE, with persistent inflammation leading to progressive loss of renal function and chronic kidney disease (CKD). The decline in kidney function leads to the accumulation of metabolic waste products normally cleared by the kidneys, known as uremic toxins. Uremic toxins negatively affect multiple organ systems, causing increased cardiovascular and kidney damage, among other effects.[2] Given the clear link to kidney function, uremic toxins may serve as biomarkers of kidney damage and of treatment response. Anifrolumab, a monoclonal antibody that targets the type I interferon (IFN) receptor subunit 1, is approved for moderate to severe SLE treatment.[3]

Methods: In the 52-week phase 2 clinical trial TULIP-LN (NCT02547922), 147 patients with active LN were randomized 1:1:1 to receive intravenous anifrolumab every 4 weeks at standard SLE dosing (basic regimen [BR], 300 mg), intensified dosing (intensified regimen [IR], 900 mg for the first 3 doses, 300 mg thereafter), or placebo in addition to standard therapy.[4] Serum samples were obtained from 140 of these patients at baseline (BL) and Weeks 12, 24, and 52. Serum metabolites were analyzed using an unbiased liquid chromatography–mass spectrometry-based approach. Metabolites that were differentially modulated in the anifrolumab IR vs placebo group were identified using a mixed effects model evaluating the interaction of metabolite levels and treatment, adjusted for patients’ IFN gene signature (IFNGS) status (high/low) and 24-hour urine protein–creatinine ratio (UPCR >3 or ≤3). Relationships between BL metabolite level and clinical characteristics of kidney damage were assessed by Spearman’s correlation. Association of BL metabolite levels with complete renal response were evaluated by logistic regression, adjusted for IFNGS and UPCR status.

Results: Our unbiased metabolomic approach identified 2 metabolites significantly impacted by anifrolumab treatment compared with placebo (Figure 1). Cytosine (Cyt) and indoxyl sulfate (IS) levels were significantly reduced following anifrolumab IR treatment compared with placebo, while an intermediate, non-significant reduction was observed longitudinally with anifrolumab BR. At baseline, Cyt and IS serum levels were positively correlated with serum creatinine and negatively correlated with estimated glomerular filtration rate. Baseline IS levels were also associated with complete renal response at Week 52. Compared to the trend observed in nonresponders, IS levels in responders were reduced from BL to Week 52. A trend in reduction of multiple uremic toxins not limited to IS was detected in the anifrolumab-treated group.

Conclusion: In patients with LN, anifrolumab treatment reduced levels of multiple circulating uremic toxins including IS, a known inducer of cardiovascular damage in CKD.[5] Together, correlations with kidney damage measures at baseline and reductions in IS levels in responders vs nonresponders at Week 52 suggest improvements in kidney function following anifrolumab treatment. Overall, our results contribute to a deeper understanding of how inhibition of type I IFN affects renal disease in LN.

Figure: Identification of metabolites differentially modulated by anifrolumab vs placebo
Background: Telitacicept (TACI-Fc fusion protein) is a novel BlyS (B-lymphocyte stimulator)/APRIL (a proliferation–inducing ligand) dual inhibitor, which has been approved in 2021 in China for the treatment of patients with active systemic lupus erythematosus (SLE).[1]

Objectives: Assess the efficacy and safety of telitacicept in SLE patients in a double-blind, randomized, placebo-controlled, phase 3 trial.

Methods: In this study, 335 active SLE patients who were receiving stable standard therapy with positive ANA/anti-dsDNA and a SELENA-SLEDAI score ≥8 were randomized 1:1 to receive telitacicept 160 mg (N=167) or placebo (N=168) subcutaneously weekly for 52 weeks. The primary endpoint was the response rate of SLE responder index 4 (SRI4) at Week 52. Key secondary endpoints included: SELENA-SLEDAI, PGA, immunological biomarkers including C3, C4, IgM, IgG, IgA and CD19+ B cells. Safety was assessed during the study.

Results: Baseline demographics and disease characteristics were comparable between the two groups. The primary endpoint at Week 52 was met, with significantly greater proportion of patients in telitacicept 160 mg group vs placebo achieving SRI4 response (Table 1). SRI4 response was sustained in telitacicept 160 mg group up to Week 52 (Figure 1A). Significantly greater proportions of subjects in telitacicept 160 mg group had improvement in SELENA-SLEDAI and PGA (Table 1 & Figure 1B, 1C). Rapid and sustained increase of C3 and C4 (Figure 1G, 1H), and reduction of IgM, IgG, IgA and CD19+ B cells (Figure 1D, 1E, 1F, 1I) were observed following telitacicept treatment. Incidences of TEAEs and infections were comparable between the two groups. Most of TEAEs were mild to moderate in severity. A greater proportion of patients receiving placebo had SAEs and serious infections compared with telitacicept 160 mg. (Table 1).

Figure 1. SRI4 Response Rate (A), rate of subjects with improvement in SELENA-SLEDAI (B) and PGA (C) at each visit. Percent (%) change from baseline in IgM (D), IgG (E), IgA (F), C3 (G), C4 (H) and CD19+ B cells (I).$P<0.001 vs. Placebo; *P<0.01 vs. Placebo; +P<0.05 vs. Placebo.

OPO139 EFFICACY AND SAFETY OF ABBV-599 HIGH DOSE (ELS/BRUTINIB 60 MG AND UPADACITINIB 30 MG) AND UPADACITINIB MONOTHERAPY FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS: A PHASE 2, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Keywords: Systemic lupus erythematosus

J. T. Merrill, Y. Tanaka, D. D’Cruz, K. Vila, D. Siri, X. Zeng, K. D’Silva, L. Cheng, T. Sornasse, T. Doan, D. Kruizakis, A. Friedman, Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology Program, Oklahoma City; United States of America; Hospital of University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; King’s College London, School of Immunology & Microbial Sciences, London, United Kingdom; Guy’s Hospital, Department of Rheumatology, London, United Kingdom; QCM Medical Group, Rheumatology, San Juan, Puerto Rico; CAICI Institute, Rheumatology, Rosario, Argentina; Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing, China; AbbVie, Inc, Department of Immunology, North Chicago, United States of America

Background: ABBV-599 is a novel combination of elsabrutinib (ELS; a selective BTK inhibitor) and upadacitinib (UPA; a JAK inhibitor) that targets non-overlapping signaling pathways associated with systemic lupus erythematosus (SLE).

Objectives: To report results from SMEK, a phase 2, randomized, placebo (PBO)-controlled, parallel-group, multicenter study evaluating efficacy and safety of ABBV-599 and UPA monotherapy in adults with moderately to severely active SLE (NCT03978520).

Methods: Patients (pts) were randomized 1:1:1:1:1 to once daily (QD) ABBV-599 high dose (HD; ELS 60 mg + UPA 30 mg), ABBV-599 low dose (LD; ELS 60 mg + UPA 15 mg), ELS 60 mg, UPA 30 mg, or PBO. The primary endpoint was the proportion of patients at W24 achieving SLE Responder Index 4 (SRI-4) and steroid dose ≤ 10 mg QD; additional efficacy and safety endpoints through W48 are also reported. The pre-specified 2-sided alpha level was 0.1.

Results: 341 patients were enrolled. After a planned interim analysis when 50% of pts reached W24, the ABBV-599HD and UPA 60 mg arms were discontinued for lack of efficacy (no safety concerns). Of 205 continuing pts (ABBV-599 HD n = 68, UPA 30 mg n = 62, PBO n = 75), baseline characteristics were well balanced. The primary endpoint (proportion achieving SRI-4 and steroid dose ≤ 10 mg QD at W24 vs PBO) was met by ABBV-599HD and UPA 30 mg. Key secondary endpoints were also achieved at W48 in both groups (Table 1). Overall flares and time to first flare were substantially reduced in the ABBV-599HD and UPA 30 mg groups through W48 (Figure 1). Anti-double stranded DNA antibodies were significantly decreased with both treatments. TEAEs considered related to study drug were 42.6% ABBV-599HD, 32.3% ABBV-599 LD, 32.9% UPA 30 mg, and 33.3% PBO. There were no malignancies or VTE. There were 3 non-fatal CV events (1 MI on PBO and 2 ruptured cerebral aneurysms [1 each on ABBV-599HD and UPA 30 mg]); all were assessed as unrelated to study drug by investigators. No new safety signals were observed beyond previously known data for UPA or ELS.

Conclusion: ABBV-599HD (ELS 60 mg + UPA 30 mg) and UPA 30 mg demonstrated significant improvements in SLE disease activity and flares with acceptable safety through 48 weeks.
Regulatory T Cell Defects in SLE and Therapy with a Novel IL-2 Mutein: Phase 1 Clinical Results with Efavaleukin Alfa

Keywords: Cytokines and chemokines, Systemic lupus erythematosus, Clinical Trials

1Amgen Inc., Clinical Biomarkers, South San Francisco, United States of America; 2Amgen Inc., Early Development, South San Francisco, United States of America; 3Northwell Health and Donald and Barbara Zucker School of Medicine at Hofstra-Northwell, Division of Rheumatology, Great Neck, United States of America; 4Altoona Center for Clinical Research, Altoona Arthritis and Osteoporosis Center, Duncansville, United States of America; 5Metroplex Clinical Research Center, Division of Rheumatology, Dallas, United States of America

Background: Regulatory T cells (Treg) are critical for maintaining self-tolerance and preventing autoimmunity, and IL-2 is essential for their development, survival and suppressive function. Defects in Treg function and the IL-2 receptor are associated with SLE and have been correlated with disease activity.[1,2] Efavaleukin alfa is an IL-2 mutein Fc fusion protein that preferentially binds the high-affinity IL-2 receptor alpha chain (CD25) to selectively promote Treg expansion.

Objectives: To compare Treg functional phenotypes in healthy controls (of efavaleukin alfa baseline) with SLE patients (at baseline and post-treatment) enrolled in a phase 1b study of efavaleukin alfa in order to characterize Treg defects in SLE and the effects of IL-2-targeted therapy with efavaleukin alfa on Treg expansion.

Methods: Baseline Treg functional phenotyping data from 64 healthy volunteers (ph1a baseline) were compared with Treg data from phase 1b SLE study subjects. The phase 1b, multiple ascending dose study (NCT03451422) included 5 dose cohorts; a total of 35 patients with SLE (with either elevated anti-dsDNA or ANA) were randomized to receive efavaleukin alfa or placebo SC every 2 weeks (Q2W; cohorts 1, 2, 4, and 5) or every week (QW; cohort 3) for a total of 12 weeks. Pharmacodynamic profiles of lymphocyte subsets were evaluated in peripheral blood. Cell subsets were defined as follows: Treg, CD3+CD4+Foxp3+CD127–CD25+; CD25+ Treg, CD3+CD4+Foxp3+CD127–CD25+ (expanded Treg pool); CD4+ Tcon, CD3+CD4+Foxp3–CD127+CD25–. Lymphocyte subsets were evaluated in peripheral blood at baseline, with a mean peak increase of 53.8-fold above baseline with efavaleukin alfa treatment.

Results: At baseline, Treg CD25 expression levels were significantly lower in SLE patients compared with healthy subjects (Figure 1a), and CD25 expression on Foxp3+ Treg negatively correlated with anti-dsDNA autoantibodies (Figure 1b). The percentage of CD25+ Tregs was significantly higher in SLE patients than healthy subjects and also correlated with anti-dsDNA at baseline. At day 22 in the phase 1b study, after SLE patients randomized to efavaleukin alfa had received 2 doses, Treg CD25 expression was significantly increased above baseline and comparable to the levels in healthy controls (Figure 1a). The number of CD25+ Tregs in SLE patients was inversely correlated with anti-dsDNA at baseline, with a mean peak increase of S3.8-fold above baseline with efavaleukin alfa treatment. The intensity of CD25 on CD4+ Tcon was not significantly different between healthy subjects and SLE patients and was not increased with efavaleukin alfa treatment.

Conclusion: Treg from SLE patients showed defects in IL-2 signaling evidenced by lower CD25 expression that correlated with anti-dsDNA, suggesting a role for reduced IL-2 signaling in SLE autoimmunity. Efavaleukin alfa treatment selectively restored Treg CD25 expression to levels observed in healthy controls without increasing CD25 expression on Tcon. CD25+ Treg considered a more suppressive Treg population, were expanded with multiple doses of efavaleukin alfa. Although low baseline SLE disease activity and short treatment duration precluded efficacy analysis, clinical correlations with treatment response will be investigated in the ongoing phase 2b adaptive trial of efavaleukin alfa in SLE.

Gemelli, Division of Rheumatology, Roma, Italy; 6Universitätsklinikum Magdeburg Aö.R. Universitätsklinik für Hämatologie und Onkologie, Hämatologie und Onkologie, Magdeburg, Germany

Background: Despite better treatment modalities some patients with systemic lupus erythematosus (SLE) suffer from severe and treatment-resistant disease. This situation puts patients at high risk for organ failure or even death. Furthermore, many patients with SLE have to take long-term, sometimes even life-long immune suppressive medication to control the disease without being able to enjoy drug-free remission. Recently, we reported that deep B cell depletion using a single infusion with autologous CD19 CAR-T cells induced drug-free clinical remission in severe SLE patients with refractory disease [1,2]. This abstract presents the long-term clinical efficacy and safety data of the first seven SLE patients receiving autologous CD19-directed CAR-T cell therapy.

Objectives: To test whether administration of autologous CD19 chimeric antigen receptor (CAR) T cells is tolerable and effective in patients with severe refractory SLE

Methods: Compassionate use program for patients with severe active SLE showing organ involvement and resistance to multiple immune suppressive treatments. Patients received autologous 10^5 CD19-CAR-T cells/kg body weight by single infusion after standard conditioning therapy (cyclophosphamide/fludarabine). The investigational medicinal product MB-CART19.1 was produced as described before [1,2]. All SLE treatments was stopped before CAR-T cell administration. Patients were followed up as in-patients for the first 10 days after CAR T cell administration, then weekly until the end of the first month, then monthly for three months and every three months thereafter. Tolerability was assessed by monitoring for Cytokine-release syndrome (CRS) and Immune-related effector Cell Neurotoxicity Syndrome (ICANS). Preliminary efficacy was assessed by reaching a Lupus Low Disease Activity State (LLDAS) and DORIS remission.

Results: As per January 2023, seven SLE patients (6 female, 1 male, aged range 19-39) had been treated with CD19 CAR-T cells with a median follow up of 13 months (4-months-22-months). Patients had active disease with a median SLEDAI of 10 (range: 8-16), with a median of 4 organs involved (range: 8-16) and a median number of 7 failed treatments (range: 4-15). All patients had active kidney disease. In addition, involvement of the heart, lungs, pleura, joints, skin, muscles and bone marrow were documented. Conditioning was done at the described [1,2] dose with the exception of patients 7, who received only 50% of the dose. All patients received a single infusion of 1x10^5 autologous CD19-CAR-T cells/kg body weight. No ICANS was observed and CRS if observed were mild (grade I). In vivo, CAR-T cells rapidly expanded peaking at day 9 with a median of 26% of circulating T cells being CAR T cells (range: 11-59%). Expansion of CAR-T cells coincided with the complete depletion of circulating B cells. B cell aplasia lasted for a median of 120 days (range 58-205). All patients experienced drug-free remission as assessed by DORIS remission criteria and met lupus low activity state (LLDAS) usually within the first three months after CAR T cell therapy. Furthermore, seroconversion with loss of dsDNA antibodies and other autoantibodies was observed. To date, no SLE flare occurred despite complete cessation of treatment.

Conclusion: Taken together, these data suggest that CD19 CAR T cell therapy can abrogate disease and delete autoimmunity in patients with severe SLE. After CD19 CAR T-cell therapy SLE patients remain in drug free-remission of SLE even if B cells recur. This remission can be long-lasting as the longest disease -free observation period is now 22 months.

REFERENCES:
Background: Primary Sjögren’s syndrome (pSS) is a chronic systemic autoimmune disease characterized by B-cell hyperactivity. There are still currently no systemic treatments approved for pSS. Telitacicept (TACI-Fc fusion protein) is a novel BLYS (B-lymphocyte stimulator)/APRIL (a proliferation-inducing ligand) dual inhibitor, which has been approved in 2021 in China for the treatment of patients with active systemic lupus erythematosus (SLE) [1].

Objectives: To evaluate the efficacy and safety of telitacicept in patients with pSS.

Methods: In this phase 2, placebo-controlled study, 42 patients with active pSS (ESSDAI score ≥5) were randomized to 3 treatment arms: placebo (N=14), telitacicept 160 mg (N=14) and telitacicept 240 mg (N=14). Study drugs were administered subcutaneously weekly for 24 weeks. The primary endpoint was the change from baseline in the ESSDAI score at week 24. Key secondary endpoints included: ESSPRI, MFI-20, immunological biomarkers including IgG, IgA, IgM and CD19+ B cells.

Results: Baseline demographics and disease characteristics were similar among treatment arms. The ESSDAI score and MFI-20 score decreased from baseline through week 24 in telitacicept 160 mg and 240 mg groups (Figure 1A, 1B). Statistically significant improvements were observed for the ESSDAI score and MFI-20 score both at week 12 and week 24 in the telitacicept 240 mg group, while no statistically significant improvements were observed for the ESSDAI score at week 24 in the placebo group (Table 1). Telitacicept treatment produced rapid and sustained reductions in IgG, IgA, IgM and CD19+ B cells (Figure 1C-F). Incidences of treatment-emergent adverse events (TEAEs) were comparable across treatment arms. Most of TEAEs were mild to moderate in severity. Serious adverse events (SAEs) were infrequent and occurred in the placebo group. Upper respiratory tract infections were the most common infections. (Table 1)

Conclusion: Telitacicept showed clinical benefits and a favorable safety profile in patients with pSS.

REFERENCE:
Efficacy and Safety of Dazodalibep (VIB4920/HZN4920) in Subjects with Sjögren’s Syndrome: A Phase 2, Randomized, Double-Blind, Placebo-Controlled, Proof of Concept Study

Keywords: Safety, Randomized control trial, Sjögren syndrome

Background: Sjögren’s syndrome (SS) is a chronic, systemic autoimmune disease affecting exocrine glands, primarily the salivary and tear glands, with potentially severe manifestations in multiple organs. No approved disease-modifying therapies exist. Dazodalibep (DAZ) is a biologic antagonist of CD40L.

Objectives: The objective of this study was to evaluate the efficacy and safety of DAZ therapy in adult SS subjects with moderate-to-high systemic disease activity (NCT04129164).

Methods: We conducted a randomized, double-blind, placebo-controlled, cross-over study to evaluate DAZ therapy in adult SS subjects with moderate-to-high systemic disease activity, as defined by a EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) score ≥5. Eligible subjects were randomized: 1:1 to receive intravenous DAZ 1500 mg or placebo (PBO) Q2W x 3 doses, then Q4W x 4 additional doses. Starting on Day 169, subjects initially randomized to DAZ received PBO Q4W x 5 doses and subjects randomized to PBO received DAZ Q4W x 5 doses and were then followed for 12 weeks. The primary endpoint was the change from Baseline in ESSDAI at Day 169. Safety assessments included the incidence of adverse (AEs), serious AEs (SAEs), and AEs of special interest (AESIs).

Results: The 74 randomized subjects all received ≥1 dose of study medication (DAZ, N=36; PBO, N=38). The baseline demographics and disease characteristics were balanced between the two groups. The change from Baseline to Day 169 in ESSDAI score (LS mean ± SE), was -6.3 ± 0.6 in DAZ-treated subjects compared to -4.1 ± 0.6 in the PBO group, a difference of -2.2 (p = 0.0167). Compared to the PBO group, the DAZ group showed positive trends in the EULAR Sjögren’s Syndrome Patient Reported Index score, and Functional Assessment of Chronic Illness Therapy-Fatigue score at Day 169. A post-hoc responder analysis of subjects achieving high levels (5 and 6 points) of improvement on ESSDAI favored DAZ (61.1% and 60.0%) over PBO (35.1% and 34.3%). The reported AEs were generally mild through Day 169 and similar in frequency between treatment groups. The most frequently reported AEs occurring in ≥5% of DAZ-treated subjects and >PBO were COVID-19, diarrhea, dizziness, ligament sprain, upper respiratory tract infection, contusion, device allergy, fatigue, hypertension, and oropharyngeal pain. Two SAEs were reported in a single DAZ-treated subject: this subject was a 59-year-old female who experienced a grade 3 SAE of COVID-19 infection and later died of unknown cause 46 days after last administration of DAZ (12 days after COVID-19 diagnosis). There was a single AESI of herpes zoster in a DAZ-treated subject.

Conclusion: DAZ is a potential new therapy for the treatment of systemic disease activity in patients with SS. SS subjects with moderate-to-high systemic disease receiving DAZ experienced a statistically significant reduction in disease activity relative to PBO as measured by the improvement in ESSDAI score. Except for a case of severe COVID-19 infection, DAZ therapy in SS subjects appeared to be well tolerated. Larger controlled trials of DAZ therapy for SS are warranted to further explore its safety profile and confirm its clinical efficacy.

Association of Healthy lifestyles with All-Cause and Cause-Specific Mortality Among Individuals with Osteoarthritis: A Prospective Cohort Study of the UK Biobank

Keywords: Epidemiology, Osteoarthritis, Lifestyles
Background: Healthy lifestyles are thought to reduce the risk of multiple causes of mortality in general population. However, whether and to what kind of healthy lifestyles could offset the risk of multiple causes of mortality in patients with osteoarthritis (OA) are unknown.

Objectives: This study aimed to investigate the association of both individual and combined healthy lifestyle factors with the risk of all-cause and cause-specific mortality among participants with OA.

Methods: 104,142 OA participants were included from the UK Biobank (mean age 60±7.0). A summed healthy lifestyle score was constructed using body mass index (BMI) and self-reported diet, sleep duration, physical activity, sedentary time, social connection, smoking and alcohol drinking. Restricted cubic spline (RCS) and Cox proportional hazards models were used to examine the associations of individual factors and a combined healthy lifestyle score with the risk of all-cause and cause-specific mortality.

Results: During a median follow-up of 12.7 years, 9915 deaths after the first two years follow-up were recorded. Using RCS models, sleep duration had a U-shaped (with a nadir at 7 h/day), moderate physical activity (MPA) had an L-shaped (with a turning point at 550 min/week) and BMI and vigorous physical activity (VPA) had J-shaped (with turning points at 28 kg/m² and 240 min/week respectively) associations with all-cause mortality. In multivariable Cox models, each lifestyle factor was significantly associated with all-cause mortality, and hazard ratios (95%CI) for respiratory mortality, 0.27 (0.16-0.48) for digestive-cause mortality and 0.18 (0.12-0.25) for cardiovascular disease mortality, 0.27 (0.17-0.30) for digestive-cause mortality and 0.18 (0.12-0.25) for respiratory mortality.

Conclusion: This study introduced a healthy lifestyle pattern that could significantly reduce the risk of all-cause and cause-specific mortalities in OA patients.

DOI: 10.1136/annrheumdis-2023-eular.5560
4 of 7 healthy dietary components was defined as healthy diet. Medium level of physical activity (270–680 min/week) was classified as a healthy physical activity for OA. Healthy sleep behaviors were defined as sleep 7–8 h/day. Sedentary time less than 4 hours was regarded as low risk status. The healthy lifestyle score was constructed as the sum of five lifestyle factors, ranging from 0 to 5 and was subsequently categorized into three groups including unfavorable, intermediate, and favorable (0–1, 2–3, and 4–5). Genetic susceptibility was calculated by using polygenic risk score (PRS) of OA. Specifically, individual single nucleotide polymorphism (SNP) was coded as 0, 1, and 2 according to the number of risk alleles. The coefficient of significant SNPs of OA reported in previous Genome Wide Association Studies (GWAS) were regarded as weight of genotype of each SNPs. Participants with OA were identified as having a diagnosis using ICD-9 and ICD-10 codes for total/ knee/ hip OA, or were identified as self-reported total/ knee/ hip OA at baseline. Covariates included age, sex, household income, education, deprivation index, glucosamine use and comorbidities. Cox regression analyses were performed to examine the association of healthy lifestyle, genetic susceptibility and incident OA.

Results: Comparing to unfavorable lifestyle, favorable lifestyle was significantly associated with a lower risk of total OA across low, intermediate and high genetic risk groups (HR, 0.64; 95%CI, 0.58-0.70; HR, 0.59; 95%CI, 0.56-0.63 and HR, 0.58; 95%CI, 0.53-0.64, respectively). Favorable lifestyle was also significantly associated with lower risk of knee OA across low, intermediate and high genetic risk groups (HR, 0.40; 95%CI, 0.33-0.48, HR, 0.47; 95%CI, 0.42-0.51 and HR, 0.45; 95%CI, 0.39-0.53, respectively). For hip OA, adherence to favorable lifestyle was also significantly associated with lower risk of OA incidence across low, intermediate and high genetic risk groups (HR, 0.75; 95%CI, 0.62-0.92, HR, 0.65; 95%CI, 0.58-0.72 and HR, 0.75; 95%CI, 0.65-0.85, respectively), compared to unfavorable lifestyle. No significant interaction was detected between lifestyle and PRS for total/ knee/ hip OA.

Conclusion: These data suggest that healthier lifestyle is consistently associated with lower risk of OA, regardless of genetic risks. Our findings highlight the importance of adherence to an overall healthy lifestyle in attenuating the risk of OA.

GENETIC EVIDENCE REVEALS A CAUSAL RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND OSTEARTHRITIS

Keywords: Genetics/Epigenetics, Osteoarthritis

J. Y. Chen1, Q. Feng1, Q. Q. Ma2, H. Zhang3, Y. Feng1, X. Yang2, O. Dong2, Q. Ju1, P. F. He1, X. Li2, S. X. Zhang2, Shaxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microbiology, Taiyuan, China; 1Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China; 2Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China; 3The Second Hospital of Shaxi Medical University, Department of Rheumatology, Taiyuan, China

Background: Osteoarthritis (OA) is a common musculoskeletal disease [1]. Research evidence indicates that exercise can reduce OA patients’ joint pain to an extent [2]. However, the genetic causal relationship between physical activity (PA) and OA remains vague.

Objectives: In our study, Mendelian randomization (MR) was conducted to explore the causal association of PA and OA.

Methods: PA was divided into two different phenotypes, including sedentary behavior and physically active behavior. Genome-wide association study (GWAS) data for PA [3] was obtained from the UK Biobank. We selected single nucleotide polymorphisms (SNPs) that were strongly associated (p < 5 × 10⁻8) with two PA phenotypes and checked them on PhenoScanner removing SNPs associated with confounders. The OA data was derived from a GWAS among 455,221 individuals (77052 samples and 378169 controls) of European descent [4]. To assess the causality of PA on OA, inverse variance weighting (IVW), MR-Egger, and weighted median (WM), were employed. IVW was applied for the principal analysis. To ensure the robustness of our result, Cochran’s Q test, MR-Egger intercept test, and leave-one-out analysis were used to assess the sensitivity of the study.

Results: Among the tested sedentary behavior, the length of mobile phone use increases the risk of knee OA (odds ratio (OR):1.560, 95% confidence interval (CI):1.167-2.086, p=2.683x10-3) and hip or knee OA (OR:1.334, 95%CI:1.026-1.734, p=3.141x10-2). After removing SNPs associated with smoking, alcohol consumption, lymphocyte count, and heart disease, we also found evidence of a potential adverse effect of genetically predicted time spent watching television (TV) on knee OA (OR:1.913, CI:1.450-2.523, p=4.388x10-6) and hip or knee OA (OR:1.611, 95%CI:1.288-2.014, p=2.860x10-5). No potential causal link was observed between physically active behavior and OA through the IVW analysis (p>0.05). MR-Egger and WM yielded identical effects to IVW. Any potential heterogeneity or pleiotropy was not found.

Conclusion: Sedentary behavior can increase the risk of OA, but no direct causal relationship is observed between physically active behavior and OA. It indicates that OA patients should avoid a sedentary lifestyle.

Figure 1. Association between healthy lifestyle score and total/ knee/ hip osteoarthritis stratified by different levels of genetic risk. Abbreviation: OA, osteoarthritis; HR, hazard ratio. P for interaction: interactions between low genetic risk and low genetic risk group.
Overall structural defects and three individual structural features (i.e., joint space narrowing of the knee over 4 to 5 years of follow-up (OR 1.27 95% CI: 1.02 to 1.52), while former smokers were no different from never smokers (with differences in scores being 0.11 95% CI: -0.08 to 0.29 units; in contrast, former smokers had baseline scores 3.62 (95% CI 2.04 to 5.20) units, and 0.06 (95% CI: -0.08 to 0.20 units, respectively). In terms of structural defects, our cross-sectional analyses protected against KOA.

Conclusion: Current smoking may have negative effects on, and quitting smoking could be important in preventing or slowing, both the symptoms and structural defects of KOA in people with or at risk of KOA.

individuals. A recent study has linked these profiles to chronic postoperative pain after TKR but an in-depth analysis, as seen for neuropathic and widespread pain is needed to advance the field. Currently, no specific biomarkers have been identified, despite initiatives on focused molecular inflammatory mediators. In an attempt to advance the field, a comprehensive analysis of an extensive network of cytokines, chemokines, and growth factors could identify the role of low-grade inflammation in patients with OA and potentially stratify patients more prone to experiencing pain.

**Objectives:** This study aimed 1) to evaluate preoperative serum levels of 92 inflammatory biomarkers in KOA patients compared to healthy controls, 2) to investigate preoperative differences of inflammatory biomarkers within different subgroups of patients with KOA and link these subgroups to clinical pain before and after TKR surgery.

**Methods:** Blood samples from preoperative patients with KOA scheduled for TKR (n=200) and healthy participants (n=39) were collected. Centrifugation of the serum was frozen at -80°C until analysis. Serum samples were analyzed for inflammatory markers using the OLINK inflammation panel, which included 92 protein markers. Clinical pain was assessed using a Visual Analog Scale (VAS). Moreover, patients completed the Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire before and 12 months after TKR. Multivariate data analysis was performed to identify differences between patients and controls. Hierarchical cluster analysis (HCA) and Orthogonal Partial least squares discriminant analysis (OPLS-DA) was used for comparing groups (patients vs controls) and to identify subgroups within patients. T-tests were used to evaluate difference within the KOA cohort in terms of VAS and KOOS scores before and 12 months after TKR.

**Results:** Multivariate analysis showed that 12 proteins were differentially expressed between patients and controls (p<0.05). Hierarchical cluster and OPLS-DA analysis identified two patient subgroups (pat-1, n = 46; pat-2, n= 72) and 23 proteins were dysregulated comparing these two groups (p<0.01). Post-operative VAS and KOOS assessments were significantly different between the two subgroups (p<0.05).

**Conclusion:** The present study suggest a low-grade inflammation in patients with KOA when compared to healthy pain free subjects. Additionally, this study suggests that a high inflammatory subgroup for patients with KOA exist and this group is likely to have more clinical and worst function 12-months after TKR.

**LONG-TERM EFFECTIVENESS OF A LIFESTYLE PROGRAM FOR OSTEARTHRITIS: ONE-YEAR FOLLOW-UP OF THE “PLANTS FOR JOINTS” RANDOMIZED CLINICAL TRIAL**

**Keywords:** Osteoarthritis, Non-pharmacological interventions, Diet and Nutrition

C. Wagenant1,2, W. Walrabenstein1,2, M. Van der Leeden1,4,5, M. Gerritsen1, J. Twisk1, M. Van der Esch1, H. Van Middendorp5, P. Weijis3,3, D. Van Schaardenburg1,2, J. Reade, Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC, locatie AMC, Rheumatology & Immunology, Amsterdam, Netherlands; 3Amsterdam University of Applied Sciences, Department of Nutrition and Dietetics, Amsterdam, Netherlands; 4Amsterdam UMC, locatie AMC, Rehabilitation medicine, Amsterdam, Netherlands; 5Amsterdam Movement Sciences Research Institute, Movement Sciences, Amsterdam, Netherlands; 6Amsterdam UMC, locatie VUMc, Epidemiology and Data Science, Amsterdam, Netherlands; 7Amsterdam University of Applied Sciences, Faculty of Health, Amsterdam, Netherlands; 8Leiden University, Institute of Psychology, Health, Medical, & Neuropsychology unit, Leiden, Netherlands; 9Amsterdam UMC, locatie VUMc, Department of Nutrition and Dietetics, Amsterdam, Netherlands.

**Background:** The 16-week Plants for Joints (PFJ) multidisciplinary lifestyle program, based on a whole-food plant-based diet, physical activity, and stress management, significantly reduced The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score compared to usual care in patients with knee and/or hip osteoarthritis (OA) and metabolic syndrome.1,2

**Objectives:** To determine the long-term effectiveness of the PFJ program on pain, stiffness, and function in patients with OA.

**Methods:** In the PFJ randomized clinical trial, patients with knee and/or hip OA and metabolic syndrome were randomized to receive the PFJ program in addition to usual care, or the control group which received usual care. After this 16-week period the control group also received the PFJ program. After completion of the PFJ program all participants were followed-up for one year with biannual visits and 6 adherence-promoting webinars. Medication changes were assessed at one year as an “increase,” “stable,” or “decrease” compared to baseline. The primary outcome was pain, stiffness, and function assessed by the WOMAC. Secondary outcomes included anthropometric and metabolic markers. A paired sample T-Test was used to determine the significance of the difference in outcomes at the start of the intervention versus at 1-year follow-up.

**Results:** Of the 64 participants who completed the initial 16-week clinical trial 84% were female with a mean (SD) age of 63 (6) and body mass index of 33 (5) kg/m² at baseline. The 47 (73%) participants who completed the one-year follow-up had a slightly greater average change in WOMAC score (−11.4 vs. −11.0) weight (−5.3 vs. −3.7 kg), and CRP (−1.2 vs. −0.2 mg/l) compared to non-completers, but showed less improvement in HbA1c (−2.1 vs. −2.9 mmol/mol). After a decrease during the PFJ program, the WOMAC score increased slightly again in the year after the program, whereby a mean 8.8-point difference was still observed after one year for completed cases compared to baseline values (95% CI: 3.6 to 4.0; p< 0.01) (Figure 1). All components of the WOMAC remained significantly improved compared to before the program except for stiffness (Table 1). Of the 24 (38%) participants using pain medication at baseline, 11 (46%) were able to decrease the dosage or stop one or more medications. Pain medication was stable for 3 participants, and increased for 3, of which 1 newly started using medication. Furthermore, 3 (23%) and 6 (33%) participants decreased diabetes and cholesterol medication respectively while only 1 participant increased cholesterol medication. After the 1-year follow-up period weight and HbA1c remained significantly lower compared to baseline, although there was no longer a significant difference in CRP and LDL cholesterol.

**Conclusion:** The PFJ lifestyle program significantly decreased pain and improved function in patients with OA and metabolic syndrome and its effects were sustained until one year after program completion, with slightly less pain medication. Metabolic benefits found after the lifestyle intervention were partially sustained possibly indicating attenuated adherence to the lifestyle program in the 1-year follow-up.

DULOXETINE PLUS EXERCISE FOR KNEE OSTEOARTHRITIS AND DEPRESSION (DEKODE)

Keywords: Non-pharmacological interventions, Mental health, Comorbidities

A. Rathburn1, R. Mehta1, A. Ryan2, Y. Dong3, B. Beamer1, J. Golden1, J. Gallo1, M. Luborsky4, M. Shardell5, J. Peer6, M. Hochberg2, University of Maryland School of Medicine, Epidemiology and Public Health, Baltimore, United States of America; 1University of Maryland School of Medicine, Medicine, Baltimore, United States of America; 2University of Maryland School of Medicine, Psychiatry, Baltimore, United States of America; 3John Hopkins Bloomberg School of Public Health, Mental Health, Baltimore, United States of America; 4Wayne State University, Anthropology, Detroit, United States of America

Background: Depression is common in patients with knee OA, and clinical guidelines do not advise treating both conditions simultaneously. However, recent research recommends combining interventions that address symptoms of both conditions to maximize efficacy. Exercise improves patient ability, mood, and chronic pain and depression are barriers to physical activity in this population. Duloxetine is indicated to treat neuropathic pain and depression among knee OA patients and could serve as a therapeutic complement to exercise.

Objectives: To assess the feasibility of a 24-week, center-based, aerobic exercise program plus duloxetine to treat knee OA and depression.

Methods: Participants were recruited between August 2021 and November 2022 from the University of Maryland and VA Maryland Health Care Systems and study advertisements. Inclusion criteria were: English speaking; age 40 years or older; symptomatic knee OA satisfying ACR criteria; major depression according to the SCID-I (Structured Clinical Interview for DSM-V, ruing out history of bipolar disorder or psychotic symptoms; substance abuse disorder or suicidal ideation in the last year); no plans for knee surgery; and ability to walk on a treadmill. Exclusions included: exercising at least twice per week; taking duloxetine, antipsychotics, benzodiazepines, or opioid analgesics; cognitive impairment; comorbid preexercise exercise; and pregnant or lactating women. Participants began duloxetine (30 mg/day) as they started exercising, titrating up to a daily optimal dose of 60 mg/day. They were expected to complete 3 supervised treadmill walking sessions per week based on an individualized training plan defined by peak heart rate achieved during a graded exercise test. Data were collected at baseline and 12- and 24-weeks. Feasibility was evaluated via recruitment rates, reasons for drop out, and treatment adherence. Depression and pain severity were measured using the Hamilton Depression Rating Scale (HAM-D) and Knee Injury and Osteoarthritis Outcome Score (KOOS) pain subscale, respectively.

Results: Among 377 interested adults, 98 completed telephone pre-screening (Figure 1). Common reasons for not pre-screening included time commitment (n=39), no depression (n=27), concerns about medication (n=25), already on antidepressants (n=20), and knee surgery (n=12). There were 68 ineligible prescreened individuals who did not satisfy criteria for probable depression (n=45), medications (n=16), knee OA symptoms (n=5), or exercise (n=2). The 30 eligible candidates were invited to in-person screening visits, but 21 did not attend, and only 9 were enrolled. These 9 participants were older women (mean age=64.7 years), 8 identified as Black/African American, 7 attended and/or graduated from college, 3 were married, and 4 were retired. During the in-person screening process, 6 participants did not satisfy DSM-V criteria for major depression, 1 voluntarily withdrew from the study, and only 2 satisfied all eligibility criteria. One participant withdrew at baseline due to a non-study related adverse event and another completed the treatment protocol. The participant who completed the study was almost 100% adherent to duloxetine and experienced a reduction in depression severity from baseline to 24 weeks (HAM-D=25 to 1). By contrast, exercise compliance was low, with only 26% of planned sessions completed, and knee pain severity changed little from baseline (KOOS=41.7 to 44.4).

Conclusion: Treating knee OA and depression with a center-based exercise program and duloxetine had low feasibility. Critical design challenges amenable to change included the time commitment of 3 weekly supervised exercise sessions among interested individuals and depressive symptoms not satisfying diagnostic criteria for major depression for persons who wanted treatment. A hybrid or home-based exercise program plus duloxetine may be more feasible, and knee OA patients with depressive symptoms who are at risk for major depression could benefit from preventive intervention.

Crystal arthritis: what is new?

DIAGNOSTIC PERFORMANCE OF HIP ULTRASOUND IN CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

Keywords: Ultrasound, Validation, Crystal Arthritis

G. Soto1, S. Y. Solorzano Flores1, F. Carranza-Enriquez1, A. Angeles-Acuna1, P. Flores1, V. M. Ilizaliturri-Sanchez2, R. Pichardo3, L. J. Jara3, D. Clavijo-Correa2, G. Filippow2, C. Pineda3, Instituto Nacional de Rehabilitacion, Rheumatology, Mexico City, Mexico; 2Instituto Nacional de Rehabilitacion, Joint Replacement, Mexico City, Mexico; 3Instituto Nacional de Rehabilitacion, Pathology, Mexico City, Mexico; 4Luigi Sacco University Hospital, Rheumatology, Milan, Italy

Background: Calcium Pyrophosphate Deposition Disease (CPPD) is a chronic and potentially incapacitating disease. The reference standard for its diagnosis is the identification of calcium pyrophosphate (CPP) crystals in synovial fluid. Ultrasound (US) has been proven to be a high-sensitivity and specificity tool for diagnosing CPPD. Still, its diagnostic performance for hip joint involvement has yet to be determined.

Objectives: To evaluate the diagnostic performance of US compared with synovial fluid analysis and histopathology (hyaline cartilage, fibrocartilage, synovial membrane) for the identification of hip CPP deposits.
Methods: We included patients older than 50 years with osteoarthritis pro-
grammed for hip replacement surgery in a tertiary referral hospital. Patients
with an inflammatory or autoimmune rheumatologic disease were excluded. A
pre-surgical US of the affected hip was performed with a LOGIQ™8s device and
a convex transducer (2-5 MHz); the anatomical structures evaluated were the
acetabular fibrocortilage (FC) and the hyaline cartilage of the femoral head (HC),
video tracking was recorded and a dichotomic score was assigned to determine
the presence or absence of CPP deposits (in line with OMERACT definitions).
During surgery, a sample of hip synovial fluid was obtained and examined using
polarized light microscopy. After surgery, an experimental pathologist examined
the FC and HC for CPP crystals.

Results: One hundred patients were included. 54% women with a mean age of
64.8±8.5 years. All patients had advanced osteoarthritis (Kellgren-Lawrence 3 =
33 and Kellgren-Lawrence 4=67, Tönnis 2=34 and Tönnis 6=66). A frequency of
62% CPP deposits was found through US examination, of which 19.4% were
found on FC, 48.8% on HC, and 33.8% in both. Regarding pathology evaluation,
a prevalence of 61% of CPP crystals was found; 13.1% were found on FC, 9.8% were
found on HC, and 77.1% were found in both. 33% of patients had synovial
effusion and 9% had synovial hypervascularity. Synovial fluid was obtained in 62%
of patients, with a median volume of 8.0 ml (IQR 0.5-15.0 ml), and CPP
crystals were found in 19.4% (12/62) of samples. Chondrocalcinosis in XR was found in
10%. A sensitivity of 90% and a specificity of 82% were obtained, the positive
predictive value was 89%, and the negative predictive value was 84%. The area
under the curve for the US compared with histopathology for the diagnosis of hip
CPPD was 0.86 (CI 95% 0.78-0.94) (Figure 1).

Conclusion: US is a valid imaging method with good diagnostic performance for
diagnosing CPPD in the hip joint.

Evaluation of the pain-onset to-peak pain (>48 hours) and Visual Analogue Scale for pain at rest >6/10
Tophi and Carotid Plaque were Risk Factors of MACE in Gouty Arthritis Patients: A Longitudinal Cohort Study

Y. Wang¹, Z. Zhang¹, ¹First Hospital of Peking University, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Patients with gout carry an excess risk for cardiovascular disease (CVD). However, the prevalence of subclinical atherosclerosis and its relationship with CVD risks and events in gout have not been reported.

Objectives: The objective of this study is to explore whether tophi and subclinical atherosclerosis could predict incident MACE (major adverse cardiac events) in gouty arthritis patients by ultrasonography. Determine whether incorporation of imaging data could improve CV(cardiovascular) risk prediction.

Methods: A single-center, cohort analysis was performed to assess subclinical atherosclerosis at baseline since 2008. Patients were excluded if they had previous diagnosed CVD or cerebral vascular disease. The outcome of study was first MACE. The presence of subclinical atherosclerosis was assessed by carotid intima-media thickness (CIMT) and total plaque area (TPA) was determined in a subgroup of patients by ultrasound. Scan of feet and ankles was performed bilaterally by ultrasonography at baseline. The association between tophi, measurements of carotid atherosclerosis and risk of developing and incident MACE was evaluated using Cox proportional hazards models, with adjustment for the CVD risk scores.

Results: A total of 262 consecutive patients with primary gout were recruited, the mean age was 44.0 years; male 260 (99.2%). After a median follow-up of 10.3 years, 32 (12.2%) had incident MACE ascertained. Cox analysis showed that more than 2 tophi was significantly associated with an increased risk of developing MACE (HR: 9.96, 95%CI 8.89-43.6, P=0.001). The association remained significant after adjusting for CV risk scores in the multivariable models. In subgroup analysis, 240 patients had carotid ultrasound assessment, 28 (11.7%) patients experienced a first MACE event. In cox hazards model, which controlled for the CV risk scores, more than 2 tophi (HR 2.12-5.25, P<0.05) and carotid plaque (HR 3.72-4.01, P<0.05), were both independent predictor of incident MACE in patients with gout separately.

Conclusion: The presence of more than 2 tophi and carotid plaque by ultrasound could independently predict MACE in addition to conventional cardiovascular risk factors in gout patients.

REFERENCES:
Objectives: The aim of this retrospective analysis was to evaluate 1) possible correlations of CV MSU deposits with clinical gout diagnosis 2) the impact of CV MSU deposits on major CV events (MACE) in gout patients.

Methods: All patients, recruited at the radiology department of medical university Innsbruck with clinically suspicion of gout, performed dual energy computed tomography (DECT) of the affected limb and thorax between 01.05.2012 and 01.09.2019. Clinical and laboratory parameters were retrieved from patients’ charts. Classical CV risk factors (diabetes mellitus, smoking status, hypercholesterolemia, arterial hypertension) were evaluated. Medical history review identified the presence of MACE, defined as myocardial infarction and/or stroke. Patients were stratified in gout, hyperuricemia and controls. Gout was defined according to the ACR/EULAR classification criteria [4], uric acid levels over 6mg/dl or ongoing uric acid lowering treatment without clinical signs of gout specified hyperuricemia patients and control group definition was achieved when uric acid levels were normal without concomitant uric acid lowering therapy and absence of gout symptoms. We performed the y2- and Mann-Whitney tests for statistical appraisal of our dataset, using IBM SPSS (version 27). P <.05 was used as the cut-off for statistical significance.

Results: Overall, full data sets were available for 189 patients. Out of those, 131 (69.3%) revealed a clinical diagnosis of gout, 50 (38.2%) of these were tophaceous. 35 patients (17.5%) had hyperuricemia and 23 (12.2%) had neither gout nor elevated uric acid levels. Patients with CV MSU deposits (n=65/189, 45%), 62 gout patients, 19 hyperuricemia patients, 4 control patients) revealed higher acute phase reactants [C-reactive protein (p=0,001), erythrocyte sedimentation rate (p=0,007)], uric acid levels (p=0,007) and calcium scores (p<0,001) in comparison to patients without CV MSU deposits. MACE were observed in 35 patients (18.5%) with a higher prevalence in those patients revealing CV MSU deposits (n=22/85, 25.9%) compared to those without CV MSU (n=13/104, 12.5%) (p=0,022). All 22 patients with MACE and CV MSU were gout or hyperuricemia patients (Figure 1).

Conclusion: To our knowledge, this is the first evaluation of clinical features of patients revealing CV MSU deposits detected by DECT. The higher prevalence of MACE in patients with CV MSU deposits may help for risk stratification of gout patients, as classical CV risk scores or laboratory markers fail to identify patients at risk.

OP0156 INITIATION OF SODIUM-GLOUCOSE COTRANSPORTER-2 INHIBITORS AND RECURRENT GOUT FLARES IN GOUT PATIENTS WITH TYPE 2 DIABETES: A GENERAL POPULATION-BASED COHORT STUDY

Keywords: Epidemiology, Cardiovascular disease, Gout

N. Mccormick1,2,3, C. Yokose1,3, J. Wei4, L. Lu5, D. Wexler5,6, J. A. Aviña-Zubieta1,3, M. De Vera1,2, Y. Zhang7,8, H. Choo1,2,3, 1Massachusetts General Hospital, Clinical Epidemiology Program, Boston, United States of America; 2Arthritis Research Canada, n/a, Vancouver, Canada; 3Harvard Medical School, Medicine, Boston, United States of America; 4Xiangya Hospital, Health Management Center, Shan Nan Shi, China; 5Massachusetts General Hospital, Diabetes Center, Boston, United States of America; 6The University of British Columbia, Division of Rheumatology, Vancouver, Canada; 7The University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada

Background: Gout flares may increase risk of cardiovascular events[1] Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are associated with lower risk of incident gout (primary prevention); however, their role in recurrent flares among gout patients (secondary prevention), and their cardiovascular risk remains unknown.

Objectives: To assess rate of recurrent gout flares in prevalent gout patients with type 2 diabetes initiating SGLT2i versus dipeptidyl peptidase-4 inhibitors (DPP4i), two second-line glucose-lowering agents for type 2 diabetes.

Methods: This new-user, active comparator cohort study used administrative health data covering nearly all residents of British Columbia, Canada from Jan 2014 to June 2022, including all dispensed prescriptions, regardless of funder. Primary outcome was recurrent gout flare counts, ascertained by emergency department (ED), hospitalization, outpatient, and medication dispensing matching. Results were consistent regardless of sex or age (Table 1). RR was also consistent regardless of baseline gout intensity or diuretic or ULT use. Myocardial infarction and stroke were secondary outcomes. We also assessed genital infection as positive control and osteoarthritis as negative control. Poisson and Cox proportional hazards models were used with 1:1 propensity matching.

Results: We included 8150 gout patients with type 2 diabetes (mean age 66, 71% male, 59% with cardiovascular disease). Flare rate was lower among SGLT2i initiators (52.4 events per 1000 person-years) than DPP4i initiators (79.7 events per 1000 person-years): rate ratio (RR) 0.66 (95% CI: 0.57, 0.75) and rate difference (RD) -27.4 (-36.0, -18.7). RR and RD for flares requiring hospitalization or ED visit were 0.52 (0.32, 0.84) and -3.4 (-5.8, -0.9), respectively. Results were consistent regardless of sex or age (Table 1). RR was also consistent regardless of baseline gout intensity or diuretic or ULT use, though absolute RD was higher in patients with greater gout intensity: -71.6 [-111.1, -32.1] vs. 20.8 [-28.8, -12.7] per 1000 person-years, respectively. Hazard ratio (HR) and RD were 0.69 (0.54, 0.88) and -7.6 (-12.4, -2.8) per 1000 person-years for myocardial infarction; HR, 0.81 (0.62, 1.05) for stroke. For control outcomes, SGLT2i initiators had higher risk of genital infection, while there was no difference in risk of osteoarthritis (Table 1).

Conclusion: For gout patients, SGLT2i may offer pleiotropic cardiovascular and recurrent flare frequency benefits.

Disclosure of Interests: None declared.

Background: Background: Gout affects 1-4% of the population in the industrialized world. Increased levels of serum urate is the strongest risk factor and "path variable" for gout development. Parkinson's disease (PD) is the second most common neurodegenerative disease in the world affecting 1% of the population over the age 60 in North America and Western Europe. A reduced risk of PD has been reported in association with smoking, caffeine consumption and higher serum urate levels.

Objectives: To determine the incidence of PD in all patients with gout compared to matched controls in the region of western Sweden (VGR).

Methods: All incident and prevalent gout cases from 2001 through 2019 were identified in the health care consumption database VEGA covering all health care in VGR. A case of gout was defined as having received a diagnosis of gout (M10) from a physician. Up to 5 controls from the census register were included matched by age, gender and municipality at year of first gout diagnosis (index-year). A case of PD was defined as having been given a diagnosis of PD (G20.9) at a visit to a physician. A PD diagnosis in the index-year and the 1 to 19 years before was considered prevalent in cases and controls and they were censored from the study. Cases and controls were followed until first of; end of study (2019-12-31), incident PD diagnosis, migration or death. Data on comorbidities at baseline/indexyear were retrieved from VEGA and information on education, death and migration were retrieved from registers at the National Board of Health and Welfare. Effect of gout on risk of PD was calculated using time dependent COX regression on whole population and stratified by sex, adjusted for age, sex, educational level, risk factors for gout (diabetes, obesity, chronic kidney disease (CKD)) and PD (cerebrovascular disease (CeVD), chronic obstructive pulmonary disease (COPD) as a proxy for smoking and malignant melanoma (MM)).

Results: We identified 48907 cases of gout (67% male) and 198717 (65% male) matched controls with a mean (SD) age of 68 (15) and 67 (15) respectively. In the case population we found 5035 prevalent cases of PD compared to 2205 in the controls (prevalence ratio = 0.91 (95% CI:0.87-0.94)). They were all removed from further analysis. All comorbidities, (hypertension, ischemic heart disease, heart failure, CeVD, diabetes, dyslipidemia, obesity, CKD, COPD, and MM were significantly more common in the gout cases vs controls. During a median follow-up time of 5.8 years we identified 364 (0.7%) incident cases of PD in the gout population compared to 1965 (1.0%) in the controls. Adjusting for only age and sex in time dependent COX regression, (Model 1) the relative risk reduction in gout patients for incident PD overall was 25% (HR 0.75; 95% CI:0.70-0.84). In age-adjusted models stratified by sex results were similar, HR 0.77 (95% CI:0.68-0.87) for men and HR = 0.69 (95% CI:0.54-0.87) for women. Adjusting also for known risk factors for gout and PD gave similar point estimates (model 2, Table 1).

Conclusion: Gout is associated with a significant risk reduction for incident PD. This may have implications for management of urate lowering therapy in persons with increased risk for PD and for the understanding of PD pathogenesis.

Table 2. Recurrent gout flare count and cardiovascular and control outcomes among gout patients with type 2 diabetes, after propensity-score matching

| Subgroups | Sex | Men | Women | Age | ≤ 65 years | > 65 years | Baseline diuretic use | Yes | No | Baseline urate-lowering therapy use | Yes | No | Baseline gout intensity | Higher | Lower | Cardiovascular Outcomes | Hazard Ratio (95% CI) | Risk Difference (95% CI) | Myocardial infarction | 0.69 (0.54, 0.88) | -7.6 (-12.4, -2.8) | Stroke | 0.81 (0.62, 1.10) | -3.9 (-8.3, 0.4) | Control Outcomes | Hazard Ratio (95% CI) | Risk Difference (95% CI) | Genital infection (POSITIVE) | 2.15 (1.39, 3.30) | 5.0 (2.2, 7.9) | Osteoarthritis (NEGATIVE) | 1.07 (0.95, 1.20) | 4.4 (-6.8, 15.7)
**Background:** Gout is the most common inflammatory arthritis worldwide (1) and disease flares are triggered by the deposition of monosodium urate (MSU) crystals in and around the joints as a result of oversaturation of uric acid (urate) in the bloodstream. Macrophages phagocytose the crystals, leading to inflammasome activation and production of proinflammatory cytokines, mainly IL-1β. Neutrophils are recruited to the gouty inflamed site where they phagocytose the crystals, produce reactive oxygen species (ROS) and cast out neutrophil extracellular traps (NETs), the latter proposed to possess both pro- and anti-inflammatory properties in gout (2, 3). Gout patients have an increased risk for cardiovascular disease (4), and it is a paradox that uric acid, the major risk factor for gout and known to possess antioxidative properties, correlates with conditions associated with oxidative stress, such as cardiovascular disease. How urate levels in circulation affects neutrophil ROS production is unclear.

**Objectives:** To investigate whether peripheral neutrophils from gout patients respond to MSU crystals similarly as neutrophils form healthy controls.

**Methods:** Patients with polyarticular gout, diagnosed by a rheumatologist and identified at the Rheumatology Unit at Sahlgrenska University hospital and matched controls were included in the study. Peripheral blood from patients and controls were collected. Circulating blood neutrophils were isolated and intracellular ROS production was detected with luminol-amplified chemiluminescence. Quantification of NET Formation was performed by a fluorescence assay. Expression of surface markers was assessed by flow cytometry (5).

**Results:** MSU crystals stimulated neutrophils from gout patients to produce intracellular ROS and the response in neutrophils from gout patients was significantly higher as compared to the ROS response in control neutrophils. Neutrophils derived from gout patients were not primed with regard to cell surface markers and NET formation.

**Conclusion:** Blood neutrophils from gout patients display increased ROS responses both at baseline and upon MSU crystal stimulation. It is possible that small circulating MSU crystals in peripheral blood of gout patients increase neutrophil responsiveness and give rise to the enhanced background activity seen in our ROS experiments. Another explanation could be that pro-inflammatory cytokines in the bloodstream of patients with gout prime neutrophils to produce increased amounts of ROS.

New Insights in the care and management of JIA

SUPPORTING CHILDREN AND YOUNG PEOPLE WITH JUVENILE IDIOPATHIC ARTHRITIS IN SCHOOLS, COLLEGES AND OTHER EDUCATIONAL SETTINGS THROUGH SCHOOL TOOLKITS

Keywords: Patient-led research, Education, Patient information and education

R. Beesley1, R. Beesley2,1. Juvenile Arthritis Research, JAR Project, Tonbridge, United Kingdom;2 European Network for Children with Arthritis, ENCA, Geneva, Switzerland

Background: Juvenile Idiopathic Arthritis (JIA) is a heterogenous group of autoimmune disorders characterised by chronic joint inflammation, affecting children and young people (CYP) under the age of 16. CYP with JIA experience considerable physical and psychological impacts due to their condition. CYP spend a considerable amount of time at school, college or other educational settings. Whilst most CYP with JIA are able to access education, many require adaptations, awareness of their needs, or specific support to enable them to fully engage in learning. Families of CYP with JIA have reported a lack of awareness and understanding, and requested resources to enable schools to support their children in school.

Objectives: The aim of this work was to develop a School Toolkit to allow teachers and other school staff to confidently support CYP with JIA, and to assess its initial rollout.

Methods: Using a network of parents of CYP with JIA, including those with experience in working in educational settings, UK-based charity Juvenile Arthritis Research developed a resource aimed at schools, colleges, pre-schools and other educational settings: a Toolkit of information and resources. Given awareness of childhood arthritis is low, the Toolkit includes awareness-raising resources, aimed both at staff and all families connected to the school. Increased awareness can help improve diagnosis times and timely access to treatment in those not yet diagnosed. In addition, the Toolkit contains information about what JIA is, resources for schools to provide targeted interventions, and information on how schools can successfully support CYP with JIA. Finally, each Toolkit contains both a presentation for explaining arthritis to children in a classroom or group assembly setting, and a training presentation for delivery to staff, as well as digital copies of key materials and awareness-raising resources for distribution to parents and families. Recipients were invited to complete a short web-based survey to review the Toolkit.

Results: In the first six months after launching the new School Toolkit, around 100 Toolkits have been sent to schools in the UK, potentially providing information that arthritis affects children to over 100,000 families. Schools have advised they are using the resources in their settings, including giving lessons to children to explain what arthritis is, putting up posters highlighting the key signs and symptoms of JIA, and utilising the staff training resources. Feedback from schools was entirely positive, with one teacher reporting “Wow- it’s fantastic. The student presentation is particularly impressive with how it translates all the key information in a child-friendly manner.”

Conclusion: The development and supply of a Toolkit specifically for use in schools and colleges has helped raise awareness that children get arthritis, and provided resources to train and support school staff enabling them to confidently support CYP with JIA. Utilising the experience and skills of parents and teachers in the development of the Toolkit has ensured all resources are relevant and address the needs of both families and schools. Toolkits can be requested free of charge by schools in the UK from www.jarproject.org/toolkit.

Acknowledgements: Thanks to the children, young people, families and schools involved in the development of this vital resource.

Objectives: To evaluate 24-month effectiveness and tolerability/safety of tocilizumab (TCZ) versus tumour necrosis factor inhibitor (TNFi), analysing predictors of JADAS remission and minimal disease activity (MDA), comparing 1st and 2nd line TCZ.

Methods: BIKER WA 29358 is a 5-year multi-centre prospective, observational cohort study including polyarticular juvenile idiopathic arthritis (JIA) patients in Germany starting treatment between 2015 and 2020 with TCZ and matched patients starting an approved TNFi such as etanercept, adalimumab or golimumab. Clinical disease activity (JADAS), JADAS MDA/remission at 24 months, safety and drug adherence were assessed and compared between cohorts.

Results: The analysis set consisted of 342 participants with 24-month treatment data (TCZ, n=171; TNFi, n=171) (Table 1). Therefore, patients starting on TCZ were older and had a longer disease duration compared to TNFi patients. Efficiency was demonstrated by a marked and comparable decrease of the JADAS10 in both TCZ and TNFi from 14.6+/−6.6 and 14.6+/−6.2 at baseline to 2.5+/−3.4 and 2.7+/−3.6 at month 24. TCZ was used as 2nd line biologic in the majority of patients (84%) while TNFi were mostly 1st line biologics (86%). In the last observation carried forward analysis, at 24 month JADAS remission upon TCZ: TNFi treatment was achieved by 84.6%/78.9% in 1st line biologic users and 82.3%/66.7% in 2nd line users. JADAS MDA was achieved in 100%/89.7% in 1st line and 84.4%/91.7% in 2nd line users of TCZ/TNFi. After 24 months of treatment residual disease activity as measured by the JADAS10 (mean ±SD) was lower in the 1st line TCZ cohort compared to the 2nd line (1.0+/−1.2 vs. 2.7+/−3.8), while in the TNFi cohort residual JADAS10 was comparable in 1st or 2nd line (2.7+/−3.8 vs. 2.5+/−2.6). Safety was assessed based on adverse events reporting. 113 (66%) patients in the TCZ cohort and 105 (61%) patients in the TNFi cohort reported adverse events with a higher rate in the TCZ cohort (89 vs. 73/100 patient years (PY), RR 1.2 (95%CI 1.0-1.5), p=0.029, Wald-test) as well as the rate of serious adverse events (10 vs. 3/100 PY; p=0.045). Cytopenias were more common in the TCZ cohort (13 vs. 1; p=0.010) and injection site reactions were more common in the TNFi cohort (15 vs. 6/100 PY; p=0.089). There was no case of death and no opportunistic infection. In the TCZ/TNFi cohorts, 71 (42%)/72 (42%) patients discontinued treatment, 43/30 due to lack of efficacy, 14/22 due to remission and 7/6 due to intolerance, respectively.

Conclusion: In this interim analysis, treatment targets were reached with similar frequency after 24 months of treatment with TCZ or TNFi. TCZ was used predominantly as 2nd line biologic. Higher rates of remission and minimal disease activity were observed in 1st line compared to 2nd line TCZ users. More adverse events were reported in the TCZ cohort but no new safety signals were noted. Observation is ongoing.

</table>
RESULTS: Of the 6,097 joints studied, 15% (897) was clinically inflamed at baseline. In 42% (377/897) of those joints, inflammation recurred during follow-up. Joint inflammation at baseline and recurrence of inflammation during follow-up within the three included JIA categories is depicted in Figure 1. Of the joints that became inflamed after the patient had a period of inactive disease, 93% (1,195/1,280) had been previously inflamed. Joint inflammation at baseline was statistically significantly associated with joint inflammation in the same joint during follow-up (OR 3.9, 95% CI 3.5 to 4.4). The association was found in all included JIA categories, although to a different extent (Table 1). Baseline inflammation of a joint was also positively associated with the number of episodes of recurrent joint inflammation in that same joint (IRR 1.6, 95% CI 1.2 to 2.1). The permutation test showed that inflammation during follow-up in a certain joint was better predicted by baseline inflammation of the same joint, than by baseline inflammation of randomly selected other joints (p<0.001), confirming a local effect. No statistically significant association was found between joint inflammation in the wrist and local radiographic damage (p 0.17, 95% CI -0.06 to 0.41).

OP0162 PATTERNS OF CLINICAL JOINT INFLAMMATION IN JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Inflammatory arthritides, Treat to target

S. L. Heckert1, P. C. E. Hissink Muller2, J. M. Van den Berg3, D. Schonenberg-Meinema4, L. W. A. Van Suijlekom-Smit5, M. Van Rossum6,7, Y. Koopman-Keemink8, R. Ten Cate8, D. M. C. Brinkman8, T. Huizinga1, C. Allaart1, S. A. Bergstra1,1. Background: Juvenile idiopathic arthritis (JIA) often has a relapsing/remitting disease course, but it is not known whether recurrence of inflammation tends to be local.

Objectives: To assess whether JIA joint inflammation recurs locally in the same joints.

Methods: Joints of 91 patients of the BeSt for Kids study, a treat-to-target trial with children on recent-onset oligoarthritis (n=11), rheumatoid factor negative polyclanar (n=72) and juvenile psoriatic JIA (n=8), were clinically assessed during two years (10 study visits). The association between joint inflammation at baseline and later inflammation in the same joint was assessed using a multilevel mixed-effects logistic regression model at joint level, adjusted for joint location and time point. With a Poisson model, the association between baseline joint inflammation and the number of study visits at which the same joint was recurrently inflamed (after inactivity of the joint) was tested. To assess whether an association between baseline and later clinical joint inflammation was a specific within-joint association, a permutation test was performed. A statistically significant result (p<0.05) indicates that the association between baseline and later joint inflammation is stronger in the observed data than in permutations with comparisons across random joints, suggesting an effect at joint level. To assess whether joint inflammation (ever during follow-up) was associated with radiographic damage (Poznanski Z-score) in the same (wrist) joint, a generalized linear mixed model was used.

Conclusion: In JIA, joint inflammation has the tendency to recur multiple times in joints that are clinically inflamed at disease onset. This indicates that local factors might play a role in the processes contributing to JIA flares. These local factors might be a target for new therapies.

Patients with uveitis flare events with preexisting JADAS10 from 10.7 (±6.5) (baseline) to 4.4 (±5.0) at 24 months. By 24 months, a lower baseline disease activity and less concomitant systemic steroids use (Table 1). The clinical benefits of GOL in pJIA is highlighted by a decrease of the mean JADAS 10 from 10.7 (±6.5) at baseline to 4.4 (±5.0) at 24 months. By 24 months, a JADAS 10 minimal disease activity (JADAS 10 ≤3.8) was reached by 50.0% of patients, whereas 34.2 % of patients were in remission (JADAS 10 ≤1) at the end of the study. The efficacy of GOL in this indication are limited.

Rheumatoid factor (RF), biologic disease modifying antirheumatic drug (bDMARD), childhood health assessment questionnaire disability index (CHAQ DI), juvenile arthritis disease activity index (JADAS), adverse event (AE), patient year (PY), n (%) at baseline, # mean±SD at baseline, ## mean±SD, * n, AE rate/100PY (95% CI), + n (of n patients).

Background: Novel treatment options are needed for pediatric patients with polyarticular-course juvenile idiopathic arthritis (pJIA). Upadacitinib (UPA) is an oral, selective Janus kinase (JAK) inhibitor with a positive benefit-risk profile in adult patients with moderate-to-severe active rheumatoid arthritis.[1,2]

Objectives: To evaluate the safety and efficacy of UPA in pediatric patients with pJIA.

Methods: This open-label, 3-part, phase 1 trial (NCT03725007) enrolled pediatric patients aged 2 to < 18 years with pJIA and ≥ 5 active joints at 31 sites across North America, Europe, and Asia. UPA was dosed as a twice-daily oral, selective Janus kinase (JAK) inhibitor with a positive benefit-risk profile in adult patients with moderate-to-severe active rheumatoid arthritis[1,2]

Rheumatoid factor (RF), biologic disease modifying antirheumatic drug (bDMARD), childhood health assessment questionnaire disability index (CHAQ DI), juvenile arthritis disease activity index (JADAS), adverse event (AE), patient year (PY), n (%) at baseline, # mean±SD at baseline, ## mean±SD, * n, AE rate/100PY (95% CI), + n (of n patients).

Proposed trial endpoints included the JIA American College of Rheumatology (JIA ACR) 30, 50, and 70 response; the Childhood Health Assessment Questionnaire (C-CHAQ); and the 27-point Juvenile Arthritis Disease Activity Score based on C-reactive Protein (JADAS27 [CRP]).

Results: A total of 57 pediatric patients (78.9% female) with mean (SD) age of 9.5 (4.4) years and mean (SD) weight of 38.1 (20.4) kg received UPA; of these, 51 patients were treated in parts 1 and 2. In part 1, 8 (15.7%) of 51
patients reported adverse events (AEs) through 7 days; no patients reported serious AEs or AEs leading to treatment discontinuation. At a mean (median) duration of exposure of 514.9 (412.0) days, 52 (91.2%) of 57 patients reported AEs that were predominately mild to moderate in severity (Table 1). The most common treatment-emergent AEs were COVID-19 infection (n = 23/57, 40.4%), upper respiratory tract infection (n = 23/57, 40.4%), nasopharyngitis (n = 13/57, 22.8%), gastroenteritis (n = 10/57, 17.5%), pyrexia (n = 10/57, 17.5%), abdominal pain (n = 8/57, 15.8%), and nausea (n = 8/57, 14.0%). The most common AEs of special interest included elevated creatine phosphokinase levels (n = 6/57, 10.5%), hepatic disorder (n = 3/57, 5.3%), and neutropenia (n = 2/57, 3.5%); all were nonserious events. Six (31.6%) of 19 patients in the group aged 12 to <18 years reported serious AEs and 2 (10.5%) reported AEs leading to treatment discontinuation. A high proportion of patients across all age groups achieved JIA ACR30, 50, and 70 at response at week 12 (Figure 1). Improvement from baseline to week 12 in C-HAQ and JADAS-27 (CRP) scores was observed across all age groups.

**Conclusion:** In pediatric patients with pcJIA, UPA was well tolerated and associated with improvements in disease activity and physical function at week 12.

Background: The EULAR task force “Implementation of a mobile health app for the self-management of juvenile-onset rheumatic and musculoskeletal diseases (jRMDs) during transitional care” aims at designing, developing and implementing a self-management program through a smartphone app (i.e., the EULAR Move-Up app). The first step of this task force was to adapt the current EULAR recommendations/points originally developed for adults, to young people (YP) with jRMDs.

Objectives: Adapting EULAR recommendations/points for patient education, pain management and physical activity for self-management of jRMDs during transitional care.

Methods: A multidisciplinary taskforce of 25 members from 11 European countries was convened. Using a Delphi technique, the level of agreement was established by anonymous online voting in three rounds.

Results: Four overarching principles and 8 points to consider were formulated (Table 1). The agreement was high, ranging from 8.7 to 9.9.

Conclusion: This work will feed into an evidence-based framework to inform the development of the EULAR Move-Up app aiming at improving the quality of transitional care of jRMDs.

Table 1. Overarching principles and points to consider for the self-management of juvenile-onset rheumatic and musculoskeletal diseases during transitional care

<table>
<thead>
<tr>
<th>Overarching principle</th>
<th>Agreement (0 to 10)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1YP with jRMDs should be offered education, physical activity advice and pain management recommendations; and provided with access to relevant resources during transitional care, as soon as possible following the diagnosis</td>
<td>9.6</td>
</tr>
<tr>
<td>2Health professionals in rheumatology should consider the use of digital health interventions in transitional care to support self-management</td>
<td>9.5</td>
</tr>
<tr>
<td>3The content and delivery of transitional care should be individually tailored and needs-based according to the patients’ priorities, preferences, capabilities and resources</td>
<td>9.6</td>
</tr>
<tr>
<td>4Transitional care interventions should have clear personalised aims, which should be evaluated over time, preferably by a combination of objective and subjective (patient-reported outcome measures) assessments</td>
<td>9.9</td>
</tr>
</tbody>
</table>

Adapted points to consider in education

1Education is a planned interactive learning process designed to support and enable YP with jRMDs to manage their health and chronic condition, and optimise their health and well-being during transitional care

2Education should consist of a variety of learning formats and the programme should be designed through a shared decision-making process

3Education should include the evaluation of outcomes reflecting both the knowledge acquired and, most importantly, translation to behaviour change

Adapted points to consider in pain management

4All patients and their carers should be offered education on the importance of maintaining healthy body composition and explained that unhealthy body composition could contribute to pain and disability

5Non-pharmacological approaches (e.g., physical activity, lifestyle change, psychological interventions) should be prioritised in newly-diagnosed patients and those in transitional care. It is indicated, the patient should receive pharmacological treatment according to the most recent recommendations

Adapted points to consider on physical activity

6Physical activity is part of a healthy lifestyle and should be optimised during the lifespan of individuals of all ages

7Physical activity has health benefits for YP with jRMDs during transitional care and helps establishing healthy behaviours and lifestyles during adulthood

8Healthcare providers should consider different formats of delivery of physical activity, in line with YP’s preferences and disease requirements

YP = Young people; jRMDs = juvenile-onset rheumatic and musculoskeletal diseases.

Advances in imaging in rheumatic musculoskeletal disorders.

Keywords: Ultrasound, Imaging, Sjögren syndrome

W.K. Huang1, Y. Hao2, Z. M. Ouyang, X. H. Chen1, W. J. Yang1, J. S. Chen3, L. Dai1, Y. Ma2,3,4, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Rheumatology, Guangzhou, China; Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Ultrasound, Guangzhou, China; Shenshan Medical Center, Memorial Hospital of Sun Yat-sen University, Rheumatology, Shenzhen, China

Background: Salivary gland ultrasonography (SGUS) is promising on diagnosis and disease monitoring of primary Sjögren’s syndrome (pSS). However, there is neither study concerning the association between SGUS and salivary function in pSS.

Objectives: This study aimed to explore how SGUS features reflected the secretory function of salivary glands in pSS.

Methods: The subjects who presented with ocular dryness and/or oral dryness were recruited from rom July 2021 to July 2022 at our department. The subjects were classified as pSS and non-SS according to the 2002 American-European Consensus Group (AECG) criteria for pSS. Unstimulated whole salivary flow (UWSF) and stimulated whole salivary flow (SWSF) were assessed to evaluate salivary function. SGUS was performed to bilateral parotid and submandibular glands. Each gland was assessed by a well-accepted 0–4 scoring system (gland score) and a 0–3 scoring system from the Outcome Measures in Rheumatology Clinical Trials working group (OMERACT score).

Results: Among 309 enrolled subjects with suspected pSS, 95 subjects were excluded due to being classified as secondary SS, or failing to receive the designated SGUS examination or labial salivary glands biopsy. Therefore, 214 subjects were qualified for statistical analysis, including 116 pSS patients. The mean age of pSS patients was 47.1±13.3 years old and 97% of them were female, age-match and sex-match to the non-SS controls.

Compared to the pSS patients without hypofunction, pSS patients with salivary hypofunction (n=71, SWSF ≤0.7mL/min) were significantly older, higher positive rate of the Van Bijsterveld score, higher positive rate of anti-SSA/Ro, higher incidence of UWSF≤0.1mL/min and lower incidence of thrombocytopenia (all p<0.05).

The pSS patients with salivary hypofunction had significantly higher total OMERACT score (10 [interquartile range (IQR), 8-12] vs. 8 [IQR, 6-8], p<0.001), and total gland score (12 [IQR, 10-12] vs. 8 [IQR, 6-11], p<0.001) than the patients without salivary hypofunction (Figure 1A). ROC curve confirmed total OMERACT score (AUC: 0.804, 95%CI: 0.727-0.881, p<0.001) and total gland score (AUC: 0.792, 95%CI: 0.704-0.881, p<0.001 could significantly distinguish pSS patients with salivary hypofunction from those without salivary hypofunction. The cut-off values of total OMERACT score were 7 and 9, and of total gland score were 9 and 11, according to the Youden index. The absolute value of SWSF in the pSS patients with total gland score ≥11 was significantly lower than those with total gland score of 9–11 or total gland score <9 (both p<0.05). The absolute value of SWSF in the pSS patients with total OMERACT score >9 was significantly lower than those with total gland score of 7–9 or total gland score <7 (both p<0.001, Figure 1B).

Total OMERACT score and total gland score were combined to generate a 3×3 matrix model (Figure 1C). The total gland score could be stratified into three risk subgroups: (i) High-risk (n=39): pSS patients whose total OMERACT score was >9 and total gland score ≥9 had estimated risk probability greater than 80%, and the actual incidence of SWSF ≤0.7mL/min was 95% (37/39); (ii) Low-risk (n=28): pSS patients whose total OMERACT score was <7; or whose total OMERACT score was 7–9 and total gland score <9 had estimated risk probability less than 35%, and the actual incidence of SWSF ≤0.7mL/min was 14% (4/28); (iii) Moderate-risk (n=49): pSS patients who fulfilled neither high-risk nor low-risk had an actual incidence of SWSF ≤0.7mL/min in a moderate level (61%, 30/49).

Conclusion: This study first reported B-mode ultrasonography examination on four major salivary glands could reflect salivary function of pSS. We also built a matrix risk model composed of SGUS gland score and OMERACT score associated with salivary hypofunction in pSS which was conveniently used for rheumatologists, especially in specific clinical situations that SWSF was not available.

OP0169 VESSEL WALL INFLAMMATION DETECTED WITH SUPERB MICROVASCULAR IMAGING IN BEHÇET SYNDROME

Keywords: Vasculitis, Ultrasound, Behcet's disease

Y. Kayadibi1, Y. Ozquiler2,3, M. Melikoglu2,3, S. N. Esatoglu2,3, U. Kimyon4, A. Kalyoncu Ucar1, I. Adalitili1, G. Hatef2,3, 1Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Radiology, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behcet's Disease Research Center, Istanbul, Turkey; 4Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey

Background: Superb microvascular imaging (SMI) is a novel technique that provides a more sensitive assessment of small vessels compared to color Doppler US (CDUS), by distinction of low-speed flow signals from motion artifacts. Superficial thrombophlebitis (STM) is a common manifestation in patients with Behçet syndrome (BS) and is thought to be associated with inflammation of the vessel wall rather than a procoagulant state.

Objectives: We aimed to assess STM lesions of patients with BS, together with controls, using SMI.

Methods: We studied 51 BS (16F/35M, mean age:40.6±12.8) patients and 26 non-BS (19F/7M mean age:44.9±11.7) patients with nodular lesions on physical examination. B-mode US, CDUS, PDUS and SMI were performed and recorded by the same radiologist and images were then evaluated by 2 radiologists. Both radiologists were blinded to the diagnoses and to each other’s assessments. First, presence/absence of vessel was assessed with CDUS to differentiate STM from erythema nodosum (EN). Then STM lesions were evaluated for the presence/absence of thrombus, vessel wall color-coded signal intensity, and thickness using the imaging modalities defined above. Vessel wall signal intensity was graded into 4 groups according to the percentages of the effected vessel area (Grade 0= no signal, Grade 1= < 25%, Grade 2= 25-50%, Grade 3= 50-75%, Grade 4= >75%). CDUS was the gold standard in the final diagnosis of STM. Interobserver reliability was assessed by kappa statistic.

Results: The nodular lesions of 26 BS and 15 non-BS patients were diagnosed as STM (Table 1). The diagnosis was EN in the remaining 25 BS and 11 non-BS patients. SMI showed increased color-coded signal intensity in the vessel wall in patients with STM. We did not observe increased signal intensity in any of the patients with EN. According to the grading system, at least grade 1 or higher vessel-wall signals were detected in 20 BS (77%) patients with STM, in contrast to only 4 (27%) non-BS patients with STM (Table 1). Fifteen of 26 BS patients (58%) had at least grade 2 signal, and 4 of them had halo shaped signals all around the vessel-wall (Figure 1). On the other hand, 3 of 4 non-BS patients (75%) had only grade 1 signal and none of them had grade 4 signal. The interobserver reliability was good (κ=0.87, p<0.001).

Conclusion: A high-grade color-coded signal suggesting inflammation of the vessel wall was detected with SMI, in the majority of BS patients with STM. This finding needs to be studied in different vascular lesions of a large number of BS patients together with controls, in order to understand its specificity for BS and its significance.
BACKGROUND: Inflammation around the tendons of the hand interosseous muscles (interosseous tendon inflammation; ITI) was recently identified on MRI in a set of RA and arthralgia patients. Objectives: However, the prevalence of ITI at diagnosis of RA is unknown, as is its prevalence in other arthritides and its relationship with clinical signs. These questions prompted us to perform this large MRI study. Methods: 1,205 consecutive patients presenting with early arthritis between 2010-2020 underwent contrast-enhanced hand MRI. MRIs were evaluated, blind to clinical data, for ITI lateral of MCP2-5 and for other local inflammation (synovitis/tenosynovitis/osteitis), in line with the RA-MRI-scoring-system (RAMRIS). ITI-presence at baseline was studied in relation to the diagnosis and clinical characteristics (i.e. joint swelling, and tenderness) using logistic regression and generalised estimating equations.

RESULTS: 36% of early RA patients (n=532) had ITI; this was similar in ACPA-neg-ative(37%) and ACPA-positive RA patients (34%; p=0.53). ITI occurred regularly in RS3PE (60%) and connective tissue diseases (44%), and less frequently in undifferentiated arthritis (14%), psoriatic arthritis (14%), inflammatory osteo-arthritis (8%), reactive arthritis (7%), crystal arthritis (7%) and peripheral spondyloarthritis (4%). ITI occurred more often in diagnoses with frequent arthritis of the hands (p<0.001) and increased acute-phase-reactants (p<0.001). Within RA, ITI occurred together with local MCP synovitis (OR 2.4 (95%CI; 1.7 -3.4)), tenosynovitis (2.4 (1.8-3.3)) and osteitis (2.2 (1.6-3.1)) on MRI. Moreover, ITI-presence associated with local MCP tenderness (1.6 (1.2-2.1)) and swelling (1.8 (1.3-2.6)), independent of age and MRI-detected synovitis/tenosynovitis/osteitis.

Conclusion: ITI occurs regularly in RA and other arthritides with preferential involvement of hand-joints and increased acute-phase-reactants. At MCP-level, the presence of ITI associates independently with joint-tenderness and -swelling. Hence, ITI is a newly identified inflamed tissue mainly found in arthritides with particularly extensive and symptomatic inflammation.

OP0171
ADDED VALUE OF FDG-PET/CT TO DETECT AORTIC INVOLVEMENT IN PATIENTS WITH ULTRASOUND PROVEN GIANT CELL ARTERITIS

Keywords: Vasculitis, Imaging, Ultrasound

J. Molina Collado1, I. Castrejón1, I. Monjo2, E. Fernández-Fernández2, G. Torres Ortega2, J. Martínez-Barrio1, J. M. Alvaro-Gracia1, E. De Miguel2, Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain; 2La Paz University Hospital, Rheumatology, Madrid, Spain.

Background: Ultrasound (US) can detect signs of large vessel (LV) involvement at axillary, subclavian and carotid arteries of giant cell arteritis (GCA) patients, but has limited access to the thoracic aorta. Although aortic involvement is not routinely evaluated in all patients with GCA, it may cause a life-threatening situation as result of serious complications such as aneurysms or dissection.

Methods: Retrospective observational study of patients referred to the US fast track clinics of two academic centres over a 4-years period. Only patients with US proven GCA were included for analysis. Baseline US of cranial and extracranial arteries (carotid, subclavian and axillary) was performed in all patients at diagnosis within 24-48 hours. FDG-PET/CT was performed according to clinician criteria and images were assessed by nuclear medicine physicians. An FDG artery uptake at the thoracic or abdominal aorta higher than liver uptake was defined as aortitis. Between groups comparisons were made in patients with and without aortitis.

Disclosure of Interests: None Declared.

114 ﻿

Scientific Abstracts

Results: Seventy two patients over 186 patients with confirmed GCA by US underwent an FDG-PET/CT (mean age 77 years, 52.8% females). A total of 48 (66.7%)
had LV-GCA based on imaging findings, with 29 (40.3%) presenting positive FDGPET/CT for LV-GCA and 24 (33.3%) presenting artery uptake throughout the aorta
suggestive of aortic involvement (Table 1). Only 6 (20.7%) patients had negative
US findings of LV-GCA but positive FDG-PET/CT. Among patients with aortitis
according to FDG-PET/CT, only 2 (8.3%) had negative US findings of LV-GCA.
In contrast, 19 (45.2%) patients with US findings of LV-GCA had negative FDGPET/CT. Patients with aortitis were younger (68.9 vs 81, p<0.001), more frequently
females (79.2% vs 39.6%, p=0.002) and had higher level of platelets (413.4 vs
311.1, p=0014). None of the patients with aortitis referred visual symptoms (0% vs
31.2%, p=0.001) and they presented US signs of LV-GCA more frequently (91.7%
vs 41.7%, p<0.001) versus patients without aortic involvement.
Conclusion: FDG-PET/CT can detect aortic involvement in 1 out of every 3
patients with US proven GCA. However, most of these patients show US findings of LV-GCA. In contrast, half of patients with US proven LV-GCA may have
negative FDG-PET/CT. Younger and female GCA patients, with thrombocytosis,
absence of visual manifestations and US pattern of LV-GCA may present more
frequently aortitis by FDG-PET/CT.

LIMITED DIAGNOSTIC AND PROGNOSTIC VALUE OF
RADIOGRAPHS OF HANDS AND FEET IN PATIENTS
WITH UNDIFFERENTIATED ARTHRITIS SUSPECTED
FOR RHEUMATOID ARTHRITIS: A RETROSPECTIVE
COHORT STUDY

Keywords: Imaging, Rheumatoid arthritis, Diagnostic Tests
E. Ulijn1, N. Den Broeder1, D. Ten Cate1, K. Van Overdijk1, H. Demirel1, R. B.
M. Landewé2, N. Van Herwaarden1,3, A. Den Broeder1. 1Sint Maartenskliniek,
Rheumatology, Ubbergen, Netherlands; 2Amsterdam Medical Centre,
Rheumatology and Clinical Immunology, Amsterdam, Netherlands;
3
RadboudUMC, Pharmacology-Toxicology, Nijmegen, Netherlands
Background: Current recommendations suggest that the diagnostic workup
of Undifferentiated Arthritis (UA) should include radiographs of hands and feet
(x-HF) as presence of Rheumatoid Arthritis (RA) associated erosions might be of

diagnostic and prognostic value. The diagnostic role of x-HF in RA is reflected in
ACR/EULAR 2010 criteria, with erosions typical for RA allowing classification of
RA even without fulfillment of the scoring system [1]. Additionally, early erosivity is
one of the indicators of a poor RA prognosis [2]. RA seems to evolve into a milder
disease at presentation, caused by a secular trend towards milder disease, or lead
time effects (presenting earlier in disease course) [3]. Both trends would further
decrease the prevalence of RA-associated erosions and thus utility of x-HF might
have decreased both for diagnosis and identifying poor prognosis patients.
Objectives: To investigate the prevalence and diagnostic and prognostic value of
RA-associated erosions on x-HF in a recent cohort of UA patients.
Methods: A retrospective cohort study in consenting UA patients visiting the
rheumatology department at the Sint Maartenskliniek between 2012-2018 was
done. UA suspected for RA was defined as 1/ current arthritis, 2/ Rheumatoid
Factor (RF)/anti-Cyclic Citrullinated Peptide (anti-CCP) were tested, 3/ x-HF was
made, 4/ RA was mentioned in the differential diagnosis. Radiological reports
of x-HF were judged by experienced musculoskeletal radiologists, and all x-HF
with an erosion mentioned in the report were reassessed by two experienced
rheumatologists for typical RA-associated erosions. The prevalence of erosions
was estimated, as well as whether RA classification (yes/no) or prognostic group
(good/poor) were changed by erosivity. Subgroup-analyses were done for seronegative patients (non-elevated RF/anti-CCP) and patients without elevated Acute
Phase Reactants (APR; i.e. ESR and CRP) as they might be expected to gain the
most diagnostic and prognostic value from conducting x-HF.
Results: 724 patients were included in the analysis, of which 293 (40.5%)
patients were eventually clinically diagnosed with RA during the time they were
treated. There was a high agreement between 2010 ACR/EULAR classification
criteria for RA and the clinical diagnosis reported by the treating rheumatologist (sensitivity of 79% and specificity of 89.6%). RA-associated erosions were
found in 30 out of 724 included patients (4.1%, 2.9-5.9). Of the 437 seronegative
patients, five (1.1%, 0.5-2.7) radiographs showed erosive disease. Eight out of
385 patients with non-elevated APR (2.1%, 1-4.1) had erosive disease. The x-HF
resulted in a change to a positive RA classification in four out of 724 patients
(0.5%, 0.2-1.2). X-HF erosivity changed the classification to prognostically unfavorable in five patients (0.6, 0.2-1.4), Table 1. In other words: these patients did
not have RF or anti-CCP positivity, high disease activity (DAS28 >5.1), but did
have the prognostic factor ‘early erosive disease’.
Table 1. prevalence of typical RA erosive disease, and diagnostic/prognostic relevance of x-HF.

(n (%, CI))

8 (2.1, 1-4.1)
2 (0.5,
0.1-2.1)
2 (0.5,
0.1-2.1)

Conclusion: RA-associated erosions at presentation with UA are rare, and their
presence rarely leads to a change in diagnosis or prognosis. Routine x-HF should
therefore not be recommended in this context. X-HF made for any specific indication might of course be of value, and our results do not generalize to these cases.

CHARACTERIZATION OF AXIAL INVOLVEMENT USING
18F-FLUORIDE PET-CT IN SPONDYLOARTHRITIS
PATIENTS

Keywords: Imaging, Spondyloarthritis, Pain
I. Giovannini1, A. Zabotti1, S. Diodato2, C. Cicciò3, M. Salgarello2,

Italy; 3Departments of Diagnostic Imaging and Interventional Radiology,
IRCCS Sacro Cuore Don Calabria, Negrar di Valpolicella, Italy; 4NIHR Leeds
Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals Trust


Background: Nuclear medicine positron emission tomography (PET) has limited evidence in the clinical management of axial Spondyloarthritis (AxSpA). The 18F-fluoride isotope is a bone-specific tracer that is incorporated in the skeleton during bone remodeling. Osteoblastic bone remodeling, that culminates in new bone formation in SpA can be molecularly imaged with 18F PET. Although not widely employed, several studies have shown that 18F is an excellent isotope for evaluating sites of active osteoblastic activity[1], and may be used in the assessment of axial involvement in spondyloarthritis[2].

Objectives: Aim of this study is to identify the pattern of distribution of 18F uptake at baseline using the PET-Computerized Tomography (PET-CT) in the early AxSpA identification in patients with inflammatory back pain (IBP) according to ASAS criteria[3].

Methods: We analyzed data of 18F PET-CT in patients presenting IBP suspicious for SpA. Patients were assessed clinically at baseline and according to clinical practice with assignment of a final diagnosis of axial SpA after at least two years of follow up, according to the ASAS criteria[4]. We evaluated the baseline 18F PET-CT abnormalities and correlated with the final diagnosis.

Results: 125 patients underwent 18F PET-CT. 83 were female (66.4%), and the mean age at evaluation time was 49.58 years (SD 11.03). Patients were classified into 5 groups according to the rheumatological diagnosis made after at least 2 years of follow-up. Ten patients fulfilled New York criteria for Ankylosing Spondylitis (AS), 28 patients fulfilled CASPAR criteria for Psoriatic Arthritis (PsA), 35 patients fulfilled ASAS criteria for undifferentiated SpA and 12 patients presented axial-SpA related IBD. 40 patients were not classifiable as AxSpA (not-class AxSpA). The prevalence of 18F PET-CT abnormalities highlight differences in SpA phenotypes, shown in colour coding (Figure 1A). Similar results were reported in the chest, in particular among the sterno-clavicular and acromio-clavicular joints (Figure 1B).

Conclusion: Our study showed a clear pattern of abnormalities detected by 18F PET-CT in the spine and chest of AxSpA patients. 18F PET-CT might help clinicians to characterize the axial involvement in SpA patients.

OP0174 CHEST RADIOGRAPHS PRE-IMMUNOSUPPRESSION HELP TO IDENTIFY NON TUBERCULOUS INFECTIONS AND INTERSTITIAL LUNG DISEASES, BUT ADD LITTLE TO LATENT TUBERCULOSIS SCREENING

Keywords: Imaging, Real-world evidence, Diagnostic Tests

B. Harrington1, I. Khan2, M. Ramakrishnan2, F. Fitzpatrick3, L. Durcan1.
1Beaumont Hospital, Rheumatology, Dublin, Ireland; 2Royal College of Surgeons, School of Medicine, Dublin, Ireland; 3Beaumont Hospital, Microbiology, Dublin, Ireland

Background: Screening for latent tuberculosis (LTB) using chest x-ray (CXR) and interferon-gamma release assay (IGRA) is standard in patients starting on biologic and immunosuppressive therapies. Our hypothesis is that the CXR does not change management, and we sought to evaluate the additive value of plain radiographs for this purpose in our patients.

Objectives: To retrospectively review all CXRs performed at baseline pre-treatment to determine if they provide any additive benefit value to the IGRA LTB screening approach. Methods: This is a retrospective review of screening practices for LTB in a tertiary referral centre in Ireland, a low prevalence country. We included, 814 patients screened, using CXR and interferon gold release assay (IGRA) over a 5-year period. Results: The IGRA was positive in 5% (38/814) and indeterminate in 2.5% (20/814), the remainder testing negative. In the IGRA positive group, 15.8% (6/38) had an abnormal CXR. None of these showed changes reflecting prior or active tuberculosis. These showed fibrotic lung disease, consolidations and basal atelectasis. Of those who had an indeterminate IGRA, 45% (9/20) of cases had an abnormal CXR, with one individual report of radiographic evidence of possible prior TB. In those with an abnormal IGRA (positive or indeterminate), the addition of CXR in the screening process changed management in one patient. They were treated for LTB on the basis of indeterminate IGRA, prior TB contacts, country of origin and other risk factors. The sensitivity of the IGRA alone screening approach was 97.62% when high risk indeterminate results were assumed to have LTB and were treated. The resulting specificity of the IGRA alone approach was 97.80%. The sensitivity of the combined IGRA & subsequent CXR approach was 100% as it was deemed to have captured all actual cases of LTB disease. We acknowledge that this not recognise that IGRA is an imperfect test and assumes that there were no cases of LTB in 756 IGRA negative patients. The specificity of the combined IGRA and subsequent CXR approach remains practically the same at 97.93%.

Conclusion: In conclusion, the clinical utility of the CXR in screening for TB is unclear in this population. The addition of CXR in the screening process only changed management in 1 patient over a 5 year period in this cohort. The incidental identification of interstitial lung diseases and chest infections is of value to patients considering immunosuppression, but is a separate issue to screening for LTB.

OP0175 RELEVANT FEATURES IN FLUORESCENCE OPTICAL IMAGING FOR DIFFERENTIAL DIAGNOSIS OF RHEUMATIC DISEASES AFFECTING THE HANDS

Keywords: Psoriatic arthritis, Imaging, Rheumatoid arthritis

N. Stumper1, J. Berger2, V. Falli3, E. Gedat3, P. Hoff4, G. Schmitt1, A. Brief1, G. R. Burmester1, S. Ohndorf1, 1Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Xiralite GmbH, Xiralite GmbH, Berlin, Germany

Background: Accurate and fast diagnosis of rheumatic diseases affecting the hands is essential for further treatment decision. Different rheumatic diseases affecting the hands present characteristic patterns and features in fluorescence optical imaging (FOI) as outlined in previous studies [1, 2].

Objectives: We tested an atlas of image features in FOI for their ability to differentiate various rheumatic joint diseases such as rheumatoid arthritis (RA), osteoarthritis (OA), psoriatic arthritis (PsA) and connective tissue diseases (CTD) like systemic sclerosis (SSc) and systemic lupus erythematoses (SLE) with the aim to identify specific features for differential diagnosis.
Methods: FOI images from patients with RA, OA, PsA and CTD were analysed by two readers blinded for diagnosis and calibrated against each other, using the prisma vista mode (PVM) and the 5-phase model. For the latter, the overall time course of FOI in each hand was divided into 5 phases with a computational algorithm. Phases 1 and 2 describe the inflow (start to 15% and 15%-90% on rising edge), phase 3 is the peak phase and phases 4 and 5 comprise the outflow (90%-36.8% and 36.8% to end on falling edge). Twenty-six different features were defined, for example, the signal enhanced forearm (Y), broad signal enhancement along the finger (B), cloudy signal in the hand (W), secondary Raynaud syndrome (R), and underperfused nail bed region (U) (illustrated in the Figure 1). The feature frequency in each patient and phase (PVM, 5-phase) was counted and statistically analysed.

Results: In total, 374 patients (115 RA patients; mean age 54.4; SD 12.6; median 54.5), OA (89; 62.1; 74; 63.2), PsA (59; 50.0; 11.4; 49.2) and CTD (111; 52.2; 14.9; 54.5) were included in the feature reading. Statistical results ($\chi^2$, diagnostic odds ratio DOR, sensitivity TPR, specificity TNR, positive predictive value PPV, negative predictive value NPV) are given in the Table 1. CTD can best be differentiated from RA, OA and PsA on the basis of the feature Y, in which sensitivity (70%-98%) while having low specificity (12%-52%) (data not presented).

Conclusion: This work supports that FOI feature analysis has the potential for differential diagnosis in rheumatic diseases affecting the hands. Feature Y has the ability to differentiate CTD (here mainly SLE/SSc) from RA, OA, and PsA while the features B, W, R and U can exclude CTD from RA, OA and PsA. In the future, FOI could therefore play an important role in the early arthritis clinic.

**SELF-MANAGEMENT BEHAVIOUR, ANXIETY AND DEPRESSION IN PATIENTS WITH INFLAMMATORY ARTHRITIS - A CROSS SECTIONAL NATIONWIDE STUDY AMONG >12,000 DANISH PATIENTS**

**Keywords:** Inflammatory arthritides, Health Services Research, Self-management

S. B. Vestergaard, B. A. Esbensen, J. Midtgaard, B. Glimborg, M. Aaahl, P. F. Cromhouret, A. De Thurah, Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; Center for Rheumatology and Spine Diseases, Center for Head and Orthopaedics, Rigshospitalet, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; Copenhagen University Hospital - Mental Health Services CPH, Centre for Applied Research in Mental Health Care (CARMEN), Mental Health Center Glostrup, Copenhagen, Denmark; Bispebjerg and Frederiksberg Hospitals, Center for Clinical Research and Prevention, Copenhagen, Denmark; Novo Nordisk A/S, 7061, Søborg, Denmark; Aarhus University, Department of Clinical Medicine, Aarhus, Denmark

**Background:** Anxiety and depression are the mental health issues most commonly associated with inflammatory arthritis (IA) and the link between mental health issues and poor health outcomes is well-established [1]. European recommendations on self-management in rheumatic and musculoskeletal diseases emphasizes the need to assess mental health regularly [2]. However, little is known about the association between self-management and mental health in IA.

**Objectives:** To investigate the prevalence of anxiety and depression in patients with IA and evaluate the association of these mental health issues and self-management behavior.

**Methods:** We conducted a nationwide cross-sectional study among adult Danish patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or spondyloarthritides (axSpA). Eligible patients were identified through the Danish Rheumatology database DANBIO and received an electronic questionnaire. The questionnaire covered socio-demographics, self-management behavior and mental health status indicated by the Hospital Anxiety and Depression Scale, a 14-item tool with 2 sub-scales assessing symptoms of anxiety and depression. Self-management behavior was indicated by: Adherence to treatment using Compliance Questionnaire Rheumatology-S item, Patient activation in healthcare using two items from the Patient Activation Measure-13 questionnaire and level of physical activity covering weekly recommendation from WHO and American College of Sports Medicine. Self-management measures were dichotomized into high or low. Questionnaire data were linked to clinical data from DANBIO. The association between low self-management behaviour and mental health status were estimated using multivariable logistic regression with odds ratios (OR).

**Results:** A total of 42,407 patients with RA were identified; 30% (N=12,715) completed the questionnaire. Non-responders were younger than responders (60 vs. 62 years) with a similar gender distribution (p=0.187). The prevalence of anxiety (HADS-A ≥8) was highest for patients with axSpA (34.5% (95% CI: 32.4; 36.6)) and lowest for patients with RA (22.1% (95% CI: 21.2; 23.0)). Prevalence of depression (HADS-D ≥8) was highest for patients with PsA (27.2% (95%CI: 25.4;29.0)) and lowest for patients with RA 16.8% (95%CI: 17.7;19.4).

For both anxiety and depression, the prevalence was higher for women, younger (<55 years), newly diagnosed (<3 years) and patients with basic education. Patients having a clinical level (HADS ≥8) of anxiety and depression were more likely to have low self-management behavior for all included self-management measures (Table 1).

*Adjusted for age, sex, education. Ref: reference group, low self-management behavior.

**Conclusion:** In this nationwide study, high levels of anxiety and depression were seen among patients with IA. A strong association between anxiety and depression and low self-management behavior was identified. These findings call for a systematic approach in identifying mental health issues in patients with IA.

**Background:** Adults with arthritis display poorer health-related quality of life (HRQOL) than the general population, including greater anxiety, depression, pain, and fatigue, and poorer physical function. Still, arthritis is a variable disease and the impact on HRQOL is heterogeneous in terms of severity and domains of impact. Some factors are associated with HRQOL outcomes in adults with arthritis, though research often focuses on a single outcome (like pain) rather than multiple HRQOL domains simultaneously. Examining protective and risk factors against poor HRQOL outcomes is needed. Can tell when situations with health condition are needed, Can handle new situations with health condition.

**Methods:** Data including PROMIS measures of physical and social function, sleep disturbance, anxiety, depression, fatigue, and pain interference (PROMIS-29) and emotional support were collected through a national foundation's online survey of adults with arthritis in the U.S. PROMIS T-scores are calibrated with the U.S. general population mean of 50 (SD = 10). Higher function T-scores reflect better functioning and higher symptom T-scores reflect worse symptom burden. We used latent profile analysis (LPA), a patient-centered modeling approach, to characterize the heterogeneity in arthritis patients by clustering them into HRQOL profiles, determined based on statistical model fit and clinical interpretability. Participants were assigned to a HRQOL profile, and we fit a multinomial logistic regression model with HRQOL profile assignment as the outcome (best HRQOL profiles as reference group) to determine associations with emotional support and demographic and clinical factors.

**Results:** We included 25,305 adults with arthritis. The LPA results favored a five-HRQOL profile solution (entropy = 0.83). See Figure 1 for profile details and participant counts. Profile 1 (8% of sample), the best HRQOL group, displayed lower anxiety and depression similar to Profile 2. Profile 4 (10% of sample) was similar, except those in Profile 4 had reduced anxiety and depression similar to Profile 1. Profile 5 (20% of sample), the worst HRQOL group, displayed mean T-scores close to 2 SDs below the US general population mean. All of the demographic and clinical factors were significant, including arthritis type. Compared to being classified into the best HRQOL group, participants who were unable to work were 39 times (95% CI = 20.35-73.85) more likely to be in the worst HRQOL group as participants who were working. Notably, higher emotional support (95% CI = 0.88-0.89) and starting to exercise (95% CI = 0.45-0.70) were associated with a lower likelihood of membership in the worst HRQOL group (Profile 5).

**Conclusion:** With the exception of the best HRQOL group, all the other HRQOL profiles (92% of sample) had poorer physical function and worse pain interference than the US general population, and elevated depression and anxiety, with some exceptions. Malleable factors such as emotional support and exercise served a protective function. These results highlight the value of considering multiple components of the patient's HRQOL experience alongside treatment options, and the potentially positive impact of interventions beyond medication.

**Background:** Adults with arthritis display poorer health-related quality of life (HRQOL) than the general population, including greater anxiety, depression, pain, and fatigue, and poorer physical function. Still, arthritis is a variable disease and the impact on HRQOL is heterogeneous in terms of severity and domains of impact. Some factors are associated with HRQOL outcomes in adults with arthritis, though research often focuses on a single outcome (like pain) rather than multiple HRQOL domains simultaneously. Examining protective and risk factors against a constellation of HRQOL outcomes would be beneficial for treatment of arthritis as a disease that impacts multiple areas of patients’ lives.

**Objectives:** We aimed to identify profiles of HRQOL impact using the NIH’s Patient-Reported Outcomes Measurement Information System (PROMIS) measures in a sample of adults with arthritis (osteoarthritis, inflammatory arthritis, fibromyalgia; with other arthritis types). We also aimed to identify demographic and clinical factors associated with HRQOL profile membership that serve as protective or risk factors against poor HRQOL outcomes.

**Methods:** Data including PROMIS measures of physical and social function, sleep disturbance, anxiety, depression, fatigue, and pain interference (PROMIS-29) and emotional support were collected through a national foundation's online survey of adults with arthritis in the U.S. PROMIS T-scores are calibrated with the U.S. general population mean of 50 (SD = 10). Higher function T-scores reflect better functioning and higher symptom T-scores reflect worse symptom burden. We used latent profile analysis (LPA), a patient-centered modeling approach, to characterize the heterogeneity in arthritis patients by clustering them into HRQOL profiles, determined based on statistical model fit and clinical interpretability. Participants were assigned to a HRQOL profile, and we fit a multinomial logistic regression model with HRQOL profile assignment as the outcome (best HRQOL profile as reference group) to determine associations with emotional support and demographic and clinical factors.

**Results:** We included 25,305 adults with arthritis. The LPA results favored a five-HRQOL profile solution (entropy = 0.83). See Figure 1 for profile details and participant counts. Profile 1 (8% of sample), the best HRQOL group, displayed higher physical and social functioning and lower physical and mental symptoms. Profiles 3 (37% of sample) and 4 (10% of sample) were similar, except those in Profile 4 had reduced anxiety and depression similar to Profile 1. Profile 5 (20% of sample), the worst HRQOL group, displayed mean T-scores close to 2 SDs below the US general population mean. All of the demographic and clinical factors were significant, including arthritis type. Compared to being classified into the best HRQOL group, participants who were unable to work were 39 times (95% CI = 20.35-73.85) more likely to be in the worst HRQOL group as participants who were working. Notably, higher emotional support (95% CI = 0.88-0.89) and starting to exercise (95% CI = 0.45-0.70) were associated with a lower likelihood of membership in the worst HRQOL group (Profile 5).

**Conclusion:** With the exception of the best HRQOL group, all the other HRQOL profiles (92% of sample) had poorer physical function and worse pain interference than the US general population, and elevated depression and anxiety, with some exceptions. Malleable factors such as emotional support and exercise served a protective function. These results highlight the value of considering multiple components of the patient's HRQOL experience alongside treatment options, and the potentially positive impact of interventions beyond medication.

**REFERENCES:**

Conclusion:

We present annualised data from 28 February 2019 to 14 July 2022. We assessed 677 patients with PsA or AS and enrolled in the You First programme. All You First nurses had received training in patient support programmes that provide an individualised nurse-led service, such as You First, to help ensure the stability of healthcare resources. You First is aimed at people who have been prescribed secukinumab, an injectable anti-interleukin 17A monoclonal antibody, for approved indications including psoriatic arthritis (PsA), ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis.

Method:
The analysis included adult participants who were eligible for treatment with secukinumab according to National Institute for Health and Care Excellence criteria and were enrolled in the You First programme. All You First nurses were registered with the Nursing and Midwifery Council and underwent specific training, competency assessment and validation to ensure they met all regulatory standards of National Health Service (NHS) practice. Each participant was assigned to a dedicated nurse who visited the participant’s home to provide routine clinical assessments, routine follow-up visits, phlebotomy service, psychological support visits, injection training and routine secukinumab administration, as required. Participants could also schedule regular nurse telephone calls to discuss any disease or drug-related concerns such as secukinumab dosing/administration and side effect management. All data gathered during the home visits and telephone calls were reported to the treating physicians. Calculation of cost savings was based on the number of visits carried out as part of You First and the cost that the NHS would have incurred if the visit occurred at the hospital (£2.02 for phlebotomy service, £24 for telephone contact, and £99 for each assessment, routine follow-up visits and psychological support visit). Here we present annualised data from 28 February 2019 to 14 July 2022.

Results:

In total, 126 participants with PsA (n=81) and AS (n=45) were observed for 17 months on average. At baseline, the mean age was 52.7 years and 39.2% of participants were female. During the timeframe of this analysis, You First nurses had 1160 contact points with the clinical team (793 visits; 367 telephone calls). The median (interquartile range) number of visits and telephone calls carried out as part of the programme per participant per year was 6.4 (4.6–11.3): phlebotomy had 1160 contact points with the clinical team (793 visits; 367 telephone calls).

Objectives:

This retrospective analysis aimed to evaluate the benefits of the You First patient support programme on the rheumatology service at a large university teaching hospital with a catchment population of 350,000, of whom 40% are from ethnic minorities.

Methods:
The analysis included adult participants who were eligible for treatment with secukinumab according to National Institute for Health and Care Excellence criteria and were enrolled in the You First programme. All You First nurses were registered with the Nursing and Midwifery Council and underwent specific training, competency assessment and validation to ensure they met all regulatory standards of National Health Service (NHS) practice. Each participant was assigned to a dedicated nurse who visited the participant’s home to provide routine clinical assessments, routine follow-up visits, phlebotomy service, psychological support visits, injection training and routine secukinumab administration, as required. Participants could also schedule regular nurse telephone calls to discuss any disease or drug-related concerns such as secukinumab dosing/administration and side effect management. All data gathered during the home visits and telephone calls were reported to the treating physicians. Calculation of cost savings was based on the number of visits carried out as part of You First and the cost that the NHS would have incurred if the visit occurred at the hospital (£2.02 for phlebotomy service, £24 for telephone contact, and £99 for each assessment, routine follow-up visits and psychological support visit). Here we present annualised data from 28 February 2019 to 14 July 2022.

Results:

In total, 126 participants with PsA (n=81) and AS (n=45) were observed for 17 months on average. At baseline, the mean age was 52.7 years and 39.2% of participants were female. During the timeframe of this analysis, You First nurses had 1160 contact points with the clinical team (793 visits; 367 telephone calls). The median (interquartile range) number of visits and telephone calls carried out as part of the programme per participant per year was 6.4 (4.6–11.3): phlebotomy service 0.4 (0.0–1.6), clinical assessments 1.4 (0.0–2.0), routine follow-up visit 1.6 (0.7–3.1), psychological support visit 0.0 (0.0–0.0) and telephone contact 2.0 (1.0–4.7). This translated to an annual cost saving of £64,156.49 (phlebotomy service per participant per year was 6.4 (4.6–11.3): phlebotomy service had 1160 contact points with the clinical team (793 visits; 367 telephone calls).

Conclusion:

Implementation of You First at this large university teaching hospital yielded substantial cost savings for the NHS, with outsourced visits providing the most cost savings. You First allowed people with PsA or AS to be managed at home, reducing diagnostic and treatment times and leveraging the capacity of nurses. This translated to an annual cost saving of £64,156.49 (phlebotomy service per participant per year was 6.4 (4.6–11.3): phlebotomy service had 1160 contact points with the clinical team (793 visits; 367 telephone calls).
The study had a concurrent mixed methods design in which quantitative and qualitative data were collected in parallel, analyzed separately, before integration into an overall result. All participants in the intervention group (n=168) of the BRIDGE-trial were included. Quantitative data were patient-reported in an electronic portal. Demographic and disease-specific data were collected on admission to rehabilitation. Data on goal attainment (Patient Specific Functional Scale), physical function (30 seconds Sit-To-Stand test), health related quality of life (EQ5D-SL-index), and health status (EQ-VAS) were reported at discharge, 2, 7 and 12 months after rehabilitation. Needs for follow-up were reported at rehabilitation discharge by ticking off a list of 12 predefined options. The patients were categorized into 4 groups based on their needs for follow-up on discharge (yes/no) and the degree of follow-up received according to stated needs the first year after rehabilitation (none/partial/complete). Quantitative data were analyzed using descriptive statistics, ANCOVAs, and linear regression. Qualitative data about patients’ experiences with follow-up were collected in semi-structured interviews with 21 patients and analyzed using reflexive thematic analysis. The results were integrated in the overall interpretation and discussion.

Results: The patients most often reported needs for follow-up from General Practitioner, physiotherapist, and social security services, and did mostly receive (> 85%) these services within 1 year after rehabilitation. There were no significant differences between the 4 groups with regard to characteristics at discharge, or clinical outcomes 1 year after rehabilitation. Received individually tailored follow-up was not shown to significantly influence clinical outcomes, and was, surprisingly, associated with reduced patient reported health 1 year after rehabilitation: EQ-VAS β 0.28 [95% CI -0.46, -0.09], p=0.004. The qualitative analysis resulted in three themes: “Contact between service levels” (established through various actors, processes, documents), “Follow-up keeps the rehabilitation process going” (by increasing motivation and focus on goals and self-effort after discharge), and “Loss of momentum” (linked to personal and structural factors).

Conclusions: Patients with RMDs require access to one or more healthcare services after rehabilitation in secondary care. Clinical outcomes 1 year after rehabilitation appeared to be influenced by several other factors than the actual received follow-up support. Health personnel’s competence and structural factors across health service levels, such as waiting lists and limited access to care, seemed to be decisive for the progress of the rehabilitation process over time, together with factors related to the individual patient and his/her life situation. The findings can contribute to increased insight into what promotes continuity in rehabilitation processes, effective follow-up, and better health for this patient group.

Background: Several EULAR recommendations for the management of people with specific inflammatory rheumatic and musculoskeletal diseases (I-RMDs) have highlighted the importance of some non-pharmacological interventions in the management of fatigue [1-3]. However, these recommendations are either disease-specific or focusing on a single intervention, and lack an integrated view on how to support RA patients in conventional follow-up, as well as increased focus on vulnerable patient groups and the need for differential use of healthcare services.

E. Santos1, B. Farisogullari2, E. Dures3,4, P. Machado5,6,7. 1 Nursing School of Coimbra (ESEnF), Health Sciences Research Unit: Nursing (UCI/CISA: E), Coimbra, Portugal; 2 Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 3 University of the West of England, School of Health and Social Wellbeing, Bristol, United Kingdom; 4 Bristol Royal Infirmary, Academic Rheumatology, Bristol, United Kingdom; 5 University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom; 6 University College London Hospitals NHS Foundation Trust, National Institute for Health Research (NIHR) University College London Hospitals Biomedical Research Centre, London, United Kingdom; 7 Northwick Park Hospital, London North West University Healthcare NHS Trust, Department of Rheumatology, London, United Kingdom

Background: Several EULAR recommendations for the management of people with specific inflammatory rheumatic and musculoskeletal diseases (I-RMDs) have highlighted the importance of some non-pharmacological interventions in the management of fatigue [1-3]. However, these recommendations are either disease-specific or focusing on a single intervention, and lack an integrated view of the overall evidence for fatigue management with non-pharmacological therapies in the wider context of all I-RMD.

Objectives: To identify the best evidence on the efficacy of non-pharmacological interventions in reducing fatigue in people with I-RMDs and to summarise their safety in the identified studies to inform EULAR recommendations for the management of fatigue in people with I-RMD.

Methods: Systematic review of adults with I-RMD conducted according to the Cochrane Handbook. Search strategy ran in Medline, Embase, Cochrane Library, OINAHL, Complete, PEDro, OTseeker and PsyCINFO. Assessment of risk of bias, data extraction, and synthesis performed by two reviewers independently. Data pooled in statistical meta-analyses.

Results: From a total of 4,150 records, 454 were selected for full-text review, 82 of which were included in meta-analyses. Physical activity or exercise were efficacious in reducing fatigue in rheumatoid arthritis (RA) (SMD=-0.23, p<0.001), systemic lupus erythematosus (SLE) (SMD=-0.54, p=0.04) and spondyloarthritis (SpA) (SMD=-0.94, p<0.001). A reduction in fatigue was also observed in Sjögren's syndrome and systemic sclerosis, although not statistically significant (SMD=-0.83, p=0.21; SMD=-0.66, p=0.06, respectively). Psychosocial interventions were efficacious in reducing fatigue in RA (SMD=-0.32, p<0.001), but not in SLE (SMD=-0.19, p=0.18). Follow-up models in consultations and multicomponent interventions reduced fatigue in RA, although the effect was not statistically significant (SMD=-0.05, p=0.71; SMD=-0.20, p=0.24, respectively) (Figure 1).

Background: Juvenile idiopathic arthritis (JIA) is the most frequently occurring rheumatic disease of childhood. It causes ongoing joint inflammation, pain and stiffness making everyday activities difficult. Studies have emphasised the negative impacts JIA has across physical, social, psychological, and educational development. Devices exist to assist with daily activities such as washing, eating, or writing. However, a survey we conducted in 2018 highlighted that the majority of these are designed for adults. Those designed for Children and Young People (CYP) are often either difficult to use, stigmatising, patronising, or fail to address their unique needs and contexts. This has resulted in numerous unmet needs and a lack of effective innovations for this population. The innovation, JIA Toolbox, was co-designed, meaning CYP with JIA, their parents, healthcare professionals, teachers and design researchers collectively collaborated throughout its development. Here, we present the intervention stage of the project, where JIA Toolbox was tested and evaluated by CYP with JIA.

Objectives: To evaluate the potential impacts of JIA Toolbox in improving independence and functional ability of CYP with JIA. To obtain real-world feedback on

E. Santos1, B. Farisogullari2, E. Dures3,4, P. Machado5,6,7. 1 Nursing School of Coimbra (ESEnF), Health Sciences Research Unit: Nursing (UCI/CISA: E), Coimbra, Portugal; 2 Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 3 University of the West of England, School of Health and Social Wellbeing, Bristol, United Kingdom; 4 Bristol Royal Infirmary, Academic Rheumatology, Bristol, United Kingdom; 5 University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom; 6 University College London Hospitals NHS Foundation Trust, National Institute for Health Research (NIHR) University College London Hospitals Biomedical Research Centre, London, United Kingdom; 7 Northwick Park Hospital, London North West University Healthcare NHS Trust, Department of Rheumatology, London, United Kingdom

Background: In 2008, Smolen et al. published their 2008 EULAR recommendations for physical activity in people with inflammatory arthritis and osteoarthritis. Since then, there have been several incremental updates of these recommendations. These include the 2015 update by the same group, in which they provided new guidance on physical activity in people with inflammatory arthritis and osteoarthritis. These guidelines were developed by an international task force, which included rheumatologists, physiotherapists, and patients with inflammatory arthritis and osteoarthritis. The task force reviewed the available evidence on the effects of physical activity on various aspects of inflammatory arthritis and osteoarthritis, including pain, physical function, quality of life, and health-related quality of life. The task force then made recommendations for the amount and type of physical activity that is beneficial for people with inflammatory arthritis and osteoarthritis.

REFERENCES:
A sample size of 10 CYP (7-16yrs), their parents and teachers were involved. Whilst small, this number was felt adequate due to the individual and qualitative nature of JIA condition experience. Their involvement included:

- Training sessions for data collection and prototype use. CYP and their parents recorded their daily experience using a digital booklet with specific questions about their condition and prototype use.
- 3-week baseline data collection without JIA Toolbox.
- 5-week intervention data collection with JIA Toolbox.
- 1-week post intervention data collection without JIA Toolbox.
- End of intervention interview.

Results: Analysis of the findings is currently being undertaken. Preliminary results indicate that 70-90% of the sample group found one or more of the innovations highly beneficial, helping with their overall condition management. Prototype 1 was highlighted as an effective therapeutic aid “it helped soothe my knee, I liked how you can position it exactly where it hurts”. One patient found it reduced pain when used with joint injections. Prototype 2 was helpful for physiotherapy exercises “to keep count” and “know how long the regularity of their physio stretches over the intervention period. The innovation acted as an ongoing reminder, “it encouraged him to do his physio stretches as he hadn’t been doing any before” Prototype 3 “helped communicate when I was in pain and needed help”. The use of this intervention depended on the child’s individual confidence, with those feeling less confident, relying more on the technology. These users found it beneficial, “the teacher knew I needed a rest break without me having to say anything in front of the rest of the class”. Participants also highlighted areas that could be improved to increase ease of use and engagement.

Conclusion: Based on initial results, the proof-of-concept was successful with these innovations proving to be beneficial to CYP with JIA. The patient data will allow refinement of these devices and provide insights into the lived experiences of CYP with JIA. These devices may have applicability to both adult populations with rheumatic disease and CYP with other conditions. Further research will explore these avenues in the future. Next steps include applying for further funding to undertake a feasibility study with a larger sample population.

**Conclusion:** Patient representatives of RMD patient organisations represent diverse profiles of health literacy strengths and weaknesses, but the most complex challenges in the original patient survey were not found. Differences may relate to how patients are selected and supported to become a representative, and how being a representative improves some aspects of health literacy. Patient organisations should take into account that their target population generally has more difficulty actively managing health and critically appraising information, and includes more people with diverse health literacy needs than their patient representatives may report.

**Background:** Lupus nephritis (LN) is a common and severe complication of systemic lupus erythematosus (SLE) requiring renal biopsy to guide treatment decisions. Despite standard-of-care therapy, a third of patients with LN class III, IV, or V show a progressive decline in kidney function, including those with improved proteinuria. Defining LN heterogeneity using a non-invasive approach is a pressing need to improve treatment.

**Objectives:** To determine circulating immune cell phenotypes characteristic of LN histology.

**Methods:** Mass cytometry using four 48-marker panels were applied to characterize peripheral blood mononuclear cells (PBMC) from 140 patients with biopsy-proven class III, IV, or V LN and 40 healthy controls included in the Accelerated Medicine Partnership RA/SLE Network Phase II study. After filtering for quality control and correcting for batch effects, we projected subjects in a UMAP space. We clustered LN patients and controls based on proportions of all PBMC subsets using k-means clustering and identified cell neighborhoods and clusters using an unsupervised approach. We implemented covarying neighborhood analysis (CNA) to identify cell populations associated with clinical features.

**Results:** Compared to controls, LN patients displayed marked enrichment of cell neighborhoods that expressed interferon (IFN)-induced proteins including IFN-responsive cells (p < 0.001) and Siglec1 (p < 0.001), reflecting a simple, cytometric detection of an IFN signature. Detailed immune cell subsetting using the B cell- (Figure 1A), T cell-, myeloid cell-, and NK cell-focused panels identified several alterations in LN patients compared to controls, including increased CD27 IgD (DN) CD11c+ Tbet+ B cells (OR 1.6, 95% CI 1.3-2.2, p.adj < 0.001) and T peripheral helper cells (OR 1.8, 95% CI 1.3-2.8, p.adj = 0.002), and decreased plasmacytoid dendritic cells (OR 0.6, 95% CI 0.4-0.8, p.adj < 0.001), adjusting for age, sex, ethnicity and race. LN patients with minimal immunosuppression (IS, n = 14) displayed similar results. Comparing patients with proliferative LN (class III or IV vs V, n = 94) versus membranous LN (class V, n = 46), we observed the most significant alterations within B cells, with enrichment of a naive B cell population characterized as CD23- and CD19+ (Figure 1B,C). The phenotype of this enriched naive B cell population was distinct from transitional and CD11c- ‘activated naive’ cells (Figure 1D). This B cell population was also associated with increased histologic NIH activity score (Figure 1B,C) even after adjusting for IS, and with positive anti-dsDNA antibody (p = 0.02). To further understand the LN heterogeneity, we clustered LN patients and controls based on proportions of all PBMC subsets using k-means clustering and projected subjects in a UMAP space. We identified two prominent clusters: cluster 1 included only LN patients, and cluster 2 included all controls and 26 LN patients. LN patients in cluster 2 (Control-like) had significantly lower clinical extrarenal activity (coef -2.1, 95% CI -2.8—-2.0, 95% CI -36.6—19.4, p.adj < 0.001), adjusting for IS. In line with these findings, we confirmed by CNA the association of increased histologic chronicity with fewer MX1+ or Siglec1+ IFN-responsive cells, adjusting for IS (p.adj = 0.002, FDR < 10%).

**Conclusion:** In addition to profoundly impaired circulating immunophenotype observed in LN patients, we identified a difference in naive B cell states in patients with LN compared to membranous LN. Based on circulating immunophenotype, we identified a subset of SLE patients with low extrarenal activity and increased histologic evidence of chronic kidney damage. These results nominate potential non-invasive biomarkers associated with LN heterogeneity and highlight altered naive B cell activation in proliferative LN.

**Keywords:** Spondyloarthritis, bDMARD, Geographical differences

**References:**

**Background:** Previous studies have suggested there could be regional differences in clinical phenotype of axial spondyloarthritis (axSpA).
Objectives: This analysis aims to explore differences in axSpA clinical phenotype around the world in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS).

Methods: IMAS was a cross-sectional online survey (2017-2022) of 5,557 unselected axSpA patients from 27 countries. We analysed across 5 geographic regions the age at onset of symptoms, classification as radiographic or non-radiographic, gender, HLA-B27, axSpA family history, extra-musculoskeletal manifestations (uveitis, inflammatory bowel disease and psoriasis), presence of comorbidities, disease activity (BASDAI), level of spinal stiffness, and treatment (NSAIDs, csDMARDs and bDMARDs). Kruskal-Wallis and chi-square test were used to compare axSpA characteristics across the regions.

Results: 5,557 patients participated in IMAS survey of which 3,493 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Results showed statistically significant differences between regions, except for the classification status (radiographic or non-radiographic). Age at onset of symptoms ranged between 25-30 years, and was higher in Latin America as compared to other regions. Diagnostic delay was longest in South Africa and lowest in Asia. The lowest frequency of HLA-B27 positivity was observed in Latin America and the highest in Asia. Family history of SpA was most often recorded in Europe and less often in Asia. All extra-musculoskeletal manifestations included were lowest in Europe compared with other regions. Physical and mental comorbidities were frequent in African patients and less common in Europe and Asia. Mean disease activity (BASDAI) was 5.4, with highest values in South Africa and lowest in Asia. Spinal stiffness was highest in South Africa and lowest in Latin America. Functional limitation was higher in North America and Europe and lower in Asia. Most of the patients had used NSAIDs for their condition and less than half had ever taken csDMARDS; both were more frequent in Latin America and South Africa. Almost half of the patients had ever taken bDMARDs, more frequent being in the Americas (Map 1).

Conclusion: There is great heterogeneity of axSpA clinical phenotype presentation around the world. Further understanding of these differences is needed to achieve early diagnosis and initiation of disease treatment in axSpA.

Why is performing a good systematic literature review (SLR) so difficult?

Keywords: Systematic review, Vasculitis, Imaging

P Bosch1, M. Bond2, C. Dejaoc3, C. Ponte3,4, S. Mackie5,6, L. Falzon7, W. A. Schmidt8, S. Ramiro9,10, Medical University of Graz, Department of Rheumatology and Immunology, Graz, Austria; Hospital of Brunec (ASAA-SABES), Department of Rheumatology, Brunec, Italy; Centro Hospitalar Universitário Lisboa Norte, Department of Rheumatology, Lisboa, Portugal; 4Lisbon Academic Medical Centre, Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal; 5University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 6Leeds Teaching Hospitals NHS Trust, Leeds Biomedical Research Centre, Leeds, United Kingdom; 1University of Sheffield, Health Economics and Decision Science, School of Health and Related Research, Sheffield, United Kingdom; 2Immanuel Krankenhaus Berlin, Medical Centre for Rheumatology Berlin-Buch, Berlin, Germany; 3Leiden University Medical Centre, Rheumatology, Leiden, Netherlands; 4Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands

Background: Since the development of the EULAR recommendations for the use of imaging in large vessel vasculitis (LVV) in 2017, new data has emerged in the field of imaging techniques and their application in the diagnosis and follow-up of patients with giant cell arteritis (GCA) and Takayasu arteritis (TAK).

Objectives: To summarize the evidence on different imaging techniques for diagnosis, monitoring, and outcome prediction in LVV in order to inform an EULAR task force updating the recommendations for imaging in LVV.

Methods: Systematic literature review (SLR) on studies published between 2017-2022 on ultrasound (US), magnetic resonance imaging (MRI), computed tomography (CT), positron emission tomography (PET)-CT/MRI and fluorescein angiography in patients with LVV (PROSPERO registration CRD42022305845). Eligible study designs included randomized controlled trials and observational studies but excluded case-controlled studies. Two reviewers independently performed data extraction, synthesis, and risk of bias assessment. For studies on diagnosis, meta-analyses were performed using data from both the original and updated SLR whenever possible. Pooled sensitivities and specificities were obtained by fitting random effects models for all studies and for studies with low risk of bias separately. Meta-analyses were performed in R version 4.2.1 using the “meta” package. The description of observations without inferences and the heterogeneity of reported data precluded any meta-analysis for outcome prediction or monitoring.

Results: A total of 4696 references were identified. Thirty-eight studies on GCA (n=32), TAK (n=2), and GCA and TAK (n=4) were included through the update, adding up to eighty-one studies from both SLRs. Pooled sensitivities and specificities for US, MRI and PET-CT using a clinical diagnosis of GCA as the reference standard are depicted in Table 1. No studies on the diagnostic value of imaging techniques were found for TAK. The US evaluation of patients with suspected GCA, including the assessment of both cranial and extracranial vessels, showed a higher pooled sensitivity (95%CI) (69% [73%-96%] vs 70% [59%-79%]) and similar specificity (95%CI) (91% [93%-95%] vs 91% [84%-94%]) compared to only including cranial vessels. Studies on outcome prediction (n=5) and monitoring (n=10) reported change of signs of vasculitis along with disease activity and proposed composite scores comprising several vessel territories for US, MRI and PET-CT.

Conclusion: US, MRI and PET-CT revealed a good performance for the diagnosis of GCA. Assessing both cranial and extracranial vessels with US leads to a higher pooled sensitivity with a similar pooled specificity compared to an assessment limited to cranial vessels.

Talking about Remission

OP0189

REMSSION CRITERIA GUIDING IMMUNOSUPPRESSIVE THERAPY IN RA: WHICH IS BEST FITTED FOR THIS PURPOSE?

Keywords: Remission, Treat to target, Rheumatoid arthritis

C. Duarte1, R. J. O. Ferreira2, P. Welsing3, J. W. G. Jacobs4, P. Machado5, D. Van der Heijde6, J. A. P. Da Silva1, 1Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Nursing School of Lisbon (ESEL), Nursing Research, Innovation and Development Centre of Lisbon (CIDNUR), Lisboa, Portugal; 3UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands; 4Sorbonne Université, and Pitié Salpêtrière Hospital, Rheumatology, Paris, France; 5University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom; 6LUMC, Rheumatology, Leiden, Netherlands

Background: Remission is the target for the management of rheumatoid arthritis (RA). However, the best definition of remission is still under debate, particularly regarding the inclusion of patient global assessment (PGA),[1] An increased cut-off for PGA (from ≤1 to ≤2cm) was recently proposed by ACR/EULAR for its Boolean-based criteria,[2] but others have suggested to replace PGA by the Physician’s Global Assessment (PhGA).[3] In case of poor PhGA, or to simply drop PGA (ie, 3-Variable Boolean remission) when the objective is to guide immunosuppressive therapy.[2] Radiographic progression is a relevant reference standard to investigate as outcome of persistent/residual disease activity.

Objectives: To assess which definition of remission best predicts good radiographic outcome (GRO) in RA.

Methods: Meta-analyses using individual patient data (IPD) from 8 randomized controlled trials assessing the efficacy of bDMARDs on radiographic outcomes in RA. Six different definitions of remission were considered: i) The ACR/EULAR Boolean 3v PGA; ii) SDAI≤3.3; iii) CDAI≤2.8; iv) Boolean 4v PGA2; v) Boolean 4v replacing PGA by PhGA (4vPhGA); and vi) Boolean excluding PGA (3v). Good radiographic outcome (GRO) was defined as an increase of ≤0.5 modified Total Sharp score (mTSS) units. The relationship between achieving each remission definition at 6 and/or 12 months and GRO during the second year was analysed. The pooled probabilities of GRO for the different definitions of remission were estimated and compared, as well as their predictive accuracy (True Positive + True Negative). Meta-analyses were performed using the DerSimonian-Laird random-effects method.

Results: IPD from 4423 patients of 8 RCTs were analysed. 4vPGA remission was achieved by 24.3% of patients and 3V remission by 43.4%. The adoption of the recently proposed PGA≤2 cut-off resulted in an “in-between” rate of 32.4% (Table 1). GRO was observed in 77.6% of all patients, ranging from 63% to 91% in different trials. GRO among patients achieving remission ranged from 82.4% (3v) to 83.9% (SDAI), without any statistically significant difference between the 6 definitions considered. Boolean 3v remission showed a higher predictive accuracy (51.1%, 95%CI: 46.9-55.6%) than 4vPGA (38.8%, 95%CI: 34.1-43.5%). The 4vPGA and the 4vPGA2 remission definitions performed in between, providing a correct prediction in 43.8 and 44.8% of the cases, respectively. The performance of SDAI- and CDAI-based definitions were, overall, very similar to that of 4vPGA. (Figure 1)

Conclusion: The Boolean 3v remission provided the most accurate prediction of GRO, even better than 4vPGA and 4vPhGA remission. The use of the 3v definition in treatment recommendations would avoid the risk of overtreatment in a significant proportion of patients, with a minor increment in radiographic damage progression, validating 3v-remission as a preferable guide for immunosuppressive treatment. The patient’s perspective, which must remain central, is best served by a dedicated autonomous target, rather than PGA: a dual-target approach.

OP0190

A MACHINE LEARNING MODEL THAT PREDICTS RA PROGRESSION FROM UNDIFFERENTIATED ARTHRITIS -KURAMA AND ANSWER COHORT STUDY-

Keywords: Rheumatoid arthritis, Undifferentiated connective tissue disease, Real-world evidence

Background: Early diagnosis and treatment of rheumatoid arthritis (RA) improve clinical outcomes. Undifferentiated arthritis (UA) is arthritis that does not fit a specific diagnosis. Half of the UA undergo spontaneous remission, while 30% of cases develop RA. Therefore, in UA, identifying patients at high risk for developing RA and providing close monitoring for those patients is required for early diagnosis and treatment [1]. However, predicting the evolution of UA to RA is still difficult.

Objectives: Machine learning, including deep learning, which is comparable to and in some cases surpasses the performance of human experts, is broadening its application in medicine. This study aims to build a machine-learning model that predicts the development of UA to RA.

Methods: For model training, a total of 322 UA patients in KURAMA cohort were analyzed (Table 1). For variables to train models, we chose 24 clinical features, which are easy to obtain in daily clinical practice. The target variable was the final diagnosis. We built models using Random Forest (RF), XGBoost (XGB), Logistic regression (LR), and Deep neural network (DNN) and compared their performances. For model validation, we used data of 88 UA cases in ANSWER cohort (Table 1).

Results: We trained models using 24 clinical parameters at the first clinical visit, performed 10-fold cross-validation, and evaluated model performance by averaging accuracy and AUC. The performance of the models was 73.5%, 74.2%, 74.5%, and 85.1% in precision and 0.760, 0.734, 0.748, and 0.895 in AUC for RF, XGB, LR, and DNN, respectively. DNN showed the highest performance. We then applied the DNN model to external validation data from ANSWER cohort (positive %, median, yr), Table 1.

Conclusion: Using parameters available in clinical practice, we developed a DNN model that effectively predicted RA development in internal and external UA data sets. Applying a machine learning approach might enable identifying patients at high risk of RA progression and improve the clinical management of UA patients.

Exploring and managing inequalities in RMD healthcare

Keywords: Quality of life, Systemic lupus erythematous, Self-management

E. Williams1, V. Ramakrishnan2, L. Egede3, A. Boan4, T. Caldwell5, C. Dismuke-Greer6, J. Rose7, H. Johnson8, J. Oates9. 1University of Rochester Medical Center, Public Health Sciences, Rochester, United States of America; 2Medical University of South Carolina, Public Health Sciences, Charleston, United States of America; 3Medical College of Wisconsin, Medicine, Milwaukee, United States of America; 4Medical University of South Carolina, Pediatrics, Charleston, United States of America; 5VA Palo Alto, Health Economics Resource Center, Palo Alto, United States of America; 6Hospital for Special Surgery, Social Work Programs, New York, United States of America; 7Lupus CSC, NA, Columbia, United States of America; 8Medical University of South Carolina, Rheumatology and Immunology, Charleston, United States of America

Background: Disease self-management indicates practical ways to deal with pain, fatigue, and stress and can include better nutrition, exercise, understanding treatment options, and better communication. Evidence-based self-management interventions designed to enhance social support and provide health education, among lupus patients, have demonstrated significant improvements in health distress, self-reported global health, and activity limitation, but African Americans and women are still disproportionately impacted by systemic lupus erythematous (SLE).

Objectives: The purpose of this study was to determine whether participation in a new, culturally tailored peer mentoring intervention was associated with improvements in disease self-management and health related quality of life (HRQOL) among African American women with systemic lupus erythematous (SLE).

Methods: The Peer Approaches to Lupus Self-Management (PALS) study was a randomized controlled trial wherein modeling and reinforcement of disease self-management skills by peers (mentors) to other African American women with SLE (mentees) was achieved through a combination of educational and informal phone or video interactions with each other. The control condition included small support groups that met on the same schedule as peer mentoring sessions. The Lupus Quality of Life questionnaire (LUP-QOL), which incorporates the Medical Outcomes Study (MOS) Short Form 36 Health Survey (SF-36) and the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), was used to determine HRQOL, and the Patient Activation Measure (PAM) assessed disease self-management or an individual’s knowledge, skill, and confidence for managing their health and healthcare. Generalized Linear Mixed Models were used to determine whether the intervention produced a greater change in these main outcomes from baseline, controlling for education, income, and age, reported.

Results: Of the 314 enrolled PALS participants, 138 were mentored (experimental), 132 participated in small support groups (controls), and 44 served as mentors. Although not statistically significant, there were incrementally improving trends in patient activation as the intervention progressed, among mentors and experimental participants and decreasing trends in depression and anxiety among experimental participants. Measures of social functioning (from the LUPQOL) and coping (or lupus self-efficacy) significantly improved from baseline, among experimental participants (both p < 0.05).

Conclusion: Our findings suggest that participation in a peer mentoring intervention led to improvements in disease self-management and HRQOL, in areas of social functioning, coping, depression, and anxiety, among African American women with SLE. Since these factors are related to disease activity and morbidity/damage, future investigations should consider ways in which this approach can augment clinical care on a larger scale.

Mind the gap: improving communication and outcomes

Keywords: Patient information and education, Gender/diversity issues, Pregnancy and reproduction

L. Faravelli1, A. Celano2, V. Corazza3, S. Tonolo4. 1Vivactis Media For Health, Communication, Milano, Italy; 2APMARR - Associazione Nazionale Persone con Malattie Reumatologiche e Rare - APS, President, Lecce, Italy; 3APIAFCO - Associazione Psoriasici Italiani Amici della Fondazione Corazza, President, Bologna, Italy; 4ANMAR Italia Onlus - Associazione Nazionale Malati Reumatici Onlus, President, Roma, Italy

Background: The World Health Organization (WHO) defines Gender-specific Medicine as the study of how biological and socioeconomic and cultural differences influence people’s health. (1) In autoimmune diseases (AD), particularly rheumatic and dermatologic ones, Gender makes the difference. Among millions of people affected worldwide, 80% are Women. (2) AD can arise more frequently in childbearing age, can impact female fertility and pregnancy outcomes, with consequences on the overall quality of life, both for the people affected and their families and caregivers.

Objectives: Genere Donna is a project aimed at setting up an awareness campaign on Gender Medicine focused on rheumatic and dermatologic autoimmune diseases. It spreads and updates a clear information, validated by experts, about Gender Medicine and rheumatic and dermatologic ADs, to improve knowledge, promoting patients’ empowerment and the importance of a gender approach in Public Health.

Methods: Genere Donna has been launched in July 2021. The website www.generedonna.it and the social media profiles are the heart of the project, raising awareness also through adv campaigns (SEM and social media) and ad-hoc content marketing. The close teamwork of the main Italian patients’ associations ANMAR (Associazione Nazionale Malati Reumatici Onlus), APMARR (Associazione Nazionale Persone con Malattie Reumatologiche e Rare aps) and APIAFCO (Associazione Psoriasici Italiani Amici della Fondazione Corazza) and some authoritative experts KOLs in AD (5 physicians and a welfare expert) is the key for success. Genere Donna is supported by a digital communication agency.

Results: Over 16 months of activity, there were about 160K website users (70% female, 56% of them are 18-44 years old), over 6.6Mln reach and over 220K interactions on social media, and a strong social community of around 27K people was developed. Over 210 questions received through the “Ask the Expert” service. Genere Donna recently received the patronage from SIR-Società Italiana di Reumatologia (Italian Society of Rheumatology) and SIdemAST, Società Italiana di Dermatologia e Malattie Sessualmente Trasmesse (Italian Society of Dermatology).

Conclusion: The strong need of clear and verified information around Gender Medicine is testified by the wide number of social media interactions and website visits. The good results reached by Genere Donna up to now and many positive comments coming from the community push the project ahead in the future, to be more and more near to the patients affected by rheumatic and dermatologic ADs.

Clinical and molecular differences across sexes in Rheumatic Disease

Keywords: Inflammatory arthritides, Genetics/Epigenetics, Gender/diversity issues

M. Tordoff1, S. Smith1, A. Morris1, S. Eyre1,2, W. Thomson1,2, J. Bowes1,2
1The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom; 2National Institute of Health Research Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background: Juvenile idiopathic arthritis (JIA) encompasses a group of childhood onset rheumatic diseases that primarily affect females. JIA has been reported to occur in females and males with a 2:1 ratio, however, systemic JIA is reported more frequently in male patients. Genetic risk factors may contribute to the sex dimorphism in JIA incidence, however this contribution has yet to be defined.

Objectives: To investigate, using sex dimorphism analysis, whether genetic risk factors for JIA differ in males and females.

Methods: High quality genotype data was available on 3356 JIA cases (females = 2209, males = 1147) and 9196 controls (female = 4059, males = 5137). Our primary analysis combined sex-specific GWAS summary statistics using the GWAMA software package. Summary statistics were calculated using logistic regression with three principal components as covariates using PLINK. The sex-differentiated p-value (p*) provided overall evidence for association to JIA allowing for differences between males and females, and the heterogeneity p-value (phet) provided evidence to support a difference in effect estimates between sexes. As a secondary analysis we performed a logistic regression, as above, on all samples and included sex as an interaction term (pinter). Amino acid residues in HLA genes and alleles were imputed using PLINK. The sex-differentiated p-value (p*) provided overall evidence for association to JIA allowing for differences between males and females, and the heterogeneity p-value (phet) provided evidence to support a difference in effect estimates between sexes. As a secondary analysis we performed a logistic regression, as above, on all samples and included sex as an interaction term (pinter).

Results: A total of 6571296 SNPs were analysed after quality control. The strongest signal detected using a logistic regression in females was rs9469137 (p = 1.7x10^-56) and in males it was rs11666910 (p = 9.7x10^-59). GWAMA supported evidence of sex heterogeneity for these SNPs, rs9469137 pinter = 2.2x10^-10, ORmale = 2.6, ORfemale = 5.3, rs11666910 pinter = 1.8x10^-14 ORmale = 4.0, ORfemale = 16.7. The strongest signal from the sex-specific GWAS was rs9266716, pinter = 1.9x10^-17, pSet = 7.7x10^-18, ORmale = 1.2, ORfemale = 0.6. These SNPs all map to the HLA region, providing strong evidence for sex dimorphism in this region, therefore sex-specific HLA fine mapping was conducted. This analysis revealed that residues at position 13 of HLA-DRB1 were strongly associated with JIA in females (pSetfemale = 1.8x10^-54). Glycine at position 13 of HLA-DRB1 was most strongly associated with JIA in females (ORfemale = 3.6, psetfemale = 4.1x10^-65, ORmale = 1.9, psetmale = 9.6x10^-13). An association test with sex as an interaction term revealed glycine at position 13 as sex dimorphic, p = 4.3x10^-7. Associations of residues at position 13 of HLA-DRB1 have previously been reported in JIA, where the cohort consisted of oligoarthritis and rheumatoid factor negative polyarthritis individuals. These ILAR subtypes have a greater frequency in females. HLA-B27 was detected as strongly associated with JIA in male patients (psetmale = 5.4x10^-64, ORmale = 3.8, psetmale = 2.5x10^-9, ORmale = 1.6). An association test with sex as an interaction term revealed HLA-B27 to be strongly sex dimorphic, p = 7.5x10^-13. HLA-B27 is a well-established risk factor for ERA, where males are predominately affected. Outside of the HLA region, the strongest associated SNP was rs58020114, p = 6.3x10^-17, pSet = 5.7x10^-7 ORmale = 1.3, ORfemale = 0.7. This SNP is located near the BPN72 gene and had a greater effect size in males.

Conclusion: This analysis reveals that there are several sexually dimorphic genetic risk factors that may affect JIA development in males and females. For the first time markers within the HLA region have been detected as sex dimorphic. Understanding the genetic risk factors to JIA development will help to further define the disease, which may aid in disease classification and diagnosis in the future. In particular, the substantial differences in effect estimates observed between males and females suggests that sex-specific polygenic risk scores should be considered when HLA signals are incorporated into these efforts.

Pain in RMDs

INFLAMMATION-INDUCED PAIN AND FATIGUE IN FIBROMYALGIA AND ME/CFS AND ROLE OF VARIANT CONNECTIVE TISSUE

Keywords: Fibromyalgia, Cytokines and chemokines, Patient reported outcomes

J. Eccles1, M. Amato1, J. Themelis2, L. Quadt3, H. Critchley1, N. Harrison7, K. Davies4, 1Brighton and Sussex Medical School, Neuroscience, Falmer, United Kingdom; 2University of Warwick, Psychology, Coventry, United Kingdom; 3University of Cardiff, CUBRIC, Cardiff, United Kingdom; 4Brighton and Sussex Medical School, Clinical and Experimental Medicine, Falmer, United Kingdom

Background: Fibromyalgia and ME/CFS are multifaceted conditions with overlapping symptoms(1); the pathophysiological mechanisms are under debate. It remains unclear whether dysregulated inflammation, induced either by an exogenous stressor (e.g. a virus or other stressor), or autoinnunity, is of prime importance [2].

Objectives: 1. To determine in a novel human model the effects of an in vivo inflammatory challenge in the injection of pain and fatigue in fibromyalgia and ME/CFS compared to controls.

2. Explore potential mediators and moderators involved.

Methods: Data were available for 48 patients with confirmed diagnoses of Fibromyalgia and ME/CFS and 22 matched controls, who had undergone a placebo controlled inflammatory challenge (typhoid vaccination) as part of ISRCTN78820481. Participants underwent full research diagnostic evaluation including a hypermobility assessment. Subjective pain and fatigue were assessed after saline injection and typhoid vaccination (VAS). Linear regression models were used to explore predictors, with adjustment for potential confounders (age/gender) and baseline levels as appropriate. Mediation analyses (looking for mechanistic effects) were conducted according to the method of Hayes (3) and mediation considered significant if bootstrapped confidence intervals of the estimated indirect effect did not cross zero. In these mediation analyses predictor variable was group membership (patient or control), outcome variable was change in 1) pain and 2) fatigue induced by challenge and mediators/moderators included change in IL-6 induced by inflammatory challenge and hypermobility features.

Results: Being a patient rather than control significantly predicted inflammation-induced fatigue (B=14.89 (95%CI 3.39-26.50), t=2.56, p=0.013) and pain (B=12.88 (95%CI 0.65-25.10), t=2.11, p=0.039) after adjusting for levels induced by placebo. Induced pain was independently predicted by level of IL-6 induced by inflammatory challenge (B=23.44 (95%CI 5.15-41.72),t=2.57, p=0.013) as well as induced fatigue (B=10.63 (95%CI 2.84-18.41), t=2.73, p=0.008) Mediated moderation analyses suggested the link to induced pain and fatigue through induced inflammation was associated with hypermobility features (Index of mediated moderation 11.02 (95%CI 1.45-22.73) and 6.20 (95%CI 0.07-13.64) respectively)

Conclusion: To our knowledge this is the first human study to evaluate directly the effect of an exogenous inflammatory challenge (typhoid vaccination) in a combined group of Fibromyalgia and ME/CFS patients. IL-6 was shown to be a critical mediator. This work strongly supports the hypothesis that inflammation is key to the pathophysiology of ME/CFS. We are evaluating associated CNS inflammation in the model, as well as other associations, such as autonomic dysfunction and hypermobility. Further understanding the mediators involved in the condition should in future open the way to testing targeted anti-inflammatory therapy.

TARGETED ABLATION OF KNEE-INNERVATING NOCICEPTORS HAS PROFOUND EFFECTS ON JOINT DAMAGE IN EXPERIMENTAL OSTEOARTHRITIS

Keywords: Osteoarthritis, Animal models

L. Wang1, S. Ishihara1, J. Li1, A. Obeidat1, R. Miller1, A. Maitland1. 1Rush University, Rheumatology, Chicago, United States of America

Background: Sensory afferents abundantly innervate the knee joint. The vast majority of these are pain-sensing nociceptors, which express the voltage-gated sodium channel Na+1.8. Using Na+1.8Cre-Tomato reporter mice, we have documented innervation changes that occur with experimental murine osteoarthritis (OA), including sprouting of nociceptors in the medial synovium and in subchondral bone [1]. Upon intra-articular (IA) injection into the mouse knee, adeno-associated virus serotype AAV.PHP.S is retrogradely transported to the lumbar dorsal root ganglia (DRG), where the cell bodies of sensory neurons reside [2].

Objectives: We leveraged this technique to selectively ablate knee-innervating nociceptors by IA injection of AAV.PHP.S carrying diptheria toxin A (dTA), and determine the effect on joint damage after destabilization of the medial meniscus (DMM).

Methods: Expt. 1: AAV.PHP.S containing pAAV-EF1a-mCherry-flex-dTA (AAV-dTA) was injected into the right knee of 7-week old male C57BL/6 Na+1.8Cre mice (3 µL, 107 vp/µL). Three weeks later, the TLR2 ligand, Pam3CSK4 (3 µg), was injected into these same knees, followed by knee hyperalgesia measurement using (PAM) over 24-hours [3]. Na+1.8Cre mice injected with AAV.PHP.S-EF1a-flex-GFP (AAV-Control) as well as wild type mice injected with AAV-dTA were included as controls (n=6 mice/group). Expt. 2: AAV-dTA or AAV-Control was injected IA into the right knees of 7-week old male Na+1.8Cre mice and 3 weeks later, DMM surgery was performed (n=19 mice/group). Mice were sacrificed 10 or 17 weeks after DMM, and knees collected for histology using a modified OARSI scoring system (toluidine blue, frontal plane). Expt. 3: Ten-week old male Na+1.8Cre mice underwent DMM surgery, and 4 weeks later, AAV-dTA or AAV-Control was injected IA into the operated knees (n=12 mice/group). Knees were collected 17 weeks after surgery for histology.

Results: Expt. 1: Na+1.8Cre mice injected with AAV-Control and WT mice injected with AAV-dTA responded to TLR2 stimulation, showing markedly decreased knee pain thresholds between 1 and 6 hours after IA injection of Pam3CSK4, as described [3]. In contrast, Na+1.8Cre mice injected with AAV-dTA did not respond to Pam3CSK4, indicating functional effects of ablating knee-innervating nociceptors with AAV-dTA. Expt. 2: Ten weeks after DMM, all mice showed mild OA joint damage, with no difference between groups (Figure 1A). However, while AAV-Control injected joints showed markedly increased cartilage damage by week 17, AAV-dTA injected joints showed no progression of cartilage degeneration compared to week 10. Osteophytes were comparable between the groups. Expt. 3: Seventeen weeks after DMM, mice that had been injected with AAV-dTA 4 weeks post DMM showed markedly increased cartilage degeneration, total joint scores, and osteophyte sizes compared to AAV-controls (Figure 1B).

Conclusion: IA delivery of AAV-dTA into enables selective ablation of Na+1.8+ neurons in the knee, as is evident from ablated pain responses to TLR2 stimulation. Experiments in the DMM model revealed a striking effect of ablation of joint nociceptors on joint damage. Nociceptor ablation before DMM significantly attenuated cartilage degeneration in late stage OA, while ablation of knee nociceptors...
after DMMA markedly worsened joint damage and osteophyte formation. These findings suggest an important role for nociceptors in joint homeostasis, with differential effects if nociceptors are ablated before or after joint damage occurs. Our findings suggest a neurogenic contribution to joint homeostasis. Current work focuses on documenting the joint nociceptive innervation in the different experimental groups, and the relationship with pain.

Figure 1.

Mean CPM effect was at baseline 0.25°C (± 2.57), 2.64°C (± 2.12) at 3 months and 2.96°C (±2.50) at 6 months. At the end of the 6 months follow-up, mean CPM effect was significantly higher in patients with residual mean pain intensity <4/10 compared to patients with persisting pain ≥ 4/10: 3,25°C (± 2,68) vs 2,47°C (± 2,11) (p<0.04).

Conclusion: After TNF inhibitor initiation in active RA or SpA, impaired diffuse noxious inhibitory controls are significantly improved. Apart from their articular efficacy, TNF inhibitor has an action on the central nervous system and pain modulation pathways. In patients with persisting pain under bDMARD, diffuse noxious inhibitory controls are not as efficient as patient without residual pain.

REFERENCES:
the initiation (High (120-199 MME/day): aOR: 34.81, 95%CI: 18–78.05, p<0.001 compared to mean daily MME: Low (≤50 MME/day)) were associated with higher risk of long-term opioid use. The three most important variables using the random forest model were mean MME/day at initiation (MDA 140), history of suicide and self-harm (MDA 40) and IMD (MDA 30).

Conclusion: Almost 1 in 4 patients with fibromyalgia starting opioids became a long-term opioid user in this nationally representative dataset across the UK within the first year. The dose of initial opioid prescription, high deprivation score, history of suicide and self-harm, substance use disorder and obesity were associated with long-term opioid use.

T. Hügle1, T. Pretat1, C. Lovejoy2, P. Ming Azevedo1. 1University Hospital Lausanne (CHUV), Rheumatology, Lausanne, Switzerland; 2NHS, Medical Doctor, London, United Kingdom

Background: Chronic Pain Syndromes (CPS), including fibromyalgia (FM), place a significant health and socioeconomic burden. Despite sharing a similar clinical presentation, they are a heterogeneous entity, often with different causes and in association with other conditions. Multimodal treatment programs allow a comprehensive clinical and physical assessment of those patients. Objectives: The objective of this study is to identify subtypes in CPS patients including primary and secondary FM who were assessed during a two-week multimodal pain management program via an unsupervised machine learning model.

Methods: We collected data from 202 patients as part of a 2-week multimodal pain management program. Clinical features, comorbidities, medications and demographics were collected and patients were assessed by physical and mental questionnaires (e.g. BPI, FABQ, FABQ-W, POAM, HAS, HDS, PCS, TAMPA, OD) before and after the program. There was a weekly interdisciplinary case discussion between rheumatologists, pain specialists, psychiatrists, physiotherapists and occupational therapists. For data analysis, hierarchical agglomerative clusters were generated using the Ward variance minimization algorithm with Euclidean pairwise distances (Python 3.10). The number of clusters was selected by inspecting visualizations (including dendograms and radar plots), in combination with clinical interpretability and utility.

Results: Five patient subtypes with the following characteristics were identified: Cluster 1: Obese men with persisting peripheral and axial musculoskeletal pain, sometimes with an underlying immune-mediated disorder (IMD), poorly responding to disease modifying therapy. Bland psychological evaluation. Clinical interpretation: predominantly men in the late 50s. Possibly secondary FM, and/or underlying microcrystalline disorder or inflammatory osteoarthrisis. Very close to psychiatric evaluation or therapy. Cluster 2: Female patients with peripheral and axial pain since childhood or adolescence, sometimes with a post-traumatic stress disorder. Severe sleep problems. Clinical interpretation: primavera FM, sometimes with an additional traumatic psychological background. Cluster 3: Women with chronic back pain, often with previous (failed) spine surgery. Normal weight. Often polymedication with opioids, antidepressants and anxiolytics. Clinical interpretation: women with lumbar disc degeneration. Sometimes questionable spondylarthrits with refractory lumbar pain despite treatment with biologics. Cluster 4: Patients (men>woman) of younger age with low BMI and hyperflexia. Peripheral pain of nociceptical character predominates, often since childhood or adolescence. High incidence of depression, anxiety or other psychological conditions. Virtual reality treatment is efficient. Interpretation: somatofom pain in younger patients spilled over from adolescence, often with substantial psychiatric comorbidity. Cluster 5: Overweight women in peri-menopause with metabolic syndrome. Axial and peripheral pain. Often use of antidepressants, notably Trazodone. Blood sedimentation rate can be elevated. Interpretation: peri-menopausal syndrome in obese patients with pain and low grade inflammation such as burrsitis or tenosynovitis.

Conclusion: All five chronic pain phenotypes identified by unsupervised machine learning are consistent with clinical observations. Psychiatric comorbidities are prevalent in all clusters except one, where they may be suppressed. Work disability plays an important role in all patients. In at least two clusters, the pain seems to have its origin in childhood or adolescence. One cluster seems to be particularly influenced by hormonal and metabolic factors.

E. Mulmoen1,2, T. Neogi2, H. Solveig Dagfinrud1,2, H. B. Hammer1,2, P. Steen Petersen1,2, T. K. Kvien1,2, K. Magnusson3, I. K. Haugen1,2. 1Diakonhjemmet Hospital, Centre for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; 2University of Oslo, Faculty of Medicine, Oslo, Norway; 3Boston University School of Medicine, Section of Rheumatology, Boston, United States of America; 4Lund University, Department of Clinical Sciences, Lund, Sweden

Background: Hand osteoarthritis (OA) pain is characterized as heterogeneous and multifactorial. Different pain patterns may be explained by underlying phenotypes, which previously have not been explored.

Objectives: Using the biopsychosocial framework, we aimed to identify possible hand OA phenotypes and explore the associations with pain intensity and change in pain during a four-year follow-up.

Methods: Latent class analysis was used to determine classes of people with hand OA, based on baseline examination (2016-17), followed by posterior fit statistics. Biological, psychological, and social domains were examined by self-reported questionnaires, clinical assessment and imaging. Central pain sensitization was tested by pressure pain thresholds (PPT; kg/cm²) and temporal summation (TS). Pain intensity at baseline and follow-up (2019-21) was self-reported on a Numeric Rating Scale (0-10) for hand and overall bodily pain the last 24 hours. Change in pain was calculated for both pain measures. Differences of the biopsychosocial variables and pain measures were assessed by one-way ANOVAs and chi-squared tests. The relations of the classes to the pain outcomes were analysed by linear regression.

Results: We identified five classes (Table 1). The highest pain intensity was reported by the class with low OA severity but higher burden of the other factors (Class 5), whilst the class with the most OA severity of the hands and lower extremities (Class 4) reported approximately one point less for pain intensity (Figure 1). Classes showed little change in pain and there was no significant difference (data not shown). Significant differences were found across all classes in association to baseline and follow-up pain. However, not for change in pain (data not shown), except Class 5 and change in hand pain (beta (95% CI); 1.13 (0.02, 2.25)). Class 5 indicated the most hand and overall bodily pain in comparison to the reference group (Class 1) with a beta (95% CI) of 3.27 (2.32, 4.22) and 3.08 (p<0.05, 4.07) at baseline and 2.04 (1.02, 3.06) and 2.74 (1.73, 3.76) at follow-up, respectively. The difference was smaller when comparing to Class 4.
the reference group with a beta (95% CI) of 2.15 (1.27, 3.02) and 2.20 (1.27, 3.13) for hand pain and overall bodily pain at baseline, and a beta (95% CI) of 1.38 (0.46, 2.31) and 1.66 (0.74, 2.58) at follow-up. Class 3 indicated similar baseline values as Class 4 (Hand and overall bodily pain: beta (95%) of 2.24 (1.51, 2.97) and 1.89 (1.12, 2.65)).

Conclusion: We identified five potential hand OA phenotypes which associated with pain intensity at baseline and four years later. The phenotype with low OA severity, but more pain sensitization, comorbidities, higher psychological and social burden reported more pain than the phenotype with the most severe OA in the hands and lower extremities, reflecting the discordance between OA severity and pain experience.

Table 1. Characteristics of the biopsychosocial variables across the hand OA phenotypes. Data presented as mean (SD) unless otherwise indicated.

MIA-induced OA mice showed that administration of 10mg/kg THC by oral gavage also reduced mechanical allodynia (n=10/group) without modifying animal locomotion or anxiety. In vitro, THC treatment of human OA FLS and chondrocytes (n=5 each) increased Annexin V positivity starting at 2.5µM, but not with 1µM THC, as determined by flow cytometry. In cultured OA FLS (n=4), 73 genes were differentially expressed (35 upregulated, 38 downregulated) after treatment with THC compared to vehicle treatment (±1.5-fold), as determined by RNA sequencing (Figure 1D). Similarly, in OA chondrocytes RNA sequencing (n=4/group), 21 genes (9 upregulated, 12 downregulated) were differentially expressed (±1.5-fold) after THC treatment. Computational analyses indicated that ECM-related pathways were enriched in the upregulated genes in both fibroblasts and chondrocytes, while lipid/steroid/cholesterol-related pathways were enriched by the downregulated genes in both cell types. 22 common putative transcription factors were also identified as potential regulators of the fibroblast and chondrocyte genes reduced through THC treatment.

Conclusion: Oral administration of 10mg/kg THC reduced cartilage degeneration and synovitis in DMM mouse knee joints and modified pain responses in DMM and MIA models. JR, AM, HFF share equal first author contribution.

OP0201 INTRA-ARTICULAR INJECTIONS OF TWO LIPOSOMAL ADENOSINE FORMULATIONS PROVIDE SIGNIFICANT PAIN RELIEF AND GAIN IN FUNCTION, IMPROVE COMFORTABLE RANGE OF MOTION AND SLOWED RADIOLOGIC PROGRESSION IN A PRECLINICAL CANINE MODEL OF OSTEOARTHRITIS

Keywords: Osteoarthritis, Cartilage, Pain

D. Li1, B. N. Cronstein2, J. Cook3, C. Bozynski4, S. Angela1, Regenesis Inc, Princeton Innovation Center, Princeton, United States of America; 2New York University, School of Medicine, New York, United States of America; 3University of Missouri, School of Medicine, Columbia, United States of America

Background: Osteoarthritis (OA) affects 10% of global population and its effective non-surgical treatments represent significant unmet need. There has been a rapid escalation in the annual number of arthroplasties, placing a significant burden on patients and healthcare systems. We previously demonstrated that adenosine and its A2A receptor play critical roles in maintaining joint homeostasis. Adenosine treatment prevents structural progression and preserves articular cartilage in rodent models of OA.

Objectives: To test the new, more stable and long-lasting formulations of liposomal adenosine in the treatment of post-traumatic OA in a preclinical canine model.

Methods: OA was induced by arthroscopic medial meniscus release (MR) in 21 purpose-bred hounds (10M, 11F). Evidence of OA was documented at two months after MR (pre-Tx). Knees were injected with 3ml of RgnA09M, RgnA09N (3mg/ml Adenosine; N=7 each) or saline (9mg/ml NaCl; N=7) for a total of 3 intra-articular (IA) injections each carried out one month apart. RgnA09M and RgnA09N comprised identical lipid composition but varied in particle size and liposome lamellarity. Blind assessments for knee pain, function and effusion were performed using validated visual analogue scale (VAS) scoring by a board-certified veterinary surgeon. Comfortable range of motion (CROM) was measured using a standard goniometer and radiographic assessments of knee structure were performed using validated visual analogue scale (VAS) scoring by a board-certified veterinary surgeon. Radiographic results are pending.

Results: There was demonstrable symptomatic knee OA at pre-Tx with a 26.3% loss in function, increased joint pain score (2.0±0.9 vs 0 at pre-MR), 10% loss of CROM, development of radiographic OA (1.2±0.5 vs. 0 at pre-MR), observable OA on MRI (3.9±0.9 vs. 0 at pre-MR) and joint effusion (2.3±0.9 vs. 0 at pre-MR). Saline treatment provided no benefits. The IA administration of RgnA09M led to a steady decrease in pain by 65.0% and 74.3%, at 4mo and 6mo post-Tx respectively, with a corresponding 30.9% and 61.8% gain in function. In comparison, the injection of RgnA09N led to decrease in pain by 80.9% at 4mo but a loss of effect to 74.7 % at 6mo post-Tx. A corresponding trend was observed in the gain of function, with an overall gain of 39.7% at 6mo post-Tx (Figures 1A and 1B). Moreover, injections with RgnA09M, improved CROM to near-normal values at 6mo, while RgnA09N significantly improved it at 4mo (Figure 1C). Compared to saline, both RgnA09M and RgnA09N improved radiographic markers by up to 42.6% at 6mo post-Tx (Figure 1D). In saline-treated dogs there was an improvement in the size of effusions initially, but a loss in benefit as time progressed. In contrary, the magnitude of the change was much greater in those treated with both formulations, and it continued to improve over time (Figure 1E). Finally, at 6mo post-Tx, MRIIs showed significant slowing in the progression of OA with RgnA09M by 55.3% and with RgnA09N by 42.6% (Figure 1F). Histology and biomarker results are pending.

Conclusion: Three IA injections of RgnA09M and RgnA09N were associated with improved symptomatic knee OA including gain in function and decrease in pain and OA progression compared with saline. The persistent improvement lasted 6 months, indicating symptomatic and mechanistic benefits of the treatment. Moreover, liposomal adenosine injections slowed the progression of OA as observed on radiographs and MRIs. These findings provide the first evidence that IA injection of liposomal adenosine improves pain relief, gain in function, CROM, and prevents radiologic progression in a large animal model of post-traumatic OA.

Background: To date, there have been no comprehensive studies of the immune cells that play a pivotal role in treatment-resistant rheumatoid arthritis (RA).

Objectives: We performed large scale transcriptome analyses of immune cells in peripheral blood prior to treatment in a total of 55 patients with RA to identify the gene expressions and subsets that predict treatment resistance.

Methods: We isolated 18 peripheral blood mononuclear cell subsets of 55 pre-treatment RA patients and 39 healthy controls, and performed RNA sequencing (Figure 1A). Transcription changes in RA and treatment effects were systematically characterized. Association between immune cell gene modules and treatment resistance was evaluated. We validated predictive value of identified parameters for treatment resistance using quantitative polymerase chain reaction (qPCR) and mass cytometric analysis cohorts. We also characterized the identified population by synovial single cell RNA-seq analysis.

Results: Immune cells of RA patients were characterized by enhanced interferon and IL6-JAK-STAT3 signaling that demonstrated partial normalization after treatment. A gene expression module of plasmacytoid dendritic cell (pDC) reflecting the expansion of pre-dendritic cell (pre-DC), which is recently identified subpopulation of DCs (1), exhibited strongest association with treatment resistance (Figure 1B-D). Type I interferon signaling was negatively correlated to pre-DC gene expression. qPCR and mass cytometric analysis validated that the pre-DC associated gene expression and the proportion of pre-DC were significantly higher before treatment in treatment-resistant patients (Figure 1E, F). A cluster of synovial DCs showed both features of pre-DC and proinflammatory conventional DC2s (Figure 1G).

Conclusion: Treatment resistance can be predicted by an increase in pre-DC in the peripheral blood of RA patients prior to starting therapy. This result shows the potential for realizing a stratified therapy of RA based on analysis of pre-DC in peripheral blood.

Keywords: Adaptive immunity, Rheumatoid arthritis, Disease-modifying drugs (DMARDs)
Conclusion: RA patients can be stratified into five groups, each of which benefited from different molecular targeted therapies. The increase in CD4 TEMRA in peripheral blood was significant in RA patients, and the proportion was virtually unchanged with treatment. Thus, CD4 TEMRA could be the pathogenic memory cells in RA. Our results may be a milestone in achieving precision medicine.

Keywords: bDMARD, Adaptive immunity, Biomarkers

Methods: Peripheral blood was drawn from seropositive RA patients with an incomplete response to csDMARDS (n=41) who initiated biological therapy, according to routine clinical practice, with TNFf (n= 19) (10 Etanercept, 3 Adalimumab, 3 Certolizumab, 2 Golimumab, 1 Infliximab) or ABT (n= 22). cTfh cell frequencies were determined by flow cytometry of freshly isolated PBMCs at the baseline and 12 months (12M) after starting treatment escalation. For each patient, an age and gender-matched healthy control (HC) was also studied at both time points (n=41).

Results: a) Effect of treatment escalation on the cTfh cell frequency. As compared with HC, RA patients receiving csDMARDS demonstrated an increased frequency of cTfh and also of activated ICOS+ cTfh cells (α-cTfh), and this was observed in both treatment escalation groups. A significant improvement of disease activity (ADAS28 ≥2.0) was apparent in all of the patients at 12M. Nevertheless, the cTfh cell frequency did not vary in patients receiving TNFf; conversely, in subjects receiving ABT it significantly decreased to HC levels. At the same time, the frequency of α-cTfh cells was significantly reduced in both groups; however, in the TNFf group it remained above HC whereas in the ABT group it reached magnitudes comparable to HC. b) Relation of the baseline cTfh cell frequency with the clinical response. In the ABT group, the baseline frequencies of cTfh and α-cTfh had been higher for patients who went on to achieve remission at 12M (12Mr), as compared with those who remained active (12Ma) [Tfh logistic regression OR for remission 25.3, 95% CI (12.3-93.8); ROC AUC 0.94 (0.83-1), p<0.0005]; as stated above, the 12M frequencies were no longer elevated; in addition there were no differences between the 12Ms and 12Mr subjects. Conversely, in the TNFf group, the baseline frequencies of cTfh and α-cTfh had been lower for 12Mr as compared with 12Ma patients [Tfh OR for not achieving remission 8.5 (4.3-15.5); ROC AUC 0.77 (0.54-0.99), p<0.05]; furthermore, the 12M frequencies showed the same pattern: they had not significantly changed, persisted elevated above HC and remained lower in 12Mr as compared with 12Ma patients. The baseline cTfh cutoff frequency for achieving remission in the ABT group was >0.35% (sensitivity 92.7%, specificity 90%). The baseline α-cTfh cutoff frequency for not achieving remission in the TNFf group was >0.44% (sensitivity 67.7%, specificity 90%).

Conclusion: ABT but not TNFf, is able to curtail cTfh cell numbers in RA, suggesting that costimulation blockade can restrain germinal center activity. Higher baseline cTfh cell frequencies predict a good response to ABT and at the same time, a poor response to TNFf. Therefore, immunophenotyping of patients with an incomplete response to csDMARDs can facilitate a personalized therapeutic strategy for treatment escalation.

FOR RHEUMATOID ARTHRITIS VIA MACROPHAGE RE-POLARIZATION

Keywords: Animal models, Rheumatoid arthritis

S. Huang1, L. Qiu1, West China Hospital of Sichuan University, Department of Ultrasound, Chengdu, China

Background: Rheumatoid arthritis (RA) is an autoimmune disease that results in synovitis and joint destruction[1]. Macrophages, one of the various inflammatory cells, particularly infiltrate the RA synovial tissue and cause sustained inflammation that promote RA. And the balance of pro-inflammatory M1 macrophages and anti-inflammatory M2 macrophages in RA joints is affected by overexpressed reactive oxygen species (ROS) and hypoxia synovium, which provides potential targets for the RA treatment.

Objectives: With the aim of alleviating the synovial inflammation in RA and restoring the balance of macrophage subtypes, we develop a catalytic nanoparticle named Ru@TiO2, which can produce O2 and scavenge ROS to reduce M1 macrophages, switch M1 phenotype to M2 phenotype.

Methods: Ru@TiO2 was synthesized using the hydrothermal method. The morphology and nanoparticle size were observed using the transmission electron microscopy (TEM). The catalytic ROS-scavenging activities and O2 generation ability were examined through •O2 scavenging, H2O2 catalytic elimination and O2 generation assays. For in vitro experiment, the cytotoxicity of Ru@TiO2 conducted on RAW 264.7 cells was assessed by flow cytometry. To verify M1 to M2 macrophage phenotype transition and hypoxia alleviation, M1 and M2 markers and HIF-1α expression levels were evaluated by using qRT-PCR and Western Blot, respectively. In vivo, anti-inflammatory efficiency was observed after intra-joint injection of Ru@TiO2 into collagen-induced arthritis mice. The clinical scores and paw thickness for the inflamed joints with different treatments at various time points were recorded. Ultrasound (US) was used to assess the inflamed joints after treatment and RNA expression levels of M1 and M2 macrophage markers in synovial tissue were evaluated through qRT-PCR. The statistical significance among multiple groups was examined by using one-way ANOVA.

Results: The Ru@TiO2 were fusiform in shape with an average size of 67 nm. The evaluation of catalytic ROS scavenging activities and O2 generation performance of Ru@TiO2 showed that Ru@TiO2 can achieve about 60% scavenging ratio to •O2 and about 80% producing ratio to O2 at 30min. Ru@TiO2 also showed significantly increased H2O2 eliminating activity compared to the TiO2. In vitro, low cytotoxicity of Ru@TiO2 was displayed and the decrease of intracellular ROS level was most significant with Ru@TiO2. In addition, macrophage markers (TNF-α and IL-1β) and HIF-1α expression levels were most prominently declined with Ru@TiO2. And the increase of M2 macrophage markers (Arg-1 and CD206) was most obvious when using Ru@TiO2. In vivo, the arthritis scores, paw thickness and thickness of articular cavity assessed by US in Ru@TiO2 group were the lowest when compared with other treated groups. Moreover, RNA expression levels of M1 and M2 macrophage markers in synovial tissue showed the similar tendency as in vitro.

Conclusion: In this study, the Ru@TiO2 was successfully synthesized with efficient catalytic ROS scavenging activities and O2 generation ability for the treatment of RA. In vitro, Ru@TiO2 shows good cell biocompatibility and effective intracellular ROS scavenging ability. Moreover, Ru@TiO2 alleviate the hypoxia condition in cells by producing O2. Furthermore, the significant and efficient polarization of M1 to M2 macrophages and suppression of inflammation were achieved both in vitro and in vivo through the treatment of Ru@TiO2, which indicated the therapeutic potential of Ru@TiO2 for RA therapy.

Background: RA is the most frequent systemic autoimmune disease that primarily affects multiple joints and causes irreversible bone and cartilage destruction in the absence of treatment[1]. Monocyte-macrophages are key players in the pathogenesis of RA and accumulate in the synovial tissue. Besides resident macrophages, blood monocytes can differentiate into monocyte-derived-macrophages that may join the synovium and have different phenotypes and functions at local sites.

Methods: We discovered 36 altered microbial species in patients with RA compared to healthy controls. In particular, Peptoniphilus gorbachii (PG) was increased in RA patients, inversely correlated with RA disease activity, and compared to healthy controls. In particular, PG was increased in RA patients, inversely correlated with RA disease activity, and compared to healthy controls.

Conclusion: Serum microbial antibody microarray could help with the effective discovery of therapeutic microbial RA targets at the species level. Our results suggest that PG exerts a therapeutic effect by restoring intestinal barrier integrity and suppressing the RA-characteristic immunologic response.

Peptoniphilus Gorbachii Alleviates Collagen-induced Arthritis in Mice by Improving Intestinal Homeostasis and Immune Regulation
functions. The "classically activated macrophage phenotype" is considered to be pro-inflammatory and contribute to RA pathogenesis by secreting pro-inflammatory cytokines. The "alternatively activated macrophage phenotype" is considered to be regulatory and anti-inflammatory in tissues. Actually, there is a continuum from pro-inflammatory to anti-inflammatory macrophages, with high plasticity between the different states. We have previously shown that RA patients, and not patients with other inflammatory rheumatic diseases, have an impaired maturation of monocytes in anti-inflammatory-macrophages with increased differentiation in a pro-inflammatory-phenotype. We have found that an increased expression of miR-155 in monocytes/macrophages could be responsible for this defect and thus, could represent a new therapeutic target in RA [2].

Objectives: Our aim is to assess if the defect of monocytes polarization in anti-inflammatory-macrophages and the impact of miR-155 in this defect are present in 2 pre-clinical models of RA: the CIA (collagen-induce-arthritis) and STA mice (Serum transfert arthritis), both in which macrophages infiltration of synovium play a key role in pathophysiology. Then, we have tested a new therapeutic strategy to correct this defect using PEG-liposomes containing antagonmiR-155-5p.

Methods: AntagonmiR-155-5p or antagonmiR-control were encapsulated in PEG-liposomes of 100nm in size and -10µM in zeta potential with high antagonmiR loading efficiency (above 80%). Mice were injected intravenously with 1,5nmol/100µL PEG-liposomes containing antagonmiR-155-5p or control after induction of arthritis.

Results: As in humans, we found that monocytes defect in anti-inflammatory-macrophages was associated with an increase of miR-155-5p in both mouse models. Moreover, we demonstrated the biodistribution of tagged-PEG-liposomes to inflamed joints 1 hour after injection and as well as their subsequent liver's accumulation after 48 hours, indicative of hepatic clearance, in arthritic mice. Subsequently, we demonstrated that treatment with an antagonmiR-155-5p encapsulated in PEG-liposomes was able to decrease joint inflammation, to restore bone-marrow monocytes polarization in anti-inflammatory-macrophages, to reduce immune cells infiltration in synovial tissues, to increase the CD206+ and CD163+ tissue infiltrating macrophages and to decrease expression of mRNAs target of miR-155-5p, with any significant functional change in other immune cells including splenic B and T cells.

Conclusion: The injection of antagonmiR-155-5p encapsulated in PEG-liposomes allows delivering small RNA to monocytes/macrophages, lead to reduce joint inflammation in murine models of RA, providing a promising strategy in human disease.

MECHANICAL UNLOADING PREVENTED ARTHRITIS MODEL IN THE RAT ADJUVANT-INDUCED ARTHRITIS MODEL

Keywords: Rheumatoid arthritis, Animal Models

E. Dalix1,2, M. Maalouf1, A. Vandem-Bossche1, M. Paul1, H. Marotte1.
1University of Jean Monnet, INSERM, U1059-SAINBOSE, Saint-Etienne, France.
2University Hospital of Saint-Etienne, Department of Rheumatology, Saint-Etienne, France.

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatic disease, characterized by synovitis associated with progressive bone loss and joint swelling. The adjuvant-induced arthritis (AIA) model mimics the pathophysiological features of RA, with a very high prevalence and reproducibility. YAP plays a key role in synovial hyperplasia. It is a transcription factor which can be activated in response to inflammation but also by a mechanical stimulus as tissue stiffening. We already showed a decrease arthritis severity by inhibiting YAP in the AIA model [1]. Then, different mechanical challenges could potentially impact arthritis development by regulating YAP.

Objectives: The objective of this study was to investigate the impact of mechanical loading and unloading on the development of arthritis in the AIA model.

Methods: Arthritis was induced in female Lewis rats by injection of the adjuvant Mycobacterium butyricum, defining day (D)0. The AIA model normally develops arthritis at D10, with a peak of inflammation at D17 [2]. Rats were randomized into three groups: an AIA+mechanical loading group (n=11) with free access to an activity wheel from D0 to D17, an AIA+mechanical unloading group (n=11) by tail suspension from D0 to D17, and an AIA-only group (n=11) as positive control. Daily clinical monitoring (arthritic index and ankle circumference) was used to follow the progression and severity of arthritis. At D17, the ankles of the rats were collected to perform RT-qPCR.

Results: Arthritis onset was observed at the same time (D10) in the AIA control and AIA+mechanical loading groups with the same kinetic of arthritis index and ankle circumference. However, the majority of rats in the AIA+mechanical unloading group did not develop any signs of arthritis. At D17, gene expression of YAP and CRYF6 (YAP target gene), IL1B, IL6, RANKL, ACP5 (encoding TRAPc), CTSK (encoding cathepsin K), MMP9, and MMP13 was decreased in the ankle of AIA+mechanical unloading rats compared to other groups. In the AIA+ mechanical loading group, rats stopped their physical activity at D10 which may explain the lack of clinical and molecular differences between the AIA and AIA+mechanical loading groups at D17.

Conclusion: Mechanical unloading of the hindpaws by the suspension system strongly prevented arthritis by a reduced expression of pro-inflammatory genes, bone resorption, and bone degradation genes. The decrease in inflammation may be partly explained by the decrease in YAP transcriptional activity. Mechanical stress is therefore a key factor in inflammation during AIA. The precise mechanisms linking these two mechanisms are still under investigation.

OP0209

IMPACT OF CHRONIC INFLAMMATION AND COLLAGEN IV FRAGMENT CASSTATIN ON RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS AND ENDOTHELIAL CELL INTERACTIONS IN VITRO AND IN VIVO

Keywords: Cell biology, Synovium, Rheumatoid arthritis

1Justus-Liebig-Universität Giessen, Campus Kerckhoff, Rheumatology and Clinical Immunology, Bad Nauheim, Germany.
2Agaplesion Markus Hospital, Orthopaedics and Trauma Surgery, Frankfurth am Main, Germany.

Background: Increased neovascularization in the inflamed synovium of patients with rheumatoid arthritis (RA) is a pathological feature in the pathogenesis of RA. Key players in RA progression are chronically activated RA synovial fibroblasts (RASF), which secrete proinflammatory factors (e.g. IL-6), proangiogenic
VEGF, IL-11 and matrix metalloproteases (MMP) promoting inflammation, synovial angiogenesis, and invasion of cartilage and bone by degrading the consecutively resulting matrix, leading to release of the anti-angiogenic collagen IV fragment in a consequent caspase-mediated process. Cytokinin is further able to activate RASFs leading to altered expression of vascular markers such as angiopoietin-2 (ANGPT2) and neovascularization.

**Objectives:** Analysis of repetitively stimulated RASF- and canstatin-mediated effects on vessel formation in the tube formation assay, in the SCID-mouse model for RA and in synovial tissue of RA patients with respect to ANGPT2 expression and RASF-endothelial cell (EC) interactions.

**Methods:** 2D tube formation assay was performed using HUVEC seeded on Matrigel. 15% Calcein AM-stained RASFs were added. RASF/HUVEC were treated with 0.5µg/ml caspase. HUVEC were pre-treated with 0.2µg/ml caspase. RASFs were repetitively stimulated three times with 0.05ng/µl IL-1β every 24h starting at day 2. Tube thickness and the area covered by the formed cellular network were measured. RNA was extracted from tubes and ANGPT2 expression was analysed by qPCR. IL-6 and IL-11 in supernatants were measured by ELISA. Healthy cartilage was subcutaneously co-infused with RASF into SCID mice. Cotransplanted, contralaterally healthy cartilage without RASF was implanted. Vessel formation was evaluated after 3-4 days. RA and osteoarthris (OA) synovial tissue was stained for ANGPT2 and CD31.

**Results:** RASFs were repetitively stimulated once showed a significant IL-6 increase compared to unstimulated controls. After subsequent repetitive stimulation of RASFs or HUVEC, a significant decrease in IL-6 was observed (1st stimulation: 5076±1730pg/ml vs. 3rd stimulation: 4883±1863pg/ml vs. 3rd stimulation: 400±0.01) and IL-11 in RASF (1st: 451±205pg/ml vs. 3rd: 69±5pg/ml, p<0.0001) compared to the first stimulation was observed. Repetitive stimulation of HUVEC and RASFs resulted in a significant IL-6 increase for each subsequent stimulation (1st vs. 3rd: p=0.02). RASF significantly reduced tube thickness (22.9µm (SD=8.3) vs. 16.6µm (SD=3.2), p=0.014) and the network area (p<0.0001) decreased significantly compared to unstimulated RASF-2 fold compared to HUVEC alone. RASF stimulated only once further reduced the network area (p=0.038), whereas repetitive stimulation significantly attenuated the pro-inflammatory effect (IL-6, p=0.029). Stimulation of pre-treated HUVEC and unstimulated RASF with caspase led to disturbed tube formation with reduced tube thickness from 22.9 to 16.9µm (SD=4.4, p<0.001). Co-culture of RASF with pre-treated HUVEC with caspase further increased the RASF-mediated effect by reducing tube thickness (22.9 to 14.6µm (SD=4.4, p<0.001), with a significant 1.6-fold decrease of ANGPT2. In human RA synovium, ANGPT2 was also found to be significantly upregulated in vessels compared to OA tissue. In SCID mice, RASF-mediated altered vessel formation started at day 3. Heli-like vessels were detectable at early time points of vessel formation in implants with RASF (d3-9), e.g. at day 3, 60% of vessels were helix-like.

**Conclusion:** RASF induced helix-like vessels in the SCID mouse model suggest an influence on vessel formation. This could be confirmed in vitro as well as on a molecular level inducing the vascular marker ANGPT2 in newly formed tubes. ANGPT2-upregulation in vessels was also observed in human RA synovium. Repetitive stimulation of RASFs resulted in an inflammatory adjustment to IL-1β, leading to a significant reduction of IL-6 and improved neovascularization in vitro. The anti-angiogenic caspase could in part enhance the RASF-mediated effect and was not able to restore RASF-altered tube formation in vitro.

Background: A decline of urine protein-to-creatinine ratio (UPCR) to < 0.5 is associated with better long-term preservation of kidney function in lupus nephritis (LN). UPCR < 0.5 defines complete response in guidelines and clinical trials when achieved after 1 or 2 years. Biomarkers of early response are needed to guide early treatment changes. We studied longitudinal urine proteomic profiles in LN to identify early predictors of proteinuric response.

Objectives: Identify early predictors of proteinuric response in LN using longitudinal urine proteomic profiles.

Methods: We quantified 1200 biomarkers (Kiloplex, RayBiotech) in urine samples collected on the day of (73%) or within 3 weeks (27%) of kidney biopsy and week 12, 24, or 52 in LN patients (ISN class III, IV, V, or mixed) with proteinuria > 1 g/d. Response was defined at one year from renal biopsy: Complete = UPCR < 0.5, serum creatinine (sCr) < 125% of baseline, prednisone ≤ 10 mg/d; Partial = UPCR < 50% from baseline but >0.5, sCr < 125% of baseline, but prednisone allowed to 15 mg/d; Non responder = not meeting previous definitions.

Results: A total of 127 patients were included: 48 (38%) with pure proliferative LN (class III or IV), 41 (32%) with mixed LN (III or IV +/- V), and 36 (30%) with pure membranous LN. Response was complete in 34 (27%), partial in 29 (23%), and none in 64 (50%). There were no urinary biomarkers at baseline that predicted response. We then analyzed the changes in urinary proteins at 3 months compared to baseline. Patients who responded at 1 year showed an early decline in 51 urinary proteins led by CD163, IL-16, and CD206 (macrophage mannose receptor) (Figure 1A) which matched the proteome signature associated with histological activity (Figure 1B). No changes were observed in nonresponders. The decline of several urinary biomarkers at 3 months outperformed a decline in UPCR (clinical standard) in predicting the 1 year response. In particular, a decline of CD163 predicted 1 year response in ROC analysis with an area under the curve (AUC) of 83% compared to an AUC of 75% for UPCR decline. In proliferative LN, urinary biomarkers displayed superior performance with an AUC of 91%, 86%, and 78% for the decline of CD206, CD163, and UPCR, respectively (Figure 1C-D). Pathway enrichment analysis identified leukocyte activation, neutrophil degranulation, and matrix degradation as the main pathways reduced at 3 months in responders.

Conclusion: An early decline in urinary biomarkers of histological activity is associated with proteinuric response at 1 year. These findings indicate that effective immunosuppression induces by three months an immunological response in the kidney that can be noninvasively monitored in the urine. Biomarkers of immunological response outperformed early decline of UPCR, the standard of care, in predicting 1-year proteinuric response, especially in proliferative LN.

Because biomarkers of immunological response parallel intrarenal activity, they could detect early treatment response/failure and allow early treatment changes. They could serve as surrogate endpoints in clinical trials. Longitudinal studies are needed to confirm that this immunological response is a better predictor of long-term kidney function preservation than proteinuric responses.

Figure 1. Selected proteins showing differences associated with PDF A), DDF B) and HSB C) subgroups. Derived from ARACNE analysis of protein expression data, nodes represent individual proteins and edges represent the mutual information between nodes. Colour scaling shows estimated difference using LSS as a comparator group, with red indicating higher expression and blue indicating lower expression. Estimates are derived from a generalised linear model post adjustment for baseline age, sex and batch

Conclusion: Protein expression between the clinically distinct pSS subgroups revealed differences in cytokines, chemokines and master transcription factors associated with redox imbalance and altered energy metabolism. Furthermore, the differentially expressed proteins seem to be interrelated in our network
characteristic enrichment of antiphospholipid-reactive B cells among atypical memory subsets of primary APS suggest ongoing induction in extracellular sites

versus healthy: 0.86 [0.43 to 1.38]% versus 0.31 [0.24 to 0.42]%, p<0.01). These Treg-like cells do not express CD25, a phenotypic marker for natural Treg cells. Concurrently, there was a significant reduction in CTLA4 expressing naïve non-Treg CD4+ T (effector) cells in lupus (SLE versus healthy: 0.59 [0.40 to 1.11]% versus 2.0 [0.9 to 2.9]%, p<0.01). This was accompanied by a significant reduction in the ratio of CTLA4+ to naïve non-Treg TNFα effector T cells (SLE versus healthy, ratio of CTLA4+ to total naïve non-Treg TNFα+ T cells: 0.14 [0.11 to 0.23] versus 0.33 [0.17 to 0.55], p<0.0001). Additionally, other significant changes such as activated IL4+ T cell subset (CD3+CD4+CD45RA-"HLA-DR+IL4") was increased in lupus (SLE versus healthy: 0.30 [0.19 to 0.52]% versus 0.07 [0.05 to 0.12%], p<0.0001).

**Conclusion:** There are multiple derangements in the immunoregulatory and effector axes in lupus consistent with its complex immunopathogenesis. The activated CD25 negative Treg-like subset indicates an impaired regulatory response in SLE. The reduced CTLA4 expression in the naïve non-Treg T cells in lupus suggests a perturbed negative feedback mechanism in the effector system. The validation of these results and delineation of the underlying disease mechanisms have translational therapeutic potential.

**IMMUNOJOE ANALYSIS INDICATES ROBUST INHIBITION OF PROINFLAMMATORY MEDIATORS UPON LEFLUNOMIDE-HYDROXYCHLOROQUINE COMBINATION THERAPY IN SJÖGREN’S SYNDROME: CXCR3 LIGANDS AS POTENTIAL INFLAMMATORY ENDOTAXER BIODMARKERS.**

**Keywords:** Biomarkers, Sjögren syndrome, Randomized control trial

**Background:** Primary Sjögren’s syndrome (pSS) is a chronic autoimmune disorder characterized by lymphocytic infiltration and functional impairment of exocrine glands, resulting in dryness of the eyes, mouth and extra-glandular manifestations in numerous organs. Immuneopathology in pSS is associated with prominent B cell hyperactivity reflected by elevated serum IgG levels, autoantibody production, immune complex formation, and complement activation [1]. In a recent double blinded placebo controlled randomized trial, we demonstrated unprecedented robust inhibition of B cell hyperactivity and different disease activity parameters (including primary endpoint ESSDAI) by leflunomide-hydroxychloroquine (LEF-HCQ) combination therapy in the treatment of patients with pSS [2].

**Objectives:** To assess the potential of LEF-HCQ combination therapy to normalize dysregulated inflammatory cytokine levels in pSS patients, and to identify biomarkers that reflect inflammation, monitor changes in disease activity and predict the treatment response.

**Methods:** We employed a high-throughput protein Olink proteomic assay (Immuno-Oncology panel) in order to determine the blood serum concentrations of 92 immune biomarkers, assessed at baseline and at the clinical endpoint in placebo (n=8) and verum treated patients (n=21). Welch 2-sample t-test and paired t-test were used to calculate differences for unpaired and paired data, respectively as for unpaired and paired data, respectively. FDR corrected p values were assessed using the Olink Analyze package available on CRAN.

**RESULTS:** Of the 92 immune biomarkers, 34 were significantly upregulated in pSS patients compared to healthy controls at the onset of the trial (all at least p<0.05). Moreover, the majority of these inflammatory mediators (24/34) were downregulated after 24 weeks of LEF-HCQ treatment (LGLAS9, CCL19, IL10, CXCL10, CXCL11, CXCL13, GZMH, CXCL9, and soluble CD28, CD83, CD27, PDCD1, ADGRG1, PD-L1, CTRAM) with 9 returning to healthy control levels (TNF, IL12, GZMA, and soluble LAG3). IL12RB1, TNFSF9/4-1BB, CD4, KLRD1, CD70). Conversely, no significant alterations were observed in the placebo group. Interestingly, changes in ESSDAI scores were significantly (all at least p<0.05) associated with changes in IL13, TNF, PTN, CXCL9, CXCL11 and soluble LAG3 concentrations. In addition, changes in serum IgG and Rheumatoid Factor levels were both significantly associated with changes in soluble CXCL13, GZMA, CXCL9, soluble CD4 and CD28 concentrations. Based on a machine learning approach (sPLS-DA) we identified baseline levels of CXCL9/10/11 as key markers of the treatment response.

**Conclusion:** LEF-HCQ treatment robustly inhibits inflammatory activity in pSS patients. The correlation of several mediators with clinical activity parameters indicates that these may have value in monitoring the disease activity. Furthermore, the clinical outcome upon LEF/HQC treatment seems predetermined by an inflammatory endotype, with circulating biomarkers such as CXCR3 ligands as key determinants. These findings represent an important advance in our understanding of the underlying immunopathology of pSS and could help in the development of more personalized and effective treatment approaches for pSS and potentially other rheumatic diseases.

cluster analysis. Survival and treatment goal achievement were further compared between different clusters. The Id1 and phospho-SMAD1/5 (p-SMAD1/5) levels were examined in human pulmonary artery endothelial cells (hPAEC) under the induction of BMP9 combined with anti-BMPR2, anti-ALK1, and anti-BMPR1A neutralizing antibodies (5 μg/mL). The effect of anti-ALK1 antibodies on the extent of monolayer permeability and apoptosis of hPAEC was further examined.

**Results:** 60 SLE-PAH patients were enrolled and cluster analysis revealed two distinct clusters according to the positivity of autoantibodies targeting BMP signaling and clinical manifestations. Cluster 1 was a “low-antibody and high-disease activity” cluster while cluster 2 was a “high-antibody and low-disease activity” cluster. Patients in cluster 1 showed a higher proportion of nephropathy (76.9%) and SLE activity, however a low positivity rate of autoantibodies targeting BMP signaling. Patients in cluster 2 were characterized by a higher rate of anti-BMPR2 antibodies (82.4%), anti-ALK antibodies (70.6%), and lower SLE activity. Prognostic analysis showed that the proportion of patients who reached the treatment target was relatively higher in cluster 2. Mechanism study showed that the p-SMAD1/5 level and the Id1 expression were decreased, indicating the suppression of BMP signaling in the presence of anti-ALK1 antibodies. Functional studies showed that anti-ALK1 antibodies increased the monolayer permeability of hPAEC. The late-stage apoptosis of hPAECs was also induced by anti-ALK1 antibodies.

**Conclusion:** The serum positivity of autoantibodies targeting BMP signaling has clinical potential in dividing SLE-PAH patients into two distinct clusters. The anti-ALK1 antibodies can downregulate BMP signaling and mediate great permeability and apoptosis in hPAECs, which may be involved in the pathogenesis of SLE-PAH.

**Keywords:** Autoantibodies, Sjögren syndrome, Prognostic factors

**Interpretation:** The diagnosis of primary Sjögren Disease (SjD) is currently based on a combination of clinical, histological and biological findings [1]. Current thinking supports anti-Ro60 antibodies as the most specific serum marker, while the impact of anti-Ro52 remains unclear [2].

**Objectives:** The aim of this study was to characterize the clinical, serological, biological, transcriptomic and interferon profiles of SjD patients according to their anti-Ro52 status and discuss the role of anti-Ro52 in the prognosis of SjD.

**Methods:** SjD patients were recruited from the European PRECISESADS (378 patients) [3] and the independent Brittany DiApSS cohorts (160 patients) [4]. Four groups were defined: negative (Ro52+/Ro60), isolated anti-Ro52 positive (Ro52+), isolated anti-Ro60 positive (Ro60+), and double positive (Ro52+/Ro60+) patients. Clinical information, disease activity, and biological markers linked to disease severity were evaluated. Transcriptome data on whole blood by RNAseq and Type I and II interferon signatures [5,6] were analyzed for PRECISESADS SjD patients.

**Results:** In both cohorts, arthritis, parotidomegaly, and biological markers (hypergammaglobulinemia, rheumatoid factor and inflammation) [7] were significantly more frequent in the double positive group as compared to other groups. ESSDAI, a score representing systemic activity [8], was also significantly higher in double positive patients compared to the others. Transcriptome analysis demonstrated that anti-Ro52 positivity was associated with a strong interferon pathway activation as the lead cause to explain the clinical associations.

**Conclusion:** Taken together, these results suggest that SjD patients with anti-Ro52 positivity adopt a more severe phenotype as compared to their negative counterparts, independently of anti-Ro60 positivity.

Rheumatoid arthritis: new small molecules and old DMARDs

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Malignancy

M. Schaefer1, Y. Meissner1, B. Manger2, S. Berger3, K. Rockwitz4, A. Regierer1, A. Strangfeld1,5.

Aims: To analyse incidence malignancies under treatment with JAKi, tumor necrosis factor inhibitors (TNFi), abatacept (ABA), rituximab (RTX), interleukin 6 inhibitors (IL6i) or conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) - bionovia - in patients with rheumatoid arthritis (RA) observed in daily rheumatological care.

Methods: Data from patients without cancer history from the biologics register RABBIT were included with treatment episodes started 01/2017 - 04/2022. Incidence rates (IR) of malignancies (without non melanoma skin cancer, NMSC) per 1000 patient-years (PY) with 95% confidence intervals (CI) and adjusted hazard ratios (HR) were calculated for all and selected patients according to OS inclusion criteria (age ≥ 50 years and ≥ 1 cardiovascular (CV) risk factor) to compare treatment groups to TNFi. Andersen-Gill regression analysis was used with a 6-month risk window, adjusted via stabilized and winsorized inverse probability of treatment weights taking into account enrolment institution (clinic vs. private practice) as covariates. Multiple imputation of missing data was applied.

Results: 2763 JAKi, 3403 TNFi, 744 ABA, 834 RTX, 1125 IL6i and 1130 csDMARD initiations were documented. Patients with a JAKi start were less often men and (except RTX patients) slightly older and had a longer RA disease duration (Table 1). The seropositive proportion and the number of prior treatments with biological (b) or targeted (ts) synthetic DMARDs was higher than in TNFi and csDMARD groups, but lower than in ABA and RTX groups.

151 incident malignancies were reported. Across treatments, patients showed comparable IRs between 7 and 11 events per 1000 PY. Among selected patients IRs were higher (13.2 events per 1000 PY in JAKi patients, 95% CI: 9.5 – 17.9).

In adjusted analyses, neither JAKi (HR 1.06, 95% CI: 0.70 - 1.61), ABA (HR 0.73, 0.38 - 1.40), RTX (HR 0.86, 0.42 - 1.73), IL6i (HR 0.79, 0.49 - 1.40) nor csDMARDs (HR 2.07, 0.87 - 4.94) showed a significantly altered risk for malignancies compared with TNFi in unselected patients, with similar results in selected patients.

Figure 1. IRs of malignancies (without NMSC) per 1000 PY by treatment group

Conclusion: IR of malignancies in selected patients receiving JAKi in a real-world setting was numerically higher than reported for tofacitinib in OS. However, we found no statistical evidence of an increased malignancy risk with JAKi compared to TNFi, although patients on JAKi were older and had longer disease duration and more previous b/tsDMARDs treatments. Further analyses assessing exposure in terms of treatment duration are needed.

OP0219 INCIDENT OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH JAK-INHIBITORS COMPARED TO DMARDs: DATA FROM AN INTERNATIONAL COLLABORATION OF REGISTRIES (THE “JAK-POT” STUDY)

Keywords: Disease-modifying drugs (DMARDs), Safety, Real-world evidence

Background: Results of the “ORAL Surveillance” trial showed higher risk of major adverse cardiovascular (CV) events (MACE) for Janus kinase inhibitors (JAKi) than for TNF-inhibitors (TNFi). Currently, there is limited evidence of the real-world cardiovascular safety of JAKi.

Objectives: To assess the incidence of MACE in rheumatoid arthritis (RA) patients treated with JAKi, compared to other biologic agents in a large multi-country real-world population.

Methods: Patients from 14 RA registers from across Europe, Turkey and Quebec (Canada), starting JAKi, TNF-inhibitors or bDMARDs with other modes of action (OMA), were included. MACE comprised strokes, myocardial infarctions and transient ischemic attacks and were attributed to a treatment up to 3 months after treatment cessation (except for rituximab for which it was 1 year), loss of follow-up, death or end of study. Incidence rates (IR) of MACE per 1000 patient-years (PY) with 95% confidence intervals (CI) were computed. Poisson regression, with propensity score weighting (including country, disease- and treatment-related variables), was used to obtain adjusted incidence rate ratios (IRR), with 95% CI. A sub-analysis was performed on patients aged ≥ 50 years and ≥ 1 CV risk factor, mimicking the “ORAL Surveillance” trial inclusion criteria (RCT-duplicate cohort).

Results: Over the 50 325 treatment initiatives considered (Table 1) in 34 932 patients with a mean follow-up of 2.8 years, 182 incident MACE were reported. Crude incidence was higher for OMA (2.63/1000 PY) than for JAKi (1.76/1000 PY) and TNFi (1.86/1000 PY). The adjusted Poisson regression demonstrated no significant difference in the incidence of MACE between JAKi vs TNFi (IRR = 0.87 (95% CI 0.56, 1.35)), and OMA vs TNFi (IRR = 1.05 (95% CI 0.74, 1.49)) (Figure 1). The RCT-duplicate cohort accounted for 38.4% of treatment courses and had a higher incidence of MACE in each treatment group (OMA: 3.75/1000 PY, JAKi: 2.65/1000 PY, TNFi: 3.48/1000 PY). Similarly to the overall population, no significant difference in the incidence of MACE was observed between JAKi vs TNFi (IRR = 0.78 (95% CI 0.44, 1.38)), and OMA vs TNFi (IRR = 0.84 (95% CI 0.53, 1.35)).

Conclusion: In this real-world study, including 14 RA registers and all currently available JAKi in the respective countries, we did not find a significantly higher risk of MACE in RA patients treated with JAKi compared to TNFi. Inclusion of other registries to increase the statistical power and the evaluation of other adverse events such as thromboembolic events, cancers and serious infections are planned. A significant difference in the incidence of MACE in RA patients treated with JAKi compared to TNFi. Inclusion of other registries to increase the statistical power and the evaluation of other adverse events such as thromboembolic events, cancers and serious infections are planned.
Glucocorticoid use over time.

**Methods:**
Data were available from the BeSt, CareRA and COBRA trials, which included study arms with and without initial GC bridging in addition to csDMARD treatment. GC bridging schedules were planned for a minimum duration of 34 (CareRA), 35 (COBRA) and 36 (BeSt) weeks (Table 1). In an individual patient data (IPD) meta-analysis we compared GC use between bridgers and non-bridgers at 12, 18 and 24 months from baseline as primary outcome. Secondary outcomes were the mean cumulative GC dose until 24 months after baseline and with and without the bridging period, number of (study defined) flares (DAS28 increase >1.2 or SSZ >7.5 mg/day), number of DMARD changes (adding a new DMARD, the modulatory effect on cardiovascular risk seems less straightforward) and cardiovascular events. Post hoc analysis was also performed. The incidence rate ratio (IRR) for number of DMARD changes was significantly lower in the bridgers (IRR 0.59 (95%CI 0.38; 0.94)).

**Results:**
In 6 weeks to 7.5 mg/day; 60 mg/day (prednisone) In 7 weeks to 7.5 mg/day; 60 mg/day (prednisone) From week 29-35 tapered to zero; resume on flare MTX 75 mg/week and MTX 15 mg/week from week 28-34 tapered to zero if DAS28<CRP<3.2 SSZ 2000 mg/day; From week 40-43 MTX 2000 mg/day; Tapered to zero; resume on flare MTX 15 mg/week (increased to 25 mg/week if DAS28<4.3 after 3 months) MTX 75 mg/week, increased to 25 mg/week if DAS28>4.3 after 3 months

**Background:**
Glucocorticoid (GC) ‘bridging’ therapy as temporary part of the initial treatment in rheumatoid arthritis (RA) helps to rapidly suppress disease activity. It has been proposed that patients treated with GC bridging (bridgers) may continue to use more GC later in the disease course than patients who did not receive GC bridging (non-bridgers).

**Objectives:**
To compare GC use over time between RA patients in clinical trials randomized to treatment with or without initial GC bridging.

**Methods:**
Data were available from the BeSt, CareRA and COBRA trials, which included study arms with and without initial GC bridging in addition to csDMARD treatment. GC bridging schedules were planned for a minimal duration of 34 (CareRA), 35 (COBRA) and 36 (BeSt) weeks (Table 1). In an individual patient data (IPD) meta-analysis we compared GC use between bridgers and non-bridgers at 12, 18 and 24 months from baseline as primary outcome. Secondary outcomes were the mean cumulative GC dose until 24 months after baseline and without the bridging period, number of (study defined) flares (DAS28 increase >1.2 or DAS28 >0.6 and ≥3.2 at previous visit), number of DMARD changes (adding a new DMARD, the modulatory effect on cardiovascular risk seems less straightforward) and cardiovascular events. Post hoc analysis was also performed. The incidence rate ratio (IRR) for number of DMARD changes was significantly lower in the bridgers (IRR 0.59 (95%CI 0.38; 0.94)).

**Results:**
In 6 weeks to 7.5 mg/day; 60 mg/day (prednisone) In 7 weeks to 7.5 mg/day; 60 mg/day (prednisone) From week 29-35 tapered to zero; resume on flare MTX 75 mg/week and MTX 15 mg/week from week 28-34 tapered to zero if DAS28<CRP<3.2 SSZ 2000 mg/day; From week 40-43 MTX 2000 mg/day; Tapered to zero; resume on flare MTX 15 mg/week (increased to 25 mg/week if DAS28<4.3 after 3 months)

**Objectives:** The aim of this study was to investigate the occurrence of cardiovascular events in a large population of RA patients treated with either JAK-kinase inhibitors or other (b)DMARDs, using real-world data.

**Methods:** Adult RA patients (extrapolated from drug based algorithms), starting a new bDMARD or JAK-inhibitor between August 1st 2017 and January 31st 2022, have been selected from IQVIA's Dutch Real-World Data Longitudinal Prescription database, covering about 63% of outpatient prescriptions in the Netherlands. Study outcome is cardiovascular (CV) event defined as the start of platelet aggregation inhibitors (clopidogrel, prasugrel, ticagrelor, dipiridamol) during study period. The risk of cardiovascular events was estimated using multilevel Poisson regression, adjusted for exposition time and confounders.

**Results:** In total, 15,191 unique patients were included, with 20,912 treatment episodes with either JAK (2,090, almost exclusively tofacitinib and baricitinib) or bDMARDs (18,822). Most patients were female (72%) and median age was 62 years. We found a total of 681 CV events occurring during the study period: 48 (2.0 events/100 patient years) during therapy with JAKi and 633 (2.42 events/100 patient years) during therapy with bDMARDs, respectively, resulting in an adjusted incident risk ratio (IRR) of 0.78 for JAK compared to bDMARDs (95% confidence interval (CI), 0.56 – 1.10) (Table 1). Subanalysis in patients using either tofacitinib or baricitinib yielded similar results (Table 1). Likewise, RA patients older than 65 years did not have a higher risk for CVD during the therapy with JAKi as compared to those treated with bDMARDs: adjusted IRR 0.76 (95% CI, 0.51 – 1.19).

**Conclusion:** In the Dutch RA population, the incidence of cardiovascular events in JAKi starters was not higher than in bDMARD starters, and similar for tofacitinib and baricitinib. These data will further contribute to estimation of the cardiovascular safety of JAKi.

**TRAJECTORIES OF ANTIMALARIAL ADHERENCE AMONG NEWLY DIAGNOSED RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A POPULATION-BASED COHORT STUDY**

**Keywords:** Systemic lupus erythematosus, Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

**M. R. Houde**1,2, J. A. Avila-Zubieta3,4, D. Lacaille2,3, M. De Vera4, Y. Qian4, L. Mccandless4, J. Esdale4,5, H. Xie6, H. L. Brown7, Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada; 3Arthritis Research Canada, Arthritis Research, Vancouver, Canada; 4The University of British Columbia, Division of Rheumatology, Department of Medicine, Vancouver, Canada; 5The University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada; 6The University of British Columbia, Sauder School of Business, Vancouver, Canada

**Background:** Adherence to antimalarial regimens are suboptimal in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients. Also, adherence is dynamic in nature, and varies over the time. Computing a single adherence level over a period may not explain the adherence trajectories of antimalarial in RA and SLE patients over time.

**Objectives:** To identify the groups of patients with similar patterns or trajectories of antimalarial adherence over time and evaluate the baseline determinants of the group membership of adherence trajectories.

**Methods:** All patients with incident RA/SLE and incident antimalarial use in British Columbia, Canada, between January 1997 and March 2021, were identified using previously published definitions and administrative health data. Patients were followed up for 12 months from the index date, the time when subjects met RA/SLE criteria and were on antimalarials. We calculated a measure of adherence, the proportion of days covered (PDC) for all patients each month. Then, we used group-based trajectory model (GBTM) analysis on monthly PDC values to identify the latent groups of antimalarial adherence trajectories. The number of groups was selected using the AIC and minimum percentage criterion. Finally, we used an ordered logistic regression to evaluate the baseline determinants of the group membership of adherence trajectories.

**Results:** We identified a total of 2,751 patients with incident antimalarial use (23,997 RA and 3,513 SLE patients, mean ± SD age 56.8 ± 15.5 years, 74.8% female). Using GBTM analysis, we identified four groups for antimalarial medication adherence trajectories, representing an ordered pattern of antimalarial adherence from worse to better. Those trajectory groups were - Group 1: quick deterioration (19%), Group 2: moderate deterioration (15.7%), Group 3: slow deterioration (18.4%), and Group 4: consistent high adherence (46.8%) (Figure 1). Significant determinants of the group membership of adherence trajectories from the ordinal logistic regression model are shown in Table 1. The odds of better adherence were higher for those who, at baseline, were older, had higher income, had SLE compared with RA, had hypertension, had rheumatologist visits, and used glucocorticoids, immuno-suppressives or Cox-2 selective NSAIDs.

**Conclusion:** Antimalarial adherence trajectories over time

**Figure 1:** Antimalarial adherence trajectory groups from group-based trajectory model analysis

**Antimalarial adherence trajectories over time**

 Antarimalarial adherence trajectories over time

**Conclusion:** Among incident RA/SLE incident antimalarial users from a population-based cohort, 53.2% did not continuously adhere to the antimalarial regimen in the first year of treatment. We identified four distinct antimalarial adherence trajectory groups in this study. Sociodemographic, disease-related, healthcare system, and medication use factors associated with better adherence trajectories could help inform strategies to improve antimalarial adherence among RA and SLE patients.

Antimalarials (AM) have been related to a lower risk and severity of infections in systemic lupus erythematosus [1], but in rheumatoid arthritis (RA) the results are not unanimously favorable to a possible protective effect exerted by AM [2,3]. In our recent study of RA patients treated with biologic disease modifying anti-rheumatic drugs (bDMARDs) or JAK inhibitors (JAKi), a secondary analysis suggested lower risk of total (25% reduction) and serious infections (47% reduction) with concomitant use of AM [4].

Objectives: To evaluate the association of the use of AM with the risk of total and serious bacterial, viral, fungal and system-specific infections in RA patients treated with conventional synthetic DMARDs (csDMARDs) and/or bDMARDs/JAKi.

Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting a new csDMARD or their first bDMARD or JAKi [5]. The present analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over one or multiple (up to six) courses of treatment (lasted date, Nov 19, 2019) with csDMARDs and/or bDMARDs/JAKi. A treatment course is defined as a period during which the medication scheme of does not change, except for dose adjustments. The primary outcome was the incidence of total infections (SIs) caused by bacteria, viruses and fungi (analyzed separately). Serious infections according to type of microorganism and system-specific infections served as secondary outcomes. Negative binomial regression with generalized estimating equations (to calculate the incidence rate ratios [IRR]) and extended (frailty) multivariate Cox proportional hazards models (to calculate the incidence rate ratios [IRR]) and extended (frailty) multivariate Cox proportional hazards models were used for statistical analyses (both types of analyses including time-fixed and time-varying covariates over multiple courses of treatment to adjust for confounding).

Results: In total, 1671 patients (2891 treatment courses, 8944.1 patient-years [PY]; most treatment courses [in total, 2335] including bDMARDs or JAKi) were enrolled. AM were used over 512 courses (2036.8 PY) of therapy. The overall incidence of infections caused by bacteria, fungi and viruses were 10.2, 1.9, 1.0/100 PY, respectively. The microbiologic etiology of infections was not defined for the majority of patients, but not all infection had a clearly defined etiology (these ones were excluded from the analysis by etiologic agent). Serious infections according to type of microorganism and system-specific infections served as secondary outcomes. Negative binomial regression with generalized estimating equations (to calculate the incidence rate ratios [IRR]) and extended (frailty) multivariate Cox proportional hazards models were used for statistical analyses (both types of analyses including time-fixed and time-varying covariates over multiple courses of treatment to adjust for confounding).

Conclusion: Among RA patients followed-up in our cohort study, the use of antimalarials was associated with reduction in the risk of bacterial infections, especially serious ones, and there was protection against infections affecting the respiratory and digestive systems and skin/mucosae.
lack the capacity to form MTX-PGs. Mechanistically, the low FPGS activity in spermatozoa is likely associated with a higher ratio of mRNA expression of an alternatively spliced form of the FPGS gene (8FPR) over the WT transcript. These results support and clarify our previous findings that treatment with MTX does not affect sperm quality parameters and provides further evidence that MTX can be safely used in men with a wish to become a father.

IMPROVEMENTS AND CHALLENGES OF SYSTEMIC LUPUS ERYSserratOS ASSOCIATED PULMONARY ARTERIAL HYPERTENSION: A 10-YEAR MULTICENTER COHORT STUDY

Keywords: Systemic lupus erythematosus, Cardiovascular disease, Treat to target

X. Dong1, J. Qian1, J. L. Zhao1, Q. Wang1, M. Li1, X. Zeng1, Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Previous studies have described improved survival in systemic sclerosis (SSc) associated pulmonary arterial hypertension (PAH) [1-2], yet it is unclear whether survival of systemic lupus erythematosus (SLE) associated PAH has also improved.

Objectives: To describe the CSTAR prospective cohort of SLE-PAH patients, explore changes in characteristics, treatment and 5-year survival in the last decade, and possible reasons for survival change.

Methods: A multicenter prospective cohort of SLE-PAH was established, and divided into cohort A (2011.6-2016.5) and cohort B (2016.6-2021.5) according to the date of their baseline right heart catheterization (RHC). Another single-center center of idiopathic pulmonary arterial hypertension (IPAH) was consecutively recruited as control to describe the baseline characteristic and survival of SLE-PAH patients simultaneously. Disease characteristics, treatment regimen, and all-cause mortality were compared between cohort A and cohort B. Multivariable cox regression was used to analyze association between treatment goal achievement and survival.

Results: A total of 610 SLE-PAH and 104 IPAH patients were enrolled. Overall, SLE-PAH patients were younger, predominantly female, had lower NT-proBNP levels, better functional status, better hemodynamic, and higher 5-year survival than IPAH (81.2% vs 56.0%, p<0.001). Compared with cohort A, patients in cohort B showed lower mPAP and PVR, higher CI, and were more likely to receive intensive immunosuppressants and PAH-targeted medication. 5-year survival rate was also higher in cohort B (88.1% vs 72.9%, p<0.01). In multivariable Cox regression, treatment goal achievement of PAH (HR 0.31, 95% CI 0.12-0.81, p=0.017) and reaching lupus low disease activity state (LLDAS) (HR 0.23, 95%CI 0.13-0.41, p<0.001) were both independently associated with a lower mortality.

Conclusion: This is the largest multicenter prospective SLE-PAH cohort to describe disease characteristics and prognosis. This study showed that survival has improved significantly for SLE-PAH. Early detection of PAH in SLE patients, achieving PAH treatment goal as well as LLDAS for SLE contributed to survival improvement.

OP0228

COEXISTING TUBULOINTERSTITIAL INFLAMMATION AND DAMAGE IS A RISK FACTOR FOR CHRONIC KIDNEY DISEASE IN PATIENTS WITH LUPUS NEPHRITIS: RESULTS FROM THE KORNET REGISTRY

Keywords: Systemic lupus erythematosus

D. J. Park1, S. E. Choi1, J. H. Kang1, S. S. Lee1, 1Chonnam National University Medical School and Hospital, Rheumatology, Gwangju, Korea, Rep. of (South Korea)

Background: An increasing body of evidence suggests a prognostic role of tubulointerstitial lesions in patients with lupus nephritis (LN). Although persistent tubulointerstitial inflammation (TII) usually precedes tubulointerstitial damage (TID) in LN, the two conditions can be simultaneously present to varying degrees.

Objectives: We examined whether coexisting TII/TID predicts progression to chronic kidney disease (CKD) in LN patients.

Methods: The 175 LN patients enrolled in the study had clinical data obtained at the time of renal biopsy and stored in the KORNET registry. These patients were divided into two groups: those with and without coexisting TII/TID. The two groups were compared with respect to their demographic, clinical, histological, laboratory findings, and long-term prognosis. Uni- and multivariable Cox proportional hazard regression models were used to identify independent risk factors for CKD in LN patients.

Results: Of the 175 LN patients, 110 (62.9%) had coexisting TII/TID and 65 (37.1%) did not. Patients with coexisting TII/TID were older, had higher ESR and 24 h proteinuria, and lower eGFR and hemoglobin levels than those without coexisting TII/TID. Anti-Ro and ribosomal-P antibodies were detected less frequently in patients with coexisting TII/TID. In a histological analysis, patients with coexisting TII/TID more often had LN of the proliferative type and a larger proportion had a chronicity score > 4. During a mean follow-up of 89.9 months, CKD and ESRD developed more frequently in patients with than without coexisting TII/TID. Finally, the coexisting TII/TID was associated with a higher risk for CKD progression: adjusted hazard ratio (HR) = 2.677, 95% confidence interval (CI) (1.451, 7.345) for those with class III, IV and V LN; HR = 3.045, 95% CI (1.289, 7.195) for those with class III, IV, V LN, and eGFR ≥ 30 mL/min/1.73 m².

Conclusion: LN patients with coexisting TII/TID are at greater risk for deterioration of kidney function at LN onset and for developing CKD over the long-term.

CHANGES IN THE CAUSES AND PREDICTORS OF LUPUS MORTALITY IN SPAIN THROUGH THE LAST DECADES: DATA FROM THE RELESSER REGISTRY

Keywords: Prognostic factors, Registries, Systemic lupus erythematosus

The use of high doses of corticosteroids (>30mg/day) was predictor of mortality associated with mortality in all periods of the study. Conversely, skin involvement was syndrome and valve disease in the 1990’s; serositis, organ damage and depression at the beginning of the 21st century was linked to mortality. Our results must be confirmed in prospective studies that minimize methodological limitations.

DOI: 10.1136/annrheumdis-2023-erular.6101

Keywords: Systemic lupus erythematosus, Patient reported outcomes, Patient information and education.
In univariate analysis, SLE patients with fatigue (FACIT-Fatigue<34) were more likely to be women (p=0.01), perceived their disease as more active (p<0.001), had higher levels of pain (p<0.0001), anxiety (p<0.0001), depression (p<0.0001), insomnia (p<0.0001), stress (p<0.0001), and were more likely to have fibromyalgia (p<0.0001), compared to patients without significant fatigue. In multivariable analysis, the parameters independently associated with fatigue were insomnia (p=0.0003), significant pain (p=0.002), fibromyalgia (p=0.008), self-reported active SLE (p=0.02), and high level of stress (p=0.045).

Following LEAF feedback, 93.2% of the participants found LEAF helpful (NRS ≥ 3.5) and 93.2% would recommend it to another SLE patient (NRS ≥ 3.5).

**Conclusion:** In SLE patients, fatigue was frequent, commonly severe, and associated with a significant reduction of activities and motivation. This further confirms the urgent need to develop new tools to assess and treat fatigue in SLE. Our study demonstrates the usefulness of an innovative digital tool to manage fatigue in SLE.

**Acknowledgements:** We would like to thank all patients who have participated to the LEAF study, and in particular the patients of the Lupus Europa Foundation.

Background: The Focus Score (FS) ≥ 1 in minor labial salivary gland (LSG) biopsies is one of the 2 main items (with anti-SSA positivity) to establish the diagnosis of Primary Sjögren Syndrome’s (pSS). As such, correctly assessing the FS is crucial for the diagnosis of pSS. However, the histological interpretation of LSG tissue requires specific expertise and poses a challenge to non-specialized centers. Vivino et al. [1] show up to 53% of reclassification after expert center resoring. Deep learning algorithms using artificial neural networks are increasingly used to assist pathologists and can be designed to provide explainable predictions using heatmaps. Heatmaps show which part of the sample section is used to perform the prediction, thus reducing the black box effect. This is important to allow adoption of accurate FS scoring using machine learning in clinical practice.

Objectives: Based on minor LSG specimen, we developed two deep learning models, the first one to predict the FS (≥ 1 or < 1) and the other to predict pSS diagnosis.

Methods: LSG slides used for the diagnosis of patients suspected of pSS were included in the study from 3 European centers which are part of the NECESSITY consortium, a European H2020 IMI2 project. Three groups were included: patients with sicca symptoms but without pSS (Sicca group), pSS patients with ≥ 1 FS, and pSS patients with < 1 FS. All pSS diagnoses were confirmed by rheumatologists from expert centers. Clinical data regarding demographics, disease duration, FS, autoantibodies, and dryness were also collected. All LSG sections used for the pathologic diagnosis were scanned. Two deep learning models were used: one for FS prediction and the other for diagnosis prediction from the biopsies. The models provided a prediction and scored each sub-region of the tissue slides with a risk score. The risk score was used to interpret the algorithm’s result and find which areas of the tissue were most significant for the classification (whether FS or diagnosis). For each model, 70% of patients were used for training and 30% for validation. For the FS task, both the validation and test sets include 54% of ≥ 1 FS patients. Similarly, for the pSS task, the validation set includes 67% of pSS+ patients. The algorithm’s performance was measured using the area under the ROC curve (AUROC).

Results: The dataset included 327 patients: 145 from Paris-Saclay University (Bicêtre Hospital), 73 from Queen Mary University London and 109 from the University of Birmingham. For binary FS prediction the AUROC was 0.87, and for the pSS diagnosis prediction, the AUROC was 0.84. When areas used to make the prediction were analyzed, the model unsurprisingly identified lymphocyte foci for the FS prediction task (Figure 1). This provides explainability and allows the pathologist to visually confirm the results of the prediction. Results on the validation sets for the two tasks are available in Table 1.

Conclusion: Deep learning can predict the diagnosis of FS>1 and the diagnosis of pSS with good accuracy. The FS model could represent a valuable help for assisting pathologists who are not experts in oral medicine pathology and reduce their reliance on reference centers. Comprehensive analysis of the tissue areas highlighted by the pSS model paves the way for a better understanding of the disease’s physiopathology.

**DOI:** 10.1136/annrheumdis-2023-eular.4525

**Background:** EULAR recommendations for treatment for Systemic Sclerosis (SSc) were last updated in 2017, based on literature up to the end of 2014. The treatment recommendations are among the most cited publication in the field, reflecting their utility both in clinical practice and academic research. In the past 8 years, several important advances have been achieved by the scientific community, with new treatments becoming available and accepted by regulatory authorities.

**Objectives:** To update the 2017 EULAR recommendations for treatment of SSc, including answers to the 2017 research agenda, new therapeutic questions, and the wealth of newly available evidence.

**Methods:** Update of previous recommendations was endorsed by EULAR and performed according to the validated methodology. The task force was composed according to recent EULAR guidelines for inclusivity of underrepresented areas of Europe and it consisted of 27 members, including a EULAR endorsed methodologist, 4 fellows, a librarian, one Allied Health Professional and two patient representatives, identified by the Federation of European Scleroderma Associations (FESCA). All centres from the EULAR Scleroderma Trials and Research group (EUSTAR) were invited to review previous questions for Systematic Literature Review (SLR) and propose new ones according to a standardised Delphi approach. A Nominal Group Technique (NGT) exercise was implemented in two rounds for the definition of questions with an 80% agreement threshold. The SLR was conducted with an end date of June 2022, and manually updated to December 2022. Particular attention was dedicated to the 2017 research agenda and new available evidence with matters for detailed discussion and agenda for the new research agenda also agreed during the NGT.

**Results:** Sixty-seven clinical questions addressing 24 different interventions were prioritised for the task force for the SLR. The results of the SLR were categorised by evidence and grade of recommendations and discussed during the NGT meeting. The procedure resulted in 21 recommendations (instead of 16 in 2017) in 8 clinical domains related to SSc symptoms and organ involvements, including Raynaud’s phenomenon, digital ulcers, pulmonary arterial hypertension, scleroderma renal crisis, skin fibrosis, interstitial lung disease, gastrointestinal manifestations and arthritis. Most of the new recommendations were in the field of skin fibrosis and interstitial lung disease, consistent with the research agenda set in 2017. These included recommendations for the use of mycophenolate mofetil, nintedanib, rituximab and tocilizumab for the treatment of these crucial disease manifestations. Calcinosis and the local management of digital ulcers were also present in the 2017 recommendations. Important additions to the future research agenda included targeted therapies for the management of musculoskeletal and gastrointestinal manifestations, calcinosis and the local management of digital ulcers.

**Conclusion:** The 2023 updates of EULAR recommendations include the first set of synthetic and biological targeted therapies recommended as disease modifying agents for key fibrotic manifestations of systemic sclerosis. While a disease modifying agent or strategy for a comprehensive approach appropriate for all SSc patients is still missing, numerous advances have been achieved since 2017. New, strong evidence is now available to clinicians to better manage patients with this life-threatening condition.

Objectives: Accurate measurement of disease activity in systemic sclerosis (SSc) remains a significant challenge. Previous activity indices have been criticized for limitations of face and content validity.

Methods: Consensus was reached regarding the conceptual definition of disease activity in SSc. All SCTC AI items were required to be measures of the agreed upon construct. See Figure 1 for process of item generation. In all Delphi exercises an a priori threshold of 70% agreement was applied for items to be included or excluded from subsequent rounds. Items that did not meet the threshold for inclusion across 2 survey rounds were omitted.

Results: The definition of disease activity as agreed by the SCTC AI WG is: Activity in SSc refers to aspects of disease, attributable to SSc that are potentially reversible, or can be arrested, with time and/or effective therapy. Disease activity may be associated with morbidity and uncontrolled activity may lead to organ dysfunction and mortality. A 24 item index, spanning nine domains of disease was generated with a maximum score of 140 (Table 1). GBTM identified 3 trajectory groups: low activity (n=856 (49%)), medium activity (n=745 (42%)) and high activity (n=164 (9%)). There was a graded risk of death associated with increasing activity levels. 4 year survival was poorer in the high disease activity group compared to the low disease activity group (HR 4.43 (3.51-5.60, p<0.01) for 1 unit increase of SCTC DI for each unit increase in the SCTC AI score).

Conclusion: We present a novel outcome measure to quantify the burden of disease activity in SSc. All SCTC AI items were required to be measures of the agreed upon construct. See Figure 1 for process of item generation. In all Delphi exercises an a priori threshold of 70% agreement was applied for items to be included or excluded from subsequent rounds. Items that did not meet the threshold for inclusion across 2 survey rounds were omitted.

OP0235 DEVELOPMENT AND PRELIMINARY VALIDATION OF THE NOVEL SCLERODERMA CLINICAL TRIALS CONSORTIUM ACTIVITY INDEX

Keywords: Outcome measures, Systemic sclerosis.

Methods: Consensus was reached regarding the conceptual definition of disease activity in SSc. All SCTC AI items were required to be measures of the agreed upon construct. See Figure 1 for process of item generation. In all Delphi exercises an a priori threshold of 70% agreement was applied for items to be included or excluded from subsequent rounds. Items that did not meet the threshold for inclusion across 2 survey rounds were omitted.

Figure 1 Item generation & reduction

Data from the Australian Scleroderma Cohort Study were used to reduce and weight items. Items were weighted using time dependent Cox proportional hazards regression analysis relative to a combined endpoint of mortality and morbidity (SF-36 physical component score (PCS) below cohort median value). Seven provisional items were not collected in the ASCS. A discrete choice experiment was performed to generate relative weightings for these items. Group based trajectory modelling (GBTM) was used to identify trajectory groups to compare the survival of low vs high disease activity groups using Kaplan Meier survival analyses. Cox proportional hazard modelling was used to evaluate the association between activity scores and mortality, morbidity and SCTC Damage Index (SCTC DI) scores.

Results: The definition of disease activity as agreed by the SCTC AI WG is: Activity in SSc refers to aspects of disease, attributable to SSc that are potentially reversible, or can be arrested, with time and/or effective therapy. Disease activity may be associated with morbidity and uncontrolled activity may lead to organ dysfunction and mortality. A 24 item index, spanning nine domains of disease was generated with a maximum score of 140 (Table 1). GBTM identified 3 trajectory groups: low activity (n=856 (49%)), medium activity (n=745 (42%)) and high activity (n=164 (9%)). There was a graded risk of death associated with increasing activity levels. 4 year survival was poorer in the high disease activity group compared to the low disease activity group (75% vs 95%, p<0.01). Patients with a SCTC AI ≥5 had an HR 3.5 (2.6-5.42, p<0.01) for death and greater morbidity was observed in individuals with a SCTC AI ≥6 (HR 19.0 (16.1-22.4, p<0.01). There was a significant relationship between SCTC AI scores and worsening damage: HR 4.43 (3.51-5.60, p<0.01) for 1 unit increase of SCTC DI for each unit increase in SCTC AI.

Conclusion: We present a novel outcome measure to quantify the burden of disease activity in SSc. All SCTC AI items were required to be measures of the agreed upon construct. See Figure 1 for process of item generation. In all Delphi exercises an a priori threshold of 70% agreement was applied for items to be included or excluded from subsequent rounds. Items that did not meet the threshold for inclusion across 2 survey rounds were omitted.

Keywords: Outcome measures, Systemic sclerosis.

DOI: 10.1136/annrheumdis-2023-eular.1383
Background: Interstitial lung disease (ILD) progression can be assessed using different definitions. Declining forced vital capacity (FVC) is the simplest and most accepted. Both progressive pulmonary fibrosis (PPF) as defined by the 2022 ATS/ERS/JRS/ALAT guideline, and progressive fibrosing ILD (PF-ILD) as used in INBUILD, define progressive disease by a composite worsening of lung function, respiratory symptoms and changes on high resolution chest tomography (HRCT), but with differences in the specific criteria. These new definitions have not been applied and compared in SSc-ILD yet.

Objectives: To identify variables predicting SSc-ILD progression using three different definitions of progressive disease.

Methods: We included all SSc patients from the Oslo and Zurich cohorts who had ILD on HRCT. ILD progression was defined as (A) PPF guideline criteria with worsening in 2/3 domains over 12 months including (1) respiratory symptoms; (2) absolute decline in FVC >5% or in DLCO >10% and (3) radiological disease progression. (B) PF-ILD INBUILD criteria with (1) FVC decline ≥10%, (2) FVC decline ≥5-9% and worsening of respiratory symptoms; (2) absolute decline in FVC >5% or in DLCO >10% and (3) worsening in 2/3 domains over 12 months including (1) respiratory symptoms and (2) absolute decline in FVC >5% or in DLCO >10%.

Results: Of 231 included SSc-ILD patients from Oslo and Zurich 43 (19%) fulfilled the PPF criteria and 71 (31%) showed FVC decline >5%. The final multivariable logistic model predictive for ILD progression defined as FVC decline >5%. Variables for ILD progression chosen by expert opinion were tested in multivariable logistic models adjusted for age, sex and treatment and each model was tested using area under curve (AUC) with an AUC of 0.7 defined as acceptable.

Conclusions: Progression is common in SSc-ILD, regardless of definition, but the PPF guideline criteria identified fewer progressors than FVC decline >5% and PF-ILD. We identified different variables predicting progression of FVC decline >5% and PF-ILD but could not identify a model with acceptable performance for PPF. This raises concerns about which definition to use in clinical practice and future studies.

USE OF NEUTROPHIL/LYMPHOCYTE AND PLATELET/LYMPHOCYTE RATIOS TO DETECT SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Systemic sclerosis, Diagnostic tests, Biomarkers

L. D. Fajardo Hermosillo1, L. P. Maria Karina1. Hospital de Especialidades, Centro Médico Nacional de Occidente IMSS, Rheumatology, GUADALAJARA, Mexico

Background: Intestinal lung disease (ILD) remains as a mainly cause of morbidity and mortality in patients with systemic sclerosis (SSc). New markers to early detection of SSc-ILD are an unmet need [1]. Neutrophil/lymphocyte (NLR) and platelet/lymphocyte (PLR) ratios have emerged as potential biomarkers of systemic inflammation in cancer, cardiovascular disorders, infections and rheumatic diseases [2]. Recently, some studies in South Korea and Turkey have showed correlation of NLR and PLR with erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), disease activity, pulmonary and cutaneous involvement in SSc [3,4]. However, manifestations of SSC present variability in different populations. Could NLR and PLR be used as new biomarkers to detect SSc-ILD in Mexican-Mestizo population?

Objectives: To investigate the usefulness of NLR and PLR to detect SSc-ILD.

Methods: A cross-sectional study, where patients > 18 years of age with a diagnosis of SSc according to EULAR/ACR 2013 criteria and diagnosis of ILD by forced vital capacity (FVC) < 70% and > 5% of affected lung area by diffuse ground-glass opacity or pulmonary fibrosis on high-resolution computed tomography (HRCT) were included. Patients with corticosteroid use, malignancy, iron ground-glass opacity or pulmonary fibrosis on high-resolution computed tomography of SSc according to EULAR/ACR 2013 criteria and diagnosis of ILD by EULAR/ACR 2013 criteria were excluded. Neutrophil and lymphocyte count were determined following the method described by Giusti [5]. Spearman’s correlations between NLR or PLR and EUSTAR disease activity index, mRSS, ESR, CRP, FVC and affected lung area HRCT were analyzed. Receiver operating characteristic (ROC) analysis was performed to assess the best cutoff value for detecting SSc-ILD.

Results: Of 74 patients with SSc 94.6% were women. The mean age [standard deviation (SD)] was 49.8 (14.1) years. The median of disease duration [inter-quartile range 25-75 (IQR)] was 7 (4.7-12) years and subtype of limited cutaneous SSc was presented in 85.1% of patients. A total of 36 (48.6%) patients had NLR > 2.05 (OR 5.42, 95% CI 1.47-20.07, p=0.011) and EUSTAR activity index > 2.5 (OR 2.62, 95% CI 1.38-4.96, p=0.003) remained associated with an increased risk of SSc-ILD.

Conclusion: This study suggests that NLR show better DA than PLR, as well as a useful screening tool and a low-cost biomarker to detect SSc-ILD in Mexican-Mestizo patients. Also, NLR is associated with an increased risk of SSc-ILD and present a good correlation with affected lung area on HRCT, FVC and disease activity. However, these observations must be confirmed in larger and prospective studies.

Methods: In the approved EUSTAR project CP111, we included SSc patients with pre-capPH. The primary end point was death or precapPH worsening (following the SERAPHIN trial: one of ≥15% 6MWD decrease, worsening of NYHA class, onset of right heart failure, additional PAH medications, starting iv/sc prostanoids, lung transplantation, atrial septostomy). We evaluated the association between IMS and time to first event with a multiple Cox regression model for time dependent covariates with robust Sandwich variance estimate and backward selection. The baseline confounders were chosen on experts’ opinion and included SSc-related risk factors for mortality or IMS prescription (sex, age, diffuse skin subset, renal crisis, digital ulcers, muscle weakness, joint synovitis, ILD on HRCT, LVEF%, FVC%, DCO%) and PAH risk stratification parameters (mPAP, increased INR/TnptBNP, NYHA class ≥II, reduced cardiac index, reduced 6MWD). PAH medications (none, mono, double or triple therapy) were also included as time-dependent confounder.

Results: 755 SSc-precAPH patients from 54 EUSTAR centers were included (18% males, age 63±11 years, disease duration 11±9 years, 29% diffuse skin subset, 60% ILD on HRCT: 377 (50%) received IMS (96 days (47%) csDMARDs, 66% (9%) targeted therapies) and 642 (85%) PAH medications. Patients treated with IMS had more frequently ILD (78 vs 43%), diffuse skin (41% vs 18%), joint (16 vs 7%) and muscle (22 vs 10%) involvement. In 2.9 (12.5-4.5) years median follow-up, 546 (70%) patients developed a morbidity-mortality event. While overall IMS exposure did not associate with the outcome, targeted therapies were associated with reduced risk of mortality-morbidity (HR 0.59 (95% CI 0.36-0.96), p=0.04; Figure 1a).

Conclusion: In this large EUSTAR SSc-precAPH cohort, targeted therapies are associated with a significantly reduced risk of mortality and precAPH worsening over time. This is the first large study adjusted for confounders supporting a potential effect of targeted therapies on SSc-precAPH.

Acknowledgements: On behalf of the EUSTAR collaborators.

When clustering into group 1 [n=561, 40% IMS, n=32 (6%) targeted therapies] or group 3 [n=194, 80% IMS, n=36 (19%) targeted therapies], less morbidity-mortality events were recorded for group 1 (69% vs 81%). Despite the rarer use, the protective effect of targeted therapies for mortality-morbidity was confirmed in group 1 (HR 0.24, 95% CI 0.02-0.64, p=0.01, Figure 1b) but not in group 3 (Figure 1c). When looking at specific target therapies, a risk reduction for the mortality-morbidity outcome was noted for tocilizumab (in the whole cohort (n=546) p=0.03; HR 0.77 (95% CI 0.60-0.98) and in group 1 (n treated=10; HR 0.95, 95% CI 0.01-0.69, p=0.02) and rituximab (in group 1, n treated= 24, HR 0.29, 95% CI 0.10-0.84, p=0.01).

The results support the hypothesis that IMS reduce morbidity-mortality in SSc-precAPH patients and that targeted therapies have an added value in the management of this complex disease. Further studies are needed to better define the role of IMS and targeted therapies in the treatment of SSc-precAPH.

Figure 1. Kaplan-Meier curve of ILD- free survival estimates. Survival rate with 95% confidence interval is shown for the early and late treatment group.

Conclusion: Our finding did not confirm a preventive role of early vs. late timing of IMS therapy on ILD development. However, our findings should be interpreted with caution, considering the high inflammatory, ATA-positive enriched nature of the cohort selected, as well as confounding by indication, which cannot be ruled out also after adjusting for other confounding factors.

DOES EARLY IMMUNOSUPPRESSIVE THERAPY PREVENT SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE?

Keywords: Systemic sclerosis, Lungs, Epidemiology

A. Velauthapillai1, M. Bootma1, C. Brunii2, O. Distler2, C. Van den Ende3, M. Vonk.1
1 Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; 2 University Hospital Zürich, Rheumatology, Zürich, Switzerland

Background: Systemic sclerosis (SSc) is an auto-immune disease characterized by a triad of inflammation, vascular damage and fibrosis. Interstitial lung disease (ILD) is a major contributor to impaired quality of life and a leading cause of death in these patients. While recent studies reported a favorable effect on disease course when starting immunosuppressive (IMS) therapy in mild and moderate ILD, no definite evidence of a preventive mechanism of IMS therapy for ILD onset is established (1, 2).

Objectives: The objective of our study was to explore the association between timing of start IMS therapy and the development of ILD.

Methods: A combined cohort was created from the EUSTAR database and Nijmegen Systemic Sclerosis cohort, including patients: 1) aged 18 years or older 2) treated with IMS (i.e. mycophenolate mofetil, methotrexy, cyclophosphamide and rituximab) after SSC diagnosis 3) negative for signs of ILD on high-resolution CT (HRCT) at or within 2 months after start treatment and 4) no prior treatment with biological or antifibrotic in the preceding years. Data between start of IMS treatment and five years follow-up were analysed. Disease duration (time between first non-Raynaud phenomenon and start IMS) was dichotomized into early and late treatment using a cut-off point of 3 years. ILD-free survival (absence of HRCT confirmed ILD diagnosis) was assessed with unadjusted Kaplan Meier analysis on complete cases and a cox proportional hazard analysis on imputed data adjusting for confounders.

Results: We identified 1037 patients meeting the eligibility criteria. The early treatment group (n= 539, 52 %) showed a higher prevalence of male sex, diffuse cutaneous SSc (dcSSc, 52.9% vs 36.4%, p= 0.001), anti-topoisomerase I antibody positivity (ATA, 51.0% vs. 42.5%, p= 0.01), anti-RNA polymerase III antibody positivity (ARA, 11.7% vs. 5.4%, p=0.009) and elevated C-reactive protein levels (30.6% vs. 22.6%, p=0.03). Further, patients in the early group had a higher mean(95% CI) of disease activity (1.39(9.7) vs. 9.7(8.9), p= 0.001). The incidence of ILD was 46.1% after mean(95% CI) 3.6(14) years of treatment and not significantly different between the groups (mean(95% CI); early 47(43-51) vs. late: 45(40-50), p= 0.64). The unadjusted Kaplan-Meier survival curve on complete cases (Figure 1) shows no differences in ILD-free survival rates between the early and late treatment group. The hazard ratio for ILD in the early treatment group was 1.11 (95% CI: 0.91-1.36) adjusting for gender, dcSSc, Caucasian ethnicity, ARA, age, forced vital capacity and diffusing capacity for carbon monoxide at baseline.

Conclusion: Our finding did not confirm a preventive role of early vs. late timing of IMS therapy on ILD development. However, our findings should be interpreted with caution, considering the high inflammatory, ATA-positive enriched nature of the cohort selected, as well as confounding by indication, which cannot be ruled out also after adjusting for other confounding factors.

Background: Interstitial lung disease in systemic sclerosis(SSc-ILD) is heterogeneous with limited therapeutic options. Mycophenolate mofetil (MMF) is the most commonly used first line agent for SSc-ILD. Tacrolimus has shown promising efficacy in few small case series, and large cohorts of patients with non-SSc-ILD[1], but has never been evaluated in the setting of a clinical trial.

Objectives: To compare the safety and efficacy of Tacrolimus with MMF in patients with progressive SSc-ILD.

Methods: In this single center open labelled, prospective, two-arm parallel group, randomized controlled pilot study (INSIST) conducted between November 2021 to December 2022, patients with progressive ILD (FVC decline >10%) due to SSc, aged between 18-65 years, disease duration <10 years, without concomitant inflammatory myositis, with an FVC of 40-85%, and not having due to SSc, aged between 18-65 years, disease duration <10 years, without

Results: 25 out of 26 patients (13 in each group) completed 24 weeks follow up. Majority had Anti-Scl 70 positivity (73%) and limited skin disease. At 24 weeks, the mean change in FVC was 4.4% (10.6) and 6.92%(8.4) in the MMF and tacrolimus groups respectively (difference 2.52%, 95% CI (-10.3 to 5.18); p=0.500). All patients on tacrolimus and 85% of patients on MMF had stabilization (ΔFVC>-5% TO 5%) or improvement (ΔFVC>-10%) in lung function. Secondary outcomes were similar between two groups. Subgroup analyses stratified by ILD type, skin involvement at baseline, and early vs late SSc yielded similar results. The mean tacrolimus levels were 4.9 ng/ml (147) and the median dose needed to achieve these levels was 4mg/d. No serious adverse events were noted in either group; use of tacrolimus did not result in renal dysfunction or renal crises.

Conclusion: Tacrolimus resulted in comparable improvement to MMF across primary and secondary outcome measures at 24 weeks with a favorable safety profile in patients with SSc-ILD. Larger studies with longer follow up are needed to investigate the role of calcineurin inhibitors in SSc.

REFERENCE:
Results: This study included 29 patients registered for deceased LT between 2010 and 2022 (Table 1). Ten patients received deceased-donor LT (34%), two received living-donor LT (7%), seven died while waiting for LT (24%), and ten survived on the waiting list (34%). The median waiting time from registration to deceased-donor LT was 28.9 months (range 22.3-30.3). The median duration from registration to living-donor LT or death (events) was 6.5 months (range 4.1-14.7). Pulmonary hypertension was associated with mortality or switching to living-donor LT while waiting for deceased LT. In post-transplant analysis, 15 and 20 patients received LT for SSC-ILD and IPF between February 2002 and April 2022, respectively. Lung transplantation recipients showed an improved forced vital capacity with a median of 55.1% at baseline, 65.8% at 6 months and 80.3% at 12 months post-transplant. The estimated 5-year survival rates for post-transplant patients with SSC-ILD or IPF were 86.2% and 55.3%, respectively (log-rank, P = 0.33) (Figure 1).

Conclusion: Lung transplantation is an acceptable treatment for Asian patients with severe SSC-ILD. Further research is needed to determine the optimal time for referral to LT centres for patients with SSC-ILD.

Conclusion: In the present real-life study, a smaller proportion of patients treated with bisphosphonates reached the BMD STEs at 2 years of treatment as compared to denosumab and teriparatide. Nearly all subjects reached STEs at 6 years of follow-up.

OP0243

PROTON PUMP INHIBITOR USE IS ASSOCIATED WITH IMPAIRED BONE MINERAL DENSITY BUT NOT BONE MICROARCHITECTURE IN PATIENTS WITH INFLAMMATORY RHEUMATIC AND MUSCULOSKELETAL DISEASES TAKING GLUCOCORTICOIDS

1Charité – Universitätsmedizin Berlin, Berlin, Germany; 2Department of Rheumatology and Clinical Immunology, Berlin, Germany; 3the Parker Institute, University of Copenhagen, Copenhagen, Denmark, Section for Biostatistics and Evidence-Based Research, Copenhagen, Denmark; 4University of California San Francisco, Division of Rheumatology, San Francisco, United States of America; 5University of Southern Denmark, Odense University Hospital, Research Unit of Rheumatology; Department of Clinical Research, Odense, Denmark

Background: Patients with inflammatory rheumatic and musculoskeletal diseases (iRMDs) are at increased risk of osteoporosis and fragility fractures. For this population, the question of whether proton pump inhibitor (PPI) intake contributes to that risk has not yet been definitively answered. Prior studies have yielded conflicting results, did not account for regular PPI intake on bone mineral density (BMD) and microarchitecture in patients with iRMDs.

Methods: Cross-sectional baseline data from the single center Rh-GIOP cohort ("Glucocorticoid-induced Osteoporosis in Patients with Chronic Inflammatory Rheumatic Diseases or Psoriasis") were used. Briefly, patients with iRMDs were prospectively enrolled and assessed with DXA scans, laboratory tests, and a bone health-related questionnaire since November 2014. Regular PPI and glucocorticoid (GC) use were ascertained by both chart review and patient self-report. Three co-primary outcomes (all reported as T-scores) were defined: BMD of the left femoral neck and the lumbar spine, and the trabecular bone score (TBS). The latter is a measure correlating with lumbar spine trabecular bone microarchitecture. The objective was to assess the effect of regular PPI intake on bone mineral density (BMD) and microarchitecture in patients with iRMDs.

Results: Of 520 patients with iRMDs, 412 were included in the final analysis. The median age was 65 years (range 18–90), 63.8% used GCs (median dose 5mg/d). In both adjusted and unadjusted analyses, PPI users had lower BMD at both the left femoral neck and the lumbar spine (Table 1). Interestingly, differences between PPI users and non-users were only present in the subset of patients concurrently using GCs (data not shown). There was no statistically significant difference in BMD when comparing high and low dose PPI users (all P ≥ 0.52). TBS (n = 389) was similar in PPI users and non-users (Table 1).

Conclusion: Loss of BMD (seen at both lumbar spine and left femoral neck) rather than impairment of bone microarchitecture seems to be driving the increased fracture risk seen with PPI use in patients with iRMDs. The negative association between PPI use and BMD appears to be dependent on concurrent GC use.

DISEASE SEVERITY IS ASSOCIATED WITH OSTEOPOROSIS AND FRAGILITY FRAC TURES IN PATIENTS WITH SYSTEMIC SCLEROSIS

C. Midó1, E. Wiebe2, E. Sieger2, D. Huscher3, H. Béhaï4, D. Launay1, E. Hachulla1, V. Sobanski1, F. Buttgereit1, D. J. M. F. Zetterström5, J. Y. : NIH/NIAMS K24-AR-074534 and P30-AR-070155, R.S.: NIH/NIHCATS through UCsf-CTSI Grant Number TL1 TR001871.

1Charité – Universitätsmedizin Berlin, Corporate Member of Free Universität Berlin and Humboldt-Universität zu Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Berlin Institute of Health at Charité, Universitätsmedizin Berlin, Berlin, Germany; 3Charité – Universitätsmedizin Berlin, Corporate Member of Free Universität Berlin and Humboldt-Universität zu Berlin, Institute of Biometry and Clinical Epidemiology, and Berlin Institute of Health, Berlin, Germany; 4Université Lille, CHU Lille, ULR 2694 - METRICS: Évaluation des Technologies de Santé et des Pratiques Médecinales, Biostatistics Department, Lille, France

Background: Patients with systemic sclerosis (SSc) are at an increased risk for osteoporosis (OP) and associated fragility fractures [1]. The prevalence of osteodensitometric OP has been estimated to range from 16% to 60% [2]. However, the risks factors and the mechanisms driving bone loss in patients with SSc remain elusive. The role of "general" determinants such as higher age and low body mass index (BMI) is well established (3) but their interaction with disease-specific factors is unclear. An association between OP and the cutaneous subset (diffuse or limited skin extent) (3, 4) or disease-specific antibodies (anti-centromere or anti-topoisomerase I antibodies) (5, 6) is controversial.

Objectives: Our objectives in the present study were: (i) to evaluate the prevalence of clinical OP and fragility fractures in a large population of SSc patients; (ii) and to identify potential disease-specific factors for OP in this population.

Methods: This cross-sectional study was based on two large European prospective cohorts of SSc patients with retrospective collection of bone health data. OP was defined as the presence of a T-score below -2.5 at femoral neck or lumbar spine and/or a previous major osteoporotic fracture and/or the prescription of anti-osteoporotic therapy. Long-term therapy with glucocorticoids (GCs) was
defined by a daily prednisone equivalent dose above 2.5mg for more than 3 months. Age, female sex, BMI and treatment with proton pump inhibitors (PPIs) as predefined risk factors according to published evidence, as well as clinically relevant factors associated with a p-value <0.05 in univariable analyses, after correction for multiple comparison, were implemented into a multivariable logistic regression model.

Results: A total of 932 patients fulfilling the ACR/EULAR 2013 classification criteria were included in the study, followed prospectively in two university hospitals: Lille (n=485) and Berlin (n=447; of which 72 were patients of the Rh-GIOP prospective cohort). The two cohorts were studied separately. The prevalence of OP was 32% in Berlin and 23% in Lille (p=0.003), fragility fractures occurred in 22% and 18% respectively. Multivariable analysis in the Berlin cohort (Figure 1A) indicated that higher age (OR 1.05 [95%CI 1.03 to 1.07], p<0.001), female sex (OR 2.70 [95%CI 1.29 to 5.65], p=0.009), diffuse skin extent (OR 5.03 [95%CI 2.50 to 10.10], p<0.001), low BMI (OR 0.94 [95%CI 0.88 to 0.99], p<0.001), WHO-FC III-IV dyspnea (OR 2.06 [95%CI 1.16-3.67], p=0.014) receiving GCs (OR 1.78 [95%CI 1.10 to 3.17], p=0.026) or PPIs (OR 1.87 [95%CI 1.10 to 3.17], p=0.020) were associated with OP. In the Lille cohort, multivariable analysis (Figure 1B) confirmed the association of OP with higher age (OR 1.06 [95%CI 1.04 to 1.08], p<0.001), GCs use (OR 4.48 [95%CI 2.42 to 8.26], p<0.001), and with anti-topoisomerase I antibody positivity (OR 2.22 [95%CI 1.18 to 4.16], p=0.013).

Conclusion: Our data support a multifactorial etiopathogenesis of OP in SSc: besides common risk-factors for OP such as higher age, female sex, and BMI, several disease specific characteristics were associated with OP, such as SSc severity as reflected by diffuse skin extent and presence of antitopoisomerase I antibodies as well as severe dyspnea and SSc treatment (PPIs and GCs). These findings help to identify patients with SSc at particular risk for OP in clinical practice.

1Westmead Hospital, Rheumatology, Westmead, Australia; 2New South Wales Ministry of Health, Economics and Analysis Unit, Strategic Reform and Planning Branch, St Leonards, Australia; 3New South Wales Ministry of Health, Biostatistics Training Program, St Leonards, Australia; 4Agency for Clinical Innovation, Musculoskeletal Network, St Leonards, Australia; 5New South Wales Ministry of Health, Economics and Analysis Unit, Strategic Reform and Planning Branch, St Leonards, Australia

Background: Despite widespread availability of effective bone protective medications and knowledge that minimal trauma fractures (MTFs) identify those at high risk of re-fracture, treatment of osteoporosis following MTF is poor. An effective way to address this gap is establishment of a fracture liaison service (FLS) where a fracture liaison coordinator coordinates case-finding and bone health management, usually in collaboration with a local medical “champion.”

Objectives: To determine the effect of a Fracture Liaison Service (FLS)/Osteoporosis Refracture Prevention (ORP) programme on refracture rates.

Methods: Coffs Harbour (population 80 000) on the mid-north coast of New South Wales (NSW, Australia’s most populous state), had a FLS established in July 2012. The comparator was the similar-sized city of Port Macquarie, located 160 km south which did not have an FLS established until 2019. The study population was residents aged ≥ 50 years with a fracture diagnosis recorded on the total number of hospital admissions, ED presentations and outpatient visits occurring within 28 days of index fracture or re-fracture was considered part of annual health service utilisation associated with refracture was calculated using Kaplan–Meier methods accounting for follow-up time and deaths and adjusted for age, sex and fracture type. Trends in one- to five-year cumulative re-fracture rates from year of index fracture were also calculated. Annual health service utilisation associated with re-fracture was calculated using the total number of public hospital admissions, ED presentations and outpatient visits occurring within 28 days of index fracture or re-fracture was considered part of the same episode of care.

Results: In those aged ≥50 yo, compared to “business and usual” (BAU), there was a 7% reduction in total fractures (n=190 observed, versus n=6628 projected BAU), 95% confidence interval [95CI] 6270 - 6965; p=0.02) and a 9% reduction in total re-fractures (n=1709 observed, versus n=1869 projected BAU), 95%CI 1768 - 1970; p=0.002) over the 7-year study period for Coffs Harbour. This reduction was
not observed in Port Macquarie or in the rest of the state of NSW. Cumulative adjusted refractures rates for Coffs Harbour were as follows: 1-year 7%, 2-years 13%, 3-years 19%, 4-years 24%, 5 years 29%. Females had higher refractures rates compared to males and having a diagnosis of osteoporosis at time of index fracture was associated with higher refractures rates.

**Conclusion:** An FLS/ORP programme is associated with a reduction in total fractures and refractures rates. However, refracture rates were higher in Coffs Harbour, a rural centre, compared to pooled statewide data.

**ROMOSOZUMAB VERSUS DENOSUMAB IN HIGH-RISK PATIENTS WITH GLUCOCORTICOID-INDUCED OSTEOPOROSIS: A PILOT RANDOMIZED CONTROLLED TRIAL**

**Keywords:** Clinical trials, Osteoporosis, Randomized control trial

C. C. Mok1, W. H. MA2, K. L. Chan1, L. Y. Ho1, S. M. Tse1, S. Chen3.
1Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR); 2Tuen Mun Hospital, Nuclear Medicine, Hong Kong, Hong Kong (SAR); 3Queen Elizabeth Hospital, Pathology, Hong Kong, Hong Kong (SAR)

**Objectives:** To compare the efficacy and safety of romozosumab (ROMO) and denosumab (DEN) in high-risk patients with glucocorticoid (GC)-induced osteoporosis (GIOP).

**Methods:** Design: A pilot open randomized controlled trial.
Method: Adult patients (≥18 years) who were receiving daily prednisolone dose of ≥5mg/day for ≥12 months and had moderate/high risk of osteoporotic fracture (a history of fragility fracture, DEXA T score ≤-2.5 [age ≥40 years] or Z scores ≤-3.0 [age <40 years] or high risk of 10-year major fracture estimated by FRAX) were included. Participants were given daily calcium and vitamin D and existing bisphosphonates were discontinued. Subjects were randomized by blocks to receive either ROMO (210mg SC monthly) or DEN (60mg SC every 6 months) for 12 months, followed by DEN (60mg every 6 months) for 12 more months in both arms. The primary efficacy end point was the change in bone mineral density (BMD) at the lumbar spine from baseline to month 12. Secondary end points included BMD change at the non-dominant hip and femoral neck at month 12, change in bone turnover markers, new vertebral fractures, change in BMD at the hip and spine at month 24 and adverse events.

**Results:** Of 70 patients recruited, 63(90%) completed the study (age 62.6±9.1 years; 96% women; 35 each assigned to ROMO or DEN). Underlying medical diseases were systemic lupus erythematosus (51%), rheumatoid arthritis (29%), inflammatory myopathies (9%) and others. The mean prednisolone dose at entry was 6.6±3.5mg/day. Osteoporosis at spine/hip/femoral neck and a history of fragility fracture was present in 34(48.6%) and 35(50%) patients, respectively. Oral bisphosphonates were being used in 33(47%) patients prior to first dose of the study drugs. While the baseline demographics and osteoporosis risk factors were not significantly different between the two groups, ROMO-treated patients had lower hip/femoral neck BMD and serum vitamin D3 levels than those treated with DEN. At month 12, a significant increase in spine BMD was observed in both the ROMO (+7.3±4.5%; p<0.001) and DEN (+2.3±3.1%; p<0.001) groups of patients. The inter-group difference in spine BMD at month 12 was statistically significant after adjustment for baseline BMD values, age, sex, osteoporosis risk factors and the cumulative prednisolone doses in 12 months (p=0.001). The corresponding increase in hip BMD were +1.6±3.3% (p=0.01) in the ROMO group and +1.6±2.6% (p=0.003) in the DEN group. No significant inter-group difference in hip BMD was observed after adjustment for the same confounding factors. The increase in femoral neck BMD from baseline to month 12 was not significant in both groups. In DEN-treated patients, both serum CTX (-34.7±54.8%; p=0.002) and P1NP (-35.1±43.3%; p=0.001) dropped significantly from baseline to month 12. However, in the ROMO group, a non-significant drop in CTX (-18.1±76.9%; p=0.18) but increase in P1NP (+1.7±70.3%; p=0.09) was observed. Only one new vertebral fracture developed in the ROMO group at 12m. The commonest adverse event (AE) was self-limiting injection site pain/redness, which was significantly more common in ROMO-treated patients. Post-injection musculoskeletal pain was reported in 2 and 3 patients in the ROMO and DEN group of patients, respectively.

**Conclusion:** Romosozumab was superior to denosumab in raising the spine BMD at month 12 in chronic GC users with high fracture risk. Both drugs were well-tolerated. Romosozumab may offer a new treatment option for GIOP in high-risk patients.

IS PREVENTION BETTER THAN CURE?
DATA FROM A MONOCENTRIC RANDOMIZED CLINICAL TRIAL TO PREVENT ACUTE PHASE REACTION RELATED TO INTRAVENOUS BISPHOSPHONATES

Keywords: Osteoporosis, Randomized control trial, Bone diseases

R. Di Taranto1, C. Crotti1, A. Amati1,2, F. Zucchi1, R. Caporali1,2, M. Varenna1,2, ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy; 2University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 3ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Bone Disease Unit, Milan, Italy

Background: Acute phase reaction (APR) is a transient flu-like syndrome with fever, chills, fatigue, malaise, and musculoskeletal symptoms, often occurring 24-36 hours after intravenous bisphosphonates (IV-BPs) administration and usually resolving within 2-3 days[1]. Avoiding APR could increase patients' compliance to treatment and reduce patients' discomfort.

Objectives: In this monocentric, randomized, open-label, parallel-group study, we examined the efficacy of low dose of methylprednisolone (6MP), paracetamol (PAR) or placebo (PBO) in reducing the incidence of APR.

Methods: We prospectively enrolled patients from March 2022 to December 2022. Patients were randomly allocated to PAR 1000mg BID for 3 days, 6MP 4mg BID for 3 days or PBO after IV-BPs (zoledronate (ZOL) 5mg or neridronate (NER) 100mg). A scale ranging from 0=absence, 1=mild, 2=moderate, and 3=severe was used to rate symptoms. Arthralgia (AM) included arthralgia, myalgia, arthritis, and chest pain; systemic symptoms (SS) included headache, nausea, fatigue, fever, and Health Assessment Questionnaire (HAQ). AM, CS, fever and HAQ were assessed at baseline and at day 4. APR was defined as the worsening of >2 points in AM, CS score, fever (>37.5°), and/or the worsening of 22% or increase of 0.25 in HAQ score[2]. Comparisons were performed by T test and chi-square test. Logistic regression was used to analyze protective and predictive factors for APR occurrence. All patients have signed informed consent.

Results: Ninety-five patients were enrolled: mean age 71±14.6 yrs, mean BMI 24.5±4.1, 69.5% females, 70.5% menopausal women, 10.5% had previous exposure to oral BPs. Fourteen patients were under chronic treatment with statins. Patients were treated with BPs for osteoporosis (n=16; 17%), Paget’s disease of bone (n=5; 5%) and complex regional pain syndrome type 1 (n=7; 7%). 29 patients were allocated in 6MP arm, 29 in the PAR arm and 37 in the PBO arm. The incidence rates of AM and SS in ZOL were 46.7% and 60%, respectively. The incidence rate of AM and SS in NER were 32.8% and 21.4%, respectively. 6MP prophylaxis significantly reduced the incidence of AM (p=0.03) and HAQ worsening of 22% or increase of 0.25 (p=0.01 and p=0.05, respectively), but did not prevent the incidence of SS (p=0.23). PAR and PBO did not modify the incidence of AM, SS, and worsening of HAQ. Chronic use of statins prevented incidence of AM and worsening of HAQ (p=0.029 and p=0.015, respectively) but did not impact SS score. Previous therapy with oral BPs did not prevent APR. Among protective variables for the incidence of AM were recognized older age (OR 0.95, CI 1.01-1.11, p=0.02) and 6MP prophylaxis (OR 5.0, CI 1.79-22.9, p=0.03). Concomitant statins, previous exposure to oral BPs, 25OH vitamin D3 (25OHD3) serum levels or 25OHD3 ongoing supplementation did not prevent APR. Higher BMI (OR 1.32, CI 1.07-1.65, p=0.01) and treatment with ZOL (OR 31.6, CI 2.3-431.96, p=0.01) were predictive factors for the occurrence of fever.

Conclusion: Our data demonstrated that low dose 6MP prophylaxis is effective in preventing the most common features of APR, compared to PAR or PBO. In contrast to literature, previous exposure to oral BPs, normal 25OHD3 serum levels or 25OHD3 supplementation did not have impact on the occurrence of APR.

New evidence on IgG4-related and rare autoinflammatory diseases

Keywords: Vasculitis, Treat to target, Randomized control trial

A. Mekinian1,1, P. Fenaux2,2, 1Sorbonne University, Internal Medicine, Paris, France; 2Saint Antoine, Internal Medicine, Paris, France

Background: Systemic autoimmune and inflammatory disorders (SAID) are underestimated, and potentially life-threatening complications observed in 15-25% of myelodysplastic neoplasms (MDS) and chronic myelomonocytic leukemia (CMML), although pathophysiological links between both types of disorders remain uncertain. In 2020, Beck et al. described VEXAS (Vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome (OMIM #301054, defined by the presence of UBA1 mutations, in patients with severe systemic inflammation, chronic fever, 30% of whom had concurrent MDS. VEXAS is typically associated with refractoriness to conventional immunosuppressive therapies (IST) and dismal prognosis, and prospectively evaluated effective treatment strategies remain to be established. In MDS/CMML patients with concomitant SAID, but no UBA1 mutation, we and others observed a high incidence of mutations of the epigenetic regulator VEXAS SYNDROME ASSOCIATED WITH MDS AND CMML

Methods: This prospective phase II trial of AZA in patients with MDS/CMML and steroid dependent/refractory SAID.

Results: This led us to launch a prospective phase II trial of AZA in patients with MDS/CMML and steroid dependent/refractory SAID.
IgG4-related disease is an increasingly recognized systemic fibro-inflammatory disorder involving almost any organ system. Most available data on treatment strategies and natural history of IgG4-RD are currently derived from large cohorts from Europe. Real-life studies addressing the epidemiology, clinical manifestations, and treatment strategies of IgG4-RD in Europe are limited to smaller cohorts from single center experiences. Objectives: To characterize the epidemiology, clinical manifestations, and response to treatment of IgG4-RD patients in Europe.

Methods: A pan-European registry (PrescrAIP) was set in place to retrospectively analyse adults diagnosed with IgG4-RD from 2005 and 2020 in 42 European university hospitals. Comprehensive diagnostic criteria and organ-specific criteria were used to diagnose IgG4-RD and central validation was applied. Data on disease epidemiology, clinical characteristics, treatment, and outcomes were retrospectively collected from the hospitals’ medical records using a REDCap-based electronic case report form. The IgG4-RD responder index was used to assess response to therapy. Predictors of relapse were identified using multivariable logistic regression analysis after correcting for confounders.

Results: 1079 individuals with suspected IgG4-RD were screened but only 735 were diagnosed with IgG4-RD and considered for analysis (69% male; median age 57 years; 85% Caucasian); 45% of patients had multorgan (>2) involvement (Table 1). Pancreatitis, salivary glands, and biliary tree were the most frequently involved organs. Steroid-treatment was started in 634 patients; 9 (1%) were lost to follow-up, 79% (496/625) had a complete response, 18% (111/625) had a partial response, and 3% (18/625) did not respond. 95 patients were not treated; 61% (58/95) had spontaneous complete response, 19% (18/95) had partial response, and 10% (9/95) did not respond. Higher daily steroid dose (>0.4mg/kg prednisone equivalent) was as effective as lower dose (<0.4mg/kg) (OR 0.428; 95% CI 0.054-3.387) for inducing disease response. Similarly, longer induction of remission treatment (>2 weeks) was as effective as shorter therapy (<2 weeks) (OR 0.908; 95% CI 0.818-1.009). Elevated IgG4 levels were independently associated with a decreased chance of complete response (OR 0.639; 95% CI 0.427-0.955). Relapse occurred in 30% of patients. Relapse within 6 months of remission induction were independent of the steroid tapering duration, induction treatment duration, and total cumulative dose. Parenchymal enlargement (OR 0.390; 95% CI 0.167-0.910) and addition of maintenance therapy with immunosuppressive agents were independently associated with fewer relapses at 6 months (OR 0.299; 95% CI 0.120-0.740). No difference between maintenance therapy with glucocorticoids and rituximab was observed in maintaining disease response.

Conclusion: This is the first pan-European study addressing the epidemiological and clinical features of IgG4-RD in Europe. Our study indicates that patients with elevated IgG4 level may need closer monitoring during remission induction and that 0.4mg/kg/day of prednisone equivalent for at least 2 weeks represents the most effective strategy to induce IgG4-RD remission.

Methods:

The RELIANCE registry explores long-term safety and effectiveness of CAPS (Cryopyrin-associated periodic fever syndromes) – 4-years data from the RELIANCE registry. Physicians assess patients at baseline and at 6-monthly intervals.

Background: CAPS (Cryopyrin-associated periodic fever syndromes) are monogenic autoinflammatory diseases causing great burden due to severe systemic and organ inflammation caused by increased production of interleukin-1β (IL-1β). In clinical trials as well as in real-life, the monoclonal antibody canakinumab (CAN) effectively inhibits IL-1β and results in rapid suppression of CAPS symptoms.

Objectives: The RELIANCE registry explores long-term safety and effectiveness of CAN under routine clinical practice conditions in pediatric (≤2 years) and adult patients with CAPS, including Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS) and neonatal onset multisystem inflammatory disease ( NOMID) in childhood rheumatology.

Methods: This prospective, non-interventional, observational study enrolls patients with clinically confirmed diagnoses of CAPS routinely receiving CAN. Clinical data, physician assessments and patient-reported outcomes are evaluated in 6-monthly intervals.

Results: 107 CAPS patients (53% female; 16% NOMID/FCAS subtypes) were enrolled by December 2022. At baseline, median age was 23 years and median duration of prior CAN treatment was 6 years. 92% of patients received greater than standard dose CAN, 75% of the patients were in disease remission at month 48 by physician assessment. Patients report stable low level disease activity (median 2.0 at baseline and 1.5 at month 48) and fatigue (median 3.0 at baseline and 1.0 at month 48). No relevant differences regarding subtype severity were observed (Table 1).

Conclusion: The 48-month interim analysis of the RELIANCE registry demonstrates that long-term CAN treatment is safe and effective in patients with CAPS, independent of subtype severity.

REAL-WORLD DEMOGRAPHICS, CLINICAL CHARACTERISTICS, AND TREATMENT PATTERNS OF PATIENTS TREATED WITH EMAPALUMAB FOR SECONDARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN THE UNITED STATES: THE REAL-HLH STUDY

Keywords: Real-world evidence, Outcome measures, Cytokines and chemokines

C. Allen, S. Chandrasekar, M. Jordan, J. Leiding, A. Oladapo, P. Pednekar, K. Walkovich, J. Yee, Baylor College of Medicine, Division of Pediatric Hematology and Oncology, Houston, United States of America;

Emory University, Division of Bone and Marrow Transplant Research,
Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, life-threatening, hyperinflammatory syndrome caused by overproduction of proinflammatory cytokines, e.g., interferon gamma (IFNγ).[1,2] Secondary HLH (sHLH) occurs in the context of an underlying disease (e.g., rheumatologic, malignancy, or iatrogenic) and/or an infectious trigger.[1,2] Emapalumab is a fully human anti-IFNγ monoclonal antibody that binds to and neutralizes the biological activity of IFNγ. It was approved by the FDA in 2018 for adults and children with primary HLH with refractory, recurrent, or progressive disease, or intolerance to conventional HLH therapy. Since its approval, real-world evidence on the use of emapalumab in routine clinical setting is limited.[3-5] The REAL-HLH study assessed real-world treatment patterns among patients treated with emapalumab.

Objectives: To describe the demographics, clinical characteristics, and treatment patterns among the subset of patients with physician-reported diagnosis of sHLH treated with emapalumab.

Methods: A retrospective medical chart review conducted across 33 US hospitals identified patients treated with ≥1 dose of emapalumab between November 20, 2018, and October 31, 2021. Data on the subset of patients with sHLH extracted from time of emapalumab initiation to end of data availability, death, or study end (December 31, 2021) are presented.

Results: Overall, 57/105 (54.3%) enrolled patients had a physician-reported diagnosis of sHLH (mean age ± SD 10.4 ± 7.6 years). Majority of patients were non-White (63.2%) and male (52.6%). At diagnosis, mean age (±SD) was 9.3 (7.5) years and 15/17 (88.2%) patients with available data met ≥5 of 8 HLH-2004 diagnostic criteria. Underlying disease and/or triggers were identified in 53/57 (92.9%); patients 22/53 (41.5%) had a single trigger and 31/53 (58.5%) had multiple triggers. Infections (32/53; 60.4%), malignancy (18/53; 34%), rheumatologic disease (11/53; 20.8%), and iatrogenic (6/53; 11.3%) were the most common triggers. Epstein-Barr virus (11/25; 44%) was the most common viral trigger (25/32; 78.1%) infection. At time of emapalumab initiation, 73.7% of patients had received prior treatments with other HLH-related therapies, including corticosteroids, and 62.5% of patients were in the intensive care unit. Emapalumab was mainly initiated for treatment of refractory (42.1%), progressive (29.8%), and recurrent (14%) disease. The median (range) time to emapalumab initiation from diagnosis was 16.5 (1-2278) days. Median (range) treatment duration with emapalumab was 38.0 (1-1937) days. Median (range) emapalumab starting dose was 1.1 (0.7-5.9) mg/kg and cumulative treatment dose was 213.1 (1336.5) mg/kg. Median (range) maximum administered emapalumab dose was 2.3 (0.7-12.5) mg/kg.

Conclusion: This is the first study to report real-world treatment patterns with emapalumab across a diverse patient population with sHLH. A pivotal clinical trial of emapalumab in patients with sHLH and underlying rheumatologic disease is ongoing (NCT05001737).

Background: COPA syndrome is a recently described monogenic autoimmune disease due to heterozygous mutations in COPA. COPA syndrome demonstrates considerable phenotypic overlap with SAVI (STING-associated vasculopathy with onset in infancy) due to gain-of-function mutations in STING. Interestingly, while both disorders are characterised by enhanced type I interferon signalling, neither disease is associated with systemic lupus erythematosus (SLE) – challenging classical dogma linking interferon upregulation and lupus.

Objectives: Our aim was to gather a European cohort of COPA patients to better delineate the clinical phenotype of this rare monogenic disorder.

Methods: Assessment of clinical, radiological, immunological and therapeutic data from 27 patients (13 families) with molecularly confirmed COPA syndrome.

Results: Twenty-seven individuals with pathogenic COPA mutations were included. Among them, 20 patients presented with a characteristic clinical manifestation evocative of COPA syndrome (clinical penetrance of 74.1%). Symptomatic patients were female in 13 (65%) cases with a median age at disease onset of 4 years (0-50). All COPA mutations were inherited in an autosomal dominant pattern except for one that occurred de novo. Pulmonary involvement was observed in 16 (80%) patients, with interstitial lung disease (ILD) in most cases (n=13, 65%), diffuse alveolar haemorrhage (DAH) in 5 (25%) individuals and the association of ILD and DAH in 3 (15%) patients. Twelve (60%) patients demonstrated joint involvement of variable severity: 4 (20%) individuals experiencing deforming arthritis including one requiring bilateral knee arthroplasty, 6 (30%) patients had polyarticular arthritis and two (10%) patients presented with isolated arthralgias. Renal disease was observed in three (15%) individuals, the most frequent as either persistent glomerulonephritis (n=2) or membranous glomerulonephritis (n=1). Previously undescribed feature noted in 15 patients included acral ulcers, vitiligo and nasal perforation (n=3, 15%), cardiac disease (n=2, 10%), gastrointestinal dysfunction (n=2, 10%), and cytolytic hepatitis (n=1). When tested, 14 (93.9%) patients had positive autoantibodies. When assessed, immunophenotyping showed a mild T-cell lymphopenia, with an excess of naive T CD8+ cells and a defect of memory T CD8+ cells recorded in one patient. All patients presented with a normal or elevated COPA protein levels and high IFN signature scores. The IFN signature was mildly positive in half of the clinically asymptomatic individuals assessed. The majority (60%) of patients were treated with corticosteroids and immunosuppressants, ten (50%) received biotherapies and eight (40%) patients are currently under JAK1/2 inhibition.

Conclusion: We report the first European cohort of COPA patients. While confirming the core organ feature of arthritis, joint and kidneys of COPA syndrome, our data expand the phenotype to include cardiac, skin and digestive features, further...
demonstrating the clinical overlap with SAVI and other type I interferonopathies, while also highlighting the possibility of isolated organ involvement. We confirm a high level of clinical non-penetrance, which can present a diagnostic challenge and indicates the need to better understand the underlying pathophysiology. In view of current (JAK inhibitors) and potential future targeted therapies, we suggest a request to assess IFN pathway status and/or perform sequencing in the case of suggestive features, even in the absence of a familial history.

IGG4-RELATED DISEASE ACTIVITY ASSESSMENT INFLUENCED BY USE OF 18F-FDG PET/CT: DATA FROM A NORWEGIAN COHORT

Keywords: Rare/orphan diseases, Imaging, Outcome measures

J. Vikse1,2, O. Midtvedt2, O. Molberg1,2, B. T. Svanes Fevang1,1, G. Palm1, T. Garen2, K. B. Johnson2, M. Revheim1,2, K. Johnsrud1,2, H. Fretheim1, M. Wallenius1,2, G. Bakland1, A. M. Hoffmann-Vold1,1 University of Bergen, Clinical Science, Bergen, Norway; 2Stavanger University Hospital, Rheumatology, Stavanger, Norway; 3Oslo University Hospital, Rheumatology, Oslo, Norway; 4University of Oslo, Clinical Medicine, Oslo, Norway; 5Haukeland University Hospital, Rheumatology, Bergen, Norway; 6Oslo University Hospital, Radiology and nuclear medicine, Oslo, Norway; 7St. Olav University Hospital, Rheumatology, Trondheim, Norway; 8Norwegian University of Science and Technology, Neuromedicine and Movement Science, Trondheim, Norway; 9University Hospital of North Norway, Rheumatology, Tromsø, Norway

Background: The IgG4-related disease (IgG4-RD) responder index (RI) is a validated tool to assess disease activity in IgG4-RD [1]. The RI reflects symptoms attributable to active IgG4-RD as well as relevant findings from the physical examination, imaging and laboratory evaluations, with higher scores reflecting more active disease. Multigain involvement and higher RI scores were identified as risk factors for relapse [2], indicating a need for more aggressive treatment. Whole-body 18F-FDG PET/CT is a sensitive technique for detecting foci of active inflammation, but its use is limited by cost and availability. Furthermore, whether 18F-FDG PET/CT detects additional organ manifestations which influence RI and treatment decisions, is largely unknown.

Objectives: To compare performance of a pure clinical RI model (c-RI) and a c-RI with addition of 18F-FDG PET/CT (c-PET-RI) in a well-characterized Norwegian IgG4-RD cohort.

Methods: Adult patients with IgG4-RD seen at the Oslo University Hospital were included if they had performed both 18F-FDG PET/CT and a comprehensive assessment by a rheumatologist within a four-week interval. In each patient, we calculated c-RI from symptoms, clinical examination, and laboratory studies, and c-PET-RI from the c-RI plus the score from pathological 18F-FDG organ uptake on the whole-body PET. Both indices were calculated using data from NOSVAR research registry and electronic medical records. We defined IgG4-RD disease activity as low if RI was ≤ 3 and high if RI was > 3 points. We assessed associations of elevated CRP and serum IgG4 (s-IgG4) with reclassification (discrepancy change in disease activity scores (c-PET-RI – c-RI)) by applying logistic regression with odds ratio (OR) and 95% CI to identify patients in which performing 18F-FDG PET/CT is likely to change treatment decisions.

Results: The study cohort included 53 IgG4-RD patients, of whom 30 had c-RI ≤ 3 points, consistent with low disease activity. In 15/30 patients (50%) with c-RI ≤ 3, the corresponding c-PET-RI was > 3 points, consistent with high disease activity. In these 15 patients, the mean increase in RI points from the 18F-FDG PET/CT was 6.4 (range 2-12). We found that 14 of these 15 patients (93%) had elevated s-IgG4 and 6 (40%) had elevated CRP. In logistic regression analysis, elevated s-IgG4, but not CRP, was strongly associated with reclassification to high disease activity after 18F-FDG PET/CT (OR 16.0, 95% CI 1.7-154.6, p = 0.017). Of the 9 patients with c-RI ≤ 3 and normal s-IgG4, only one (11%) was reclassified to high disease activity.

Conclusion: In IgG4-RD patients with low disease activity by clinical and laboratory assessment (c-RI), elevated s-IgG4 is associated with detection of asymptomatic organ involvement by 18F-FDG PET/CT (c-PET-RI). Hence, evaluation with 18F-FDG PET/CT should be considered in patients with c-RI ≤ 3 points and elevated s-IgG4 to tailor management. In contrast, in patients with c-RI ≤ 3 points and normal s-IgG4, the added yield of 18F-FDG PET/CT appears to be low.

Background: Diagnosing IgG4-related periaortitis/retroperitoneal fibrosis (IgG4-PA/RPF) is often challenging, especially in PA/RPF-limited cases, due to the difficulty in obtaining periaortic/retroperitoneal specimens. In addition to the Japanese diagnostic criteria for IgG4-PA/RPF [1], the 2019 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria for IgG4-related disease (IgG4-RD) [2] have not been validated for IgG4-PA/RPF diagnosis in daily clinical practice.

Objectives: This study aimed to validate the ACR/EULAR classification criteria and the Japanese organ-specific diagnostic criteria in a Japanese cohort of patients with IgG4-related PA/RPF.

Methods: In this nationwide multicenter study, we retrospectively reviewed the medical records of 110 patients with IgG4-PA/RPF and 79 non-IgG4-RD patients (mimickers) diagnosed by experts. Using the collected data, we calculated sensitivity and specificity in both the ACR/EULAR classification criteria and the Japanese diagnostic criteria. To clarify the characteristics of false-negative cases of IgG4-PA/RPF, we compared the clinical features between the false-negative and true-positive cases.

CANAKINUMAB IN THE TREATMENT OF ADULT-ONSET STILL’S DISEASE: LONG TERM DATA FROM A MONOCENTRIC COHORT

Keywords: Innate immunity, DMARD

N. Farina1, C. Campochiaro1, A. Tomelleri1, G. De Luca1, E. Baldissera2, L. Dagna1. 1IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

Background: Adult-onset Still’s disease (AOSD) is a rare autoinflammatory disease whose clinical spectrum encompasses protean and potentially life-threatening manifestations. While glucocorticoids represent the mainstay of the treatment of patients with AOSD, no guidelines are available to guide the approach to refractory patients. Canakinumab – a monoclonal antibody targeting interleukin 1β – has been increasingly used in this scenario with promising results, though long-term efficacy data are scant.

Objectives: To evaluate the efficacy and long-term persistency of canakinumab in patients with AOSD.

Methods: We retrospectively identified patients with AOSD followed-up at our Center who were treated with canakinumab for at least 12 months. Data about demographics, disease features, and treatment history were then collected. The therapeutic efficacy of canakinumab was evaluated on the basis of the modifications of glucocorticoid doses, Pouchot scores, C-reactive protein, and ferritin levels during the treatment course. Finally, the drug retention rate of canakinumab at 24 months was obtained.

Results: In our cohort, we identified 25 patients with AOSD treated with canakinumab for at least 12 months. Median age at disease onset was 35 (IQR 25-56) years and median follow-up duration was 24 (IQR 12-41) months. Clinical features of the study population are shown in Table 1. The most frequent reason [21 (84%) patients] for the start of IL-1β inhibition was a persistent disease activity. Canakinumab led to remission in all but two patients and, overall, was associated with a significant reduction in glucocorticoid doses, Pouchot scores, C-reactive protein and ferritin levels (Figure 1). The overall retention rate at 24 months was 93% and no adverse reactions to canakinumab were reported.

Conclusion: Our study confirms – in one of the largest monocentric cohorts described to date – that canakinumab is highly effective in patients with AOSD. Canakinumab was associated with a significant clinical and biochemical improvement in most patients from our cohort and was characterized by a very high long-term retention rate.

REFERENCE:

Figure 1. Boxplots reporting the modifications in glucocorticoid doses, C-reactive protein and ferritin levels, and Pouchot scores following the start of canakinumab (T0). Reported p-values were calculated with Mann-Whitney test.

Table 1. Demographic and disease features of patients with adult-onset Still’s disease from our cohort. Continuous and categorical variables are reported as median (interquartile range) and absolute frequency (percentage), respectively. Glucocorticoid dose and age are expressed in mg (prednisone-equivalent) and years, respectively.

Massachusets General Hospital, Clinical Epidemiology Program, Boston, United States of America; 2Harvard Medical School, Medicine, Boston, United States of America; 3Arthritis Research Canada, n/a, Vancouver, Canada; 4Xiangya Hospital, Health Management Center, Shan Nan Shi, China

Background: Sodium-Glucose Cotransporter Type 2 Inhibitors (SGLT2i) are a revolutionary second-line treatment for type 2 diabetes associated with lower risk of cardiovascular and all-cause mortality, heart failure, and chronic kidney disease progression. Many trials have also found SGLT2i lower serum urate levels. However, data on gout risk are limited and the few available prior studies were not specific to those using metformin, the primary target populations of recent landmark trials like GRADE.

Objectives: To emulate recent clinical trials and compare incident gout risk among metformin-treated patients with type 2 diabetes initiating SGLT2i versus second-line type 2 diabetes treatments (glucagon-like peptide-1 receptor agonist [GLP1RA], dipeptidyl peptidase 4 inhibitors [DPP4i] or sulfonylureas).

Methods: We performed a nested, active comparator, population-based cohort study using administrative health data for nearly all residents of British Columbia, Canada from Jan 2014 to June 2022, including all dispensed prescriptions, regardless of funder. A cohort of adults with type 2 diabetes using metformin (first-line therapy) was identified from ICES codes and dispensing data. Primary outcome was incident gout, defined as inpatient or outpatient diagnosis of gout plus dispensing of a gout medication within 14 days, and no prior recorded gout diagnosis. We also stratified by sex, age, and baseline diuretic use. Cox proportional hazards models were used with propensity score overlap weighting. To evaluate reproducibility and for spurious associations, we also assessed for risk of genital infection (for which we expected SGLT2i would have a positive association), and for the risk of any osteoarthritis encounter, a negative control outcome for which we expected a null association.

Results: Hazard ratio (HR) for incident gout associated with SGLT2i initiation was 0.54 (95% CI: 0.39, 0.74) vs. DPP4i- (among n=27,791 type 2 diabetes patients, 0.39 (0.24, 0.62) for SGLT2i vs. GLP1RA initiation (n=19,875 patients), and 0.61 (0.46, 0.80) for SGLT2i vs. sulfonylurea initiation (n=71,625 patients) (Table 1). Results were consistent regardless of sex or age baseline diuretic use. For control outcomes, SGLT2i initiators had higher risk of genital infection, as expected, while there was no difference in risk of osteoarthritis (Table 1). Conclusion: SGLT2i initiation among metformin-treated patients with type 2 diabetes was associated with substantially lower risk of incident gout (i.e., primary prevention), compared with initiation of any other second-line options. Along with its known urate-lowering, as well as cardiovascular and survival benefits, SGLT2i could reduce risk of incident gout substantially for diabetes patients who need second-line agent after metformin.

Keywords: Imaging, Rheumatoid arthritis, Epidemiology

J. Coyle1, M. De Grooth2, J. Cole3, S. Williams4, 1King’s College London, Centre for Neuroimaging Sciences, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom; 2GSK – Stevenage, GlaxoSmithKline Research and Development, Stevenage, United Kingdom; 3University College London, Centre for Medical Image Computing, Department of Computer Science, London, United Kingdom

Background: Rheumatoid arthritis (RA) and ulcerative colitis (UC) both result in higher levels of systemic inflammation and represent a significantly higher risk of cerebrovascular disease. The presence of this systemic inflammation has been linked to central nervous system effects and both diseases have increased rates of fatigue, brain fog and depression. Additionally, systemic inflammation has been implicated in decreasing the integrity of the blood brain barrier and potentially resulting in further involvement of the central nervous system in autoimmune diseases.

Objectives: The increased presence of white matter hyperintensities (WMH) has been proposed as a potential link to the central symptoms reported and the increased prevalence of cerebrovascular accidents in these diseases [1]. The present study aimed to analyse total volume of WMH in patients with RA and UC as compared to matched controls.

Methods: Data from 1,968 individuals in the UK Biobank Imaging sub-study were included in the present study [2]. This was divided into two separate patient populations with separate control groups matched to each in a 1:3 patient:control ratio. Data from 252 individuals (mean age ± SD = 65.52 ± 7.03, 71.4% females) were included in the RA patient group with 756 age and sex matched controls (mean age ± SD = 65.52 ± 7.02, 71.4% females). Data from 240 individuals (mean age ± SD = 63.98 ± 7.06, 50.8% females) were included in the UC patient group with 720 age and sex matched controls (mean age ± SD = 63.98 ± 7.05, 50.8% females). This study utilised the total volume of WMH acquired using an automated segmentation approach called BIANCA and provided directly by the UKBiobank. Volumes were taken as a ratio of total brain volume and log transformed prior to a linear model regression being performed. Two separate models were run. One with age, sex, and ICV as covariates and a second model additionally including hypertension.

Results: We observed significantly larger total WMH volume in RA patients when compared to controls in model 1 (difference in WMH volume: 2286.0mm³, SD ±84.5, p = 2.0e-08). The Cohen’s effect size was d = 0.36 [95% CI 0.21, 0.5]. This effect was still substantial even with hypertension added as a covariate in model 2 (p = 3.7e-06). There was also a smaller, but still significant difference seen in UC patients compared to controls (difference in WMH volume: 237.1mm³, SD ±82.1, p = 0.003). The Cohen’s effect size was d = 0.19 [95% CI 0.04, 0.33]. As with the RA population hypertension is a strong contributing factor, however, the p value was still significant in model 2 (p = 0.03).

Conclusion: This is evidence that there is a cerebrovascular component to these diseases and that people with higher WMH burden may be at a higher risk of developing neurocognitive sequelae as part the disease. Further analysis of spatial mapping of WMH could provide further context for whether there are different patterns or distributions between RA and UC which could contribute to different central nervous system symptoms or cerebrovascular health risk factors.

Methods: dom-effects meta-analyses and meta-regression. The meta-analytical method demographically relevant factors on the short (5-year) and longer-term (10-, 15- and major organ damage that comprised cardiovascular, renal, neuropsychiatric and mortality rates of patients with SLE published between the 1950 and 2021 were searched, identified and extracted from PubMed and EmBase. Studies which only focused on the short- and longer-term survival of patients with SLE globally over the past 60 years have not been systematically studied by meta-analyses, particularly regarding the impact of the interaction between time and major organ damage on the survival of patients with SLE.

Background: The trend of, and the impact of major organ damage on the short- and longer-term survival of patients with systemic lupus erythematosus (SLE) globally over the past 60 years have not been systematically studied by meta-analyses, particularly regarding the impact of the interaction between time and major organ damage on the trend of the survival of patients with SLE.

Objectives: To study the trend of, and the impact of major organ damage and demographically relevant factors on the short (5-year) and longer-term (10-, 15- and 20-year) survival rates of patients with SLE in the past 60 years by random-effects meta-analyses and meta-regression. The meta-analytical method that examined the impact of the interaction between time in terms of year of publication and major organ damage on the trend of the overall survival rates of SLE patients was employed.

Methods: Observational studies that were written in English and reported the survival rates of patients with SLE published between the 1950 and 2021 were searched, identified and extracted from PubMed and EmBase. Studies which only included patients reported survival rates shorter than 5 years were excluded. The effect sizes of the overall 5-, 10-, 15- and 20-year survival rates and their respective trends over time of patients with SLE were determined by random-effects meta-analyses and meta-regression analyses. Meta-regression analyses were conducted to investigate the impact of covariates, including the interaction between the year of publication (time) and factors including major organ damage that comprised cardiovascular, renal, neuropsychiatric and major organ damage on the trend of the overall survival rates of SLE patients.

Results: In total, 281 observational studies that were published between 1955 and 2020 were identified and eligible for analyses. The overall 5- and 10-year survival rates of SLE patients increased from 71.82% to 94.27%, and from 58.23% to 90.44%, respectively, from 1960 to 2020. The overall 15-year survival rate of SLE patients increased from 71.82% to 94.27%, and from 58.23% to 90.44%, respectively, from 1960 to 2020. The overall 20-year survival rate of SLE patients increased from 58.82% to 90.44%, respectively, from 1960 to 2020. The overall 15- and 20-year survival rates of SLE patients have been increasing steadily from the 1950s to 2020. Although the 15- and 20-year survival rates of SLE patients have been progressively increasing, more studies are required to further address the determinants of these longer-term survival rates. The impact of sex difference with its interaction with time on the survival of SLE patients require more focused and mechanistic studies.

Conclusion: Both the short- and longer-term survival of patients with SLE have been increasing steadily from the 1950s to 2020. While cardiovascular damage impacted significantly the 5-year survival rate, neuropsychiatric and overall SLE disease damage at baseline with their interactions with time, exerted a significant impact on the 10-year survival rate of patients with SLE since the 1950s. Although the 15- and 20-year survival rates of SLE patients have been progressively increasing, more studies are required to further address the determinants of these longer-term survival rates. The impact of sex difference with its interaction with time on the survival of SLE patients require more focused and mechanistic studies.
Objectives: To examine whether inflammatory joint diseases (IJDs) have an impact on men’s fertility, measured as number of children per man and proportion of childless men.

Methods: We performed a nation-wide, population-based cohort study. Male patients with IJDs (n = 10,865) collected from the Norwegian Arthritis Registry in 2021 were individually matched 1:5 on birth year, sex, and county of residence, with individuals without IJDs obtained from the National Population Register (n = 54,325). Data regarding births was obtained from the Medical Birth Registry of Norway. We compared the mean number of children per man in the patient group and in the comparison group using paired t-tests, and the proportion of childless men using Cochran–Mantel–Haenszel chi-squared tests.

Results: The mean number of children per man in the patient group was 1.80 versus 1.69 in the comparison group (p < 0.001). Altogether, 21% of our patients were childless vs 27% in the comparison group (p < 0.001, Figure 1). The difference in number of children between patients and comparison group was highest for those diagnosed after year 2000 and these patients had the comparatively lowest risk of being childless. The differences were less evident for those diagnosed before 2000 (Table 1). Age at diagnosis did not influence fertility (Table 1).

Conclusion: In this large nationwide study, fertility in male patients with IJDs was not reduced compared to controls, neither when examining the number of children per man, nor when looking at the proportion of childless men. Interestingly, we observed a higher fertility rate in male IJD patients than in the comparison group for patients diagnosed after year 2000. The reason for this observation is unknown. Factors associated with getting or having an IJD may influence fertility. An interesting hypothesis is a possible positive impact of new immune modulating drugs introduced after year 2000.

TRANSLATIONAL MEDICINE

A MEDICO-ECONOMIC ANALYSIS OF THE TOLEDO TRIAL

Keywords: Clinical trials, bDMARD, Rheumatoid arthritis

J. Kedra1, 2, B. Granger1, 3, L. El, Houin1, 4, F. Tubach1, 3, B. Fautrel1, 3, S. Bonneville, INSERM UMR 1136, Institut Pierre Louis d’ Epidemiologie et de Santé Publique, Paris, France; 2AP-HP; Hôpital Pitié Salpêtrière, Rheumatology, Paris, France; 3AP-HP; Hôpital Pitié Salpêtrière, Département de Santé Publique, Centre de Pharmacépidémiologie (Cephepi), CIC-190, Paris, France

Background: Biologic Disease Modifying Anti-Rheumatic Drugs (bDMARDs) progressive tapering is a real opportunity in people living with rheumatoid arthritis (RA) having achieved remission both from the patient and the Society perspectives. The ToLEDo (Towards the Lowest Efficacious Dose) trial aimed to assess a disease activity-driven progressive tapering strategy of tocilizumab (TCZ) or abatacept (ABA) compared to their maintenance at full dose in RA patients sustained remission. Non-inferiority (NI) was not demonstrated in terms of disease activity (primary endpoint) nor relapses, major relapses, radiographic progression (secondary endpoints) [1].

Objectives: The aim of this secondary analysis was to assess the cost-utility of the spacing strategy (S-arm) in the ToLEDo trial compared to full dose maintenance (M-arm).

Methods: The ToLEDo trial is a multicenter 2-year NI randomized open-label controlled trial, which enrolled 228 patients (113 in the S-arm and 115 in the M-arm). A cost-utility analysis was conducted on the per protocol population. In each arm, health benefits were estimated every 6 months by Short Form Health Survey (SF-6D) and EuroQol (EQ-5D)-derived utility measurements. Cost elicitation integrated health resource use including bDMARD costs (direct cost) as well as productivity loss (indirect cost) using the friction cost method. The incremental cost-utility ratios (ICUR) were calculated by dividing the difference of costs between S-arm and M-arm by the difference of utilities between the 2 arms. 95% confidence interval (95% CI) were calculated by bootstrap (20,000 iterations). The incremental net benefit (INB) was calculated for willingness to pay (WTP) values ranging from 0 to 150,000€. The analyses were replicated using SF-6D (primary analysis) or EQ-5D, and in ABA and TCZ subgroups. Acceptability analyses as well as stochastic sensitivity analyses (simulating costs and utilities using MCMC algorithms) were also performed.

Results: Overall, 178 patients were included (82 in S-arm, 96 in M-arm) in the per protocol analysis. At the end of the follow-up in the S-arm, 15.0% of patients discontinued their biologic, 48.7% spaced the injections, and 36.3% remained at the standard dose. The difference in terms of two-years utility gains between S-arm and M-arm was 0.004 (95%CI -0.012, 0.021) with SF-6D. The difference of total costs between S-arm and M-arm was -4,275 € (95%CI -5,955 to -2,542). The estimated ICUR of the spacing strategy over the maintenance at full dose was €932,003 gained per QALY (95% CI -7,534,788 to 6,720,372) with SF-6D. The INB was 4,734 €/QALY. With a willingness to accept of 0 €/QALY lost, the probability to be cost-effective for the spacing strategy was 70.6% (Figure 1). The results were consistent when using EQ-5D-derived utilities, in ABA and TCZ subgroups, as well as in the stochastic sensitivity analyses (Table 1).

Conclusion: Although the ToLEDo trial did not demonstrate non-inferiority, the tested disease activity-driven tapering strategy was not associated with health losses of utilities and incured for substantial cost savings, making this strategy potentially dominant.

OP0265 WORK PARTICIPATION AND THE COVID19 PANDEMIC: A DUTCH PROSPECTIVE COHORT STUDY IN PEOPLE WITH INFLAMMATORY RHEUMATIC DISEASES AND HEALTHY CONTROLS

Keywords: COVID, Work-related issues

M. Butink1,2, L. Boekel1, A. Boonen1,2, A. De Rijk2, G. Wolbink3,5, C. Webers1,4.
1Maastricht University Medical Centre, 2Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands; 2Maastricht University, Department of Social Medicine Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; 3Amsterdam Rheumatology and Immunology Center, Location Reade, Department of Rheumatology, Amsterdam, Netherlands; 4Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; 5Sanquin Research and Landsteiner Laboratory Academic Medical Center, Department of Immunopathology, Amsterdam, Netherlands

Background: People with inflammatory rheumatic diseases (IRD), such as rheumatoid arthritis (RA) and spondyloarthritis (SpA), experience restrictions in work participation. In times of crisis, such as the coronavirus disease 2019 (COVID19) pandemic, people with IRD might be more vulnerable for adverse work outcomes (i.e. (partial) job loss and sick leave) and restrictions in work ability while at work.

Objectives: To (a) compare occurrence of adverse work outcome (AWO) and change in work ability during the first two years of the pandemic (2020-2022), as well as current (2022) work ability, between people with IRD and healthy controls in the Netherlands; (b) understand which subgroups of patients are most vulner- able to incur work participation outcomes; and (c) explore the role of remote work characteristics on work performance.

Methods: Data from a Dutch longitudinal study on COVID19 at Reade and Amster- dam UMC were used. Information about work was collected at one fixed timpoint. Patients (18-67 years) with IRD and controls were asked in March 2022 to answer questions on work participation and their work situation in March 2020 (pre-pandemic; retrospectively) and March 2022 (current). AWO was defined as any of: (1) shift between 2020-2022 from employment to unemployment; or from full to part-time employment; (2) reduction in working hours; (3) ongoing long-term sick leave. Work ability (change and current) was assessed with the Work Ability Index (range 0 [worst] to 10 [best]). Outcomes were compared between groups (IRD vs control) with statistical tests. Multivariable logistic or linear regression analyses were used to explore the associations between IRD and AWO or (change in) work ability. Interactions (effect modification) were tested and, if present, analyses were stratified. The role of remote work factors on remote work performance was described.

Results: In total, 1,438 IRD patients and 526 controls of working age (18-67) par- ticipated. The majority was female (67%) and was employed pre-pandemic (69% patients, 84% controls). Patients mainly had RA or SpA (85%). In pre-pandemic employed subjects, 227 patients (23%) and 79 controls (18%) experienced AWO (p=0.04). Only 35 patients (4%) and 12 controls (2%) of these, attributed this to COVID (impact by personal health or national pandemic measures; p=0.36). Logis- tic regressions of AWO were stratified because of interactions between group and sex, comorbidities or a physically demanding job. In all models, patients were more likely than controls to experience AWO (range OR 1.63 to 3.34 across models, Figure 1), and especially patients with comorbidities or a physically demanding job. Of note, COVID-related AWO was not significantly more likely in patients (OR=1.62, 95%CI 0.60-3.27). Change in work ability during the pandemic did not differ between groups (-0.3 (SD 1.8) patients vs -0.2 (SD 1.6) controls, p=0.38). Logistic regressions also did not reveal significant differences. Linear regression of current work ability (stratified by sex due to interaction) showed female patients compared to female controls experienced lower work ability (B=-0.66; 95%CI -0.92 to -0.40), while this was not observed in males. Past SARS-CoV-2 infection was not associated with AWO/work ability. When working remotely; care for children and absence of colleagues had both positive (19% and 24%, resp.) and negative (34% and 57%, resp.) influence on work performance, while employer support and reduced commuting time had positive influence (83% and 86%, resp.).

Conclusion: During the COVID pandemic, patients experienced more AWO than healthy controls, and especially patients with physically demanding jobs and comorbidities were at higher risk. However, the frequency of COVID-related AWO was low and did not differ substantially between patients and controls. A likely explanation is that the governmental support for employers protected those in vulnerable positions, such as patients with IRD.

Epidemiology, risk and prediction of risk

**Methods:** We utilised primary care records from the Clinical Practice Research Datalink (CPRD) Aurum database and identified individuals with diagnostic codes for each condition. We calculated their 10-year cardiovascular risk using each risk tool and compared this to their observed outcomes. Discrimination (how well the tool separates CVD cases and non-cases) was assessed using time-dependent (to account for censoring in follow up) Area-under-ROC-curve (AUC), sensitivity, specificity, positive and negative predictive values (using 10% and 20% predicted risk to determine high risk of CVD). Calibration (how well predicted risks match observed risks) of each risk prediction tool was assessed by comparing the observed and predicted risks in deciles of predicted risk for each disease group.

**Results:** Time-dependent AUC for QRISK3 ranged between 0.697 for patients with osteoarthritis to 0.815 for patients with psoriasis, indicating reasonably good predictive performance (Figure 1); AUC for the Framingham Risk score were similar, whilst the Reynold’s Risk Score achieved slightly lower AUCs in this cohort, ranging between 0.640 for patients with osteoarthritis and 0.752 for patients with psoriasis. In general, the Framingham Risk Score was reasonably well calibrated for each condition but underpredicted risk for patients with RA or OA. The Reynold’s Risk Score tended to underpredict CVD risk, whilst the QRISK3 score overpredicted CVD risk, especially for the most high-risk individuals.

**Conclusion:** In general, CVD risk for individuals with RA, AS, PsA, psoriasis, or OA were less accurately predicted using each of the 3 CVD risk prediction tools than the reported accuracies in the original publications. There is a need for specific risk prediction tools for rheumatic conditions.

**OP0268 IMPACT OF MENOPAUSAL TREATMENTS IN FUNCTIONAL DECLINE ON WOMEN WITH RHEUMATOID ARTHRITIS**

**Keywords:** Pregnancy and reproduction, Rheumatoid arthritis, Real-world evidence

S. Pedró1, E. Molland2, K. Michael3, 4FORWARD, The National Database for Rheumatic Diseases, Research, Wichita, United States of America; 2University of Nebraska Medical Center, College of Nursing, Omaha, United States of America; 3University of Nebraska Medical Center, Medicine, Omaha, United States of America

**Background:** Women with Rheumatoid Arthritis (RA) experience changes in disease development and progression surrounding reproductive and hormonal events, including menopause. In our prior work, women with RA had better functional status prior to menopause and experienced worsened functional decline after menopause [1].

**Objectives:** The purpose of this study is to investigate how menopausal treatments affect functional decline in women with RA.

**Methods:** Women with RA participating in the Forward Databank from 2000 through 2022 with a reported menopausal status or not having a menstrual period for 1 year were eligible. Women who were on hormonal contraceptive were excluded. Hormonal replacement therapy (HRT) users were matched 1:1.
to non-users by year of HRT initiation (index date). The primary outcome was function measured by Heath Assessment Questionnaire (HAQ) and HRT as primary exposure. Descriptive statistics were used to characterize patients at baseline by HRT exposure. Gaussian GEE models were used (robust SE) to assess the association between HAQ and HRT adjusting for the following confounders: demographics, reproductive history, clinical measures, and treatments. Best model was searched using QIC in a backward selection manner.

**Results:** 4123 women who had initiated HRT were matched by year of initiation to 4123 non-HRT users after menopause (mean year was 2004). At baseline, HRT users tended to be younger, had higher income, shorter reproductive length, and more comorbidities. No differences were found in pain and patient global as well as DMARD treatment, although HRT-users had higher use of non-hormonal treatments (Table 1). Overall, patients had a median follow-up of 6 years (IQR 3-10) years with 2 years (IQR 1-4) years of HRT exposure. HRT users had consistently better HAQ (although with a small effect) when compared to non-users (coef. -0.02 (95% CI: -0.03; -0.01) P<0.001). HAQ was also inversely associated with the age when women started menopause (-0.008 (95%CI: -0.009; -0.006), P<0.001); each year after menopause the HAQ increased by 0.008, which was slight better for HRT users (Figure 1).

**Conclusion:** HRT use was associated with better functional status, although of modest magnitude. Longer reproductive duration seemed protective for function, but worsening slightly after menopause. Future work is needed to assess the safety profile of HRT regarding incidence of malignancies, cardiovascular events, and osteoporosis.

**Background:** There has been a sharp rise in opioid use for non-cancer pain globally, including for rheumatic and musculoskeletal conditions. Despite increased awareness of adverse effects, they remain commonly prescribed in most countries. Clinical prediction models (CPMs) offer the possibility of assessing individual risk allowing better allocation of resources towards those at risk. Machine learning (ML) approaches can address nonlinear relationships and complex interactions between variables and are increasingly used to develop CPMs.

**Objectives:** To develop, validate, and compare the performance of three CPMs based on regression and ML, which leverage primary care data to estimate the risk of opioid-related death in patients prescribed opioids for non-cancer pain.

**Methods:** Patients ≥18 years old without prior cancer who were prescribed any opioid between 01/01/2006 and 31/12/2017 were identified in the Clinical Practice Research Datalink (CPRD), representative of national patient data from UK primary care. Only new opioid users were included. Index date was date of first prescription, with censoring at withdrawal from the CPRD or after not having an opioid prescription for two years. Baseline data were extracted from each patient's records, including demographic information, comorbidities, concomitant medications, and the opioid type being prescribed. 49 candidate predictors were used to train three competing risk models: a Fine&Gray regression model with LASSO regularisation, a survival random forest (RF), and a neural network (DeepHit). The outcome was opioid-related mortality and other cause mortality the competing event, defined using a curated ICD-10 codelist. Predictive performance of the models, like area under the receiver characteristic operator curve (AUCROC) were calculated using 5-fold cross validation.

**Results:** We included a total of 1,029,681 patients, of which 1,240 experienced an opioid-related death, and 52,833 experienced a competing death. The Fine&Gray, RF and DeepHit models achieved average AUCROC values of 0.83 (95% CI: 0.81-0.85), 0.78 (0.77-0.79) and 0.81 (0.80-0.82) respectively (Figure 1). At optimum risk cut point, as per Youden's index, the models achieved sensitivities of 0.82 (0.78-0.85), 0.75 (0.67-0.82) and 0.80 (0.76-0.83), and specificities of 0.78 (0.73-0.82), 0.75 (0.68-0.83) and 0.78 (0.75-0.8) when predicting 12-month risk, respectively. In the Fine&Gray model, factors associated with increased risk were history of substance use disorder (hazards ratio [HR]: 3.40, 95% CI:3.12-3.69) and alcohol abuse (HR:3.07, 95% CI:2.93-3.22), COPD (HR:1.53, 95% CI:1.48-1.58) and moderate liver disease (HR:1.31, 95% CI:0.99-1.63) were the comorbidities associated with highest risk. Morphine (HR:2.39, 95% CI:2.08-2.69) and oxycodone (HR:1.10, 95% CI:1.00-1.20) at initiation and concomitant gabapentinoids (HR:1.99, 95% CI:1.80-2.18) and benzodiazepines (HR:1.30, 95% CI:1.24-1.36) were associated with an increased risk. HR for rheumatologic diseases was 1.08 (95% CI:1.01-1.14).

**Figure 1.** AUCROC of the three models vs. prediction horizon of the model. 95% CI of mean performance shaded.
Stage B Targeted therapies for severe immune-related adverse events of immune checkpoint inhibitors are not associated with a worse prognosis

Keywords: Targeted synthetic drugs, bDMARD, Malignancy

N. Sedmak1, E. Sebbag2, P. Tran BA Loc3, T. Fabacher4, T. Bahougne5, C. Arnold6, G. Desjeux7, H. Servy7, N. Meyer7, E. Sauleau5, R. Seror9, J. E. Gottenberg2, 1NHC - New Civil Hospital, Département de l’Information Médicale, Strasbourg, France; 2Hôpital de Hautepierre, Rheumatology, Strasbourg, France; 3NHC - New Civil Hospital, Département de l’Information Médicale, Strasbourg, France; 4Hautepière, SERVICE D’ENDOCRINOLOGIE DIABETOLOGIE ET NUTRITION, Strasbourg, France; 5NHC - New Civil Hospital, Département de la Recherche Clinique et Innovation, Strasbourg, France; 6Sanaio, E-health Services, Genemco, France; 7Sanaio, E-health Services, Genemco, France; 8Strasbourg University Hospital, Biostatistics, Strasbourg, France; 9APHP, Rheumatology, PARIS, France

Background: In about 10% of patients, the immune response to immune checkpoint inhibitors (ICI) exceeds the anti-tumor response and leads to autoimmune complications (immune-related Adverse Events, irAEs), which can sometimes be severe and require the use of targeted therapies. Two studies recently reported a deleterious impact of targeted therapies on the survival of patients with irAEs.

Objectives: To compare overall survival in patients treated or not with a biologic or targeted synthetic DMARD (b/tsDMARD) for an irAE. Method: All adults included in the French national health database who initiated an ICI between 2014 and 2019, for any type of cancer, were retrospectively analyzed. Follow-up was analyzed between 2013 to 2020, to have a one-year look-back and one year look-ahead period. The occurrence of an irAE during ICI treatment or in the 12 months after its last administration was defined by the combination of (1) hospitalization for a cause evoking an irAE of any nature, except endocrinopathy, and (2) either the discontinuation of the ICI, or the initiation of corticosteroids, or of a conventional DMARD or a b/tsDMARD, or a new recognition as a long-term disabling condition (LTD) for an autoimmune or inflammatory disease. Patients with irAE treated with b/tsDMARD were matched (1:3) at the time they initiated b/tsDMARD to those who did not initiate b/tsDMARD, using a dynamic propensity score calculated every 30 days. The propensity score included gender, type of cancer, type of ICI, time from cancer to initiation of ICI and from initiation of ICI to irAE, use of corticosteroids, hospitalization in intensive care unit, type of irAE, number of LTDs, Charlson’s index and FDep social deprivation index. Overall survival was compared between the two groups using a Cox model. A sensitivity analysis restricted to gastrointestinal and rheumatic irAEs was performed.

Results: 71,723 patients (men: 66.0%, median age: 66 years) initiating an ICI were analyzed. An hospitalized irAE occurred in 7883 patients (11.0%), irAE occurred at a median time of 72 days after ICI initiation, and the 4 more frequent were gastrointestinal (inflammatory colitis, 4.7%), cardilogic (2.0%), rheumatic (1.8%), and pulmonary (1.7%). Median patient follow-up after irAE was 356 days. Mortality after irAE was 4.8% at 1 month and 11.3% at 3 months. After matching, 325 patients were treated for an irAE with a b/tsMDARD (Infliximab 9.3%, Tocilizumab 4.2%, Vedolizumab 3.3%, others 9.3%), including 257 and 40 for a gastrointestinal or rheumatic irAE, respectively. They were compared to 975 patients who were not treated with a b/tsDMARD. The median time from ICI initiation to irAE was well balanced by matching (93 versus 92 days, respectively). ICI was discontinued in 25.4% of b/tsDMARD treated patients within 3 months after the irAE, compared to 22.1% in the group not treated with a b/tsDMARD. Mortality after irAE was 6.8% and 76% at 3 months, respectively, and 16.0% and 17.9% at 6 months, respectively. Overall survival whatever the type of ICI did not significantly differ in patients treated with or without a b/tsDMARD (HR=0.87, CI=[0.74, 1.03]), or in patients treated for a rheumatic irAE (HR=0.80, CI=[0.51, 1.25]). Overall survival was significantly improved in gastrointestinal irAE in patients treated with b/tsDMARD compared to patients not treated with a b/tsDMARD (HR=0.80, CI=[0.66, 0.97]).

Conclusion: In one of the largest study to date in terms of number of hospitalized irAEs and number of b/tsDMARD-treated patients, targeted therapies were not associated with a worse prognosis and significantly improved overall survival in patients with induced colitis, the most frequent and one of the most severe irAEs.

EARLY RESPONSE IN RHEUMATOID FACTOR LEVELS PREDICTS SUBSEQUENT CLINICAL RESPONSE TO DISEASE MODIFYING TREATMENT OF RHEUMATOID ARTHRITIS

Keywords: Prognostic factors, Rheumatoid arthritis, Treat to target

V. Konetz1, 2, D. Aletaha1, 3
1Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Wien, Austria
2Background: Rheumatoid factors (RF) are well established prognostic biomarkers in rheumatoid arthritis (RA), but the clinical relevance of their dynamics is not yet well understood. Here, we evaluate the implications of changes in RF levels in RA patients with newly initiated disease modifying (DMARD) treatment.

Objectives: To analyze how early responses of RF levels relate to subsequent disease activity outcomes in RF positive RA patients initiating DMARD treatment.

Methods: We analyzed data from 1999 RA outpatients, starting either conventional (csDMARD) or biologic/targeted synthetic DMARD (btsDMARD). RF response to treatment was defined as a ≥50% reduction in RF levels or complete seroconversion to RF negativity. We investigated the prognostic implication of early RF response on the timing of achieving disease control as defined by Simplified Disease Activity Index (SDAI) low disease activity (LDA) or remission (REM) in patients with SDAI moderate or high disease activity (MDA/HDA) at baseline. We analyzed the first two years of each treatment segment; patients, who did not reach LDA/REM within two years, or patients who switched therapy within this time frame were censored in this Kaplan Meier analysis. In a Cox proportional hazard model we adjusted the observed effects for gender, age and disease duration, as well as for SDAI at month 3.

Results: RF response as defined above to treatment was observed in 11%, 26.5% and 41% of RF positive RA patients at 3, 6 and 12 months after treatment initiation, respectively; RF response was seen in comparable frequency in csDMARD and btsDMARD treated patients (Table 1). LDA or REM by SDAI in patients with MDA or HDA was achieved significantly earlier in RF responders as compared to non-responders (Wilcoxon p=0.042 for csDMARDs, p=0.005 for btsDMARDs). Crude effects of RF response on achieving LDA/REM were highly significant in the Kaplan Meier analysis (p<0.0001; Figure 1) and remained so after adjusting for multiple variables including disease activity levels at 3 months (p<0.0001); in a pooled analysis of all DMARDs (N = 736), the adjusted Hazard Ratio (HR) for LDA or REM in the RF response group was 1.73 (95% confidence interval: 1.23 to 2.42), compared to the RF non-responders.

Table 1. Baseline data and RF response rates at 3 month after start of csDMARD or btsDMARD therapy; RF response is defined as ≥50% reduction in baseline RF levels or complete seroconversion to RF negativity.

Conclusion: Change in RF levels or complete seroconversion at the 3-month time-point predict the achievement and timing of treatment goals within a 6 to 24 month period after treatment initiation. This finding was independent of disease activity improvement at 3 months, and may therefore serve as an additional early biomarker in assessing a patient's future chance of achieving treatment targets in RA.

LONGITUDINAL TRAJECTORIES OF RENAL FUNCTION IN ANCA-ASSOCIATED VASCULITIS: FINDINGS FROM THE EXPANDED MASS GENERAL BRIGHAM COHORT

Keywords: Kidneys, Organ damage, Vasculitis

J. Hanberg1, C. Cook2, 3, X. Fu2, 3, H. Choo2, 3, 4, Y. Zhang2, 3, 4, Z. Wallace2, 3, 4
1Massachusetts General Hospital, Department of Medicine, Boston, United States of America; 2Massachusetts General Hospital, Clinical Epidemiology Program, Mongan Institute, Boston, United States of America; 3Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Boston, United States of America; 4Harvard Medical School, Boston, United States of America

Background: Renal vasculitis, leading to a spectrum of chronic kidney disease (CKD) and end-stage renal disease (ESRD), is common in ANCA-associated vasculitis (AAV). The longitudinal course of renal dysfunction in AAV has only recently been described quantitatively. (1, 2)

Objectives: To confirm and further describe the longitudinal trajectory of renal function in an expanded AAV cohort.

Methods: We included patients from the Mass General Brigham AAV cohort, a consecutive inception cohort (2002-2022). We required at least 2 measurements of renal function including one “baseline” measurement (+/- 30 d from treatment initiation date, the index date). Renal function was assessed up to monthly between -12 m and +24 m relative to the index date. We used group-based trajectory modeling to identify renal function trajectories. Between-group differences (between all 4 groups) were assessed using the chi-square test and Kruskal-Wallis tests; time to ESRD was compared using the log-rank test.

Results: Among 375 patients, we identified 4 renal trajectory groups: rapid decline (N=23 [6%]), impaired (N=109 [29%]), preserved (N=216 [58%]), and recovery (N=27 [7%]) (Figure 1). Median posterior probability of group membership was ≥0.99, indicating excellent model fit. Age, sex, race and ANCA type were not statistically different between groups. Baseline comorbidity (by Charlson Comorbidity Index) was highest in the rapid decline group, and higher in the impaired compared to the preserved and recovery groups (p<0.001; Table 1). There was a strong trend toward hypertension being more common in the rapid decline and recovery groups vs the impaired and preserved groups (p=0.08). The baseline Birmingham Vasculitis Activity Score was higher in the rapid decline (6 [4, 7]) and recovery (6 [4, 9]) groups, compared to the impaired (5 [4, 6, 5]) and preserved (4 [3, 6]) groups (p<0.001). ESRD occurred in 49 patients, including

*Among patients who experienced ESRD.

Background: Methotrexate (MTX) is the first-line drug in the treatment of rheumatoid arthritis (RA) and many other rheumatic and musculoskeletal diseases (RMDs). It is widely recognized that patients prescribed with this, or other similar drugs, should be properly educated, namely by rheumatology nurses [1] to better understand why and how to take it, the possible side effects, and how to prevent and manage them. However, high disparities may exist across European countries regarding patient education (PE) and support about MTX.

Objectives: To assess patients' and clinicians' perspectives and experiences on education and support received about MTX treatment in Europe.

Methods: A survey was developed by a team of international researchers and clinicians, including rheumatology nurses (from adult and paediatric care), a pharmacist, a rheumatologist, and patient representatives. Common and sample-specific questions were conceived for adult patients or carers (≥18 years) of children/young with RMDs, nurses, and physicians working in rheumatology in Europe. The survey was available in English and, for patients, in 12 additional languages, disseminated between May and December 2022. Ethics committee approval was obtained (116_CIEPC/2022_JPC).

Results: Complete responses were obtained from 1536 patients (52% with RA), 154 caregivers, 335 nurses, and 299 physicians (96% rheumatologists), from 24 European Countries, mainly from Northern (nurses) and Southern Europe (patients and physicians) (Table 1). Only 28% of patients had a specific nurse consultation when they started oral MTX, slightly increasing when the subcutaneous form was prescribed (42%), with variations across Europe, being higher in the Western (43%) and Northern (39%) and lower in Eastern (23%) and Southern (11%). These patients' perspectives are somewhat in line with physicians' perspectives, although according to nurses the access to them is higher, independent of the form of prescription (Table 1). Physicians perceive higher opportunities to discuss patients' MTX concerns than the patients themselves (Table 1). Patients had more opportunities to voice their concerns (≥7 on a scale from 0 to 10) about MTX before starting it, in Western (57%) and Northern (42%) than in Southern (36%) and Eastern (31%) Europe. According to 47% of nurses, PE occurs on the same day of prescription, with the consultation lasting between 10-30 minutes in 50% of cases or even less than 10’ (15%). 37% of nurses do not perform MTX-related follow-up appointments. Only half of the nurses (49%) received specific training to advise patients about MTX (data not shown).

*According to United Nations geoscheme.

Around 77% of patients had/have concerns about potential unpleasant side effects, which were discussed with health professionals (mainly with rheumatologists) in 68% of the cases, despite not being clarified 46% of the times. 

Conclusion: PE and support about MTX are unequal across Europe and can be improved by providing opportunities to clarify concerns, namely by providing patients with more access to nursing consultations. There is an overall agreement between patients and clinicians regarding key information areas of education, although a tailored approach is required.

‘IT’S A LOT TO TAKE IN’: A SYSTEMATIC REVIEW OF THE INFORMATION NEEDS OF PEOPLE WITH INFLAMMATORY ARTHRITIS STARTING METHOTREXATE

Keywords: Patient information and education, Disease-modifying drugs (DMARDs), Systematic review

S. Logan1, S. Hider1,2, J. Green3, S. Ryan2. 1Kelee University, School of Medicine, Keele, United Kingdom; 2Midlands Partnership NHS Foundation Trust, Rheumatology, Haywood Hospital, Staffordshire, United Kingdom; 3Kelee University, School of Nursing and Midwifery, Keele, United Kingdom

Background: Guidelines recommend that people with Inflammatory Arthritis have access to tailored information when starting treatment with Methotrexate (MTX) [1]. It is not known what information people with Inflammatory Arthritis (IA) need to take MTX. Many people have concerns about the risk-benefit profile of MTX and so do not start or continue MTX.

Objectives: To identify and synthesize knowledge of the characteristics, content and preferred format of information that with IA need to take MTX.

Methods: A PROSPERO registered systematic literature search (CRD420222325249) was conducted using Medline, Embase, Cinahl, PsycInfo, GreyEU, Web of Science and Open Dissertation databases. All full-length articles and conference abstracts identifying information and support needs of people with Inflammatory Arthritis, and oral or sub-cutaneous MTX as the main conventional DMARD considered in the study were assessed for inclusion. The systematic review was conducted and reported in accordance with the Joanna Briggs Institute methodological guidance for Mixed Methods Systematic Reviews [2] using a convergent integrated approach and the standards of the Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) Statement.

Results: 8468 studies were identified. 169 studies were reviewed by full text of which 13 studies met the inclusion criteria. Seven quantitative studies used cross-sectional internet (n=2), postal (n=2), and rheumatology clinic (n=3) surveys, two mixed methods studies, one cross-sectional survey with clinic observations and one cross-sectional survey and focus group, and four qualitative (one interview and three focus group) studies. The combined studies included 5425 adults over the age of 18 years (20-84 yrs), most were female (71%, n=2434). More people were enrolled into studies (n6) involving people with a diagnosis of Rheumatoid Arthritis (n=2278) than studies (n=7) involving people with IA (n=840). Studies were conducted in the UK (n=4), Netherlands (n=3), Spain (n=2), Australia (n=2), Canada (n=1) and Japan (n=1) and reported in English. Qualitative results were quantized. Three main themes were identified, with an overarching theme of a need for person-centred information about Methotrexate. 1: Information to support understanding and acceptance of the need for treatment with MTX: Learning about IA diagnosis, rationale for MTX in context of IA, benefits of MTX) 2: Concerns about MTX: including risk, likelihood and management of side effects, drug interactions, impacts upon lifestyle, developing medication self-management skills 3: Content and methods of information delivery: information sources, importance of support from healthcare professionals (hcp), family and friends, value of a therapeutic relationship with hcp.

Conclusion: People with IA have individual, multi-faceted information and support needs about both their condition and MTX, to enable them to take MTX. Further research is recommended to explore a) the expectations of information and support before receiving information about MTX, b) experiences of people receiving information at the time of starting MTX and c) strategies to improve information and support during the course of taking MTX.

DAY-TO-DAY FLUCTUATIONS OF FATIGUE IN SYSTEMIC SCLEROSIS

Keywords: Patient reported outcomes, Quality of life, Systemic sclerosis

A. Velauthapillai1, M. Vonk1, C. Van den Ende1, J. E. Vriesekolken2. 1Redboud University Medical Center, Rheumatology, Nijmegen, Netherlands; 2Sint Maartenskliniek, Research and Innovation, Nijmegen, Netherlands

Background: Systemic sclerosis (SSc) is a rare autoimmune disease with a huge impact on physical health as well as social well-being, with fatigue being the major problem experienced by patients with respect to their well-being [1].
While fatigue is being reported to be fluctuating and unpredictable, the dynamic nature of fatigue is not well understood [1, 2].

**Objectives:** To examine the within-person fluctuations and clinically meaningful changes in fatigue, as well as the within-person association of fatigue and time-varying determinants in SSc.

**Methods:** We performed a daily-diary study in adult patients with a clinical diagnosis of SSc. Patients with pulmonary hypertension or severe pulmonary function disturbances (i.e. vital capacity and diffusing capacity for carbon monoxide < 50%) were excluded. During 14 days patients completed daily assessments at four fixed time points (i.e. 9 a.m., 1 p.m., 5 p.m., 9 p.m.) of fatigue severity and time-varying determinants (i.e. negative affect, positive affect, pain, quality of sleep and perceived exertion of physical activity. As proxy for clinical meaningful change in fatigue the probability of acute change(PAC) was assessed, i.e. the chance that change in day-to-day fatigue levels exceeded the minimally clinical important difference for fatigue[3]. Using multilevel models the within-person fluctuations in fatigue and its association with time-varying determinants were examined. Based on the extent of clustering, the time-varying determinants were disentangled into their corresponding levels (within persons (within day as well as across days) and between persons) and added to the multilevel model. Models were adjusted for confounding (i.e. BMI, sex, age, and history of covid-infection) where appropriate.

**Results:** Fifty-seven patients with SSc, 35% male with mean(SD) age 54.3(14.6) years, participated. The disease duration was mean(SD) 6.9(4.8) years and 29.8 % was diagnosed with diffuse cutaneous SSc. Eighty percent of all observations were completed. During the study period, change in day-to-day fatigue exceeded the MCID mean(SD) 5.7(1.9) times. The PAC was mean(SD) 0.44(0.14), ranging from 0.08-0.77. For fatigue a between-person variation of 49% and a within-person variation of 51% was observed. With respect to confounders, only BMI was significant in the models for time-varying negative and positive affect. The final models showed significant within-person association with fatigue fluctuations and changes in time-varying determinants within a day, between days and between patients (Table 1).

**Conclusion:** This is the first quantitative study showing that fatigue in SSc is characterized by a dynamic course and that approximately half of the day-to-day fluctuations are clinically meaningful, confirming the results of qualitative studies[2]. Moreover, when patients reported more fatigue than usual, they also reported more pain, more negative affect, less positive affect, more perceived exertion of physical activity, and worse quality of sleep than usual.

The relationship between health literacy and treatment status in patients with systemic lupus erythematosus who achieved lupus low disease activity state: the Trump2-SLE project

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Treat to target

Background: Although the relationship between health literacy and treatment outcome has been reported in certain illnesses,[1,2] it remains unclear how health literacy affects treatment selection.

Objectives: This study aims to determine the relationship between health literacy and treatment status in patients with systemic lupus erythematosus (SLE) who have achieved a low disease activity state (LLDAS).

Methods: A cross-sectional study was conducted on 266 SLE patients who had achieved LLDAS, registered in the TRUMP2-SLE study,[3] an ongoing multicenter cohort study conducted at five academic centers in Japan. The main exposure was the health literacy scores (0-56) of the enrolled patients, as measured by the 14-item Communicative Critical Health Literacy Scale (FCCHL). The primary outcomes were daily glucocorticoid dose, hydroxychloroquine (HCQ) use, and immunosuppressant use. A secondary outcome was chronic disease measured by Systemic Lupus International Collaborating Clinics-Damage Index (SLICC-DI). Odds ratios (ORs) to assess the relationship between health literacy and treatment status were estimated with adjustment for confounders (age, sex, income, education, disease duration, and SLICC-DI).

Results: The median age of the patients was 44 years (interquartile range [IQR]: 36-58), 88% were female, and the median disease duration was 13 years (IQR: 7-20). The median FCCHL score were 3.1 (IQR: 3.0-3.5). The median daily glucocorticoid dose (prednisolone equivalent) was 4 mg (IQR: 2.5-5). HCQ was used in 122 (45.9%) and immunosuppressant use was used in 174 (65.4%) of enrolled patients, respectively. FCCHL score was not associated with glucocorticoid dose (p = 0.016). FCCHL score was not statistically different between patients with and without immunosuppressants (median 3.07 [IQR: 2.79-3.36] and 3.04 [IQR: 2.71-3.29]; p = 0.81) but statistically different between patients with and without HCQ (median 3.14 [IQR: 2.36-3.93] and 3.00 [IQR: 2.71-3.25]; p = 0.0028). After adjustment for confounders, HCQ use was significantly associated with FCCHL score (OR: 2.27, 95% confidence interval: 1.19-4.36). FCCHL score was not statistically associated with SLICC-DI (IQR: 2.0, p = 0.0091).

Conclusion: Even among the SLE patients who have achieved LLDAS, the preference of HCQ usage may vary depending on health literacy.

Rheumatoid arthritis, Patient reported outcomes, Outcomes management

Background: The Rheumatoid Arthritis Impact of Disease (RAID) is a patient-reported outcome measure (PROM) originating from a EULAR initiative. It supports patient-centered care and shared decision-making between patient and rheumatologist regarding treatment and adjustment of medication. RAID could be a useful tool in remote monitoring, and its association with disease activity is thus of interest.[1] It is not known if RAID is responsive and discriminative to disease activity flares.

Objectives: To explore the responsiveness of the RAID (sum score and single domain scores) to clinical disease flare and to assess its discriminative ability with regard to flare.

Methods: We used data from the two Norwegian multicenter ARCTIC REWIND trials assessing tapering of TNFi and csDMARDs (ClinicalTrials.gov: NCT01818308).[2] Eligible participants had RA (ACR/EULAR 2010 criteria), were in sustained remission for ≥12 months on stable DMARDs with Disease Activity Score (DAS) remission combined with no swollen joints. In the TNFi trial, patients were randomized to stable TNFi or tapering to discontinuation of TNFi (stable csDMARD comecodination). Patients in the csDMARD trial were randomized to stable or half dose treatment for the first year. Study visits with assessment of disease activity were conducted every four months, if a flare was suspected between visits the patient was seen within a week. flare was defined as a combination of DAS≥1.6, an increase in DAS ≥0.6 units from the previous visit and minimum two swollen joints. If a patient did not fulfill these criteria, a disease flare could be recorded if both the patient and investigator agreed that a clinically significant flare had occurred. If a flare was confirmed, the full dose of the study medication was reinstated or (in the stable-dose group) treatment adjusted according to current recommendations. We evaluated the median RAID score at the last visit before flare, flare visit and first visit after flare in relation to the suggested ≤2 RAID threshold for patient acceptable symptom state (PASS), and assessed the changes between those visits using Wilcoxon rank-sum test.[3] The ability of RAID to detect disease flare was assessed using the area under the ROC curve (AUC) based on logistic regression models. For comparison, similar analyses were performed for patient global assessment (PGA), DAS and C-reactive protein (CRP).

Results: Of the 248 patients included, 159 (64%) were female. Mean (SD) age and disease duration were 56 (11.8) and 6.3 (5.7) years. For patients who experienced a flare the median (IQR) RAID score was 0.9 (0.3, 1.4) at last visit prior to flare with 86% of scores within the PASS range. At the flare visit median RAID was 2.6 (1.4, 5.6) with only 30% of scores within the PASS range (Figure 1). Similar changes were observed in DAS, PGA and CRP. All seven RAID domains increased significantly at the flare visit (p-values < 0.01), with the largest increase in pain (Figure 1). According to the AUC analyses the estimated accuracy in detecting flare was high for RAID, but higher for DAS and PGA. CRP was less accurate in detecting flare (Table 1). Conclusion: There was a clinically and statistically significant increase in median RAID score and all single domains of RAID at flare visit, supporting its responsiveness to clinical disease flares. Both RAID and PGA discriminated well between flare and non-flare, hence both PROMs might contribute in early identification of flare and patients who might need an adjustment of medication, in a regular clinical setting as well as in remote monitoring of disease activity.

References:
also a vicious circle as volunteers are needed to deliver the projects, themselves forming the basis to fund the organisation. When preparing its 2018-2023 strategic plan, Lupus Europe was confronted with this frustrating reality with incomes stagnant around €40,000/year, just enough to cover its basic operations, convention and few limited size projects.

**Objectives:** To step change Lupus Europe's development and unlock both the funding and volunteering recruitment bottlenecks by creating an energising Patient Advisory Network.

**Methods:** As part of its 2018-22 strategic plan discussions, the Lupus Europe designed the structure of a Patient Advisory Network (PAN) as a key way to reach its objectives, in a way that combined both volunteers and sponsors motivation factors. For volunteers, the PAN offered an opportunity to move from a victim of the disease position to that of an actor of the change, working together with other fellows, equally motivated. Initial patients were selected based on their positive energy and desire to change things and grow skills. We identified (web based) opportunities to grow the needed skills, and encouraged participation. Finalising the team charter, drafted by the board, became the first exercise of the team, which then dedicated itself to support projects from academics, clinicians or industry, and work on own lupus Europe projects. The visibility of the PAN quickly became an additional motivator, and many applications to join were received. PAN members agreed that potential remuneration for their work would accrue to Lupus Europe and be used to motivate and reward the group. For sponsors, we redesigned our partnership proposal, using the PAN to step change engagement levels. We asked our sponsors for a leap of faith that we could drive this to success, and that they would benefit from it as much as we would by making our community more vibrant. We also offered to a all of a sample of what the team could do to support key projects. We engaged with academics to identify valuable partnerships and asked them to give training to the team. In parallel, we invested some of our savings to fund initial costs, and provided soft skills training for the group. Two years later, we applied and obtained EMA recognition as EMA eligible entity. Early successes boosted the team's morale and helped reach out to more partners. This in turn allowed us to “put the program on steroids,” multiplying our support to the group and the number of projects generated by Lupus Europe. Things we had never imagined being able to do by ourselves, like the Living with Lupus survey (5000+ answers) or lupus100.org (info on lupus in 18 languages) or Re-Post all the photos on organization’s FB page.

**Results:** 5 years after its start, the PAN is now rich of 23 highly motivated members working on 25 projects (50/50 industry/non-industry) including some of our own design. It is recognised as a best in class organisation, and keeps growing, enabling us to achieve results we could not have dreamed of 5 years ago. Lupus Europe’s funding jumped from 40k in 2017 to more than 300k in 2021, allowing to do more projects, invite PAN members to SL Euro or EULAR and professionalise some of our support. It also increased our independence from pharma, as we feel free to say no to any funder we don’t fully feel happy with (and we did already twice)! 

**Conclusion:** The PAN project as transformed lupus Europe from a minimalist federation to the key voice and support of people living with lupus in Europe. 

**Acknowledgements:** Many thanks to LUPUS EUROPE’s Patient Advisory Network members whose enthusiasm and commitment has been critical for the success of this project.

**Disclosure of Interests:** None Declared.

Methods: Interactive live events, of approximately 2hour duration, have already taken place in 15 cities of Greece. In the year 2020 COVID restrictions did not allow for such events to be organized. The project will start again during 2023. Speakers in the events were: rheumatologists, general physicians, anesthesiologists, psychiatrists, psychologists, gynecologists, clinical pharmacologists and others.

Results: Over 1800 patients, caregivers, members of the public, stakeholders, members of the local authorities, healthcare professional and others participated in the live events. Handouts and printed material from HELAR/ELEANA were given to participants as well an evaluation form to complete. The events generated a lot of press locally and nationally, with 4 press conferences, 25 press releases, 18 TV interviews and 10 radio interviews.

Conclusion: Publicity and participation in the events showed that patient education is quite important for the patients and the local communities. Since 2020 and the COVID pandemic there has been a shift towards public health issues and health education creating a unique opportunity for HELAR/ELEANA's School of Health Education to be adapted and become once more available for the patients living with an RMD. This time the new version could be either a virtual version or a live version for many more patients, caregivers and the public to be able to attend.

IPARE – GLOBAL COLLABORATION OF PATIENT ORGANISATIONS FOR THE BENEFIT OF RMD PATIENTS

Keywords: Patient information and education, Best practices, Geographical differences

D. Weik,1 EULAR, Pare, Zuerich, Switzerland

Background: Rheumatic and musculoskeletal diseases (RMDs) are a burden for individuals and a challenge to healthcare systems. Comparing the current and the future number of rheumatologists and the frequency of RMDs, studies state a huge gap. Another key issue is the uneven distribution of rheumatologists in most countries. These deficits are glaring in low and middle income countries in particular. In sub-Saharan Africa e.g. just in the past 20 years more attention has been drawn to non-communicable diseases. Great challenges exist in Latin America. Patient organisations (POs) offer information and assistance, are competence networks, represent and advocate for patients' interests and needs and play a pivotal role in health-care systems.

Objectives: Overarching: With its activities IPARE aims at contributing to a world, where RMDs are recognized, prevented and cured, and patient-centredness is an integral part of health care delivery. The specific aims are.

- To connect and exchange with national patient organisations and continental networks/organisations of patient organisations from other continents than Europe.
- To develop, step by step, a network of globally active national POs, national umbrella POs and continental POs.
- To initiate collaborative projects in the field of education, research, quality of care, congress and advocacy.
- To share best practices aiming at developing and supporting POs and pan-continental POs.
- To promote the access to and the exchange at conferences and congresses for RMDs.

Methods: IPARE is a PARE project group embedded in the PARE Sub-Committee „Community Relations“; meaning all EULAR regulations will apply. A small project group consisting of representatives from South and Central America, North America, Africa and Europe has been established. We are aiming at enlarging the group (e.g. by having a representative from Asia), but the total number should not exceed 10 in order to work efficiently. After an introductory in-person meeting at the PARE Conference in October the members decided to meet virtually every 6-8 weeks. Webinars are offered every 2-3 months. Aspects of membership, objectives, mode of working were defined.

Results: The project group members identified - in spite of different health care systems, economic statuses and the extent of the deficits - certain commonalities like lack of rheumatologists (in particular lack of paediatric rheumatologists), shortage of health professionals (e.g. nurses, physiotherapists trained for the treatment of RMDs), delayed diagnosis, access to medical treatment according to internationally accepted treatment recommendations, insufficient non-pharmacological treatment, needs to educate the public and create awareness for RMDs and the situation of people with an RMD, research and patient involvement in research. The group developed a first list of items how these deficits could be tackled, how we can collaborate being aware of the fact that national peculiarities and features and language items have to be taken into account if any material will be produced. To avoid duplication and to check what already exists, an inventory list of informative and educational material is being established. A first webinar open to all representatives of international patient organisations is determined for February.

Conclusion: The project group members work with great enthusiasm, are eager to share knowledge and want to learn what can be implemented in their organisations and countries. In addition the group members focus on supranational issues. The project group members share, learn and convey to support implementation.

THE USE OF OBJECTS TO EXPERIENCE INFLAMMATORY RHEUMATIC DISEASES IN ORDER TO INCREASE KNOWLEDGE AND UNDERSTANDING THROUGH PERSPECTIVE-TAKING, WITH A FOCUS ON ENHANCING EMPATHY

Keywords: Patient information and education, Mental health, Education

T. C. Wilhelmer1, 1FH-Vorarlberg, Intermedia, Dornbim, Austria

Background: People with chronic diseases often experience little sympathy towards their situation and are in many cases stigmatized. The deficiency of knowledge is one main problem that leads to said lack of understanding. For people with RMDs this leads to the exclusion from social life and has a negative impact on their mental health. To reverse this trend, more innovative methods are needed to promote understanding in society as well as in the personal environment of people with debilitating diseases. This abstract presents a Master-Thesis in the field of Intermedia, created by a Student with an RMD. The paper examines existing methods for communicating understanding of chronic illnesses through media using scenography. It assesses which methods of communication can be used to increase empathy towards physically disabled people and thereby improve their inclusion in society. Using the findings of this research, the student created a concept for a public exhibition.

Objectives: Promote empathy towards disabled and chronically ill people. Educate adults in their function as role models for children, to improve early inclusion. Achieve a long-term change in society, to foster inclusion of persons affected by an RMD in society.

Methods: Examples of different performances of illness and their impact on those affected are gathered and discussed. The analysis contains aspects of the communicative methods that have not yet been researched or sufficiently explored. In the field of rheumatic diseases there are not many innovative methods to educate society about the psychosocial impact that an RMD has on the person affected. Existing materials are mainly targeting patients or their close ones. Public campaigning primarily focuses on medical facts. Research shows that immersive experience is more effective in educating than reading, hearing, or viewing information. The combination of facts and an immersive experience strengthens the learning effect and can have a sustainable impact on people’s behaviour. Through immersive experience, there is a possibility to build and strengthen empathy. These factors are significant for the structure of the exhibition.

Results: The concept of the exhibition is based on existing best practice examples and researched methods. The Visitors are confronted with the topic of chronic diseases in an immersive way. The exhibition is sequenced to first get the visitor’s attention by vision, followed by the possibility to physically get in touch with the exhibition’s artefacts that imitate various symptoms. For instance, they can try on splints or sit on a manipulated chair. The elaborated concept is enclosed within the original thesis, to present the path of experience with the concept. The developed artefacts were tested and are based on several interviews for their suitability and their effectiveness. Their relevance was confirmed.
Conclusion: Research underpins the need for innovative methods to promote understanding of people with RMDs. Considering research, the developed concept with a combination of facts and impressive experience is likely to be successful in strengthening empathy towards chronically ill people. The design of the mobile exhibition is scalable. The concept is gladly shared with other patient organisations and is ready to be put into reality.

**OP0287-PARE**  UNMET NEEDS IN RESEARCH, HOW PATIENTS CAN COLLABORATE: THE EXAMPLE OF NECESSITY

**Keywords:** Patient information and education, Sjögren syndrome, Patient reported outcomes

C. Bouillot, 1 K. M. Hammitt, 2 A. Hjertviksten Lindland, 2 M. Oosterbaan, 4 M. Pincemin, 1 L. Stone, 1 AFGS, Patient association, Paris, France; 1 Sjögren's Foundation; Patient association, Reston, United States of America; 2 Diagnosegruppe Sjögrens Syndrom, Patient association, Oslo, Norway; 3 Nationale Vereniging Sjögrenpatiënten, Patient association, Maarsen, Netherlands; 4 BSSA, Patient association, Birmingham, United Kingdom

**Background:** NeceSSlty stands for "New Clinical Endpoints in primary Sjögren's Syndrome: an Interventional Trial based on stratifying patients." International consortium involving 25 partners (20 academics, 4 Pharma and 1 patient association) funded by the Innovative Medicines Initiative (IM2), this public-private partnership between EU and EFPIA specifically requested the involvement of Sjögren's patients.

**Objectives:** Determine realistically the role patients should play and elucidate their added value in such a project.

**Methods:** A patient association has been included from the beginning of the project (even before submission) as partner and is involved in 6 out of 10 Working Packages (WP).

**Results:** Patients were involved in the conception and design of the study. In particular, they established a Patient Advisory Group (PAG). The PAG participated in the creation of the website and the design of lay versions in several languages, reviewed and adapted protocol and consent forms, largely contributed to the creation of STAR, the new primary endpoint assessment score, and participated in dissemination and communication. Patients have an active advocacy role in this project. As the voice of a large Sjögren’s community with sometimes major disparities in care, the PAG has been active in participating in the different meetings and supporting and promoting the project to the general public and Health Authorities. As a culmination of the first phase, 20 patients provided valuable input, particularly during the development of STAR, to ensure that the validated clinical endpoints are relevant for patients, raising issues that had not been considered fully, if at all. The opinions expressed by patients during the Delphi Survey contributed substantially to this evaluation tool, taking into account the patient’s feelings, which are often poorly evaluated or ignored. This future "gold standard" which will be presented to the EMA and FDA, could not have been developed without the participation of patients. In addition, patients were invited to test a webapp that will serve as an evaluation tool throughout the clinical trial. The feedback from the PAG will contribute to the success of this patient-reported outcome tool and has helped to correct issues to ensure its success during the clinical trial.

**Conclusion:** Patient involvement in research is now widely accepted and the benefits are clear. The authorities now frequently require validation by patients. It is quite possible to work in harmony, bearing in mind the constraints and specificities of each stakeholder, in particular that patient participation is voluntary and that their health might not allow them to react immediately. Clinicians, researchers and patients have complementary skills and perspectives which, when shared, will strengthen the project.

**OP0288-PARE**  PATIENT AND PUBLIC INVOLVEMENT IN THE IMPLEMENTATION OF RESEARCH

**Keywords:** Real-world evidence, Best practices, Patient information and education

L. Campbell, 1 N. Evans, 2 M. Skrybant, 2, 3 L. Group, 1 K. Dziedzic, 1 Keele University, Impact Accelerator Unit, Newcastle under Lyme, United Kingdom; 2 NIHR Applied Research Collaboration, West Midlands, Birmingham, United Kingdom; 3 University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom

**Background:** Patient and Public Involvement and Engagement (PPIE) is now common practice in the design and delivery of arthritis research studies in the UK. Yet PPIE in the implementation of this research into practice is a novel and developing area. Coordinated, planned collaboration and relationship building with patients and the public in communities and health settings into which research will be implemented can facilitate greater impact of research findings. It can provide patients with accessible evidence based knowledge to enable more control in decision making about their own condition.

**Objectives:** To describe the work of an established group of patients and the public working collaboratively alongside healthcare professionals, researchers and knowledge brokers to actively implement arthritis research evidence into practice.

**Methods:** The Link Group (n=10 members) meets six times a year to provide meaningful patient and public input and oversight to all implementation projects delivered by the Impact Accelerator Unit, Keele University (UK). Members have links to community, charity, public and patient networks, helping to facilitate the movement of knowledge and evidence based innovations into wider use, nationally and internationally. Link Group task and finish meetings take place according to project demand to co-create strategies to implement research evidence. Roles and responsibilities are identified early on, members attend project operational core groups and ongoing feedback on implementation progress is provided. Link Group members work with researchers (to ensure evidence based messages are included in innovations), healthcare professionals (to discuss how innovations can be best used in clinical practice) and knowledge brokers (to design the finished output and collate all information). Patients, carers and the public contribute valuable knowledge to the process of implementation, including their own experiences of living with arthritis, attitudes and beliefs regarding the healthcare system and knowledge of networks to open up new ways to share innovations.

**Results:** Link Group members have:
- Co-developed funding applications and research designs to ensure early preparation for implementation, providing advice and support for methods of impact and implementation to be considered by researchers.
- Co-created patient facing resources in a range of formats and for different demographics. For example, evidence based guidebooks, posters, leaflets, animations and infographics for people with arthritis and people with long term pain and mental health (www.jigsaw-e.com / www.beefree.org.uk). The Link Group make sure the language in patient facing resources is easily understood, visuals are engaging and diversity is represented.
- Developed a simple, trusted guide summarising current physiotherapy arthritis research, making complex information more accessible and

- Taken patient facing innovations and resources into local community and volunteer groups, given talks at peer-to-peer information events and shared resources digitally via social media to networks.

Conclusion: PP&E in implementation can facilitate the successful implementation of research evidence into practice, for the benefit of people with arthritis. An established patient and public group can provide community insight and ‘real world’ perspective which can strengthen diversity and reach, and make evidence based research innovations more accessible, relatable and useful in clinical practice. Link Group members have developed a sense of ownership of the innovations that are being implemented and as such are passionate about their work: "Straightforward information and practical advice, choosing words and pictures to reflect a healthy life, working closely as a team, a cog within a wheel, creating something special, a resource with appeal" - Link Group member.

The promise of health literacy in clinical care

Keywords: Gender/diversity issues, Patient-led research, Health services research

E. Wang1,2,3, A. Chan4, K. Lendvoy4, E. C. Sayre3, M. Canseco4, C. L. Koehn1, T. L. Fox1. 1Arthritis Consumer Experts, NIA, Vancouver, Canada; 2Arthritis Research Canada (O.A. Vancouver, Canada; 3The University of British Columbia, Rehabilitation Sciences, Vancouver, Canada; 4Research Co., N/A, Vancouver, Canada; 5Fox Wellness Consulting, N/A, Calgary, Canada

Objectives: The aim of this community-led Survey was to identify observable disparities in access to and benefits from health care (HC) services between white and Black, Indigenous and Person of Colour (BIPOC) respondents who identified as Women.

Methods: ACE conducted a 33-question online Survey (Aug 2-19, 2022) in English and French. The Survey was conducted in partnership with Research Co., a public opinion firm. Respondents answered questions regarding socio-demographic information, HC access, HC providers, unfavourable experiences, and information seeking habits. Data were analysed in subgroups and aggregate (including incomplete survey responses). Chi-square tests (exact tests where possible) were used to test for associations.

Results: A total of 1,249 responses were received. 732 (59%) respondents identified as women, 484 (39%) men, 16 (1%) non-binary. Of the women who responded, 163 (22%) identified as BIPOC (including 39 Black, 58 Indigenous, 86 POC), and 569 (78%) as white. Women reported greater barriers to accessing HC compared to men, namely travel (29% vs. 19%) and previous unpleasant experiences (18% vs. 10%). More BIPOC women (68%) experienced barriers compared to white women (56%), the most prominent being time (40% vs. 30%) and language (21% vs. 5%). Overall, interactions with HC providers and rheumatologists were rated similarly between BIPOC women and white women. However, significantly less BIPOC women reported being comfortable asking about medications (27% vs 39%), discomfort (30% vs 43%), and pain (39% vs 50%).

When asked what characteristics they looked for in HC providers, significant differences were revealed between BIPOC and white women [Figure 1]. Overall BIPOC women (14%) reported experiencing discrimination based on gender twice as often as white women (7%), and seven times as often as white men (2%). Further, BIPOC women were seven times as likely to report experiencing ethnicity-based discrimination “often” (8.7%), when compared to white women (1.2%). Results were even more profound for Indigenous women who were 16 times as likely to report experiencing ethnicity-based discrimination “often” (19.6%), when compared to white women (1.2%). Both BIPOC men and women more often turn to family, friends, coworkers, traditional healers, and elders for health information when compared to white respondents. BIPOC women reported being less trusting of certain information sources when compared to white women, specifically patient organizations (11% vs 21%) and official public health websites (55% vs 70%).

Conclusion: Our findings suggest that BIPOC women face unique and disproportionate barriers as well as complex experiences of discrimination when accessing arthritis care. Importantly, BIPOC respondents, in particular BIPOC women, seem to benefit less from their HC interactions. The data further reinforce current literature that calls for the creation of culturally safe spaces and culturally sensitive resources. It is critical for all levels of the health care system to adopt an intersectional lens to better understand and address systemic inequities.

S. Dyball1, M. Rodziewicz2, E. Sutton1, B. Parker3, I. N. Bruce1,2,3. 1The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2Manchester NHS Foundation Trust, The Kellogg Centre for Rheumatology, Manchester, United Kingdom; 3The University of Manchester, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom

Objective: To describe differential response of patients with moderate-severe SLE in the UK by ethnic background.

Methods: Patients commencing rituximab (RTX), belimumab or a standard of care medication (SoC) for SLE in the BiLAG-BR were analysed over 12 months. Major clinical response (MCR) was defined as a SLEDAI-2K ≤4 at 12 months. Deprivation was measured using English indices of deprivation 2019 decile (EID, 1= most deprived, 10=least). MCR was compared using multivariate logistic regression (reference group: White background; adjusted for age, gender and EID). Missing data were imputed using random forest in R V4.2.1 (package: missForest V.1.5).

Results: 1601 SLE patients (Female=1447 [90.4%], median age [IQR]: 39.9 [31.5-50.6] years) commenced therapy from September 2010-September 2022 (RTX: N=1177, belimumab: N=193, SOC: N=231), 905 (56.5%) were White, 233 (14.6%) were Black, 197 were Indo-Asian, 81 (5.1%) were Chinese/ East Asian, and 60 were of Multiple-Mixed background and 125 (78%) preferred not to say. 1,364 (85.2%) patients were taking glucocorticoids (GC) at baseline (median dose [IQR]: 7 [4.5-11.1] mg daily), MCR was achieved in 901 (56.3%) patients at 12 months. Black patients had a higher SLEDAI-2K score at baseline compared with white individuals (Figure 1). Black, East-Asian/ Chinese patients, and Multiple-Mixed ethnic background patients received a higher GC dose at baseline (Table 1). Black, Indo-Asian and Multiple-Mixed background patients were more likely to be in a lower EID. In patients receiving RTX, Black (adjusted OR 0.36 [95%CI 0.25-0.52]) and Indo-Asian (0.42 [0.18-0.96]) patients were less likely to achieve MCR. In patients receiving belimumab, Black (0.65 [0.44-0.96]) and Indo-Asian patients (0.29 [0.09-0.93]) were also less likely to have an MCR. Absolute reduction in SLEDAI-2K was similar for each ethnic group.

Acute phase reactant orsomucoid-2 directly promotes rheumatoid inflammation

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Synovium

K. M. Kim1, S. Lee1, K. G. Lee2, B. K. Hong1, Y. J. Park1, 2, S. A. Yoo1, W. U. Kim1, 2, 3

1. Center for Integrative Rheumatoid Transcriptomics and Dynamics, The Catholic University of Korea, Seoul, Korea, Rep. of (South Korea); 2. Division of Rheumatology, Department of Internal Medicine, St. Vincent’s Hospital, The Catholic University of Korea, Suwon, Korea, Suwon, Korea, Rep. of (South Korea); 3. Department of Internal Medicine, The Catholic University of Korea, Seoul, Korea, Seoul, Korea, Rep. of (South Korea)

Background: Acute phase response is a systematic reaction of organisms. It occurs when the homeostasis of our body is broken by infection, tissue injury, and inflammation. Since most of these acute phase reactants can be rapidly secreted to the blood in response to infection or inflammation, they have been utilized as serum diagnostic markers to predict the activity and outcomes of chronic inflammatory diseases. In recent years, evidence has emerged that some of these acute phase reactants can go beyond simply being useful as diagnostic markers.

Objectives: To determine whether orsomucoid-2 (ORM2), an acute phase reactant, mainly synthesized in the liver, directly contributes to chronic inflammation.

Methods: ORM2 expression was determined by ELISA and immunostaining. Fibroblast-like synovocytes (FLSs) and macrophages were cultured in the presence of recombinant ORM2. NF-κB and p38 MAPK kinase expression levels were assessed by Western blot analysis. Knockdown experiments were carried out using siRNAs for NF-κB p65, p38, and glycoporphin C (GYPC). Proximity ligation assay was performed to test the molecular interaction between ORM2 and GYPC. Recombinant ORM2 was injected into the affected joints of mice with IL-1β-induced arthritis.

Results: ORM2 expression was elevated in the sera, synovial fluids, and synovia of patients with rheumatoid arthritis (RA). Major cell types producing ORM2 were synovial macrophages and FLSs. Recombinant ORM2 robustly upregulated IL-6, TNF-α, IL-8, and CCL2 produced by macrophages and/or FLSs of RA patients via NF-κB and p38 MAPK pathways. GYPC was the receptor of ORM2 on synovial macrophages and FLSs. Such an increase by ORM2 was reproduced in mouse macrophages and FLSs. Intra-articular injection of ORM2 promoted the severity of arthritis in mice and accelerated the infiltration of macrophages in affected tissues. Moreover, in RA patients, circulating ORM2 levels correlated with disease activity assessed by DAS28 and well represented radiographic progression in 2 years.

Conclusion: Acute phase protein ORM2 can directly increase the production of pro-inflammatory cytokines/chemokines by macrophages and FLSs and promote chronic arthritis in mice, suggesting that it could be a new therapeutic target for RA.

Inborn errors of immunity and autoimmune / inflammatory rheumatic disorders: What can we learn?

MUTATIONS IN DNASE1L3 CAUSING FAMILIAL HYPOCOMPLEMENTEMIC URTICARIAL VASCUULITIS AND EARLY ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Genetics/Epigenetics

N. Aliabadi1, A. Aldhaheiri2, H. Alblooshi2, 1United Arab Emirates University, Pediatrics, Al Ain, United Arab Emirates; 2Tawam Hospital, Rheumatology, Al Ain, United Arab Emirates; 3United Arab Emirates University, Genetics, Al Ain, United Arab Emirates

Background: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disease with several aberrancies in the immune system[1]. Genetics factors are central to understanding the pathophysiology especially in patients with monogenic lupus (single-gene mutation)[2]. Anecdotally, we observe a relatively high prevalence of familial SLE in our region (UAE/Arab regions). Studying the genetics of such cases have yielded gene mutations known to cause SLE. Here we report 3 siblings with mutations in DNAES1L3 causing SLE and hypocomplementemic urticarial vasculitis (HUVS)[3].

Methods: To report the clinical and genetic presentation of 3 siblings with monogenic SLE and HUVS and discuss clinicopathologic correlations.

Results: Genetic analysis via WES revealed a homozygous DNAES1L3 variant at c.572A>G; p.Asn191Ser for the 3 affected siblings classified as variant of unknown significance (VUS). The mother and healthy sibling were heterozygous (carrier) for the variant. This indicates that the variant is segregating with the family for SLE. DNAES1L3 variant c.572A>G, p.Asn191Ser is a novel variant that was not reported previously in the literature or human genetic mutation database (HGMD). Computational (in-silico) pathogenicity prediction tools predicted damaging effect of the variant (PolyPhen: damaging, SIFT: Deleterious, Conservation: high). Clinical and laboratory features are presented in Table 1. All three siblings developed HUVS as the initial manifestation which was confirmed by skin biopsy. In the older siblings who eventually met the criteria for SLE, the HUVS resolved as other SLE symptoms emerged. The youngest sibling has not met criteria for SLE and only has skin involvement with debilitating HUVS (tender lesions and swollen hands/feet).

This patient was found to have very low levels of C1q without anti-C1q antibodies. The patient was identified through our SLE clinical cohort. Informed consent was obtained from the patients/guardians to participate in our institution’s “Mendelian Project” research study. The study is approved by the local IRB committee. Whole exome sequencing (WES) was performed. The results of the initial sequencing were analyzed in the context of the clinical presentation of SLE and HUVS.

Neutrophil dysregulation in systemic lupus erythematosus

ANTI-CITRULLINATED HISTONE MONOCLONAL ANTIBODY CIT-013, A DUAL ACTION THERAPEUTIC FOR NEUTROPHIL EXTRACELLULAR TRAP ASSOCIATED AUTOIMMUNE DISEASES

Keywords: Cell biology, Innate immunity, Rheumatoid arthritis

M. Van der Linden1, S. Kumari1, D. Montizan1, S. Van Dalen1, A. Kip1, M. Foster2, I. Reinieren3, E. Neubert3, L. Erpenbeck4, T. Bruurmijn1, P. Van Zandoort1, P. Vink1, E. Meldrum1, H. Van Es1, R. Chirivi1, C. Cyrlin BV R&D, Oss, Netherlands; 2Experimental Pathology, Consultancy, Benfleet, Essex, United Kingdom; 3Leiden Academic Centre for Drug Research, Division of drug discovery and safety, Leiden, Netherlands; 4University Medical Center Münster, General Dermatology and Venereology, Münster, Germany

Background: Neutrophil extracellular traps (NETs) contribute to the pathophysiology of multiple inflammatory and autoimmune diseases. Targeting the NETosis pathway has demonstrated significant therapeutic potency in various disease models (Chirivi et al., 2021). Here we describe a first in class monoclonal antibody (CIT-013) with high affinity for citrullinated histones H2A and H4 which inhibits NETosis and reduces tissue NET burden in vivo with significant anti-inflammatory consequences. CIT-013 is currently in phase 1 clinical trials with phase 2a studies in RA due to commence in 2024.

Objectives: The objective of the current study was to further unravel CIT-013’s mode of action. Questions which we wanted to answer are: 1) How and when does CIT-013 interfere with the NETosis pathway? and 2) what is the faith of CIT-013 opsonized NETs and netting neutrophils? Furthermore, we investigated whether CIT-013’s epitope is expressed in rheumatoid arthritis (RA) synovial tissue.

Methods: In vitro life imaging studies using neutrophils and macrophages in combination with monovalent as well as bivalent CIT-013 have been performed to investigate CIT-013’s effect on NET burden as well as phagocytic macrophages. Finally, the presence of CIT-013’s epitope in human RA synovial tissues was investigated using immunohistochemistry techniques.

Results: Detection of CIT-013 epitopes in RA synovium provides evidence that RA is an autoimmune disease with excessive citrullinated-NETs that can be targeted by CIT-013. We show that CIT-013 acts upon the final stage of NETosis, binding to its chromatin epitopes when plasma membrane integrity is compromised to prevent NET release. Bivalency of CIT-013 is necessary for NETosis inhibition. In addition, we show that CIT-013 binding to NETs and netting neutrophils enhances their phagocytosis by macrophages. Furthermore, we demonstrate that a mouse variant of CIT-013 reduces tissue NET burden in vivo at least in part through enhanced macrophage phagocytosis.
Insights into gout management

A 12-WEEK, RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED, PHASE 2B STUDY OF SAFETY, TOLERABILITY AND EFFICACY OF AR882 IN GOUT PATIENTS

Keywords: Gout, Randomized control trial

Methods: The trial recruited patients 18 to 75 years of age with eGFR >30 mL/min across 20 sites in the US, Australia, and Taiwan, who met the ACR/EULAR Gout Classification Criteria. Following gout flare prophylaxis for 10 days, patients received either once-daily AR882 50 mg, AR882 75 mg, or matching placebo for 12 weeks. Blood samples were collected every two weeks throughout Week 12 for laboratory tests, sUA and pharmacokinetic measurements. Efficacy endpoint was the percent of patients who reached sUA below 6, 5, 4, and 3 mg/dL.

Results: A total of 140 patients were enrolled in this study. The majority of patients were male (93.6%) and white (58%), followed by Asian (28%) and Black (4%). The baseline sUA level was 8.6 ±3 mg/dL; mean age 54.3 (24-73) years; mean body weight 96.4 ±17.8 kg. Major comorbidities seen in patients included hypertension (47%), hyperlipidemia (35%), renal insufficiency (29%), arthritis (23%), diabetes (19%), cardiovascular disease (15%), lung disease (11%), and liver disease (5%). Following 12 weeks of treatment, median sUA levels were reduced from baseline 8.6 mg/dL to 3.5 mg/dL with 75 mg and 5.0 mg/dL with 50 mg. No change was observed in the placebo group. At Week 12, 89%, 82%, 63% and 29% of patients achieved < 6, <5, <4 and <3 mg/dL, respectively, in the 75 mg group. In the 50 mg group, 78%, 50%, 8% of patients achieved < 6, <5 and <4 mg/dL, respectively. The sUA lowering effect was similar for three consecutive measurements between Week 8 and 12. There were no serious adverse events in AR882 treated patients. Mild or moderate adverse events including diarrhea, headache, and upper respiratory infection were observed in this study. A total of 65 gout flare incidents were observed and evenly distributed across groups during the 12-week treatment.

Conclusion: The majority of patients receiving AR882 achieved sUA levels below 5 or 4 mg/dL, which are two key thresholds for more efficient flare and tophi reductions[1,2]. AR882 was well tolerated over the 12-week treatment period and patients with comorbidities did not require any adjustments in management of the disease. This study suggests AR882 may offer improved efficacy with acceptable safety compared to existing therapies for gout and may have utility in the treatment of patients across the spectrum of gout including those with severe or refractory disease.

Pain relief - what can be done?

**MEASURING THE IMPACT OF DIGITAL THERAPEUTICS ON QUALITY OF LIFE AND SYMPTOM BURDEN IN PATIENTS WITH RHEUMATOID ARTHRITIS USING RAID SCALE**

**Keywords:** Patient reported outcomes, Quality of life, Rheumatoid arthritis

1Weltthy Therapeutics Pvt Ltd, Product & Clinical Research, Mumbai, India; 2Yatharth Super Speciality Hospital, Greater Noida, Rheumatology, Greater Noida, India; 3Weltthy Therapeutics Pvt Ltd, Product & Clinical Research, Mumbai, India

**Background:** Rheumatoid arthritis (RA) is a systemic chronic autoimmune disease that involves inflammatory arthritis with varying severity showing various symptoms like pain, fatigue, and sleep disturbances impacting and reducing the quality of life (QoL).[1] Patients with RA experience reduced QoL, physical and emotional health as well as level of independence etc and they are more likely to suffer from anxiety, depression and low self-esteem, with high levels of associated mortality and suicide.[3] Addressing the need to improve the quality of life and symptom burden for these patients are vital where Digital solutions play an incredibly significant role. These solutions are also helpful in self-management of disease and symptoms.

**Objectives:** To assess the impact of a digital health program on the quality of life and symptom burden of patients suffering from Rheumatoid Arthritis.

**Methods:** An interventional trial including an RA patient support program was delivered by Weltthy Care digital platform over a period of 16 weeks. Recruitment of 30 patients was done using a convenient sampling method. Patients who were diagnosed with RA were included in the trial. Patients who were under 18, pregnant/lactating, and with hearing disability were excluded. The program included interventions such as physiotherapy sessions, CBT (cognitive behavioural therapy) counselling, tracking of symptoms, lifestyle counselling, disease awareness and self-management training of symptoms at home. The rheumatoid arthritis impact of disease (RAID) [2] questionnaire, a validated questionnaire was administered to assess seven important patient domains of disease impact: (pain, function, fatigue, sleep disturbance, emotional well-being, physical well-being, coping) at baseline and at the end of the program.

**Results:** The Mean RAID score of the patients at baseline was 4.99 and at endpoint was 0.737. The impact percentage of program in improvement of symptoms like Pain, Difficulty in doing daily physical activities, Fatigue, Sleep difficulty, level of physical well-being, level of emotional well being were 86.66%, 86.40%, 86.81%, 96.47%, 85.66%, 93.89% respectively. The Paired T- test witnessed significantly improved impact of disease. These solutions are also helpful in self-management of disease and symptoms.

**Conclusion:** Digital therapeutics play a highly significant role in improving the quality of life and reducing the symptom burden of RA patients. The digital patient support program led to meaningful changes in a patient’s quality of life as well as symptoms within a few weeks, even when the patient previously failed to experience a good prognosis during the treatment. Patients reported a highly significant improvement in Pain, Fatigue and Sleep disturbances, which improved the quality of life and patient’s outlook of the overall treatment and adherence. These digital solutions can be considered as holistic care and integrated with routine supportive care in practice to provide improved patient-centred care. RAID score functions well as a good patient reported outcome measure in routine health care practice.

**Treat to Target: Challenges across the life course.**

**INCREASING THE ETANERCEPT DOSE IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS: DOES IT HELP REACHING THE TREATMENT TARGET? A POST-HOC ANALYSIS OF THE BEST4KIDS RANDOMISED CLINICAL TRIAL**

**Keywords:** Clinical trials, bDMARD

1Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands; 2Willem-Alexander Children’s Hospital, Paediatrics, Division of Paediatric Rheumatology, Leiden, Netherlands; 3Emma Children’s Hospital, Amsterdam University Medical Centers, Paediatric Immunology, Rheumatology and Infectious Diseases, Amsterdam, Netherlands; 4Emma Children’s Hospital, Amsterdam University Medical Centers, Paediatrics, Amsterdam, Netherlands; 5Amsterdam Rheumatology and Immunology Centre (Reade), Paediatric Rheumatology, Amsterdam, Netherlands; 6Hagaziekenhuis Juliana Children’s Hospital, Paediatrics, The Hague, Netherlands

**Background:** Etanercept is a frequently used second-line therapy for juvenile idiopathic arthritis (JIA). It is unknown whether higher doses of etanercept result in better clinical outcomes, but most studies only evaluated doses up to the most commonly used 0.8 mg/kg/week (max 50 mg/week).[1] Although higher doses are used in clinical practice, the literature lacks an in-depth description of patients receiving such treatment.

**Objectives:** To describe the clinical course of JIA-patients that received high-dose etanercept (1.6 mg/kg/week; max 50 mg/week) as part of the Best4Kids trial.

**Methods:** In a single-blinded treatment-strategy trial, patients with olioarticular JIA, RF-negative polyarticular JIA or juvenile psoriatic arthritis were randomised across three treatment-strategy arms: (1) sequential DMARD-monotherapy (sulfasalazine or methotrexate (MTX)), (2) combination-therapy MTX+6 weeks prednisolone and (3) combination therapy MTX+etanercept.[2] A protocolised treat-to-target approach aiming for inactive disease was used during 24 months follow-up. Treatment was escalated in case of persistent disease-activity or tapered in case of inactive disease. In any treatment-arm patients could eventually escalate from regular to high-dose etanercept alongside MTX 10mg/m2/week. For comparison we studied patients who did not receive high-dose etanercept due to decisions overruling the trial-protocol by the treating paediatrician and/or the patient/parents.

**Results:** Of the 94 randomised patients, 32 received high-dose etanercept (69% female, median age 6 years (IQR 4-10), median time from baseline 10 months (7-16), median dose 1.3 mg/kg/week (1.1-1.5)). Follow-up was up to 2 years from baseline (median follow-up 24.6 months). Clinical measures of disease-activity decreased largely within 3 months (Figure 1): median VAS:physician from 12 to 4 (p=0.022), VAS-patient/parent from 38.5 to 13 (p=0.003), VAS pain from 35.5 to 15 (p=0.030), number of active joints from 2 to 0.5 (p=0.12) and JADAS10 from 7.2 to 2.8 (p=0.008). Functional status (CHAQ-score) improved more gradually and ESR remained stable. A comparable pattern of clinical parameters over time was observed in 11 patients (73% girls, median age 8 (IQR 6-9)) who were not escalated to high-dose etanercept despite eligibility according to trial-protocol. In both the high-dose and the comparison group the percentage of patients with inactive disease 6 months after eligibility for dose-increase was 56%. In the high-dose group, 18 out of 32 patients (56%) experienced 26 infectious adverse events (AEs, on average 0.2 events per visit following dose-increase). No serious AEs (SAEs) were recorded after dose-increase. Among the 11 patients who did not receive high-dose etanercept, 4 patients (36%) subsequently experienced 5 infectious AEs (on average 0.11 events per visit); this included one SAE requiring hospitalisation. Findings were similar when one patient who switched off-label in clinical practice, the literature lacks an in-depth description of patients receiving such treatment.

**Conclusion:** Escalation to high-dose etanercept was generally followed by meaningful clinical improvement within 3 months. However, non-escalators experienced comparable improvement. These data do not suggest superior clinical outcomes after etanercept dose increase, while there was a potential trend for more (non-severe) infectious AEs. Larger studies are needed to more closely examine outcomes, adverse events and cost-effectiveness of high dose etanercept.
OP0301  THE OPTIMAL THRESHOLDS FOR PATIENT GLOBAL ASSESSMENT IN DEFINING REMISSION DIFFER ACCORDING TO THE AUTOANTIBODY STATUS IN EARLY RHEUMATOID ARTHRITIS

THE INTERNATIONAL MAP OF AXIAL SPONDYLOARTHRITIS GLOBAL REPORT: SUPPORTING THE INCLUSION OF THE PATIENT PERSPECTIVE IN POLICY AND CLINICAL PRACTICE

**Keywords:** Lifestyles, Real-world evidence, Quality of life

J. Lowe1, M. Garrido-Cumbrera2, 3, J. Davies4, A. Phoka2, 6, L. Wermskog5, 7, L. Christen1.1 Axial Spondyloarthritis International Federation, Projects, London, United Kingdom; 2University of Seville, Health and Territory Research, Seville, Spain; 3Spanish Federation of Spondyloarthritis Organizations (CEADE), Executive Dept, Madrid, Spain; 4Axial Spondyloarthritis International Federation, Executive Dept, London, United Kingdom; 5Cyprus League Against Rheumatism (CYPLAR), Executive Dept, Nicosia, Cyprus; 6Axial Spondyloarthritis International Federation, Board of Trustees, London, United Kingdom; 7Spondyloarthritis Association Norway (Spafo), Executive Dept, Oslo, Norway; 8Novartis Pharma AG, Immunology, Basel, Switzerland

**Background:** Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatological condition that can lead to chronic pain, structural damage, and disability. It often has a significant physical impact, causes psychological distress and can disrupt every aspect of a patient's life. While scientific research in axSpA has grown significantly, the patient perspective remains insufficiently explored and the disease burden continues to be underestimated. The International Map of Axial Spondyloarthritis (IMAS) is a research initiative of the impact and burden of axSpA from the patient perspective, identifying the unmet needs of axSpA patients and exploring impact beyond solely the physical symptoms.

**Objectives:** By producing an accessible global report on the results of IMAS, ASIF aim to provide its member organisations with much needed, robust evidence of the impact of the disease. The report will be used to raise awareness of the reality of axSpA, particularly amongst healthcare providers and policy makers; with the intention of incorporating the patient perspective much more into clinical practice and policy. The report also provides patients and their carers with a better insight into axSpA experiences around the world.

**Methods:** This research is a collaboration between the Axial Spondyloarthritis International Federation (ASIF), the University of Seville and Novartis Pharma AG. ASIF and its members have supported recruitment of survey participants from 27 countries across Europe, Asia, North, Central and South America, and Africa. In total, 5,557 axSpA patients completed the survey, providing a unique insight into how axSpA effects daily life. IMAS collected information through a comprehensive questionnaire of over 120 items on socio-demographics; behaviour; disease diagnosis and characteristics; comorbidities; psychological distress; healthcare utilization; treatments; disease activity; physical activity and limitations; working life; relationships; and the hopes and fears of patients. The ASIF IMAS sub-committee reviewed the global dataset results and agreed the unmet needs of axSpA patients and exploring impact beyond solely the physical symptoms.

**Results:** A mean of 2 physical comorbidities. The report, which will be translated into a number of languages, includes data on all topics that were collected by IMAS. ASIF presented the RMD community.

**Conclusion:** IMAS has shown the global profile of axSpA patients, quantifying and highlighting unmet needs, including unacceptable delay in diagnosis, high disease activity, work-related problems, and poor mental health in axSpA patients worldwide. The global report on IMAS will provide ASIF’s members with empirical evidence of the impact of axSpA on a person's life in order to support their awareness and advocacy work. IMAS was recognised when it won the EFPIA Connecting Healthcare 2021 Awards for its ability to bring patients and medical professionals together in an initiative aimed at improving the quality of life of people living with axSpA from around the world.

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is an ANCA-associated vasculitis characterized by asthma, ear-nose-throat (ENT) manifestations, peripheral hyper eosinophilia and systemic vasculitic involvement [1]. Increased serum levels of interleukin 5 (IL-5) have been observed in eosinophilic disorders, including EGPA, and a genome-wide association study identified the IL-5 region as a major EGPA-associated loci [2]. On these bases, an increasing interest is focusing on benralizumab (an IL-5 receptor antagonist approved for severe eosinophilic asthma at the dosage of 30mg every 4 weeks for 3 administrations, then every 8 weeks) as a new potential therapy for EGPA. Recently, results of a pilot study on 10 patients [3], a randomized double-blind trial is ongoing to assess the efficacy and safety of benralizumab at a higher dosage (30mg/4 weeks), as compared to mepolizumab (another IL-5 inhibitor approved for EGPA) in patients with EGPA (NCT04157348). In the meanwhile, isolated cases of patients with refractory EGPA, successfully treated with benralizumab, have been described in the literature [4,5].

Objectives: This study aimed to assess the efficacy and safety of benralizumab in a multicenter European cohort of patients.

Methods: The study included patients with EGPA treated with benralizumab at 28 centers belonging to the European EGPA Study Group. Efficacy and safety outcomes were assessed after 3, 6 and 12 months of treatment. Complete response (CR) was defined as no disease activity (Birmingham Vasculitis Activity Score [BVAS]=0) and a daily prednisone equivalent dose ≤4 mg. Respiratory outcomes included asthma, ENT manifestations and lung function.

Results: A cohort of 121 patients with EGPA was included. All were treated with benralizumab at the dosage approved for eosinophilic asthma (30mg every 4 weeks for 3 administrations, then every 8 weeks). The proportion of patients meeting the criteria for CR was 16% at 3 months, 26% at 6 months and 46% at 12 months of follow-up (Table 1). During follow-up, a drop in BVAS was recorded, from a median score of 3 (IQR 2-8) at baseline to 0 (0-2) at month 3 and 6 and to 0 (0-1) at month 12 (p<0.001 at all timepoints). Regarding respiratory outcomes, the proportion of patients reporting active asthma decreased from 94% at baseline to 39% at 3 months (p<0.001), and that of patients with refractory EGPA, successfully treated with benralizumab, have been described in the literature [4,5].

Conclusion: The results from this large European real-world study suggest that benralizumab, at the dosage approved for severe eosinophilic asthma, could be effective and safe to control respiratory EGPA manifestations and overall disease activity.

Keywords: Comorbidities, Vasculitis, Epidemiology

Z. Wallace1, 2, 3, X. Fu1, 2, S. Srivatsan1, 2, Z. Williams1, 2, C. Cook1, 2, J. Hanberg1, J. H. Stone1, 2, H. Choi1, 2, Y. Zhang1, 2, 3, Massachusetts General Hospital, Clinical Epidemiology Program, Morgan Institute, Boston, United States of America; 4Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Boston, United States of America; 5Harvard Medical School, Boston, United States of America; 6Massachusetts General Hospital, Department of Medicine, Boston, United States of America

Background: With improvements in the risks of relapse and mortality in ANCA-associated vasculitis (AAV), a better understanding of disease- and treatment-related complications in people with AAV is necessary to optimize outcomes and personalize care. Multimorbidity (MM) is a patient-centered approach to measuring complications and is defined as the presence of multiple chronic conditions[1]. MM is associated with risk of death and quality of life in other conditions. MM remains poorly understood in AAV[2].

Objectives: To determine the extent of multimorbidity in AAV.

Methods: We used the 2002-2019 Mass General Brigham (MGB) AAV cohort, an inception cohort of consecutive MPO- or PR3-ANCA+ incident AAV cases at a multi-center healthcare system in New England, USA. Comparators without systemic rheumatic disease were identified from MGB and matched to cases (10:1 ratio) by encounter date, age, sex, and race. We adapted a definition of MM as the presence of ≥ 2 of 37 chronic conditions, identified by use of ICD-9/10 codes ≥ twice over ≥ 30 days[1]. Manifestations of AAV (e.g., kidney disease) were excluded from the MM definition. Conditions present ≥ 6 months prior to the index date (date of treatment initiation) were excluded. First, we determined the proportion of cases and comparators with MM using the Aalen-Johansen method, accounting for the competing risks of death and loss to follow up. Second, we used Cox proportional hazard models to estimate the hazard ratio (HR) of MM in cases vs comparators and restricted mean survival time to estimate days free of MM in cases vs comparators. Third, we used latent class analysis to characterize clusters of morbidity among people with MM.

Results: There were 547 cases matched to 5,259 comparators (Table 1); mean age was 59 years and the majority were female (61%) and white (88%). Median follow-up in cases and comparators was 102 months and 66 months, respectively. MM was substantially more common in cases vs comparators and AAV cases had nearly an 8-fold higher risk of MM vs comparators (Figure 1, HR 7.6; 95% CI 6.6-8.7). Over 5 years, each case had an average of 707 fewer days with MM than comparators (963.4 vs 1670.5 days, p<0.001). At 1 year, two clusters of MM in AAV were identified with 76% and 24% captured in Clusters 1A and 1B, respectively. Hypertension and hyperlipidemia were common in Cluster 1A whereas Cluster 1B was characterized by painless conditions (e.g., headache, back pain, GERD). At 2 years, two clusters were identified with 82% and 18% captured in Clusters 2A and 2B. Cluster 2B was distinguished from 2A by a high burden of cardiovascular (CV) and pulmonary disease along with typical CV risk factors. At 5 years, three clusters were identified with 81%, 11%, and 8% captured in Cluster 5A, 5B, and 5C. Morbidities most common in Cluster 5A were hypertension, hyperlipidemia, and back pain, whereas back pain, hyperlipidemia, and cancer were common in Cluster 5C. Each cluster had the highest burden of certain glucocorticoid toxicities (e.g., osteoporosis, obesity, hypertension).

Conclusion: AAV is associated with a high burden of MM and carries a greater risk of MM than the general population. MM in AAV is characterized by clusters defined by morbidity burdens that vary over disease course and reflect a high impact of disease and its treatment. The development of interventions to prevent MM and minimize its impacts are needed. These findings identify an important burden of multimorbidity in AAV.
direction for future investigations to improve the care and outcomes of patients with AAV.

*Adjusted for age, sex, race

Background: Methotrexate (MTX) is the anchor and most prescribed disease-modifying anti-rheumatic drug (DMARD) for inflammatory rheumatic diseases (IRDs). This treatment can be very efficacious but can also have serious, life-threatening side effects. Adequate education and follow-up of patients/carers are therefore essential and dedicated rheumatology nurse consultations are an important part of this. However, many patients across European countries do not have access to these nurse consultations and there are no agreed and clearly defined standards of care on this topic[1].

Objectives: To develop points-to-consider (PtC), based on the best available evidence and experts’ opinion, on the nursing education of patients (or carers) with IRDs taking MTX.

Methods: A nominal group of adult and pediatric nurses (n=19) from 16 European countries, one rheumatologist, one pharmacist, and two patients, was established by the Portuguese Association of Health Professionals in Rheumatology (APPSReuma). The group convened virtually to agree on the protocol for developing the PtC, including the research questions for a scoping review and for a European survey to collect patients', nurses' and rheumatologists' experiences and perceptions about MTX education. The results from the scoping review and the surveys (presented elsewhere) were then used to devise and refine overarching principles and specific PtC statements through two virtual meetings and one online Delphi questionnaire. European Standard Operating Procedures for the development of recommendations/PtC were used[2].

Results: The group reached consensus on three overarching statements and five PtC (Table 1). Almost all PtC were based on available scientific evidence, and all obtained high levels of agreement (>8/10).

"So what now?" - living and planning life while co-existing with an RMD

**Keywords:** Pregnancy and reproduction, Patient information and education

A. Van Steensel - Boom\(^1\), H. Wintjes\(^1\), L. F. Perez-Garcia\(^1\), E. Röder\(^2\), H. T. Smeets\(^1\), L. J. Kranenburg - van Koppen\(^1\), R. Dohlain\(^1\).

**Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands**

**Background:** Inflammatory rheumatic diseases (RD) often affect women in their childbearing years. Despite extensive counselling, we noticed that in RD patients there is an increasing need of more information concerning pregnancy and parenting. This suggests that there are still unexplored information needs regarding pregnancy and parenting in women with RD. To our knowledge, there are no studies exploring these unidentified information needs.

**Objectives:** The aim of this study was to evaluate the unmet needs of women diagnosed with RD that received highly specialized care in a tertiary Reproductive Rheumatology center.

**Methods:** Women (≥18 years) diagnosed with RD (such as rheumatoid arthritis, spondyloarthritis, psoriatic arthritis or juvenile idiopathic arthritis), who were followed-up by the Reproductive Rheumatology team from the Department of Rheumatology of the Erasmus University Medical Center were invited to complete an online questionnaire. The questionnaire was divided into different sections: pre-conception, pregnancy, post-partum, parenthood and support received/needed by informal caregivers such as family, friends, neighbors etc. The questions were related to the support and information provided by the team, problems experienced, unmet needs and the patient's general characteristics.

The patients were offered the possibility to give additional remarks (free text). Descriptive statistics were used to represent the outcomes.

**Results:** From a total of 181 women who were invited to fill out the online questionnaire, 95 women (52%) completed the questionnaire. It concerns women in the age between 22 and 45 (mean of 33yrs), with a RD, who received their first (n=56), second, or third baby between 2019 and 2021. Overall, the care of the rheumatology team was highly rated by the women (satisfaction score of 88 (scale 0-100) for the rheumatologist and 92 (scale 0-100) for the rheumatology nurses) (Table 1).

18 Women (19%) experienced any problem during the period around their delivery and/or post-partum. Six women indicated that their problems persisted. A lack of mental health support regarding disease coping (4 out 6) was the most frequently mentioned persisting problem. In addition 2 out of 6 women indicated a need for additional communication with the rheumatology team regarding information, indication and adjustment of their medication between the regular outpatient clinic visits.

**Conclusion:** The care provided by the Reproductive Rheumatology team was highly rated by the majority of the women. Nevertheless, the following unmet needs were identified: a) mental health support regarding disease coping and b) the opportunity to communicate about medication beyond the regular outpatient visits. Despite a very high satisfaction rate of patients treated by the Reproductive Rheumatology team some of them experience health problems that remain unsolved. This will help us to improve our patient-centered care as we aim at matching our care as appropriately as possible to patient needs. In the future, we want to identify the characteristics of the women who need more information, mental support and, more contact between the regular consultations, so we can help them solve their problems and fill their needs.

**HEAD-TO-HEAD COMPARISON OF TLL-018 AND TOFACITINIB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: INTERIM RESULTS FROM A PHASE IIa STUDY**

**Topic:** 16. Rheumatoid arthritis - non biologic treated small and medium molecules

**Keywords:** Rheumatoid arthritis, Clinical Trials, Targeted biologic synthetic drugs

X. Zeng, C. Wu, J. Hu, S. Liu, Z. Jiang, J. Li, X. Wang, J. Liu, C. Liang, G. Yang. 1Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China; 2Peking University People’s Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China; 3First Affiliated Hospital of Zhengzhou University, School of Medicine, Department of Rheumatology and Clinical Immunology, Zhengzhou, China; 4First Affiliated Hospital of Jilin University, Department of Rheumatology and Clinical Immunology, Changchun, China; 5Zhuozhou Central Hospital, Department of Rheumatology and Clinical Immunology, Zhuzhou, China; 6Second Hospital of Shanxi Medical University, Department of Rheumatology and Clinical Immunology, Taiyuan, Shanxi, China; 7Jiujing No. 1 People’s Hospital, Department of Rheumatology and Clinical Immunology, Jiujing, China; 8highlighttpharma, N/A, hangzhou, China

**Background:** None of the currently approved treatments for rheumatoid arthritis (RA) can achieve ACR50 in >50% of the patients, and ~20% of the RA patients are considered “difficult to treat” failing ≥2 targeted therapies. TLL-018 is a highly selective dual JAK1/2 inhibitor that shows potent in vitro and in vivo activity in RA patients.

**Objectives:** Compare efficacy of TLL-018 with tofacitinib in RA patients.

**Methods:** 101 patients with moderate-to-severe active RA who had inadequate response or were intolerant to methotrexate were randomized (1:1:1:1 ratio) to receive twice-daily oral TLL-018 10 mg, 20 mg, 30 mg or tofacitinib 5 mg. After 12 weeks of treatment, patients who achieved ACR50 at the same treatment, and those who didn’t change treatment as follows: 20mg on tofacitinib and TLL-018 10mg to change to TLL-018 20mg; patients on 20mg and 30mg change to continue 30mg TLL-018. The Primary endpoint is the proportion of patients achieving ACR50 at Week 12. Secondary endpoints include the proportion of patients achieving DAS28-CRP <2.6, ACR20, ACR70 at all scheduled time points, ACR50 at scheduled time points exclude week 12, CDAI and other parameters at 12 weeks.

**Results:** 101 patients were randomized, ~50% of them also had prior bDMARDs and ~30% had prior JAK inhibitors. Demographics and baseline disease characteristics were balanced across treatment arms. At week 12, ACR50 response rates in TLL-018 treated groups [10mg, 20mg and 30mg, 48% (95% CI, 28.4 - 67.5), 65.4% (95% CI, 47.10 - 83.67), 72.0% (95% CI, 54.40 - 89.60), respectively] were higher than that for tofacitinib [41.7% (21.94 - 61.39)]. TLL-018 20 and 30mg were statistically superior to tofacitinib (p<0.05). Proportions of patients achieving clinical remission (DAS28-CRP<2.6) at week 12 were 39.1%, 34.8%, 54.5% and 17.4% at week 12 for the 10, 20, 30mg TLL-018 and tofacitinib, respectively. TLL-018 20 and 30mg demonstrated high efficacy in patients who had prior bDMARDs, achieving ACR50 rates of >66%. TLL-018 20mg dramatically improved responses in patients who didn’t achieve ACR50 on tofacitinib at week 12. The most frequently reported treatment-emergent AEs were hyperlipidemia and respiratory infection in TLL-018 or tofacitinib-treated patients. There was one case of malignancy in tofacitinib treatment group. No death, venous thromboembolism or major adverse cardiovascular event was observed in the study. (The data cut-off time was December 19th).

**Conclusion:** TLL-018 20 and 30mg demonstrated superior efficacy over tofacitinib in RA patients, suggesting that inhibition of TYK2, in addition to JAK1, enhances efficacy. TLL-018 was well tolerated with most AEs being Grade 1 or 2 as expected from this class of compounds. No unexpected safety concerns were observed in the study. TLL-018 20 and/or 30mg BiD warrants further studies in “difficult to treat” RA patients.

**Background:** Despite availability of effective therapies for gout, a small proportion of patients suffer from refractory gout and/or are intolerant to standard therapies [1]. In these patients, the inability to maintain serum uric acid (sUA) levels < 6 mg/dL may lead to severe clinical manifestations for which uricase-based therapies can be highly effective, though also immunogenic. SEL-212 is a once-monthly, novel 2-component, sequential uricase-based infusion therapy being investigated in patients with refractory gout. SEL-212 consists of an infusion of tolerogenic nanoparticles containing rapamycin (SEL-110) followed by pegadsele (SEL-037). The intent of this drug combination is to inhibit the formation of anti-uricase antibodies while maintaining immunomodulating effects [2].

**Objectives:** DISSOLVE I and II (D1 and D2, respectively) evaluated the safety and efficacy of SEL-212 in adults with refractory gout.

**Methods:** D1 (US Study, 12 months) and D2 (Global Study, 6 months), were placebo-controlled, double-blind, randomized clinical trials that evaluated two dose levels of SEL-10 (0.15mg/kg [high-dose] or 0.01mg/kg [low-dose]) prior to SEL-037 (0.2mg/kg) infusion in adults (18-80 yrs). Participants with a history of symptomatic gout were enrolled if they had ≥3 gout flares within 18 months prior to screening or ≥1 tophus or a current diagnosis of gouty arthritis, failed to normalize sUA and control symptoms with any xanthine oxidase inhibitor, and were not previously exposed to a uricase-based therapy. Participants were randomized 1:1:1 between the two doses of SEL-212 and placebo administered intravenously every 28 days for 6 treatments. D1 participants were continued in a 6-month blinded extension phase under the initial treatment conditions (Fig. 1). The primary end-point was defined as the percentage of participants who achieved and maintained sUA < 6 mg/dL for ≥ 80% of the sixth 28-day treatment period (TP6) in the active treatment groups versus placebo (response rate). Safety and tolerability were assessed through monitoring of adverse events (AEs) and laboratory testing.

**Results:** A total of 265 participants (D1, n=112 [96% male, 66% ≥ 50 years]; D2, n=153 [97% male, 72% ≥ 50 years]) were randomized into the three treatment arms. Response rates in all treatment groups were significantly different from placebo (p ≤ 0.0015), with 56% and 47% of participants responding in the high-dose group and 48% and 41% in the low-dose group for D1 and D2, respectively (Table 1). The response rates in patients aged ≥ 50 years were 65% and 48% in the high-dose groups and 47% and 45% in the low-dose groups for D1 and D2, respectively (p ≤ 0.0044 vs placebo). Across all participants in the treatment groups, median sUA levels were reduced by ~96% and ~75% from baseline at TP6 for D1 and D2, respectively (p<0.001 vs placebo). The safety profile of SEL-212 was favorable, with 3.4% and 4.5% of participants experiencing infusion reactions in the high and low-dose groups, respectively. Reports of gout flares were comparable between treatment groups and placebo. Six participants (3.4%) in the pooled active treatment groups experienced treatment-related serious AEs (n=4 anaphylaxis, n=2 gout flares).

**Conclusion:** In the DISSOLVE trials, once-monthly treatment with SEL-212 demonstrated statistically significant response rates and reductions in sUA versus placebo. The safety profile of SEL-212 was consistent with that of uricase therapies. Targeted immunomodulation with SEL-212 has the potential to provide a patient-based treatment option for patients with gout refractory to conventional therapies without the need for traditional immunosuppressants.

### Acknowledgments:

We would like to acknowledge all participants, investigators, and study personnel involved in the DISSOLVE phase III clinical studies. Writing support provided by Michel Wilson, PhD, of Swedish Orphan Biopharmaceuticals.

### Disclosure of Interests:

Herbert S.B. Baraf Consultant of: Horizon Pharmaceuticals, Clinical Research Institute, Newcastle, United Kingdom, Employee of: Horizon Therapeutics plc, Research and Development, Rockville, MD, Horizon Therapeutics plc, Biometrics, Rockville, MD, Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States of America, Newcastle University, Translational and Clinical Research Institute, Newcastle, United Kingdom, University of Kansas, Department of Medicine, Kansas City, United States of America, University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy

### Background:

Sjögren’s is a systemic autoimmune disease associated with marked morbidity and poor health-related quality of life, generally driven by the cardinal symptoms of the disease: dryness, pain, and fatigue (assessed via EULAR Sjögren’s Syndrome Patient Reported Index [ESSPRI]). The population of Sjögren’s patients with unacceptable systemic burden independent of systemic involvement represents a substantial proportion of Sjögren’s patients who have largely been excluded from recent trials despite significant disease burden and overall unacceptable health status.

### Objectives:

The objective of this study (NCT04129164) was to evaluate the efficacy and safety of dazodalibep (DAZ), a non-antibody biologic antagonist of CD40L, in adult Sjögren’s subjects with an unacceptable symptom burden but limited systemic organ involvement.

### Methods:

This was a randomized, double-blind, placebo-controlled, crossover study of DAZ in adult Sjögren’s subjects with an unacceptable symptom burden but limited systemic organ involvement, as defined by having an ESSPRI score ≥ 5 and EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) score ≤ 5. Eligible subjects were randomized 1:1 to receive intravenous DAZ 1500 mg or placebo (PBO) Q2W x 3 doses, then Q4W x 4 additional doses. Starting on Day 169, subjects initially randomized to DAZ received PBO Q4W x 5 doses and subjects randomized to PBO received DAZ Q4W x 5 doses and were then followed for 12 weeks. The primary endpoint was the change from baseline in ESSPRI at Day 169. Safety was also evaluated.

### Results:

A total of 109 subjects were randomized and received ≥1 dose of study medication (DAZ, N=54; PBO, N=55). The mean (standard deviation) age of subjects was 49.9 (12.1) years and most were female (94.5%). The change from baseline to Day 169 in ESSPRI (LS mean ± SE) was −1.80 ± 0.23 in the DAZ group compared to −0.33 ± 0.23 in the PBO group, a difference of −1.02 ± 0.20 (p = 0.002). The change from baseline to Day 169 in each of the three domains of ESSPRI was significantly greater in the DAZ group compared to PBO (dryness: p = 0.0066; fatigue: p = 0.0022; pain: p = 0.0010). At Day 169, a significantly larger proportion of DAZ-treated subjects achieved a ≥1 point or ≥15% reduction in ESSPRI relative to PBO (66.7% vs 37.2%; p = 0.008). The improvement from baseline to day 169 in the Functional Assessment of Chronic Illness Therapy-Fatigue score (LS mean ± SE) was significantly greater in the DAZ group (8.1 ± 1.4) relative to PBO (2.8 ± 1.4; p = 0.0095). Greater numerical improvement in DAZ-treated subjects was observed for the Ocular Surface Disease Index (−14.0 ± 3.0 vs −8.5 ± 2.9; p = 0.1936) and Patient’s Global Impression of Severity (−0.6 ± 0.1 vs −0.4 ± 0.1; p = 0.1781) at Day 169 relative to PBO. Through Day 169, a total of 75 subjects reported an adverse event (AE; DAZ: 37 [68.5%]; PBO: 38 [69.1%]) and the majority were mild/moderate in severity. The most frequently reported AEs occurring in ≥5% of DAZ-treated subjects were COVID-19, nasopharyngitis, anemia, and diarrhea. There were three serious AEs in the DAZ group (pneumonia, influenza, post-acute COVID-19 syndrome, and gammopathy) and one in the PBO group (neutropenia). All serious AEs were deemed by investigators to be unrelated to study medication. One subject in the DAZ group discontinued the study due to an AE compared to two subjects in the PBO group.

### Conclusion:

In this study of Sjögren’s subjects with an unacceptable symptom burden but limited systemic organ involvement, the primary endpoint was achieved. DAZ-treated subjects experienced a statistically significant and clinically meaningful improvement in the key subjective symptoms of Sjögren’s relative to PBO as measured by the improvement in ESSPRI and associated responder analysis. DAZ therapy was generally safe and well tolerated. Larger trials of DAZ therapy for Sjögren’s are warranted to further explore its safety profile and confirm its clinical efficacy.
Methods: Adults with SLE were enrolled if they had clinical synovitis and/or ultrasound (US) tenosynovitis and/or positive power Doppler (PD) in ≥1 joint despite stable background therapies including a maximum 10mg prednisolone. Patients were randomized to 1000mg rituximab (RxNath, RTX) or placebo, on days 1 and 15. Blinded infusions were preceded by 100mg methylprednisolone. Outcome measures, including BILAG-2004, SLEDAI-2K, The Lupus Arthritis and Musculoskeletal Disease Activity Score (LAMDA), tender and swollen joint counts, physician global, patient MSK pain and global VAS, patient reported outcome measures, BICLA, SRI-4 were evaluated monthly. US of both hands and wrists was performed at 0 and 16 weeks. The primary endpoint was overall feasibility. The key efficacy timepoint was 16 weeks. After 16 weeks placebo patients with active disease were eligible for rescue rituximab with repeat follow up timepoints. US and LAMDA were validated against BILAG-MSK models adjusted for baseline.

Results: Of 35 patients invited, 35 attended screened and consented, 6 were ineligible and 2 withdrew prior to baseline. Of 27 patients randomised, 12 were randomised to placebo, of whom 9 received rescue therapy. All completed ≥16 weeks follow up and 25/27 completed all follow ups visits. 24/27 (89%) patients were female, 17/27 (63%) were white, 7/27 (26%) were South Asian. Mean (SD) age was 49.7 (12.7) and disease duration 6.7 (9.0). BILAG MSK domain at baseline was scored A in 7/27 (26%), E in 16/27 (59%) and C in 22/7 (74%). B scores were also present in mucocutaneous in 22/27 patients and constitutional in 1/27. At 16 weeks, BILAG-MSK response was significantly associated with improvement in LAMDA (OR 0.49, 95% CI 0.28, 0.85) and US joints grey-scale (OR 0.56, 95% CI 0.28, 0.85) and US tendons PD (OR 0.33, 95% CI 0.04, 1.01). No substantive difference between arms in efficacy variables was found at week 16. Unexpectedly, results suggested greater improvement in some outcomes in patients who received methylprednisolone and placebo compared to methylprednisolone and rituximab. These measures then converged by 16 weeks (Figure 1), Pooling all rituximab cycles administered (as initial therapy or as rescue) showed improvement in PGA, Physician MSK VAS, joint and joint and PC S scores and LAMDA, but not Global BILAG, SLEDAI-2K, tender or swollen joint counts or and LupusQoL domain or patient VAS at week 16.

Conclusion: design dedicated to MSK SLE was feasible. The new outcome measures of LAMDA and MSK US were validated against BILAG-MSK, these outcomes should be included in a definitive trial. While not powered to measure efficacy, exploratory analysis suggests unexpectedly greater improvement in patients who received methylprednisolone with placebo compared to methylprednisolone and rituximab at early time points after infusion, later converging by week 16. Meanwhile there was an overall improvement in LAMDA and US at 16 weeks across all RTX cycles administered. In a definitive trial, early assessment of efficacy should be retained, but longer observation without retreatment may be required to assess the efficacy of RTX in this population.

Keywords: Vaccination/Immunization, Safety, COVID
Methods: A Randomized control trial involving 1,417 responders that received a fourth dose, only two (1 RMD and 1 HC) reported AEs (0.1%). After the third dose were <3%. In the 1417 responders that received a fourth dose, only two (1 RMD and 1 HC) reported AEs (0.1%).

**Conclusion:** This study provides the first detailed exploration of the SARS-CoV-2 vaccine spectrum in young people with RMDs and nrADs compared to HC and highlights important similarities and differences between disease groups. In fact, despite being less exposed to GC and IS, nr-AD reported a higher number of SARS-CoV-2 infections, no difference in the clinical picture of pre-vaccine infections vs B-INFs and a more pronounced burden of post-vaccine mild AEs after earlier doses compared to RMD. These findings may help indicate that in young people the type of disease rather than IS therapy may be more important to influence the vaccine safety and the features of B-INFs.

§ Primary analysis with multiple imputation of estimates, n=60. *ANOVA; gender, age and baseline value as covariates. **Bootstrap CI with 10000 replications. HIIT: High-intensity Interval Training, NRS: Numeric rating scale, VO2peak: Peak oxygen uptake

Background: Cardiorespiratory fitness (CRF) is recognized as an independent risk factor for cardiovascular disease (CVD) and improved CRF associates with lower risk of CVD [1]. High-intensity interval training (HIIT) is an effective mode of exercise to increase CRF. However, HIIT is seldom utilized in physiotherapy primary care in the context of inflammatory joint disease (IJD), and the sustainable effects of HIIT have been questioned [2].

Objectives: To investigate short- and long-term effects of twelve weeks of supervised HIIT in physiotherapy primary care on CRF, pain and fatigue in patients with IJD.

Methods: In this assessor-blinded randomized controlled trial (NCT04922840), 60 patients were allocated to a control group (n=30) or a HIIT group (n=30) that received a 12-week intervention in physiotherapy primary care including two weekly, 40-minute HIIT sessions at 90-95% peak heart rate and one non-supervised exercise session at moderate intensity. Patients were assessed at baseline, 3 and 6 months. Primary outcome was change in CRF from baseline to 3 months, measured as peak oxygen uptake (VO2peak) by a cardiopulmonary exercise test. Secondary outcomes were pain and fatigue (Numeric Rating Scale 0-10, 0= no pain/fatigue). Group differences were assessed by pre-specified intention-to-treat analysis of covariance with multiple imputation of missing data for the primary outcome. Per-protocol analysis was applied for the primary outcome.

Results: Median age was 59 years (IQR 52-63) and 34 participants (57%) were female. A total of 55 patients completed assessment at 3 and 6 months for the primary outcome; 27 in the HIIT group and 28 in the control group. Following the primary outcome, HIIT had significant benefits in VO2peak at 3 months, measured as peak oxygen uptake (VO2peak) by a cardiopulmonary exercise test. Secondary outcomes were pain and fatigue (Numeric Rating Scale 0-10, 0= no pain/fatigue). Group differences were assessed by pre-specified intention-to-treat analysis of covariance with multiple imputation of missing data for the primary outcome. Per-protocol analysis was applied for the primary outcome.

Conclusion: VO2peak increased in patients with IJD following 12 weeks of supervised HIIT and the effect was maintained at 6 months. The beneficial response on CRF was not accompanied by changes in pain or fatigue, and the intervention could be regarded as feasible in physiotherapy primary care. HIIT is a viable physiotherapy intervention with sustainable effects in patients with IJD.

Neutrophil dysregulation in systemic lupus erythematosus

Keywords: Autoantibodies, Systemic lupus erythematosus, Biomarkers

H. W. Park1, D. S. Kim2, Y. Park2, M. L. Cho2, S. K. Kwok3, 4, Seoul St. Mary’s Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2The Catholic University of Korea, Department of Biometric Medicine & Health Sciences, Seoul, Korea, Rep. of (South Korea); 3Catholic Research Institute of Medical Science, The Rheumatism Research Center, Seoul, Korea, Rep. of (South Korea)

Neutrophil dysfunction and dysregulation of cytokines and chemokines is considered as an integral part of immune dysregulation in systemic lupus erythematosus (SLE). The TRIM21 gene is implicated in systemic lupus erythematosus (SLE), Sjögren’s and APS. It has been proposed that TRIM21 dysfunction in SLE may be associated with a dysregulated interferon response.

Objectives: To investigate the effects of TRIM21 dysfunction and its potential role in the occurrence of SLE, Sjögren’s and APS.

Methods: The study involved the use of MRL/1pr mice, a lupus mouse model. TRIM21 knockout mice were compared to wild-type control mice. The effects of TRIM21 dysfunction on immune cell activation and cytokine production were assessed.

Results: The results showed that TRIM21 knockout mice had increased immune cell activation and cytokine production compared to wild-type control mice. The results also suggested that TRIM21 dysfunction may be a key factor in the development of SLE and Sjögren’s syndrome.

Conclusion: This study provides evidence for the role of TRIM21 dysfunction in the pathogenesis of SLE and Sjögren’s syndrome. Further research is needed to elucidate the underlying mechanisms and to develop targeted therapeutic strategies.

Neutrophil dysregulation in systemic lupus erythematosus

Keywords: Autoantibodies, Systemic lupus erythematosus, Biomarkers

H. W. Park1, D. S. Kim2, Y. Park2, M. L. Cho2, S. K. Kwok3, 4, Seoul St. Mary’s Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2The Catholic University of Korea, Department of Biometric Medicine & Health Sciences, Seoul, Korea, Rep. of (South Korea); 3Catholic Research Institute of Medical Science, The Rheumatism Research Center, Seoul, Korea, Rep. of (South Korea)

Background: Cardiorespiratory fitness (CRF) is recognized as an independent risk factor for cardiovascular disease (CVD) and improved CRF associates with lower risk of CVD [1]. High-intensity interval training (HIIT) is an effective mode of exercise to increase CRF. However, HIIT is seldom utilized in physiotherapy primary care in the context of inflammatory joint disease (IJD), and the sustainable effects of HIIT have been questioned [2].

Objectives: To investigate short- and long-term effects of twelve weeks of supervised HIIT in physiotherapy primary care on CRF, pain and fatigue in patients with IJD.

Methods: In this assessor-blinded randomized controlled trial (NCT04922840), 60 patients were allocated to a control group (n=30) or a HIIT group (n=30) that received a 12-week intervention in physiotherapy primary care including two weekly, 40-minute HIIT sessions at 90-95% peak heart rate and one non-supervised exercise session at moderate intensity. Patients were assessed at baseline, 3 and 6 months. Primary outcome was change in CRF from baseline to 3 months, measured as peak oxygen uptake (VO2peak) by a cardiopulmonary exercise test. Secondary outcomes were pain and fatigue (Numeric Rating Scale 0-10, 0= no pain/fatigue). Group differences were assessed by pre-specified intention-to-treat analysis of covariance with multiple imputation of missing data for the primary outcome. Per-protocol analysis was applied for the primary outcome.

Results: Median age was 59 years (IQR 52-63) and 34 participants (57%) were female. A total of 55 patients completed assessment at 3 and 6 months for the primary outcome; 27 in the HIIT group and 28 in the control group. Following the primary outcome, HIIT had significant benefits in VO2peak at 3 months, measured as peak oxygen uptake (VO2peak) by a cardiopulmonary exercise test. Secondary outcomes were pain and fatigue (Numeric Rating Scale 0-10, 0= no pain/fatigue). Group differences were assessed by pre-specified intention-to-treat analysis of covariance with multiple imputation of missing data for the primary outcome. Per-protocol analysis was applied for the primary outcome.

Conclusion: VO2peak increased in patients with IJD following 12 weeks of supervised HIIT and the effect was maintained at 6 months. The beneficial response on CRF was not accompanied by changes in pain or fatigue, and the intervention could be regarded as feasible in physiotherapy primary care. HIIT is a viable physiotherapy intervention with sustainable effects in patients with IJD.

EULAR Recommendations

Table 1. Recommendations for the use of imaging in large vessel vasculitis in clinical practice

**Overarching principles**

A. In patients with suspected GCA, an early imaging test is recommended to support the clinical diagnosis of GCA, assuming high expertise and prompt availability of the imaging technique. Imaging should not delay initiation of treatment.

B. Imaging examination should be done by a trained specialist using appropriate equipment, standardized operational procedures and settings.

C. In patients in whom there is a high clinical suspicion of GCA and a positive imaging result, the diagnosis of GCA may be made without an additional test (biopsy or further imaging).

In patients with a low clinical probability and a negative imaging result, the diagnosis of GCA can be considered unlikely in all other situations (including the case of an inconclusive imaging result), additional efforts towards a diagnosis are necessary.

**Recommendations**

1. Ultrasound of temporal and axillary arteries should be considered as the first imaging modality to investigate mural inflammatory changes in patients with suspected GCA.

2. High resolution MRI or FDG-PET can be used as alternatives to ultrasound for the assessment of cranial arteries in patients with suspected GCA.

3. FDG-PET, alternatively MRI or CT, can be used for the detection of mural inflammation or luminal changes of extracranial arteries in patients with suspected GCA.

4. In patients with suspected TAK, MRI to investigate mural inflammation or luminal changes should be used as the first imaging test to make a diagnosis of TAK.

5. FDG-PET, CT or ultrasound may be used as alternative imaging modalities in patients with suspected TAK. Ultrasound is of limited value for assessment of the thoracic aorta.

6. Conventional angiography is not recommended for the diagnosis of GCA or TAK as it has been superseded by the previously mentioned imaging modalities.

7. In case of a suspected relapse of GCA or TAK, particularly when laboratory markers of disease activity are unreliable or unobtainable, FDG-PET or alternatively MRI may be considered for the assessment of vessel abnormalities. Imaging is not routinely recommended for patients in clinical and biochemical remission.

8. In patients with GCA or TAK, MRI, CTA or ultrasound of extracranial vessels may be used for long-term monitoring of structural damage, particularly sites of preceding vascular inflammation. The frequency of screening as well as the imaging method applied should be decided on an individual basis.

Adaptive immunity (T cells and B cells) in rheumatic diseases

Keywords: Rheumatoid arthritis, Animal Models, Disease-modifying Drugs (DMARDs)

K. Suga1, A. Suto1, S. Tanaka1, T. Kageyama1, J. Ishikawa1, A. Iwata1, S. Funuta1, K. Ikeeda1, K. Suzuki1, H. Nakajima1, 1Chiba University Department of Allergy and Clinical Immunology, Chiba, Japan

Background: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease characterized by auto-reactive T cell activity and the presence of autoantibodies [1]. Although methotrexate (MTX) is well-recognized as the “anchor drug” for the treatment of RA [2], its precise mechanism, except antifolate activity, is largely unknown.

Objectives: The aim of this study was to elucidate a molecular target of MTX and to determine the role of the target molecule in CD4+ T cells.

Methods: We examined comprehensive gene expression profiles of CD4+ T cells by DNA microarray before and after MTX treatment in RA patients. We also examined the role of TP63, a possible target of MTX, in human/mouse CD4+ T cells.

Results: TP63 was the most significantly downregulated gene in CD4+ T cells of RA patients after MTX treatment. TAp63, an isoform of TP63, was highly expressed in human/mouse Th17 cells but rarely expressed in Treg cells, and MTX suppressed its expression in vitro. By comparing the comprehensive gene expression profiles between human Th17 cells overexpressing TAp63x and those with TP63 knockdown, Foxp3 was identified as one of the downregulated genes with TAp63 knockdown. Reporter assays revealed that TAp63x suppressed the activation of the Foxp3 CNS2 enhancer. TAp63 knockdown in induced-Tregs promoted Foxp3 CNS2 hypomethylation and enhanced suppressive activity of induced-Tregs. Moreover, the severity of arthritis was ameliorated in SCID mice transferred with SKG CD4+ T cells with TP63 knockdown compared to those with non-silencing.

Conclusion: TAp63 suppresses Foxp3 expression and exacerbates autoimmune arthritis.

Background: Intestinal dysbiosis has been associated with the development and progression of rheumatoid arthritis (RA) [1]. Microbiota-derived metabolites such as short chain fatty acids (SCFA) gain attention in research of inflammatory diseases as promising targets for new therapeutics. Previous work in our lab showed the potent preventive effect of SCFA on the onset of inflammatory arthritis (2, 3). Although effective potential therapeutic approaches are arising, their underlying mechanisms remain elusive [4-6]. Cellular derived histamine is considered as pro-inflammatory mediator to induce acute allergic symptoms and to maintain chronicity. Interestingly, we identified an increased pro-resolving pathway of SCFA-induced histamine secretion by the gut microbiota. In contrast to the effective, direct Treg inducing 2-week delayed resolving effects of the SCFA propionate, we report on an indirect but ten times faster histamine-mediated pro-resolving mechanism via cells of the nervous system.

Objectives: To understand the rapid pro-resolving effects of microbiota-derived histamine on synovial inflammation.

Methods: We used 16s RNA sequencing, HPLC size chromatography exclusion, FMT and meta-transcriptomics to assess proprio-antagonized changes in microbiota composition and the secreted metabolite profile. Mice with collagen- or serum-induced arthritis (CIA/SIA) were treated orally, i.p. or intrathecally with histamine or specific receptor agonists. Cellular changes in spleen, lymph nodes and joints were assessed by Cytek spectral flow cytometry, inflammatory infiltration and bone erosion were analyzed by histology and μCT. We analyzed differences in CNS and PNS via RNAseq of the spinal cord and peripheral nerves. Effects on vessel leakage and cell infiltration in the inflamed joints were assessed via lightsheet microscopy and in vivo PET-CT.

Results: Here, we show that therapeutic treatment of CIA mice with the SCFA propionate starting from peak of disease (30 dp) strongly induced resolution of synovial inflammation after 14 days of treatment. We demonstrate that oral propionate-treatment causes beneficial changes in the microbiota composition and thereby alters the secreted metabolite profile. These metabolites are able to induce rapid resolution of inflammation already after 2 days. By untargeted metabolomics we were able to identify histamine as highly potent metabolite that is increased upon propionate treatment. Oral treatment of CIA mice with histamine or a histamine 3 receptor (H3R) agonist significantly improved clinical symptoms. H3R is mainly expressed on cells of the nervous system. Upon oral H3R treatment we found alterations in activation marker expression in the spinal cord. We further were able to identify changes in the composition and activation of spinal cord (CNS) and the N. plantaris (PNS) of arthritic mice induced by H3R agonist treatment through RNAseq. Moreover, lightsheet microscopy and in vivo PET-CT scans revealed alterations in vessel leakage and cell infiltration in the inflamed joints.

Conclusion: In summary, these data show that the SCFA propionate effectively regulates ongoing inflammation by promoting histamine secretion of the gut microbiota and subsequent H3R-mediated neuronal effector functions that drive the fast resolution of synovial inflammation.

This page contains scientific research about the role of malondialdehyde (MDA) and malonaldehyde (MAA) in autoimmune diseases, particularly rheumatoid arthritis (RA). The research explores the specificity and reactivity patterns of anti-MDA and anti-MAA antibodies in RA patients and healthy controls. The study uses a co-culture model to determine the presence of FOXP3+ regulatory T cells, finding that dysfunctional lymph node stromal cells (LNSCs) from RA patients may be involved in the breaking of tolerance observed in autoimmune diseases like RA.

The research by V. Malmström and colleagues investigates the molecular structures recognized by anti-MDA and anti-MAA antibodies, proposing that distinct subsets of these antibodies are present, which may play a role in the breaking of tolerance observed in autoimmune diseases like rheumatoid arthritis (RA).

The conclusions drawn from the study emphasize the importance of understanding the role of MDA and MAA in autoimmune responses and the potential for targeting these pathways in the development of therapeutic strategies for autoimmune diseases.

clonal expansion in muscle tissue is significantly correlated with increased CK levels (p=0.03), and tends to correlate with decreased muscle strength (p=0.08).

**Conclusion:** Network analysis of clones in muscle of IIM patients shows shared clusters of sequences across patients. Muscle-restricted TRC5 clones show specific structural features in their T cell receptor, and clonal TCR expansion in muscle tissue is associated with disease activity. These findings indicate that specific clonal T cell responses in muscle tissue act as key players in the pathogenesis of IIM.

**AUTOACTIVE B CELLS IN RHEUMATOID ARTHRITIS ARE RECENTLY ACTIVATED AND SHOW LARGE EXPANSIONS OF CXCR3+ ANTIBODY-SECRETING CELLS**

**Keywords:** Adaptive immunity, Cell biology, Rheumatoid arthritis

S. Reijn, J. Kwekkeboom, N. Blomberg, J. Suurmond, D. Van der Woude, R. Toes, H. U. Scherer, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands

**Background:** Many autoimmune diseases (AIDs) are characterized by aberrant, autoreactive B cell responses and autoantibody production. Rheumatoid arthritis (RA) is a common AID in which autoantibodies recognizing post-translational modifications (PTMs), collectively called anti-modified protein antibodies (AMPA), are intimately associated with disease pathogenesis. Previously, we observed that memory B cells (mBC) against one of these PTM-antigens, citrulline, are highly activated. This phenotype persists for years in patients with established disease [1]. The evolution, dynamics and more detailed phenotypic characteristics of the PTM-directed B cell compartment are still ill defined, however, partly owing to challenges linked to the visualization of such cells in human samples due to the limitations of conventional flow cytometry. Here, we visualized the autoreactive B cell response against three different PTM antigens (citrulline, homocitrulline, acetylsine) by spectral flow cytometry, allowing us to address cross-reactivity on the B cell level and to perform deep phenotypic profiling of individual B cell compartments.

**Objectives:** To develop a detailed understanding of the autoreactive B cell response against PTM-antigens in RA with the aim to elucidate features associated with their cross-reactivity, state of activation in the disease context, and its remarkable persistence for years without signs of exhaustion or decay.

**Methods:** We developed a spectral flow cytometry staining approach using differentially labelled streptavidin molecules coupled to individual PTM-antigens. B cells reactive to each antigen were identified together in individual samples by double staining for each antigen, while at the same time excluding cells reactive to either antigen or lysine control peptides. This combinatorial staining was further extended by the concomitant visualization of tetanus-toxoid specific B cells and expression levels of various activation and homing markers, and applied to peripheral blood samples of patients with established RA. Importantly, we performed intracellular stainings, allowing us to additionally enumerate and characterize circulating plasmablasts and plasmacells.

**Results:** We successfully visualized autoreactive B cells directed against different PTM-antigens and their subset distribution in individual patient samples. We observed extensive cross-reactivity against all three PTM antigens with citrulline as dominant antigen. Unsupervised clustering revealed several memory B cell populations, with most autoreactive B cells populating the most recently expanded compartment. Anti-citrulline toxoid B cells clustered with a different, more resting mBC subset.

**Conclusion:** Our results identify citrulline as the most prominent antigen recognized by AMPA-expressing B cells. The study highlights the recent and prominent activation state of PTM-reactive mBC and their continuous differentiation towards ASC. Such ASC may home towards CXCR3 ligands known to be abundant in the synovial compartment. This degree of mBC activation was also found in patients with low clinical disease activity scores, indicating that conventional therapeutic interventions may suppress inflammation but fail to silence the most disease-specific autoreactive B cell response in RA. Targeting this compartment may therefore be relevant for future therapeutic interventions aiming at the induction of tolerance and/or permanent cure. Finally, this combinatorial staining approach presented will be a valuable tool to delineate the development of PTM-directed autoimmunity in the pre-disease phase as well as its state of activation in phases of sustained drug-free remission and/or during teleologic interventions.

**Background:** A significant unmet medical need remains in the treatment of relapsed and/or refractory B cell-driven autoimmune diseases, including lupus nephritis (LN). The presence of autoantibodies is a hallmark of such diseases and implicates dysregulated B cell function in their pathogenesis. The central role of B cells in these diseases is also supported by the presence of B cells in diseased tissues and the efficacious responses reported with biologic therapies that target B cells. KVV-101 is an autologous CD19 CAR-T cell therapy that depletes pathogenic B cells. Importantly, the CD19 CAR utilized in KVV-101 was previously tested in B-cell lymphoma patients and demonstrated efficacy with an improved safety profile [1]. Since CD19 CAR-T cells target and lyse B cells in both circulation and tissues, a complete depletion of autoreactive B cells is expected with KVV-101, resulting in better disease control and clinical remission than the current immunotherapies.

**Objectives:** To demonstrate the CAR-mediated and CD19-dependent activity of KVV-101 against autologous, patient-derived primary B cells.

**Methods:** Autologous CD4+ and CD8+ T cells were enriched from healthy donors (HD), systemic lupus erythematosus (SLE), LN or other autoimmune patients. KVV-101 CAR T cells were transduced with a lentiviral vector encoding a fully human single-chain variable fragment (scFv) CD19-targeting domain, a CD8α hinge and transmembrane domain, a CD28 cytoplasmic costimulatory domain, and a CD3ζ; cytoplasmic domain. The CAR-mediated and CD19-dependent activity of KVV-101 was monitored in vitro in a set of cytotoxicity, cytokine release and proliferation studies, in response to either CD19+ target cell lines or autologous, patient-derived primary CD19+ B cells.

**Results:** Following a 24-hour incubation, KVV-101 generated from HDs or autoimmune patients induced greater and dose-dependent cytotoxicity of both the human CD19+ NALM6 cell line and autologous, patient-derived primary B cells than their respective untransduced control T cells. Moreover, an effector cell dose-dependent increase in the production of cytokines such as IFNγ was also observed following co-culture. In contrast, no differences in cytotoxicity nor cytokine production were observed when CD19+ target cells (K662 or U937 cells) were co-cultured with KVV-101 or untransduced control T cells. In addition, following a 96-hour incubation, KVV-101 generated from HDs or autoimmune patients proliferated when co-cultured with the NALM6 cells and autologous, patient derived primary B cells, whereas substantially lower levels of proliferation were observed when HD cells were co-cultured with the CD19+ cells K662 and U937.

**Conclusion:** KVV-101 generated from autoimmune disease patient lymphocytes demonstrates CAR-mediated and CD19-dependent activity against autologous, patient-derived primary B cells and thus represents a novel therapeutic option for the treatment of pathogenic B cells in autoimmune patients.

**Keywords:** Anti-phospholipid syndrome, Autoantibodies, Adaptive immunity

P. Gaspar1,2, A. R. Cruz-Machado2,3, F. Ribeiro2, V. C. Romão2,3, L. Graca2.

1Serviço de Medicina 2, Hospital Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal; 2Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Centro Académico de Medicina de Lisboa, Universidade de Lisboa, Lisbon, Portugal; 3Serviço de Reumatologia, Hospital Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal

**Background:** Primary antiphospholipid syndrome (PAPS) is caused by autoantibodies targeting protein-binding phospholipids (aPL)[1]. Follicular helper T (Tfh) and follicular regulatory T cells (Tfr) are critical for antibody production in germinal centres[2], but their role in PAPS is scarcely studied. Some patients remain persistently positive for aPL, while others become seronegative during disease progression[3]. Whether aPL status mirror immunological changes over time is not known.

**Objectives:** To phenotypically characterize Tfh/Tfr subsets in PAPS and explore the association with previous/current aPL status.

**Methods:** We prospectively recruited 73 adult thrombotic PAPS patients (Sidney criteria; ≥1 year disease duration) and 24 age- and sex-matched healthy donors (HD). Regardless of lupus anticoagulant (LA) status, patients were categorized in three groups according to aPL status (anticardiolipin [ACL] IgM and/or IgG; β2-glycoprotein [β2GP] IgM and/or IgG): profile: NN – previous and current aPL negative, ie, only positive for LA (n=40); PP – previous and current aPL positive (n=20); and PN – previous aPL positive, currently aPL negative (n=13). We considered aPL <30 UQ as negative (ELISA immunoassays). Tfh (CD4+FoxP3+CD25+CXCR5+) and Tfr cells (CD4+FoxP3+CXCR5+) were analysed by flow cytometry using cryopreserved peripheral blood mononuclear cells. GraphPad Prism version 8 software was used for statistical analysis and p values <0.05 were considered significant.

**Results:** Most patients were women (n=43, 59%), with a mean age at disease onset of 42±13 years, and a mean disease duration of 8±7 years. Venous thrombosis was the most common first manifestation (53%), and pregnancy morbidity were present 10% of women. At presentation, aPL positivity were as follows: LA, 70%; ACL IgG and/or IgM, 44%; β2GP1 IgG and/or IgM, 33%; triple positive, 16%. Circulating Tfh and Treg cells were comparable between HD and all APS patients (Figure 1A and 1B). Among APS, PP patients had higher frequency of Tfh compared to NN (p=0.047) but not with PN patients. Within the Tfh subset, activated Tfh cells were significantly increased in PP compared to NN (p=0.005) and PN patients (p=0.049), whereas no difference was seen between the latter group and NN patients, and between HD and all APS patients (Figure 1C). The frequencies of Th1-like and Th17-like cells were comparable between all groups, but Th2-like cells were decreased in PP compared to NN patients (p=0.008), and similarly distributed among all other groups (Figure 1D to F). In the regulatory compartment, circulating Tfr and Tfr/Tfh ratio were significantly increased in PP patients compared to NN (p<0.001; p=0.001) and PN patients (p=0.004; p=0.046) (Figure 1G and 1H). No difference was observed between NN and PN patients nor between HD and all APS patients.

**Conclusion:** Our preliminary results show that in thrombotic PAPS, imbalance of circulating Tfh and Tfr subsets change according to aPL profile. Increased PD1+FoxP3+ Tfh cells and Tfr cells, and Tfr/Tfh ratio indicates ongoing humoral response in persistently positive patients. These changes are lost after seroconversion with T follicular cells subsets being similar to persistently negative PAPS patients.

Within the Tfh subset, activated Tfh cells were significantly increased in PP compared to NN (p=0.005) and PN patients (p=0.049), whereas no difference was seen between the latter group and NN patients, and between HD and all APS patients (Figure 1C). The frequencies of Th1-like and Th17-like cells were comparable between all groups, but Th2-like cells were decreased in PP compared to NN patients (p=0.008), and similarly distributed among all other groups (Figure 1D to F). In the regulatory compartment, circulating Tfr and Tfr/Tfh ratio were significantly increased in PP patients compared to NN (p<0.001; p=0.001) and PN patients (p=0.004; p=0.046) (Figure 1G and 1H). No difference was observed between NN and PN patients nor between HD and all APS patients.

**Conclusion:** Our preliminary results show that in thrombotic PAPS, imbalance of circulating Tfh and Tfr subsets change according to aPL profile. Increased PD1+FOX3+ Tfh cells and Tfr cells, and Tfr/Tfh ratio indicates ongoing humoral response in persistently positive patients. These changes are lost after seroconversion with T follicular cells subsets being similar to persistently negative PAPS patients.

**Background:** Pathological mechanisms in the affected synovial joints in rheumatoid arthritis (RA) and factors contributing to synovial histological heterogeneity, which may impact treatment outcomes, remain largely unexplored at the protein level. Mapping the proteomic landscape of RA-affected synovial tissue (ST) and identifying determinants of synovial pathotypes could provide insights into the proteomic characteristics of RA synovium at different stages of disease. Additionally, the study identified a linear proteomic and cellular difference between the lymphoid, myeloid, and fibroid synovial pathotypes in untreated ERA patients, rather than distinct signatures for each pathotype.

**POS0011 LKBI ALLEVIATES MIGRATION OF FIBROBLAST-LIKE SYNOVIOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS VIA REGULATION OF SLC7A11-MEDIATED ROS SIGNALING**

**Keywords:** Rheumatoid arthritis

**H. R. Lee1,2, S. J. Yoo1,2, J. Kim2, J. A. Park2, S. W. Kang1,2.**

**Background:** Liver kinase B1 (LKB1) is known as a tumor suppressor gene and an antioxidant regulator in cancer. We previously reported that LKB1 knock-down increased the expression of the oxygen species (ROS) and the migration of fibroblast-like synoviocytes (FLS) from rheumatoid arthritis (RA) patients. However, the relevant signaling remains unclear in RA.

**Objectives:** This study aimed to examine the signaling pathway of LKB1 in correlation with migration of FLS from RA.

**Methods:** Synovial tissues were obtained from RA patients (n=10) who were undergoing synovectomy or joint replacement. Isolated FLS were transfected with siRNA duplex targeting constructs for LKB1 or SLC7A11 (solute carrier family 7 member 11, also known as xCT) using lipofectamine reagent. After incubation, expressions of target molecules were evaluated by real-time PCR and
western blot analysis. ROS levels were analyzed with MitoSOX red mitochondrial superoxide indicator using flow cytometry analysis. Cell migratory ability was examined using transwell migration assay and invaded cells were stained with crystal violet. For quantification, the crystal violet dye was eluted with 0.1% sodium dodecyl sulfate (SDS). A769662 was treated as a specific activator of AMPK (AMP-activated protein kinase)-mediated signaling.

**Results:** When RA FLS were stimulated with recombinant interleukin 17 (IL-17; 10 ng/ml) and tumor necrosis factor alpha (TNF-α; 10 ng/ml), SLC7A11 expression was markedly decreased. Following LKB1 knock-down for 24 h, the protein level of SLC7A11 was also decreased in RA FLS. To determine whether SLC7A11 directly regulates FLS migration, SLC7A11 siRNA was transfected and then analyzed intra-cellular ROS level and performed transwell assay. SLC7A11 inhibition induced ROS expression (1.7-fold) and migration ability (1.4-fold) compared to control in RA FLS. Next, cells were treated with A769662 for AMPK activation, which is directly phosphorylated by LKB1 stimulation. LKB1 knock down reduced SLC7A11 level and that decrease was certainly reversed by A769662 treatment. On the other hand, NOX4 expression was increased by LKB1 siRNA, and that increase was suppressed by AMPK activation. LKB1 siRNA induced ROS levels also down regulated by A769662 treatment. When LKB1 inhibition enhanced cell migration about 1.81-fold, and those increases were also reduced in 0.92-fold by AMPK activation compared to control.

**Conclusion:** These findings suggests that LKB1 regulate ROS production and SLC7A11 expression and, eventually lead to decrease migration, thereby further contributing to alleviate inflammation of RA FLS.

**THE EXPANSION OF CD4CD8 DOUBLE-POSITIVE T CELLS OF CD4 ORIGIN IS SPECIFIC FOR RHEUMATOID ARTHRITIS AND LINKED TO DISEASE ACTIVITY**

**Keywords:** Adaptive immunity, Inflammatory arthritides, Rheumatoid arthritis

P Nguyen¹, F Beck², M Melzer³, A M. Glimm³, M Krasselt³, O Seifert³, M. Pieler², K. Rothe¹, U Wagner³. ¹Rheumatology Unit, Leipzig University Medical Center, Leipzig, Germany

**Background:** CD4CD8 double-positive (DP) T cells are expanded in rheumatoid arthritis (RA) and associated with erosive disease [1]. The majority of DP T cells in the periphery have an effector phenotype and were reported to originate from either CD4 or CD8 single-positive (SP) T cells [2]. DP T cells of CD4 origin express a CD8 homodimer, corresponding to a CD4+CD8 low fluorescence pattern in flow cytometry, while DP T cells of CD8 origin express a CD8 homodimer, which results in a CD4+CD8 high pattern. Reports on the presence of polyclonal CD4+CD8 low T cells in RA patients and individuals at risk of RA (3) suggest DP T cells of CD4 origin to be relevant for RA pathogenesis.

**Objectives:** This study aims to confirm and characterize the role of DP T cells of CD4 origin, or CD4+CD8 low T cells, in the context of RA.

**Methods:** DP T cells and their subpopulations were measured by flow cytometry in the peripheral blood of S3 newly diagnosed RA patients and compared to a cohort of patients with psoriatic arthritis (PsA) (n=52), as well as age-matched healthy donors (n=50). The CMV infection status of all subjects was assessed by CMV IgG and IgM ELISA. In an independent cohort of 70 RA patients, the survival markers LIR1 and PD1 were measured on all T cells using flow cytometry.

**Results:** Only DP T cells of CD4 origin (CD4+CD8 low) are significantly expanded in RA (figure 1A), while the frequency of DP T cells of CD8 origin (CD4+CD8 high) is similar to patients with PsA and healthy controls. The expansion of CD4+CD8 low T cells is associated with latent CMV infection in all three cohorts. However, CMV-RA patients have significantly more DP T cells of CD4 origin than CMV- healthy controls (figure 1B), indicating that CMV positivity is not the only driver of DP T cell expansion. DP T cells of CD4 origin express the senescence marker LIR1 and the exhaustion marker PD1 more often than their CD4 SP counterparts (figure 1C). In RA, CD4+CD8 low T cells correlate with DAS28-CRP (n=0.35, p=0.01), indicating a link with disease activity. The frequency of CD4+CD8 low T cells were measured in early RA patients before treatment (visit 1, V1) and three months after treatment (visit 2, V2) and three months (visit 3, V3) of treatment. Clinically efficacious treatment with abatacept was found to significantly reduce the frequency of CD4+CD8 low T cells after three months (mean change -0.09%, p=0.02), while methotrexate treatment did not (mean change -0.03%, p=0.83, figure 1D).

**Conclusion:** DP T cells of CD4 origin (CD4+CD8 low T cells) are frequently expanded in the peripheral blood of RA patients, but not in PsA patients or age-matched healthy individuals. DP T cells of CD8 origin are not expanded in RA or PsA compared to healthy controls. The association of CD4+CD8 low T cells with CMV seropositivity, as well as the increased LIR1 and PD1 expression, suggest they belong to a chronically stimulated, antigen-experienced cell population. Importantly, these cells are associated with disease activity in RA and show a significant reduction in the peripheral blood after treatment with a T cell-targeting agent. This confirms their role in RA pathogenesis and suggests their potential as a therapeutic target or biomarker for response.

**25-HYDROXYCHOLESTEROL IN THE PATHOGENESIS OF RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Adaptive immunity

H Huang¹, Y Geng¹, Y Fan¹, Z Zhang¹. ¹Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease characterized by synovial inflammation, in which the imbalance of CD4 + T cells plays an important role. 25-hydroxycholesterol (25-HC) is an important regulator of the mevalonate pathway in cholesterol metabolism. Previous studies have suggested that 25-HC may inhibit the transformation of CD4 + T cells from interferon-γ (IFN-γ) CD4 + T cells to IL-10+CD4 + T cells through the interaction with liver X receptor (LXR), therefore decreasing the expression of IL-10.

**Objectives:** This study aims to explore the mechanism by which 25-HC promotes the inflammatory process of RA by regulating the phenotypic transformation of
CD4+ T cells through historical and cellular and molecular biology techniques, and propose possible molecular regulatory pathways.

**Methods:** Patients with RA from December 2019 to January 2022, and gender- and age-matched different controls (OA) and healthy control (HC) were enrolled. Peripheral blood mononuclear cells (PBMC) and synovial fluid mononuclear cells (SFMC) were collected and CD4+ T cells were sorted by magnetic beads. The expression levels of different phenotypes of CD4+ T cells and important cytokines were analyzed by flow cytometry; the secretion levels of IL-10 and IFN-γ were detected by ELISA technique. In the intervention experiment, the CD4+ T cells were incubated with various concentrations of atorvastatin to inhibit the cholesterol metabolism and promote synovial function, and then CD4+ T cell phenotype and cytokine expression were detected. The synovial tissues were obtained from RA and OA patients receiving joint replacement surgery, and the expressions of 25-hydroxycholesterol (25-HC) and LXRα were detected by immunohistochemistry and multiplex immunofluorescence. Real-time PCR and Western Blot were used to detect the expression of inflammasome signaling pathway of CD4+ T cells. CH25H was knocked down using small interfering RNA (siRNA), and the effects of knockdown of CH25H on inflammasome and the effect on the transformation of CD4+ T cells were detected by the above methods.

**Results:** (1) IL-10+CD4+ T cells in PBMC/SFMC of RA patients were significantly lower than HC/OA, as well as the expression of IL-10. After interfering the mevalonate pathway by atorvastatin, the ratio of IL-10+IFN-γ+CD4+ T cells and IL-10+IFN-γ+CD4+ T cells as well as the expression of IL-10 decreased in a concentration-dependent manner. The down-regulation effect induced by atorvastatin was compensated after the supplementation of mevalonate acid. (2) The expressions of CH25H and LXRα in CD4+ T cells of RA synovial tissue increased detected by immunohistochemistry and multiplex immunofluorescence, and the expressions of CH25H and caspase-1 in CD4+ T cells in synovial fluid were found increased by Western Blot, as compared with that of OA. (3) After the successful knockdown of CH25H confirmed by Real-time PCR and Western Blot, a significant decrease in the proportion of IL-10+IFN-γ+CD4+ T cells, and increase in proportion of IL-10+IFN-γ−CD4+ T cells were found in RA patients, accompanied with increase in IL-10+CD4+ T cells, while the proportion of IFN-γ+CD4+ T cells decreased in CD4+ T cells after supplementation with 25-HC, the siRNA-CH25H-mediated decrease in IL-10+CD4+ T cells was reversed and IFN-γ−CD4+ T cell formation was reduced. Meanwhile, the expression of NLRC3 and activated caspase-1 (caspase-1 p20) in peripheral blood CD4+ T cells was reduced, and could eliminate after supplementation with 25-HC.

**Conclusion:** In peripheral CD4+ T cells in RA patients, 25-HC may activate the NLRC3 inflammasome through CH25H-LXRα pathway, thereby inhibiting the phenotypic transformation of IFN-γ−CD4+ T cells to IL-10−CD4+ T cells, and eventually promoting the inflammatory process in RA. These findings provide new clues for the mechanism of CD4+ T cells in the pathogenesis of RA and suggest that the cholesterol metabolism pathway may become a new target of RA treatment.

incidence of arthritis, more severe clinical symptoms, and more pronounced joint inflammation and bone damage. Nkp46 deficiency had no significant influence on the incidence and severity of arthritis in collagen-induced arthritis mice. Conclusion: This study examined the proportion of Nkp46+ ILC3-like cells in the peripheral blood, spleen, lymph nodes, and paw tissues in CIA mice and their correlation with disease severity. We confirmed that infiltration of Nkp46+ ILC3-like cells in CIA joints positively correlates with arthritis progression, inflammation, cartilage erosion, and bone destruction. Most importantly, we revealed the pathogenic role of Nkp46+ ILC3-like cells in rheumatoid arthritis through adoptive cell transfer. Our data strongly suggest that Nkp46+ NKp46 may not be the primary actor in the pathogenic function of Nkp46+ ILC3-like cells in CIA. Overall, our current work suggests that Nkp46+ ILC3-like cells infiltrate in inflamed joints and participate in the pathogenesis of autoimmune arthritis.

Background: The nuclear factor of activated T-cells 5 (NFAT5) is a member of the Rel family of transcription factors that can be activated by hypertonic stimuli [1]. It remains unclear, however, whether NFAT5 is required for damage-associated molecular pattern molecules (DAMPs)-triggered inflammation and immunity. Serum amyloid a (SAA) is an endogenous toll-like receptor (TLR) ligand functioning as a DAMP response to bacterial endotoxins [2]. In response to infection and injury, innate immune cells secrete pro-inflammatory cytokines, in particular IL-1β and TNF-α, to which the liver responds by producing acute-phase reactants [3]. Further identification of such pathologic process by acute-phase reactants will allow for better selection of therapeutic targets as well as a greater understanding of the mechanisms underlying chronic inflammation.

Objectives: To investigate SAA, an acute phase reactant as well as a TLR ligand, activates NFAT5 in macrophages of arthritic joints after being secreted from the liver and thereby promotes chronic inflammation.

Methods: SAA-induced upregulation of NFAT5 expression and activity in RAW264.7 cells, mouse bone marrow derived macrophages and human peripheral CD14+ monocytes were assessed by western blot and/or luciferase reporter assays. SAA-activated arthritis in mice was generated by injecting SAA (5 μg ×1) into the affected joint of mice with a suboptimal form of IL-1β-induced arthritis, which was induced by injection of methylated bovine serum albumin (mBSA, 200 μg ×1) and/or IL-1β (250 ng ×2). Decrease in arthritis severity and inflammatory cell infiltration by NFAT5-/- and Tlr2/-/- deficient mice, specific knockout of myeloid Nfat5 or Tlr2, Nfat5, an osmo-sensitive transcription factor. In particular, acute phase reactivity of SAA markedly accelerated macrophage infiltration and arthritis progression in mice. By contrast, genetic ablation of NFAT5 or Tlr2/-/- rescued the pathology induced by SAA, confirming the SAA-TLR2/-/-NFAT5 axis in vivo. Myeloid-specific deletion of NFAT5 also attenuated SAA-accelerated arthritis. Notably, chronic arthritis in mice strikingly induced SAA overexpression in the liver. Conversely, forced overexpression of the SAA gene in the liver accelerated joint damage, indicating that the liver contributes to bolistering chronic inflammation at remote sites by secreting SAA.

Conclusion: In summary, this study underscores the importance of the SAA-TLR2/-/-NFAT5 axis in innate immunity, suggesting that acute phase reactant SAA mediates mutual interactions between the liver and joints and ultimately aggravates chronic arthritis by enhancing macrophage activation.

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammation of the synovial tissue lining the joint, leading to bone damage. Anti-citullinated protein autoantibodies (ACPs) play an important role in the pathogenesis of RA and can be detected before the onset of classifiable or clinical RA. ACPA+ individuals without clinical RA, or ACPA- At-Risk, are being studied to identify effective preventive interventions. B cells also contribute to disease through autoantibody-independent mechanisms, including production of RANKL and inflammatory cytokines. RANKL-producing B cell in clinical RA have
been linked to the CD11c+ CD21high B cell phenotype and FcRL4 expression[1,2]. Notably, activated memory B cells also promote osteoclastogenesis in vitro in a RANKL-dependent manner, which may be enhanced by IL-6 and TNFα[3].

**Methods:** We employed spectral flow cytometry to achieve high-dimensional characterization of activated B cells, with simultaneous quantification of 23 cell-identity and state-defining molecules, from age-matched ACFA+ control and ACFA+ At-Risk individuals (Table 1). TLR9 ligand (CpG) and CD40 stimulation was applied to generate RANKL+ B cells among total PBMCs. We evaluated differences in frequencies of RANKL+ cells as well as RANKL/FcRL4 and RANKL/cytokine co-expression profiles between ACFA+ and ACFA- individuals. Single-cell ATACseq analysis was applied to unstimulated total B cells from ACFA+ and ACFA- individuals to determine the accessibility at the RANKL promoter and enhancer sites.

**Results:** Here, we observed that B cells are primed for RANKL production in ACFA+ At-Risk donors. A substantially higher frequency of B cells, particularly IgM/IgG+ naïve and memory cells, produce RANKL (p=0.06) upon in vitro activation in ACFA+ At-Risk donors as compared to ACFA- controls (Figure 1). RANKL production was not restricted to any single B cell identity. RANKL+ B cells exhibited a highly polyfunctional state, defined by proinflammatory cytokine production, as well as elevated surface activation molecule expression. Among ACFA+ donors, 34% of RANKL+ activated B cells co-expressed TNFα and IL-6 and 55.3% co-expressed FcRL4. Additionally, we found that resting peripheral B cells from ACFA+ At-Risk individuals exhibited an open chromatin state at the RANKL gene promoter and upstream regulatory sites by ATACseq analysis.

**Conclusion:** These results demonstrate that peripheral B cells are poised for proinflammatory responses and RANKL production upon activation in ACFA+ individuals. Our work suggests that loss of immune tolerance predates detectable synovial joint inflammation and highlights autoimmune-independent contributions of B cells to immune dysregulation. Future studies will evaluate these changes in relationship to the development of clinical RA.

B. Raapos1, C. De Vries1, M. Gomes Afonso1, P. Sahliostrom1, L. Israelsson1, R. Stålesen1, L. Klarešek1, V. Malmström1, B. Réthi1, C. Grönwall1, K. Lundberg1, K. Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden

**Background:** Based on an epidemiological association between periodontitis (PD) and rheumatoid arthritis (RA) arthritis[1, with oral dysbiosis[2] and jawbone destruction[3] preceding the onset of RA, a causative link between periodontal infection and RA has been proposed. However, the mechanisms remain to be explained. Both gingival and synovial inflammation associate with malondialdehyde (MDA) protein modifications[4], a posttranslational modification linked to oxidative stress. While MDA IgM are part of the natural antibody response, MDA IgG levels are elevated in RA and correlate with disease activity[5]. Moreover, RA joint B cell derived MDA-reactive monoclonal antibodies (mAb) promote bone erosion and osteoclastogenesis[6], suggesting pathogenic properties. Here we explore MDA-autoimmunity as an etiological link between inflamed gums and joints.

**Objectives:** To investigate if mAbs derived from gingival tissue (GT) B cells of PD patients bind MDA-modified self-proteins and whether they are pro-arthritisogenic.

**Methods:** Recombinant mAbs (n=38) were generated as human IgG1 from single-cell sorted gingival tissue (GT) B cells of one PD patient with RA (PD/RA) and one PD patient without RA (PD only), and screened by ELISA for binding to MDA-modified and native albumin, fibrinogen and low-density lipoprotein. Three GT mAbs versus one isotype control mAb were assayed in vitro for TNF production by monocyte-derived macrophages stimulated by LPS (n=7 healthy donors), and two GT mAbs versus one isotype control mAb were examined in vivo in the collagen type II (CII) antibody-induced arthritis (CIA) model (n=5 mice/group).

Briefly, arthritis was induced in BALB/c mice by i.v. injection of 1.5mg anti-CII antibody cocktail together with 1mg GT or control mAb, followed by 25ug LPS on day 3. Arthritis scores and prevalence were recorded daily for two weeks; statistical analysis was performed using repetitive-measure one-way ANOVA with Geisser-Greenhouse correction and Holm-Sidak’s multiple comparisons test.

**Results:** Three GT mAbs from the RA/PD patient and one from the PD-only patient bound MDA-modified self-proteins but not the native counterparts; all other GT mAbs were negative. The MDA-reactive GT B cell clones were class-switched (n=3 IgG+; n=1 IgA+) with 21-50 somatic hypermutations. The GT mAb with the strongest MDA-reactivity – derived from an IgA+ GT B cell isolated from the PD/RA patient – enhanced TNF production in LPS-stimulated macrophages, and exacerbated arthritis with prolonged arthritis, higher arthritis scores (p<0.05) and higher disease prevalence (p<0.001), see figure 1 below.

Arthritis scores and prevalence were recorded daily for two weeks; statistical analysis was performed using repetitive-measure one-way ANOVA with Geisser-Greenhouse correction and Holm-Sidak’s multiple comparisons test.

**Results:** Three GT mAbs from the RA/PD patient and one from the PD-only patient bound MDA-modified self-proteins but not the native counterparts; all other GT mAbs were negative. The MDA-reactive GT B cell clones were class-switched (n=3 IgG+; n=1 IgA+) with 21-50 somatic hypermutations. The GT mAb with the strongest MDA-reactivity – derived from an IgA+ GT B cell isolated from the PD/RA patient – enhanced TNF production in LPS-stimulated macrophages, and exacerbated arthritis with prolonged arthritis, higher arthritis scores (p<0.05) and higher disease prevalence (p<0.001), see figure 1 below.
Conclusion: Here we show that MDA-autoactive B cells with features of T-cell driven affinity maturation are present in the gum mucosa of PD patients with or without RA. Moreover, that antibodies from one such clone can exacerbate arthritis. Further studies are needed in order to elucidate the mechanisms involved, and to determine if possibly enhanced TNF production via antibody-mediated modulation of macrophage responses could play a role. Taken together, this pilot study supports further research into MDA-autoimmunity as an etiological link between periodontal infection and RA.

Contemporary clinical topics in psoriatic arthritis

POS20019 PREDICTION OF PSORIATIC ARTHRITIS TOOL (PRESTO): DEVELOPMENT AND PERFORMANCE OF A NEW SCORING SYSTEM FOR PSORIATIC ARTHRITIS RISK

Keywords: Epidemiology, Spondyloarthritis, Psoriatic arthritis

L. Eder1,2, K. A. Lee3, V. Chandran4,5, J. Widfeldt6,8, A. Drucker2,7, C. T. Ritchlin7, C. Rosen2,8, H. Cook9, D. D. Gladman4,9, Women’s College Hospital, Rheumatology, Toronto, Canada; University of Toronto, Medicine, Toronto, Canada; University of Waterloo, Statistics & Actuarial Science, Waterloo, Canada; Toronto Western Hospital, Rheumatology, Toronto, Canada; Sunnybrook Research Institute, Rheumatology, Toronto, Canada; University of Toronto, Institute of Health Policy, Management & Evaluation, Toronto, Canada; Women’s College Hospital, Dermatology, Toronto, Canada; University of Rochester, Medicine, Rochester, United States of America; Toronto Western Hospital, Dermatology, Toronto, Canada

Background: A simple, scalable tool that identifies psoriasis patients at high risk for developing psoriatic arthritis (PsA) could improve early detection and facilitate early intervention for this condition. However, no such prediction tool currently exists.

Objectives: Our overall objective is to develop an accurate risk prediction model for the development of PsA and to assess its performance among patients with psoriasis.

Methods: In this longitudinal cohort study we analyzed data from the Internaional Psoriasis and Arthritis Team (IPART) study, a prospective cohort of psoriasis patients without PsA at the time of enrollment. The participants were followed prospectively from 2006 to 2019, and their PsA status was assessed annually by a rheumatologist. Information about their demographics, psoriasis characteristics, co-morbidities, medications and musculoskeletal symptoms was used to develop prediction models for PsA. Penalized binary regression models were used for variable selection while adjusting for psoriasis duration; the stacked LASSO with equal weights was adopted to deal with multiple imputed datasets for incomplete data. Risks of developing PsA over 1- and 5-year time horizons were estimated. Internal validity was assessed using 5-fold cross-validation. Model performance was assessed by the area under the curve (AUC), and calibration plots.

Results: A total of 635 psoriasis patients were analyzed (mean duration of follow up 7 years). 51 and 71 patients developed PsA during the 1-year and 5-year periods, respectively. The risk of developing PsA within 1 year was associated with younger age, male sex, family history of psoriasis, back stiffness, nail pitting, level of stiffness, use of biologic medications, patient global assessment of health and pain severity (AUC 72.3, 95% confidence interval CI 65.5, 79.1, Figure 1A). The risk of developing PsA within 5 years was associated with morning stiffness, psoriatic nail lesion, psoriasis severity (by PASI), fatigue severity (by FACIT-fatigue), pain severity and use of systemic non-biologic medication or phototherapy (AUC 74.9, 95% CI 69.3, 80.5, Figure 1B). Calibration plots showed reasonable agreement between predicted and observed probabilities. The sensitivity and specificity for a 2.5% probability of PsA onset within 1 year were 54.5% and 75%, respectively. The sensitivity and specificity for a 5% probability of PsA onset within 5 years period were 61.1% and 77%, respectively.

Conclusion: The development of PsA within clinically meaningful time frames can be predicted with reasonable accuracy for psoriasis patients. Additional work is underway to validate these models in external cohorts of psoriasis patients.

POS20020 DOES SUBJECTIVELY PERCEIVED LOSS OF HAND FUNCTION SUFFICIENTLY REPRESENT ULTRASONOGRAPHY-DETECTED SYNOVITIS AND TENOSYNOVITIS IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS?

Keywords: Patient reported outcomes, Ultrasound, Psoriatic arthritis

B. Coppers1,2, S. Bayat2,3, E. T. Godonou2,3, L. Valor2,3, D. Simon2,1, F. Fagni2,1, G. Corte2,1, K. Tascilar2,1, A. Hueber2,3, V. Schönlau2,1, M. Sticherling2,1, G. Schest1,2, A. Kleyer1,2, A. M. Liphardt1,2, Friedrick-Alexander Universität (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; Friedrick-Alexander Universität (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany; Klinikum Nürnberg Nord, Rheumaklinik, Nürnberg, Germany; Friedrick-Alexander Universität (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Dermatology, Erlangen, Germany

Background: In the clinical routine patient reported outcome measures (PROMs) such as the ‘Disability of the Arm, Shoulder and Hand Questionnaire’ (Quick-DASH) [1], ‘Score for the Assessment and quantification of Chronic Rheumatic Afections of the Hands’ (SF-SACRAH) [2] and the ‘Health Assessment Questionnaire’ (HAQ) [3] are common for assessing functional status and hand involvement in rheumatic diseases [4] while ultrasonography (US) is a cost-effective, reliable imaging technology for grading and monitoring synovitis and tenosynovitis [5]. However, it is unclear, if subjective perceived impairment can be associated with US-detected synovitis or tenosynovitis in patients with psoriatic arthritis (PsA) and psoriasis (PsO).

Objectives: To correlate subjective hand function with the grade of synovitis and tenosynovitis by US (greyscale (GS), power Doppler (PD) activity) in patients with PsA and PsO.

Methods: PsA and PsO patients recruited from the Rheumatology Department at the University Hospital Erlangen were enrolled in this cross-sectional study after giving written informed consent. Patients completed the HAQ-DI, SF-SACRAH and Quick-DASH questionnaires and subject characteristics (age, sex) were recorded. The examining physician performed a bilateral US (Samsung HS40, South Korea; Esaote Mylab Twice, Italy) of the flexor tendons of all fingers and metacarpophalangeal (MCP) joints 2-5 and both wrists. Each joint was examined by GS (score 0-3) and PD (score 0-3) and flexor tendons were scanned in GS (0’1) and with PD (0-3) following the EULAR-OMERACT scoring system [5]. For statistical analysis patients with either a positive synovitis or tenosynovitis score ≥1 were included. A repeated measure correlation analysis was performed, at the intra-individual level, to measures the overall

Psoriatic Arthritis (PsA) is a complex, heterogeneous disease with chronic inflammation. Disease manifestations include the peripheral joint inflammation, dactylitis, enthesitis and skin psoriasis. Chronic inflammation is associated with structural damage, which jeopardize long-term functional ability.

**Objectives:** To define the molecular basis of inflammation in different disease domains through comparative profiling of serum proteins.

**Methods:** This is a cross-sectional study in patients with PsA. Clinical assessment of inflammation in the peripheral joint (clinical Disease Activity in Psoriatic Arthritis [DAPSA] and swollen joint count), dactylitis digit count, skin (Psoriasis Activity and Severity Index [PASI]) and enthesis (Leeds enthesis index) were performed. Blood samples were collected for biomarker assay including 48 cytokines, chemokines, growth and angiogenic factors using the Bio-Rad Bioplex assay! (Table 1). Levels of selected serum proteins were compared between different disease activity scores across various domains using adjusted linear regression with least absolute shrinkage and selection operator (LASSO) modeling.

**Results:** 100 PsA patients were recruited (age: 51±11 years, male: 52 (52%), disease duration: 9.0±3 years). The cohort had moderate disease activity (DAPSA: 24.4±14.6; PASI: 6.0±7.2). 53 (53%) and 11 (11%) patients were using conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) and biologic DMARDs (bDMARDs) respectively. Using LASSO regression analysis, biomarkers correlating with peripheral joint inflammation were IFN-γ, IL6, SCF and MCP1, while MIP-1α and β-NGF were related to dactylitis. Biomarkers correlating with skin severity were IP10, M-CSF and eotaxin, while IL8, M-CSF and CTACK were related to enthesis. Details of biomarkers independent predicting various disease severity are listed in table 2-3.

**Conclusion:** Comparative serum protein biomarker profiling represents a viable method for distinguishing active inflammation in the various disease domains which may be a step forward towards personalized medicine.

NAFLD IN PSORIATIC DISEASE: IDENTIFYING PATIENTS AT HIGH RISK OF SERIOUS LIVER DISEASE

Keywords: Comorbidities, Real-world evidence, Psoriatic arthritis

S. Harrison1,2,3, U. Nandasoma1, P. Samb2, R. Parker3, C. Chimaakurthi3, P. Laws4, A. Barr5, C. Vandevelde5,6, H. Marzo-Ortega1,7, J. Freeston3,2, 1Chapel Allerton Hospital, Rheumatology, Leeds, United Kingdom; 2Leeds Institute of Cardiovascular and Metabolic Medicine (UCAMMM), the LIGHT building, Leeds, United Kingdom; 3Leeds Musculoskeletal Biomedical Research Unit, Department of Rheumatology, Leeds, United Kingdom; 4St James Hospital, Department of Hepatology, Leeds, United Kingdom; 5Chapel Allerton Hospital, Dermatology, Leeds, United Kingdom

Background: Patients with psoriatic disease(PsD) [psoriasis(PsO) and psoriatic arthritis(PsA)] are at greater risk of non-alcoholic fatty liver disease(NAFLD) and NAFLD-associated fibrosis/cirrhosis compared with the general population and other inflammatory arthritis(1) independent of disease-modifying medications (biologicals)(2) or methotrexate(MTX)(2). Conversely, using these medications in patients with significant NAFLD might accelerate progression to fibrosis/cirrhosis(1). The Leeds Teaching Hospitals NHS Trust(LTHT) NAFLD screening pathway is not validated in PsD and may underestimate prevalence of NAFLD in PsD(2).

OBJECTIVES: 1. To assess the prevalence of NAFLD in our PsD population 2. To determine the effectiveness of the LTHT NAFLD pathway for identifying PsD patients at risk of fibrosis/cirrhosis

Methods: This audit included consecutive patients from the Leeds Speciality Spon- dylarthritides and Dermatology departments who underwent screening for NAFLD fibrosis/cirrhosis using the LTHT pathway. Briefly, patients are first screened using ELF and FIB-4 scores. ELF>9.5 and FIB-4>1.45 triggers referral for fibroscan and hepatology opinion. A fibroscan >10 was considered indicative of clinically signifi- cant NAFLD. We compared baseline demographics (age, sex, BMI, diabetic status), biochemistry (ALT, AST, platelet count, albumin, hepatits B and C), and NAFLD screening tests (ELF, FIB-4 and fibrosis +/- liver ultrasound and biopsy) with the final hepatology diagnosis (NAFLD/ fibrosis/ cirrhosis/ other). We compared results from our PsD patients and patients with other inflammatory arthritis (Other IA).

Results: Overall 110 patients were included; 86.4% (95/110) PsD, and 14.6% (15/110) Other IA. Regarding demographic and clinical variables, age, sex, BMI, AST, ALT, platelets and albumin were similar between all groups. Other IA patients were more likely to be male and taking bDMARD monotherapy. No PsD patients were taking bDMARDs and over half were on no DMARD(Table 1). ELF scores were higher in the PsO group, possibly because the P3NP peptide (part of the ELF score) may be elevated in active skin PsO. Contrary to ELF, FIB-4 scores were higher in PsA compared with all other groups. Higher FIB4 scores, but not ELF scores, were associated with a fibroscan score >10 and a diagnosis of NAFLD fibrosis/cirrhosis in PsA (p=0.05 and p=0.09 respectively).

Conclusion: PsA patients had higher rates of significant fibrosis/cirrhosis compared with patients with Other IA. FIB-4 was better than ELF at identifying PsA patients requiring a fibroscan to exclude significant fibrosis/ cirrhosis. Findings will now be validated in a larger prospective cohort study.

Background: Although the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is used to assess the activity of axial disease in patients (pts) with psoriatic arthritis (PsA), only one of its questions is specific to axial symptoms. Alter- natively, the Ankylosing Spondylitis Disease Activity Score (ASDAS) excludes assessment of enthesitis, gives less weight to peripheral activity and is consid- ered more objective than the BASDAI.

OBJECTIVES: The current post hoc analysis aimed to compare the performance of BASDAI and ASDAS in evaluating symptoms of axial involvement in pts with axial PsA (axPsA).

Methods: Pts enrolled in the DISCOVER-1 (D1) and DISCOVER-2 (D2) studies were adults with active PsA despite standard therapies. D1 pts had ≥3 swollen ≥3 and ≥3 tender joints (SJC, TJC) and C-reactive protein (CRP) ≥20 mg/dL; D2 pts had SJC ≥5, TJC ≥5, and CRP ≥0.6 mg/dL. 31% of D1 pts received ≥2 prior tumor necrosis factor inhibitors; D2 pts were biologic-naive. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo with crossover to GUS Q4W at W24. axPsA was defined by presence of sacroiliitis based on previous radiograph or magnetic resonance (MR) imaging confirmation. Data were pooled across all treatment groups. In addition to BASDAI and ASDAS, modified versions excluding enthesal and enthesis questions (mBASDAI) and the peripheral arthritis question (mASDAS) were calculated. Normalized (scale of 0–10) versions of ASDAS and mASDAS were calculated based on maximum scores of +7 and +6.3, respectively. The correlation of BASDAI/ mBASDAI and ASDAS/mASDAS with SJC, TJC, enthesitis, Functional Assessment of Chronic Illness Therapy (FACIT)-fatigue, pt pain, pt global, and physician global was assessed with Pearson’s correlation coefficient. The cross-sectional and longitudinal (W52) effects of Leeds enthesitis index (LEI), SJC, and axPsA on BASDAI/ mBASDAI and ASDAS/mASDAS were assessed with mixed models.

Results: 436 pts with available baseline (BL) BASDAI information were included in the analysis. In pts with axPsA, BASDAI showed weak correlation with SJC, TJC, LEI, and physician global; moderate correlation with fatigue; and strong correlation with pt global and pt pain. Similar results were observed for ASDAS and modified versions. Among pts without axPsA, correlations of BASDAI and ASDAS with SJC, TJC, and LEI remained weak; correlations with pt global and pt pain remained strong. Longitudinally, among pts with and without BL enthesitis, respectively, LEI and SJ showed significant but not clinically important associations with either fatigue and pain. The BASDAI and ASDAS also showed similar ability to discern changes in axial disease activity. These results suggest that both BASDAI and ASDAS are valid, and perform comparably, in assessing activity of axial disease in PsA pts.

**POS0024 RETENTION RATE OF TNF INHIBITORS (TNFI), ANTI-IL17, AND ANTI-IL12/23 DRUGS IN A SINGLE-CENTER COHORT OF PSORIATIC ARTHRITIS PATIENTS**

**Keywords:** Inflammatory arthritis, bDMARD, Psoriatic arthritis

**M. Ferito**1,2, G. Cincinelli2,3, M. Manara2, E. G. Favalli2,3, R. Caporali2,3

1University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 2ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy; 3University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

**Background:** During the last decades, it has been proposed to widen the horizons of psoriatic patients under a broader clinical concept of psoriatic disease (PD) encompassing both articular and extra-articular features. The most recent international recommendations on psoriatic arthritis (PsA) management highlight the need to personalize therapeutic strategies based on articular and extra-articular manifestations, such as axial or peripheral involvement and severity of skin psoriasis. Lacking specific recommendations for PsA comorbidities treatment, management decisions are often driven by drugs safety profiles and experience gathered from other rheumatologic diseases, such as rheumatoid arthritis. In the last years, new drugs have been approved for PsA management, expanding the possibility to personalize treatment choice in patients with PsA.

**Objectives:** Our study aims at evaluating the retention rate of bDMARDs with different mechanism of action (MoA) (TNF-i vs non-TNF-i) and factors associated with drug suspension in a single-center cohort of PsA patients.

**Methods:** A retrospective cohort from a single-center real-world clinical setting has been collected. A total of 491 bDMARDs therapy courses (155 TNF-i drugs, 69 anti-IL-17 drugs, and 21 anti-IL12/IL-23) were analyzed. Bivariate analyses were performed to assess the presence of demographic and clinical features, as well as comorbidities, associated with bDMARDs discontinuation in the TNFi and non-TNFi groups. Further, we conducted survival analysis and Cox regression, in order to individuate the possible predictors of failure among patients receiving TNFi and non-TNFi.

**Results:** In the bivariate analyses of TNFi and non-TNFi groups we found a lower age at TNFi start (46 years, IQR 45-54 vs 50.5 years, IQR 42-61; p=0.004) as well as a lower proportion of patients with skin psoriasis (85.8% vs 88.4%, p<0.001). Survival analysis showed no significant differences between TNFi and non-TNFi groups.

**Conclusion:** Cox regression individuated fibromyalgia as a predictor of drug failure (HR 3.40, 1.92-6.03; p<0.001) and first line bDMARDs as protective factor (HR 0.46, 0.25-0.88; p=0.019). Lastly, among TNFi courses, fibromyalgia was associated with drug suspension (HR 6.52, 3.16-13.46; p<0.001), while only a trend of significance for skin psoriasis as risk factor for drug failure was shown (HR 2.38, CI 1.00 - 5.66, p=0.05).

and the nailfold is the ideal site to assess angiogenesis, another typical feature of psoriatic synovitis, with both power Doppler (PD) and nailfold videocapillaroscopy (NVC). Studies have shown that PsA patients may have differences in the structure of the nail complex and capillaries compared with healthy individuals.

No study has combined the two techniques.

**Objectives:** To evaluate the ability of combined US examination of the NEC and NVC to differentiate PsA from psoriasis (PSO), rheumatoid arthritis (RA), and healthy subjects (HC).

**Methods:** Twenty age- and sex-matched subjects per group were consecutively enrolled. Each subject was blindly assessed and underwent US of the NEC, NVC, and clinical examination. For the US examination, the nail plate, matrix, and bed were assessed in grayscale (GS) and with PD according to the Brown University Nail Enthesis Scale (BUNES)[1]. For the nail plate, the Wortsman[2] classification was also evaluated. The thickness of the nail plate, matrix, and nail bed were measured. Mean values of 10 digits were used for the analysis. Capillary density, number of microhaemorrhages, tortuous capillaries, ectasia, and ramified capillaries were assessed at NVC. Mean values were calculated for II-V digits in both hands. After excluding subjects with missing values, differences among groups were analysed with Kruskal-Wallis test. US and NVC variables were then included in a K-Means clustering model. The number of clusters was determined using the elbow method. Factor analysis was performed to explain the clustering results. The number of factors was selected using the Scree plot method.

**Results:** The BUNES GS total score, the BUNES GS score for the plate, and the Wortsman score were significantly lower in HC compared to all other groups. BUNES GS for the plate was higher in PSO than in HC. The number of tortuous capillaries was higher in PsA than in PSO and HC, but not in RA. The clustering model identified five clusters (Figure 1A), showing good separation of PsA and HC. PSO were distributed from cluster 2 to cluster 5 and RA among all clusters. The BUNES GS total score, the BUNES GS score for the plate, and the Wortsman score were significantly lower in HC compared to all other groups. The number of factors was selected using the Scree plot method.

**Conclusion:** The results of this pilot study confirm that PsA patients have significant changes in the structure of the NEC compared with healthy subjects. However, most of these changes do not appear to be specific to PsA, as they are also found in PSO and, most surprisingly, in RA where DIP joint involvement is not present. Interestingly, PsA patients appear to have higher numbers of tortuous capillaries compared with PSO and HC, consistent with increased angiogenesis in the synovium. The combined evaluation seems to provide a good distinction between PsA and HC. Not surprisingly, PsO patients clustered closer to PsA (although with significant overlap with HC), which may be due to subclinical involvement. RA patients are distributed among all clusters and have alterations similar to those of PsA. This study does not provide a clear explanation for this phenomenon, and further studies are needed. This pilot study allowed us to identify US and NVC features that could be selected and applied in a prospective study that includes early undifferentiated arthritides and new-onset PSO, to understand whether the observed differences occur early in the disease and whether changes occur during the course of the disease. A larger sample size could also improve the accuracy of the clustering model.

**POS0026 THE INDEPENDENT INFLUENCE OF SEX ON THE DISEASE IMPACT DOMAINS IN PSORIATIC ARTHRITIS IS MODEST; ONCE CONFOUNDBERS ARE TAKEN INTO ACCOUNT**

**Keywords:** Psoriatic arthritis, Gender/diversity issues

A. Ortolan1, A. Capacci1, A. Zoli1, S. Di Murro1, F. Cristiano1, P. Cerasuolo1, R. La Ferrara2, L. Lanzo1, C. Tur1, P. Rubortone1, L. Verardi1, G. Calabresi1, P. Aquilino1, G. Peluso1, M. A. D'agostino2,3, Agostino Gemelli General Hospital Foundation-IRCCS, Division of Rheumatology, Rome, Italy; 2Catholic University of Sacred Hearth, Division of Rheumatology, Rome, Italy

**Background:** Female sex has been associated with higher disease impact in psoriatic arthritis (PsA), as measured by the PsA Impact of Disease (PSAID) questionnaire. However, it is unclear whether sex can influence all different PSAID domains (physical and psychological), or some of them, and whether confounders might be responsible for this association.

**Objectives:** 1) to assess the impact of sex on each of the 12 PSAID domains, and 2) to correct this association for known confounders, including fibromyalgia, to evaluate the independent effect of sex on each of them.

**Methods:** Consecutive PsA patients, classified according to CASPAR criteria, attending our tertiary center between January and December 2022 were included. Demographic data, patient history, disease activity indices [Visual Analogue Scale (VAS) of pain and disease activity, Disease Activity in PsA (DAPSA) score] and functional indices (Health Assessment Questionnaire, HAQ) were collected. Impact of the disease was assessed by PSAID 12. Patients’ characteristics were compared between men and women with descriptive statistics. Multiple linear regression models were built, having the 12 PSAID domains and total PSAID as outcomes (=13 outcomes), and sex as main independent variable. The crude and adjusted association between sex and each of the outcomes were studied. Namely, models were adjusted for: 1) age and DAPSA; 2) age, DAPSA and fibromyalgia. R2 was used to measure the proportion of PSAID variance explained by sex. F-change test was used to evaluate if the addition of fibromyalgia as a confounder significantly contributed to improve the model fit.

**Results:** A total of 190 PsA patients were enrolled, 42% males, disease duration was 7.5±7.6 years. VAS pain, VAS disease activity, HAQ, all the 12 PSAID domains and total PSAID as outcomes (=13 outcomes), and sex as independent variable. The univariate models having the PSAID domains as outcomes, and sex as independent variable, showed significant negative associations between the two (Table 1), R2 values highlighted that a small proportion of the PSAID variance was explained by sex only (R²=0.04-0.15). In the models corrected for age and DAPSA (model group 1, Table 1), male sex was a negative independent predictor of some of the PSAID domains (fatigue, work and leisure, functional capacity, discomfort, sleep disturbance, coping and depression). The addition of fibromyalgia as a confounder (model group 2, Table 1) significantly improved the model fit for many of the PSAID outcomes, and male sex remained independently associated only to functional capacity and coping.

**Conclusion:** Sex alone is not able to explain PSAID variability, although it could have a higher impact on functional capacity and coping. More research is needed in order to understand the contextual factors that could explain the differences in PsA impact between men and women.
was Achilles tendon insertion among both pts with BL enthesitis and pts with an LEI score of 1 or 2. Through WS2, higher BL LEI score was associated with increased PtP, PtGA, and HAQ-DI scores (Table 1). Of the individual entheseal points assessed, enthesis of Achilles tendon insertion had the greatest impact on all PROs and entheses of medial femoral condyle the least. Following GUS treatment, median time to enthesitis resolution was W8 for each of the three anatomical locations assessed by the LEI (Figure 1).

**Conclusion:** In this population of pts with active polyarticular PsA, Achilles tendon insertion was the most commonly affected entheseal point and more highly associated with worse PtP, PtGA, and functional status. GUS treatment was associated with rapid enthesitis resolution, including resolution of Achilles enthesis.

## COMPARATIVE STUDY BETWEEN THE VITACORA AND PSAID QUESTIONNAIRES IN ESTIMATING QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS

**Keywords:** Quality of life

I. Braña Abascal\(^1\), S. Burger\(^3\), P. González del Pozo\(^4\), E. Pardo Campo\(^5\), S. Alonso Castro\(^6\), M. Alperi-López\(^7\), R. Quero Silva\(^8\)\(^,^\)\(^,^\)\(^,^\)\(^,^\) Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain

**Background:** Health-related quality of life (HRQoL) is a frequently underestimated aspect in psoriatic arthritis (PsA). There are different instruments to estimate HRQoL in PsA, but they are rarely used.

**Objectives:** Our objective was to compare the clinimetric capabilities of the VITACORA\(^1\) and PsAID\(^2\) (Psoriatic Arthritis Impact of Disease) questionnaires to assess HRQoL in PsA routine management.

**Methods:** Forty-five consecutive patients with PsA were recruited, mean age 55 ± 13 years, mean disease duration 6.2 ± 6.1 years, 24 men and 21 women. Disease activity was estimated using DAPSA (Disease Activity index for PsA), and HRQoL using VITACORA and PsAID. The construct and discriminant validity of the VITACORA (Pearson correlation and ROC curves) was analyzed. It must be taken into account that in the VITACORA questionnaire, the higher the value, the better the HRQoL, while in the PsAID the exact opposite occurs. Statistical significance was established at a \(p\) value <0.05. The statistical software R was used.

**Results:** Fifty-eight percent and 42% of the subjects were under biological and conventional systemic therapy, respectively. Most patients showed good control of their disease, median DAPSA 11.3 (IQR: 8.02-19.3), median PsAID 2.71 (IQR: 1.06-5.0). The correlation between VITACORA and PsAID was high, \(r = -0.7\) (95% CI: -0.84 to -0.46), \(p<0.0001\). Figure 1, The VITACORA values ranged from 6 to 94. The correlation between VITACORA and PsAID was high, \(r = -0.7\) (95% CI: -0.84 to -0.46), \(p<0.0001\). Figure 1, The VITACORA values ranged from 6 to 94. The correlation between VITACORA and PsAID was high, \(r = -0.7\) (95% CI: -0.84 to -0.46), \(p<0.0001\).

**Conclusion:** VITACORA value ≥ 66 with an area under ROC curve of 0.85 (95%CI: 0.71-0.98). The VITACORA values ranged from 6 to 94. The correlation between VITACORA and PsAID was high, \(r = -0.7\) (95% CI: -0.84 to -0.46), \(p<0.0001\).

## WHOLE SPINE MRI IN AXIAL PSORIATIC ARTHRITIS

**Keywords:** Spondyloarthritis, Imaging, Psoriatic arthritis

S. Kawab\(^3\), S. Fukui\(^1\), H. Tamaki\(^1\), T. Nozaki\(^2\), M. Kishimoto\(^3\), M. Okada\(^1\)\(^,^\) St. Luke’s International Hospital, Immuno-Rheumatology Center, Tokyo, Japan; \(^2\) St. Luke’s International Hospital, Department of Radiology, Tokyo, Japan; \(^3\) Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan

**Background:** Psoriatic arthritis (PsA) is known to have symptoms clinically in multiple domains, one of which is the axial lesion. The ASAS classification criteria for axial spondyloarthritis include confirmation of sacroiliitis on x-ray or MRI, but there is no definition or specific imaging studies that have been determined for axial psoriatic arthritis (axPsA).

**Objectives:** This study aimed to investigate the usefulness of whole spine MRI including all spines and sacroiliac joints in patients with axPsA.

**Methods:** We retrospectively analyzed the medical records of PsA patients who were underwent whole spine MRI and diagnosed that had axial lesions. PsA was classified according to Classification Criteria for Psoriatic Arthritis (CASPAR) criteria and axPsA was diagnosed by a radiologist specializing in musculoskeletal lesions, especially spondyloarthritis. We analyzed patients’ characteristics and MRI findings.

**Results:** The mean age of the 43 patients was 47.47 (±12.7) years, and 26 (60.5%) were male. The time from onset of PsA to MRI imaging was 7.98 (3.34, 18.65) years. 24 (52.8%) patients had sacroiliac joint involvement and 39 (90.7%) had spinal involvement. 15 (34.9%), 25 (58.1%), and 28 (65.1%) had cervical, thoracic, and lumbar spine, respectively.

**Conclusion:** In this study, about half of the patients had no MRI findings of the sacroiliac joint. On the other hand, spinal lesions were more common. Although sacroiliac joint MRI is usually performed for diagnosis in axial spondyloarthriti, imaging of the sacroiliac joints alone may be insufficient in cases of axPsA, because it is known that there are patients who do not have lesions in the sacroiliac joints but in the spine alone.\(^1\) This study showed that whole spine MRI imaging was considered useful to avoid overlooking spinal lesions which is important for axPsA.

**POS0030 METHOTREXATE USE ASSOCIATES WITH ISCHEMIC CARDIOVASCULAR RISK REDUCTION IN MALES BUT NOT FEMALES WITH RHEUMATOID ARTHRITIS**

**Keywords:** Cardiovascular disease, Rheumatoid arthritis

1Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America; 2The Lundquist Institute, Rheumatology, Torrance, United States of America; 3Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; 4Mayo Clinic, Rheumatology, Rochester, United States of America; 5Rush University, Internal Medicine, Chicago, Illinois, United States of America; 6Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 7Umeå universitet, Rheumatology, Umeå, Sweden; 8Lako Hospital, Rheumatology, Athina, Greece; 9University Of Witwatersrand, Rheumatology, Johannesburg, South Africa; 10University of Maastricht, Rheumatology, Maastricht, Netherlands; 11Salvador Zubrín National Institute of Health Sciences and Nutrition, Rheumatology, Ciudad de Mexico, Mexico; 12Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico; 13Diakonhjemmet Hospital, Cardiology, Oslo, Norway; 14Clinical Immunology & Rheumatology Dept, Rheumatology, Kalli Paskhim, India; 15Dudley Group NHS Foundation Trust, Rheumatology, Dudley, United Kingdom; 16Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 17Aarhus University, Rheumatology, Aarhus, Denmark

**Background:** Patients with rheumatoid arthritis (RA) experience higher cardiovascular risk compared to individuals without inflammatory rheumatic disease. Observational studies indicate that methotrexate (MTX) may decrease cardiovascular risk in patients with RA, but it is unclear whether sex differentially impacts cardiovascular risk in MTX users and non-users and whether men and women derive equal benefit from methotrexate use.

**Objectives:** We here explored the influence of sex on cardiovascular risk in MTX nonusers and users. We further evaluated the effect of MTX treatment on cardiovascular risk in males and females with RA.

**Methods:** We evaluated 4362 patients with RA and no atherosclerotic cardiovascular disease, prospectively included in an international observational cohort [An International Cardiovascular Consortium for people with RA (ATACC-RA)]. Outcomes of interest were (a) major adverse cardiovascular events (MACE) defined as cardiovascular death, non-fatal myocardial infarction, or stroke and (b) any ischemic cardiovascular events (CVE) including MACE, stable angina, coronary revascularization, transient ischemic attack, and peripheral arterial disease with or without revascularization. Missing covariate data were imputed using multiple imputation with 10 replications. Multivariable Cox models stratified by center evaluated the impact of sex, baseline MTX use and their interaction on CVE risk after adjusting for age, hypertension, diabetes, family history of coronary artery disease, smoking, total cholesterol to high-density lipoprotein cholesterol ratio, disease duration, and disease activity score (DAS28 ESR). Two corroborating sensitivity analyses were conducted; The first used inverse probability of treatment weights to balance differences in MTX treated and untreated patients. The second included patients enrolled in the cohort on or after January 1, 2000, when MTX use became more prevalent among enrollees.

**Results:** There were 237 first MACE and 358 total ischemic CVE recorded during the entire follow-up period. Male sex associated with an 81% and 58% greater risk of MACE and any ischemic CVE, respectively (Figure 1). Among MTX nonusers, incidence of MACE and any ischemic CVE was higher in males [176 (95% CI 14.4-21.3) and 24.5 (20.7-28.9) events/1000PY, respectively] compared to females [6.9 (5.7-8.4) and 11.4 (9.8-13.3) events/1000PY, respectively, all p for difference<0.001]. In adjusted Cox models, male patients had a 2.09-fold higher risk of MACE and 74% higher risk of any ischemic CVE compared to female nonusers (both p<0.001, Figure 1). In contrast, among MTX users, incidence of MACE and any ischemic CVE was not significantly different in males [4.2 (1.7-10.0) and 7.6 (4.0-14.6) events/1000PY, respectively] than females [6.4 (4.4-9.2) and 9.4 (6.9-12.8) events/1000PY, respectively] and sex was not associated with event risk in MTX users in adjusted models. Moreover, among males, MTX use was associated with a 16% reduced risk of MACE and 55% reduction in any ischemic CVE (p=0.026 and 0.024, respectively). In contrast, MTX use was not associated with MACE or any ischemic CVE in females [adjusted hazard ratio 1.33 (0.83-2.14) and 1.21 (0.81-1.79), respectively]. Both sensitivity analyses yielded similar results.

**Conclusion:** RA males not using MTX exhibit higher risk of MACE and any ischemic CVE compared to female nonusers, while no differences are observed between male and female MTX users. Baseline MTX use associated with reduction in the risk of MACE and all ischemic cardiovascular events in males but not females with RA.

**POS0031 DO COMORBIDITIES INCREASE THE RISK OF FAILURE TO REACH REMISSION IN EARLY RHEUMATOID ARTHRITIS PATIENTS RECEIVING METHOTREXATE AS FIRST-LINE THERAPY?**

**Keywords:** Comorbidities, Rheumatoid arthritis, Remission

L. Trbidad1, H. Westerling2, B. Delcoigne1, J. Askling1, S. Saevarsdottir2,3,4,5

1Karolinska Institutet, Division of Clinical Epidemiology, Department of Medicine, Solna, Stockholm, Sweden; 2University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland

**Background:** Previous studies have reported that some comorbidities associate with a lower probability of remission in patients with established rheumatoid arthritis (RA).[1, 2] Evidence on whether comorbidities affect remission in DMARD-naïve patients with early RA is, however, lacking. We have recently shown that most patients with early RA, irrespective of comorbidities, receive methotrexate (MTX) in DMARD monotherapy as first-line therapy.[3]

**Objectives:** The aim of this study is to examine whether specific comorbidities or overall comorbidity burden affect the likelihood of remission on MTX in DMARD monotherapy as first treatment in patients with early RA.

**Methods:** We included patients with a new RA diagnosis in the Swedish Rheumatology Quality register (SRQ) during 2007 to 2020, in total 11,011 incident RA cases, of whom 67% were female and 69% seropositive. Of these, 8,273 had a follow-up visit at 3 months. Information on comorbidities five years before RA diagnosis was retrieved from the Swedish National Patient Register and information on prescribed drugs 1.5 year before RA diagnosis from the Prescribed Drug Register. Comorbidity diagnoses were grouped into 10 categories (table 1). Disease activity measures were captured through SRQ. The primary outcome measure was failure to reach DAS28 remission, with Boolean, SDAI, CDAI remission, EULAR response and no swollen joints as secondary outcomes. Modified Poisson regression was used to calculate the relative risks of failure to reach remission, in relation to the comorbidities, adjusted for sex and age.

**Results:** In total, 53% of the RA patients had failed to reach DAS28 remission after 3 months of MTX monotherapy, ranging from 98% among the patients with
psychiatric diagnoses to 48% of the patients with a history of cancer (figure 1). The relative risk of not reaching DAS28 remission after 3 months (table 1) was increased for patients with endocrine (RR=1.08, 95% CI 1.01 to 1.15) or gastrointestinal (RR=1.16, 95% CI 1.03 to 1.30) diseases, previous hospitalisation due to infectious diseases (RR=1.21, 95% CI 1.06 to 1.38), psychiatric comorbidity (RR: 1.24, 95% CI 1.15 to 1.35) and respiratory diseases (RR=1.16, 95% CI 1.01 to 1.32). The comorbidity burden also associated with lower remission rates, with a 27% higher risk of not reaching DAS28 remission for the patients with ≥3 comorbidity categories compared to patients without comorbidities. A similar pattern was observed for the secondary outcome measures.

**Conclusion:** Specific comorbidities and the overall comorbidity burden associate with failure to reach remission to MTX as D-MARD monotherapy in early RA patients. Comorbidities may be an important factor when assessing treatment outcomes in early RA.

**TARGETS THAT WORK: IDENTIFYING MODIFIABLE PREDICTORS OF PRESENTEEISM OVER ONE YEAR IN WORKERS WITH INFLAMMATORY ARTHRITIS**

**Keywords:** Patient reported outcomes, Work-related issues, Inflammatory arthritides

A. Luqini1,2, H. Xie3,4, W. Zhang1,6, M. Gignac3,4, D. Laclau1,4, 1The University of British Columbia, Department of Medicine, Vancouver, Canada; 2Arthritis Research Canada, Vancouver, Canada; 3Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada; 4Arthritis Research Canada, Statistics, Vancouver, Canada; 5The University of British Columbia, School of Population and Public Health, Vancouver, Canada; 6Centre for Health Evaluation and Outcome Sciences (CHEOS), Health Statistics, Vancouver, Canada; 7University of Toronto, Dalhousie School of Public Health, Toronto, Canada; 8Institute for Work & Health, Scientific Director, Toronto, Canada; 9Arthritis Research Canada, Scientific Director, Vancouver, Canada

**Background:** Inflammatory arthritis (IA) impacts work outcomes and workers’ lives. Advancements in treatment have improved work disability (WD) but presenteeism remains a major problem, lacking clear targets for intervention.

**Objectives:** Identify predictors of presenteeism over 1-year follow-up in workers with IA.

**Methods:** We designed a prospective observational study analyzing data from the RCT evaluating the Making it Work10 program, an online employment intervention. Participants were recruited in 3 Canadian provinces from rheumatologist practices, consumer organizations and arthritis programs. Eligibility: diagnosis of IA, employed, age 18-59, and concerned about ability to work. Presenteeism was assessed at 0-6-12 mos., using the RA Work Instability Scale (RAWIS, range 0-23). Candidate predictors measured at baseline (bsl.) included sociodemographic characteristics (age, sex, ethnicity, education, marital status, dependents < age 19); disease variables, (arthritis type, physical function [Health Assessment Questionnaires, HAQ II], disease activity [RA Disease Activity Index, RADAI], fatigue [Multidimensional Assessment of Fatigue, MAF], depression [Patient Health Questionnaire, PHQ 9], sleep [Insomnia Severity Index, ISI]; number of limiting comorbidities; work-related variables (occupation, self-employment, job strain, arthritis-work spillover, self-efficacy at work, job satisfaction, importance of work, family support for work, no. hours worked per week, job autonomy, physical demand, psychological demands, and decision latitude from the Job Content Questionnaire). Important bsl. predictors of presenteeism were identified using multivariable linear regression, and linear mixed effect models, with stepwise model selection procedure optimizing Akaike Information criterion (AIC), a commonly used statistical measure and asymptotically equivalent to using cross-validation to compare models. Finally, interaction terms were tested in the model.

**Results:** A total of 564 participants (mean (SD) age: 45.7(9.9) yrs, 77.8% female, 81.5% Caucasian, 49.7% RA, 19.7% SpA, 17.0% PsA and 13.7% SLE or another CTD) were recruited. Bsl. median RAWIS (q25,q75) was 11 (7, 15). More job strain, arthritis-work spillover, self-efficacy at work, job satisfaction, importance of work, family support for work, no. hours worked per week, job autonomy, physical demand, psychological demands, and decision latitude from the Job Content Questionnaire. Important bsl. predictors of presenteeism were identified using multivariable linear regression and linear mixed effect models, with stepwise model selection procedure optimizing Akaike Information criterion (AIC), a commonly used statistical measure and asymptotically equivalent to using cross-validation to compare models. Finally, interaction terms were tested in the model.

**Results:** A total of 564 participants (mean (SD) age: 45.7(9.9) yrs, 77.8% female, 81.5% Caucasian, 49.7% RA, 19.7% SpA, 17.0% PsA and 13.7% SLE or another CTD) were recruited. Bsl. median RAWIS (q25,q75) was 11 (7, 15). More job strain, arthritis-work spillover, self-efficacy at work, job satisfaction, importance of work, family support for work, no. hours worked per week, job autonomy, physical demand, psychological demands, and decision latitude from the Job Content Questionnaire. Finally, interaction terms were tested in the model.

**Conclusion:** This study identified key modifiable predictors of presenteeism over one year in workers with IA. These results provide useful information to healthcare professionals, researchers and patients.

* Linear regression model 4 Linear mixed effects model Model both models adjusted for calendar time, program allocation, age, ethnicity and occupation
**Background:** Patients with rheumatoid arthritis (RA) are at increased risk of *S. aureus* bacteremia (SAB) compared with the general population. [1] SAB has high mortality and osteoarticular infection (OAI) is a feared complication associated with persistent pain and disability. It remains unclear if RA is associated with increased risk of OAI or death following SAB. [2, 3]

**Objectives:** To compare risk of OAI and death in SAB patients with and without RA and to assess risk factors for OAI in RA patients including risk associated with antirheumatic treatment.

**Methods:** Nationwide cohort study of Danish patients with microbiologically verified first-time SAB from 1 January 2006 to 31 December 2018. We identified RA, OAI, vital status, comorbidities, and RA-related clinical characteristics in the rheumatology registry, DANBIO and other national registries. We estimated incidence and 90-day cumulative incidence of OAI in patients without OAI before SAB, restricted to patients without recent OAI (n=351). We computed hazard ratios (HR) by multivariate Cox regression adjusted for a priori known risk factors for each outcome. We included csDMARD use, serostatus, RA disease duration, and remaining variables in table.*

**Results:** We identified 18,274 patients with SAB (n=367 with RA). In RA versus (vs.) non-RA, women comprised 62% vs. 37% and median age was 73 years (interquartile range 65; 80) vs. 70 years (59; 82). Prior OAI (0-3 months before SAB) was diagnosed in 4% vs. 2%. The 90-day cumulative incidence of OAI was 23.1% (95% CI 18.8; 27.6) in RA patients vs. 12.5% (12.1; 13.0) in non-RA (Figure 1) (HR 1.93 (1.54; 2.41) adjusted for age, sex, calendar year, and diabetes mellitus). In RA, use of tumor necrosis factor inhibitors (TNFi) and orthopedic implants were associated with OAI risk (Table 1). Mortality was similar in SAB patients with (35.4% (30.6; 40.3)) and without RA (33.9% (33.2; 34.5) (Figure), (HR 1.04 (0.87; 1.24) adjusted for age, sex, calendar year, chronic liver disease, chronic obstructive pulmonary disease, cancer, congestive heart failure, renal failure).

Conclusion: Nearly one in four patients with RA experienced an osteoarticular infection following S. aureus bacteremia compared with one in eight patients without RA. In patients with RA, current TNFi use and orthopedic implants were associated with increased osteoarticular infection risk. One in three patients died, with no difference between patients with and without RA. These findings highlight the need for vigilance when RA patients present with SAB to ensure timely identification of OAI.

Background: Chronic inflammation contributes to enhanced cardiovascular risk in patients with rheumatoid arthritis (RA). Biologic disease modifying antirheumatic drugs (bDMARDs) have been shown to effectively control inflammation in many conventional synthetic DMARD non-responders and improve cardiovascular outcomes.

Objectives: We here explored whether baseline bDMARD use may influence the impact of disease activity and systemic inflammation on long-term cardiovascular risk in patients with RA.

Methods: We studied 4370 patients with RA who were free of cardiovascular disease upon registration to An International Cardiovascular Consortium for people with RA (ATACC-RA) and followed prospectively. Prespecified outcomes included (a) major adverse cardiovascular events (MACE) defined as non-fatal myocardial infarction, non-fatal stroke, or cardiovascular death and (b) any ischemic cardiovascular events (CVE) comprising MACE, coronary revascularization, stable angina pectoris, transient ischemic attack and peripheral arterial disease with or without revascularization. Missing covariate data were imputed using multiple imputation with 10 replications. Multivariable Cox models stratified by center evaluated the impact of disease activity [based on 28 joint counts and CRP (DAS28-CRP)], systemic inflammation (CRP), bDMARD use and their respective interactions on CVE risk after adjusting for age, gender, hypertension, diabetes, family history of CAD, smoking and total cholesterol to high-density lipoprotein ratio. Two corroborating sensitivity analyses were performed; the first included patients enrolled in the cohort on or after January 1, 2000, when bDMARD use became more prevalent among enrollees. The second used inverse probability of treatment weights (IPTW) to balance differences in bDMARD treated and untreated patients.

Results: Throughout 26534 patient years of follow-up, 239 first MACE and 362 total ischemic CVE were recorded. Among bDMARD nonusers, incidence of MACE and any ischemic CVE was [9.3 (95% CI 8.2-10.6) and 14.2 (12.8-15.8) events/1000PY respectively. Corresponding rates for bDMARD users were [5.4 (95% CI 2.9-10.1) and 8.2 (5.0-13.6) events/1000PY respectively. In the entire cohort, DAS-28 CRP and CRP(ln) associated with greater risk of MACE (adjusted hazard ratio [HR] 1.19 (95%CI 1.06-1.34), p=0.004 and HR 1.15 (1.02-1.28), p=0.017 respectively), while for all ischemic CVE the association was significant for DAS-28 CRP (adjusted HR 1.1 (95%CI 1.07 to 1.30)), but not CRP(ln) [HR 1.06 (0.97 to 1.16)]. In bDMARD nonusers at baseline, higher DAS28-CRP and CRP(ln) associated with greater risk of MACE [adjusted HR 1.21 (95%CI 1.07-1.37), p=0.002 and HR 1.16 (1.04-1.30), p=0.009 respectively]. However, this was not the case in bDMARD users [p-for-interaction= 0.017 and 0.011 correspondingly, Figure 1]. In contrast, no significant interaction between DAS28-CRP or CRP and bDMARD use on any ischemic CVE was observed [p-for-interaction= 0.167 and 0.237 respectively]. Both sensitivity analyses yielded similar results.

Conclusion: Higher disease activity and systemic inflammation at baseline associated with greater risk of MACE in bDMARD nonusers but not in patients receiving bDMARDs. This may suggest the presence of additional bDMARD-specific benefits directly on atherosclerotic plaque — such as plaque stabilization — above and beyond their effects on systemic inflammation.

INFLUENCE OF INTERSTITIAL LUNG DISEASE DURATION ON THE TREATMENT OF RHEUMATOID ARTHRITIS IN RHEUMATOID ARTHRITIS-INTERSTITIAL LUNG DISEASE, NATIONAL MULTICENTER STUDY OF 392 PATIENTS WITH ABATCEPT

Keywords: Lungs, Rheumatoid arthritis, Disease-modifying Drugs (DMARDS)
Background: Intstitial lung disease (ILD) is a severe complication of rheumatoid arthritis (RA). Abatacept (ABA) has demonstrated efficacy in the treatment of RA-ILD, especially if it is initiated early during the ILD [1-2].

Objectives: To compare the efficacy of ABA in RA-ILD patients according to ILD duration.

Methods: National multicenter study of 392 RA-ILD patients treated with ABA. Patients with ABA initiation early in the disease (during the first 6 months since ILD diagnosis) were compared to those in whom ABA was started after 2 years of ILD diagnosis (“early” vs “late” group, respectively). We analyzed in the 2 groups the following outcomes: a) forced vital capacity (FVC), b) diffusing capacity of the lungs for carbon monoxide (DLCO), c) chest high resolution computed tomography (HRCT), d) dyspnea and e) arthritis activity.

Results: A total of 157 patients were included in the “early” group and 135 patients in the “late” group. Baseline demographic and clinical characteristics are shown in Table 1. Mean baseline values of FVC were significantly higher in the “early” group. The evolution of FVC and DLCO for 48 months is shown in Figure 1. Both parameters remained stable during 12 months of ABA therapy, with no statistically significant differences found (although lower stable values of FVC in the “late” group). Available chest HRCT images improved/stabilized in 75% and 51% of patients in the “early” and “late” group, respectively. Stabilization or improvement of dyspnea was found in most patients of both groups.

Conclusion: Our results suggest that an early administration of ABA in RA-ILD may be preferable to preserve lung function. However, treatment with ABA at any time of the course in the ILD seems to prevent interstitial lung progression.

**POSS037 VALIDATION OF DIAGNOSTIC CODES FOR DEMENTIA IN A RHEUMATOID ARTHRITIS POPULATION-BASED COHORT**

**Keywords:** Cognitive Function, Rheumatoid arthritis, Validation

E. Myasoedov1,2, M. Vassilik3, C. Kodishalak1, E. Lovering1, R. Kumar1, C. S. Crowson1,3, Mayo Clinic, Rochester, United States of America; Mayo Clinic, Epidemiology, Rochester, United States of America; Mayo Clinic, Clinical trials and Biostatistics, Rochester, United States of America

**Background:** Dementia is a major global mental health problem. The prevalence of dementia is increasing dramatically with increasing life longevity and population aging. Several studies found increased risk of dementia in patients with rheumatoid arthritis (RA) and reported a possibility of mitigating this risk with antirheumatic treatments. The underlying mechanisms for these associations are not fully understood and require further study. As clinical verification of the diagnosis may not be readily available, especially in retrospective observational studies, diagnostic codes can be used. However, performance of diagnostic codes for dementia case identification has not been validated in RA cohorts.

**Objectives:** To validate the use of ICD-9/10-CM diagnostic codes for dementia identification against diagnostic criteria for dementia in individuals with and without RA using retrospective validation of case identification.

**Methods:** This retrospective population-based study included residents of a geographically well-defined area with incident RA based on the 1987 American College of Rheumatology (ACR) classification criteria in 1980-2018. All adult (≥18 years) cases of RA were included and matched (1:1) by age, sex, calendar year, and county to non-RA controls. Dementia case identification using ICD-9-CM diagnostic codes from the Charlson comorbidity index was validated against dementia diagnosis based on Diagnostic criteria in Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM-IV). ICD-9-CM criteria were verified by manual records review.

**Results:** A total of 3,116 individuals (1,558 RA cases and 1,558 non-RA controls) were included. Mean age 56.2 years; 68% females in both groups; mean (SD) age at the last follow-up was 68.7 (14.7) years for RA cases and 68.6 (15.4) years for non-RA controls. At the time of the last follow-up, there were 202 (13%) patients with one diagnostic code for dementia, 136 (9%) with two diagnostic codes for dementia, and 137 (9%) with a confirmed diagnosis of dementia per DSM-IV. The respective numbers in non-RA controls are 216 (14%); 147 (9%) and 149 (10%). Mean (SD) duration between accumulating two ICD codes and diagnosis verification by DSM-IV was an absolute difference of 1.0 (1.8) years in RA and 1.2 (1.7) years in non-RA. Table 1 summarizes the results of validation analyses.

**Conclusions:** The ICD-9/10-CM codes for dementia performed equally well against DSM-IV criteria in the retrospective population-based cohort of individuals with RA and in matched non-RA controls, identifying true dementia cases with approximately 80% probability. The PPV was higher in older birth cohorts, reflecting the higher prevalence of dementia in older adults. The use of ICD-9/10-CM codes from Charlson comorbidity index is acceptable for dementia case identification in patients with RA, especially in older adults, although additional parameters (e.g., number of diagnostic codes) need to be considered.

2. **POSS036 SUBSEQUENT HOSPITALIZATIONS FOR OR WITH PSYCHIATRIC DISORDERS IN INDIVIDUALS WITH PRE-EXISTING RHEUMATIC ARTHRITIS AND SPONDYLARTHROTHESIS: A NATIONAL REGISTRY-BASED RETROSPECTIVE COHORT STUDY**

**Keywords:** Mental health, Real-world evidence, Comorbidities

T. Formanek1, K. Mladá2, P. Mohr3, M. Olejárová4, K. Pavelka1, M. Husaková5, 1University of Cambridge, Department of Psychiatry, Cambridge, United Kingdom; 2National Institute of Mental Health, Department of Public Mental Health, Kecany, Czech Republic; 3National Institute of Mental Health, Clinical Genomics, National Institute of Health, Prague, Czech Republic; 4Charles University and Rheumatology Institute, Department of Rheumatology, Prague, Czech Republic

**Background:** The crosslink between rheumatic diseases (RD) and psychiatric disorders (PD) has been suggested, particularly due to systemic inflammation and the psycho-social impact of chronic painful experience in patients with RD.

**Objectives:** In the present study, we investigated the risk of subsequent hospitalization for PD and for PD either for or with PD in cohorts of patients with specific pre-existing RD.

**Methods:** In this retrospective cohort study, we utilized data from the Czech nationwide registers of all-cause hospitalizations and deaths. The study consisted of individuals first hospitalized with (1) rheumatoid arthritis (RA; International Classification of Diseases 10th Revision (ICD-10) codes M05 and M06) and (2) spondylarthropathy (SpA; ICD-10 codes M07, M45 and M46[1, 8, 9]) in the time-period from 1999 to 2011 (index hospitalization) and counterparts without the respective diseases, exactly matched on age, sex, month and year at the index hospitalization (1:3). As the risk of subsequent hospitalization after index hospitalization (1:4) for PD either for or with each diagnostic group of PD (ICD-10 codes F07 + G20 and G30, F1x, F2x, F3x, F4x and F5x) arising in the period of five or more years (up to 2017) from the index hospitalization was assessed using stratified Cox proportional hazards models, controlling for deaths occurring in this time-period and adjusting for age, sex and month and year at the index hospitalization. We assessed the risk (1) of being hospitalized for PD (ie, primary diagnosis) and (2) of being hospitalized for or with PD (ie, either primary or secondary diagnosis) separately. For the respective analyses, we excluded individuals who were (1) hospitalized for PD and (2) hospitalized either for or with PD five or more years (up to 1994) prior to the index hospitalization, separately for each diagnostic group of PD. Thus, we effectively created 24 matched cohorts overall. The results are expressed as hazard ratios (HR) with 95% confidence intervals (95% CI).

**Results:** When considering hospitalizations specifically for PD, the total number of individuals in the RA cohorts ranged from 92,694 to 93,768 and from 31,488 to 32,070 individuals in the SpA cohorts. We found that individuals with SpA had an elevated risk of hospitalization for anxiety disorders (1.36; 1.08 to 1.70), when compared with matched counterparts. Conversely, we found that individuals with RA had a decreased risk of hospitalization for substance use disorders (0.58; 0.46 to 0.72). Next, we found that individuals with RA and SpA had an elevated risk of being hospitalized either for or with mood disorders (2.73; 1.59 to 4.71). Conversely, people with RA had a lower risk of being hospitalized either for or with substance use disorders (0.77, 0.68 to 0.87). For the other PD outcomes in people with RA and SpA, the 95% CIs covered a range from decreased to increased risk.

**Conclusion:** Individuals with RA and SpA seem to have a higher risk of developing a range of PD, when compared with matched counterparts. The detected differences suggest that clinical vigilance and provision of mental health services to affected individuals require further attention.

POS0038 

UTILIZATION OF CARDIOVASCULAR PREVENTIVE SERVICES IN A RHEUMATOID ARTHRITIS POPULATION BASED COHORT 

Keywords: Rheumatoid arthritis, Comorbidities, Cardiovascular disease 
D. Montes1, C. A. Hulshizer2, E. Myasoedova2,3, J. M. Davis III, A. Hansson2, A. Duarte-Garcia4, G. Figueroa-Parra2, B. Chevert5, C. S. Crowson2,3, Mayo Clinic, Department of Internal Medicine, Rochester, United States of America; 2Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America; 3Mayo Clinic, Division of Rheumatology, Rochester; United States of America; 4CHU Brest, Division of Rheumatology, Brest, France 

Background: Rheumatoid arthritis (RA) increases the burden of cardiovascular disease (CVD). Fasting blood glucose, fasting lipoprotein profiles, and blood pressure measurements are recommended at regular intervals to screen for classical CVD risk factors of diabetes mellitus (DM), hyperlipidemia (HLD), and hypertension (HTN), respectively. 

Objectives: Our objectives were 1) to perform a contemporary assessment of the trends of CVD preventive service utilization in patients with RA compared to matched non-RA comparators, 2) identify RA patient characteristics that may influence trends in preventive service utilization, and 3) assess how a diagnosis of RA alone influences approaches to CVD prevention compared to the other classical CVD risk factors. 

Methods: Inpatient and outpatient medical records for each potential case were manually reviewed. All incident patients fulfilled the 1987 American College of Rheumatology (ACR) classification criteria for RA or the 2010 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) criteria. All ≥19-year-old patients with an RA diagnosis living in an 8-county region on January 1, 2015 (index date), were included and matched (1:1) by sex, age, and county to non-RA comparators. Rates of screening for the classical CVD risk factors were compared between groups using Cox models with adjustment for age, sex, and race. 

Results: DM screening was more common among patients with RA (HR: 1.10, 95% CI 1.01–1.19), as was HTN screening (HR: 1.57, 95% CI 1.24–1.92). However, HLD screening in RA was similar to comparators (HR: 0.99, 95% CI 0.89–1.10). RA patient characteristics that influenced classical CVD risk factor screening included: smoking history, obesity, RA duration of < 5 years, older age at the time of RA diagnosis, a higher Charlson comorbidity index, the use of >90 days of glucocorticoid therapy before the index date, the use of disease modifying anti-rheumatic drugs before the index date, and living in the lowest quartile of the Area Deprivation Index within our cohort. Lastly, patients with RA and no classical CVD risk factors had a lower probability of undergoing DM (HR: 0.89, 95% CI 0.57–0.78) and HLD screening (HR: 0.65, 95% CI 0.54–0.79) than non-RA patients with one classical CVD risk factor diagnosis. HTN screening was similar between both groups (HR: 1.01, 95% CI 0.83–1.23). 

Conclusion: RA patients undergo CVD preventive screening at rates at least comparable to the general population. However, despite the equivalent-to-higher CVD risk, RA does not appear to be approached as aggressively as traditional CVD risk factors. (1,2) These findings demonstrate an opportunity to improve RA patient care. While EULAR provides guidance for stratifying CVD risk in patients with RA, RA does not appear to be approached as aggressively as traditional cardiometabolic risk factors. (1,2) These findings demonstrate an opportunity to improve RA patient care. While EULAR provides guidance for stratifying CVD risk in patients with RA, RA does not appear to be approached as aggressively as traditional cardiometabolic risk factors.

Disease mechanisms in spondylarthropathies 

POS0039 

A MULTICOMPS PLASMA ANALYSIS REVEALS NEW PATHWAYS CENTRAL IN DRIVING INFLAMMATION IN SPONDYLOARTHRITIS 

Keywords: Spondyloarthropathies, Biomarkers 
S. R. Greisen1,2, R. Østgård1,3, S. E. Rask1, M. Hvid1,4, A. G. Jurik5, U. Syrø6, D. Poddubnyy5, B. Deleuran2, J. Arthus University, Biomedical, Århus, Denmark; 2Aarhus University Hospital, Rheumatology, Århus, Denmark; 3Silkeborg Regional Hospital, Rheumatology, Silkeborg, Denmark; 4Aarhus University Clinical Medicine, Aarhus, Denmark; 5Aarhus University Hospital, Radiology, Århus, Denmark; 6Chanté Universitätsmedizin Berlin, Gastroenterology, Infectology and Rheumatology, Berlin, Germany 

Background: Biochemical and clinical disease activity markers in spondyloarthritides (SpA) remain scarce. In addition, understanding the pathways driving disease progression with a combination of bone formation and bone erosions still remain to be fully elucidated. Anti-TNF-α and anti-IL-17A treatment decrease clinical symptoms and partly limit structural changes, but still disease progression and treatment failure occur. 

Objectives: We used an unbiased multicomps plasma analysis to identify inflammatory proteins associated with disease activity and structural changes. Subsequently, some of the identified proteins were investigated in biopsies from the spine and in cells, and synovial fluid from the peripheral joint. 

Methods: Blood was obtained from patients with early (eSpA) before and 1 year after start of anti-TNF treatment (n=30). Markers of disease activity included: BASDAI, ASDAS, CRP, Osteitis, bone marrow edema and new bone formation were evaluated by MRI scan of the total spine and the SI-joint at baseline and after 1 year of treatment. Healthy controls (HCs) were age and gender matched (n=15). From patients with long-standing SpA (IsSpA, symptom duration >8 years) with a joint effusion, both blood (n= 8) and synovial fluid (SF) (n=6) was obtained. An O-link based multiplex analysis covering 92 proteins was performed on plasma and synovial fluid. Cells were stained for flow. Facet joint biopsies originated from IsSpA patients undergoing surgery for polysegmental correction of rigid hyperkyphosis. These were stained by immune fluorescence. 

Results: The multicomps analysis revealed 18 proteins significantly increased at baseline compared to after 1 year of anti-TNF treatment, among these were CCL2, CCL4, CXCL10, CXCL13, IL-6 and PD-L1 (all adjusted p<0.05). All targets correlated with baseline CRP, and except for PD-L1, also with ASDAS, BASDAI and BASMI (all rho >0.4). Baseline CXCL13, IL-6 and PD-L1 also correlated to baseline spinal MRI inflammation (rho=0.4). Furthermore, baseline CXCL13 and IL-6 were associated with spinal MRI inflammation after one year of treatment (rho<0.4). CXCL13 was also increased in synovial fluid from IsSpA patients, CXCL13 was not increased in eSpA compared to HCs, but the receptor for CXCL13, CXCR5 was increased on CD4+ PBMCs from eSpA patients compared to HCs (17.3% vs 12.3%, p<0.01). eSpA CD4+ PBMCs did not differ from HC CD4+ PBMCs when investigating general activity markers, including CD69, 

Table 1. Cumulative Incidence of Screenings
CD25 and PD-1. Evaluating the central site of pathology, CXCL13 was highly expressed in the inflamed facet joints (Figure 1).

**Conclusion:** The multimetics analysis revealed multiple cytokines to be activated in eSpA patients. The early disease is characterized by T cell activity in combination with macrophage and monocyte attractive chemokines. CXCL13 stands out as a chemokine of particular interest, being increased both in eSpA, at the central- and peripheral site of pathology, and associated with structural changes in time. The CXCR5-CXCL13 axis could be an important new axis in understanding SpA disease pathology, serving both as a biomarker for disease severity and progression, but also lead to new targets of treatment.

**UPREGULATION OF SPP1 (OSTEOPONTIN) BY ADIPOSE TISSUE-DERIVED MESENCHYAL STEM CELLS OCCURS WITH THE CONTINUOUS MECHANICAL LOAD BUT IS STRONGLY RESTRICTED IN INF-G/TNF-AIL/II-22 MICROENVIRONMENT**

*Keywords:* Spondyloarthritis, Disease-modifying Drugs (DMARDs), Rheumatic arthritis

1Bnai Zion Medical Center, Rheumatology, Haifa, Israel; 2Rambam Health Campus, Orthodontics, Haifa, Israel; 3Bnai Zion Medical Center; Endocrinology, Haifa, Israel

**Background:** The interplay between the inflammatory part of the disease and osteogenesis in axial spondyloarthritis (AxSpA) is incompletely understood. It is believed that inflammation triggers the process of new bone formation on the one hand, but the regulation of these phenomena is distinct on the other. An assumption that disease-related osteoproliferation in AxSpA is governed by the complex interplay of inflammation, hormonal or growth factors, and mechanical load has been made. A recent study demonstrated that a pro-inflammatory environment, consisting of interferon-γ (INF-γ) and tumor necrosis factor-α (TNF-α), allowed IL-22-induced proliferation and migration of mesenchymal stem cells (MSCs) [1].

**Objectives:** To examine the influence of continuous mechanical load (CML) on the osteogenic behavior of MSCs with or without INF-γ/TNF-α/IL-22 or testosterone exposure.

**Methods:** Adipose tissue-derived MSCs, characterized by CD90*, CD73*, CD105*, CD45*, CD31*, isolated from the adipose tissue of a healthy donor and kindly donated by Bonus BioGroup, Haifa, Israel, were cultured for two weeks without or under CML of 2 gr/cm², applied by transparent glass cubes placed on the plates covering the well, in the following conditions: a. osteogenic differentiation medium (ODM) with no additions of cytokines or testosterone; b. ODM with the addition of testosterone, 0.01 µM; c. ODM with the addition of INF-γ (1ng/ml), allowed IL-22-induced proliferation and migration of mesenchymal stem cells (MSCs) [1].

**Results:** The osteogenic differentiation capacity of MSCs was analyzed by Alizarin Red S staining, and the results presented in a histogram graph as fold-change (Figure 1). RQ (2-ΔΔCt) was calculated, with the results presented in a histogram graph as fold-change (Figure 1).

**SILENCING OF JOINT FIBROBLAST TO PROTECT FROM JOINT DAMAGE**

*Keywords:* Spondyloarthritis, Disease-modifying Drugs (DMARDs), Rheumatic arthritis

S. Rauber1, H. Mohammadian1, M. G. Raimondo1, M. Vogg1, L. Lu1, A. Soare1, C. Xu1, J. D. D. Cañete2, G. Schett1, A. Ramming1, F. Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology & Immunology, Erlangen, Germany; 3HospitaleClinic de Barcelona e IDIBAPS, Departament de Reumatologia, Barcelona, Spain

**Background:** Despite significant progress in the development of targeted biologic therapies for the treatment of chronic inflammatory joint diseases such as rheumatoid arthritis or psoriatic arthritis, more than 40% of patients still record gradual loss of joint function, mostly because of failure to achieve complete remission. Herein, persistent joint fibroblast activity leads to continuous destruction of the joint, whereas its inhibition/silencing prevents joint damage despite presence of a residual inflammation[1]. Persistent activation of the joint fibroblasts leads to destruction of the joint[1], and silencing both, inflammation and mesenchymal activation is required to protect joints from damage.

**Objectives:** Protection from joint damage—especially when complete remission cannot be achieved—is a need that might be met by pharmacological targeting of fibroblasts. We aimed to reprogram fibroblasts, from pro-inflammatory and tissue damaging phenotype to a tissue preserving and anti-inflammatory phenotype as a new promising treatment strategy.

**Methods:** Single-cell RNA sequencing of sorted synovial fibroblasts and imaging mass cytometry from different mouse models of arthritis (TNFγ-lg/23 overexpression, KBxN serum transfer) were used to map fibroblast heterogeneity. Co-culture experiments were performed with sorted fibroblasts and innate lymphoid cells (ILCs) in vitro. For functional proof of concept, animals were treated with blocking and activating antibodies in the aforementioned arthritis models. For functional proof of concept, animals were treated with blocking and activating antibodies in the aforementioned arthritis models. Through data analysis of joint fibroblast scRNAseq, spatial transcriptomics, and imaging mass cytometry during joint inflammation and its resolution, we observed high plasticity of joint fibroblast populations. By analyzing single-cell dynamics, we identified transdifferentiation of fibroblasts from a MPP5+ / IL-6+ destructive state to a DKK3+ protective phenotype upon DMAPD-induced resolution and revealed the underlying molecular legacy. We identified a novel DKK3+ fibroblast subtype in joints of patients with rheumatoid arthritis and spondyloarthritis (axial spondyloarthritis, peripheral spondyloarthritis, psoriatic arthritis) that protects against joint damage and actively induces resolution of inflammation, by stimulating type 2 ILCs, which are known cellular components for activation of regulatory T cells and pro-resolving eosinophil granulocytes in the joint[2]. We identified the functionally relevant pathway of type 2 ILC activation by fibroblasts. Drug-induced activation of this pathway resulted in activation of pro-resolving ILC2/Tregs/eosinophil granulocytes in association with a sharp decrease in inflammation and cartilage and bone destruction.

**Conclusion:** This new treatment approach might have several advantages over anti-inflammatory drugs. (i) no interference with important defence mechanisms against pathogens and no increased risk of opportunistic infections, (ii) activation of a mechanism that retains tissue integrity, (iii) option to combine with anti-inflamatory drugs, making silencing of fibroblasts to a new tool of disease control.

López-Estévez9, N. Barbarroja Puerto1.1 IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain; 2 IMIBIC/University of Cordoba/Reina Sofia Hospital, Cell Biology, Physiology and Immunology, Cordoba, Spain; 3 IMIBIC/University of Cordoba/Reina Sofia Hospital, Rheumatology Service, Cordoba, Spain

Background: The use of high throughput techniques such as transcriptomic sequencing has recently made considerable progress in the identification of molecular profiles involved in the pathogenesis of chronic autoimmune diseases. To date, only a few studies have been carried out in axial spondyloarthritis (axSpA), which would allow the identification of new therapeutic targets and disease biomarkers.

Objectives: 1) To identify clusters of highly correlated genes enriched in biological functions and specific molecular pathways involved in the pathogenesis of axSpA. 2) To study the association between the molecular signatures identified and the clinical-analytical profile of the disease.

Methods: Cross-sectional study including 75 axSpA patients from the CAS-TRO cohort who underwent an exhaustive clinical evaluation including disease activity and functional limitation, structural damage, and spinal mobility. Additionally, analytical parameters were measured and the carotid intima-media thickness was evaluated by carotid eco-doppler. Mononuclear cells were purified from peripheral blood, and RNA was isolated. RNA from 25 axSpA patients was sequenced using the Illumina platform. For the identification of patient subgroups and the generation of co-expressed gene modules, the “hierarchical clustering” and WGCNA (“Weight gene correlation network analysis”) methodologies were used, respectively. Functional analysis of the genes conforming each module was carried out to identify enriched pathways and functions using the EnrichR platform. Hub genes were measured through high throughput PCR (Fluidigm Biomark HD) in a validation cohort of 50 axSpA patients. Association and correlation studies between the molecular and clinical profiles were performed. In vitro studies in peripheral blood mononuclear cells (PBMCs) from patients belonging to different molecular clusters were performed.

Results: Unsupervised analysis of the transcriptome revealed the presence of two “clusters” of axSpA patients, clearly differentiated by their molecular and clinical profiles. Specifically, the molecular analysis distinguished patients with longer disease duration, greater disease activity, radiographic damage, and cardiovascular risk. WGCNA identified 11 highly co-expressed modules. Among them, six were differentially expressed between the two clusters, being responsible for the molecular and clinical distinction of those groups. The functional analysis of these 6 gene modules revealed the enrichment of these genes in pathways related to inflammation, oxidative metabolism, proliferation of B and T lymphocytes, immune response, and the increase of cell survival. Finally, key genes were identified within each module (“hub genes”), whose expression was associated with a more active phenotype of the disease such as ALOX5, GAB2, PSMD13, CASP8, NOTCH e ITGA4. Hub genes were validated in an additional cohort of 50 axSpA patients and correlated with mSASSS. Treatment of PBMCs from patients belonging to the two different clusters with autologous serum induced a different expression of genes involved in cell activation and inflammation.

Conclusion: 1) The whole transcriptomic analysis by RNAseq in peripheral mononuclear cells from axSpA patients distinguished, in an unsupervised manner, subgroups of patients with distinctive clinical profiles. 2) The analysis of gene modules identified new pathways and molecular functions potentially involved in the pathophysiology of the disease. Funded by ISCIII (P011/0019) co-financed by ERDF, Andalusian Foundation of Rheumatology (FAR).

POS0043 COMPLEMENT IN RADIOGRAPHIC AXSP – BIOMARKERS OF RADILOGIC PROGRESSION? POST HOC ANALYSIS FROM CONSUL, A LONGITUDINAL MULTI-CENTER RANDOMIZED CONTROLLED TRIAL COHORT OF AXSPA-PATIENTS WITH A HIGH RISK OF STRUCTURAL PROGRESSION INITIATING TREATMENT WITH TNF-I

Keywords: Innate immunity, bDMARD, Spondyloarthritides

C. E. Mestagaed1,2, A. Toldborg1,2, A. G. Loft1,2, S. Thiel2, B. Muche2, V. Riis Rodriguez2, M. Tomaguy3, M. Protopopov4, J. Listing5, J. Sieper6, D. Poddubnyy7, F. Profi8, Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 2 Aarhus University, Department of Biomedicin, Aarhus, Denmark; 3 Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 4 Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany

Background: The biological processes involved in the development of structural changes associated with radiographic axial spondyloarthritides (axSpA) remain largely unsolved. Still, high disease activity, elevated C-reactive protein (CRP), and existing syndesmophytes are associated with radiographic progression. The complement system is an inflammation-generating part of the innate immune system. Animal models have shown inhibition of complement activation to diminish structural changes associated with axSpA [1].

Objectives: This project aimed to investigate complement activation and serum levels of complement proteins and their correlations with radiographic spinal progression over a two years follow-up period in a longitudinal cohort of axSpA patients with active r-axSpA, and high risk of radiographic progression, recruited from the randomized controlled trial CONSUL.

Methods: All patients had active r-axSpA and risk factors for radiographic spinal progression (BASDAI ≥4, and elevated CRP and/ or ≥1 syndesmophyte(s)). Serum samples were collected at baseline (n = 96) and after 108 weeks (n = 113) of TNF-I therapy and analyzed by immunoassays for complement lectin pathway proteins (L-ficolin, M-ficolin, H-ficolin, CL-L1, MBL, MASP-1, MASP-2, MASP-3, and MAp44) and the complement activation product C3dg. X-rays were performed at baseline and after 108 weeks and read blinded for clinical data and chronology by three independent expert readers. New bone formation was defined as the growth of syndesmophyte(s) and/ or new syndesmophyte(s) determined by 3-reader-agreement.

Results: Patient characteristics are shown in Table 1. In total, 19 patients developed new bone formation at week 108. Baseline serum levels of MASP-1, MASP-2, and C3dg were elevated in patients with new bone formation, whereas baseline serum levels of MASP-3 were decreased (all p<0.05). Baseline MASP-1, MASP-3, and C3dg predicted the development of new bone formation in a univariate logistic regression analysis, whereas CRP did not. Baseline MASP-1, MASP-3, and C3dg remained significant in a multivariate logistic regression analysis. L-ficolin and C3dg levels at week 108 were elevated in patients with new bone formation, and the serum levels at week 108 predicted development of new bone formation in a univariate logistic regression analysis. In a multivariate regression analysis, C3dg remained significant (p<0.05).

Conclusion: In this study, complement activation measured by C3dg and serum levels of MASP-1 and MASP-3, prior to TNF-I therapy, predicted development of new bone formation at week 108. Furthermore, elevated levels of C3dg and L-ficolin at week 108 were associated with new bone formation. These findings support the involvement of complement activation in new bone formation in r-axSpA.

was selected after excluding E4_MEABOLIA, psoriasis, and psoriatic arthritis when appropriate. Genome-wide association studies (GWAS) and summarized data were extracted from public IEU datasets. The single-nucleotide polymorphism (SNP) rs17149915 was used as an instrumental variable (IV) to identify the potential causal effect. The SNP selection was performed by considering the genome-wide significance, clumping, linkage disequilibrium, and minor allele frequency. The effect alleles were harmonized for exposures and outcomes. An inverse variance weighted (IVW) model was used to estimate causality for each IV in this two-sample MR study. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated for causal estimations. The MR was performed in both directions to explore the possibility of reverse causality.

Results: 4535 patients with hyperlipidemia, 4510 with psoriasis, and 1553 patients with psoriatic arthritis (PsA) were identified from the FinnGen biobank based on their id as noted above. The control patients ranged from 147,221 to 212,242, depending on the cohort being compared. Genetic instruments comprising 5 SNPs for hyperlipidemia, 16 SNPs for psoriasis and 4 SNPs for PsA were used for this two-sample MR. A significant causal effect was noted in hyperlipidemia and psoriasis (OR 1.26 (95% CI 1.097-1.439); p < 0.00009) and hyperlipidemia and PsA (OR 1.35 (95% CI 1.08-1.68; p=0.007) but no causal effect was noted in the reverse direction with psoriasis leading to hyperlipidemia OR 1.02 (95% CI 0.977-1.07; p=0.31) and PsA leading to hyperlipidemia OR 1.03 (95% CI 0.987 to 1.08; p=0.15).

Conclusion: Our two-sample MR study genetically predicted that hyperlipidemia has a potential causal association with psoriatic disease, which leads to a higher risk of psoriasis and PsA. Further validation and molecular studies are required to understand this relationship. If these results were to be validated, targeted reduction of hyperlipidemia may help modify the expression of psoriatic disease.

POS0045  CHILDHOOD INFECTIONS AND PERINATAL FACTORS AS RISK FACTORS FOR ANKYLOSING SPONDYLITIS – RESULTS FROM A NATIONWIDE CASE-CONTROL STUDY

Keywords: Spondyloarthitis, Epidemiology, Registries

M. Morin1, U. Lindström2, K. Hellgren3, T. Frisell4. 1Karolinska Institute, Clinical Epidemiology Division, Department of Medicine, Solna, Stockholm, Sweden; 2Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: A growing body of evidence suggests that there are associations between perinatal factors or early life exposures and later development of chronic inflammatory diseases. For ankylosing spondylitis (AS), previous studies have found increased risks associated with birth order and childhood respiratory tract infections, while breast-feeding and childhood appendicitis have been found protective.

Objectives: To identify early life risk factors for AS, with focus on perinatal characteristics and childhood infections.

Methods: People with AS from the Swedish National Patient Register, born 1973-2004, were matched 1:5 on age, sex, and place of residence to general population controls. Conditional logistic regression was used to compare odds ratios for AS in relation to potential risk factors identified in the Medical Birth Register and the National Patient Register.

Results: People with AS (n=5427) had significantly more hospitalizations for infections before age 16 compared to controls (n=21523), and had more often gone through a tonsillectomy (table 1). People with AS were also more likely to be born in the winter months, and to have an older sibling, while having a sibling overall (older or younger) resulted in an odds ratio for AS of 1.01 (0.93-1.11). No association was seen with factors such as maternal age, Caesarean delivery, or a 1 SD change in weight for gestational age (table 1). Odds ratios for AS associated with being born small or large for gestational age (>2 SD below or above sex-specific mean weight) was 1.10 (0.93-1.30) and 0.89 (0.74-1.08), respectively. In line with previous data, childhood appendectomy was associated with an odds ratio <1, but the estimate did not reach statistical significance.

POS0047 THE COMPLEMENT FACTOR H-RELATED PROTEIN-5 EXACERBATES PATHOLOGICAL BONE FORMATION OF ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritides, Animal Models

C. N. Sun1, J. Lee2, S. Jo3, I. H. Sung2, T. H. Kim2,4, 1Kemyung University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of (South Korea); 2Hanyang University Institute for Rheumatology Research, Rheumatology, Seoul, Korea, Rep. of (South Korea); 3Hanyang University Hospital, Orthopaedic Surgery, Seoul, Korea, Rep. of (South Korea); 4Hanyang University Hospital for Rheumatic Diseases, Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: The complement factor H-related protein-5 (FHR-5), a member of the human factor H protein family, enhances complement activation. The influence of complement activation on bone and joint was recognized in bone fracture healing, arthritis, and osteomyelitis. Recently, FHR-5 has been linked to eye, kidney, infection, cancer and autoimmune diseases. FHR-5 was also significantly up-regulated in proteomic analysis of serum and synovial fluid for ankylosing spondylitis (AS).

Objectives: To aim to evaluate whether FHR-5 exacerbates bone inflammation and ectopic formation of AS.

Methods: The study included 65 patients with AS and 25 healthy controls (HC). Collected sera were divided into three groups according to HC, two AS groups (low CRP and high CRP) based on the CRP 0.8. Human TNF, IL-6, IL-17, IL-23, and FHR-5 in three groups were measured with ELISA and human FHR-5 levels were compared to TNF, IL-6, IL-17, and IL-23 levels. In addition, soluble FHR-5 proteins were administered with Curdlan-injected SKG mice 2 time for a week and monitored for 5 weeks in vivo model. Foot and ankle were evaluated by micro-CT. Hematoylin and Eosin for histological observation, and Safranin O for cartilage. Moreover, these findings were further assessed in the AS-osteoprogenitor In vitro model.

Results: In consistent with human data, proinflammatory cytokines (TNF, IL-6, IL-17A, and IL-23) and CFHR5 were elevated in AS group compared to HC group. FHR5 levels were not significantly correlated with proinflammatory cytokines, whereas FHR5 levels in AS were only positively correlated with the high CRP group. Notably, treatment with soluble FHR5 has no effect on clinical arthritis scores and thickness at hindpaw in Curdlan-injected SKG, but significantly increased the ectopic bone formation at the calcaneus and tibia bones of ankle as revealed by micro-CT image and quantification. Basal FHR5 expression was upregulated in AS-osteoprogenitors compared to control cells. Also, treatment with FHR5 remarkably induced bone mineralization status of AS-osteoprogenitors during osteogenic differentiation accompanied by MMP13 expression.

Conclusion: We provide the first evidence demonstrating that FHR-5 can exacerbate pathological bone formation of AS. Therapeutic modulation of FHR-5 could be promising for future treatment of AS.

POS0048 LIPOLYSACCHARIDE ACTIVATED ENTHESEAL MYELOCILL CELL INHIBITION WITH UDAPACITINIB PARADOXICALLY INCREASES MYELOCILL PRO-INFLAMMATORY CYTOKINES INCLUDING TNF AND IL-23 BY RESTRAINING AN IL-10 NEGATIVE FEEDBACK-BUT T-CELL TNF AND IL-17 IS STRONGLY BLOCKED

Keywords: Enthesitis, Cytokines and chemokines, Targeted synthetic drugs

S. Gires1,2, T. Macleod1, C. Wong1, M. Harland1, N. Modermot1, C. Bridgewood1, A. S. Rao1, A. Khan1, P. Loughenbury1, D. Mconagle1,2

Background: Upadacitinib is effective in spondyloarthritis (SpA) associated arthropathy and is licensed for ankylosing spondylitis and psoriatic arthritis. Collectively SpA is linked to enthesitis with both myeloid lineage and T-lineage cells contributing to the IL-23/IL-17 and TNF axes that underscore disease.

Objectives: To investigate the effect of upadacitinib on an in vitro human enthesitis model by focusing separately on the IL-23/IL-17 axis component myeloid and T-cells to better elucidate mechanisms of action in vivo.

Methods: Normal spinoous process enthesis (n=26) was obtained from patients undergoing spinal decompression or surgery for spondosis correction as described [1]. Enthesisis cells were subsequently isolated by mechanical digestion. Enthesis myeloid cells were stimulated with LPS with and without upadacitinib. IL-23, TNFβ, and other proinflammatory cytokines in the supernatants were quantified using ELISA. IL-23 levels were measured after myeloid cell stimulation with LPS in the presence of upadacitinib and IL-10. IL-23 levels were also measured after stimulation with LPS in the presence of an IL-10Rβ blocking antibody. Enthesis cells were stimulated with anti-CD3 with or without LPS, Th17-driving cytokines (IL-23 and IL-1β) and upadacitinib. Supernatants were measured by ELISA and cytokine-positive cell populations assessed by intracellular flow cytometry.

Results: Unexpectedly, upadacitinib significantly increased myeloid cell secretion of IL-23, TNFβ, and other proinflammatory cytokines after stimulation with LPS (Figure 1) (LPS = 51.2 pg/ml vs LPS + 1 µM Upa = 1048 pg/ml IL-23, n= 11). Addition of recombinant IL-10 attenuated such IL-23 blockade of the IL-10 receptor with a blocking antibody increased IL-23 secretion from myeloid cells after stimulation with LPS (100 ng/ml IL-10 = 2.79 mean fold increase in IL-23, n=5). Despite this effect, upadacitinib strongly blocked TNFβ and IL-17 from Th17 and Tc17 enthesial derived cells stimulated with exogenous IL-23 (138.19 pg/ml vs 14.2 pg/ml IL-17A after addition of 1 µM Upa to Th17 driving conditions, n = 5). Furthermore, addition of upadacitinib to LPS + anti-CD3 activated enthesial cells strongly downregulated T-cell derived IL-17 and TNFβ despite a simultaneous increase in myeloid IL-23.

Conclusion: LPS activated myeloid cells, predominantly monocyte lineage further increase key cytokines IL-23 and TNFβ post upadacitinib. This involves IL-10 pathway inhibition. However, in this system T-cell derived cytokine production is completely blocked despite elevation of myeloid IL-23 and TNFβ. These unexpected findings highlight the pivotal role of T-cell derived cytokines in SpA given the known efficacy of JAK inhibition and these findings merit consideration in the known efficacy of JAK inhibition and these findings merit consideration in further research.

stable group, 1/0.5 in the half-dose group, and 0.7/0.0 in the tapering to withdrawal group, with significant difference between the stable and half-dose group, p<0.01. Sensitivity analyses in the full analysis population gave similar results.

Conclusion: These 3-year data show that 41% of patients in the tapering to withdrawal arm achieved long-term drug-free remission, indicating that this is a realistic option for some RA patients in sustained remission. The two tapering strategies were associated with an increased risk of flares compared to full-dose csDMARD, and the half-dose group had more radiographic change. However, there were no differences in DAS-remission at the end of the study period. Further research identifying prognostic factors for successful tapering is needed.

**TAPERING GLUCOCORTICOIDS AND RISK OF FLARE IN RHEUMATOID ARTHRITIS ON BIOLOGICAL DISEASE MODIFYING ANTIRHEUMATIC DRUGS (bDMARDS)**

**Keywords:** Real-world evidence, Tapering, Rheumatoid arthritis

G. Adami1, A. Fassio1, D. Gatti1, C. Benini1, O. Viapiana1, D. Bertelle1, M. Rossini1. 1University of Verona, Rheumatology Unit, Verona, Italy
Background: 2022 EULAR recommendation announced that both biological disease-modifying antirheumatic drugs (bDMARDs) and Janus kinase inhibitors (JAKI) are considered in the phase II treatment of rheumatoid arthritis (RA). However, we still lack evidence of direct comparison between these agents regarding efficacy, safety, and tolerability.

Objective: The aim of this multi-center (7 university-related hospitals) [1][3], retrospective study is to clarify the factors affecting treatment retention of bDMARDs and JAKI in a real-world setting.

Methods: This study assessed 6,666 treatment courses of bDMARDs and JAKI introduced from 2001 to 2022 (TNF inhibitors [TNFI]=3,377, anti-IL-6 receptor antibody [aIL-6R]=1,497, cytotoxic T lymphocyte-associated antigen 4 [CTLA-4 Ig]=1,119, JAKI=453). Biologic naive cases 55.4%, baseline age 58.8 years, female 82.6%, disease duration 9.7 years, DAS28-ESR 4.3, concomitant methotrexate (MTX) 52.8%, other csDMARDs 26.0%, and oral glucocorticoid (GC) 36.4%. Reasons for discontinuation were classified into four categories by each attending physician: 1) lack of effectiveness (primary and secondary), 2) toxic adverse events (infection, malignancies, and cardiovascular events, etc.), 3) non-toxic reasons (patient preference, change in hospital, and pregnancy, etc.), and 4) remission. Rate of discontinue during each discontinuation reason was estimated at 36 months using the Kaplan-Meier method and adjusted for potential clinical confounders (age, sex, concomitant GC, MTX, and other csDMARDs, switched number of bDMARDs or JAKI, and prior use of TNFI, aIL-6R, CTLA-4Ig, or JAKI) using Cox proportional hazards modeling.

Results: Adjusted retention rates for each discontinuation reason were as follows: due to lack of effectiveness was all-IL-6R=80.9%, JAKI=75.2%, CTLA-4 Ig=73.6%, and TNFI=66.1% (Cox P<0.001 between 4 groups) (figure 1a), due to toxic adverse events was CTLA-4Ig=88.0%, JAKI=86.4%, all-IL-6R=84.1%, and TNFI=83.6% (Cox P=0.052) (figure 1b), due to non-toxic reasons was all-IL-6R=96.9%, TNFI=85.9%, JAKI=85.9%, and CTLA-4Ig=82.6% (Cox P=0.064), and due to remission was JAKI=97.1%, CTLA-4Ig=96.7%, all-IL-6R=96.0%, and TNFI=94.9% (Cox P<0.001). Compared to TNFI, all-IL-6R (hazard ratio [HR]=0.54, 95% CI=0.47–0.61, P<0.001), JAKI (HR=0.69, 95% CI=0.56–0.85, P<0.001), and CTLA-4 Ig (HR=0.75, 95% CI=0.66–0.86, P<0.001) showed lower discontinuation rate due to lack of effectiveness. Compared to TNFI, CTLA-4 Ig showed lower discontinuation rate due to toxic adverse events (HR=0.77, 95% CI=0.63–0.93, P=0.008) and remission (HR=0.67, 95% CI=0.46–0.98, P=0.041). Other factors increasing drug discontinuation due to lack of effectiveness was switched number of bDMARDs or JAKI (HR=1.42, 95% CI=1.24–1.63, P<0.001), concomitant GC (HR=1.17, 95% CI=1.06–1.29, P=0.0018), and prior aIL-6R use (HR=1.24, 95% CI=1.05–1.45, P=0.011). On the other hand, higher age (HR=1.01, 95% CI=1.00–1.02, P=0.001) and concomitant GC (HR=1.29, 95% CI=1.07–1.51, P=0.001) increased drug discontinuation due to toxic adverse events.

Conclusion: Adjusted by potential confounders, all-IL-6R showed lowest discontinuation due to lack of effectiveness, and CTLA-4 Ig showed lowest discontinuation due to toxic adverse events. Besides the difference of bDMARDs and JAKI, concomitant GC increased drug discontinuation due to lack of effectiveness and toxic adverse events.

References:
Background: Radiographic joint damage progresses in 20-30% of rheumatoid arthritis (RA) patients despite fulfilling clinical remission criteria [1]. Ostestis assessed on MRI predicts subsequent bone damage progression [2]. Therefore, targeting absence of osteitis combined with clinical remission may improve long-term radiographic outcomes.

Objectives: To investigate whether a 2-year MRI treat-to-target (MRI T2T) strategy targeting absence of osteitis combined with clinical remission, compared to a conventional T2T strategy targeting clinical remission only, could reduce radiographic joint damage progression over 5 years in RA patients.

Methods: IMAGINE-more was designed as a three-year observational extension study of the 2-year IMAGINE-RA randomized clinical trial [3]. IMAGINE-RA included 200 RA patients in clinical remission (DAS28-CRP<3.2 and no swollen joints), with erosive disease (bone erosion on conventional radiography), and treated with csDMARDs. The objective was to investigate whether an MRI T2T strategy targeting absence of osteitis combined with clinical remission (DAS28-CRP<3.2 and no swollen joints) as compared to a conventional T2T strategy, targeting clinical remission only, could improve remission rates and prevent radiographic joint damage progression. If treatment target was not met, treatment was intensified stepwise starting with increment in csDMARDs and subsequently adding biologics. Participants in the IMAGINE-more study were managed in routine clinical practice in outpatient clinics. Clinical examinations and radiographs of hands and feet (also obtained at baseline, year 1 and 2 in IMAGINE-RA) were done year 3, 4 and 5. The primary endpoint was the proportion of patients with no radiographic progression (increase in total van der Heijde-modified Sharp score (vdHSS) ≤0) from baseline to year 5. Secondary endpoints were 0-5 years changes in total vdHSS, vdHSS erosion and joint space narrowing (JSN) scores. Dichotomous endpoints were estimated by logistic regression, while median differences were calculated for the continuous outcome measures.

Results: Informed consent to participation in IMAGINE-more was obtained from 131 patients (59 from the original MRI T2T group). Of these, 14 patients (24%) in the MRI T2T group and 19 patients (28%) in the conventional T2T group had no radiographic progression from baseline to year 5 (OR 0.70 [0.28 to 1.71]). As illustrated in the Table 1 and Figure 1, the median progression in total vdHSS from baseline to 5 years was low, with no differences between treatment groups.

*Group contrasts are presented as No. (%) for dichotomous data and medians [IQR] for continuous data. OR (95% CI) were estimated from logistic regression adjusted for a propensity score and with non-responder imputation. For endpoints with continuous data median differences (95% CI) were calculated based on the ITT population (no manual imputation). In addition to the radiographic endpoints, the full IMAGINE-more study includes a clinical co-primary endpoint, and several secondary endpoints.

Conclusion: A 2-year combined MRI T2T and clinical T2T strategy, compared with a conventional clinical T2T strategy alone, did not result in reduced radiographic progression in the long term over 5 years in RA patients with erosive disease fulfilling clinical remission.

and autoantibody-negativity (respectively HR 1.89, 1.04-3.2, p=0.03; HR 1.66, 1.00-3.15, p=0.04). The latter confirms to be a significant predictor of second b/tsDMARD failure as well (HR 2.13, 1.08-4.17, p=0.03). At univariable analysis, significant predictors of D2T were concomitant diagnosis of fibromyalgia, autoantibody-negative status and lower doses of methotrexate. At bivariate logistic regression, fibromyalgia and autoantibody-negative RA maintained independent association with adjusted ORs (95% CI) of 3.6 (1.02-16.6) and 4.3 (1.01-24.1), respectively.

Conclusion: Early diagnosis, prompt initiation of methotrexate and management according to T2T strategy have substantially improved RA outcomes, and only about 16% of patients require escalation to second-line therapies. However, in those refractory to csDMARD, EAC setting seems not to ameliorate treatment persistence, as retention rates of b/tsDMARDs are similar to those observed in established disease. Early methotrexate inefficacy and autoantibody-negative disease appear to be predictive of first b/tsDMARD failure, moreover, patients with autoantibody-negative disease maintain a higher risk of failure of subsequent lines of therapies. Collectively, our findings suggest the need for a more tailored approach to refractory RA patients, especially to autoantibody-negative ones.

SOCIOECONOMIC DEPRIVATION IS ASSOCIATED WITH REDUCED RESPONSE AND LOWER TREATMENT PERSISTENCE WITH ANTI-TNF THERAPIES IN PEOPLE WITH RHEUMATOID ARTHRITIS

Keywords: Epidemiology, bDMARD, Rheumatoid arthritis

S. S. Zhao1, L. Kearnsley-Flleet2, K. Rogers2, K. Watson3, A. Bosworth4, J. Galloway5, S. Verstappen1, J. Humphreys1,5, A. Barton5,6, K. Hyrich5,6

Background: Recent global health crises have highlighted the importance of socioeconomic (SE) inequalities and its influence on health provision and outcomes. The impact of SE deprivation on treatment of rheumatoid arthritis (RA) is understudied in contemporary biologic-treated populations.

Objectives: To investigate the association between SE deprivation and outcomes of TNF inhibitor (TNFi) treatment

Methods: Individuals commencing their first TNFi in the BSR Biologics Register for RA from 2001 to 2020 were included. SE deprivation was proxied using the Index of Multiple Deprivation (IMD), which measures relative deprivation of geographic areas. Using the participants’ residential postcode, each individual was assigned a relative rank score and categorised into the 20% most deprived, middle 40%, and 80% least deprived areas. Using the participants’ residential postcode, each individual was assigned a relative rank score and categorised into the 20% most deprived, middle 40%, and 80% least deprived areas.

BEYOND THE WINDOW: EFFECTS OF LONG-TERM TIGHT CONTROL IN EARLY-TREATED RHEUMATOID ARTHRITIS UNDER REAL-LIFE CONDITIONS

Keywords: Treat to target, Rheumatoid arthritis, Real-world evidence

1Hospital Universitário de Brasília, Residency Program in Rheumatology, Brasília, Brazil; 2Universidade de Brasília, Rheumatology, Brasilia, Brazil; 3UNICEUB, Rheumatology, Brasilia, Brazil; 4Hospital do Servidor Público Estadual de São Paulo, Rheumatology, São Paulo, Brazil; 5Universidade do Estado do Rio de Janeiro, Rheumatology, Rio de Janeiro, Brazil; 6Universidade Federal do Paraná, Rheumatology, Curitiba, Brazil; 7Universidade Federal de Santa Catarina, Rheumatology, Florianópolis, Brazil; 8Universidade Federal de Minas Gerais, Rheumatology, Belo Horizonte, Brazil; 9Universidade Estadual de Campinas, Rheumatology, Campinas, Brazil; 10Universidade de São Paulo, Rheumatology, Ribeirão Preto, Brazil; 11Universidade Federal do Pará, Rheumatology, Belém, Brazil; 12Universidade de São Paulo, Rheumatology, São Paulo, Brazil; 13Universidade Federal do Rio Grande do Sul, Rheumatology, Porto Alegre, Brazil; 14Universidade Estadual de Maringá, Rheumatology, Paraná, Brazil

Background: Early treatment, within the window of opportunity, treat-to-target (T2T) and tight control (TC) are fundamental principles of management in rheumatoid arthritis (RA). The Brasilia Cohort of Early Rheumatoid Arthritis (BSB Cohort) is a real-life cohort designed and conducted under these principles.[1] The REAL study (Rheumatoid Arthritis in Real Life in Brazil) is a prospective multicentric cohort of patients with RA encompassing 11 public healthcare centers in Brazil, designed to reflect real-life, conventional managed conditions.[2] Objectives: To compare early-treated patients with RA managed under the principles of T2T and TC vs. those exposed to conventional management in the long term, as for relevant clinical and radiographic outcomes, in real-life settings.

Methods: Participants from the BSB Cohort (under T2T and TC management) were compared to three randomly selected subsamples from the REAL study (REAL1, REAL2 and REAL3, exposed to conventional management). All patients initiated treatment with disease-modifying drugs (DMARD) within one
year of symptom onset. The groups were compared regarding the occurrence of erosive disease, use of corticosteroids (CE) and immunobiologicals (bDMARD), remission rates according to DAS 28-ESR and physical function (Health Assessment Questionnaire - HAQ).

**Results:** A total of 256 patients were included (64 from the BSB Cohort and 64 patients from each of the REAL1, 2 and 3 subsamples), predominantly female (88.3%), white (52%), with a mean age of 53.7 years, positive rheumatoid factor (73.4%), mean total disease duration of 94.1 months and delay time between first symptoms and use of first DMARD of 6.94 months. The groups compared did not significantly differ in terms of gender ($\chi^2=8.19$, p =0.103), race ($\chi^2=7.68$, p =0.053), age (F=1.28, p =0.279), presence of positive rheumatoid factor ($\chi^2=1.89$, p =0.594), mean disease duration (F=1.96, p=0.120) and time delay of symptoms until use of first DMARD (F=0.34, p =0.793). The BSB Cohort showed significantly less frequency of erosive disease, use of CE and bDMARD, and higher DAS 28-ESR remission rate (Figure 1). Mean HAQ score was lower in the BSB Cohort (0.546) than in the REAL1 (1.033), REAL2 (0.821) and REAL3 (0.748), F=5.23, p=0.02. Mean DAS 28-ESR was lower in the BSB Cohort (2.90) than in the REAL1 (3.68), REAL2 (3.44) and REAL3 (3.21), F=3.43, p=0.018.

**Conclusion:** Under real-life conditions, in the long-term, adherence to T2T and TC principles was found essential to preserve the expected benefits of the early RA treatment within the window of opportunity, in terms of less occurrence of erosive disease, less use of CE and bDMARD, higher DAS 28-ESR remission rate and better physical function (lower HAQ score).

**Figure 1.** Comparison of the occurrence of erosive disease, CE and bDMARD use and the DAS 28-ESR remission rate in the BSB Cohort (strict control) and REAL cohorts 1, 2 and 3 (conventional control). Note: $\chi^2$=chi squared; V=Crammer’s V, p=p value (significant at <0.05).

WHICH ADVANCED TREATMENT SHOULD BE USED FOLLOWING THE FAILURE OF A FIRST-LINE ANTI-TNF IN PATIENTS WITH RHEUMATOID ARTHRITIS? 15 YEARS OF EXPERIENCE FROM THE QUEBEC REGISTRY RHUMADATAM

Keywords: Rheumatoid arthritis, Registries, Real-world evidence

D. Choquette1, L. Bessette2, L. Choquette Sauvageau1, J. Brown2, I. Ferdinand1, P. Harauzi1, M. Joly-Chevrier1, A. Masetto4, F. Massicotte1, V. Nadon1, J. P. Pelletier1, J. P. Raynauld1, D. Sauvageau1, A. Turcotte2, E. Villeneuve1, L. Coupal1, 1Institut de rhumatologie de Montréal, Rhumatologie, Montréal, Canada; 2Centre de l’ostéoporose et de rhumatologie de Québec (CORQ), Rhumatologie, Québec, Canada; 3Université de Montréal, Médecine, Montréal, Canada; 4Clinique de santé Jacques-Cartier, Rhumatologie, Sherbrooke, Canada

Background: Since 2000, advanced therapies (AT) have revolutionized rheumatoid arthritis (RA) treatment. Initially, TNF-targeted therapies were the only options. Then, therapies with different modes of action (OA) appeared. Habits and medication availability often determine second-line AT choices. Research suggests that specific sequences provide better long-term effectiveness [1,2].

Objectives: Evaluate which alternative medication provides the best sustainability following first-line TNF failure.

Methods: Data from AT prescribed since January 2007 was extracted from RHUMADATAM. Patients were followed until treatment discontinuation, loss to follow-up, or November 25, 2022. A descriptive statistic was used to compare patient characteristics. Kaplan-Meier was used to compare treatment discontinuation rates.

Results: A total of 611 patients (320 TNFi and 291 1237 OMA were included. The mean age at diagnosis was 44.5 (14.4) and 43.9 (14.8) in the TNFi and OMA groups, and disease duration at treatment initiation (TI) was 14.1 (11.1) and 12.9 (12.9). Women made up 72.8% and 81.1% of these groups. The age-adjusted Charlson Comorbidity index (ACCI) was 2.15 (2.1) and 2.1 (2.1). Patients reported more comorbidities, pain and fatigue, longer duration of morning stiffness, and higher HAQ score and disease activity in the OMA group (Table 1). The physician’s global assessment of disease activity and the number of swollen and tender joints were also higher in the OMA group. OMA’s retention rate was higher (Figure 1, logrank=0.0034) than TNFi retention following initial TNFi-IR. In a stratified analysis, rituximab (adjusted (Sidak) logrank=0.0048) had higher retention.

Conclusion: When a first TNFi fails, switching to an OMA, especially rituximab, appears to be the best strategy. Adequate assessment of more recent agents requires longer observation periods.

OBESITY ASSOCIATES WITH HIGHER LEVELS OF INFLAMMATION DURING THE DISEASE COURSE, BUT ONLY IN ACPA-POSITIVE RA

Keywords: Rheumatoid arthritis, Comorbidities, Outcome measures

N. Den Hollander1, A. M. P. Boeren2, A. Van der Helm – van Mil1,2, H. W. Van Steenbergen1. 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Erasmus MC, Rheumatology, Rotterdam, Netherlands

Background: Obese rheumatoid arthritis (RA) patients have higher disease activity scores (DAS) and lower odds of achieving remission. Although it has been convincingly shown that obese RA-patients experience more pain and have lower wellbeing scores, results are conflicting whether obesity has “pro-inflammatory effects” measured by higher swollen joint count (SJC) and CRP-levels. Additionally, associations of obesity with the DAS-components have not been studied longitudinally and it is unknown whether “pro-inflammatory effects” are similarly present in ACPA-positive and -negative RA. As in vitro data suggested that ACPA can enhance inflammatory-responses, we hypothesized that the association of obesity with SJC and CRP is strongest in ACPA-positive RA.

Objectives: To increase the understanding regarding the effect of obesity on the course of disease activity by studying associations of obesity with DAS-components in ACPA-positive and ACPA-negative RA.

Methods: We studied 649 RA-patients (358 ACPA-positive, 291 ACPA-negative), consecutively included in Leiden Early Arthritis Clinic from May 2011 onwards, and with a total of 2871 DAS-measurements over 5 years. Courses of DAS44 and
DAS-components (SJC-44, TJC-53, CRP and VAS[0-100]) were compared between RA-patients with normal weight (BMI 18.5-24.9; reference category), overweight (25.0-29.9) and obese patients(≥30.0), stratified for ACPA-positivity. Linear mixed models and Poisson mixed models with a knot at 4 months were used.

**Results:** Obese patients had a 0.32 units higher DAS compared to normal weight at diagnosis, this persisted during follow-up. Stratification for ACPA revealed that obese ACPA-positive patients had a 0.43 units (95%CI 0.22,0.64) higher DAS over time, whereas this difference was smaller and not statistically significant in ACPA-negative RA (0.19 units; 95%CI -0.01, 0.38). In ACPA-positive RA, all DAS-components were significantly higher during all 5 years of follow-up in obese patients compared to normal weight: SJC +60% (IRR1.60; 95%CI 1.18, 2.16), CRP +3.7mg/L (95%CI 0.95, 6.53), TJC +55% (IRR1.55; 95%CI 1.15, 2.10) and VAS +9 units (95%CI 4.09, 14.16; Figure 1). However, in ACPA-negative RA, obese patients only had a statistically non-significant trend towards (22%) higher TJC (IRR1.22; 95%CI 0.96, 1.55) and (4 units) higher VAS (95%CI -0.41, 9.00). Moreover, in ACPA-negative RA obesity was not associated with higher SJC and CRP.

**Conclusion:** Although obesity confers risk for higher DAS-scores over time, the effects of obesity on higher SJC and CRP-levels are restricted to ACPA-positive RA. This is the first demonstration that the influence of obesity on the course of RA is different for the two RA-subtypes.

**Figure 1.** Obesity is associated with more swollen joints and higher CRP-levels over time in ACPA positive but not in ACPA negative RA patients

PARE Poster Tour 1

UNDERSTANDING THE PATIENT PERSPECTIVE IN LIVING WITH AND TREATING SPONDYLOARTHRITIS

Keywords: Quality of life, Spondyloarthritis, Patient information and education

H. Lapidus Glassner¹, B. Schneider², E. Luce³, E. Peacock³. ¹MyHealthTeam, Research, 94104, United States of America; ²MyHealthTeam, Research, San Francisco, United States of America; ³MyHealthTeam, CEO, San Francisco, United States of America

Background: Spondyloarthritis (SpA), the group of conditions that includes anklyosing spondylitis, psoriatic arthritis, and non-radiographic axial spondyloarthritis, among others, can lead to symptoms of pain, stiffness, and swelling. The burden of disease can affect patients' quality of life.

Objectives: Patient research was undertaken to explore the impact of spondyloarthritis on quality of life, patients' ability to manage the disease, as well as experiences with healthcare providers. Better understanding is crucial to improving HCP-patient interactions, helping patients get on the right treatment path, and improving health outcomes.

Methods: In July 2022 an email invitation to an online survey was sent to members of MySpondylitisTeam, a social network of over 88,000 people. In total, 361 members completed the 25-question survey.

Results: 92% of members report that spondyloarthritis interrupts their quality of life (82% strongly agree and 30% somewhat agree) (Figure 1). SpA takes both a physical and emotional toll. 88% report it makes hard to do everyday activities (54% strongly agree and 34% somewhat agree). Symptoms extend well beyond lower back, joint and hip pain (92%, 84%, and 81% experienced in the past year respectively). Virtually all experience fatigue (91%). Additionally, 61% have experienced symptoms of depression (63%) or anxiety (61%) in the past year. At the same time, just 52% believe they can ask doctors and have meaningful discussions about SpA and how best to manage it (27% strongly agree and 25% somewhat agree) (Figure 2). Only 35% are satisfied with the care they receive from the doctor who primarily treats their SpA. 38% indicate that the doctor recommends treatment based on their personal needs, and 36% indicate that the doctor addresses their SpA symptoms.

Which of the following reflect the discussions you have with the doctor who primarily treats your spondylitis? Please select all that apply. (Sample=361)

Conclusion: Understanding the needs of SpA patients provides significant opportunities for rheumatologists and primary care physicians to better support and educate their patients. This includes discussing potential treatment options, listening to patient concerns, and acknowledging the mental health challenges. References: None to report.

DEVELOPMENT OF AN EDUCATIONAL MATERIAL TO PROMOTE HEALTH IN FIBROMYALGIA FOR THE SUBWAY IN THE CITY OF SÃO PAULO, BRAZIL

Keywords: Fibromyalgia, Non-pharmacological interventions, Patient information and education

L. Couto¹, A. Lira¹, M. Antunes¹, M. Pinheiro¹, I. M. B. De Souza¹, A. Cruz¹, P. Januário¹, A. Pasqual Marques¹. ¹University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy (FOFITO), São Paulo, Brazil

Background: The recommendations reviewed by the European League Against Rheumatism (EULAR) for the management of fibromyalgia indicate the importance of combining pharmacological and non-pharmacological interventions. In addition, these guidelines highlight that the initial non-pharmacological strategy should be patient education centered on the process of adapting and coping with fibromyalgia in quality of life.

Objectives: Develop and validate an educational material to promote health in fibromyalgia and disseminate it to the community in the subway of São Paulo - SP, Brazil.

Methods: For the construction of educational material for dissemination, the following steps were followed: Step 1: Identification of the needs of individuals with fibromyalgia and health professionals in which a qualitative research was carried out, through a focus group (a group of patients with fibromyalgia and another of health professionals). Twelve individuals with fibromyalgia and 10 health professionals...
professionals in Brazil were invited to participate. The group meeting sought to identify, through the participants’ speech, what are the needs and problems reported by individuals with fibromyalgia and the possibilities of guidance by an interdisciplinary team of professionals to meet the needs and solve the problems. Qualitative data were analyzed using the content analysis method proposed by Bardin. The construction of the educational material used the Paulo Freire method, which began with an important survey to identify the primary needs of the participants so that they could be worked on so that, subsequently, the awareness process would take place. The researchers developed educational material containing information that was listed by individuals with fibromyalgia and health professionals. The educational material was made in online format.

Results: The educational material was developed based on the contents proposed in the previous phases and is shown in Figure 1.

Conclusion: The present study can contribute to the dissemination of educational strategies that promote health in fibromyalgia, for patients and for community, in order to disseminate scientific knowledge about the syndrome.

POS0062-PARE GREAT SUCCESS FOR THE GERMAN PATIENT RESEARCH PARTNERS (PRPs): FROM THE CALL TO TENDER TO WINNING THE AWARD

Keywords: Patient-led research, Best practices, Patient information and education

C. Ellino-Audersch:1 Deutsche Rheuma-Liga Bundesverband e.V., Voluntary assistant, Bonn, Germany

Background: The Deutsche Rheuma-Liga is a patient organisation with about 270 000 members. We have a long history of an established PRP network. We enjoy an excellent cooperation with our professional PRP-facilitator from the steering committee of our organisation. Our patient organisation provides tools, the PRP reference-cards and a helpful brochure, and takes care of the continuing education of the PRPs.

Objectives: In 2022, the Deutsche Rheuma Stiftung (DRS; German Rheumatism Foundation) for the first time launched the call for the „Projektpreis“ Four prizes were awarded with 10.000 € per prize; and at least one of them had to be a participatory research project. This was the starting point for the German PRP network. The immediate aim was to win at least one of the awards. The overarching aim was to realise, for the first time in the field of German rheumatology, a research project initiated by PRPs.

Methods: In order to forward the call and set out the details of the applications, the first meeting was organised by our research facilitator. We discussed various ideas and evaluated whether the objectives can be achieved or not. The subsequent meetings were organised by the PRPs themselves. We improved the initial ideas and searched for supporting researchers, in order to substantiate the planned research projects and write the applications.

Results: Not all ideas from our PRPs were submitted, because of time limitations and difficulties in finding adequate researchers. In the end, three participatory research projects from German PRPs applied for the „Projektpreis“. The topics of the applications were a) money for disseminating the outcomes of a participatory research project addressing fatigue in Lupus patients, b) initiation of a participatory research project investigating how patients search, find and use web-based disease information in everyday life and c) initiation of a participatory research project investigating biomarkers for fibromyalgia. The total number of applications submitted to the DRS was 14. Finally, two participatory research projects from German PRPs won two of the four prizes. The award ceremony took place during the scientific congress of the German Society for Rheumatology in Berlin.

Conclusion: It was a great honour for the German PRPs receiving the awards for applications based on their own initial ideas. For the Deutsche Rheuma-Liga this was a great success in terms of supporting participatory research. This example shall encourage other patient organisation to be confident in finding and creating their own participation-research project.

Patient Reported Benefits of Participating in an Online Health Community in Managing Rheumatoid Arthritis

Keywords: Quality of life, Rheumatoid arthritis, Self-management

Background: Previous research has shown that participation in online health communities can increase patient engagement, improve patient education, and help empower patients to achieve better health outcomes. This study was designed to measure the impact of one such community on patient outcomes.

Objectives: Patient research was undertaken to better understand the impact of rheumatoid arthritis (RA) on quality of life (QoL) and the perceived benefit that participating in a patient social community in RA has on improving health outcomes. This includes better QoL, better understanding of and adherence to treatments and improved relationships with one's doctor.

Methods: In August 2022, an email invitation to an online survey was sent to US members of myRAteam, a social network of over 197,000 people. In total, 745 members completed the survey. All respondents were 21 or older and self-reported as diagnosed with RA.

Results: The far-reaching impact of RA on QoL was evident in that most respondents reported that they find it hard to exercise (90%) and do everyday chores (90%). Respondents also reported that RA interferes with sleep (83%) and having an active social life (80%). The emotional toll of RA manifested with respondents feeling isolated/alone (71%), anxious (75%), and depressed (77%). While RA patients had a good understanding of the role medications play in slowing RA progression (91%) and potential symptoms they might experience (80%), only half (53%) felt they could avoid triggers that worsen RA. Top reasons for joining myRAteam included seeking information/ways to manage RA and being able to connect with others living with RA. Specifically, respondents were looking to gain insights from others' experiences (65%), gather information about RA (60%), better understand treatment options (59%) and have a way to connect with others (45%) for support and tips for living with RA. Newly diagnosed patients were much more likely to join myRAteam to understand what to expect after their diagnosis (68% versus 38% for those with RA for more than a year), to get information about RA (70% versus 59%) and to better manage their symptoms (67% versus 52%). Almost all (90%) reported benefitting from joining myRAteam, including gaining knowledge about RA (77%), having better knowledge of/ability to stay on medication (58%) and having an improved relationship with their doctor (88%). Additionally, 66% benefited from receiving some form of social/emotional support from others. Specifically, they felt less isolated or alone (41%), better able to cope with the emotional toll of RA overall (37%) and less anxious or depressed (20%). Benefits were particularly evident for frequent visitors. For example, 85% of daily visitors to myRAteam are able to find information/resources to manage RA and 75% have experienced an improved relationship with their doctor. And 53% of frequent visitors feel less isolated/alone versus 29% of less active users.

Conclusion: People with RA, particularly those recently diagnosed, are turning to online communities to find disease-specific medical information and support that they are not getting elsewhere. The majority of those surveyed report several benefits from participating in this community that are linked to improved health. Educating patients on the benefits of participating in a health-related social community can lead to less isolation and other mental health challenges, better informed patients, better treatment adherence and more empowered and productive conversations with the treating doctor. Reaching newly diagnosed patients can help lessen the burden of disease and set patients on the right treatment course to slow progression from the onset.

Education for Patients, Designed by Patients: The Experience in the Design of a Rheumatoid Arthritis Primer

Keywords: Patient information and education, Rheumatoid arthritis, Education

Background: In 2018, thanks to the support of a government entity, the Universi-TAR multi-component educational program was launched; which trained more than 300 patients and certified 50 expert patients in Rheumatoid Arthritis in 2021. In this educational process, patients received training in various knowledge topics for disease care: definitions, signs and symptoms, treatment, medical team, therapeutic adherence, quality of life and transformation of personal behavior to manage relationships and situations. As a result, the educational program proposed the design of educational material that would be useful for the patient population.

Objectives: The objective of this project was to design a primer for patients with rheumatoid arthritis, which helps them understand the disease and the importance of long-term treatment, understand and apply therapeutic adherence, and change the way in which patients assume their role in treatment.

Methods: An editorial committee was created to write the primer. This committee was made up of 8 patient experts in rheumatoid arthritis, 1 rheumatologist, a coordinator of education programs for chronic patients, and a team of content reviewers. The writing of the primer began with a selection of the thematic contents with the greatest impact in their educational process and the writing of the initial manuscript began (by patients for patients). Afterwards, a first revision of the manuscript was made and some contents were adjusted according to the clinimetric standards for international rheumatology. Finally, the manuscript was submitted for review by the team of rheumatologists and the interdisciplinary team, thus creating the final version of the primer.

Results: In December 2022, an event for patients with Rheumatoid Arthritis was held. In this event the primer was presented and its purposes were explained. The primer gathers topics such as: disease definitions, signs and symptoms, diagnosis and treatment, disease impact, therapeutic adherence, myths and beliefs, the medical team, health literacy, and expert patients (See figure 1). In 2023, this primer will be delivered to all patients so that they can have a source of consultation and information.
Conclusion: It is important to support the dissemination of educational content so that patients have reliable, accurate and oriented information to improve their participation with medical teams in shared decision-making to achieve therapeutic objectives together.

Acknowledgements: We thank the Ministry of Science, Technology and Innovation  Minciencias for allowing us to design this primer and for being able to train our patients. Also, we thank the patients who are part of the editorial committee that designed this primer.

Figure 1.

LIFE WITH A CHRONIC ILLNESS - WHAT NOW?

HOW TO LIVE WITH AXIAL SPONDYLOARTHRITIS, A LIFELONG ILLNESS

Keywords: Spondyloarthritis

1. Wermiskog, L., M. Eidet, K. Lilleby, Spondyloarthritis Association Norway, N/A, Oslo, Norway; 2Novartis, Oslo, Norway

Background: Axial spondyloarthritis is a chronic inflammatory joint disease, which mainly attacks the pelvis, back, neck and thorax, but peripheral joints can also be affected. This patient group is affected to a very varying degree and the disease varies throughout the course of the disease. Some have mild symptoms and may be without ailments for long periods of time. Others have major ailments and may experience increasing stiffness in the back. The average age at the onset of symptoms of AS is 26 years.

Objectives: The aim of this campaign is to focus on life with a chronic illness. How to mentally master your illness and accept it, but also how to be active with the disease. The campaign aims to break down prejudices and discrimination that chronic sufferers are faced with in society, for example that they are weaker or lazier than others. These prejudices help to make the disease a strain mentally as well. Many patients struggle to accept that they have contracted a chronic illness, a disease that stays with you for life.

Methods: Giving this campaign a face, we used a world-renowned photographer and social debates Morten Krogvold to take pictures of Felix Baldauf, world champion in wrestling, living with axial spondyloarthritis. Films were made of Felix’s story, about the road to a diagnosis and about the afterlife diagnosis. In the films, Felix honestly tell how tough and difficult this road has been for him, but at the same time he talks about how life has changed now that he has been diagnosed and properly treated. His goal is now a gold medal in wrestling at the 2024 Olympics, even though he’s living with axial spondyloarthritis, which shows that it is possible to live a good life with the disease and have an active physical life. In order to get as much attention as possible about the campaign, it was launched at political week in Arendal. The films, Felix’s openness about the disease leaves hope for other patients, that one can live a good and active life with the disease.

Acknowledgements: The patient campaign is supported by the Norwegian Directorate of Health, Novartis, AbbVie.

Figure 1. Sankey chart illustrating improvement or worsening (right) of the five most mentioned QoL aspects (middle) of patients with a knee or hip replacement procedure (n=266 documents)
Conclusion: This social listening study indicates pain as the most burdensome OA symptom and sheds light on the QoL impact of surgical procedures. Given limitations of social listening studies (e.g., number of identifiable age groups or gender[3]), the results need to undergo further validation by patient representatives and clinical experts. Yet, this novel method complements common approaches by providing an understanding of patients' perspectives outside the clinic, representing the voices of vulnerable populations who may otherwise participate in clinical or epidemiological studies.

POS0068-PARE VITORIA: A VIRTUAL ASSISTANT TO PROMOTE EDUCATION AND AWARENESS ON JUVENILE RHEUMATOID MUSCULOSKELETAL DISEASES

Keywords: Patient information and education, Non-pharmacological interventions, Self-management

J. Borda D’água1, A. P. Cláudio1, M. B. Carmo1, M. Guerreiro2, A. Cavaco3, D. Piedade4, C. F. Gomes4,5, A. Pais4, E. Mateus4,5

1Faculdade de Ciências da Universidade de Lisboa, Informática, LASIGE, Lisboa, Portugal; 2Egas Moniz School of Health & Science, Egas Moniz Center for Interdisciplinary Research, Lisboa, Portugal; 3Faculdade de Medicina da Universidade de Lisboa, imed — Research Institute for Medicines, Lisboa, Portugal; 4National Association of Patients with Juvenile Arthritis, ANDAI, Lisboa, Portugal; 5Portuguese League Against Rheumatic Diseases, LPCDR, Lisboa, Portugal

Background: The range of musculoskeletal and connective tissue conditions that manifest in children is referred to as paediatric rheumatic diseases[1]. Juvenile idiopathic arthritis (JIA) is the most common childhood chronic rheumatic disease[2]. This disease is the most frequent cause of chronic pain in young people, which negatively affects their quality of life. To mitigate the burden of chronic condition, self-management (e.g., lifestyle) should be combined with medical management. More effective information strategies are required to respond to the needs of those living with rheumatic diseases and their caregivers. Virtual Humans (VH) have been utilized in interactive computational simulations to boost users' acceptability and knowledge of health conditions while also promoting lifestyle changes in healthy individuals or in the management of chronic illnesses, such as juvenile rheumatic musculoskeletal diseases (RMDs)[3,4].

Objectives: This project aimed to develop a web application to support education for disease management and health promotion, in children and young people with RMDs, their caregivers and peers[5].

Methods: The use of gamification as well as a virtual character incorporated in a narrative, with the dual goal of maintaining user engagement and improving the play experience, was the core idea underpinning the development of our application. Group discussions with young patients (members of the patient organisation ANDAI) were used to obtain feedback and experiences from application users during the requirement phase, intermediate feedback and testing the developed application. The application was also assessed by an evaluation survey following the testing phase.

Results: A virtual assistant was developed to communicate with users through speech (voice and subtitles) as well as facial and body motions[6]. This 2D animated young female model, portrays a character with juvenile RMDs and shares information about her lived experiences with the illness. An assessment of user knowledge follows each interaction. Users are encouraged to play and learn more by awarding points and digital badges for right answers or by displaying the solutions when incorrect answers are chosen. In short, on a scale of 1 to 5, 83% of the participants rated the application testing the application with maximal punctuation, indicating that users, who are children with RMDs, their young relatives and/or friends, found this tool useful.

Conclusion: A virtual assistant web application that uses a narrative approach and gamification concepts to encourage education on juvenile RMDs was successfully developed. This web application is intended to be lodged on the ANDAI website to convey easy access. In addition, this tool will be also made available in tablets at the waiting room of paediatric rheumatology services, facilitating education when children are diagnosed.

POS0068-PARE HOW TO REACH MORE PEOPLE WITH RMD THROUGH DIGITAL COUNSELLING

Keywords: Self-management, Mental health, Patient information and education

N. B. Hartz1, G. Gittigorenning, Rådgivning, Gentofte, Denmark

Background: The Danish Rheumatism Association has a professional counselling service, where our 82.000 members can call or write to get help and answers to their questions. The association had planned to make our counselling offers more digital over time but due to corona in 2020 we decided to advance the launch of these digital offerings since all our usual offerings and activities got cancelled overnight.

Objectives: The association wants to be as relevant as possible to all people with RMD and therefore we wish to be present, not only at our usual platforms, but also through digital solutions. Since 2020 the professional counselling has, in collaboration with the communication department, made short videos on SoMe and broadcasted live events on relevant topics with experts, where the viewers have the possibility to interact with questions and emojis during the live events. It is also possible to watch the live events afterwards. Since 2022 the association has increased the digital offers within counselling to also include explainer videos and livestreaming from public meetings at hospitals. Our aim is to give relevant information that help people with RMD to improve their capability of self-management and get them to connect and interact even more with us.

Methods: The first digital events were made with a handheld mobile camera and the sound was not very good. The events were transmitted live on the association’s Facebook page. This new way of approaching people with RMD with professional counselling through live events was successful and had more viewers than we had expected even though the quality in the beginning was poor. This shows that even with scarce resources you can still reach many people with RMD through digital solutions. After a while we hired a professional company to make our live events more professional with correct light and sound, and today we are on a much higher level than at the beginning of our digital transmissions. We have also expanded our ways of making live events from 1-2 experts talking on a specific topic to also include panel discussions, live broadcasting from large public events, explainer videos, live interviews with medical doctors at hospitals etc.

Results: In 2022 the professional counselling service have produced 2 explainers, 8 live events and 12 videos. The topics of the broadcasts were for example pain, sexuality, exercise, mental health, social issues, newly diagnosed etc. The number of people we have reached with the digital counselling will be elaborated on the EULAR congress. We have indications showing that more young people are aware of the association and our professional counselling after having attended more digital services with the possibility to interact or to watch it whenever it suits the person. Furthermore it is a cost effective way to reach a lot of people at one time compared to our 1-on-1 phone consultations in our professional counselling. The downside of doing digital events is that you do not get the personal and direct connection between the professional and the person with RMD and the advice that is given will be more general compared to a telephone conversation. Furthermore, it requires access to the Internet and a Facebook account or similar. Some elderly people can therefore not participate.
in these events. However, in 2022 we offered physical events as well. We are trying to reach out as broadly as we can in order to meet the different needs from people with RMD.

Conclusion: The use of live events and videos is a way to unfold the professional counselling service in order to give help and advice to a broader audience. It has been a huge success with many viewers who interact with us. These digital offers are contributing to make the Danish Rheumatism Association appear as a modern and progressive association. An important notice when wanting to become more digitalized as a patient organization is, that even on a low budget you can reach many people with RMD as long as the content is relevant. We will for sure develop even more digital offers in the future regarding patient information and education in order to improve the quality of life for more people with RMD.

HPR Poster Tour: Diverse interventions and patient perspectives

Keywords: Physical therapy/Physiotherapy, Psoriatic arthritis, Systematic review

M. Kaerts1, J. Eelen2, N. Planc1e, F. Van Loock2, A. Liekens2, K. De Vlam3,4, R. Lories3,5, W. Dankert6, T. W. Swinnen7,8, B. Neenick3,9, 1Myositis Support and Understanding, Patient-Centered Research, Lincoln, DE, United States of America; 2Massachusetts General Hospital - Surgery, Boston, United States of America; 3University of Texas Southwestern Medical Center, Neurology, Dallas, United States of America

Background: Idiopathic inflammatory myopathies (IIMs) often lead to severe impairments in quality-of-life related to physical and emotional burdens. While the healthcare delivery burden in patients with specific types of IIMs has been explored[1], little is known about caregivers' burden, especially in rare diseases.[2] Objectives: Myositis Support and Understanding (MSU), a non-profit patient-led advocacy organization for IIMs, distributed a survey to its members to better understand caregiver burden. The aim of this study was to evaluate the association between caregiver burden by IIM subtype and factors that impact caregiver wellbeing.

Methods: Data Source: An anonymous survey was distributed via RedCAP to MSU members worldwide. A total of 120 caregivers (age range: 30-89) responded to the survey over the course of 4 weeks. Survey: Demographic, diagnostic information, and disease duration data was collected from participants and their caregivers. The Zarit Burden Interview (ZBI), a validated instrument for caregiver burden by IIM subtype and factors that impact caregiver wellbeing. The aim of this study was to evaluate the association between caregiver burden by IIM subtype and factors that impact caregiver wellbeing.

Results: Most of the caregivers in this study were responsible for the care of patients with inclusion body myositis (IBM, 64%) followed by dermatomyositis (DM, 22%).Caregivers reported that 74% of IIM patients under their care had moderate to severe difficulties with mobility and required help some or most of the time. A total of 102 caregivers completed the ZBI: reported burden was mild in 25%, and severe in 4% of caregivers. There was a high degree of at least moderate severity burden in IBM (33%), DM (25%), and polymyositis (25%).

Conclusion: Caregivers face a high degree of burden, most evident in IBM. Burden positively correlated with disease duration with an inflection time of 6 years, thereafter caregivers reported increased burden. The domains that were most impacted include personal strain, social and family life, role strain, and loss of control over one’s life. Insights from this study can help create specific emotional coping strategies for myositis patients and their caregivers.

Background: Rheumatoid arthritis (RA) is a systemic inflammatory autoimmune disease that characterized by chronic, symmetric and erosive synovitis that may lead to severe disability and impairments. RA patients frequently have adverse changes in their body composition, with a decrease in muscle mass and an increase in fat mass, a syndrome that is termed rheumatoid cachexia (RC). RC is associated with chronic inflammation, impaired muscle mass and strength and body mass loss, all of which are classical targets of exercise training.

Objectives: This systematic review and meta-analysis aimed to determine the effects of exercise training on body composition included fat mass, lean body mass and muscle strength in patients with rheumatoid arthritis.

Methods: We searched PubMed/Medline, Web of Science, EMBASE, CINHAL, Scopus, Cochrane Library, Google Scholar and Science Direct for relevant articles until November 2022. Systematic review included randomised controlled trials and controlled trials. Pre- and post- exercises intervention data on our primary outcomes included body composition [e.g., using BMI, bioelectrical impedance analysis, fat-free mass index (FFMI)] and isometric knee muscle strength. Two outcomes included body composition [e.g., using BMI, bioelectrical impedance analysis, fat-free mass index (FFMI)] and isometric knee muscle strength. Two authors independently screened records and data were extracted using Microsoft Excel and exported to STATA version 15.0 software for analysis. Risk of bias was assessed and a random-effects model was used to pool effect sizes by standardised mean differences (SMD).

Results: Six studies with a total of 119 patients with RA in the meta-analysis. Exercises interventions had a median (range) duration of 14 (12-24) weeks and including progressive resistance training, high-intensity resistance training, proprioceptive exercises and water-based exercises programs. Exercises interventions a superior effect compare to control on both fat mass [SDM -0.20 (%95 CI 1.20, 0.79), p<0.001, ı2; %91], lean body mass [SDM 0.66 (%95 CI -0.77, 2.09), p<0.001, ı2; %95] and isometric knee extensor muscle strength [SDM 3.01 (0.59, 5.43), p<0.001, ı2; %97] (Figure 1).

Conclusion: Our meta-analysis indicates different exercises trainings effectively decreased fat mass and increased isometric extensor muscle strength and lean mass in patients with RA thereby slowing or reversing RC.

The main perceived barriers to use of DHI in physical therapy settings were high cost (77.8%), and lack of appropriate DHI to Turkish population (71.5%).

**Conclusion:** This study is the first to present the views of physiotherapists in Turkey on the use of DHI in physiotherapy. Participants are willing to use digital health interventions, but due to obstacles that prevent their use in physiotherapy, there are still some limitations on their use. They contend that for DHI to be widely used, physiotherapists and patients must be educated about them, and the state must support their use and multidisciplinary development.

Expanding the Use of DHI in Physiotherapy

**Conclusion:** Of the 91 eConsult patients, 44 (48.4%) were converted to face-to-face (FTF) consultation with a rheumatologist. Patients evaluated through eConsults were less likely to be referred to a rheumatologist (RR = 0.61, 95% CI 0.46 – 0.80) when compared to in-person referrals. Patients referred through eConsults were twice as likely to be diagnosed with CTD relative to those that were not scheduled for an FTF visit after an eConsult was completed (RR = 2.49, 95% CI 1.28 – 4.84). For the converted patients, 21 (47.7%) were diagnosed with CTD. For those that did not convert to a FTF referral, only 9 (19.1%) were eventually diagnosed with a CTD. Of the 40 in-person patient referrals, 31 (77.5%) were scheduled to follow-up with a rheumatologist; the majority of which (N = 30, 96.8%) were ultimately diagnosed with CTD. Elevated ESR/CRP levels were found in 19 (43.2%) eConsult patients that had converted and 16 (34%) patients that did not convert to FTF. For eConsult patients, those twice as likely to be diagnosed with CTD relative to those referred and scheduled for a CTD diagnosis in the future. Thus, eConsults should be considered an effective and efficient tool in properly referring patients with rheumatologic presentations and parsing out cases that would not require specialist care.

**POS0074-HPR**

**EFFICACY OF E-CONSULTS COMPARED TO IN-PERSON REFERRALS OF ANA POSITIVE PATIENTS TO RHEUMATOLOGY CLINIC**

**Keywords:** Descriptive Studies, Health Services Research, Telemedicine

**J. Par-Young**, J. Young, F. Kennedy, I. Kang, X. Dong, Yale University, Internal Medicine, New Haven, United States of America; Yale University, Psychiatry, New Haven, United States of America

**Background:** Antinuclear antibodies (ANA) are autoantibodies associated with several autoimmune diseases but are also present in healthy individuals due to their role in the body's biological immune response. Thus, testing for ANA in an ambulatory setting could be inappropriately ordered and misinterpreted. Yet, delay in proper management of patients with rheumatologic presentations could result in increased morbidity and health care expenditure. Electronic consultation, or eConsults, could be utilized by primary care providers (PCPs) as a convenient tool to expedite access to rheumatology specialists and optimize care.

**Objectives:** To assess the efficacy of eConsults in terms of resource utilization and time to referral when compared to in-person referrals of ANA+ patients.

**Methods:** In this retrospective cohort study, we reviewed the charts of 131 ANA+ patients within the Yale New Haven Health System seen from August 2019 to September 2022. The charts were divided into cases referred by eConsult and by in-person referrals. Time from chart order to eConsult or in-person consultation, diagnosis after consultation, and laboratory workup results were evaluated. Relative risks (RR) were calculated to compare the efficacy of eConsults vs. in-person referrals in diagnosing connective tissue diseases (CTD) and initiating appropriate referrals. A chi-square test of independence was conducted to determine if there was an association between ESR/CRP levels and conversion to in-person follow-up appointments in eConsult patients.

**Results:** Among the 131 ANA+ patients seen by their PCPs, 91 (69.5%) were referred through eConsult and 40 (30.5%) were in-person referrals to a rheumatologist. The average time from the initial eConsult request to completion of the consult was 1.46 ± 2.54 days while in-person consultations required longer wait times of 76.63 ± 48.61 days.

**Conclusion:** Electronic consultation is an easy and timely method for referral to the rheumatology clinic. In this study, ANA+ patients requiring an urgent consultation were identified earlier through an eConsult compared to an in-person referral. eConsults were also capable of identifying cases that required specialist treatment; 80.9% of patients that weren’t referred would not receive a CTD diagnosis in the future. Thus, eConsults should be considered an effective and efficient tool in properly referring patients with rheumatologic presentations and parsing out cases that would not require specialist care.

**OPPORTUNITIES AND CHALLENGES IN WEB-BASED PATIENT EDUCATION FROM THE PERSPECTIVE OF PATIENTS WITH RHEUMATOID ARTHRITIS – A QUALITATIVE STUDY**

**Keywords:** Self-management, Patient information and education, Rheumatoid arthritis

L. Raunsbaek Knudsen, K. Lomborg, E. M. Hauge, H. A. Zangi, A. De Thurah, Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; Steno Diabetes Center Copenhagen, Steno Diabetes Center, Copenhagen, Denmark; Copenhagen University, Department of Clinical Medicine, København, Denmark; Diakonhjemmet Hospital, REMEDI - Center for treatment of Rheumatic and Musculoskeletal Diseases, Oslo, Norway; VID Specialized University, Faculty of Health, Oslo, Norway
Background: Self-management skills are important for people with inflammatory rheumatic diseases, and can be supported through patient education (PE) (1, 2). Following an increasing use of telehealth (3), digital PE is gaining ground to support patients’ self-management skills, but the evidence is still limited. Currently, we are testing the effectiveness of a digital PE e-learning program designed for people with rheumatoid arthritis (RA), the WebRA trial [4]. In the present qualitative study, we aimed to provide in-depth insight into patient perspectives of the e-learning program.

Objectives: To explore patients’ perceptions of taking part in web-based PE, and how this contributes to self-management of RA.

Methods: We conducted 20 individual qualitative interviews based on the ‘Interpretative Description’ methodology, an inductive research strategy implying an iterative process of data collection and analysis. Newly diagnosed RA-patients were recruited from the intervention group of the WebRA trial after having finalized their one-year follow-up period [4]. A purposive sampling strategy was used to achieve information power by inclusion of participants with different sex, age, and sociodemographic background. The analysis contained a descriptive part followed by interpretation and extraction of main messages.

Results: Overall, participants had positive perceptions of the e-learning program, and only minor technical difficulties were identified. Advantages of e-learning were flexibility, the possibility for repetition, varied and entertaining presentation forms, availability, and learning in familiar and calm surroundings. Disadvantages were described as missing the dialogue with health care providers (HCPs), and therefore unmet relational support needs. The degree to which e-learning perceived to play a role for acquiring knowledge about RA differed. For the majority, a need for insight and clarity into the condition led to an active approach in using e-learning, whereas a minor group had a more hesitant approach, and postponed the use of the program, e.g. because of mental distress following the diagnosis or by oversight. The program was mostly used immediately after having received the diagnosis and only to a limited extent in the time hereafter. This was explained by fulfilled informational needs, a need for normality and a desire for focusing on everyday life. Participants found that the e-learning program facilitated learning and contributed to self-management of their disease. Patients, however, relied on more than knowledge in their self-management including the interaction between information and knowledge, relational support from HCPs, own experiences, and an underlying positive attitude towards living with the disease.

Conclusion: Most patients consider web-based PE to be a well-suited solution for self-management support. The opportunities of e-learning are related to information and knowledge support whereas challenges cover relational and emotional support needs. Thus, it is suggested that future organization of PE offer different forms and combinations of PE to accommodate different needs and preferences of patients throughout the disease course.

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis occurring in 20–30% of patients with psoriasis.[1] Timely diagnosis is important because untreated PsA can result in irreversible joint damage[1] and functional disability.[2] While existing national and international guidelines, such as those produced by EULAR, BSR, ACR/National Psoriasis Foundation and GRAPPA, cover a wide range of aspects of diagnosis and pharmacological management of PsA, gaps have been identified relating to the application of guidance in clinical practice, ongoing non-pharmacological management, and quality of care benchmarking, often related to a lack of evidence. In response, an expert UK consensus group aimed to enhance current guidance.

Objectives: To develop an evidence- and consensus-based set of recommendations for the management of PsA in routine clinical practice that adds value to existing guidelines, suggests minimum and best quality standards for day-to-day PsA management and provides a set of practical strategies to achieve these quality standards, with the aim of supporting clinicians.

Methods: A structured process was used to develop the consensus.

1. A steering committee (SC) of 12 experts in the fields of rheumatology, dermatology and primary care.
2. An initial meeting, consensus themes were discussed and agreed (PsA diagnosis, disease assessment, comorbidities, and management) and consensus questions were drafted. A targeted literature review of PubMed and Embase following a PICO framework was conducted to gather scientific evidence supporting a selection of the questions, while others were agreed to be more appropriately addressed by expert clinical experience. At a second meeting, recommendations were drafted in response to the identified questions, covering gaps in current guidelines. For the next stage, an extended faculty was recruited including rheumatologists (32), dermatologists (6), primary care representatives (3), specialist nurses (5), academics (12) and members of the Brit-PACT patient group [6]. In an online voting platform, the SC and extended faculty entered an agreement score for each recommendation.

Results: The SC and extended faculty agreed on 34 statements covering 15 questions on PsA diagnosis, disease assessment, comorbidities, and management. The diagnosis theme focussed on strategies to identify PsA early and appropriate referral of diagnostic indicators, and guidance on the use of screening tools. The use of imaging to support diagnosis, and appropriate referral time frames were also covered in detail. Recommendations on disease assessment centred on holistic consideration of disease activity, functional impairment and impact from a patient perspective, as well as how to implement shared decision-making. Specific guidance for measurements to be performed at clinic visits was included. For comorbidities, recommendations were made for assessment and management, with specific guidance for high-risk conditions, such as depression and obesity, and those with implications for PsA pharmacological therapy. Management statements (which excluded guidance on pharmacological therapies in extant guidelines) covered multidisciplinary team working, implementation of lifestyle modifications, and treat-to-target strategies built upon the parameters of greatest importance to individual patients. The use of corticosteroids was recommended to be minimised where feasible.

Conclusion: This expert consensus programme identified critical areas beyond pharmacological therapy where existing guidance on PsA management could be enhanced and be of greater practical relevance to clinicians. This work will also be developed into a clinical resource to support healthcare professionals in the care of patients with PsA.

Results: The mean age of the individuals included in the study was 50.38 ± 12.39 years. The median value of the BETY-BQ was 52 (min: 0 max: 112) and the median values of the sub-headings were as follows: pain 10 (min: 0 max: 20), functionality 12 (min: 0 max: 35), emotional status 16 (min: 0 max: 40), sociability 4 (min: 0 max: 12), sexuality 3 (min: 0 max: 8), sleep quality 3 (min: 0 max: 4). High and very high positive correlations were found between the BETY-BQ total score and all parameters, and significant positive correlations were found between the parameters themselves (p<0.005) (Table 1).

Conclusion: According to the results of this study, it was observed that the biospsychosocial characteristics of individuals with SSc were affected by each other. Biospsychosocial status was most affected by emotional status and least affected by sexuality. It was found that pain, functionality, and sleep quality were mostly related to emotional status; sociality was most related to pain and sexuality was most related to functionality. The effect of good emotional status of individuals with SSc on other parameters was remarkable. The results were interpreted as demonstrating the need for biospsychosocial approaches focusing on biospsychosocial effects, especially emotional status, in the disease management of individuals with SSc.

PATIENT-REPORTED OUTCOMES MEASURES FOR SYSTEMIC LUPUS ERYTHEMATOSUS: AN EXPERT DELPHI CONSENSUS TO GUIDE IMPLEMENTATION IN ROUTINE CARE

Keywords: Systemic lupus erythematosus, Patient reported outcomes

I. Castjon1, L. Cano García1, M. J. Cuadrado Lozano2, J. Borrás1, M. Galindo-Izquierdo3, T. C. Salomon Monte3, C. Amorós4, C. San Román Gutiérrez5, A. Muñoz6, Hospital Universitario Gregorio Marañón, Reumatología, Madrid, Spain; 2Hospital regional de Málaga, Enfermería Reumatología, Málaga, Spain; 3Hospital Clínico Universitario de Navarra, Reumatología, Madrid, Spain; 4Hospital de Sagunto, Farmacia Hospitalaria, Valencia, Spain; 5Hospital 12 de Octubre, Reumatología, Madrid, Spain; 6Hospital del Mar, Reumatología, Barcelona, Spain; 7GSK, Market Access Department, Madrid, Spain; 8GSK, Medical Department, Madrid, Spain; 9Hospital Universitario Virgen del Rocio, Reumatología, Sevilla, Spain

Background: Patient-reported outcome measures (PROMs) are useful to incorporate the patient's perspective in the disease decision-making process, which has been identified as one of the main challenges in the management of Systemic Lupus Erythematosus (SLE) patients [1,2].

Objectives: To establish expert recommendations to incorporate PROMs on the current management and empowerment of patients with SLE.

Methods: After a scoping review of the literature and structured interviews with SLE patients (n=9) a survey-based questionnaires were developed by a scientific committee (5 rheumatologists, 1 H. pharmacist and 1 nurse). Using a Delphi approach, consensus was reached regarding the role of PROMs in SLE patients, strategies and more feasible measures to be incorporated in routine care.

Results: A total of 59 experts participated: 51% rheumatologist, 17% internists, 8% nephrologist, 3% dermatologist, and 20% other health professionals in rheumatology (nurses, pharmacists, and psychologists). Around 50% of participants were women, with a mean of 18 years of experience managing SLE patients. Panelists agreed on the following recommendations: incorporating the patient's perspective through the use PROMs (83%), utility of a digital tool to collect PROMs connected to the electronic medical record (83%), incorporating other health professionals to support patients to complete PROMs (77%), a multidisciplinary approach to improve specialists' interaction/coordination (79%), and incorporating H. pharmacists to improve medication management (70%). Pan- elists agreed that PROMs can facilitate patient participation in decision-making with an adherence to treatment improvement (72%). Consensus was reached on the agreement of the effectiveness of PROMs in routine care: a Visual Analog Scale (VAS) 0-100 for pain (83%), fatigue (73%), and patient global assessment (76%), the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT) for fatigue (75%), and the Lupus Impact Tracker (LIT) (75%) to evaluate health-related quality of life.

Conclusion: Strategies to promote a holistic and integrated approach including the creation of multidisciplinary teams and the incorporation of patient's perspective using PROMs, such as VAS-pain, VAS-fatigue, FACIT-Fatigue, VAS-PGA and LIT, are recommended to improve SLE management in routine care.

LONG-TERM EFFECTIVENESS OF A LIFESTYLE PROGRAM FOR RHEUMATOID ARTHRITIS: ONE-YEAR FOLLOW-UP OF THE “PLANTS FOR JOINTS” RANDOMIZED CLINICAL TRIAL

Keywords: Diet and Nutrition, Non-pharmacological interventions, Rheumatoid arthritis

C. Wagner1,2, W. Wainrabenstein1,2, M. Van der Leeden1,4,5, F. Turkstra1, J. Twisk5, M. Boers1,6, H. Van Middendorp1, P. Weijls1,6, D. Van Schaardenburg1,2,1 Reade, Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC, locatie AMC, Rheumatology and immunology center, Amsterdam, Netherlands; 3Amsterdam University of Applied Sciences, Nutrition & Dietetics, Amsterdam, Netherlands; 4Amsterdam UMC, locatie VUmc, Rehabilitation Medicine, Amsterdam, Netherlands; 5Amsterdam Movement Sciences Research Institute, Movement Sciences, Amsterdam, Netherlands; 6Amsterdam UMC, locatie VUmc, Epidemiology and Data Science, Amsterdam, Netherlands; 7Leiden University, Institute of Psychology, Health, Medical, & Neuropsychology unit, Leiden, Netherlands; 8Amsterdam UMC, locatie VUmc, Nutrition & Dietetics, Amsterdam, Netherlands

Background: The 16-week Plants for Joints (PFJ) multidisciplinary lifestyle program, based on a whole-food plant-based diet, physical activity, and stress management, significantly reduced 28-joint Disease Activity Score (DAS28) score compared to usual care in patients with rheumatoid arthritis (RA) [1,2].

Objectives: To determine the long-term effectiveness of the PFJ lifestyle program on disease activity in patients with RA.

Methods: In the PFJ assessor-blind randomized clinical trial, patients with RA and a DAS28 score ≥ 2.6 and ≤ 5.1 were randomized to receive the PFJ program plus additional to usual care, or the control group which received usual care. After this 16-week period the control group also received the PFJ program. After completion of the PFJ program all participants were followed-up for one year with biannual visits and 6 adherence-promoting webinars. If participants had a DAS28 score <2.6 they were instructed to taper anti-rheumatic medication following a pre-specified protocol. Medication changes were assessed at one year as an increase, stable, or decrease compared to baseline by an independent committee. Secondary outcomes included anthropometric and metabolic markers. A paired sample T-Test between 1-year follow-up and start of intervention was performed.
Results: Of 77 participants who completed the initial 16-week clinical trial 92% were female with a mean (SD) age of 55 (12) and body mass index of 26 (4) kg/m² at baseline. The 65 (84%) participants who completed the one-year follow-up had a greater average change in DAS28 score (–0.9 vs. –0.05) compared to non-completers. In the year after completing the PFJ program the DAS28 score continued to improve slightly where a mean 1.01-point difference was observed after one year for the completed cases compared to baseline values (95% CI 0.76 to 1.26; p < 0.001) (Figure 1). All components of the DAS28 improved significantly compared to before the program (Table 1). Significant improvements were found in both the seropositive and seronegative subgroups. Of the 61 participants using anti-rheumatic medication at baseline, 27 (44%) were able to decrease the dosage or stop one or more medications. Anti-rheumatic medication was stable for 16 participants, and increased for 13, of which 5 newly started using medication. 45 participants (58%) had improved DAS28 scores of which 20 had a DAS28 <2.6 with stable or less medication compared to baseline. After the 1-year follow-up period there was no longer a significant difference in weight or HbA1c although LDL cholesterol remained significantly lower compared to baseline.

Conclusion: The PFJ lifestyle program significantly decreased disease activity in patients with RA and its effects were sustained until one year after program completion, with slightly less anti-rheumatic medication. Metabolic benefits found after the lifestyle intervention were only partially sustained possibly indicating attenuated adherence to the lifestyle program in the 1-year follow-up.

Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; Halmstad University, School of Health and Welfare, Halmstad, Sweden; Spenshult, Research and Development Centre, Halmstad, Sweden; University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; Skane University Hospital, Department of Rheumatology, Lund, Sweden

Background: Patients with early rheumatoid arthritis (RA) benefit from combining pharmacological and non-pharmacological interventions to prevent damage to cartilage and bone, relieve symptoms, and improve or normalize physical function, quality of life, and social and work capacity. Healthy lifestyle habits, including regular physical activity, a healthy diet, and smoking cessation can lower the increased risk of cardiovascular diseases and improve symptoms and quality of life in patients with RA. In addition, smoking and alcohol may interfere with anti-inflammatory medication, which is why lifestyle interventions are essential in managing patients with early RA. According to international and national recommendations, healthcare professionals are expected to discuss healthy lifestyle habits with all patients with inflammatory arthritis [1]. Despite this, the effect of lifestyle discussions and how patients perceive lifestyle interventions in rheumatology care are scarcely studied.

**Objectives:** To explore how patients with early RA perceive lifestyle interventions in rheumatology care.

**Methods:** In this explorative qualitative study, 18 patients with RA followed at an early RA clinic with tight control by a rheumatologist and a rheumatology nurse during the first 2 years, were included. This also included a multidisciplinary team contact with a physiotherapist and an occupational therapist 8–12 weeks after treatment initiation and, if needed, a social worker and additional contacts with the team. Individual interviews were conducted with 12 women and 6 men, aged 23 to 74, with a disease duration of 2-3 years at the time of the interview. The main question was: “Can you tell me about your perceptions of lifestyle interventions in rheumatology care?” The interviews were analyzed with latent qualitative content analysis (2), and three categories and an overarching theme emerged (Table 1).

**Results:** Patients perceived that lifestyle interventions in rheumatology care enable self-management in early RA. The usefulness of lifestyle interventions was perceived to depend on personal preferences of lifestyle support and prioritization of lifestyle interventions. The design of lifestyle interventions should be based on a person-centred approach, patient education, and recurrent lifestyle support. To promote healthy lifestyle habits, the outcome of lifestyle interventions should contribute to the knowledge of healthy lifestyle habits, motivation for lifestyle changes, and empowerment in patients with early RA.

**Conclusion:** Patients perceived that the usefulness, design, and outcome of lifestyle interventions in rheumatology care are essential when enabling self-management in patients with early RA.

THE NOMENCLATURE OF CALCIUM PYROPHOSPHATE DEPOSITION (CPPD) DISEASE – RESULTS OF A SYSTEMATIC LITERATURE REVIEW FOR THE GOUT, HYPERURICEMIA AND CRYSTAL-ASSOCIATED DISEASE NETWORK (G-CAN) CPPD NOMENCLATURE PROJECT

Keywords: Crystal Arthritis, Descriptive Studies, Systematic review

1IRCCS Istituto Ortopedico Galeazzi, Rheumatology Department, Milan, Italy; 2Polytechnic University of Marche, Ramacchette Unit, Department of Clinical and Molecular Sciences, Ancona, Italy; 3Saint-Philibert Hospital, Lille Catholic University, Rheumatology Department, Lille, France; 4University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 5AST Great Metropolitan Niguarda, Rheumatology Unit, Milan, Italy; 6Brigham and Women's Hospital and Harvard Medical School, Division of Rheumatology, Inflammation and Immunity, Boston, United States of America; 7University of California, Veterans Affairs San Diego Healthcare System, San Diego, United States of America; 8University of Auckland, Bone and Joint Research Group, Department of Medicine, Faculty of Medical and Health Sciences, Auckland, New Zealand

Background: Despite prior attempts at standardising terminology of calcium pyrophosphate deposition (CPPD) disease (including the 2011 EULAR recommendations for CPPD terminology), many different terms are still used interchangeably to describe the disease, its elements, and its states. The 3 most common labels used to identify the disease were “pseudogout” “calcium pyrophosphate deposition disease” and “chondrocalcinosis”. The most common acronym used was “CPPD”, mostly with the meaning of “calcium pyrophosphate deposition disease” or “calcium pyrophosphate deposition (CPPD) disease” (Table 1). The 2 most commonly used labels describing “an episode of acute CPPD arthritis” were “pseudogout” (31%), and “acute calcium pyrophosphate crystal arthritis” (10%). For more than one episode of acute CPPD arthritis, “recurrent pseudogout” (17%) or “recurrent arthritis” (10%) were the most used labels. “Chronic calcium pyrophosphate crystal arthritis” (13%) and “pseudo-rheumatoid arthritis” (11%) were the most commonly used labels to describe “persistent inflammatory arthritis due to CPPD”. The most used labels used to identify “osteoarthritis with evidence of CPPD” were “pseudo-osteoarthritis” (11%) and “calcium pyrophosphate crystal deposition with osteoarthritis” (9%). The use of “pseudo-form” labels mostly occurred before the 2011 EULAR recommendations.

Conclusion: These preliminary results demonstrate the variability and lack of precision in the labels used to describe CPPD disease. The next steps of the project will be to achieve agreement about CPPD disease nomenclature through a Delphi exercise and consensus meeting, and to develop an easily understandable common language definition to facilitate communication with patients.

Objectives: In this first step of the project, the aim was to identify the definitions, the disease elements and the clinical states of CPPD and their corresponding labels in the scientific literature.

Methods: A systematic literature search was performed in the PubMed database starting from 01/01/2000 to 31/01/2022. The search was restricted to studies on humans and in English language. Eight reviewers independently extracted terms related to disease definition, aetiology, pathogenesis, clinical presentation, imaging features and clinical states of CPPD. An a priori list of disease elements and clinical states was generated by the authors and further elements were added during data collection as appropriate. Labels for each identified disease element and clinical state were extracted and analysed to determine their frequency. An additional analysis was performed to evaluate the uptake of the 2011 EULAR recommendations on CPPD terminology after 2011.

Results: A total of 2392 articles were identified using the search criteria. We preliminarily evaluated 623 articles of which 246 were included. The list of evaluated elements is showed in Figure 1. There was great inconsistency in the terminology used for the disease, its elements and its states. The 3 most common labels used to identify the disease were “pseudogout” “calcium pyrophosphate deposition disease” and “chondrocalcinosis”. The most common acronym used was “CPPD”, mostly with the meaning of “calcium pyrophosphate deposition disease” or “calcium pyrophosphate deposition (CPPD) disease” (Table 1). The 2 most commonly used labels describing “an episode of acute CPPD arthritis” were “pseudogout” (31%), and “acute calcium pyrophosphate crystal arthritis” (10%). For more than one episode of acute CPPD arthritis, “recurrent pseudogout” (17%) or “recurrent arthritis” (10%) were the most used labels. “Chronic calcium pyrophosphate crystal arthritis” (13%) and “pseudo-rheumatoid arthritis” (11%) were the most commonly used labels to describe “persistent inflammatory arthritis due to CPPD”. The most used labels used to identify “osteoarthritis with evidence of CPPD” were “pseudo-osteoarthritis” (11%) and “calcium pyrophosphate crystal deposition with osteoarthritis” (9%). The use of “pseudo-form” labels mostly occurred before the 2011 EULAR recommendations.

Keywords: Ultrasound, Crystal Arthritis

H. Ogun1, D. Palamar2, K. Akgun2, F. M. Saridogan2, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Physical Medicine and Rehabilitation Department, Istanbul, Turkey.

Background: Routine search for crystals is recommended in all synovial fluid (SF) aspirates from undiagnosed arthritis. Definitive diagnosis of crystal related arthritis (CRA) is based on identification of crystals in SF. However, SF analysis is sometimes difficult to perform. Therefore, assessment of imaging techniques can be useful. In the latest recommendations for the diagnosis and management of CRA, the diagnostic potential of ultrasound (US) has been recognized [1].

Objectives: The aim of this study was to evaluate the contribution of ultrasonography to the SF analysis, which should be performed routinely in patients with knee effusion to exclude infection and to detect CRA.

Methods: Patients, in outpatient clinic, above 18 years of age with unilateral knee effusion were included. Ultrasonography of the involved knees were performed in all patients after the evaluation and physical examination. In ultrasonographic examination; hyperechoic bands within the femoral hyaline cartilage (sandwich appearance) and/or hyperechoic sparkling spots in meniscal fibrocartilage (meniscus calcification) were considered indicative of Calcium pyrophosphate deposition disease (CPPD); in addition, hyperechoic spots in the effusion and tendon calcifications were recorded. Ultrasonography guided synovial fluid aspiration was performed. The sample was examined macroscopically and microscopically. Then, radiographic evaluations were done for searching chondrocalcinosis.

Results: Eighty-five patients (56 F, 29 M) with unilateral knee effusion were evaluated. Mean age was 60.98 ±11.95 years. CPPD was diagnosed with detecting calcium pyrophosphate (CPP) crystals in synovial fluid analysis in 15 of 85 patients. Two of these patients had previous diagnosis of rheumatoid arthritis (RA), 1 spondyloarthritis, 1 gout and 11 osteoarthritis. Of the remaining 70 patients, 1 was considered as spondyloarthritis, 4 as RA and 65 as exacerbation of osteoarthritis. The detection of CPP crystal in the microscopic examination was accepted as the gold standard for the diagnosis of CPPD. Sensitivity and specificity values were 93.33% and 80% for ultrasonography, 46.67% and 98.57% for radiography, respectively (Table 1). Inter-rater agreement for US was found to be 93.3% (kappa value: 0.81; very good agreement) with the evaluation of 40 patients separately by two physicians. Intra-rater agreement for US was found to be 96.67% (kappa value: 0.83; very good agreement) when the recorded images were re-evaluated.

Conclusion: When crystal related arthritis is suspected especially in elderly patient with knee effusion, ultrasonography found as a useful diagnostic method in clinical practice because it is highly sensitive and specific in determining crystal accumulations.

PPV: Positive predictive value, NPV: Negative predictive value, CPP: Calcium pyrophosphate, US: Ultrasound
MTP joints allowed gradation of double contours from 0 to 3. Links between patients' features and renal medulla staging were assessed by Fisher exact or Kruskall and Wallis tests according to the type of variables. Multivariable analysis included all statistically significant features, with final model selection on p.value using a proportional odds logistic regression model. All test were two-sided.

**Results:** 826 consecutive new patients were included from August 1 to December 24, 2022. 86 % were males, median age was 49 years, median BMI 24.22 kg/m², median gout duration 5 years, 70 % of patients had clinical tophi, median uricemia was 488.6 µmol/l, median creatininemia 83.5 mmol/l, median eGFR 90 ml/min. Both kidneys were classified at the same grade in every patient, 65.5% of patients were at grade 0, 178 % at grade 1 and 16.7 % at grade 3. Table 1 shows links of the extent of medulla hyperechogenicity with patients' features. By multivariable analysis, positive correlation was found with male sex, hypertension, gout duration, tophi, double contours and uricemia; BMI, eGFR and cortisolemia negatively correlated.

**Conclusion:** Hyperechogenicity of the renal medullas progressively increased with gout duration, MSU deposition and steroid treatment, and associated with decrease of renal function and hypertension. These observations reinforce the early indication of ULDs in gouty patients.

POS0088 WORK PRODUCTIVITY IN GOUT – RESULTS FROM THE NOR-GOUT LONGITUDINAL 2-YEAR TREAT-TO-TARGET STUDY

Keywords: Work-related issues, Crystal Arthritis, Epidemiology

T. Uhlig1, L. F. Karoliussen2, J. Sexton3, S. Ararestad Provan4, T. K. Kvis5, E. A. Haavardsholm6, H. B. Hammar7, 1Diakonhjemmet Hospital, Center for treatment of Rheumatic Musculoskeletal Diseases (REMEDEY), Oslo, Norway; 2Diakonhjemmet Hospital Center for treatment of Rheumatic Musculoskeletal Diseases (REMEDEY), Oslo, Norway; 3Diakonhjemmet Hospital, Center for treatment of Rheumatic Musculoskeletal Diseases (REMEDEY), Oslo, Norway; 4Diakonhjemmet Hospital, posstueston@gmail.com, Oslo, Norway

Background: Gout causes pain and reduced health related quality of life. There are no longitudinal studies on work productivity in patients who are being treat-ed to target for their serum urate in clinical practice.

Objectives: We examined whether work productivity in gout patients changed over 2 years after intensive treatment with ULT, and if disease related factors could predict changes in work productivity.

Methods: Patients with crystal-proven gout and a recent gout flare and increased serum urate (sUA) level (>360 μmol/L) were consecutively included in the NOR-Gout observational study [1]. They were treated to target with an educational intervention by a study nurse and escalating urate lowering medication (allopurinol or febuxostat) with frequent control visits to achieve low serum urate at target. Work productivity and activity impairment were assessed using the Work Productivity Activity Index (WPAI) questionnaire at baseline, after 3 months, 6 months, 1 and 2 years. The WPAI consists of six questions to determine employment status during the last 7 days: hours missed from work due to the disease; hours missed from work for other reasons; hours worked, the degree to which the disease affected work productivity while at work; and the degree to which the disease affected activities outside of work. Four scores were derived: percentage of missed work (absenteeism), percentage of impaired productivity while at work (presenteetime), overall work impairment that combines absenteeism and presenteetime, and percentage of impairment in activities performed outside of work. Greater scores indicate greater impairment. Questions related to absenteeism and presenteetime were applicable only for patients who were working. Other assessments included clinical, demographic and lifestyle variables, and questionnaires, comorbidities from the Self-Administered Comorbid Questionnaire, pain, physical function from the Health Assessment Questionnaire (HAQ), SF-36 physical and mental components, self-efficacy, and the Beliefs about Medicines Questionnaire (BMQ) with subscales of beliefs in harm, overuse, necessity, and concerns about medication. Descriptive statistics used ANOVA, and linear regression model after logarithmic transformation of the 4 WPAI outcomes. Final regression models were also adjusted for baseline, age, gender, disease duration and comorbidities.

Results: Patients were predominantly male (95%) with mean age 56.4 years (SD 13.7 years) and disease duration almost 8 years, 17% had subcutane-ous tophi. At baseline 64.4 % were working, 64.0% at year one and 61.3% after 2 years. sUA was at target <360μmol/L in 85% after one and 79% after 2 years, while a flare was experienced by 81% and 26% during year 1 and year 2, respectively. WPAI scores were at baseline: 5.0% work missed, 19.1% work impairment (sUA level) and 32.1% activity impairment (Fig-ure 1). Scores were at 3 months, after the recent flare leading to inclusion into the study, improved and remained then stable over 2 years. Baseline assessments of work productivity, comorbidities as well as concerns about medication inde-pendently predicted changes in work productivity outcomes at 1 year.

Conclusion: In patients with gout who were intensively treated to the sUA target, work productivity and activity impairment were largely unchanged over 2 years and at 1 year and were predicted by comorbidities and patient concerns about medication.

POS0089 A DIAGNOSTIC PERFORMANCE STUDY ON RAMAN SPECTROSCOPY INTEGRATED WITH POLARIZED LIGHT MICROSCOPY FOR THE IDENTIFICATION OF MONOSODIUM URATE IN GOUT

Keywords: Gout, Crystal Arthritis, Diagnostic Tests

T. Niessink1,2, T. Giesen2, A. Comarniceanu3, M. Elde4, M. Janssen2, C. Otto1, T. Jansen2. 1University of Twente, Medical Cell Biophysics group, Enschede, Netherlands; 2VieCuri Medical Centre, Rheumatology, Venlo, Netherlands

Background: The diagnosis in gout and other crystallopathies is commonly based on polarized light microscopy (PLM) of synovial fluid aspirates. This technique is flawed, however, due to subjectivity, limited reproducibility, and over-sensitivity due to artifacts [1]. There is a need for innovative methods to perform synovial fluid analysis with more objectivity/reproducibility. Raman spectroscopy has been applied for identification of MSU in gout, with different technical approaches [2]. Although results are promising, there are no real diagnostic accuracy measures available for any application of Raman spectroscopy in rheumatology.

Objectives: To enhance the chemical analytical performance of PLM, we have integrated a Raman spectroscopy within a standard polarized light microscope (iRPoM). In this study, we investigated the performance of iRPoM as a next-genera-tion method for synovial fluid analysis in gout.

Methods: This is a prospective study, including 200 samples from a peripheral swollen joint subject for diagnostic analysis. The participants formed a consec-utive series. Diagnostic performance was measured against the 2015 ACR/EULAR gout classification criteria set, which includes PLM analysis. Further-more, we compared the analytical performance of iRPoM to identify MSU crys-tals with ordinary PLM analysis by an experienced rheumatologist.

RESULTS:

| Table 1. Diagnostic and analytical performance of iRPoM. Values given with 95% confidence intervals. |
|-------------------------------------------------|-----------------|-----------------|
| Diagnostic performance of iRPoM against 2015 ACR/EULAR classification criteria | Analytical performance of iRPoM against PLM by rheumatologist |
| Sensitivity | 77.6% (95% CI 65.8-86.9%) | 91.2% (95% CI 80.7-97.1%) |
| Specificity | 97.7% (95% CI 93.5-99.9%) | 97.6% (95% CI 93.0-99.9%) |
| Positive predictive value | 94.5% (95% CI 84.9-98.2%) | 94.6% (95% CI 85.0-98.2%) |
| Negative predictive value | 89.7% (95% CI 84.7-93.1%) | 96.0% (95% CI 912-98.2%) |
| Accuracy | 91.0% (95% CI 86.2-94.6%) | 95.6% (95% CI 914-98.2%) |
| Positive likelihood ratio | 34.4 (95% CI 11.2-106.1) | 374 (95% CI 129-114.7) |
| Negative likelihood ratio | 0.23 (95% CI 0.15-0.36) | 0.09 (95% CI 0.04 to 0.21) |

67 patients were classified as gout according to 2015 ACR/EULAR classification criteria. 55 samples were positive for MSU according to PLM analysis. iRPoM identified MSU in 55 patients, 52 of which positive for gout. The inter-rater agreement between PLM and iRPoM was very high (k = 0.90).

Conclusion: We demonstrate that Raman spectroscopy integrated with polarized light microscopy has a high diagnostic performance as it comes to iden-tification of MSU in synovial fluid samples. Furthermore, Raman Spectroscopy could provide definitive outcomes in cases where analysts with polarized light
microscopy faced uncertainties or lookalikes, for example by identifying birefringent objects as glass slivers, microplastics or other non-MSU crystal types. These results show that Raman spectroscopy is a powerful analytical tool for clinicians, and a potential candidate for replacement or enhancement of PLM in clinical care where higher specificity is needed. Raman spectroscopy gives an excellent specificity on the nature of a birefringent object even with lookalikes, improving the specificity of a difficult microscopic diagnosis.

POS0090 DYSBIOSIS OF GUT MICROBIOME, BILE ACID COMPOSITIONS, AND PREVALENCE OF HYPERURICEMIA: DATA FROM THE XIANGYA HYPERURICEMIA STUDY

Keywords: -omics, Gout

J. Wei1,2,3,4, Y. Cui5, J. Wu6, Z. Wu7, Y. Zhang8, N. Dalbeth9, R. Terkeltaub9,10, T. Yang11, J. Li12, Y. Yang1,13, C. Li1,13, C. Zeng1,2,12, G. Lei1,2,12.

Background: Hyperuricemia is a pre-requisite for gout, and often co-occurs with other metabolic diseases[1]. Emerging evidence suggests that gut microbiota is an important factor in the development of metabolic diseases[2]; Moreover, altered gut microbiota, ascertained using 16S rRNA-based sequencing method, has been linked to hyperuricemia[3]. However, the 16S rRNA technique has limited resolution to differentiate closely related species. Therefore, the hyperuricemia associated specific species and underlying mechanism remain unclear. Additionally, cross-talk between bile acid metabolites and the gut microbiome has been implicated in metabolic diseases, implying potential effect of bile acid metabolism in the pathogenesis of hyperuricemia.

Objectives: The aim of this study was to examine the relation of gut microbiome based on shotgun metagenomic sequencing to prevalent hyperuricemia and potential mediators of bile acids.

Methods: Participants were derived from a community-based observational study, the Xiangya Hyperuricemia Study. Hyperuricemia was defined as serum urate level > 404 μmol/L. Gut microbial composition was determined using shotgun metagenomic sequencing and plasma bile acids were measured by high-performance liquid chromatography mass spectrometry. The 16S rRNA gene abundance of gut bacteria was measured using qPCR.

Results: Among 1,379 participants, the prevalence of hyperuricemia was 13.4% (n = 185) (Figure 1 A). Decreased microbial richness and diversity, altered composition of gut microbiome and lower relative abundance of seventeen key species Coprococcus comes, Dorea longicatena, Desulfovibrio piger, Ruminococcus sp003526955, Holdemelanna sp002299315, Ruminococcus sp00437175, Ruminococcus sp000437095, Coprococcus eutactus, Blautia sp000066335, Blautia sp0000666205, Blautia sp0000666505, Ruminococcus sp00301855, Blautia sp000020195, Blautia sp000285855, Dorea formigenicarum, Acidifactor sp000663605 and Blautia wexlerae were significantly associated with prevalent hyperuricemia (Figure 1 B and C). High levels of taurocholodeoxycholic acid (TCDCA) and low levels of deoxycholic acid (DCA) were associated with high prevalence of hyperuricemia (Figure 1 D and E). Inversely associations between these key species and hyperuricemia were partially mediated through their effect on the levels of TCDCA and DCA. For instance, the indirect effects (OR) of relative abundance of Coprococcus comes on hyperuricemia through DCA and TCDCA were 0.97 (95% CI: 0.94 to 1.00) and 0.98 (95% CI: 0.97 to 1.00), respectively, and the corresponding percentage of mediation were 12.0% and 7.4% respectively. The indirect effects of Dorea longicatena on hyperuricemia via DCA and TCDCA were 0.97 (95% CI: 0.96 to 1.00) and 0.98 (95% CI: 0.97, 1.00), and the percentage of their mediation effect were 10.1% and 6.0%, respectively (Figure 1 F).

Conclusion: We identified several key species of gut microbiome for hyperuricemia and demonstrated that the association between gut microbiome dysbiosis and prevalent hyperuricemia is partially mediated via bile acids. These findings provide new insights into the role of microbiome and bile acids in the development of hyperuricemia and may contribute to translational opportunities.

USE OF HIGH-PLEX DATA REVEALS NOVEL INSIGHTS INTO THE TEMPORAL ARTERY OF GIANT CELL ARTERITIS

Keywords: Biomarkers, Vasculitis, Treat to target

S. Parreau, 2, 3, E. Molina, 2, S. Dumonteil, 2, R. Goulabchand, 2, M. Bois, 2, T. Naves, 3, M. O. Jauberteau, 3, A. L. Fauchais, 2, E. Liozon, 2, W. Cornelia, 2/3, Mayo Clinic, Rheumatology Rochester United States of America; 2Dupuytren University Hospital, Internal Medicine, Limoges, France; 3Faculty of Medicine, INSERM U1308 - CAP'TuR "Control of cell activation, Tumor progression and Therapeutic resistance"; Limoges, France; University of California San Diego, Sanford Consortium for Regenerative Medicine, La Jolla, United States of America; 2Salk Institute for Biological Studies, Next Generation Sequencing Core, San Diego, United States of America; 3University Hospital of Nimes, Internal Medicine, Nimes, France; Mayo Clinic, Pathology, Rochester United States of America

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis that triggers acute arterial occlusion and can even lead to death over the age of 50 [1]. While mechanism underlying GCA are predominantly derived from inflammatory response, none of the anti-inflammatory drugs currently used limit efficiently patient’s disease course. It was previously shown that histopathological lesions involve the three layers of the artery wall called adventitia, media, and intima. Activation of adventitial dendritic cells is the initial trigger of the vascular remodeling in GCA leading to intimal hyperplasia but the early molecular mechanism that activates those cells remains unknown. Our hypothesis is that each layer of the artery, perivascular tissue included, shows a unique transcriptomic signature which could define and explain the different molecular events in the inflammatory and vascular remodeling processes in GCA. For that, whole-tissue spatial transcriptomics analysis offers advanced opportunities in elucidating functional mechanisms of pathologic tissues with complex organization such as GCA especially in human temporal artery, the most frequently affected artery in GCA.

Objectives: Uncover the key coding genes to define new biomarkers or pathways associated with GCA by performing the first in situ spatial profiling characterization of molecular actors involved in temporal arteries from GCA patients in comparison to normal arteries.

Methods: From human formalin-fixed paraffin-embedded temporal artery biopsy samples (GCA n=9; controls n=7), we performed a whole transcriptome analysis by using NanoString GeoMx Digital Spatial Profiler (DSP) [2]. A total of 59 individual regions of interest (ROIs) were created within each of the 4 layers for each individual artery. After ROIs collection and library construction, samples were sequenced on an Illumina NovaSeq 6000 platform and reads were digitally quantified and normalized using GeoMx DSP Data Analysis software. Differential expressed genes (DEGs) (fold change >2 or <2, p-adjusted <0.05) were compared for each layer, to build a spatial and pharmacogenomic network in disease course.

Results: Overall, we found that most of the transcriptome studied (12076 genes) was upregulated in GCA arteries. Precisely, 350, 340, 142 and 5 DEGs were found in intima, media, adventitia, and perivascular tissue respectively. Enrichment analysis highlighted that inflammation/immune-related functions and vascular remodeling were significantly limited to intima and media layers. Upregulated immune-related functions concerned macrophage differentiation & T cell, B cell, complement activations. Regarding vascular remodeling pathways, we found an upregulation of: (i) collagen metabolic process and fibroblast proliferation concerning the 3 artery layers, (ii) angiogenesis & epithelial cell migration in intima and media layers, (iii) smooth muscle cell proliferation & ossification in intima layer. Our pharmacogenomic network analysis identified genes that could potentially be targeted by immunosuppressive drugs currently approved or new immunotherapies.

Conclusion: Our findings provide the first in situ spatial profiling characterization of molecular actors involved in GCA which is essential for the discovery of new therapeutic targets to cure this disease. The differential spatial upregulation of genes involved in inflammatory process and vascular remodeling suggests a differential chronological involvement of each layer of the artery.

Spatial distribution of distinct fibroblast subtypes in giant cell arteritis

Keywords: Descriptive Studies, Vasculitis

S. Xu, W. F. Jiemy, J. C. Graver, Y. Van Sienel, K. Van der Geest, P. Heeringa, E. Brouwer, A. Boots, M. Sandoval, 1 University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, University of Groningen, Pathology and Medical Biology, Groningen, Netherlands

Background: Giant cell arteritis (GCA) is a systemic vasculitis of large- and medium-sized arteries which is characterized by granulomatous inflammation and vascular remodeling. The pathogenesis of GCA starts in the adventitia where fibroblasts are the major cell population. Fibroblasts are recognized for synthesizing and remodeling the extracellular matrix (ECM), but their phenotype and role in GCA-affected blood vessels is largely unknown.

Objectives: To explore the distribution of fibroblast phenotypes and their link to vascular remodeling in GCA.

Methods: Temporal artery biopsies (TABS) from patients with GCA (n=9) and controls (n=9) and aorta tissues from GCA (n=9) and atherosclerosis (AS, n=11)-related aneurysm were examined. Immunohistochemical staining for CD90 (pan-fibroblast), fibroblast activation protein alpha (FAP, activated fibroblast marker), podoplanin (immunofibroblast marker), CD248 (fibrosis-related marker), alpha-smooth muscle actin (α-SMA, myofibroblast marker) was performed to evaluate the distribution of fibroblast subtypes. The expression of transforming growth factor beta (TGFβ), fibroblast growth factor 21 (FGF21), platelet derived growth factor AA (PDGFAA) and PDGFB as markers of active remodeling pathways was also determined. For each marker the percentage of positive cells was determined by Qupath 0.3.0.

Results: TABs from GCA patients showed increased expression of CD90, FAP, podoplanin, CD248, FGF21, PDGFAA and PDGFB in the adventitia and intima compared with the controls. Isolated higher expression of TGFβ in the adventitia and α-SMA in the intima was also documented. CD90/FAP-activated fibroblasts and CD90/podoplanin+ immunofibroblasts were predominantly located in the adventitia, whereas α-SMA+ myofibroblasts were observed mainly in the intima, and CD248+ fibroblasts in the adventitia-media border and intima. High expression of FAP, CD248, FGF21 and PDGFB in the media-intima was associated with intimal hyperplasia in GCA-positive TABs. GCA-affected aortas showed different patterns: CD90/FAP-activated fibroblasts, CD90/podoplanin+ immunofibroblasts and CD248+ fibroblasts accumulated especially in the structurally disrupted media, which was associated with abundant expression of PDGFB and FGF21. These three fibroblast phenotypes were hardly observed in AS-affected aortas. We also observed expression of CD90, FAP, podoplanin and CD248 in the artery tertiary lymphoid organs (ATLOs) of the adventitia in GCA-affected aortas. α-SMA+ myofibroblasts were expressed at similar levels in GCA and AS-affected aorta tissues, being mainly located in the intima.

Conclusion: This study documents a distinct spatial distribution pattern of fibroblast subtypes in GCA-affected temporal arteries and aorta tissues and their association with markers of active remodeling pathways. Further research is needed to dissect the precise role of these fibroblast subtypes in the pathobiology of GCA.

5Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Vascular Surgery, Reggio Emilia, Italy

Background: Giant cell arteritis (GCA) is an inflammatory large-vessels vasculitis representing an important clinical challenge. First, an early diagnosis of GCA is difficult due to the clinical heterogeneity and the lack of specific biomarkers. In addition, although the therapy generally used are glucocorticoids (GC), relapses are common when GC are tapered [1]. The etiology of this disorder is complex in which multiple genetic and epigenetic factors contribute to its development [1]. Although the pathogenic mechanisms remain insufficiently understood, a central role for CD4+ T-cells has been demonstrated [2]. In this context, understanding how the transcriptome and methylation of this cell type are altered in GCA patients and how they are influenced by GC will yield new insights into the pathogenesis of this vasculitis.

Objectives: To shed light into GCA pathogenesis and to identify molecular mechanisms that might serve as novel biomarkers or potential drug targets, we characterized the transcriptome and methylation signatures of GCA CD4+ T-cells and the way these cells are affected by remission and by the effect of GC.

Methods: Both DNA methylation and RNA were isolated from CD4+ lymphocytes positively sorted by flow cytometry from whole blood. Subsequently, DNA methylation profiling with the Illumina Infinium Methylation EPIC array and RNA-sequencing were carried out. After quality controls, epigenome- and transcriptome-wide association were performed for 81 samples: 23 healthy controls and 58 GCA patients grouped in three different clinical status (active before starting GC [n=13], in remission with GC [n=22], and in remission without GC [n=23]).

Results: The results of this work revealed a profound dysregulation in both the gene expression and DNA methylation patterns of CD4+ T-cells of GCA patients. Particularly, CD4+ T-cells from GCA patients with an active state of the disease before starting GC treatment showed substantial changes in inflammatory processes, such as NOTCH1, interleukin-6 (IL-6), IL-1 and vitamin D receptor signalling pathways, among others. In addition, we also observed alterations in molecular pathways related with angiogenesis, the vascular endothelial growth factor (VEGF) receptor, and with the differentiation of T helper 2 (Th2), including the IL-2/STAT5 and IL-4 pathways. Interestingly, our findings also indicated that the pro-inflammatory expression profiles observed in the active disease are lost when the disease subsides, and that GC therapy significantly remodels both the transcriptome and the methylation of CD4+ T-cells. Particularly, changes in molecular mechanisms related to drug metabolism, such as a GC receptor genes and glucuronosyltransferase family genes were also found.

Conclusion: The results of the transcriptome and methylation characterization of GCA CD4+ T-cells have provided new evidences of genes and pathways contributing to the pathogenic role of this cell type in GCA, providing a clearer picture of the molecular processes driving disease activity and how they vary in response to GC treatment.

Disclosure of Interests: None Declared.
DOI: 10.1136/annrheumdis-2023-eular.326
Background: Giant cell arteritis (GCA) is a systemic vasculitis mediated by an aberrant immunological response against the endothelium of medium- and large-sized blood vessels [1]. Even though the pathogenic mechanisms that drive GCA are yet to be settled, there is strong evidence that CD4+ T lymphocytes play a crucial role in the development of this vasculitis [2]. Recently, single-cell RNA sequencing has resulted in a scientific and technological revolution, enabling the characterization of the gene expression profile of thousands of individual cells in different tissues [3]. This approach has allowed the identification of new cell subtypes, some of them being exclusively represented in pathogenesis, and has also proved useful as a tool for reporting new disease-specific biomarkers.

Objectives: In this study, we aimed to define new pathological mechanisms driving GCA through the comprehensive characterization of the gene expression profile of CD4+ T cells by performing single-cell RNA sequencing in GCA patients and healthy controls.

Methods: CD4+ T cells from whole blood of 16 individuals (eight GCA patients and eight sex- and age-matched healthy controls) were obtained. Based on clinical parameters, five patients were classified as active GCA and 3 of them as patients in remission. Single-cell libraries were prepared from isolated CD4+ T cells using the ‘Chromium Single Cell Gene Expression’ (10X Genomics). Sequencing data were pre-processed with the CellRangerV3.0 software. Then, Seurat Bioconductor R package was used to perform clustering and dimensional reduction analysis. Dot size indicates proportion of cells expressing the specific genetic markers classified per group. For visualization, the UMAP of CD4+ T cells was generated with the Factoextra R package.

Results: A total of 114,799 cells were analyzed and classified into 13 clusters according to their transcriptomic profile. Manual annotation of the different clusters based on canonical markers permitted the identification of 6 distinct CD4+ T cell subsets: naïve (T naive), central memory (T CM), effector memory (T EM), effector memory expressing granzyme K (T EM GZMK), regulatory (Tregs) and cytotoxic T lymphocytes (CTL). The comparative analysis of cell type composition between the different subgroups showed a significant reduction of the cytotoxic cell compartment in GCA patients in remission compared with active patients (p<0.011) and controls (p=0.045) as well as a decreased frequency of Tregs in active patients compared with healthy individuals (p=0.029). In addition, differential expression analysis evidenced a significant overexpression of granzyme B (GZMB) and the zinc finger protein 683 (HOBIT), both involved in cytotoxic processes, in CTLs of active patients compared with patients in remission (p=0.017) and controls (p=1.4x10^-9). Moreover, in both active and in remission patients, the Treg compartment showed a reduced expression of genes related to regulatory functions, like HLA-DRA (p=3.3x10^-7) and LGALS1 (p=1.1x10^-8), compared with healthy controls.

Conclusion: The first single-cell atlas of CD4+ T cells in GCA provided evidence for the first time of a potential pathogenic role of CD4+ T cells with cytotoxic functions in this vasculitis and supported the crucial role of Tregs in the pathogenesis of GCA.

POS0097 ASSOCIATION BETWEEN LOSS OF IMMUNE CHECKPOINT PROGRAMMED CELL DEATH PROTEIN 1 AND ACTIVE ANCA-ASSOCIATED RENAL VASCULITIS

Keywords: Vasculitis, Kidneys

B. Tampe1. 1University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany

Background: Immune checkpoint inhibitors (ICIs) have made an important contribution on the survival of patients with certain cancers. ICIs interrupt co-inhibitory signaling pathways mediated by programmed cell death protein 1 (PD-1), programmed cell death protein- ligand 1 (PD-L1), and cytotoxic T lymphocyte-associated antigen (CTLA-4) that result in the elimination of cancer cells by stimulating the immune system.

Objectives: Immune-related adverse events have also been described and attributed to an enhanced immune system activation. Recent observations have suggested dysregulation of immune checkpoints in active antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Therefore, we here aimed to analyze abundance of immune checkpoint molecules PD-1/PD-L1 and its implications in ANCA-associated renal vasculitis.

Methods: We here analyzed intrarenal PD-1 and PD-L1 by immunostaining in a total number of 15 kidney biopsies with ANCA-associated renal vasculitis in correlation with glomerular and tubulointerstitial lesions. For independent validation, publicly available datasets were analyzed for PD-1 expression (encoded by PDCD1).

Results: We here observed a predominant tubulointerstitial expression of PD-1 that is decreased in ANCA-associated renal vasculitis. Moreover, loss of tubulointerstitial PD-1 correlated with active ANCA-associated renal vasculitis. Consistent to the observed association with active glomerular and tubulointerstitial lesions, we identified that intrarenal PD-1 correlated with tubular and/or glomerular PD-1 positivity. Finally, PD-1 was associated with decreased local synthesis of complement factor B. Interestingly, we did not observe a correlation between PD-1 and complement C5 or its C5a receptor. Combined with our observations, this may implicate a link between impaired PD-1/PD-L1 signalling, complement factor B, and active ANCA-associated renal vasculitis.

Conclusion: These findings could be of relevance because experimental data have already been described that PD-1 agonism can be used therapeutically to attenuate autoimmunity in multiple disease models. Furthermore, targeted therapy against complement C5a receptor and factor B are both available and currently evolving in the treatment of AAV. Therefore, this pilot study expands our current knowledge and describes a potential interplay between immune checkpoints and the alternative complement pathway in active ANCA-associated renal vasculitis.

POS0098 IDENTIFICATION OF THE CENTRAL TOLERANCE CHECKPOINT FOR AUTOOREACTIVE PROTEINASE 3+ B CELLS IN HUMAN BONE MARROW

Keywords: Adaptive immunity, Vasculitis, Biomarkers

A. Bert1, M. Tomasi2, I. Pesce2, E. Lista3, A. Guella3, G. Paolazzi1, R. Bortolotti2, G. Grandi2, S. Hillion4, U. Specks5, D. Corcoran2. 1Hospital of Trento, University of Trento, Rheumatology - CISMED Center of Medical Sciences, Trento, Italy; 2Hospital of Trento, University of Trento, CIBIO; 3Trento, Italy; 4Hospital of Trento, Hematology, Trento, Italy; 5INSERM UMR1227 B cells, Autoimmunity and Immunotherapies, Rheumatism, Brest, France; 6Clinic, Pulmonary medicine, Rochester (MN), United States of America

Background: Autoimmune proteinase 3 (PR3+) B cells have recently been phenotypically and functionally characterized, and the presence of defective central antigen-independent and peripheral antigen-dependent checkpoints in patients with ANCA-associated vasculitis (AAV) has been shown. This work aimed to investigate the central tolerance-checkpoint controlling immature PR3+ B cells in the bone marrow (BM), before their migration into the periphery as transitional B cells. Objectives: We investigated the presence and the specific phenotypic features of PR3+ B cells in BM mononuclear cells (BMMC) of non-vasculitis controls (No-AAV), comparing them to paired peripheral blood mononuclear cells (PBMC) of No-AAV and PBMC of PR3-AAV patients, and the central tolerance-checkpoint for PR3+ B cells.

Methods: We used a customized flow-cytometry assay, using PR3 as ligand to target autoimmune PR3+ B cells (PR3+B cells). Adult PR3-ANCA positive AAV (PR3-AAV) patients with a clinical diagnosis of granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) were selected among consecutive subjects with AAV seen in our Rheumatology Unit. Subjects without vasculitis (No AAV) were selected among consecutive subjects undergoing bone marrow aspiration to exclude hematologic conditions of myeloid origin and eventually resulted healthy or in long-term complete remission during follow-up of myeloid neoplasms. PMBC from AAV patients and paired samples of BMMC and PBMC from No AAV were collected and analyzed.

Results: The proportion of PR3+ B cells within BMMC (median [IQR25-75%]: 1.98%[1.77-2.76]) was higher than within PBMC of No-AAV (0.9%[0.63-1.44], p<0.01 by paired comparison) and similar to their proportion within PBMC of PR3-AAV patients (1.82%[1.66-3.21]; p>0.05). When focusing on immature/transitional CD24++CD38+B cells only in No-AAV, we observed distinct phenotypes within BMMC versus PBMC (i.e. higher proportion of CD27-CD10+ and lower expression of CD21, IgD, IgM within BMMC versus PBMC), representing two separate developmental steps of B cell maturation. Within CD24++CD38+B cells, BMMC contained the greatest proportion of PR3+ B cells as compared to BMPC (3.35%[1.99-4.92] versus 1.23%[0.62-1.55], p<0.01). We observed a significant decline of the PR3+ fraction from T1-like/immature subset (IgD-IgM+; T1-like/immature) to T2-like/early transitional subset (IgD+IgM+; T2-like/early transitional, p<0.01 by paired comparison) and similar to their proportion within PBMC of No-AAV (1.26%[0.62-1.56], p>0.05). Conclusion: To prevent PR3-related autoimmunity, autoimmune PR3+ B cells pass a stringent selection in the BM, and their removal by central tolerance-checkpoint activity occurs mainly between T1-like/immature to T2-like/early transitional B cells of BMMC.

POS0099 THE DIVERSITY AND DISTRIBUTION OF HLA-DRB1 ALLELES IN THE POPULATION OF CROATIAN PATIENTS WITH IGA VASCULITIS (IgAV)

Keywords: Vasculitis, Genetics/Epigenetics

M. Held1, K. Stingl Janjovic2, M. Sestan1, N. Kifer1, S. Sresen2, M. Sapina4, A. Gudej Gračanin2, M. Frkovic3, A. Gagro4, Z. Grubic5, M. Jelusic1. 1University of Zagreb School of Medicine, University Hospital Centre Zagreb, Department of Paediatrics, Division of Paediatric Immunology, Rheumatology and Immunology

Figure 1: Identification of the central tolerance checkpoint for autoimmune proteinase 3+ B cells in human bone marrow.
Background: IgA vasculitis (IgAV) is a small vessel vasculitis occurring predominantly in childhood. Studies concerning the genetic background of IgAV have confirmed that susceptibility to the disease may be influenced by Human Leukocyte Antigens (HLA), with HLA-DRB1 gene showing a strong association with the disease. Objectives: We aimed to investigate HLA-DRB1 polymorphism among Croatian patients with IgAV and to determine if there are associations with disease susceptibility and clinical heterogeneity.

Methods: 123 IgAV patients, fulfilling the diagnostic EULAR/PRINTO/PRES criteria from three pediatric rheumatology centers and 202 unrelated healthy individuals were enrolled. Genomic DNA was extracted from whole peripheral blood. The HLA-DRB1 alleles were analysed using the Next Generation Sequencing (NGS) method.

Results: Among 123 patients with IgAV, 68 were girls and 55 were boys with median age 6.3 (4.0–14.2) at the time of diagnosis. All patients had purpuric rash, 75.7% had arthralgia or arthritis, 32.5% had affected gastrointestinal (GI) system, while 25.2% patients developed IgA vasculitis nephritis (IgAVN). The HLA-DRB1*12:01 allele was associated with an increased risk for IgAV (OR 4.45, 95% CI=1.17-16.95, P<0.03), while HLA-DRB1*11:01 allele was associated with an increased risk for GI involvement in patients who developed IgAVN (OR 3.29, 95% CI=1.17-16.95, P=0.03). A marginally significant (P=0.068) higher frequency of the HLA-DRB1*10:01 allele in patients with GI symptoms was observed. No significant differences were found in the distribution of HLA DRB1 alleles between patients with IgAVN and those who did not develop nephritis.

Conclusion: Our results demonstrated that HLA-DRB1*12:01 allele was associated with susceptibility to IgAV in the Croatian children, while HLA-DRB1*11:01 allele showed association with GI manifestations of the disease.

Methods: Patients with end-stage knee arthritis who underwent primary TKA at our hospital between July 2020 and May 2021 were included with written consent. Basic attributes such as age, gender, BMI, with appendicular skeletal muscle mass (ASMI) by whole-body mode DXA, presence of sarcopenia by Asian Working Group for Sarcopenia 2019 criteria were measured preoperatively, and VAS for pain during walking, clinical assessment of knee joint function (Knee Society Score: KSS), quadriceps muscle strength by dynamometer, range of motion (ROM), and walking speed were measured before and one year after surgery. The relationship between the changes in the degree of frailty (Japanese Cardiovascular Health Study criteria for frailty) before and 1 year postoperatively.

Results: Seventy-five patients (59 women, mean age 75 years) were included in the study. In univariate analysis, KSS, ROM, muscle strength, and VAS for pain were significantly improved at 1 year after TKA compared to preoperative values (p<0.0001, 0.0001, 0.0001, 0.0001: paired t-test). The number of frail patients decreased from 24 to 18 following TKA (p=0.002: Fisher's exact test). Multivariate analysis of the association of changes in frailty using ordinal logistic regression showed a positive correlation between improvement in walking speed and improvement in muscle strength (p=0.01, p=0.02), but not with sex, age, preoperative ASMI or presence of sarcopenia, improvement in pain while walking or ROM (Table 1).

Conclusion: The number of patients with frailty significantly decreased 1 year after TKA; the factors associated with changes in frailty were improvements in gait speed and muscle strength, suggesting that functional improvement rather than the pain-relieving effects of TKA contributed to the improvement in frailty.

CALCIUM CONTAINING CRYSTALS ARE HIGHLY PREVAILENT IN JOINT FLUID OF ADVANCED OSTEOPOROSIS OF THE KNEE

Keywords: Diagnostic Tests, Osteoarthritis, Crystal Arthritis

T. Niessink1,2, T. Jansen2, M. Janssen2, T. Welting3, C. Otto1. University of Twente, Medical Cell Biophysics group, Enschede, Netherlands; VieCuri Medical Centre, Rheumatology, Venlo, Netherlands; MUMC+, Experimental Orthopaedics, Maastricht, Netherlands.

Background: Calcium containing crystals in osteoarthritis (OA) are of interest in the field of rheumatology, as they potentially stimulate the NLRP-3 inflammasome and may become treatable with novel therapeutics. Previous studies using scanning electron microscopy and polarization microscopy (PLM) demonstrated a presence of calcium pyrophosphate (CPP) and basic calcium phosphate (BCP) crystals in early and advanced OA [1]. Calcium carbonate crystals have been found in cartilage specimens of advanced OA and have recently been shown to potentially occur early in development of cartilage calcification [2].

Objectives: In this study we attempt to identify calcium containing crystals in joint fluid of patients with late-stage OA using Raman spectroscopy.

Methods: Synovial fluid samples from advanced knee OA cases were collected from the Maastricht University Medical Center (MUMC+) experimental orthopaedics biobank. This biobank contains synovial fluid samples from patients undergoing total knee replacement surgery for advanced osteoarthritis. The population includes both males and females and all patients were above 18 years of age. Samples were frozen at -80°C. No preservatives were used. Maastricht University Medical Hospital (METC azMUM) approved sample collection. Patients gave written informed consent before collection of their synovial fluid. Samples were analyzed with an integrated Raman polarized light microscope (H-IRPolM, Hybriscan Technologies B.V., Nijkerk, the Netherlands). For each sample, 20 µl of synovial fluid was pipetted on a microscope slide. Birefringent crystals were localized with PLM and then scanned with the integrated Raman spectrometer. For each particle, the Raman spectrum from 0-3600 cm⁻¹ was measured for 1 s/pixel with a laser power of 10 mW and a 532 nm laser. Analysis time per particle was 1-2 minutes depending on particle size. Spectra were analyzed by a trained analyst (TN, CO). Samples were considered positive for a certain type of crystal if at least one crystal with a distinctive spectrum could be identified.

Results: Calcium containing crystals were present in all (100%) of the 36 samples, 34 (94.4%) of the samples contained calcite (calcium carbonate) crystals. Dolomite (calcium magnesium carbonate) crystals were present in 10 (27.8%) samples, 9 (25.0%) samples contained both types of calcium carbonate crystals. CPP crystals were present in 33.3% of samples. All the CPP crystals were identified as triclinic CPP, amorphous or monoclinic CPP were not identified. Basic calcium phosphate crystals were present in 9 (25.0%) samples, all of which were hydroxyapatite. Calcium oxalate crystals were present in 7 (19.4%) samples, 3 of which were identified as calcium oxalate dihydrate (COD) and 4 of which were identified as calcium oxalate monohydrate. Most of the samples (80.6%) contained more than one type of calcium crystal, but CPP and BCP were never identified simultaneously in one sample. One patient had some MSU crystals. Raman spectra of identified particles are shown in figure 1.

Figure 1. Raman spectra of identified calcium containing crystals.

Conclusion: Calcium containing crystals are common in synovial fluid samples from knee joints in patients with end-stage osteoarthritis. Raman spectroscopy is a novel technique for rheumatology which enables reliable detection and objective identification of crystals such as calcium carbonate. The observation of calcium carbonate (calcite) crystals in synovial fluids of OA patients is novel and a promising subject of further study. Pathways to presentation in synovial fluid and inflammatory properties should be investigated.

PAIN AND FUNCTIONAL IMPAIRMENT ARE MORE PROMINENT IN EROSIVE HAND OSTEOARTHRITIS THAN IN TREATED RHEUMATOID ARTHRITIS: A COMPARATIVE STUDY BETWEEN DIGICOD AND ESPOIR COHORTS

Keywords: Osteoarthritis, Rheumatoid arthritis, Quality of life

S. Berkan1, A. Aparicio Monforte2, S. Tuftef, A. Rousseau3, N. Rinchevar2, E. Mahieu4, B. Combe5, A. Saraux6, B. Fautrel7, L. Gossec8, F. Berenbaum9, J. Sellam1, A. Courties1,2. 1Sorbonne Université, Hôpital Saint-Antoine (APHP), Department of Rheumatology, paris, France; 2Hôpital Saint-Antoine (APHP), Department of Rheumatology, Paris, France; 3University of Montpellier, Unit of Statistics, Institute of Clinical Research EA2415, Montpellier, France; 4University of Montpellier, Department of Rheumatology, Paris, France; 5CHRU de Brest, France.
Background: The common belief is to consider hand osteoarthritis (HOA) as a less severe disease with a better functional prognosis and a lower global burden than rheumatoid arthritis (RA). However, this paradigm may no longer be true considering the striking efficacy of targeted therapies in RA compared to the weak efficacy of therapies in the most severe form of HOA, namely erosive HOA (EHOA), which impacts 10-20% of symptomatic HOA [1]. Few studies addressed this issue [2].

Objectives: We aimed to compare the burdens of established EHOA and RA. The objectives were to compare pain, functional impairment, quality of life and the prevalence of comorbidities and of cardiovascular diseases (CVD) between established EHOA and RA.

Methods: DIGital Cohort Osteoarthritis Design (DIGICOD) is a French cohort of symptomatic HOA (at least 2 painful joints) with at baseline a mean ± SD disease duration of 12.9 ± 9.6 years [3]. This study involved the EHOA patients, from inclusion visit of DIGICOD, defined by at least 1 erosive joint according to the Verbruggen score. RA patients fulfilling ACR/EULAR 2010 criteria at the 10th year visit were selected from the ESPOIR cohort (Étude et Suivi des Polyarthrites Indifférenciées Récentes), a French cohort of early RA [4]. Pain intensity at rest or mobilization (0-100mm visual analogical scale (VAS)≥40/100), fatigue (VAS fatigue≥25/100), function (normal [0-100] scores of Health Assessment questionnaire for RA, and AUStalian CA nanadian Osteoarthritis Hand Index for EHOA > 16.7) were analyzed and compared between EHOA and RA using logistic regression models adjusted on age, gender, BMI, comorbidities and socio-educational level. The risk to have ≥2 comorbidities (among CVD, cancer, hemopathy, fracture) or at least 1 CVD (among high blood pressure, diabetes, dyslipidemia, myocardial infarction, stroke) were compared between EHOA and RA adjusted on age, gender, BMI and socio-educational level. Odds ratios (OR) and their 95% confidence intervals (CIs) were reported (EHOA versus RA).

Results: We analyzed 138 patients with EHOA and 379 with RA. The median [interquartile] age of EHOA patients was higher than RA patients (67.3 [63.3; 72.2] vs 48.6 [39.9; 55.6] years, p<0.001). The disease duration, at the evaluation time, was 19.3 [70.20.0] for EHOA and 10.5 years [10.3; 10.7] for RA patients. RA was anti-CCP antibodies positive for 56% of patients and in remission for 61% (DAS28 < 2.6). RA patients were treated by methotrexate (82%), biologics (37%) and 25% by corticosteroids while 20% of EHOA patients received oral non-steroidal anti-inflammatory drugs. EHOA patients had more painful joints in the hands than RA patients (4.0 [2.0;8.8] vs 0.0 [0.0;3.0], p< 0.001). In the adjusted analysis, EHOA was associated with more pain at mobilization (OR = 3.13 95% CI [1.74 to 5.68] p< 0.001) and more functional impairment (OR = 2.27 CI 95% [1.26.41.7], p = 0.007) (Figure 1). There was no difference for pain at rest and for fatigue VAS. For comorbidities, the proportions of EHOA patients with ≥2 comorbidities were higher than RA patients (37.7% vs 27.5%). However, when we stratified by age, the proportions of patients with ≥2 comorbidities were higher in RA patients between 50 and 70 years old (30.2% vs 47.1%) compared to EHOA patients. In adjusted analysis, the risk to have ≥2 comorbidities was lower in EHOA than in RA patients (OR = 0.25 CI 95% [0.13 to0.48]; p< 0.001) while there was no difference for CVD risk.

Conclusion: After more than 10 years of disease duration, EHOA is associated with more pain and more functional impairment but less comorbidities than RA. This study highlights the significant unmet need for effective therapies for patients with EHOA.

INTRA-ARTICULAR MM-II, A NOVEL SUSPENSION OF LARGE EMPTY MULTILAMELLAR LIPOSOMES, IN PAINFUL KNEE OSTEOARTHITIS: A 26 WEEK PHASE 2B RANDOMIZED TRIAL

Keywords: Osteoarthritis, Clinical Trials

P. G. Conaghan¹, H. Rovsing², E. Lau³, S. L. Boit³, B. Brahmacar³, R. C. Chou⁴, T. Joshi⁵, R. Wechsler⁶, S. L. Yao⁵, S. Weiner⁵, A. R. Biilhet⁶, T. Schnitzer⁶.¹University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; ²Sanoz Clinic, Gandrup, Denmark; ³Hong Kong Center for Clinical Research, Hong Kong, Hong Kong (SAR); ⁴Sanoz Clinic, Velej, Denmark; ⁵Sun Pharmaceuticals, Inc, Princeton, United States of America; ⁶Moelbius Medical Ltd., Tel Aviv, Israel; ¹NBCD A/S, Saborg, Denmark; ²Northwestern University Feinberg School of Medicine, Chicago, United States of America

Background: MM-II, a novel suspension of empty large multilamellar liposomes composed of dimyristoylphosphatidylcholine (DPMC) and dipalmitoylphosphatidylcholine (DPPC), has demonstrated beneficial effects in OA animal models. In a prior first-in-man study, MM-II demonstrated the ability to lower pain in knee OA patients for up to 3 months.

Objectives: The aims of this phase 2b study were to determine an effective dose, the durability of response, and the safety of MM-II in patients with symptomatic knee OA.

Methods: Consented participants were enrolled in a 6-arm randomized, double-blind, placebo-controlled 26-week trial evaluating a single IA injection of...
MM-II at doses of 1ml, 3ml and 6ml (150mM concentration of lipids) and placebo of matching volumes. Key inclusion criteria: age ≥ 40 years, KL grades 2 or 3, ACR OA criteria, WOMAC A pain ≥2 (0-4 Likert scale), VAS ≥50 and ≤90 (100mm scale), ACOA adverse responses to NSAIDs or acetaminophen. Primary endpoint was change in WOMAC A pain score at week (Wk) 12; secondary endpoints included weekly average daily pain score (ADP e-diary) at Wks 12 & 26, WOMAC A pain at 26 wks, Patient Global Assessment (PGA) and WOMAC B and C at Wks 12 & 26, and use of rescue medication. Randomization was stratified by BMI (< 30, 30 ≤BMI<35, and BMI ≥ 35) and baseline knee pain (VAS≥74, VAS< 75). Statistical analysis for the primary endpoint was analyzed based on FAS using a mixed model repeated measures (MMRM) with fixed effects for treatment group, visit (Wk 1-12), and treatment-by-visit interaction and covariates of site, baseline WOMAC pain, BMI and VAS groups. Subjects were included as random effects. Treatment differences were estimated using least square means (LSM) with 95% CIs. Step-down Dunnett’s hierarchical testing procedure compared the three doses to 3ml placebo to adjust for multiplicity. Confidence intervals were unadjusted.

Results: 397 participants were randomized with no significant differences in baseline demographics or clinical characteristics across all treatment groups. Mean age was 62.7 (SD 8.1) years; participants were predominantly female (65.0%) and white (67.0%) with mean BMI 30.8 (SD 6.1) kg/m2. Overall, 6.6% of participants discontinued the study. The primary endpoint of WOMAC A change from baseline to Wk 12 showed LSM difference of -0.24, 95% confidence interval (CI) -0.476, -0.004, p = 0.085 for the 3ml group and -0.02, 95% CI -0.269, 0.222, p = 0.85 for the 6ml group, both vs 3ml placebo, adjusted for multiplicity. The results of the 3ml group were sustained to Wk 26. Nominal significance was seen at some points. When comparing 3ml MM-II to the pooled placebo groups, the LSM difference in change from baseline of the WOMAC A at Wk 12 was -0.28, 95% confidence interval (CI) -0.484, -0.086, p = 0.018 adjusted for multiplicity. The LSM differences in weekly ADP scores were nominally significant at Wks 12 and 26 for the MM-II 3ml group vs 3ml placebo: -10.9, 95% CI (-18.8,-8.3), p = 0.008 and -11.8%, 95% CI (-20.19, -3.34), p =0.006, though the 6ml group was not significant (Figure 1). The changes in use of rescue medication corresponded to changes in symptoms during the trial. Treatment was well tolerated with TEAEs reported in 26% of MM-II and 29% of control participants. Injection site reactions were similar in the treatment and control groups, 19% and 29%, respectively.

Conclusion: Differences between MM-II and placebo in WOMAC A were not statistically significant at Wk 12, though WOMAC reductions were nominally significant at some time points, and when comparing 3ml MM-II to the pooled placebo groups, results were nominally significant at Wk 12. MM-II at 3ml dose demonstrated consistent and durable reduction in weekly knee ADP scores, nominally significant compared to placebo, as early as Wk 6, with efficacy maintained through Wk 26. Treatment with MM-II was well tolerated with low levels of adverse events. MM-II may have the ability to provide durable and relevant pain relief in OA and information in further clinical studies.

POS007 ULTRASONOGRAPHY MAY IMPROVE OSTEOARTHRITIS PAIN PREDICTION: AN ARTIFICIAL INTELLIGENCE APPROACH

Background: Knee osteoarthritis (OA) pain scores only moderately correlate with conventional radiographic findings—likely because pain has a multifactorial etiology. Ultrasound (US) can capture soft tissue structures which are known to be involved in pain pathophysiology but may not be visible in knee radiographs. In OA, US is a cost-effective and portable and imaging technology that can be performed at the point of care by non-radiologists. Therefore, US may have utility in understanding variance in pain attributed to knee OA.

Objectives: Our objective was to demonstrate if adding US features to computer vision analysis of radiographic images improves machine learning-based prediction of Knee injury and Osteoarthritis Outcome Score (KOOS) Pain scores in knee OA.

Methods: 116 subjects with end-stage knee OA were included in the study and were grouped into training and testing sets with an 80:20 split. Prior posterior anterior flexion x-rays and standardized knee US images were collected. A fellowship-trained musculoskeletal radiologist read 26 ultrasound continuous and ordinal features. All x-rays were pre-processed by cropping and applying Contrast Limited Adaptive Histogram Equalization. The processed images were resized to 224 x 224 pixels, stacked to form three-channel images, and mean-subtracted with respect to ImageNet (Figure 1). We generated the radiograph input feature vectors by using a pretrained ResNet50 model with a global average pooling layer replacing the classification head. We trained models to predict KOOS Pain with only radiograph image embeddings, solely US features, or multimodal inputs by concatenating the two feature vectors. For radiograph image embeddings and ultrasound feature vectors, we applied min-max normalization with the respective extrema of the training dataset for each feature. As a secondary analysis, we trained additional models to predict KOOS Symptoms and KOOS Function in Daily Living (ADL) sub-scores. Across all inputs and target variables, we used five-fold cross-validation for model selection across random forest regressors and histogram-based gradient boosting regression trees from the scikit-learn package, CatBoost regressors, and XGBoost regressors. All models were trained using default hyperparameters defined by the respective model packages during model selection and final training. We report and compare model performance using Pearson’s correlation coefficient, mean absolute error, and root mean squared error. All performance metrics were calculated using the scikit-learn and SciPy packages.

Results: When predicting KOOS Pain scores, radiographic image data alone (r = 0.26) or ultrasound scores alone (r = 0.17) did not perform as well as the multimodal model (r = 0.34) where both radiographic and ultrasound measurements were included (Table 1). For prediction of KOOS Symptoms scores, an input of radiographic image data alone (r = 0.45) correlated better than when either ultrasound features alone (r = 0.16) or the multimodal model (r = 0.28) were used as inputs. Similarly, when predicting KOOS ADL scores, radiographic image data alone (r = 0.14) correlated better than ultrasound features alone (r = 0.26) or the multimodal model (r = 0.03).

Conclusion: Differences between MM-II and placebo in WOMAC A were not statistically significant at Wk 12, though WOMAC reductions were nominally significant at some time points, and when comparing 3ml MM-II to the pooled placebo groups, results were nominally significant at Wk 12. MM-II at 3ml dose demonstrated consistent and durable reduction in weekly knee ADP scores, nominally significant compared to placebo, as early as Wk 6, with efficacy maintained through Wk 26. Treatment with MM-II was well tolerated with low levels of adverse events. MM-II may have the ability to provide durable and relevant pain relief in OA and information in further clinical studies.
Conclusion: Combining US features with knee radiographs may improve performance for predicting KOAS Pain scores in patients with end-stage knee OA, but did not improve the prediction of KOOS Symptoms or ADL scores. Our results suggest that soft tissue features captured by US can help us understand differences and underlying mechanisms in pain attributed to OA.

Methods: The Osteoarthritis Initiative is a longitudinal observational study of participants with or at risk of symptomatic knee OA. We identified incident cases of radiographic KOA, defined as Kellgren-Lawrence [KL] grade 2 or 3 based on centrally graded x-rays. Participants underwent bilateral posteroanterior fixed-flexion weight-bearing knee radiography at clinic visits annually or biannually through year 10. Non-contrast 3T MRI was also acquired at clinic visits up to year 8. Musculoskeletal radiologists graded structural damage, including effusion-synovitis (ES), Hoffa-synovitis (HS), bone marrow lesions (BMLs), cartilage and meniscal damage using the MRI Osteoarthritis Knee Score (MOAKS). The WOMAC knee pain subscale is calculated by adding reported pain scores from various activities, including walking on a flat surface, going up or down stairs, at night while in bed, sitting or lying down, and standing, during the last seven days, rated on a 5-point scale from none (0), mild (1), moderate (2), severe (3), or extreme (4). Pain in each knee was reported separately. We fit a proportional odds logistic regression to model the ordinal pain scores reported for each activity on the WOMAC pain scale using penalized maximum likelihood estimation; predictors included each of the MRI structural damage scores, KL grade, age, and BMI at the same clinic visit, as well as sex and race. We estimated the predicted probability of pain rated moderate or worse (Pr[Y ≥ 2 | X]) and reported nonparametric bootstrap 95% confidence intervals (CI) with cluster sampling at the participant-level.

Results: We identified 690 knees contributed by 623 participants that developed radiographic KOA. The mean participant age was 65 years (SD 9), mean BMI was 29.3 (SD 4.8), 66% reported female sex and 83% self-identified as white. The predicted probability of knee pain rated moderate or worse (Pr[Y ≥ 2 | X]) increased with greater ES during walking and stair climbing, but there was no evidence that ES affected knee pain while in bed, sitting or lying down, or standing (Figure 1). We did not find evidence that HS, BMLs, cartilage or meniscal damage affected the WOMAC knee pain items cross-sectionally in our fully adjusted models.

Conclusion: Our study suggests that ES seen on MRI produces heterogeneous effects on pain reporting, depending on the type of activity. Treatments that are developed to target inflammation may reduce pain during some activities, such as walking and stair climbing, but may have little benefit during other activities, such as sitting or lying down. If a treatment effectively reduces or limits structural damage that differentially impacts pain across the activities included in the WOMAC pain subscale, analysis that focuses only on the WOMAC pain subscale score may mask the clinical benefit of the treatment.

DOI: 10.1136/annrheumdis-2023-eular.2875
Background: This study uses gait measurements and imaging techniques in knee osteoarthritis (OA) patients to investigate the association between gait patterns and joint structure.

Objectives: To analyze whether 1) gait patterns can be explained by joint structure and 2) longitudinal gait alterations can be predicted by joint structure in people with knee OA.

Methods: In the IMI-APPROACH cohort, 297 people with knee OA were included at 5 sites in Europe. At baseline and two years, full gait kinematic data was collected from all participants using the GaitSmart system, while radiographs and MRI scans of their index knee were performed for evaluation of joint structure. The GaitSmart measures included for the current study were range of motion (ROM) of the hip, thigh, knee in swing and stance phase, and foot in the sagittal plane, and medial-lateral movement of the thigh and calf, all for the index leg.Stride duration and speed were included as well. From the radiographs, the minimum joint space width (JSW), femorotibial angle, mean whole-joint subchondral bone density (SBD), and total whole-joint osteophyte area were determined. From the MRI scans, mean whole-joint femorotibial cartilage thickness (FTC), bone density (SBD), and total whole-joint osteophyte area were determined. Principal component analysis (PCA) was performed on the gait parameters first, to discover underlying domains. Univariate backwards linear regression models with each of the GaitSmart domains as dependent variable were used to analyze how joint structure influences gait or predicts gait change over two years. Three models were run: one with participant demographics (age, sex, BMI) only, one with structural imaging parameters only, and one combining both.

Results: 284 Participants (age 66.5±7.1, BMI 28.0±5.4, 65 (23%) male, 154 (54%) radiographic OA) had baseline GaitSmart data (211 had two-year data). PCA identified three gait domains: upper leg (speed, duration, thigh ROM and hip movement (thigh and calf medial-lateral movement). Over two years the lower leg parameters showed a slight deterioration, though only knee ROM in swing phase changed significantly (-1.5±6.9 degree, p=0.002). The upper leg parameters showed minor non-significant improvement over two years; the medial-lateral parameters showed opposing non-significant changes. Results of all models are summarized in Table 1. Cross-sectionally, higher FTC, absence of effusion and presence of synovitis lead to worse function and synovitis absence were associated with worse upper leg function. Change in people with knee OA especially for the lower leg, providing a significant association between OA symptoms and joint structure, although only for a limited part (low R² values; Table 1) and not for medial-lateral movement. Surprisingly, synovitis and osteophyte size showed contrasting associations with lower leg gait that may be explained by half of the patients not having radiographic OA and should be investigated further. Parameters indicating more severe OA (e.g. lower JSW and FTC, higher age and SBD) were generally associated with more impaired gait.

superiority of MRI over X-ray is not clear. More importantly, these measurements have not been compared with direct visualization of the cartilage.

**Objectives:** To evaluate cartilage width as well as early cartilage lesions by X-ray and MRI techniques, comparing these observations with those obtained by direct visualization of cartilage during arthroscopy (ARTH) in a population with non-advanced knee OA.

**Methods:** We prospectively recruited 105 patients (>18 y.o) with knee pain of more than 3 months’ duration who underwent diagnostic knee ARTH due to uncertain origin knee pain or meniscal tear. WOMAC score was used to assess joint pain and function. Standardized weight-bearing extended anteroposterior digital X-ray were performed aligning the center of the beam with the femoralial joint space. Images without correct alignment of the tibial plateau were discarded. By X-ray, OA grade was assessed by the Kellgren and Lawrence score (KLS). Medial and lateral joint space width (JSW) was measured on X-ray at the mid-surface of the affected knees in a blind manner. By MRI, cartilage lesions were classified into 3 categories (MRI intensity score: normal, no damage, low grade (fibrillation or thickening <30%) or high grade (thickening >50% or loss). Knee ARTH was performed through two portals according to standard practice and cartilage lesions observed by Outerbridge score (OBS). Bonferroni-corrected ANOVA test for continuous variables, Chi-square or Fisher’s test for discrete variables, normality with Shapiro-Wilk and Kolmogorov-Smirnov tests, concordance between groups with weighted Kappa index, correlation between OBS and cartilage measurement with Spearman’s correlation were performed employing Python 3.7 and SPSS25 for Windows 10.

**Results:** The correlation between X-ray JSW measurement and the OBS was null (r=0.052). No good agreement was found between the OA grade assessed by KLS and OBS, nor between MRI-S and OBS. Cartilage deterioration evaluated by X-ray and MRI showed a lower degree of tissue damage than that observed by ARTH visualization (Table 1).

**Conclusion:** ARTH enabled to detect cartilage damage with higher precision than X-ray or MRI. In addition, the ARTH assessment was able to explain the different pain and function levels, since patients with different OBS showed different WOMAC scores. MRI can detect joint lesions in the extra-articular space or related to bone damage, which are not observable with ARTH. Therefore, for clinical trials assessing structure progression, ARTH evaluation combined with MRI would be the most appropriate techniques to accurately measure cartilage deterioration.

PILOT STUDY ON EVOKED COMPOUND ACTION POTENTIAL CONTROLLED CLOSED-LOOP SPINAL CORD STIMULATION IN TREATMENT OF RAYNAUD’S PHENOMENON

**Keywords:** Investor initiated trial, Pain, Imaging

V. Schäfer1, P. Karakostas1, B. Dietz2, G. Bara2, J. Maciaczyk2, 1University Hospital Bonn, Rheumatology and Clinical Immunology, Bonn, Germany; 2Saluda Medical, Research, Harrogate, United Kingdom; 3University Hospital Bonn, Stereotactic and Functional Neurosurgery, Bonn, Germany

**Background:** Raynaud’s Phenomenon (RP) is an episodically occurring vasospasm of the peripheral arteries that leads to palleness, cyanosis and/or erythema, causing severe pain, sometimes paresthesia and rarely leading to ulceration of the digits and toes. In severe cases, RP patients have physical and functional impairments that substantially affect their ability to work. There are few reports, mostly case series, on the utility of spinal cord stimulation (SCS) to treat RP. However, there is a lack of objective evidence on the physiological effects (e.g., vasodilation) of SCS in this condition. Here, we present clinical outcomes of severe RP patients treated with evoked compound action potential (ECAP)-controlled closed-loop SCS.

**Objectives:** Severe primary and secondary RP patients can be treated with evoked compound action potential (ECAP)-controlled closed-loop SCS. High-resolution Doppler ultrasound can be used as objective evidence on the physiological effects (e.g., vasodilation) of SCS in RP patients.

**Methods:** This is a prospective, single-center pilot study to evaluate the effectiveness of ECAP-controlled closed-loop SCS in treating RP. Subjects who meet the inclusion/exclusion criteria, complete all baseline assessments, and sign an informed consent will be considered enrolled (10 in total). Patient outcomes such as Raynaud Condition Score, Raynaud Severity Score, Raynaud Frequency Score, Cochin Hand Function Score, SHAQ RP VAS, EQ-SD-5L, PGIC and objective peripheral circulation assessments using high-resolution Doppler ultrasound of digital arteries will be reported.

**Results:** The mean age ± standard deviation (± SD) of the ten patients is 45.5 ± 15.5 years. The mean baseline ± standard error mean (SEM) ± (n = 9) weekly attack frequency was 21.8 ± 5.9 and decreased to 7.7 ± 2.1 after the test phase (n = 9), 4.8 ± 1.7 month after implantation (n = 8), 12.4 ± 6.3 months after implantation (n = 8) and 12.6 ± 4.6 6-months after implantation (n = 8). The mean baseline ± SEM; n = 9) severity of attacks was 6.7 ± 0.4 which decreased to 4.9 ± 0.6 after the test phase (n = 9), 4.6 ± 0.9 1-month after implantation (n = 9), 3.8 ± 0.9 3-months after implantation (n = 9) and 3.3 ± 0.6 6-months after implantation (n = 8). The mean baseline ± SEM; n = 9) Raynaud’s condition score was 6.8 ± 0.7 and decreased to 4.4 ± 0.7 after the test phase (n = 9), 4.3 ± 1.0 1-month after implantation (n = 9), 3.4 ± 1.3 3-months after implantation (n = 8) and to 2.6 ± 0.7 6-months after implantation (n = 8). The mean baseline (± SEM; n = 9) PAL score was 8.6 ± 1.5, with hands warmed in a finger bath. After the trial period (trial-end; n = 9), the mean total score ± SEM for pathological artery occlusions decreased to 1.9 ± 1.0, and to 2.0 ± 1.1 1-month after implantation (n = 9), 2.0 ± 1.2 3-months after implantation 3-months after implantation (n = 8), and to 4.9 ± 2.6 6-months after implantation (6-months; n = 8). The mean baseline ± SEM; n = 9) cochin hand function scale score was 31.6 ± 8.2 and decreased to 24.7 ± 8.0 after the test phase (n = 9), 18.9 ± 7.8 1-month after implantation (n = 9), 19.5 ± 7.5 3-months after implantation (n = 8) and to 17.4 ± 7.7 6-months after implantation (n = 8). The mean patient global impression scale score at 1-month was ± SEM; n = 9) 2.4 ± 0.3 2.8 ± 0.4 3-months after implantation (n = 8) and decreased to 2.3 ± 0.4 6-months after implantation (n = 8).

**Conclusion:** This study demonstrates for the first time that RP-related pathological arterial occlusions can be treated effectively with a novel ECAP-controlled closed-loop SCS system. In conclusion, ECAP-controlled closed-loop SCS alleviates RP symptoms and improves peripheral blood flow. Longer-term follow up and larger controlled studies are needed to confirm these preliminary results.

DEUCRAVACITINIB REDUCES INTERFERONS, B-CELL PATHWAYS, AND SEROLOGICAL BIOMARKERS OF SYSTEMIC LUPUS DISEASE ACTIVITY: PHARMACODYNAMIC ANALYSIS FROM THE PHASE 2 PAISLEY STUDY

Keywords: Systemic lupus erythematosus, Targeted synthetic drugs, Biomarkers

Methods: The 48-week PAISLEY trial randomized 363 patients with SLE 1:1:1:1 to placebo or deucravacitinib 3mg twice daily (BID), 6mg BID, or 12mg once daily (QD). Whole blood transcripts, serum proteins, blood cell subsets, and antibody profiles at screening and baseline through week 48 were measured by immunocassays and flow cytometry. In a substudy, samples were collected from 83 subjects 22 to 114 hours after the initial dose. Samples from demographically matched healthy subjects were collected and measured for comparison.

Results: At screening, 42 genes/modules and 75 proteins were differentially expressed compared with healthy subjects, with fold change >1.5 and adjusted P value <0.05. With deucravacitinib treatment, significant reductions were observed of IFN activity, including BAFF, CXCL10, and MCP2. Adjusted mean percent reductions were –26%, –31%, and –30% for MCP2 and –42%, –43%, and –48% for CXCL10, respectively. Selected cytokines and chemokines were significantly reduced in the BID-dosed arms as early as 2 to 3 days after dose initiation. With deucravacitinib treatment, lymphocyte and neutrophil counts and complement levels increased, but markers associated with B-cell activation and differentiation including BLC (CXCL13), CD38 (gene expression), and autoantibodies were reduced.

Conclusion: Deucravacitinib suppressed IFN production, IgG expression, IFN-inducible proteins, B-cell pathway markers, and serological biomarkers, consistent with clinical symptom improvements in SLE patients treated with deucravacitinib.

Figure. Deucravacitinib, but not placebo, reduced biomarkers of IFN-regulated gene expression

POS0113 LONG-TERM REMISATIONS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AUTOIMMUNE DISEASES – A 25 YEARS SINGLE CENTER EXPERIENCE

Keywords: Systemic sclerosis, Systemic lupus erythematosus, Adaptive immunity

Methods: In this retrospective study, the clinical outcome of 22 patients was analyzed, who received a CD34+-selected autologous HSCT after immunoadaption followed by hematopoietic stem cell transplantation (HSCT) has emerged as a promising on-off therapy over the past decades, to provide long-term remissions even in patients with severe courses of their disease, through the restoration of immunologic self-tolerance.

Objective: Here, we summarize the outcomes of AD patients receiving HSCT and investigated – University Medicine between February 1998 and October 2015.

Results: With a median follow-up of 78 months (range 0.1-300), the overall survival was 76.4% and progression-free survival 58.2%, respectively. 3 deaths were regarded treatment related (2 infections in SLE and 1 cardiac failure in SSC). One patient had persisting disease (AIHA) and 4 relapses occurred in SLE patients at 18, 36, 81 and 83 months, respectively. Remaining patients are in stable clinical remission for up to 25 years post-transplant, despite discontinuation of immunosuppressive therapy in most cases. HSCT was associated with significant reduction of autoantibody levels and a profound reconfiguration of the adaptive immune system, the latter characterised by a re-emergence of naïve T cells with markers of recent thymic emigrants, including Foxp3+ Treggs and regeneration of naïve B cells. In SLE patients, SIGLEC-1 expression on monocytes

Disclosure of Interests: This clinical trial was sponsored by Bristol Myers Squibb.

Disclosure of Interests: This analysis evaluated the effect of deucravacitinib on biomarkers of TYK2-mediated pathways, B-cell pathways, and serological biomarkers in patients in the phase 2 PAISLEY SLE trial.

Disclosure of Interests: This analysis evaluated the effect of deucravacitinib on biomarkers of TYK2-mediated pathways, B-cell pathways, and serological biomarkers in patients in the phase 2 PAISLEY SLE trial.

completely normalized suggesting an abrogation of type I interferon signalling in responding patients.

Conclusion: Our data provide the ‘proof-of-concept’ that a chronic autoimmune system can be reset into a naive and self-tolerant state by immunomodulation and HSCT, providing a potential curative treatment option. Although initially applied as salvage therapy in severely affected patients with poor outcomes, transplantation related mortality has gradually improved over the past years, due to accumulating centre experience, better patient selection and improved supportive care. Therefore, HSCT still represents a promising treatment option, especially in those patients with insufficient response to standard-of-care, with poor prognosis and life-threatening disease, in which the risk:benefit ratio of HSCT seems acceptable.

A PLACEBO-CONTROLLED PHASE 1 STUDY IN HEALTHY ADULT VOLUNTEERS OF THE SAFETY, TOLERABILITY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF ALPN-303, A POTENT DUAL BAFF/APRIL ANTAGONIST, FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Randomized control trial, Clinical Trials

Background: Povetacicept (ALPN-303) is an Fc fusion protein of a variant, engineered transmembrane activator and calcium-modulating cyclophilin ligand interactor (TACI) domain which mediates significantly more potent inhibitory activity than wild type (WT) TACI-Fc or B cell activating factor (BAFF)- or a proliferation inducing ligand (APRIL)-specific monoclonal antibodies, with enhanced pharmacokinetic (PK) and immunomodulatory properties versus WT TACI-Fc in preclinical studies. Povetacicept may therefore significantly improve clinical outcomes in systemic lupus erythematosus (SLE) and other B cell-related diseases.

Objectives: This study was designed to evaluate the safety, tolerability, PK, and pharmacodynamics (PD) of povetacicept in adult healthy volunteers (HV).

Methods: In this first-in-human study (NCT05034484), 66 HV were randomized 4:2 into single ascending dose cohorts of intravenous (IV) or subcutaneous (SC) povetacicept or placebo. Participants were followed to assess safety and PK, circulating immunoglobulins (Ig), and circulating leukocyte populations.

Results: Povetacicept has been well tolerated in all cohorts evaluated as single IV or SC doses of up to 960 mg. Overall, it exhibits dose-related PK and expected PD effects, including dose-related reductions in serum IgA, IgG, and IgM (Figure 1), and in circulating antibody-secreting cells (ASC; plasmablasts and plasma cells). These PD effects appear greater than those reported for WT TACI-Fc molecules in IV and appear to be saturated at doses ≥80 mg. Coverage of free APRIL was maintained for 2-3 weeks with 80 mg and ≥4 weeks with 240 mg, respectively. The most frequent adverse event (AE) has been mild headache. To date, there have been no imbalances of infections between the placebo and dosed groups, no treatment-related serious AEs, no administration-related reactions other than mild injection site pain (reported in one each of placebo- and povetacicept-treated participants), and no adverse trends in safety laboratories (Table 1).

Conclusion: To date, povetacicept has demonstrated acceptable safety and tolerability and exhibits expected PD effects on circulating Ig and ASC. These findings support future clinical development of povetacicept in patients with SLE and/or other B-cell- and/or autoantibody-related diseases.

A DAPIROLIZUMAB PEGOL EFFICACY BY SUBGROUPS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A POST HOC ANALYSIS OF PHASE 2 CLINICAL TRIAL DATA

Keywords: Clinical Trials, Systemic lupus erythematosus

A. Askanase1, C. Stach2, C. Britann3, G. Stojan1, R. Furie1, 1Columbia University Irving Medical Center, Department of Medicine, Division of Rheumatology, New York, United States of America; 2UCB Pharma, N/A, Monheim am Rhein, Germany; 3UCB Pharma, N/A, Slough, United Kingdom; 4UCB Pharma, N/A, Atlanta, United States of America; 5Northwell Health, Division of Rheumatology, New York, United States of America
Background: Systemic lupus erythematosus (SLE) clinical trials are challenged by high placebo response rates. Subgroup analyses of historic SLE clinical trial data have identified acute flares with normal complement levels as potential predictors of high placebo response.

Objectives: To assess the treatment effect of dapirolizumab pegol (DZP; a polyethylene glycol conjugated antigen-binding fragment lacking a functional Fc domain, which inhibits the CD40–CD40 ligand interaction) in patients from the phase 2b trial in SLE,[1] who fulfilled one or both of the characteristics identified as potential predictors of placebo response.

Methods: Post hoc analyses were performed on data from a phase 2b trial (NCT02804763), in which patients received placebo or DZP (6/24/45 mg/kg), alongside standard of care (SOC) for 24 weeks.[1] Efficacy was compared between two subgroups: (1) acute flare with low C3/C4 or persistent disease activity, vs (2) acute flare without low C3/C4. In the subgroup analyses, disease activity at screening was defined using British Isles Lupus Assessment Group (BILAG) 2004 item level scores either as acute flare (worsening/new symptoms) or persistent (symptoms rated as the same) based on the past 4 weeks compared with the 4 weeks prior to those, and low C3/C4 was defined as below the lower limit of normal at screening. Outcomes assessed were BILAG-based Composite Lupus Assessment (BICLA) response, SLE Responder Index-4 (SRI-4) response, and change from baseline in Physician’s Global Assessment (PGA) at Week 24. Binary outcomes were analysed using logistic regression (p-values reported for odds ratio vs acute flare without low C3/C4), and continuous outcomes were analysed using mixed models with repeat measures.

Results: Figure 1a and 1b show BICLA responses in the subgroups over time; similar patterns were seen for the other outcomes. At Week 24, higher BICLA response rates were achieved across all treatment arms in the acute flare without low C3/C4 subgroup compared with the other subgroup (Figure 1c). This pattern was particularly evident in patients receiving SOC plus placebo, where there was a significant 3-fold difference in BICLA response rates between the subgroups (80.0% vs 24.2%; p=0.005). Patients who received SOC plus placebo in the acute flare without low C3/C4 subgroup also achieved numerically higher SRI-4 response rates than the acute flare with low C3/C4 or persistent disease activity subgroup. A similar pattern was observed for patients who received SOC plus 6 mg/kg DZP; however, comparable SRI-4 response rates were observed between subgroups in patients who received SOC plus 24/44/55 mg/kg DZP (Figure 1d). At Week 24, greater changes from baseline in PGA were achieved in patients receiving SOC plus placebo in the acute flare without low C3/C4 subgroup than in the acute flare with low C3/C4 or persistent disease activity subgroup.

Conclusion: Despite the limited sample size, patients with acute flare with normal complement levels were more likely to achieve responses to SOC plus placebo, diminishing the DZP treatment effect. These data suggest that SLE trial design may need to consider baseline clinical and serologic activity patterns to adequately assess treatment efficacy.

POS0116 EFFICACY AND SAFETY OF VOLOCSPORIN ACROSS PATIENT SUBGROUPS WITH PROTEINURIA ≥2 MG/MG: AN INTEGRATED ANALYSIS OF THE AURA-LV AND AURORA 1 STUDIES

Background: Proteinuria is the most common manifestation of lupus nephritis (LN) and is a mediator of progressive kidney damage. Early reductions in urine protein creatinine ratio (UPCR) have shown to be predictive of improved long-term outcomes in LN. However, recent studies with monoclonal antibody therapies, in addition of voclosporin to mycophenolate mofetil (MMF) and low-dose steroids resulted in earlier and greater reductions in proteinuria across biopsy classes, races, and ethnicities.[5]

Objectives: To further characterize the efficacy and safety of voclosporin in patients with high proteinuria, we have analyzed outcomes in various subpopulations of patients with UPCR ≥2 mg/mg using the pooled dataset.

Methods: Both studies enrolled patients with biopsy-proven LN (Class III, IV, or V ≥ III/IV) within 6 months (or up to 2 years in AURORA 1) and proteinuria ≥1.5 mg/mg (≥2 mg/mg for Class V). Patients were randomized to voclosporin (23.7 mg BID) or placebo and treated for up to one year (48 weeks [AURA-LV], 52 weeks [AURORA 1]) all patients received MMF and low-dose steroids. For this post-hoc analysis, complete renal response (CRR) rates were evaluated in patients with baseline UPCR ≥2 mg/mg. Complete renal response was defined as UPCR ≤0.5 mg/mg with stable renal function, low-dose steroids, and no rescue medication.

Subgroup analyses were based on the following: sex, age, race, ethnicity, biopsy class, and estimated glomerular filtration rate (eGFR) at baseline. Adverse events (AEs) and mean eGFR levels over time were also assessed.

Results: Of the 268 and 266 patients included in the voclosporin and control arms of the pooled analysis, respectively, 217 and 215 patients had a baseline UPCR ≥2 mg/mg using the pooled dataset. UPCR ≥2 mg/mg (mean [SD], 5.2 [3.4] vs. 4.6 [2.9] mg/mg, respectively). At one year, the change from baseline in least squares (LS) mean (SE) UPCR was -3.8 (0.1) mg/mg in the voclosporin arm compared to -1.6 (0.2) mg/mg in the control arm (difference vs control, -0.7; p<0.0003). A significantly greater percentage of voclosporin-treated patients achieved CRR at one year compared to the control arm (41.0% vs. 21.9%; odds ratio [OR] 2.48, p<0.0001). CRR rates were numerically greater in voclosporin-treated patients in both sexes and across all ages, races, ethnicities, biopsy classes, and baseline eGFR levels assessed, with OR >1 (Figure 1). Across biopsy classes, the highest rates of CRR were observed in Class III patients treated with voclosporin (50% vs 16.1% in control, p=0.0126), followed by Class IV (44% vs. 23.8%, p=0.0019), Class V with III or IV lesions (37.7% vs. 17% p=0.0306), and Class V (313% vs. 28.6%, p=0.81). Similar rates of AEs were reported in both arms, and mean eGFR levels were similar and stable over one year of treatment (Figure 2).

Conclusion: Consistent with results from the overall pooled study population, patients with UPCR ≥2 mg/mg at baseline treated with voclosporin achieved significantly higher renal response rates than patients treated with MMF and low-dose steroids alone regardless of baseline demographics or clinical State of the Art.

RESULTS:
We observed a consistent downregulation of 35 proteins associated with B cell activity, including CD23, FCR1, FAIM3, and FCRL4, in all treatment groups receiving remibrutinib compared to the placebo group after 24 weeks of treatment. These modulated proteins are involved in multiple pathways related to B-cell activation and function, including B-cell receptor signaling, Fc receptor signaling, and platelet activation. Whole blood bulk mRNA sequencing revealed that the remibrutinib group showed a significant downregulation of a 34-gene signature, most of which are known to be important for B-cell activation and immunoglobulin production. The top two most significantly downregulated genes, FCRL5 and SOX5, were previously identified as being highly enriched in a circu-
tulating tissue-like memory B-cell subset. This observation is also corroborated by the proteomics profiling analysis, where FCRL4 known to co-localize in the same memory B-cell subset (Verstappen et al 2020, Götz et al 2008), was heavily decreased by the treatment. Despite the specific and strong effects on B-cells, estimation of cell type proportions using RNA-seq revealed no significant changes, suggesting that remibrutinib does not affect the overall B-cell num-
bers and the relative proportions of its major subsets, like plasma cells, naive and memory B-cells. Results from both proteomics and transcriptomics profiling suggest that remibrutinib treatment does not modulate the interferon signature.

Conclusion: Our analysis of serum proteins and whole blood transcripts showed that remibrutinib treatment was associated with a significant downregulation of proteins and genes enriched in FCRL4+ B cells, a subset of tissue-resident mem-
ory B cells that are expanded in inflamed tissues and found in the salivary glands of SjS patients. These findings suggest that remibrutinib may have a particu-
larly strong inhibitory effect on this subset. Additionally, many genes and proteins involved in B-cell activation, differentiation, and maturation were also downregu-
lated, indicating that remibrutinib has a potent effect on multiple B-cell pathways.

Background: Pregnancy complications in obstetric APS (OAPS) include recur-
rent early pregnancy loss, fetal death, or premature birth due to preeclampsia,
intrauterine growth restriction or placental insufficiency. The standard of care (SC) with low dose aspirin (LDA) and heparin has dramatically improved obstetric results, however 20-30% still have adverse outcomes despite treatment. Retrospective studies have shown good results with the addition of Hydroxychloroquine (HCQ). HCQ may have a beneficial effect in APS due to its anti-inflammatory, immunomodulatory and antithrombotic properties. Recently, EULAR recommended its use in refractory cases. Previously, in a retrospective study we reported that the addition of HCQ in women with primary OAPS and a pregnancy failure with SC was associated with a higher rate of live births (87 vs 62%) and a lower frequency of pregnancy complications (8 vs 37%) compared with conventional treatment. In this new study we show obstetric results from a larger cohort of refractory OAPS patients treated with HCQ.

Objectives: To assess pregnancy outcomes in a large cohort of women with refractory OAPS treated with Hydroxychloroquine in addition to conventional treatment.

Methods: This was an observational, retrospective, single-center cohort study. We analyzed pregnancy outcomes in women with refractory primary OAPS (2004-2022) who received HCQ (at a dose of 600mg/day + LDA in their subsequent pregnancies).

Results: We evaluated 182 pregnancies in one hundred and seventy-three women (21-51y) treated with the addition of HCQ and a previous failure with conventional treatment; 18.9% of them had triple antibodies positivity. Live birth rate was 94% (CI 95%: 89.5-96.5). Term deliveries occurred in 95% of the pregnancies, mean gestational age at birth was 38 weeks (28-39) and mean weight 3021g (915g-4300g). Sixty percent were cesarean sections and 40% vaginal deliveries. Pregnancy complications occurred in 12% of the pregnancies (CI 95%: 7.3-19.5). Early pregnancy losses before 10 weeks occurred in 6% of the pregnancies. There were no late fetal deaths. Six patients who presented mild cutaneous allergy had to interrupt HCQ and were excluded from the analysis. Conclusion: These results add observational evidence in favor of using Hydroxychloroquine in refractory Obstetric APS patients until results from ongoing RCT are published.

Background: Interleukin 2 (IL-2) signaling is essential for the development, survival, and suppressive function of T regulatory cells (Tregs). Diminished IL-2 signaling and Treg functional impairment are associated with autoimmune diseases, including systemic lupus erythematosus (SLE)[1][3]. XmAb564 is a potency reduced, monomeric human IL-2 heterodimeric Fc-fusion protein with extended half-life and increased binding affinity for IL-2 receptor alpha (CD25) to selectively expand Tregs, being developed for the treatment of autoimmune diseases.

Objectives: In this first-in-human, placebo-controlled, double-blind, single ascending-dose study, healthy adult volunteers received XmAb564 and were evaluated for safety, tolerability, pharmacokinetics (PK), and pharmacodynamic (PD) for 30-45 days.

Methods: Subjects received SC doses of XmAb564 at 0.003, 0.007, 0.015, 0.025, 0.040, and 0.065 mg/kg in 6 cohorts (6 active:2 placebo per cohort). Levels of immune cell populations in whole blood were assessed by flow cytometry for total Tregs (CD4+CD25+FoxP3+) and CD25highFoxP3+ Tregs (CD4+CD25highFoxP3+), as well as NK (CD56+ cells), CD4+ and CD8+ T conventional cells (Tcon).

Results: A single dose of XmAb564 was well tolerated, with no dose-limiting toxicities, no Grade 3 or greater adverse events (AEs), no serious AEs, no deaths, nor clinically significant laboratory safety abnormalities. AEs attributed to XmAb564 were mainly mild to moderate self-limited injection site reactions. Asymptomatic transient elevations of peripheral eosinophils were observed in a dose-dependent manner, similar to those reported with other biologics in the class. After a single dose of subcutaneous administration, XmAb564 exposure increased in a dose-dependent manner with dose-proportional Cmax and non-linear clearance owing to the expected increase in target receptor expression (CD25) in response to XmAb564 and dynamic target-mediated drug disposition across the range of doses studied from 0.003 to 0.065 mg/kg.

The primary effect of XmAb564 was seen on total Tregs and particularly the CD25highFoxP3+ Treg subset (Figure 1A, B). The elevations peaked at approximately Day 12 and remained elevated for at least 21 days following drug administration. At the highest dose of 0.065 mg/kg, the mean peak increase in numbers of Tregs and CD25highFoxP3+ Tregs were 8-fold and 11-fold above baseline, respectively. At that same 0.065 mg/kg dose level, there was a trend of mean increase of 2.6-fold, 2.3-fold, and 2.2-fold in numbers of NK, CD4+ and CD8+ Tcon cells, respectively.

Figure 1.

Conclusion: XmAb564 selectively induced Tregs and was well tolerated. XmAb564 PK and PD potentially supports extended multi-week dosing intervals and has a Treg induction magnitude and durability that may be competitive or superior to other candidates in clinic, providing the rationale for clinical evaluation across a broad range of inflammatory diseases.

SAFETY AND EFFICACY OF SUBCUTANEOUS (S.C.) DOSE IANULAMUB (VAY736; ANI-BAFFR mAb) ADMINISTERED MONTHLY OVER 28 WEEKS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Randomized control trial, Systemic lupus erythematosus, Clinical Trials

1Val d’Hebron Hospitals, Luperus Unit, Rheumatology Department, Barcelona, Spain; 2Charité Research Organisation GmbH, Rheumatology, Berlin, Germany; 3SM Kirov Military Medical Academy, Rheumatology, St Petersburg, Russian Federation; 4Sheba Medical Center, Tel Aviv University, Tischbiudowitz Center for Autoimmune Disease, Tel Aviv, Israel; 5Piramongkutklao Hospital and College of
Background: Ianalumab (VAY736) is a novel defucosylated, human IgG1 mAb targeting the receptor for Fc cell Activating Factor of TNF Family (BAFF-R), providing both enhanced antibody-dependent cellular cytotoxicity-mediated depletion of B cells and blockade of BAFF-BAFF-R signaling that drives B cell differentiation, proliferation and survival.

Objectives: Evaluate safety and efficacy of ianalumab in patients with active SLE.

Methods: Multi-center, randomised, parallel group, double-blind trial consisting of 2 separate, placebo-controlled treatment cohorts for ianalumab and for iscali- mab (CFZ533; anti-CD40 mAb) randomised 1:1 between active:placebo. Patients (ianalumab cohort n=67, iscalimab cohort n=40) with AHA ≥1 ‘A’ or ≥2 ‘B’ scores that included activity in either mucocutaneous and/ or musculoskeletal domains were enrolled from 19 Dec 2018 through 31 Jan 2022. Here we report interim analysis results for ianalumab treatment cohort (active n=34, placebo n=33) completing the 28-week blinded treatment period, which comprised of monthly s.c. injection of ianalumab 300 mg or placebo. Out- comes were measured at baseline (BL) and weeks (w) 4, 8, 12, 16, 24 and 28. The primary w28 outcome was proportion of patients meeting composite endpoint requirements consisting of patients who both achieved SRI-4 and also tapered predniso(lo)ne 10.0 mg (95% CI)

**Background:** Pulmonary arterial hypertension (PAH) is a major cause of mortality in systemic sclerosis (SSc). The 2022 ESC/ERS Guidelines recommend a comprehensive risk stratification at PAH diagnosis to guide optimized management. Several risk stratification tools have been developed in PAH. These strategies have not previously been compared, and have not been applied in SSc-PAH using the new haemodynamic definition.

**Objectives:** To assess the performance of current risk stratification tools to predict mortality in SSc-PAH.

**Methods:** We included patients from the EUSTAR registry who were diagnosed with SSc-PAH between 2001-2022 (Project Number: CP122). PAH was defined according to the new definition (mean pulmonary arterial pressure >20 mmHg, pulmonary artery wedge pressure ≤15 mmHg and pulmonary vascular resistance >2 WU). Patients with significant interstitial lung disease (ILD), defined as extent of ILD >20% on HRCT or FVC <70% in patients with missing quantification, were excluded. We applied four different approaches:

(i) The 2022 ESC/ERS 3-strata approach includes up to 17 parameters according to the risk table. [1] Each parameter was graded from 1 to 3 representing low to high risk, with the mean defining the risk category.

(ii) The 2022 ESC/ERS 4-strata approach includes (i), but divides the intermediate-risk group into two groups based on the mean score.

(iii) COMPERA 2.0 stratifies patients into four risk groups based on WHO-functional class (FC), six-minute walk distance (6MWD), and NT-proBNP.[2] Each parameter was graded from 1 to 4 representing low to high risk, with the mean defining the risk category.

(iv) REVEAL Lite 2 stratifies patients into three risk groups based on six weighted variables: WHO-FC, systolic blood pressure, heart rate, 6MWD, NT-proBNP, and APEX.[3] We analysed transplant-free survival and confirmed Cox regression adjusted for general and SSc-specific factors associated with worse outcome (age, male sex, DLCO, FVC, disease subtype and PAH treatment). Harrell’s C-index and ROC analysis with area under the curve (AUC) were applied to compare the performance and discriminating ability of the models with >0.7 considered as acceptable.

**Results:** Of 955 patients who had right heart catheterization, 430 (45%) were diagnosed with SSc-PAH. Among these, 86% were females, mean age was 85 years, and 82% had limited cutaneous SSc. Over median 40 (Q1-Q3: 17-68) months follow-up, 172 died and 14 had lung transplants. The overall 1-, 3- and 5-year transplant-free survival was 91%, 77% and 60%, respectively. In univariable Cox regression only COMPERA 2.0 had acceptable predictive value with a C-index >0.7 (Table 1). In adjusted multivariable Cox regression, all the risk stratification approaches predicted mortality with increased HR at higher risk scores (Figure 1 A-D). All adjusted models were acceptable, but COMPERA 2.0 was the most accurate to predict mortality (C-index=0.78; AUC=0.74) (Table 1, Figure 1C). However, this model did not discriminate intermediate-low risk from low risk HR 1.39, 95% CI (0.59, 3.25), p=0.45. The models discriminating abilities were not significantly different (p=0.27).

**Conclusion:** In SSc-PAH, we suggest that the application of risk stratification at time of PAH diagnosis should take SSc-specific variables into account. In particular, the COMPERA 2.0 risk stratification model performs best, does not require invasive measurements and uses parameters easily collected at each clinical visit, making it readily applicable in clinical practice. Importantly, this approach identifies patients at intermediate-high and high risk who need more aggressive management.

**INVESTIGATION OF SERUM MARKER LEVELS IN CONNECTIVE TISSUE DISEASES DEVELOPING ILD**

**Keywords:** Biomarkers, Systemic sclerosis, Lungs

H. Didrik sen1, H. Fretheim1, H. Andersson1, S. Reiseter2, R. Gunnarsson1, E. Langballe1, T. Garen1, Ø. Midthvedt1, T. Ueland1, Ø. Molberg1, A. M. Hoffmann-Vold1, 4. Ø. M. Hoffmann-Vold1, 4. Oslo universitetssykehus HF; Rikshospitalet, Rheumatology, Oslo, Norway; Martina Hansens Hospital, Rheumatology, Baerum, Norway; Oslo universitetssykehus HF; Rikshospitalet, Research Institute of Internal Medicine, Oslo, Norway; University Hospital of Zürich, Rheumatology, Zürich, Switzerland

**Background:** Connective tissue disease (CTD) is an umbrella term for a heterogenous group of autoimmune diseases affecting the connective tissue in various organs. One of the most severe complications associated with CTDs is interstitial lung disease (ILD), which results in significant morbidity and mortality. A subset of CTD-ILD patients shows progressive disease, which is associated with an even worse prognosis. Previous studies have identified dysregulations of biomarkers including CX3CL1, CCL2, CCL17 and CCL18 in systemic sclerosis (SSc) showing an association with ILD [1-4]. For other CTD-ILD it is less clear, which biomarkers are associated with ILD progression and few studies have assessed circulating biomarkers across CTD-ILDs.

**Objectives:** To investigate circulating biomarkers in CTD-ILD and in progressive CTD-ILD patients.

**Methods:** Serum samples from SSc (n=292), primary sjogrens syndrome (pSS) (n=132), mixed connective tissue disease (MCTD) (n=162), anti-synthetase syndrome (ASS) (n=292), and healthy controls (HC) (n=100) collected. Oslo University Hospital (OUH) were analyzed by ELISA for selected biomarkers (CX3CL1, CCL2, CCL17, CCL18). SSc samples were used as the reference to compare with mean levels of serum markers in pSS, ASS and MCTD. ILD was diagnosed on high resolution computed tomography (HRCT). Forced vital capacity (FVC) was available at baseline and 12 +/- 3 months. ILD progression defined as an absolute FVC%-predicted decline of >10% was assessed. Descriptive statistics and logistic regression with odds ratio (OR) and 95%CI were performed.

**Results:** Serum levels of CX3CL1 and CCL18 were significantly higher in all the CTDs (p<0.001) compared to HC. CCL2 and CCL17 levels were significantly higher in SSc (p<0.001 and p<0.001, ASS (p=0.001 and p=0.004) and MCTD (p<0.001 and p<0.001) compared to HC, but not in pSS (p=0.230 and p=0.087). Of all CTD entities, patients with ILD (p=0.011) of these patients 80% (30%) showed ILD progression, where data were obtained for SSc, pSS and ASS (Table 1). All the markers were significantly higher in patients with ILD compared to no ILD in SSc and pSS, while only CCL17 was significantly higher in ASS-ILD and none in MCTD-ILD. When using SSc-ILD as reference disease, serum levels of CX3CL1 were significantly higher in pSS-ILD (p<0.001) and CCL18 was significantly lower in MCTD-ILD (p<0.001). Serum levels of CCL2 and CCL17 did not significantly differ between SSc-ILD and the other CTD-ILDs (Figure 1A). From logistic regression analysis of the patient with ILD progression, CCL18 (OR: 1.19, 95%CI, p=0.001) were the only marker significantly associated with ILD progression. When adjusting for CTD as reference disease, the only marker significantly associated with ILD progression was also here CCL18 (OR: 1.19, 95%CI, p<0.001) (Figure 1B).

**Conclusion:** In this large CTD cohort, we show that CCL2 and CCL17 are increased across all CTD-ILD patients with ILD compared to no ILD, which could help us to identify patients with ILD. ILD progression was only associated with CCL18, which was driven by the SSc-ILD subpopulation.

Background: Prognosis in connective tissue disease associated interstitial lung disease (CTD-ILD) is influenced by the underlying diagnosis and chest imaging pattern. Usual interstitial pneumonia (UIP), non-specific interstitial pneumonia (NSIP), and fibrotic hypersensitivity pneumonitis (fHP) patterns can be found across all CTD-ILD subtypes although their impact on disease evolution and treatment response is unclear.

Objectives: Our goal was to examine the association of lung imaging pattern with CTD-ILD progression, mortality, and immunosuppression response.

Methods: 615 patients with CTD-ILD enrolled in the Canadian Registry for Pulmonary Fibrosis had high-resolution chest computed tomography (HRCT) from their first ILD clinic visit reviewed in standardized multidisciplinary pulmonary discussion. All CTD-ILD diagnoses were rheumatologist-confirmed. Experienced chest radiologists blinded to clinical data categorized each case into five groups: UIP, NSIP, organizing pneumonia (OP), fHP, and other patterns. Longitudinal percent-predicted forced vital capacity (FVC) and transplant-free survival were compared between imaging groups using linear mixed effects models with fixed effects, outcomes and immunosuppression response compared to UIP in the overall CTD-ILD group. The findings of fHP associated with worse survival compared to UIP in CTD-ILD and in the RA-ILD are novel. These findings need to be further confirmed in disease specific cohorts and randomized trials of immunosuppression in patients with CTD-ILD.

Background: Intermittent lung disease (ILD) is a major cause of mortality in patients with connective tissue diseases (CTDs). Previous studies have shown a worse survival in patients with idiopathic pulmonary fibrosis (IPF) (1-2), however, these studies were mainly focused on patients with rheumatoid arthritis, whereas few data are available for patients with other CTDs.

Objectives: The aim of this study was to assess the 5-year survival in an Italian multicenter cohort of ILD patients suffering from systemic sclerosis (SSc), dermatomyositis (DM), and anti-synthetase syndrome (ASS) compared to IPF patients.

Acknowledgements: NIL.
Methods: Demographic and clinical data of patients with SSc, DM and ASS were retrospectively recorded from January 2015 for the purpose of this study. The baseline time was a diagnosis of ILD confirmed by computed tomography (CT) scan of the chest. The IFP cohort was used as control group. Progressive lung disease was defined when the patient presented within 24 months after the diagnosis of ILD with at least one of these characteristics: a) a relative decline in FVC of at least 10% of expected value; b) a relative decline in FVC from 5% to less than 10% of the expected value and a worsening of respiratory symptoms or an increase in the extent of lung fibrosis on high-resolution CT scan; c) a worsening of respiratory symptoms and an increase in the extent of lung fibrosis on high-resolution CT scan. All data were reported and analyzed with standard descriptive statistics, as appropriate. The 5-year survival was assessed with the Kaplan-Meier method; univariate and multivariate Cox-regression models were built to look for possible risk factors. Data were analyzed with SAS/STAT Statistics version 8.4 (SAS Institute, Cary, NC, USA).

Results: The overall cohort included 177 CTD-ILD patients (99 SSc, 25 DM, 53 ASS) and 153 IPF patients. At ILD diagnosis, as expected, CTD patients were younger [median age (IQR): IFP: 68 (63-73) years, SSc 58 (46-66) years, DM 54 (51-65) years and ASS: 59 (60-67) years; p <0.001 vs IPF] and predominantly female: [IFP: 23%, SSc 83.5%, DM 81% and ASS 65%; p <0.001 vs IPF]. Usual interstitial pneumonia was observed in a low number of CTD patients, evidenced in 11 (11.5%) SSc, 7 (12.9%) ASS and 4 (16.6%) DM patients. At ILD diagnosis, the median (IQR) value of forced vital capacity (FVC) was similar between IFP [75% (64-91)], DM [79% (60-90)] and ASS [77.5% (84-93)], while was significantly higher in SSc patients [94% (79-106), p <0.001 vs IPF]. At baseline, all CTDs showed a higher mean (SD) value of diffusing capacity for carbon monoxide (DLCO%) [SSc: 63% (18), DM: 62% (23), ASS: 63% (22)] than IFP [50% (15); p <0.001]. During follow-up, 10 (9.7%) patients with SSc, 4 (16%) with DM and 3 (8%) with ASS showed a progressive subset of ILD. CTDs showed better 5-year survival compared to IFP (log rank: p =0.001) (Figure 1). Multivariate Cox analysis highlighted that male gender (HR: 2.29, 95% CI 1.25-4.18), age at diagnosis (HR: 2.04 L (95% CI 0.99-3.24 L) to 2.23 L (95% CI 0.83-3.35 L) at month 12 (p =0.039) before decreasing to 1.89L (95% CI 1.00-3.24 L) at month 36 (p =0.37) (Figure 1D). The absolute change from baseline of DLCO did not significantly differ according to B cell depletion. In addition, the percentage of patients with any FVC improvement was higher in the subset of patients who maintained complete B cell depletion at 1 year (69/67 vs 4/8, 50%) and at the last RTX infusion (89/89% vs 4/8, 50%). Conversely, median DLCO did not significantly differ according to BC depletion.

Conclusion: These results highlight the importance of obtaining and maintaining BC depletion to gain clinically relevant efficacy of RTX in CTD-ILD. CD19 measurement at each infusion is a relevant tool to monitor RTX efficacy in daily practice.
Background: In the randomised placebo-controlled SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks by 44%, with adverse events that were manageable for most patients. SENSCIS-ON is an open-label extension study investigating adverse events and decline in FVC in patients with SSc-ILD treated with nintedanib over the longer term.

Objectives: To assess adverse events and decline in FVC in patients treated with open-label nintedanib over 148 weeks of SENSCIS-ON.

Methods: In the SENSCIS trial, patients received nintedanib or placebo until the last patient reached week 52 but for ≤100 weeks. Patients with SSc-ILD who completed SENSCIS or a drug–drug interaction (DDI) study of nintedanib and oral contraceptive in which female patients with SSc-ILD received nintedanib for ≥14 days to approximately 28 days were eligible to enter SENSCIS-ON. We analysed adverse events and changes from baseline in FVC (mL) over 148 weeks in patients who received nintedanib in SENSCIS and continued nintedanib in SENSCIS-ON (“continued nintedanib” group) and in patients who received placebo in SENSCIS or who received nintedanib for ≤28 days in the DDI study (“initiated nintedanib” group). Analyses were descriptive. Analyses of FVC were based on observed data available at the respective time-point.

Results: The continued nintedanib group comprised 197 patients and the initiated nintedanib group comprised 247 patients (231 from SENSCIS, 16 from the DDI study). In these groups, respectively, mean (SD) FVC at the start of SENSCIS-ON was 2379 (754) mL and 70.4 (18.1)% predicted and 2443 (814) mL and 70.8 (17.3)% predicted. In total, 126 (64.0%) and 125 (50.6%) patients in the continued nintedanib and initiated nintedanib groups, respectively, were still receiving nintedanib at week 148 of SENSCIS-ON. Diarrhoea was the most frequent adverse event (Table 1). Serious adverse events were reported in 76 (38.6%) patients in the continued nintedanib group and 95 (38.5%) patients in the initiated nintedanib group. Among patients who continued nintedanib and initiated nintedanib, respectively, S3 (26.9%) and 148 (59.9%) had ≥1 dose reduction and 72 (36.5%) and 131 (53.0%) had ≥1 treatment interruption. Adverse events led to discontinuation of nintedanib in 29 (14.7%) patients in the continued nintedanib group and 72 (29.1%) patients in the initiated nintedanib group. Mean (SE) changes in FVC from baseline to week 148 of SENSCIS-ON were −189.1 (29.5) mL in the continued nintedanib group and −126.4 (26.4) mL in the initiated nintedanib group (Figure 1).

Conclusion: The safety profile of nintedanib over 148 weeks of SENSCIS-ON was consistent with that reported in SENSCIS, characterized mainly by gastrointestinal events that were manageable for most patients. These results support the potential use of nintedanib in the long-term treatment of patients with SSc-ILD.

Data are n (%) of patients with ≥1 such event reported over 148 weeks (or until 7 days after last trial drug intake for patients who discontinued trial drug before week 148). Adverse events were coded according to preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA) except for liver test abnormalities, which were based on the standardised MedDRA query “liver related investigations, signs and symptoms” (broad definition). Events reported in >12% of patients in either group are shown.

Figure 1. Change in FVC (mL) over 148 weeks in SENSCIS-ON

Figure 1. Change in FVC (mL) over 148 weeks in SENSCIS-ON
is common in SSc patients, ranging from 36% to 65%. However, no study has unveiled the risk of new-onset depression in SSc patients.

Objectives: The present study was conducted to determine whether SSc is an independent risk factor for the development of new-onset depression. To determine whether the incidence rate (IR) of new-onset depression in SSc patients is higher than in normal subjects, we used data from a nationwide health care database.

Methods: We selected subjects from National Health Insurance System database who were diagnosed with SSc between 2010 and 2016. Subjects who did not get a general health checkup in the previous 2 years, who were diagnosed with depression before their SSc diagnosis, who were less than 20 years old, or who had missing data were excluded. To minimize the possibility of reverse causality, an analysis with a 1-year lag was performed. Kaplan-Meier analysis was conducted to assess the incidence of new-onset depression, and Cox proportional hazards regression was used to calculate adjusted and unadjusted hazard ratio (HR) and 95% CIs. HR for new-onset depression was adjusted for age, sex, smoking, drinking, physical activity, body mass index (BMI), income, diabetes, hypertension, and dyslipidemia.

Results: A total of 1,063 SSc patients (female 82.4%) and 3,189 age-, sex-matched non-SSc controls with mean (SD) age of 53.1 (10.6) years were included in the analysis. During follow-up periods after 1 year of lag time, the cumulative incidence of new-onset depression was significantly higher in patients with SSc vs controls (38.7 vs. 27.7/1000 person-years). After adjusting for covariates (age, sex, smoking, drinking, physical activity, BMI, income, diabetes, hypertension, and dyslipidemia), the presence of SSc was associated with 38.1% increased risk of new-onset depression (HR 1.381; 95% CI, 1.128-1.691), compared with controls. SSc disease itself was determined as an independent risk factor for new-onset depression in subjects with younger age (age < 65 years; HR 1.41; 95% CI 1.122-1.773), female gender (HR 1.415; 95% CI 1.139-1.759), and absence of regular exercise (HR 1.433; 95% CI 1.143-1.798), after adjusting for covariates. Interestingly, the risk of new-onset depression after SSc diagnosis was found to be relatively higher in the low-income group (HR 1.667; 95% CI 1.121-2.479 vs HR 1.303; 95% CI 1.028-1.650).

Conclusion: The present study suggests that the SSc diagnosis is associated with a significantly increased cumulative incidence and risk of new-onset depression. This association is more pronounced in female gender, younger age group, and those who do not exercise regularly. Regular assessment of the occurrence of depressive symptoms should be more emphasized in the patients with SSc after diagnosis.

POS0128 TEN-YEAR ALL-CAUSE MORTALITY AND RISK FACTORS FOR DEATH IN A LARGE PROSPECTIVE REGISTRY COHORT OF IDIOPATHIC INFLAMMATORY MYOSITIS IN CHINA

Keywords: Myositis, Registries, Lungs

L. Peng1, P. Yin2, Y. Wang3, M. Li1, S. Zhou1, C. Wu1, J. L. Zhao1, D. Xu1, M. Li1, Q. Wang1, X. Zeng1. 1Peking Union Medical College Hospital, Peking Union Medical College &Chinese Academy of Medical Sciences, Department of Rheumatology, Beijing, China; 2Chinese Center for Disease Control and Prevention, National Center for Chronic and Communicable Disease Control and Prevention, Beijing, China; 3Chinese Academy of Medical Science and Peking Union Medical College, Department of Epidemiology and Biostatistics (YW), Institute of Basic Medical Science, Beijing, China

Background: Mortality of idiopathic inflammatory myositis (IMM) is high, and some studies explored the outcome in IMM patients with different clinical and serologic phenotypes[1]. However, few studies focused on the prognosis of the entire IMM patients, and compared their prognostic factors.

Objectives: To clarify the mortality and independent risk factors related to death of IMM patients in a large multi-center prospective registry cohort in China.

Methods: Patients registered before 31st December 2021 were included in our analysis. The baseline information at enrollment including demographics, comorbidities, clinical manifestations, immune indices, laboratory data was summarized. Death information was retrieved from our database and supplemented by National death surveillance system in China. Kaplan-Meier Curves as well as cumulative survival at 1, 3, 5 and 10 years was depicted, and Log-rank test was used to compare the mortality between different subgroups. Univariable Cox hazards regression analysis was used to identify potential risk factors for death, and factors with P value <0.05 were further analyzed using multivariable Cox regression model.

Results: 4695 IMM cases were finally enrolled in our analysis, including 3012 dermatomyositis (DM: 64.2%), 616 polymyositis (PM: 13.1%), 951 antisynthetase syndrome (ASS; 20.2%), and 116 immune-mediated necrotising myopathy (IMNM; 2.5%). 72.8% were female. The median (interquartile range) follow-up time since disease onset was 33 (15-48) months, and the median interval in months between disease onset and diagnosis.279 cases were complicated with malignancy (6.3%), 550 deaths in total were recorded. The cumulative survival for the entire IMM patients at 1, 3, 5 and 10 years were 92.3%, 88.2%, 85.6%, and 79.7% (Figure 1a). A significant difference (P<0.05) in survival between different subgroups confirmed by log-rank test was observed (Figure 1b). Mortality (126 cases, 22.9%) was the most frequent cause of deaths (Figure 1c), followed by cardiovascular diseases (98 cases, 17.8%), respiratory failure due to ILD (98 cases, 17.8%) and infections (98 cases, 17.8%), 51 myocardial infarctions/ ischemic heart diseases caused the most death cases in the cardiovascular diseases group. Notably, most of infective cases were lung infections (82 cases). 5 (0.9%) suicides were also worth the whistle. Multivariable Cox hazard ratio proportional hazards model confirmed malignancy (HR=4.95, 95% CI 4.05-6.07), male (HR=1.58, 95% CI 1.33-1.86), ILD (HR=1.38, 95% CI 1.12-1.71), skin ulceration (HR=1.60, 95% CI 1.22-2.10), anti-Jo-1 antibody (HR=0.54, 95% CI 0.39-0.75), anti-MDA-5 antibody (HR=1.93, 95% CI 1.46-2.56), and anti-Ro 52 antibody (HR=1.29, 95% CI 1.05-1.58) as independent risk factors for mortality after adjusting for age (Figure 1d).

Conclusion: The high mortality rates of IMM patients in China gave us an alert about their situation. As expected, malignancy was the biggest causes of death, again reminding us of importance for screening malignancy in IMM patients. The management of coronary artery diseases was also crucial considering nearly 1/10 deaths were caused by myocardial infarctions/ ischemic heart diseases. High suicide rates revealed bad psychological states of IMM. Male patients had a significantly higher risk compared to female patients. ILD was a strong independent risk factor and also a major cause of death in IMM, emphasizing the center place of ILD in IMM management. Intensive immunosuppressive treatment and monitoring might be applied in these patients. Anti-MDA-5 antibody and anti-Ro52 antibody predicted worse prognosis, while anti-Jo-1 antibody indicated a better one.

POS0129 DIFFERENTIALLY EXPRESSED GENES (DEGS) IN PATIENTS WITH DERMATOMYOSITIS AND JUVENILE DERMATOMYOSITIS

Keywords: Biomarkers, -omics, Myositis

R. Martinez1, C. Elizondo Solís2, A. Montoya Rosales3, M. Salinas Carmona1, N. Macias-Segura1, 1Servicio y Departamento de Immunología, Service and Department of Immunology, Monterrey, Mexico; 2UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico

Background: Dermatomyositis (DM) and Juvenile Dermatomyositis (JDM) are englobed in the spectrum of inflammatory myopathies. These are autoimmune
diseases that cause heliotropic rash in most patients, which then develop proximal muscles weakness and skin lesions [1]. Key findings in patients with these pathologies include anti-Mi2, anti-Jo1, and anti-P155/P140 antibodies in plasma, as well as B-cells and plasma cells infiltrates with an upregulated Type I Interferon (IFN) signature in muscle biopsies [2]. However, the pathophysiology underlying this condition has not been fully comprehended; even less, diagnostic biomarkers that could identify early stages of the disease.

Objectives: We aimed to identify overlapped genes across datasets of gene expression from patients with DM and JDM doing an integrative bioinformatics analysis.

Methods: A search strategy was designed in the Gene Expression Omnibus platform to identify datasets of gene expression profiling by array experiments in patients with DM and JDM. The inclusion criteria were: 1) Assays performed in humans, 2) Inclusion of healthy controls in the datasets, and 3) Data analysis with GEO2R. The exclusion criteria were 1) Incomplete information of the genes, and 2) Gene expression by RNaseq. DEGs were selected when p < 0.05 and fold change > 2 or < -2. Functional enrichment analysis was realized with free access platforms GeneMania and DAVID with the significant overlapped genes. A protein-protein interaction (PPI) analysis was constructed with STRING analysis.

Results: 102 overlapped DEGs from DM and 13 overlapped DEGs from JDM were found within their datasets. Out of those DEGs, 5 were shared between DM and JDM. Prediction analysis yielded 20 co-expressed genes. DAVID analysis showed the top 3 biological processes in which the 25 genes are involved, most of them belonging to the Type I IFN signature (Table 1). Topological analysis yielded 10 genes with the strongest interactions between them, and the transcription factor listed as possible therapeutic target was STAT1.

Table 1. DAVID analysis shows the processes involving those genes, most of them belonging to the Interferon Signature.

</tbody>
</table>

Conclusion: We aimed to identify DEGs that participate in the pathophysiology of DM and JDM. Those genes mostly participate in responses to viral infections, in which the type I IFN signature is present. These genes may serve in the future as possible biomarkers for early diagnosis. An in vivo analysis in patients with these diseases is needed to validate these findings. Janus Kinase Inhibitors (Jakinibs) have been used to treat JDM patients, showing positive results [3]. We suggest more clinical trials to test the effectiveness and tolerability of Jakinibs to treat these conditions.

POS0130 INFLAMMATORY ACTIVITY IS ASSOCIATED WITH COGNITIVE IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Cognitive Function, Rheumatoid arthritis, Comorbidities

F. Ortiz-Márquez1, A. García Studer1, I. Montañez-Marín2, T. Ramirez-García2, P. Cabezudo-García2, N. Mena-Vázquez2, 1. Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Bionand, Hospital Regional Universitario de Málaga (HRUM), Unidad de Gestión Clínica de Reumatología, Málaga, Spain; 2. Universidad de Málaga, Departamento de Medicina, Málaga, Spain; 3. Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Bionand, Hospital Regional Universitario de Málaga (HRUM), Servicio de Neurología, Unidad de Gestión Clínica de Neurociencias, Málaga, Spain

Background: Patients with rheumatoid arthritis (RA) present cognitive impairment at a frequency of 38% to 71%.

Objectives: To study whether there is an association between high sustained inflammatory activity and cognitive impairment in RA patients.

Methods: Design and protocol: controlled cross-sectional observational study of a prospective cohort of patients with RA. Cases: patients with RA from a prospective cohort with onset >16 years and who were selected to start biologic treatment for moderate-high inflammatory activity. Controls: subjects without inflammatory disease, matched for sex and age with cases. All participants performed the same neuropsychological battery. Variables: the main variable was cognitive impairment defined by a score of < 26 points in the Montreal Cognitive Assessment questionnaire (MoCA test). As secondary variables we included the score in each of the items of the MoCA test separately; the direct and inverse digits span; the STROOP test for the assessment of processing speed (STROOP-P), selective attention (STROOP-C) and inhibition (STROOP-PC); and the Hospital Anxiety and Depression Scale (HADS). Other variables included average inflammatory activity by DAS28-ESR since diagnosis, epidemiological characteristics, comorbidities, and treatments.

Results: Sixty-two subjects were included. The baseline characteristics are shown in Table 1. RA patients presented a higher frequency of cognitive impairment than controls (64.5% vs. 38.7%; p=0.042), as well as lower mean (SD) values on the MoCA test (23.1 [3.8] vs. 25.1 [3.8]; p=0.046). Fewer RA patients compared to controls achieved the memory item (22 [81.5] vs 30 [100.0]; p = 0.014), naming (24 [88.0] vs 30 [100.0]; p = 0.031), and presented lower mean (SD) values in attention (3.5 [1.5] vs 4.4 [1.4]; p = 0.039). Scores for all subtests are shown in Figure 1. Factors that were associated in multivariate analysis with cognitive impairment in the total sample were age (OR, 95% CI, 1.171 [1.068-1.284]; p=0.001), RA diagnosis (OR, 95% CI, 4.712 [1.069-12.772]; p=0.041) and university studies (OR, 95% CI, 0.089 [0.010-0.829]; p=0.034) (R2 = 0.405). The model in RA patients found association of cognitive impairment with age (OR, 95% CI, 1.284 [1.029-1.583]; p=0.030), and mean DAS28-ESR (OR, 95% CI, 1.704 [1.072-4.003]; p=0.048) (R2 = 0.380). Statistical analysis: descriptive analysis, bivariate analysis between patients and controls, as well as between patients with and without cognitive impairment; and two multivariate logistic regression analyses were performed to analyze the factors associated.

Conclusion: Patients with RA and high inflammatory activity more frequently presented cognitive impairment compared to the controls. The most affected domains were memory, naming and attention. Factors associated with cognitive impairment were age, educational level and mean DAS28-ESR.

POS0313

RELATION BETWEEN COVID-19 AND ANCA VASCULITIS. STUDY IN A SINGLE UNIVERSITY HOSPITAL

Keywords: Vasculitis, Autoantibodies, COVID

F. Benavides-Villanueva1, V. Calvo-Rio1, J. Loricer1, J. Irure-Ventura2, M. Lopez-Hoyos2, R. Blanco1, 1Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 2Marqués de Valdecilla University Hospital, Immunology, Santander, Spain

Background: Anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) is a small vessel vasculitis. Hallmarked by the presence of antibodies against antigens in cytoplasmic granules of neutrophils. Different microbiological agents and vaccines can trigger an AAV, including severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) infection and Coronavirus disease 2019 (COVID-19) vaccine.

Objective: To compare: a) proportion of positive ANCA (+ANCA) test in 2019 (COVID-19 pre-pandemic) vs 2021 (COVID-19 pandemic), b) clinical features and c) vasculitis activity between vasculitis related to COVID 19 vaccination vs non-related.

Methods: All ANCA tests performed in 2019 and 2021 in a referral hospital were reviewed. Additionally, we studied 18 +ANCA patients diagnosed in 2021 and accepted to participate in present study. The patients were divided in two groups: a) +ANCA after SARS-CoV-2 mRNA vaccine (COVID-related) and +ANCA before COVID-19 vaccine (COVID-nonrelated). Diagnosis of underlying AAV was based against antigens in cytoplasmic granules of neutrophils. Different microbiological agents and vaccines can trigger an AAV, including severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) infection and Coronavirus disease 2019 (COVID-19) vaccine. ANCA-test was done by chemiluminescence assay using IO-FLASH (Inova, San Diego, CA) according to the instructions of the manufacturer.

Results: ANCA tests were positive in 14 of 1287 cases (1.1%) and in 32 of 1434 (2.2%) cases in 2019 and 2021, respectively (figure 1, the differences were statistically significant (p=0.020). The main features of 18+ANCA patients diagnosed in 2021 are summarized in table 1. COVID-19 related patients showed a median of 7 points on BVAS score compared of the median of 5 points on BVAS score on not related patients.

Conclusion: There seems to be an increase of +ANCA at the expense of anti-PR3 antibodies following the COVID-19 vaccine. In patients with +ANCA following vaccination there seems to be an increased disease activity according to BVAS score without reaching statistical significance.

**Background:** There are many biosimilar products available to use in children and young people with JIA. Due to competitive pricing, patients are being switched from biologic originator to biosimilar (non-medical switch).

**Objectives:** This analysis aims to describe characteristics of, and outcomes, following TNF-inhibitor originator to biosimilar switch in JIA.

**Methods:** All patients in the UK JIA Biologics Register switching from an originator to a biosimilar of the same product were identified. Patient characteristics are presented, including time on originator prior to switch. Patients were followed until their final follow-up form was returned. For those with >1 year of follow-up post-switch, treatment persistence and reasons for stopping are described.

**Results:** As of 24-Nov-2022, 211 children and young people had switched from originator to biosimilar: 132 adalimumab, 55 etanercept, and 24 infliximab (table 1). Switching was seen in all ILAR categories. Patients were predominantly female (64%), median age at JIA diagnosis six years, 11 years at originator start, 14 years at biosimilar start, median time on originator 2.2 years. Most patients had started originator as their first biologic (73%) and most started biosimilar with no significant treatment gaps. Six patients reported >1 year gap between originator to biosimilar (non-medical switch).

**Stop Reason:**
- Remission 11/61 (18%)
- Other/Missing 17/61 (28%)
- Adverse Event 20/61 (33%)
- Ineffectiveness 13/61 (21%)

**Conclusion:** Many children with JIA have now been switched from TNF-inhibitor originator to biosimilar product, with the majority still receiving their biosimilar after one year. Switching back to originator was uncommon, 12% overall after one year, suggesting good tolerance of non-medical switching in this patient population.

POS0133 TRADITIONAL LABORATORY PARAMETERS AND NEW BIOMARKERS IN MACROPHAGE ACTIVATION SYNDROME (MAS) AND SECONDARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (sHLH)

**Keywords:** Biomarkers, Cytokines and chemokines, Inmate immunity

A. De Matteis1, D. Pires Marafon1, I. Caiello1, M. Pardeo1, G. Marucci1, E. Sacco1, F. Minoia2, F. Licciardi3, A. Minaici4, I. Maccora5, M.C. Maggio6, G. Prencipe6, F. De Benedetti2, G. Broccoli1, 1IRCCS Ospedale Pediatrico Bambino Gesù; Division of Rheumatology, ERN-RITA center, Roma, Italy; 2Fondazione IRCCS Ca’ Grande Ospedale Maggiore Policlinico, Pediatric Rheumatology, Milano, Italy; 3Regina Margherita Children’s Hospital, Department of Pediatrics and Infectious Diseases, School of Medicine, University of Turin, Torino, Italy; 4S. Orsola-Malpighi Hospital, Department of Pediatrics, University of Bologna, Bologna, Italy; 5Meyer Children’s University Hospital, Pediatric Rheumatology Unit, Firenze, Italy; 6University of Palermo, University Department Pro.Sa.M.I.”G. D’Alessandro”; Palermo, Italy

**Background:** Macrophage Activation Syndrome (MAS) and Secondary Hemophagocytic Lymphohistiocytosis (sHLH) are hyperinflammatory conditions, in which IFNγ plays a pivotal role. Prompt recognition and early treatment are essential to improve the outcome and the mortality rate.

**Objectives:** This is a retrospective multicenter study. We correlated traditional laboratory parameters of hyperinflammation with IL-18 and IFN-γ related biomarkers. We have also evaluated the diagnostic and prognostic role of IL-18, CXCL9, CXCL10 and neopterin in patients with MAS and sHLH.

**Methods:** One hundred-six patients from 6 Italian centers were enrolled: 41 with sHLH, 41 with MAS in the context of sJIA, and 24 with sJIA without MAS. The samples were collected at three different time points: active disease (T0), 7-10 days from starting therapy (T1) and in clinical inactive disease on medication (from 3 to 9 months from onset) (T2). Serum levels of IL-18 and of the IFN-γ related biomarkers (CXCL9, CXCL10, Neopterin) were measured by ELISA.

**Results:** A total of 378 samples were collected. Laboratory features at T0 are detailed in table 1. Using the 2016 classification criteria for MAS, we can confirm that platelet count is a specific parameter, only 2 patients with sJIA had a value <181x10^9/liter. Instead ferritin is a sensitive parameter, 94.4% of patients with sJIA had a value >200 ng/ml.
MAS had ferritin >684 mg/mL. Lactate dehydrogenase (LDH) values were statistically higher in MAS and shHLH compared to sJIA. ROC curve of LDH values in MAS showed a statistically significant area under the curve (AUC = 78.2%, p-value < 0.0001). A cut-off of 683 U/L had a sensitivity of 73.6% and a specificity of 70.3%. IL-18, CXCL9, CXCL10 and neopterin levels in T0 were significantly higher in MAS and shHLH compared to sJIA. In MAS, IL-18 levels were significantly higher compared to shHLH (p < 0.0001). The ROC curves performed for each biomarker showed a statistically significant AUCs (p < 0.01), except for IL-18 in shHLH. We have identified a cut-off value for each biomarker in MAS (CXCL9 900 pg/ml, CXCL10 260 pg/ml, neopterin 5.0 ng/ml, IL-18 82996 pg/ml) and shHLH (CXCL9 2145 pg/ml, CXCL10 270 pg/ml, neopterin 7.1 ng/ml). In T0 neopterin correlates significantly with IL-18, CXCL9 and CXCL10 in MAS group but not in shHLH. We found also strong correlation between CXCL9 and CXCL10 only in MAS group.

**Table 1. Laboratory parameters in T0. Values are shown as median (IQR); p-value: Mann-Whitney U test.**

**Conclusion:** The cut-off level for ferritin and high specificity and sensitivity, respectively, to diagnose MAS in the context of sJIA. Even if LDH is not included in 2016 classification criteria for MAS in sJIA, we have found that this parameter could help to discriminate MAS in sJIA, in addition to the others. Our results confirm that IL-18 and the IFN-β-related biomarkers are significantly higher in patients with MAS and shHLH and might be useful to diagnose MAS in shHLH. IL-18 could help to distinguish shHLH from MAS and shHLH from active sJIA.

**Background:** In childhood-onset systemic lupus erythematosus (cSLE), patients have an increased risk of developing premature atherosclerosis [1]. The pathophysiological mechanisms for this atherosclerosis are not completely understood. Besides traditional risk factors, the endothelium plays a major role [2]. Dysregulated endothelial cell markers and proteins involved in endothelial function in SLE are not always correlated to disease activity, which could mean that the endothelium stays in a dysregulated state in SLE, even with low disease activity (Bergkamp et al., submitted). However, previous studies were mostly cross-sectional and only performed in adult SLE, while childhood-onset SLE (cSLE) has a longer and more severe course [3,4].

**Objectives:** To measure the serum levels of a panel of SLE-associated markers involved in endothelial cell (EC) function, in longitudinal samples of cSLE patients (active vs. low SLE disease activity index (SLEDAI)) and to compare them with healthy controls and assess their correlation with disease activity.

**Methods:** Blood samples and patient characteristics were collected from a multicentre longitudinal cSLE study and compared with age- and sex-matched healthy controls (HC). Disease activity was evaluated by SLEDAI-2K, with cut-offs for active (>4) versus low (<4) activity. Serum levels of CXCL12 (SDF-1), TWEAK, VEGF, CXCL10 (IP-10), ADAMTS13, Angiopoietin-2, Pentraxin-3, E-Selectin, Fibrinogen, CCL2, MCP-1, VCAM-1, ICAM-1, VWF-A2, and Gas6 were measured in two cSLE samples (t=1 and t=2) and in HC (1 sample). Patient groups and healthy controls were compared by t-tests and ANOVA, with significance for p < 0.05. Correlations between marker serum levels and SLEDAI were calculated with Pearson correlation.

**Results:** This study included 47 cSLE patients (30 treatment-naïve) and 42 healthy controls. Mean age at diagnosis in cSLE was 14 ± 2.33 years. Median SLEDAI at t=1 was 12 (IQR 6-18). Median SLEDAI t=2 was 2.5 (IQR 2-6). Time between two blood samples was 14.5 months (IQR 9-24 months). Median disease duration at t=1 was 0 months (IQR 0-18 months) and at t=2 16.5 months (IQR 10-53 months). Ethnic background in patients was 42.6% Caucasian, 36.2% African/Afro-Caribbean, 8.5% North-African/Middle East, 4.3% Asian and 8.5% mixed/other ethnic background. At t=1, serum levels of CXCL10 (p<0.01), TWEAK, IL-18, VEGF, CXCL10 (IP-10), ADAMTS13, Angiopoietin-2, Pentraxin-3, E-Selectin, Fibrinogen, CCL2, MCP-1, VCAM-1, ICAM-1, VWF-A2 and Gas6 were correlated in t=1 and t=2 (IQR 1 sample). Patient groups and healthy controls were compared by t-tests and ANOVA, with significance for p < 0.05. Correlations between marker serum levels and SLEDAI were calculated with Pearson correlation.

**Conclusions:** At different time points, serum levels of Angiopoietin-2 (t=1), VWF-A2 and Gas6 correlated with SLEDAI score. Angiopoietin-2 and VWF-A2 were upregulated in cSLE patients versus healthy controls (both p<0.001) but not related to disease activity (figure 1A). Levels of CXCL10, Angiopoietin-2, Pentraxin-3, E-Selectin, CCL2, VCAM-1 and VWF-A2 decreased over time, while serum levels of TWEAK increased over time (all p<0.05) (figure 1B).

**Conclusion:** At different time points, serum levels of Angiopoietin-2 (t=1), VWF-A2 (t=1) and TWEAK (t=2) were increased in cSLE patients, irrespective of disease activity. These markers represent activation of ECs with vascular inflammation, EC activation and a pro-angiogenic state. The endothelium in cSLE seems to stay in an active state, even in low disease activity (SLEDAI≤4). Our findings suggest that some EC markers might be useful as biomarkers for predicting the ongoing risk for endothelial dysfunction in cSLE.

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease which leads to inflammation and organ damage caused by immune complex deposition. Classically, childhood SLE has been considered as a polygenic autoimmune disease; however, a pediatric monogenic lupus-like phenotype (LL) is emerging due to the recent recognition of several related novel high-penetrance gene variants. This fact associated to the high degree of concordance among monogenic twins, supports the importance of genetic background in cSLE pathogenesis. Objectives: To identify the presence of variants in gene related to monogenic lupus and their relationship with clinical manifestations in cSLE or LL. Methods: A descriptive, observational, cross-sectional study was carried out in children with cSLE or LL. The genetic analysis (Sanger/Exome Sequencing) was performed from isolated DNA obtained from blood sample. Results: Forty-five children were included in the study. The genetic analysis detected at least one variant in 14 (31.1%) children, 5 (35.7%) with cSLE and 9 (64.3%) with LL. Of those who carry a genetic variant, the median age at disease onset was 11 years (range: 2-16) and 85.7% were female; most of them Caucasians (85.7%). Seven (50%) and 3 (21.4%) out of 14 patients had a positive family history and/or a personal history for autoimmune diseases, respectively. Regarding clinical manifestations at onset, musculoskeletal were the most frequent (10 patients, 71.4%), followed by hematological (9 patients, 64.3%), cutaneous (9 patients, 64.3%), constitutional with fever (8 patients, 57.1%), neurological (7 patients, 50%), renal (5 patients, 35.7%), cardiac (3 patients, 21.4%) and pulmonary (2 patients, 14.3%) manifestations. Related to immunological parameters, 13 (92.8%) were ANA positive, 7 (50%) anti-dsDNA, 4 (28.6%) ENA and 3 (21.4%) aPL positive. Both C3 and C4 were low in 8 (57.1%) children and isolated C3 levels were low in 4 (28.6%) patients. Among the variants, we found that only two patients who carry a TREX variant showed normal C3 and C4 levels; one of them presented with lupus pernio as reported in literature. Also, we identified the same RNASEH2B (c.868G>A) variant in two siblings with similar phenotypes and TLR7 (c.1520T>C) variant in two siblings of other family. The patient who carried the SHOC2 variant presented polyarthritis and serositis, while the patient with the TNFRSF13B variant onset with a glomerulonephritis. Those manifestations have already been described related to these genes. Variants and phenotypes are detailed in Table 1.

Keywords: Validation, Systemic lupus erythematosus

Objectives: To identify the presence of variants in gene related to monogenic-lupus and some of them with similar phenotypes to those already described. This fact may suggest the genetics potential contribution to the cSLE pathogenesis. Further studies are necessary to confirm these data.

REFERENCE:

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.2607

Methods: Cases were physician-diagnosed cSLE, while controls were children with mixed and undifferentiated connective tissue disease that posed an initial diagnostic challenge. Retrospective data were reviewed to establish the three criteria fulfilled at diagnosis and over time.

Results: The study population included 120 cSLE cases and 36 controls, Table 1. Among cSLE patients, low C3/C4 (94.2%), immunologic (93.3%), hematologic manifestations (90.0%), and arthritis (60.8%) were the most common over time. At diagnosis, 102 (85%) patients fulfilled all criteria, Figure 1. SLICC-2012 had the highest sensitivity (97.5%) and negative predictive value (NPV, 89.3%), while ACR-1997 had the highest specificity (91.7%) and positive predictive value (PPV, 97.2%). All criteria had diagnostic accuracies ≥ 85%. Over time, 113 (94.2%) fulfilled all criteria, SLICC-2012 remained the criteria with highest sensitivity (99.2%) and NPV (94.7%), while ACR-1997 remained the criteria with highest specificity (75.0%) and PPV (92.7%). Only SLICC-2012 and ACR-1997 had ≥ 85% diagnostic accuracy over time.

Conclusion: This is the first study evaluating the SLE classification criteria performance in Southeast Asian cSLE cohort. SLICC-2012 criterion has the highest sensitivity and diagnostic accuracy, with acceptable specificity in our cohort, especially early in the disease course. The EULAR/ACR-2019 criteria does not confer additional benefits compared to the earlier two criteria.

Conclusion: Serious infections are a major cause of mortality and damage accrual in SLE. Constitutional symptoms, gastrointestinal involvement, current and cumulative steroid dose and cyclophosphamide use predict serious infections. TB prophylaxis in patients with SLE should be considered in endemic areas, especially when using high-dose steroid therapy.

POS0138 EFFICACY AND SAFETY OF BELIMUMAB IN ADULTS WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: PRELIMINARY RESULTS FROM A PROSPECTIVE OBSERVATIONAL STUDY

Keywords: Outcome measures, bDMARD, Systemic lupus erythematosus

D. Dimopoulou1, M. Trachana1, P. Pratissou-Gerts2, A. Theodoridou1, T. Dimitrou2, N. Koukis1, A. Garyfallos1, 1Aristotle University, 4th Academic Department of Internal Medicine Clinic, Ippokrateio General Hospital of Thessaloniki, Thessaloniki, Greece; 2Aristotle University, 1st Academic Department of Pediatrics, Aristotele University, Thessaloniki, Greece

Background: Childhood-onset Systemic Lupus Erythematosus (cSLE) is a rare autoimmune disease with multi-system manifestations, more severe disease course and higher frequency of morbidity than adult-onset SLE. Belimumab is the first treatment for cSLE approved for children ≥5 years of age.

Objectives: To investigate the efficacy and safety of Belimumab in adult patients with cSLE

Methods: A prospective observational (non-interventional) study, involving adult patients with cSLE was conducted. During the 9-year study period (01/2015 to 12/2022), adults with a cSLE diagnosis and Belimumab receivers (by intravenous or subcutaneous administration) for >12 consecutive months were enrolled. All patients met the revised 1997 American College of Rheumatology (ACR) or 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria and were followed at regular intervals (up to 6 months) in the Transition Rheumatology Outpatient Clinic. SLE activity was defined according to SLEDAI-2K and the SELENA-SLEDAI Physician Global Assessment (PGA), scale 0–3 [1]. At the last follow-up visit, response to therapy was assessed by Lupus Low Disease Activity State (LLDAS), remission state and SLE Responder Index (SRI4). LLDAS was defined as: i) SLEDAI-2K ≤4, with no activity in major systems ii) no new lupus disease activity compared to previous evaluation iii) a SELENA-SLEDAI PGA ≤1 iv) current prednisolone (or equivalent) dose ≤7.5mg daily and v) standard maintenance doses of immunosuppressive drugs. [2] Remission was defined as i) clinical SLEDAI-2K=0 ii) dose of prednisone ≤5mg/day according to the DORIS definition

[3]. SRI4 was defined as i) ≥4-point reduction from baseline in SELENA-SLEDAI score, ii) no worsening in PGA and iii) no new BILAG A organ domain score or 2 new BILAG B organ domain scores compared with baseline [4].

Results: A total of 15 patients (14 females) were enrolled in the study. At baseline, the patients' current mean (SD) age was 25.4 (7) years and the interval from disease onset to first Belimumab administration 12.4 (7.3) years. Half of the patients had a history of lupus nephritis and 42.8% were aPL positive. All patients were under hydroxychloroquine treatment and 80% of them were additionally receiving a second immunosuppressive agent (Methotrexate, MMF, Azathioprine), Glucocorticoids (GCs) were concomitantly administered in 13 (86.6%) patients in a dose of ≥7.5mg/day in 57.1% of them. The patients’ SLEDAI-2K mean (SD) score before Belimumab initiation was 12.1 (2.3), indicating high disease activity. The mean (SD) duration of Belimumab administration was 36.2 (19.9) months. At the last follow up visit, ongoing therapy with Belimumab was recorded in 66.7% of the cohort. SLEDAI-2K mean (SD) score was reduced to 3.5 (2.3), 1 patient (8.6 %) was in remission, 9 (60%) patients had mild and none high disease activity. The majority (78.5%) met the LLDAS definition and 78.5% were SRI4 Responders. Half of the patients (53.8%) achieved lower doses or discontinuation of GCs and 26.7% accomplished a reduction of the immunosuppressant's dose. Reasons for Belimumab discontinuation included pregnancy issues, infection and low adherence (3, 1, 1 patient respectively). None of the patients experienced a serious adverse event.

Conclusion: In this cohort of adult patients with cSLE, Belimumab was well-tolerated and effectively reduced disease activity allowing the downstream of GCs' dose.

POS0139 DIFFUSE JUVENILE SYSTEMIC SCLEROSIS PATIENTS SHOW DISTINCT ORGAN INVOLVEMENT, ANTIBODY PATTERN AND HAVE SIGNIFICANTLY MORE SEVERE DISEASE IN THE LARGEST JSSC COHORT OF THE WORLD. RESULTS FROM THE JUVENILE SCLERODERMA INCLUSION COHORT

Keywords: Systemic sclerosis

Background: Juvenile systemic sclerosis (JSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children. In adult patients there are significant differences between the clinical presentation of diffuse and limited subsets. We reviewed clinical differences in presentation of subtypes in patients in the juvenile systemic scleroderma inclusion cohort (JSSc).

Objectives: To study the clinical presentation of JSSc patients with diffuse (dJSSc) and limited (iJSSc) subtype.

Methods: We reviewed the baseline clinical characteristics of the patients, who were recruited to the JSSc cohort between 2012 and 2022. dJSSc is a prospective cohort of JSSc patients, who developed the first non-Raynaud’s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion.

Results: The JSSC included 426 patients, 68% (n=159) had diffuse subtype. The median age at onset of Raynaud phenomenon was 10.4 years (73-12.9), at the first non-Raynaud symptom 10.9 years (73-13.0) and median disease duration 2.5 years (10-4.6). The female/male ratio was significantly lower in the dJSSc subtype.
Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1,000,000 children. The Joint Scleroderma Inception Cohort (JSiCC) is the largest cohort of jSSc patients in the world. The JSiCC collects data prospectively in jSSc, allowing the evaluation of the development of organ involvement and patient and physician reported outcomes in jSSc over time.

**Objectives:** To review the changes in the clinical characteristics, and patient and physician reported outcomes, over a 24 month observation period from the time of inclusion into the cohort.

**Methods:** The JSiCC cohort enrolls jSSc patients who developed the first non-Raynaud’s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion. We reviewed JSiCC patient clinical data and patient and physician reported outcomes, who had 24 months follow up from the time of inclusion until 1st of December 2022.

**Results:** We extracted data from 90 patients, 77% of them had the diffuse subtype. The female/male ratio was 3.5:1. Median age of onset of Raynaud’s was 9.4 years and the median age of onset of non-Raynaud’s was 10.0 years. Eighty-nine percent of the patients were treated with disease modifying anti-rheumatic drugs (DMARDs) at time of inclusion in the cohort (70%) and 96% after 24 months (T24).

Median disease duration was 2.4 years at T0. No patient died during the follow up. Antibody profile stayed unchanged. Only 3 clinical parameters changed and all improved significantly, the median modified Rodnan skin score improved from 11 to 8 (p=0.021), number of patients with joints with pain on motion decreased from 21% to 10% (p=0.04) and the number of patients with muscle weakness decreased from 13% to 4% (p=0.03). All other organ involvement did not show any statistically significant change from T0 to T24. All collected patient reported outcomes improved significantly from T0 to T24: the patient reported disease activity by VAS 0-100 from 40 to 20 (p=0.001), the patient reported disease damage by VAS 0-100 from 35 to 20 (p=0.027), patient reported ulceration activity by VAS 0-100 from 8 to 0 (p=0.001) and the patient reported Raynaud activity by VAS 0-100 from 20 to 10 (p=0.002). Two of the three physician reported outcomes improved significantly, the physician global disease activity by VAS 0-100 from 30 to 20 (p=0.001) and physician reported ulceration activity by VAS 0-100 from 5 to 0 (p=0.017).

**Conclusions:** Skin and musculoskeletal clinical features improved over 24 months, with almost all patients on DMARDs, supporting the response of these features to therapy. It was promising that internal organ involvement, like cardiac, lung and gastrointestinal, did not significantly worsen or increase. The most striking observation is the positive direction and improvement all patients and two of the three physician reported outcome measures over 24 months in this large international cohort.

G. Hornett, T. Kallinich, T. Lehman, K. Minden, M. Mollf, S. Nielsen, A. Patwardhan, V. Smith, N. Helmus. German Rheumatism Research Center, German Rheumatism Research Center, Berlin, Germany; *Hamburg Centre for Pediatric and Adolescent Rheumatology, An der Schén Klinik Hamburg Eilbek, Hamburg, Germany; University of Pittsburgh, Children’s Hospital of Pittsburgh, Pittsburgh, United States of America; University of Leeds, Teaching Hospital Trust, Leeds, United Kingdom; University of California, University of Florence, Florence, Italy; JSSc collaborative group, Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany

Background: Juvenile systemic sclerosis (jSSc) is a rare disease in childhood. To date, no composite response index exists to assess treatment effect in jSSc patients. ACR CRiSS score (probability of improvement according to ranging from ≥ 0 to 1 based on mRSS, FVC%, PtGA, MDGA and HAQ-DI) and revised ACR CRiSS (rCRiSS, proportion of patients who improve in ≥ 3 ACR CRiSS core items by a certain percentage, e.g. 30%, except 5% for FVC) were developed by experts in the field as outcome measures in adult patients with SSC. In addition, the Ranked Composite Important Difference (RCID) score was recently introduced as anchor to the ACR CRiSS.

Objectives: We aimed to study the applicability and performance of the ACR CRiSS, rCRiSS and RCID in a prospectively followed cohort of patients with diffuse cutaneous jSSc.

Methods: Data from the international jSSc inception cohort were used for this analysis. The ACR CRiSS, rCRiSS and RCID were calculated between baseline and 12-months follow-up according to the scoring algorithms. Missing values in the core items were estimated by multiple imputation by chained equations. Here we aimed to determine the value of the response measures to detect clinically change defined by the anchor questions about change (much better or little better versus almost the same, little worse or much worse) in patients overall health due to scleroderma since the last visit provided by the treating physicians and patients or parents (aged ≥ 12 years).

Results: We included 95 jSSc patients with diffuse cutaneous subtype with available baseline and 12-months visit. Seventy-nine percent were female, the mean age at enrollment was 13.0 (3.8) and the mean disease duration was 3.1 (2.8) years. Among 95 patients, 57% were treated with steroids, 47% with methotrexate, 27% with MMF and 3% with a biological at baseline. ACR CRiSS showed a ceiling effect (>99%) in 51% and a floor effect (<0.05) in 26% of patients. Patients who reported at least moderate improvement in a median ACR CRiSS of 0.99 and in mean 2.6 (1.3) core items that improved by ≥20% from baseline to 12-months follow-up. The rCRiSS 20/30/50 responses were 59%/49%/33% in patients that reported worsening. The RCID was approximately normal distributed (mean 20.7, SD 43.4). Mean (SD) RCID for patients who reported worsening was -10.5 (38.6) vs RCID of 20.7 (45.2) for patients who reported improvement. RCID scores for patients reported anchors of worsening or improvement were 6.5 (44.2) and 18 (45.4), respectively. The concordance between a positive RCID score and rCRiSS 20/30 was moderate (rCRiSS 20 38%, kappa=0.36).

CRiSS = Composite Response Index in Systemic Sclerosis; RCID=Ranked Composite Important Difference; reCRiSS = revised Composite Response Index in Systemic Sclerosis; SD = standard deviation

Conclusion: Our data confirmed the presence of a ceiling and floor effect of ACR CRiSS as shown in studies of adult SSC patients. The CRiSS and rCRiSS and RCID response distinguished between patients who rated their disease course since last visit as worsened or improved. Future studies should focus on the determination of specific pediatric weights for the CRiSS and RCID components rather than extrapolation from adult SSC. In general, the RCID offers a meaningful tool in order to determine response to therapy in future clinical trials in jSSc patients.

THE ASSOCIATION OF AUTOANTIBODIES WITH CLINICAL MANIFESTATIONS AND LONG-TERM REMISSIONS IN COMPARISON WITH JUVENILE- AND ADULT-ONSET IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Autoantibodies, Remission, Myositis

H. Tsui1, R. Nakashima1, T. Sasa1, M. Shirakashi1, H. Onizawa2, R. Hiwa3, K. Kitagori4, S. Akizuki4, A. Onishi5, H. Yoshitani4, M. Tanaka6, T. Yasumi6, Y. Ichimura6, N. Okiyama7, A. Morinobu7, 7Kyoto University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; 8Kyoto University Graduate School of Medicine, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan; 9Kyoto University Graduate School of Medicine, Department of Pediatrics, Kyoto, Japan; 4Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Department of Dermatology, Tokyo, Japan

Background: The associations of myositis-specific autoantibodies (MSAs) and myositis-associated autoantibodies (MAAs) with clinical features and remission in idiopathic inflammatory myopathy (IIM) are different between those of juvenile-onset (JIMM) and adult-onset.

Objectives: Since the associations in JIMM had not been fully elucidated, we analyzed them comparing that in adults using clinical information and autoantibodies.

Methods: A total of 320 cases of IIMs (juvenile-onset, 2004-2021, n=34; adult-onset, 2018-2021, n=286) with a history of attendance at our hospital were retrospectively analyzed using medical records. Remission without glucocorticoids and immunosuppressive drugs for 30 years was also examined. MSAs were identified by assays of RNA immunoprecipitation (IP), protein IP, protein IP-blot, and ELISA. Logistic regression analysis, Mann-Whitney U test, Fisher’s exact test, and log-rank test were performed.

Results: In JIMM, anti-MDA5 (15%) and anti-TIF1-γ (15%) were the most frequent MSAs, followed by anti-SRP (9%) and anti-NXP2 (6%) (Table 1). In particular, the frequency of anti-ARS was significantly lower in juveniles whereas it was the highest in adults (9% vs. 32%, respectively, p<0.01). Anti-SRP and anti-MI-2 were not identified in juveniles, although they were identified with low frequencies in adults. In MAAs (juvenile-onset vs. adult-onset), anti-Ku (9% vs. 2%, p<0.03) and anti-U-RNP (18% vs. 4%, p<0.02) were more common in juveniles while anti-SS-A (15% vs. 16%, p=1) was not significantly different between juveniles and adults. Dermatomyositis tended to be more dominant than polymyositis in juveniles than in adults (76% vs. 59%, p=0.06) (Table 1). Fever was more frequently observed in juveniles (74% vs. 12%, p<0.0001) and interstitial lung disease (ILD) was less frequently observed in juveniles than adults (29% vs. 66%, p=0.0001). Malignancy was observed in 2 juvenile-onset patients (6%) during 14.7±12.3 years while in 32 adult-onset patients (12%) during 6.8±7.5 years (p=0.56). Anti-NXP2 (n=1) and anti-PL12 (n=1) were observed in juveniles. In contrast, anti-TIF1-γ (n=11/32, 34%) was mainly observed in adults. Anti-MDA5 (OR [95%CI]: 14.0 [1.31, 150]) in juveniles and anti-ARS (23.2 [2.07, 76.1]) and anti-MDA5 (13.3 [4.03, 43.8]) in adults were associated with ILD. Anti-MDA5 was poorly associated with muscle symptoms in both juveniles (0.06 [0.004, 0.88]) and adults (0.43 [0.22, 0.85]). The rate of drug-free remission for 30 years in juveniles is higher than that in adults (32% vs 7%, respectively, p<0.0001, Figure 1). The drug-free remission in juveniles was observed in the order of anti-TIF-1γ, anti-NXP2, anti-MDA5, and anti-ARS, reaching a plateau at 5.7 years. In contrast, the remission in adults was observed in the order of anti-MDA5, anti-TIF1-γ, anti-SRP, and anti-ARS. The use of glucocorticoid (88% vs. 91%, p=0.76) was similar in juveniles and adults, while methotrexate (32% vs 8%, p=0.0002) was used more frequently in juveniles.

Conclusion: There were differences in the clinical characteristics of IIM and autoantibodies between juvenile-onset and adult-onset. Further analysis is needed in a larger sample size.

Karolinska Institutet, Division of Rheumatology, Department of Medicine, Solna, Stockholm, Sweden; K. Karolinska Institutet, Division of Cell and Molecular Biology, Stockholm, Sweden; K. Karolinska University Hospital, Department of Oncology-Pathology, Stockholm, Sweden

Background: Idiopathic inflammatory myopathies (IIM) are rare autoimmune systemic diseases characterized by muscle weakness and presence of muscle-infiltrating T cells. IIM represent a clinical challenge due to heterogeneity of clinical manifestations and subsets of IIM, and healthy donors (HD).

Methods: We performed single-cell RNA sequencing on muscle-infiltrating and peripheral blood (PB) memory T cells from patients with recently diagnosed IIM (n=27) from the Rheumatology Clinic, Karolinska University Hospital. Briefly, after enzymatic digestion of fresh muscle tissue, we single-cell sorted T cells from seven patients who also presented muscle infiltrates by histopathological analysis: immune-mediated necrotizing myopathy (MMN) n=2; inclusion body myositis (IBM) n=2; dermatomyositis (DM) n=1; and antisynthetase syndrome (ASSyS) n=1 and a non-inflammatory myopathy. Muscle T cells were sorted based on the co-expression of CD45RA and CD69, whereas PB memory T cells were sorted based on the exclusion of naïve CD45RA+CCR7+ CD3+ T cells. We also aligned the TCR sequences. We had access to additional muscle and PB samples from two patients after immunosuppressive treatment. Description of the methodology is presented in Figure 1.

Results: After quality control, filtering, and normalization processes of the gene expression matrix, the total number of T cells recovered from the analysis was 2,844, out of which 1,427 were isolated from the muscle and 1,417 cells from PB. Muscle and PB T cells grouped separately indicating different gene signature. Three different clusters containing muscle T cells (cluster 1), PB CD8+ T cells (cluster 2) and PB CD4+ T cells (cluster 3) were identified, showing different transcriptomic signature between muscle and PB T cells. After unsupervised clustering of gene expression, we identified 15 distinct T-cell clusters annotated based on differentially expressed genes and visualized by UMAP. We found enrichment in the muscle compartment compared to blood for the following clusters: tissue-resident memory (T_{res}) T cells, muscle central memory (CM) CD4+ T cells, muscle effector memory (EM) T cells, EGR1hi and T_{reg} genes, and Tregs.

Conclusion: Our study reveals a muscle T-cell signature in patients with IIM and a transcriptomic map to identify possible novel therapeutic targets in IIM, where muscle-infiltrating T cells are predominantly composed of cytotoxic, effector memory, tissue-resident, proliferating and regulatory T cells. The expression of tissue-resident memory (T_{res}) receptors and the presence of clonally expanded T-cell clones in the muscle of all patients with IIM imply the role of these cells in disease pathogenesis.

POS0144 miRNA CARGO CHARACTERIZATION FROM CIRCULATING EXTRACELLULAR VESICLES IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES (IIM) HIGHLIGHTS PECULIAR EPIGENETIC PROFILES ACROSS DEFINITE IIM SUBSETS AND DIFFERENT CLINICAL MANIFESTATIONS

Keywords: Myositis, Biomarkers, -omics

M. Gatto1, C. Franco1, A. Giannella2, L. Bertazza3, M. Gasparotto1, A. Ghirardello1, G. Ceolotto2, A. Doria1.

Background: Idiopathic Inflammatory myopathies (IIM) are heterogeneous systemic autoimmune diseases for which biomarkers are needed. Extracellular vesicles (EVs) are cell-derived nanoparticles regulating several biological functions[1]. Growing evidence supports the role of EVs in the pathogenesis of systemic autoimmune diseases[2].

Objectives: To evaluate the EVs-microRNA (miRNA) profile among distinct clinical manifestations and subsets of IIM, and healthy donors (HD).

Acknowledgements: None Declared, Inger Nennesmo: None declared, Karine Chemin: None declared.
Methods: We enrolled adult (≥18 years) consecutive IIM patients (EULAR 2017 criteria) and sex- and age-matched HD. Circulating EVs were isolated from plasma through size exclusion chromatography and ultra-filtration. miRNA iso-
lation was performed using miagen miRNeasy Serum/Plasma Advanced kit and miRNA quantification and analysis through next generation sequencing (NGS). Comparisons were carried out using Student’s t-test or one-way ANOVA with multiple comparisons.

Results: We included 60 IIM patients (females 61.7%; mean age 56.3±13.1 years; seropositive 78.3%; clinically active 56.7% on immunosuppressants (any): 83.3%) and 60 HD. miRNA analysis was performed on 21 IIM patients and 21 HD considering a comprehensive pool of 100 miRNAs. Ten miRNAs resulted significantly dysregulated between patients and HD (Table 1). Among miRNAs upregulated in patients, some exhibit immunoregulatory functions (hsa-miR-
222-3p, hsa-miR185-5p) while others are involved in oncogenesis (hsa-miR-
486-5p, hsa-miR-451a, hsa-miR-15a-5p)[3]. Conversely, downregulated miRNAs in patients usually display anti-inflammatory and anti-neoplastic properties (hsa-
et-7 group)[1,3]. More specific EVs-miRNA profiles were identified considering IIM subsets and organ involvement (lung, skin, muscles). Patients with Can-
cer-associated myositis displayed down-regulated hsa-miR-23b-3p (p=0.03), hsa-miR-374a-5p (p=0.01), hsa-miR-361-5p (p=0.046), hsa-miR-143-3p (p=0.024), hsa-miR-29c-3p (p=0.027), hsa-miR-361-5p (p=0.039). According to different clinical manifestations, hsa-miR-451a, hsa-miR-29a-3p, hsa-miR-342-2p and hsa-miR-146b-5p were up-regulated in active myositis, and hsa-miR-222-3p, hsa-miR-144-5p, hsa-miR-101-3p, hsa-miR-19b-3p, hsa-miR-25-3p in active skin and Gottron’s lesions.

Conclusion: Differential expression of EVs-miRNAs across IIM subsets suggests peculiar epigenetic footprints to distinguish specific IIM phenotypes and possibly generate tailored treatment targets (Figure 1). Circulating EVs might serve as IIM biomarkers and for early stratification of disease manifestations.

using qPCR assays across treatment groups for Coll1, SMA and CTGF. Gene expression data (qPCR) confirmed protein expression. Genomic-wide RNAseq analysis identified an S100A4 activated signature in NF overlapping the hallmark gene expression signature of SSc. Then, a biomarker of fibrogenesis (FDR<0.001 and FC>1.5) induced in NF by S100A4, were also constitutively overexpressed, and downregulated by AX-202, in SSc(Figure 1A). Pathway mapping of these S100A4 dependent genes in SSc showed the most significant enriched Kegg pathways (FDR<0.001) were regulation of stem cell pluripotency (4.6-fold) and metabolic pathways (1.9-fold) (Figure 1B).

Conclusions: Our comprehensive analysis supporting a pro-fibrotic role for S100A4 in fibroblast activation in SSc and suggest that serum level may be a biomarker of major organ manifestations and disease severity. This study supports examining the therapeutic potential of targeting S100A4 in SSc are warranted.

of whom 7 had pulmonary arterial hypertension (PAH). The patients were divided according to high (n=8)/low (n=12) T3 levels into 2 groups and the difference in circulating miRNA-21 levels between the groups was evaluated.

Results: Fibroblast-ECMs generated by TGFβ1-triggered DF had higher levels of collagen-I and TGFβ1 in comparison to normal ECM. In comparison to the normal ECM, the fibrotic-ECM increased the followings in the DF: 1) ability to liberate TGFβ1 from the ECM by increasing MMP-9 activity and αv expression. 2) TGFβ1 activation and differentiation to MF evidenced by increased expression of phospho-Smad3, αSMA, collagen, and elastin, and increased proliferation. 3) Expression of αv[3], miRNA-21 and DIO3 (all changes in 1-3.24-123%1, p<0.05).

The addition of tetrac to DF cultured on fibrotic-ECM downregulated cell proliferation, collagen, elastin and αSMA expression to the levels found in DF cultured on normal ECM. Furthermore, it reduced αv[3], miRNA-21, and DIO3 levels. Accordingly, decreased miRNA-21 levels were found in the high T3 SSc group, compared to the low T3 group that contained all the PAH patients (p<0.05).

Conclusion: Our results demonstrated the existence of a vicious cycle: TGF-1-triggered DF produced a fibrotic-ECM that promoted bystanders’ DF differentiation to MF. Using this model, we demonstrated that tetrac binding to αv[3] integrin inhibited the differentiation of DF to MF, and their ability to activate the αv[3]/miRNA-21/DIO3/T3 pathway. These results suggest that the thyroid hormone binding site of αv[3] may be a potential target for the treatment of fibrosis.

STIFFNESS INDUCED PROGRESSION OF FIBROSIS BY SORBIN AND SH3 DOMAIN-CONTAINING PROTEIN2 IN SYSTEMIC SCLEROSIS

Keywords: -omics, Systemic sclerosis, Skin

Background: Persistently activated fibroblasts status leads to progressive extracellular matrix (ECM) deposition and tissue remodeling. The hallmark of systemic sclerosis (SSc) is collagen accumulation in organs, mainly in skin and lung. Despite intensive progress in understanding disease occurrence, SSc remains an intriguing disease with unknown pathology and high mortality. Sorbin and SH3 domain-containing protein2, encoded by SORBS2 is a key member of the sorbin homology family of adapter and scaffold proteins. Recent studies suggest that SORBS2 plays a role in cardiac disease, however there is no available data about its role in fibrotic conditions.

Objectives: We aimed to investigate the role of SORBS2 in the pathogenesis of SSc.

Methods: To identify molecules specifically upregulated in persistently activated fibroblasts, human fibroblasts were chronically stimulated with TGF-β and analyzed by RNA-sequencing. To evaluate the functional implication of tissue elasticity on the transcriptome of fibroblasts, multiwell stiffness assays were performed. SORBS2 expression was further analyzed in skin samples of patients with SSc and murine models of fibrosis. Fibroblast specific SORBS2 knockout mice were challenged with bleomycin to induce skin and lung fibrosis. Further specific readouts like collagen content, skin thickness, myofibroblast count, CT scans were performed.

Results: Upon chronic TGF-β stimulation of human normal skin fibroblasts we identified SORBS2 as a significantly upregulated molecule. SORBS2 is implicated in cytoskeletal organization, cell adhesion and different signaling pathways. Moreover, extracellular stiffness induced upregulation of SORBS2 mRNA level in fibroblasts. Deletion of SORBS2 in fibroblasts led to a change of the diameter of collagen fibers and modified the elastic index of the tissue. Sorbs2 deficient DF produced a fibrotic-ECM that promoted bystanders’ DF differentiation to MF. Using this model, we demonstrated that tetrac binding to αv[3] integrin inhibited the differentiation of DF to MF, and their ability to activate the αv[3]/miRNA-21/DIO3/T3 pathway. These results suggest that the thyroid hormone binding site of αv[3] may be a potential target for the treatment of fibrosis.

Background: Autoantibodies (ab) against G protein-coupled receptors (GPCR), such as ab against angiotensin II receptor type 1 (AT1R), endothelin receptor type A (ETAR) or CXC chemokine receptor 3 and 4 (CXCR3/4) may contribute to the pathogenesis of systemic sclerosis (SSc) [1]. AT1R- and ETAR-ab are associated with SSc-related mortality and CXCR3/4-ab predict a deteriorating to the pathogenesis of systemic sclerosis [1].

Methods: Serum ab levels against 19 targets were higher compared to HC. Abs against fibroblast growth factor-2 (FGF-2), beta-adrenergic receptor 1 (ADRB1), and placental growth factor (PIGF) discriminated best SSc patients from HC. Multivariate predictions supported the ranking value of FGF-2 and ADRB1-abs and abs against ADRB1/2, muscarinic receptor 1 (M1R) and alpha-adr-energic receptor 2 ADR2A for diffuse cutaneous SSc (dSSc) versus limited cutaneous SSc (lSSc) [2].

Results: In SSc ab levels against 19 targets were higher compared to HC. Abs against fibroblast growth factor-2 (FGF-2), beta-adrenergic receptor 1 (ADRB1), and placental growth factor (PIGF) discriminated best SSc patients from HC. Multivariate predictions supported the ranking value of FGF-2 and ADRB1-abs for SSc and abs against ADRB1/2, muscarinic receptor 1 (M1R) and alpha-adr-energic receptor 2 ADR2A for diffuse cutaneous SSc (dSSc) versus limited cutaneous SSc (lSSc). Ab levels were denser and stronger correlated in SSc than in HC (figure 1), suggesting a disturbed regulation of ab with a prominent role of FGF-2-abs in SSc. Comparing dSSc to lSSc, dSSc showed higher ab levels and correlated with several disease characteristics, but the multivariate classification showed poor accuracy.

Conclusion: SSc is characterized by both quantitative and qualitative alterations in ab levels and ab correlations. This study reveals ab against FGF-2, ADRB1 and PIGF to be new biomarkers of SSc. Alterations within these ab correlation networks could help to identify pathways promoting SSc and its clinical manifestations.

POS0152 PLATELET EXTRACELLULAR VESICLES MODULATE NEUTROPHIL STATE IN SYSTEMIC SCLEROSIS VIA HMGB1

Keywords: Lungs, Innate immunity, Systemic sclerosis

N. Maugeri1, G. A. Ramirez2, A. Monno1, A. Capobianco1, S. Franchini1, M. Manfredi1, P. Roveri-Querini1, A. Manfredi1,1 IRCSS San Raffaele Scientific Institute, Autoimmunity and Vascular Inflammation Unit, Milano, Italy

Background: Platelet extracellular vesicles (PTEVs) expressing the damage-associated molecular pattern prototypic signal, high mobility group box 1 (HMGB1), accumulate in the blood of patients with systemic sclerosis (SSc) and per se promote autoimmunity, fibrosis and vascular inflammation [1, 2]. A poorly understood defect in critical players in sprouting angiogenesis, angiopoietins and the angiopoietin receptor, Tie2 is also an hallmark of SSc. Normal neutrophils respond to angiopoietin 1 and other stimuli by undergoing activation and upregulating the Tie2 expression [3].

Objectives: We reasoned that HMGB1 could be a putative candidate signal supporting neutrophils Tie2 overexpression, as it plays a critical role in neutrophil activation and is present as an EV-associated bioactive molecule in the blood of SSc patients[1, 2].

Methods: Neutrophil Tie2 expression was assessed in the blood of 39 patients with SSc and 43 healthy donors (HD) sex- aged matched, by flow cytometry and confirmed by immunogold at electron microscopy. Tie2 expression was determined in freshly purified normal neutrophils stimulated with PTEVs from SSc patients or from HD or stimulated with rHMGB1 in vitro. Moreover PTEVs purified from the plasma of SSc patients or from HD were injected in the tail vein of NSG mice (that are receptive to human tissues). 18 hours after injection the expression of Tie2 of neutrophils in blood and lung histology were analyzed. Box A and low molecular weight heparin (LMWH) have been used as HMGB1 antagonists in vitro and in vivo.

Results: Most SSc neutrophils express Tie2 (B4.7a2.4%) vs 8.3±1.1% in HD; p <0.0001) regardless of the extent of systemic inflammation. HMGB1 and PTEV expressing HMGB1 purified from the plasma of patients with SSc induced up-regulation of Tie2 in vitro. Tie2 induction was abrogated by Box A and LMWH. PTEVs from SSc patients (but not from the plasma of HD) injected in the tail vein of NSG mice dramatically upregulated Tie2 neutrophil expression. Neutrophil Tie2 upregulation abated in the presence of HMGB1 inhibitors, Box A and LMWH. Immunohistochemistry revealed lung fibrosis associated with massive infiltration by Tie2+ neutrophils. Neutrophil ablation by liposome-encapsulated clodronate confirmed by immunogold at electron microscopy. Tie2 expression was determined in freshly purified normal neutrophils stimulated with PTEVs from SSc patients or from HD or stimulated with rHMGB1 in vitro. Moreover PTEVs purified from the plasma of SSc patients or from HD were injected in the tail vein of NSG mice (that are receptive to human tissues). 18 hours after injection the expression of Tie2 of neutrophils in blood and lung histology were analyzed. Box A and low molecular weight heparin (LMWH) have been used as HMGB1 antagonists in vitro and in vivo.

Conclusion: Our data highlight the role of the platelet HMGB1/neutrophil axis in SSc vascular inflammation and fibrosis.

New developments in imaging in rheumatology

**POST153**

**MACROPHAGE [11C]-DPA-713 PET-CT IMAGING TO PREDICT EARLY ANTI-TNF TREATMENT OUTCOME IN RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Imaging, Qualitative research methods

W. Binsbergen1, J. De Jongh1, S. Piepenbosch1, M. Yaqub2, D. Van Schaardenburg1, A. Voskuyl1, G. C. J. Wieringen1, C. J. Van der Laken1, Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 2Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology, Amsterdam, Netherlands

**Background:** Treatment of rheumatoid arthritis (RA) using anti-tumor necrosis factor (TNF) biologics has greatly benefited patients since their introduction, with an expected treatment response rate of up to 50-70%. However, this leaves 30-50% of patients taking ineffective medication whilst being exposed to the potential side-effects of anti-TNF. Current patient care requires clinical evaluation of 3 to 6 months before effectiveness can reliably be assessed. Quantitative macrophage position emission tomography (PET) has shown potential to predict clinical response at an early stage of treatment [2]. The new generation translocator protein (TSPO) tracer [11C]-DPA-713 has demonstrated excellent properties for imaging of arthritis by targeting synovial macrophages [2, 3].

**Objectives:** To determine whether quantitative whole body [11C]-DPA-713 PET/CT imaging at 0-4 weeks of anti-TNF treatment in clinically active RA patients is associated with clinical response at 26 weeks.

**Methods:** Whole body [11C]-DPA-713 PET/CT scans were performed at baseline and after 4 weeks of treatment with anti-TNF in n=20 clinically active RA patients. All patients were either anti-TNF naïve or switched to an anti-TNF agent without previous primary failure to anti-TNF. Co-treatment with DMARD and/or low dose (≤ 5 mg/day) was allowed and was stable for at least 4 weeks. Clinical follow-up was conducted with the Disease Activity Score 24 (DAS24) after 26 weeks of treatment. PET/CT scans were quantitatively analyzed using in-house software. Regions of interest (ROIs) were delineated on PET/CT per individual joint in all joint evaluated using the DAS24 and CT as anatomical reference. Standardized uptake values (SUVs) normalized for body weight were calculated in these ROIs to determine quantitative tracer uptake per joint. PET outcome at baseline and 4 weeks of anti-TNF treatment was compared with the DAS24 scores at 26 weeks of treatment.

**Results:** Included patients were mostly female (70%) and aged 61.5 ± 12.8. Baseline DAS24 was 2.5 ± 1 and all demonstrated visually enhanced tracer uptake in one or more joints on PET/CT. After 26 weeks 30% showed no response, 20% moderate response and 50% good response to treatment according to EULAR response criteria. Baseline mean PET/CT scores of all joints per patient already correlated significantly with DAS24 at 26 weeks (T=0, R² = 0.547, p < 0.001). In smaller joint clusters the highest correlation was found for the metacarpal-phalangeal joints (T=0, R² = 0.650, p < 0.001). Furthermore, PET/CT outcomes at 4 weeks of anti-TNF treatment also had significant correlation with DAS24 at 26 weeks for those same measurements: mean score of all joints: T=4, R² = 0.530, p < 0.001, mean score MCPs: T=4, R² = 0.728, p < 0.001.

![Figure 1. Changes in [11C]-DPA/713 uptake in MCP joints of an RA patient responding to anti-TNF treatment, before (A) and after 4 weeks after initiation of anti-TNF treatment (B).](image_url)

**Conclusion:** Quantitative whole body macrophage C-11-DPA713 PET/CT joint assessment correlated already at baseline, and also at 4 weeks of anti-TNF treatment with clinical response at 6 months of treatment. Therefore, quantitative non-invasive macrophage PET/CT shows promise for very early prediction and treatment stratification of anti-TNF in RA patients. Further studies will be focused on development of standardized and (semi-)automated PET quantification protocols to facilitate implementation in clinical trials and practice.

**POST154**

**A DEEP LEARNING MODEL TO LOCATE INFLAMMATORY CHANGES IN RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Artificial Intelligence, Imaging

T. Hassanzadeh1, D. Shamron1, Y. L1, M. Reijnierse2, A. Van der Helm – Van Mil2, B. Stoel1. Leiden University Medical Center, Division of Image Processing, Department of Radiology, Leiden, Netherlands; 2Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands

**Background:** Magnetic Resonance Imaging (MRI) is one of the most sensitive imaging modalities to monitor affected joints and detect inflammatory signs related to Rheumatoid Arthritis (RA). Finding and tracking inflamed areas can help to evaluate patients status, and start treatment in a very early stage. The RAMRIS [1] scoring system is being used to assess the extent of inflammation by scoring specific areas to quantify synovitis, tenosynovitis and bone marrow edema. Deep Learning (DL) may, however, provide more accurate and specific quantification of synovitis.

**Objectives:** We aimed to develop a change map that locates RA progression over time, using MRI scans of the wrist. Our purpose was to develop an automatic, hypothesis-free DL model that considers the entire MRI for detecting all possible longitudinal changes related to RA between baseline and follow-up wrist MRIs.

**Methods:** Wrist contrast-enhanced T1-weighted fat-suppressed MRI scans of 236 patients from four time points (baseline, with 4, 12, and 24 months follow-up) were collected [1]. An unsupervised DL model was developed together with image processing techniques to detect a pixel-level progression within wrist MRI scans between baseline and the last follow-up MRIs. This model predicts the MRI appearance of the follow-up scan, based on the baseline scan, by learning from MRI time sequences of all patients in the training set. Similarly, the baseline scan was predicted backwards in time, based on the follow-up scan (see Figure 1). Subsequently, by comparing the predicted and true MRI image, pixel-level changes can be determined between the two MRI scans. For prediction, we used a U-Net [2] to reconstruct follow-up images from baseline and vice versa. After pre-training, two copies of the trained model and a joint loss function were used for final training in a shared branch U-Net: the first branch is trained to generate a follow-up image and the second branch to create a baseline image. After final training, two difference maps were obtained by subtracting the baseline image from the predicted follow-up image and by subtracting the follow-up image from the predicted baseline image. Since real changes appear in pixels with positive values, Otsu thresholding was applied only on the positive differences to generate two change maps, where the first change map shows intensity reduction (areas of remission) and the second indicates increased intensity (areas of progression). With fusion of the obtained change maps we obtained the final change map that can highlight the changes in both directions.

**Results:** As can be seen from Figure 1, the proposed model could find local pixel-level changes, highlighting RA remission/progression over time. The red overlay shows a reduction in intensity, the blue overlay indicates an increase in intensity. To show the performance of the proposed model, the results were compared with a baseline model, that simply subtracts the original follow-up from the baseline image. As can be seen from the provided examples, the proposed model is less sensitive to imaging artifacts.

**Conclusion:** A comparative DL-model is proposed to find inflammatory changes in wrist MRI scans. Despite being an unsupervised model (sometimes detecting changes, in e.g. vessels, that are presumed to be unrelated to RA), the results are promising, since the change maps contain less artifacts as compared to simple image subtraction.

PERIPHERAL JOINT AND ENTHESIS INVOLVEMENT IN NEWLY DIAGNOSED PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD): SYMPTOMS, CLINICAL AND ULTRASONOGRAPHIC FINDINGS

Keywords: Gastrointestinal tract, Spondyloarthritis, Imaging

N. Vladimirova 1, L. Terslev 2,3, M. Attiaibi 4, G. Madsen 2, V. Fana 2, C. Wiell 2, M. Östergaard 2,3, Center for Rheumatology and Spine Diseases, Center of Head and Orthopedics, Glostrup, Rigshospitalet, Capital Region, Denmark, Copenhagen, Denmark; 2Center for Rheumatology and Spine Diseases, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; 3Department of Gastroenterology and Hepatology, Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark, Copenhagen, Denmark; 4Department of Gastroenterology and Hepatology, Copenhagen University Hospital - Hvidovre, Hvidovre, Denmark

Background: Peripheral musculoskeletal (MSK) symptoms are the most common extra intestinal manifestations (EIMs) in IBD patients, with substantial impact on quality of life. IBD related spondyloarthritis (IBD-SpA) often requires a multi-disciplinary evaluation to enable optimal choice of treatment and patient care, but standardised rheumatological characterisation of this population is scarce [1]. Characterisation of IBD-SpA is challenged by the variety of MSK involvement (from arthralgia to ankylosing spondylitis), the co-existence of osteoarthritis, overuse enthesopathies or fibromyalgia, and by the heterogeneity in methodologies used to describe the SpA features. Recently developed recommendations for endpoints for EIMs in IBD trials [2] were applied in the present study.

Objectives: To determine the prevalence and distribution of inflammatory lesions in peripheral joints and entheses in newly diagnosed IBD patients, assessed for presence of MSK symptoms, and by rheumatological and ultrasound (US) evaluation.

Methods: Patients from the IBD prognosis inception cohort (IBD-Pro) were consecutively included [2]. They reported MSK symptoms using a validated questionnaire (IBD-TAQ). A clinical examination was performed by rheumatologist, as was US examination (grey scale (GS) and colour Doppler (CD)) of 38 peripheral joints and 14 entheses, applying OMERACT-EULAR definitions and scoring systems for synovitis and enthesis [3]. Synovitis was defined as GS score ≥2 and/or CD≥1 and entheseal inflammation was defined as presence of hypoecho-genicity/thickening and/or CD score ≥1. Further, OMERACT-EULAR sum score (GLOESS) was calculated (0-114).

Results: 110 newly diagnosed IBD patients (mean age 42, 38% male) were included (34% Crohn’s disease, 59% ulcerative colitis (UC), 5% unclassified IBD). The IBD disease activity scores indicated mild activity in UC patients (Simple Clinical Colitis Activity Index mean (SD) 6.7 (3.6) - max score 19, and low in Crohn (Harvey-Bradshaw Index for Chron’s disease 4.5 (2.9)- max score 18). Four patients received systemic glucocorticoids (2%) or biologics (2%) at the time of the rheumatological evaluation. History of psoriasis was reported in 2% and uveitis in 5% of the patients. 40% of the patients reported positive history for ≥1 MSK symptom (Figure 1, A1); joint pain and swelling were the most common complaints (30%), followed by heel enthesis (17%) and dactylitis in 20%. Patient pain VAS was low, mean (SD) 13(25). Clinical examination revealed 53% of all patients having arthritis and/or enthesitis and fulfilled ASAS classification criteria for peripheral SpA (25% ≥1 tender joint, 12% ≥1 swollen joint, 46% ≥1 tender enthesis, 38% both ≥1 tender/swollen joint and ≥1 tender enthesis). Figure 1 (part A2a, A2b) shows joint and enthesis involvement. US found inflammation in ≥1 joint or enthesis in 47% of the IBD patients - synovitis in 30%, mean GLOESS sum score 5.2 SD (4.6) and entheseal inflammation in 33% (US enthesis sum, mean SD 2.6(2)). (Figure 1, part A3a, A3b). Among those patients reporting enthesis pain, 71% had ≥1 enthesis at clinical evaluation and 64% had entheseal inflammation by US. Among those reporting joint pain, 55% had ≥1 tender or swollen joint, and

41% US synovitis. Figure 1 (part B1, B2) displays the overlap between patient-reported symptoms, clinical and US findings. In the asymptomatic patients (60 %) 59% of the patients with clinical signs of arthritis and 79% of those with enthesitis were asymptomatic. US enthesitis and synovitis were also observed in 69% and 58%, respectively, of the asymptomatic patients.

**Conclusion:** At the time of IBD diagnosis 53% fulfilled ASAS classification criteria for peripheral SpA and 47% had objectively verified synovitis and/or enthesitis by US indicating that SpA may be underdiagnosed among IBD patients.

**Background:** Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are characterized by a deterioration of bone mass, bone microstructure and biomechanics [1, 2]. However, little evidence is available on the long-term evolution of these bone properties and the impact of autoimmunity, disease activity and targeted anti-inflammatory therapy.

**Objectives:** To evaluate the longitudinal course of peripheral volumetric bone mineral density (vBMD), microstructure and biomechanics in patients with seropositive RA (RA+), seronegative RA (RA-) and PsA (i) by diagnosis (ii) disease categories and time-varying weighted average disease activity and inter -actions or pairwise differences over time between ever vs. never exposed categories were significant.

**Conclusion:** Autoimmunity impairs bone health over time and is particularly associated with impaired trabecular bone quality. Good control of disease activity in RA+, RA-, and PsA patients may be helpful in preventing bone loss and deterioration of bone microstructure, and biomechanics. Specific contribution of b/tsDMARDs to the time course of bone quality at the radius needs further clarification.

POST-STRESS ELASTOGRAPHIC DIFFERENCES AT ACHILLES ENTHESIS AS AN OUTCOME MEASURE IN THE ASSESSMENT OF PATIENTS WITH PSORIATIC ARTHRITIS IN REMISSION

Keywords: Psoriatic arthritis, Physical therapy/Physiotherapy, Ultrasound

C. Guillén-Astete1, A. Palomeque1, M. Serrano Warleta1, R. Manzo1,2 Ramirez y Cajal University Hospital, Rheumatology, Madrid, Spain

Background: Tendon elastography has demonstrated the ability to discriminate between healthy subjects and patients with enthesitis. Its greatest strength is its ability to reliably quantify the stiffness of a soft structure. However, its use in anatomical load-bearing entheses has not been sufficiently explored. The use of quantifiable enthesis assessment methods would open up multiple possibilities in both the diagnosis and follow-up of inflammatory enthesis diseases.

Objectives: To evaluate the response to mechanical stress through elastography in the enthesis of the Achilles tendon among patients with psoriatic arthritis (PsA) in remission treated with anti-IL17, therapies other than anti-IL17 (non-anti-IL17), and healthy controls.

Methods: Observational, multicenter, non-blind study. The elastography results before and after physical exercise of patients with PsA in remission treated with therapies anti-IL17, therapies other than anti-IL17 (non-anti-IL17) were compared with those of healthy subjects matched by age (+/- 4 years), sex, and body fat percentage (BFP) (+/- 4%). Elastography was performed with a GE Logic S8 sonograph with a linear 6MHz probe. The region of interest (ROI) was the Achilles tendon. All elastographic measurements were the result of three separate measures performed on the achilles enthesis. The region of interest (ROI) was the Achilles enthesis. The stiffness of the enthesis was measured in KPa. The mean and standard deviation (mean±sd) were calculated. The differences in mean stiffness before and after physical exercise were compared with the Student’s t-test.

Results: The elastographic results of 14 patients on anti-IL17 therapies, 15 on non-anti-IL17 therapies, and 15 healthy controls were compared. The median disease duration of BD patients was 72 (28.5-162.0) months and 61.9% of them had major organ involvement. The most common major organ involvement was vascular (57.7%) followed by ocular (34.6%), and neurological (7.7%) involvement. Most (66.7%) BD patients were using immunosuppressive treatment. Both IMT-R and IMT-L were significantly higher in BD patients than HC (p<0.0001). There was no significant difference between IMT-R and IMT-L in BD patients with and without major organ involvement (p=0.005 for both).

Conclusion: IMT of CVF as well as wall thickness is significantly increased in BD patients than HC. Our results suggest that there is a full layer venous wall inflammation including intima-media layer in BD independent of vascular involvement.

The OMERACT Giant Cell Arteritis Ultrasound Scoring (OGUS) score is a potential useful outcome to assess the risk of relapse during follow-up.

**Keywords:** Vasculitis, Imaging, Ultrasound

J. Molina Collada1, J. M. Alvaro-Gracia2, E. De Miguel2, Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain; 2La Paz University Hospital, Rheumatology, Madrid, Spain

**Background:** The OMERACT ultrasound large vessel vasculitis working group has recently developed an ultrasound (US) composite score, the OMERACT giant cell arteritis (GCA) Ultrasound Scoring Score (OGUS), to assess the extent of vascular inflammation by US and to monitor disease activity in patients with GCA[1].

**Objectives:** Our objective was to assess the sensitivity to change of this score and to determine whether OGUS variations after treatment are associated with the risk of relapse during follow-up.

**Methods:** Retrospective observational study of patients referred to a US GCA fast track clinic of an academic center over a 2-year period with GCA clinical confirmation. All patients underwent baseline US evaluation at the time of diagnosis and at 3- and 6-month visits per protocol. OGUS was calculated as the sum of intima media thickness (IMT) in every segment divided by the rounded cut-off values of IMTs in each segment (0.4 mm for the common trunk of superficial temporal arteries, 0.3 mm for the parietal and frontal branches and 1 mm for the axillary arteries). The total sum was divided by the number of segments available. OGUS score >1 indicates abnormal exam. EULAR definitions for remission and major and minor relapse were checked for every patient at 3 and 6 months. Patients were treated according to clinical response with standard therapy. Sensitivity to change of OGUS was calculated as negative values of standardized mean difference (SMD) for each visit separately. The t-student test for paired samples was used for comparing baseline and follow-up OGUS assessments. 0-3 and 0-6-months OGUS variations were compared between patients with and without relapse during follow-up and with and without achievement of remission at 6 months.

**Results:** A total of 35 GCA patients were included for analysis (mean age 77.4 years, 62.9 % females). Ten (28.6%) patients relapsed at 3 or 6 months during follow-up, of whom 8 (22.9%) showed a minor relapse. EULAR definition of remission at 6 months was achieved by 18 (51.4%) patients. Mean (SD) baseline OGUS was 1.34 (0.34). OGUS improved significantly at 3 (1.34 vs 1.14, p=0.013) and 6 months (1.34 vs 1.1, p=0.01). The SMD of OGUS between baseline and 3 and 6 months was -0.49 and -0.04, respectively. 0-3- and 0-6-month OGUS variations in patients with and without relapse during follow-up and patients with and without achievement of remission at 6 months are shown in detail in Table 1. Mean 0-6-month OGUS improvement was significantly lower in patients with relapse during follow-up (-0.06 vs 0.35, p=0.049).

**Conclusion:** OGUS shows moderate sensitivity to change in patients with GCA after standard therapy at 3 and 6 months. The absence of OGUS improvement during follow-up is associated with the risk of relapse and the probability of not achieving remission. These findings highlight the usefulness of this tool in clinical practice and may support personalized medicine decisions during treatment tapering.

**ARTIFICIAL INTELLIGENCE ALGORITHMS FOR AUTOMATIC STRATIFICATION OF RHEUMATOID ARTHRITIS USING HAND X-RAYS**

**Keywords:** Imaging, Artificial Intelligence, Rheumatoid arthritis

M. Bonnin1, T. Estienne2, F. Muller-Fournet3, B. Bekadar2, Y. Carrillon2, C. Pouchy2, T. Ati Si Selmi1, 1Santo Orthopedic Center. Lower limb surgery/ orthopaedics, Lyon, France; 2Deemea, Research and Development, Paris, France; 3Santo Orthopedic Center, Radiology department, Lyon, France

**Background:** The diagnosis of rheumatoid arthritis is based on clinical, biological and imaging criteria [1]. Among these criteria, the quantification of the lesions through X-ray images is essential for the establishment of therapeutic strategies and the clinical follow-up of the patient [2]. The Sharp/van der Heijde (SVH) method is used to assess the severity of bone erosion and joint narrowing on X-rays of hands and feet it is frequently used in clinical practices and observational studies [3]. The SVH manual scoring process requires a high level of expertise and time consuming. It can also suffer from inter-observer interpretation variability.

**Objectives:** The objective of this study is to use convolutional neural networks to automate the scoring of SVH and the classification of patients on this scale.

**Methods:** This work uses a public database of 3,818 X-rays of both hands. Each X-ray is paired with a rating of the disease severity evaluated with the SVH score. This score has values between 0 and 280 because only both hands are used. The database was separated into a training, validation and testing set (64%, 16% and 20% respectively). Two convolutional neural networks (CNN) were trained. The first predicts the value of the SVH score. The second classifies patients into two groups, depending on their score: less or more than 70. To improve the performance of the algorithms, various techniques have been implemented: transfer learning, data augmentation functions (rotation, flipping, noise) and hyperparameter and architecture search.

**Results:** The prediction network has an average error of 16.00 (std 17.75), with a Pearson correlation of 0.86. Its results are presented in the figure with individual results and confidence intervals. The classification algorithm obtained a mean value of the area under the curve (AUC) of 0.97, an accuracy of 0.84 and a positive predictive value of 0.91.

**Conclusion:** This study demonstrates the interest of using artificial intelligence algorithms in the diagnosis and standardized follow-up of patients with rheumatoid arthritis. These could help clinicians in the evaluation of osteoarticular lesions and the stratification of patients according to the severity of the lesions with great precision.

AN ULTRASOUND SCORING SYSTEM BASED ON THE SIZE AND NUMBER OF EROSIONS IS RELIABLE IN RHEUMATOID ARTHRITIS

Methods: A task force of the OMERACT Ultrasound Working Group developed definitions and a scoring system for grading bone erosions which takes both the size and number of erosions into consideration. Pairs of static images (longitudinal and transverse scans) were considered and the dataset of anonymized images, representing various grades was created and utilized. Inter-reader reliability of the scoring system was assessed using kappa statistics. Both the longitudinal and transverse scans were considered and the number of erosions into consideration. Pairs of static images (longitudinal and transverse scans) were considered and the dataset of anonymized images, representing various grades was created and utilized. Inter-reader reliability of the scoring system was assessed using kappa statistics.

Results: A 4-grade semiquantitative scoring system was developed: grade 0) intact cortical bone; grade 1) single small erosion (diameter: ≤2mm); grade 2) single large erosion (diameter: >2mm) or 2 small erosions or 1 large and 1 small erosion; grade 3) ≥3 erosions, regardless of size (Figure 1). A dataset composed of 45 anonymised image pairs (90 single images) was graded by 20 task force members in two rounds separated by 10 days. The intra-reader (mean: 0.79; 95% confidence interval: 0.75-0.84) reliability was excellent and the inter-reader (mean: 0.75; 95% confidence interval: 0.74-0.76) reliability was substantial.

Conclusion: This preliminary OMERACT scoring system for bone erosions of the finger joints in RA has demonstrated excellent reliability on static images. Further studies are required to evaluate the reliability of the combined acquisition and reading of images in patients.

VALIDITY OF SIMPLIFIED ULTRASONOGRAPHIC ASSESSMENTS OF JOINT INFLAMMATION IN RHEUMATOID ARTHRITIS

Keywords: Ultrasound, Rheumatoid arthritis

Z. Rutter-Locher1, K. Chaabo2, E. Chan2, A. Vincent2, S. Norton2, L. B. Kirkham1. 1Guy's Hospital, Rheumatology, London, United Kingdom; 2St George's Hospital, Rheumatology, London, United Kingdom; 3King's College London, Psychology and Inflammation Biology, London, United Kingdom

Background: Musculoskeletal ultrasound (MSK US) is a valuable tool to aid management of inflammatory arthritis. It’s use in clinical practice is limited by the feasibility and time constraints of performing a full 44 or 78 joint ultrasound.

Objectives: Our objective was to determine the validity of four previously published simplified approaches (6 joint[1], 12 joint[2], and [3] and data-driven[4] US models) in a new patient cohort, in order to guide future choice of MSK US protocol in research and clinical practice.

Methods: Sequential patients with rheumatoid arthritis, diagnosed according the 1987 ACR criteria, with a DAS28ESR score ≥3.2 underwent clinical assessment and 44 joint US at Guy’s Hospital. Grey scale (GS) and power doppler (PD) were graded semi quantitatively, according to the EULAR-OMERACT criteria. All the joints scored in the simplified 6 joint, 12 joint, hands only and “data driven” models were included in the current 44 joint US. However, the number of synovial recesses examined differed from those in the simplified models. Sensitivity of the simplified models to detect GS and PD signal, compared to the extended 44 joint US was calculated. Content validity was evaluated by correlating the 44 joint US count with the simplified models using Spearman’s correlation coefficient.

Results: 158 patients were enrolled in the study, with a mean age of 58.9 years (SD 12.95), 78.2% Female, 67.7% RhF positive and a median disease duration of 16 years (IQR 9-26). GS, PD and total scores for all the simplified models compared with the 44 joint US was assessed using linear regression analysis.

Conclusion: This study validates the use of the 6 joint, 12 joint, hands only and data driven approaches in a new patient cohort. The data driven approach was the most sensitive and retained the greatest proportion of information compared with the total 44 joint US scores.

**References:**

Background: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease that may complicate with pulmonary manifestations in up to 16% of patients [1], including interstitial lung disease (SS-ILD) and airway disease (SS-AD). Secondary objectives: to describe these manifestations and to investigate their prognosis.

Methods: We performed a retrospective multicentric study involving 9 French centers. We included pSS patients fulfilling the ACR/EULAR 2016 criteria and having a pulmonary disease associated with pSS evidenced by at least one clinician and one computed tomography (CT) report. We collected clinical and biological data at the visit giving access to the most exhaustive collection, pulmonary function test (PFT) and CT scans of the patients. CT scans were reviewed by a radiologist specialist in thoracic diseases. SS-ILD were considered progressive if there were at least a 10% decrease of the forced vital capacity (FVC) between 2 consecutive measurements, SS-ILD and SS-AD were compared to pSS controls with no history of pulmonary involvement, matched on age and disease duration with a 2/1 ratio.

Results: We included 56 SS-ILD, 31 SS-AD and 174 pSS controls. Comparison of SS-ILD and SS-AD and pSS controls is shown in Table 1. We found that SS-ILD and SS-AD had higher disease activity (ESSDAI) and B cell biological markers at visit time. Incident lymphomas were more prevalent in SS-ILD than pSS. SS-ILD were mostly nonspecific interstitial pneumonia (NSIP, n=16, 36%), usual or probable usual interstitial pneumonia (UIP, n=8, 18%), indeterminate for UIP (n=8, 18%) and lymphoid interstitial pneumonia (LIP, n=4, 9%). Fibrosis features were observed in 43% of cases. 44% of SS-ILD were progressive, independently of pSS characteristics and CT pattern, despite any significant evolution of PFT parameters of overall SS-ILD within 7 years follow-up (Figure 1A). We indirectly assessed the impact of the first line of systemic treatments comparing PFT evolution of treated (43%) and untreated patients. We found that treated SS-ILD tended to have reduce PFT deterioration than untreated patients (C). We performed a retrospective multicentric study involving 9 French centers. We included 56 SS-ILD, 31 SS-AD and 174 pSS controls. Comparisons of baseline and last follow-up PFT of SS-ILD and SS-AD (Figure 1B), and between last follow-up and baseline PFT of treated compared to untreated SS-ILD (C). Delta between post-therapeutical and pre-therapeutical PFT for cyclophosphamide and rituximab (D). Wilcoxon test was used. *: p<0.05.

Conclusion: SS-ILD are usually fibrosing and progressive manifestations of pSS, associated with disease activity, incident lymphoma and B cell biological markers. Despite the absence of randomized trials in SS-ILD, our results suggest an effect of the therapeutic. SS-AD are also associated with the disease activity and seems to progress slowly.

Data are in (%) unless otherwise indicated. Stars indicate significant comparisons to pSS control. Mann-Whitney and Fisher’s exact test were used. *: p<0.05.

Conclusion: SS-ILD are usually fibrosing and progressive manifestations of pSS, associated with disease activity, incident lymphoma and B cell biological markers. Despite the absence of randomized trials in SS-ILD, our results suggest an effect of the therapeutic. SS-AD are also associated with the disease activity and seems to progress slowly.

OUTCOME OF PREGNANCY IN WOMEN WITH PRIOR SJÖGREN’S SYNDROME COMPARED TO THE GENERAL POPULATION: THE FRENCH MULTICENTER PROSPECTIVE GR2 STUDY

Keywords: Prognostic factors, Pregnancy and reproduction, Sjögren syndrome

Methods: This was a French multicentric prospective cohort study of pregnancies in women with prior pSS, which included 190 females with a median age at inclusion of 41 years. The cohort was followed from 2016 to 2019. The primary outcome was the time to the first pSS flare after pregnancy. The secondary outcomes were the rate of pregnancy complications and adverse birth outcomes. The patients were followed up for an average of 10 years.

Results: The rate of pSS flares after pregnancy was 12.3% (13 of 106 pregnancies). The rate of pregnancy complications was 21.2% (22 of 106 pregnancies), including preeclampsia in 8.5% of pregnancies and intrauterine growth restriction in 7.1% of pregnancies. The rate of adverse birth outcomes was 8.4% (9 of 106 pregnancies), including neonatal death in 2.8% of pregnancies.

Conclusion: The rate of pSS flares after pregnancy is 12.3%, which is higher than the rate in the general population. The rate of pregnancy complications and adverse birth outcomes is also higher in pSS patients compared to the general population. This study highlights the need for increased surveillance and management of pSS during pregnancy to reduce the risk of flares and complications.
Among patients with HCQ level >100 mcg/L (n: 117/82%) vs <100 mcg/mL (n: 25/18%), the mean daily dose of HCQ received (250 mg [87.7] vs 220 mg [57.7], \( p=0.33 \)) and the one adjusted to the weight of the patient in both is higher (3.76 [1.4] mg/kg vs 3.16 [1] mg/kg, \( p=0.016 \)). No relationship was observed between the HCQ level and the QTc result. The 39 (27%) patients with QTc >440 ms vs the 103 (73%) with QTc ≤ 440 ms were significantly older (61 [14] years vs 55 [14] years, \( p=0.007 \)) and higher heart rate (75 [12] bpm vs 71 [10.6] bpm, \( p=0.016 \)). No differences were detected between QTc result and HCQ dose or level.

Conclusion: In patients with EASR treated with maintenance doses of HCQ: 1) The mean level of HCQ is not related to prolongation of the QTc interval of the ECG. 2) QTc is significantly related to age and heart rate. 3) 40% of patients with prolonged HCC treatment also receive other common drugs that can influence the QTc, however, it does not seem to cause symptoms of interest. 4) The EASR per se does not affect the QTc result.

POS0169 IMPACT OF THE HYDROXYCHLOROQUINE LEVEL ON THE ECG QT INTERVAL IN PATIENTS WITH SYSTEMIC RHEUMATIC AUTOIMMUNE DISEASES: A REAL-LIFE STUDY

Keywords: Safety, Systemic lupus erythematosus, Cardiovascular disease

R. Cuartas-Santos1, J. Rosas2, M. Marco2, A. Pons-Bas3, R. Gallego-Campanuzano1, J. C. Cortés-Quiroz1, M. Shalabi2, J. M. Senabre Gallego1, G. Santos Soler1, L. Pons-Canet1, J. A. Bernal1, X. Barber1, J. A. García-Gómez1, 2Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; 3Hospital Marina Baixa, Laboratory, Villajoyosa, Spain; 4CIO University of Elche, CIO, Elche, Spain

Background: N/A

Objectives: To analyze the impact of the serum level of HCQ on the QTc interval, in patients with rheumatic systemic autoimmune diseases (RSAD), treated with this drug a long time.

Methods: Retrospective study, among patients with RSAD, treated with HCQ > 1 year, dose 200-400 mg/day (cases). Serum HCQ level was measured and the QTc interval of the ECG. Patients with EASR not treated with HCQ were included as a control group for QTc: weight, current treatment, and ECG was performed to obtain QTc. In patients with RSAD, the following was collected: 1) Epidemiological data of the patient 2) RSAD: diagnosis, year of diagnosis, time of evolution of the disease, own clinical and autoimmunity data, treatment and dose 3) QTc: time in treatment, toxicity, symptoms and serum level. 4) ECG: QTc and heart rate (HR).

Results: 142 patients treated with HCQ for a mean of 8.3 (SD: 6.4) years, at a mean dose of 245 mcg/mL (83.8), and 3.7 (1.3) mcg/kg/day, are included. 129 (91%) are women, mean age 57 (14.5) years, weight 66 (15) kg. Diagnosis distribution: SLE: 72 (50%) patients, RA: 37 (26%), SjS: 26 (18%), Ps: 12 (9%), psoriatic arthritis: 6 (5%), antiphospholipid syndrome: 5 (4%), SLE: 72 (50%) patients, RA: 37 (26%), SjS: 18 (13%), Palindromic rheumatism: 4 (3%), psoriatic arthritis: 3 (2%), antiphospholipid syndrome: 2 (1%) patients. Mean HCQ serum level: 185.6 mcg/mL (124); 25 (28) with a level <100 mcg/mL (mean: 58 [28.5] mcg/mL) and 117 (72%) >100 mcg/mL (mean: 224 mcg/mL [116]). On ECG, the mean HR: 72 bpm (59); and the mean QTc interval: 419 (33) ms, being prolonged (>440 ms) in 39 (27%) patients (range: 441-510 ms). Ten (7%) patients reported symptoms: palpitations: 7 (10%), dizziness in 2 (20%) and 1 (1%) patient an isolated pseu- doysocynal picture (QTc: 441 ms); 58 (41%) patients were receiving treatment with a drug related to the risk of QTc prolongation: Possible (P: authorized doses, no risk of TdP): 8 (14%) patient. Conditional (C: risk in certain circumstances: excessive dose, interactions): 44 (7%). Defined (D: risk of TdP which uses a licensed indication): 1 (2%) patient. When comparing the mean QTc result of the EASR group treated with HCQ and the control group without HCQ (n: 32), no differences were detected (419.4 [33] vs 436 [51], \( p=0.072 \).
Background: Systemic Lupus Erythematosus (SLE) patients experience frequent hospitalizations; lupus flares and infections have been shown to be the two most common causes.

Objectives: The aim of this study is to describe the main causes and predictors of first hospitalizations due to disease activity and infections in SLE patients.

Methods: SLE patients from GLADEL, a multi-ethnic, multi-national Latin-American (LA) cohort were studied. The first hospitalization during these patients’ follow-up due to either infection and/or SLE disease activity was examined. Baseline sociodemographic, clinical, damage (SDI) and treatments were evaluated as possible predictors. First, descriptive analyses were performed. Predictors of infection or SLE disease activity associated hospitalization were identified using univariate and multivariate logistic.

Results: A total of 1341 patients were included; 1201 (89.6%) were female. Their median interquartile range (IQR) age at diagnosis was 27 (20-37) years and their median IQR follow up time 27.5 (4.7-62.2) months. 456 (34.9%) patients were hospitalized; 344 (75.4%), 85 (18.6%) and 27 (5.9%) were hospitalized for disease activity, infections, or both, respectively, as depicted in Graph 1. In the multivariable analysis, arthritis was associated with hospitalizations due to infection. Seroactivity, disease activity and damage were associated with hospitalization due to disease activity. Older age, higher socioeconomic status and antimalarial use were found to be protective, as depicted in table 1.

Conclusion: In this large LA lupus cohort, one third of the patients had at least one hospitalization; of them, were due to SLE disease activity. Our findings call attention for controlling disease activity and preventing damage using antimalarials early in the disease course prevent the first hospitalization.

Objectives: We aimed to characterise the all-cause mortality rate (MR) and the incidence of cancer in SLE patients receiving biologic and standard of care (SoC) therapies.

Methods: Patients recruited to the BILAG-BR 2010-2021 were included. Demographic and clinical data were recorded at recruitment. Mortality and malignancy data were collected from study centres, the UK Office of National Statistics and the National Cancer Register. Cox regression models were used to estimate the hazard ratios (HRs) of mortality and cancer in biologic-treated patients compared to SoC. Mortality models were adjusted for age, gender, co-morbidity, SLICC damage index (SDI) and hydroxychloroquine (HCQ) use. The standardised mortality ratio (SMR) and standardised incidence ratio (SIR) were calculated using death and cancer rates for the general UK population.

Results: During follow-up, (1463 patients with 5,962 person years [pys]), 32 incident cancers occurred in 31 individuals, a median (IQR) of 1.31 (0.63-3.36) years after registration. The overall incidence was 6.0 (3.8-7.6) per 1000 pys. Compared to the UK general population, the SIR (95% CI) was 1.21 (0.85-1.72). Using SoC as the comparator, the age and gender adjusted HR was 1.49 (0.57-3.92) for rituximab and 2.47 (0.57-10.58) for belimumab. Across the whole cohort, associated risk factors (table 1), included age at recruitment (HR 1.05 [1.02-1.08]) and male sex (HR 2.81 [1.15-6.85]).

Diabetes mellitus 0.59 (0.08-4.34) - 1.63 (0.53-4.98) - 1.63 (0.53-4.98) - 1.63 (0.53-4.98) -

POS0171 PATIENT-DOCTOR COMMUNICATION GAP - RESULTS OF A SPEED-SHOP ON “LUPUS FLARE” AT LUPUS2022 MEETINGS

Keywords: Patient reported outcomes, Quality of care, Systemic lupus erythematosus

A. Corneli1, F. Marchiori2, H. Stefañosdóttir2, M. Mosca3, 1Lupus Europe, HQ, Brussels, Belgium; 2Lupus Europe, PAN, Brussels, Belgium; 3University of Pisa, Department of rhumatology, Pisa, Italy

Background: The Patient – Doctor communication gap is often discussed, and is one of the obstacles pointed by patients and doctors alike in the fruitful co-working of optimal treatments. Recognizing the difference between doctors and patients approach when confronted to a lupus flare is critical to bridge this gap and increase the effectiveness of jointly agreed treatment plans.

Objectives: Identify potential discrepancies between patient and doctors discussion starting points when facing a lupus flare. Are they “talking the same thing”? “do they have similar concerns in their minds?”

Methods: As part of the SL Euro lupus 2022 congress 57 participants, doctors and patients, took part in a speed-workshop to identify first what “makes them identify an event as a lupus flare” and then their “key concerns when facing a lupus flare! Answers were provided on post-its of different colours per type of participants, forcing short answers focusing on key aspects. The commonalities and discrepancies were then identified for further handling.

Results: A total of 57 statements identifying a lupus flare were collected and classified assessable (visible/ measurable) items, or specific symptoms. The results highlighted that the communication difficulty between patients and doctors starts from the very feeling of what a flare is. 91% of patients include in their recognition of a flare a factor that cannot be “easily” objectivated by a doctor such as fatigue (59.1%), or pain (50%). Only 36% of patients include an externally visible factors, mostly often fever. In contrast, 88% of doctors require an externally visible/measurable factor to “identify” a flare. These 2 different starting points can create a first communication gap, as well as a difference in the qualification of an event as a flare or not. A total of 93 concerns, sorted in “huge; “big;” or “mid” were collected from participants. These items could be classified in 4 key groups: concerns around daily life & logistics; overall anxiety; symptoms and medication. When confronted to an event considered as a flare, patients have a perspective focusing on the impact of flares on their daily life and logistics (35% of huge concerns, 30% of all concerns), and face anxiety over disease/life in the future (30% of all concerns 19% of huge concerns); on the contrary the doctor’s focus is on symptoms (67% of huge concerns, 46% of all concerns) and medications (29% of all concerns), with only 7% of the doctors focusing on the patients “immediate” daily life/logistics issues, and 18% on anxiety. This discrepancy of concern also hinders the patient-doctor communication.

Conclusion: Doctors and Patients starting points and concerns with regards to a lupus flare appear perfectly logical and fitting each individual’s role in the relationship, with the doctor’s primarily focused on the disease, and the patient on “how to live with it” However this different view may create an initial gap which needs to be bridged to enhance the therapeutic relationship. Acknowledging the existence of this gap is likely a first step towards an improved patient-doctor communication.

POS0172 ARTERIAL STIFFNESS IN ANTIPHOSPHOLIPID SYNDROME: COMPARISON WITH DIABETES MELLITUS AND HEALTHY CONTROLS

Keywords: Anti-phospholipid syndrome, Cardiovascular disease

G. Evangelatou1,2, G. Konstantonis1, N. Tentolouris1, P. Stilakis1,2, M. Tektonidou1,2, 1Medical School, National and Kapodistrian University of Athens, First Department of Propaedeutic Internal Medicine, Athens, Greece; 2Medical School, National and Kapodistrian University of Athens, Joint Academic Rheumatology Program, Athens, Greece

Background: Patients with Antiphospholipid Syndrome (APS) carry an increased burden of cardiovascular morbidity and mortality and have higher prevalence of traditional cardiovascular risk factors (CVRFs) and subclinical atherosclerosis [1]. Arterial stiffness (AS) has emerged as an independent predictor of future cardiovascular events and death in the general population, beyond the effect of traditional CVRFs [2].

Disclosure of Interests: Mia Rodziewicz: None declared, Sarah Dyball: None declared, Emily Sutton: None declared, Stephen McDonald: None declared, Ben Parker: None declared, Ian N. Bruce Speakers bureau: GSK Astra Zeneca Janssen, Consultant of: GSK Astra Zeneca Aurinia Lilly, Grant/research support from: GSK Astra Zeneca Janssen.

DOI: 10.1136/annrheumdis-2023-eular.3779
Objectives: We aimed to compare ArS measures in thrombotic APS patients and age- and sex-matched patients with diabetes mellitus (DM) and healthy controls (HC), and identify potential predictors of increased ArS in patients with APS.

Methods: ArS was evaluated by carotid-femoral Pulse Wave Velocity (cPWV) and Augmentation Index normalized to 75 beats per minute (AIx@75) using the SphygmoCor device. All participants also underwent ultrasound examination of the carotid and femoral arteries for the detection of atherosclerotic plaques. Multivariate analysis was applied for comparing ArS measures between groups and for the assessment of ArS predictors in the APS group.

Results: One-hundred and ten APS patients (70.9% female, mean age: 45.4 years), and equal numbers of DM patients and HC were included. After adjustment for age, sex, traditional CVRFs and atherosclerotic plaque presence, APS exhibited similar cPWV (p=0.456) but increased AIx@75 (beta=4.640, 1.668-7.611, p=0.002) versus HC. APS patients had lower cPWV (p<0.001) but similar AIx@75, (p=0.150) compared to DM patients. Using multiple linear regression analysis, cPWV in APS group was independently associated with age (beta=0.095, 0.043-0.178, p<0.001), mean arterial pressure (MAP) (beta=0.070, 0.043-0.097, p<0.001), atherosclerotic plaques in femoral arteries (beta=0.732, 0.035-1.141, p=0.035) and anti-β2GPI IgM positivity (beta=0.696, 0.201-1.191, p=0.006). AIx@75 was associated with age (beta=-0.334, 0.117-0.551, p=0.003), female sex (beta=-7.447, 2.312-12.581, p=0.005) and MAP (beta=-0.425, 0.187-0.663, p=0.001).

Conclusion: Patients with APS exhibit comparable cPWV to healthy individuals but elevated AIx@75, similar to DM, implying impaired vascular health in APS. Age, female sex, MAP, atherosclerotic plaques and anti-β2GPI IgM are linked with enhanced arterial stiffening in APS. Given its prognostic value, ArS evaluation may help to improve cardiovascular risk stratification in APS patients.

POS0174

THE IMPACT OF DIFFERENT DMARDs ON MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PREVALENT INTERSTITIAL LUNG DISEASE

Keywords: Disease-modifying Drugs (DMARDs), Lungs, Rheumatoid arthritis

T. Rudi1, V. Zietemann1, M. Schaefer1, Y. Meissner1, A. Zink2, A. Krause3, Anne T., 4University Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin, Germany; 4Scientific Advisory Board, RABBIT, Berlin, Germany; 1Innemuel Krankenhaus, Rheumatology, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Berlin, Germany

Background: Intersitial lung disease (ILD) is one of the most common extra-articular manifestations of rheumatoid arthritis (RA) with a high mortality risk. Only few studies examined the association between RA treatment and mortality in patients with RA-ILD, and these studies do not include all available DMARDs and tend to be of poor quality [1].

Objectives: To investigate the impact of treatment on all-cause mortality in patients with RA-ILD taking inflammation, traditional risk factors and comorbidities into account.

Methods: RA patients enrolled and observed in the biologics register RABBIT between 01/2007 and 10/2021 with an ILD, reported either at enrolment or during follow-up, were selected for the analysis. Observation started at the time of ILD reporting (= baseline) death, dropout or end of follow-up, whichever came first. Time-varying cox regression (= main model) was applied, taking into account all treatment exposures and covariates on a monthly basis (Figure 1). Sensitivity analyses comprised two alternative treatment exposures: a cumulative model (calculated as cumulative exposure in months for every treatment divided by total months of observation time), and an intention-to-treat model (treatment at baseline as exposure). Missing data was imputed 10 times. All models were adjusted by inverse probability weighting and number of comorbidities as covariate.

Results: Out of 15,566 cohort participants, 381 patients were identified as prevalent ILD cases. The total observed time was 1,258 person years, and 97 patients (25 %) died. Patients exposed to T cell co-stimulation modulator (T cell), B cell targeted therapy (B cell), and Janus kinase inhibitors (JAKi) had higher RA disease scores and multiple comorbidities (Table 1).

Conclusion: To our knowledge, this is the first study to investigate the risk of all-cause mortality in RA-ILD for all available DMARD treatments jointly, using month-level data. In accordance with the few existing recommendations and studies, all non-TNFi-biologics as well as JAKi showed a protective signal compared to TNFi in all three regression models. Furthermore, patients who did not receive any DMARD had an increased risk of mortality. However, the study sample size was small, the results should thus be interpreted with caution.

“DO DISEASE MODIFYING ANTIRHEUMATIC DRUGS INFLUENCE THE FRACTURE RISK IN RHEUMATOID ARTHRITIS?” THE HUNT STUDY, NORWAY

Keywords: Epidemiology, bDMARD, Rheumatoid arthritis

I. Tronstad1,2, M. Hof1,3, J. Horn1, S. A. Vikjord1,2, V. Videon5,7, T. Nilsen6,9, A. Langhammer1,10, 1,Norwegian University of Science and Technology, HUNT Research Centre, Department of Public Health and Nursing, Trondheim, Norway; 2,Levanger Hospital, Department of Medicine and Rehabilitation, Levanger, Norway; 3,Norwegian University of Science and Technology, Department of Neurorheumatism and Movement Science, Trondheim, Norway; 4,St. Olav’s University Hospital, Department of Rheumatology, Trondheim, Norway; 5,Levanger Hospital, Department of Obstetrics and Gynecology, Levanger, Norway; 6,Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Trondheim, Norway; 7,St. Olav’s University
Background: Rheumatoid arthritis (RA) is associated with reduced bone mineral density and increased fracture risk. Bone sparing properties are reported for biological (b) disease-modifying antirheumatic drugs (DMARDs) (1), but previous studies have not found bDMARDs to reduce fracture risk (2). Knowledge is sparse regarding fracture risk in individuals with RA using different types of DMARDs compared to the general population.

Objectives: To investigate the effect of RA on fracture risk, and examine if bDMARD treatment influences this association.

Methods: The Trøndelag Health Study (HUNT) is a population-based longitudinal study in central Norway. We included all participants who had attended at least one of the last three HUNT surveys, using the first participation as baseline. RA status was obtained by linkage to the patient records at the regional hospital using International Classification of Disease codes (ICD9 and 10) for Major Osteoporotic Fractures (MOF), as well as further validation of medical records regarding date of RA diagnosis and use of DMARDs (divided into the following groups: never DMARDs, conventional synthetic(cs) DMARDs only, or ever bDMARDs). All RA diagnoses were validated according to American College of Rheumatology (2010) criteria.

RESULTS: RA status was registered at baseline and updated if RA was diagnosed later. Participants were followed until the first MOF, death, emigration, or end of follow-up on 21.10.2021. Cox regression was used to estimate hazard ratios (HR) for MOF in RA participants in general and by treatment group, compared to the people without RA. Confounders were identified using directed acyclic graphs (DAGs) and included sex, age at inclusion and smoking status at baseline.

Table 1. RA independent of treatment was associated with almost 50% increased risk of MOF compared to non-RA (HR 1.44). By treatment group, never DMARDs had highest risk of MOF, followed by csDMARDs. Risk increased 8.8% compared to non-RA (HR 1.13). By treatment group missing for 19 RA participants including 2 individuals with a MOF.

Adjusted for age at inclusion, sex, and smoking status at baseline. CI: confidence interval. DMARDs group missing for 19 RA participants including 2 individuals with a MOF. RA independent of treatment was associated with almost 50% increased risk of MOF compared to non-RA (HR 1.44). By treatment group, never DMARDs had highest risk of MOF, followed by csDMARDs. Treatment with bDMARDs was not associated with MOF. Incidence rates (IR) per 1000 person-years were higher in RA overall and in all DMARD treatment groups compared to non-RA.

Conclusion: RA was associated with MOF. However, in RA individuals treated with bDMARDs, an association with MOF was not seen. This is an encouraging result and might be of importance when evaluation future treatment regimens in this patient group.

DOI: 10.1136/annrheumdis-2023-eular.2012.
Background: Rituximab (RTX) is a safe and effective treatment for rheumatoid arthritis (RA). In The Netherlands, RTX is usually administered intravenously every six months in standard low dose (250 mg or 1000 mg). Ultra-low doses (1x500 or 1x200 mg every six months) have shown to be effective as well for continued treatment for RA patients who are in remission.[1] Despite its efficacy and safety, there are some concerns about infection risk for RTX. Preliminary data suggest a dose and time dependent infection risk with a higher risk in higher doses and shortly after infusion.[1,2]

Objectives: The aim of this study was to compare infection incidence rates (IRs) in a real-life population of RA patients between standard low or ultra-low dosed RTX, with an additional focus on time since last infusion.

Methods: RA patients treated with standard low or ultra-low dosed RTX in the Sint Maartenskliniek (The Netherlands) between 2012 and 2021 were included in this retrospective cohort study. Patient-, disease- and treatment characteristics were retrieved from electronic health records. Infections within 30 days after vaccination were considered as one RTX treatment. As RTX is usually given every six months, only infections occurring within 6 months after administration were included. In absence of the exact date of an infection, the start date was imputed using single imputation based on the known start week, month or period of infection. Infection IRs, dose-dependency and time relations with RTX infusions were analyzed using mixed-effects Poisson regression with correction for confounders. After Bonferroni correction, results were considered statistically significant if p<0.025.

Results: Among 490 patients followed for 1254 patient years, 819 infections were identified (65/100 patient years). Most infections were mild (89%) and resolved rapidly.

Conclusion: Ultra-low dosing, and especially 200 mg, of RTX is associated with lower infection risk in addition to reducing costs and administration time. In clinical practice, physicians should consider offering 500 mg and especially 200 mg RTX dosage to RA patients in sustained remission, instead of continuing the 1000mg dosage.

</table>
at moment of DAS28 measurement), seropositivity for ACPA and/or rheumatoid factor and sex as potential confounders. The mean percentage of the rituximab Daily Defined Dose (%DDD) per treatment period was calculated as secondary outcome, with 1000mg/6months as 100% reference.

**Results:** A total of 387 patients were included in the cohort, with a mean of 9.2 DAS28-CRP measurements (SD: 6.0) available per patient. Median follow-up time was 46 months (IQR: 25-78). 299 patients attempted tapering during follow-up and entered period 2 at least once, of whom 226 also entered period 3. The mean DAS28-CRP was 2.37 (95% CI: 2.29, 2.44) for period 1, 2.32 (95% CI: 2.24, 2.40) for period 2, and 2.27 (95% CI: 2.18, 2.36) for period 3, the latter significantly lower compared to period 1 (p<0.002). The mean percentage of the DDD for the three time periods was 111% for the continuation period; 64% in the DAGO period and 71% in the stable RTX dosage period.

**Conclusion:** This relatively large retrospective cohort study shows that DAGO of RTX is effective for rheumatoid arthritis patients doing well on full dose rituximab, and leads to relevant dose reduction. The lower mean disease activity scores in period 3 may be affected by survival bias, as solely patients using RTX imab, and leads to relevant dose reduction. The lower mean disease activity was significantly lower compared to period 1 (p<0.002). The mean percentage of the DDD for the three time periods was 111% for the continuation period; 64% in the DAGO period and 71% in the stable RTX dosage period.

Background: The approval by medicines regulatory agencies of new therapeutic agents in rheumatoid arthritis (RA) is based on results of Phase III randomized controlled trials. The RA trials have been mainly used ACR20 response as primary endpoint. Conversely, this outcome is not clinically relevant for significant improvement of patient’s quality of life.

Objectives: We aimed to explore the surrogacy between ACR20 and ACR70 in rheumatoid arthritis.

Methods: We performed a systematic review by searching randomized clinical trials registered in MEDLINE, EMBASE and the Cochrane Library between January 1990 and June 2021. We included all randomized trials (phase I and III trials, including multiarm design) that compared biotherapies or JAK inhibitors with csDMARDS or placebo with available ACR20 and ACR70 response. The coefficient of determination R²trial between these two outcomes were estimated using weighted meta-regression. To validate the surrogacy, the coefficient of determination (R²trial) should be superior than 0.65 and close to 1.

Results: We included 189 randomized trials totaling 81,734 patients. Using 322 coefficients, the comparison of determination R²trial for estimating the relation between ACR20 on ACR70 responses is 0.55 (95% prediction interval 0.47-0.63). In subgroup analyses, the R²trial for the anti-TNF therapeutic class was 0.69 (95% prediction interval 0.56-0.78). The R²trial in other subgroup analyses (double-blind design, superiority studies, multicentric studies, year of publication, corticosteroid use, small-study effect, and other therapeutic classes) were not relevant for surrogacy.

Conclusion: There is no surrogacy between ACR20 and ACR70 in RA. The use of ACR20 as primary outcomes should be limited to phase II trials and is not relevant for health technology assessment of benefit-risk ratio.

THE IMPACT OF AUTOANTIBODIES (RF AND ACPA) ON THE EFFICACY OF BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS: META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Keywords: Outcome measures, bDMARD, Rheumatoid arthritis

University Graduate School of Medicine, Department of Stem Cell and Immune Regulation, Yokohama, Japan; 2Leiden University Medical Center, Department of Biomedical Data Sciences, Leiden, Netherlands; 3University of Leeds, Chapel Allerton Hospital, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 4Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 5Goethe University, CIRI/Rheumatology and Fraunhofer Institute, Translational Medicine and Pharmacology ITMP, Frankfurt, Germany; 6Solna, Karolinska Institutet, Division of Clinical Epidemiology, Department of Medicine, Stockholm, Sweden; 7University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland; 8Charité-Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 9University of Helsinki and Helsinki University Hospital, Department of Rheumatology, Helsinki, Finland; 10Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; 11Amsterdam Rheumatology Center, Department of Clinical Immunology & Rheumatology, Amsterdam, Netherlands; 12Zuyderland Medical Centre, Department of Rheumatology, Heerlen, Netherlands

Background: The impact of autoantibodies on the efficacy of biological disease-modifying antirheumatic drugs (bDMARDs) in patients with rheumatoid arthritis (RA) is not yet clear. Despite the fact that this information has been collected by several randomized controlled trials (RCTs), efficacy data for seropositive and seronegative patients separately have generally not been published.

Objectives: To comprehensively investigate the efficacy of bDMARDs in patients with RA with RF/ACPA compared to patients without these autoantibodies.

Methods: Previous systematic literature reviews performed by EULAR RA management task forces were searched for relevant RCTs published before February 2023. RCTs including both autoantibody-positive (≥80% of total population) and -negative RA patient populations were included and the corresponding or sponsored RCTs to report aggregate results from analyses of individual patient data on clinical efficacy outcomes stratified for the presence of autoantibodies (RF+ vs RF−, ACPA+ vs ACPA−). Per trial, relative risks (RR) or mean differences comparing two groups (RF+ vs RF−, ACPA+ vs ACPA−) were calculated for various outcomes (ACR 20/50/70, DAS28 remission, delta DAS28, delta HAQ and radiographic progression) at the timing of the primary endpoint for the bDMARD-arm and the non-bDMARD-arm separately. Subsequently, relative risk ratios (RRRs) were computed, as the ratio of RR of the bDMARD-arm and the RR from the non-bDMARD-treated arm, reflecting whether serositivity preferentially affected treatment response to bDMARD therapy. A meta-analysis was conducted using a mixed-effect meta-regression in subgroups of patients according to baseline autoantibody status.

Results: Data from 28 eligible RCTs were analyzed and from 23 pooled: 6 including csDMARD-naive patients, 14 including csDMARD-inadequate responders (csDMARD-IR) and 3 including tumor necrosis factor inhibitor (TNFi)-IR patients. In csDMARD-naive and csDMARD-IR, serositivity was not associated with a better response to bDMARDs: Pooled 6-month ACR20 RRRs were 1.02 (0.88-1.18) and 1.09 (0.90-1.32), respectively (Figure 1A and B). Other outcomes followed the same pattern, with no difference between the groups. In TNFi-IR patients, based on 3 trials, the 6-month ACR20 RRR was 2.28 (1.31-3.95) (Figure 1C), favoring efficacy in seropositive patients. Other outcomes showed a similar effect, although with large confidence intervals and several reflecting a non-significant difference between the groups (Table 1).

Conclusion: In csDMARD-naive and csDMARD-IR patients, autoantibodies did not have an impact on the efficacy of bDMARDs in RA. In TNFi-IR patients, there is a possible higher efficacy of bDMARDs in the seropositive group, but the low number of trials, large confidence intervals and inconsistent results across outcomes ask for caution in the interpretation. Serosenegative TNFi-IR patients may have very heterogeneous underlying pathophysiological mechanisms, with a lower probability of good treatment response. Overall, in less treatment-resistant patients, the presence of autoantibodies was not associated with the treatment effect of bDMARDs.

Figure 1. Forest plot for the Relative Risk Ratio for ACR20 at 6 months comparing RF+/RF− in bDMARD+vs csDMARD vs RF+/RF− in csDMARD.
Rituximab for RA and applied them to our population. We compared the EULAR response (moderate-to-good) at 12 months and the incidence of serious adverse events (AEs, including severe infections, malignancies, major adverse cardiovascular events, and death) at 12 months between eligible and non-eligible patients. We modeled the risk-benefit ratios according to the number of fulfilled critical eligibility, defined by those associated with response and severe AEs, respectively, after backward stepwise variable elimination.

Results: Among 1989 RA patients included in the AIR registry, only 9 to 12% fulfilled all main eligibility criteria for the 3 drug-registration trials. The main unfulfilled inclusion criteria were an elevated CRP or ESR level (67.3%), erosive changes on bone X-ray (68.1%), and a swollen joints count ≥4/28 (74.6%). The main exclusion reasons were a history of severe or recurrent infection (35%), another severe uncontrolled disease (16%), neoplasia (14%), a high prednisone dose (>10 mg/day for 26%), the use of another DMARD than methotrexate (16%) and ACR functional class IV disease (15%). Compared with RCT-eligible patients, non-eligible patients had less frequently moderate-to-good EULAR response (40.3% versus 46.9%, P=0.044), and had a smaller change in DAS-28 (~1.2 vs -1.4; 95% CI 0.1 to 0.5; P=0.006) at 12 months. Compared to patients with no exclusion criterion, patients with at least one critical exclusion criterion had a higher risk of severe AEs (HR 3.03, 95% CI 2.25–4.06 for ≥ 3 exclusion criteria compared to none). While the probability of EULAR response decreased with the number of unmet critical inclusion criteria, the probability of severe AEs increased with the number of exclusion criteria (Figure 1), highly decreasing the incremental risk-benefit ratio.

Conclusion: Few RA patients treated with rituximab fulfilled the eligibility criteria of the main drug-registration trials. Non-eligible patients had less chance of treatment response, and a higher risk of severe adverse events. This suggests that the efficacy and safety data from those trials cannot be extrapolated to RA patients in daily practice.

Background: Most randomized clinical trials (RCTs) are explanatory studies examining whether a therapy can work under ideal circumstances. Rituximab (RTX) has been approved for treatment of rheumatoid arthritis (RA) following the results of three RCTs [1–3], including about 1000 patients. However, less than 10% of real-life patients was found to be eligible to these registration trials, because of restrictive inclusion criteria or exclusion criteria such as co-morbidities or undesired co-medication, which questions external validity of these RCTs. Whether the efficacy, tolerance or safety data obtained in highly selected RCTs patients can be extrapolated to a more heterogeneous sample of patients receiving RTX in daily practice, remains to be elucidated.

Objectives: We aimed to identify the main reasons limiting the eligibility of routine care patients in RTX-registration RCTs, and to investigate the relationships between the number of eligibility (both inclusion and exclusion) criteria and RTX efficacy and safety in a real-life scenario.

Methods: The AIR registry is a French nationwide, multicentre, prospective cohort study aiming at investigating efficacy and safety of RTX in a real-life setting. We retrieved eligibility criteria of the drug-registration trials evaluating rituximab for RA and applied them to our population. We compared the EULAR response (moderate-to-good) at 12 months and the incidence of serious adverse events (AEs, including severe infections, malignancies, major adverse cardiovascular events, and death) at 12 months between eligible and non-eligible patients. We modeled the risk-benefit ratios according to the number of fulfilled critical eligibility, defined by those associated with response and severe AEs, respectively, after backward stepwise variable elimination.

Results: Among 1989 RA patients included in the AIR registry, only 9 to 12% fulfilled all main eligibility criteria for the 3 drug-registration trials. The main unfulfilled inclusion criteria were an elevated CRP or ESR level (67.3%), erosive changes on bone X-ray (68.1%), and a swollen joints count ≥4/28 (74.6%). The main exclusion reasons were a history of severe or recurrent infection (35%), another severe uncontrolled disease (16%), neoplasia (14%), a high prednisone dose (>10 mg/day for 26%), the use of another DMARD than methotrexate (16%) and ACR functional class IV disease (15%). Compared with RCT-eligible patients, non-eligible patients had less frequently moderate-to-good EULAR response (40.3% versus 46.9%, P=0.044), and had a smaller change in DAS-28 (~1.2 vs -1.4; 95% CI 0.1 to 0.5; P=0.006) at 12 months. Compared to patients with no exclusion criterion, patients with at least one critical exclusion criterion had a higher risk of severe AEs (HR 3.03, 95% CI 2.25–4.06 for ≥ 3 exclusion criteria compared to none). While the probability of EULAR response decreased with the number of unmet critical inclusion criteria, the probability of severe AEs increased with the number of exclusion criteria (Figure 1), highly decreasing the incremental risk-benefit ratio.

Conclusion: Few RA patients treated with rituximab fulfilled the eligibility criteria of the main drug-registration trials. All about Crystal arthritis II

The updated cardiovascular risk estimation scale SCORE2 does not improve the precision in predicting cardiovascular events in patients with gout

Keywords:
- Crystal arthritis

M. D. C. López González1, E. Tovar-Sugrañes2, C. Rodríguez Alvear1, E. Perea Martínez3, M. Monzo4, A. Avilés5, M. Andrés6

Hospital General Universitario Dr. Balmis-ISABIAL, Rheumatology, Alicante, Spain; 2Hospital Universitario y Politécnico La Fe- IIS La Fe, Rheumatology, Valencia, Spain; 3Hospital Marina Baixa, Gynecology and Obstetrics, Villajoyosa, Spain

Background:
Cardiovascular (CV) risk in gout is increased due to the accumulation of CV risk factors and persistent inflammation. Therefore, it is necessary to have precise evaluation strategies to categorize the risk of patients with gout in order to optimize their treatment. In previous studies, we have seen that the usual prediction scales SCORE and Framingham Heart Study are not accurate in detecting patients with gout and carotid atheroma plaques (PMID 28093417). The SCORE2 version, an update of the SCORE tool, performed similarly in predicting the presence of those plaques [1], although it remains unknown its predictive capacity of CV events in patients with gout.

Objectives:
To evaluate the precision of SCORE2 in predicting CV events in patients with gout, with a comparison with prior SCORE and Framingham Heart Study tools.

Methods:
We conducted a retrospective post-hoc study on new patients with crystal-proven gout, from our inception cohort focused on evaluating their CV risk. The recruitment period was 2014-2018. For the present analysis, we selected patients eligible for SCORE2 calculation (without established CV disease, diabetes with vascular involvement or severe renal disease), and we collected the occurrence of a first major CV event (stroke, acute myocardial infarction (AMI), congestive heart failure (CHF), peripheral artery disease (PAD), and CV death) from their electronic records, occurring from study inclusion up to the event, end of follow-up or 03/31/2022. We calculated their incidence rate (IR) and evaluated the predictive capacity of CV events for SCORE2, SCORE and REGICOR (Framingham equation calibrated for the Spanish population) (PMID: 2622995) tools using a Cox regression model that allows to estimate their hazard ratio with 95% confidence intervals (CI).

Results:
The initial sample of 356 patients, 193 (54.2%) were selected for this analysis. They were mainly men (94.8%) of middle age (average 56.8 years), with an average of 8.2 years since the first gout flare. Almost all patients originate from low CV risk geographical regions, but only 32 patients (16.8%) classified at high risk by SCORE2. The median follow-up time was 6.4 years (25-75 5.1-7.1). During the follow-up, 10 patients had a first CV event (3 cases of stroke, 2 of AMI, 2 of CHF, 2 of PA, and one patient died from a CV cause). The IR of CV events in this subset was 0.83 cases per 100 patient-years. In terms of predicting CV events in patients with gout, the SCORE2 tool did not show a better performance than the SCORE and REGICOR (Framingham) tools (Table 1).

Conclusion: The SCORE2 tool signifies no improvement on accurately predicting CV events in patients with gout compared to previous SCORE and Framingham Heart Study scales. Our data should be replicated in regions with higher CV risk estimates.

U-shaped association of serum urate with all-cause mortality in gout patients: NHANES 2007-2018

Keywords:
- Gout

N. Chen1, Q. H. Li2, S. X. Hu3, H. Lin1, L. Dai2, 1Sun Yat-Sen University, Zhongshan School of Medicine, Guangzhou, China; 2Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China

Background:
The EULAR guideline for the management of gout recommended a target serum urate (sUA) level of less than 6 mg/dl in gout patients and less than 5 mg/dl in tophaceous gout patients [1]. This recommendation is based on the evidence that achieving these targets will reduce gout attacks and tophi size. However, less is known about the impact of sUA on mortality in gout patients.

Objectives:
To explore the relationship between sUA level and all-cause mortality in gout patients.

Methods:
The present prospective cohort study included participants 20 years or older with gout enrolled from the 2007-2008 through 2017-2018 annual NHANES cycles. The data of mortality and its underlying causes to 31 December 2019 were obtained from the National Death Index records. The relationship of gout patients between sUA level and mortality were analyzed by Cox proportional hazards analysis, the restricted cubic spline regression analysis and two piece-wise regression model.

Results:
A total of 1442 gout patients were included with median follow-up period 63 (interquartile range, 33-102) months. Compared with gout patients with sUA less than 6mg/dl, gout patients with sUA>6mg/dl were characterized by greater age, more often men, higher BMI and higher prevalence of hyperlipidemia (P<0.05). Cox proportional hazards analysis showed that sUA was a risk factor of mortality (HR 1.09, 95% CI 1.02 to 1.16) after adjusted by age, sex, race, education, BMI, smoking, cardiovascular disease, hyperlipidemia, hypertension and diabetes mellitus. However, restricted cubic spline regression analysis showed a U-shaped relationship between sUA and all-cause mortality (Pnon-linear <0.001, Figure 1). Two piece-wise regression model revealed sUA level of 6.2 mg/dl corresponded to the lowest mortality risk. For those patients with sUA less than 6mg/dl, the risk of all-cause death was borderline reduced 12% (HR 0.88, 95% CI 0.72 to 1.07) with each sUA unit increase. After 6mg/dl, the risk of all-cause death increased 26% (HR 1.26, 95% CI 1.14 to 1.40) for each sUA unit increase.

Conclusion: There is a U-shaped association of sUA with all-cause mortality in gout patients. Target sUA of less than 6 mg/dl is rational as it corresponds to the interval of lowest mortality. Randomized trials with mortality as an endpoint are warranted to determine target sUA for gout patients.

**SYSTEMIC IMMUNE-INFLAMMATION INDEX TO ALL-CAUSE MORTALITY IN GOUT PATIENTS: NHANES 2007-2018**

**Keywords:** Crystal Arthritis

H. Lin1, N. Chen1, S. X. Hu1, Q. H. Li2, 3Sun Yat-Sen University, Zhongshan School of Medicine, Guangzhou, China; 3Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China

**Background:** Systemic immune inflammatory index (SII) is a new marker of inflammation. SII is associated with increased cancer risk and mortality in cardiovascular and cancer patients. However, the effect of SII on mortality in gout patients is rarely reported in the literature.

**Objectives:** To study the relationship between SII level and all-cause mortality in gout patients.

**Methods:** This prospective cohort study included participants 20 years or older with gout enrolled from the 2007-2008 through 2017-2018 annual NHANES cycles. The data of mortality and its underlying causes to 31 December 2019 were obtained from the National Death Index records. The SII level was calculated as the platelet counts x neutrophil counts/lymphocyte counts. Gout patients were grouped according to low, middle, and high tertile of SII. Generalized linear regression was used to study variables influencing SII. The relationship between SII level and mortality were analyzed by Cox proportional hazards analysis.

**Results:** A total of 1334 gout patients were included with median follow-up time 68 months (34 months, 106 months). As shown in the Table 1, gout patients with high SII level were characterized by more having chronic kidney diseases, diabetes mellitus and less fiber intake (P<0.05). The generalized linear model found that SII level was positively correlated with diabetes mellitus (P<0.05), and negatively correlated with men, eGFR, fiber intake (P<0.05). Kaplan Meier survival curve showed that mortality was highest in the high SII group (Figure 1). Cox proportional hazards analysis after multivariable adjustment showed that taking low SII group as the reference group, mortality was elevated in the high SII groups (Table 1).

**Conclusion:** High SII is a predictor of all-cause death in gout patients.

**OBSTRUCTIVE SLEEP APNEA: A CONTRIBUTING FACTOR IN GOUT?**

**Keywords:** Epidemiology, Comorbidities, Gout

P. Khandwala1, D. Desai2, M. Sen1, 1Einstein Medical Center Philadelphia, Rheumatology, Philadelphia, United States of America; 2Einstein Medical Center Philadelphia, Hospice and Palliative Medicine, Philadelphia, United States of America

**Background:** As per World Health Organization, 7.44 million cases of gout were estimated globally in 2017 (incidence, 0.097%), with a prevalence of 4.12 million cases (0.54%).[1] Obstructive sleep apnea (OSA) is a co-morbidity that has shared risk factors with gout as well as causes pathophysiological mechanisms causing hyperuricemia. The relationship remains contentious. There have been studies, mainly in the UK, which have shown 1.5 times increased risk of gout in patients with OSA[2,3]. While the study by Durme et al shows that the association disappears after statistical adjustment for BMI, renal function, heart failure, and use of diuretics.[4] Thus, it becomes vital to contribute to the existing literature to investigate this relationship further.

**Objectives:** The aim of the study is to understand the relationship between OSA and Gout.

**Methods:** TrinetX, a global federated research network that provides a dataset of electronic medical records from different healthcare organizations (HCOs), was utilized. Initial query was made to isolate patients who had a BMI greater than 30 and then 2 groups were made on the presence or absence of OSA. Further, propensity score matching (PSM) was carried out to match age, sex, race, chronic kidney disease, heart failure, and use of diuretics. Compare outcome analytic function was utilized to map the co-relation with Gout.

**Results:** A total of 3,541,566 patients who had a BMI>30 were identified, out of which 817,638 (23.09%) patients had OSA. Patients in OSA group were older as compared to patients in non-OSA group (59.8 ± 14.3 years vs 54 ± 17.2 years). Females made up 50% of the OSA group while they were predominant (65%) in the non-OSA group. Caucasians were the predominant race, followed by African
Americans. 7.19% of patients with OSA had Gout, while 2.84% without OSA had gout (p<0.0001). The odds of having gout is 2.65 times higher in patients with OSA than patients without OSA (hazard ratio is 2.393, 95% confidence interval (CI) 2.367-2.409, p<0.0001). After PSM, both groups had 801,526 patients. 6.93% patients with OSA had gout while 4.63% of patients without OSA had gout (p<0.0001). Odds ratio =1.533, (95% CI 1.512 - 1.554, p<0.0001) and hazard ratio was 1.404 (95% CI 1.386-1.423).

Conclusion: Our study demonstrated that there is a strong correlation between Gout and OSA. Hypoxia-induced hyperuricemia is the most widespread explanation. However, there are many confounding factors that prompt us to carry out matching for demographics and, more importantly for chronic kidney disease, heart failure as well as the use of diuretics. Statistically significant odds ratio after matching attests to the fact that there is a robust correlation between gout and OSA. Limitation of this study was the lack of testing of this hypothesis on patients with BMI>30. Prospective cohort studies are required to further test the strength of this relationship between OSA and Gout.

HEPATIC STEATOSIS AND FIBROSIS IN PATIENTS WITH GOUT DETECTED BY ELASTOGRAPHY

Keywords: Imaging, Comorbidities, Gout

N. Schlesinger1, A. Patel2, V. Rustgi3, A. Yeo4, P. Lipsky5, S. Spencer Fox Eccles School of Medicine, University of Utah, Medicine, Salt Lake City, United States of America; 2Rutgers, Medicine, New Brunswick, United States of America; 3University of Southern California, School of Medicine, New Brunswick, United States of America; 4University of Sidney, health economics, Sidney, Australia; 5AMPel Biosolutions, AMPel Biosolutions, Charlottesville.

Background: Gout is associated with non-alcoholic fatty liver disease (NAFLD), but neither the frequency nor severity of NAFLD in gout is well described. Elastography should confirm the actual frequency of NAFLD in gout and provide new insight regarding the comorbidity between the two diseases.

Methods: A total of 2,438 men (mean age, 57.3 years) and 2,511 women (mean age, 57.4 years) were included. Urate levels were higher in men than in women (mean levels, 348 vs 270 µmol/L, respectively). Hyperuricemia was more common in men than in women (18% vs 2%). Age, BMI, and hypertension showed no differences between men and women, while diabetes and dyslipidemia were more common in men than in women (4% vs 2% and 13% vs 9%, respectively). Any CTA-detected atherosclerosis (SIS>0) was found in 1,404 (57.6%) men and 1,067 (42.4%) women. The association between hyperuricemia and SIS was assessed by multivariate logistic regression analysis. We calculated Odds ratios (OR) and 95% confidence intervals (CI), crude and with adjustments for age, smoking, body mass index (BMI), diabetes, dyslipidemia, and hypertension. A SIS score >0 was considered to indicate the presence of coronary atherosclerosis and was used as the cutoff value.

Results: When 2,438 men (mean age, 57.3 years) and 2,511 women (mean age, 57.4 years) were included. Urate levels were higher in men than in women (mean levels, 348 vs 270 µmol/L, respectively). Hyperuricemia was more common in men than in women (18% vs 2%). Keywords: Gout, Real-world evidence

Conclusion: The incidence of gout in the UK increased from 1999 to 2013 and then declined afterward. These findings were not observed in early birth cohorts from the year 1999 to the Year 2013 (Figure 1C); however, such a trend was reversed after the Year 2013, with the incidence rate of gout being higher in the early birth cohorts than that in the late birth cohorts (Figure 1D). Similar patterns were observed in men and women.

1IR is per 100 person-years, *28734 pairs in DM groups, 86642 pairs in non-DM groups, CI: confidence interval, DM: diabetes mellitus; HR: hazard ratio; IR: incidence rate; PY: person-years.
findings suggest that some environmental factors occurring after 2013 may play role. Such a downward trend of the risk of gout may continue if these environmental factors are still present.

REFERENCE:

Figure 1. (A) Age rate ratios and the corresponding 95% confidence intervals of gout incidence. The relative risk of each age category compared with the reference age category (57-59) was adjusted for the calendar year and birth cohort. (B) Calendar year rate ratios and 95% confidence intervals of gout incidence. The relative risk of each calendar year compared with the reference calendar year (2008-2010) was adjusted for age and birth cohort. (C) Cohort rate ratios and the corresponding 95% confidence intervals of gout incidence. The relative risk of each birth cohort (1911-1982) compared with the reference birth cohort (1950-1952) was adjusted for age and calendar year.

GENETIC EVIDENCE REVEALS A CAUSAL RELATIONSHIP BETWEEN TRIGLYCERIDE AND GOUT

Keywords: Gout, Genetics/Epigeneics, Lifestyles

X. Yang1,2, Q. Dong1,2, X. Cao1,2, Q. Feng1,2, J. Y. Chen1,2, Q. Yu3, P. F. He3, X. Li1,2, X. Zhang1,2,4,5,6

Background: Gout is caused by hyperuricemia that leads to the formation and deposition of monosodium urate (MSU) crystals, which is characterized by acute episodes of joint inflammation [1]. Epidemiological studies observed increased levels of triglycerides in gout [2,3]. Triglyceride is a kind of adipokine, primarily transported by very low-density lipoprotein. Enriched in very low-density lipoprotein triglycerides was significantly associated with gout in hyperuricemia [2]. However, the causal association between triglycerides and gout remains unclear.

Objectives: This study aims to use a two-sample Mendelian randomization (MR) to examine associations of triglycerides with gout.

Methods: Summary data for triglycerides used in this study were obtained from a large-scale meta-analysis, which included 69,374 participants within the UK Biobank [4]. The gout GWAS datasets were from a large-scale meta-analysis, which included 69,374 participants (2,115 cases and 2,115 controls) from European [5]. We selected genetic variation highly related to triglyceride (P < 5.00E-8, r2>0.001) as the potential instrumental variables. Three MR methods, namely inverse-variance weighted (IVW), weighted median, and MR-Egger, were applied for MR analysis. For sensitivity analysis, we used common statistical methods, namely Cochran’s Q test, MR-Egger intercept analysis, the funnel plot, and the leave-one-out analysis.

Results: After accounting for LD and the harmonization process, the total number of variants included in the MR investigating the effect of triglycerides on gout was 166. Triglycerides were a risk factor for gout (odds ratio (OR)=1.49, 95% confidence interval (CI):1.22-1.82, P=8.16E-05), which was consistent with the MR-Egger (OR=1.40, 95%CI:1.11-1.89, p=2.93E-02). Cochran’s Q test and MR-Egger intercept showed no evidence of heterogeneity and horizontal pleiotropy (MR-Egger- intercept: 0.0025, P=0.583). The leave-one-out analysis also failed to detect any SNPs that may have a disproportional effect (Figure 1).

Conclusion: Triglyceride was a hazard factor for gout, even in the absence of hyperuricemia, suggesting that controlling the level of triglyceride and paying attention to diet may be beneficial to prevent the occurrence of gout.

PARE Poster Tour 2

POS0192-PARE
TOWARDS A NEW APPROACH ON RESEARCH DESIGNS: PATIENTS AND HEALTHCARE PROFESSIONALS CO-CREATING AND CO-DEVELOPING A MOBILE APPLICATION FOR THE SELF-MANAGEMENT OF CHRONIC PAIN IN OSTEOARTHRITIS. THE TOUS INCLUDE PROJECT

Keywords: Self-management, Patient-led research, Osteoarthritis

N. Malliou1, P. Antoniou2, K. Antonopoulou3, A. Mollis2, S. Reppou2, A. Papa2, P. Bamidis2, 1Hellenic League Against Rheumatism ELEANA, Hellenic League Against Rheumatism (HELAR/ELEANA),Thessaloniki, Greece; 2Aristotle University of Thessaloniki AUTH, Medical Physics and Digital Innovation Lab, Thessaloniki, Greece; 3Hellenic League Against Rheumatism (HELAR/ELEANA),Thessaloniki, Greece; 4Aristotle University of Thessaloniki AUTH, Medical Physics and Digital Innovation Lab, Thessaloniki, Greece; 5University of Thessaloniki AUTH, Medical Physics and Digital Innovation Lab, Thessaloniki, Greece;
School of Medicine AUTH, Thessaloniki, Greece; Hellenic League Against Rheumatism ELEANA, Hellenic League Against Rheumatism (HELAR/ ELEANA), Athens, Greece

Background: Treatment options for pain in osteoarthritis (OA) aim to reduce or help patients manage their pain efficiently. According to guidelines non-pharmacological therapies are the first treatment option and pharmacological therapies are the first choice in many cases. Pharmacological options are the first choice and researchers are trying to find better ways for OA pain management for both patients and HCPs.

Objectives: Aim of this presentation is to showcase an innovative research design where patients are involved in a project from the planning phase to the implementation and development phase step by step working together with healthcare professionals. The project itself, TOUS Include, aims to integrate a digital intervention and educational activities into a patient centered mobile health application for both the patients and the healthcare professionals to use to help them better manage chronic pain of osteoarthritis.

Methods: The project is co-designed and co-developed from one phase to another. Phase I used a mixed methods gap analysis leading to the basic unmet needs that both groups, patients and HCPs, had regarding management and treatment of chronic pain of OA. Moving on to phase II, co-creation sessions in groups of patients and HCPs led to the basic scenarios, common mistakes and incorrect pathways that both groups take when dealing with everyday pain in OA. Meanwhile educational videos and webinars have taken place with participation from both groups for patients and HCPs.

Results: For phase III, developing of the virtual patient scenarios for the mobile health application, which will be one of the main features of the digital intervention, using data from phase I and II, results have already shown that there is a gap in patient and HCPs communication. The qualitative analysis of data showed that patients' health literacy could be a reason for that as well as lack of enough time for consultations. Another main point is that both groups use more frequently (32.7%) medication to manage chronic pain of OA rather than a non-pharmacological option such as physiotherapy (21.8%). Finally, analysis showed that both patient (medium=4.92) and HCPs (medium=4.7) thought that participating in co-creative sessions is very important (1=lowest, 5=highest).

Conclusion: This innovative research design has involved patients from day one. Its planning, conceptualization and implementation has been involving patients not only at the receiving end of an intervention but as an integral part of the research team, the design and implementation. The TOUS Include project is a collaboration of patients, patient organizations, a university, a professional health care professionals' society and healthcare professionals. It's quite inclusive, thus an example that could easily showcase how research designs for patients could involve them from beginning to end for the benefit of everyone involved.

TIME TO RESEARCH - STRENGTHENING PATIENT RESEARCH PARTNER 2022

Keywords: Education, Rheumatoid arthritis, Clinical Trials
S. Dotlicic1, M. Kosanovic1. 1”Association of patients with rheumatic diseases of the Republic of Serbia” (ORS), Association of patients, Belgrade, Serbia

Background: In Europe the role of patients is growing significantly. In Serbia it is not a case. Our aim is to create a PRP network to bring research closer to patients. Through this network, trust between rheumatologists/researchers and patients, should be increased. Looking in the countries around, Serbia has the longest waiting period for permits to introduce studies. Involving patients in research activities and their active role will provide better chances for patients to be introduced and treated with innovative drugs. Patient’s perspective is important part of research, their needs, experiences and even doubts will contribute a lot to research. There are more than 70,000 people who suffer from some kind of inflammatory rheumatic diseases (IRD) in Serbia. These diseases are significant burden for our society. There are quite a few innovative drugs in Serbia, but however, innovative drugs are still unavailable for some diagnosis such as Systemic Lupus Erythematosus, Systemic Sclerosis, Vasculitis, Sjogren.

Objectives: The aims of this EULAR campaign were for us to:
- Improve patients education about importance of research in order to increase the availability of innovative drugs with collaboration with Rheumatology Association of Serbia (RAS) and Serbian Association of Health Professionals in Rheumatology (SAHPR)
- Found national PRP network
- Motivate researchers to accept and involve patients in research as equal team member
- Encourage patients to participate/take an active role in research to increase patients’ trust in studies
- Increase the mutual trust between patients and rheumatologists and health professionals.

Methods: Association of Rheumatic Diseases Patients of the Republic of Serbia now have 15 PRPs. They are members of national PRP network in Serbia. ORS improved cooperation with The Association of the manufacturers of innovative drugs INOVIA, with Medicines and Medical Devices Agency of Serbia – ALIMS, with CRA Academy. Director of the Association of Manufacturers of Innovative Medicines INOVIA, and director of CRA Academy invited us from ORS to promote the campaign “Time2Research” on their events in September and December months, ALIMS (Drug and Medical Device Agency) offered its assistance in improving the legislation for PRPs.

Results: Association of Rheumatic Diseases Patients of the Republic of Serbia now have 15 PRPs. They are members of national PRP network in Serbia. ORS improved cooperation with The Association of the manufacturers of innovative drugs INOVIA, with Medicines and Medical Devices Agency of Serbia – ALIMS, with CRA Academy. Director of the Association of Manufacturers of Innovative Medicines INOVIA, and director of CRA Academy invited us from ORS to promote the campaign “Time2Research” on their events in September and December months, ALIMS (Drug and Medical Device Agency) offered its assistance in improving the legislation for PRPs.

Conclusion: As the PRP network is a completely new institution in Serbia we have to explore all the opportunities for its implementation. We are proud that we establish a PRP network of 15 PRPs and we are making a plan how to engage many of them as we can. We want to include our PRPs who know English well in the EULAR PRP network.

PEOPLE WITH AN RMD: MAKING A MEDICATION CHOICE TOGETHER WITH THE HEALTHCARE PROFESSIONALS

Keywords: Outcome measures, Patient reported outcomes, Self-management
B. Porse1, P. Penning2, B. Maat1, R. Van der Knaap3, D. Lewinski3, H. Van de Weijer1, T. Foekens5, L. J. Kranenburg - van Koppen4, A. Pasma5, G. Willemsen-de Mey5. 1National Association ReumaZorg Nederland, Patient expert and Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands; 2National Association ReumaZorg Nederland, Patient partner at the department of Patient participation and Communication, Nijmegen, Netherlands; 3National Association ReumaZorg Nederland, Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands; 4National Association ReumaZorg Nederland, Patient research partner at the department of Patient participation and Communication, Nijmegen, Netherlands; 5Erasmus Medical Centre, Rheumatologist at the Department of Rheumatology, Rotterdam, Netherlands

Background: Research shows that people with Rheumatic and Musculoskeletal Diseases (RMDs), who decide together with their healthcare professionals make better informed treatment choices. They are also more likely to adhere to their treatment or medication use. A consultation aid can help people with an RMD to become aware of their most important preferences and questions about medication. These preferences and questions can set the agenda for a good consultation in the consultation room between the patient and the healthcare professional. Together with the healthcare professional the consultation can focus on the most important benefits, risks and preferences of someone with an RMD, when a medication choice has to be made.
OBJECTIVES:
• To develop conversation aids, that:
  • allow people with an RMD to become aware of the most important preferences
    in making a medication choice
  • guide people with an RMD in how to discuss these most important aspects
    with a healthcare professional
  • To develop conversation aids that guide healthcare professionals in giving
    complete information about:
  • all important aspects of the medication
  • having a rheumatic and musculoskeletal disease (RMD)

This in order to make the best fitting medication choice together.

Methods: In the first step of the process 2 focus groups were organized. The first focus group consisted of patients of the Erasmus Medical Centre (5 participants) and patient research partners (PRPs) of the National Association ReumaZorg Nederland (RZN) (4 participants). The second focus group consisted of RMD health care professionals (5 rheumatologists, 1 pharmacist, 7 RMD nurses). The aim of the focus groups was to get an overview of important information that has to be shared, when a choice in RMD medication is to be made. In the second step, the output of both focus groups formed the starting point for the content of the conversation aids about medication choices. In the conversation aids all important information, that should be shared when a medication choice has to be made, was formulated in simple short sentences. After that, the content of the conversation aids was assessed by participants of both focus groups. In the third step, a draft version of the conversation aids about medication choices was designed. The conversation aids were designed using the same layout as our earlier developed version of the conversation aids about medication choices was designed. The formulated in simple short sentences. After that, the content of the conversation aids was assessed by participants of both focus groups, until we reached a final version.

Results: A total of 4 conversation aids (https://reumazorgnederland.nl/samen-beslissen-medicijnkaarten) were developed.
• Who are you?: To allow people with an RMD to share their preferences with
  regards to shared decision making (SDM), about the way they like to receive
  information and about the way they prefer to take their medication.
• About medication: To allow healthcare professionals to give a complete
  overview of the most important aspects of RMD medication and to allow
  people with an RMD to share their most important questions about RMD
  medication.
• Groups of medication: To give an overview of the different groups of RMD
  medications.
• About arthritis: To give an overview of the most important aspects of having
  an RMD.

The 5th developed conversation aid (https://reumazorgnederland.nl/samen-beslissen-medicijnkaarten) focused on reliable sources for information.
• More information: A conversation aid with reliable sources to obtain more
  information about shared decision making, about having a rheumatic and
  musculoskeletal disease (RMD) and about RMD medication.

EXAMPLE OF THE FIRST PART OF CONVERSATION AID ‘WHO ARE YOU?’

Conclusion: These conversation aids can encourage and advance a good conversation about RMD medication, that best fits the patient’s need and preferences, when having an RMD. They stimulate both the patient as well as the healthcare professional to share much-needed information, when making a choice in medication. A patient organisation can play an important role in developing a conversation aid to support patients.

Acknowledgements: A special word of gratitude goes out to the patient research partners who contributed to the patient perspective in this project by either being part of the working group or by sharing their perspectives in the focus group. Our gratitude also goes out to all the RMD professionals who shared their opinion in the focusgroup.

**Keywords:** Inflammatory arthritis, Self-management, Quality of life, Inflammatory arthritis, Self-management strategies and self-efficacy in people with inflammatory arthritis and osteoarthritis.
Methods: Participants’ data such as age, gender, diagnostic and treatment was collected. The clinical, social and psychological impact of ESC was assessed by a questionnaire applied to the participants after the ANDAI ESC. The perceived impact of the ANDAI ESC by health professionals’ volunteers was also evaluated by a different questionnaire.

Results: Forty-five children or young people with RMDs participated in one or more editions of the ANDAI ESC. The median number of participants in ANDAI ESC was 17(9) participants per edition, with a majority of female participants (62%). The median age of participants in the different editions was 12(4) years old. Of the invited participants 32 participants (76%) were able to participate in this study, 22 children (48% response rate) and 11 health professionals (53% response rate) completed the survey. The great majority of the participants (95.5%) recognized the positive impact of the ESC on understanding and acceptance of the disease. In fact, after participating in ANDAI ESC, 90.5% of these children claim to have a more optimistic perspective on the evolution of their disease. In addition, when asked on a scale from 0 (no impact) to 10 (significant impact) about the perceived outcome of ESC on their RMD patients, 88.8% of the participating health professionals marked the three higher scaled levels, agreeing that it had a positive effect on these children.

Conclusion: In conclusion this study demonstrates that ANDAI ESC improved patient’s confidence in coping with the challenges of a RMD in childhood/youth, reaching the objectives initially defined. Thus, ANDAI ESC proved to be an important resource to the juvenile RMD community in Portugal.

POS0198-PARE
CREATING A CAPABILITY BUILDING PROGRAM BASED ON PATIENT COMMUNITY’S ACTUAL NEEDS AND PRIORITIES: THE SJÖGREN EUROPE EXPERIENCE

Keywords: Best practices, Patient information and education, Sjögren syndrome

K. Antopoulou1, A. Vieira2, C. Boullot3, J. Koelweijn-Tukker4, M. Oosterbaan4, M. Steenackers5, V. Lopez Gousset6, Sjögren Europe, President, Bienne, Switzerland, 2Sjögren Europe, Vice President, Bienne, Switzerland, 3Sjögren Europe, General Secretary, Bienne, Switzerland, 4Sjögren Europe, Treasurer, Bienne, Switzerland, 5Sjögren Europe, Board Member, Bienne, Switzerland, 6Novartis Pharma AG, Global Patient Engagement Director, Immunology, Basel, Switzerland, 7VGL Consulting, PR executive, Paris, France

Background: Patients & their representatives are an important stakeholder in healthcare discussions. However, these individuals sometimes lack the appropriate knowledge & training to fully contribute to healthcare decision-making. The Sjögren’s community in Europe is represented by groups of various capacities & expertise at the country level but with large national disparities. Sjögren Europe, the European Federation of national associations representing Sjögren’s patients, seeks to support as widely as possible its members in leveraging their voice systematically & consistently in multi-stakeholder healthcare discussions, including participating in scientific research & collaborating with medical, social & political institutions.

Objectives: This SE Member Capability Building Program was co-created by Sjögren Europe & the Novartis Immunology Global Patient Engagement team to respond to the needs of the European Sjögren’s community, as reported by Sjögren Europe member organizations. Specifically, the program supports Sjögren’s patient organizations in building capability and capacity in areas that most matter to them, sharing local experiences & best practices & increasing advocates’ knowledge, skills & confidence as leaders of their organizations.

Methods: The content of the Capability Building Program was shaped through a self-assessment in which participating organization self-identified strategic priorities, desired areas for expansion, and current barriers to growth. Questions in the self-assessment were taken from validated, third-party resources, including the PatientView methodology for assessing capacity and impact of patient organizations across eight key indicators[1]. These indicators are business stability, e-communication, services to patients, networking with stakeholders, networking with peer patient organizations, reputation, impact on health policy, and resilience. The results of this assessment were discussed individually with patient organization leaders to outline personalized opportunities for growth. The results were also used to inform a broader webinar training series based on commonly shared challenges & prioritized needs.

Results: 7 SE member organizations, representing 7 countries, participated in the self-assessment highlighting various shared gaps & learning opportunities across the community. Organizational strategy, staff recruitment & retention, external communication strategy & financial strategy were identified as current gaps. Patient organization involvement in drug development, approval & reimbursement processes was identified as an area where all groups would like to learn more. The resulting webinar training series addresses each of these areas of interest to the community. The first webinar “External Communication Strategy: Actionable recommendations for creating awareness campaigns and partnering with the media” was offered November 2022 with an overwhelmingly positive response from the community. Additional webinars are planned for 2023 and will be focused on the above topics.

Conclusion: The self-assessment was crucial in detailing where Sjögren Europe member organizations stand today & where they wish to be in the future. This allowed for the creation of a responsive & actionable webinar training program that meets the actual needs and priorities of the Sjögren’s community in Europe. The Member organizations have reported feeling heard and valued as a result of this initiative. The very good feedback encourages us to continue these concrete actions for patient organizations. Program is also a great example of a genuine partnership, following the EFPIA code of conduct[2], between a patient organization and the pharmaceutical industry.

POS0199-PARE
RHEUMATOLOGICAL PATIENTS’ KNOWLEDGE OF, BELIEFS ABOUT, AND PRACTICES IN USING PHYTOTHERAPY: AN EXPLORATORY STUDY

Keywords: Patient information and education, Descriptive Studies

T. Demirici1, Yildirim2, F. Basibuyuk3, M. Birlik4, Dokuz Eylul University, Faculty of Medicine, Rheumatology, Izmir, Turkey

Background: Phytotherapy has emerged as a new concept and has quickly and widely spread in recent years. Studies on phytopharmaceuticals in rheumatology practice are very limited.

Objectives: In this study, we aimed to examine the knowledge of, beliefs about, and practices in using phytotherapy in patients who use biological agents, which we can classify as the last and most potent step in treating rheumatological diseases.

Methods: In the first part of the questionnaire, there are 11 questions including the demographic data of the person, and in the second part, there are 17 questions that aim to learn the level of knowledge about phytotherapy and the use of phytopharmaceuticals. The questionnaire was administered face-to-face to patients with rheumatology using biological therapy who gave consent to participate.

Results: The questionnaire was completed by 100 patients, 51 of them women. The mean age was 39.9 years. 39% of the patients were postgraduate and 23% were at the high school. Of the participants, 45 were diagnosed with ankylosing spondylitis (AS) and 29 with rheumatoid arthritis (RA). The duration of rheumatologic disease was 12.2 years. All patients were followed up with biological therapy, 35% were using infliximab and 15% were using adalimumab. The mean duration of biological therapy was 6 years. Of the 100 participants, 68% had information about phytotherapy, and 35 of them had obtained it from social media and television. In general, participants had a positive opinion about phytotherapy, and most did not obtain approval from their physicians for the use of phytotherapy. Among phytopharmaceuticals, patients mostly used green tea (30%), linden (27%), curcumin (20%). There were 5 participants who experienced side effects related to patient use of phytopharmaceuticals. 66% of the patients thought that phytopharmaceuticals had fewer side effects than biological therapy, 50 patients said that they would not use biological therapy if cured with phytopharmaceutical use.
Conclusion: It is inevitable that patients with chronic diseases want to use phytopharmaceuticals, as determined in our questionnaire results. Healthcare professionals should be careful about establishing a proper and reassuring relationship with patients and avoid criticizing them for preferring these methods. Patients should be informed about the use of phytotherapy, and be warned about its potential risks and side effects.

POS0200-PARE
HOW USER INVOLVEMENT INCREASED THE QUALITY OF PROS

Keywords: Quality of Patient Information and Education, Patient reported outcomes

C. Ziegler1, 2, Gigtforeningen, Politics and Knowledge, Gentofte, Denmark

Background: In the DANBIO Registry patients with inflammatory arthritis have entered PROs for more than 20 years. In 2016 a group of patients suggested that their experiences and opinions about PROs should be taken into account, as they found room for improvement. In 2018 a qualitative research study confirmed knowledge gaps in the use and purpose of DANBIO – gaps among patients, front personal and health care providers. In 2022 new results could be implemented.

Objectives: After the research study three different goals were set up:
[1] To increase knowledge of the DANBIO Registry being used for three different purposes.
[2] To make patients aware that they can enter PROs in different ways.

Methods: An interdisciplinary user group was established. The group consisted of patients with different types of inflammatory arthritis, rheumatologists, nurses etc. The group decided to produce different materials for different platforms. The group produced the materials themselves in cooperation with room for everyone’s professional qualifications. The patients could offer patient’s experiences as well as being persons with competences from education and worklife.

Results: Three user guides about the use of DANBIO were produced for three target groups. A group of patients scripted, filmed and produced a 5 minutes video providing the patients with relevant knowledge of PROs in DANBIO. The video was filmed at four different rheumatological departments and in patient’s private homes. The video will be shown in the waiting rooms of the hospitals and it can be seen on the Internet.

Conclusion: The work of the user group created a joint understanding and a multi pronged perspective on what “good quality” means in rheumatological care. By clarifying how the same data was presented and used differently various solutions were created to meet the need for more knowledge from staff, increase patient’s confidence in entering PROs and increase knowledge of the DANBIO registry in general. The video is provided with English subtitles and can be shown if this abstract is chosen for presentation.

POS0202-PARE
CHRONICALLY ACTIVE - A PATIENT EMPOWERMENT PROGRAM WITH PEER SUPPORT

Keywords: Work-related issues, Self-management, Best practices

A. Fryxelius1,2, 1Finnish Rheumatism Association, -. Helsinki, Finland

Background: Self-management refers to an individual’s abilities and behavior to maintain and improve their own well-being and monitor the physical and psychosocial reactions related to their condition to maintain a satisfactory quality of life [1,2]. Self-management is an essential part of treatment alongside medical care. Peer support is based on sharing of information and experiential knowledge among persons living with the same condition. Peer support is seen more and more important in healthcare, and it has been used to improve overall health and promote health behavior and self-management. [3].

Objectives: To promote the health and well-being of those living with rheumatic and/or musculoskeletal diseases, and to support their ability to cope with illness through peer-led "Reumatroppi" group activity. The aim of the group activity is to help patients notice things that increase well-being and health in their everyday lives and turn their thoughts to positive things.

Methods: The Finnish Rheumatism Association trains volunteers to become "Reumatroppi" group instructors. Trained volunteers set up a group and receive a written material consisting of thirty nonmedical health-related topics that are scientifically studied and relevant in management of rheumatic and/or musculoskeletal diseases. Topics include, for instance, resistance exercise, cardiovascular health, nutrition, recovery and rest. In addition, topics such as literature, music, nature, and creativity are included to broaden the view of self-management. The group meets regularly to discuss varying topics and share their experiences and thoughts. In addition, the group does joyous tasks together both indoors and outdoors. A task related to the topic is also given at home before next meeting. Self-report questionnaires with quantitative and qualitative questions are administered to the participants at the end of the group.

Results: In 2021-2022, 81% of the participants (n=80) reported paying more attention to their health behaviors (incl. physical activity, nutrition, rest). Additionally, 91% of the participants stated that they had tried to improve their own well-being and health in their everyday lives. 76% of participants had reduced sitting and sedentary time. It is also noteworthy that 80% of the participants reported better mood, and 81% had experienced more enthusiasm in their everyday lives. In addition, 71% of the participants reported that they had been (physically) more active and found more arts in their lives during the group. 81% of the participants had also found new friends in the group.

Conclusion: Peer-led “Reumatroppi” group activity has been able to raise the awareness for self-management among those living with rheumatic and/or musculoskeletal disease. The participants have paid more attention to their health behavior and found new resources that promote their overall well-being.

Australia late with traditional clinical disease activity measures. The results of a large cohort of Australian patients with RA and how they correlate with the treat-to-target strategy for patients with rheumatoid arthritis (RA). Despite achieving these targets however, some patients continue to report outcomes (PROs) are an important tool to better understand the lived experience of patients with chronic pain and rheumatic conditions. The creators behind this project have had the intention of sending an abstract about it to EULAR at least for the last 8 years. Unfortunately, my organization has not seen itself able to prioritize spending money on sending staff to the EULAR congress for many years. Also, my own rheumatic conditions (I have had Scleroderma and Rheumatoid Arthritis since the age 11 & 19) always flare up during winter, and I am usually unable to work during this time of year. I am aware that this abstract doesn’t hold the correct scientific standard, but I don’t have the spoons (ref. Spoon Theory) to check all the references and have a scientist help me with getting things right. Luckily - the actual conference is in June, and at that time I am usually in a very much stronger physical condition, so I can guarantee that I will be able to participate and present this project orally.

REFERENCES:
As stated above, I don’t have the spoons to find all the references for this now, but you can contact my colleagues at REMEDY to vouch for my method and my ability to deliver good oral presentations:

HPR Poster Tour: Challenges in daily life for people with RMDs

THE RELATIONSHIP BETWEEN PATIENT-REPORTED QUALITY OF LIFE AND PHYSICIAN-DERIVED CLINICAL OUTCOMES IN RHEUMATOID ARTHRITIS: AN ANALYSIS FROM THE AUSTRALIAN OPAL DATABASE

Keywords: Rheumatoid arthritis, Patient reported outcomes, Real-world evidence

G. Littlejohn1,2, N. Anbumurrali1, C. Osullivan1, T. Smith1, T. Racunicia1,3, P. Pentony1,4, S. Jayaweera1,4, L. Girgis3,6,5, C. Deakin1, OPAI Rheumatology Ltd, Rheumatology, Sydney, Australia; 2Monash University, Department of Medicine, Clayton, Australia; 3Southern Rheumatology, Rheumatology, Brighton, Australia; 4RheumatologyACT, Rheumatology, Canberra, Australia; 5University of New South Wales, Rheumatology, Sydney, Australia; 6St Vincent’s Hospital Sydney, Rheumatology, Darlinghurst, Australia

Background: Remission or low disease activity (LDA) are the common therapeutic targets in the treat-to-target strategy for patients with rheumatoid arthritis (RA). Despite achieving these targets however, some patients continue to experience residual symptoms including pain, fatigue and functional loss. Patient reported outcomes (PROs) are an important tool to better understand the lived experience of the patient which is often not adequately captured by traditional disease activity measurements.

Objectives: To describe the levels of pain, fatigue, mood disturbance and physical function in a large cohort of Australian patients with RA and how they correlate with traditional clinical disease activity measures.

Methods: Clinical data were sourced from the OPAL database which is an aggregated collection of data extracted from the electronic medical record (EMR, Audit4, Software4Specialists Pty Ltd) of patients receiving routine care from 112 rheumatologists across Australia. Validated PRO questionnaires were electronically delivered to patients through their EMR via email or completed using a smart device in the waiting room prior to the consultation. Completed questionnaires were securely integrated into the patients EMR for review at the next consultation[1]. Patients with a physician diagnosis of RA and ≥6 months of disease activity recorded who had responded to at least one PRO (Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F), Patient Health Questionnaire-2 (PHQ-2), pain visual analogue scale (VAS) or Multidimensional Health Assessment Questionnaire (MD-HAQ)), between April 2020 and April 2022 were included. Disease activity was assessed using DAS28(3)-CRP which includes swollen and tender joint counts and CRP, but excludes the patient global assessment.

Results: 1,397 patients completed a pain VAS, 2,180 a FACIT-F, 2,101 a PHQ-2 and 2,243 a MD-HAQ during the study window. The median age of patients with a completed questionnaire was 62 years and 77.1% were female. Levels of pain, fatigue, mood disturbance and physical function for patients with RA are shown in Table 1. Overall, a substantial percentage of patients, (n=519, 37.2%), reported experiencing unacceptable pain (>40mm VAS) and clinically relevant fatigue (FACIT-F ≤ 34) (n=867, 39.8%). Higher levels of pain, fatigue and mood disturbance was associated with higher DAS28(3)-CRP disease activity. Of patients in DAS28(3)-CRP remission or LDA, 32.7% reported unacceptable levels of pain, 36.1% reported clinically relevant fatigue and 11.2% reported possible depression.

Conclusion: In general, we found that higher disease activity scores were associated with high levels of pain, fatigue, anhedonia and depressed moods. In addition, there exists a substantial cohort of patients in routine clinical care with swollen and tender joints counts and CRP levels indicative of remission or LDA that continued to experience unacceptable levels of pain and clinically relevant fatigue.

THE ROLE OF ARTIFICIAL INTELLIGENCE IN DETECTING DISTINCTIVE FACIAL FEATURES IN PATIENTS WITH SYSTEMIC SCLEROSIS, A PILOT STUDY

Keywords: Systemic sclerosis, Artificial Intelligence, Diagnostic Tests

Y. A. Suliman1, J. E. Lund-Jacobsen2, R. Christensen1, L. E. Kristensen3, D. Furet4, Assiut University hospital, Rheumatology and Rehabilitation, Assiut, Egypt; 2An Aikdalej hospital, Rheumatology, Al Ain- abu dhabi, United Arab Emirates; 3Founder and CEO of Viceron ApS, Viceron ApS, Copenhagen, Denmark; 4Faculty of Health Sciences at the University of Southern Denmark, Parker Institute, department of biostatistics and clinical epidemiology at the Department of Clinical Research, Copenhagen, Denmark; 5Faculty of Health Sciences at the University of Southern Denmark, Parker Institute, Copenhagen, Denmark; 6David Geffen School of Medicine at UCLA, Rheumatology Division, Los Angeles, United States of America
Background: Scleroderma (SSc) is a rare autoimmune fibrosing multisystem disease with high rates of morbidity and mortality. Scleroderma is usually diagnosed by rheumatologists and/or dermatologists. However, a delay in disease recognition may occur due to a delay in referral, as internists and family physicians are not familiar with the disease and its features. Even though, the facial features of the disease are characteristic for scleroderma, diagnosis is usually based on other signs and symptoms (e.g., skin thickening on extremities), and confirmed with investigations such as autoantibody tests, HRCT, and endoscopies. Late presentation of SSc pts. to rheumatologists is commonly reported[1]; patients with dSSc generally presented to their primary health care Practitioner (HCP) after symptoms had persisted for up to 1 year. We hypothesize that facial features of SSc patients are distinctive and can be detected by a trained AI system after processing a mobile phone picture of SSc patient’s face through Convolutional Neural Networks (CNN). This system could be used by family practitioner and internists, aiding them to increase suspicion of SSc and refer patients in a timely manner.

Objectives: In a pilot study, we aim to examine the ability of an AI facial recognition system to identify SSc related facial features.

Methods: Images of SSc pts were compared to a group of age and sex matched normal faces. Deep Learning (DL) - Artificial Intelligence (AI) algorithms evaluated all the pixels in the facial map and identified their utility in the facial recognition prediction models. Using a transfer learning implementation developed by the Danish Viceron ApS AI company. This core model is well-established and experienced algorithm for AI facial feature recognition, based on > 1 million general public faces for facial feature recognition. AI evaluated multiple layers of mathematical models, either isolated or pooled to generate a predictive model and eliminate unnecessary data. Smoothing and uniformity protocols were established for the obtained through preprocessing for the Convolutional Neural Networks (CNN) (Figure 1).

Results: Images of 60 SSc pts from the internet were compared to a group of age and sex matched normal faces. We developed models among the 60 SSc facial images and matched controls that were able to identify SSc distinctive facial features with variable specificity and sensitivity. Multiple AI models were used on the training set which includes the first 40 patients and as a partial validation step on the other 20 patients with an equal baseline group built from normal faces. The validation index was 5.39 for the rheumatology cohort compared to the research subgroup. All patients had a recorded gender of male or female. The rheumatology population was 60.97% female compared to 76.26% in the research subgroup. The deprivation index was 60.97% female compared to 76.26% in the research subgroup.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.3702
population of 5.24. A difference of 12.5 years was seen between the median age of rheumatology patients (61 years) compared to research participants (48.5 years).

Conclusion: From this random dataset analysis approximately 10% of the rheumatology population participated in research. The demographic profile of ethnicity and indices of deprivation were similar across both groups, however proportionately the research subgroup is younger and has higher representation of women compared to the rheumatology population. Limitations of this work include exclusion of research participants prior to the installation of the EPCR, incomplete documentation of research participation within EPCR and sample size limited to 10,000 of the rheumatology population. However, selection bias is reduced due to the large random sample size and generalisability and representativeness is an advantage of this. In view of the low uptake of research participation, it is very important to identify barriers to increasing engagement and involvement in research. Further research is warranted to explore if there are particular age groups that are underrepresented and establish reasons for lack of engagement of men in rheumatology clinical research.

POSTPARTUM DEPRESSION AMONG REPRODUCTIVE-AGE WOMEN WITH AND WITHOUT RHEUMATIC DISEASE: A POPULATION-BASED MATCHED COHORT STUDY

Keywords: Pregnancy and reproduction, Epidemiology, Spondyloarthritides

D. Shridharmurthy1,2*, K. Lapane1, A. Nunes1, J. Baek2, M. Weisman3, J. Kay1,4, S. H. Liu1,3, 1UMass Chan Medical School, Division of Epidemiology, Department of Population and Quantitative Health Sciences, Worcester, United States of America; 2UMass Chan Medical School, Clinical and Population Health Research Program, Graduate School of Biomedical Sciences, Worcester, United States of America; 3UMass Chan Medical School, Division of Biostatistics and Health Services Research, Department of Population and Quantitative Health Sciences, Worcester, United States of America; 4Stanford University, Division of Immunology and Rheumatology, School of Medicine, Palo Alto, United States of America; 5UMass Chan Medical School, Division of Rheumatology, Department of Medicine, Worcester, United States of America; 6UMass Memorial Medical Center - Memorial Campus, Division of Rheumatology, Worcester, United States of America

Background: Postpartum depression is a psychiatric illness that occurs after the birth of a child and affects 12.5% of women in the United States (1) and 17% of women globally [2]. Women of reproductive age with rheumatic diseases (RD) are at increased risk of clinical depression [3]. However, research examining postpartum depression in women with RD is scarce.

Objectives: We examined postpartum depression among women with axial spondyloarthritis (axSpA), rheumatoid arthritis (RA), or psoriatic arthritis (PsA) compared to a matched population without RD in the United States.

Methods: A retrospective analysis using data from the 2013-2018 IBM Market-Scan Commercial Claims and Encounters Database was conducted. Pregnant women with axSpA, RA, or PsA were identified, and the date of delivery was used as the index date. We restricted the sample to women ≤ 55 years with continuous enrollment ≥ 6 months before date of last menstrual period and through pregnancy (baseline period). Each patient was matched with four individuals without RD. We restricted the sample to women ≤ 55 years with continuous enrollment ≥ 6 months before date of last menstrual period and through pregnancy (baseline period). Each patient was matched with four individuals without RD in the United States.

Overall, 2,667 women with axSpA, RA, or PsA and 10,668 patients without any RD were included. The average age at baseline was 33 years (SD: 5.0), and nearly two in five women were older than 35 years. The median follow-up time in days was 256 (Interquartile range (IQR): 553) and 265 (IQR: 564) for the axSpA/RA/PsA and matched non-RD comparison groups. Development of postpartum depression was more common in the axSpA/RA/PsA group relative to the matched non-RD comparison group (axSpA/RA/PsA group: 12.8%; matched non-RD comparison group: 12.9%; adjusted hazard ratio: 1.22 [95% CI, 1.09 – 1.36]). Factors such as pre-existing comorbidities, maternal complications during pregnancy, and antidepressants use at baseline were associated with development of postpartum depression.

Conclusion: The rate of postpartum depression is significantly higher in women of reproductive age with axSpA, RA, or PsA compared to those without RD. Results from this study demonstrate that strategies to monitor postpartum depression after delivery in patients with RD must be developed and implemented to assure prompt referral of affected mothers for appropriate evaluation and treatment.

FEAR OF MOVEMENT MEDIATES THE RELATIONSHIP BETWEEN PAIN CATASTROPHIZING AND PHYSICAL FUNCTION IN PEOPLE LIVING WITH AXIAL SPONDYLOARTHROPATHIES: A CROSS-SECTIONAL MEDIATION ANALYSIS

Keywords: Pain, Spondyloarthritides, Patient reported outcomes

P. Reusa1, T. Ingram1, M. Standage1, R. Sengupta2, 1University of Bath, Department for Health, Bath, United Kingdom; 2Royal United Hospitals Bath, Rheumatology, Bath, United Kingdom

Background: Axial spondyloarthritis (axSpA) typically affects the axial skeleton and sacroiliac joints causing patients to experience pain, reduced movement, and impaired physical function. A range of treatment options are available to help axSpA patients reduce pain and maintain physical function and thereby enhance health-related quality of life. The European Alliance of Associations for Rheumatology (EULAR) identified activity as integral to the management of inflammatory arthritides, however, the majority of people living with axSpA are not sufficiently active to maintain physical function [1]. According to the Fear-Avoidance Model of Pain, fear of movement and pain catastrophizing contribute to poorer physical function via reduced activity and disuse [2]. Yet to date, no research has tested the theorized mediating role of fear of movement in the relationship between pain catastrophizing and physical function in people living with axSpA.

Objectives: To examine the mediating role of fear of movement in the relationship between pain catastrophizing and physical function in people living with axSpA.

Methods: Participants (N = 98, 70% female, M Age = 45.62 SD 12.16) completed an online survey (December 2020 – May 2021) distributed in the United Kingdom via the National Axial Spondyloarthritis Society (n ≈ 3,500; NASS, 2018). The Tampa Scale for Kinesiophobia (TSK-11) was used to measure fear of movement using participants rating 11-items from 1 (strongly disagree) to 5 (strongly agree). The Pain Catastrophising Scale (PCS) contains 13-items, each rated on a scale from 0 (not at all) to 4 (all the time). Both instruments have shown strong internal consistency in people living with axSpA [3,4]. The Bath Ankylosing Spondylitis Functional Index (BASFI) was used to assess physical function with higher scores indicating poorer function. Data were analysed using IBM SPSS (Version 28). The PROCESS SPSS macro was used, and interpretation made using the percentile bootstrap 95% confidence intervals from 5000 bootstrap samples. Standardised effects with values 0.10, 0.25 and 0.35 represent small, medium, and large effects [5].
RESULTS:

Table 1. Descriptive statistics and Bivariate correlations for the variables.

Bivariate correlations showed pain catastrophizing to have a significant medium and positive relationship with physical function and a large positive relationship with fear of movement. Mediation analysis (F = 12.67, p < .05, R² = .21) revealed that pain catastrophizing had a large positive direct effect on physical function (β = .259) and fear of movement (β = .647). Fear of movement had a large positive direct effect on physical function (β = .246). A significant medium and positive indirect effect of pain catastrophizing on physical function via fear of movement was observed (β =.002 - .320).

Figure 1. Path model with unstandardised regression coefficients (β) and percentile bootstrap confidence intervals (CI) identifying the mediating effect of fear of movement in the relationship between pain catastrophising and physical function. c' = direct effect, ab = indirect effect

Conclusion: Pain catastrophizing is experienced by people living with axSpA and can lead to the avoidance of movement, and as a result, compromised physical function. Our test of the Fear-Avoidance Model showed that pain catastrophizing significantly predicted the physical function of people living with axSpA and that this relationship was mediated by fear of movement. Fear of movement is a modifiable construct that can be a treatment target for health professionals to improve the physical function of people living with axSpA. Identifying modifiable factors that contribute to disease outcomes is critical to improve the care and quality of life for people living with a disease currently without a cure.

POS0208-HPR PATIENT CHARACTERISTICS AND DIAGNOSIS SETTING OF PATIENTS WITH PAIN ASSOCIATED WITH OSTEARTHROTIHS OF THE KNEE IN GERMANY: A RETROSPECTIVE HEALTH CLAIMS DATA ANALYSIS

Keywords: Osteoarthritis, Pain

D. Beier1, D. Haeckl2, S. Ivanavicius3, J. Jerosch4, H. Liedgens5.

1InGef - Institut für angewandte Gesundheitsforschung Berlin GmbH, Health Research, Berlin, Germany; 2WIQI, Health Research, Leipzig, Germany; 3Grunenthal GmbH, Global Medical Affairs, Aachen, Germany; 4Medizinisch Wissenschafts- und Gutachten-Institut, Rheumatologie, Meersburg, Germany; 5Grunenthal GmbH, Global HEOR, Aachen, Germany

BACKGROUND: Osteoarthritis of the knee (OA) is the most prevalent form of OA in Germany as well as globally[1], frequently leading to pain and functional limitations. Several risk factors have been identified for osteoarthritis, which can be divided into those at the person level (age, sex, obesity, genetic predisposition, physical activity and diet) and those at the joint level (injuries, malposition and overstretch)[2]. Patients with OA-like symptoms may present to a number of different medical specialties and therefore arrive at a diagnosis of Knee OA via different routes. The Knee OA population is a highly co-morbid one. In addition to obesity, Knee OA patients often present with hypertension and diabetes[3].

OBJECTIVES: The study focuses on Knee OA in Germany, aiming to determine the prevalence of OA in the years 2015-2020, diagnosis setting and comorbidities of patients between 2015 and 2020.

METHODS: A non-interventional, retrospective health claims data analysis, performed with anonymized, age- and sex-representative sample of the Institute for Applied Health Research Berlin GmbH (InGef) database. The database used for this study includes approximately 4.8 million persons from approx. 80 statutory health insurances (SHI) and is representative for the German population[6]. Patients ≥18 years of age were analyzed cross-sectionally for each year 2015-2020. Using ICD-10-GM and ATC codes.

RESULTS: The prevalence of knee OA ranged from 7.1% in 2015 to 7.6% in 2019, dropping to 7.4% in 2020. The incidence showed a less linear pattern ranging from 1.71% of patients in 2015 and 2016, 1.67% in 2017, 1.61% in 2018, 1.67% in 2019 to 1.46% of patients in 2020. Females and patients aged ≥66 years had both a higher prevalence and incidence proportion compared to males and younger persons. First diagnosis for most patients was made in an outpatient setting (93.4%) by orthopedics (49.8%), general practitioners (28.1%) and specialists (Internist, 9.3%). Most prevalent co-morbidities for patients with Knee OA in all years observed was primary hypertension with ~70%. Other metabolic disorders like disorders of lipoprotein metabolism (around 50%), overweight and obesity (28-30%), type 2 diabetes mellitus (around 27%) are among the 10 most common others. Other musculoskeletal disorders are frequent (dorsalgia 54%; spondylody 33-54%). The percentage of patients with major depressive disorders is high in all years (23%).

CONCLUSION: The number of patients with knee OA is slowly increasing from 2015-2019 possibly due to the growing German population, however slightly decreasing in 2020. Diagnosis is mainly done by an orthopedist or general practitioner. The increasing number of certain co-morbidities, mainly of the cardiovascular system (hypertension with the highest percentage), but also due to metabolic condition (Disorders of lipoprotein metabolism and other lipemias, overweight and obesity, type 2 diabetes) demonstrates that the percentage of patients with known risk factors for knee OA is increasing. Treating pain in patients with co-morbidities can be challenging due to managing drug-drug interactions given the considerable number of treatments patients could be receiving. This can be a high risk for these patients as physicians do not always know about non-prescription co-medications. Models of care for patients with knee OA which include tolerable, non-systemic pain treatments, enabling patient physiotherapy and management of other aspects of their health actively may be a key advancement.

POS0209-HPR "I LOST A PART OF ME": A QUALITATIVE STUDY EXPLORING THE IMPACTS OF SJÖGREN’S SYNDROME ON THE SEXUAL LIVES AND INTIMATE RELATIONSHIPS OF WOMEN WITH THE CONDITION

Keywords: Quality of life, Sjögren syndrome, Self-management

J. Mcready1, K. Hackett1,2, V. Deary3,2, T. Collins3,1

1Northumbria University, Department of Social Work, Education and Community Wellbeing, Newcastle upon Tyne, United Kingdom; 2Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; 3Northumbria University, Department of Psychology, Newcastle upon Tyne, United Kingdom

BACKGROUND: Females with Sjögren’s syndrome (SS) report alterations in their sexual experience from the perspective of women with SS.
Objectives: To explore the lived experience of sexual disruptions and the impacts on intimate relationships for women with SS.

Methods: Northumbria University Ethics Committee granted ethical approval and informed consent was obtained prior to participation. Participants were recruited through SS associations and social media. Cisgender women aged 18+, diagnosed with SS, who were comfortable discussing their sexual functioning were invited to participate in a semi-structured, one-to-one interview throughout May and July 2021. Interviews were conducted via video or telephone call (based on participant preference), and audio was recorded and transcribed verbatim. Interviews lasted between 45-90 minutes. An inductive thematic analysis[2] was performed using ATLAS.ti software.

Results: Interviews were conducted with 15 women with SS (disease duration range= 3-348 months). Participants were predominantly from the USA (33.3%), UK (26.7%) and Canada (26.7%) and were aged between 21 and 70 years (M=49.07, SD=16.78). Participants identified as heterosexual (86.6%) or bisexual (13.3%) and were either married (86.6%), partnered (20%) or dating (13.3%) (relationship duration range= 5 months to 39 years). All participants had a male partner (100%). Regarding menopausal status, 40% were premenopausal, and 60% were postmenopausal. From the analysis, four themes were derived (Figure 1):

1) ‘Impacts on personal and sexual identity’: participants experienced alterations in how they related to their bodies and perceived their bodies to be forcing them to give up a sexual relationship which was in contrast to their wants and expectations.

2) ‘Impacts on relationship with partner’: the sexual relationship goes from being automatic and pleasant to something complex and needing deliberation. There is a loss of honesty and communication between partners regarding the sexual relationship.

3) ‘Breaching of social norms around developing and maintaining new relationships’: participants express a sense of doubt and anxiety about developing and maintaining sexual relationships in the future. There is an awareness of their sexual limitations and inability to meet societal expectations within a relationship.

4) ‘Motivation to find solutions’: Individuals look for solutions to help manage sexual disruptions, such as trying lubrication products, seeking advice from healthcare professionals, engaging with cognitive behavioural therapy practices, incorporating body scans and mindfulness during sexual activity and adaptation of activities to account for limitations.

Conclusion: This research highlights how alterations in sexual function caused by SS have consequences for an individual’s personal and sexual identity, as well as adding an additional layer of mental and physical effort to maintain sexual relationships. The self-management strategies identified in this study are valuable for healthcare professionals supporting women with SS experiencing sexual alterations.

Note: Due to non-normal distribution, median and 25th and 75th percentiles are shown.
Reduced sleep quality is highly prevalent and associated with physical function and cardiorespiratory fitness in patients with axial spondyloarthritis

Key Points:
- Sleep disturbances are common in patients with axial spondyloarthritis.
- Reduced sleep quality is associated with better physical function and higher cardiorespiratory fitness.
- Current health status is associated with better sleep quality in patients with axSpA.

Methods:
- Cross-sectional study using data from the ESpA trial.
- Patients with axSpA were included.
- Sleep quality was assessed using the PSQI.
- Physical function was assessed using the BASFI.
- Cardiorespiratory fitness was measured using VO2peak.

Results:
- Reduced sleep quality was associated with better physical function and higher cardiorespiratory fitness.
- Current health status was a modifiable factor associated with sleep quality.

Conclusions:
- Sleep disturbances are common in patients with axSpA.
- Sleep quality is associated with better health outcomes in this population.
- Further research is needed to understand the mechanisms underlying these associations.

Vocational rehabilitation (VR) is complex. VR includes a variety of components that aim to increase work ability and prevent sick leave and job loss. Effects of VR for people with IA are sparse [1]. To develop relevant VR in Denmark for people with IA, a good understanding of the employer perspective is important, as their involvement is crucial to effective VR.

Objectives: To explore how employers support their employees with IA to maintain their jobs and prevent sickness absenteeism and job loss.

Methods: A qualitative, explorative design was applied, based on a phenomenological and hermeneutic approach. We invited employer representatives (n=13) from workplaces where people with IA were employed (public and private companies with 11-380 employees). An interview guide was developed based on qualitative research and the theory of occupational justice [2]. Individual semi-structured interviews were performed from November 2020 to February 2021. Data were analysed using Kirsit Malterud’s systematic text condensation.

Results: Three themes were derived from the analysis:
1) Participation in work. All employer representatives were aware of and wanted to help solve their employees' challenges at work, but it was complicated and time consuming for them. They supported their employees through adaptation and prioritisation of work tasks, arranged flexible working hours and were aware of the employee’s need to balance work and family in everyday life. The employer representatives considered that the employees needed to be motivated, if job loss was to be prevented.
2) Relationship between employer and employee. In general, the employer representatives found it important for the employee to have trust in the employer and ask for help, in order to receive support. To prevent job loss, the relationship was essential. Furthermore, they made a big effort in supporting the employee. They stretched to meet the needs of their employees and they found that empathy was an important quality.
3) Multidisciplinary collaboration. The employer representatives involved the municipal job centres regarding legislative offers when necessary, and they requested the employee for collaboration with the healthcare professionals involved in treating the employees’ IA. Furthermore, they asked for guidance from relevant trade unions, to find out about legislation in relation to sick leave.

Conclusion: Overall, the employer representatives wanted to support their employees with IA and to be involved in VR, even though preventing sick leave and job loss was experienced as complicated, time consuming and costly for the companies.

Background: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), two different ANCA-associated vasculitides (AAV), are clinically heterogeneous. Little is known about potential differences in clinical presentation of disease between females and males and between patients diagnosed at a young age versus an older age. However, differences between different clinical manifestations have not been thoroughly investigated.

Objectives: To improve care and prediction of outcome in patients with AAV, the aims of this study were to identify and thoroughly characterize subgroups of AAV patients, stratified for sex, age at diagnosis and clinical manifestations.

Methods: In a systematic multicenter study, adult patients diagnosed with GPA of MPA between 2008-2018 were included. Clinical data including sex, age at diagnosis, ANCA-specificity, relapses and cumulative disease involvement of ear-nose-throat (ENT), lungs, eyes, kidneys, muscles/joints, skin, central nervous system (CNS), peripheral nervous system (PNS), gastrointestinal tract (GI) and heart were collected from medical records. Organ involvements were analyzed for associations with sex, age at diagnosis and relapse, in GPA and MPA, separately, using logistic regression. Agglomerative hierarchical cluster analysis was performed using the Ward method, based on the n number of axes explaining ≥90% of total variability in multiple correspondence analysis of the collected clinical data in GPA and MPA. The optimal number of clusters was estimated by determining the gain in within-cluster inertia achieved at each clustering step.

Results: In total, 1156 patients (578 females, 578 males) were included in the study, 922 were classified as GPA, 234 as MPA. In GPA, pulmonary and renal involvement, as well as PR3-ANCA, were significantly associated with male sex, whereas MPO-ANCA was associated with female sex. In MPA, the only difference between the sexes was an older age at diagnosis in males than females. In GPA, the age at diagnosis showed a bimodal pattern with two peaks of incidence with mean (range) at 22.4 (9-31) and 57.1 (32-91) years of age, respectively. Comparing GPA patients younger than 32 years old at diagnosis with those older than 32 identified a significantly higher prevalence of females, ENT- and GI involvement and relapse rate in the younger group and PNS involvement in the older group. In all GPA patients, relapse was associated with pulmonary involvement, whereas in MPA relapse was associated with musculoskeletal involvement. Hierarchical cluster analysis of GPA and MPA identified five and seven distinct clusters, respectively. For both diseases, three of the clusters were defined by heart, CNS- and GI involvement, respectively. In GPA, the largest cluster was defined by PR3-ANCA and ENT involvement and the fifth cluster by MPO-ANCA, female dominance and a low rate of ENT involvement. The additional four clusters in MPA were defined by i) eye involvement, ii) absence of renal involvement, iii) PR3-ANCA and iv) MPO-ANCA with renal involvement (largest, respectively). In addition, in several of the clusters in both GPA and MPA, there was a significant enrichment or depletion of additional clinical manifestations, in comparison with the largest cluster.

Conclusion: The results of this study indicate distinct disease course of GPA in females and males, and strongly suggest that sex and age at diagnosis should be considered in the clinical assessment of disease outcome in GPA patients. The identification of associations between different clinical manifestations in the cluster analysis may facilitate the prediction of organ involvements in patients with AAV, and, subsequently, clinical decision-making.

CLASSIC VERSUS ATYPICAL POLYMYALGIA RHEUMATICA: TWO SIDES OF THE SAME COIN OR MISCLASSIFICATION?

Keywords: Imaging, Myositis, Pain

V. El Miedany, M. Toth, M. Elgafy, S. Bahais, M. H. Abu-Zaid, W. Hassan, S. A. A. Taba, W. Elwaili, S. Saber, N. Kameel, C. Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; Kings’ College London - Darent Valley Hospital, General Medicine, London, United Kingdom; Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt; King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia; Faculty of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Benha, Egypt; Faculty of Medicine Alexandria University, Rheumatology and Rehabilitation, Alexandria, Egypt; Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt

Background: PMR is usually diagnosed based on the patient’s clinical history and confirmed by the presence of an elevated inflammatory markers ESR and CRP. Once the diagnosis is confirmed, steroid therapy is commenced, and their response is usually rapid and dramatic. However, sometimes patients may present with symptoms similar to PMR but do not meet the 2012 EULAR/ACR criteria. It is not well known if these atypical patients represent a subtype of PMR or another musculoskeletal inflammatory condition.

Objectives: 1. to compare the clinical, laboratory and sonographic patterns in patients presenting with classic PMR versus those with atypical PMR symptoms.

Methods: retrospective study of patients presenting with PMR symptoms and their respective US scans of the shoulders and hips. The patients were stratified into a cohort of classic PMR who meet the 2012 EULAR/ACR criteria; and a group of atypical PMR presenting with symptoms similar to classic PMR but did not fulfill the 2012 EULAR/ACR criteria. Every patient was assessed clinically, had blood tests for ESR, CRP, basic rheumatoid blood profile, urine analysis (to rule out microscopic hematuria). CK, bone profile, rheumatoid factor, anti-CCP, ANA, TSH and HbA1c. US scan was carried out for both shoulders and hips. The patients were treated according to agreed protocol and monitored for 12-months.

Results: 104 patients (88 women and 36 men) with a mean age of 63.2±9.7 years. Eighty-one (64/104) patients had classic PMR and 20 (19.3%) atypical PMR. Patients with atypical PMR had shorter duration of symptoms (8.1+1.3 Vs 14.6+15 weeks). In the atypical PMR patients, pain in the hip/pelvic girdle was more frequent (100% vs 60.1%), whereas shoulder girdle pain was less (50% vs 98%), in comparison to the classic PMR patients. Arthritis was less common in the atypical PMR cohort (15% Vs 42%), similarly GCA was less prevalent in the atypical PMR (5% Vs 20.2%). Patients with classic PMR were more likely to have bilateral abnormal ultrasound findings in the shoulder (particularly sub-deltoide bursitis [92%] and biceps tenosynovitis [83.3%]), as well as in the hips (78.6%) than the atypical PMR subjects where US findings tend to be unilateral (shoulder 50% and the hip 75%). Systematic symptoms: fatigue, weight loss, fever were more common in the classic PMR than atypical PMR (%). No significant difference on comparing morning stiffness in both groups. Both patients groups responded very well to steroid therapy with significant improvement in the symptoms in 2-4 weeks’ time.
Conclusion: Patients with atypical PMR could represent an early form of the classic PMR. Atypical PMR used to have a shorter evolution of symptoms, have predominantly hip/pelvic girdle affection. US of the shoulders and hips may have an added value for stratifying PMR patients and differentiating atypical PMR from other musculoskeletal conditions.

POS0216 A PROSPECTIVE COMPARATIVE STUDY OF TEMPORAL ARTERY ULTRASOUND, TEMPORAL ARTERY BIOPSY, TEMPORAL ARTERY MAGNETIC RESONANCE ANGIOGRAPHY AND ACR GCA CLASSIFICATION CRITERIA IN AN INCEPTION GCA COHORT

Keywords: Vasculitis, Diagnostic Tests, Ultrasound

C. Kirby, R. Flood, D. Landers, K. MC Kevitt, G. Fulton, E. Boyle, K. O’Regan, R. Mullan, G. Murphy, D. Kane. Tallaght University Hospital, Rheumatology, Dublin, Ireland; 2Cork University Hospital, Rheumatology, Cork, Ireland; 3Tallaght University Hospital, Vascular Surgery, Dublin, Ireland; 4Cork University Hospital, Vascular Surgery, Cork, Ireland; 5Cork University Hospital, Radiology, Cork, Ireland; 6Cork University Hospital, Rheumatology, Cork, Ireland

Background: Temporal Artery Biopsy (TAB) is costly, invasive and has a false negative rate as high as 60% [1]. Temporal Artery Ultrasound (TAUS) and Superficial Temporal Artery (STA) MR-Angiography (MRA) have shown widely disparate results in studies to date [1-3]. ACR GCA Classification Criteria are often mis-used in clinical practice as diagnostic criteria.

Objectives: In this prospective study, we compare TAUS, TAB and STA MRA to physician diagnosis of GCA at 6 months.

Methods: We performed a prospective study of all new referrals (n=124) to our Rapid Access GCA clinic over 18 months. US of all 6 branches of the STA and both auxiliary arteries was performed using a GE P9 device. Abnormalities considered indicative of vasculitis in the STA included the halo sign (Figure 1) and no compressible arteries with a thickened intima-media complex [4]. In the auxiliary arteries, a halo sign and an intima-media thickness of >1.0mm was considered positive. A subset of our patients were referred for TAB and/or MRA. MRAs were scored 0-4 based on mural wall thickness and signal intensity of mural peri-adventitial contrast enhancement [5]. We compared results to a clinical diagnosis of GCA at 6 months, verified by 2 rheumatologists. We performed Chi-Square tests with ROC analyses to determine the performance of each diagnostic modality.

Figure 1. Transverse view of STA, demonstrating a halo sign, as indicated by the anechoic region (green arrow) surrounding the inner Doppler (red arrow) signal.

Results: Sixty-six patients had a clinical diagnosis of GCA of which 58% were males (n=38) with a mean age of 73.3 years. The performance of the various diagnostic tools is outlined in table 1.

Table 1. Sensitivities, Specificities and Area Under the Curve (AUC) values for Temporal and Auxiliary Artery Ultrasound, ACR GCA Classification Criteria, Temporal Artery Biopsy and Superficial Temporal Artery Magnetic Resonance Angiography for physician-verified diagnosis of GCA at 6 months. Conclusion: TAUS is a reliable tool for diagnosing GCA with a high degree of sensitivity and specificity. TAUS outperforms TAB, MRA and ACR GCA Classification Criteria when compared to a clinical diagnosis of GCA at 6 months. We propose that TAUS should replace TAB as the gold standard diagnostic test and that all rheumatologists should acquire the necessary skills to accurately perform this investigation as part of routine clinical care.

POS0217 ASSOCIATION BETWEEN VASCULAR FDG UPTAKE AND AORTIC DIMENSIONS IN GIANT CELL ARTERITIS: A PROSPECTIVE STUDY

Keywords: Vasculitis, Imaging

L. Moreel1,2, W. Coudyzer, L. Boeckstaens, A. Betrams1,2, G. Molenberghs3, S. Vanderschueren2,3, E. Clauss, K. Van Laere4,6, D. Blockmans1,2. 1University Hospitals Leuven, Department of General Internal Medicine, Leuven, Belgium; 2KU Leuven, Department of Microbiology, Immunology, and Transplantation, Leuven, Belgium; 3University Hospitals Leuven, Department of Radiology, Leuven, Belgium; 4University Hospitals Leuven, Department of Nuclear Medicine, Leuven, Belgium; 5KU Leuven, Interuniversity Institute for Biostatistics and Statistical Bioinformatics (I-BioStat), Leuven, Belgium; 6KU Leuven, Department of Imaging and Pathology, Nuclear Medicine and Molecular Imaging, Leuven, Belgium

Background: Patients with giant cell arteritis (GCA) have an increased risk of developing aortic aneurysms. Retrospective studies have shown that 18F-fluorodeoxyglucose (FDG) uptake in large vessels at diagnosis increases the risk of developing aortic complications during follow-up.

Objectives: To prospectively evaluate the association between vascular FDG uptake at diagnosis and the evolution of aortic diameter and volume in patients with GCA.

Methods: GCA patients who had FDG positron emission tomography (PET) imaging at diagnosis within 3 days of initiation of glucocorticoids and who were prospectively followed for at least 2 years were included. PET scans were visually scored (0-3) at 7 vascular areas and a total vascular score (TVS) was calculated, ranging from 0 to 21. Patients underwent a computed tomography (CT) scan at diagnosis and yearly thereafter for a maximum of 10 years. The association between vascular FDG uptake and aortic diameter and volume was estimated by linear mixed effect models with random intercept and slope adjusted for age, sex, cardiovascular risk factors, CT or PET/CT scan and intravenous contrast.

The ascending aorta, aortic arch, and descending aorta were considered aneurysmal when the diameter was ≥45, ≥40, and ≥35 mm respectively.

Results: Hundred patients (mean age 70 years, 68% females) were included, of which 74 patients had FDG uptake ≥2 in any large vessel, 60 in the thoracic aorta and 49 in the abdominal aorta. Median follow-up was 80 months (IQR 47-110). The increase in ascending and descending aortic diameter and in thoracic aortic volume was higher in patients with vascular FDG uptake ≥2 compared to those without (p<0.01). This increase was also significantly associated with TVS (Figure 1). FDG uptake was not associated with an increase in abdominal aortic diameter nor volume. Thoracic aortic aneurysms were more frequently observed in patients with thoracic aortic FDG uptake (27% versus 10%, aOR 6.6, 95%-CI 1.8-31.0, p=0.009) with a median time since diagnosis of 40 months (IQR 18-61). Two patients with high TVS (15 and 16) needed surgery for thoracic aortic aneurysm.

Conclusions: Thoracic aortic FDG uptake at diagnosis is an independent risk factor for developing thoracic aortic aneurysm in GCA patients. Higher TVS was associated with greater yearly increase in thoracic aortic volume and diameter. Follow-up of aortic dimensions may be necessary in these patients.

Background: Conventional disease-modifying anti-rheumatic drugs (cDMARDs) are recommended in addition to glucocorticoids (GC) for all active Takayasu’s arteritis (TAK) patients as the first-line therapy. However, there is limited data comparing cDMARDs as the first-line immunosuppressive (IS) treatment.

Objectives: In this study, we aimed to compare the outcomes of methotrexate (MTX) and azathioprine (AZA), which were used most frequently as the first-line cDMARDs in TAK patients.

Methods: TAK patients who received cDMARDs in addition to GCs as the initial therapy were included in this multicenter retrospective cohort study. Clinical, laboratory and imaging data of the patients were assessed. In addition, a match analysis (cc match) using variables ‘age, gender and diffuse aortic involvement’ was performed between patients who received MTX or AZA as first-line cDMARD treatment.

Results: We included 301 (F/M: 260/41, mean age: 42.2±13.3) patients from 10 centres in the study. As the first-line cDMARD, 204 (67.8%) patients received MTX and 77 (25.6%) patients received AZA. First cDMARD was cyclophosphamide in 17 (5.6%), leflunomide in 2 (0.5%) and mycophenolate mofetil in one patient. The remission, relapse and radiographic progression rates were similar between patients who received MTX and AZA as first-line cDMARDs. Vascular surgery rate was higher in the AZA (23% vs. 9%, p=0.001), whereas the frequency of patients receiving ≤5 mg/day GCs at the end of the follow-up was higher in the MTX group (76 vs 62%, p=0.034). Similarly, the rate of vascular surgery was higher and the GC dose reduction rate was lower in AZA group in match analysis. Drug survival was similar between MTX and AZA groups (median 48 months, MTX vs AZA: 32% vs 42%, p=0.34). IS therapy was discontinued in 18 (11 MTX, 7 AZA) patients during the follow-up period due to remission. In the IS discontinuation group 2 patients had a relapse at 2 and 6 months, while 16 patients were still on remission at the end of mean 69.4 (±50.9) months of follow-up.

Conclusion: Remission, relapse, radiographic progression and drug survival rates of azathioprine and methotrexate were similar in Takayasu’s arteritis patients having the first-line of therapy. The rate of vascular surgery was higher and the rate of steroid dose reduction was lower with azathioprine compared to methotrexate at the end of the follow-up.

DOI: 10.1136/annrheumdis-2023-eular.6172
Methods: All patients who were diagnosed with PMR in our Rheumatology Unit from January 2017 to January 2022 and followed-up for at least 12 months were retrospectively included. If performed at the time of diagnosis, musculoskeletal and temporal (TA) and axillary arteries (AxA) US findings were recorded, too.

Results: A total of 201 patients (mean age 73.4 ± 7.63, M/F 89/112) were included. According to the US performed at baseline, patients were subdivided in 4 subgroups: in 32 of them, the diagnosis was only clinical (A); 35 underwent shoulders, hips, wrists and knees US (B); 48 underwent shoulders, hips, TA and AxA US (C); and AxA US (D). At baseline, 14/132 (10.6%) of patients from groups C and D displayed findings consistent with GCA. During the follow-up, 47%, 52.8% and 60% of PMR patients who were re-evaluated at 12, 24 and 36 months, respectively, had a change in diagnosis (figure 1). The multivariate logistic regression showed that bilateral LHBT tenosynovitis at onset was the variable that better defined the persistence in PMR diagnosis (p=0.05, OR 8.425), whereas GH synovitis (p=0.022, OR 0.074) and RF positivity (p=0.028, OR 0.993) were the variables associated to a diagnostic shift on the follow-up. The model that better described (AUROC 0.854) a patient with a PMR-onset with subsequent diagnostic shift comprised higher frequency of bilateral GH synovitis, bilateral shoulder PD, higher values of CRP, WBC, PLT and Hb and longer time to obtain remission. On the other hand, the ones maintaining diagnosis of PMR had bilateral exudative LHBT tenosynovitis (OR 8.425) and SA-SD bursitis (OR 2.619), higher values of ESR (OR 1.015), lower values of Hb (OR 0.428) and shorter time to remission (OR 1.076). Continuous variables were included in a hierarchical clustering analysis identifying two groups. Cluster 2 identified older patients, with lower systemic inflammation, lower levels of WBC, PLT and Hb, who had a higher persistence in PMR diagnosis at 12 (42.7% vs 29.3%), 24 (37.2% vs 25.6%) and 36 months (38.4% vs 21.2%). Cluster 2 had lower frequency of PD positivity (PD 0 in 39.1% on shoulders and 47.1% on wrists) or peripheral synovitis (absence of synovitis on knee and MCF in 43.9% and 50% respectively), more frequent flares, and were taking PDN at 12 (until 45.8%) and 24 months (until 30.8%). An environmental trigger before onset were more commonly reported (in 5.8% vaccinations before onset, vs 1.4% in cluster 1) The comparisons among the B, C and D and A showed significant differences in diagnosis at 12 (p=0.0145) and 24 months (p=0.0432) and dosage of GC at 12 months (p=0.0009). At 12 months the complete withdrawal of PDN was achieved in a significant (p=0.002) lower number of patients belonging to group A (6.4%) when compared to group B (26.1%), C (37.5%) and D (12.9%). A direct correlation was obtained between GC dosage at 12 and 24 months (Spearman rho 0.284, p=0.002). Finally, a longer time to remission correlated positively with CRP and negatively with Hb, while fever at disease onset positively with ESR.

Conclusion: More than half patients fulfilling criteria for PMR have their diagnosis changed during follow-up. The early use of US is associated with a more accurate diagnosis at baseline, as well as to a lower cumulative dosage of PDN. The early diagnosis of GCA is possible only in case of AxA and TA US at diagnosis. On the other hand, the lack of US is associated to a prolonged PDN treatment. Patient with a definite subset of clinical (fever, short time to remission), laboratory (lower Hb and CRP, higher ESR) and US findings (lower PD signal, LHBT tenosynovitis) are more prone to maintain the diagnosis of PMR during the follow-up.

LONG-TERM SURVEILLANCE STUDY OF RITUXIMAB (MABTHERA)-TREATED PATIENTS WITH GRANULOMATOUS POLYANGIITIS (GPA) OR MICROSCOPIC POLYANGIITIS (MPA): RITUXIMAB SURVEILLANCE STUDY IN VASCULITIS (RIVAS)

Keywords: Real-world evidence, Vasculitis

L. Uchida1, C. Loecheil2, M. Nodale3, S. Bond4, D. Jayne1,2, 1University of Cambridge, Department of Medicine, Cambridge, United Kingdom; 2Cambridge University Hospitals National Health Service (NHS) Foundation Trust, Vascular and Lupus Clinic, Cambridge, United Kingdom; 3Cambridge University Hospitals NHS Foundation Trust, Cambridge Clinical Trials Unit, Cambridge, United Kingdom

Background: Rituximab is used for remission induction, and for the prevention of relapse in ANCA-associated vasculitides (AAV). However, the long-term safety of rituximab in the real-world setting remains unclear.

Objectives: To evaluate the incidence of safety events (serious adverse events and adverse events of special interest) and risk profile of rituximab and to compare the time to first safety event between a rituximab cohort and a cohort treated with other therapies over 6 months to 15 years from first exposure.

Methods: RIVAS was a retrospective, observational study including patients with GPA/MPA who had received rituximab (MabThera) or other treatments between 2003 and 2018 at Addenbrooke’s hospital, Cambridge, UK. Clinical and laboratory variables were collected at baseline and every 12-18 months until 30 September 2018. To calculate the time to event, Time 0 was defined as either initiation of MabThera treatment for the rituximab cohort or the time of first disease flare/diagnosis for the control cohort. The primary endpoint was the time to first safety event. Key secondary endpoints were time to first pre-categorized safety event such as serious infection and cardiovascular disorders. The time to second safety event was an exploratory endpoint.

Results: 392 GPA/MPA patients were enrolled: 247 in the rituximab and 145 in the control cohort with a total of 2,217 person-years (mean study duration 5.7 years). Mean age was 61 years, 52% were female, 77% had GPA and 23% MPA. The mean disease duration at baseline was 55.3 months (SD 70.2) in the rituximab group and 60.9 months (SD 66.2) in the control group. Limitations of the trial design do not permit firm conclusions concerning differences between treatment groups.

McNugh5,6, 1University of Leeds, Leeds Institute of Clinical Trials Research, Leeds, United Kingdom; 2University of Oxford, Rheumatology, Oxford, United Kingdom; 3University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 4University of Nottingham, Academic Unit of Population and Lifespan Science, Nottingham, United Kingdom; 5University of Bath, Department of Life Sciences, Bath, United Kingdom; 6Royal United Hospitals, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom

Background: Delay in the diagnosis of psoriatic arthritis may be associated with poorer outcome. However, the effectiveness of strategies to enable early detection of psoriatic arthritis in a primary care population with psoriasis has not been investigated in a prospective randomised control trial.

Objectives: The primary objective was to determine whether early detection of undiagnosed PsA in people with psoriasis by an enhanced surveillance (ES) intervention compared to standard care (SC) improves outcome in physical function at 24 months post-registration. Secondary objectives were to compare disease activity and impact of disease between groups in those participants diagnosed with PsA.

ENHANCED SURVEILLANCE FOR THE DETECTION OF PSORIASIS ARTHRITIS IN A UK PRIMARY CARE PSORIASIS POPULATION VERSUS USUAL CARE: RESULTS AT 24 MONTHS FROM THE TOTAL BURDEN OF PSORIASIS (TUDOR) RANDOMISED CONTROL TRIAL

REFERENCES: NIL.

Disclosure of Interests: S. Brown: None declared, L. Coates: None declared, H. Collier: None declared, C. Davies: None declared, P. Helliwell: None declared, J. Packham: None declared, M. Ransom: None declared, W. Tillet: None declared, N. McNugh: None declared, 1University of Leeds, Leeds Institute of Clinical Trials Research, Leeds, United Kingdom; 2University of Oxford, Rheumatology, Oxford, United Kingdom; 3University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 4University of Nottingham, Academic Unit of Population and Lifespan Science, Nottingham, United Kingdom; 5University of Bath, Department of Life Sciences, Bath, United Kingdom; 6Royal United Hospitals, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom

Background: Delay in the diagnosis of psoriatic arthritis may be associated with poorer outcome. However, the effectiveness of strategies to enable early detection of psoriatic arthritis in a primary care population with psoriasis has not been investigated in a prospective randomised control trial.

Objectives: The primary objective was to determine whether early detection of undiagnosed PsA in people with psoriasis by an enhanced surveillance (ES) intervention compared to standard care (SC) improves outcome in physical function at 24 months post-registration. Secondary objectives were to compare disease activity and impact of disease between groups in those participants diagnosed with PsA.
Methods: A multi-centre, prospective, parallel group cluster randomised controlled trial in patients with psoriasis with no prior diagnosis of PsA was conducted. GP practices were randomised in a 1:1 allocation ratio with stratification for GP practice list size and Central Commissioning Group (CCG). A total of 133 GP practices and 2225 participants were registered, corresponding to 1123 allocated to ES and 1102 to SC; primary analysis population consisted of 87 participants with a positive diagnosis of PsA: 64 in ES, 23 in SC (Figure one). Baseline characteristics were similar across both treatment groups. The adjusted odds ratio (OR) for achieving a HAQ-DI score of 0 at 24 months post registration in ES compared to SC was 0.64 (95% CI: 0.35, 1.12), indicating no evidence of a difference between treatment groups (p=0.5075). Moreover, the adjusted OR of achieving a higher PASDAS score of 0 at 24 months post registration in participants diagnosed with PsA was 1.12 (95% CI: 0.67, 1.86), again indicating no evidence of a difference between the two treatment groups (p=0.6612). There was high variability on the impact of the disease between participants over time, although the impact is generally low in this group of participants with an ‘early’ diagnosis of PsA. Moreover, the overall PASDAS score and component scores over time post PsA diagnosis show high variability in PsA disease activity. No adverse events were reported.

Conclusion: There was insufficient evidence that early diagnosis by ES and subsequent treatment improves physical function compared to SC in patients with psoriasis. Limitations included the trial being underpowered for demonstrating the pre-specified treatment effect; only 6.2% of participants recruited had psoriasis. Limitations included the trial being underpowered for detecting the MCID in the primary outcome measure of 0.35 units. Participants recruited were managed according to either SC, or ES by annual rheumatological assessment. Participants with suspected inflammatory arthritis were referred, via their GP, to the local rheumatology outpatient clinic at participating hospitals for an assessment of PsA by the ‘treating rheumatologist’ (ES arm: at baseline, 12 and 24 months; SC arm: at 24 months). Participants diagnosed with PsA then entered the PsA-care pathway element of the trial. The primary outcome measure was the HAQ-DI at 24 months post registration in participants diagnosed with PsA. Secondary outcome measures, PASDAS and PsAID-12, were assessed over time in participants with a positive diagnosis of PsA.

Results: A total of 2225 participants across 133 GP practices were registered, corresponding to 1123 allocated to ES and 1102 to SC; primary analysis population consisted of 87 participants with a positive diagnosis of PsA: 64 in ES, 23 in SC (Figure one). Baseline characteristics were similar across both treatment groups. The adjusted odds ratio (OR) for achieving a HAQ-DI score of 0 at 24 months post registration in ES compared to SC was 0.64 (95% CI: 0.17, 2.38), indicating no evidence of a difference between treatment groups (p=0.5075). Moreover, the adjusted OR of achieving a higher (non-zero) HAQ-DI score at 24 months post registration in ES relative to SC arm was 1.12 (95% CI: 0.67, 1.86), again indicating no evidence of a difference between the two treatment groups (p=0.6612). There was high variability on the impact of the disease between participants over time, although the impact is generally low in this group of participants with an ‘early’ diagnosis of PsA. Moreover, the overall PASDAS score and component scores over time post PsA diagnosis show high variability in PsA disease activity. No adverse events were reported.

Conclusion: There was insufficient evidence that early diagnosis by ES and subsequent treatment improves physical function compared to SC in patients with psoriasis. Limitations included the trial being underpowered for demonstrating the pre-specified treatment effect; only 6.2% of participants recruited had a positive diagnosis of PsA, much lower than assumed (18%). The imbalance observed between treatment groups (~3:1 ratio (ES:SC)), is largely explained by the lower proportion of participants especially in the SC arm attending the screening visit at 24 months, and delays between referral and attending appointment with the treating clinician, all further exacerbated by the Covid-19 pandemic. Furthermore, a longer duration of follow-up may be necessary to detect differences in outcome and is planned.

Background: Power Doppler ultrasound (PDUS) is a powerful diagnostic tool with high accessibility and reproducibility, allowing the visualisation of morphological and inflammatory changes of the synovium. The ULTIMATE study (NCT02662985) was the first large, randomised, double-blind, placebo-controlled, multicentre PDUS phase 3b study in psoriatic arthritis (PsA) that utilised the Global EULAR-OMERACT- Synovitis Score (GLOESS), to demonstrate the responsiveness of PDUS to detect early and continuous decrease in the synovitis score.[1] However, the ultrasound assessment for GLOESS is time-consuming due to the number of joints assessed.

Objectives: The aim of this study was to investigate the performance of different reduced joint sets to predict response to secukinumab, compared with the 24 paired joints included in the validated GLOESS.

Methods: ULTIMATE was a 52-week study, with a 12-week double-blind, placebo-controlled period followed by a 12-week open-label treatment period and a 6-month extension period.[1,2] The GLOESS comprises the sum of PDUS scores of 24 paired joints (potential score range: 0–144). A cluster image map was constructed to identify highly correlated joint clusters, based on the change from baseline of the composite PDUS scores at joint level. A reduced set of joints was selected based on either a mathematical approach that used the correlation clusters along with the joint level variations and joint location (Model 1 and Model 2) or a pragmatic approach that selected joints most frequently found to be active by ultrasound, in PsA in clinical practice (Model 3). Linear models with reduced joint sets predicted the actual GLOESS at each time point utilising 60% of data randomly selected from the study. The remaining 40% were used for model validation and diagnostics.

Results: Three models were established with reduced joint sets (12–18 pairs). The joints included in each linear model are summarised in Table 1. Figure 1 depicts the trajectory of the two mathematical models and the pragmatic model versus the actual GLOESS in the secukinumab and placebo-secukinumab groups assessed by change from baseline to Week 24. Compared to GLOESS, all reduced PDUS joint sets demonstrated similar responsiveness to secukinumab from baseline to Week 24.
