The primary outcome was incident BFF (inc-BFF). Follow-up started at BMD measurement (baseline) and continued until the development of the first fracture or censoring at death, loss to follow-up or end of the study. In these subjects, T-scores and pr-BFF were calculated and T-score < -2.5 in the lumbar spine (LS) or femoral neck (FN), or presence of pr-BFF was evaluated as primary osteoporosis criteria matched (pr-OP). Potential key factors for incident BFF, such as age, disease duration of RA, anti-citrullinated peptide antibodies (ACPA), rheumatoid factor (RF), remission rate using clinical disease activity index (CDAIRR), C-reactive protein, Health Assessment Questionnaire Disability Index, pain score using a visual analog scale (PS-VAS), vector magnitude (Vxy) using Joint Index Vector (JIV), body mass index (BMI), presence of comorbidities such as hyper-fallability (Fall), lifestyle-related diseases (LSD), cognitive impairment (CI), estimated glomerular filtration rate calculated with cystatin C (eGFR_CysC), anti-osteoporotic drug administration and glucocorticoid administration, and serum albumin level (ALB) were chosen as variants. Receptor operation characteristics (ROC) curve was evaluated for each variant in regard to inc-BFF and the Cut-off index (COI) for each variant was determined. A Cox regression analysis with a multivariate mode in the variants that had statistical significance with the ROC. Kaplan-Meier survival curve (K-M) was examined for each variant in regard to COI. Finally, the K-M study examined the chi-square test by dividing it into positive pr-OP, positive all single significant variants, and positive combined conditions, and simultaneously calculated inc-BFF rates for each subgroup. Differences in BFF rates were compared for each matching pair. Statistical significance was set at less than 5% for all statistical methods.

Results: A total of 239 patients were recruited. The mean age was 73.6 years and the mean follow-up period was 52.4 months. In the ROC study, pr-OP, ACPA, CDAIRR, PS-VAS, Vxy, Fall, LSD, CI, eGFR_CysC, and ALB demonstrated statistical significance with the COI of presence, 0.9 (U/mL), 0.52, 25.0 (mm), 0.012, presence, presence, presence, 50.7 (ml/min/1.41m2), and 4.0 (g/dL), respectively. In these, PS-VAS, Vxy, and ALB had significant risk ratios with values of 1.04, 0.07, and 0.20, respectively, Hazard ratios of each variant in the K-M study were 3.51, 4.56, and 1.81, however, p-values were <0.001, <0.01, and 0.07 for PS-VAS, Vxy, and ALB, respectively. The BFF rate in the pr-OP and PS-VAS ≥ 25.0 subgroups were 4.5%, 12.9%, 14.7%, and 37.9% in the negative/negative, negative/positive, positive/negative, and positive/positive groups, respectively, whereas the BFF rate in the pr-OP and Vxy ≥ 0.012 subgroups were 4.3%, 8.3%, 6.3%, and 32.4% in the negative/negative, negative/positive, positive/negative, and positive/positive group, respectively. When PS-VAS and Vxy were combined to matching either of these, the BFF rate in the subgroups were 5.6%, 12.5%, 12.8%, and 49.0% in the negative/negative, positive/positive, positive/negative, and positive/positive group, respectively. When PS-VAS and Vxy were combined, the BFF rate in the pr-OP and PS-VAS ≥ 25.0 subgroups were 4.5%, 12.9%, 14.7%, and 37.9% in the negative/negative, negative/positive, positive/negative, and positive/positive group, respectively.

Conclusion: These results suggest that Vxy > 0.012 and PS-VAS > 25mm are available risk indicators for inc-BFF. The composite indicator should be more predictable.

following co-variates: age, sex, race, BMI, comorbidities, education level, smoking, SLE duration, self-reported lupus disease activity, SLE organ damage measured by BILD (Brief Index of Lupus Damage), and other medications. Results of LASSO analyses are reported as incidence rate ratios (IRRs).

**Results:** 512 participants qualified for the analysis; 46.3% reported GC use in at least one 6-month period. Over 90% of the cohort was male, mean age 58 ±13 years, SLE duration 24 ±12 years. GC users were significantly less likely to be male or white, had more comorbidities, had lupus of greater duration, were more likely to also be taking immunosuppressive medications, and reported more active SLE and greater disease damage (BILD). In bivariate analyses (Table 1), GC users reported significantly more rheumatology and other doctor visits, and more PT/OT visits. They also reported more lung function, blood, and urine tests. There was no difference between GC users and non-users in the occurrence of a hospitalization, but users had significantly longer hospitalizations. The multi-variable LASSO regression analyses [1] revealed similar results, with significantly higher IRRs for GC users for rheumatology and other visits, blood and urine tests, and hospitalizations. In analyses based on GC dosage, IRRs for rheumatology visits, other medical visits and blood tests were significantly elevated for each dosage group compared to the no-GC group; the highest GC dosage group also had significantly elevated IRRs for lung and urine tests and hospitalizations.

**Conclusion:** GC use is associated with greater healthcare utilization among this cohort with SLE, even after adjusting for a wide range of sociodemographic and disease-related factors. Additional analyses are needed to explore whether greater GC use reflects more severe disease, and/or whether GC use itself leads to increased healthcare utilization.

**AB0034 DEVELOPMENT OF PERSONALISED CARE PACKAGES FOR PEOPLE WITH EARLY RHEUMATOID ARTHRITIS: A MIXED-METHODS STUDY**

**Keywords:** Inflammatory arthropathies, Qualitative research methods, Rheumatoid arthritis

**M. Day** 1, 2, A. Busby 3, H. Lemp 4, E. Nikphorou 5, 6 1Queen Elizabeth Hospital, Rheumatology, London, United Kingdom; 2University of Liverpool, Institute of Life Course and Medical Science, Liverpool, United Kingdom; 3University of Hertfordshire, Centre for Health Services and Clinical Research, Life and Medical Sciences, Hatfield, United Kingdom; 4King's College London, Centre for Rheumatoid Arthritis, London, United Kingdom; 5King's College Hospital, Rheumatology, London, United Kingdom

**Background:** Disease management in early rheumatoid arthritis (RA) needs careful assessment of various aspects of the patient and their condition. We previously showed a need to address socioeconomic (SE) factors to improve clinical and patient-reported outcomes in RA, and benefits of a syndemics approach to care. We aimed to design a tailored care package which is acceptable, beneficial and relevant to the care of people with early RA.

**Objectives:** i) Determine aspects of care that people with early RA find beneficial to be included in potential care packages, based on individual needs and disease characteristics; ii) determine factors considered important by patients and healthcare professionals caring for people with RA to be included in care packages.

**Methods:** This work comprised two stages: i) three workshops involving healthcare professionals caring for people with RA, and patients with RA, using a modified-Deelphi approach; ii) online survey informed by outcomes from the workshops, featuring responses from an expanded cohort of participants from the above two groups (Figure 1). Purposeful sampling was used to identify potential UK-based participants including patients, rheumatology healthcare professionals, members of national rheumatology charities, and academics with an interest in RA. The online survey was based upon: i) key themes identified by the thematic analysis from the workshops; ii) results from previous findings from quantitative datasets conducted prior to this study, e.g. SE circumstances, clinical factors, and disease outcomes. Views were sought on future ‘care packages’ for people with early RA relevant to disease progression/ stages.

**Results:** Thematic analysis from the workshops identified two conceptual care pathways, with distinct MDT care packages, allowing for expansion of the core MDT as needed. The first pathway related to the time prior to RA diagnosis. Attendees considered this an early opportunity to potentially change the disease course, highlighting the importance of exploring risk factors e.g. obesity, smoking, social deprivation and isolation. The second pathway related to individuals with existing RA, with participants emphasising the importance of the right MDT member at the right time. Core care packages were suggested, containing three distinctive components: 1) early care package (up to 6 weeks post-diagnosis) with introduction to MDT; 2) personalised holistic care package in collaboration with AHPs; 3) continuity of care package between primary and secondary providers. Thematic analysis results also informed the survey. We received 41 responses: 17 (43%) rheumatology consultants, 7 (18%) specialist nurses, 6 (15%) rheumatology trainees, 5 (13%) occupational therapists, 3 (8%) physiotherapists, 1 (3%) patient and 1 (3%) dietician. 34 (82.9%) of respondents agreed people with RA need access to the same ‘early care package’, (a core MDT) at diagnosis. A further 35 (85.4%) approved that the care package for people with early RA can be tailored to individual’s clinical, psychological and social needs at subsequent reviews. There was strong consensus for the following two statements: A care package with core members of the multidisciplinary rheumatology team need to be available to people newly diagnosed with RA (mean 9.05, using scale 0-10) and ‘Personalised comprehensive care packages, comprising a core plus various additional members of the multidisciplinary team, need to be offered and adapted according to a person’s individual disease characteristics and socio-economic circumstances’ (mean 9.49). Fleiss’ Kappa calculations demonstrated fair level of agreement amongst respondents in the quantitative survey questions.

**Conclusion:** We identified two care pathways with tailored care packages to optimise management in people with RA. Our results reiterate the benefits of holistic care in early and established disease. This can be further explored using syndemics to focus and better understand the relationships between bio-psych-social factors influencing RA disease outcomes.

EFFICACY AND SAFETY OF NINTEDANIB IN INTERSTITIAL LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS: A SINGLE CENTER 6 MONTHS OBSERVATIONAL STUDY

Keywords: Lungs, Rheumatoid arthritis

O. Murata1, T. Okawara1, M. Fujimoto1, T. Nakai.1Iwate Medical University School of Medicine, Division of Allergy and Rheumatology, Department of Internal Medicine, Morioka, Japan

Background: Nintedanib, an intracellular inhibitor of tyrosine kinases, inhibits processes involved in the progression of lung fibrosis [1]. Although the efficacy and safety of nintedanib have been demonstrated for interstitial lung disease (ILD) associated with systemic scleroderma (SSc) [2-4], information of the efficacy and safety of nintedanib in patients with rheumatoid arthritis (RA) is limited [5].

Objectives: The aim of this study was to compare the efficacy and safety of nintedanib in patients with RA-ILD with those in patients with ILD associated with collagen tissue diseases, including SSc-ILD.

Methods: We extracted patients who visited our department and were received nintedanib and had pulmonary function tests performed 6 months after. Then, they were divided into two groups, which were RA group and non-RA group. Clinical and epidemiological parameters, fibrosis pattern on HRCT, pulmonary function at the time of nintedanib administration and 6 months after nintedanib administration and adverse events were compared between the two groups. Those data were collected from medical records and statistically analyzed.

Results: Ten patients were enrolled. RA group had 6 patients and non-RA group had 5 patients. Among the RA and non-RA group, 50% and 60% were women, respectively (P=0.74). Age at the time of nintedanib administration was 70.8±5.5 years and 59.0±9.1 years, respectively (P=0.035). At the time of nintedanib administration, oral glucocorticoids (GC) were used in 83.3% and 100%, oral GC dose was 8.5±10.9 mg/day and 9.4±1.7 mg/day, and immunosuppressants were used in 83.3% and 100% (P=0.27, 0.17, and 0.27, respectively). Usual interstitial pneumonia (UIP) pattern on HRCT was 100% and 40%, and nonspecific interstitial pneumonia pattern on HRCT was 0% and 60%, respectively (P=0.013). At the time of nintedanib administration, FVC was -1977±867.2 ml and 1654±507.3 ml, %FVC was 66.9±20.7% and 53.2±10.9%, and %DLco was 54.8±8.9% and 46.2±15.9% (P=0.58, 0.36, and 0.51, respectively). After 6 months of nintedanib treatment, ΔFVC was -18.3±10.35 ml and -24.0±1.91 ml, %ΔFVC was -7.05±6.7% and -10.9±9.0%, and %ΔDLco was 0.36±1.9% and -0.50±1.9% (P=0.52, 0.20, and 0.28, respectively). The incidence of adverse events was 50% and 40%, respectively. In the both groups, there were no patients with severe adverse events and acute exacerbations of ILD, and the continuation rate was 100%, respectively.

Conclusion: This observational cohort study revealed that there was no statistically significant difference in the reduction of respiratory function in both FVC, %FVC, and %DLco in the RA group compared to the non-RA group, and the safety was also comparable between the two groups. Although RA-ILD have more UIP pattern on HRCT than SSc-ILD, nintedanib may be effective for RA-ILD as same as SSc-ILD.

ACPA TITER IS AN INDEPENDENT DETERMINANT OF SERUM CTX IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

Keywords: Prognostic factors, Rheumatoid arthritis, Bone diseases

G. Adami1, G. Orsolini1, A. Fassio1, D. Bertelle1, C. Benini1, O. Viapiana1, D. Gatti1, M. Rossini1.1University of Verona, Rheumatology Unit, Verona, Italy

Background: Serum C-terminal telopeptide of type I collagen (CTX - a marker of bone resorption) and ACPA titer have been associated to higher erosive score in rheumatoid arthritis (RA) and lower bone mineral density (BMD), even in patients with pre-arthritis. Prominent inflammatory status cannot totally explain such association. The interplay between ACPA, disease activity, BMD and CTX is still unclear.

Objectives: To investigate the determinants of CTX serum levels in RA patients. Methods: We conducted a cross-sectional analysis on RA patients with active disease activity failure to first-line cDMARDs candidate to bDMARDs. Clinical, laboratoristic and demometric and BMD parameters were collected. ACPA, CTX, Pnococollagen I Intact N-Terminal Peptide (P1NP), Dkk1, Sclerostin (SOST), 25-OH-Vitamin D (25OHD), FSH, RANKL, OPG, B-ALP were done. Potential predictors of serum were analyzed using hierarchical regressions. Potential predictors were selected based screened via simple regression analyses which included CTX and a single candidate baseline predictor in each model. Any baseline predictor with p < 0.10 entered the multivariable model (model 1). We also conducted a multivariable linear regression forcing variables associated with CTX serum levels from the literature (model 2). Results were analyzed using GraphPad Prism version 9.5.0 for Windows, GraphPad Software, San Diego, California USA.

Results: We enrolled 62 RA patients in the study. DAS28-CRP at baseline was 4.17 (SD 1.28). 80.6% of patients were ACPA positive. The factors associated with CTX serum levels in the univariate analysis were: ACPA titer, DAS28-CRP, B-ALP, P1NP and BMD levels (table 1). ACPA titer was the only independent factor significantly associated with CTX serum levels in both model 1 and model 2 (table 1).

Conclusion: We found that ACPA titer is an independent determinant of serum CTX levels in RA patients with active disease activity.

Rheumatoid arthritis - comorbidity and clinical aspects

**Keywords:** Rheumatoid arthritis

X.Y. Yin1,2, Q.Y. Su1,2, J.N. Liu1,2, J. Luo1,2, Q. Yu4, P.F. He4, X. Li1,2,3, X. Zhang1,2,3, Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China;2Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China;3The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China;4Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease characterized by persistent immune response leading to arthritis and destruction. Mounting evidence has suggested that dysbiosis of the intestinal microbiome is a vital environmental factor that triggers the onset of RA[1]. Unraveling the interactions between the gut microbiome and metabolome could provide new insights to discover novel targets for treating various inflammatory diseases. However, the current understanding of the potential association between intestinal microbiota and RA still needs to be improved.

**Objectives:** Recent studies have reported that the change in the interaction between the microbiome and the immune system is one of the characteristics of RA. Therefore, we conducted a meta-analysis and Mendelian randomization (MR) to explore the association and causality between RA and intestinal flora.

**Methods:** The PubMed, Embase, Medline, Web of Science, CNKI, Wangfang, VIP, and CBM databases were searched from the establishment of the databases to January 1, 2023, to retrieve trials about RA and intestinal flora. We performed a meta-analysis to calculate the odds ratio (OR) and 95% confidence intervals (95%CI). In addition, we conducted a bi-directional MR study to explore the causal relationship between RA and intestinal microbial composition. Single nucleotide polymorphisms (SNPs) associated with RA from 22 genome-wide association studies (14,361 cases and 43,923 controls) were selected as instrumental variables (IVs) at a genome-wide significance level. The aggregated statistical data of intestinal microbiota were obtained from a large-scale multiracial GWAS meta-analysis, including 18,340 people from 24 cohorts. The random-effects inverse variance weighted method (IVW) was used to combine the causal effect of IVs. Sensitivity analyses were performed to test the robustness of our findings. All analyses were conducted in R 4.2.1 and STATA 12.0.

**Results:** We included 17 case-control studies that examined 1,062 RA patients and 921 healthy controls (HCs). Compared with HCs, decreases in α-diversity indices were consistently found in RA (Shannon-Wiener diversity index (SMD=-0.038, 95% CI -0.935 to -0.281, p<0.001); Simpson index (SMD=-0.558, 95% CI -0.891 to -0.225, p<0.001); ACE index (SMD=-0.414, 95% CI -0.697 to -0.132, p<0.001); Chao1 index (SMD=-1.373, 95% CI -1.980 to -0.766, p<0.001); Evenness index (SMD=-1.863, 95% CI -3.181 to -0.544, p<0.0004)). There was no significant difference in observed species between the two groups (SMD=-4.342, 95% CI -9.098 to 0.415, p=0.11). Further, we conducted a bi-directional MR analysis to test the causal relationship between RA and intestinal microorganisms, which included three phyla (Firmicutes, Proteobacteria, Actinobacteria), six families (Bacteroidaceae, Actinomycetaceae, Clostridiales, Lactobacillaceae, Bifidobacteriaceae, Lachnospiraceae) and seven genera (Bifidobacterium, Butyrivibrio, Escherichia Shigella, Lachnospiraceae, Lactobacillus, Actinomyces, Bacteroides). However, no genetic prediction causal relationship was found between them (all p>0.05). These results were robust in a wide range of sensitivity analyses.

**Conclusion:** This study suggested a significant correlation between RA and lower intestinal microflora abundance. This may provide new insights into the development mechanism of RA mediated by intestinal microbiota and may provide a evidence for regulating intestinal microbiome to target the treatment of RA.

**REFERENCE:**

Based on the multivariate study, a high CRP and SJC were found to be predictive factors to sleep disorders according to the PSQI score. On the other hand, the presence of extra-articular manifestations, female gender, and higher VAS were considered as predictive factors of the disorder conformity with the Ewoore score.

Conclusion: Sleep disorders are common among RA patients and they were essentially related to disease activity and functional disability, so it is important to guarantee the remission or low disease activity to improve sleep quality in these patients.

DEPRESSION IN RHEUMATOID ARTHRITIS: PREVALENCE AND PHENOTYPIC CHARACTERISTICS - A SINGLE CENTER EXPERIENCE

Keywords: Rheumatoid arthritis, Mental health

C. E. Ionescu 1, C. Popescu 1, M. Agache 1, G. Dinache 1, C. Codreanu 1.
1Rheumatic Disease Center DR ION STOIA Bucharest, Rheumatology, Bucharest, Romania

Background: Psychiatric comorbidities are frequent extra-articular manifestations in rheumatoid arthritis (RA) and depression is the most common [1]. A 2013 study estimated that 16.8 % of RA patients suffer from major depressive disorder, being more prevalent than diabetes, Parkinson’s disease or cancer [2-3]. Patients with RA have constitutional symptoms, frequently encountered in depression, like fatigue, weight loss, insomnia and lack of appetite. The overlap of depression in inflammatory immune mediated diseases is recognized for some time [4]. Studies show that immune mediated inflammation affects and modulates neurogenesis, neurotransmission, neuroendocrine activity and neuroplasticity [5]. Depression has important effects on RA mediated inflammation affects and modulates neurogenesis, neurotransmission, neuropsychological disorders, disease mediated inflammation affects and modulates neurogenesis, neurotransmission, neuropsychological disorders, disease severity or its activity [6].

Objective: The scope of this article is to highlight the importance of managing depression in RA. The primary objective was to estimate the prevalence of depression in a cohort of RA patients. The secondary objective was to describe the phenotypic characteristics of RA patients with depression.

Methods: RA patients from the Center of Rheumatic Diseases in Bucharest were included in the study if the patients were at least 18 years-old and had two or three follow-ups, after 2019. The protocol included collection of demographic, clinical and biological data. Prevalence of depression is derived from patients’ medical history, known depression. Demographical characteristics and RA phenotype were compared between the two groups. Disease activity was estimated with DAS28 and its components, tender joint count, swollen joint count, CRP and were followed over time to compare disease activity between patients with known depression and patients without depression.

Results: We collected data from 203 patients with RA, among whom 37 were known with depression, generating a prevalence of 18.2%. A meta-analysis from 2013 reported that 16.8% of RA patients with RA suffer from a major depression disorder [1]. Most of the patients with depression were women (67.2%). Female sex is a potential risk factor for depression [7]. The prevalence of active smoking among the depression subgroup was higher (8.1%, 1.8%, p = 0.041). Depression is a known risk factor for negative behaviors like smoking [8]. Patients had a longer disease duration (in median, 13 years compared to 10 years, p = 0.059) and also the seropositivity prevalence was lower. In 2022 a correlation between depression and seronegative RA was found [9]. DAS28 and the components of DAS28 were higher in the depression RA subgroup; DAS28 was higher at all time points (p < 0.001). Higher tender joint count was expected (p < 0.001), but swollen joint count was also higher among depressive RA patients (p < 0.001), as well as CRP (p = 0.009, Figure 1).

Conclusion: Depression is prevalent among RA patients and it has an important impact on the quality of life; so depressive symptoms should be addressed in clinical practice. The correlation between the prognosis of rheumatic disease and depression is strong, regardless of the direction of causality. The assessment of depression could be a psychomarker for assessing RA prognosis. DAS28 is used to make therapeutic decisions, so given that depression scores increase DAS28, it follows that they also influence therapeutic decisions.

ENDOCRINE DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS AND THEIR RELATIONSHIP TO DISEASE SEVERITY

Keywords: Comorbidities, Rheumatoid arthritis, Descriptive Studies

M. K. Garg 2, P. S Kumar 3, S. Nandagopaul 3, K. Shukla 3, M. Gopalakrishnan 1, 1All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India; 2All India Institute of Medical Sciences, Endocrinology and Metabolism, Jodhpur, India; 3All India Institute of Medical Sciences, Biochemistry, Jodhpur, India

Background: Rheumatoid arthritis (RA) is known to be associated with multiple endocrine dysfunctions including hyperprolactinemia, hypothyroidism, hyperandrogenism, and hypogonadism. The link between endocrine system and synthetic cytokines in RA is attributed to the presence of functional receptors for glucocorticoids, androgens and estrogen in the synovioites which function as an intracellular system [1,2].

Objective: To describe endocrine dysfunction in patients with RA and to determine its relationship with disease severity and disease duration.

Methods: We studied RA patients diagnosed using ACR/EULAR 2010 at our clinic in Jodhpur, India from January 2021 to August 2021 after written informed consent and Ethical Committee approval. We collected the clinical, demographic, treatment history and calculated disease severity with Disease Activity Score (DAS28) and Simplified Disease Activity Index (SDAI). Serum samples for thyroid profile, prolactin, dehydroepiandrosterone sulfate (DHEAS), testosterone, cortisol, Tumor Necrosis Factor alpha (TNF-α) and Interleukin 6 (IL-6) were collected and stored at -80°C and analysed by chemiluminescent immunoassay (Siemens Advia Centaur® immunoassay system, USA) as per the standard hospital protocol. Spearman’s correlation was used to determine the relationship between endocrine dysfunction with disease severity scores and total disease duration.

Results: Among the 160 patients included in the study, 4 were on levithroxine supplementation for hypothyroidism. Thirteen patients (8.8%) had primary hypothyroidism, 2 patients (1.3%) had subclinical hypothyroidism with no cases of central hypothyroidism and 31 patients (20.9%) had sick euthyroid syndrome (Table 1). Hyperprolactinemia was seen in 24.3% patients and the mean level of serum prolactin increased as the disease severity increased but it was not statistically significant (Figure 1). DHEAS levels were below the accepted age and gender cut-offs in 58.4% patients while 56.6% had low testosterone. Among the 99 patients who had random cortisol values, 36 patients (36.4%) had adrenal insufficiency (random cortisol range<3 μg/dl). Serum cortisol was negatively correlated with serum TNF-α but had no relationship with serum IL-6. None of the endocrine parameters were correlated with disease severity scores (SDAI/ DAS) or their individual components.

Conclusion: Considerable percentage of patients with RA have endocrine dysfunction compared to the general population, likely secondary to raised inflammatory cytokines produced at synovial tissues. However, they do not correlate to disease activity or disease duration in RA.

REFERENCES:
Conclusion: To our knowledge this is the first study evaluating drug safety and pregnancy outcome in Indian RA patients. Most RA patients can have successful pregnancy. SSZ, HCQ, Azathioprine and low dose prednisolone are safe during pregnancy. Limited data indicates patients can have successful pregnancy without out MTX washout but more data is required.

RELATIONSHIP BETWEEN NUTRITIONAL STATUS AND OSTEOPEOROSIS IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Osteoporosis, Diet and Nutrition, Rheumatoid arthritis

M. Arthaud1, M. Ghali1, J. Mahboub1, S. Zrou1, I. Beija1, M. Touzi1, N. Bergaaou1
Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia

Background: Malnutrition is a recognised risk factor for osteoporosis. These two conditions are frequent comorbidities in rheumatoid arthritis (RA), especially in elderly patients.

Objectives: The aim of our study was to evaluate the association between malnutrition and osteoporosis among elderly patients followed for RA.

Methods: This is a cross-sectional study including patients followed for RA aged 65 years or older. Nutritional status was assessed by body mass index (BMI) and the Mini-Nutritional Assessment (MNA) questionnaire. Patients were divided into 2 groups according to the MNA: an “impaired nutritional status” group with an MNA score ≤23.5 and a “normal nutritional status” group with an MNA ≥24.

Results: There were 63 patients (52 women and 11 men). The mean age was 68.1±4.35 years. The median duration of RA was 11 years with a IQR of [4-16]. The mean DAS28-VA was 3.72±1.48. The mean total MNA score was 20.19±4.71 [8-27.5]. According to the MNA, 76.2% of the patients had an “altered nutritional status” and 23.8% of the patients had a “normal nutritional status”. The mean BMI was 27.97±5.44 kg/m². Osteoporosis was found in 25 patients (39.7%). In the “impaired nutritional status” group according to the MNA, there were significantly more osteoporotic patients (p=0.05). The mean T-score at the lumbar spine was significantly lower in patients with MNA indicating “impaired nutritional status” (-1.89±1.18 SD vs -1.03±0.76; p=0.001). A lower BMI was significantly associated with osteoporotic patients (-2.36±1.17 SD vs -1.53±0.81; p=0.04), as was the mean T-score at the femoral site (-1.89±1.18 SD vs -1.03±0.76; p=0.001). A lower BMI was significantly associated with the T-score at the femoral site (p=0.04) but not at the lumbar spine site (p=0.18).

Conclusion: Our study showed that in elderly patients followed for RA, malnutrition diagnosed with the MNA score was significantly associated with osteoporosis and lumbar and femoral T-scores, and low BMI was associated with the femoral site T-score.

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory disorder affecting the joint synovium. Foot involvement is frequent throughout the disease course[1]. However, definition of foot involvement differs, with some scientific works using patient reported outcomes, especially pain, rather than arthritis detected by clinical examination or ultrasound[2,3].

Objectives: Primary – to study the frequency and pattern of foot involvement in RA patients. Secondary – to compare patients with or without foot involvement concerning sociodemographic, clinical, radiographic and laboratory characteristics.

Methods: Single center, retrospective study including patients evaluated in our center with a diagnosis of RA, between June-December, 2022. All patients fulfilled the 2010 ACR/EULAR classification criteria for RA. Patient records were searched for sociodemographic, clinical, laboratory, and radiographic data. Multimorbidity was defined as the coexistence of 2 or more comorbidities. Patients were divided into two groups, according to the presence/absence of cumulative foot involvement, defined as the presence of clinical arthritis or synovitis in ultrasound. Descriptive analysis used mean, median, standard deviation, and inter-quartile range for continuous data, as well as frequency counts and percentages for categorical variables. A statistical analysis was performed, with a statistically significant p-value ≤ 0.05. The two groups of patients (with/without foot involvement) were compared using parametric and non-parametric tests for continuous variables, and Chi-squared test for categorical variables.

Results: 110 patients were enrolled, with an mean age of 62.97 ± 13.81 years. 84 patients were women (76.3%). Cumulative foot involvement was found in 71 patients (64.55%). The foot was the most frequently affected area (69.01% of the patients with foot involvement, n=49), followed by the tibiotalar joint (53.52%; n=38), the mid foot (12.68%; n=9) and the hindfoot (11.27%; n=8). Patients with foot involvement were more likely to receive a biologic disease modifying anti-rheumatic drug (p < 0.05). We found no statistically significant differences between patients with or without foot involvement concerning gender, age at diagnosis, disease duration, multimorbidity or anti-citullinated protein antibodies positivity, bone erosions, multimorbidity, inflammatory markers levels, number of tender or swollen joints at last evaluation, mean Disease Activity Score (DAS)28-C-reactive protein (CRP) and DAS28-erythrocyte sedimentation rate (ESR) or Health Assessment Questionnaire Disability Index Score (HAQ-DI).

Conclusion: In our study, objective foot involvement in RA was frequent and associated with higher probability of biological therapy. However, it did not correlate with poor prognosis factors[4] such as seropositivity, bone erosions or high disease activity measured by DAS28-ESCR and DAS28-ESR. We found no higher differences between patients with or without foot involvement regarding gender, age at diagnosis, disease duration, multimorbidity or anti-citullinated protein antibodies positivity, bone erosions, multimorbidity, inflammatory markers levels, number of tender or swollen joints at last evaluation, mean Disease Activity Score (DAS)28-C-reactive protein (CRP) and DAS28-erythrocyte sedimentation rate (ESR) or Health Assessment Questionnaire Disability Index Score (HAQ-DI).

Disclosure of Interests: None Declared.

ASSESSMENT OF KIDNEY INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Kidneys, Rheumatoid arthritis, Comorbidities

S. Monova1, T. Todorov2, D. Monova3, 1Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria; 2Medical University - Sofia, Department of General and Clinical Pathology, Sofia, Bulgaria; 3Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria

Background: In rheumatoid arthritis (RA) kidney is commonly affected organ with clinical presentation characterized by proteinuria and microalbuminuria, followed by chronic renal failure. RA is associated with reduced kidney function, possibly due to chronic inflammation or the use of nephrotoxic therapies. Renal diseases occurring in patients with RA may have a variable clinicopathological picture. Little is known about the effects of using the novel biological agents on the risk of kidney diseases.

Objectives: The aim of this study was to determine the relationship between effect of therapy and kidney involvement in patients with RA and evaluated the histopathological findings and associated clinical manifestation.

Methods: In this retrospective study 275 patients with diagnosis of RA were included. In 48 patients renal biopsy was performed. The patients were divided in three groups according to changes in management of RA: 1991-2001, 2002-2011 and 2012-2022 year. Data of demographic characteristics, clinical symptoms and pathological diagnosis were extracted from medical records and pathological reports (1,2,3).

Results: In our study amyloidosis was the most common histologic pattern, followed by chronic glomerulonephritis (GN) and tubulointerstitial nephritis. Renal amyloidosis was diagnosed in 13 patients, membranous GN – in 9, mesangio-proliferative GN - in 7 patients, focal segmental necrotizing GN – in 5, focal segmental sclerosis – in 4, minimal change disease – in 3, tubulointerstitial nephritis – in 7 patients. Between 1991 and 2001 the most common clinical manifestation was nephritic syndrome and the most common histopathological findings - renal amyloidosis, followed by membranous GN and focal segmental necrotizing GN. The membranous GN was related to the use of gold and its frequency decreased after 2001. The mesangio proliferative GN was the leading cause of kidney disease between 2002 - 2011 years and focal segmental sclerosis – between 2012-2022. In our study 68 patients had a decrease of glomerular filtration rate (GFR) < 60 mL/min/m2. No kidney biopsies were performed in these cases because no urine abnormalities were detected. We found that age, duration of the disease, arterial hypertension, C-reactive protein were significant risk factors for GFR decline in patients with RA. Patients with RA who are treated with biologic agents are less likely to experience progressive decline in kidney function than those not receiving biologic treatment (hazard ratios [HRs] [95% CI], 0.68-1.00).

Conclusion: In all patients with RA, renal function should be monitored and in the case of pathological results, renal biopsy should be performed. In RA patients with renal disorder, suspected causal drug should be removed from the treatment and specific immunosuppressive therapy initiated. Improved pain management associated with biologic treatment may help to reduce the need for potentially nephrotoxic anti-inflammatory agents such as NSAIDs and certain types of non-biologic DMARDs, which could consequently reduce the risk of drug-induced nephrotoxicity and thereby contribute to the lower risk of renal diseases.

ORBITAL MYOSITIS ASSOCIATED WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW OF CLINICAL FEATURES AND PARACLINICAL DATA

Keywords: Rheumatoid arthritis, Myositis, Systemic review

J. Mahdavi1. 1Aurak University of Medical Sciences, Students Research Committee, Arak, Iran (Islamic Republic of)

Background: Orbital myositis (OM) is an inflammatory condition that mainly involves extraocular muscles. The exact etiology of this disease is not known [1]. However, rheumatoid arthritis (RA) has been reported as a possible cause of OM in some cases.

Objectives: The aim of this study was to assess the clinical features and paraclinical data of patients with OM associated with RA.

Methods: This study is a systematic review that followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The search was performed in PubMed, Web of Science, Scopus, and ScienceDirect for English articles published between 1990 and 2022. Google Scholar was also utilized to find more studies. The keywords used were: “orbital myositis,” “ocular myositis,” and “rheumatoid arthritis.” There was no limitation in age, gender, nationality, and severity of disease.

Results: A total of 6 studies, describing 5 females and 1 male with age ranging from 38 to 61 years, were included [2-7]. The time between the diagnosis of RA and OM was different, with a maximum of 34 years. The most common sign/symptom found in the patients was diplopia (5 cases) followed by proptosis (3 cases), headache (2 cases), drooping eyelid, periorbital swelling, pain on eye movement, conjunctival
cherosis, and eye movement limitation (each 1 case). In physical examination, decreased vision and weakness/paralysis of the orbital muscles including medial, lateral, and superior rectus were found. Laboratory data revealed increased thyroxi ne-stimulated lymphocyte transformation, elevated inflammatory markers including ESR and CRP in 1 case. MR/CT showed thickening of the involved orbital muscles in all cases and tendon enlargement in 2 cases. Although most of the patients were being treated with corticosteroids had good outcomes, paresis of the orbital muscles and mild restriction of horizontal movements due to fibrosis remained as sequel in 2 cases.

Conclusion: Although more research is needed on the relationship between RA and OM, RA should be considered as a rare possible cause of OM, which can lead to nonspecific findings such as headache and elevated inflammatory markers to ocular manifestations like diplopia, proptosis, and drooping eyelid. In addition, in patients with RA and ophthalmological diseases, it is recommended that OM be evaluated as a differential diagnosis to avoid irreversible complications with timely treatment.

CURRENT CARDIOVASCULAR RISK (MANAGEMENT) IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS

Keywords: Cardiovascular disease, Rheumatoid arthritis

R. Raadsen1,2, R. Hanssilaar1,2, A. Van Kuijk1, M. T. Nurmohamed1,2.
1Amsterdam Rheumatology Centre, Location Reade, Department of Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC, location VUMc, Department of Rheumatology, Amsterdam, Netherlands

Background: Patients with rheumatoid arthritis (RA) are at an increased risk for developing cardiovascular diseases. While advice regarding cardiovascular risk screening and management in RA patients has been incorporated in several guidelines in recent years, its implementation and adherence is still poor (1, 2).

Objectives: To assess the cardiovascular disease risk in patients with newly diagnosed RA, and evaluate whether advice to initiate preventive medical treatment of high risk patients was followed.

Methods: All patients with RA, aged 40-70 years, are screened for cardiovascular diseases and risk factors within the first year after diagnosis at the outpatient rheumatology clinic of Reade, as part of standard care. Screening includes a rheumatological evaluation of cardiovascular risk and calculated 10-year cardiovascular mortality risk-distribution calculated using SCORE1. Risk distribution is defined as low (<1%), intermediate (1-5%), high (5-10%) and very high (>10%). The national pharmacy network was consulted for whether or not patients started antihypertensive or statin medication after screening.

Results: A total of 125 RA patients were included in this study. The mean age was 56 years and 78% was female. Median RA disease duration at screening was 6 months. 6 patients (5%) indicated to have been screened before, and used antihypertensive medication. During screening, hypertension was found in 46% of patients, with 57% occurring in men and 43% in women. Dyslipidemia was found in 33% of patients, with 36% in male patients and 32% in female patients. 21% of female patients and 46% of male patients currently smoked. Hypertension and dyslipidemia are shown in Table 1. A low 10-year cardiovascular mortality risk was found in 36% of patients, an intermediate risk in 49%, a high risk in 11% and a very high risk in 4% of patients (Figure 1). Only 26% of high and very high risk patients started antihypertensive or statin medication after screening.

Conclusion: An increased cardiovascular disease risk in RA patients, especially male patients, is often present soon after diagnosis, with a large proportion having undiagnosed and untreated hypertension and hypercholesterolemia. Even with structural screening and informing the GP, treatment of cardiovascular risk factors in high risk patients remains insufficient. Obviously, a better collaboration between GPs and rheumatologists is urgently needed to lower the cardiovascular burden of our patients.

EVALUATION OF CARDIOVASCULAR RISK AND OSTEOMETABOLIC ALTERATIONS IN A POPULATION OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS: PRELIMINARY RESULTS OF A MULTIDISCIPLINARY PROSPECTIVE STUDY

Keywords: Comorbidities, Rheumatoid arthritis, Real-world evidence

S. Parisi1, M. C. Ditto1, C. Lopez2, G. Beccuti2, F. Broglio2, E. Ghigo2, E. Fusaro3.
1Azienda Ospedaliero Universitaria Città Della Salute e della Scienza di Torino, Rheumatology Unit, Turin, Italy; 2Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Endocrinology, Diabetes and Metabolism Unit, Department of Medical Sciences, Turin, Italy

Background: Rheumatoid Arthritis (RA) is associated with increased cardiovascular (CV) morbidity and mortality and osteoarticular alterations risk, associated with chronic inflammation, the use of glucocorticoids (GC) and the reduced physical exercise.[1]

Conclusion: Evaluation of cardiovascular risk and osteoarticular alterations in a population of patients affected by Rheumatoid Arthritis: Preliminary results of a multidisciplinary prospective study.

REFERENCES:

**Objectives:** The objective of the study is to cross-sectionally estimate cardiovascular risk and osteometabolic status in patients (pts) with RA and to evaluate the association with some disease parameters such as positivity of autoantibodies, disease activity and steroid therapy.

**Methods:** At the current time, 61 consecutive pts with diagnosis of RA, admitted to the Rheumatology Unit of the University Hospital of Turin, were prospectively recruited and assessed for cardiometabolic risk by the Endocrinology Unit, by undergoing laboratory and instrumental tests.

**Results:** The following prevalences were observed: arterial hypertension (52%), type 2 diabetes mellitus (7%), dyslipidemia (56%), osteoporosis (42%), and vertebral fracture (30%). At the univariate analysis, the enrolled pts were divided according to serodiagnosis, GC therapy and disease remission. No statistically significant results were highlighted stratifying population by serodiagnosis. Pts with high disease activity showed lower bone mineral density (BMD) values [BMD femoral trochanter: 0.53 ± 0.07 vs 0.60 ± 0.05 (g/cm²); p=0.031] and T-score value on bone densitometry [T-score Femoral total: -1.89 ± 0.53 vs -1.07 ± 0.83; p=0.005], higher percentage of osteoporosis [67% vs 27%; p=0.047] and vertebral fractures [80% vs 12%; p=0.001], and higher sarcopenia score [SARC-F: 5 (3-7) vs 2 (2-4); p=0.020], in comparison with pts with remission disease. These differences were not confirmed when the population was divided according to the use of GC therapy. For CV risk factors, disease activity group showed a trend of higher prevalence compared to remission group, but without reaching statistical significance. At the multivariate analysis, advanced age (p=0.001), GC therapy (p=0.021) and copeptin (p=0.002) showed an inverse association and lumbar T-score (p=0.002) a direct one a lumbar trabecular bone score (TBS). Moreover, male gender (p=0.001) revealed a direct and significant association, while copeptin (p=0.086) an inverse and not significant one with percentage of lean mass on total densitometry, correcting for advanced age, disease activity, and disease activity. In the last model, advanced age (p=0.001) and copeptin (p>0.001) showed a direct and significant association with HeartSCORE, correcting for parameters of disease while serodiagnosis, duration of disease, GC therapy, and disease activity.

**Conclusion:** At univariate analysis osteometric alterations were associated with disease activity, but not with GC therapy and serodiagnosis. At the multivariate analysis, the association of disease activity and TBS values, did not reach the statistical significance, probably for the loss of statistical power. However, GC therapy, as well as advanced age, low lumbar T-score and high value of copeptin, remained independently associated with lower TBS value. Disease parameters were not associated with lower percentage of lean mass at total body densitometry and higher HeartSCORE values, while advanced age and copeptin were associated with bone health and cardiovascular risk.

DOI: 10.1136/annrheumdis-2023-eular.1834
Background: Rheumatoid arthritis (RA) is known as a risk factor for osteoporosis. However, few patients with osteoporotic fractures have measured bone mineral density (BMD) before fracture[1]. Therefore, there is still a need for the development of a simple screening method.

Objectives: The previous studies showed that BMD correlates with the second metacarpal cortical index (2MCI)[2,3,4]. This study aims to build a machine learning model that effectively predicts BMD from plain X-rays to identify high-risk patients for osteoporosis.

Methods: Among the RA patients enrolled in KURAMA cohort between 2012 and 2020, 362 patients received a set of tests, including Dual-energy X-ray absorptiometry (DXA) and bilateral hand X-rays multiple times with a minimal interval of two years. 2MCI was defined as the ratio between the thickness of the cortex and the width of the bone of the second metacarpal(Figure1). We examined the correlation between changes in 2MCI and BMD of the hip and the forearm. Then, we built a machine learning model that predicts BMD using 2MCI and clinical variables. In addition, we evaluated the robustness of the model using an external validation dataset.

Results: The mean age was 62.6 years, and the mean disease duration was 14.1 years. Baseline cross-sectional analysis showed a significant correlation between 2MCI and BMD of the hip and forearm (p<0.01). Longitudinal analysis showed a significant correlation between changes in BMD and 2MCI (p<0.01). For exploring the best machine learning model, we used Pycaret and found that Bayesian Ridge showed the best performance for predicting BMD of the hip using 2MCI and clinical parameters (MAPE; Mean Absolute Percentage Error = 0.109). Furthermore, model validation using an external dataset revealed good generalized performance (MAPE=0.145).

Conclusion: Establishing a simple and efficient screening method for osteoporosis is a social issue in an aging society. This study showed that Bayesian Ridge showed the best performance for predicting BMD of the hip using 2MCI and clinical parameters (MAPE; Mean Absolute Percentage Error = 0.109). Furthermore, model validation using an external dataset revealed good generalized performance (MAPE=0.145).

Objectives: The aim of our study was to determine whether psychological status has an impact on coping strategies in patients with rheumatoid arthritis (RA).

Methods: We conducted a single-centre cross-sectional study for 6 months from 28 March to 28 September 2021 in which we included patients with RA fulfilling the ACR/EULAR 2010 criteria. Characteristics of RA including disease duration and disease activity by the DAS 28 CRP were recorded. The Brief Cope score was used to assess coping strategies. Five grouped coping strategies were evaluated: problem-focused strategies, cognitive restructuring-based strategies, support-based strategies, avoidance-based strategies, and distraction-based strategies. We assessed anxiety and depression using the Hospital Anxiety and Depression Scale (HAD).

Results: Sixty-five patients were included (89.2% women). Mean age was 58.6 ± 9.9 [24-73 years]. Mean duration of RA was 15 ± 10.6 years. Median DAS28 CRP was 3.4 (IQR 25-75: 2.6- 4.8) [1.54-6.77]. Median anxiety score was 6 (IQR 25-75: 1-10). Twelve patients (18.5%) had anxiety. Median depression score was 7 (IQR 25-75: 1-13). Eighteen patients had depression (27.7%). Problem-focused and support-based strategies were the most used among all patients, with respective means of 5.6 and 5.5. The association of grouped coping strategies with depression and anxiety is shown in Table I.

Table I: Association of grouped coping strategies with depression and anxiety

<table>
<thead>
<tr>
<th>Depression</th>
<th>Anxiety</th>

BONN PULSA: PULMONARY SCREENING IN ARTHRITIS - PREVALENCE OF PULMONARY MANIFESTATIONS IN PATIENTS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, AND PERIPHERAL SPONDYLOARTHRITIS

Keywords: Diagnostic Tests, Psoriatic arthritis, Rheumatoid arthritis

Background: Pulmonary impairment in rheumatic diseases is a common, but poorly understood and deficient screened and managed extraarticular manifestation, which causes a huge increase in morbidity and mortality[1]. As previous studies focused on rheumatoid arthritis (RA) and in some intent on psoriatic arthritis (PsA), data for patients with peripheral spondyloarthritis (pSpA) is lacking.

Objectives: To investigate the prevalence of clinical and subclinical pulmonary manifestations in newly diagnosed patients with RA, PsA, and pSpA and to compare different baseline examination results to develop a screening proposal for detecting patients at risk.

Methods: This clinical-prospective, longitudinal cohort study included a diagnostic workup consisting of a questionnaire for patient history, a physical examination, a body plethysmography with CO diffusion capacity (DLCO), a 6-minute walk test, laboratory parameters, and a chest x-ray (CXR) at the time of the initial diagnosis of arthritis disease, and at four additional time points in three-month intervals. This paper focuses on the baseline characteristics.

Results: 54 outpatients (26 RA, 24 PsA, 4 pSpA) and 26 age- and gender-matched controls were examined. Pulmonary impairment, in the sense of a morphologically abnormal CXR, was diagnosed in 19 arthritis patients (38.0%), 38.8% of these suffered from clinical symptoms, such as cough and/or dyspnea. However, 63.2% presented subclinical, asymptomatic pulmonary abnormalities (see Figure 1). The baseline results of several examinations are illustrated in Table I. An elevation of rheumatoid factor (> 14 IU/ml) showed an association with the manifestation of RA (p=0.002) as well as with the presence of pulmonary affection (p=0.008). In addition, the mean age of patients with pulmonary abnormalities (57.0 ± 12.8 yrs.) was different from that of patients without such abnormalities (43.9 ± 14.3 yrs.), with a p-value of 0.002. The association between the activity of arthritis disease, assessed by Disease Activity Score in 28 joints using CRP (DAS28CRP), and CXR findings proved to be significant (p=0.011). A DAS28CRP less than 3.2 (remission or low disease activity) indicated non-pathological findings in CXR.

Conclusion: The prevalence of pulmonary manifestations was more than one-third, of which more than two-thirds presented asymptomatic. The large proportion of asymptomatic subjects highlights the need for the implementation of a pulmonary screening at the initial diagnosis of arthritis disease. By alerting physicians, especially in the observed age cohort of 57 years with elevated RF levels, morbidity and mortality could be reduced.

PROFESSIONAL COUNTRY-WIDE SURVEY ON CLINICAL DECISION-MAKING IN THE TREATMENT OF RHEUMATOID ARTHRITIS

Keywords: Work-related issues, Disease-modifying Drugs (DMARDs), Best practices

O. Rusinovich1, E. Calvo-Anaran2, M. D. C. Uyaguari Morocho3, A. Pareja Martinez4, P. Navarro Palomo5, P. Navarro5, M. Cantalejo Moreira1, A. J. Diaz Oca6, M. Machattu7, M. Alonso de Francisco2, C. Navarro Joven5, M. Fernandez Castro5, H. Godoy2, C. Merino Argumánez2, B. Garcia-Magallon2, J. Sanz7, C. Barbadillo Mateos6, J. Campos Esteban2, J. L. Andreu Sanchez5, L. F. De Villa2, S. Gonzalez Pascua5, 1Hospital Universitario de Fuenlabrada, Rheumatology, Fuenlabrada, Spain; 2Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain; 3La Paz University Hospital, Rheumatology, Madrid, Spain; 4Hospital Universitario del Sureste, Rheumatology, Arganda del Rey, Spain; 5Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain; 6Hospital Universitario de Fuenlabrada, Internal Medicine, Fuenlabrada, Spain

Background: Incorporation of conventional synthetic (cs), biological (b) and targeted synthetic (ts) disease-modifying drugs (DMARDs) has enriched the therapeutic arsenal, but at the same time has complicated the decision-making process, since it requires considering not only the profile of each patient and the characteristics of each drug, but also the high cost of many of them and diverse administrative limitations.

Objectives: To analyze the way of acting of Spanish rheumatologists in different clinical situations in order to understand the decision-making process in the treatment of rheumatoid arthritis (RA).

Methods: A questionnaire that consisted of 15 questions was sent to several groups of rheumatologists country wide between October 19 and 26, 2022. Descriptive statistical analysis and Pearson’s Chi2 test were performed to compare responses to the items by the different groups, significance level 0.05 (p<0.05 N.S.).

Results: A total of 108 questionnaires were collected. Work experience of the respondents is reflected in Table 1. In patients with recent-onset RA associated with poor prognostic factors, in addition to corticosteroids half of the respondents (50%) opt to start treatment with csDMARD + rapid escalation to b/tsDMARD if clinical response is insufficient. The most relevant factors when choosing the drug is the patient’s profile (47.2%), followed by clinical practice guidelines (34.3%). The most relevant factors for choosing each DMARD were: anti-TNF - cost-effectiveness (47.2%); anti-IL6 - efficacy (72.2%); abatacept - efficacy and safety in patients with RA-associated interstitial lung disease (53.7%); rituximab - its safety in patients that didn’t respond to other treatments (76.9%); and JAK inhibitor - its possibility of use in monotherapy (40.7%). The most important factors that lead to change treatment are the disease activity measures (57.4%) and personal perception of the clinician based on anamnesis and physical examination (31.5%). If there is a good therapeutic response, the majority of respondents first taper the b/tsDMARD (50%). If bDMARD-b/tsDMARD combination therapy is used, 59.3% of respondents try to maintain csDMARD in addition to b/tsDMARD.

Conclusion: The study revealed a striking heterogeneity in the way of acting in complex clinical situations, which confirms that the decision-making process depends on many factors but also that there is still room for homogenizing clinical practice guidelines. However, there seems to be agreement on the need to minimize systemic exposure to corticosteroids, on the use of disease activity measures to evaluate therapeutic response and on the wide acceptance of biosimilar drugs.

UTILITY OF EPITHELIAL CELL BIOMARKERS TO ASSESS SEVERITY AND DISCRIMINATE BETWEEN DIFFERENT PATTERNS OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Biomarkers, Lungs

1Hospital General de Aguadors Dr. Fernandez, Internal Medicine, Buenos Aires, Argentina; 2Fleni, Rheumatology, Buenos Aires, Argentina; 3Fundación Favaloro, Rheumatology, Buenos Aires, Argentina; 4Hospital General de Aguodos Dr. Fernandez, Pneumonology, Buenos Aires, Argentina; 5Hospital de Rehabilitacion Geriatrica M. F. Fernandez, Radiology, Buenos Aires, Argentina; 6CIAC - Centro Integral de Alta Complejidad, Rheumatology, Salta, Argentina; 7Sr Hospital del Milagro, Rheumatology, Salta, Argentina

Background: Several biomarkers have been studied in rheumatoid arthritis (RA) interstitial lung disease (ILD), but their clinical application has not been well established yet [1]. Given that usual interstitial pneumonia (UIP) is the most common pattern of ILD in patients with RA, the utilization of biomarkers that give information about the epithelial cell activation could be an interesting approach to assess the severity of lung disease in these patients [2).

Objectives: To know the ability of CA19-9, CA125 and CEA to discriminate different patterns on HRCT and assess the severity of ILD in patients with RA.

Methods: We conducted a cross sectional study. Patients with a diagnosis of RA-ILD who were evaluated in three different rheumatic diseases clinics between December 2021 and January 2023 were consecutively included. The diagnosis of RA was defined according to ACR/EULAR 2010 classification criteria. The diagnosis of ILD was confirmed by an experienced radiologist. We performed HRCT, lung function tests, joint disease evaluation, and blood extraction to determine the values of CA 19-9, CA 125, CEA, rheumatoid factor (RF) and ACPAs. The pattern found on HRCT was classified in UIP pattern, probable UIP, indeterminate for UIP, and suggestive of another diagnosis, as proposed the inter society consensus of 2022 [4]. The score proposed by Goh was calculated to determine the extension of lung opacities (inflammatory, fibrotic, and total extension scores) [5]. The joint disease activity was assessed using the DAS28 score. The values of the biomarkers in serum were measured by electrochemiluminescence. T-test, Mann Whitney test, and Chi square were used for comparisons. The Spearman test was used for correlation analysis.

Results: We included 38 patients, 29 were women (76.3%). The mean (SD) age was of 62.1 (11.5) years. The median (IQR) of DAS28 was 3.3 (2.6-4). Regarding serologic tests, 35/36 (97.2%) and 36/37 (97.3%) were positive for ACPAs and RF respectively. In relation to lung disease, the mean (SD) of FVC% was 83.8 (11.5) and the median (IQR) of DLCO was 59 (52-81). Eighteen patients (47.3%) showed UIP or probable UIP pattern in the HRCT, while 20 (52.7%) had another pattern. The median (IQR) of Goh score for total lung disease extension was 20 (8-25). Patients with UIP pattern showed significantly higher values of CA19-9 [11.5 (7-35.7) vs 6.5 (2-12.5), p=0.017] and a trend to higher values of CA125 [22 (15-52) vs 14 (11.4-20.7), p=0.06] than those with other patterns. The values of CA19-9 showed a good correlation with total Goh score (r=0.52, p=0.02) and fibrosis Goh score (r=0.65, p=0.03) in patients with UIP pattern. Also, the values of CEA showed an acceptable correlation with total Goh score (r=0.46, p=0.05) and fibrosis Goh score (r=0.43, p=0.07) in patients with UIP pattern.

Conclusion: Patients with RA-ILD and UIP pattern showed higher plasmatic values of biomarkers that reflect epithelial cell activation. Also, the values of some of these biomarkers showed good correlation with the extension of the disease on HRCT. Therefore, these biomarkers could be a useful tool to identify a more aggressive clinical behavior in patients with RA-ILD.

AB0364 CIGARETTE SMOKING AMONGST RHEUMATOID ARTHRITIS PATIENTS IN A TERTIARY CENTER IN SOUTH AFRICA

Keywords: Patient reported outcomes, Descriptive Studies, Rheumatoid arthritis

S. Le Roux1, H. Bagula1, S. A. Didi2, R. Van Zyl-Smit2, B. Hodgkinson1, Grote Schuur Hospital, Department of Medicine, Cape Town, South Africa; Grote Schuur Hospital, Rheumatology, Department of Medicine, Cape Town, South Africa; Grote Schuur Hospital, Pulmonology, Department of Medicine, Cape Town, South Africa

Background: Cigarette smoking is associated with poorer outcomes amongst rheumatoid arthritis (RA) sufferers, with poorer disease control, increased extra-articular complications and more comorbidities[1]. There are currently no data from sub-Saharan Africa.

Objectives: To describe the prevalence of cigarette smoking, and explore disease control, comorbidities, extra-articular disease and attitudes of smokers to their habit amongst RA patients in an outpatient clinic at tertiary level public hospital in South Africa. Further, we asked patients about the impact of prohibition during the COVID pandemic.

Methods: A cross-sectional study of consenting adult outpatients with RA meeting the EULAR/ACR 2010 Classification Criteria. Demographic, clinical and patient-reported outcome measures (PROMs) including the Health Assessment Questionnaire-Disability Index (HAQ-DI), FACTIT-fatigue, CRP, self-reported painful joint count ≥16/54, and/or symptom checklist ≥16/60. MDS2 checklist including DEP, medical history queries, and FAST4 and MDS2 indices.

Results: Of 632 patients (536 females), the mean (SD) age and disease duration were 55.4 (13.0) and 10.1 (9.3) years. A poor socio-economic setting (SES) (defined using a pooled index) was noted in 67.0%. The mean (SD) Clinical Disease Activity Index (CDAI) and HAQ-DI were 14.3 (11.8) and 3.2 (0.7). The cohort included 218 (34.5%) smokers, and 89 (14.1%) ex-smokers, and more males smoked (49/218 vs 47/141, p = 0.0002). Compared to non- or ex-smokers, smokers had lower BMI (29.7 vs 32.7 (p = 0.01), higher anxiety scores (8.8 vs 8.0, p = 0.048) and incidence of COPD (7.8% vs 1.0%, p < 0.005). The vast majority (74.1%) had two or more comorbidities, and the commonest comorbidities were hypertension, dyslipidaemia and diabetes. There were no significant differences in age of RA onset, disease duration, SES, number of comorbidities, CDAI nor its individual components, extra-articular diseases nor in HAQ-DI, FACTIT, depression or pain scores. Of 160 patients who completed the smoking questionnaire, 83 (51.9%) believed smoking worsened their arthritis, and 119 (74.4%) reported receiving smoking cessation advice at the RA clinic. Participants’ most common reasons for smoking were emotional support (32.2%), nicotine craving (21.7%) and pain control (27.3%). Although 50.1% felt that living with RA made quitting difficult, 86.9% had considered quitting, and almost half (45.6%) had previously quit for more than 3 months. The Fagerström score revealed mild, moderate and severe nicotine dependence in 67.5%, 24.4%, and 7.5% respectively. The Fagerström score was significantly associated with anxiety (r = 0.2, p = 0.02) and depression (r = 0.0, p = 0.005). Smoking prohibition during COVID pandemic resulted in 60.0% (96) patients quitting or reducing cigarette consumption. Patients felt that helpful services from their RA team might include referral to a smoking cessation clinic (48.1%) and availability of more reading material (36.1%).

Conclusion: Among this cohort of indigent RA patients, a third of RA patients are smokers, with higher prevalence in males, and associated with lower BMI and higher anxiety scores but with no differences in disease parameters or other factors. Smoking is a modifiable risk factor, of great importance given the high prevalence of comorbidities in the cohort. Only half the cohort were aware that smoking worsened their RA disease control. The mild to moderate nicotine dependence in this cohort, together with patients’ willingness to quit should encourage both patient and health care providers to promote engagement in smoking cessation.

DOI: 10.1136/annrheumdis-2023-eular.4130
Background: Patients with rheumatoid arthritis (RA) are assessed in clinical trials and clinical care according to a core dataset and derived indices, which include tender (TJC) and swollen (SJC) joint counts, erythrocyte sedimentation rate (ESR), and patient (PaGA) and/or physician global assessments (PhGA). Many clinical trials require TJC and/or SJC ≥6 for enrollment, and improvement criteria require that SJC and TJC are ≥20%, 50%, or 70% better. It has been reported that TJC, PaGa, and PhGa may be elevated by comorbidities in the presence of little or no (or high) inflammatory activity, associated with high levels of fibromyalgia (FM), depression (DEP), fatigue (FT), back pain (Bpain), neck pain (Npain), and/or joints with deformity/limited motion (DJC). The likelihood and extent of elevations of RA measures associated with these comorbidities have not been extensively analyzed. FM, DEP, BPain, Npain, and FAT can be screened for on a multidimensional health assessment questionnaire (MDHAQ), and DJC can be included on a 28 joint count.

Objectives: To analyze RA patients seen in a routine care academic setting for possible elevations of SJC, TJC, ESR, PaGa, and PhGa associated with positive screening for FM, DEP, FT, BPain, Npain, and DJC.

Methods: A cross-sectional study was conducted at a routine care visit of RA patients to an academic rheumatology setting. All 7 RA core dataset measures were collected, including SJC, TJC, ESR, PaGa, and PhGa. The patient self-report measures were collected on an MDHAQ, completed by all patients in 5-10 minutes at this setting, which includes queries for FT, Npain, BPain, and indices to screen for FM - FAST4 (fibromyalgia assessment screening tool), and DEP - MDS2 (MDHAQ depression screen). FAST4 and MDS2 agree more than 80% with reference standards but can be feasibly collected in routine care on a single questionnaire. Patients were classified into 2 groups according to clinically relevant cut-points for each potentially non-inflammatory variable, and the number of patients above and below these cut points compared by chi square analyses.

Results: In 125 RA patients with complete data, significant differences (p<0.01) were seen for TJC <6 vs ≥6, PaGa <3 vs ≥3, and PhGa <3 vs ≥3, according to positive FAST4 FM, DEP MDS2, Bpain and Npain, FAT ≥3/10, and DJC ≥6. No significant differences were seen according to ESR <30 vs ≥30 or SJC <6 vs ≥6, other than a difference in SJC <6 vs ≥6 for patients with DJC <6 vs ≥6 (Table 1).

Conclusion: TJC, PaGA, and PhGa, but not ESR or SJC, are associated with positive screening for FM, depression, back pain, neck pain, fatigue, and joints with deformity/limited motion, that may not result from inflammatory activity. These elevations may affect DAS28 and CDAI scores, interpretation for treat-to-target, and general management. It is feasible to screen for these comorbidities in routine care, which may enhance clinical decisions and outcomes.

**Background:** Differences in physicians’ assessment of disease activity and patients’ perception of disease activity have been described [1]. Two of the most important disease-related symptoms experienced by patients are fatigue and depression, which are not routinely assessed by physicians [2].

**Objectives:** To study the differences between patient and physician perspectives on fatigue and depression, as well as on other biological, clinical and self-reported disease variables in a group of patients with established rheumatoid arthritis (RA).

**Methods:** Patients with RA (ACR/EULAR,2010) followed up by the Arthritis Unit who agreed to participate in this study were included consecutively in the Arthritis Unit for 3 months. They fulfilled 3 questionnaires to evaluate fatigue and depression: 1. MDHAQ, that includes: 0-10 physical function (FN) according to modified HAQ (0-10), visual analogue scale (VAS) 0-10 for pain (PN), VAS 0-10 for fatigue (VAS-Fatigue) (in the question 9, considering high fatigue with >5 cut off) and patient global assessment (PGA) to calculate RAPID3, a review of 60 symptoms (ROS60) and self-assessment 48 joint count (RADAI48). 2. FACIT-(FS)=FACIT-Fatigue, 13 questions (0-4 score) with a global score of 0-52 (lower scores indicate worse fatigue). 3. Patient Health Questionnaire 9= PHQ9, 10 questions with PHQ9-10 screened for depression. Physical articular examination (28TJC, 28SJC), laboratory test (CRP, ESR), composite EULAR disease activity indices (DAS28, DAS28 CRP, CDAI and SDAI), demographic (sex, age, BMI), patient’s disease characteristics and the Physician Global Assessment (PhGA) for the disease were collected. A descriptive analysis of the variables was done, and Pearson’s correlation between PhGA and PGA, and the rest of variables studied was performed.

**Results:** A total of 75 patients (84% females) with RA were recruited, with a mean age of 62±11.6 years, a mean disease duration of 14.6± 5 years and a mean BMI of 22.8 ± 8.0. 64% were under with bDMARD and 45.3% with glucocorticoids treatment. Depression (PHQ9>10) was observed in 12 patients (16%) and in 31 (41.2%) of patients we observed high fatigue (VAS-fatigue≥5/10). Correlation results between PGA and Fatigue (FS) were almost good for VAS-Fatigue (r=0.604, p<0.001) and for PHQ9>10(r=0.616, p<0.001), and almost good for FACIT9(r=-0.517, p<0.001). On the other hand, correlations between PhGA were smaller with fatigue (Fatigue (FS): r=0.477, p<0.001) and with depression (PHQ9: r= 0.477 p<0.001). Correlation of the rest of studied variables (DAS28, CDAI, SDAI, 28TJC, 28SJC, CRP, ESR and ROS) were smaller for PhGA than for PGA, except for 28SJC, where the assessment of physician is closer to that the patient (Table 1).

**Conclusion:** The patient’s perception of disease status is better than the physician’s perception of these two important comorbidities associated with RA, as well as disease activity indices. Clinicians have to take into account scores on fatigue and depression questionnaires or scales when assessing patients with RA.

**Background:** Clinical RA-associated ILD (RA-ILD) presents in almost 10% of RA patients but subclinical RA-associated ILD is detected in 20-60%. The course of subclinical RA-ILD is not fully known. Some patients have disease progression to pulmonary symptoms, decreased respiratory functional status and high levels of morbidity and mortality. It is necessary to improve ways to determine risk of progression in patients with subclinical RA-ILD.

**Objectives:** To describe a cohort of patients with clinical and subclinical Rheumatoid Arthritis-associated Interstitial Lung Disease (RA-ILD) and to compare the evolution and progression of both.

**Methods:** Ambispective observational study of a cohort of patients with RA-ILD confirmed by respiratory function tests (RTF) or high-resolution computed tomography (HRCT). From January 2019 to December 2021, all patients with these diagnoses from RA monographic clinic were included consecutively. Data on the onset of ILD were included retrospectively and data at the end of follow-up prospectively (last review). The % of patients who had subclinical ILD was evaluated before and after treatment modified in 10 patients with clinical ILD and in 7 with subclinical ILD (p=0.053). At the moment of ILD diagnosis, the treatments were better in the clinical ILD. The reason for requesting HRCT when they were diagnosed was different, defined as pulmonary symptoms, decreased respiratory functional status and high levels of morbidity and mortality; or 4) death. Demographic variables, activity data (DAS28/SG accumulated 24 months prior to the diagnosis of ILD), RF and ACPA levels, RA severity data and treatments. Descriptive analysis, χ2 or t-Student, and multivariate logistic regression analysis were performed to find predictive variables for the evolution of ILD.

**Results:** 50 patients with RA-ILD were included, 18 (36%) had subclinical ILD. The reason for requesting HRCT when they were diagnosed was different, defined as pulmonary symptoms, decreased respiratory functional status and high levels of morbidity and mortality; or 4) death. Demographic variables, activity data (DAS28/SG accumulated 24 months prior to the diagnosis of ILD), RF and ACPA levels, RA severity data and treatments. Descriptive analysis, χ2 or t-Student, and multivariate logistic regression analysis were performed to find predictive variables for the evolution of ILD.

**DOI:** 10.1136/annrheumdis-2023-eular.5434
**Conclusion:** In our cohort, the prevalence of subclinical ILD was high (36%). Although RFT at diagnosis of ILD, specifically DLCO levels, were higher in subclinical ILD than in clinical ILD, progression at the end of follow-up was the same in both groups. The UIP pattern was independently associated with progression. Therefore, taking into account that ILD is one of the main causes of mortality in our patients, we must actively search for this condition in order to treat it early and improve the prognosis.

**DISORDERS OF PERIPHERAL LYMPHOCYTE SUBSETS IN RHEUMATOID ARTHRITIS PATIENTS COMPLICATED WITH HASHIMOTO’S THYROIDITIS**

**Keywords:** Comorbidities, Rheumatoid arthritis, Descriptive Studies

T. Cheng1,2, S. X. Zhang1,1,2,2,2, H. Zhang3, X. Li1,1,2,2. 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 3Shanxi Medical University, First School of Clinical Medicine, Taiyuan, China

**Background:** Hashimoto’s thyroiditis (HT) is an organ-specific autoimmune disease that is not rare in RA. Hypothyroidism can affect the prognosis and quality of life in patients with RA [1]. Many studies showed that immune cells play a critical role in HT [2-3]. However, the alterations of lymphocyte subsets in RA patients with HT are unclear.

**Objectives:** This study aimed to assess the absolute numbers and proportions of peripheral lymphocyte subsets in RA with HT and investigate the clinical significance.

**Methods:** A total of 1636 RA patients and 54 gender- and age-matched healthy controls (HCs) were enrolled in this study. Patients were divided into RA-non-HT and RA-HT groups according to the thyroid peroxidase antibody (TPOAb) and thyroid globulin antibody (TgAb). Peripheral lymphocyte subsets of all participants were assessed by flow cytometry. All clinical and laboratory data were analyzed by SPSS 23.0.

**Results:** Among 30 (1.83%) RA-HT patients, there were more female (P=0.005), suggesting female was more susceptible to developing HT (Figure 1A). In addition, there were higher levels of erythrocyte sedimentation rate (ESR) (P=0.045) and C-reactive protein (CRP) (P=0.042) than those in RA-non-HT (Figure 1B-C). Compared with those of HCs and RA-non-HT, the level of circulating Th17 in RA-HT patients was significantly increased (P<0.05), while those of Tregs decreased (P<0.05), leading to a higher ratio of Th17/Treg (P<0.01). Notably, the level of B cells and Th1 cells, as well as the Th1/Th2 ratio, increased in the RA-HT compared with those of the RA-non-HT (P<0.05) (Figure 1D-F).

**Conclusion:** The occurrence of RA-HT is closely related to female patients with high disease activity. Disorders of lymphocyte subsets, especially Th17/Treg imbalance, may contribute to HT in RA, which deserves more clinical attention.

Rheumatoid arthritis - comorbidity and clinical aspects

Prevalence of cachexia in a population of Moroccan women with rheumatoid arthritis

AB0371 PREVALENCE OF CACHEXIA IN A POPULATION OF MOROCCAN WOMEN WITH RHEUMATOID ARTHRITIS

Keywords: Diet and Nutrition, Descriptive Studies

H. Elhani1,2, H. Taoufik1, A. Majjad1, L. Taoubane1, N. El Guardi1, A. Bezza1,7

Background: Prevalence of cachexia in a population of Moroccan women with rheumatoid arthritis.

Objectives: The objective of our study is to assess body composition in women with rheumatoid arthritis (RA) compared to healthy controls. Methods: We conducted a case-control study of 112 female patients with rheumatoid arthritis according to ACR/EULAR 2010 Rheumatoid Arthritis Classification Criteria; and 224 healthy women of the same age. Body composition and bone mineral density (BMD) results were obtained by Dual-Energy X-Ray Absorptiometry (DXA). Rheumatoid cachexia (RC) was defined as a Lean mass Index (LMI) below the 10th percentile and a Fat mass index (FMI) above the 25th percentile compared with the control group. We performed a comparison between RA patients and healthy controls and then performed multiple regression looking for factors associated with rheumatoid cachexia.

Results: The prevalence of rheumatoid cachexia was 42.85% while the mean body mass index (BMI) was the same in both groups. RA patients had higher fat mass and lower lean mass compared with healthy controls. In our population, 78.6% of patients were on methotrexate and 12.5% on TNF inhibitor. Comparison between patients with and without CR showed that patients with CR have high disease activity, with the presence of more bone erosions. Regression showed that CR was significantly associated with bone erosions and disease activity (OR at 33.51 (8.42 - 131.70) and 8.98 (1.64 - 49.20) respectively) This was independent of age, erythrocyte sedimentation rate, C-reactive protein, duration of disease, cumulative steroid dose, and use of conventional or biologic background therapies.

Conclusion: Our study showed that nearly half of our RA patients have CR even with high BMI. CR in our work is associated with the presence of high disease activity, and the presence of bone erosions.

The impact of body mass index on bone mineral density in rheumatoid arthritis

AB0373 THE IMPACT OF BODY MASS INDEX ON BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

Z. Baba1, A. Rati1, F. E. Chekhou1, A. Mougui1, I. El Boucht1, Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology, Marrakech, Morocco

Background: It has long been thought that a higher body mass index is protective against osteoporosis. However, recent studies showed an increase in fracture risk in obese individuals.

Objectives: To study the impact of body mass index (BMI) on bone mineral density (BMD) during rheumatoid arthritis (RA).

Methods: Retrospective study including 260 RA patients meeting the ACR/EULAR 2010 criteria. We collected demographic, clinical, biological, and bone densitometric data from patients.

Results: The mean age was 49.91 ± 12.97 years. The sex ratio F/H was 6.6. The mean DAS28-VA was 5.32 ± 1.35. According to the DAS28-VA, 60.7% of the patients were high activity. The mean BMI was 26.26 ± 4.83 Kg/m2. 21.9% of patients were obese. 31.5% were overweight and 2.3% were underweight. The mean BMD was 0.856 ± 0.200 g/cm² at the femoral neck and 0.950 ± 0.219 g/cm² at the lumbar spine. The mean T-SCORE was -1.41 ± 1.48 at the femoral neck and -1.90 ± 1.58 at the lumbar spine. Osteoporosis at one of the two sites was found in 38.4% of patients. Eleven patients (4.8%) had a severe fracture and 6 patients (2.6%) a non-severe fracture. A negative correlation was found between BMI and the presence of osteoporosis at one of the two sites (r=-0.138; p=0.04). BMI was also correlated with T-Score and BMD at the lumbar spine (r=-0.196; p=0.007 and r=-0.278; p=0.001 respectively). No correlation was found between BMI and T-Score and BMD at the femoral neck level as well as fracture occurrence.

Conclusion: In our study, BMI correlated with BMD and T-SCORE at the lumbar spine, and negatively correlated with the presence of osteoporosis.

Depression in rheumatoid arthritis: a cross-sectional study from a tertiary care hospital in north India

AB0373 DEPRESSION IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY FROM A TERTIARY CARE HOSPITAL IN NORTH INDIA

Keywords: Rheumatoid arthritis, Descriptive Studies, Mental health

V. Pai1, S. S1, S. V. Rawat4, All India Institute of Medical Sciences, Dept of Internal Medicine - Division of Clinical Immunology & Rheumatology, Rishikesh, India; 4All India Institute of Medical Sciences, Dept of Psychiatry, Rishikesh, India

Background: Rheumatoid arthritis (RA) is a chronic inflammatory polyarthritis, with deformities associated with poor functional outcome. Psychiatric comorbidities are common among them, contributing to poor outcome.

Objectives: This study was aimed at determining prevalence of depression in RA and its association with disease severity.

Methods: This is a cross-sectional study carried out in the OPD/IPD of Rheumatology in a tertiary care hospital in India. This study recruited 272 patients classified as RA, fulfilling 2010 ACR/EULAR criteria, with minimum duration of illness of at least 1 year. Patients with prior psychiatric illness were excluded. Informed consent was taken from all participating patients, after institute ethical clearance. RA disease activity was measured using DAS28 ESR, and these patients were screened for depression with PHQ-2 questionnaire. [1] Patients with depression were further assessed with Depression, Anxiety and Stress Scale (DASS) for depression severity. [2] The functional status was assessed with Health Assessment Questionnaire–Disability Index (HAQ-DI). Data were interpreted by descriptive statistics, and correlation assessed using Spearman correlation coefficient. Regression analysis was used to find odds of significant variables associated with depression.

Results: Twenty-three percent of these patients had depression according to PHQ-2 screen. Forty-four (69.8%) of these had depression on further assessment using DASS questionnaire. The median DAS-28 in mild, moderate, severe and extremely severe depression groups were 4.6, 4.9, 6.4 and 5.3, respectively. There was a significant difference between the 5 groups in terms of DAS-28 (X² = 42.209, p = <0.001), with the median DAS-28 being highest in severe depression group. It had a strong association with DASS depression score and with significant p value of <0.001. There was a weak positive correlation between DAS-28 and DASS depression score, though this correlation was not statistically significant (rho = 0.18, p = 0.167). With further regression analysis, it was clear that, TJC, SJC, and ESR, were significantly associated with depression. All of these parameters had an odds ratio of >1, indicating that if each of them increased, odds of having depression would significantly increase.

Conclusion: Depression, though very common, is yet an underestimated co-morbidity in RA and contributes to their functional impairment/ morbidity. RA patients with high TJC, SJC, ESR and disease activity were found to have depression of more severity, which favors the inflammatory hypothesis of depression.[3] Depression, is indeed an under-estimated yet significant comorbidity in patients with RA. This is often missed or over looked by rheumatologists/ clinicians. Early identification with subsequent referral to concerned specialty will definitely improve functional outcomes.

### AB0375  DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS (D2T-RA): CLINICAL ISSUES AT EARLY STAGES OF DISEASE

**Keywords:** Rheumatoid arthritis, Disease-modifying Drugs (DMARDs), Epidemiology

D. Freites Nuñez1, L. León1,2, A. Madrid García3,4, P. Lopez Viejo1, I. Garcia Alvaro5, M. Novella-Navarro5, Z. Rosales1, B. Fernandez1, L. Abasolo5,  
1Hospital Clinico San Carlos, Rheumatology, Madrid, Spain;  
2Instituto de Investigación Sanitaria San Carlos (IdiSSC), Rheumatology, Madrid, Spain;  
3Universidad Camilo Jose Cela, Health Sciences, Madrid, Spain;  
4Hospital Universitario La Princesa, Rheumatology, Madrid, Spain;  
5Hospital Universitario La Paz, Rheumatology, Madrid, Spain

**Background:** Most studies on difficult-to-treat rheumatoid arthritis (D2T RA) have focused on established RA. Our study aimed to examine whether disease activity in the early stages of RA could influence progression to a D2T RA under real-life conditions. Other clinical and treatment-related factors were also analyzed.

**Methods:** A longitudinal multicenter study of RA patients was conducted from 2009 to 2018. Patients were followed up until January 2021. D2T RA was defined based on EULAR criteria (treatment failure, signs suggestive of currently active/progressive disease, and management being perceived as problematic by the rheumatologist and/or patient). The main variable was disease activity in the early stages. The covariates were sociodemographic, clinical, and treatment-related factors. We ran a multivariable logistic regression analysis to investigate risk factors associated with progression to D2T RA.

**Results:** The study population comprised 631 patients and 35 (5.87%) developed D2T RA. At the time of diagnosis, the D2T RA group were younger, with a higher disability, DAS28 score, tender joint count and pain scores. In our final model, DAS28 was not statistically significantly associated with D2T RA. No differences were found between groups for therapy. Disability was independently associated with D2T RA (OR: 1.89; p=0.01).

**Conclusion:** In this cohort of patients newly diagnosed with RA, our results do not allow us to prove the influence of active disease according to DAS28. However, we did find that younger patients and those with elevated initial disability scores are more likely to develop D2T RA regardless of other factors.

### AB0376  CARDIOVASCULAR RISK STRATIFICATION ACCORDING TO SERUM NON-HDL CHOLESTEROL LEVELS IN PATIENTS WITH RECENTLY DIAGNOSED RHEUMATOID ARTHRITIS.

**Keywords:** Biomarkers, Comorbidities, Rheumatoid arthritis

K. Zoupidou1, M. Krikelis2, D. Moschou2, S. Tournis3, K. Makris4, S. Gazi5,  
1Attikon University Hospital, Athens, Greece;  
2KAT General Hospital, Athens, Greece;  
3National and Kapodistrian University of Athens, Greece;  
4Hospital Clinico San Carlos, Rheumatology, Madrid, Spain;  
5Hospital Universitario La Princesa, Rheumatology, Madrid, Spain

**Background:** Myostatin is expressed in skeletal muscles and exerts a negative feedback in myogenesis. Chronic inflammation has been associated with increased serum myostatin levels (Baig MH, Front Physiol. 2022).

**Methods:** To analyze whether disease activity in the early stages of RA could influence progression to a D2T RA under real-life conditions. Other clinical and treatment-related factors were also analyzed.

**Results:** In our cohort, 47% (n=148) had seropositive disease. Mean values for ESR, CRP, DAS28 (ESR) and HAQ-DI were 29 ± 20 mm, 1.6 ± 2.6 mg/dl, 3.9 ± 1.7 and 0.9 ± 0.6 respectively. The mean serum CRP levels were 5.9 ± 13 μg/ml. According to the DAS28 (ESR) score, 17% (n=5) patients were in disease remission, 20% (n=6) had low disease activity, 40% (n=12) had medium disease activity and 23% (n=8) had high disease activity. Serum myostatin was not associated with disease activity (p=0.32), patient functionality (p=0.08) or the inflammatory burden attributed to active disease (p=0.67 for ESR and p=0.83 for CRP). Seropositive disease did not correlate with serum myostatin levels (p=0.08).

**Conclusion:** In post-menopausal women with rheumatoid arthritis, serum myostatin levels are independent of disease activity, patient functionality, inflammatory burden, RF or ACPR seropositivity. Except for inflammation per se, other disease parameters associated with RA influence the regulation of myostatin.

**REFERENCE:**  
Background: It is estimated that rheumatoid arthritis (RA) increases the risk of cardiovascular disease (CVD) by 50% compared to the general population [1,2]. Non-HDL cholesterol (non-HDL CT) has become an innovative marker of cardiovascular risk (CVR). According to the recommendations of the ESC of 2022 [2], patients with RA start from an intermediate CVR and recommend non-HDL TC levels <130mg/dL.

Objectives: To evaluate long-term risk of CVD according to non-HDL CT levels in a cohort of patients with recently diagnosed RA who started biological therapy and describe its characteristics.

Methods: 71 patients with RA under biological treatment were reviewed. Demographic, clinical, and analytical data were obtained at the time of diagnosis. To estimate the risk of CVD in the long term, we applied the model developed by Brunner F. J. et al. [3]. Based on this, the patients were stratified into 5 CVR groups according to the non-HDL CT and grouped into three age ranges. Statistical analysis was carried out using IBM-SPSS Statistics version 26.

Results: The demographic, clinical, laboratory characteristics and CVR groups are indicated in Table 1. Regarding the mean age according to the CVR group: in the 8 patients of group 1 it was 38.13 ± 15.28 years - 7 with age < 45 years and one > 60 years -; in group 2 it was 42.92 ± 11.76 years - 17 patients < 45 years, 10 between 45 and 59 years and 2 ≥ 60 years -; in the 31 patients of group 3 it was 51.45 ± 11.49 years - 8 < 45 years, 15 between 45-59 years and 8 ≥ 60 years -. In the 2 patients in group 4 it was 52.5 years (45-59) and the patient in group 5 was 36 years old at diagnosis. No significant correlations were found between CRP, ESR, RF, ACPAs levels and presence of radiographic erosions with nonHDL CT values. Significant differences (p value < 0.01) were observed between the youngest individuals (age < 45 years) in groups 1 and 2 with respect to individuals older than 60 years in risk groups 3 or 4. The application of the current model -Figure 1- estimated a mean probability of CVD of 9.7% at 75 years with a reduction to 3.54% after a 50% decrease in non-HDL TC. A single fatal cardiovascular event was recorded in an obese, hypertensive, and diabetic man, classified in risk group 3.

Conclusion: In our cohort of patients with new-onset RA, the majority (46%) were classified as CVR group 3 (nonHDL CT 145-184 mg/dL), despite approximately 50% being <45 years of age. Exposure from an early age to a moderate increase in non-HDL CT induces an increase in long-term CVR, approximately 50% being <45 years of age.

AB0377 CHARACTERISTICS OF BLOOD TEST RESULTS IN D2T RA BEFORE INITIATING DMARDS TREATMENT: HIGHER IFN AND LESS IL-6 INVOLVEMENT WERE PRESUMED BY PROPENSITY SCORE MATCHING ANALYSIS

Keywords: Rheumatoid arthritis, Biomarkers

Y. Nishiura1,2, Y. Nakai1, M. Tokunaga1, Y. Koyama1,1 Japanese Red Cross Okayama Hospital, Division of Rheumatology, Center for Autoimmune Diseases, Okayama, Japan; 2Okayama University Hospital, Center for Graduate Medical Education, Okayama, Japan

Background: Difficult-to-treat rheumatoid arthritis (D2T RA) is a new concept of RA patients who do not achieve remission despite several types of treatment. It remains to be elucidated what makes the clinical differences between D2T RA and non-D2T RA.

Objectives: To analyze blood test results of D2T RA patients and non-D2T RA patients before initiating treatment to see if there are differences in their trends and characteristics.

Methods: We conducted a retrospective, observational cohort study using blood tests, including patients diagnosed with RA who attended our institute. The patients were divided into two groups; those who satisfied EULAR definition of D2T were included as D2T-RA, and the others who did not meet the definition after at least 2 years of treatment were included as non-D2T RA patients. To eliminate the influence of treatment on blood test data and disease activity, only patients whose blood test data existed prior to starting treatment with disease modifying antirheumatic drugs (DMARDs) were picked from both groups. The two groups were then matched 1:1 using propensity scores adjusted for gender, age, duration of RA disease, BMI, smoking habits, and DAS28-ESR. Comparisons were made between these two adjusted groups for each blood test item using an independent-samples t-test. SPSS statistical software was used.

Results: Ninety-four RA patients (mean age 60.3±12.6 years, 74% female) were included, 23 (mean age 55.4±13.2 years, 83% female) belonged to D2T RA and 71 (mean age 61.8±12.1 years, 72% female) to non-D2T RA. Of these, 13 cases of D2T RA and 2 cases of non-D2T RA were excluded due to lack of blood test data before starting DMARDs therapy. D2T RA patients were 57.6 ± 11.1 years old (86% female) and non-D2T RA patients were 57.0 ± 10.1 years old (100% female). In D2T RA, mean corpuscular volume (MCV: D2T vs non-D2T = 95.6±3.8 vs 85.6±3.9, p=0.001), mean corpuscular hemoglobin (MCH: 32.0±1.7 vs 28.7±1.7, p=0.003), serum transferrin saturation (TSAT) ratio (Fe*100/TIBC: 32.3±7.3 vs 19.3±9.6, p=0.020) and lactate dehydrogenase (LDH: 203±33U/L vs 164±16U/L, p=0.026) were significantly higher. On the other hand, unbound iron binding capacity (UIBC: 184±42 vs 253±35, p=0.007) was significantly lower in D2T RA. Although it was not reaching statistical significance, lower lymphocyte count (1068±304/μ vs 1816±867/μ, p=0.052), fewer red blood cell (RBC: 4.03±0.34*10^12/μl vs 4.45±0.51*10^12/μl, p=0.096) and higher neutrophil ratio (76.9±8.2% vs 66.5±10.7%, p=0.005) were observed in D2T RA.

Conclusion: In a comparison of blood test results before initiating treatment, the differences between D2T and non-D2T cases were mainly related to iron metabolism and white blood cell differential. Patients with non-D2T RA had significantly lower...
TSAI than patients with D2T RA, with a trend toward having a microcytic hypochromic anemia. This reminds us of the involvement of hepcidin and may suggest that Inter-

AB0381 TREATMENT EXPECTATIONS OF PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE STARTING METHOTREXATE

Keywords: Rheumatoid arthritis
U. Kiltz1,2, A. Petridou1,2, N. Timmesfeld1, W. Rief1, K. Schmidt2, D. Krause3,4, U. Binge1, J. Braun1, Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany; 2Rheumazentrum Ruhrgebiet, Rheumatology, Heme, Germany; 3Ruhr University Bochum Faculty of Medicine, Department of Medical Informatics, Biometry and Epidemiology, Bochum, Germany; 4University of Marburg, Division of Clinical Psychology, Marburg, Germany; 5University Hospital Essen, Department of Neurology, Essen, Germany; 6Rheumatology Practice Gladbeck, Rheumatology, Gladbeck, Germany

Background: Although the long-term efficacy, tolerability, and safety of methotrexate (MTX) in patients with rheumatoid arthritis (RA) are well documented, the clinical response and incidence of adverse events (AE) vary. Data on adherence to MTX in RA patients vary between retention rate of 35% to 80% in 5 years. In addition to aspects of safety, important determinants for continuing MTX therapy are patient-associated factors including individual treatment preferences and expectations.

Objectives: This study investigated treatment expectations in RA patients who were about to start MTX therapy, and aim to identify variables associated with discontinuation of MTX.

Methods: Consecutive patients with RA who were about to start MTX were prospectively included after informed consent. Treatment expectations, medication-related beliefs and AE, treatment satisfaction and health-related quality of life were assessed using the generic rating scale for previous experiences, expectations and effects of treatment (G-EEE), the general assessment of side effects (GASE), the beliefs about medicines questionnaire (BMQ), the treatment satisfaction questionnaire for medication (TSQM) and the EuroQol-5 dimensions (EQ-5D) before treatment initiation (T0), and after 3 months (T1). Treatment adherence to MTX was checked at month 6 (T2). Associations treatment expectations and adherence to MTX were explored by regression analyses.

Results: A total of n=100 consecutive RA patients before starting MTX treatment were included (Table 1). A history of inadequate response to sulfasalazine was determined in n=6 (6%) and to hydroxychloroquine in n=1 patient, respectively. At T0, patients perceived the need for treatment with MTX as high, and they were only moderately concerned regarding potential adverse events of this therapy. Treatment expectations regarding the decrease of pain levels and development of adverse events did not differ much between T0 and T1, when disease activity had significantly decreased and physical function increased. MTX was withdrawn in 3 out of 59 patients (5.0%) and in 13 out of 64 patients (20.3%) assessed at T1 and T2, respectively, with a mean of 16.0 (5.9) weeks after treatment initiation. The most frequent reason for discontinuation of MTX was the occurrence of adverse events (n=12) followed by infections or malignancies (both n=2). There was no significant relationship between patients' treatment expectations at T0 and their adherence to MTX at T2.

Conclusion: In this study, we found no evidence for the assumption that patients' expectations before the start of MTX did substantially influence adherence to treatment.

COMPARISON OF CARDIOVASCULAR RISK SCALES ACCORDING TO TIME OF EVOLUTION IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Cardiovascular disease, Rheumatoid arthritis

I. J. Colunga-Pedraza1, D. A. Galazar-Delgado1, J. R. Azpini-López2, V. M. Betrán-Arias1, H. González González1, N. De Avila González1, J. Eleuterio González, Rheumatology, Monterrey, Mexico

Background: Rheumatoid arthritis (RA) is a chronic, systemic and multifactorial disease. RA patients are at increased risk of cardiovascular (CV) mortality, with atherosclerotic CV disease being the leading cause of death. The traditional risk factors cannot explain such an increase by themselves. (1) There are many algorithms for CV risk (CVR) prediction, and results obtained by these must be multiplied by 1.5 factor, since the EULAR recommendation from 2016. (2) Objectives: To compare CVR by six scales: Framingham lipids and BMI, ACC/ AHA ASCVD 2013, Reynolds (RRS), SCORE 2 and QRSK III, according to the time of disease evolution in RA patients.

Methods: Descriptive, comparative, and cross-sectional study. We enrolled RA patients between 40 and 75 years old who fulfilled ACR/EULAR 2010 classification criteria and recruited in the Rheumatology service from a tertiary care hospital. Patients were divided by time of disease evolution into quartiles. CVR results from scales were multiplied by 1.5 factor according to EULAR 2016 recommendation. Normality was assessed by Kolmogorov-Smirnov test. Variables with a non-normal distribution were described by median and interquartile range (p25-p75). Differences between groups was analyzed by Kruskal-Wallis test or Chi-squared, accordingly.

Results: Total of 406 RA patients were included. Demographic characteristics are shown in table 1. For longer disease evolution, CV scales showed an increased (except for FRS; p< 0.123), just like anti-citrullinated peptide antibody (p<0.001), rheumatoid factor IgG (p<0.003), IgM (p=0.00) and IgA (p=0.00).

Conclusion: CVR increased according to disease duration. Despite that most of the scales showed such increased, CVR varies between them, which may be attributable to the variables evaluated in each one. More studies are required to define which scale is the best to predict in RA patients.

CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS: A COMPARATIVE TRANSTHORACIC ECHOCARDIOGRAPHY STUDY

Keywords: Comorbidities, Rheumatoid arthritis, Heart

R. Sarrai1, M. Brahim1, H. Ibn Hadj Amor2, O. Jomaia3, A. Ben Salem4, B. Jebali, S. Kraiem, R. Rouabbia, H. Hachfi, Y. Mohamed5. 1Taher Star University Hospital, Rheumatology, Mahdia, Tunisia; 2Taher Star University Hospital, Cardiology, Mahdia, Tunisia

Background: Cardiac involvement in rheumatoid arthritis (RA) is one of the most frequent and severe extra-articular manifestations, but it is often under-diagnosed. Objectives: In this context, we conducted this study, whose objective is to determine the prevalence and types of cardiac abnormalities in patients with RA using the transthoracic echocardiography (TTE) and to compare them with control subjects. Methods: We performed a comparative cross-sectional study conducted in Taher Star Hospital, Mahdia, Tunisia. Each patient underwent a TTE coupled with Strain technique.

Results: Seventy-two patients with RA according to the ACR/EULAR 2010 criteria and 72 control subjects (control group) were included. In our study, there was a clear female predominance in both groups with a sex ratio of 0.07 in the RA group and a sex ratio of 0.05 in the control group (p=1). The mean age of RA patients was 52.9 ± 11.72 years [21-75] years and that of the control group was 49.26 ± 10.74 years [19-76] years (p<0.06). Abnormalities detected by TTE were more frequent in subjects with RA compared with the control group (80.6% vs 81.6%; p< 0.05) and they were asymptomatic in 65.8% of cases of RA group. Pericardial effusion was more frequent in the RA group compared with the control group but without significant difference. Valvular involvement was significantly more frequent in patients with RA compared to the control group (48.5% vs 14%; p<0.01) with predominance of tricuspid involvement (31.9%). Left ventricular diastolic dysfunction was more frequent in RA patients compared with the control group with a significant difference (36.1% vs 13.9%; p<0.01). Regarding the left ventricular systolic dysfunction, left ventricular ejection fraction impairment was absent in both groups, but subclinical left ventricular myocardial damage assessed by the Global Longitudinal Strain (GLS) method was detected in 37.5% of RA patients and 16.6% of control subjects (p<0.01). The mean of GLS in RA patients was -17.8% ± 2.9 [-22 to -10.7%]. While it was -19.4% ± 1.9 [-24.7 to -15.7%] in control subjects. Left ventricular hypertrophy was detected on TTE in 22.2% of RA patients and in 6.9% of control group (p<0.01). Pulmonary arterial hypertension was present only in the RA group (2.8% of cases).

Conclusion: Our study showed that cardiac involvement is more frequent in RA than the general population, hence the interest of systematic screening, in order to improve the quality of life and the vital prognosis of patients.

AB00364 CHANGES IN LEFT VENTRICULAR SYSTOLIC AND DIASTOLIC FUNCTION IN PATIENTS WITH AUTOIMMUNE INFLAMMATORY DISEASES

J. R. Azpíri-López1, D. Á. Galazar-Delgado2, I. J. Colunga-Pedraza2, A. G. Arias-Peralta1, V. M. Beltran-Aguilar2, V. Gonzalez-Gonzalez2, N. De Avila Gonzalez2, J. A. Cardenas-de la Garza2. 1Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico; 2Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico

Background: Rheumatological diseases such as rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and psoriatic arthritis (PsA) increase the cardiovascular (CV) risk by the development of a pro-inflammatory state that can affect the ventricular function of the heart. (1)

Objectives: To compare left ventricular (LV) systolic and diastolic function in patients with RA, SLE, and PsA as compared with healthy controls.

Methods: A cross-sectional and comparative study. Patients included in the cohort were between 30–75 years old, who fulfilled 2019 ACR/EULAR Criteria for SLE, and Controls. A transthoracic echocardiogram was performed by a certified cardiologist blinded to clinical data. Normality was assessed by the Kolmogorov-Smirnov test and the Kruskal-Wallis test for comparison among groups. P value <0.05 was considered significant.

Results: 186 patients were included in the study, divided into groups as its shown in Table 1. Most of them were women (148); the most common comorbidities were hypertension (36%), 20.8%, and 17.5% in the RA, SLE, and Control groups, respectively, and dyslipidemia (73.9% in the PsA group). Echocardiographic findings are shown in Table 1. Conclusion: LV systolic and diastolic function changes in the rheumatic population, especially RA, SLE, and PsA, are higher in comparison with healthy people and affect the prognosis in these patients, those changes can be detected by echocardiogram, which is a safe tool that may prevent complications and improve the prognosis with early detection and management of this CV involvement.

AB00385 RISK FACTORS AND CARDIOVASCULAR DISEASES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN A TERTIARY GOVERNMENT HOSPITAL IN THE PHILIPPINES

M. A. Yano1, E. Salido1. 1Division of Rheumatology, Department of Medicine, Philippine General Hospital, University of the Philippines Manila, 1000, Philippines

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammatory arthropathy and extra-articular involvement [1]. Comorbidities are highly prevalent in patients with RA, [2] in particular cardiovascular disease (CVD), which is responsible for over 50% of premature deaths among these patients.[3] It causes lower life expectancy in 3 to 10 years and higher mortality rate compared to the general population. [4]

Objectives: To describe cardiovascular (CV) diseases and their risk factors among patients with rheumatoid arthritis.

Methods: This is a review of the medical records of patients with rheumatoid arthritis, ambulatory and hospitalized, at the Philippine General Hospital from January 2019-December 2022. Results: There were 123 patients included in the study, 95.1% were females with a mean age and disease duration of 51.31 and 9.78 years, respectively. Only a few (6.5%) were hospitalized. Disease activity was low in 41.5% and moderate in 35% based on disease activity score (DAS 28) and/or clinical disease activity index (CDAI) scores. Methotrexate (54%) was the most commonly used conventional synthetic disease modifying antirheumatic drug (csDMARD). The use of glucocorticoids was observed in 51.2% while no patients were on biologic (DMARD) at the time of data collection. There were 12 (9.7%) patients with CV diseases, namely myocardial infarction, heart failure, and stroke. There were 87 (70%) patients with at least one CV risk factor and 60 (48%) with multiple risk factors. The risk factors identified were: dyslipidemia (43.1%), hypertension (40.7%), elevated body mass index (35.7%), and diabetes mellitus, (15.4%). However, there were 18 (14.6%) patients without a lipid determination. Five hospitalized patients (4%) died, three from infectious causes, one from malignancy, and one from myocardial infarction.

Conclusion: The majority (70%) of our cohort had at least one CV risk factor and 10% had an identified CV disease. Dyslipidemia was the most common CV risk factor. The high proportion of patients with CV disease and risk factors highlights the need to add the screening and management of CV diseases as a priority among patients with rheumatoid arthritis.

Andrea, Rheumatology Unit, Vercelli, Italy; IRCCS Sacro Cuore Don Calabria Hospital, Unit of Rheumatology, Verona, Italy; Santa Corona Hospital, Pietra Ligure, Unit of Diagnostic and Interventional Radiology, Pietra Ligure, Italy

Background: Current and previous EULAR recommendations (1,2) suggest using JAK-inhibitors (JAKis) for treating Rheumatoid Arthritis (RA). However, little is known about differences of patients who are JAK-inhibitors (JAKis) naïve and patients who have already experienced at least one JAKi.

Objectives: To analyse differences between JAK-naive and JAKis not naïve patients in a real life setting.

Methods: All patients with RA on JAKis were prospectively followed up for 12 months in this multicentric study conducted in 23 centres. For each patient, the following variables were recorded: sex, age, disease duration at JAKi prescription, smoking, BMI, comorbidities, positive RF/ACPA, DSAS28-ESR at baseline, and 6 and 12 months, cDMARDs and prednisone at baseline, JAKis discontinuation, JAKis-naive. Statistics were performed by R (2022.12.0).

Results: 864 patients were included (Table 1). Among them, 731 (84.60%) were JAKis naïve, whereas 122 (14.12%) were not naïve (missing data in 11.27%-patients). 473 (55.22%) patients were treated with baricitinib (JAK-naive were 412, 87.3%), 213 (24.6%) with tofacitinib (JAKis-naive 187, 87.79%), 111 (12.84%) with upadacitinib (JAKis-naive 78.37%) and 62 (7.17%) with filgotinib (JAKis-naive 72.58%). Significant differences between JAKis-naive and not naïve were found for hypercholesterolemia (p=0.04), hypertension (p=0.02), previous cancer (p<0.001), disease duration (p<0.001), line of treatment (p<0.001). No difference was found for JAKis discontinuation (p=0.13) (Table 1).

Conclusion: Our data suggest that line of treatment and disease duration result higher in JAKis naïve compared to naïve ones. Notably, JAKis naïve and not naïve did not differ regarding drug discontinuation, suggesting a similar continuation rate irrespective of previous JAKis.

AB0387 PREDICTIVE FACTORS OF DETECTION OF ULTRASOUND SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS WITH CONCOMITANT FIBROMYALGIA

**Keywords:** Rheumatoid arthritis, Fibromyalgia, Ultrasound

S. Miladi1, B. A. Hiba1, F. Alia1, S. Ben Yaacoub1, M. Yasmine1, H. Bousaâ1, L. Souabni1, K. Ouenniche1, K. Selma1, C. Selma1, K. Ben Abdelghani1, L. Ahmad1.1 Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia

**Background:** Recent studies have shown that ultrasound (US) assessment of disease activity in rheumatoid arthritis (RA) with associated fibromyalgia (FM) before disease-modifying antirheumatic drug (DMARD) escalation is primordial.

**Objectives:** The purpose of this study was to identify predictive factors of detection of US synovitis and Doppler activity in RA patients with and without concomitant FM.

**Methods:** Cross-sectional study that included patients with diagnosis of RA (ACR/EULAR, 2010 criteria) with concomitant FM (ACR 2016) and to compare it to RA patients without FM. Demographic and RA characteristics were collected. US examination of 22 joints was blindly performed by a single physician. US-detected synovitis was defined and scored 0-3 using the OMERACT scoring system at the joint level for both grey-scale (GS) and Doppler power Doppler (PD). The number of joints with ≥ grade 1 GS synovitis and those with ≥ grade 1 DP were calculated. Multiple linear regression analysis performed, adjusting for clinical and demographic variables.

**Results:** Eighty patients distributed into 40 patients in each group were recruited. Epidemiological characteristics and RA characteristics were comparable between the two groups. Multivariate analysis in RA with FM group showed that DAS28 V3 and male gender were positively associated with the presence of US synovitis, while Patient Global Activity expressed a negative association. Our study shows that a high DAS28 V3 seems to be significantly associated with rheumatoid arthritis (RA) which may falsely increase RA activity by modifying the subjective components of disease activity scores.

**Conclusion:** Our study confirms the overestimation of disease activity by the clinical scores in RA with concomitant FM. DAS28 V3 score and US assessment would represent a better alternative.

AB0388 RHEUMATOID ARTHRITIS WITH CONCOMITANT FIBROMYALGIA: THE ROLE OF ULTRASOUND IN ASSESSING DISEASE ACTIVITY

**Keywords:** Fibromyalgia, Rheumatoid arthritis, Ultrasound

S. Miladi1, B. A. Hiba1, B. A. Hiba1, F. Alia1, H. Bousaâ1, M. Yasmine1, L. Souabni1, K. Ouenniche1, K. Selma1, C. Selma1, K. Ben Abdelghani1, L. Ahmad1.1 Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia

**Background:** Fibromyalgia (FM) is a chronic painful condition frequently associated with rheumatoid arthritis (RA) which may falsely increase RA activity by modifying the subjective components of disease activity scores.

**Objectives:** The aim of our study was to compare clinical scoring and ultrasound (US) assessment in RA patients with concomitant FM to RA patients without FM.

**Methods:** Cross-sectional study that included patients with diagnosis of RA (ACR/EULAR 2010 criteria) with concomitant FM (ACR 2016) and to compare it to RA patients without FM. Demographic and RA characteristics were collected. US examination of 22 joints was blindly performed by a single physician. US-detected synovitis was defined and scored 0-3 using the OMERACT scoring system at the joint level for both grey-scale (GS) and Doppler power Doppler (DP). The number of joints with ≥ grade 1 GS synovitis and those with ≥ grade 1 DP were calculated. Multiple linear regression analysis performed, adjusting for clinical and demographic variables.

**Results:** Eighty patients distributed into 40 patients in each group were recruited. Epidemiological characteristics and RA characteristics were comparable between the two groups. Biologic DMARDs prescription was more frequent in RA with FM patients than control group (p=0.04). Subjective activity parameters were higher in RA with FM group (p<0.05). DAS28 was significantly greater than DAS28 V3 in RA with FM group (p=0.000). FM group had significantly less US synovitis (p=0.035) and less Doppler activity (p=0.035). Grey scale (GS) US score (p=0.87) and DP US score (p=0.160) were similar in the two groups. Multivariate analysis in RA with FM group showed that DAS28 V3 and male gender were positively associated with the presence of US synovitis, while Patient Global Activity expressed a negative association.

**Conclusion:** Our study confirms the overestimation of disease activity by the clinical scores in RA with concomitant FM. DAS28 V3 score and US assessment would represent a better alternative.

AB0389 EXTRA-ARTICULAR MANIFESTATIONS ARE FREQUENT IN SOUTH INDIAN PATIENTS WITH RHEUMATOID ARTHRITIS AND ARE INDEPENDENT OF THE DISEASE ACTIVITY OR SEROPOSITIVE STATUS.

**Keywords:** Rheumatoid arthritis, Comorbidities, Inflammatory arthritides

H. Gangadharan1, R. Thomas2, R. T. R.1.1 Government Medical College Kottayam, Department of Internal Medicine, Kottayam, India; 2Government Medical College Kottayam, Department of Community Medicine, Kottayam, India

**Background:** Extra-articular manifestations are seen in around 40% of patients with Rheumatoid arthritis (RA) in western studies and increase the mortality in patients with RA [1]. There is a paucity of data from India, especially from South India on the prevalence and associations of extra-articular manifestations in RA.

**Objectives:** To estimate the frequency of extra-articular manifestations (EAM) and their associations with disease characteristics in patients with Rheumatoid arthritis attending the Rheumatology clinic of a tertiary care teaching hospital in South India.

**Methods:** A cross-sectional study of 316 consecutive patients fulfilling the 2010 ACR EULAR classification criteria of RA was done at a Rheumatology clinic in South India between October 2020 and December 2022. The various EAM studied were keratoconjunctivitis sicca, Interstitial lung disease (ILD), pleuritis/pleural effusion, bronchiectasis, small airway disease, pericarditis/ pericardial effusion, myocarditis, subcutaneous nodules, peripheral neuropathy, anaemia and Rheumatoid vasculitis. The comorbidities studied were diabetes mellitus, systemic hypertension, coronary artery disease, chronic obstructive pulmonary

disease, hypothyroidism, and stroke. Various parameters like age, gender, disease duration, comorbidities, seropositivity, erythrocyte sedimentation rate (ESR), smoking, disease activity score (DAS28 ESR), and methotrexate use were compared between patients with EAM and those without EAM. Comparisons between groups were made with the chi-squared test when testing categorical variables and the Mann-Whitney U test or Independent samples t test for continuous data. A binomial logistic regression analysis was also carried out to find the independent factors associated with EAM.

Results: Among the 316 patients, 272 were female (86.1%). The mean age of the study population was 51.6 ± 11.38 years and the median disease duration was 36 months (84). 141 patients (44.6%) had at least one comorbidity and 23 patients (7.3%) were current or former smokers. 264 patients (84.1%) were Rheumatoid factor (RF) positive and 298 patients (94.6%) were cases of seropositive RA (RF and/or Anti CCP positive). The median ESR was 50 mm/hour and the median DAS 28 ESR was 4.65. 164 patients (51.9%) were methotrexate naive. At least one EAM was seen in 134 patients (42.4%) and the most frequently seen EAM was anaemia (48 patients, 15.2%). Keratoconjunctivitis SICCA was seen in 32 patients (10.1%) and symptomatic ILD was seen in 30 patients (9.5%). Rheumatoid vasculitis was seen in 20 patients (6.3%). Age, disease duration, and ESR (table 1) were found to have significant association with extra-articular manifestations by univariate analysis. On binomial logistic regression, disease duration (p=0.002) and ESR (p=0.047) were found to have a significant association with the presence of extra-articular manifestations.

Conclusion: Extra-articular manifestations were seen in a significant proportion of our RA patients irrespective of the seropositivity status, disease activity, or methotrexate use and had a positive association with disease duration and ESR.

Keywords: Rheumatoid arthritis, Cardiovascular disease

C. Bentivenga, M. Ardhaoui, M. Ghali, J. Mahbouba, S. Zrour, I. Beija, M. Touzi, N. Bergaoui, S. Orsola-Malpighi Polyclinic IRCCS, Medicina Interna Cardiologica-Borghi, Bologna, Italy; S. Orsola-Malpighi Polyclinic IRCCS, Medicina Interna ad indirizzo reumatologico, Bologna, Italy

Background: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease of unknown etiology characterized by joint inflammation and multiple comorbidities, with a prevalence of approximately 1% of the adult population. It is considered an independent cardiovascular (CV) risk factor, in fact it is associated with significantly increased CV morbidity and mortality. The renin angiotensin system (RAS) is a hormonal cascade with pleiotropic effects. Not only is it crucial in blood pressure regulation but it also plays an important role, among many other effects, in inflammation. High circulating levels of proinflammatory cytokines such as TNF-α and IL-6 are critical in the pathogenesis of RA as well as in determining increased CV morbidity and mortality among these patients. TNF-α and IL-6 activate the systemic and local RAS; in turn, Angiotensin II (Ang II) increases several proinflammatory cytokines among which TNF-α and IL-6. Therefore, a self-perpetuating vicious circle between RAS and cytokines is triggered. Activation of the classical RAS leads to Angiotensin II (Ang II) formation which binds to Ang II receptors type 1 (AT1R) and 2 (AT2R), RAS overactivation is essential in determining vascular inflammation and endothelial dysfunction through its proinflammatory and profibrotic effects.

Objectives: To determine whether RAS activity is higher among RA patients.

Methods: Leukocyte AT1R and AT2R mRNA was extracted and measured by real-time polymerase chain reaction analysis (RT-PCR) from 18 RA patients with stable disease and no traditional CV risk factors (mean age 52.17±11.4) and 10 healthy controls (mean age 43.8±8.61). Intergroup comparisons were made using the Mann-Whitney U test.

Results: A significantly higher expression of AT1R was found in RA patients compared to healthy controls (p=0.01). Even though the finding did not reach statistical significance, AT2R expression was also higher in RA patients (p=0.072).

Conclusion: The results suggest AT1R and possibly AT2R upregulation in RA patients, indicating that RAS overactivation could contribute to the increased CV risk observed in RA patients. If such findings are confirmed by further research, they could have important implications in terms of prevention and treatment strategies for RA patients as RA is associated with an elevated CV risk that is often overlooked and underdiagnosed in these populations.

AB0392  RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: RISK FACTORS

Keywords: Rheumatoid arthritis, Organ damage, Lungs

M. Slouma1, S. Bouzidi1, L. Metoui1, R. Dahiri1, I. Ghassala1, B. Louziri1, 2. The Principal Military Hospital of Instruction of Tunis, Rheumatology, Tunisia; 2. The Principal Military Hospital of Instruction of Tunis, Internal medicine, Tunis, Tunisia

Background: Intersitial lung disease (ILD), a severe extra-articular manifestation of rheumatoid arthritis (RA), contributes to significantly increased morbidity and mortality [1].

Objectives: Our study aimed to determine the risk factors of RA-associated ILD.

Methods: We conducted a retrospective, monocentric study over 4 years (2016-2022). Patients with RA, fulfilling the ACR/EULAR 2010, were included. ILD was defined as the presence of a radiologist-defined pattern consistent with ILD on chest computed tomography. Potential risk factors included age, sex, smoking, obesity, immunopositivity, extra-articular manifestations, disease activity, and medications. A statistical study was carried out using SPSS software.

Results: We included 128 patients with RA. The mean age was 53.0±12.87 years, with a male-to-female ratio of 0.31. The mean disease duration was 8.88±7.33 years. Nineteen patients had a confirmed ILD. usual interstitial pneumonia was the most frequent subtype of ILD (63%, n=12). Using logistic regression analysis, the significant risk factors of ILD were: age (>60 years) (OR=29.516, IC95% [1.416-615.176], p=0.029), the erosive nature of RA (OR=24.302, IC95% [1.185-498.175], p=0.038), the presence of cutaneous rheumatoid nodules (OR=52.558, IC95% [1.696-1628.890], p=0.024) and ocular involvement (OR=45.377, IC95% [1.825-1128.183], p=0.020).

Conclusion: Our study showed that older patients (age>60 years), with an erosive RA, cutaneous rheumatoid nodules, and ocular manifestations are at higher risk of developing ILD. These findings suggest that an early screening of ILD in these patients can be advised.

AB0394  DYSLIPIDEMIA IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Comorbidities, Rheumatoid arthritis

I. Klymas1, 2. Shupyk National Healthcare University of Ukraine, Department of Therapy, Family Medicine, Hematology and Transfusiology, Kyiv, Ukraine

Background: Patients with rheumatic diseases characterized by a pronounced inflammatory process. Systemic chronic inflammation, which is characteristic of patients with rheumatoid arthritis (RA), determines the high risk of developing metabolic disorders. Most often, patients with RA have disorders of lipid metabolism.

Objectives: To investigate the dyslipidemia frequency in RA patients and in the control group without autoimmune and inflammatory diseases.

Methods: We investigated 126 RA patients (102 women and 24 men, average age 43.8±2.6 years) and 30 subjects (control group) without autoimmune and inflammatory diseases (25 women and 5 men, average age 42.4±2.6 years). RA was diagnosed according to ARA criteria (1987); patients with hepatitis, alcohol abuse, >55 years old were not included. Statistical analysis was performed using program Statistica. The reliability of differences was defined at p<0.05.

Results: The evaluated lipid metabolism in RA patients and control group are presented in Table 1.

* - the difference between groups is significant, p<0.05.

In conduct an analysis of lipid metabolism in RA patients and in the control group, a high level of statistical significance p<0.001 was found in the indicators of lipid metabolism in patients with RA compared with those of the examined control group.

Conclusion: Disorders metabolism of lipids have a high prevalence among patients with RA. For the purpose of timely diagnosis of metabolic disorders of lipid metabolism in patients with RA, it is recommended to carry out a laboratory blood test with the determination of lipidogram indicators at least once a year.

Rheumatoid arthritis - biological DMARDs.

Background: Biological disease-modifying antirheumatic drugs (bDMARDs) have revolutionized the treatment of chronic inflammatory rheumatic diseases. However, the physician and the patient should be aware of possible adverse reactions. Skin is one of the most frequent organs involved in bDMARD adverse reactions and immune-mediated skin lesions (IMSL) have rarely been described before in cohort studies and their incidence is unknown.

Objectives: To explore the cumulative incidence, type of lesions, management and outcomes of IMSL related to bDMARD in a large cohort of patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA).

Methods: We conducted a retrospective single-center study including patients with RA, axSpA and PsA followed at a Rheumatology Department from a University Hospital Center between April 2000 and December 2021, treated with at least one bDMARD for at least 6 months. Sociodemographic characteristics, disease duration, age at diagnosis, concomitant immunosuppressive medications, type and duration of the treatment with bDMARD and number of previous bDMARD were collected. For all patients with IMSL, age at onset, disease duration at the time of the IMSL, culprit bDMARD and duration of the treatment, specific management and outcomes were collected. Descriptive statistics for continuous variables were presented with mean and standard deviation and categorical variables were presented with absolute and relative frequencies.

Results: A total of 441 patients with RA, 386 with axSpA and 162 with PsA were included. The majority were female (63.4%), with a mean age of 54.3 ± 12.8 years. An important proportion of patients (47.5%, n=471) were using bDMARDs and the most prescribed bDMARD was adalimumab (21.8%), followed by etanercept (16.5%). Twenty-seven (2.7%) patients presented IMSL potentially related to the bDMARD. Regarding the patients with IMSL, 55.6% were females, mean age at the onset of IMSL was 48.4 ± 12.0 years, mean duration of the treatment with bDMARDs was 4.3 ± 4.5 years and mean duration of the treatment with the culprit bDMARD was 2.9 ± 2.1 years. The majority of patients had SpA (n=14), followed by RA (n=10) and PsA (n=3). Adalimumab was the culprit agent in half of the patients (n=14), followed by etanercept (n=4), golimumab (n=3), infliximab (n=3), rituximab (n=2) and tocilizumab (n=1). Four patients (14.8%) needed hospitalization with the purpose of performing a clinical, laboratory and histological investigation. In most patients, skin lesions resolved completely with topical (n=12) or systemic (n=6) treatment. IMSL led to withdrawal of bDMARD in 18 patients (66.7%). More information about the type of IMSL was described in table 1.

Conclusion: IMSL related to bDMARDs are unusual events with an estimated cumulative incidence of 2.9%, in our sample. The most frequent IMSL were psoriasis and cutaneous manifestations of DLE and the most frequent culprit bDMARD was adalimumab. The majority of patients didn’t need hospitalization and presented complete resolution of IMSL. IMSL led to withdrawal of the bDMARD in 2/3 of patients.

**NO CLINICALLY RELEVANT CHANGES IN COAGULATION ACTIVATION BETWEEN PATIENTS INITIATING TNF-BLOCKERS VERSUS JAK-INHIBITORS**

**Keywords:** bDMARD, Cardiovascular disease, Rheumatoid arthritis

R. Hansildaar\(^1,2\), R. Raadsen\(^1,2\), M. Heslinga\(^2\), M. T. Nurmoehamed\(^1,2\).

\(^1\)Amsterdam Rheumatology Centre, Location Reade, Department of Rheumatology, Amsterdam, Netherlands; \(^2\)Amsterdam UMC, location VUMc, Department of Rheumatology, Amsterdam, Netherlands

**Background:** Rheumatoid arthritis (RA) is associated with a 2-fold higher risk of venous thromboembolism (VTE) compared with the general population \([1]\). The immune system and hemostatic system are closely linked by a shared origin. Inflammation affects thrombotic responses by upregulating procoagulants and downregulating anticoagulants and fibrinolysis \([2]\). Tumor necrosis factor (TNF), an important mediator in the inflammatory pathway, induces a disbalance between the coagulation system and fibrinolytic system, resulting in a hypercoagulable state. In addition, several studies have suggested that some Janus kinase-inhibitors (JAKI) might be associated with an increased risk for VTE \([2]\). However, the underlying pathogenic mechanisms have yet to be elucidated.

**Objectives:** To compare changes in hemostatic parameters during treatment with TNF-blockers (aTNF) and JAKI in RA.

**Methods:** Biomarkers for the coagulation system, including D-dimer, fibrinogen, PT, aPTT, F1+2, TAT, F IX and VWF, were prospectively measured in 121 consecutive RA patients: 83 patients treated with aTNF and 38 patients with JAKI. Data were collected at baseline, after 1, 3, and 6 months.

**Results:** Mean age for all patients was 57 (±14) years, 76\% were female. Mean DAS28-CRP at baseline for TNF-inhibitor group was 3.6 (±1.3) and 4.1 (±1.4) for JAKI group, steadily declining in aTNF users, while decreasing in JAKI users with an intermittent peak at 3 months. Baseline coagulation markers levels were comparable between the groups. D-dimer and VWF levels were slightly higher in the JAKI group (p = 0.30 and p = 0.08, respectively), while F IXa levels were lower (p = 0.17).

D-dimer and fibrinogen levels steadily declined in the aTNF group, while decreasing in JAKI users with an intermittent peak at 3 months with a subsequent decline thereafter (Figure 1). In aTNF users, TAT increased slightly during follow-up, VWF, PT and aPTT remained relatively stable, while F IXa and F 1+2 showed an increase after 3 months of follow-up, after which they returned to baseline. In JAKI users, D-dimer, fibrinogen, VWF and F 1+2 fluctuated, with a peak after 3 months and then a subsequent decline. F IX and PT initially decreased slightly but increased steadily after 6 months, while TAT and aPTT remained stable during follow-up.

**Conclusion:** The pro-thrombotic tendency in active RA declined during effective treatment with both aTNF as well as JAKI. A gradually decrease in D-dimer and fibrinogen was seen after 6 months of treatment. The transient increase of coagulation activation in JAKI users at three months coincided with increased disease activity. Altogether, our data suggests that an increased VTE risk in the first six months due to either treatment aTNF or JAKI seems unlikely. Whether or not the risk increases beyond this time period remains to be investigated.

**Background:** The ORAL-surveillance trial showed a higher risk of major adverse cardiovascular events (MACE) and cancer in patients with rheumatoid arthritis (RA) taking tofacitinib, a Janus kinase inhibitor (JAKI), compared to those taking tumor necrosis factor alpha inhibitors (TNFIs). However, little is known regarding the comparative safety of these two drug classes relative to non-TNFi biologics.

**Objectives:** To assess the comparative safety of TNFi’s, non-TNFi’s, and JAKI’s in RA patients for the risk of MACE (e.g., myocardial infarction, cardiac arrest, sudden death, stroke, percutaneous coronary intervention, and coronary artery bypass graft), cancer, deep vein thrombosis (DVT), and pulmonary embolism (PE).

---
Methods: We performed a retrospective cohort study using IBM Watson MarketScan databases (2012-2019) of RA patients 18-64 years of age who initiated treatment with TNFi's, non-TNFi's, or JAKi's on or after January 2012. We used Cox Proportional hazards models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for developing MACE, cancer, DVT, and PE within 2 years of initiation in patients on non-TNFi's or JAKi's relative to TNFi's, adjusting for multiple confounders, including age, gender, geographic region, year of initiating a biologic, Charlson Comorbidity Index, frailty status, healthcare utilization within 12 months prior to starting treatment (i.e., major infection requiring hospital admissions, general hospital admissions, outpatient visits, and emergency department visits), and RA severity (i.e. disease-modifying antirheumatic drug, nonsteroidal anti-inflammatory drug, glucocorticoid, and opioid fills 3 months prior to starting treatment).

Results: A total of 39,032 drug initiation events met eligibility criteria for our study (73.6% initiation of TNFi's, 18.6% non-TNFi's, and 7.8% JAKi's). The mean age of the patients in each of the groups ranged from 47-49 years old; the majority were female. The mean follow-up time was 349 days for TNFi's, 272 days for non-TNFi's, and 266 days for JAKi's. Non-TNFi's were associated with an increased risk of MACE, cancer, and DVT, though the incidence of adverse health outcomes overall was still quite low (Table 1). In multivariable models, patients who started non-TNFi's had a significantly higher risk of MACE (HR 1.75; 1.34-2.28), incident cancer (HR 2.06; 1.70-2.50), and DVT (HR 1.84; 1.45-2.32) compared to those who initiated TNFi's. Patients who filled JAKi's had a significantly higher risk of developing cancer compared to those who filled TNFi's (HR 1.48; 1.09-2.03).

Conclusion: TNFi's may be safer for RA treatment than non-TNFi's and JAKi's for RA in this generally younger and predominantly female population. However, since most RA patients initiate treatment with TNFi's, results could be confounded by the possibility of more severe or prolonged disease in patients on non-TNFi's and JAKi's. These findings need to be replicated in other study populations. Future steps include looking at the risk conferred by individual non-TNFi's towards these risks. Studies with longer follow-up are needed for better assessment of cancer risk among these drug classes.

Table 1. Incidence per 10,000 person-years of each adverse health outcome* stratified by drug class in RA patients 18-64 years of age.

quickly after discontinuation. Besides, severe infection occurred in 2.3% of RA patients (Figure 1).

**Conclusion:** Abatacept was effective and well-tolerated in RA patients. The incidence of adverse events was high, but most were mild and recovered quickly after discontinuation.

**REFERENCES:**

**RESULTS:** Abatacept was effective and well-tolerated in RA patients. The incidence of adverse events was high, but most were mild and recovered quickly after discontinuation. Besides, severe infection occurred in 2.3% of RA patients.

**OBJECTIVES:** Examine the treatment pathway, factors associated with drug initiation and treatment discontinuation in patients with RA treated with either IL-6 inhibitors versus non-IL-6 biologic disease modifying anti-rheumatic drugs (bDMARDs).

**METHODS:** A retrospective cohort study of RA patients in the Secure Anonymised Information Linkage databank, including primary care, secondary care and rheumatology clinic records of over 90% of the population in Wales, UK. Patients initiated on first treatment initiation, discontinuation and clinical outcomes including infection and hospitalisation were analysed using Cox regression analysis.

**RESULTS:** Data from 4922 patients with RA were analysed. The majority of patients had taken at least one conventional synthetic disease modifying anti-rheumatic drug (csDMARD) 95.7%, (4,691/4,922) while 29.6% (1,457) went on to take bDMARDs. Of these, 2% (97) biologic-naive patients were treated with IL-6 inhibitors. Earlier treatment with bDMARDs was associated with increased disease duration (HR: 1.11, 95% CI: 1.07 to 1.15) while younger age at diagnosis, orthopaedic surgery pre-treatment and kidney disease reduced the likelihood of being treated with biologics. Previous history of infection was associated with increased likelihood of treatment with IL-6 inhibitors rather than non-IL-6 bDMARDs (HR: 1.73, 95% CI: 1.15 to 2.59). The rate of treatment discontinuation was significantly higher in the non-IL-6 bDMARDs-treated patients compared to the IL-6 inhibitor treated individuals (difference: 9.4, 95% CI: 1.1 to 15.7). Treatment failure, orthopaedic surgery pre-treatment and steroid use was associated with non-IL-6 bDMARDs treatment failure (HR: 1.64, 95% CI: 1.00 to 2.68; HR: 1.82, 95% CI: 1.26 to 2.08, respectively). No factors were associated with treatment failure in the IL-6 inhibitor treated patients.

**Conclusion:** Patients treated with IL-6 inhibitors and other biologics were similar in demographics but had a different comorbidities pre-treatment; there was more orthopaedic surgery in those who went on to be treated with non-IL-6 biologics and more prior history of infections and kidney disease in those treated with IL-6 inhibitors. Treatment failure was higher in the non-IL-6 bDMARDs-treated patients.

AB0401

EFFICACY OF ABATACEPT FOR SUPPRESSING RADIOGRAPHIC PROGRESSION OF CERVICAL LESIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARISON WITH METHOTREXATE TREATMENT: THREE YEARS OF FOLLOW-UP – A MULTICENTER REGISTRY STUDY –

Keywords: Rheumatoid arthritis, bDMARD

Y. Kanayama1, K. Hattori1,1Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyata, Japan

Background: Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with biological agents are more clinically effective than the DMARDs that were in use previously, in particular with their efficacy in suppressing joint destruction having been emphasized. We reported the efficacy of infliximab, anti-tumor necrosis factor antibodies for suppressing the radiographic progression of RA cervical lesions at ACR2009, EULAR2010, 11, 12, 13, 14, 16, 18, 19 and 20. However there is still few studies of efficacy of against RA cervical lesions of Abatacept (ABT) that inhibits T cell activation by binding to CD80/86.

Objectives: To evaluate the efficacy of ABT for suppressing the radiographic progression of RA cervical lesions comparison with MTX for 3 years.

Methods: We used ABT or MTX for treating Japanese patients with active RA who fulfilled the ACR criteria in 1987. The final study cohort of each 49 and 75 patients received continuous ABT and MTX treatment for at least 3 years. For evaluation of cervical lesions, the atlanto-dental interval (ADI), the space available for the spinal cord (SAC), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at initiation and Year 1, 2, 3.

Results: In the patients receiving ABT (n=49) and MTX (n =75), the number of female were each 39(80%) and 52(69%) cases(p=0.206). The mean age was 67.1 ± 13.1 and 63.6 ± 11.0 years old (p=0.010); disease duration was 17.3 ± 14.0 and 8.0 ± 9.5 years (p<0.001) and the mean dose of MTX was 8.1 ± 3.5 and 8.2 ± 2.9 mg/w (p=0.970). Clinical findings related to RA were as follows; CRP 2.2± 2.1 and 1.7± 2.3 mg/dl(p=0.010); ESR 44.1 ± 21.1 and 31.9 ± 21.8mm/h(p<0.001); MMP3 273 ± 303 and 223 ± 350mg/ml(p=0.002); the number of RF-positive 48(98%) and 60(80%) cases(p=0.004); DAS28-ESR 5.12 ± 1.03 and 4.30 ± 1.38 (p<0.001); ADI 3.7 ± 2.5 and 2.6 ± 2.6 (p=0.001); SAC 18.6 ± 2.9 and 20.8 ± 2.5 (p=0.001) and Ranawat value 14.4 ± 2.0 and 16.0 ± 1.5 mm (p<0.001). The respective changes in cervical lesion parameters after 1 year were as follows: ADI: 0.20 ± 0.41 and 0.25 ± 0.45 mm (p = 0.528); SAC: −0.14 ± 0.35 and −0.17 ± 0.38 mm (p = 0.633); and Ranawat value: −0.18 ± 0.39 and −0.13 ± 0.34 mm (p = 0.449). The respective changes in cervical lesion parameters after 2 years were as follows: ADI: 0.35 ± 0.56 and 0.55 ± 0.70 mm (p = 0.126); SAC: −0.27 ± 0.49 and −0.45 ± 0.62 mm (p = 0.087); and Ranawat value: −0.27 ± 0.49 and −0.33 ± 0.55 mm (p = 0.528). The respective changes in cervical lesion parameters after 3 years were as follows: ADI: 0.47 ± 0.77 and 0.71 ± 0.80 mm (p = 0.063); SAC: −0.39 ± 0.73 and −0.63 ± 0.82 mm (p = 0.040); and Ranawat value: −0.41 ± 0.71 and −0.44 ± 0.66 mm (p = 0.606) in the patients receiving ABT and MTX (Figure 1). The numbers of patients who did not show progression in ADI, SAC and Ranawat value were each 33(67%) and 37(49%) cases(p=0.048); 37(76%) and 40(53%) cases(p=0.013) and 35(71%) and 49(65%) cases(p=0.478) after 3 years. Also the number who was able to suppress progression in all three parameters were each 32 cases (65%) and 37 cases (49%) receiving MTX (p=0.128) after 3 years (Figure 2).

Conclusion: This study suggested that ABT treatment can be used to suppress the progression of RA upper cervical lesions more than MTX treatment.

Bae13, E. Keystone14, 1Seoul National University College of Medicine and Hospital, Clinical Pharmacology and Therapeutics, Seoul, Korea, Rep. of (South Korea); 2Gachon University Gil Medical Center, Clinical Trial Center, Incheon, Korea, Rep. of (South Korea); 3Chungbuk National University Hospital, Clinical...
Background: CT-P47 is a recombinant humanized monoclonal antibody that was developed as a proposed biosimilar of tocilizumab.

Objectives: The purpose of this study was to compare the pharmacokinetic (PK), safety, and immunogenicity of CT-P47 and EU-approved tocilizumab (EU-tocilizumab) up to 42 days after a single subcutaneous injection of 162 mg of each product in healthy subjects.

Methods: 289 healthy subjects aged 19 to 55 years were randomly assigned 1:1 to receive either CT-P47 or EU-tocilizumab. The primary PK endpoints included area under the serum concentration-time curve from time zero to infinity (AUC0-inf), area under the concentration-time curve from time zero to the last quantifiable concentration (AUC0-last), and maximum serum concentration (Cmax). Secondary endpoints were additional PK, safety, and immunogenicity.

Results: Demographics and baseline characteristics were well balanced between groups. The 90% confidence intervals for the geometric least squares mean ratios of each of the primary PK parameters (AUC0-inf, AUC0-last, Cmax) were within the predefined equivalence margin of 80% to 125% (Table 1). Secondary PK variables (Tmax, t1/2, CL/F, Vz/F, %AUCext) were also comparable between groups. Mean serum concentrations of tocilizumab observed through 42 days post-dose were comparable between groups (Figure 1). Overall, 55 (38.2%) and 72 (51.4%) subjects reported ≥1 treatment-emergent adverse event (TEAE) in the CT-P47 and EU-tocilizumab groups, respectively. Most of the TEAEs were grade 1 or 2 in intensity and TEAEs considered to be related to study drug were reported by 47 (32.6%) and 61 (43.6%) subjects, respectively. Neutrophil count decreased was the most commonly reported TEAE overall (14 [9.7%] and 15 [10.7%] subjects, respectively). There were 3 treatment-emergent serious adverse events (2 [1.4%] and 1 [0.7%] subjects, respectively). Of these, only 1 case was considered to be related to study drug (EU-tocilizumab: headache). Overall, 20 (13.9%) and 29 (20.7%) subjects in the CT-P47 and EU-tocilizumab groups, respectively, had ≥1 positive result post-treatment for anti-drug antibodies (ADA) and 17 (11.8%) and 20 (13.9%) subjects, respectively, had ≥1 post-treatment positive result for neutralizing antibody. Primary PK parameters of AUC0-inf, AUC0-last, and Cmax were slightly lower in subjects with at least 1 ADA positive compared with those subjects with all ADA negative, at post-dose, among groups in the PK set.

Conclusion: This study demonstrated PK equivalence of CT-P47 to EU-approved tocilizumab in healthy subjects. Safety profiles, including immunogenicity, were comparable between groups.

LONGITUDINAL ANALYSIS OF CHANGES IN THE FINE ARTICULAR STRUCTURE BY CTLA4-IG USING HR-pQCT IN RHEUMATOID ARTHRITIS

Keywords: Imaging, Rheumatoid arthritis, Real-world evidence

N. Iwamoto1, K. Chiba2, S. Sato3, K. Watanaabe4, K. Shiaraishi5, N. Ohki6, A. Kawakami1, 7Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan, 8Nagasaki University Graduate School of Biomedical Sciences, Department of Orthopedic Surgery, Nagasaki, Japan, 9Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan, 10Nagasaki University Graduate School of Biomedical Sciences, Department of Radiological Sciences, Nagasaki, Japan

Background: Although the clinical effect of CTLA4-ig (abatacept: ABT) on rheumatoid arthritis (RA) has been shown by a several kinds of large scale clinical trials and postmarketing surveillances, detail of its effect at a local joint has not been sufficiently analyzed. Recently, it has been shown that CTLA4-ig has not only inhibition effect on T-cell activation but also has inhibition effect on osteoclast differentiation by directly affecting osteoclast precursors.[1] therefore analysis of the effect on changes in the bone structural at an actual clinical site has been expected. A novel imaging test method of High Resolution peripheral Quantitative CT (HR-pQCT) can detect fine structure of bones that could not have been detected in the past and it can evaluate not only conditions of joint destruction but also periarticular osteoporosis.

Objectives: To compare the changes in fine articular structure including bone erosion and micro-architecture by ABT and csDMARD in patients with RA using HR-pQCT.

Methods: In this open-label, parallel-group study, twenty patients who started newly csDMARD and 15 patients who started ABT were enrolled. Fine articular structure in 2.3 metaphcal head were assessed by HR-pQCT every 6 month for 12 months. Synovitis was assessed by musculoskeletal ultrasound (MSUS) and magnetic resonance imaging (MRI) of wrist and fingers. We also measured...
the bone mineral density (BMD) of lumber spine. The estimated difference in
adjusted mean and mean (ABT–csDMARD group) and 95% CIs and P-values were
calculated using a linear mixed model with treatment group, allocation
factor, baseline disease activity, observation time-point, and treatment group x
observation time-point as fixed effect, patients as random effect, and baseline
value as covariates.

Results: Baseline characteristics including disease activity were similar between
the ABT and csDMARD groups. The mean ± disease activity scores (DAS28-
ESR) from baseline to 12 months were −1.61 (ABT) and −1.71 (csDMARDs). The
determined mean change in disease activity from baseline to 12 months
was −1.86 mm², −0.20 mm², −0.35 mm², and −0.09 mm², respectively (Table 1). During observational period (12 months),
only one new erosion detected by HR-pQCT appeared, and 14 erosions were
repaired in ABT group, whereas, in csDMARD group, 5 new erosions appeared,
and 5 erosions were repaired. Regarding synovitis, changes in synovitis score
defined by MSUS and the RA-MRI score (RAMLUS) were similar between those
two groups. Compared with patients in the csDMARD group, those in ABT group
had better bone micro-architectures improvement (Table 1). In the other hand,
% change of BMD of lumbar at 12 months were less improved in ABT group as
compared csDMARD group (0.17%, 1.82%, respectively).

Conclusion: Our results indicated that the ABT could repair bone erosions and
had better inhibitory effect of bone erosion, improvement periarticular osteoporosis
as compared with csDMARD treatment regardless of improvement of disease
activity, synovitis and progress of systemic osteoporosis. Thus, CTLA4-Ig treatment
might be beneficial not only in terms of inhibition of bone erosion but also improvement of bone micro-architecture.

Background: Interleukin 6 inhibitors (IL-6i) can increase LDL cholesterol levels, which raises concerns about the risk of myocardial infarction (MI) in patients with rheumatoid arthritis (RA) receiving this therapy.

Objectives: This study aims to compare the risk of MI between people with RA in the UK clinical setting receiving IL-6i or tumour necrosis factor inhibitors (TNFi) overall or by line of therapy (LoT).

Methods: Patients with RA registered between 01/10/2001 and 30/05/2022 with BSRBR-RA starting IL-6i or TNFi therapies were included. Occurrence of MI was identified from clinical follow-up forms and through cause of death reported by the UK national death register. Only those MI occurring whilst patient was actively receiving drug were included. The risk of MI in patients receiving IL-6i compared to TNFi was compared using Cox regression, adjusted for baseline co-variates using propensity scores (PS, see Table 1). Follow-up commenced at the start of the drug of interest and patients were censored at occurrence of MI, death, discontinuation of therapy or last follow-up visit, whichever came first. Multiple imputation was used for missing data. To account for known differences in LoT usage of TNFi and IL6i (with IL6i more likely at a later line bDMARD), overall analyses adjusted for LoT and secondary analyses by LoT were conducted. Direct switches between originator to biosimilars were considered the same treatment.

Results: A total of 30,022 IL6i or TNFi LoTs in 20,898 patients were included (3,278 IL-6i; 26,744 TNFi), representing 119,797 person-years of exposure. Compared to patients receiving TNFi, patients starting IL-6i treatment were older, had longer disease duration, less likely to use methotrexate and steroids, and had more comorbidities. During follow-up, 409 MIs occurred, 30 on IL-6i and 379 on TNFi. After PS adjustment, the risk of MI was not significantly different between the two treatment overall (HR 0.87, 95% CI 0.56-1.37) or by line of therapy (LoT).

Conclusion: This study could not identify any difference in risk of MI between IL-6i and TNFi treatment after patient characteristics and LoT were considered.

AB0406 EFFICACY OF TNF-ALPHA INHIBITORS IN MANAGEMENT OF IMMUNE CHECKPOINT INHIBITOR RELATED ARTHRITIS

Keywords: Malignancy, Inflammatory arthritides, bDMARD

M. Callan1, 1Chelsea & Westminster Hospital, Rheumatology, London, United Kingdom

Background: Use of immune checkpoint inhibitors (ICI) has revolutionised management of multiple malignancies but may be complicated by development of immune-related adverse events including inflammatory arthritis. Once triggered, arthritis may persist, with 50% patients having ongoing symptoms even 1 year after stopping ICI treatment. EULAR guidance, based on small retrospective and prospective studies and case reports, recommends treatment with corticosteroids, with escalation to DMARDs particularly where arthritis remains active at doses of prednisolone >10mg [1]. There is some evidence to support use of bDMARDs DMARDs in management, but a lack of studies using validated rheumatology scoring tools to objectively assess ICI arthritis response to biologic agents [2-4].

Objectives: The aim of this study was to assess efficacy of TNF-alpha inhibitors in ICI arthritis, using change in Clinical Disease Activity Index (CDAI) as an outcome measure. The CDAI was chosen as it is independent of ESR and CRP which may be influenced by other complications of malignancy and its treatment.

Methods: This was a single centre retrospective study of 65 patients referred with musculoskeletal symptoms following use of an ICI. Patients with ICI arthritis treated with a TNF-alpha inhibitor were identified and their notes systematically reviewed for information about malignancy diagnosis, use of ICI, presentation with inflammatory arthritis and its response to treatment, with arthritis activity monitored using the CDAI.

Results: 40 of the 65 patients referred presented with an inflammatory arthritis and 9 were treated with a TNF-alpha inhibitor to manage arthritis. These included 4 male and 5 female patients, with mean age 65 years. 5 patients had melanoma, 2 renal cell cancer, 1 mesothelioma and 1 gall bladder adenocarcinoma. All 9 patients had received treatment with a PD-1/PDL-1 inhibitor, with 5 patients also receiving a CTLA-4 inhibitor. 1 patient had a prior diagnosis of psoriatic arthritis and 1 had a prior diagnosis of rheumatoid arthritis. Both experienced increased arthritis activity following ICI treatment. The remaining 7 patients developed new onset polyarthritis following ICI treatment, with 1 of 7 being anti-CCP and RF positive. Prior to use of a TNF-alpha inhibitor, all 9 patients had received treatment with prednisolone. 4 patients had been treated with methotrexate, of whom 3 had also had sulfasalazine. 6 of 9 patients received adalimumab as a first biologic, with the other 3 receiving infliximab. CDAI prior to use of a TNF-alpha inhibitor ranged from 20 to 62, with a mean of 32.8 ± 2 patients had moderate disease activity (CDAI±10 and ±22) and 7 patients had high disease activity (CDAI>22). The CDAI at follow up ranged from 4 to 31 with a mean of 13.2. 5 patients had low disease activity (CDAI<10), 4 patients had moderate disease activity and 2 patients had high disease activity at this time. Use of a TNF-alpha inhibitor was associated with a clinically meaningful improvement in CDAI in 8 of 9 patients at follow up after a mean of 11 weeks of treatment, including 1 patient who continued with ICI treatment.

Conclusion: This single centre retrospective study suggests efficacy of TNF-alpha inhibitors in management of ICI arthritis. Similar to previous work, this study is small and limited by lack of a control cohort but has the advantage of using a validated rheumatology scoring tool to confirm diagnosis in arthritis activity. TNF-alpha inhibitors have a shorter time to onset of action than csDMARDs and so offer an opportunity for early control of ICI arthritis, with potential for use in parallel with continued ICI treatment if needed for management of the underlying malignancy.

DOI: 10.1136/annrheumdis-2023-eular.1095
Keywords: bDMARD, Rheumatoid arthritis, Biomarkers

Methods: This study assessed 5,343 treatment courses of bDMARDs and JAK inhibitors introduced from 2001 to 2022 (TNF inhibitors [TNFi]=2,724, anti-IL-6 receptor antibody [aIL-6R]=1,227, cytotoxic T lymphocyte-associated antigen-4-Ig [CTLA4-Ig]=906, JAK inhibitors=486; bDMARDs/JAK inhibitors naive cases 56.0%, baseline age 60.0 years, female 83.5%, disease duration 10.3 years, DAS28-ESR 4.3, RF positivity 78.3%, ACPA positivity 82.8%, combined methotrexate [MTX] dose 8.4mg/week [47.8%), and prednisolone [PSL] dose 5.9mg/day [28.2%]). Patients were classified into three groups according to their serum RF (IU/mL) and ACPA (U/mL) titer: negative (RF<15 or ACPA<4.5), low positive (15<RF<100 or 4.5<ACP<100), or high positive (RF>100 or ACPA>100), respectively. Reasons for discontinuation were classified into four categories by each attending physician: 1) lack of effectiveness (primary and secondary), 2) toxic adverse events (infection, malignancies and cardiovascular events, et al.), 3) non-toxic reasons (patient preference and pregnancy, et al.), and 4) remission. Retention rates of each discontinuation reason were estimated at 24 months using the Kaplan-Meier method and adjusted for potential clinical confounders (age, sex, concomitant PSL and MTX, switched number of bDMARDs or JAK inhibitors, and prior use of TNFi, aIL-6R, CTLA4-Ig, or JAKi) using Cox proportional hazards modeling.

Results: Adjusted discontinuation rates for each reason were as follows: due to lack of effectiveness was all-6L-21.4%, JAKi=27.1%, CTLA4-Ig=30.4%, and TNF=38.2% (Cox P=0.001 between 4 groups), due to toxic adverse events was CTLA4-Ig=12.1%, all-6L=12.5%, TNF=13.3%, and JAKi=14.6% (Cox P=0.369 between 4 groups). When categorized by RF (Figure 1a), adjusted discontinuation rates due to lack of effectiveness were listed in ascending order as follows (respectively): RF negative (all-6L, 16.2%; TNF, 30.5%; CTLA4-Ig, 33.8%; JAKi, 39.9%; Cox P=0.001), low positive (all-6L, 19.6%; JAKi, 21.7%; CTLA4-Ig, 26.6%; TNF, 29.9%; Cox P=0.001) and high positive (all-6L, 25.4%; JAKi, 28.1%; CTLA4-Ig, 31.2%; TNF, 38.6%; Cox P=0.001). When categorized by ACPA (Figure 1b), discontinuation rates due to lack of effectiveness were listed in ascending order as follows, respectively: ACPA negative (all-6L, 20.9%; TNF, 28.8%; JAKi, 30.7%; CTLA4-Ig, 43.4%; Cox P=0.001), low positive (all-6L, 19.2%; JAKi, 26.4%; CTLA4-Ig, 27.3%; TNF, 33.6%; Cox P=0.001) and high positive (all-6L, 23.1%; JAKi, 25.6%; CTLA4-Ig, 29.7%; TNF, 35.2%; Cox P=0.001).

Conclusion: Considering lack of effectiveness, all-6L showed highest continuation rates compared to other agents regardless of RF/ACPA positivity or titer levels. On the other hand, CTLA4-Ig and JAKi showed higher continuation rates, although TNFi showed lower continuation rates in RF/ACPA-positive (low or high titer) cases compared with RF/ACPA-negative cases.

AB0408 DESCRIPTIVE STUDY ON USE OF BIOSIMILARS IN RHEUMATOID ARTHRITIS IN UNIVERSITY HOSPITALS PLYMOUTH, UNITED KINGDOM

Keywords: Descriptive Studies, Real-world evidence, bDMARD

A. Edirinweera¹, T. Aung¹, O. Savanovic-Abel¹. ¹University Hospitals Plymouth, Rheumatology, Plymouth, United Kingdom

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease of unknown etiology marked by a symmetric, peripheral polyarthritis. Treatment of RA should be aimed at reaching a target of sustained remission or Low Disease Activity (LDA) in every patient. [1] Given the heterogeneity of the disease, there are multiple disease modifying anti rheumatoid drugs (DMARDs) available including biologics and biosimilars with different modes of action to achieve disease remission or low disease activity. A biosimilar medicine is a biological medicine manufactured to be similar to an existing licensed “reference” biological medicine, with no meaningful differences from reference medicine in terms of quality, safety or efficacy. However, it has been observed significant number of patients going back on bio-originator drugs complaining either side effects or less efficacy of biosimilar. This study is aimed at looking at real rate of bio-similar (BS) switching back to bio-originator (BO) due to various reasons.

OBJECTIVES:
1) To look for rate of switching back to bio-original and reasons behind
2) Biosimilar persistence rate in RA and side effect profile
3) To look for any association between concurrent use of methotrexate with biosimilar persistence rate.

Methods: Descriptive study was done at department of rheumatology University Hospitals Plymouth (UHP). All patients with the diagnosis of Rheumatoid arthritis, treated with biological DMARDs were screened till October 2019. Data were gathered about switching back to BO from BS and if switched reason for switch, persistence rate of biosimilar, duration of biosimilar, disease activity measured by DAS 28 before and 6 weeks after biosimilar, side effects and concurrent use of methotrexate with biosimilar. Data were analyzed as percentages and chi-square is used to find associations.

Results: Total number of 590 patients with RA on biological DMARDs were screened. Most popular first choice of BS was etanercept (318) followed by rituximab (177), adalimumab (85) and infliximab (9). Only 19 patients out of 318(5.9%) patients treated with etanercept BS went back to BO due to inefficacy and side effects. 222/318 (69.8%) remained on etanercept. Switching back rate of adalimumab BO was only 9.4% (8/85) while 73% remained on adalimumab BS. (62/85). For rituximab, 9 out of 177 (5.08%) patients went back to original; 6 due to inefficacy and 3 side effects. 147/177 (83.05%) remained on BS rituximab. Only one patient out of 9 treated with infliximab went back on original drug due to inefficacy. Commonly observed side effects of BS are infections, allergic reactions, and gastrointestinal disturbances. Average DAS 28 score difference after 6 weeks of commencement of BS was calculated only for adalimumab and etanercept. There was a 2.27 reduction of DAS 28 in adalimumab group (from 5.22 to 2.95) while the reduction was 1.67 for etanercept group (from 5.14 to 3.47). Looking at association between persistence rate of BS and concurrent use of methotrexate, only RA etanercept group showed a significant association with a p value of 0.000041.

Conclusion: Significant number of patients with RA are treated with biosimilar in UHP. Re switching to bio-originator is not very commonly seen. Most of the patients could tolerate biosimilar well and persistence rate is impressively high with good response reflected by reduction of average disease activity in studied cohorts. Among side effects infection, allergic reaction and GI side effects are common. Concurrent use of methotrexate showed positive correlation with persistent rate of biosimilar only in one group (RA treated with etanercept) but not others, hence does not give strong ground to the hypothesis that methotrexate minimizes immunogenicity for biosimilar.

AB0409 TIME TO FIRST REMISSION AND PREVALENCE OF SUSTAINED REMISSION AFTER ETANERCEPT BIOSIMILAR (ETA-B) OR ORIGINATOR (ETA-O) INITIATION IN RHEUMATOID ARTHRITIS (RA)

Keywords: Real-world evidence, bDMARD, Rheumatoid arthritis

C. S. Moura¹, D. Choquette², G. Boire³, W. P. Maksymowych¹, L. Lukusa¹, L. Yan¹, M. G. Birck¹, S. Bernatsky¹, ², ³Research Institute of the McGill University Health Centre, Centre for Outcomes Research and Evaluation, Montreal, Canada; ¹CHUM - Centre hospitalier de l’Université de Montréal, Institut de Rhumatologie de Montréal, Montréal, Canada; ²Université de Sherbrooke, Faculty of Medicine, Sherbrooke, Canada; ³University of Alberta, Department of Medicine, Division of Rheumatology, Edmonton, Canada; ²McGill University, Epidemiology, Biostatistics and Occupational Health, Faculty of Medicine, Montréal, Canada

Background: The first biosimilar etanercept (ETA-B) was approved in Canada in 2016, but real-world data comparing the effectiveness of ETA-B versus their equivalent originator (ETA-O) remains scarce.

Objectives: To compare time to remission throughout follow-up and sustained RA remission in the first 12 months.

Methods: We studied etanercept-naive RA patients starting ETA-B or ETA-O between January 2015 and May 2022 from three prospective research cohorts related to the Early Undifferentiated Polyarthritides (Sherbrooke), RA Pharmacovigilance Program and Outcomes Research in Therapeutics (Edmonton), and RHUMADATA³ (Montreal) registries. We restricted analyses to RA patients with at least one follow-up visit after treatment initiation and with enough data to calculate remission. Remission was defined as Disease Activity Score 28-CRP or -ESR ≤2.6, Simplified Disease Activity Index ≤ 3.3, or Clinical Disease Activity Index ≤ 2.8. We used Cox regression to compare ETA-B versus ETA-O regarding time to first remission during follow-up (among those without remission at baseline) and logistic regression to assess sustained remission (remission in two consecutive visits) in the first 12 months of follow-up. Models were adjusted for sex, age, body mass index (BMI), RA duration, and smoking status at cohort entry. We also adjusted for high/moderate disease activity and the use of corticosteroids, methotrexate (MTX), or hydroxychloroquine (HCQ), all at etanercept initiation.

Results: We studied 150 RA patients initiating etanercept (65% on the biosimilar) between 2015-2022. Sex distribution was similar among ETA-B and ETA-O, but the biosimilar group has a longer disease duration and moderate/higher disease activity at baseline. Among 125 participants without remission at baseline, the median time to first remission was 8.7 months with ETA-B versus 14.5 with ETA-O. In the multivariate analysis (Table 1A), we were unable to detect a clear difference in time to achieve first remission when comparing ETA-B to ETA-O (hazard ratio, HR = 1.43, 95% confidence interval, CI 0.65-3.13). Obesity (BMI>30) was negatively associated with the outcome. Sustained remission in the first 12 months of follow-up was observed in 16.3% of ETA-B initiators versus 17.3% with ETA-O. After multivariate analysis (Table 1B), we were unable to establish any clear difference between ETA-B versus ETA-O (OR 1.16, 95% CI 0.31-4.74). HCQ was positively associated with sustained remission within the first 12 months.

Conclusion: In this pooled analysis of three Canadian RA cohorts, we were unable to detect clear differences in achievement or sustained remission when comparing ETA-B and ETA-O.

</table>

Serum levels were associated with the achievement of LDA/remission when patients were stratified according to the route of antiIL6 administration. Leptin levels in both groups (SC and IV) were very similar at baseline and 6M and regarding changes on adipokine profile between baseline and 6M, we observed a decrease in leptin and an increase in adiponectin levels both in SC and IV (Table 1).

BMI showed a significant positive correlation with leptin, and overall and stratifying by route of administration, both at baseline and 6M. Adiponectin did not show a significant correlation with BMI.

Figure 1.

Conclusion: Obesity and serum adipokines did not show association with the achievement of LDA/remission in patients treated with antiIL6 regardless the route of administration. Furthermore, IV and SC treatments could be used both in obese and normal-weight RA patients expecting the same efficacy.

OBESEITY AND ADIPOSE TISSUE CYTOKINES IN RHEUMATOID ARTHRITIS: DOES THE ROUTE OF ADMINISTRATION OF THE IL6 INHIBITORS MATTER?

Keywords: bDMARD, Rheumatoid arthritis, Comorbidities

M. Novella-Navarro1, F. Genre Romero2, A. Martinez-Feito2, V. Pulito-Cuezo2, I. Monjo2, D. Peiteado1, M. A. González-Gay4, C. Plasencia1, A. Balsa1.

1Hospital Universitario La Paz, Rheumatology, Madrid, Spain; 2DINAV, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic Bone Diseases of the Musculoskeletal System, Santander, Spain; 3Hospital Universitario La Paz, Immunology, Madrid, Spain; 4IIS-Fundación Jiménez Díaz, Rheumatology, Madrid, Spain

Background: Obesity has been associated with the response to biologic disease modifying anti-rheumatic drugs (bDMARDs). Obese patients have lower response to anti-TNF drugs than to other cytokine-targeted drugs, such as anti-IL6[1]. IL6 receptor inhibition is effective in the treatment of rheumatoid arthritis (RA), and there are two ways of administration: intravenous (IV) weight-adjusted tocilizumab and subcutaneous (SC) fixed-dose tocilizumab or sarilumab. However, evidence regarding the influence of body mass index (BMI) and these different routes of administration is still scarce.

Objectives: To analyze the role of BMI in the clinical response to antiIL6 therapy in its different routes of administration in patients with RA. To perform an in-depth analysis of the pathophysiology of obesity by assessing serum adipokine levels and their potential changes according to treatment.

Methods: This study involved 65 patients with RA starting IV tocilizumab at 8mg/kg every 4 weeks or SC antiIL6 tocilizumab 162mg/week or sarilumab 200mg/14days. Demographic and clinical characteristics before antiIL6 initiation (age, sex, smoking habit, age at diagnosis, concomitant and previous treatments and BMI) were collected. Laboratory parameters such as rheumatoid factor and anti-citrulinated peptide antibody were also assessed. Adipokine serum levels (leptin and adiponectin) were measured at baseline and after 6 months (6M) of treatment. Clinical response to treatment was assessed by Clinical Disease Activity Index (CDAI) 6M after initiation of the bDMARD. Differences between variables were assessed using the X2 test and Mann-Whitney test. Correlations between BMI, adipokines and other quantitative variables were assessed using the Pearson or Spearman coefficients. P-values ≤0.05 were considered statistically significant.

Little is known about the association between ethnicity and response to TNF inhibitors (TNFi) in people with rheumatoid arthritis (RA). This study examines the association between self-reported ethnicity and DAS28 response after 6 months of treatment in patients starting their first TNFi using data from the British Society for Rheumatology Biologies Register for RA.

**Methods:** 14133 RA patients with self-reported ethnicity starting their first TNFi were included. Due to a very low proportion of non-white patients, ethnicity was divided into white or non-white for analysis. Outcomes included the change in disease activity using DAS28, the proportion of patients who achieved DAS28 remission and EULAR response at month 6. Adjusted regression models appropriate to outcome were used to compare between the two groups. Multiple imputation was used to account for missing data.

**Results:** Of 14133 patients starting TNFi with recorded ethnicity, only 607 (4.3%) recorded themselves as non-white (389 Asian, 134 Black, 57 Mixed ethnicity and 27 other) (Table 1). At start of TNFi, non-white patients were younger (non-white vs. white: mean 51 vs. 57 years; p<0.001), with shorter disease duration (median 8 vs. 10 years; p<0.001), higher proportion of females (86% vs. 76%; p<0.001) and fewer current cigarette smokers (9% vs. 20%; p<0.001). Non-white patients had less improvement in DAS28 at month 6 (adjusted regression coefficient (95% confidence interval (95%CI)): 0.3 (0.04-0.5)). However, using the white patients as a reference, non-white patients were not associated with the achievement of DAS28 remission (adjusted odds ratio (95%CI): 0.7 (0.5-1.1)) or EULAR response (aOR (95%CI): 0.8 (0.7-1.0)) at month 6.

**Discussion:** Recruitment to the BSRBR-RA of non-white patients was exceptionally low compared to expected population distribution – the reasons for this are not immediately evident. Among those recruited, there were no significant differences observed in initial treatment response although non-white patients were younger, more likely to be female, had shorter disease duration and less likely to be smokers. Further evaluation into both ways to increase representativeness in our national RA treatment register and influence of ethnic differences on longer term outcomes with biologic therapies is warranted.

**Conclusion:** Recruitment to the BSRBR-RA of non-white patients was exceptionally low compared to expected population distribution – the reasons for this are not immediately evident. Among those recruited, there were no significant differences observed in initial treatment response although non-white patients were younger, more likely to be female, had shorter disease duration and less likely to be smokers. Further evaluation into both ways to increase representativeness in our national RA treatment register and influence of ethnic differences on longer term outcomes with biologic therapies is warranted.

**References:**

this finding. Immunogenicity results were similar in both treatment groups. Treatment-emergent adverse events (TEAEs) were usually mild or moderate and occurred at similar frequency with both drugs. There were no discernable patterns in terms of the nature, frequency or other characteristics of serious or treatment-related TEAEs to suggest a difference between drugs.

Conclusion: Equivalent efficacy, immunogenicity and safety at W24 of MSB11456 and EU-approved tocilizumab was demonstrated in patients with moderate to severe RA. Pharmacological and clinical similarity of these drugs was supported, therefore MSB11456 can be considered as biosimilar to EU-approved tocilizumab.

**Table 1. Comparison of hemoglobin and disease activity between initial and 1 year follow up in anemia patients**

**Background:** Rheumatoid arthritis is a systemic disease with various extra-articular symptoms. Anemia is common comorbidity of RA.

**Objectives:** The purpose of this study is to compare the effect of tocilizumab and TNF-α inhibitors on hemoglobin changes and disease activity changes in RA patients. This study aims to determine whether tocilizumab is more effective in controlling hemoglobin elevation and disease activity in patients with anemia.

**Methods:** The data in this study derived from the Korean College of Rheumatology (KOCRO) registry. Of the patients registered in KOCRO registry, patients using tocilizumab and TNF-α inhibitors were enrolled in this study. To exclude the effects of previously used biologic DMARDs, patients who started the first biologic DMARDs and have been using one biologic DMARD for more than 1 year were included in this study. Anemia was defined as Hb levels <12.0/g/dl in women and <13.0/g/dl in men according to the World Health Organization (WHO) criteria at index date.

**Results:** Among rheumatoid arthritis patients with anemia, there were 126 patients in the tocilizumab group and 248 patients in the TNF-α inhibitor group. Initial and follow-up data collected after 1 year of biologic use were analyzed. After initiation of treatment, Hb and Hct were significantly elevated in tocilizumab group. Mean increases in Hb and Hct were 1.56 and 3.53 in tocilizumab group, 1.02 and 2.64 in TNF-α inhibitor group. DSAS2-ESR and RAPID3 decreased significantly in tocilizumab group after using biologics. In tocilizumab group, DSAS2-ESR decreased by 3.35 and RAPID3 decreased by 8.31. The changes in SJC, PGA, PhGA, SDAI and CDAI were not different between the two groups.

**Conclusion:** In RA patients with anemia, although tocilizumab was more effective than TNF inhibitors in increasing Hb, there was no difference between the two drugs in controlling disease activity. During the course of this research, the results of the DSAS2-ESR and other outcome measures did not match. In patients treated tocilizumab, assessment of disease activity using the TNF-α inhibitor group as a control. Tocilizumab was more effective than TNF-α inhibitors in increasing Hb.

Turesson1,2, Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden, 3Skåne University Hospital, Department of Rheumatology, Lund, Sweden

**Background:** Factors related to the use of biologic disease modifying anti-rheumatic drugs (bDMARDs) in rheumatoid arthritis (RA) have varied in prior studies. Objectives: This study aims to identify characteristics at the time of diagnosis that may be related to the initiation of treatment with bDMARD within the first three years following diagnosis.

**Methods:** All patients with early RA diagnosed at the outpatient clinics of Skåne University Hospital in 2012-2016 were identified using the local patient administrative system. Diagnoses were validated in a structured review of the medical records. Patients with a confirmed RA diagnosis, aged ≥18 years with symptom duration <12 months at diagnosis, and who fulfilled the 2010 ACR/EULAR classification criteria for RA were included.

**Results:** A total of 1393 patients met the inclusion criteria. In the bDMARD group, 80.8% of patients achieved ACR20 at W24, compared to 84.8% in the TNF-α inhibitor group. ACR50 was achieved in 60.6% of patients in the bDMARD group and 62.3% in the TNF-α inhibitor group. ACR70 was achieved in 39.1% in the bDMARD group and 38.4% in the TNF-α inhibitor group. ACR90 was achieved in 60.6% in both groups. DAS-ESR remission or LDA at W24 was achieved in 63.1% and 63.5% of patients in the bDMARD and TNF-α inhibitor groups, respectively. DAS28-CRP change from baseline at W24, LSM (SE)a 0.01 (-0.21, 0.19) aANCOVA (analysis of covariance) model with fixed effects for treatment and previous biologic DMARDs.

**Acknowledgements:** NIL.

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.4237
Conclusion: Lower age and higher tender joint count at diagnosis were associated with an increased likelihood of starting bDMARD therapy within the first 3 years in early RA. The impact of age on the subsequent start of bDMARD therapy was not explained by other patient factors.

AB0415 CAN WE PREDICT THE RISK FACTORS FOR SWITCHING IN THE FIRST YEAR OF THERAPY WITH BDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS?

Keywords: bDMARD, Rheumatoid arthritis, Real-world evidence

A. Martin1,2, D. Santos Oliveira1,2,3, R. Nicolau1,4, T. Martins-Rocha1,2, A. Bernardo1, S. Pimenta1,2, M. Bernardes1,2, L. Costa,1 São João University Hospital Center, Rheumatology, Porto, Portugal; 2 Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal; 3 Faculdade de Medicina da Universidade do Porto - FMUP CINTESIS, Porto, Portugal; 4 Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal

Background: Biological Disease-modifying Antirheumatic Drugs (bDMARD) have improved the clinical course and quality of life of patients with rheumatoid arthritis (RA). However, some patients failed to respond or have an insufficient response to bDMARD, early in the course of the treatment, and the reasons why this happens aren't fully understood.

Objectives: To determine the percentage of RA patients who failed to respond to bDMARD and need to switch in the first year of treatment, describe their characteristics, and identify specific baseline features as possible predictors of bDMARD early failure.

Methods: An observational monocentric retrospective cohort study was conducted with RA patients (according to 2010 ACR/EULAR criteria), registered in the national database (Reuma.pt) that started their first bDMARD between June 2000 and December 2021 and had a minimum follow-up of 12 months. Demographic data, disease characteristics, laboratory parameters and treatment at baseline were collected. Disease activity scores (CDAI, SDAI and DAS-28-CRP), functional scores (HAQ) and clinical response to treatment (according to EULAR and ACR response criteria) were collected at 3, 6 and 12 months after the start of bDMARD. The proportion of patients who failed to respond (according to treat-to-target strategies) and who switched to another bDMARD was calculated. Patients who discontinued treatment in the first year due to adverse events were excluded. Chi-square test, t-test and Mann-Whitney U test were conducted (categorical, normally and not normally distributed continuous variables, respectively). Also, a multivariate logistic regression analysis was performed. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated. A p-value <0.05 was considered statistically significant.

Results: 437 (364 females, 83.3%) patients with RA were included. The mean age was 52.4 ± 11.4 years and the disease duration was 11.6 ± 8.6 years. The majority of these patients started an anti-TNF-α agent as their first bDMARD (n=315, 72.1%). The remaining patients started rituximab (n=66, 15.1%), tocilizumab (n=51, 11.7%) and abatacept (n=5, 1.1%). For 398 patients (91.3%) started their first bDMARD (n=315, 72.1%). The remaining patients started a regional healthcare register, and data on level of formal education, country outside Europe were statistically significant baseline predictors of bDMARD start in patients with RA within 3 years after diagnosis.

Table 1: Predictors at RA diagnosis for a first bDMARD/bDMARD in patients with early RA within 3 years after diagnosis. Logistic regression.

DOI: 10.1136/annrheumdis-2023-eular.4638
Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept (ABA) has demonstrated efficacy in RA-ILD [1-2]. Clinical trials have shown equivalence in subcutaneous (SC) and intravenous (IV) administration of ABA for articular manifestations [3]. However, it has not been studied in RA-ILD.

Objectives: to compare the effectiveness of ABA in RA-ILD patients according to the route of administration (IV-ABA vs SC-ABA).

Methods: National multicenter study of RA-ILD patients treated with ABA. They were divided into 2 groups according to the route of administration: a) IV, and b) SC. We analyzed from baseline the following outcomes in both groups: a) forced vital capacity (FVC), b) diffusing capacity of the lungs for carbon monoxide (DLCO), c) chest high resolution computed tomography (HRCT), d) dyspnea (assessed with the modified Medical Research Council scale), e) arthritis activity (assessed with DAS28-ESR or described in clinical records), and f) sparing corticosteroids effect.

Results: We studied a total of 392 [SC-ABA/IV-ABA: 288/91 (available data)] patients. Baseline demographic and clinical characteristics are shown in Table 1. Patients were followed-up for a median [IQR] of 24 [10-48] months. FVC and DLCO remain stable during the first 24 months in both SC-ABA and IV-ABA [Figure 1]. Dyspnea stabilized or improved in 85% of patients (89% of IV-ABA; 83% of SC-ABA). ABA was withdrawn in 80 patients: 60 (39%) in SC-ABA group and 20 (22%) in IV-ABA group. ILD worsening and articular inefficacy were the most common reasons of ABA discontinuation.

Conclusion: In RA-ILD, ABA seems equally effective and safe regardless of the route of administration IV or SC.

ELEVATED ANA AS A PREDICTOR OF THERAPEUTIC FAILURE TO BIOLOGICAL ANTI-TNF AGENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: bDMARD, Autoantibodies, Rheumatoid arthritis

Introduction: Autoantibodies are present in 10% of patients with rheumatoid arthritis (RA). Their presence is considered a marker of disease activity and adverse outcomes. Anti-nuclear antibody (ANA) was previously reported to be more frequent in therapeutic failures to biological disease-modifying anti-rheumatic drugs (bDMARD). However, the role of ANA as a predictor of failure is not clear, mainly due to small sample sizes and retrospective analyses. Therefore, this study aimed to evaluate if ANA is a predictor of therapeutic failure in bDMARD therapeutic failures in RA patients treated with infliximab (IFX) or etanercept (ETN).

Methods: A single-centre observational cohort study was conducted. RA patients treated with IFX or ETN were included. All patients fulfilled the American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for RA and received at least 3 months of treatment with IFX or ETN. ANA was measured at baseline before starting treatment and before treatment withdrawal in patients withdrawn due to therapeutic failure. The presence of ANA was measured using an ELISA test (HumaLab, Spain) and classified as positive when the titer was >1/80. ANA positivity was compared with therapeutic failure to IFX or ETN. A logistic regression analysis was performed using ANA positivity and therapeutic failure to IFX or ETN as dependent variables.

Results: A total of 309 RA patients were included, of whom 135 were ANA-positive and 174 were ANA-negative. Thirty-two therapeutic failures were counted in the elevated ANA group and 16 in the negative ANA group. A higher percentage of failures was observed in ANA-positive patients. A higher percentage of therapeutic failure was observed in patients with a higher ANA level. No relationship was found between the ANA pattern and the presence of failure. The presence of an elevated ANA multiplies by 2.4 the risk of presenting therapeutic failure to IFX or ETN in patients with RA.

Conclusion: ANA is a predictor of therapeutic failure to IFX or ETN in patients with RA.

OUTCOMES FROM COMPACT STUDY

BIOSIMILAR IN A REAL-WORLD STUDY: FINAL

PATIENTS RECEIVING GP2015 (ETANERCEPT
SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS
FUNCTIONAL OUTCOMES OF THE SELF-INJECTION ASSESSMENT
QUESTIONNAIRE IN RHEUMATOID ARTHRITIS, AXIAL
Spondyloarthritis, Patient reported outcomes

1University Hospital, Wuerzburg, Rheumatology/Clinical Immunology, Department of Internal Medicine II, Wuerzburg, Germany; 2Robert Jones and Agnes Hunt Orthopedic Hospital NHS Foundation Trust, Rheumatology, Oswestry, United Kingdom; 3New Cross and Cannock Chase Hospitals, University of Wolverhampton, Department of Rheumatology, Wolverhampton, United Kingdom; 4Sandoz Hexal AG, Rheumatology, Holzkirchen, Germany; 5Hospital Neuwittelsbach, Center for Rheumatology and Gastroenterology, Munich, Germany

Background: COMPACT is an international, non-interventional cohort study evaluating the effectiveness, safety and quality of life in patients (pts) with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) or psoriatic arthritis (PsA) treated with GP2015, an approved etanercept (ETN) biosimilar, in real-world conditions.

Objectives: To assess patient usage behaviour and feelings of self-administered injection with auto-injector device using the Self-Injection Assessment Questionnaire (SIAQ) in pts with RA, axSpA and PsA receiving GP2015.

Methods: Pts aged ≥18 years from Germany and UK who initiated treatment with GP2015 were enrolled in this study. The SIAQ, a questionnaire developed to assess overall pt experience with subcutaneous self-injection, was used to assess the perceived confidence on self-injection, potential barriers as well as satisfaction with self-injection via device before the first self-injection (PRE module) and after dosing (POST module).[1] In COMPACT study, the POST module was assessed which comprised of 21 items grouped into 6 hypothetical domains: “feelings about injection”, “self-image”, “self-confidence”, “skin reaction” (injection-site reactions), “ease of use of self-injection device”, and “patient satisfaction”. Domain scores were rated on a 10-point scale, i.e., 0 (worst experience) to 10 (best experience).

Data was analysed from the first collected SIAQ responses during the study and was summarised using descriptive statistics. The final SIAQ scores by domain in pts with RA, PsA and axSpA and by study group in pts with RA are reported here.

Results: A total of 458 pts from Germany (RA: 285, PsA: 79, axSpA: 94) and 273 pts from UK (RA: 174, PsA: 54, axSpA: 45) responded to the questionnaire. Overall, each domain showed high SIAQ scores which were consistent across all indications. The “self-image” and the “skin reaction” domains were scored highest (Figure 1). RA pts who had prior experience with biologic or non-ETN targeted medication (Group A + B) had mean scores mostly higher than or equal to those of biologic-naïve pts (Group C + D). RA pts who switched from iETN (reference ETN or biosimilar ETN other than GP2015) to GP2015 treatment (Group A) reported high SIAQ scores in all domains, which can be explained by good patient experience with the device (Table 1).

Conclusion: The SIAQ showed high acceptance of the auto-injector device in both countries where the survey was performed across all indications. Most RA pts were satisfied with auto-injector device usability after switching from iETN to GP2015, demonstrating no major concerns after switching.

MATERIAL AND NEONATAL ANTIBODY LEVELS UPON PERTUSSIS VACCINATION IN PREGNANT WOMEN ON IMMUNE-MODULATING THERAPY FOR RHEUMATIC DISEASE

Keywords: Vaccination/Immunization, bDMARD, Pregnancy and reproduction

N. Ghalandari1, 2, M. Immink3, E. Röder1, P. Bruining-Verhagen7, H. T. Smeele1, H. J. M. J. Crijns4, N. Van der Maas5, M. Bekker6, L. Sanders7, R. Dolhain1, 1Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands; 2Dutch Rheumatology Evaluation Board (CBG-MEB), GIMB, Utrecht, Netherlands; 3National Institute for Public Health and the Environment (RIVM), Center for Infectious Disease Control, Bilthoven, Netherlands; 4Dutch Medicine Evaluation Board (CBG-MEB), Wetenschap, Utrecht, Netherlands

Background: While protection against pertussis following maternal tetanus-diphtheria-and-acellular-pertussis (Tdap) vaccination has been demonstrated in term-born infants from healthy mothers[1], no evidence is available on Tdap vaccination in combination with immune-modulating therapy during pregnancy.

Objectives: In this pilot-study, we explored whether treatment with Tumor Necrosis Factor alpha inhibitors (TNFi) in pregnant women with rheumatic disease interferes with Tdap vaccine response and/or affects maternal IgG antibody concentrations against the relevant antigens in the newborns.

Methods: Patients included by a rheumatologist during pregnancy received a Tdap vaccination in their late-second or early-third trimester. Blood samples were drawn during the first trimester, three months after delivery and from the umbilical cord. IgG antibody levels against Tdap-included antigens were measured using a bead-based multiplex immunoassay. Findings on patients exposed to TNFi were compared with those from TNFi-unexposed patients and with data from a historical comparator study among healthy Tdap vaccinated mother-infant-pairs (n=53). [2]

Results: 66 patients (46 exposed and 20 unexposed to TNFi) were enrolled. No differences in IgG antibody levels against Tdap-included antigens were observed between TNFi-exposed and unexposed patients before and after Tdap vaccination (Figure 1). In cord sera however, antibody levels against pertussis toxoid were significantly lower after TNFi-treatment (35.94±1.99 IU/mL, 95% CI: 20.68-62.45) compared with no TNFi (94.61±1.99 IU/mL, 95% CI: 48.89-183.07) and with cord blood from the comparison cohort of healthy women-infant-pairs (125.12±1.99 IU/mL, 95% CI: 90.75-172.50). We observed similar differences for filamentous hemagglutinin, pertactin, tetanus toxoid, and diphteria toxoid.

Conclusion: These preliminary data indicate no reduced IgG antibody response upon maternal Tdap vaccination in pregnant women following immune-modulating treatment, although our findings suggest that TNFi during pregnancy induce lower maternal antibody levels against Tdap-included antigens in newborns.

1Vrije Universiteit Brussel (VUB), Biostatistics and Medical Informatics Research Group, Department of Public Health, Brussels, Belgium; 2Université Catholique de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et systémiques, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; 3Cliniques Universitaires Saint-Luc, Department of Rheumatology, Brussels, Belgium; 4Reuma-Instituut Hasselt, Department of Rheumatology, Hasselt, Belgium; 5University Hospitals Leuven, Division of Rheumatology, Leuven, Belgium; 6KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium

Background: The Janus Kinase (JAK) inhibitor Upadacitinib (UPA) has shown efficacy in rheumatoid arthritis (RA) in trials, yet real-world evidence is lacking.

Objectives: We aimed to assess short-term effectiveness of UPA for standard of care for RA.

Methods: Data from participants included in the electronic platform “Tool for Administrative Reimbursement Drug Information Sharing” (TARDIS) are analysed. TARDIS collects data from all Belgian RA patients on advanced therapy during submissions of reimbursement requests for drug initiation or prolongation. Patients initiating UPA between 01/11/2020-31/12/2021, ≥18 years and DAS28≥3.7 were included. Effectiveness was based on drug retention, proportion of patients achieving remission (DAS28 <2.6), low disease activity (LDA, DAS-28 ≥3.2), HAQ-Di≥0.5 (HAQ≥0.5) as well as a clinical meaningful HAQ-Di-decrease (MCID, HAQ) since baseline of 0.22 at the first follow-up month at 3 months. Sensitivity analyses by 1st, 2nd or 3rd-line advanced therapy were performed.

Results: From 13 175 patients in TARDIS in the relevant time period, 996 patients on UPA could be included. Table 1 details this population. Of 871 patients with drug information at next follow-up, 783 (90%) continued UPA, and 42 (5%), 22 (3%), and 18 (2%) changed to a TNFi, non-TNFi and other JAKI respectively. In other effectiveness analyses, 705/996 (71%) patients were included. Remission and LDA were reached in 60% (421/705) and 74% (521/705) of patients respectively. HAQ25, HAQ50 and MCID HAQ were reached in 11% (78/705), 26% (183/705) and 67% (475/705) of patients. Effectiveness slightly decreased with increasing line of therapy (Figure 1).

Legend: Numbers given are mean ± SD or number, proportion. TNFi = tumour necrosis factor inhibitor, JAKI = Janus Kinase inhibitor, HAQ = health assessment questionnaire, PGA= Patient Global assessment; CRP= C-reactive protein; ESR= erythrocyte sedimentation rate; TJC= tender joint count; SJC= swollen joint Count; DAS28 = disease activity score based on the 28 joints. *Missing HAQ(0-3) scores were imputed by regression using age and HAQ(0-60) scores. **for 6 patients this was undefined.

Scientific Abstracts
Conclusion: Most patients continued UPA treatment. UPA improved clinical outcomes after 3 months in patients with moderately to severely active RA in a real-world setting, even in 3rd line of advanced therapy.

Background: Sarilumab was launched the second interleukin 6 receptor inhibitor (IL-6Ri) as a treatment for patients with rheumatoid arthritis (RA) in Japan. Tocilizumab, that was known as first IL-6Ri, showed excellent therapeutic effect without methotrexate (MTX) for RA. However, it was unknown that the effect on concomitant use of MTX in RA patients treated with sarilumab.

Objectives: We evaluated the effect on concomitant use of MTX in RA patients treated with sarilumab.

Methods: This study used a multicenter database included 673 RA patients treated with b/tsDMARDs. We finally analyzed 72 RA patients treated with sarilumab. Thirty-three RA patients were combined with MTX (MTX group) and 39 RA patients were not combined with MTX (non-MTX group). The continuation rate and efficacy at 52 weeks after sarilumab treatment in each group was evaluated.

Results: Non-MTX group was older, longer disease duration, and lower eGFR compared with baseline in RA patients treated with sarilumab.

Conclusion: Sarilumab improved disease activity in patients with RA regardless of concomitant use of MTX.

IMPROVEMENT OF ULTRASONOGRAPHIC FINDINGS IN JAK INHIBITOR TREATED JAPANESE RHEUMATOID ARTHRITIS PATIENTS COMPARISON WITH TNF INHIBITOR THERAPY

Keywords: Rheumatoid arthritis, Ultrasound, bDMARD

1Yodogawa Christian Hospital, Orthopaedic Surgery and Rheumatology, Osaka, Japan; 2Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan

Background: JAK inhibitor (JAKi) and TNF inhibitor (TNFi) are the important therapeutic agents for the treatment of rheumatoid arthritis (RA). However, there is still few studies of improvement of ultrasonographic findings in RA treatments compared with JAKi and TNFi.

Objectives: To evaluate the improvement of ultrasonographic findings in JAKi treated RA patients comparison with TNFi.
Methods: Participants comprised 40 and 43 Japanese RA patients who had recently received each JAKI (BAR26, PEF9, UPAS) and TNFi (CZP30, ADAS, ETN4, GLM4). All patients with a diagnosis of RA according to the 2010 ACR/ EULAR criteria. Patients underwent clinical and laboratory assessments every 4 weeks from baseline to 24 weeks, and US assessments at baseline, 4, 12 and 24 weeks. Gray scale (GS) and power doppler (PD) signals were scored using a semi-quantitative scale from 0 to 3 at 26 (0-78) synovial sites (22 joints) in the following joints: bilateral first to fifth metacarpophalangeal (MCP) joints (dorsal recess), first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) (dorsal recess) joints; and the wrists (dorsal radial, median and ulnar). We evaluated the improvement of GS and PD score from baseline to week 24. Results: In the patients receiving JAKi (n=40) and TNFi (n=43), the mean age was 56.0 vs 54.0 years old (p=0.514), disease duration was 73 vs 59 years (p=0.343), the rate of MTX use was 70% vs 86% (p=0.076), the mean MTX dose was 10.0 vs 9.9 mg/wk (p=0.888), the rate of ACPO positive was 90% vs 79% (p=0.171), the rate of b/ts DMARDs naïve patients was 65% vs 91% (p=0.005), DAS28-ESR was 5.03 vs 4.69 (p=0.102), CDAI was 24.5 vs 19.2 (p=0.038), GS score was 22.1 vs 18.3 (p=0.535) and PD score was 15.1 vs 11.1 (p=0.625). The degree of improvement respective changes in GS and PD score from baseline to 4, 12 and 24 weeks were as follows: GS: -5.7 vs -4.7 (p=0.762) and PD: -6.6 vs -3.1 (p=0.489) after 4 weeks, GS: -9.3 vs -6.7 (p=0.975) and PD: -8.7 vs -4.6 (p=0.340) after 12 weeks, GS: -11.5 vs -9.7 (p=0.732) and PD: -9.5 vs -7.1 (p=0.802) after 24 weeks between JAKi and TNFi (Figure 1, 2). Next, the improvement rate of respective changes in GS and PD score from 4, 12 and 24 weeks were as follows: GS: -16.2% vs -20.7% (p=0.463) and PD: -29.7% vs -30.8% (p=0.144) after 4 weeks, GS: -30.2% vs -27.9% (p=0.884) and PD: -34.0% vs -32.0% (p=0.830) after 12 weeks, GS: -42.4% vs -38.4% (p=0.712) and PD: -41.6% vs -54.0% (p=0.865) after 24 weeks between JAKi and TNFi. Next, we evaluated the improvement of ultrasonographic findings between b/ts DMARDs naïve and switch, with and without MTX in the JAKi-treated patients. The degree of improvement respective changes in GS and PD score from baseline to 24 weeks were as follows: GS: -42.4% vs -39.4% (p=0.712) and PD: -41.6% vs -54.0% (p=0.865) after 4 weeks, GS: -56.0 vs 54.0 years old (p=0.514), disease duration was 73 vs 59 years (p=0.343), the rate of MTX use was 70% vs 86% (p=0.076), the mean MTX dose was 10.0 vs 9.9 mg/wk (p=0.888), the rate of ACPO positive was 90% vs 79% (p=0.171), the rate of b/ts DMARDs naïve patients was 65% vs 91% (p=0.005), DAS28-ESR was 5.03 vs 4.69 (p=0.102), CDAI was 24.5 vs 19.2 (p=0.038), GS score was 22.1 vs 18.3 (p=0.535) and PD score was 15.1 vs 11.1 (p=0.625). The degree of improvement respective changes in GS and PD score from baseline to 4, 12 and 24 weeks were as follows: GS: -5.7 vs -4.7 (p=0.762) and PD: -6.6 vs -3.1 (p=0.489) after 4 weeks, GS: -9.3 vs -6.7 (p=0.975) and PD: -8.7 vs -4.6 (p=0.340) after 12 weeks, GS: -11.5 vs -9.7 (p=0.732) and PD: -9.5 vs -7.1 (p=0.802) after 24 weeks between JAKi and TNFi (Figure 1, 2). Next, the improvement rate of respective changes in GS and PD score from 4, 12 and 24 weeks were as follows: GS: -16.2% vs -20.7% (p=0.463) and PD: -29.7% vs -30.8% (p=0.144) after 4 weeks, GS: -30.2% vs -27.9% (p=0.884) and PD: -34.0% vs -32.0% (p=0.830) after 12 weeks, GS: -42.4% vs -38.4% (p=0.712) and PD: -41.6% vs -54.0% (p=0.865) after 24 weeks between JAKi and TNFi. Next, we evaluated the improvement of ultrasonographic findings between b/ts DMARDs naïve and switch, with and without MTX in the JAKi-treated patients. The degree of improvement respective changes in GS and PD score from baseline to 24 weeks were as follows: GS: -13.8 vs -7.1 (p=0.313) and PD: -10.8 vs -6.9 (p=0.334) between b/ts DMARDs naïve and switch patients, GS: -11.7 vs -11.0 (p=0.988) and PD: -9.2 vs -10.0 (p=0.656) between with and without MTX patients. Conclusion: The present study provides evidence supporting the improvement in ultrasonographic findings in RA was similar for both JAKi and TNFi. Also in the JAKi-treated patients, similar improvement in ultrasonographic findings was observed regardless of whether the patients were naïve or switch, with and without MTX.

AB0424 IMPACT OF BASELINE RHEUMATOID FACTOR TITERS AND ANTI-TNF MOLECULAR STRUCTURE ON THE RETENTION RATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: bDMARD, Real-world evidence, Rheumatoid arthritis
J. Calvo Gutierrez1,2,3, R. Ortega Castro1,2,3, M. C. Ábalos-Aguilera1,2, F. J. Cepas1,3, D. Ruiz1,2, M. Rojas-Giménez1,2,3, M. L. Ladehesa Pineda1,2,3, A. Escudero Contreras1,2,3, C. López-Medina1,2,3, Reina Sofia University Hospital, Rheumatology, Cordoba, Spain; 2Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), GC05 group, Cordoba, Spain; 3University of Cordoba, Medical Surgical Sciences, Cordoba, Spain

Background: Rheumatoid Factor (RF) is an antibody against the Fc portion of IgG forming immune complexes that contribute to the Rheumatoid Arthritis (RA) process. RF also binds the Fc region of many monoclonal antibodies (mAB), leading to lower drug levels and potential early withdrawal. Conversely, the absence of FC portion in Cetolizumab Pegol (PEG) may lead to a higher retention rate in comparison with other drugs in RA patients with higher RF titers.

Objectives: a) To evaluate the retention rate to any anti-TNF according to the baseline RF titers in patients with RA and b) to compare the retention rate to PEG vs. other anti-TNF in patients with high RF titers.

Methods: Longitudinal, retrospective and unicentre study including patients with a diagnosis of RA and treated with any anti-TNF (mAB (Adalimumab, Golimumab and Infliximab), fusion protein (Etanercept) or PEG (Certolizumab Pegol)) between 2007 and 2022. RF levels before anti-TNF initiation as well as the dates of both initiation and treatment withdrawal were collected. Log-rank test and Kaplan-Meier curves were conducted to evaluate the retention rate to each molecular structure in patients with high RF titers (≥110 IU/ml).

Results: A total of 356 patients with RA treated with anti-TNF and with available titers of RF were included. Mean age was 52.0 (11.2) years and 80.1% were female. A total of 254 (71.3%) were RF positive. Retention rate to any anti-TNF was similar in RF positive vs. negative, and between RF <110 IU/ml vs RF ≥110 IU/ml (considering the median titre of RF (110 IU/ml) as the cut-off). In addition, the retention rate to each molecular structure were compared in patients with high RF titres (≥110 IU/ml).

Conclusion: Higher RF titers before anti-TNF initiation were associated with a shorter retention rate in patients with RA. However, no differences were found between molecular structures, although patients treated with PEG seem to have a longer retention rate. These results confirm the possible effect of the RF in binding the Fc portion of the drug.

Figure 1. Retention rate to any anti-TNF according to the RF titers (A) and retention rate of each molecular structure in patients with high titers levels (≥110 UI/ml) (B).
REAL-WORLD EFFECTIVENESS OF FILGOTINIB IN BELGIAN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Real-world evidence, Rheumatoid arthritis, Targeted synthetic drugs

1Vrije Universiteit Brussel, Biostatistics and Medical Informatics Research Group, Department of Public Health, Brussels, Belgium; 2Université catholique de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; 3Cliniques Universitaires Saint-Luc, Department of Rheumatology, Brussels, Belgium; 4Reuma-Institut Hasselt, Department of Rheumatology, Hasselt, Belgium; 5University Hospital Leuven, Department of Rheumatology, Leuven, Belgium; 6KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium

Background: Filgotinib (FIL), a preferential Janus Kinase (JAK) inhibitor targeting the JAK1 enzyme, has demonstrated efficacy in rheumatoid arthritis (RA) in clinical trials. FIL is reimbursed in Belgium since August 2021 for adult patients with moderate to severe RA with a DAS28 score >3.7 and inadequate response or intolerance to 2 conventional DMARDS including Methotrexate. Today, limited data exist on the real-world effectiveness of FIL in RA.

Objectives: Our aim was to examine the short-term effectiveness of FIL in a heterogeneous RA population.

Methods: Patients were included from the electronic platform “Tool for Administrative Reimbursement Drug Information Sharing” (TARDIS). Data from all Belgian RA patients on biologic and targeted therapy are collected in this platform during the submission of a request for initiation or prolongation of reimbursement of these drugs. The study population included adult patients ≥18 years starting FIL between August 2021 and November 2022. Baseline characteristics (demographics, clinical characteristics, treatment history) of Belgian RA patients treated with FIL were recorded. Effectiveness of FIL was determined by the patient proportion achieving remission (DAS28 <2.6), low disease activity (DAS28 ≤3.2), HAQ-DI≤0.25 (HAQ25) and minimum HAQ-DI-decrease (MCID_HAQ) since baseline of 0.22, at the first follow-up visit, structuredly planned in TARDIS after 3 months. Sensitivity analyses were performed in patients starting FIL as 1st, 2nd or 3rd+line advanced therapy.

Results: In total, 405 RA patients on FIL were included, representing all newly initiated FIL patients. Table 1 gives detailed information on demographic, clinical characteristics and treatment history. Of the 228 patients with information on treatment at the next follow-up moment, 210 (92%) continued FIL, and 6 (3%), 9 (4%) and 3 (1%) changed to a TNFi, non-TNFi and JAKi respectively. In total, 193/405 (48%) patients could be included in the effectiveness analysis. Remission and low disease activity were reached in 61% (117/193) and 81% (156/193) of patients respectively. Baseline mean ±SD DAS28 was 4.9 ±0.8. The DAS28 change from baseline to follow-up was 2.5 ±1.2, resulting in a mean ±SD DAS28 of 2.4 ±1.1 at first follow-up. HAQ25 and MCID_HAQ were reached in 21% (41/193) and 70% (136/193) of patients. FIL efficacy slightly decreased with increasing line of therapy (Figure 1).

AS patients combined at 18 months after initiating MSB11022 biologic therapy. This real-world evidence analysis suggests that patients switching to MSB11022, adalimumab biosimilar, will more likely maintain on therapy compared to patients initiating MSB11022 therapy. In both cases, inflammatory arthritis patients had high adherence to MSB11022 therapy. **REFERENCES:**

crude incidence of serious AEs was 9.2/100PY for certolizumab and 6.6/100 PY for golimumab. The incidence of any (total) AEs was 37.1/100 PY for certolizumab and 59.8/100 PY for golimumab. The risk of serious and total AEs (primary outcomes) did not differ significantly between the study groups (Figure 1). There was also no significant difference in the risk of infections and other secondary outcomes. Persistence of treatment and reasons for interruption of therapy course also were not significantly different between certolizumab and golimumab (Table 1).

Table 1. Results of univariate and multivariate frailty Cox proportional hazards models estimating the hazard of treatment interruption with golimumab versus certolizumab users (reference). Results are hazard ratios, 95% CIs, and P values.

**EIGHT-MONTH FOLLOW-UP OF THE NON-MEDICAL SWITCH FROM ETANERCEPT BIO-ORIGINATOR TO GP-2015 OR SB4 ETANERCEPT BIOSIMILARS IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHRITIDES: A MONOCENTRIC OBSERVATIONAL STUDY**

**Keywords:** bDMARD, Rheumatoid arthritis, Spondyloarthritides

**Background:** After the expiration of bio-originators’ licenses, the development of less expensive biosimilars has prompted the switch to these drugs. Data on the switch from etanercept (ETA) bio-origginators to biosimilars are reassuring [1-2] but still limited.

**Objectives:** This observational study evaluated the real-life effectiveness of a non-medical switch from ETA bio-originator to GP-2015 or SB4 biosimilars in our cohort of patients with inflammatory chronic arthritis.

**Methods:** We enrolled consecutive adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) classified according to standard criteria switched from ETA bio-originator to GP-2015 or SB4 biosimilars for administrative/economic reasons. The date of the switch was the baseline (T0). Patients were reassessed after 4 (T4) and 8 months (T8). At T0, T4, and T8, data on demographic and clinical/laboratory features were registered. Patient-reported outcomes (PROs), such as visual analog scale (VAS 0-10) for pain and global assessment (PGA) and functional status by Health Assessment Questionnaire (HAQ) were used, together with disease-specific scores (DAS28-CRP for RA, DAPSA for PsA, ASDAS-CRP and BASDAI for AS). We assessed the same data at the time of early discontinuation for inefficacy (loss or lack of efficacy – LoE or LaE) or adverse events (AEs).

**Results:** One hundred and twelve patients switched from ETA bio-originator to GP-2015 [45 RA, F:M=33:12, median age 67 years (IQR 24), median disease duration 214 months (IQR 180), median exposure to bio-originator 126 months (IQR 97), 48 PsA, F:M=18:30, median age 59 years (IQR 18), median disease duration 168 months (IQR 120), median exposure to bio-originator 120 months (IQR 96); 19 AS, F:M=7:12, median age 55 years (IQR 16), median disease duration 162 months (IQR 245), median exposure to bio-originator 132 months (IQR 89)] No differences were found in the clinical and laboratory parameters compared to T0 in RA and PsA, while AS patients showed an improvement of BASDAI at T8 compared to T4 (p=0.0273). Interestingly, at T8 RA patients experienced a worsening in the HAQ (p=0.0313) with respect to T0 (figure 1A) and PsA patients had a worsening of VAS pain compared to T4 (p=0.0371) (figure 1B). Four (8.8%) RA patients discontinued GP-2015 at T4 due to AEs (1 for recurrent infection of upper airways, 1 for injection site reaction, 1 for skin cancer, 1 for breast cancer). One (2%) PsA patient discontinued GP-2015 at T4 due to AE (oral ulcers). Twenty-eight patients switched from ETA bio-originator to SB4 [14 RA, F:M=13:1, median age 63.5 years (IQR 33), median disease duration 144 months (IQR 206), median exposure to bio-originator 84 months (IQR 96)]; 11 PsA, F:M=6:5, median age 54 years (IQR 12), median disease duration 205 months (IQR 198), median exposure to bio-originator 177 months (IQR 164); 3 AS, F:M=3:0, median age 56 years, median disease duration 210 months, median exposure to bio-originator 120 months]. An improvement of DAPSA at T4 compared to T0 was observed in PsA patients (p=0.0469). At T8, no differences were found compared to T0. One (9%) PsA patient discontinued GP-2015 at T4 due to AE (infections of upper airways, 1 for injection site reaction, 1 for skin cancer, 1 for breast cancer). One (2%) PsA patient discontinued GP-2015 at T4 due to AE (oral ulcers).

**Conclusion:** Our data indicate that the switch to GP-2015 or SB4 ETA biosimilars from ETA bio-originator does not bear clinical and laboratory differences in patients with chronic arthropathies. The worse outcome in PROs, which we also observed in the adalimumab bio-originator to biosimilar switch (3), does not reflect a worsening of disease activity indexes and could indicate a possible nocebo response.

MEDICATION ADHERENCE IN PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS TREATED WITH BIOLOGIC OR TARGET-ETIOLOGIC DMARDs: EVALUATION OF PREDICTIVE FACTORS IN AN ITALIAN MONOCENTRIC COHORT

Keywords: Quality of care, Patient information and education, Rheumatoid arthritis

L. Moschetti1, C. Bazzani2, F. Delvecchio3, F. Franceschini1.
1Rheumatology and Clinical Immunology Unit, ASST Spedali Civili di Brescia and University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy

Background: In rheumatoid arthritis (RA), medication non-adherence can be considered one of the primary determinants of therapeutic failure.

Objectives: To evaluate 1) the prevalence of treatment adherence in RA patients (pts) treated with biologic or target-etiologic DMARDs followed in a tertiary rheumatologic center and 2) the factors associated to a better treatment adherence.

Methods: An observational retrospective single center study was conducted enrolling adult RA pts treated with b/ts-DMARDs, in monotherapy or in combination with methotrexate. Demographic data, clinical characteristics and outcomes measures were collected. To evaluate the comorbidities the Rheumatic Disease Comorbidity Index (RDCI) was used. Treatment adherence was assessed through self-reported adherence rate (SRAR) rated on a visual analogue scale (VAS, 0-100 mm) and 5-item Compliance Questionnaire for Rheumatology (CQFR). Pts were considered adherent if SRAR ≥80/100. All the participants were required to complete: VAS pain questionnaire, Patient Global Assessment (PGA), Health Assessment Questionnaire (HAQ), Depression Anxiety Stress Scales (DASS21), Insomnia Severity Index and self-reported VAS therapy satisfaction scale (0-100 mm, higher values indicate higher satisfaction).

Results: Among the 116 pts (Table 1) evaluated, 57% described themselves as being adherent to their treatment (median SRAR: 80 [60-90]; median satisfaction level: 80 [90-90]). According to CQRS, 97% of the pts presented a high adherence level; 28/116 pts declared a treatment suspension during the previous month; in most cases the withdrawal was reasonable (due to vaccinations, infections, surgery). The comparison between adherent and non-adherent pts is shown in Table 1: a significant association between non-adherence and higher DAS28, HAQ and VAS pain scores was observed; in addition, an association was found between adherence and treatment satisfaction level. No significant differences in demographic features, educational level, work status, comorbidities and therapeutic formulation/plan/type were found. Patient’s reported outcomes scores regarding insomnia/anxiety/depression/stress were higher in non-adherent pts but not statistically different.

Conclusion: Treatment adherence is still a complex process difficult to measure. Our data show a discrepancy between SRAR and CQRS adherence assessment (57% vs 97%). In our cohort of pts, regularly followed-up in a tertiary outpatient clinic, the prevalence of adherence is overall higher as compared with that reported in literature (medication adherence in RA pts: 30-80%)[1]. In this study, treatment adherence seems to be associated with a higher therapy satisfaction level and a lower disease activity, pain perception, and physical disability. However, a cause-effect relationship still remains difficult to analyze.

Background: Treatment with biotechnological anti-interleukin (IL)-1 agents is recommended in patients with Still’s disease especially in cases refractory to glucocorticoids and conventional disease modifying anti-rheumatic drugs (cDMARDs), avoiding a long-term glucocorticoids exposure. In cases with refractory arthritis, IL-6 inhibitors have shown to be effective on articular inflammatory involvement.

Objectives: The objective of the present study is to evaluate any difference in the effectiveness of the IL-1β antagonist canakinumab prescribed as first-line biologic agent between the systemic and the chronic-articular Still’s disease.

The objective of the present study is to evaluate any difference in the effectiveness of the IL-1β antagonist canakinumab prescribed as first-line biologic agent between the systemic and the chronic-articular Still’s disease.
Methods: Data were drawn from the retrospective phase of the AutoInflammatory Disease Alliance (AIDA) international registry dedicated to Still’s disease. Patients affected by Still’s disease classified according to internationally accepted criteria (Yamaguchi criteria and/or Fautrel criteria) and treated with canakinumab as first-line biologic agent were enrolled.

Results: A total of 26 patients (17 females, 9 males; 18 patients developing Still’s disease after the age of 16 years) were enrolled; 16 (61.5%) patients suffered from the systemic pattern of the disease; 10 (38.5%) patients suffered from the chronic-articular type. No differences were observed between the systemic and the chronic-articular Still’s disease in the frequency of complete response, of flares after the start of canakinumab (p=0.701) and in the persistence in therapy (p=0.62). No statistical differences were observed between the two groups after 3 months, 12 months and at the last assessment in the decrease of: the systemic activity score (p=0.06, p<0.17, p=0.17, respectively); the disease activity score on 28 joints (p=0.54, p=0.37, p=0.98, respectively); the glucocorticoid dosage (p=0.15, p=0.50, and p=0.50, respectively); the use of concomitant disease modifying anti-rheumatic drugs (p=0.10, p=1.00, and p=1.00, respectively). No statistically significant differences were observed in the decrease of erythrocyte sedimentation rate (p=0.34), C reactive protein (p=0.48), and serum ferritin levels (p=0.34) after the start of canakinumab.

Conclusion: Canakinumab employed for Still’s disease has been effective in controlling both clinical and laboratory manifestations disregarding the type of disease course when used as first-line biotechnological agent. These excellent results might have been further improved by the early start of IL-1 inhibition.

COMPARISON OF SYMPTOMATIC AND DISEASE-MODIFYING TREATMENT IN RHEUMATOID ARTHRITIS WITH CONCOMITANT FIBROMyalGIA

Keywords: Disease-modifying Drugs (DMARDs), Rheumatoid arthritis, Fibromyalgia

B. A. Hiba1, S. Miladi1, F. Alia1, H. Bousaa1, M. Yasmine1, L. Souabni1, K. Queretche1, K. Selma1, C. Selma1, K. Ben Abdelghani1, L. Ahmad1, Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia

Background: There is evidence that concomitant fibromyalgia (FM) among rheumatoid arthritis (RA) patients makes the management of RA challenging by inflicting subjective disease activity parameters.

Objectives: Thus, the aim of this study was to compare symptomatic and disease-modifying treatments in RA patients with and without concomitant FM.

Methods: This was a cross-sectional study including patients with an established RA according to the 2010 ACR/EULAR criteria. All patients were screened for concomitant FM in 2016 ACR criteria. Patients were divided into 2 groups: RA and RA+FM. Demographic and RA characteristics were collected. P<0.05 was accepted for significance. Multiple linear regression analysis performed, adjusting for clinical and demographic variables.

Results: Eighty patients distributed into 40 patients in each group were recruited. Epidemiological characteristics, RA characteristics and disease activity scores were comparable between groups. Costs and atafniouex subluxation were significantly more frequent in RA+FM group (p=0.006 and p=0.049 respectively). No significant difference in corticosteroids prescription was found between the groups (p=0.88), nor in non-steroidal anti-inflammatory drugs prescription (p=0.48). Of the RA patients with concomitant FM, 52% were treated with biological therapy vs. 18% of RA patients without concomitant FM (p=0.04). Tumor necrosis factor inhibitors were the most frequently prescribed in the two groups (47.5% of RA patients with FM vs 12.5 in RA patients, p=0.03). No significant difference was noted between the groups regarding conventional Disease-modifying anti-arthreumatic drugs (DMARDs) prescription (p=0.052). Multiple linear regression in RA+FM group showed that FM is an independent factor for biological DMARDs prescription (B=0.284, p=0.018). Conclusion: Our study showed that concomitant FM in patients with RA was associated with a higher use of biological treatments. This raises the question of whether the more frequent use of biologics in these patients is justified by inflammation, or by persistent pain and other centrally mediated symptoms.

BIOLOGICAL THERAPIES SURVIVAL FOR RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS SPONDYLOARTHRITIS AND JUVENILE ONSET ARTHRITIS. A COHORT STUDY FROM BIOBADAGUAY

Keywords: Inflammatory arthritides, bDMARD

G. Avila1, S. Cabrerra-Villalba1, P. Melgarejo2, L. Roman3, Z. Morel3, R. Rolón1, M. Zarza1, M. Soto Esteve2, E. Leiva3, A. Amnárrila3, P. Pusiñen3, C. Parodi1, C. Díaz3, B. Acevedo6, A. Fernandez7, V. Valinoti1, P. DE Abreu Trigueros3, 1Hospital Central del Instituto de Previsión Social, Rheumatology, Paraguay; 2Hospital de Villar Elisa, Rheumatology, Villar Elisa, Paraguay; 3Hospital Central del Instituto de Previsión Social, Reumatología Pediatrica, Asunción, Paraguay; 4Instituto Nacional De Reumatología, Rheumatology, Montevideo, Uruguay; 5Hospital de Clinicas de la Universidad Nacional de Asunción, Rheumatology, Asunción, Paraguay; 6COSEM, Rheumatology, Montevideo; 7COSEP, Sociedad Paraguaya de Reumatología, Rheumatology, a, Paraguay

Background: BIOBADAGUAY is the Paraguayan/Uruguayan registry of adverse events in patients with inflammatory rheumatic conditions under biologic therapy (BT). The registry includes patients with different diagnosis that share similar biological therapies indication. However, different pathogenesis, patients' characteristics and treatment options can affect the survival of the BT.

Objectives: To analyze survival of biological therapies among patients with chronic inflammatory arthritides in the BIOBADAGUAY registry.

Methods: Patients with chronic inflammatory arthritides (CIA) such us rheumatoid arthritides (RA), spondylarthritises (SpA), psoriatic arthritides (PsA) and juvenile onset arthritides (JIA) enrolled in BIOBADAGUAY where analyzed. Other diseases included in the registry were grouped as others. Drug survival and clinical and epidemiological predictors were studied. Fewer than 25 registries were not included in the study. Survival analysis was performed using Kaplan-Meier estimators, and Cox proportional hazard models were used to estimate hazard ratios (HRs).

Results: A total of 1378 treatments (876 RA, 176 SpA, 40 JIA, 88 PsA, 98 others) were included. The mean BT survival according to diagnosis was 300.9 (95%CI, 230.6-444.4) weeks (wks) for RA; 541.6 (95%CI, 409.6-541.6) wks for SpA; 154.1 (95%CI, 125.0-194.7) wks for JIA and 555.3 (95%CI, 282.1-616.1) wks for PsA. In the general analysis, when survival was compared between different diagnosis, it was found that BT survival for SpA patients (p<0.05; HR=1.23 [95% CI 0.97-1.56]) was higher than other CIA. On the other hand, JIA diagnosis was significantly associated with a lower BT survival (p<0.05; HR=1.85 [95% CI 1.36-2.52]). In the general analysis, no significant differences between BT were found (p>0.05). When each drug survival was analyzed according to diagnosis, adalimumab showed a significant difference in SpA patients (p<0.05; HR=0.55 [95% CI, 0.39-0.78]) and JIA patients (p<0.05; HR=1.8 [95% CI 1.36-2.52]). Etanercept had a significant difference in RA patients (p<0.05; HR=0.57 [95% CI, 0.40-0.82]) and JIA patients (p<0.05; HR=2.07 [95% CI, 1.39-3.06]). Following these results we analyzed JIA patients and found that remission was the principal reason of discontinuation in this group of patients (p<0.005, HR=10.70 [95% CI, 5.91-19.36]). Multivariable analysis showed that the number of previous BTs (p<0.01, HR=1.18 [95% CI, 1.03-1.34], corticosteroid treatment (p<0.05, HR=1.18 [95% CI, 0.91-1.40]), SpA presentation (p<0.01, HR=0.68 [95% CI 0.51-0.91]) and JIA diagnosis (p<0.02; HR=1.14 [95% CI, 1.06-2.02]) were associated with BT survival.

Conclusion: In this study we found different survival profiles according to diagnosis. This could be related to different pathogenesis, discontinuation motives and treatment options in different health systems.

ADHERENCE TO BIOLOGIC THERAPIES IN INFLAMMATORY RHEUMATIC DISEASES: INFLUENCE OF ROUTE OF ADMINISTRATION

Keywords: Spondyloarthritis, bDMARD, Rheumatoid arthritis

F. Wertiann Ep Amin,1 I. Mahmoud,1 S. Bouden1, R. Leila1, R. Tekaya1, A. Ben Tekaya1, H. Sahli1, O. Saidane1, L. Abdelmoula1, H. Sahloul1, O. Saidane1, M. Elleuch1,1 Tunis, Rheumatology of Charles Nicolle Hospital, Tunis, Tunisia; 2Tunis, Rheumatology of Rabta Hospital, Tunis, Tunisia

Background: Inflammatory rheumatic diseases are a debilitating disease affecting the joints and periarticular structures and leading, more or less rapidly, to cartilage and bone destruction. It is a major source of chronic pain and physical, psychological, and social disability, it affect approximately 1% of the world’s population [1]. For more than 20 years, biotherapies have revolutionized the treatment of these inflammatory diseases and have largely contributed to the improvement of their prognosis [2]. Adherence to biologic therapies conditions the effectiveness of the treatments then the improvement of patients’ quality of life [3].

Objectives: To evaluate and compare adherence to biologic disease-modifying antirheumatic drugs (bDMARDs) according to the route of administration and the molecule used (Infliximab, Tocilizumab, Etanercept, Adalimumab, Certolizumab, and Golimumab) in patients with inflammatory rheumatic diseases.

Methods: This is a descriptive cross-sectional study with repeated data collection, bi-centric carried out in the rheumatology departments and outpatient clinics at Charles Nicolle Hospital and Rabta Hospital in Tunis and conducted over a period of 01 year and 02 months between 02/02/2021 and 03/04/2022. 71 adult patients with rheumatoid arthritis, spondyloarthritits or juvenile idiopathic arthritis were recruited, their adherence rate in the last 3 months before inclusion should be >80%. The collection of socio-demographic, clinical and therapeutic data was established with the help of a pre-established form, from medical files completed by questioning the patients during a direct interview or through a telephone communication. Adherence rate was calculated by determining the ratio of treatments cures (number of biologic injections taken during a year divided by the number of annual biologic injections prescribed).

Results: Within the study population, adherence was estimated at 85.9%; in the group of patients using intravenous biotherapy was 82.1% (Infliximab 86%, Tocilizumab 75% p=0.04) and in the group of patients using subcutaneous treatment was 87% (Golimumab 89%, Etanercept 92%, Certolizumab 89%, Adalimumab 87% p=0.3). Adherence to biologic therapy was significantly higher in the subcutaneous group than in the intravenous group (p=0.01). The causes of poor adherence presented by the patients in this study were: stock-outs of biological treatment and delay in renewal by the national health insurance (CNAM) in thirteen-eight cases (54%p<0.001), recurrent infections in thirty-three cases (46% p<0.005) and the COVID 19 pandemic and its consequences in thirty patients (42%, p=0.28).

Conclusion: Adherence to biologic treatment is influenced by the route of administration, drugs type, recurrent infections and drugs availability. All this factors must be treated to improve therapeutic adherence then the efficiency of the biologic therapy which contributes to the preservation of physical capacities and an improvement in the quality of life.

Conclusion: Minor differences in immunogenicity (ADAs, ADA titles and nAbAs) between BI 695501 and adalimumab RP were observed across these 3 indications. The proportion of ADA- and nAb-positive patients increased from baseline in all 3 RCTs, and were similar in RA and CD RCTs, but rates were higher in PsO RCT. Subgroup analysis by patient sex showed the same trend. These differences may be partially explained by concomitant background therapy. In RA trial, stable doses of ADA, 6-MP or MTX in 36% of CD patients and the absence of background therapy in PsO RCT. Comparisons are limited by different visit schedules in the trials. Historical comparisons to RP data are complicated by recent differences in regulatory requirements for increased ADA assay sensitivity and stringency for biosimilar products than those originally used for the RP. Acid dissociation followed by an electrochemiluminescence assay (ECL: MSD platform; Meso Scale Diagnostics LLC, USA). Assay sensitivity was 50 ng/mL, and drug tolerance ±30 μg/mL (free drug) at the low positive control level.

Results: Data are presented in Table 1.

**V. Strand**, S. Bender, D. Mccabe, Stanford University School of Medicine, Immunology/Rheumatology, Palo Alto, United States of America; **Alyxam Pharmaceuticals, Inc.,** Biostatistics, Cambridge, United States of America; **Boehringer Ingelheim USA, Immunology/Biosimilars, Ridgefield, United States of America**

**Background**: The VOLTARE trials program compared safety, efficacy, and immunogenicity of biosimilar BI 695501 with adalimumab reference product (RP) for indications including moderate-severely active rheumatoid arthritis (RA), Crohn’s disease (CD), and chronic plaque psoriasis (PsO). Details of each active-comparator, randomized controlled trial (RCT) are published. [1,2,3]

**Objectives**: Here we compare immunogenicity across these indications and by patient sex.

**Methods**: Immunogenicity was assessed at various timepoints by the proportion of patients with anti-drug antibodies (ADAs) and neutralising antibodies (nAbs), using acid dissociation followed by an electrochemiluminescence assay (ECL: MSD platform; Meso Scale Diagnostics LLC, USA). Assay sensitivity was 50 ng/mL, and drug tolerance ±30 μg/mL (free drug) at the low positive control level.

**Results**: Data are presented in Table 1.
(0.6%). Relapses were observed in 24 (14.4%) patients while on biologic therapy optimization, being more frequent with certolizumab and abatacept. The lowest rates of relapse were observed with infliximab, adalimumab and etanercept, while certolizumab and abatacept had the shorter time to relapse (table 1). Overall, the relapse rate was 5.5 per 100 patient-years with RA at risk (p=0.021) (figure 1).

**Conclusion:** Tapering bDMARD strategy was effective in our large RA cohort with 85.6% of patients remaining in remission during the follow up. Adalimumab, etanercept and tocilizumab were the bDMARDs with the longest time to relapse. These findings support the use of the tapering strategy in patients with established RA.

In a multivariate regression model, number of previous bDMARDs (OR 2.13; 95% CI 1.47 to 3.10, p=0.001) and treatment with adalimumab (OR 4.60; 95% CI 1.96 to 10.80, p=0.001) were statistically significant predictive factors for IMSL development.

**Conclusion:** In our cohort, we found that a younger age at diagnosis, longer disease duration, longer duration of bDMARD treatment, higher number of previous bDMARDs and treatment with adalimumab were independently associated with an increased risk of IMSL development. In the multivariate regression model, number of previous bDMARDs and exposure to adalimumab were statistically significant predictive factors for IMSL development. Further research is required to better understand and recognize the risk factors for IMSL.

</table>
Background: Rheumatoid arthritis (RA) is an independent risk factor for osteoporosis, which influences bone remodeling processes via increased production of proinflammatory cytokines, especially tumor necrosis factor (TNF)-α, or through hormone-mediated mechanisms. The presence of other classical risk factors for osteoporosis additionally raises the risk of changes in bone tissue. Some of the most commonly used biological drugs in the osteoporosis treatment are those that inhibit TNF-α action. Apart from reducing inflammation, these TNF-inhibitors suppress osteoclast activity.

Objectives: To determine the impact of osteoporosis risk factors on the bone turnover marker levels in RA patients treated with TNF-inhibitors.

Methods: This 12-month-long study included 50 patients with RA who received a drug from the TNF-inhibitor group. In order to enter the study, patients had to fulfill certain inclusion/exclusion criteria considering the RA duration, the RA treatment method, the degree of joint damage, and the presence of other diseases affecting bone tissue. Data regarding traditional risk factors for osteoporosis and fractures were collected, such as menopause length, body mass index, previous fractures due to minor trauma, family history of osteoporosis and osteoporotic fractures, reduced physical activity, cigarette smoking, and alcohol consumption. Serum levels of the bone synthesis marker procollagen type I N propeptide (P1NP), and the bone resorption marker beta C-terminal telopeptide of type I collagen (b-CTX) were assessed via ECLIA method at the baseline and upon TNF-inhibitor therapy completion.

Results: The mean age in this cohort was 51.6 years. A higher percentage increase in P1NP and b-CTX was recorded in patients aged below 50 years, as well as those of normal weight (BMI = 18.50−24.99 kg/m²). P1NP: Wilk's lambda =0.83, F = 9.56, p = 0.003; b-CTX: Wilk's lambda = 0.77, F = 14.16, p = 0.000). A greater increase in the P1NP and b-CTX levels was also observed in non-smokers (28.70% and 27.50%) relative to smokers (27.50% and 7.75%). Menopause length had a statistically significant effect on both P1NP (Wilk's lambda = 0.84, F = 8.18, p = 0.006) and b-CTX (Wilk's lambda = 0.77, F = 13.31, p = 0.001) concentrations, whereby the highest percentage increase in P1NP (29.85%) was related to menopause duration below 2 years. On the other hand, the greatest b-CTX increase (10.2%) was recorded in patients that had entered menopause 2−3 years ago. Physical activity had a significant effect on changes in P1NP (Wilk's lambda = 0.84, F = 8.67, p = 0.005) as well as b-CTX (Wilk's lambda = 0.78, F = 13.30, p = 0.001) values. Further, P1NP percentage increase was higher in patients without family history of osteoporosis, while the opposite was true for the b-CTX levels. Finally, number of previous fractures was inversely correlated with the P1NP and b-CTX percentage increase.

Conclusion: After 12-month TNF-inhibitor treatment, although a significant increase in both bone turnover markers was achieved, it was greater in the bone synthesis marker P1NP. Younger age, normal body weight, shorter menopause duration, greater physical activity, negative osteoporosis family history, and non-smoking emerged as the most important factors associated with the P1NP percentage increase.

AB0441 JANUS KINASES INHIBITORS THERAPY FOR THE TREATMENT OF RHEUMATOID ARTHRITIS: AN OVERVIEW OF SYSTEMATIC REVIEWS AND META-ANALYSES

Keywords: Rheumatoid arthritis, Qualitative research methods

X. Shen1, X. Guo2, X. Gao1,2, J. Zhang3, X. Hou4, Z. Feng1, 1China Three Gorges University, College of Medicine and Health Sciences, China Three Gorges University, Yichang, China; 2China Three Gorges University, Institute of Rheumatology, the First College of Clinical Medical Sciences, China Three Gorges University, Yichang, China; 3China Three Gorges University, Medical College of Basic Sciences, China Three Gorges University, Yichang, China

Background: Janus kinases (JAK) inhibitors are a family of intracellular tyrosine kinases that act as hubs in the signaling process of many cytokine receptors, mediating inflammation and autoimmune diseases. It was reported that JAK inhibitors played an important role in inhibiting bone destruction by inhibiting the phosphorylation of proteins. In recent years, JAK inhibitors have been widely used to treat Rheumatoid Arthritis (RA) and proved to have an obvious curative effect. However, the efficacy and safety of the clinical use of JAK inhibitors need to be further verified.

Objectives: To access the methodological, reporting and evidence quality of systematic reviews and meta-analyses of JAK inhibitors for RA.

Methods: We comprehensively searched the literature in CNKI, Wanfang Data, VIP, PubMed, Web of Science databases from inception to November 2022. A Measurement Tool to Assess systematic Reviews (AMSTAR-2) tool and the Preferred Reporting Items for Systematic reviews and Meta-analyses (PRISMA) were used to access the methodological and reporting quality. The level of evidence quality was evaluated by employing the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) scale.

Results: The AMSTAR-2 tool showed that half of the included literature had low quality, and the other 6 literatures had a very low quality. The study process lacked certain normativity, which had a certain impact on the implementation of the study and the evaluation of outcomes. The PRISMA statement showed that there were numerous vulnerabilities in the methodology module of each document, which was mainly manifested in the scheme and registration. The GRADE analyses showed that the quality of the evidence for the outcome measures was moderate to low. The results showed that JAK inhibitors had certain advantages in the proportion of patients with ACR20, 50 and 70 after treatment for 3 months or 6 months. In addition, this study found that JAK inhibitors could alleviate adverse reactions. Furthermore, all the included literature had certain deficiencies in randomization, blinding, allocation, etc. There was a risk of bias, which directly reduced the evidence level of RCT trials and showed that the included studies had defects in the design of trial protocols.

Conclusion: The effectiveness of JAK inhibitors for RA has certain advantages compared with placebo, and more studies need to be demonstrated than other drugs. However, the safety is uncertain and need further explored.

AB0442 RETROSPECTIVE ANALYSIS ON JAK INHIBITORS AT SINGLE CENTRE IN THE UK

Keywords: Safety, Rheumatoid arthritis, Targeted synthetic drugs

D. Nagra1, K. Bechman1, M. Russell1, E. Alvey1, C. Baldwin1, G. Bird1, S. Steer1, C. Byrne1, K. Lawan1, V. Vescovi1, M. Adams1, M. Nursoly1, S. Norton1, A. Mahto1, A. Rutherford1, J. Galloway1, E. Nkhipgorou1, King’s College London, Centre for Rheumatic Disease, London, United Kingdom

Background: There are limited real world data on the use of JAK inhibitors (JAKi). In 2022, the EMA suggested that JAKi should only be used if alternative therapies are not available in patients over 65 years, smokers or in those with cardiovascular or cancer risk factors.

Objectives: We conducted a retrospective study to describe the demographics, duration of therapy and adverse events profile of patients prescribed JAKi.

Methods: Baseline data including age, gender, smoking status, ethnicity, co-morbidities, cardiovascular risk factors, rheumatic diagnosis, concomitant csDMARD use and prior biological therapies was collected. Duration on therapy and reasons for stopping JAKi were identified. A Cox proportional hazard model was used to plot survival of drug therapy, by JAKi drug. Data was analysed on the STATA platform.

Results: In total, 151 patients were prescribed a JAKi since 2017. The average age was 55, with a female predominance, (n=125, 83%), and the majority had rheumatoid arthritis. Baricitinib and Filgotinib represented the most commonly prescribed JAKi. Over ¼ of the cohort were using JAKi monotherapy (28%). For those on combination therapy, methotrexate was the most commonly prescribed (53%). The median number of prior biologics was 1 (IQR 1-2), with TNFi the most frequently prescribed (66%). 48% had cardiovascular risk factors or cardio- vascular disease; this was more prevalent in patients prescribed baricitinib or triflartitin compared to upadacitinib or filgotinib (57%) versus (38%). During JAKi therapy 3 patients developed cancer, 2 had VTEs (both on Baricitinib) and 5
had new mental health diagnoses. The reason for stopping therapy was equally split between drug failure (46%) and adverse events (45%). Drug survival over 2 years was numerically higher for Filgotinib and Upadacitinib. Cycling between individual JAKi are likely to reflect drug availability and emergence of safety warnings over time.

**Department of Internal Medicine, Kristiansand, Norway;** Epidemiology, Oslo, Norway

**Objectives:** To explore long-term drug effectiveness and survival of bs-RTX GP2013 in rheumatoid arthritis (RA) patients both naïve to and mandatory switched from bo-RTX in ordinary outpatient clinic.

**Methods:** Retrospective observational cohort study including adult RA patients treated with bs-RTX between 2018 and 2021 in Norway. Patients were examined and monitored with recommended disease activity measures and patient-reported outcomes (PROs). Drug survival was assessed with Kaplan-Meier survival analysis.

**Results:** 110 RA patients (71.8% women) treated with bs-RTX were identified (88 mandatory switched from bo-RTX, 22 RTX-naïve), baseline median (IQR) age was 68.0 (59.0-76.0) years, disease duration 13.0 (7.4-18.7) years, 93.6% were RF and 96.3% ACPA positive, 30.0% currently used csDMARDs (26.4% methotrexate). Statistically significant difference between bs-RTX-naïve and bs-RTX-switched patients was found for disease duration (3.0 vs 14.2 years, p<0.01), current steroids use (68.2% vs 35.2%, p=0.01) and first cycle bs-RTX dose: 90.9% bs-RTX-naïve received 2000mg, while 85.3% bs-RTX-switched 1000mg or 500mg. During 2-year follow-up disease activity and PROs measures remained stable in switchers and improved in those starting naïve on RTX (Table 1).

**DOi:** 10.1136/annrheumdis-2023-eular.z2555
Overall drug survival for bs-RTX was 80.0% (95% CI 71.2-86.3%) after 1 year and 57.7% (95% CI 47.8-66.3%) after 2 years. Drug survival in RTX-switched patients was significantly higher than in bs-RTX-naïve (Figure 1).

**Background:** In North African countries, few data are available on the safety of biotherapies.

**Objectives:** To evaluate safety of biological therapy (excluding infections) in a population with rheumatoid arthritis (RA) followed in the RBSMR (Registry of Biological therapies in rheumatic diseases of the Moroccan Society of Rheumatology).

**Methods:** This work was based on data from inclusion and 3 years of follow-up. It concerns 223 patients with RA receiving biotherapies, included between May 2017 and December 2018. Safety was evaluated at inclusion and every 6 months for 3 years. Serious adverse events were defined as those that are life-threatening or that required hospitalization or permanent stopping of current biological agent.

**Results:** 223 patients were included in the study. The mean age was 51.8 ± 11.3 years, 87.4% were females, average duration of RA was 20.8 [13.9 - 31.3] months. The median duration of exposure to biotherapies was 3.1 [0 - 18.23] months. Patients were receiving anti-TNFα in 16.6% (37/223) of case, Rituximab (RTX) in 59.6% (133/223) and Tocilizumab (TCZ) in 23.8% (53/223). About 70% (155/223) of patients had an association with a csDMARDs. At inclusion, 19.73% (44/223) of patients had previously developed 59 adverse events (AEs) (n=14). The occurrence of noninfectious AEs differs depending the biological agent.

AB0445 CHARACTERISTICS OF FIRST-LINE UPADACITINIB INITIATORS AND FACTORS CONTRIBUTING TO PRESCRIBING UPADACITINIB AS FIRST-LINE B/T SDMARD

Keywords: Disease-modifying Drugs (DMARDs), Real-world evidence, Rheumatoid arthritis

W. Krueger1, L. Harold2, A. Sima3, T. Eckmann3, R. Kilpatrick4, 1AbbVie Inc, n/a, North Chicago, United States of America; 2University of Massachusetts, Medical School, Worcester, United States of America; 3CorEvitas, n/a, Waltham, United States of America

Background: EULAR guidelines recommend switching to or adding a b/tsDMARD in patients with rheumatoid arthritis (RA) who do not respond or have an inadequate response to csDMARDs. Traditionally, TNF inhibitors (TNFi) are prescribed as the first b/tsDMARD. In Dec 2021, the upadacitinib (UPA) label in the US was updated to restrict use to those who have had an inadequate response or intolerance to one or more TNFi.

Objectives: In the period prior to the UPA label change in the US (through Jan 2022), (1) compare characteristics of patients with RA receiving UPA as first b/tsDMARD, (2) explore the reasons why UPA was chosen as first-line advanced therapy. Methods: Using CorEvitas RA registry data from Aug 2019 to Jan 2022, patients who initiated UPA or TNFi at or after enrollment in the registry with no history of prior b/tsDMARD use were evaluated. The patients’ providers indicated which factors (they choose more than one) contributed to prescribing UPA as first-line advanced therapy based on medical record chart review.

Results: Few differences in demographics, comorbidities, and disease activity at initiation were observed between the 815 TNFi initiators and 142 UPA initiators identified. UPA initiators were older (mean [SD] age 58.9 [12.8] vs 56.7 [13.9] yrs), had a higher proportion of White patients (87% vs 83%), and were less likely to be working (44% vs. 53%), and have private insurance (73% vs 68%). UPA initiators had more frequent history of cardiovascular disease (16% vs 10%), joint deformity (17% vs 12%), and subcutaneous nodules (13% vs 10%), but less frequent history of anxiety/depression (29% vs 34%) than TNFi initiators. UPA initiators had greater disease severity, including mean CDAI (23.7 [14.9] vs 19.0 [13.0]), and tender (8.4 [7.7] vs 6.6 [6.7]) and swollen (6.1 [5.1] vs 4.3 [5.1]) joint counts, self-reported pain (54.5 [28.7] vs 50.3 [28.3]), and proportion with morning stiffness (89% vs 85%). UPA initiators were more likely to have a history of multiple csDMARDs (43% vs 35%), monotherapy b/tsDMARD initiation (22% vs 22%) and use of NSAIDs (53% vs 48%). For 142 patients initiating UPA as first-line, 34 providers (87% response rate) indicated major factors in the choice of prescribing UPA as first-line advanced therapy were the patient’s level of disease activity (75%), patient’s disease progression (61%), patient preference (51%), and patient’s disease profile (43%). These reasons contributed to any part of the prescription decision in 89%, 96%, 77%, and 79% of patients, respectively. Oral delivery was indicated as a contributing factor by almost all (91%) of the 109 patients that were prescribed UPA as first-line therapy and indicated patient preference was a factor in prescribing UPA. Side effects were not a concern when deciding to prescribe UPA in at least 50% of the patients included in this study.

Conclusion: In a real-world cohort of patients with RA initiating a first-line b/tsDMARD, those who received UPA were more likely to have previously failed multiple csDMARDs, to initiate as monotherapy, and to have technically poor disease activity based on both physician and patient measures compared to patients who received TNFi. Clinical factors including disease activity, disease progression, and disease profile influenced the prescribing decision by providers as well as patient preference.

Background: BIOBADAGUAY is the Paraguayan/Uruguayan registry of adverse events (AE) in patients with inflammatory rheumatic conditions under biologic therapy (BT).

Objectives: Determine the frequency and severity of AE of patients under BT in the BIOBADAGUAY registry.

Methods: Prospective, observational study of undetermined length to verify the efficacy, safety, and survival of the BT. The methodology applied is available at https://biobadaguay.ser.es. For the present study epidemiological and clinical variables, BT, type, and severity of AE were analyzed. The incidence rate (IR) was calculated as the total number of adverse events per 1000 patients/year and the incidence rate ratio (IRR) was analyzed using the Poisson regression model. (Significance value 0.05)
Background: Treatment maintenance in young women with rheumatoid arthritis (RA) may be influenced by factors such as fears of side effects on fertility and conception.

Objectives: We aimed to assess the therapeutic beliefs of patients with RA during the preconception period and to investigate associated factors.

Methods: We conducted a cross-sectional study including patients diagnosed with RA before menopause. We assessed beliefs about treatment during the preconception period using the French version of Beliefs about Medicines Questionnaire (BQM). The questionnaire assessing specific beliefs is composed of 10 items: 5 items to assess beliefs regarding the necessity for treatment and 5 items to assess concerns.

Results: We included 31 females (mean age: 49.7±10.4 years). RA was erosive in 93% of cases. Coxitis was noted in 6 patients (19%). There was no influence on concerns. The disease duration had a statistically negative correlation with concern score (r=-0.480, p=0.006). Contraception use was not influenced by either therapeutic necessity or concerns (p=0.129 and p=0.140, respectively).

Conclusion: This study showed that beliefs about therapeutic necessity during the preconception period were more important than concerns. We emphasize the importance of therapeutic patient education to fight against negative beliefs.

Conclusion: AE were in general non-severe, and infections were the most frequent. RA and concomitant treatment corticosteroid presented a higher IRR of global AE, whereas PsA and AS a lower IRR of AE. Second and subsequent cycles of BT were significantly associated with a higher IRR of global AE compared to the first cycle of BT (Table 1). Treatment with anti-TNF was significantly associated with lower IRR of global and mortal AE compared to non-anti-TNF (Table 1).

Rheumatoid arthritis - non biologic treatment and small molecules

Keywords: Rheumatoid arthritis, Genetics/epigenetics, Biomarkers

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterised by joint swelling, joint compression and synovial joint destruction, where inflammation and bone destruction can lead to significant functional impairment. Recently, several studies have reported the identification of new biomarkers of RA, such as osteoprotegerin (OPG), osteocalcin (OCN) and osteopontin (OPN) [1], all three of which play a significant role in regulating bone metabolism and influencing osteoclast synthesis and secretion. Although OPG, OCN and OPN are strongly correlated with RA, it is not clear whether there is a causal relationship between them.

Objectives: The aim of this study was to assess whether OPG, OCN and OPN are causally related to the risk of RA in a Two-Sample Mendelian randomisation (TSMR).

Methods: The genetic instrumental variables (IVs) for OPG, OCN and OPN exposure from a large genome-wide association study (GWAS) meta-analysis including 21,758, 1322 and 3301 participants, respectively. The GWAS data for RA were selected from an independent RA GWAS analysis that included 29,880 RA cases of European ancestry and 73,758 controls. Significant (P < 5 x 10^(-8) and independent (r2 < 0.001) SNP in genome-wide association studies were selected as IVs for performing MR analyses. The causal relationship between OPN, OCN and RA risk was assessed by TSMR analysis using inverse variance weighting (IVW) methods as the primary analysis, supplemented by weighted median, MR-Egger regression, Leave-one-out analysis and Mendelian Randomization Pleiotropy RESidual Sum and Outlier (MR-PRESSO) were used to detect and correct for the effects of multiple-confounders [2].

Results: The Eighteen, seven and nine SNPs were selected as IVs for OPN, OCN and OPN respectively. The results of the IVW method (OPN/OP = 1.091, 95% CI: 0.980-1.0597, p = 0.3440; OPG/OP = 1.0396, 95% CI: 0.9327-1.1588, p = 0.4827; OCN/OP = 1.077, 95% CI: 0.990-1.077, p = 0.812) showed that there was no strong evidence of a relationship between the production of OPN, OCN and OPN in people of European ancestry and RA risk. Further sensitivity analyses verified the robustness of the above associations, with MR-Egger regressions showing no evidence of pleiotropy (OPNP = 0.8703; OPG = 0.7043; OCN = 0.6356) and heterogeneity analyses showing no heterogeneity (OPNP = 0.7880; OPG = 0.2451; OCN = 0.5651). The leave-one-out method analysis indicated that genetically determined PN, OPG and OCN were not influenced by single SNP in association with RA risk.

Conclusion: We did not find any evidence of a causal relationship between OPN, OCN and RA risk. Further research is needed to elucidate the potential mechanisms underlying the role of OPN, OPG and OCN in the development of RA.

**Conclusion:** JAKIs are effective across a range of rheumatological diagnoses in a South London real-world analysis, including patients with bDMARD-naive and bDMARD-refractory disease. JAKIs are generally well tolerated and adverse events in this study were in keeping with the current literature.

**Background:** Tofacitinib, an oral Janus Kinase inhibitor, is indicated for the treatment of adult patients with moderate to severe active rheumatoid arthritis (RA).

**Objectives:** To describe the safety profile of Tofacitinib in a French prospective observational study DeFacTo.

**Methods:** The safety profile of tofacitinib was assessed using interim data from a descriptive analysis of patients who took at least one dose of tofacitinib in the DeFacTo study.

**Results:** Among 314 patients enrolled in the study, 306 received tofacitinib and were included in the safety analysis, including 274 patients with a follow-up ≥ 18 months (POP2) on 03/15/22 date of analysis with a median exposure duration of 538 [Q1; Q3: 381; 554] days, 113 patients (41.2%) were still on tofacitinib (39 discontinued, 122 missing data regarding prescription). At inclusion, 78.3% of the 306 pts were women with a mean (± standard deviation) age of 59.5 ± 11.5 years, mean disease duration of 8.9 years [Q1; Q3: 4.1; 8.9]. There was a history of cardiovascular (CV) disease in 11.9% of cases (including 4.6% myocardial infarction (MI), 5.0% stroke/transient ischemic attack (TIA), 1.7% heart failure, and 1.7% peripheral arterial disease). 5.6% history of cancer, 16.8% history of infection, and 46.6% smoker/former smoker. Tofacitinib was prescribed in combination with a csDMARD in 61.1% of patients and corticosteroids in 56.2% of patients. The results showed that adverse events (AEs) were reported in 54.2% of the 306 patients, 14.4% were considered as serious. Infections were found in 22.2% of patients, no deaths were reported (Table 1).

**Conclusion:** These intermediate, descriptive results show a safety profile of tofacitinib in real-life RA similar to the one previously reported in clinical and observational studies. [1-2]

**REFERENCES:**

**Acknowledgements:** This study was sponsored by Pfizer.
Objectives: The aim of this study was to evaluate the clinical efficacy of baricitinib in a real-life setting in a cohort of RA patients.

Methods: This multicenter retrospective observational study included patients from 25 rheumatology centers diagnosed with RA and treated with baricitinib. The following were recorded for each patient: gender; age; duration of disease; presence of rheumatoid factor and anti-citrulline antibodies; concomitant treatment with conventional synthetic (cs) DMARDs; previous treatments with biological (b) or ts DMARDs. In order to evaluate the clinical efficacy, the retention rate was evaluated, calculated by means of the Kaplan-Meier method. The variables under examination were reported as frequencies and median with relative interquartile range.

Results: We included 478 patients of which 380 (79.5%) were female. 296 (60.1%) patients tested positive for rheumatoid factor (RF) and 264 (55.2%) for anti-citrulline antibody (ACPA). The parameters analyzed are shown in Table 1. 105 (22.0%) patients were treated with baricitinib as first line (after csDMARD); the remaining patients had failed at least one bDMARD and 9 (1.9%) also failed a tsDMARD. In 34.7% of cases baricitinib was used as monotherapy, the most frequently used csDMARD was methotrexate (29.2%). The median period of therapy was 674 days (298-1097). The survival rate at 6 months was 94.6%, at 12 months it was 87.9%, at 24 months it was 81.7% and at 48 months was 53.4% (Figure 1). The main causes that led to the discontinuation of baricitinib therapy were: primary ineffectiveness (23.4%), secondary ineffectiveness (4.2%) and adverse events (3.7% 5 TEP/DVT). The concomitant steroidal therapy seems to be a negative prognostic factor (HR 1.65 95% CI 1.03-2.63; p=0.035) as well as the line of therapy (HR 1.35 95% CI 1.15-1.58; p=0.000).

Conclusion: The efficacy of baricitinib in the treatment of RA in a real-life context appears consistent with what was reported by the pivotal studies. Furthermore, from this preliminary experience, seropositivity and combo therapy seems to not correlate with a better retention rate, while concomitant steroidal therapy and line of treatment are a negative prognostic factor.

Background: Filgotinib (FIL) is a Janus kinase (JAK) 1 preferential inhibitor, approved for treatment of moderate to severe active RA in Europe, the UK, and Japan. Graded laboratory abnormalities from placebo-controlled analyses and long-term data on lymphocytes have been reported previously.

Objectives: Report the effect of FIL on laboratory parameters in the FINCH 4 long-term extension (LTE).

Methods: Safety was assessed from LTE baseline (BL) to data cutoff (1 Jun 2020) in patients (pts) receiving ≥1 FIL dose (FIL 200 mg [FIL200] or 100 mg [FIL100]) in FINCH 4 (NCT03025308). Laboratory abnormalities were graded per Common Terminology Criteria for Adverse Events v4.03. Frequencies and exposure-adjusted incidence rates (EAIRs)/100 pt-years of exposure (PYE) for graded abnormalities are reported. Median laboratory parameters are reported to LTE Week (W) 48.

Results: In FINCH 4, 2729 pts received FIL for 4198.08 PYE (mean 80.3 weeks); exposure was similar between dose groups. Frequency and EAIR of laboratory abnormalities were similar for anemia, decreased platelets, and increased alanine aminotransferase (ALT), aspartate aminotransferase (AST), and serum creatinine, and higher in the FIL200 vs FIL100 group for neutropenia, increased creatinine kinase (CK), hypophosphatemia, and cholesterol (high) (Table 1; graded data not shown). No Grade 4 decreased phosphate laboratory abnormalities were observed and hypophosphatemia was not associated with adverse events. Laboratory abnormalities led to discontinuation of FIL in 7 pts: ALT and AST increased, 3 (0.2%, FIL 200); ALT increased, 1 (<0.1%, FIL 100); and neutropenia 3 (0.3%, FIL 100). From LTE BL to W48, hemoglobin, platelets, ALT, and AST were relatively stable, with no clear differences between doses, or between pts with or without prior FIL. Neutrophil count was relatively stable from LTE BL to W48. Neutrophils decreased for the FIL200 group with no prior FIL exposure, remaining stable from W24. CK and serum creatinine were relatively stable from LTE BL to W48 in pts with prior FIL exposure; in pts with no prior FIL, initial increases plateaued by W6 and W12, respectively, remaining stable. Changes in phosphate levels from LTE BL were small, remaining within normal range (2.2–5.1 mg/dL). Triglycerides were stable over time with no differences between groups. Total cholesterol, high-density lipoprotein (HDL), and low-density lipoprotein (LDL) levels were stable in pts with prior FIL exposure. In pts with no prior FIL exposure, small increases in total cholesterol, HDL, and LDL plateaued by W24, remaining stable. The LDL:HDL ratio was stable, with no differences between groups (Figure 1).

Conclusion: Laboratory abnormalities were generally mild to moderate, similar to previous observations. Frequency and EAIR were higher in the FIL200 vs FIL100 group for neutropenia, increased CK, hypophosphatemia, and high cholesterol.

Acknowledgements: We thank the physicians and patients who participated in these studies. The FINCH studies were co-funded by Gilead Sciences Inc. BARICITINIB IN THE TREATMENT OF PATIENTS WITH MODERATE TO SEVERE ACTIVE RHEUMATOID ARTHRITIS IN CHINA: 24-WEEK RESULTS OF POST-MARKETING SAFETY STUDY

Keywords: Real-world evidence, Safety, Rheumatoid arthritis

1Peking Union Medical College Hospital (PUMCH), Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing, China; 2Yiyang Central Hospital, Department of Rheumatology and Clinical Immunology, Yiyang, China; 3Zibo Central Hospital, Department of Rheumatology and Clinical Immunology, Zibo, China; 4Huashan Hospital Affiliated to Fudan University, Department of Rheumatology and Clinical Immunology, Shanghai, China; 5The Third Affiliated Hospital, Sun Yat-Sen University, Department of Rheumatology and Clinical Immunology, Guangzhou, China; 6Sinopharm Dongfeng General Hospital, Hubei University of Medicine, Department of Rheumatology and Clinical Immunology, Shiyian, China; 7Eli Lilly and Company, LCCDMAC, Shanghai, China

Background: Baricitinib, an orally selective inhibitor of JAK1 and JAK2, was approved for adult patients with moderate-to-severe rheumatoid arthritis (RA) in China. The recommended dose is 2mg once daily and 4mg once daily in patients who have inadequately responded to baricitinib 2mg once daily (for 3 months) or TNF inhibitors. A single-arm, prospective, non-interventional post-marketing safety study (PMSS) was conducted in Chinese RA patients to describe the safety and effectiveness of baricitinib at 24 weeks.

Objectives: To describe the safety and effectiveness of baricitinib in real-world setting of treating patients with moderate to severe active RA.

Methods: This PMSS (starting July 2020) included 667 patients with RA treated with baricitinib (2 mg or/and 4mg/day) and followed up for 24 weeks. Safety and effectiveness (disease activity) were assessed for 24 weeks. All statistical analyses are descriptive.

Results: Safety analyses included 667 patients (females=82.3%, mean age=53.3 years, mean RA duration 8.69 months). 106 (15.9%) were ≥65 and <75 years and 19 (2.8%) had previously received biological therapy. Baricitinib dose regimen was as follows: 2 mg/day, n = 580 (87.0%); 4 mg/day, n = 53 (79%); 2/4 mg, n = 34 (5.1%). Concomitant use of MTX and leflunomide occurred in 54.3% and 35.5%, respectively. The overall exposure of baricitinib was 262.1 patient-years; 197 (29.5%) patients withdrew from the study, mostly for patient’s decision (n = 101). Adverse events (AEs) occurred in 250 (37.5%) patients: Serious (7.9%); 34 (5.1%). Two patients (0.3%) died: one of pneumonia and one with no cause reported. The incidence of serious infection, herpes zoster and hepatotoxicity was 0.6%, 1.0%, and 3.4%, respectively. No case met laboratory criteria for potential Hy’s Law (ALT/AST ≥3 x ULN and TBL ≥2 x ULN). Malignancy occurred in one patient (thyroid cancer). No venous thromboembolism (VTE) or major adverse cardiovascular event (MACE) were reported during the study observation period (Table 1). In the effectiveness analysis at Week 24, the proportions of patients achieving remission/ low disease activity were 66.6% (235/353) for DAS28-CRP, 64.6% (228/353) for SDAI, and 63.5% (242/381) for CDAI (Figure 1).

Conclusion: In conclusion, the safety and effectiveness profile of baricitinib in this Chinese PMSS was generally similar to that in the global RA population with no VTEs or MACE reported and no new safety signals.

BARICITINIB AS MONOTHERAPY FOR TREATMENT OF RHEUMATOID ARTHRITIS: SUMMARY OF DATA FROM FIVE REAL-WORLD DATA SOURCES

**Keywords:** Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Real-world evidence

**Background:** EULAR recommendations suggest that use of interleukin-6 inhibitors and Janus kinase (JAK) inhibitors are preferred in rheumatoid arthritis (RA) when combination therapy with conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) is not indicated due to intolerance of csDMARDs. Monotherapy data for the JAK1/JAK2 inhibitor baricitinib (BARI) in patients with inadequate response to csDMARDs or biologic DMARDs (bDMARDs) are limited.

**Objectives:** To present an overview of baseline characteristics and effectiveness outcomes for patients with moderate-to-severe RA receiving BARI as monotherapy and combination therapy for up to 1 year in real world European settings.

**Methods:** BARI-related real-world data from available European registries, long-term observational studies and retrospective chart review, obtained from published sources or investigators, were reviewed. Baseline and effectiveness data, separately from each source, were reviewed for patients who received BARI as monotherapy and for those receiving BARI in combination with csDMARDs with findings presented descriptively as mean ± standard deviation (SD) or number (%) of patients. No statistical modelling was applied. Disease activity score for 28-joint low disease activity (LDA) and remission data were collected from ORBIT-RA, RSBR-RA and the Erlangen Baricitinib cohort; and Clinical Disease Activity Index (CDAI) LDA and remission data were collected in RA-BE-REAL, ORBIT-RA and SCQM-RA.

**Results:** In BARI cohorts, monotherapy was used by 51.0% of patients in RA-BE-REAL, 61.5% in ORBIT-RA, 60.1% in SCQM-RA, 39.4% in BSRBR-RA and 67.6% in the Erlangen Baricitinib cohort. Across all databases, most patients were female, and in general, patients who received BARI as monotherapy appeared to be older, with a longer disease duration and numerically larger likelihood of previous treatment with a bDMARD than those who received the drug in combination (Table 1). Available LDA and remission rates from patients with data in the different databases are shown in the Figure 1; 40.7–78.4% of patients receiving BARI monotherapy and 33.3–80.8% receiving BARI in combination achieved either LDA or remission states at 1 year.

**Conclusion:** Approximately 40–78% of patients achieved LDA or remission after up to 1 year of monotherapy across the different data sources and populations with RA, although the numbers of patients with data up to 1 year were small for most registries. These findings suggest that BARI monotherapy is a suitable treatment option for patients with RA.

For RA-BE-REAL, BSRBR and SCQM-RA, this was treatment at baseline; for the Erlangen Baricitinib cohort this was treatment before or at baseline DMARD, biologic disease-modifying anti-rheumatic drug; Combi, combination; MTX, methotrexate; NR, not reported; SD, standard deviation.
Background: The use of JAK inhibitors (JAKi) may be challenged in rheumatoid arthritis (RA) by the multiplicity of previous treatment lines and the presence of comorbidities that may trigger the occurrence of potentially severe side effects.

Objectives: To assess the efficacy and safety profile of JAKi in active RA patients with refractory disease and/or risk factors for JAKI.

Methods: Retrospective routine care study carried out between 2018 and 2022 in the Rheumatology department of Cochin Hospital. We selected from our electronic medical report database RA patients initiating a JAKi between 2018 and 2021 who presented active disease (i.e. by a DAS28 >3.2) and at least one of the following criteria: age ≥65 years, presence of comorbidities (cardiovascular risk factors including active smoking, obesity, atherosclerotic cardiovascular (CV) disease, history of venous thromboembolism (VTE), previous malignancy, severe infection including herpes zoster), failure to at least two targeted biological therapies and inability to taper corticosteroids below 7.5 mg/day. Efficacy was assessed at the first visit following the initiation of treatment and at the last available visit up to December 2022. The number and causes of treatment discontinuations were collected during the exposition period.

Results: We included 83 RA (68 females, 82%) initiating a JAKi, with a mean age of 59.4±14 years and a mean disease duration of 16±3 years. Patients had a mean DAS28 of 4.60±1.42, they had received 3±2 previous lines of biologics, 63% belonged to the group “age ≥65 years and/or presence of at least one CV risk factor” and 20% received corticosteroids ≥7.5 mg/day. The first visit treatment was scheduled 3 or 6 months following JAKi initiation, and the last visit occurred 15±10 months after the baseline visit. The DAS28 and other parameters assessing disease activity were markedly reduced at the first and the last available visit compared to the baseline visit (Table 1). Low disease activity (DAS28 <3.2) was reached in 51% of patients at the first visit and 47% at the last visit. No difference of efficacy was observed according to the treatment line. A total of 35 patients (42%) discontinued the JAKi during a mean observation period of 20±10 months (Figure 1). The mean time to discontinuation was 10±8 months. Treatment retention was 70% at 12 months and 58% at the last visit. Discontinuations were related to inefficacy (n=21, 25%), side effects (n=11, 13%) and desire for pregnancy (n=3, 4%). The side effects leading to discontinuation were: VTE (n=2), myocardial infarction (n=2) (these 4 events occurred in the group of patients aged ≥65 years with or without presence of at least one CV risk factor), non-severe infections (n=2), allergy (n=2), gastrointestinal symptoms (n=2) and headache (n=1). No cancer was recorded during the observation period.

Conclusion: In a population of RA enriched with refractory and at-risk-comorbid RA patients, JAKi demonstrated potent efficacy with a safety profile consistent with this population. Our results support the statement from the PRAC to use with caution JAKi in patients aged ≥65 years and/or with at least one CV risk factor.
BACKGROUND: The use of molecular targeted therapies has improved the clinical course and quality of life of patients with rheumatoid arthritis (RA); however, a percentage of patients experience treatment failure in the clinical course and quality of life of patients with rheumatoid arthritis.

Methods: The study is a collaborative international cross-sectional retrospective study involving RA patients on treatment with biologics or Janus kinase inhibitors (JAKi) attending Hokkaido University Hospital (Japan) or Hospital Virgen de las Nieves, Department of Rheumatology, Granada, Spain.

Results: One-hundred-twenty-four Japanese RA patients, 100 females, median age at entry 66 yrs [IQR 54-72], median disease duration 12 yrs [IQR 7-20] were included. One-hundred-seven (86%) patients were on biologics and 17 (14%) on JAKi, median treatment duration of 4 yrs [IQR 1-7]. Concomitant treatment with conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) and glucocorticoids were reported in 84% and 53% of patients, respectively. Ninety-six (77%) patients were responders to treatment defined as disease activity score 28 (DAS28)-ESR <3.2 and DAS28-28CRP <2.7. All patients had food consumption in the last month and 82% reported intake of n-3 PUFAs from fish (fatty fish) (<1 time/week 33%, 21 time/week 49%). A higher estimated daily intake of n-3 PUFAs from fish was found in the responder group compared to the non-responder group [median grams, 1.01 (IQR 0.47-1.44) vs 0.51 (IQR 0.34-1.14), p<0.044]. The Spanish cohort comprised of 62 RA patients, 47 females, median age at entry 58 yrs [IQR 49-66], median disease duration 12 yrs [IQR 5-21]. Fifty-nine (95%) patients were on biologic therapies and three (5%) on JAKi, median treatment duration of 3 yrs [IQR 1-8]. Concomitant treatment with csDMARDs and glucocorticoids were reported in 38% and 42% of patients, respectively. Thirty-four (55%) patients were responders to treatment. All patients had consumption of fish in the last month and 77% had consumed fatty fish (<1 time/week 31%, ≥1 time/week 46%). No difference in estimated intake of n-3 PUFAs from fish was observed in this cohort.

Conclusion: Fish consumption may have a positive effect on the response to treatment of Japanese RA patients receiving targeted therapy.

</table>
Of the 88 patients who discontinued a JAK inhibitor, 86% were female and 14% male. Median age was 60 years (IQR 53-70 years), and median duration of drug intake was 45.60 weeks (IQR 19.29-74.07). Of these 88 patients, 77% were Caucasian, 20% from the Indian subcontinent, and the remaining patients mixed race, Asian other, and not stated. Furthermore, 65.9% of patients were on concomitant DMARDs, 71.6% had received a previous biologic drug (median number of previous biologics was 1 [0-2]). Diagnosis was seropositive RA (rheumatoid arthritis) in 59.1%, seronegative RA in 27.3%, PsA (psoriatic arthritis) in 11.4%, and 2.2% in RA/PsA overlap. Of the 88 patients where the JAK inhibitor was discontinued, reasons included primary inefficacy 37.5%, toxic adverse events 35.2%, non-toxic reasons 17.05%, secondary inefficacy 5.68%, disease remission 1.14%, and not stated 3.41%. Adverse events of interest included viral infections 6.81%, non-viral infections 4.54%, malignancy 2.27%, and MHRA alerts 9.09%. In this multi-ethnic population, the most common reasons for discontinuation were primary inefficacy and toxic adverse events, although patients are screened for risk factors prior to commencement, and MHRA alerts led to discontinuation if risk factors developed during treatment.

Conclusion: In this real-world population, tofacitinib followed by baricitinib had the highest discontinuation rates. While discontinuation rates for the 2nd generation JAK inhibitor appear more promising, patient numbers were lower. The most common reasons for discontinuation were primary inefficacy and toxic adverse events. Further real-world observational data is needed, particularly from multi-ethnic patient populations, to increase confidence levels in JAK inhibitor prescribing.

Background: There is no consensus among rheumatologists on giving local anesthesia to the overlying skin prior to an intra-articular injection of glucocorticoid.

Objectives: Compare procedural pain in intra-articular injection between using local anesthesia to overlying skin or not.

Methods: Open label randomized controlled trial included patients with rheumatoid arthritis or spondyloarthritis undergoing intra-articular injections (of glucocorticoid) to paired medium-large joints. First the left joint was injected followed by right joint after a gap of 10-minutes. Randomization was done by online software using serial permuted blocks of varying sizes (4, 6 and 8) whether local anesthesia (5 ml of 2% Lignocaine using a 23G needle) would be given to the left or right joint. Primary endpoint was immediate procedural pain felt by the patient using the Numerical Rating Scale and Faces Pain Scale-Revised. Secondary endpoints were 1-hour pain assessment, patient preference and complications. Paired t-test and Wilcoxon Signed Ranked test was used (paired data). Trial#CTRI/2021/07/034777

Results: This study included 42 patients undergoing paired joint injections (84 joints); joints were knee (21 patients. 42 joints), wrists (14 patients, 28 joints), ankles (5 patients, 10 joints) and elbows (2 patients, 4 joints). In 21 patients, the left joint was given local anesthesia and in the other 21 patients, the right joint was given local anesthesia. Most had rheumatoid arthritis (37) and minority had spondyloarthritis [5]. Their mean age (±SD) was 44.6 ± 14 years and 71% were females. There was a significantly lower immediate procedural pain in the joint over which the skin was given local anesthesia compared to that not (4.7 (1.7), 5.6 (1.6), p=0.01, difference -1.1, 95% CI -1.5 to -0.7) (Table 1, Figure 1A). There was no difference in complications of hypopigmentation or purpura nor in residual pain prick-site at 1-month.

Conclusion: Local anesthesia of the overlying skin led to a definite but modest reduction in pain felt by the patient during intraarticular injection.

Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 4. Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

Background: Interleukin (IL)-2 is a key cytokine for tipping the balance of Treg and effector T cells, which can effectively relieve rheumatoid arthritis (RA).

Objectives: This study aimed to systematically evaluate the efficacy and safety of low-dose IL-2 therapy in RA.

Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM, and Technology Journal Database were performed. Original case reports, case series, observational studies, and clinical trials reporting the efficacy or safety data on RA patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I² and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

Results: Thirteen studies comprising 1161 patients were identified (Table 1). After the low-dose IL-2 treatment, there were significant decreases in diseases activity measures such as DAS28 (SMD= -2.631, 95% CI (-3.526,-1.737), P<0.001; SJC(SMD=-1.966, 95% CI (-1.497,-0.464), P<0.001; TJC(SMD= -1.032, 95% CI (-1.585,-0.487), P<0.001), and CRP (SMD= -0.824, 95% CI (-0.997,-0.652), P<0.001). The values of BUN were increased and the values of Cr was no statistical differences. The value of ALT was increased while the value of AST was decreased. Blood cell counts such as WBC, PLT and LY were significantly increased and RBC was no statistical difference. Meanwhile, the value of Hb was also no statistical difference (Figure 1). Besides, the numbers of CD4+T cells, CD8+T cells, Th1 cells, Th2 cells, Th17 cells and Tregs were significantly increased after IL-2 injection (SMD= 0.819, 95%CI (0.692,0.946), P<0.001; SMD= 0.388, 95%CI (0.222,0.554), P<0.001; SMD= 0.634, 95%CI (0.436,0.832), P<0.001; SMD= 0.521, 95%CI (0.366,0.676), P<0.001; SMD= 0.626, 95%CI (0.475,0.776), P<0.001; SMD= 1.177, 95%CI (0.941,1.412), P<0.001), while there were no statistical differences in the number of NK cells after IL-2 treatment. Importantly, the ratio of Th17/Tregs was significantly decreased(SMD= -0.700, 95% CI (-0.852,-0.549), P<0.001) and the ratio of Th1/Th2 was no statistical difference (Figure 2).

Figure 1. meta-analysis of less mean FVC decrement in RA-ILD patients treated with anti-fibrotic drugs.

Figure 2. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I² and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

AB0466 IDENTIFICATION OF POTENTIAL BLOOD BIOMARKERS FOR JAK INHIBITOR TREATMENT-RELATED PATHWAYS THROUGH BULK RNA SEQUENCING ANALYSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Genetics/epigenetics, Targeted synthetic drugs

H. H. Chen1, T. M. Ko2. 1Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 2National Yang Ming Chiao Tung University, Department of Biological Science and Technology, Hsinchu, Taiwan, Republic of China

Background: Targeted small molecule therapy that inhibits receptor-mediated signaling via Janus kinase (JAK)–signal transducer and activator of transcription (STAT) pathways has become an established strategy for the treatment of rheumatoid arthritis (RA). The rationale for using these inhibitors is that JAKs have critical roles in specific pathological mechanisms and thus their targeted inhibition can lead to effective disease control. Despite JAK inhibitors (JAKi) having been approved for the treatment of RA and other systemic or organ-specific autoimmune diseases, the DAS28 response to JAKi is highly variable, emphasizing the need for reliable biomarkers.

Objectives: To reveal the potential impact of JAKi on treating RA patients, we aim to identify the biomarkers related to the responses of JAKi from blood bulk RNA-seq.
Methods: To better understand the molecular mechanisms of JAKI, we analyzed the global transcriptomics profile (using bulk RNA-seq) in peripheral blood mononuclear cells (PBMCs) that were collected from three RA patients before and after the treatment of JAK.

Results: Comparing the responder and non-responder groups, we identified 1366 upregulated differentially expressed genes (DEGs) and 1630 DEGs. To reveal further insight into the biological roles of the DEGs, we performed GO pathway analysis. Compared with responders, we found that the non-responders have a higher inflammation rate. In addition, non-responders have higher expression of genes that are involved in the JAKs signaling pathway. Specifically, gene profiling of non-responder represents higher Type I and II interferon pathway. In contrast, gene profiling of the responder represents a higher IL-12 pathway.

Conclusion: These changes were accompanied by changes in broader immune cell composition, based on the deconvolution of bulk RNA-sequencing data. In summary, our study revealed several phenotypic and cellular changes that underlie the clinical improvement with JAKI.

Background: Tofacitinib, baricitinib, upadacitinib and filgotinib are the Janus kinase inhibitors (JAKi) approved for the treatment of rheumatoid arthritis (RA) in the UK. We report our real-world experience in a cohort of RA patients commenced on JAKi in a regional centre in the UK.

Objectives: To study drug retention rates and adverse events of JAKi in RA patients in the real-world scenario.

Methods: Data of patients with RA initiated on JAKi from February 2018 to August 2022 were retrospectively collected from hospital and primary care records. Kaplan-Meier curve was plotted for the cumulative drug retention rate. Crude event rates for various adverse events were calculated per 100 patient-years. Hazard ratios were calculated for adverse events for tofacitinib vs baricitinib after adjusting for baseline variability using inverse probability of treatment weighting (IPTW). Statistical analysis was done using R studio.

Results: During the study period 356 patients were initiated on JAKi (Baricitinib: 266, Tofacitinib: 48, Upadacitinib: 33 and Filgotinib: 9). Baseline characteristics of patients are given in Table 1. Over 734.6 patient-years follow up 92 (25.6%) discontinued JAKi. Drug retention rate at 2 years, 3 years and 4 years was 74.2%, 67.5% and 61.5% respectively (Figure 1). Most common reason for discontinuation was lack/loss of response (42.3%). Infections led to discontinuation in 13 patients and cardiovascular events in 5 patients. Lymphopenia, rash, oral ulcer, anemia, weight gain, high cholesterol, diverticulitis, and lymphedema were the other adverse events which resulted in discontinuation. Ten patients died while on treatment with JAKi. Six patients had a major adverse cardiovascular event (MACCE) - 4 acute coronary events and 2 strokes. Nine patients had a venous thromboembolic event (VTE) while one patient had central retinal artery occlusion. Event rates for MACCE and VTE were 0.8(0.3-1.7) and 1.2(0.5-2.3) respectively. Herpes zoster (HZ) occurred in 13 patients with an event rate of 1.8(1.0-3.1). Incident malignancies were noted in 14 patients on JAKi. Event rate was 1.1(0.5-2.2) for malignancies excluding 6 non-melanoma skin cancers. There were no statistically significant differences in the incidence of adverse events between tofacitinib and baricitinib. Hazard ratios for discontinuation, MACE, Pulmonary embolism, HZ, and malignancy were 0.7 (0.4-1.4), 2.0 (0.3-10.8), 0.8(0.2-3.3) and 1.2(0.3-5.0) respectively for tofacitinib compared to baricitinib. Upadacitinib and filgotinib had shorter follow up duration to draw any meaningful conclusion.

Conclusion: JAKi in this real-world population of RA patients had high persistence rates. MACE, VTE, HZ and infections remain adverse events of concern.

Background: Many studies have reported the reduction or discontinuation of biologics in the treatment of rheumatoid arthritis (RA). In contrast, studies on tapering methotrexate (MTX) have been limited [1,2]. We prospectively reported whether bone destruction will progress at 48 weeks after tapering or discontinuing MTX in 79 RA patients in this meeting[3]. 34 patients (total 113 patients) were added for further analysis.

Objectives: According to tapering response, predictors for successful tapering MTX and progression of bone destruction were determined.

Methods: The subjects were RA patients who had maintained low disease activity or lower for 24 weeks or more in DAS28-CRP after MTX administration. Patients having PUDS Grade 2 or 3 per site by bilateral hand ultrasonography (26 areas) were excluded in this study owing to risk for joint destruction. Tapering of MTX dose was done every 2-3 months based on “shared decision between the patient and doctor.” The joint destruction was evaluated by joint X-ray evaluation by modified total Sharp scoring (mTSS) at 1 year after the start of methotrexate treatment.
of tapering MTX. Evaluation of clinical disease activity, severe adverse events, and the continuation rate during MTX tapering were also evaluated. According to tapering response, predictors for successful tapering MTX and progression of bone destruction were determined. Statistical analysis was performed by t-test, Mann-Whitney U test or one-way analysis of variance using EZR ver 1.37[4].

Results: Patients’ demographic data were as follows, mean age:60.8 yrs, female: 88 pts:25pts, disease duration: 66.1 months, mean MTX dose: 8.51mg/week, mean DAS28-CRP: 1.55, ACPA:179.9 U/ml, ACPA positive(%): 72.6, RF: 48.1 IU/ml, RF(%):48.1, mean mTSS:176, ΔmTSS=1-8.8% (10 cases) According to previous report, 113 RA patients were divided into three groups; Flared (F) group (22 patients), Less tapering (L), Good tapering (G) group (54 patients). As shown in Table 1A, significant differences were observed among the three groups in MTX dose at 6M(F vs G, P<0.01, L vs G, P<0.01), MTX dose at 12M(F vs L, P=0.01, F vs G, P<0.01, L vs G <0.01) and ΔmTSS/y(P<0.01), CDAI, SDAI, doctor VAS at 12M(P<0.01), MMP3 at 12M(P<0.05). Severe adverse events; cancer(stomach, lung) 2, MTX associated lymphoma(brain) 1, pneumoniae 1 . These results indicated baseline mTSS may be a predictor for flare and flare response may be a predictor for joint destruction. Baseline CDAI may be a predictor for good response.

Conclusion: Baseline mTSS may be a predictor for flare and flare response. Baseline CDAI may also be a predictor for good response.

**EFFECT OF TOFACITINIB IN MODULATING PLATELET FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Safety, Targeted synthetic drugs

**D. Mauro1, D. Iacono1, I. Pantano1, M. Raimondi1, M. L. Marchesano1, F. Riccio1, A. Pellegrino1, V. Liakouli1, F. Ciccia1.** University of Campania L. Vanvitelli, Rheumatology Unit, Department of Precision Medicine, Naples, Italy

**Background:** Recent data suggested an association between Tofacitinib treatment and increased cardiovascular events in patients with Rheumatoid arthritis. Janus Kinase inhibitors (JAKi), specifically JAK3, have been demonstrated to be one of the regulators of platelet function. Treating platelets with thrombin induces tyrosine phosphorylation of the JAK3 target substrates STAT1 and STAT3, and JAK3 deficiency in mice aggravates inflammation and improves event-free survival in thromboplastin-induced thromboembolism.

**Objectives:** This study aimed to study the ability of the JAK1/JAK3 inhibitor, Tofacitinib, to influence platelet activity in patients with Rheumatoid Arthritis.

**Methods:** We enrolled patients with a diagnosis of RA according to the ACR/EULAR 2010 ACR/EULAR criteria. Peripheral blood was obtained from RA patients at the baseline and after 1, 3, and 6 months of Tofacitinib therapy. Platelet aggregation assay was performed by optical aggregometry stimulated with the thromboxane A2 receptor in RA patients and controls. The aggregation test was performed before starting the therapy with Tofacitinib and after one month, three months and six months.

**Results:** 35 RA patients treated with Tofacitinib were recruited, 86% female and 14% male, with a mean age of 56.5 years (SD 9.7 yrs.), mean disease duration 16.3 years, mean ESR 28.2 mm, mean CRP 0.9 mg/dl, mean SDAI 18.2 and mean prednisone equivalent dose 3.75 mg/die. 78% of the patients were positive for Rheumatoid factor and 57.1% for ACPA. Looking at the classical risk factors, 35.7% had hypertension, 21.4% had hypercholesterolemia, 16.2% had diabetes, and 14.2% were smokers.; only one patient had a previous cardiovascular event. The platelet aggregation was not influenced by Tofacitinib treatment at any time point (T1, T3 and T6) at any Thromboxane dose (5uM and 20 uM), furthermore did not differ from patients and controls basally (64%, SD 15.84% vs 62%, SD 10.5%).

**Conclusion:** In conclusion, Tofacitinib does not increase platelet aggregation in patients treated for Rheumatoid Arthritis.

a biochemical adherence guided intervention is superior to standard clinical care in RA patients prescribed MTX.

**Methods:** RA patients prescribed oral MTX for ≥ two years were randomised 1:1 to receive biochemical adherence biofeedback or control. Clinico-demographics, biochemical MTX adherence and DAS-28 were measured at baseline and three months. Participants in the intervention cohort were telephoned with their biochemical adherence results and adherence was explored. The semi-structured interviews were used to evaluate a sample of patient perspectives about and engagement with the intervention. Pre-treatment DAS-28 scores were recorded in 53 (36.6%) with a mean score of 5.07. DAS-28 scores following commencement of filgotinib were recorded in 57 (82.8%) patients.

**Results:** 57 trial participants were recruited, withdrawal rate was 14% and reasons given were intercurrent illness, lost contact, withdrawn consent and one patient died during follow-up leaving full outcome data available for 49 participants. A total of nine semi-structured interviews were recorded and analysed in the qualitative arm of the study. The themes from the interviews were grouped in relation to the core concepts of normalisation process theory, these were: coherence, cognitive participation, collective action, reflexive monitoring. Density mapping of the themes suggested that comprehension of the study purpose might have been limited. However, there were high levels of reflexive monitoring and most of the reflections were of a positive nature. Additionally, the intensity of data relating to cognitive participation and collective action suggest that participants were fully engaged in the trial and were supportive of the intervention and trial process.

**Conclusion:** The results of the MIRA trial have demonstrated that the use of a biochemical adherence blood test with biofeedback is feasible as part of a clinical trial. Qualitative findings suggested that participants reported that they were happy to take part in the trial. In contrast to expectations, participants were happy to have their MTX adherence monitored.

**AB0472**

**FILGOTINIB FOR RHEUMATOID ARTHRITIS - AN OBSERVATIONAL STUDY TO ASSESS CLINICAL EFFECTIVENESS IN NHS LoTHIAN**

**Keywords:** Real-world evidence, Targeted synthetic drugs, Rheumatoid arthritis

**C. Box1, E. Swann1, H. Harris1, N. McKay1. Western General Hospital, Rheumatic Diseases Unit, Edinburgh, United Kingdom

**Background:** Filgotinib (Jysela) is a Janus-kinase (JAK) inhibitor which in 2021 was approved for use in the UK in moderate or severe rheumatoid arthritis (RA) either as monotherapy or in combination with Methotrexate. A reduced dose of 100mg is recommended for patients aged 75 years or over, or with moderate or severe renal impairment. Clinical efficacy of filgotinib alongside a conventional disease-modifying anti- rheumatic drug (CDMARD) was demonstrated in the FINCH 1 and FINCH 2 trials [1,2] but evidence of real-world effectiveness is currently limited.

**Objectives:** To describe a cohort of patients prescribed filgotinib (Jysela) for RA in NHS Lothian and assess clinical response and discontinuation rates in regular clinical practice.

**Methods:** The electronic patient record was reviewed for patients prescribed filgotinib in NHS Lothian between December 2021 and August 2022. Baseline data was recorded including time since diagnosis of RA, previous and concurrent treatment, duration of treatment with filgotinib and discontinuation reason if applicable. Comorbidities of intestinal lung disease (ILD), prior venous thromboembolism (VTE), major adverse cardiovascular events (MACE) or malignancy were recorded. Steroid prescriptions at the time of commencing filgotinib were recorded. DAS-28 scores within 6 months prior to starting filgotinib were recorded where they had been performed, along with most recent DAS-28 scores.

**Results:** 145 patients were prescribed filgotinib for RA; 106 females and 39 males. Median age was 64 years. Median treatment duration was 213 days. 35 (24.1%) patients were treated with the reduced 100mg dose. 14 (9.7%) discontinued treatment. 120 (82.8%) were previously treated with an alternative biologic DMARD. 59 (40.7%) had failed multiple biologic DMARDs of different classes (19 (13.1%) acitretin from a Janus-kinase (JAK) inhibitor. Pre-treatment DAS-28 scores were recorded in 53 (36.6%), with a mean score of 5.07. DAS-28 scores following commencement of filgotinib were recorded in 29 (20.0%), with a mean score of 3.50. Pre-treatment tender (TJC) and swollen (SJC) joint counts were recorded in 86 (59.3%), with mean TJC 10.35 and SJC 6.50. Post-treatment counts were recorded in 46 (31.7%), with mean TJC 4.65 and SJC 2.91. Pre-treatment patient visual assessment score (VAS) of global health was recorded in 71 (49.0%), with mean VAS 62. Post-treatment VAS was recorded in 32 (22.1%), with mean VAS 43. 12 (8.3%) patients had DAS-28 scores recorded before and after. 7 were classed as a good response by EULAR criteria, 2 were a moderate response, and 3 were non-responders.

**Conclusion:** The drug survival rate of 90.3% after efficacy assessment at clinical review suggests a good tolerance, patient acceptability and clinical effectiveness. This Edinburgh-based, real-world, unselected patient cohort includes a high rate of multidrug-resistant RA yet sustains a high drug survival rate at 6 months. The cohort is limited by the lack of accurate DAS-28 recording in the clinical record. This may in part reflect the Lothian model of treating imagingConfirmed synovitis in the absence of a DAS-28 result.

**THE EFFICACY OF METHOTREXATE MONOTHERAPY STRATEGY CHOSEN AS FIRST-LINE DMARD THERAPY IN PATIENTS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS: RETROSPECTIVE EVALUATION OF SINGLE TERTIARY CENTER EXPERIENCE**

**Keywords:** Remission, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

**N. Erdik1, C. Arslanlık Güneyşi1, S. M. Türk1, G. Yavuzel1, D. Karatas1, M. Kalıcık Unan1, E. Günöl1, Sakarya University, Rheumatology, Sakarya, Turkey

**Background:** Rheumatoid Arthritis (RA) is a chronic systemic disease in which immunologically mediated inflammation of synovia-lined joints can disrupt joint structure and function. Methotrexate is the first recommended conventional disease-modifying antirheumatic drugs (DMARD) when diagnosed in patients with RA. The goal of treatment is to achieve low disease activity or remission (1).

**Objectives:** It was aimed to retrospectively evaluate the response of patients who received methotrexate (MTX) monotherapy as a first-line DMARD strategy in newly diagnosed RA patients.

**Methods:** Between January 2018-September 2022, 642 patients diagnosed with RA in the Department of Internal Medicine Rheumatology of Sakarya University were retrospectively analyzed. All patients fulfilled the criteria for the 2010 Rheumatoid arthritis classification. Patients with newly diagnosed RA and obtaining MTX monotherapy as the first conventional DMARD strategy were included in the study. Patients diagnosed in another center and initially started conventional DMARD combination therapy were excluded from the study. Patients who discontinued treatment due to side effects were excluded and 73 were included in the analysis age, sex, disease-modifying antirheumatic factor and anticitrulized peptide antibody levels of the patients were recorded. Disease activity was evaluated at 0-3-6 months with the Disease Activity Score Calculator for Rheumatoid Arthritis (DAS-28). Data were analyzed using the computer program SPSS 21. Wilcoxon Signed Rank test and Friedman test were used from non-parametric tests. p<0.05 was considered statistically significant.

**Results:** The mean age of the patients was 54.8±11.65 years. Before MTX treatment, 27 (37.0%) patients had moderate DAS-28 scores and 46 (63.0%) patients had high disease activity. In the third months after MTX treatment, 44 (60.3%) patients were in remission or low disease activity, and 29 (39.7%) patients were moderate or high disease activity. In the sixth months after MTX treatment, 61 (83.6%) patients were in remission or low disease activity, and 12 (16.4%) patients were moderate or high disease activity (Table 1). The median DAS-28 score of the patients before MTX treatment was 5.51 (min-max: 3.49-7.77), the median score of the third months after treatment was 2.86 (min-max: 0.77-5.63) and the sixth months after treatment was 2.33 (min-max: 0.77-5.24). A significant improvement was observed in the DAS-28 score evaluated during the
treatment (p<0.001). When the patients were divided into two groups, seronegative and seropositive, DAS-28 scores were found to be significantly decreased after treatment in both groups.

### Table 1. Disease activity rates before and after treatment.

Conclusion: Methotrexate is the first recommended conventional DMARD when diagnosed in patients with rheumatoid arthritis. However, clinical practice for monotherapy or combination use is quite heterogeneous. In this study, it was shown that the efficacy of MTX monotherapy was high in patients who were planned as the first conventional DMARD strategy, and the rate of patients who achieved the goal the sixth months increased.

### AB0474 REAL-WORLD SINGLE CENTER USE OF UPADACITINIB IN RHEUMATOID ARTHRITIS PATIENTS, INCLUDING THOSE REFRACTORY TO FIRST-GENERATION JAK INHIBITORS

**Keywords:** Rheumatoid arthritis, Targeted synthetic drugs, Real-world evidence

Ikoma City Hospital, Orthopaedic Surgery, Ikoma-city, Japan; Nara Hospital, Kindai University, Orthopaedic Surgery, Ikoma-city, Japan

**Background:** In practice, bDMARDs and subsequent first-generation JAK inhibitors (JAKi) have significantly improved the management of rheumatoid arthritis (RA), but there are still patients refractory or intolerant to multiple biologic DMARDs. The fact that first-generation JAKi inhibit more than one JAK molecule has given rise to hopes that second-generation JAKi with enhanced kinase selectivity may maximize efficacy and enable a safer profile. Although some Japanese patients taper off UPA due to their light weight, advanced age, or complications, more than 60% of patients maintained efficacy with UPA at 7.5 mg/day or less, suggesting that taper-off is feasible. After disease activity decreased, tapering or discontinuation of concomitant MTX was prioritized, but there were no cases of apparent flares, again confirming the efficacy of UPA alone. In addition to the long-term safety of UPA, head-to-head between JAKi and bDMARDs should be considered in the future.

### AB0475 TRANSCRANIAL DIRECT CURRENT STIMULATION DECREASES CHRONIC PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS: A RANDOMIZED, CONTROLLED, DOUBLE-BLIND CLINICAL TRIAL

**Keywords:** Rheumatoid arthritis, Pain

Doenças Autoimunes, Serviço de Reumatologia, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; HCPA, Laboratório de Doenças Autoimunes, Serviço de Reumatologia, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; HCPA, Laboratório de Dor e Neuromodulação, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; HCPA, Serviço de Pesquisa e Desenvolvimento em Engenharia Biomédica, Porto Alegre, Brazil

**Background:** Rheumatoid Arthritis (RA) patients often present chronic pain that may persist beyond therapeutic control of objective signs of inflammation and may cause significant physical and psychological impairments. Complex mechanisms encompassing peripheral and central sensitization seem to be involved. In fibromyalgia patients, Transcranial Direct Current Stimulation (tDCS) appears to be effective for decreasing chronic pain symptoms.

**Objectives:** To verify the effect of active tDCS on pain and clinical symptoms in RA patients.

**Methods:** This double-blind randomized pilot clinical trial recruited women aged between 18 and 70 years diagnosed with RA and stable (3 months) low inflammatory status (CRP < 10 mg/L, ESR < 20 mm/h, swollen joint count ≤ 1 and persistent pain (VAS-pain > 4cm), from the Rheumatology ambulatory clinic of Hospital de Clínicas de Porto Alegre/Brazil. The patients were randomized into two different groups: active tDCS (A-tDCS) and Sham (S-tDCS). The 20 sessions of tDCS (2mA) were applied at home daily, for 20min, 5 days/week. Main outcome was pain by visual analogue scale (VAS cm) after 4 weeks. Additional evaluations: pressure pain threshold (PPTKg), disease activity (DAS28-CRP), physical function (HAQ-DI), fatigue (FACT-F), central sensitisation (Central Sensitization Inventory - CSI), and safety: The Paired-sample t test, the Wilcoxon test, the T-tests for independent samples, the Mann-Whitney test and the Generalized estimating equations (GEE) were performed using a gamma model were performed (accepted at p<0.05).

**Results:** Twelve patients have completed this pilot study (A-tDCS, n=6 and S-tDCS, n=6). At baseline, there are no differences in clinical features between groups (Table 1). After the 4-week intervention, the time of intervention was associated with changes on VAS-pain (p=0.004). There was between groups a trend towards a statistically significant difference for the A-tDCS group (p=0.05). Both groups had improvement in pain within 6 months and UPA was resumed after a temporary suspension. 2 patients discontinued UPA due to inadequate efficacy and 8 due to adverse events. Adverse events requiring hospitalization were bacterial pneumonia, cutaneous hemorrhage, and sudden death with suspected acute myocardial infarction.

**Conclusion:** UPA was effective in RA patients, including first-generation JAK-resistant patients, with few cases of discontinuation due to inadequate efficacy. Although some Japanese patients taper off UPA due to their light weight, advanced age, or complications, more than 60% of patients maintained efficacy with UPA at 7.5 mg/day or less, suggesting that taper-off is feasible. After disease activity decreased, tapering or discontinuation of concomitant MTX was prioritized, but there were no cases of apparent flares, again confirming the efficacy of UPA alone. In addition to the long-term safety of UPA, head-to-head between JAKi and JAK inhibitors should be considered in the future.

p, Difference value at baseline and after intervention with tDCS (within groups)(p≤0.05)*.

Conclusion: These preliminary findings revealed that daily treatment with tDCS compared to sham stimulation over 4 weeks may improve the chronic pain in RA patients, despite the placebo effect observed for physical function, fatigue, PPT and central sensitization. The intervention was well tolerated. Thus, tDCS appears to be a promising auxiliary tool in the treatment of patients with low-inflammation RA who have chronic pain, but larger and longer studies are needed to confirm this observation and optimize it.

(ii) explore changes in laboratory parameters; (iii) find potential predictive factors associated with response to therapy.

**Methods:** Medical records of consecutive RA patients treated with UPA and referred to three Italian tertiary Centers were prospectively reviewed. Adult patients meeting ACR/EULAR classification criteria for RA were enrolled.

**Results:** Our real-life experience confirms the efficacy in terms of clinical and US improvement as well as displaying a good safety profile. The combination therapy with a conventional immunosuppressants predicts a significantly lower clinical and US improvement, likely reflecting a more severe and aggressive course worthy of ad-hoc and more in-depth investigation. An improvement in the SDAI and DAS28CRP was observed, already from the first month of therapy and has been maintained over time. In conclusion, these results demonstrated the short term efficacy of Upadacitinib 15mg for up to 6 months and providing a prompt improvement of PROs. Even if further studies are needed to clarify those results, these novel findings may provide new insight for the management of UPA treatment in clinical practice.

**FRENCH REAL-LIFE DATA ON THE 18-MONTH EFFECTIVENESS OF TOFACITINIB ACCORDING TO CONCOMITANT USE OF CSA DMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS: INTERIM RESULTS OF THE OBSERVATIONAL STUDY, DeFacTo**

**Keywords:** Targeted synthetic drugs, Real-world evidence, Rheumatoid arthritis

**Abstract:**

Concomitant use of csDMARDs and tofacitinib, an oral JAK inhibitor, is indicated for the treatment of adult patients with moderate to severe active rheumatoid arthritis (RA) for which we have no real-life effectiveness data in a French RA population.

**Objectives:** To describe tofacitinib effectiveness profile according to concomitant use of csDMARD in a French prospective observational study, DeFacTo.

**Methods:** DeFacTo, an ongoing observational study with the primary objective of identifying predictive factors of Tofacitinib maintenance in real-life RA patients. The results described here are based on a descriptive interim analysis of its effectiveness at 18 months.

**Results:** Among 314 pts enrolled in the study, 301 (POP1) were included in this effectiveness analysis, including 274 (POP2) patients with follow-up ≥ 18 months on 03/15/2022 (date of analysis) with a median exposure duration of 538 [Q1; Q3: 381; 554] days. At baseline, among POP2: 168 (POP3) patients were treated with tofacitinib used concomitantly with at least one csDMARDs vs 106 (POP4) tofacitinib monotherapy. In POP3 vs POP4 respectively, 76.8% vs 84.9% were female, with a mean (± SD) age of 59.5 (10.8) vs 59.9 (12.1), median disease duration of 8.6 years [Q1-Q3: 3.2; 18.6] vs 11.1 [Q1-Q3: 5.3; 19.4], 85.3% vs 52.4% patients had erosions, 80.5% vs 76.5% had FR+ and 77.7% vs 75.0% had ACPA+. Median CRP was 7.0 [Q1-Q3: 2.9; 18.0] vs 8.0 [Q1-Q3: 3.0; 18.1], and mean DAS28-4 CRP was 4.4 ± 1.1 vs 4.7 ± 1.0, in POP3 and POP4 respectively. Result showed a decrease in inflammatory markers, pain, and DAS28-CRP activity scores in both groups. At 18 months of follow-up, 24.4% and 24.5% of the pts achieved DAS28-CRP remission in POP3 and POP4 respectively (Table 1).

Note that missing data and treatment discontinuation were considered as failures which resulted in an underestimation of LDA and remission at 18 months.

Rheumatoid arthritis - non biologic treatment and small molecules.

BARCITINIB AND UPADACITINIB AFFECT THE LEVELS OF BONE DESTRUCTION MARKERS AND BONE FORMATION INDICATORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Bone diseases, Disease-modifying drugs (DMARDs)

A. Felis-Giemza1, W. Kurowska2, M. Marecka-Kuzdub1, E. Kuca-Warnawen3, M. Mallasiski4, W. Mallasiski3, 5 National Institute of Geriatrics, Rheumatology and Rehabilitation, Biological Therapy Center, Warsaw, Poland; 6 National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland

Background: Janus kinase inhibitors (JAKis) baricitinib and upadacitinib inhibit the radiographic progression of joint damage in patients with rheumatoid arthritis (RA) [1-3]. Recent findings indicate that treatment with JAKi can lead to the repair of arthritic bone erosions [4]. However, although the immunomodulatory effects of JAKis have been extensively studied in inflammatory diseases, the effects of JAKis on bone metabolism in patients with RA are not fully understood.

Objectives: To investigate the effect of baricitinib and upadacitinib on the levels of bone destruction markers and bone formation indicators in the peripheral blood of patients with RA.

Methods: The study included 14 patients with RA (all women, aged 23–65 years, mean age 47.7 ± 12.4 years) with high disease activity at baseline (median [DAS 28-ESR 5.62, range 3.85–11.50]), and 9 patients (n=5) after 5–6 months of therapy. Peripheral blood samples were collected from patients prior to JAKi treatment, and during therapy with baricitinib 4 mg once daily (n=9) or upadacitinib 15 mg once daily (n=5). Concentrations of C-telopeptide fragments of type I collagen (CTX-I), osteocalcin, Receptor Activator for Nuclear Factor kappa B Ligand (RANKL), and osteoprotegerin (OPG) were measured in plasma by the enzyme-linked immunosorbent assays. Changes in the variables were assessed using paired Student t-test or Wilcoxon matched-pair rank test (depending on the type of data distribution).

Results: The median duration of treatment with JAKi was 12 months (range 7–18 months). Eleven (78.6%) patients were treated for more than 12 months. The effects of JAKis were analyzed in two-time intervals: after 5–6 months of therapy and after 12 months of therapy. The median DAS 28-ESR decreased to 2.83 (range 1.13–7.56, p=0.014) after 5–6 months of therapy, and to 2.53 (range 0.75–7.34, p=0.002) after 12 months of therapy. The concentration of bone turnover marker CTX-I decreased gradually during JAKi treatment from a median pre-treatment level of 247.1 ng/ml (range 50.0–1228.0 ng/ml) to 186.0 ng/ml (range 0.0–394.0 ng/ml) after 5–6 months of therapy, and 76.0 ng/ml (range 0.0–481.0; p=0.031) after 12 months of therapy. Conversely, treatment with JAKi resulted in a gradual increase in the median osteocalcin concentration from a pre-treatment level of 17.0 ng/ml (5.0–370.0 ng/ml) to 24.0 ng/ml (6.92–92.0 ng/ml and 28.6 ng/ml (11.0–43.0 ng/ml) after 5–6 months and 12 months of therapy (p=0.027), respectively. In a subgroup of 6 patients (2 treated with upadacitinib and 4 treated with baricitinib), a decrease in RANKL/OPG concentration ratios were observed after 5–6 months of therapy, and after 12 months of therapy (from pre-treatment median ratio of 0.23, range: 0.09–1.26 to 0.11, range: 0.00–0.87 after therapy; p=0.03). In 5 patients, the RANKL/OPG ratio did not change during treatment with baricitinib or upadacitinib.

Conclusion: The decrease in the concentration of CTX-I, a marker of bone destruction, with a simultaneous increase in the concentration of osteocalcin, a marker of bone formation, and a decrease (at least in a subgroup of patients) in the concentration of RANKL, a stimulator of bone resorption, in relation to its treatment with baricitinib or upadacitinib.

THERAPIES IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Keywords: Clinical Trials, Randomized control trial, Rheumatoid arthritis

Z. Yang1, Q. Liang1, Y. Liang3, M. Wang1,2,3,4,5, R. Huang1,3,4,5, G. Wang1,2,3,4,5, 6 University of Chinese Medicine, The Second Affiliated Hospital, Guangzhou, China; 7 University Medical Center Utrecht, Center for Molecular Medicine, Utrecht, Netherlands; 8 Guangzhou University of Chinese Medicine, Guangdong Provincial Key Laboratory of Clinical Research on Traditional Chinese Medicine Syndrome, Guangzhou, China; 9 Guangzhou University of Chinese Medicine, Guangdong-Hong Kong-Macau Joint lab on Chinese Medicine and Immune Disease Research, Guangzhou, China; 10 The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, State Key Laboratory of Dampness Syndrome of Chinese Medicine, Guangzhou, China

Background: Former findings suggested that MTX-based combination therapies show improved efficacy and safety compared to monotherapy [1]. Several studies [2] have been conducted analysis on MTX-based combination therapies, but there is a lack of systematic analysis involving MTX+TCM (Traditional Chinese medicine) therapies.

Objectives: To assess the effectiveness and adverse events of Methotrexate-based (MTX-based) combination therapies (especially MTX + TCM therapies) in rheumatoid arthritis (RA) treatment.

Methods: A comprehensive search of PubMed, Embase, the Cochrane Library, China National Knowledge Infrastructure (CNKI), the Database for Chinese Technical Periodicals and Wanfang data was done without language restriction. A systematic review and network meta-analysis included randomized controlled trials of MTX-based combination therapies and methotrexate monotherapy. The ability of different regimens to reduce rheumatoid factors and inflammatory indicators and the probability of adverse reactions were compared. This study has been registered with PROSPERO under the number CRD42022265799.

Results: A total of 37 studies, including 3119 patients, were eligible for inclusion. Meta-analysis results showed that methotrexate combined with other DMARDs or Traditional Chinese Medicine (TCM) could reduce serum Rheumatoid Factor (RF) and C-reactive protein (CRP) levels to some extent, but the therapies combined with TCM were more effective and had a lower rate of adverse effects. The results of RF reducing ability were ranked in ascending order: MTX+LEF+TCM > MTX+SSZ+HCQ > MTX+LEF+SSZ+HCQ > MTX+LEF+MTX-TCM > MTX+HCQ > MTX. While the results of CRP reducing ability were ranked in ascending order: MTX+LEF+TCM > MTX+SSZ+HCQ > MTX+LEF+MTX-TCM > MTX+HCQ.

Conclusion: Overall, MTX-based combination therapies are an effective treatment, and the combination of TCM and MTX-based combination therapies is more effective and safer. For treating rheumatoid arthritis or patients with an inadequate response to MTX, MTX-based combination therapies remain an alternative, cost-effective option. To support and validate the potential of TCM and MTX-based combination therapies in treating RA, large-scale, high-quality RCTs should be conducted in the future to provide more accurate and complete data.

DBL 1111
Phase 3 SELECT clinical trial program, UPA has been shown to be effective and well tolerated in patients with RA [2]. However, data on the use of UPA in real-world clinical practice are limited.

Objectives: To evaluate UPA effectiveness in RA patients and to report the main reasons of suspension and the most relevant factor related to treatment persistence.

Methods: In 25 Italian rheumatological referral centers, all RA consecutive patients who received UPA were enrolled. Anamnestic data, treatment history and RA disease activity at baseline were recorded. The 6 and 12 months UPA retention rate was assessed with the Kaplan-Meier curve methods. The Cox analysis investigated the effect of age, sex, smoke habit, ACPA/RF presence, disease duration, DAS28-CRP line of treatment, concomitant csDMARD treatment on UPA retention rate. A p-value < 0.05 was considered statistically significant.

Results: The one-hundred-eleven enrolled patients median age 57 (IQR 50-65 yrs); M:F 28:83; disease duration 78 (IQR 40-170) months. The median observation period was 6.1 (IQR 3.2-10.2) months. The observation lasted 812 patient-months. The majority of patients (54.0%) were in mono-therapy and received steroid (respectively 54.0% and 58.6%) (Table 1). The UPA retention rate at 6, 12 months was, respectively 90.4% and 74.7% (Figure 1). The main discontinuation reason was lack of efficacy (42% of interruptions), cancer onset and infections (both 11%). No thromboembolic events were reported. According to the Cox analysis, no one of the above mentioned parameters were associated to high risk of treatment interruption.

Disclosure of Interests: None Declared.

AB0482 CLINICAL SAFETY AND FEASIBILITY OF A NOVEL IMPLANTABLE NEUROIMMUNE MODULATION DEVICE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Randomized control trial, Non-pharmacological interventions

Background: An urgent need exists for differentiated RA therapies that are safer and cost-effective. A novel neuroimmune modulation device for treating rheumatoid arthritis. The JAK-1 inhibitor filgotinib has been recently licensed for Rheumatoid Arthritis (RA), thus real-world evidence is lacking.

Objectives: The RESET-RA Study (NCT04539964) was designed to determine the safety and feasibility of a novel neuroimmune modulation device for treating rheumatoid arthritis. Presented here are data on the surgical implantation and use of this device in the first 60 human subjects enrolled in the study.

Methods: The RESET-RA study is a randomized, double-blind, sham-controlled, multi-center, two-stage pivotal study to evaluate the safety and efficacy of a novel neuroimmune modulation device in patients with moderate-to-severe RA who are incomplete responders or are intolerant to one or more biologic or targeted synthetic DMARDs. The device system (SetPoint Medical, Valencia, CA) consists of 2 implanted components: a miniature, rechargeable leadless pulse generator that is surgically implanted in the neck on the left vagus nerve and a silicon sleeve referred to as a positioning and orientation device (POD) that holds the generator in close approximation to the nerve. The vocal cord paresis resolved following vocal cord augmentation with injectable filler and speech therapy.

Results: All device implant procedures were completed with no intraoperative complications, infections, or surgical revisions. No unanticipated adverse events (AEs) were reported during the perioperative period and at the end of 12 weeks of follow-up. No study discontinuations were due to AEs, and no subjects died during the study. There were no serious AEs related to the device, stimulation, or explant procedures. There were two serious AEs related to the implant procedure: vocal cord paresis and prolonged hoarseness were reported in two subjects and are known risks of implanting a device on the vagus nerve. The vocal cord paresis resolved following vocal cord augmentation with injectable filler and speech therapy.

Conclusion: Initial results demonstrated that implantation and programming of the device was safe and the surgical procedure and device were well tolerated. Full results from this study, including the clinical efficacy, will be presented after the study is fully enrolled and data is analyzed to determine potential of neuroimmune modulation for treating rheumatoid arthritis.

AB0483 FILGOTINIB IS EFFECTIVE AND SAFE IN RA PATIENTS AFTER FAILURE TO MULTIPLE BDMARDS AND TO OTHER JAK INHIBITORS: DATA FROM A MONOCENTRIC PERSPECTIVE COHORT STUDY

Keywords: Rheumatoid arthritis, Real-world evidence, Targeted synthetic drugs

F. Arru1, M. Zen1, M. Salvato1, F. Vesentini1, K. Botsios1, T. Del Ross1, M. Favaro1, A. Giolo1, A. Doria1

Background: The JAK-1 inhibitor filgotinib has been recently licensed for Rheumatoid Arthritis (RA), thus real-world evidence is lacking.

Methods: In this prospective monocentric study, we included all patients with RA (ACR/EULAR 2010 criteria) regularly followed-up (every 2-6 months), undergoing therapy with filgotinib between 09/2021-01/2023. Disease activity was measured by DAS28-CRP, OARSI, and SDAI; global assessment of patients (Pt) and physician (Ph) were evaluated by DAS28-CRP, OARSI, and SDAI; TJC, SJC, patients (Pt) and physician (Ph) were evaluated by DAS28-CRP, OARSI, and SDAI.

Results: We enrolled 58 RA patients: 33 (62%) on filgotinib monotherapy, 5 (9%) on filgotinib-rich DMARD, 20 (34%) on filgotinib plus concomitant csDMARDs and glucocorticoids (GC), comorbidities, and adverse events (AE) during filgotinib treatment were collected. Discontinuations for inefficacy or AE were recorded.

Conclusion: Among patients with ≥6 months of follow up there was a significant improvement in swollen and tender joint counts, PtGA, PhGA and composite disease activity measures (Table 1). Seventeen patients (57%) achieved DAS28-4.4 and SDAI <10.2. Disease activity was measured by DAS28-4.4, OARSI, and SDAI; global assessment of patients (Pt) and physician (Ph) were evaluated by DAS28-4.4, OARSI, and SDAI. Multifailure patients and those failing a prior JAKi showed a similar DAS28-4.4 response; in addition, multi-failure and filgotinib monotherapy patients reached comparable DAS28-4.4 remission rates (Table 1). Among patients reaching 12 month follow-up, response rates were maintained (Table 1). During filgotinib therapy there was a trend towards a reduction in both GC users and mean GC dose (Table 1).

Overall, 17 patients (29%) experienced ≥1 AE, of whom 2 (3%) were SAE (ILD progression, 1 death due to pneumonia). Six patients (10%) discontinued...

n.c. not calculated; n.s. not significant

 filgotinib: 1 (2%) due to primary inefficacy, 5 for AE/SAE (9%). No cardiovascular events were recorded.

Conclusion: Real-world treatment with filgotinib was associated with clinical improvement and low AE rate. Multi-failure and JAKi experienced patients benefited from filgotinib therapy. In this cohort of RA patients with low prevalence of comorbidities, no MACE or venous thrombotic events were observed.

AB0485 DO JAK INHIBITORS IMPROVE PATIENT FATIGUE IN RHEUMATOID ARTHRITIS? RESULTS FROM A PATIENT SURVEY

Keywords: Inflammatory arthritides, Rheumatoid arthritis, bDMARD

G. Dulay1, L. Gohl1, Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom

Background: Fatigue is a common symptom reported by up to three-quarters of patients with Rheumatoid Arthritis (RA) [1]. There is often no clear correlation between fatigue and RA disease activity [2]. There is a paucity of data on treatment of fatigue in patients with RA [2]. Fatigue remains one of the key unmet needs in patients with RA. Janus Kinase inhibitors (JAKi) are a group of targeted synthetic treatments used in RA with good clinical efficacy data in randomised controlled trials. There is clinical data to suggest that JAKi treatment can improve fatigue in patients with rheumatoid arthritis: a current perspective. Rheumatol Int 2016;36:685–95.

Objectives: The aim was to establish whether fatigue was 'significantly improved' with JAKi treatment. Only patients with a diagnosis of Rheumatoid Arthritis and features or a history of fatigue were included. A second question was incorporated to assess whether any improvement seen was noticed within the first 2 weeks of treatment.

Methods: A simple clinic-based patient survey was undertaken in patients with RA on a JAKi treatment. The first 20 patients with RA and fatigue are included in this sample. The following binary question(s) were asked: 1) Has your fatigue 'significantly improved' on JAKi treatment? 2) If so, was the improvement seen within 2 weeks of starting JAKi treatment? All patients had been on JAKi treatment for at least 12 weeks. The questions were asked prospectively to patients whilst receiving treatment on JAKi treatment for at least 12 weeks.

Results: 13 out of 20 (65%) patients said that their fatigue had 'significantly improved' on JAKi treatment. 7 out of these 13 (54%) patients said that the improvement occurred within 2 weeks of starting JAKi treatment. Out of the 20 patients included in this sample, 11 were on Baricitinib, 5 on Upadacitinib and 4 on Filgotinib. No patients in in this sample were on Tofacitinib. Most frequent AEs with Tofa was urinary tract infections(UTI) (11.9%, 7 cases) and headaches (8.47%, 5 cases). There were 3 cases of herpes zoster (5.1%), one of which was recurrent, and 2 cases respectively of tachycardia and gastrointestinal intolerance (3.4%). With Baricitinib, 2(5%) cases of UTI and 2(5%) of influenza A were reported. Most

Conclusion: Whilst acknowledging the modest sample size and simplicity of our patient survey, our data suggests some benefit of JAKi treatment on fatigue in patients with RA. The benefits seen are broadly in keeping with what is seen in our wider local clinical practice. Our survey suggests that the improvement in fatigue can occur rapidly, with the majority of patients noting improvement within just 2 weeks. More detailed (including qualitative) data would be useful to support these initial findings from this patient survey and explore the role of JAKi treatment on fatigue in patients with RA.

AB0485 SAFETY ANALYSIS OF JAKINIBS IN REAL CLINICAL PRACTICE IN A COHORT OF 116 PATIENTS

Keywords: Safety, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

L. Salvatierra Velasco1, A. Belmonte Mora1, J. Rubio Ubeda2, P. Morales-Garrido3, J. Salvatierra1, E. Eya1, Hospital Universitario Clínico San Cecilio, Reumatología, Granada, Spain

Background: Janus kinase inhibitors (JAKinibs) have demonstrated efficacy in the treatment of rheumatoid arthritis (RA) and spondyloarthritis (SpA), although their safety profile continues to be analysed due to the possible increase in hematological alterations, thromboembolism, increase in neoplasms.

Objectives: To evaluate in real clinical practice the AEs of JAKinibs in a cohort of patients with RA and SpA. In addition, adherence and reasons for discontinuation (1st or 2nd failure, AE) are analysed.

Methods: Observational study of 116 patients diagnosed with RA or SpA who received treatment with JAKinibs (tofacitinib, baricitinib, upadacitinib) after failure of treatment with different classical synthetic (FAMEsc) or biological (FAMEb) disease-modifying drugs. The following data were analysed: demographic characteristics of the patients, years of disease progression, 1st or 2nd failures and AE.

Results: Mean age was 52 years, with Baricitinib being older (60 years -SD 13.6), higher prevalence of females in all groups, and a disease progression time of about 10 years. Mean number of FAMEsc was 1.6 and mean number of FAMEb was 2.3 to Tofacitinib(Tofa), 2.76 to Baricitinib(Bari) and 4.4 to Upadacitinib(Upa). 71 (63%) patients had active corticosteroid therapy. The median treatment time with Tofa was 8.8 months, Bar 9.5 and Upa 2.4 months. Most frequent AEs with Tofa were urinary tract infections(UTI) (11.9%, 7 cases) and headaches (8.47%, 5 cases). There were 3 cases of herpes zoster (5.1%), one of which was recurrent, and 2 cases respectively of tachycardia and gastrointestinal intolerance (3.4%). With Baricitinib, 2(5%) cases of UTI and 2(5%) of influenza A were reported. Most
frequent AEs related to Upadacitinib are gastrointestinal intolerance, labialis and facial herpes, anterior uveitis and recurrent UTI, with 1 case for each adverse event. There were 4 success with Baricitinib treatment: 2 due to severe COVID, 1 influenza A and 1 due to stroke. 17 patients had 1st failure to Tofa(28.81%), 9 to Baricitinib(20.0%) and 3 to Upa(18.75%); 7(11.86%) and 2(5%) patients had 2nd failure to Tofa and Baricitinib respectively, no with Upa. Mean CRP to Tofa-SD 18.9-was 17.19, 20-SD 2.27- to Bar and 24.2-SD 27.40- to Upa. Mean ESR-SD 15.3- was 25.4, -SD 26.4 and 44.3 -SD 32-, respectively. At 6 months, 36(82%) were continuing on Tofa, 22(56%) on Bar and 4(27%) on Upa. At 12 months, 27(46.6%) were still on Tofa and 12 on Bar(30.8%) and no patients were on upa.

**Figure 1.** Months stay pharmaco

**Conclusion:** Most frequent adverse events with JAKinibs are mild infections, except gastrointestinal complaints with upadacitinib. Serious adverse events, including 3 deaths from viral infections, were observed, mostly in patients over 65 years. Most frequent cause of discontinuation was treatment failure. We believe that further observational studies are needed to stratify and profile the risk of infection with JAKinibs.

**Keywords:** Rheumatoid arthritis

W. Lahmar1, M. Slouma2, G. Mohamed3, O. Dhi4, N. Abdedil5, L. Metoui1, R. Drif1, A. Gharasia1, 1Military Teaching Hospital, Rheumatology, Tunis, Tunisia; 2Military Teaching Hospital, Gastroenterology, Tunis, Tunisia; 3University of Tunis El Manar, Internal Medicine, Medecine, Tunis, Tunisia

**Background:** The relationship between hepatic fibrosis and cumulative doses of methotrexate (MTX) in rheumatoid arthritis (RA) patients is an emerging discussion. Hypoalbuminemia is known to be a potential risk factor for toxicity by methotrexate, mainly hematological toxicity and myelosuppression.

**Objectives:** The aim of our study was to investigate the biological associated factors with liver fibrosis in RA patients treated with MTX.

**Methods:** It was a cross-sectional study over nine months [April-December 2021], including RA patients under MTX, recruited from the Rheumatology department of Military Hospital. Liver stiffness was assessed by Fibroscan. Fibrosis and significant liver fibrosis were defined as liver stiffness higher than 6 and 8kPa, respectively. Liver enzymes (AST and ALT), alkaline phosphatase (ALP) and albuminemia were measured. Statistical analyses were performed using SPSS.

**Results:** Sixty-eight patients were included. The mean age was 51.60±11.82 years. The male-to-female ratio was 0.45. The mean disease duration was 8.29 ± 6.48 years. The mean weekly intake of methotrexate was 13.76±3.91mg. The mean cumulative dose was 3508.87±3390.48 mg. The mean values of albuminemia were: 4.50 ± 1.53 kPa. AST (r:0.036, p=0.335) ALT (0.086, p=0.476), nor ALP (r:0.111, p=0.560).

**Conclusion:** Hypoalbuminemia leads to an increase in unbound MTX. It is this fraction that contribute to the development of liver damage. Along with the biological liver function, a particular attention is then needed to serum albumin when treating RA patients with MTX.

Igarashi1, S. Nagaoka1, 1Yokohama Minami Kyousei Hospital, Department of Rheumatology, Yokohama, Japan; 2Saiseikai Yokohamashi Nanbu Hospital, Department of Rheumatology, Yokohama shi Konan ku Konanat1 3-2-10, Japan

**Background:** Peficitinib (PEF) is the third Janus-kinase inhibitor (JAK) approved for rheumatoid arthritis (RA) in Japan. Although PEF has the characteristic action of inhibiting all JAK subtypes, mainly JAK3, in vitro [1,2], there is slightly less variety of clinical studies showing the efficacy of PEF for RA compared with other JAKi; it is necessary to verify the clinical efficacy and safety [3,4].

**Objectives:** To examine the efficacy and safety of PEF for RA and explore the predictive factors related to the discontinuation due to the inadequately effective.

**Methods:** Patients who received PEF for RA at Yokohama Minami Kyousei Hospital and Saiseikai Yokohamashi Nanbu Hospital from July 2019 to December 2022 were included in the study. Patient background, clinical parameters, administration period of PEF, reason for discontinuation of PEF were collected retrospectively from the electronic medical records. All analyses were performed using SPSS. The log-rank test was used to compare continuation rates, and binomial
logistic analysis was used to explore predictive factors related to the discontinuation of PEF due to the inadequate effective.

Results: Fifty-seven patients were included in the study. The mean age at PEF initiation and DAS28-ESR were 75.6 ± 13.3 years old and 4.9 ± 1.3, respectively, and DAS28-ESR was significantly improved by 3.1 ± 1.1 at six months after (p < 0.005). The 1-year continuation rate of PEF among all patients was 42.8 %, and the rate among patients who had not previously used biologics and JAKi (NAIVE) was significantly higher than among those who had previously used them (EXPERIENCE) (Figure 1). Univariate analysis of factors associated with discontinuation of PEF due to inadequate response identified the following factors: younger age at PEF initiation, seropositivity for anti-CCP antibodies (ACPA), and EXPERIENCE (Table 1). Of these factors, multivariate analysis showed significant differences in age at PEF initiation and ACPA seropositivity (Table 1), but no significant differences in persistence rates were found between patients with and without ACPA in sera in this analysis population (1-year continuation rate: 42.9% vs. 76.3%, p = 0.081). There were several limitations in this study as follows; the race of the patients was Japanese only, the study was retrospective, validation by a multiracial prospective study would have been desirable, and the small number of cases may have resulted in the imprecision of statistically significant differences, and further accumulation of cases is desirable.

Conclusion: PEF demonstrated certain effects on the elderly RA population in real-world clinical practice in Japan. This study suggests that patient characteristics that could be expected to be effective, being particularly elderly and ACPA-negative, were suggested, but in addition, patients who had not previously used biologics and JAKi were shown to have a higher continuation rate.

AB0488

COMPARISON OF TWO METHOTREXATE INITIATION STRATEGIES IN RHEUMATOID ARTHRITIS IN CURRENT PRACTICE

Keywords: Treat to target, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

P. Vidal1, M. Thomas2, A. Combier2, A. Steelandt2, J. Narváez3, J. M. Nolla4, Y. Alainore5, J. Avouac6,7, Beilite University Hospital, Rheumatology, L'Hospitalet de Llobregat, Spain; 8Cochin Hospital, Rheumatology, Paris, France

Objectives: To compare the efficacy and tolerance at 3 and 6 months of two methotrexate (MTX) initiation strategies in rheumatoid arthritis (RA).

Methods: Retrospective, monocentric, cross-sectional study including patients with RA who initiated MTX as first-line therapy during the last 2 years according to one of the following 2 strategies: a “classic” strategy defined by an initiation of oral MTX at a dose of 10-15mg/week or an “aggressive” strategy, defined by an initiation of subcutaneous (SC) MTX at a dose of 15mg/week or >15mg/week either orally or SC. Each strategy allowed the possibility to increase the doses and/or switch to the SC route at 3 months. Efficacy was assessed at 3 and 6 months using the DAS28-CRP. The tolerance of each strategy was also assessed at month 3 and 6.

Results: We included 101 patients (85 women) with a mean age of 55±12 years and disease duration of 5±6 months. The frequency of rheumatoid factors, anti-CCP antibodies and erosions was 83%, 81% and 38% respectively. 61 patients initiated MTX according to the “classic” strategy, with an increase of dose and/or a switch to the SC route at 3 months for 31 patients, and 40 patients started treatment according to the “aggressive” strategy, with an increase of dose and/or switch to the SC route at 3 months for 14 patients. There was no difference between these 2 groups in terms of age, gender, disease duration, antibody status, frequency of bone erosions, body mass index, comorbidities and disease activity at baseline. Efficacy at 3 months was significantly higher with the “aggressive” strategy (reduction of the DAS28-CRP from 4.3±3.9 to 2.3±2.7, mean difference of 2.0±1.1, p<0.001) compared to the “classic” strategy (reduction of the DAS28-CRP from 4.0±0.6 to 2.8±0.7, mean difference of 1.2±0.9, p=0.12) (Figure 1). The improvement of tender/swollen joint counts, patient global assessment and CRP levels was also significantly more important at 3 months with the “aggressive” strategy (Table 1). At 6 months, although the DAS28-CRP was similar in the 2 groups (Figure 1), less patients from the “aggressive” strategy subgroup required an escalation to a targeted biologic/synthetic therapy compared to the “classic” strategy (24/40, 60% vs. 16/61, 26%, p=0.021). Only one patient was discontinued because of insufficient response (24/40, 60% vs. 16/61, 26%, p=0.021). The frequency of hepatic cytolysis at month 3 was higher in the aggressive strategy (24/40, 60% vs. 16/61, 26%, p=0.021). The frequency of asthenia at 3 months was similar in both groups (7/40, 18% vs. 6/61, 10%, p=0.25). Only one infection was reported (2/40, 5% vs. 1/61, 1.6%, p=0.057). The frequency of digestive side effects at 3 months was significantly lower in the “aggressive” strategy (3/40, 7.5% vs. 16/61, 26%, p=0.021). At 6 months, although the cumulative incidence of side effects was 23% with the “aggressive” strategy compared to 46% with the “classic” strategy (p=0.015). Only one treatment discontinuation was noted in the “aggressive” subgroup vs. 9 in the “classic” subgroup (p=0.042).

Conclusion: This study suggests that it is possible to use a more aggressive initiation strategy of MTX in RA in routine clinical practice. This strategy allows to obtain an earlier clinical response and it is associated with a better tolerance than the classic strategy. These results need to be confirmed in prospective studies.

PGA-VAS: patient Global Assessment - Visual Analogic Scale
RESULTS:

A total of 208 patients included in the analysis with mean (SD) age of 55.7 (11.1) years. The mean (SD) time of JAK-i exposure was 25.6 (17.5) months. Of the 208 patients, 133 (64.1%) were female. The average (SD) age at JAK-i initiation was 55.4 (10.8) years. The starting date of JAK-i was between January 2018 and December 2020. The mean (SD) time of JAK-i therapy initiation was 25.6 (17.5) months. The mean (SD) age at JAK-i initiation was 55.4 (10.8) years. The starting date of JAK-i was between January 2018 and December 2020. The mean (SD) time of JAK-i therapy initiation was 25.6 (17.5) months.

Methods: All JAK-i prescriptions were captured electronically from the database of the pharmacy of Hamad Medical Corporation (HMC) from January 2018 to November 2020. Patients with non-dispensed prescriptions were excluded from the analysis. Electronic medical records of patients who received any class of JAK-i were reviewed retrospectively to identify demographic and clinical characteristics, starting and stopping date of JAK-i, MACE and malignancy events post JAK-i initiation.

Results: 219 JAK-i course therapies (tofacitinib 193, upadacitinib 14 and baricitinib 12) were identified from the database of the pharmacy of HMC. Six patients were excluded from the analysis as they were prescribed with JAK-i but their prescriptions were not dispensed. Five patients received two classes of JAK-i due to treatment failure. Mean (standard deviation [SD]) age at JAK-i initiation was 54.9 (14.8) years. Females were 72% of the cohort. JAK-i was prescribed for the following indications: rheumatoid arthritis (RA) 129 (59%), psoriatic arthritis (PsA) 28 (13.1%), alopecia areata 29 (13.6%), spondyloarthritis (SpA) 16 (7.5%), inflammatory bowel disease (IBD) 8 (3.8%), other rheumatic diseases 5 (2.3%). Two patients were having IBD with peripheral and axial SpA involvement. In patients with rheumatic diseases, JAK-i was received in 102 (55%) b-DMARDs naïve patients, post one b-DMARDs in 38 (20%) and post ≥ 2 in 46 (25%) patients. The comorbidity profile (hypertension, dyslipidemia, diabetes mellitus, and coronary artery disease) was 27%, 25%, 23%, and 5.6%, respectively. New cancer diagnosis (follicular thyroid) was confirmed in one patient post tofacitinib and one patient developed lymphoma relapse after tofacitinib initiation.

One ischemic cerebrovascular accident (CVA) identified post tofacitinib initiation. This patient was in atrial fibrillation when CVA occurred. No venous thromboembolism events reported from this cohort.

Conclusion: MACE and malignancy rates are very low in JAK-i users in Qatar population. Comparator group is needed for further evaluation the association of the use of JAK-i and risk of MACE and malignancy.

PREVALENCE OF RISK FACTORS FOR CARDIOVASCULAR EVENTS, MALIGNANCY OR THROMBOEMBOLIC EVENTS IN RHEUMATOID ARTHRITIS UNDER JAK INHIBITORS IN A REAL-LIFE MONOCENTRIC COHORT

Keywords: Comorbidities, Real-world evidence, Safety

I. Giovannini1, R. Agarinis1, S. Cacioppo1, S. Sacco1, G. De Marchi1, E. Di Pois1, A. Zabotti1, L. Quartuccio1, S. De Vita1. Rheumatology Clinic, Azienda Sanitaria Universitaria Friuli Centrale c/o University of Udine, Udine, Italy

Background: Rheumatoid arthritis (RA) is an inflammatory, autoimmune disease, characterized by joint inflammation that can lead to irreversible joint damage and significant disability. The immunomodulatory therapies have dramatically changed the patient management, and the introduction of Janus kinase inhibitors (JAKi) leads the way to an oral, efficacious treatment for RA. Among JAKi, tofacitinib and baricitinib are considered as pan-JAKi (pJAKi) while upadacitinib and filgotinib as selective JAKi (sJAKi) drugs. However, recent safety issues has been highlighted, and the 2022 update of the EULAR recommendations for the management of RA suggests to consider the use of a JAKi only after risk assessment [1].

Objectives: This study aims to describe a monocentric experience of JAKi treatment in RA patients in a real-life setting, focusing on the prevalence of emerging risk factors.

Methods: Patients diagnosed with RA according to 2010 ACR/EULAR criteria and treated in a routine clinical setting with JAKi were retrospectively recruited from our rheumatologic clinic from May 2017 to August 2022. We evaluated the risk assessment according to the 2022 update of the recommendation, as reported below, to describe a real-life experience in the use of JAKi. In details we evaluated: age (over 65 years), smoking status, cardiovascular risk factors (such as diabetes, obesity, hypertension), risk factors for malignancy (current or previous history of malignancy other than successfully treated non-melanoma skin cancer), risk factors for thromboembolic events (history of myocardial infarction or heart failure, cancer, inherited blood clotting disorders or a history of blood clots, as well as patients taking combined hormonal contraceptives or hormone replacement therapy, undergoing major surgery or immobile).

Results: 205 RA patients treated with JAKi were included in our study. 133 underwent pJAK treatment, and 77 underwent sJAK treatment. Overall, 167 JAKi treatments were started in female patients. 128 were positive for rheumatoid factor, and 102 for anti-citrullinated protein antibodies. 96/205 JAKi treatments were started in patients over 65 (46.8%), 45 were smokers (22%), 76 presented...
cardiovascular risk factors (37%), 20 showed risk for malignancy (9.8%) and 21 for risk factors for thromboembolic events (10.2%). More details are reported in Table 1. At least 2 risk factors were reported in 30.7%, of the population, and 11.7% presented at least 3 risk factors.

**Conclusion:** This study highlights the relative high prevalence of risk factors in a real-life population of RA patients treated with JAKi. The clinical effectiveness of JAKi has already been assessed by clinical trial and real-life experience, whereas the safety issue still remains to be further explored. Further studies are needed to define the RA sub-populations at highest risk for safety, and those patients who could benefit from an early JAKi treatment.

### Conclusion:
The originality of our study was to compare the four different molecules in a real-life study. We prove that JAK inhibition is effective in a real-world population of RA patients. The lack of diversity between JAK-Is in efficacy outcomes, adverse reactions and infections could be explained by considering that their selectivity has only been demonstrated in vitro-studies. Meta-analyses performed on clinical trials confirmed lack of diversity in outcomes [2]. Furthermore, JAK is known to dimerize when activated in biological systems, but the percentage of different dimers is unknown. Therefore, further comparative studies are needed to verify their selectivity in real-life studies.

**Background:** In recent years the use of Janus Kinase Inhibitors (JAK-Is) in rheumatoid arthritis (RA) has entered daily practice. In vitro studies they have shown a different selectivity [1], which however has not yet been confirmed in real life studies. Furthermore, considering recent developments, an in-depth study investigating the global safety of these drugs is needed.

**Objectives:** To address potential differences in the safety of Janus kinase inhibitors and short-term efficacy on disease activity we characterized their safety profile in RA patient population.

**Methods:** Single center retrospective observational study. The sample consisted of 68 patients receiving any of the following JAK-is: Tofacitinib, Upadacitinib, Filgotinib, Baricitinib, with a mean of 19.3 months of therapy and a diagnosis of RA according to the ACR/EULAR 2010 criteria. We collected and recorded the clinical features; any infections or adverse reactions during therapy; clinicality at time 0 and at 6 months. For the statistical analysis, the χ² (chi-square) test was used to evaluate whether there were statistical differences with respect to categorical variables, Anova one-way to evaluate any statistical difference with respect to continuous variables; mixed effects model and paired t-test for clinimetry comparison.

**Results:** We found no statistically significant differences between JAK-Is in the following outcomes: symptomatic Covid, p=0.388, new malignancies p=0.348, cardiovascular events p=0.788, thrombocytosis p=0.681, neutropenia p=0.962, lymphopenia p=0.935, anemia p=0.227, need to use glucocorticoids p=0.161, need to Dmards p= 0.217, permanent discontinuation of therapy = 0.353. In our sample we had only development of 2 cardiovascular events, 1 DVT and a new diagnosis of cancer. Anova one-way showed no difference in the number of zoster episodes (p=0.587), or other serious infections (p=0.193). The paired t-test showed that there was a class effect on the reduction of activity indices already after 6 months of therapy (DAS 28 pcr p=0.017, SDAI p=0.054, CDAI p=0.021). However, the mixed effects model showed that there was no molecule more effective in reducing disease activity considering the outcomes at 6 months (DAS 28 pcr p=0.445, SDAI p=0.639, CDAI p=0.467).

**Conclusion:** The originality of our study was to compare the four different molecules in a real-life study. We prove that JAK inhibition is effective in a real-world population of RA patients. The lack of diversity between JAK-Is in efficacy outcomes, adverse reactions and infections could be explained by considering that their selectivity has only been demonstrated in vitro-studies. Meta-analyses performed on clinical trials confirmed lack of diversity in outcomes [2]. Furthermore, JAK is known to dimerize when activated in biological systems, but the percentage of different dimers is unknown. Therefore, further comparative studies are needed to verify their selectivity in real-life studies.

**REFERENCES:**
Conclusion: Compared to other JAK inhibitors, FIL did not reduce Hb levels and that could be maintained for a long time. In patients with anemia concerned with JAK inhibitors, switching to FIL is possible to make RA treatment safer and more successful.

REFERENCES:

Background: Janus kinase (JAK) inhibitor is a great addition to the therapeutic options for rheumatoid arthritis (RA). However, the clinical efficacy and safety of tofacitinib comparing with methotrexate (MTX) was not elucidated.

Methods: In this open-label, randomized, and controlled clinical trial, treatment naive RA patients at the status of medium or high disease activity [simplified disease activity index (SDAI)>3.3] were randomized at 1:1 ratio into TOFA and MTX groups. Patients in TOFA group received tofacitinib 5mg twice per day and patients in MTX group received MTX 10-15mg once per week betamethasone 1ml muscle injection at enrollment. The rate of disease activity improvement (defined as SDAI decreased >50% against baseline or at least 10) at week 12 was taken as primary outcome. Patients who did not achieve improvement transferred to the other group. Secondary outcomes included the rates of remission, low disease activity (LDA) and change of disease activity scores.

Results: 100 patients were enrolled in the study with 49 in TOFA group and 51 in MTX group. The improvement rate was much higher in TOFA group than in MTX group [29.3% (12/41) vs 7.5% (3/40), p=0.025]. The rate of remission and low disease activity at week 4 and week 12 were comparable between the two groups. The change of SDAI [17.9 (7.3-30.3) vs 10.8 (5.5-17.4), p=0.062], CDAI [7 (4.9-16) vs 15 (7.5-26), p=0.011], DAS28-CRP [2.1 (1.2-3.4) vs 1.4 (0.7-2.1), p=0.010] and DAS28-ESR [3.8 (2.5-5.2) vs 2.7 (1.8-3.9), p=0.005] at week 12 were all more significant in TOFA group than in MTX group. The total adverse event rate was high in MTX group than in TOFA group [28% (14/50) vs % (4/49), p=0.022]. Considering specific adverse events, the rates of liver damage [16% (8/50) vs 0, p=0.001] and dizzy [6% (3/50) vs 0, p=0.041] were higher in MTX group than in TOFA group.

Conclusion: For treatment naive RA patients, tofacitinib can bring higher rate of improvement of disease activity.

Vela Casasempere1,4, Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL), Rheumatology, Alicante (Alicante), Spain; Instituto d’Investigació Sanitària La Fe de València, Rheumatology, València, Spain; Hospital la Fe, Rheumatology, Valencia, Spain; General University Hospital of Alicante, Rheumatology, Alicante, Spain
Background: Cumulative data show how an excess body weight may hamper the activity of some anti-rheumatic drugs in rheumatoid arthritis (RA), but we lack studies in this regard on the new JAK-kinase inhibitors (JAKinibs). Objectives: To prospectively evaluate the impact of adiposity on the anti-inflammatory response of JAKinibs in RA.

Methods: Observational, prospective, single-center exploratory study. We sequentially included adult patients from tertiary center clinics, with a clinical diagnosis of RA and a new JAKinib prescription by their treating rheumatologists. Only JAKinibs-naïve patients were allowed. For this analysis, during the follow up, csDMARD was required to remain unchanged. Patients participating in weight loss or bariatric surgery programs were also excluded. We used three different definitions for adiposity: A) body mass index (BMI), as kg/m2; B) body fat percentage, measured by impedanceadmetry; and C) blood levels of LDL and HDL cholesterol and triglycerides. We defined dyslipidemia as total cholesterol >200mg/dl and/or triglycerides >150mg/dl at blood tests. The potential modulating effect of adiposity on the effectiveness of JAKinib therapy was assessed on the change of DAS28-ESR and DAS28-ESR between baseline and 3 months later (when the peak action of JAKinibs is theoretically met). ANOVA regression was used to compare changes in DAS28 CRP/ESR regarding adiposity variables. When significant associations were found, a multivariate linear regression model was built. Software R v.4.2.1 was used.

Results: From an initial sample of 20 patients, 4 were excluded from analysis (2 stopping JAKinib due to intolerance, 2 as the csDMARD dose was modified), which finally left 16 participants. Median age was 57/years (IQR 50.75 to 65.5) and 76% were females. Four patients were bDMARD-naïve and 9 were on concurrent csDMARD. 75% (n=12) of the subjects received 4mg bactracinib daily, the remaining 4 cases received 15mg upadacitinib daily. Median BMI was 27.7kg/m² (IQR 26.25 to 31.38), being 31.5% obese. Median body fat percentage was 34.95% (31.38 to 40.55). Ten patients achieved the the dyslipidemia cutoff, 75% of whom received lipid lowering treatment. Patients had mostly moderate-high activity measured by DAS28 at baseline (81.25%), while after 3 months no patient was on high activity and 62.5% and 56.25% (CRP/ESR) showed low activity and remission, respectively. The results for the association analyses between adiposity and changes in DAS28-ESR are given in Table 1. No association was found neither for BMI or body fat percentage. While a positive, independent effect of triglycerides was noted (not with LDL or HDL). No adiposity variables were found associated with changes in DAS28 CRP.

Table 1. DAS28-ESR regression analysis. Covariates included on multivariate model were JAKinib choice, time between visits and concurrent csDMARD.

Conclusion: No relevant impact of adiposity was noted on the anti-inflammatory effect of JAKinibs after three months of use in RA patients. Our findings support no dose adjustment for JAKinibs, independently of their weight or adiposity. This study should be replicated in larger studies to confirm our observations.

AB0495

EFFICACY AND SAFETY OF VITAMIN D IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Vitamin D

Objective: The aim of this study was to summarize the association between serum vitamin D levels and RA and systematically evaluate the efficacy of VA supplementation in RA treatment.

Methods: Literature searches were conducted using PubMed, EMBASE, Web of Science, Clinical Trials.gov, Wanfang database, Weipu database, Chinese National Knowledge Infrastructure and Cochrane databases to identify available articles (up to January 1, 2023). Meta-analysis was used for the meta-analysis. And the results are presented both tabulated and graphically.

Results: In the study between serum vitamin D levels and RA, 26 studies, including 3,328 patients and 2,223 healthy controls, were identified (Table 2). Compared with the control group, the serum vitamin D level in the RA group was significantly reduced[SMD=-1.523, 95%CI (-1.590,-1.457), P=0.000]. Vitamin D was inversely correlated with disease activity. About the efficacy of VA supplementation in RA treatment, 7 studies comprising 392 patients were identified (Table 1). After the VA treatment, 91.28% of patients had distinct clinical remission, 47.72% were completely cured. After receiving VA therapy, patients with RA had significant decreases in DAS28[SMD=-2.19, 95%CI (-2.58,-1.80), P=0.000], ESR [SMD=-2.12, 95%CI (-2.50,-1.74), P=0.000], CRP [SMD=-1.84, 95%CI (-2.22,-1.45), P=0.000], SJC [SMD=-2.53, 95%CI (-2.71,-2.34), P=0.000], TJC [SMD=-3.45, 95%CI (-3.67,-3.23), P=0.000], and the Morning stiffness time [SMD=-2.32, 95%CI (-2.72,-1.92), P=0.000]. None serious adverse events were reported among all these studies. Meta-analysis of 2 studies, including 420 patients with RA, showed that the incidence of adverse events was 19.46%.

Conclusion: Patients with RA had vitamin D deficiency, which was associated with the activity. Vitamin D supplementation did statistically significantly improve the RA.

**AB0496** TREATMENT WITH UPADACITINIB IN RA PATIENTS FOR WHICH BIOLOGICAL THERAPY FAILED

**Keywords:** Rheumatoid arthritis, Patient reported outcomes, Disease-modifying Drugs (DMARDs)

L. Robles Kirkegard1, E. Rubio Romero2, P. León3. 
1Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Madrid, Spain; 2Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Sevilla, Spain; 3Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Sevilla, Spain

**Background:** Upadacitinib is a JAK inhibitor recently approved for rheumatoid arthritis treatment with promising results in its studies for severe moderate RA for which conventional therapies failed.

**Objectives:** To study and describe the evolution of patients diagnosed with RA and treated with Upadacitinib who had inadequate response to biological therapy in association or not with DMARDs and GC for 1 year.

**Methods:** A population of 23 patients (19 of them female) with RA on treatment with Upadacitinib was analyzed over one year. Using patient-reported outcomes (PROs) to measure disease activity by visual analogue scale (VAS), the HAQ Disability Index (HAQ-DI), Disease Activity Score (DAS28), and morning stiffness duration. The average ± SD was 53 ± 10 years and time of disease evolution (average ± SD) = 176 ± 23.3 years. Pretreatment DAS28 was (average ± SD) = 7.32 ± 2.41. The initial VAS was (average ± SD) = 7.32 ± 1.88. HAQ (average ± SD) = 2.2 ± 0.5. All patients received previous biologic treatments and 61% (14 patients) combined therapy with DMARDs. Only 2 cases had no glucocorticoid treatment prior to treatment with Upadacitinib.

**Results:** In 3 months time, most patients (81%, n = 21) treated with Upadacitinib were able to reduce the GC dose, and this reduction was maintained 6 months from the beginning of the treatment. After one year of treatment (n = 14), 71% of patients reduce the dose of GC by 53% with respect to the initial dose. Upadacitinib enabled 50% of patients who initiated treatment to discontinue corticosteroid therapy completely. After 3 months of treatment, most patients experienced an enhancement in DAS28 (89%, n = 18), with an average improvement in DAS28 (average ± SD) = 1.87 ± 1.09. After one year of treatment most patients (92%, n = 14) achieve a reduction in DAS28 (average ± SD) = 3.81 ± 1.56 units from baseline. Disease remission (DAS28 <3.2) was achieved in up to 25% of patients who initiated treatment with Upadacitinib. Regarding the pain (VAS), 67% of the patients showed improvement after 3 months (n=18), reaching 71% after 6 months (n=17). After 12 months of treatment (n = 14), 85% of patients experienced an improvement in pain, with the final (average ± SD) VAS being 5 ± 2.32 points. Sixty-eight percent of treated patients showed a reduction in morning stiffness after 3 months (n = 19), and this improvement increased up to 84% of treated patients at 6 months (n = 19) and remained so until 12 months (n = 14). Side effects were observed in five patients, consisting of dizziness and nausea. In no case were they a reason for the withdrawal of the drug. Treatment was withdrawn in three patients due to primary failure.

**Conclusion:** Treatment with Upadacitinib allows GS dose reduction, as well as an improvement in DAS28, VAS and morning stiffness at three months and six of treatment. These data are in line with the evidence published in Upadacitinib pivotal studies, meaning a good alternative in the treatment of patients with moderate or severe RA.

**AB0497** THE ROLE OF CORTICOSTEROIDS (PREDNISONE) IN THE TREATMENT OF NEWLY DIAGNOSED RHEUMATOID ARTHRITIS

**Keywords:** Rheumatoid arthritis

B. Barac1,2, A. Zekovic1, T. Divjakovic4, S. Lukovic1, G. Radunovic1,2. 1Institute of Rheumatology, Clinical V Department, Belgrade, Serbia; 2University of Belgrade, Faculty of Medicine, Beograd, Serbia; 3Institute of Rheumatology, Clinical III Department, Belgrade, Serbia; 4Institute of Rheumatology, Clinical IV Department, Belgrade, Serbia

**Background:** The use of corticosteroids (CSs) in patients with newly diagnosed rheumatoid arthritis (RA) is important in order to reduce the inflammation as well as bridging until achieving the full effect of the basic therapy. In previous years, there were recommendations for the use of different doses of CSs [1-2].

**Objectives:** To compare the therapeutic effect of initially higher doses of CSs, prednisone (0.3-0.5 mg/kg) with a standard low-dose daily therapy (7.5 mg) in patients with newly diagnosed RA.

**Methods:** Two groups of 50 patients each with newly diagnosed RA were followed up for a period of 24 months. The groups were homogeneous in terms of sex, age and BMI. The group one (I) consisted of 50 patients who were initially treated with doses of prednisone 0.3-0.5 mg/kg (average initial dose 25mg) by bridging until achieving the full effect of basic therapy with Methotrexate (MTX) (in an average dose of 15 mg/week). The group two (II) consisted of 50 patients who were treated according to standard recommendations with an initial dose of an average of 7.5 mg of prednisone with MTX in an average dose of up to 15 mg/week. In both groups, the doses of prednisone were gradually reduced over a period of 3-6 months. During a period of 24 months (at 6, 12 and 24 months), the following parameters were monitored in all patients: DAS28, HAQ, VAS, CDAI. We also compared the number of corticosteroid-independent patients after 6, 12 and 24 months in both groups, the percentage of patients in remission (DAS28<2.6) and the percentage of patients with a good EULAR DAS28 response (CRP<3.2 and 24-month HAQ<1.0). The group of newly discovered comorbidities during the mentioned therapy, such as newly discovered hypertension, osteoporosis and diabetes mellitus (DM) type II, was also monitored.

**Results:** Highly statistically significantly lower values of the DAS28 score (p<0.01) were found in the group I of patients, treated initially with higher doses of CS after 6 and 12 months, as well as statistically significantly lower values after 24 months (p<0.5). Statistically significantly lower HAQ values were also found in group I after 6, highly statistically significantly lower after 12 and statistically significantly lower after 24 months of follow-up (p<0.05). For pain VAS, statistically significantly lower values in group I after 6 and 12 months (p<0.01) and statistically significantly lower values after 24 months. CDAI values were also statistically significantly lower in group I after 6 and 12 months. A statistically significantly higher percentage of patients were in remission and had a better EULAR response in the group I after 6, 12 and 24 months from the start of therapy (p<0.05). Also in the group I which was initially treated with higher doses of CSs, statistically significantly lower number of patients were corticosteroid-dependent after 6, 12 and 24 months. A special difference between the groups is represented by a highly statistically significantly lower number of comorbidities in group I after 24 months from the start of therapy, such as newly discovered hypertension, DM type II and osteoporosis.

**Conclusion:** The initial use of higher doses of corticosteroids (0.3-0.5 mg/kg) compared to the recommended daily doses of up to 7.5 mg in patients with newly diagnosed rheumatoid arthritis, provide significantly better clinical response in all the parameters DAS28, VAS, CDAI, HAQ, a higher level of corticosteroid-independent patients as well as a lower number of side effects such as newly discovered hypertension, osteoporosis and diabetes mellitus type II, 24 months after starting basic therapy.

Background: Targeted synthetic therapeutics brought revolutionary progress in rheumatoid arthritis (RA) management and culminated a paradigm shift over a decade. However, only a subset of patients responded clinically and achieved sustained remission. The interindividual factors may vary in failure of therapeutic target and clinical response.

Objectives: We investigated the clinical and sociodemographic predictors of Tofacitinib response in RA patients at three, six and twelve months.

Methods: This retrospective study included 164 RA patients from the nationwide MARBLE registry who received Tofacitinib. Patients' clinical data were extracted from medical records. The response to Tofacitinib in terms of clinical remission, low disease activity (LDA) and DAS28 improvement (EULAR response) were measured at baseline, 3 months, 6 months and 12 months of therapy based on disease activity score (DAS)28 for RA. Factors predicting treatment response were analysed using binary logistic regression analysis.

Results: Our data revealed that at 3-month, 6-month and 12-month of Tofacitinib treatment, 17.7%(n=29), 6.7%(n=111) and 60.4%(n=99) RA patients achieved low disease activity/clinical remission. Further analysis demonstrated the response to Tofacitinib in terms of clinical remission, low disease activity (LDA) and DAS28 improvement (EULAR response) were measured at baseline, 3 months, 6 months and 12 months of therapy based on disease activity score (DAS)28 for RA. Factors predicting treatment response were analysed using binary logistic regression analysis.

Conclusion: In this study, step-down MTX approach was effective in inducing remission in most of the patients enrolled. According to data reported in other studies (2,3), one third of them showed adverse events leading to the withdrawal of the drug. On the contrary, different studies in which MTX was used as in current clinical practice (at lower dosages) showed lower efficacy: in the ORAL START study, ACR70 response was reached only in 12% of naïve patients 6 months after MTX monotherapy (4), whereas in the PREMIER study, 26% of patients receiving MTX monotherapy obtained ACR70 response after one year [5]. Thus, short-term higher dose MTX usage could be more effective in order to reach remission earlier. Nonetheless these results should be confirmed in larger populations of patients. In conclusion, this approach could be considered as a valid regimen for a more optimal use of MTX.

Keywords: Disease-modifying drugs (DMARDs)

M. Pendolino1, T. Serban1, D. Camellino1, P. Diana1, A. Giusti1, G. Bianchi1.

1S.C. Reumatologii, ASL3 Genovese, Scienze Mediche, Genoa, Italy

Background: Methotrexate (MTX) is the cornerstone of Rheumatoid Arthritis (RA) treatment, showing a suitable efficacy-safety profile, relatively low-cost, and versatile routes and dosage administration. However, there are no clear indications yet on the optimal use of MTX in RA, whereas existing recommendations disagree on relevant aspects (eg. route, starting and maximal dose, titration increase/decrease, and intervals to monitor toxicity) [1].

Objectives: To evaluate the efficacy and the safety of a step-down strategy to use subcutaneous (sc) MTX in patients with RA.

Methods: STEMETRA is a 16-week open-label, monocentric, pilot study. The protocol treatment schedule consisted of the administration of MTX 50 mcg/ week for 4 consecutive weeks, followed by 25 mcg/week for 4 weeks, and then 15 mcg/week for 4 weeks. All patients received oral supplementation of folic acid (leucovorin) 12 mg. 12 hours after the injection of MTX.

Results: Fifteen patients (10 females and 5 males; mean age, 60 years (±11) diagnosed with RA according to 2010 ACR/EULAR classification criteria and naïve to any RA treatment were enrolled. One patient was lost to follow-up after week 12; 4 patients withdrew because of adverse events; therefore, 10 patients concluded the study. A total of 14 adverse events occurred in 7 patients; 7 were of mild severity and tolerated by patients, 3 solved, and 4 were persistent and lead to withdrawal of the drug (Table 1). Mean DAS28 (CRP) at baseline was 5.6 (±1.4), whereas, at week 16, mean DAS28 (CRP) was 16.6 (±1). Most patients who concluded the study achieved ACR70 response and the state of remission (7 out of 10), whereas 3 still showed moderate disease activity.

Conclusion: In this study, step-down MTX approach was effective in inducing remission in most of the patients enrolled. According to data reported in other studies (2,3), one third of them showed adverse events leading to the withdrawal of the drug. On the contrary, different studies in which MTX was used as in current clinical practice (at lower dosages) showed lower efficacy: in the ORAL START study, ACR70 response was reached only in 12% of naïve patients 6 months after MTX monotherapy (4), whereas in the PREMIER study, 26% of patients receiving MTX monotherapy obtained ACR70 response after one year [5]. Thus, short-term higher dose MTX usage could be more effective in order to reach remission earlier. Nonetheless these results should be confirmed in larger populations of patients. In conclusion, this approach could be considered as a valid regimen for a more optimal use of MTX.

**STUDY OF THE USE AND PRESCRIPTION OF ANALGESICS DURING RHEUMATOID ARTHRITIS (RA)**

**Keywords:** Rheumatoid arthritis, Pain

**Methods:** This is a 5-month cross-sectional survey including patients with rheumatoid arthritis, meeting the ACR/EULAR 2010 criteria consulted during the study period were included. The use of analgesics was evaluated via a questionnaire with 14 questions. Data was processed by statistical analysis using SPSS 2021 Software.

**Results:** There are 168 patients, including 24 men and 144 women. The average age was 49.91±12.96 [20–90]. The average age at onset was 41.69±14.85. The average age of diagnosis for RA was 47.17±13.71 years. The average DAS28 was 5.32±1.35. Only 69 patients were taking analgesics. The majority of patients were on disease modifying drug (DMARD) (76%), 145 (86%) were on corticosteroids, 46 (27.3%) were on non-steroidal anti-inflammatory drugs and 89 (53%) were taking analgesics. At the time of the survey, 79 patients were not taking analgesics. 69 patients were taking a Tier 1 analgesic; 20 patients were taking a Tier 2 analgesic, none of the patients were taking a Tier 3 analgesic. Analgesics were never used alone. The difference between a pure analgesic and a non-steroidal anti-inflammatory was only known by 15 patients (9%). For only 25 patients, analgesics were effective on diurnal pain in 25 patients and for 64 patients (72%) on nocturnal pain. Only 14 patients, or 15% were taking pain relievers at a fixed time. 60 (67%) only during flare-ups, and 15 (16%) were taking pain relievers at a fixed time with increased dose in case of flare-ups. The prescription of analgesics was the fact of the rheumatologist in 89% of cases, and self-medication in the only 11% of cases.

**Conclusion:** In RA, as in all chronic painful diseases involving functional prognosis, pain is the essential symptom to treat. In our study, the use of analgesics was 53%.

**PREVALENCE AND ASSOCIATED FACTORS FOR CONVENTIONAL DISEASE MODIFYING ANTI RHEUMATOID DRUG FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A TERTIARY CARE HOSPITAL IN SOUTHERN SRI LANKA**

**Keywords:** To target, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

**Methods:** We reviewed 203 patients in Rheumatology department at Navarra University Hospital who underwent treatment with JAKI (Barcitnib, Filgotinib, Tolctinib and Upadacitinib) and the significant adverse events occurred.

**Results:** Of our sample of 203 patients, 81.2% were diagnosed RA, 8.8% with PsA, 7.5% with SpA and the remaining 2.5% were indeterminate arthritis. We found that out of the patients diagnosed with RA, 10.83% had a significant adverse event (22 events in total). A 0.5% had a myocardial infarction, 1.5% stroke, 2.1% arterial thrombosis, 2.1% venous thrombosis, 1.5% developed some type of malignancy and 3.6% reactivation of herpes zoster. One arterial thrombosis happened in the indeterminate arthritis group.

**Conclusion:** In our series, out of 203 patients treated with JAKI, 11.33% had a significant adverse event. The most common adverse event was the herpes zoster reactivation (3.44%), followed by arterial and venous thrombosis (2.46 and 1.97% respectively). Longer-term follow-up and greater number of patients are necessary to ratify these data.

helps with good response rate for cDMARDs. Introduction of injectable version of methotrexate could have helped in some intolerable side effects of methotrexate however, efficacy of this measure will depend on several factors such as cost, willingness of patients to self-inject etc. Finally, conventional DMARDs still play a significant role in the management of this debilitating disease with a comparatively low cost and an acceptable side effect profile.

AB0503 GENICULAR ARTERY EMBOLIZATION IN THE MANAGEMENT OF PERSISTENT JUVENILE IDIOPATHIC ARTHRITIS OF THE KNEE: A CASE REPORT

Keywords: Synovium, Non-pharmacological interventions, Inflammatory arthritides

M. Badii1, D. Parhar2,3, S. Badii4, D. Lu5,6. 1The University of British Columbia, Medicine/Rheumatology, Vancouver, Canada; 2The University of British Columbia, Radiology, Vancouver, Canada; 3Harvard University, TH Chan School of Public Health, Cambridge, United States of America; 4Canada’s Michael Smith Genome Sciences Centre, Computational Science, Vancouver, Canada; 5The University of British Columbia, Radiology, Vancouver, Canada; 6University of Miami, Miller School of Medicine, Miami, United States of America

Background: Genicular artery embolization (GAE) is rapidly gaining popularity for treatment of patients with recurrent hemarthrosis following knee arthroplasty, and for pain relief in mild-to-moderate osteoarthritis (OA) [1]. Despite the growing evidence of the safety and efficacy of GAE in improving pain and disability in OA, it has yet to be reported in the treatment of patients with inflammatory arthropathy, such as rheumatoid arthritis (RA) or juvenile idiopathic arthritis (JIA).

Objectives: To apply GAE on an adult patient with oligoarticular JIA of the knee and refractory to biologic therapy, and measure improvement of pain symptoms.

Methods: A 40-year-old woman with history of oligoarticular JIA presented with progressively worsening right knee pain and swelling. She had tried several treatments in the past including oral analgesia (NSAIDS, acetaminophen, and opioids), multiple intra-articular steroid injections, therapeutic arthrocentesis, multiple DMARDs (MTX, SSZ, LEF), and had been on biologic therapy (adalimumab) for the past 8 months, with no noticeable improvement from any of these strategies. Prior to GAE she had pain score of 8/10 on VAS, and Oxford Knee Score (OKS) of 25. The GAE procedure was subsequently performed on an outpatient basis under conscious sedation. A four French angiled tip catheter was advanced into the distal SFA and angiography was performed. This demonstrated characteristic synovial hyperemia (“blush”) of the synovium along the medial joint space supplied by the musculoarticular branch of the descending genicular artery (DGA), as well as the lateral synovium supplied by the inferior lateral genicular artery (ILGA). Super-selection of the DGA was performed using a 1.9 French microcatheter, with repeat angiogram confirming synovial hyperemia. After administration of intra-arterial nitroglycerin, the DGA was then embolized with 1.0 cc of 100 – 300 µm Embospheres (Merit Medical Systems, South Jordan, UT). Post-embolization super-selective angiogram confirmed a “pruned-tree” appearance of the DGA branches, with no further hyperemia, in keeping with a successful embolization.

Results: The patient tolerated the procedure well and was discharged home same-day. At 6 and 12 months follow-up, the patient continued to report substantial improvement in her symptoms with a pain rating of 1 out of 10 on both rest and mobilization. Her OKS was 35 at 12 months. Her right knee remained in remission on Adalimumab for 12 months post procedure. Figure 1 shows the comparison of the pre and post GAE fat saturated T1 image. Pre GAE, there were synovial thickening and enhancement of the knee capsule. As shown in Figure 1, at 12 months post GAE significant retraction and devascularisation of the synovium has occurred.

Conclusion: We report the first case of GAE in a patient with inflammatory arthropathy, which showed dramatic and sustained reduction in pain. Though the efficacy, safety, and long-term clinical durability still need further evaluation in the context of inflammatory arthropathy, the positive result in this case posits an exciting avenue for further investigation into the role of transarterial embolization in rheumatologic disease.

AB0504 CARDIOVASCULAR AND ADVERSE EVENTS RISK WITH TOFACITINIB IN RHEUMATOID ARTHRITIS IN THE DOMINICAN REPUBLIC

Keywords: Targeted synthetic drugs, Rheumatoid arthritis, Cardiovascular disease

R. A. Alvarez Santana1, D. García1, L. Perez2, T. Polanco Mora3, L. Concepción Sanchez1, I. Paulino1, I. Mercedes4, E. Rodríguez Bautista1, T. Valdez2, A. Feriz3, R. Muñoz Louis1. 1Hospital Padre Billini, Rheumatology, Santodomingo, Dominican Republic

Background: Rheumatoid arthritis (RA) is a systemic autoimmune inflammatory disease that affects the synovial membrane of small joints. Tofacitinib (TOF) is the first Janus Kinase Inhibitor (JAKi)s approved by the European Medicines Agency and the Food and Drug Administration for the treatment of RA. This inhibits JAK1 and JAK3 involved in cytokine signaling proinflammatory in RA. Concepcion et al. [1] found that 16% of the patients on TOF presented adverse events (AEs) and the most frequent of these was dyslipidemia, followed by elevated liver enzymes. Ytterberg et al found an increased risk of MACE with the use of tofacitinib recently [2].

Objectives: To evaluate the risk of cardiovascular and adverse events with tofacitinib in rheumatoid arthritis.

Figure 1. Modulation of Synovitis Pre and Post GAE: Pre GAE sagittal and coronal post contrast (gadolinium) fat saturated T1 image demonstrated synovial thickening and enhancement of the knee capsule (A+B). Coronal digital subtraction angiogram demonstrating corresponding arterial neovascularization/synovitis blush targeted by GAE (C). Post GAE (12 month) sagittal post contrast (gadolinium) T1 fat saturated image demonstrating significant retraction and devascularisation of the synovium (D).
Methods: Retrospective, longitudinal, descriptive. Records from the database of the Rheumatology service of the Hospital Docente Padre Billini were reviewed between January 2016 and December 2021. Inclusion criteria: ≥18 years, diagnosis of RA according to the ACR/EULAR 2010 criteria, TOF 5mg every 12h ≥3 months. Exclusion criteria: patients with ≤3 months of treatment, history of cardiovascular event, liver disease, moderate anemia, severe neutropenia, history of herpes, absence of ≥ 2 visits. A descriptive analysis of AEs and Major Adverse Cardiovascular Events (MACE) were performed using SPSSv23.

Results: 215 met inclusion criteria. 87% (187) female. Mean age 57 ± 11.5 years. Mean disease duration 7.6 ± 2.3 years. HTA 49.8% (107), IMC >30kg/m2 12.6% (27), DM 11.6% (25). Mean treatment with TOF 5 ± 1.7 years. AEs and MACE 54%/101. AEs 73.3%/77 (4%) Hypercholesterolemia 26.7% (27), ALT or AST >3ULN 12.9% (13), herpes virus infection 8.9% (9), PMN: >500 8.9% (9), <500: 7.9% (8), UTI 4.0% (4), severe anemia 4.0% (4). MACE 26.7%/27 (mean age 60.2 ± 9.1 years [Acute myocardial infarction (AMI) 63%/17), deep vein thrombosis 29.6%/8), cerebrovascular accident 7%/2)

Conclusion: In our review, AEs were found in half of the patients evaluated. Most of MACE events were associated with older age; the most frequent was AMI. Infections were found in a lower proportion. Little risk of infectious processes is demonstrated with the use of TOF. We must take precaution in those over 55 years of age and with cardiovascular risk comorbidities with the use of TOF consistent with that reported in the world literature.

AB0505
INTEGRATIVE MEDICINE APPROACH TO SUSTAIN LONG-TERM CONTROL IN CHRONIC RA: AN OBSERVATIONAL PROSPECTIVE STUDY OF A COMBINATION REGIME OF CONVENTIONAL DMARD AND AYURVEDIC HERBAL DRUG

Keywords:
Tapering, Rheumatoid arthritis, Safety

M. Saluja1, K. Adam1, R. Patil1, A. Chopra1. Center for Rheumatic Diseases, Rheumatology, Pune, India

Background: Prolonged drug treatment in RA is complicated by related toxicity, inadequate efficacy, other health issues, cost, and compliance. Ayurveda (India) drugs (Ayur) have popularly treated arthritis since ancient times. Few controlled, extended duration studies, both as mono or combination (Ayur plus modern medicine/M-Med) showed impressive outcomes (especially safety). In 2018, we introduced limited integrative treatment in rheumatology practice (community) to improve the outcome of long-drawn chronic RA. We present preliminary experience.

Objective: To evaluate the one-year outcome of a combination treatment of conventional DMARD with standardized Ayur (herbal drug).

Methods: Consenting patients of chronic RA and clinically well-controlled disease (last 6 months) were selected in no particular order; supervised ongoing standard care with DMARD with/without steroids (previous period, median 5.5 years). SC-1 (Ayur) was added in a fixed stable dose (1 gm tablet, bid); standardized medicinal plant extracts (1 tablet containing 100mg Withania somnifera, 500mg Boswellia serrata, 50mg Curcuma longa, 400mg Phyllanthus emblica), as per Ayurveda pharmacopoeia. M-Med (RA) were adjusted at 12-16 weeks intervals based on clinical judgment. Standard follow-up (FU) procedures included a predefined routine drug toxicity checklist. An Excel (Microsoft) based analysis was performed; standard deviation in parentheses, single sample paired T-test (P: two-tailed). Disease activity was classified according to the standard DAS 28 score. 453 patients qualified (one-year uninterrupted combination treatment and sufficient data) for analysis: 32% remission, 38% low activity (LDA), and 30% borderline moderate activity (MDA). Six months prior, 51% of the latter cohort (mean DAS=3.33 (0.95) were in remission/LDA.

Results: At baseline, the median of age and RA symptom duration respectively was 56 years (12.5) and 11 years (74); 80% seropositive RF: 91% erosive/RA deformity; mean pain VAS (10cm line)=2.78(1.23), mean HAQ (validated Indian version, maximum score 24)=3.17 (2.95), mean DAS28=2.9 (0.76), 47% steroids (mean daily dose ≤5 mg pred), median ESR=30 (19.4), 22% Hydroxychloroquine, 22% Sulfasalazine,74% Methotrexate (mean 16.3 mg weekly (4.48), and Combo DMARD 23%. At 1 year FU, 51% sustained remission/LDA, and 12% MDA; median ESR=30mm (18.8), mean DAS=2.35 (0.87) (p=0.00), 14% Sulfasalazine, 18% Hydroxychloroquine, 49% steroid, 70% Methotrexate (mean 15.5 mg (4.6). Though statistically significant, several changes (core variables) were small and clinically considered unimportant. 32% cohort reported brief arthritis flares (1-5) versus 40% in the previous year. 409 clinical adverse events/AE (none serious/hospitalization) were reported during the study period; 121 non-related (drugs), 68 unspecified drugs, 34 Hydroxychloroquine, 25 Sulfasalazine, 136 Methotrexate, and 21 SC-1 (mostly gut and dyspepsia, infrequent mild transaminitis); correspondingly 472 AE were reported in the previous year (non-SC-1), FU data will be presented. The absence of control, placebo response, and floor and ceiling effect (outcome) may complicate the clinical interpretation of the results. Patients continued to be followed till date.

Conclusion: SC-1 (Ayurveda) further improved disease control, albeit modest, and safety in long-drawn chronic RA when combined with ongoing standard modern drugs under prolonged rheumatology care. This augurs well for the future. But first, controlled evaluation (integrative medicine) studies are warranted.

DOES JANUS KINASE INHIBITOR INCREASE THE RISK OF HERPES ZOSTER IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SAUDI ARABIA? A MULTICENTER RETROSPECTIVE COHORT STUDY

Keywords:
Rheumatoid arthritis, Safety, Infection-related RMDs

1King Faisal Specialist Hospital and Research Center, Internal Medicine, Jeddah, Saudi Arabia; 2King Abdullah University Hospital, Internal Medicine, Division of Rheumatology, Jeddah, Saudi Arabia; 3King Abdulaziz University, Department of Infectious Disease and Department of Infection Control and Environmental Health, Jeddah, Saudi Arabia; 4Al Azhar University, Rheumatology, Asir, Saudi Arabia; 5Umm Alqura University, Medicine, Division of Rheumatology, Makkah, Saudi Arabia

Background: Currently, there is an advancing interest in the Janus kinase (JAK) intracellular pathway since targeted inhibitors are proving to be excellent in the treatment of Rheumatoid arthritis (RA). Nevertheless, this new therapeutic era of small molecules comes at a cost, JAKi is associated with a heightened risk of reactivation of dormant infections herpes zoster (HZ) virus infection. Furthermore, the incidence of HZ in rheumatoid arthritis using JAKi is higher in eastern Asian countries making this study essential for the assessment of its safety among the middle eastern population in a real-world setting.

Objectives: To evaluate the risk of serious infection (SI) and herpes zoster (HZ) in rheumatoid arthritis patients receiving JAK inhibitors.

Methods: Multicenter retrospective cohort study in Saudi Arabia. Rheumatoid arthritis patients aged 18 and above from the period of 2007-2022 were included. Medical records were reviewed, and patients were phone interviewed during 2022 to register an outcome of HZ infection. Chi-square was used to assess for the correlation between various risk factors and HZ infection.

Results: From a total of 308 patients, 108 were on JAKi. JAKi didn’t significantly increase the risk of reactivation of dormant infections herpes zoster (HZ) virus infection. Furthermore, the incidence of HZ in rheumatoid arthritis using JAKi is higher in eastern Asian countries making this study essential for the assessment of its safety among the middle eastern population in a real-world setting.

Conclusion: In this multicenter study in Saudi Arabia, JAKi were not associated with the development of HZ among Rheumatoid Arthritis patients in real world setting. Asian ethnicity and etanercept usage were significantly associated with HZ infection.

Background: Filgotinib is well-known to inhibit bone destruction in patients with RA, particularly those with poor prognostic factors. Recently, Filgotinib, especially at dose 200mg/d has been reported to have good results inhibiting joint damage in patients with rapid radiographic progression (RRP) condition compared to non-RRP condition in post-hoc study of Finch1 (Methotrexate (MTX) iR) or non-iR condition. However, little has been reported about the joint protective activity by Filgotinib in the real world. On the other hand, we previously demonstrated that extensive MRI bone edema (BE) in the hand and radiographic progression by reducing bone edema (RPG) were treated with filgotinib were examined to check for extensive BE in their most active joint, as radiographically assessed using standardised progression assessment in RA (SPA-RAPID). Finally, the RRPs in the first year of filgotinib treatment were assessed.

Methods: All 32 patients with inadequate response to MTX/Biologics/JAKi who were treated with filgotinib were examined to check for extensive BE in their most active joint, as radiographically assessed using standardised progression assessment in RA (SPA-RAPID). Finally, the RRPs in the first year of filgotinib treatment were assessed.

Results: As shown in Table 1, most of the patients were treated with filgotinib 200mg/d+MTX. Patients 1-4 (12 months) and patients 5-6 (2-3 months) had extensive BE in hand and RRP condition at baseline. Finally, the RRPs in the first year of filgotinib treatment were assessed.

Conclusion: Filgotinib (200mg/d)+MTX may be useful therapy for RRP by reducing bone edema (RPG) and inhibiting radiographic progression.

EFFICACY OF SULFASALAZINE MONOTHERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAD FACTORS ASSOCIATED WITH PREFERENCE FOR SULFASALAZINE OVER METHOTREXATE AS THE FIRST-LINE DRUG

Keywords: Rheumatoid arthritis

K. Hatteri1, Y. Kanayama1, 1Toyota Kosei Hospital, Orthopaedics, Miyoshi, Japan

Background: Methotrexate (MTX) is the first-line drug in treating patients with rheumatoid arthritis (RA) [1], while some patients have baseline factors and comorbidities which discourage use of MTX. While treatment with sulfasalazine (SSZ) is often performed in these cases, the efficacy of SSZ monotherapy was not well evaluated using recent disease activity assessment measures such as DAS28-CRP, CDAI and HAQ-DI.

Objectives: The aim of this research is to evaluate the efficacy of SSZ monotherapy in RA patients who had baseline factors and comorbidities associated with preference for SSZ over methotrexate as the first-line drug.

Methods: 78 treatment-naïve RA patients who started treatment with SSZ were included. We compared outcomes of SSZ monotherapy in patients with and without each of the following baseline factors and comorbidities: age 75 years or more, seronegative RA, moderate disease activity or less (DAS28-CRP, CDAI and HAQ-DI), and presence of comorbidities in lung, renal and liver.

Results: Baseline disease activity was higher among patients with 75 years old or more compared with those with under 75 years old (DAS28-CRP as 4.9 and 3.9, CDAI as 24 and 17 and HAQ-DI as 1.4 and 0.8), while those were similar at week 24 (DAS28-CRP as 3.3 and 3.2, CDAI as 14 and 12 and HAQ-DI as 0.6 and 0.5). There was no significant difference in disease activity at baseline and week 24 regardless seronegative or seropositive RA. There were also no significant differences in disease activity at baseline and week 24 regardless presence or absence of comorbidities in lung, renal and liver. Disease activity at week 24 tended to be higher among patients with high disease activity at baseline comparing to those with moderate or less disease activity at baseline, whereas no statistically significant difference was observed baseline DAS28-CRP as 5.0 and 3.3 and DAS28-CRP at week 24 as 3.5 and 2.9).

Conclusion: SSZ was similarly effective in treating elderly RA patients, patients with seronegative RA and RA patients with comorbidities in lung, renal and liver, comparing in treating those without any baseline factors and comorbidities.

CLINICAL EQUIVALENCE OF GENERIC AND BRANDED TOFACITINIB IN REAL-WORLD: A PROSPECTIVE LONGITUDINAL COHORT STUDY IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Real-world evidence, Rheumatoid arthritis

J. Zhao1, H. Huang2, Z. Zhang1. 1Peking University First Hospital, Rheumatology and Clinical Immunology Beijing, China

Background: The efficacy and safety of Xeljanz® have also been confirmed in RA patients. Varieties of generic tofacitinib have been developed in different countries. However, there is no study comparing the efficacy and safety between generic and brand-name tofacitinib yet.

Objectives: In the current study, we compared the efficacy, safety, and cost-effectiveness between a Chinese generic tofacitinib Kelejia® and the brand-name tofacitinib Xeljanz® in RA patients from a prospective real-world cohort.

Methods: PA: RA patients receiving tofacitinib, either generic (Kelejia®, generic group) or branded (Xeljanz®, branded group) were enrolled. All the patients were followed up until the discontinuation of tofacitinib or last visit. Primary outcome was simplified disease activity index (SDAI) defined remission rate at month 6. Secondary outcomes included the rates of remission and low disease activity (LDA) defined by other composite scores; EULAR response rate and ultrasonic synovitis scores at month 1, 3, 6 and 12. Cost-effectiveness was investigated. Propensity score-based inverse probability of treatment weighting (IPTW) was adopted to reduce selection bias.

Results: 204 patients were enrolled, with 59 in generic group and 145 in branded group. The SDAI defined remission was achieved in 41.1% and 39.2% patients in generic group and branded group at month 6, respectively (p=0.854). The rates of remission and LDA achievement, the changes of clinical disease activity scores, power doppler (PD) and gray scale (GS) synovitis scores at months 1, 3, 6 and 12 from baseline were all comparable between two groups. Similar proportions of patients in two groups achieved moderate/good response. Rates of drug retention (78.0% vs 77.2%, p=0.911) and adverse effect (5.1% vs. 4.8%, p=1.00) were also similar in two groups. Both Kelejia® and Xeljanz® were cost-effective, but Kelejia® had lower average cost-effectiveness ratio.

Conclusion: Generic tofacitinib (Kelejia®) showed equivalent clinical efficacy and safety, and better cost-effectiveness comparing with its originator (Xeljanz®). Kelejia® can be an alternative to brand-name Tofacitinib.

COST-EFFECTIVE ANALYSIS OF GENERAL TARGETED SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUG - TOFACITINIB IN RHEUMATOID ARTHRITIS (TIRA CEA STUDY)

Keywords: Rheumatoid arthritis, Targeted synthetic drugs

D. Syngle1, I. Verma2, K. Chauhan3, S. Patyal3, A. Syngle4,4,1, Healing Touch Foundation, Research & Innovations, Chandigarh, India; 2MM College of Pharmacy, MMU, Pharmacy Practice, Mullana, India; 3Healing Touch City Clinic, Internal Medicine & Rheumatology, Chandigarh, India; 4Fortis Hospital Mohali, Internal Medicine & Rheumatology, Sahibzada Aji Singh Nagar, India

Background: With the introduction of generic version of toDMARD tofacitinib in different parts of the world, its important to perform a cost-effective analysis of introducing generic tofacitinib to the current treatment sequence for patients with moderate-to-severe rheumatoid arthritis who have inadequate response or intolerance to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs-IR).

Objectives: Perform pharmacoeconomic analysis of introducing generic tofacitinib into the current treatment sequence for patients with moderate-to-severe rheumatoid arthritis who are csDMARDs-IR.

Methods: A prospective, observational study was conducted in 55 consecutive RA Indian patients (Table 1) meeting 2010 Rheumatoid Arthritis Classification Criteria with active disease and an inadequate response or intolerance to conventional disease-modifying antirheumatic drugs randomized to receive tofacitinib 5 mg bd as an add on therapy. All study patients attended the rheumatology OPD with 3 months follow-up. Average cost effectiveness analysis was done by taking HAQ-DI score as a measure of effectiveness. Total cost estimation included cost of the treatment, monitoring cost and adverse effect management.

Table 1. Demographic, clinical and biochemical characteristics of 55 Rheumatoid Arthritis patients

Results: RA patients included in study had established disease with 18.18% males and 81.82% females and 49% were seropositive. Majority of the study RA patients (89%) were on a background regimen of two synthetic DMARDs (MTX and HCO-80%, MTX and LEP-5.45%, SSZ and HCG-3.63%), and 1.61% of the RA patients were on a combination of three sDMARDs. After 3 months treatment with generic tofacitinib and other csDMARDs, the ASES-28 score improved from 5.31 ± 2.16 to 3.81±1.21, p<0.01 and the mean disability index estimated by HAQ-DI reduced from 1.93a to 0.60 to 0.62 ± 0.37, p<0.01. The direct medical cost of treatment of RA per month was 3032.81 rupees (34.39 Euro or 37.31 USD). The average cost effectiveness ratio for the treatment with generic tofacitinib and continuing the use of csDMARDs was Rs 3,998.71 (equivalent to 44.67 Euro or 48.48 USD) to gain or improve one unit of HAQ-DI score. Cost percentage for each head is depicted in Graph 1.

Conclusion: Treatment with generic tofacitinib is effective to control the disease activity and improves disability in RA. Incorporating generic tofacitinib into the csDMARD treatment sequence in active RA patients who have inadequate response or intolerance to csDMARDs is effective to improve the disability index. These results, reflecting the additional costs associated with deteriorating health condition, support the importance of using generic tofacitinib.

SLE, Sjögren’s and APS - treatment

**Keywords:** Rheumatoid arthritis, Clinical trials, Systemic lupus erythematosus

S. Cohen1, J. Beebe2, V. Chindalore3, S. Guan4, M. Hassan-Zahrae5, C. Hyde6, S. Koride7, B. Levin8, S. Lubaczewski9, M. Salganik10, A. Sloan11, E. Stevens12, E. Peeva13, M. Vincent14, D. Martin15, M. Chu16, Metropolis Clinical Research Center, NA, Dallas, United States of America; 2Pfizer Inc, NA, Cambridge, United States of America; 3Pinnacle Research Group, LLC, NA, Anniston, United States of America; 4Clinical Research of West Florida, NA, Clearwater, United States of America; 5Pfizer Inc, NA, Collegeville, United States of America; 6Pfizer Inc, NA, Groton, United States of America

**Background:** PF-06835375 is a humanised, afucosyl IgG1 antibody selective against C-X-C chemokine receptor type 5 (CXCRRS), a receptor expressed on B cells, bona fide T follicular helper (Th) cells and circulating T follicular helper-like (cT) cells. PF-06835375 is in development for autoimmune diseases through depletion of CXCRRS-positive B and Th cells and antagonism of C-X-C motif chemokine ligand 10-dependent signalling.

**Objectives:** This first-in-human study evaluated the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of PF-06835375 in patients with seropositive systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA).

**Methods:** This multi-centre, double-blind, placebo-controlled Phase 1 study enrolled patients aged 18–70 years with seropositive SLE (diagnosed by Systemic Lupus International Collaborating Clinics classification criteria, and positive anti-nuclear antibody titre ≥1:80 and/or anti-dsDNA and/or anti-Smith antibodies) or RA (diagnosed by 2010 ACR/EULAR criteria and positive rheumatoid factor and/or anti-citrullinated peptide antibody), with no minimum disease activity requirement. Patients were randomised to intravenous (IV) PF-06835375 (0.03, 0.1, 0.3, 1 or 6 mg) or placebo in 6 sequential single ascending dose (SAD) cohorts, or to subcutaneous (SC) PF-06835375 (0.3, 1, 3, 6 or 10 mg) or placebo administered on Days 1 and 29 in 5 multiple ascending dose (MAD) cohorts. Pre-and post-dose corticosteroids were permitted to manage infusion or injection reactions at the investigator’s discretion. Primary endpoints were incidence of treatment-emergent adverse events (TEAEs) of all causality, infections and laboratory, vital sign and electrocardiogram (ECG) abnormalities. Secondary endpoints were PK parameters, change in circulating CXCRRS-positive B- and cTfh-cell counts and incidence of anti-drug antibodies (ADAs).

**Results:** In total, 74 patients were randomised and 73 were treated (SAD cohorts: SLE, n=17; RA, n=14; MAD cohorts: SLE, n=22; RA, n=20). Corticosteroids were given in PF-06835375 3 and 6 mg IV cohorts and 3, 6 and 10 mg SC cohorts. Mean (standard deviation) age was 53.3 (10.7) years. Most patients were female (n=65, 89.0%) and White (n=54, 74.0%). In total, 62 patients (84.9%) experienced TEAEs; most were mild or moderate. Serious adverse events were reported in 3 patients (9.7%). One patient (1.4%) discontinued due to a TEAE of disease progression (placebo SC cohort). The most common TEAEs were headache (n=18, 24.7%), pyrexia (n=11, 15.1%) and urinary tract infection (n=9, 12.3%). All infections were mild or moderate. Laboratory abnormalities (placebo IV SAD, PF-06835375 1 mg IV SAD and PF-06835375 3 mg SC MAD) and ECG abnormalities (PF-06835375 0.1, 1 and 6 mg IV SAD) were reported as TEAEs in individual patients. No deaths occurred. In IV SAD cohorts, median T1/2 ranged from 2–4 h and mean CL ranged from 0.021–0.313 L/h. Exposure (AUC0–∞ and C0–∞) generally increased dose-proportionally for doses ≤1 mg and more than dose-proportionally for doses >1 mg. In SC MAD cohorts, median T1/2 ranged from 121–171 h and mean CL/F ranged from 0.07847–0.1171 L/h. Exposure (AUC0–∞ and C0–∞) generally increased dose-proportionally. B- and cTfh-cell counts generally showed dose-dependent reductions across cohorts (range of maximum mean depletions: 673–89.3% and 62.4–98.7%, respectively, in MAD cohorts; Figure 1). Mean duration of B- and cTfh-cell depletion extended up to 7.16 and 62.0 days, respectively, in SAD, and 78.5 and 109.5 days, respectively, in MAD cohorts. ADA data did not suggest any clinically relevant impact on PK, PD or safety.

**Conclusion:** PF-06835375 was generally well tolerated in patients with seropositive SLE and RA with potent and prolonged B- and cTfh-cell depletion, supporting further development as a treatment for autoimmune diseases.

**AB0512 INCIDENCE, PREVALENCE AND CURRENT TREATMENT PRACTICE OF SYSTEMIC LUPUS ERYTHEMATOSUS: A GERMAN CLAIMS DATA ANALYSIS**

**Keywords:** Epidemiology, Real-world evidence, Systemic lupus erythematosus T. Alexander1, M. Schulte2, J. Borchert3, T. Garcia3, E. Schrom1, 1Charité – Universitätsmedizin Berlin, Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Amgen GmbH, Medical Affairs, Munich, Germany; 3WG2 GmbH, Analytic, Leipzig, Germany; 4Amgen GmbH, Health Economics and Outcomes Research, Munich, Germany

**Background:** Despite recent advances in the management of systemic lupus erythematosus (SLE), patients still suffer from reduced quality of life and increased mortality compared to the general population [1]. The latest data for Germany report a prevalence of 38.6 – 55.8 cases per 100,000 between 2009 and 2014, however more recent data as well as investigations on treatment algorithms in a real world setting are limited [2].

**Objectives:** To investigate incidence and prevalence of SLE for Germany and to evaluate treatment sequences in adult patients with SLE in Germany.

**Methods:** In this retrospective claims data analysis, 3017 patients with SLE diagnosis between January 2012 and December 2019 were identified for incidence and prevalence analysis. Out of these, 941 incident patients between January 2012 and December 2017 were selected for analysis of current treatment practice. For this analysis, only patients initiating SLE treatment according to guidelines were considered [1]. The date of the earliest prescription for SLE treatment on or following the SLE diagnosis (index date) was defined as start of sequence of therapy (SOT) 1. A new treatment added or switched to resulted in a new SOT. Up to 3 SOTs were measured during follow-up. SLE severity was recorded as previously described [2].
Conclusion: While incidence of SLE is stable, prevalence is rising among German patients with statutory health insurance. Our data show that for newly diagnosed patients a combination of medication frequently including corticosteroids is required over time to control their disease. These data suggest a persistent unmet need for more effective treatment strategies for better SLE disease management and complement a recent US claims data analysis [3].

AB0514  LABORATORY MARKER IMPROVEMENTS FOLLOWING LONG-TERM TREATMENT WITH ANIFROLUMAB IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN THE PLACEBO-CONTROLLED TULIP EXTENSION STUDY

Keywords: Biomarkers, Randomized control trial, Systemic lupus erythematosus 

1University of Leeds, Leeds Institute for Infection & Immunity, School of Medicine, Leeds, United Kingdom; 2Hospital La Pitié-Salpêtrière, French National Reference Center for SLE, Paris, France; 3University of California, San Diego, Rheumatology, Allergy and Immunology, La Jolla, CA, United States of America; 4The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester; United Kingdom; 5University of Occupational and Environmental Health, The First Department of Internal Medicine, School of Medicine, Kitakyushu, Japan; 6Allegheny Health Network, Lupus Center of Excellence, Autoimmune Institute, Pittsburgh, PA, United States of America; 7AstraZeneca, Clinical Development, Late Respiratory & Immunology, BioPharmaceuticals R&D, Warsaw, Poland; 8AstraZeneca, Clinical Development, Late Respiratory & Immunology, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America; 9AstraZeneca, Biometrics, Late Respiratory & Immunology, BioPharmaceuticals R&D, Gothenburg, Sweden; 10AstraZeneca, Clinical Development, Late Respiratory & Immunology, BioPharmaceuticals R&D, Cambridge, United Kingdom.

RESULTS: Incidence rates were stable in both genders in Germany between 2012 and 2019, with women showing 3-4 fold higher incidence rates than men. In contrast, prevalence was rising from 40.5 in 2012 to 59.9 per 100,000 people in 2019, with a stronger trend in female patients (Figure 1). The mean (SD) age of the 941 incident patients identified for the treatment practice analysis was 50.6 (15.5) years. 74.4% were female and the mean (SD) follow-up duration was 1836 (634) days. 681 (70.3%) patients initiated SLE treatment (SOT1), with 246 (26.1%) progressing on to SOT2 and 113 (16.6%) on to SOT3. Monotherapy were most commonly prescribed in SOT1 (52.4%), while the use of combination therapies increases with SOT (SOT1 47.6%, SOT2 76.8%, SOT3 77.9%). Antimalarials in combination with corticosteroids were the most prescribed therapy during SOT1 (30.1%), immunosuppressants combined with corticosteroids during SOT2 (32.5%) and antimalarials combined with immunosuppressants and corticosteroids in SOT3 (36.3%). Combination therapies with biologics were used in 2.5% of patients in SOT2 and 8.8% of patients in SOT3 (Table 1). Disease severity increases with SOT.

Conclusion: Antimalarial-induced cardiomyopathy is a rare complication of prolonged use of antimalarial treatment. It can present with a conduction disorder, heart failure, or ventricular hyper trophy [1]. A systematic review has highlighted that early recognition and drug withdrawal are crucial and can potentially lead to recovery of cardiac function in up to 45% of patients. Despite this, there remains a significant risk of irreversible damage and death despite discontinuation (12.9% and 30.8% respectively) [2].

Methods: We identified a selection of patients with a diagnosis of a Connective Tissue Disease who had been prescribed Hydroxychloroquine for longer than 5 years. We performed cardiac screening including N-terminal-pro-BNP (NT-pro-BNP), Troponin I (Tnl), Creatine Kinase (CK) and an Electrocardiogram (ECG). A basic tool was used to determine the need for further investigations (Echocardiogram +/- Cardiac magnetic resonance imaging) to evaluate the presence or absence of Hydroxychloroquine-induced cardiomyopathy.

Results: A total of 124 patients met the specified criteria of which 115 were female (92.7%) and 9 were male (7.3%) with a mean age of 48 years. The underlying diagnoses included Systemic Lupus Erythematosus (n=103, 83.1%), Mixed CTD (n=9, 7.3%), Sjögren’s Syndrome (n=6, 4.8%), Undifferentiated CTD (n=3, 2.4%), and Systemic Sclerosis (n=1, 0.8%). A total of 40 patients (32.3%) had been prescribed Hydroxychloroquine for 5-10 years duration compared to 84 patients (67.7%) who had been prescribed for over 10 years duration. Daily Hydroxychloroquine dose varied from 0-200mg (n=15, 12.1%), 200mg (n=55, 44.3%), 200-400mg (n=13, 10.5%), and 400mg (n=41, 33.1%). Abnormal results which warranted further investigation included raised levels of NT-pro-BNP (76%), Tnl (4.2%), and CK (11.7%), and specific features seen on ECG (19.3%). A total of 31 patients were investigated using Echocardiography and none of these patients exhibited features suggestive of cardiomyopathy.

Conclusion: We did not identify any patients within this cohort with features suggestive of Hydroxychloroquine-induced cardiomyopathy. Despite the condition being rare, the true prevalence is unknown. Clinicians should remain vigilant and consider including a cardiovascular risk assessment in the long-term management of patients taking Hydroxychloroquine especially in high-risk patients such as those with a high cumulative dose of the medication [3].

Background: Anifrolumab is a type I interferon (IFN) receptor antagonist approved for treating adults with moderate to severe SLE [1]. The efficacy and safety of anifrolumab was evaluated in two 1-year phase 3 TULIP studies (NCT02446891, NCT02446899), and patients completing treatment in TULIP-1/-2 could enter the 3-year, placebo-controlled long-term extension (LTE) study (NCT02794285) [2–4]. Multiple serological markers are available to monitor SLE; notably, lymphopenia is associated with higher SLE disease activity and damage [5]. Assessing the long-term impact of anifrolumab on lymphocytes and other laboratory markers is of clinical interest.

Objectives: To compare the change over time of laboratory markers in blood samples from adults with SLE treated with anifrolumab vs placebo over the 4-year TULIP-LTE period.

Methods: Eligible patients fulfilled 1997 ACR criteria for SLE at TULIP entry, completed the TULIP treatment periods, and reconsented to participate in the LTE study. Here, we analyze data from patients who were randomized to anifrolumab 300 mg or placebo at TULIP entry and who did not change treatment over the TULIP-LTE period. Blood samples were collected from baseline (BL) until Week 208. Laboratory measurements (lymphocytes, hemoglobin, platelets, complement C3 and C4, anti–double-stranded DNA antibodies) were analyzed using standard cell count and enzyme-linked immunosorbent assays. Mean changes from BL to Week 208 were analyzed descriptively.

Results: We present data on 536 patients (anifrolumab 300 mg, n = 358; placebo, n = 178). Assessing lymphocytes over time revealed a numerically greater increase in the anifrolumab vs placebo group during the TULIP studies which was maintained through the 3-year LTE period (Figure 1). BL laboratory characteristics and changes from BL to Week 208 are shown in the Table 1. Numerically greater increases in hemoglobin levels and platelet counts from BL to Week 208 were observed in patients treated with anifrolumab compared with placebo; mean platelet and hemoglobin levels remained in the normal range at BL and Week 208. Among patients with low C3 levels at BL, there was a numerically greater mean improvement in C3 levels to Week 208 with anifrolumab vs placebo.

Conclusion: Long-term improvement of lymphocytes and other laboratory markers, compared with placebo, indicates that type I IFN inhibition with anifrolumab normalizes SLE-related hematological parameters in patients with SLE. This normalization may relate to disease activity reduction and be relevant to long-term health outcomes and complications.

AB0515 PHARMACOKINETICS, SELECTIVITY PROFILE, AND EXPOSURE-RESPONSE RELATIONSHIPS FOR EFFICACY AND SAFETY IN A PHASE 2 STUDY OF DEUCRAVACITINIB, AN ORAL, SELECTIVE, ALLOSTERIC TYK2 INHIBITOR, IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Targeted synthetic drugs

T. Ide1, M. Chiney1, H. Y. T. Bach1, V. Gotti1, B.Murphy1, C. Hobay2, Q. Zhao3, U. Aras1, Julius Strober2, Clinical Pharmacology, University of Pennsylvania, United States of America; 1Bristol Myers Squibb, Clinical Pharmacology, Princeton, United States of America; 2Bristol Myers Squibb, Clinical Development, Princeton, United States of America; 3Bristol Myers Squibb, Research & Early Development, Princeton, United States of America

Background: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis [1,2]. Deucravacitinib binds to the unique TYK2 regulatory domain, conferring greater functional selectivity vs JAK inhibitors, which bind to the catalytic domain. Deucravacitinib showed superior efficacy vs placebo in a phase 2 trial in SLE (NCT03252587) [3].

Objectives: This analysis assessed the pharmacokinetics (PK), selectivity profile compared to JAK inhibitors, and exposure–response (E-R) relationship for efficacy and safety of deucravacitinib in SLE.

Methods: In the phase 2 trial, patients with active SLE were randomized 1:1:1:1:1 to placebo or deucravacitinib (3 mg BID, 6 mg BID, 12 mg QD). PK analysis included pooled concentration data from 266 SLE patients and 328 phase 1 participants. IC50 was determined by in vitro whole blood assays and plotted against PK profiles. E-R analyses included data from 356 patients. Logistic regression analyses assessed the relationship between deucravacitinib exposure and probability of achieving efficacy endpoints and safety events at weeks 32 and 48.

Results: Deucravacitinib PK in SLE patients was not meaningfully different from that in phase 1 participants. At 12 mg QD, deucravacitinib Cmax was 80 fold lower than JAK 1/3 IC50, and 47 fold lower than JAK 2/2 IC50 (Figure 1). In the E-R analyses, the probability of achieving SRI(4) and BICLA at week 32 increased with increasing deucravacitinib Cmax with 3 mg BID providing near-maximal response. The E-R relationship for infection and infestation was relatively flat, while skin and subcutaneous tissue disorders increased with increasing deucravacitinib Cmax. These E-R relationships were similar at week 48.

Conclusion: Deucravacitinib PK in SLE patients is not meaningfully different from that in phase 1 participants. At clinically relevant exposures, deucravacitinib demonstrates highly selective inhibition of TYK2 vs JAK 1/2/3. The deucravacitinib E-R relationships are well characterized for various efficacy endpoints and safety events.

Background: Litifilimab (BII8059) is a humanised IgG1 monoclonal antibody targeting BDC2A2, a receptor predominantly expressed on plasmacytoid dendritic cells, that negatively regulates production of Type I IFN and proinflammatory chemokines and cytokines [1,2]. Both Part A (SLE) and Part B (CLE) of the randomised, placebo-controlled Phase 2 LILAC study of litifilimab (NCT02847598) met their primary efficacy endpoints at Weeks 24 and 16, respectively [1,2].

Objectives: To evaluate the effect of litifilimab treatment on IFN gene signature (IFNGS) scores and IFNα levels in LILAC participants.

Methods: Expression of a 22-IFNGS and IFNα concentrations were examined over time in whole blood and serum samples, respectively, from the LILAC modified intent-to-treat population (mITT; Part A N=120, Part B N=132) with a baseline biomarker value and at least one post-baseline value. Treatment effects were estimated using a mixed-effects model repeated measures approach (MMRM) and the dose-response relationship was estimated in Part B using a previously described MCP-Mod method [2].

Results: Few participants had low baseline IFNGS scores, so only data for participants with high baseline IFNGS scores are described here.

AB0519 LONG-TERM SAFETY OF BELIMUMAB AMONG ADULT PATIENTS WITH SLE: POOLED DATA FROM THREE OPEN-LABEL EXTENSION STUDIES OVER 11+ YEARS

Keywords: Clinical trials, Safety, Systemic lupus erythematosus

A. Mian1, P. Curtis1, C. Henning2, M. Khamashta3, B. Cervera4, D. J. Wallace5, M. Tektonidou7, T. Atsumi8.

1GSK, Global Medical Affairs, Brentford, United Kingdom; 2GSK, R&D Biostatistics, Brentford, United Kingdom; 3GSK, Global Medical Affairs, Durham, NC, United States of America; 4GSK, Medical Affairs, Dubai, United Arab Emirates; 5University of Barcelona, Department of Autoimmune Diseases, Hospital Clinic, Institut d’Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Catalonia, Spain; 6Cedars-Sinai Medical
Background: Belimumab is approved for the treatment of systemic lupus erythematosus (SLE) in >75 countries [1]. Clinical trials and long-term extension (LTE) studies have demonstrated the consistent safety profile of belimumab in patients with SLE receiving standard therapy (ST) [2-4]. A pooled analysis of LTE studies could provide a more robust dataset to explore the long-term safety of belimumab.

Objectives: To evaluate the long-term safety of belimumab in adult patients with SLE using pooled data from three multicentre, LTE studies.

Methods: This post hoc analysis pooled data from three belimumab LTE studies: LBS002 LTE (Phase 2; GSK Study 112626) [2], BLISS-LT (including US patients only; Phase 3; GSK Study 112233) [3], and BLISS-52 + BLISS-LT (excluding US patients from BLISS-52; Phase 3; GSK Study 112234) [4]. Patients were eligible for LTE studies if they completed their treatment through Week 72 (LBS002 and BLISS-LT trials), or Week 48 (BLISS-52 trial). LBS002 LTE also required an improvement in physician global assessment at Week 72 or 68 versus at first belimumab dose. From the start of each LTE, all enrolled patients received open-label belimumab 10 mg/kg intravenously every 28 days plus ST, regardless of study drug allocation in prior trials. Adverse events (AEs) were assessed at each infusion visit and summarised (based on observed data) any time post baseline (first belimumab dose in prior trial or LTE), and in each year.

Results: In total, 1304 patients were enrolled into the three LTE studies and 1299 (99.6%) received ≥1 dose of study drug (pooled safety population). Cumulative belimumab treated patient-years was 7040.1. Overall, 604 (46.5%) patients completed their respective studies. The main reasons for withdrawal included ‘withdrawal by patient’ (18.3%) and AE (10.6%). In the pooled safety population, 1054 (81.1%) and 616 (47.6%) patients received steroids and immunosuppressants at baseline, respectively. Over 11+ years, 1267 (97.5%) patients had ≥1 AE (incidence generally decreased yearly; Table 1), while 525 (40.4%) had ≥1 serious AE (SAE) and 139 (10.7%) experienced ≥1 SAE resulting in discontinuation (incidence of each was stable over time). By system organ class, infections and infestations were the most common AE of special interest (post-infusion systemic reactions (79.6) and respiratory, thoracic, and alimentary (78.8))

Scientific Abstracts
Deucravacitinib is a first-in-class, oral, selective, allosteric TYK2 inhibitor, Type I IFN) linked with systemic lupus erythematosus (SLE) pathogenesis. Deucravacitinib was efficacious compared with placebo in a phase 2b clinical trial (3, 4, 5). 

Objectives: 

To develop a customized IFN 5-gene signature score, assess the pharmacodynamic effects of deucravacitinib on the IFN score, and evaluate the score's association with SLE disease activity and clinical response in the phase 2b trial.

Methods: 

Patients with active SLE were randomized equally to oral placebo or deucravacitinib (3 mg BID, 6 mg BID, or 12 mg QD). DXTerity chemical kinase-dependent probe amplification was used to measure 51 immune system-related genes from whole blood. IFN genes were selected based on distribution, correlations, hierarchical clustering, and consistency of K-means clusters. Serum proteins, blood cell subsets, and antibody profiles were measured by immunofluorimetry and flow cytometry. SRI(4) and BICLA were measured at weeks 32 and 48.

Results: 

An IFN 5-gene (MX1, HERC5, IFIT1, RSAD2, and EIF2AK2) signature score was identified and used to classify patients into IFN-high or IFN-low subgroups (Figure 1). Higher baseline IFN score was associated with higher baseline SLEDAI and CLASI disease activity scores, higher levels of IFN activity biomarker, and lower complement and antibody profiles. Baseline IFN score was not predictive of SRI(4) response. A higher baseline IFN score was associated with a significantly higher probability of BICLA response with deucravacitinib 3 mg BID relative to placebo (P=0.014).

Conclusion: 

These data support the IFN 5-gene signature score as a biomarker to classify patients with SLE into IFN-high or IFN-low subgroups; however, clinical response by IFN score was inconsistently improved (Table 1). IFN-regulated gene expression performs well as a pharmacodynamic biomarker to confirm deucravacitinib mechanism of action and to aid in phase 3 dose selection.

Objectives: To evaluate global patterns in treatment of SLE and identify the prevalence of comorbidities.

Methods: We identified SLE patients from the COVAD 2 database, consisting of over 20,000 respondents worldwide. Healthy controls (HC) were included to account for variations across different regions.

Results: 24,000 patients were included in the analysis. Patients from low-medium HDI (lmHDI) countries were younger than those from high very high HDI (hvhHDI) countries (median age 32 vs 41, IQR 27-41 vs 40-52 years, p<0.0001). Disease duration was shorter in lmHDI countries (median 7 vs 10 years, IQR 5-15 vs 5-15 years, p=0.0011). A higher proportion of SLE patients from lmHDI countries were on Cs (73% vs 99%, p=0.0002), antimalarials (81% vs 68%, p=0.0002) and IS (66% vs 53%, p=0.0009) compared with patients from hvhHDI countries. Disease duration varied with azathioprine prescribed more frequently in lmHDI countries (p=0.049). Biologics use was more common in hvhHDI countries (7% vs 2%, p=0.0055). Comorbidity prevalence was similar between groups, however when adjusted for age, patients with chronic kidney disease were significantly younger in lmHDI countries (36.7 vs 44.6 years, p=0.015) and had shorter duration of disease (5 vs 15 years, p<0.0001). Outcomes were better in hvhHDI countries (71 vs 22% p=0.0002).

Conclusion: To our knowledge, this is the largest study evaluating treatment and comorbidity incidence in SLE populations based on country HDI. We identified striking differences in pharmacological management globally. Cardiovascular comorbidities were seen in younger patients and earlier in the disease course in lmHDI countries, suggestive of premature organ damage. This could be due to limited global access to high-cost medication and increasing access may improve outcomes. Our results call for review of cardiovascular risk guidelines and regional approaches to preventive action as well as pharmacological and non-pharmacological management of patients with established cardiovascular comorbidity.

TOXIC EPIDERMAL NECROLYSIS(TEN) IN SYSTEMIC LUPUS ERYTHEMATOSUS(SLE): RESULTS FROM A MULTI-INSTITUTIONAL COHORT FROM INDIA

Keywords: Skin, Systemic lupus erythematosus, Descriptive Studies

K. Chandrasekar1, A. Jain2, P. Ghosh2, A. Balakrishnan1, S. Manu1, S. Mukherjee3, A. Paruthi1, P. Srivastava1, A. Singh1, A. Wakhlu1, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India; 1SMS Medical College & Attached Hospital, Clinical Immunology and Rheumatology, Jaipur, India; 2IPGME&R and SSKM Hospital, Clinical Immunology and Rheumatology, Kolkata, India; 4St John’s Medical College Hospital, Clinical Immunology and Rheumatology, Bengaluru, India; 5King George’s Medical University, Clinical Immunology and Rheumatology, Lucknow, India; 6SMS Medical College & Attached Hospital, Internal Medicine, Jaipur, India; 7Star clinics, Clinical Immunology and Rheumatology, Ahmedabad, India; 8Apollo Medicos Super Specialty Hospitals, Clinical Immunology and Rheumatology, Lucknow, India

Background: Toxic Epidermal Necrolysis(TEN) is a rare but life-threatening manifestation of Systemic Lupus Erythematosus (SLE). Epidermal necrolysis (EN), including Stevens–Johnson syndrome and TEN, is commonly drug induced. Furthermore, flares of SLE may present as EN (TEN-like LE). To the best of our knowledge, this is the largest series of SLE-TEN.

Objectives: The current study aimed to study the clinical characteristics and outcome of SLE-related TEN in the Indian population.

Methods: All patients satisfying ACR/EULAR 2019 criteria for SLE and clinically diagnosed with TEN were retrospectively reviewed and compiled from 7 rheumatology centres across India. Drug-induced TEN were excluded from the analysis.

Results: 16 patients (1 child) were included in the study. The majority of patients were females (13/81.25%). The median age of presentation was 25 (8-50) years, and one-third of patients (5/31.25%) presented with TEN as one of their first manifestations. All patients of TEN had active lupus in their home and exact cause of death could not be ascertained.

Conclusion: TEN was a presenting manifestation in one-third of the patients with active disease in more than one domain. More than half of the patients had renal involvement and a quarter had Neuropsychiatric lupus (NPSLE). Anti-dsDNA, Anti-SSA positivity and low complement were common in patients with SLE-TEN. All patients required high-dose steroids for acute management of TEN, with maintenance therapy being guided by other domains involved. Though IVIG is often mentioned in literature as the treatment of choice for TEN, most patients with SLE-TEN did well with pulse and oral steroids suggesting IVIG could be reserved for patients with severe, resistant disease or in patients with concomitant sepsis.

IN SLE PATIENTS TREATED WITH BELIMUMAB TYPE I INTERFERON AND BAFF GENE SIGNATURES PREDICT CLINICAL RESPONSE: EVIDENCE FOR REVERSAL OF MOLECULAR PATHWAYS LINKED TO ACTIVITY AND SEVERITY UPON TREATMENT

Keywords: bDMARD, Systemic lupus erythematosus

Background: Belimumab, a monoclonal antibody against B-cell activating factor (BAFF), is the first biological agent approved in patients with systemic lupus erythematosus (SLE) with persistently active or flaring disease [1].

Figure 1. Clinical features of Patients with SLE-TEN (Created with Biorender.com)
Objectives: To determine molecular signatures that may predict response to therapy based on RNA sequencing analysis and the impact of belimumab on previously defined molecular signatures of SLE activity and severity [2,3].

Methods: Whole blood transcriptome samples were obtained from 38 patients with active moderate to severe SLE at baseline and 6 months after initiation of treatment with belimumab. Disease activity was determined using the SLE-DAI-2K while response to treatment was defined as the achievement of lupus low disease activity state (LLDAS) at 6 months (M6). DESeq2 was used to call differentially expressed genes (DEGs) and weighted correlation network analysis (WGCNA) was applied to uncover gene module-trait associations. The impact of the belimumab treatment on the SLE severity signature was evaluated [2].

Results: From 38 patients treated with belimumab, 35 (92.2%) were women, mean age (SD) was 48.2 (±13.5) years and mean SLEDAI-2K (SD) at baseline was 7.2 (±2.1). A total of 44.4% achieved LLDAS at M6. Both, the presence of a molecular signature of type I interferon signaling and the upregulation of BAFF expression correlated with response to treatment at M6 (p = 0.05 and p = 0.02 respectively). Treatment with belimumab reversed the innate and adaptive immune system signatures in responders at 6-months. Within the non-responders, baseline transcriptome, disturbances related to metabolic processes and rRNA biogenesis were predominantly enriched. A tendency towards downregulation of the severity disease transcriptional signature upon treatment with belimumab was also observed in 6-month responders (p = 0.3203).

Conclusion: Both the presence of type I interferon and BAFF gene expression signatures at baseline correlates with response to treatment with belimumab while metabolic processes and rRNA biogenesis correlate with no response.

Treatment with belimumab might ameliorate the molecular signatures indicative of disease severity in the 6-month-responders. These data provide a mechanistic basis for the response to treatment.

SUSTAINED RESPONSES TO ANTI-CD38 TREATMENT WITH DARATUMUMAB IN A PATIENT WITH REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Adaptive immunity

T. Alexander1,2, L. Ostendorf2, R. Biesen3, A. Radbruch4, G. R. Burmester1, F. Hiepe1,2, *Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin and Berlin Institute of Health, Rheumatology and Clinical Immunology, Berlin, Germany; 2Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Autoimmunology, Berlin, Germany; 3Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Nephrology and Intensive Care Unit, Berlin, Germany; 4Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Cell Biology, Berlin, Germany

Background: Given their contribution to the chronicity of autoimmune response, long-lived plasma cells (PCs) resemble an attractive treatment target in systemic lupus erythematosus (SLE) and other autoantibody-mediated diseases. We have recently reported the successful treatment of daratumumab, a CD38-targeting human monoclonal antibody, in two refractory patients with SLE [1], demonstrating a clinically relevant depletion of long-lived plasma cells with marked reduction of anti-double-stranded DNA (dsDNA) antibodies and marked clinical improvement in both cases over a follow-up period of 12 months.

Objectives: Here, we describe the long-term clinical and serologic responses of daratumumab treatment in one patient with SLE with a follow-up of 36 months.

Methods: A 51-year-old woman, who suffered from active lupus nephritis WHO class-III/V with nephrotic syndrome, pericarditis, arthritis and skin rash despite treatment with mycophenolate mofetil (MMF), cyclosporine A (CsA), hydroxychloroquine (HCQ) and glucocorticoids (GC), had received 4 weekly intravenous doses of 16mg/kg daratumumab as add on to background medication, which was complemented by subcutaneous 200mg belimumab weekly, starting 4 months after the initiation of daratumumab. Autoantibodies were investigated with ELISA and type-I interferon (IFN-I) activity investigated by measuring SIGLEC-1 expression on monocytes with flow cytometry.

Results: During follow-up, the patients’ Urinary Protein/Creatinine Ratio (UPCR) declined from 1197 mg/g at 12 months to 467 mg/g Creatinine at the last follow-up, while serum creatinine remained within normal levels (Figure 1A). No flares or novel disease manifestations occurred during the 3-year observation period, although the dosage of MMF was tapered to 1g daily at 21 months and prednisolone discontinued at 33 months, respectively, after the first daratumumab administration. Serologically, serum anti-dsDNA antibodies further decreased from 254 IE/ml at the 12 months follow-up to 38 IE/ml at 36 months (Figure 1B), and complement levels for C3 were consistently within the normal range (Figure 1C). Serum IgG levels remained stable after previous substitution with two doses of 30g intravenous immunoglobulins (Figure 1D). In addition, her initially increased type-I interferon activity, determined by the flow cytometric assessment of SIGLEC-1 on freshly isolated monocytes, completely normalized during follow-up, an effect most strongly observed during the first weeks following daratumumab therapy (Figure 1E). At the last follow-up, she was in complete clinical remission, with a SLEDAI-2K of 2 due to slightly elevated dsDNA antibodies (Figure 1F). No severe adverse events occurred during follow-up, and no hospitalization was required for the management of SLE, infections or comorbidities.

Conclusion: Our data demonstrate that the administration of daratumumab as induction therapy for refractory and serologically active SLE may provide sustained clinical responses, when combined with immunosuppression and/ or belimumab as maintenance therapy to prevent recurrence of autoreactive PCs. Apparently, depletion of long-lived PCs resulted in a therapeutically relevant reduction of autoantibodies and IFN-I activity, indicating a profound disease modification with resetting the chronic autoimmune immune system into an earlier stage of development, regaining responsiveness to standard therapies. These data suggest further studies to investigate the safety and efficacy of daratumumab in SLE and other autoantibody-mediated autoimmune diseases.

**AB0526** EVALUATION OF SATISFACTION AND EFFICACY OF SWITCHING FROM INTRAVENOUS TO SUBCUTANEOUS BELUMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN DAILY CLINICAL PRACTICE

**Keywords:** bDMARD, Patient reported outcomes, Systemic lupus erythematosus

¹Hospital Clinic de Barcelona, Rheumatology Department, Barcelona, Spain; ²Hospital del Mar/Parc de Salut Mar-IMIM, Rheumatology Department, Barcelona, Spain; ³Hospital de Bellvitge, Rheumatology Department, L’Hospitalet de Llobregat, Barcelona, Spain; ⁴Hospital Universitario Germans Trias i Pujol, Rheumatology Department, Badalona, Spain; ⁵Hospital Vall d’Hebron, Rheumatology Department, Barcelona, Spain; ⁶Hospital de la Santa Creu i Sant Pau, Rheumatology Department, Barcelona, Spain; ⁷Hospital Moisès Broggi, Rheumatology Department, Barcelona, Spain

**Background:** In 2017, Belimumumab (BEL) was approved in subcutaneous (SC) version [1]. The effectiveness after switching from intravenous (IV) to SC and patient satisfaction in daily clinical practice has not been studied. During the pandemic, patient follow-up and treatment were significantly affected, including the administration of IV biologic therapies. In some patients, a change from IV to SC, including BEL therapy, was required [2].

**Objectives:** Our aim was to evaluate in daily clinical practice satisfaction to BEL SC therapy in patients previously treated IV BEL. We hypothesized that SC BEL in SLE patients previously treated with IV BEL was similar in effectiveness and conferred higher satisfaction.

**Methods:** Observational, multicenter study, conducted in 7 reference centres in Catalonia (Spain). Inclusion criteria: Stable SLE patients (EULAR/ACR 2019) on treatment with BEL SC and previous use of BEL IV (at least 3 months of treatment with BEL IV before switching). Since there are no well-validated tools for SC BEL treatment satisfaction, we used RASQ-SC, validated in patients with lymphoma who switched from Rituximab IV to SC treatment [3], modified for BEL treatment.

**Results:** Twenty-seven patients were included. Demographic and general characteristics are summarized in Table 1. The mean time from treatment with BEL IV before switch to SC was 26 (SD 21) months. 84% of patients reported confidence in BEL SC. 80% felt that treatment with BEL SC was convenient or very convenient. 85% felt they had gained time with the change. 88% would recommend the SC injection to other patients (Figure 1a,b,c,d). Disease activity (mean SLEDAI) and remission rates remain stable after switching. Patients did not require higher doses of glucocorticoids after the switch (Table 1). No major new side effects were reported.

AB0527  FACTORS ASSOCIATED WITH GLUCOCORTICOID-FREE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH BELIMUMAB IN THE REAL-WORLD SETTINGS: A SINGLE-CENTER RETROSPECTIVE COHORT STUDY IN JAPAN

Keywords: Real-world evidence, Tapering, Systemic lupus erythematosus

T. Yamane1, A. Hashiramoto2, 1Kakogawa Central City Hospital, Department of Rheumatology, Kakogawa, Japan; 2Kobe University Graduate School of Health Sciences, Department of Biophysics, Kobe, Japan

Background: The treatment of patients with systemic lupus erythematosus (SLE) involves the progression of organ damage due to both the disease itself and glucocorticoid-induced adverse events [1]. Therefore, achieving glucocorticoid-free status is one of the most important goals in the treatment of SLE [2]. Belimumab has been reported to be effective in SLE patients, particularly with high disease activity, by inhibiting the B-lymphocyte stimulator (BLyS) to reduce disease activity, relapse rate, organ damage, and steroid dosage [3,4].

Objectives: Review the profile of patients who can achieve glucocorticoid-free status with belimumab administration, retrospectively.

Methods: We retrospectively reviewed 47 Japanese SLE patients who received belimumab for at least 1 year in addition to standard of care, including glucocorticoids. Patients were classified into two groups: glucocorticoid-free (GC free) and others (GC continue) as of August 2022. Trends in C3, C4, and dsDNA antibody titers, SLEDAI-2K scores, and daily glucocorticoid dosage were examined at the start of belimumab and thereafter; at months 12 and 24. At the time of belimumab initiation, differences between the two groups were also examined for age, duration of disease, time from onset or last relapse to belimumab initiation, C3, C4, dsDNA antibody titer, daily glucocorticoid dose, SLEDAI-2K, with or without concomitant hydroxychloroquine and concomitant immunosuppressive drugs, and duration of belimumab treatment. Incidence of adverse event or relapse during the course were also followed. P values were determined using Wilcoxon's signed rank test, Mann-Whitney U test, and Fisher's exact test.

Results: 9 patients (19%) were classified as GC free. In overall patients, C3, C4, dsDNA antibody titer, and SLEDAI score showed significant improvement at 12 and 24 months compared to the baseline. The daily GC dosage was significantly reduced while it was increased in 2 patients (5%). Though there was no significant difference in SLEDAI, C3 was significantly higher in the GC free group at the baseline (P=0.032). There were no cases of discontinuation of belimumab due to adverse events or relapse during the course.

Conclusion: Although low C3 patients are more likely to benefit from belimumab because of higher serum BLyS levels [5], it is worthwhile to introduce belimumab for GC-free even in patients with high C3 levels.

Background: Belimumab (BLM) is a recombinant human IgG1 monoclonal antibody that inhibits B-cell activating factor. It is commonly used for treatment of systemic lupus erythematosus (SLE) patients with inadequate control to first-line treatments and inability to taper GC daily dose to acceptable levels. More recently it has been approved for patients with active lupus nephritis.

Objectives: To report baseline profile of SLE patients treated with BLM enrolled in a SLE Spanish registry.

Methods: Multicenter retrospective and longitudinal cohort study including SLE patients treated with BLM in 18 Spanish rheumatology units. Demographic, clinical and treatments were collected at baseline, 6, 12 months and in the last visit available. Patients starting BLM in different periods (2010-2015 and 2016-2021) were compared regarding the reason of prescription of the drug.

Results: 324 patients (91% female, 84.8% caucasian) were enrolled. Mean (±SD) age at diagnosis: 31.8 years (±11.9); mean disease duration of 8.7 years (±9.07) and mean follow-up 3.8 (±2.7). A total of 319 (98.45%) subjects met SLE 1997 ACR or SLICC 2012 criteria; 217 (68.2%) were anti-dsDNA positive and 224 (69.8%) had low complement levels. At baseline, the mean SLEDAI-2K score was 10.4 (±5.25); 152 (47.5%) of patients had damage with a mean SDI score of 10.3 (±9.07) and mean follow-up 3.8 (±2.7). A total of 319 (98.45%) subjects met SLE criteria.

Methods:
- Two hundred and forty patients (74.3%) received BLM as mono therapy. It was prescribed due to active disease in the vast majority of patients and/or as GC sparing agent. Activity in articular and cutaneous domains were the main reasons of indication. No changes in prescription habits were identified over time.
- There were no statistically significant differences in any of the prescription reasons when comparing the periods 2010-2015 and 2016-2021.

Conclusion: In the majority of patients, belimumab was prescribed after the use of other DMARDs and more than 50% of patients had received at least 2 DMARDs and were receiving GC at medium doses. One third of patients received BLM as monotherapy. It was prescribed due to active disease in the vast majority of patients and/or as GC sparing agent. Activity in articular and cutaneous domains were the main reasons of indication. No changes in prescription habits were identified over time.

Figure 1. Cumulative probability of new-onset organ damage (A) and renal damage (B) in SACQ patients maintain glucocorticoids, withdraw glucocorticoids but flares, and successful withdraw glucocorticoids.

Conclusion: Our results suggest that low-dose glucocorticoids withdrawal under tight surveillance could be considered after achieving the clinical state as SACQ to prevent the accrual of renal damage.

DESIGN OF 2 PHASE 3, DOUBLE-BLIND, PLACEBO-CONTROLLED, GLOBAL TRIALS OF DEUCRACVINIB, AN ORAL, SELECTIVE, ALLOSTERIC TYROSINE KINASE 2 (TYK2) INHIBITOR, IN PATIENTS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Clinical Trials, Systemic lupus erythematosus

Objectives: Here, we describe 2 phase 3 trials currently underway to assess the efficacy and safety of deucravacitinib in patients with active SLE. These phase 3 trials have been designed to replicate the successful elements of the phase 2 trial, including its glucocorticoid-tapering strategy and rigorous management structure [3].

Methods: In these phase 3, randomized, double-blind, placebo-controlled, global trials (POETYK SLE-1 [NCT05617677], POETYK SLE-2 [NCT05620407]), adults (aged 18-75) with active SLE on background standard-of-care treatment will be randomized (1:1) to placebo or deucravacitinib for 52 weeks of double-blind treatment (Figure 1). Patients on glucocorticoids will be instructed to taper, unless significant disease activity is present, to a threshold dose level during the double-blind treatment period. At week 52, patients may choose to continue in a 104-week open-label extension phase, in which all patients receive deucravacitinib. Key eligibility criteria and study design are depicted below (Figure 1).

Primary Endpoint
- Proportion of patients who achieve a ≥ 50% reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI-50) among patients with CLASI activity score ≥ 10 at baseline
- Proportion of patients who achieve Lupus Low Disease Activity State (LLDAS)
- Proportion of patients maintaining ≥ 7.5 mg/day glucocorticoid dose from weeks 24 to 52
- Proportion of patients who achieve a ≥ 50% reduction in active joints (Joint-Count 50) among patients with ≥ 6 active joints at baseline
- Change from baseline in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score

Conclusion: Here, we describe 2 phase 3 trials currently underway to assess the efficacy and safety of deucravacitinib in patients with active SLE. These phase 3 trials have been designed to replicate the successful elements of the phase 2 trial, including its glucocorticoid-tapering strategy and rigorous management structure [3].

Results: Planned randomization in each trial includes 490 patients (245 per treatment group) in 27 countries across North and South America, Europe, and Asia-Pacific.

DOI: 10.1136/annrheumdis-2023-eular.3881
Background: We have recently published a working definition of disease modification in lupus nephritis (LN) as ‘minimising disease activity with the fewest treatments as disease-modifying is critical in informing treatment decisions’ [1]. As an increasing number of LN medications become available, classification of treatments as disease-modifying is critical in informing treatment decisions.

Objectives: To apply the proposed disease modification criteria to LN treatments.

Methods: Based on a review of a selection of LN clinical trial (n=21) and practice/observational publications (n=18) and authors’ clinical experience, we determined whether the LN treatments satisfied the renal disease activity and organ damage disease modification criteria. The proposed disease modification criteria were examined at three time points as shown in Table 1.

Results: All LN treatments met at least one of the renal disease modification criteria at any time point (Table 1), with hydroxychloroquine meeting the criteria for confirmed disease modification at >5 years (no change in Systemic Lupus International Collaborating Clinics/American College of Rheumatology Disease Index [SDI] or delayed progression beyond 5 years). Belimumab met more criteria across the three time points than any other biologic treatment. Based on the reviewed literature, many criteria were inconclusive or not available for evaluation. Glucocorticoids did not meet the disease modification criteria beyond 5 years given their negative impact on organ damage progression.

Conclusion: We examined the evidence in the literature for the disease modification potential of LN therapies at 1, 2–5, and >5 years. Categorisation of treatments as disease-modifying is challenging, as studies use multiple agents, and study designs, patient populations, and endpoints/definition of renal response are not consistent between studies. The criteria allowed for the differentiation between LN therapies; future studies will evaluate the minimum number of criteria required to designate disease modification at each of the three time points, so that disease modification can be considered in the care of patients with LN and LN trial design.

THE USE OF BDMARDS IS ASSOCIATED WITH A LOWER PREVALENCE OF BILATERAL CAROTID PLAQUE IN PSA

Keywords: Cardiovascular disease, bDMARD

D. A. Galazar-Delgado, J. C. Colunga-Pedraza, J. R. Azpiroz-López, N. De Ávila González, V. M. Beltran-Aguilar, V. Gonzalez-Gonzalez, A. G. Arias Peralta, J. A. Cardenas-de la Garza. 1Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico; 2Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico

Background: Psoriatic arthritis (PsA) is an autoimmune rheumatic disease (ARD) [1]. PsA have excessive cardiovascular risk (CVR) because of systematic inflammation that triggers endothelial dysfunction, which in turn induces atherosclerosis and CV disease [2]. Possible beneficial effects of biologic disease modifying antirheumatic drugs (bDMARDs) in patients with ARDs have been seen, particularly those with psoriatic arthritis. Treatment with TNF inhibitors seems to improve endothelial dysfunction and atherosclerosis [3].

Objectives: To evaluate the presence of carotid disease in patients with PsA using biologics or non-biologics.

Methods: This was a cross-sectional, descriptive study. PsA patients aged 40-75 years, who fulfilled the 2006 CASPAR criteria were recruited. Carotid ultrasound was performed on all study participants, and the presence of carotid plaque (CP), defined as carotid intima-media thickness (cIMT) ≥1.2mm or focal thickness >0.5mm, was assessed. Patients were divided into 2 groups according to whether they use bDMARDs or not. Comparisons were done with Chi-square test, Student's T test and Mann-Whitney's U-test. A p-value ≤0.05 was considered significant.

Results: A total of 67 patients were recruited. Demographic characteristics are shown in Table 1. Twenty-seven were under bDMARD treatment, twenty-five of these were using an anti-TNF. We found a difference in C-reactive protein (CRP) levels (p=0.004), lower in patients with bDMARDs and in the presence of bilateral CP (p=0.041), less prevalent in patients with bDMARDs. The rest of the variables studied did not show significant differences.

Conclusion: We found that PsA patients under bDMARDs therapy had lower levels of CRP and less prevalence of bilateral CP in PsA, therefore strengthens the theory that the less inflammation the less bilateral carotid plaque is present.

AB0533  EFFECT OF RENIN-ANGIOTENSIN SYSTEM INHIBITORS ON RENAL REMISSION IN LUPUS NEPHRITIS: A REAL-WORLD SINGLE-CENTER STUDY

Keywords: Clinical trials, Systemic lupus erythematosus, Kidneys

X. Zhang1,2, H. Huang1,3, Y. Fan1, Z. Zhang1,3, 1Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China

Background: Renin-angiotensin-system inhibitors (RASI) reduce urinary protein excretion and protect renal function in both diabetic and nondiabetic nephropathy. Few studies have focused on RASI in LN patients.

Objectives: The study aimed to provide real-world evidence to assess the effect of RASI in LN patients.

Methods: A total of 233 LN patients were included; 155 were RASi users, and 78 were not. The rate of proteinuria partial recovery (PPR), complete remission (CR), total remission (TR), the decline and decline rate of proteinuria at 6 and 12 months were compared by Chi-square test and Kaplan–Meier analysis. Propensity score matching (PSM) was performed.

Results: The cumulative rates of PPR, TR and CR were 144 (99.4%), 115 (76.1%), and 83 (56.0%) in the RASi group and 73 (97.3%), 64 (83.5%) and 54 (71.3%) in the no RASi group, respectively. There was no statistically significant difference in the cumulative rates of PPR, TR and CR between the two groups (p=0.601 and 0.203). The baseline data are as follows:

AB0534  TREATING SYSTEMIC LUPUS ERYTHEMATOSUS IN THE 21ST CENTURY: COMBINING RITUXIMAB WITH BELIMUMAB

Keywords: Systemic lupus erythematosus, Treat to target

B. Issayeva1, A. Mesynkina2, E. Aseeva2, S. Solovyev2, N. Nikishina2, S. Issayeva1, M. Sarapbayeva2, A. Armanzhlova2, A. Razikova1, A. Abdulgaziz1, Astfenidiyar, Kazakhstan National Medical University, Rheumatology, Almaat, Kazakhstan; Federal State Research Institute (FSRI) named after V.A. Nasonova, Rheumatology, Moscow, Russian Federation

Objectives: erection of combination therapy with rituximab and belimumab in patients with systemic lupus erythematosus.

Methods: The study included 15 SLE pts (1M/14F) criteria with high (SLE-DAI≥20) and moderate (SLE-DAI<20–20pts.) disease activity; out of them 4 patients had lupus nephritis, 2- vasculitis, 1 pts had kidney damage, cerebrovasculitis and vasculitis. All patients fulfilled the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) disease classification criteria [1] for SLE Others have predominantly mucocutaneous and articular manifestations of SLE. The dose of oral glucocorticoids (GC) was: 60 mg in one patient with vasculitis, LN, cerebrovasculitis, and one patient with vasculitis received 20 mg of prednisone; in 11 patients from 10 to 5 mg; in 2 patients without oral glucocorticoids. All patients with SLE with kidney damage and vasculitis received mycophenolate mofetil or cyclophosphamide. Rituximab (RTM) was administered at a dose of 500-2000 mg, followed by the addition of belimumab (BLM) after 1-6 months at a standard dose of 10 mg/kg once a month - a total of 7 infusions. The following parameters were evaluated: the effectiveness of therapy, the concentration of autoantibodies, the dose of oral corticosteroids initially at the time of RTM administration and then every 3 months after the initiation of BLM therapy.

Results: 13 pts demonstrated the decrease in clinical and laboratory SLE activity, starting from 3mo of follow-up. After the start of BLM infusions, a decrease in SLE activity was observed in all patients. Among them, 10 had SLEDAI-2K activity of less than 4 points. SLEDAI-2K Me 10 [10,16]; after treatment of RTM and BLM 4(2,6). Only one patient (No4) had a relapse of SLE, due to the delay.

in receiving the infusion of BLM. He was receiving standard GC doses. In dynamics, a decrease anti-double DNA titres (Me 101 [36;200]U/ml vs 28 [8.67]E2/μm), C3 (0.49 [0.42;0.79] g/l vs 0.71 [0.59;0.87] g/l), C4 (0.06 [0.045;0.1] g/l vs 0.12 [0.07;0.14] g/l) was registered. The GC dose was reduced in most patients (Table 1), but the previously prescribed immunosuppressive therapy continued. There were no cases of severe infection. We have not detected any new organ damage.

Conclusion: Combination therapy allows to gain control over disease activity in short time, due to the effect of RTM, while added BLM provides further prolongation of the effect achieved, minimizing the risk of flare. The use of such therapy contributes to a rapid and effective reduction in the activity of the disease, improvement of laboratory markers of SLE (at to ds-DNA, C3, C4), the use of lower doses of oral GCs. This combination may be used as a method of choice in pts with severe SLE involving vital organs, and in persistent cutaneous-articular disease and high immunological activity.

EFFICACY AND SAFETY OF BELIMUMAB IN PATIENTS WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS:A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Systematic review, Systemic lupus erythematosus, Targeted synthetic drugs

L. Yang1,2, Q. Y. Su1,2,3, R. X. E. Yang1,2, J. J. Cao1,2, P. Su1,2, H. Niu1,2, S. L. Liu1,2, J. D. Li1,2, Q. Yu4, P. F. He4, X. L. Zhang1,2,3, S. X. Zhang1,2,3,1Shanxi Medical University, Ministry of Education, Key laboratory of Cellular Physiology, Taiyuan, China; 2Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 3Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 4Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

Background: Childhood-onset systemic lupus erythematosus (cSLE) is associated with higher disease severity than adult-onset lupus. Abnormal activation of B cells is a crucial link in their pathogenesis. Belimumab is a specific inhibitor of the soluble B lymphocyte stimulator and inhibits its binding to receptors and thus its activity [1,2]. However, the current clinical research evidence of this drug in children is insufficient, the relevant clinical data are mostly from prospective studies in adults, and there are no exact guidelines for clinical application in children.

Objectives: This study aimed to investigate the efficacy and safety of belimumab for treating children with cSLE.

Methods: We systematically searched PubMed, EMBASE, Wan Fang Data, Web of Science, the Cochrane Library, and Medline for randomized controlled trials, original case reports, and case series that described belimumab’s efficacy in treating cSLE. A random-effects meta-analysis was performed to calculate its efficacy. Inconsistency was evaluated using the I2 and Egger tests to evaluate potential publication bias (STATA v12.0).

Results: Five studies with 325 patients were included in the meta-analysis (Table 1). The age range of the included participants was less than 18 years; most were women. All patients received belimumab at a dosage of 10 mg/kg every 2 weeks for the first three doses. Then every 4 weeks thereafter: SLEDAI-2K was the main score which was significantly reduced compared with the baseline(SMD= -1.108, 95%CI [-1.131, -0.901], P<0.001). The number of oral corticosteroids was significantly decreased after the belimumab therapy(SMD= -1.219,95%CI [-1.72, -0.70], P<0.001). Both Anti-double stranded DNA (Anti-dsDNA) and anti-nuclear antibodies (ANA) positive patients also decreased obviously(RR= 0.56, 95%CI [0.37;0.85], P=0.007; RR= 0.90, 95%CI [0.83;0.98], P=0.012). Infection and thrush were the main adverse effects with rates of 26% and 4%, respectively, but all were classified as mild-moderate treatment-emergent adverse events. Serious adverse reactions are rarely reported.

Conclusion: Belimumab treatment in cSLE minimizes the use of hormones, and the incidence of adverse events such as infections was low, suggesting belimumab can effectively reduce disease activity safely and reliably. Long-term efficacy and safety still need a multicenter, large sample, long-term, in-depth research.

**CORRECTION OF OMEGA-3 FATTY ACID DEFICIENCY AND IMPROVEMENT IN DISEASE ACTIVITY IN SLE PATIENTS TREATED WITH A CONCENTRATED EXTRACT OF KRILL OIL (AKM-3031)**

**Keywords:** Diet and Nutrition, Systemic lupus erythematosus, Randomized controlled trial

J. E. Salmon, D. J. Wallace, Y. Fu, P. Lingard, Hospital for Special Surgery, Rheumatology, New York City, United States of America; Cedars-Sinai Medical Center, Rheumatology, Beverly Hills, United States of America; University of Maryland Medical System, Rheumatology, Baltimore, United States of America; AMPLE BioSolutions, Research and Development, Charlotteville, United States of America

**Background:** Omega-3 fatty acids play a critical role in regulating inflammation. Patients with SLE have been reported to be deficient in omega-3 fatty acids, and deficiency could play a role in the ongoing inflammation characteristic of this disease. Previous work has produced conflicting results regarding the capacity of Omega-3 supplementation to control SLE disease activity.

**Objectives:** The goals of this study were to determine the level of omega-3 deficiency in SLE patients and to determine whether supplementation with a concentrated extract of krill oil rich in omega-3 fatty acids (AKM-3031) could overcome the deficiency in SLE patients and decrease disease activity.

**Methods:** This was a randomized double blind controlled multicenter study of patients with active SLE (SLEDAI >6) and 6 patients meeting entry criteria were randomized to receive AKM-3031 (4 grams/day) or identical placebo capsules containing mixed oils simulating that in a western diet (NCT03826311). Patients received investigational product or placebo daily for 24 weeks, at which time placebo patients could opt to receive AKM-3031 for the subsequent 24 weeks, whereas those receiving AKM-3031 continued on the medication. The primary outcome was the correction of the red blood cell omega-3 index determined by OmegaQuant. Changes in clinical features and adverse events were collected throughout the trial.

**Results:** 79 subjects were enrolled in the study; 97% of the patients were women and 56% were of European and 35% of African Ancestry. At baseline, the mean omega-3 index was 4.65±1.09, below the lower limits of normal for the North American population (6.0). After 4 weeks of treatment with AKM-3031, the omega-3 index significantly increased to 5.65±1.09 to 7.21±1.57 (P < 0.0001), whereas no significant change was noted in the patients receiving placebo. Increases in the omega-3 index in AKM-3031 treated patients persisted throughout the 48 weeks of the trial. Notably, when patients were changed from placebo to AKM-3031 at 24 weeks, there was a rapid increase in the Omega-3 index (4.62±1.39 to 6.58±1.85, P = 0.0001). The total number of adverse events was less in the AKM-3031 group (186) than in the placebo group (342), most were mild or moderate and no serious adverse events were noted. Although there were no significant changes in disease activity when the entire groups were examined, there was a significant decrease in disease activity measured by SLEDAI-2K at 4, 8 and 16 weeks (P = 0.0007, 0.04, 0.02, respectively) in the patients receiving AKM-3031 with high disease activity baseline (SLEDAI >8).

**Conclusion:** Treatment of SLE patients with AKM-3031 rapidly corrects the Omega-3 deficiency characteristic of these patients. AKM-3031 was safe and decreased disease activity in those with more active SLE. These results suggest benefit of Omega-3 deficiency correction with AKM-3031 in SLE patients with active disease and warrant a more extensive evaluation.

**RITUXIMAB THERAPY IN LUPUS NERITRIS RESISTANT TO CONVENTIONAL THERAPY — A SINGLE CENTER EXPERIENCE (CASE SERIES)**

**Keywords:** Systemic lupus erythematosus, Real-world evidence, Safety

E. Firtal Senturk, H. Oğun, I. Durukan, B. Yurttaş, S. Uğurlu, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; Tekirdag Ismail Fehmi Cunaloglu City Hospital, Department of Internal Medicine, Division of Rheumatology, Tekirdag, Turkey

**Background:** Lupus nephritis (LN) can be a cause of morbidity and mortality in a significant portion of patients. The treatment of lupus nephritis can be challenging in some patients who are resistant to conventional immunosuppressive treatment.

**Objectives:** Rituximab is a promising agent for treating resistant LN patients. We evaluated the response of LN patients who were treated with rituximab treatment in our clinic retrospectively.

**Methods:** We evaluated LN patients who were followed and treated with at least one course of rituximab in our clinic between 2010-2022. LN was confirmed by renal biopsy. Creatinine clearance, serum creatinine, 24-hour proteinuria and Systemic Lupus Erythematosus Disease Activity Index-2000 (SLE-DASI) were analyzed before and after Rituximab treatment. Primary end point was current prednisolone dose ≤5mg and 24-hour proteinuria ≤500mg. Also, we evaluated the side effect of rituximab.

**Results:** Forty seven patients (34 F, 13 M) were treated with rituximab. All patients had active lupus nephritis at initiation. Mean of disease duration was 10.44 ± 6.9 years. All patients were initially treated with high dose steroids. The other medications, the patients were previously treated with, were cyclophosphamide (n = 35), mycophenolate mofetil (n = 31), azathioprine (n = 6), cyclosporine (n = 2). Patients received an average of 4.1 ± 3.68 courses of rituximab (Table 1). The median value of pre-treatment proteinuria was 3050 (1370, 5175) mg/day. The median value of proteinuria after the final course was 747 (396, 1500) mg/day (p = 0.01). Serum creatinine level was changed from 0.94 ± 0.59 to 0.98 ± 0.68 (p = 0.53). Mean serum creatinine clearance was increased from 102.01 ± 43.2 to 109.1 ± 51.3 (p = 0.28). Mean SLE-DASI-2K was reduced from 16.3 ± 6.2 to 7.2 ± 4.8 (p = 0.01). While initial steroid dose was 24.13 ± 18.47 mg/day, steroid dose at last rituximab course was 7.5 ± 5.8 mg/day (p = 0.01). End stage renal disease was developed in 3 (%6) patients. For primary end point of view, current prednisolone dose ≤5mg and 24-hour proteinuria ≤500mg were achieved in %31, %36 of patients respectively. Both criteria was met by %25.5 of patients. During the treatment, 2 patients had serum reaction, 3 had pneumonia, 3 had herpes zoster. Three patients had hippocagamoglobinemia and treated with intravenous immunoglobulin. No one was died of lupus nephritis.

**Conclusion:** In lupus nephritis patients resistant to conventional therapy, rituximab can be tried as an alternative treatment choice. In our single center, most of the patients were class IV nephritis whom we observed the efficacy of rituximab. Generally, the side effects were acceptable. Rituximab could be a good option as a steroid reducing agent and exhibit a favorable clinical response in these patients.

**LOW-DOSE BELIMUMAB AND ANTIMALARIAL AGENTS PREVENT RENAL FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM FOUR RANDOMISED CLINICAL TRIALS**

**Keywords:** Systemic lupus erythematosus, bDMARD, Kidneys

---
Background: Lupus nephritis (LN) is one of the most severe manifestations in systemic lupus erythematosus (SLE), constituting a substantial cause of end-stage kidney disease, dialysis, and mortality. Prompt and adequate treatment of LN, and prevention of renal flares are key components of disease management towards improved outcomes in patients with SLE.

Objectives: We aimed to determine the effect of the use of antimalarial agents (AMA) and different doses and pharmaceutical forms of belimumab on preventing renal flares in patients with active SLE.

Methods: We pooled data from the BLISS-52, BLISS-76, BLISS-SC and BLISS-Northeast Asia randomised clinical trials of belimumab (N=3225), that included patients with seropositive (antinuclear antibody titres ≥1:80 and/or anti-dsDNA levels ≥30 IU/mL), active SLE yet no severe ongoing renal disease. Participants were allocated to receive intravenous (IV) belimumab 1 mg/kg (N=599), IV belimumab 10 mg/kg (N=1033), subcutaneous (SC) belimumab 200 mg (N=556) or placebo (N=1077) in addition to standard therapy. Additionally, we classified patients as AMA users if they had received hydroxychloroquine, chloroquine, mepacrine, or quinine sulphate in stable doses for at least 30 days prior to the trial commencement. The outcome of the present post-hoc analysis was development of renal flares, defined according to the analysis plan within the BLISS programme. The hazard of renal flare was assessed with Cox proportional hazards regression models, adjusted for age, sex, ethnicity, previous renal involvement, baseline proteinuria and glomerular filtration rate, and use of glucocorticoids and immunosuppressants.

Results: In total, 192 patients developed a renal flare after a median of 197 days. In multivariable Cox regression analysis, use of AMA was associated with a lower risk of renal flares (HR: 0.64; 95% CI: 0.54–0.76; p=0.026). Compared with placebo, the risk of renal flares was lower among patients receiving IV belimumab 1 mg/kg (HR: 0.44; 95% CI: 0.25–0.79; p=0.006) and IV belimumab 10 mg/kg (HR: 0.63; 95% CI: 0.45–0.87; p=0.005), but not SC belimumab 200 mg (HR: 0.90; 95% CI: 0.57–1.42; p=0.648). When analysing all study arms with and without antimalarials separately, patients receiving IV belimumab 1 mg/kg along with AMA experienced the lowest rate of renal flares (18.5 (7.4–38.1) cases per 1000 person-years). Using patients who received placebo but not AMA as the reference comparator, patients receiving IV belimumab 1 mg/kg (OR: 0.30; 95% CI: 0.13–0.70; p=0.005) and patients receiving IV belimumab 10 mg/kg (OR: 0.45; 95% CI: 0.27–0.75; p=0.002) were protected against renal flares only when belimumab use was combined with AMA.

Conclusion: In this RCT setting, belimumab and AMA protected against renal flares in patients with active seropositive SLE yet no ongoing severe renal involvement. The protective effect of IV belimumab against renal flares appeared optimal when belimumab was combined with AMA. The prominent effect of low-dose belimumab motivates investigation of the efficacy of intermediate doses of belimumab.

ANIFROLUMAB FOR REFRACtORY SKIN DISEASE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A SINGLE CENTER CASE SERIES

Keywords: Systemic lupus erythematosus, Skin, bDMARD

S. Flouda1, E. Sampatakaki1, G. S. Moyisoud1, M. Kosmetatou1, K. Kouna1, D. Katsifis Nezis1, A. Filippopoulou1, K. Zoupidou1, P. Katsimpri1, D. Boumpas1, A. Fanourakis1,2, Attikon University Hospital of Athens, Greece, Rheumatology and Clinical Immunology Unit, National and Kapodistrian University of Athens, 4th Department of Internal Medicine, Chaidari, Greece; 2Laiko University Hospital of Athens, First Department of Propaedeutic Internal Medicine and Joint Rheumatology Program, Athens, Greece

Background: Anifrolumab (ANI) a human monoclonal antibody to type I interferon receptor subunit has been recently approved for the treatment of SLE. In SLE, the skin is not only a target but also a key driver of the autoimmune response via the production of IFN.

Objectives: To evaluate the efficacy of ANI in real-life under the early access program (09/2021 – 03/2022).

Methods: A total of seven patients (all female, mean age 50 years, disease duration 15 years) with SLE- diagnosis based on ACR1997 or SLICC or EULAR/ACR 2019 classification criteria for SLE and inadequate response to prior immunosuppressive therapies, received ANI from 09/2021 until 03/2022 as part of an early access program. Patients’ demographics, clinical and laboratory characteristics, disease activity (SLEDAI-2K, CLASI) were recorded at baseline and first months of the administration of ANI.

Results: Active skin disease was the dominant clinical manifestation of all patients for the administration of ANI (subacute cutaneous lupus in 6/7, discoid lupus in 3/7, severe chemo-ulcer lesions in one patient). Patients had received an average of 5.1 immunosuppressive drugs before ANI, with an inadequate response. The mean (SD) SLEDAI-2K index at baseline was 6.9 (1.1) and the mean (SD) prednisone dose 2.7 (2.8) mg/day. In reference to the skin disease, mean (SD) CLASI (Activity/Damage) before first administration of ANI was 9.9/1.4 (6.3)/2.2). A rapid response of the skin disease, especially, subacute cutaneous lupus lesions, was observed from the first injection of ANI. As expected, the results were less prominent in patients who had discoid lupus lesions, although patients reported subjective improvement. The mean (SD) SLEDAI-2K, CLASI and daily prednisone dose are 3.4 (1.8), 3/1 (1.4/2.2) and 2.5 (2.5) mg, respectively. After a mean (SD) follow-up of 5.7 (2.0) months, one patient discontinued ANI due to VZV infection.

Conclusion: IFN inhibition is effective for the treatment of refractory cutaneous lupus disease manifestations. The prompt response of the dermatologic disease to ANI likely reflects the beneficial effects of neutralization of IFN on the autoimmune and vasculopathic processes in SLE.

COAGULATION AND HAEMOSTASIS PARAMETERS IN PREGNANT WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND HEALTHY CONTROLS WITH AND WITHOUT PREECLAMPSIA

Keywords: Pregnancy and reproduction, Systemic lupus erythematosus

D. Lin1, I. Gunnarsen2, N. Mahmoud Houari Soutari3, S. Lalic-Cosic4, A. MC Nicholas5, R. Chariot6, K. Bremme7, F. Franceschini7, E. Svenningsson8, L. Andreoli7, A. Antovic9, ASST Spedali Civili di Brescia and University of Brescia, Rheumatology Unit, Department of Medicine, Brescia, Italy; 2Karolinska Institutet and Rheumatology, Karolinska University Hospital, Department of Medicine, Division of Rheumatology, Stockholm, Sweden; 3Karolinska Institutet & Clinical Chemistry, Karolinska University Hospital, Drottningholm University Medicine & Surgery, Stockholm, Sweden; 4University of Belgrade, Department of Medical Biochemistry, Faculty of Pharmacy, Belgrade, Serbia; 5Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden; 6Karolinska University Hospital, Department of Hematology, Stockholm, Sweden; 7Karolinska Institutet, Department of Women’s and Children’s Health, Stockholm, Sweden

Background: Women living with Systemic Lupus Erythematosus (SLE) are at increased risk of pregnancy complications, including preeclampsia (PE). Placental dysfunction is the key pathological event, but the underlying mechanisms are scarcely known.

Objectives: This study aimed to investigate global hemostatic assays in pregnant SLE patients in relation to PE and the use of anti-thrombotic prophylaxis.

Methods: Patients with SLE were sampled during the third trimester of gestation for coagulation and haemostasis (C&H) assays: 1) overall coagulation potential (OCP); 2) overall haemostatic potential (OHP); 3) overall fibrinolysis potential (OFP); 4) plasma levels of fibrinogen and D-dimer. Pregnant healthy controls (HC) with and without PE were also analysed.

Results: Twenty-two consecutive pregnant SLE patients, 80 pregnant HC without PE, and 42 pregnant HC with PE were analysed. Disease characteristics, pregnancy features, and coagulation parameters are reported in Table 1. No thrombotic or bleeding events occurred in SLE patients. Four SLE patients experienced PE (18.2%) despite treatment with low dose acetylsalicylic acid (LDASA) ± low molecular weight heparin (LMWH). These patients displayed significantly lower OCP and OFP, but not OHP, as compared to SLE without PE. Among 4 SLE+PE patients, the 2 treated with LMWH tended to have lower OCP, OFP and OHP values as compared to the 2 untreated patients (134.9±190.7 vs 372.3±254.6; 90.6±128.2 vs 202.2±241.1; 16.4±23.3 vs 45.4±10.1). Among SLE patients treated with LMWH, undetectable
OCP, OHP, and OFP were found in 1 out of 2 SLE+PE and 1 out of 6 SLE without PE. No differences across groups were found for fibrinogen and D-dimer levels. OCP, OHP, and OFP were found in 1 out of 2 SLE+PE and 1 out of 6 SLE without PE. No differences across groups were found for fibrinogen and D-dimer levels.

Conclusion: DMARDs can stabilize pulmonary functions and delay worsening in patients with pSS-ILD. REFERENCES:

Disclosure of Interests: None Declared.

AB0542 PRIMARY SJÖGREN’S SYNDROME AND INTERSTITIAL LUNG DISEASE. RESULTS OF AN OBSERVATIONAL COHORT

Keywords: Lungs, Disease-modifying drugs (DMARDs), Sjögren syndrome

P. Muñoz Reinoso1, F. J. Toyos Sáenz de Miera1, L. M. Fernández-Maeztu1, V. Ymass2
1Hospital Universitario Virgen Macarena, Reumatología, Sevilla, Spain

Background: Primary Sjögren’s Syndrome (pSS) is a chronic systemic autoimmune disease of unknown etiology, with an estimated prevalence of 0.25% (0.15-0.43). It has a broad clinical spectrum and extraglandular manifestations such as Interstitial Lung Disease (ILD), being one of the main contributors to morbidity and mortality in patients with pSS [1].

Objectives: Analyze the clinical characteristics of patients with pSS and ILD, describe the patterns of lung involvement and the evolution of the disease as well as the treatments that were used.

Conclusion: DMARDs can stabilize pulmonary functions and delay worsening in patients with pSS-ILD.
Methods: Observational, retrospective, single-center study in the Hospital Universitario Virgen Macarena Rheumatology department, from 2010 to 2022, including patients with pSS according to EULAR/ACR criteria and ILD. The data obtained from the medical records was analyzed by the statistical software SPSS v28. This study has been approved by the CEIC.

Results: 19 patients were included, 17 (89.5%) women, with a mean age of 66.4 years (62-71). All presented antinuclear and anti-SSA antibodies, 31.6% (6) anti-SSB antibodies and 43.8% (7) Rheumatoid Factor, 63.2% (12) hypergammaglobulinemia and none hypocomplementemia. 36.8% (7) were former smokers. The extraglandular manifestations and comorbidities are shown in Table 1. The mean age at diagnosis of ILD was 60.1 years (53-65.8). The time elapsed until the diagnosis was 93 months (12-198), however, in 52.6% (10) the diagnosis of ILD was prior to pSS diagnosis for approximately 17 months (6-27). The most common radiological pattern with 63.2% (12) is non-specific interstitial pneumonia, two patients presented lymphocytic interstitial pneumonia, two usual interstitial pneumonia, one organizing pneumonia and the rest of them other patterns. Two patients required lung biopsy. Prior to diagnosis, 3 patients were being treated with hydroxychloroquine, the rest had not required treatment with immunomodulators. Once diagnosed, 52.6% (10) required immunosuppressants (Graph 1). 80% (8) continue in treatment, 7 with mycophenolate mofetil with a mean duration of 48 months (20-75). 47.4% (9) required oral glucocorticoids at some point. 88.2% (8) had end-stage renal disease. Among these cases, 47.4% (9) required immunosuppressants (Graph 1). The mean time elapsed until the diagnosis was 45 months (12-78). The time elapsed until the diagnosis was 93 months (12-198), however, in 52.6% (10) the diagnosis of ILD was prior to pSS diagnosis for approximately 17 months (6-27). The most common radiological pattern with 63.2% (12) is non-specific interstitial pneumonia, two patients presented lymphocytic interstitial pneumonia, two usual interstitial pneumonia, one organizing pneumonia and the rest of them other patterns. Two patients required lung biopsy. Prior to diagnosis, 3 patients were being treated with hydroxychloroquine, the rest had not required treatment with immunomodulators. Once diagnosed, 52.6% (10) required immunosuppressants (Graph 1). 80% (8) continue in treatment, 7 with mycophenolate mofetil with a mean duration of 48 months (20-75). 47.4% (9) required oral glucocorticoids at some point. 88.2% (8) had end-stage renal disease. Among these cases, 47.4% (9) required immunosuppressants (Graph 1). The mean time elapsed until the diagnosis was 45 months (12-78).

Conclusion: Intestinal lung disease is an extraglandular manifestation present in patients with pSS, therefore being essential the early diagnosis. In our case, the progression of the disease and the other due to a head trauma. Significant differences between patients with and without treatment. The mean duration of symptoms was 4 months. All cases had severe GU and GI activity (both BiLaG A).

AB0543 CHARACTERISTICS AND TREATMENT OUTCOMES OF ASIAN SLE PATIENTS WITH CONCOMITANT GENITOURINARY AND GASTROINTESTINAL INVOLVEMENT

Keywords: Kidneys, Gastrointestinal tract, Systemic lupus erythematosus

K. L. Ng1, T. Mahadevan1, M. H. Nordin1, A. Mohamed Ismail2, 1Raja Perempuan Zainab II Hospital, Rheumatology Unit, Kota Bharu, Malaysia
Background: SLE is a chronic autoimmune disorder which affects multi-organ systems. We report a case series of SLE with concomitant genitourinary (GU) and gastrointestinal activity in our centre.

Objectives: To describe the characteristics, treatment response and outcomes of these cases.

Methods: The clinical notes were reviewed and descriptive statistical tests were used. Results: 7 cases were recorded from 2019 to 2022. All were females with median age of onset 23 ± 18.9 years old. Case 5 and 6 had prior diagnosis of SLE with lupus nephritis (LN). The initial symptoms were episodic abdominal pain, associated with vomiting and/or diarrhea. 2 cases had urinary symptoms too. The mean duration of symptoms was 4 months. All cases had severe GU and GI activity (both BiLaG A).

Nearly all had clinically or biopsy-proven proliferative LN (mean 24 hour urine protein = 4.99g/d). 3 patients also had ureterohydronephrosis and/or interstitial cystitis. Intestinal pseudo-obstruction (IPO) and lupus mesenteric vasculitis (LMV) were found in 2 and 5 cases, respectively. Serositis and mucocutaneous lesions were more frequent too. Almost all cases had high titres of ANA (≥ 1:320) and dsDNA, with prevalent positive anti-Ro. Other remarkable findings were low complements (especially C3) and normal ESR/CRP. Antiphospholipid antibodies were negative in all but one cases. Treatment wise, all had IV hydrocortisone and high dose prednisolone. 6 cases had pulsed methylprednisolone and IV cyclophosphamide therapy (NIH regimen). Case 7 had concurrent C. difficile infection and received mycophenolate mofetil (MMF) therapy once the infection resolved. In all cases, the extra renal features and urinary symptoms fully resolved. In term of LN, 4 patients did not achieve remission with NIH regimen and needed MMF therapy; and only 50% attained complete remission subsequently. In general, the outcomes of all patients were good except for Case 1 who developed contracted urinary bladder needing ileal conduit urinary diversion.

Conclusion: Concomitant IPO/LMV with LN and urinary tract abnormalities are rare clinical syndromes in SLE. Our patients shared similar clinical features as reported by Echeverry et al [1]. The treatment response was generally good with no recurrence of IPO/LMV and favourable renal outcomes.

PHENOTYPING ON MUCOSAL MOLECULAR SIGNATURE OF PATIENTS WITH ULCERATIVE COLITIS ANALYSIS

Keywords: Gastrointestinal tract, Autoantibodies, -Oomics

M. R. Chen1,2, Q. Wang1,2, J. W. Hao1,2, M. J. Chang3,4, S. X. Zhang1,2, Q. Yu1, P. F. He1,3, 4Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China; 5Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 5Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision, Taiyuan, China; 6Shanxi Medical University, School of Management, Taiyuan, China; 5Shanxi Medical University, Medical Data Sciences, Taiyuan, China

Background: Ulcerative colitis (UC) is an inflammatory bowel disease characterized by idiopathic and recurrent mucosal inflammation, whereas disease heterogeneity has not sufficiently translated into current clinical subclassifications [1].

Objectives: This study aims to identify and characterize subgroups of patients with similar target status and molecular biomarkers to reliably predict treatment response which is of great interest for the treatment of UC patients.

Methods: 16 microarray datasets including 602 colon tissue samples (455 patients with UC and 147 healthy controls) were both obtained from GEO database. Depend on up-regulated differentially expressed genes (DEGs), unsupervised clustering [2] was applied to group the samples and pathways and biomarkers associated with UC was unearthed by gene-set enrichment analysis. Xgboost classifier was used for evaluating the efficacy of different biologics in patients with UC.

Results: According to the 267 upregulated DEGs of UC, colon tissue samples were classified into three subtypes (A-C) with distinct molecular and cellular characteristics. Subtype A is designated as epithelial hyperplastic subtype with epithelial features while subtype C was characterized by the immune activation subtype with prominent immune cells and proinflammatory signatures. The subtype B is named mixed, which is in between the above two and is moderately activated in all signaling pathways. It is worth noting that, compared with subtype C as refractory UC patients, subtype A shows stronger correlation with the excellent reactions of biological agents while subtype C was characterized by the immune activation subtype with epithelial features. Subtype A is designated as epithelial hyperplastic subtype with epithelial features while subtype C was characterized by the immune activation subtype with immune activation features.

Conclusion: These results, based on the most comprehensive microarray provide an in-depth understanding of the pathophysiological characteristics of UC, and build an accurate typing model for ulcerative colitis, which can benefit clinical treatment.

EFFECT OF BELIMUMAB ON CLINICAL Profiles AND DAILY Living SCORE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Biomarkers, bDMARD, Mental health

T. Ishizuka1, K. Fujioka1, M. Tangiku1, H. Tani1, A. Maeda1, A. Kato1, 1Gifu Municipal Hospital, Center of General Internal Medicine, Gifu, Japan

Background: Belimumab (BE) was shown to decrease disease activity, glucocorticoid intake, and flare rates, thereby suppression of damage progression, and also has been included in the 2019 EULAR recommendations on SLE management as an approved biological drug to be used in patients with a refractory response to a standard of care regimen.

Objectives: We have examined the effect of belimumab on activities of daily living score (AS), immunological data, disease activities and dose of PSL in patients with SLE.

Methods: We selected 36 cases (F/M 30/6) from 2018 to 2022 in patients with SLE treated with BE (iv or sc) to clarify the effect of BE on immunological data, disease activities (SLEDAI), AS (Lupus 26: 849, 2017), and dose of PSL after treatment for 6 months (M), 12M and 24M.

Results: Mean BMI and duration of disease were 20.5±3.7 kg/m2 and 15.7±13.8 years. Two cases could not continue due to arthralgia and loss of hair within 24M. After treatment with BE for 6M and 12M, anti-dsDNA antibodies (AU/ml) were significantly decreased for 12 M and 24 M, respectively (p<0.05, before 61±103, 6M 28±48, 12 M 19±23), and C3, C4 and CH50 (U/ml) were significantly increased (p<0.05-0.02, before 10.8±10.6, 6 M 6.1±3.7, 12 M 5.7±3.0). AS scores were also significantly improved (p<0.01-0.05), before 28.4±14.2, 12 M 14.8±15.8, 24 M 16.8±10.9. Especially, anxiety, depression and loss of concentration, which were important marker for activities of living score, were not significantly changed.

Conclusion: Effects of BE on immunological data, disease activities, and daily living scores, induction of clinical remission and dose reduction of prednisolone were tolerable without major adverse effects in patients with SLE.

DISGN OF ANIFROLUMAB STUDY OF TREATMENT EFFECTIVENESS IN THE REAL WORLD (ASTER): A MULTI-NATIONAL, OBSERVATIONAL, POST-LAUNCH STUDY TO DESCRIBE THE CLINICAL EFFECTIVENESS OF ANIFROLUMAB IN ROUTINE CLINICAL PRACTICE IN PATIENTS WITH SLE

Keywords: Real-world evidence, Quality of life, Systemic lupus erythematosus

M. Mosná1, C. Emmass2, C. Nan3, H. Strinadel-Farrant4, S. Chen5, L. Carly6, B. Desta7, C. Seo8, S. Chen9, A. Sonrentino10, 1University of Pisa, Clinical and Experimental Medicine, Pisa, Italy; 2AstraZeneca, Respiratory & Immunology Evidence, BioPharmaceuticals Medical, Cambridge, United Kingdom; 3AstraZeneca, CVRM Evidence, BioPharmaceuticals Medical, Malmö, Sweden; 4AstraZeneca, Oncology Outcomes Research, Global Medical Affairs, Cambridge, United Kingdom; 5AstraZeneca, Evidence Delivery, BioPharmaceuticals Medical, Malmö, Sweden; 6AstraZeneca, Biostatistics, Cambridge, United Kingdom; 7AstraZeneca, BioPharmaceuticals Business Unit, Gaithersburg, MD, United States of America; 8AstraZeneca, Patient Centered Science, BioPharmaceuticals Medical Evidence, Gaithersburg, MD, United States of America; 9AstraZeneca, BioPharmaceuticals Medical, Gaithersburg, MD, United States of America; 10AstraZeneca, Global Medical Affairs, Respiratory & Immunology, BioPharmaceuticals Medical, Cambridge, United Kingdom

Background: Real-world evidence (RWE) on prescription medication use for systemic lupus erythematosus (SLE) is limited, and no real-world studies to date have investigated medication use post-launch with anifrolumab, a type I interferon receptor inhibitor. ASTER is the first multi-national, real-world study to examine patients with SLE receiving standard therapy who initiate anifrolumab treatment as an add-on biologic.

Objectives: To describe the study design of ASTER.

Methods: ASTER (NCT05637112) is a longitudinal, observational cohort study with 1 year of retrospective baseline data and 3 years of follow-up after first anifrolumab initiation until patient discontinuation, death, loss to follow-up or end of study (whichever occurs first). Adults with an SLE diagnosis per the 2019 European Union revised classification criteria with Disease Activity Score 28 (DAS28) >3.2 and Disease Activity Score 54 (DAS54) >1.6 and who were on routine follow-up were eligible to participate.
League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) criteria for SLE who start anifrolumab per the approved country-specific label are eligible. Patients who are anifrolumab experienced, currently in anifrolumab early access/compassionate use programs, or in a clinical trial with an investigational product are excluded. Eligible patients will be enrolled at a routine clinical visit before the first anifrolumab infusion. Key study measures and data collection methods are presented in the Table. Patient-reported outcomes (PROs) and diaries are selected and designed based on patient feedback. Key endpoints of disease activity and the proportion of patients attaining a Lupus Low Disease Activity State will be collected. For patients who discontinue anifrolumab, data collection will continue for the entire follow-up period, unless they withdraw consent.

Results: About 500 patients are expected to be enrolled from Austria, Canada, Denmark, France, Germany, Israel, Italy, Norway, Spain, and Sweden, with 15–200 patients per country. The study will be open for enrollment in 2023 and data collection is expected to finish in 2029. Data will be collected at baseline and at quarterly (Year 1) or biannual visits (Year 2 and 3). Electronic case report forms will be used to record patient information using the Medidata RAVE system. MyRecô software will be used to record PROs via a mobile application and collect physician-completed assessments via a web platform. Results will primarily be descriptive.

Conclusion: ASTER will provide physicians with valuable insights into the effectiveness of anifrolumab in patients with SLE in routine clinical practice. ASTER will generate comprehensive RWE of anifrolumab to inform patients about its impact on disease activity and health-related quality of life outcomes in global real-world settings.

Conclusion: The clinical outcome at the end of 12 months of maintenance therapy was found to be satisfactory, with all the LN patients being responders to treatment. The MMF regimen was the preferred treatment regimen over the equally efficacious cyclophosphamide-based regimens due to the ease of administration and the lack of requirement of hospitalization during the period of the COVID pandemic. The high cost of MMF increased the direct cost borne by the patient due to its unavailability in the hospital pharmacy. Hence there is a need to review the hospital pharmacy stock at regular intervals and streamline the procurement system for drugs during public health emergencies such as the pandemic.

INTRAVENOUS IMMUNOGLOBULIN IN PREGNANT WOMEN WITH SEVERE ACTIVE LUPUS: A CASE SERIES

Keywords: Systemic lupus erythematosus, Pregnancy and reproduction

Background: Systemic lupus erythematosus (SLE) is a chronic, progressive, autoimmune disorder characterized by chronic inflammation of multiple organs and tissues; mediated by autoantibodies and immune complexes. Approved treatments are few and often associated with limitations including suboptimal response. IVIG is a novel high affinity, fully human, aglycosylated, immunoglobulin G1 (IgG1) monoclonal antibody that selectively blocks the neonatal Fc receptor (FcRn) and displays no effector function. Clinical studies conducted with IVIG in patients with SLE have demonstrated rapid and durable serum IgG and polyreactive autoantibody reductions.

Objectives: To describe the protocol of a Phase 2 study evaluating the efficacy and safety of IVIG in pregnant patients with active SLE.

Methods: This is a phase 2, multicenter, randomized, placebo-controlled, double-blind, parallel-group study enrolling active adults with active, autoantibody-positive SLE with an inadequate response to one or more standard of care treatments. The study consists of a 6-week screening period, a 52-week double-blind treatment period, and a 6-week follow-up period. A target of approximately 225 participants will be enrolled. Participants will be randomized in a 1:1:1 ratio to receive IVIG dose 1, dose 2 or placebo intravenously every 2 weeks through Week 50.

Results: The primary efficacy endpoint is the percentage of participants achieving ≥50% reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index activity score (CLASI), ≥50% reduction in active joints, ≥4 points improvement in SLE Disease Activity Index 2000 (SLEDAI 2K), and British Isles Lupus Assessment Group Composite Lupus Assessment response (BICLA); time to first disease flare; and reduction in corticosteroid use. The percentage of participants achieving an SRI-4 composite response at Week 52 will also be assessed. Safety endpoints include adverse events (AEs), serious AEs, AEs of special interest (severe infections, Grade ≥3 hyperbilirubinemia), and AEs leading to treatment discontinuation throughout Week 58. Additional assessments include pharmacokinetic, pharmacodynamic, and immunogenecity evaluations.

Conclusion: This ongoing phase 2 study will evaluate the safety and efficacy of IVIG in adults with active SLE, using multiple clinical outcome measures.

Disclosure of Interests: None Declared.

**EFFECT OF BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH MINIMAL OR NO STEROID**

**Keywords:** Systemic lupus erythematosus

Y. J. Lee¹, S. M. Ahn¹, S. Hong¹, J. S. Oh², C. K. Lee¹, B. Yoo¹, Y. G. Kim¹. ¹Asan Medical Center Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); ²Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)

**Background:** Belimumab is the only biologic agent approved for systemic lupus erythematosus (SLE). In cornerstone clinical trials, belimumab demonstrated SRI-4 response in patients with moderate disease activity, and real-world studies showed consistent findings (1–3). In these studies, SRI-4 was significantly associated with baseline features including high SELENA-SLEDAI, dose of steroid, smoking status, BLyS level, and combining polyarthritis (2, 3). However, most previous studies have been conducted in patients with use of steroids, with mean prednisolone-equivalent dose of approximately 10 mg/day (1–3). Therefore, the effect of belimumab has been focused on the steroid sparing.

**Objectives:** Here, we aimed to identify the effect of belimumab in SLE patients treated with minimal or no steroid with mild-to-moderate activity.

**Methods:** We retrospectively reviewed the electronic medical records of patients (age ≥ 18 years) who first received belimumab from May 2021 to June 2022 and maintained use at least 6 months. We only included patients who received prednisolone-equivalent ≤5 mg or without steroid (for more than 1 year). The primary endpoint was SRI-4 response in 6 months, and secondary endpoint was improvement in serology, including C3, C4, and anti-ds-DNA, at 6 months. Analysis Of Variance (ANOVA) with Bonferroni’s post hoc analysis were performed to compare the continuous variables.

**Results:** In total, 31 patients were included, with 12 minimal steroid users and 19 non-steroid users. The mean age was 39.2 (±11.4) years, and 90.3% were female. Baseline SELENA-SLEDAI was 6.0 (4.0–9.0). The primary endpoint was significantly improved over time (P=0.016) showed significant improvement over time during treatment. Univariable analysis showed baseline SELENA-SLEDAI and arthritis were significantly associated with SRI-4 response at 6 months, and SELENA-SLEDAI only remained significant in multivariable logistic regression analysis.

**Conclusion:** In our cohort study, belimumab was shown to be effective in improving SELENA-SLEDAI, anemia and low C4 in patients who did not use or did use minimal dose of steroids. Therefore, the effect of belimumab can be expected even in patients not taking steroids.

**LOW-DOSE IL-2 CHANGED THE PROPORTION OF LYMPHOCYTE SUBSETS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME**

**Keywords:** Sjögren syndrome, Cytokines and chemokines

X. M. Wang¹,², Q. Y. Su¹,²,³, J. X. Zhang¹,², P. H. Chai¹,², H. C. Li¹,², Q. Yu⁴, P. F. He⁵, X. Li¹,²,³, S. X. Zhang¹,²,³. ¹Shanxi Medical University, Ministry of Education Key Laboratory of Cellular Physiology, Taiyuan, China; ²Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; ³Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; ⁴Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

**Background:** Primary Sjögren’s syndrome (pSS) is a chronic inflammatory autoimmune illness characterized by various immune abnormalities. Abnormalities in the proportions of blood T lymphocyte subtype, that is Th17/Treg, were detected in pSS patients. Interleukin (IL)-2 is a crucial cytokine for tipping the balance of regulatory T (Treg) cells and effector T cells, which can effectively relieve pSS.

**Objectives:** This study aimed to systematically evaluate the changes in the number of lymphocyte subsets after low-dose IL-2 therapy for pSS.

**Methods:** Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM, and Technology Journal Database were performed. Original case reports, case series, observational studies, and clinical trials reporting the changes in lymphocyte subsets on pSS patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I² [2], and Egger tests were used to test the evidence of publication potential bias (STATA v.12.0)

**Results:** A total of 3 studies comprising 929 patients were identified (Table 1). The numbers of Th17 cells and Tregs were significantly increased after IL-2 injection (SMD=0.325, 95% CI (0.060, 0.590), P=0.016; SMD=1.085, 95% CI (0.469, 1.701), P=0.001), while there were no statistical differences in the ratio of Th17/Treg (SMD=0.263, 95% CI (-0.602, 0.076), P=0.129) between before and after IL-2 treatment (Figure 1).

**Conclusion:** Low-dose IL-2 was promising in treating pSS, which could promote the proliferation and functional recovery of Tregs and regulate the balance between Treg cells and effector T cells towards Treg cells.

CHARACTERISTICS OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT THE START OF BIOLOGICAL THERAPY AND AT FIRST FOLLOW-UP

Keywords: bDMARD, Systemic lupus erythematosus

A. D. Bilous1, M. M. Tamas2, I. Mihus2, C. Pamfil2, I. Felea1, L. Damian1, L. Muntean1, I. Filipescu2, I. Szabo2, S. P. Simon1, S. Rednic2

1Emergency Clinical County Hospital Cluj-Napoca, Rheumatology, Cluj-Napoca, Romania; 2Iuliu Hatageganu University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by heterogeneity of clinical manifestations ranging from mild skin and joint disease to severe, organ or life-threatening manifestations. It has an unpredictable tendency to flare up. Given the complex pathogenesis of SLE, involving both the adaptive and innate immune systems, the efficacy of steroids, antimalarials and immunosuppressants is limited in some cases, highlighting the need for new therapies with a targeted mechanism of action. Belimumab (BEL) is approved as an add-on therapy for active LES with positive antoautoantibodies despite standard treatment, while Rituximab (RTX) remains for off-label use in severe manifestations in many European countries.

Objectives: The aim of the current study is to describe the characteristics of SLE patients receiving biologic therapy with Belimumab or Rituximab at baseline and at first follow-up visit in a tertiary rheumatology center.

Methods: We retrospectively analyzed the electronic medical records of patients with SLE who started treatment with BEL and/or RTX. Demographic, clinical and paraclinical data as well as disease activity score at the time of starting treatment with biologics and at first follow-up visit were collected.

Results: Eighteen SLE patients were analyzed: 88.88% female, mean age at diagnosis 32±15 years, mean disease duration 7±5 years. The first follow-up visit was performed between 4 to 6 months after baseline. Eleven (61.1%) patients were treated with BEL, 5 (27.7%) RTX and 2 (11.1%) with both BEL and RTX. Hydroxychloroquine (HQ) was co-prescribed with biologics in 16/18 patients (88.8%). Azathioprine was prescribed in 6 patients (33.33%) and mycophenolate mofetil in 4 patients (22.22%). At the start of the biological treatment, all patients received steroids with a mean dose of 20±17mg prednisone/day. One patient was able to discontinue the steroid, while in the others the prednisone dose decreased to 8.5±4.8mg/day after 4-6 months. RTX was prescribed in 5 (27.77%) patients for lupus nephritis. All patients previously received cyclophosphamide. In one case, RTX was prescribed for severe thrombocytopenia, in another because of an overlap with active rheumatoid arthritis. Belimumab was prescribed in patients with more pronounced constitutional, articular, cutaneous and hematological features and mild renal involvement. In one case, BEL was prescribed for lupic enteritis. The mean SLEDAI score before starting treatment with the biologic was 12±3; the mean SLEDAI score at the first follow-up visit was 8±3. In 11 (61.1%) patients, its safety and efficacy.

Conclusion: Biological therapy has been shown to control the disease activity and to reduce the need for steroids in SLE patients. RTX was used in patients with more severe manifestations such as lupus nephritis and severe thrombocytopenia.

Background: Despite recent advances in the management of rheumatic diseases with the emergence of new targeted therapies, treatment options remain limited in systemic lupus erythematosus (SLE) [1] and disease may be refractory to conventional treatment.

Objectives: To evaluate the off-label use of biologics in a large cohort of lupus patients, its safety and efficacy.

Methods: Retrospective analysis of the Attikon SLE lupus cohort comprising over 800 patients in total in order to identify patients receiving off-label targeted therapies. Indication of the treatment, clinical characteristics and outcomes were recorded.

Results: A total of 52 patients received 54 off-label targeted therapies. Most of them were women (86.3%). Mean age (SD) at SLE diagnosis was 46.4 (15.2) years and mean disease duration (SD) at off label treatment initiation was 8.8 (10.8) years. Mean SLEDAI (SD) before treatment initiation was 6.6 (3.7). The most frequently used off-label treatment was rituximab (84.6%) followed by tocilizumab (9.6%) and jak inhibitors (5.8%). The main indications were persistent, severe, refractory musculoskeletal and mucocutaneous activity (44.2%), neuropsychiatric SLE (23.1%), hematological disease (13.5%) and lupus nephritis (11.5%). Six months after treatment, mean SLEDAI decreased in all patients to a mean of 4.3 (2.7). Mean drug survival was 2.2 (1.2) years. The dose of corticosteroids after 6 months of treatment was substantially decreased to 4.3 mg (versus 12.7 mg at baseline). No moderate/severe adverse effects were recorded.

Conclusion: The use of off-label targeted therapies allows disease activity improvement with a corticoid sparing effect even in a subset of patients with long-standing, refractory manifestations.

Background: Anifrolumab (ANI) is a monoclonal antibody to the type I interferon receptor recently approved by EMA as an add-on therapy for the treatment of moderate to severe SLE. As of this writing, real world data on its use is still lacking. Objectives: To depict the clinical characteristics of SLE patients treated with ANI. To evaluate short-term effectiveness and safety of ANI in clinical practice.

Methods: Multicenter prospective cohort study on adult patients with SLE treated with ANI for compassionate use. Demographic data, clinical and treatment history, and SLICC Damage Index (SDI) were retrieved from clinical charts. SLE-DAI-2K, SLE-DAS, daily pred dose, number of tender (Tj) and swollen (Sj) joints, Cutaneous LE Disease area and severity index (CLASI-A), and Physician Global Assessment (PGA) were recorded at baseline, 1, 3, and 6 months of follow-up. Remission (according to 2021 DORIS definition) [1] and low disease activity (according to LLADAS definition) [2] were assessed at 6 months. Adverse events (AE) were recorded at each visit.

Results: 20 patients (90% female, 90% Caucasian, median age 48 (range 24-68), median disease duration 12 (4-27) years from 9 referral centers were included. 100% of patients had a history of articular involvement, 95% of skin rash, 50% of hematological involvement, 30% of nephritis, 25% of serositis, and 10% of neuropsychiatric involvement. Fifteen percent had a concomitant antiphospholipid syndrome and 10% Sjogren’s syndrome. At baseline, 65% had an SDI>0 (median 2, 1-5). The median number of previous immunosuppressive therapies was 4 (1-7), while the median cumulative dose of prednisone was 10.3g (5-90). Reasons for adding ANI to treatment were persistently active disease (83.3%) or disease flare (16.7%). Main active manifestations were: mucocutaneous (70%), articular (40%), and hematological (25%). Concomitant therapies were glucocorticoids in 94.1% (pred-median daily dose 7.5mg, range 0-29), conventional DMARD in 84% (pred-median dose: 1.6mg, range 0-25), hydroxychloroquine in 74% of cases. At 1 month after starting ANI, a significant decrease in all the activity indices was recorded: mean±SD SLEDAI from 7.6±4.2 at baseline to 6.1±3.5 (p=0.02), CLASI-A from 8.8±9.7 to 3.6±6.2 (p=0.01), and PGA from 1.3±0.5 to 1.0±0.6 (p=0.005), SLE-DAS from 9.6±6.5 to 6.8±5.2 (p=0.04), SJ from 1.6±0.6 to 0.5±0.2 (p=0.02). The improvement was maintained trough the 6 months of follow-up. A reduction in the mean daily dose of glucocorticoids was observed at all time points, but statistical significance was not reached (Table 1). LLADAS and remission were achieved by 75% of patients at 6 months of follow-up. One patient discontinued treatment after 2 infusions due to a lack of response. Nine AE were recorded, mainly mild viral infections including one herpes zoster reactivation. Only one AE (thrombocytopenia) led to treatment discontinuation. Conclusion: ANI demonstrated a rapid efficacy on skin manifestation, arthritis, and overall disease activity in patients with SLE refractory to the standard of care. The good safety profile is also confirmed in this real-world analysis.

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multisystem involvement characterized by the production of multiple autoantibodies and the consumption of complements. Rituximab, a chimeric anti-CD20 antibody, was already approved for treating B-cell lymphoma and autoimmune diseases.

Objectives: This study aimed to systematically evaluate the efficacy and safety of rituximab in treating SLE.

Methods: We systematically searched PubMed, EMBASE, Web of Science, Cochrane Library, CNKI, FDA.gov, Clinical trials.gov, Wanfang database, and Weipu database (from database inception to January 1, 2023) for studies of rituximab in the treatment of SLE. Observational studies, case series, and randomized controlled trials reporting the efficacy or safety data on SLE treated with rituximab were included in this meta-analysis. We selected the effect model according to the heterogeneity of the meta-analysis. If I² < 50, a fixed effect model was used.

Results: A total of 8 studies with a total of 353 patients were included. After treatment with rituximab, the SLEDAI scores were significantly decreased [SMD=2.289, 95%CI (1.411, 3.167), I²=64.5%, p<0.001]. Four studies mentioned clinical responses, 91.9% of patients with SLE who received rituximab had distinct clinical remission compared with 72.1% of patients with SLE who received conventional medication. The incidence of adverse events was 76.1% and 21.83%, in which pulmonary infection and gastrointestinal disease were the most common events, and no serious adverse events were reported among all these studies. Besides, we observed not only remarkable increases in complement C3 and C4 after rituximab injection [SMD=1.102, 95%CI (0.322, 2.422), I²=95.5%, p=0.010; SMD=1.102, 95%CI (0.102, 2.103), I²=93.6%, p<0.001] but also significant decreases in IgA and IgG [SMD=1.372, 95%CI (0.322, 2.422), I²=95.5%, p=0.010; SMD=1.102, 95%CI (0.102, 2.103), I²=93.6%, p<0.001] in 1 study. An increase in IgM was notified in another study. 

Conclusion: Rituximab was effective and well-tolerated for the treatment of SLE, which had a low incidence of adverse events.

REFERENCE:

To see the efficacy of upadacitinib in the management of primary Sjogren syndrome.

Methods: A 68-year-old woman presented with pain in multiple joints for 16 years with intermittent use of NSAIDs. She had no low back pain and no self or family history of psoriasis or red eye. She denied dry mouth but required frequent water drinking during meals to aid swallowing and occasionally used artificial tears. MTX was started for her two-month articular flare and positive rheumatoid factor (RF). MTX caused severe vomiting and hyponatremia, and she was hospitalized. After the correction of hyponatremia, she was put on tofacitinib. We reevaluated the case when she came to us. She had grade 2-3 tenderness of most peripheral joints and was bedridden. Immunological parameters revealed RF 127 IU/ml (reference value <14), anti-SSA antibody 147 U/ml (normal <3.2), anti-SSB antibody 149 U/ml (reference value <8) and anti-CCP antibody; ANA, anti-nda DNA Ab were negative. There was no erosion on the X-ray hands. Schirmer’s test was positive (3mm bilaterally). Unstimulated salivary flow after five minutes was 0.04 ml/min (<0.1 ml/min indicates salivary hypofunction). She fulfilled the 2016 ACR/EULAR classification criteria, and we diagnosed her with primary Sjogren syndrome. Considering her age, she was switched to upadacitinib, as European Medicines Agency restricted the use of tofacitinib beyond 65 years.

Results: Her EULAR Sjogren Syndrome’s Disease Activity Index (ESSDAI) [1] was six at baseline, indicating moderate disease activity. Her joint pain improved significantly within two months with infrequent use of pilocarpine in the sixth month. Six months after treatment with upadacitinib, ESSDAI came down to 2; the Patient’s Global Assessment score was 0.02 and achieved STAR (Sjogren’s Tool for Assessing Response) response 7 (STAR responder if score ≥5) [2].

Conclusion: To our knowledge, this is the first case report on the efficacy of upadacitinib in pSS. Further high-quality clinical trials are required to confirm the benefit of upadacitinib in pSS.

Background: Lupus nephritis (LN) is one of the most harmful clinical manifestations in systemic lupus erythematosus (SLE) patients. Despite of the existence of standard treatment protocols, a percentage of patients cannot be controlled with classical immunosuppressant drugs. This is the reason for exploring new therapies, such as rituximab (RTX), in order to achieve a better management of LN [1,2].

Objectives: To assess the efficacy of RTX in LN treatment.

Methods: A systematic review was performed using Medline, Embase, Cochrane Library and Web of Science databases. Two independent reviewers selected the records that fitted the inclusion and exclusion criteria. Statistical analysis was carried out with Stata 15.1 for MacOS (StataCorp). Relating to meta-analysis, odds ratio (OR) was chose as measure of association in registries with control group and a prevalence meta-analysis was conducted in those registries without it.

Results: 436 papers were obtained from the search, finally 32 articles were analysed. Meta-analysis of registries with control group showed a significant higher rate of total response in LN patients treated with RTX, compared to control group (p=0.005) after 52 weeks of follow-up. A non-significant higher rate of complete response in LN patients treated with RTX, compared to control group (p=0.062) was found after 52 weeks of follow-up. As well, a non-significant higher rate of complete response in LN patients treated with RTX compared to control group was found. Prevalence meta-analysis of registries without control group showed response in more than 50% of LN patients treated with RTX.

Conclusion: RTX seems to be effective in long-term treatment LN patients (52 weeks). More clinical trials are needed for clear indication of RTX for SLE treatment and its inclusion in general clinical practice.

AB0562 BELIMUMAB FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN REAL WORLD: A SINGLE CENTER STUDY

Keywords: Real-world evidence, Kidneys, Systemic lupus erythematosus

J. J. Fragojo Gil1, P. Martinez Calabuig1, L. Salvador Malcas1, R. González Mazarillo1, A. Rueda1, J. J. Lerma1, C. Molina Almela1, M. D. Pastor Cubillo1, C. Campos Fernández1. 1Hospital General Universitario de Valencia, Servicio de Reumatología, Valencia, Spain; 2Hospital de Sagunto, Reumatología, Port de Sagunt, Spain

Background: Belimumab efficacy and safety has been studied through randomized controlled trials in Systemic Lupus Erythematosus (SLE) patients even in cases with kidney involvement. However, more evidence is needed not only from long-term trials but also from real world conditions especially in Lupus Nephritis (LN) patients.

Objectives: To analyze the effectiveness and safety of Belimumab in SLE patients with data from a Real-World cohort.

Methods: A single center observational study was performed including SLE patients who had initiated treatment with Belimumab from September 2017 to January 2023. Demographic, clinical, laboratory, effectiveness and safety variables were collected. Effectiveness was evaluated according to changes from the baseline in SLEDAI-2K and disease activity markers (proteinuria, complement consumption and/or Anti DNAds). Safety data was collected including any adverse event (AE) due to any cause. AE was considered serious (SAE) if it was life-threatening or result in hospitalization, disability or in death.

Results: Overall, 15 patients were included in the study, whom baseline characteristics are exposed in the Table 1. Nine patients were still receiving the drug with a mean drug survival of 15.6 months. Belimumab allowed steroid tapering in all cases, but treatment was discontinued just in 1 patient (7%). Treatment also improved disease activity markers in all (100%) patients. Belimumab was well tolerated, and the AE reported were infection (14 events) and malaise in 1 patient. In 11 cases, infection was mild (9 upper respiratory tract infection, 1 urinary tract infection and 1 gastroenteritis). 3 severe infections were registered (1 pneumonia, 1 pyelonephritis and 1 meningitis). Regarding LN patients, treatment exposure achieved was 10.85 patients/year. Renal Biopsy demonstrated class III in a patient (20%) and class IV in 4 patients (80%). Mean proteinuria at baseline was 6.66g/24h. In 3 cases, Belimumab was started in the first 6 months after LN diagnosis was established. In 4 cases (80%), Belimumab addition allowed significant reduction of proteinuria and corticosteroids. In 2 out 5 (40%) treatment was discontinued, one case due to an insufficient response and in the other, to a SAE (Cryptococcus neoformans meningitis).

Conclusion: Belimumab maintained an acceptable safety profile and an adequate effectiveness. Intravenous and subcutaneous formulations showed similar performance. Belimumab addition resulted in reduction in proteinuria and corticosteroid use.

SLE, Sjön’s and APS - clinical aspects (other than treatment).

Keywords: Patient reported outcomes, Outcome measures, Systemic lupus erythematosus.

R. Rex1, E. Hettel1, V. Strand2, S. May3. 1Sphero Global Insights, Market Research, Exton, United States of America; 2Stanford University, Immunology/ Rheumatology, Palo Alto, United States of America

Background: SLE patients present significant challenges in the management of their condition.

Objectives: This study aims to uncover differences in physician perceptions and real-world treatment patterns and outcomes among moderate to severely active patients in the EUS (France, Italy, Spain, Germany, and UK).

Methods: 1,279 moderate-to-severe (M/S) adult SLE patient records were collected in collaboration with 289 EUS rheumatologists via an online survey platform from November 2021 through January 2022.

Results: 22% of moderate-to-severe EUS SLE patients in the chart audit were receiving belimumab to treat their SLE. In half of those cases where patients were NOT on belimumab they were not considered good candidates for the therapy. The key reason for not initiating belimumab treatment being that patients were “well-controlled” on their current pharmacologic regimen. Closer inspection of these “well-controlled” patients (n=228) at the chart level revealed clinical aspects that highlight a potential gap in patient care. The majority of SLE patients in the “well-controlled” subset had moderately active disease, but over one-in-ten were classified with severe disease. On average, 40% of “well controlled” SLE patients had one or more flares over the past year. One-third of the “well controlled” patient subset suffers from at least one moderate-to-severe manifestation of their SLE, with musculoskeletal, dermatologic, and renal manifestations being most prevalent. 29% of “well controlled” patients have at least one moderate-to-severe symptom of their disease. These include pain/stiffness, fatigue, synovitis, malar rash, photosensitivity, edema, fever, and alopecia.

</table>

Further, one-third of “well controlled” SLE patients are on steroids, with 40% on a higher dose (>3mg/day) to control their disease. The mean overall dosage of the group was 9.4mg/day, a potentially harmful dosage particularly if used long term.

Figure 1.

Conclusion: EUS physicians’ perception of “well controlled” SLE may not align with some patients’ clinical reality. Use of belimumab or other advanced therapies in these cases may lead to improved patient outcomes and less reliance on steroids, which are often associated with adverse effects, even at low doses.

REFERENCES:

[1] At the time of fielding, anifrolumab had not yet been approved for treatment of SLE in the EUS.

“Timely administration of immunosuppressants, either biologics or non-biologics, should be performed for a better control of disease activity coupled with an early steroid sparing effect.”

TIGIT ACTIVATOR ALLOVIRATES SYSTEMIC LUPUS ERYTHEMATOSUS BY NEGATIVELY REGULATING TH1-LIKE TREG CELL DIFFERENTIATION

Keywords: Treat to target, Cell biology, Systemic lupus erythematosus

X. MA1, S. Yu1, J. Gu1, H. Jiang1, Y. Shan2. 1The First Hospital of China Medical University, Department of Pediatrics, Shen Yang, China; 2University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan

Background: Systemic lupus erythematosus (SLE) is a heterogeneous inflammatory chronic autoimmune disorder characterized by autoimmune tolerance deficiency [1]. T Regulatory cells (Tregs) play an important role in maintaining immune homeostasis. In inflammatory setting, the plasticity of Tregs increased with acquiring effector T helper (Th) phenotype, resulting in the reduction of immunosuppressive ability. It is reported that the frequency of Th1-like Treg cells, which has low suppressive function, increased in autoimmune diseases [2]. T cells Immunoglobulin and Traftm domain (TIGIT) is a co-inhibitory receptor, which can suppress the response of effector T cells. It is identified that the expression of TIGIT on Tregs significantly decreased in SLE [3-4]. Interferon-α (IFN-α) is a crucial pleiotropic cytokine with a high level in SLE and can promote type I immune response. IFN-α depends on AKT/mTOR signaling while phosphorylating JAK/STAT pathway to regulate the polarization of Th1 [5].

Objectives: The study is to evaluate the characteristics and differentiation mechanisms of Th1-like Treg cells in SLE patients and the role of TIGIT in regulating immunosuppressive function.

Methods: The frequency of Foxp3+Tbet-Th1-like Tregs of peripheral blood mononuclear cells (PBMCs) from SLE patients and healthy controls were analyzed by flow cytometry. PBMCs and CD4+ T cells were isolated and cultured under stimulation of IFN-γ and/or TIGIT activator. The expression of characteristic markers of Th1-like Tregs, and the activation of AKT/mTOR/STAT pathway were assessed using flow cytometry and PCR.

Results: Th1-like Tregs with low TIGIT expression expanded in SLE patients. IFN-α promoted the conversation of Tregs to Th1-like Tregs through phospho-rylated STAT4. TIGIT reactivation reversed the polarization of Th1-like Tregs and plasmablast differentiation induced by IFN-α through AKT/mTOR/STAT4 pathway. Conclusion: Our findings indicate that the expansion of Th1-like Tregs and the decreased expression of TIGIT may contribute to the tolerance deficiency in SLE. TIGIT can reverse IFN-α-induced Th1-like Tregs and the impairment of immunosuppressive function, which is a potential therapeutic target for SLE.

URIC ACID LEVELS, CARDIOVASCULAR RISK AND DISEASE ACTIVITY: THE BERMUDA TRIANGLE IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Cardiovascular disease, Sjögren syndrome

A. Alunno1, F. Carubbi1, F.M. Mariani1, C. Marini1, E. Campanozz2, P. Altieri1, C. Forni1,10 Laboratory Medicine and Nephrology Division, University of Udine, Italy; Department of Life, Health and Environmental Sciences, Udina, Italy

Background: Over the last decade, several observational studies provided evidence on the association between serum uric acid (SUA) levels and cardiovascular (CV) risk in the general population and identified SUA as a risk factor worth assessing in the setting of CV prevention also in patients without gout. Patients with primary Sjögren’s syndrome (pSS), as those with other systemic autoimmune diseases, have a higher CV risk compared to the general population but studies assessing the role of SUA levels in the CV scenario of pSS are lacking.

Objectives: To explore the relationship between SUA levels, CV risk and CV events in patients with pSS and without gout and/or nephrolithiasis.

Methods: We retrospectively investigated pSS patients fulfilling the 2016 ACR/EULAR classification criteria. We recorded clinical, serological and CV-related variables while SUA levels were assessed at enrollment. In eligible patients (European individuals without previous CV events or diabetes) the 10-year risk of fatal and non-fatal CV disease events was calculated using the SCORE (individual aged 40-69 years) and SCORE2-OP (individuals aged over 70 years) risk prediction algorithms. Adherence to the Mediterranean Diet in the previous 12 months was also measured.

Results: We observed a strong relationship between disease activity, interstitial lung disease (ILD) and the occurrence of previous CV events in a cohort of 105 pSS patients. The association between ILD and CV events was dependent on higher SUA levels but independent of other traditional CV risk factors and on adherence to the Mediterranean diet. All 3 cases of previous non-fatal stroke were reported by female patients aged <65 years, with higher SUA levels and 2 of them also had pSS-ILD. Forty (51%) of the 79 patients eligible for the calculation of the 10-year risk of fatal and non-fatal CV risk had a risk higher than the cut-off recommended for their age, 6 (7%) have the same risk and showed the lowest levels of total cholesterol, LDL cholesterol and triglycerides (all p<0.05). Only 10/23 (43%) patients have at least one CV risk factor and none of them showed more than 2 CV risk factors.

Conclusion: This study is the first to investigate in depth the role of SUA in the CV scenario of pSS. Our findings underline the importance of assessing SUA levels in pSS in addition to the other traditional CV risk factors and are in line with the ESC advise that although evidence to use the 1.5 correction factor in comparable tissue diseases is not yet solid enough to inform recommendations, it seems prudent to take into account the presence of such conditions when there is doubt regarding initiation of preventive interventions to ultimately achieve a better stratification and management of CV risk.

Background: Due to its multisystemic involvement, systemic lupus erythematosus (SLE) can have a significant impact on patients’ quality of life (QoL). Sexual dysfunction is a key component of QoL but is often underestimated. Little is known about sexual dysfunction in SLE patients, a condition that primarily affects women during their fertile age.

Objectives: We aimed at determining the prevalence of sexual dysfunction among women with SLE and predictors thereof.

Methods: We performed a cross-sectional multicenter study in which women (18-70 years-old) with a clinical diagnosis of SLE (according to their treating rheumatologist) were included. An anonymous online questionnaire of them is similar, though the onset timing, symptoms and signs, and other clinical characteristics are different.

Objectives: To compare the clinical characteristics of SLE combined with symptomatic ONFH and AVN.

Methods: We retrospectively analyzed the clinical data of 86 cases of SLE with symptomatic ONFH and AVN treated in the Department of Rheumatology and Immunology of The First Affiliated Hospital of Xi’an Jiaotong University from April 2013 to December 2021, and compared the similarities and differences between them.

Results: A total of 2730 patients with SLE were reviewed, including 60 patients combined with ONFH (male 9, female 51) and 26 patients combined with AVN (male 2, female 24). Morbidity of ONFH was significantly higher than AVN. Compared with AVN group, the course of SLE was longer (71.33±5.33 vs 48.69±35.11) months, the size of glucocorticoids (GCs) use was longer (674.7±51.71 vs 377.7±42.73) months, and the cumulative dosage of GCs was larger (9.1±5.46 vs 6.0±2.66) g in ONFH group. SLEDAI score was lower in ONFH group than in AVN group (2.57±3.39 vs 4.46±4.81). The ONFH group had more Raynaud’s phenomenon and lower serum Vitamin-D3 level compared with AVN group. Anti-cardiolipin antibodies (ACA) positive (15.38%) and edema as the initial symptom (46.15%) were more common in AVN group. Bilateral lesions were more common in ONFH group (88.33% vs 42.31%). All of the above differences were significant (P<0.05).

Conclusion: Our results indicate that the long time and large cumulative dose exposure of GCs, stable SLE state, Raynaud’s phenomenon and low Vit-D3 value are more suggestive of ONFH than AVN. ACA positive and edema as an initial symptom are just the reverse.

SEXUAL DYSFUNCTION IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Quality of life, Real-world evidence

M. H. Fernandes Lourenço1,2, R. Pinheiro Torres1,2,3,2. Rodrigues-Manica4, V. Fraga1, C. Abreu1, R. Costa1, C. Matos1, B. Mendes1, B. Samões1, I. Silva1, F. M. Pimentel-Santos1,2,3,5, M. Costa1, J. Branco1,2,3, A. Sepriano1,2,3, Hospital Egas Moniz, Rheumatology, Lisboa, Portugal; 1Novo Medical School, Faculdade de Ciências Médicas, Lisboa, Portugal; 2Comprehensive Health Research Center, CHRC, Lisboa, Portugal; 3Hospital Garcia de Orta, Rheumatology, Almada, Portugal; 4Hospital de Santa Maria, Rheumatology, Lisboa, Portugal; 5Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 6Centro Hospitalar de Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal

Background: Due to its multisystemic involvement, systemic lupus erythematosus (SLE) can have a significant impact on patients’ quality of life (QoL). Sexual dysfunction is a key component of QoL but is often underestimated. Little is known about sexual dysfunction in SLE patients, a condition that primarily affects women during their fertile age.

Objectives: We aimed at determining the prevalence of sexual dysfunction among women with SLE and predictors thereof.

Methods: We performed a cross-sectional multicenter study in which women (18-70 years-old) with a clinical diagnosis of SLE (according to their treating rheumatologist) were included. An anonymous online questionnaire...
was performed where data on demographics (e.g., age), symptoms of depression and anxiety [Hospital Anxiety and Depression Scale (HADS)], health-related QoL (Short Form Health Survey Index 36 Item (SF36)) and sexual function [Female Sexual Function Index (FSFI)] - a 19-item patient-report outcome that assesses female sexual function]) were collected. Data on clinical features (disease activity according to the Safety of Estrogens in Lupus National Assessment-SLE Disease Activity Index (SELENA-SLEDAI), organ involvement and evaluation of comorbidity (Charlson Comorbidity Index)] and on treatment status were collected from medical records.

The main outcome was sexual dysfunction, defined as FSFI<26.5 (validated cut-off). A multivariable logistic regression was performed to test the association of clinical and demographic characteristics with sexual dysfunction (present vs absent).

**Results:** In total, 194 female patients with SLE were included (mean age 44 years-old [standard deviation (SD) 11]). The mean SELENA-SLEDAI score was 1.7 (SD 2.2), corresponding to low disease activity, and 94% of patients were on classical disease-modifying antirheumatic drugs. The mean value of HADS was 9 (0–21), for both depression and anxiety scores. Regarding SF36, the mental component had a mean value of 61 (0–100) and the physical one of 70 (0–100). Sexual dysfunction was present in 128 (66%) patients. In the multivariable analysis (Table 1), older age (OR: 1.04; 95% CI: 1.01; 1.07), higher SELENA-SLEDAI (OR: 0.96; 95% CI: 0.91; 1.01), higher HADS depression score (OR: 1.20; 95% CI: 1.01; 1.43), as well as a lower (that is, worse) SF36 mental component score (OR: 0.97; 95% CI: 0.95; 0.98) were independently associated with sexual dysfunction.

**Conclusion:** Sexual dysfunction is common in women with SLE and is influenced by both physical and mental health components. Clinicians should consider both for the optimal management of their patients in order to improve their sexual QoL.

**RELATIONSHIPS AMONG ANXIETY, DEPRESSION AND DISEASE ACTIVITY IN ASIANS SYSTEMIC LUPUS ERYTHEMATOSUS: PATIENTS FROM KAZAKHSTAN AND KIRGHIZSTAN**

**Keywords:** Quality of life, Systemic lupus erythematosus

**B. Issayeva**, G. Kolubaeva, A. Aseeva, N. Nikishina, A. Mesnyankina, S. Soloviyev, S. Issayeva, M. Bichanova, A. Bichan. Asfendiyarov Kazakh National Medical University, Rheumatology, Almaty, Kazakhstan; National Center of Cardiology and Internal Medicine named after Academician M. Mirshaimov (NCICM), Rheumatology, Bishkek, Kyrgyzstan; RHEUMATOLOGY, Federal State Research Institution (FSRI) named after V.A. Nasonova, Rheumatology, Moscow, Russian Federation

**Background:** Depression and anxiety cause severe loss of quality of life for patients with systemic lupus erythematosus. The causes and factors that contribute to these psychological manifestations in lupus are difficult to disentangle.

**Objectives:** The aim of this study was to determine factors associated with anxiety and depression in Asians systemic lupus erythematosus patients (pts) from Kazakhstan and Kirghizstan.

**Methods:** 1060 SLE pts who fulfilled SLICC 2012 criteria were enrolled into the study. The SLLEDAI 2K index activity, SLLEDAI damage index, depressive and anxiety symptoms were assessed by the Hospital Anxiety and Depression (HAD) scale (0-21 points).

**Results:** 1060 Lupus pts were studied, respectively. The pts were predominantly female (92%) and of indigenous nationality (Kazakh 10%, Kirghiz 54%/Russian 36%) with a mean SO age 34.6±11.8 years. The mean disease duration (Me) was 4 [1;9], the disease activity (SLLEDAI 2K) 13.23±8.74, SLLEDAI damage index 1.36±0.82. More than half of the pts (619 [58.3%]) had abnormal points by HADS scale. 304 (29%) pts had abnormal points by HADS scale. 156 (41%) pts had abnormal HADS-A ≥ 8 points and 42 (41%) pts had abnormal HADS-D ≥ 8 points. 304 (29%) pts had abnormal HADS-A ≥ 8 points and 81 (79%) pts had abnormal HADS-D ≥ 8 points. The pts with abnormal HADS-A were older (36.0±12.1 versus 31.5±11.86 years; p=0.002), with disease onset at a more later age (31.5±11.86 versus 26.4±12.69 years; p=0.0002), with higher SLE activity by SLLEDAI 2 K (14.78±8.59 versus 12.22±8.30; p=0.01). The pts with abnormal HADS were treated with higher doses of glucocorticoids (22.33±12.6 versus 18.5±12.0 mg per day; p=0.005).

**Conclusion:** Fatigue and anxiety symptoms are common (58,3%) in SLE pts and significantly higher among Asians pts (46%). Such factors as pts age, age of SLE onset, duration of illness, SLEDAI ≥ 2 K, and dosage of corticosteroids were strongly associated with abnormal HADS.

**DO ADULT WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS REACH FITNESS STANDARDS FOR MAINTAINING PHYSICAL INDEPENDENCE IN LATER LIFE? ASSOCIATIONS WITH FATIGUE AT 2-YEAR FOLLOW-UP**

**Keywords:** Non-pharmacological interventions, Systemic lupus erythematosus, Lifestyles

B. Gavilán Carrera, A. Soriano Maldonado, J. A. Vargas-Hitos; Hospital Universitario Virgen de las Nieves, Departamento de Medicina Interna, Granada, Spain; Instituto de Investigación Biosanitaria, Ibs.GRANADA, Granada, Spain; University of Almería, Department of Education, Almería, Spain; University of Almería, SPORT Research Group (CTS-1024), CERNEP Research Center, Almería, Spain

**Background:** Maintaining physical fitness (i.e. muscle strength and cardiorespiratory fitness) is a key factor in preserving independence in later years [1]. Because people with systemic lupus erythematosus (SLE) present with reduced fitness levels [2,3], this population could be at risk of premature loss of independence. In addition, higher levels of physical fitness have been related to better SLE symptomatology, including fatigue [2,3], one of the most limiting symptoms. However, it is unclear whether physical fitness have a predictive role on future levels of fatigue in this population.

**Objectives:** This study aimed to analyze, in a sample of adult women with SLE: i) the proportion of participants that reach the proposed standards of fitness for muscle strength and cardiorespiratory fitness to maintain independence in the later life and ii) the association between reaching these standards of fitness and fatigue levels at 2-year follow-up.

**Methods:** This follow-up study included a total of 26 women with SLE (age: 41.3±13.3 years) with low disease activity index (Systemic lupus erythematosus disease activity index (SLEDAI): mean 10±1.9). The 30-s chair stand and 6-min walk tests from the Senior Fitness Test Battery were used to assess muscle strength and cardiorespiratory fitness. The percentage of participants reaching the criterion-reference for women 60-64 years old (15 repetitions [in the 30-s chair stand test] and 571,5 meters [in the 6-min walk test]) was calculated. Linear regression models adjusted by age were used to analyze the association of reaching the fitness criterion-reference and fatigue levels at 2-year follow-up. Five dimensions of fatigue (general, physical, reduced activity, reduced motivation and mental fatigue) were assessed using the multidimensional Fatigue Inventory (MFI).

**Results:** A total of 42.3% participants did not reach the criterion-reference for muscle strength and 50% of participants did not reach the criterion-reference for cardiorespiratory fitness. Reaching the criterion-reference for cardiorespiratory fitness was associated with lower physical fatigue at 2-year follow-up (β=-0.55, P<0.05). There was no association with other dimensions of fatigue or reaching the criterion-reference for muscle strength.

**Conclusion:** In this relatively small sample of adult women with SLE, up to half of participants have reduced physical fitness that exposed them to a premature loss of functioning and independence in their later life. Reaching a minimum level for cardiorespiratory fitness, but not for muscle strength, predicted lower physical fatigue in the future. Exercise interventions aimed at increasing physical fitness
could be a promising approach to reduce the decline in functioning and contrib-
ute to lower fatigue in this population.

Figure 1: Immunohistochmical staining of left atrial appendage

Table 1: Clinical and Tissue analysis of LA appendage

CONCLUSION: A comparison of SLE and RA patients complicated with heart
disease revealed that the SLE patients tend to be younger at diagnosis than RA
patients and had a longer morbidity period. It is possible that various autoan-
tibodies, such as antiphospholipid antibodies, anti-Ro/SSA antibodies, and
anti-U1RNP antibodies were involved and had immunological effects on the
myocardial tissue. In contrast, in RA patients complicated with heart disease, the
autoantibodies observed in SLE were negative, and immunoglobulins were not
deposited in the myocardial tissue of the RA patients who underwent surgery,
suggesting that immunological involvement was poor and older diagnostic age
was involved.

matism 2013; 43: 77-95
Breastfeeding avoidance in women with SLE is frequently the result of a confluence of individual preference, clinical advice, and societal context. An implementation of patients-to-patients network, together with an update of health practitioners, may help to increase the frequency of breastfeeding in women with SLE and subsequently improve patients’ care.

In Figure 1 implementation points suggested by patients.

Keywords: Outcome measures, Health services research, Skin
literature review. Interviews included open-ended and semi-structured questions on CLE diagnosis and their patients’ signs/symptoms, and data were evaluated by thematic analysis. Two quantitative activities were conducted: first, clinicians sorted a list of skin signs/symptoms as 1) not characteristic, 2) moderately characteristic, or 3) highly characteristic of CLE or cutaneous SLE disease activity. Second, they classified CLE signs/symptoms as most closely associated with CCLE/DLE, SCLE orACLE. Data were analyzed using an inferential (ranking task) or formal (classification task) consensus model.

Results: Eleven dermatologists and 10 rheumatologists (US n=13; Europe n=8) were interviewed. Most dermatologists (70%) had 5–10 years experience managing patients with CLE; 56% of rheumatologists had 21–25 years’ experience. The most frequently mentioned signs included erythema/rash (100%), malar rash (71%), palpable lesions (57%) and scale (57%). Photosensitivity (76%), itch (62%) and skin pain (57%) were the most frequently mentioned symptoms. Of the 33 skin signs presented, both specialties ranked photosensitive rash (weighted average dermatologist score 2.80; rheumatologist score 2.95) and erythema (2.95; 2.81) highest. However, some key differences were identified. For example, dermatologists ranked polycyclic (2.72) and annular (2.61) lesions (typical of SCLE) as highly characteristic of CLE, but rheumatologists ranked them as low or moderately characteristic (1.55 and 2.23, respectively). Also, dermatologists ranked markers of DLE, such as follicular plugging (2.68 and 2.36), higher than rheumatologists. Consensus analysis showed robust agreement between dermatologists (effect size ratio 17.95; average competence 0.86) and modest agreement between rheumatologists (6.13; 0.67) in classifying skin manifestations by CLE subtype. Manifestations with the strongest agreement included acute alopeia (ACLE n=20; SCLE n=0; CCLE/DLE n=1), malar rash (n=21; n=0; n=0, respectively), dyspigmation without scarrring (n=1; n=18; n=2), psoriasiform annular plaques (n=0; n=18; n=1), and irreversible scarring alopecia (n=0; n=21; n=0). Variation was evident for signs more often associated with SCLE, including non-scarring photosensitive dermatitis (n=8; n=13; n=0). Multidimensional scaling showed notable differences in consensus between dermatologists and rheumatologists; while coherent clusters of symptoms were mapped to the CLE subtypes by dermatologists, the pattern for rheumatologists was more diffuse, suggesting a less consistent conceptualization of SCLE and CCLE.

Conclusion: Despite agreement on the importance of erythema and characterization of CLE as a photosensitive rash, differences between the specialties were apparent when rating CLE signs that typically accompany non-systemic, cutaneous disease. This might reflect increased training among dermatologists in clinical-histopathologic description of lesions. The conceptual model proposed will facilitate efforts to design measurement approaches to evaluate disease activity in clinical research and practice.

Background: Health-related quality of life (HRQoL) is impaired in systemic lupus erythematosus (SLE) patients, but its association with physicians reported disease activity is modest to none.

Objectives: To determine the impact of patients reported disease activity on their HRQoL.

Methods: We evaluated patient-reported disease activity on SLE patients from the Almenara Lupus Cohort. Disease activity was assessed using the Lupus Foundation of America Rapid Evaluation of Activity in Lupus (LFA-REAL) patient-reported outcome (PRO) which ranges between 0 and 1200 (the higher the score is, the worse the activity is); HRQoL was ascertained using the LupusQoL which ranges between 0 and 100 (the higher the score is, the better the HRQoL). Generalized estimating equations were performed for each domain of the LupusQoL and the LFA-REAL PRO measured at the previous visit; multivariable models were adjusted for possible confounders (age at diagnosis, gender, educational level, disease duration, SLEDAI/2K, SDI, prednisone dose, antimalarials and immunosuppressive drug use and the same domain of LupusQoL) measured at the same visit as the LFA-REAL PRO. B was reported per 10 units increase of the LFA-REAL PRO.

Results: A total of 259 patients and 582 visits were included. Mean (SD) LFA-REAL PRO was 242.91 (178.92). The most affected LupusQoL domains at baseline were burden to others 575 (SD 315), intimate relationship 64.1 (SD 33.1) and body image 62.6 (SD 30.7). LFA-REAL PRO predicted a worse HRQoL in all domains, even after adjustment by possible confounders (Table 1).

Conclusion: A higher patient-reported disease activity predicted a worse HRQoL in SLE patients, even after adjustment for possible confounders. Strategies to improve how the patients feel and manage their disease could be useful to improve their HRQoL. Patient-reported disease activity should be included in the evaluation of SLE patients on a regular basis.

Keywords: Sjögren syndrome, Systemic lupus erythematosus, Undifferentiated connective tissue disease.
Background: A large body of evidence has shown that type I IFN (IFN-I) biomarkers are associated with worse clinical features within each ANA-associated rheumatic disease (ARMD). IFN-I biomarkers also predict response to IFN-targeted and other therapies. DEFINITION is an observational study to explore the clinical associations of IFN biomarkers across the disease course and spectrum of ARMDs. This is a preliminary analysis for the subsection on the spectrum of established ARMD.

Objectives: To determine whether patients with high IFN-I biomarkers have greater impact of disease including disease activity, functional impairment and quality of life.

Methods: Adults with current or previous positive ANA and either criteria for any ARMD (SLE, pSS, IIM, SSC, MCTD) or consultant diagnosis of ARMD (may be undifferentiated if symptoms>12 months and/or treated with immunosuppressants. We collected demographics, deprivation, participation, cardiovascular risk and comorbidity variables, diagnostic criteria for each ARMD, quality of life and other patient-reported outcome measures, and therapies. Disease activity was summarised using a composite of validated instruments to classify each organ system as severe, moderate, mild or inactive (equal to BILAG A/D/E for SLE). IFN-I pathway activation was measured using gene expression IFN Score A and B and memory B cell tcellin. We used Spearman correlations and unsupervised hierarchical clustering and to find associations between clinical outcomes and IFN-I biomarkers.

Results: Of 294 patients, 23/294 (18%) were male, mean (SD) age was 50 (14), index of multiple deprivation decile 4.3 (3.1), Charlson comorbidity index 2.1 (1.5). Current therapy was prednisolone (24.5%), hydroxychloroquine (45.2%), methotrexate (17.7%), mycophenolate (11.9%), azathioprine (10.2%), rituximab (8.5%), cyclophosphamide (0.3%). 104 patients had SLE, 111 had UCTD, 33 and pSS, 19 had myositis, 14 had SSC and 13 had MCTD. There was a significant association between ARMD diagnosis and IFN Score A (F= 2.52, p=0.030) and memory B cell tcellin (F= 4.34, p<0.001) but not IFN Score B (F=0.66, p=0.653). In pairwise correlations only one weak relationship between SF36 PCS and memory B cell tcellin was found (R=0.33, p<0.001). No substantive relationship was found between gene expression scores and clinical features. However, unsupervised hierarchical clustering across all ARMD patients yielded 5 clusters of patients with a significant role for sociodemographic variables that revealed further relationships between IFN biomarkers and disease activity Cluster 1: mild symptoms, low comorbidity, high affluence; Cluster 2: older, high comorbidity, high affluence; Cluster 3: younger, low affluence, poor QoL; Cluster 4: higher tcellin and BILAG; Cluster 5: low IFN and BILAG.

Conclusion: There are complex relationships between IFN and clinical features across the spectrum of ARMDs. This is confounded by socioeconomic variables, which must be considered in stratification studies.

AB0577 LEFT VENTRICULAR DYSYNNCHRONY IN SUBJECTS WITH DIFFERENT SLE PHENOTYPES

Keywords: Cardiovascular disease

F. Shahab1, H. Zachrisson2, C. Svensson2, M. Ånegård2, C. Sjöwall3, D. Kyllhammar1, Linköping University Hospital, Department of Rheumatology, Linköping, Sweden; 2Department of Health, Medicine and Caring Sciences, Department of Clinical Physiology, Linköping, Sweden; 3Division of Neuro and Inflammation Sciences, Department of Clinical and Experimental Medicine, Department of Rheumatology, Linköping, Sweden

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with highly heterogenous clinical presentation involving, e.g., skin, joints, kidneys and the cardiovascular system. In prospective studies, the incidence rates of myocardial affection and stroke in patients with SLE have been shown to be higher. But, more knowledge is needed regarding early myocardial involvement and affection of the right ventricle in different SLE phenotypes.

Objectives: The aim of the present study was to investigate differences of left- and right ventricular systolic function in three, well-defined SLE phenotypes, i.e. skin- and joint involvement, lupus nephritis antiphospholipid syndrome (APS), respectively.

Methods: Transthoracic echocardiograms were performed in 60 subjects with SLE (three age- and sex-matched groups of subjects with either skin- and joint involvement, lupus nephritis or APS, respectively) included in the SLEVASK[1] cohort which represents a subgroup of the regional quality register Clinical Lupus Register in North-Eastern Gothia (Swedish acronym: KLURING). There were 54 women and 6 men, and the median age was 49.5 (range 29-68) years. Left- and right ventricular longitudinal and left ventricular mechanical dispersion, defined as the standard deviation of time to maximal myocardial shortening were measured by a commercially available software. Three subjects with clinically manifest heart failure were excluded.

Results: There were no significant differences in left- or right ventricular dimen-
sions, left ventricular ejection fraction or measures of right ventricular systolic function between the three groups. Left ventricular global longitudinal strain was reduced in subjects with nephritis (p=0.012), as compared to those with skin- and joint involvement and there was a trend for lower strain also among subjects with APS (p=0.078). Left ventricular mechanical dispersion was increased among subjects with APS (p=0.015) and nephritis (p=0.032), as compared to those with skin- and joint involvement (Table 1).

Conclusion: Reduced left ventricular global longitudinal strain and greater mechanical dispersion, a sign of a more heterogeneous contraction, among SLE patients with nephritis and APS indicate more severe cardiac involvement, as compared to those with skin- and joint involvement. A greater degree of mechanical dispersion is thought to reflect myocardial fibrosis and future studies should investigate the pathogenesis of such sub-clinical impairment of cardiac function in SLE and its impact on long-term prognosis.

AB0578 LATIN-AMERICAN SYSTEMIC LUPUS ERYTHEMATOSUS CLUSTERS

Keywords: Autoantibodies, Registries, Systemic lupus erythematosus

Background: Systemic lupus erythematosus (SLE) is heterogeneous autoimmune disease. Identification of patient clusters may be useful for the management of the disease.

Objectives: To describe different SLE clusters according to sociodemographic, clinical and serological variables.

Methods: GLADEL 2.0 was an ongoing Latin-American observational cohort initiated in 2019. Variables chosen at cohort entry to stratify patients and construct clusters were selected from sociodemographic and cumulative clinical and serological variables. Hierarchical cluster analyses were performed by the Ward method on a distance matrix using the Gower’s method.

Results: A total of 560 SLE patients were included in this analysis. Three clusters were identified. Cluster 1 (n=269) was characterized by more cutaneous, articular, renal and serosal involvement; serological manifestation was positive for antiphospholipid antibodies (aPLs). Cluster 2 (n=194) was represented by patients who rarely had renal involvement and the most frequent clinical manifestations were cutaneous and hematological; the most frequent serological manifestations were the presence of antiphospholipid antibodies (aPLs). Cluster 3 (n=97) was characterized by a lower frequency of clinical and serological involvements, with the exception of neurological domain. Cluster 1 and 2 share hematological manifestations and hypocoomplementemia (Table 1).

Conclusion: In this cohort, three patient clusters were identified. Cluster 1 patients were characterized by renal, articular, cutaneous and serositis involvement, anti-dsDNA antibodies and hypocoomplementemia. Cluster 2 patients were characterized by hematologic, cutaneous involvement, aPLs and hypocoomplementemia. Cluster 3 patients presented fewer serological findings but a higher frequency of neurological involvement. Follow up of these patients will allow for elucidation of relationship of these clusters with SLE outcomes.

ASSOCIATION OF RACE OR ETHNICITY WITH MEDICATION ADHERENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Gender/diversity issues, Systemic lupus erythematosus

R. Lomanto Silva1, G. M Swabe2, S. E. Sattui3, J. W Magnani4. 1University of Pittsburgh Medical Center, Internal Medicine, Pittsburgh, United States of America; 2University of Pittsburgh, Internal Medicine, Pittsburgh, United States of America; 3University of Pittsburgh Medical, Rheumatology, Pittsburgh, United States of America; 4University of Pittsburgh, Cardiology, Pittsburgh, United States of America

Background: Systemic lupus erythematosus (SLE) causes significant disease burden. Racial and ethnic differences in outcomes have been recognized, with increased morbidity and mortality in Black and Hispanic individuals, compared to non-Hispanic White referents. Financial barriers to treatment, such as copayments (or copays), may affect adherence to essential pharmacologic therapies, contributing to increased health adversity. Determining the contribution of copays to adherence may identify disparities in medication access and pathways to improve adherence.

Objectives: To examine the association between race or ethnicity and medication adherence.

Methods: We used administrative health claims data (Optum's De-identified Clininformatics® Data Mart Database, 2007-2021) to identify individuals with incident SLE (2 ICD-9/10 codes within 30-365 days) between 2010-19 receiving methotrexate (MTX), or combination therapy (HCQ with AZA, MMF, or MTX). Adherence was not significant (p >0.05). Treatment and prescription data were available for individuals with complete data (n=1720).

Results: We identified 12,510 individuals: age 54.2±15.5 years; 88.2% women; 10.1±4.7 years since first SLE diagnosis; 10.1±4.7 years since first lupus medication prescription. Of 9510 (76%) were on HCQ and 15% on combination therapy. Median (IQR) ≥$10 vs <$10 Copay OR (95% CI); P value

PREGNANCY OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): DATA FROM A MULTIETHNIC, MULTINATIONAL LATIN AMERICAN COHORT

Keywords: Anti-phospholipid syndrome, Pregnancy and reproduction, Systemic lupus erythematosus

1Rosario, Centro Regional de Enfermedades Autoinmunes y Reumaticas (GO-CREAR), Rosario, Argentina; 2Hospital Córdoba, Facultad de Ciencias Médicas, Universidad Nacional de Córdoba, Córdoba, Argentina; 3Hospital General de Agudos, Carlos G. Durand, Rheumatology Department, CABA, Buenos Aires, Argentina; 4GLADEL, statistician, Rosario, Argentina; 5Hospital Escuela Eva Peron,” Servicio de Reumatologia, Granadero Baigorria, Argentina; 6Hospital Padilla, Servicio de Reumatologia, San Miguel de Tucumán, Argentina; 7Hospital de las Clinicas, Universidad Federal de Goias, Goias, Brazil; 8Hospital de Clinicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Rheumatology Division, Department of Internal Medicine, Porto Alegre, Brazil;
Objectives: To study SLE pregnancy outcomes in LA:

Methods: GLADEL 2.0 is an observational prevalent/incident cohort started in 2019. To date, 43 centers from 10 LA countries have enrolled 1030 SLE patients (1982/1997 ACR or SLICC criteria). Women with ≥1 pregnancy were included. Past and ongoing (6, 12, 24 months follow-up) OM (miscarriages, fetal deaths, preeclampsia, prematurity, neonatal lupus) were evaluated.

Results: At inclusion, 329 women had had at least one pregnancy [median (IQR): 2 (1-3)]. Table 1. Of them, 293 (89.1%) had ≥1 live birth and 183 (55.6%) developed OM. Preeclampsia occurred in 49 (14.9%). Among 71 (21.6%) women with anti-SS-A(Ro)/SS-B(La) antibodies, 3 (4.2%) developed neonatal lupus (no cardiac involvement). Antiphospholipid syndrome (APS) was associated with higher risk of OM (52.2% vs 10%; p < 0.001). Of the 755 pregnancies reported, 551 (73.0%) resulted in live births, of which 79 (14.3%) were premature. The remaining pregnancies ended in 178 (23.6%) miscarriages and 41 (5.4%) fetal deaths. During 2-follow-up years (Figure 1), 24 singles pregnancies occurred. All were under antimalarials; 16 (66.7%) resulted in live births; 4 (25.0%) premature; 12 (50.0%) developed OM. There were seven (29.2%) miscarriages and one fetal loss (4.2%) related to severe preeclampsia. One cholestasis gravidarum (4.2%) lead to prematurity. There were no new cases of neonatal lupus.

Conclusion: In GLADEL 2.0 cohort, around half of the studied women presented OM being frequently related to APS. Miscarriages, prematurity, preeclampsia and fetal deaths were the most common pregnancy complications. The incidence of neonatal lupus was lower than previously reported [1].

Table 1. Characteristics of SLE women with ≥1 pregnancy at cohort inclusion related to OM1.

Objectives: To determine clinical and pathological features predicting complete clinical response (CCR) after induction therapy in crescentic lupus nephritis.

Keywords: Prognostic factors, Systemic lupus erythematosus, Kidneys

Background: Lupus nephritis (LN) is one of the major manifestations of systemic lupus erythematosus, which develops in approximately 40% of patients with systemic lupus erythematosus. Clinical presentation of LN varies between patients, from asymptomatic proteinuria to rapidly progressive glomerulonephritis. Due to improvements in treatment strategy, risk of developing end-stage kidney disease (ESKD) decreased to less than 10% in developed countries, but some patients still progress to ESKD and require renal replacement therapy. Crescent formation in the kidney pathology was not associated with cumulative CCR rates in patients with class III or IV LN, which is an important factor for CCR after induction therapy.

Method: Patients with biopsy proven class III or IV LN from 2008 to 2017 were included in the analysis. There was no significant difference in age (42.8 ± 2.6 vs 44.4 ± 2.1 years, p=0.63), disease duration (10.9 ± 1.9 vs 11.4 ± 1.7 years, p=0.85), eGFR (70.7 ± 4.9 vs 66.0 ± 4.1 ml/min/1.73m², p=0.47), and UPCR (2.3 ± 0.5 vs 2.5 ± 0.4 g/gCr, p=0.72) between the CLN and non-CLN groups. Cumulative CCR rates for 5-years were not different between CLN and non-CLN groups (83% vs 84%, p=0.96). In the non-CLN group, patients who achieved CCR had lower glomerular sclerosis (0.93 ± 0.16 vs 1.75 ± 0.27, p=0.01) and interstitial fibrosis score (0.77 ± 0.12 vs 1.25 ± 0.20, p=0.049) than those who did not achieve CCR. In the CLN group, patients who achieved CCR had lower interstitial fibrosis (0.94 ± 0.14 vs 1.67 ± 0.17, p=0.01) and tubular atrophy score (0.78 ± 0.15 vs 1.58 ± 0.19, p<0.01) than those who achieved CCR, while cellular or fibrotic crescentic score did not differ between them (2.33 ± 0.23 vs 2.50 ± 0.23, p=0.65). Multivariable analysis revealed that interstitial fibrosis was negatively associated with CCR in both CLN and non-CLN groups (odds ratio [OR] 0.11, p<0.01; OR 0.33, p=0.04, respectively). We next divided CLN patients into two groups according to the interstitial fibrosis less than 25% or not, and found significantly higher cumulative CCR rate in patients with interstitial fibrosis less than 25% (p<0.01).

Conclusion: Crescent formation in the kidney pathology was not associated with cumulative CCR rates in patients with class III or IV LN, while interstitial lesion was shared by both CLN and non-CLN as a significant prognostic factor for CCR after induction therapy.

REFERENCES:
Background: Anti-phospholipid antibodies (APL) are associated with thrombotic events or pregnancy complications leading to the so-called anti-phospholipid syndrome (APS) according to the classification criteria last updated in 2006. APL can be found in asymptomatic patients.

Objectives: We observed the clinical, biological characteristics and association with other diseases of asymptomatic APL carriers group, and we compared them with an APS patients group.

Methods: In this French multicentric retrospective cohort study we analyzed the data of 507 patients with persistent positive APL measured between 2012 and 2019. Clinical and laboratory data were collected retrospectively. Data are expressed as numbers with frequencies and median values with interquartile ranges (IQR). Qualitative and quantitative variables were compared using Fisher and Kruskal-Wallis tests. Cumulative incidence curves of relapse event were generated using Kaplan-Meier. We used Cox model to obtain Hazard Ratio (HR). Proportional hazard assumption was checked using Schoenfeld residuals. Two-sided testing was used, with p ≤0.05 considered statistically significant.

Results: We observed a majority of female patients of a younger age in the APS group when compared to the APL carriers group. Cardiovascular risk factors were similar in both groups. Systemic lupus erythematosus was more frequently associated with the APL group, but interestingly rheumatoid arthritis, ankylosing spondylarthritis and chronic kidney disease were more frequently associated with asymptomatic APL carriers. At biological level, anti-cardiolipin IgG and beta-2-glycoprotein 1 IgG positivity rates were higher in APL patients. There was no difference in mortality between APS patients group and asymptomatic APL carriers group. Interestingly, we observed a higher rate of atypical APL in primary APL carriers group. We also observed an association between autoantibodies positivity and presence of autoantibodies in the APL carriers group during the evaluation period. APS group had a higher mortality as expected. Interestingly, we observed a higher rate of atypical APL in primary APL carriers subgroup, with a trend toward a significant intergroup difference (31.1% vs 21.2%, p=0.075). There was no difference in mortality among groups.

Conclusion: APL carriers group was associated with the presence of autoimmune disease, infection and cancer. We did not observe any thrombotic events in the APL carriers group during the evaluation period. APS group had a higher mortality as expected. Interestingly, we observed a higher rate of atypical APL in primary APL carriers subgroup, with a trend toward a significant intergroup difference (31.1% vs 20.2%, p=0.075). We did not find a difference in mortality between primary and secondary APL carriers subgroups.

CONCENTRATIONS OF SERUM ADVANCED GLYcation END PRODUCTS (AGES) CARBOXYETHYLLYSINE CORRELATE WITH INDICES OF ACTIVITY AND SPECIFIC MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords:
Biomarkers, Systemic lupus erythematosus
J. Carrion Barbera1, L. Triguero2, A. Ribes2, C. Pérez2, L. Polino1, E. Beltrán1, A. Pros1, J. Montfort1, T. C. Salman Monte1, L. Tió2, Hospital del Mar, Rheumatology, Barcelona, Spain; 1Institut Mar d’Investigacions Mèdiques, Investigación celular en inflamación y cartílago, Barcelona, Spain

Background: Studies postulate that advanced glycation end products (AGEs) could have a relevant role as inducers in the chronic inflammatory pathway present in various diseases, including systemic lupus erythematosus (SLE), and that AGEs concentration could be related to disease parameters such as activity or accumulated damage. To date, these studies show conflicting results.

Objectives: To estimate correlations between the concentrations of the blood AGE carboxyethyllysin (CEL) and disease-related parameters in a population of SLE patients.

Methods: Serum CEL concentrations were determined using a specific AGEs competitive ELISA Kit in accordance with the manufacturer’s instructions in 113 SLE patients. We correlated demographic and clinical data with the results, and adjusted for age and smoking status as possible confounding factors, based on previous analysis (CEL AGEs decreased significantly with age and presence of smoking habits). The indices were analyzed both as quantitative and categorized variables according to previously established categories in the literature or to medians/tertiles depending on the distribution of the variable in our sample. CEL concentrations were classified into tertiles.

Results: Table 1 shows the distribution and correlations of our cohort characteristics according to CEL tertiles. Disease duration was inversely statistically correlated with CEL concentrations, as well as haematological alterations while alopecia was directly correlated. CEL values were statistically correlated with several markers of SLE activity: SLE disease activity index (SLEDAI), erythrocyte sedimentation rate, serum IL-6, and the count of swollen joints at the moment of the blood extraction (both in the Disease Activity Score 28 and 68).

No associations were found with autoantibodies, other disease questionnaires, or different blood AGEs and AGEs receptor.

Conclusion: The correlation of CEL AGEs values with different disease activity markers in SLE could indicate their potential use as a biomarker of activity in this disease and an associated specific phenotype with less haematological manifestations and more alopecia.

Background: Patients with Systemic lupus erythematosus (SLE) have a well-known increased risk of major comorbidities, but they are also very heterogeneous in term of prevalence of comorbid conditions. The relationship of the comorbidities with the outcomes and the severity of index disease is less known. Objectives: Evaluate the interactions between comorbid conditions, on a large multicenter SLE cohort from RELESSER registar, and its impact in severity and outcomes. Methods: Data about 14 cumulative comorbidities, as previously defined [1], where derived from patients with SLE (ACR-97 criteria) included in the retrospective phase of RELESSER. Severity Katz Index (SKI) and SLICC/ACR Damage Index (SDI) were calculated. An unsupervised cluster analysis using K-means method was implemented to define clusters. ANOVA and Tukey tests were used to compare continuous numerical variables; Kruskal-Wallis test to discrete variables and the Chi-square test (or Fisher’s exact test) to categorical ones. Results: A total of 3658 SLE patients (ACR-97 criteria) were included. Median SKI: 2 (interquartile range (IQR):1;3; median SDI:1(IQR:0;2). Demographic data are shown in Table 1. The comorbidities considered and their prevalence were: Thyroiditis (8.3%), peptic ulcer (3.8%), severe hepatopathy (1.0%), obstructive pulmonary disease (2.7%), Diabetes (5.0%), cardiovascular event (CVE) (11.0%), cardiac arhythmia (4.2%), pulmonary embolism (3.4%), dementia (0.7%), malignancy (5.9%); serious infection (19.3%), end stage renal disease (2.8%), osteoporosis (7.3%) and depression (17.1%). Four cluster, with markedly different comorbidity profiles and outcomes were identified (Table 3). One subgroup was clustered around depression (100% of the cases) (cluster 2), another cluster (cluster 3) with > 1 serious infection (100%) and cluster 4, with 100% of the CVE. In cluster 1, no patient had any of the 3 defining comorbidities in the rest of the clusters. There were no statistically significant differences between clusters in death by SLE. The clusters are characterized in more detail in table 1, where a just summary of the main comorbidities included in the analysis is displayed. Conclusion: Cluster analysis identifies well-differentiated subgroups of SLE patients as regard comorbidities and associated mortality and severity of the disease. REFERENCE: [1] Ruia-Figuerola I et al. National registry of patients with systemic lupus erythematosus of the Spanish Society of Rheumatology: objectives and methodology. Reumatol Clin 2014;10(1):17-24.
Methods: This was a retrospective study involving SLE patients admitted from February 2010 to January 2020. Demographic, clinical details, laboratory parameters, treatment received, and complications during the stay in the hospital were entered in a proforma. The cause of death was classified as disease-related, infection-associated, or both.

Results: There were 1156 SLE admissions and 135 in-hospital mortalities. 24 patients were excluded because of inadequate parameters or wrong codes. Among the 111 patients, 102 (91.9%) were females. Mean age at the diagnosis and mean duration of hospitalisation was 29.7 years (276.3-31.7) and 11 days (8.7-13.3) respectively. More than three-fourths of the total patients had skin (76.6%), Musculoskeletal (74.8%), Renal (81.1%) or Hematological (73%) involvement. Nearly half of the patients had Respiratory (42.3%) or Neurological (49.5%) involvement. Mortality was primarily due to disease activity (43.2%; n = 48) followed by mixed (infection and disease activity) (36%; n = 40). Isolated infection-associated mortality was less than the active disease (19.8%; n = 22).

A subgroup analysis of the study participants based on mortality showed that cardiac (50%) and haematological (75%) involvement were more common among the participants with disease activity. There was no significant difference between the baseline investigations and treatment administered between the groups. The details are shown in Table 1. The most common infections were due to gram-negative bacteria. Among the study participants, 45 patients (48.6%) died within six months of diagnosis. Pulmonary involvement (51.9%; n=28/54) was more common in the first six months compared to death after six months (33.3%; n=19/57) (p-value = 0.04). Cardiac involvement in the form of myocarditis was more common in the later part of the disease compared to the first six months (18.5% vs 40.4%; n=10/54 vs n= 23/40.4; p-value = 0.01).

Conclusion: Disease activity alone or in combination with infection contributes more to hospital mortality than infections alone. Though patients with disease activity-associated mortality have more haematological and cardiac involvement at presentation, there are no differences in various laboratory parameters, including complement levels among the participants in the three groups.

Table 1. Comparison of Organ involvement, Investigations, and treatment administered among mortality subgroups

AB0588 ADELUMAB FOR IMMUNE RELATED INFERTILITY: EFFICACY AND SAFETY FROM PROSPECTIVE FRENCH MULTICENTER REGISTRY

Keywords: Pregnancy and reproduction, Autoantibodies, Anti-phospholipid syndrome

N. Abisor1, M. Cheloufi2, C. Mcavoy1, A. Guedon1, O. Fain1, G. Kayem2, A. Mekimen1.

1 Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service de médecine interne et Inflammation-Immunopathologie-Biothérapie Department (DMU 03), Paris, France; 2 Hôpital Armand-Trousseau, APHP Sorbonne Université, Service de Gynécologie Obstétrique, FHU PREMA, Paris, France

Background: Recurrent miscarriage (RM) is a frequent condition affecting about 1–3% of couples and is one of the most frustrating and difficult areas in reproductive medicine since the etiology is often unknown and evidence-based diagnosis and treatment strategies are scarce. Likewise, recurrent implantation failure (RIF) is considered after at least 3 unsuccessful transfers of good quality embryos, and remains unexplained in 45% of infertile couples.

Objectives: The primary objective of this study was to describe a real-life prospective cohort of women with unexplained RM and/or RIF under adalimumab, to analyze the impact of the treatment on live birth rates and to evaluate its safety.

Methods: The French infertility multicenter FALCO registry is an ongoing registry from 2017 including patients with unexplained recurrent miscarriages and implantation failures from several university hospitals. Inclusion criteria were [1] at least 3 recurrent miscarriages before 12 weeks of gestation and/or at least 3 implantation failures of at least 2 good quality embryos transfers; [2] absence of any cause for recurrent miscarriages and implantation failures such as uterine, genetic, infectious, hormonal, thrombophilia and autoimmune diseases. The following data was collected:

- Clinical data including age, number of pregnancies, number of consecutive miscarriages, body mass index, tobacco and alcohol use, tea or coffee consumption during pregnancy, dietary habits, presence of endometriosis, adenomyosis and assessment of the uterine cavity by hysteroscopy or hysterosonography.
- Laboratory analysis of usual recurrent miscarriages etiological screening: parental karyotypes, ovarian reserve parameters (FSH (IU/L), LH (IU/L), Estradiol (pg/ml), AFC (Antral Follicular Count), AMH rate (ng/ml)), thyroid-stimulating hormone (TSH) levels (mUI/l) and biomarkers of immune origin (anti-nuclear antibodies, anti-TPO/TG).

Results: Overall, between 2017 and December 2022, 2686 pregnancies from 395 patients were included with prospective follow-up. These women had history of recurrent implantation failure for 102 (26%), recurrent miscarriage for 275 (70%) and both for 18 (4%). The median gravidity was 4 [2-6]. Regarding the presence of immunity biomarkers, 283 had various autoantibodies (86.6%): 130 patients (33%) with antinuclear antibodies (>1/80e), 16 patients with antiphospholipid syndromes (5%), 44 patients with positive anti thyroid peroxidase antibodies (11%), 24 with positive anti-thyroglobulin antibodies (11%), 4 with anti-transglutaminase antibodies (11%). Most recent AMH count median was 1.73 [0.87, 3.24]. Among overall pregnancies, there were 1384 miscarriages (73.6%), 269 live births (14.3%), 89 abortions (4.7%), 24 medical terminations of pregnancies (1.3%), 55 pregnancies over 12 weeks of gestation (2.9%) and 58 extraterine pregnancies (3.1%). Among 2686 pregnancies, 494 were treated and received immunomodulatory treatment. Among these pregnancies under therapies: steroids in 332 cases (12.4%), hydroxychloroquine in 185 cases (7%), intralipids in 102 cases (3.8%), and adalimumab in 69 cases (2.6%). Patients with pregnancy under adalimumab treatment had a significantly higher rate of cumulative live birth rate than those with untreated ones: OR: 3.52 [1.63 – 7.61]; p < 0.01 after adjustment of age, pregnancy, associated treatment (progestosterone, aspirin, vitamin D, prednisone). Adverse events in Adalimumab treated pregnancies were reported in 7 women: herpes and zoster reactivation in 3 cases, cystitis and bronchitis in 4 cases, and no congenital malformation and no maternal deaths.

Conclusion: In this large prospective French cohort of women with unexplained immune origin RM and/or RIF, adalimumab has been effective to obtain a live birth pregnancy.

**CANCER PREVALENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS: A PORTUGUESE COHORT STUDY WITH 15 YEARS OF FOLLOW-UP**

**Keywords:** Systemic lupus erythematosus, Malignancy, Epidemiology

A. Saravia1, A. Maduro2, B. Mendes3, A. Carones Esteves1, M. Luis4, J. A. P. Da Silva5, L. Inês6-8, 1Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Faculty of Medicine, University of Coimbra, Rheumatology, Coimbra, Portugal; 3Universidade da Beira Interior - Faculdade de Ciências da Saúde, Rheumatology, Covilhã, Portugal

**Background:** An increased risk of malignancy was reported in patients with Systemic Lupus Erythematosus (SLE) [1-3].

**Objectives:** To estimate the prevalence of cancer in a Portuguese cohort of patients with SLE over long term follow-up.

**Methods:** Patients followed up between 01/01/2006 and 31/10/2021 at the Centro Hospitalar de Coimbra Lupus Clinic were included. All patients fulfilling SLE classification criteria (EULAR/ACR 2019 or SLICC 2012 or ACR 1999) and assessed at least in two visits were included. Cancer cases were only considered if the diagnosis was established after SLE diagnosis. Patient and SLE clinical and treatment data were collect from the cohort electronic database. Disease activity was assessed with SLE Disease Activity Score (SLE-DAS) and organ damage with the SLICC/ACR Damage Index (SDI). Associations with malignancy were tested using the Chi-square test, Fisher exact test, Student’s t-test, or Mann-Whitney U test, as appropriate. Statistical significance of Bonferroni adjustment accounting for multiple comparisons was considered for p<0.005.

**Results:** In total, 438 patients were included (mean age: 49.6±15.8 years-old; female: 85.4%; mean disease duration: 14.2±9.8 years). At the last study visit, 68.8% were in remission, and mean SLE-DAS was 1.9±2.5. The total cumulative prevalence for cancer was 7.1% (n=31), with 4 patients presenting metastatic disease at the time of cancer diagnosis. The most common malignancies were non-melanoma skin cancer (1.1%), colorectal (1.1%), hematologic (1.1%), lung (0.7%), and breast cancer (0.7%). Cancer patients were older (64.5±14.9 years, p<0.001) and had higher any-cause mortality (35.5% vs. 5.9%, p<0.001). There were no significant differences regarding disease activity at last visit, disease duration, organ damage or cumulative immunosuppressive therapy usage (38.7% vs 54%, p=0.099). Death as a direct result of malignancy occurred in 8 (72.7%) patients, accounting for 22.9% of death in our cohort.

**Conclusion:** This is the first study reporting cancer prevalence in a Portuguese SLE cohort. Our results are similar to those reported by Sultan et al (5.4%) (2), but substantially lower than those reported in a Finish cohort (22%) (3).

**CROSS-SECTIONAL ASSESSMENT OF THE QUALITY OF LIFE IN SLE PATIENTS: ROLE OF DISEASE ACTIVITY, CHRONIC DAMAGE, FIBROMYALGIA SYNDROME AND MOOD DISORDERS**

**Keywords:** Quality of life, Patient reported outcomes, Systemic lupus erythematosus

F. Natalucci1, F. Ceccarelli2, C. Massari2, C. Pirone1, G. Olivieri1, V. Orreco1, L. Picciarello1, C. Cianciarella1, C. Garuti2, S. Mancuso2, S. Truglia1, F. R. Spinelli1, C. Alessandri1, F. Conti1, 1Sapienza University of Rome, Lupus Clinic, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Sapienza Università di Roma, Rome, Italy

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by a wide spectrum of manifestations, potentially involving every system. This heterogeneity may influence different aspects of patients’ daily life, including physical ability, working and social life, thus impacting the quality of life (Qol). Among all the SLE-related manifestations, cutaneous involvement may lead to insecurity and isolation, negatively resulting in Qol.

**Objectives:** The aim of the present study was to analyse the Qol in a SLE cohort, determining the potential influence of disease activity, chronic damage, comorbidities, and mood disorders.

**Methods:** We enrolled consecutive SLE patients, diagnosed according to 2019 ACR/EULAR criteria. Clinical and laboratory data were collected, and disease activity and chronic damage were assessed by SLEDAI-2k and SDI. As controls, we enrolled patients affected by Discoid Lupus Erythematosus (DLE) and Undifferentiated Connective Tissue Disease (UCTD). The fibromyalgia diagnosis was made according to the 2016 ACR Classification Criteria. Quality of life was evaluated by using the Lupus Quality of Life questionnaire (LupusQol); furthermore, each patient filled out the Hospital Anxiety and Depression Scale (HADS) questionnaire.

**Results:** We enrolled 237 SLE patients (M/F 18/219; median age 46 years [IQR 19.5], median disease duration 156 months [IQR 180]), 24 CLE patients (M/F 5/19; median age 61.5 years [IQR 29.5]), median disease duration 92.1 months, [IQR 128.5]), and 25 UCTD (M/F 1/24; median age 40 years, [IQR 21.25]; median disease duration 66 months [IQR 103.9]). In SLE patients the median SLEDAI-2k value was 0 (IQR 2) and the SDI was 0 (IQR 1). Fibromyalgia was diagnosed in 69 SLE patients (29.1%), 5 CLE (20.8%), and 7 UCTD (28%). The comparison among these three groups of patients revealed for SLE and CLE patients a significantly lower mean values in the LupusQol domain related to Body Image (BI) (73.9±27.7 and 71.3±30.9, respectively) compared to UCTD patients (87.2±19.0; p=0.01 and p<0.03, respectively). Focusing on SLE patients, females showed significantly lower mean values compared to males for almost all domains: Pain (P [p=0.02], Intimate Relationship (IR) [p=0.001], Burden to Others (BtO) [p=0.03], Anxiety (BH) [p=0.001], Emotional Health (EH) [p=0.012], Body Image (Bl) [p=0.033] and Fatigue (F) [p=0.002]). As expected, fibromyalgia patients had lower values in all the domains of the LupusQol when compared to patients without this condition (p=0.001 for all comparisons, except for Bl p=0.006). Moreover, as reported in Figure 1, SDI values negatively correlated with all the LupusQol domains (Figure 1A); conversely, we found a positive correlation between SDI and both HADS domains (pain [r=-0.16, p=0.015]; depression [r=-0.21, p=0.009]). As expected, a strong negative correlation was identified between LupusQol score in each domain and both anxiety (BH r=-0.58, P p=-0.53, Planning p=-0.52, IR r=-0.62, EH=0.64, Bl=0.62, p<0.001 for all the analysis) and depression (BH r=-0.61, P p=-0.58, Planning p=0.63, IR r=-0.61, EH=0.55, Bl=0.60, F=0.69, BtO r=0.55, p<0.0001 for all the analysis).

**Conclusion:** The presented results confirmed the negative impact of SLE on the quality of life. Among the analyzed variables, female sex and fibromyalgia deeply influenced the outcome. The chronic damage showed to be one of the main determinants of impairment of the Qol in SLE patients and of the development of Anxiety and Depression, measured through the HADS questionnaire. Lastly, Anxiety and Depression may contribute to the worst Qol in SLE, underlying the need for comprehensive evaluation and management of the SLE-associated comorbidities.

**COVID-19 VACCINE SAFETY DURING PREGNANCY IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

**Keywords:** COVID, Pregnancy and reproduction, Systemic lupus erythematosus

N. Giannopoulou1, L. Gupta2,3,4,5, A. Andreoli2,6, D. Lin6,5, E. Nikipherou2,3,5, R. Aggarwal2, V. Aggarwal2, L. Paradisi1,2,7, 1University of Nicosia, General Hospital of Paphos, Nicosia, Cyprus; 2Sanjay Gandhi Postgraduate Institute of Medical
**Background:** Vaccinations comprise a part of the antenatal care of pregnant women, including patients with systemic lupus erythematosus (SLE) who are at increased risk of adverse pregnancy outcomes (APOs). While COVID-19 vaccination has been shown to be safe in pregnant women with SLE, data on vaccine-associated adverse events (AEs) during the antenatal and lactation period are scarce or lacking.

**Objectives:** To investigate the association between COVID-19 vaccination and AEs in pregnant SLE patients.

**Methods:** A total of 9201 complete responses were extracted on June 21st, 2022 from the COVID-19 Vaccination in Autoimmune Diseases (COVAD) 2 database, a global e-survey involving 157 collaborators from 106 countries. Among respondents, 6,787 (73.8%) women were exposed to at least one COVID-19 vaccine dose after pregnancy, among those 11 with SLE. Delayed onset (>7 days) vaccine-related AEs were excluded and triangular with disease activity, treatment changes due to flare after vaccination, and COVID-19 infections in vaccinated pregnant women with SLE. Additionally, information on health-related quality of life and physical function was recorded using PROMIS at the time of survey completion.

**Results:** The age of patients ranged from 28 to 39 years; 5,111 women were of Asian origin. None of these patients reported major vaccine AEs, including four patients with self-reported active SLE prior to the vaccination. None of them reported any change in the status of their autoimmune disease, and no hospitalisation or special treatment was recorded. Six women experienced minor vaccine AEs; two of them had active disease prior to vaccination. Four patients reported COVID-19 infection; two of them were pregnant and post-vaccination and two prior to pregnancy and vaccination. All four patients experienced symptoms of their disease, but no overt SLE flare was reported. At the time of survey completion, all patients reported their general health as being good to excellent in all aspects evaluated. Importantly, no APOs were reported. None of the patients reported thrombotic events post-vaccination, which provides some reassurance regarding COVID-19 vaccination in a patient population with a high risk for cardiovascular comorbidity and thrombosis, especially in the presence of antiphospholipid antibodies or in patients diagnosed with the antiphospholipid syndrome, a considerable portion within SLE populations. Moreover, it was reassuring to note an absence of association between experienced vaccine AEs and active disease prior to vaccination. Although minor AEs were common, they did not impair daily functioning, and the symptoms resolved in all patients after a median of 3 (IQR: 2.5–5.0) days.

**Conclusion:** Our report adds relevant evidence concerning the sensitive issue of COVID-19 vaccine AEs and flares in SLE patients during the antenatal and lactation period. Despite the small sample size, the findings provide some reassurance and can contribute to informed decisions regarding vaccination in patients with SLE and high-risk pregnancies due to their background autoimmune disease. Based on the present data, the risk/benefit ratio of COVID-19 vaccination appears favourable, with vaccines both providing passive immunisation to the fetus and active immunisation to the mother with no signals of exacerbation of the mother’s autoimmune disease.

**Acknowledgements:** The authors thank all survey respondents, as well as patient associations and all members of the COVAD study group for their invaluable role in the data collection.

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by a wide spectrum of clinical manifestations and the presence of various antibodies against antigens of the nucleus, cytoplasm, or membrane cell. Anti-La antibodies are present in 7-45% of SLE patients, usually accompanied by anti-Ro antibodies. Double anti-La and anti-Ro positivity is associated with a milder disease profile, with a lower risk of seizures and nephritis, as well as a higher frequency of arthritis. Studies analyzing the prevalence and clinical characteristics of patients with isolated anti-La in the absence of anti-Ro are lacking.

Objectives: To describe the demographic, clinical and serological characteristics and severity indices of anti-Ro-/La- patients in a retrospective cohort of SLE patients and compare them with the rest of the patients.

Methods: Retrospective cross-sectional study, in which all patients with SLE (>4 ACR-1997 criteria) registered in the RELESSLER registry were included. Sodicodemographic, clinical, serological and comorbidities variables were collected, as well as indicators of disease activity and severity. Patients were divided into 4 groups according to the presence of anti-Ro and anti-La: anti-Ro- anti-La+ group, anti-Ro+ anti-La- group, anti-Ro+ anti-La+ group and anti-Ro- anti-La- group. The anti-Ro/-La- group was compared with the other groups.

Results: Out of 3619 SLE patients, 44 (12%) had anti-Ro+La-. The mean ± SD age was 33.77 ± (±16.52) years, 88.6% were female, 90.5% were Caucasian and the mean ± SD disease duration was 135.36 ± (±88.46) months. The most frequent comorbidities were: smoking 48.8 %, dyslipidemia 47.7 % and hypertension 31.8 %. 22.13% of patients had anti-Ro+La-, 18.98% anti-Ro+/La+ and 64.02% anti-Ro- La-. Photosensitivity and oral ulcers were observed more frequently in anti-Ro+La- patients compared to anti-Ro- La- patients (60.2% vs 52.6% p=0.0471 and 59.1% vs 40.7% p=0.0194 respectively). Arthritis occurred in 77.3% of anti-Ro- La- patients, without significant differences with the other groups: 75.3% in anti-Ro+La- (p=0.8588), 73.9% in anti-Ro+La+ (p=0.7240) and 71.5% in anti-Ro- La+ (p=0.810). Twenty-five per cent of the isolated anti-La had lupus nephritis, with no significant differences compared to the other groups (29.5% in anti-Ro+La- p=0.8116, 22.9% in Ro+La- p=0.7144 and 28.6% in Ro- La- p=0.7364), 11.4% of anti-Ro- La- patients had seizures

vs 4.4% anti-Ro+/La- (p=0.0510), vs 3.3% in anti-Ro+/La+ and vs 5.2% in anti-Ro-/La+ (p=0.799). Cognitive impairment was observed in 7% of anti-Ro+/La+ patients vs 2.8% in anti-Ro-/La+ (p=0.1315) vs 1.5% in anti-Ro-/La- (p=0.0370) and vs 3.1% in anti-Ro+ (p=0.1492). No differences were observed in other SLE-associated clinical variables, immunological profile, degree of SLE activity or Katz severity index.

Conclusion: The prevalence of anti-La in the absence of anti-Ro in our SLE cohort was 12%. This group of patients presented a higher frequency of clinical manifestations such as photosensitivity and oral aphthous ulcers compared to patients with neither anti-Ro nor anti-La. In contrast with previous studies the isolated presence of anti-La is associated with greater neurological involvement in the form of seizures or cognitive impairment compared to the association of anti-Ro and anti-La or the isolated presence of anti-Ro.

TESTING A NEW FATIGUE CHECKLIST IN SLE PATIENTS FOR EVERYDAY CLINICAL PRACTICE - AN INTERIM ANALYSIS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Quality of life

C. Düsing1,2, J. Richter2, C. Elling-Audersch2, D. Fell2, M. Schmid-Holl2, O. Sander2, J. Muckel2, I. Haase1, R. Fischer-Betz1, H. Aca1, T. Fillis2, M. Schneider2, G. Chehab2,1, Düsseldorf, Clinic for Rheumatology, University Hospital Düsseldorf, Düsseldorf, Germany; 2,1 Düsseldorf, Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany; 2,3 Bonn, German-League Against Arthritis/Deutsche Rheuma-Liga Bundesverband e.V., Bonn, Germany

Background: Fatigue is a difficult subject for both physicians and patients. It is barely addressed during consultations and can therefore burden patient-physician relations. To improve communication regarding fatigue, we developed a checklist that includes suggestions for evaluating possible causes for fatigue. In this analysis, we describe our study population and report first results 3 and 6 months after using the checklist.

Objectives: The aims of our study are to validate the use of our newly developed fatigue checklist and to demonstrate that addressing fatigue in daily clinical practice and offering possible interventions can improve fatigue.

Methods: We recruited n=110 SLE patients with fatigue from our university hospital-based lupus reference centre in Düsseldorf. Fatigue was measured using the FSS (Fatigue Severity Scale). Our checklist included signs of depression and anxiety using the PHQ-4 (Patient Health Questionnaire), BMI (body mass index), physical activity, anemia, hypothyroidism and vitamin D deficiency. For each applicable cause, we listed possible interventions for free selection by the treating physician, such as replacement therapy (vitamin D, vitamin B12, iron, folic acid, erythropoietin), physical activity programs and psychosomatic counseling sessions that were discussed with the patients. We re-evaluated our patients after 3 (T1) and 6 months (T2).

Results: Baseline characteristics of patients are summarized in Table 1.

Table 1. BMI=body mass index, TSH=thyroid stimulating hormone, PHQ4=patient health questionnaire (cut-off >3 points), HAQ=health assessment questionnaire, IMET= Index for measuring restrictions on social participation (higher scores point towards more restrictions on social participation), FSS=fatigue severity scale (≥4 points equal severe fatigue)

</table>

After 3 and 6 months, we re-evaluated 83 patients and saw a significant reduction in fatigue measured by the FSS score (T1: mean difference estimate 0.367 and p-value <0.001; T2: mean difference estimate 0.303; p-value <0.005).

Conclusion: The preliminary analysis of our study shows for the first time that incorporation of a checklist procedure into the management of patients with fatigue may improve short-term outcome after 3 and 6 months of observation. The improvement of symptoms documented in our study occurred even though the suggested exercise program and psychosomatic counseling sessions were not available for use during the current observation period because of the COVID-19 pandemic. At present, the mechanisms behind the observed effect remain unclear. Our ongoing analysis will clarify whether an additional effect on fatigue will occur after all suggested interventions resulting from the use of the checklist have been executed. Finally, it will demonstrate whether the incorporation of our checklist into routine clinical practice is capable to reduce fatigue over a prolonged time period.

Keywords: Diagnostic tests, Systemic lupus erythematosus

X. Ma1, Y. Yin1, X. Zhang3, H. Jiang3, Y. Shan3. 1The First Hospital of China Medical University, Department of Pediatrics, Shenyang, China; 2Department of Pediatrics, Benxi Central Hospital, Benxi, Department of Pediatrics, Ben Xi, China; 3University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan

Background: Over the past few decades, several classification criteria have been proposed for systemic lupus erythematosus (SLE), including the American College of Rheumatology (ACR)-1997, Systemic Lupus International Collaborating Clinics (SLICC)-2012, and European Alliance of Associations for Rheumatology (EULAR)/ACR-2019. The sensitivity and specificity of these classification criteria are inconsistent for the various races of SLE patients [1-3]. Patients with SLE who are younger than 18 year old are called childhood-onset SLE (c-SLE), which differ from adult-onset SLE (a-SLE) in several ways. The applicability of classification criteria for c-SLE of different races were also inconsistent [4-6]. Now, there is a lack of data to verify the applicability of classification criteria in a-SLE or c-SLE in northern China.

Objectives: This study is to verify the applicability of classification criteria in a-SLE and c-SLE in northern China, and explore the most applicable disease evaluation standards.

Methods: 81 c-SLE vs 59 pediatric controls, 80 a-SLE vs 76 adult controls were included in the study. All the participants are Chinese descent living in northern China. The control groups were diagnosed with other rheumatic diseases. We reviewed the clinical manifestations and laboratory tests of these patients with respect to three classification criteria.
Results: The sensitivity of EULAR/ACR-2019 and SLICC-2012 was higher than that of ACR-1997 in a-SLE group, but there was no significant difference in the specificity, with AUCs of EULAR/ACR-2019 (0.863), SLICC-2012 (0.895), and ACR-1997 (0.869). In C-SLE group, the sensitivity of SLICC-2012 was higher than that of ACR-1997, and the specificity was not significantly different, with AUCs of EULAR/ACR-2019 (0.94), SLICC-2012 (0.945), and ACR-1997 (0.899). Increasing the threshold of EULAR/ACR-2019 from 10 to 11 can improve the specificity and accuracy for a-SLE, while from 10 to 14 can improve those for c-SLE.

Conclusion: EULAR/ACR-2019 and SLICC-2012 are the most appropriate classification criteria for a-SLE, and SLICC-2012 is more applicable for c-SLE from northern China. Adjusting the threshold of EULAR/ACR-2019 can improve the specificity and accuracy for a-SLE and c-SLE.

AB0597 CLINICAL SIGNIFICANCE OF ANTI-RHEUMATOID ARTHRITIS 33 ANTIBODY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Autoantibodies, Diagnostic tests, Clinical trials

Y Chen 1, W Y Lu 1, 2, 3, D Liu 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, *Shenzhen People's Hospital, Department of Rheumatology and Immunology, Shenzhen, China

Background: Evidence initially showed that anti-rheumatoid arthritis (RA) 33 antibodies were highly specific for the diagnosis of RA [1]. Later studies reported that anti-RA33 was present in various connective tissue diseases (CTDs) [2]. However, the clinical significance of anti-RA33 antibodies in CTDs is still obscure.

Objectives: To explore the clinical significance and diagnostic value of anti-RA33 antibodies in CTDs, especially systemic lupus erythematosus (SLE).

Methods: A total of 565 patients with positive anti-nuclear antibodies who had been tested for anti-RA33 antibodies were included in the study. These patients were classified into RA33-positive and RA33-negative groups according to the anti-RA33 results. The association between anti-RA33 and the clinical features of CTDs was examined. Additionally, receiver operating characteristic (ROC) analysis was performed to explore the diagnostic value of anti-RA33 antibodies in SLE and SLE-related organ involvement.

Results: SLE was the most common disease in CTD patients positive for anti-RA33 (48.8%). Compared with the RA33-negative group, the proportion of patients with SLE was significantly higher in the RA33-positive group (64.3% vs. 47.1%, p=0.0164). Compared with those negative for anti-RA33, CTD patients positive for anti-RA33 had significantly higher percentages of SLE-associated antibodies (Figure 1). Higher proportions of SLE patients with a high disease activity (41.7% vs. 24.7%) as well as lower levels of serum complement components (50.0% vs. 27.7%) were observed in the RA33-positive group (Both p<0.05) (Table 1). Furthermore, CTD patients with positive anti-RA33 were more likely to suffer from mucocutaneous (46.4% vs. 33.2%, p=0.0361) and haematological involvement (51.8% vs. 35.6%, p=0.0200) as well as interstitial lung disease (25.0% vs. 11.8%, p=0.0108). ROC analysis revealed an area under the curve value of 0.634 (95% CI: 0.587 to 0.681) for anti-RA33 in the diagnosis of SLE, with a specificity and sensitivity of 92.9% and 13.5%, respectively.

Conclusion: This study reveals a significant association between anti-RA33 and the clinical features of CTDs, especially SLE, indicating a potential clinical significance of anti-RA33 in the management of SLE.

REFERENCES:

Background: Autoimmune acquired coagulation FXIII/13 factor deficiency (AIF13D) is a rare bleeding disorder characterized by the formation of autoantibody to F13. The treatment of AIF13D requires immunosuppressive (IS) therapy in addition to hematopoietic therapy. Japanese guidance recommends high-dose glucocorticoid (GC) as initial therapy while cyclophosphamide (CPA), rituximab (RIT), and ciclosporin (CYA) are administered in refractory cases. Inchioue reported that 16 of 93 (17%) AIF13D patients had autoimmune diseases (AIDs) such as systemic lupus erythematosus (SLE) [1]. The guidance recommends that IS therapy for patients with underlying AIDs should be selected based on treatment guidelines for AIDs; however, recommendations for the choice of IS drugs are unavailable.

Objectives: To report the case of our patient and to analyze the reported cases of SLE complicated AIF13D.

Methods: We searched PubMed, Google Scholar, and Ichiushi Web for articles or abstracts written in English and Japanese using the following terms: [acquired FXIII/13 factor deficiency or inhibitors] and SLE.

Results: A 24-year-old woman from Southeast Asia presented to the emergency department with headache and nausea; a hematoma was noted in the right temporoparietal lobe on head CT. Her PT, APTT, platelet count, and bleeding time were normal. She developed impaired consciousness and underwent an emergency craniotomy to remove the hematoma. During surgery, no abnormal blood vessels were noted in the brain, and the hematoma was removed. However, recurrent hemorrhages occurred on days 2 and 13 after hospitalization, and she underwent reoperation. On day 18, F13 activity was found to be less than 3%, and an F13 preparation (Fibrogamin P) was administered. A positive cross-mixing test with normal plasma was positive for the F13 inhibitor, and a diagnosis of AIF13D was made [2]. In addition, she was diagnosed with SLE based on positive anti-nuclear and anti-dsDNA antibodies (Ab), hypocomplementemia, and lymphopenia. PSL, 50mg (1mg/kg/day) was prescribed. Owing to the local infection after cranioplasty, no IS drugs were used; hydroxychloroquine (HCQ) and belimumab were added, while tapering PSL. During 1 year period, anti-dsDNA Ab decreased and F13 activity remained above 40% without administering Fibrogamin P (Figure 1). The reported 11 cases of SLE complicated AIF13D and this case are summarized in the Table 1. IS therapy included CPA, CPA, and RIT besides GC; belimumab was added only in our case.

Conclusion: The prognosis of patients with AIF13D is poor. Even after weaning from acute hemorrhage, long-term IS therapy is often necessary and death by infection is common. Based on our experience, we suggest belimumab as a therapy option for SLE complicated AIF13D.

Figure 1. Anti-dsDNA antibody and F13 activity after hospitalization
Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disease mainly affecting exocrine glands. Extral glandular manifestations play a major role in the long-term prognosis of the disease, and neurological manifestations seem common in pSS. The early detection of haematological and immunological parameters might improve the disease evolution of patients.

Objectives: The study aimed to evaluate the predictive potential of clinical, haematological and immunological parameters for the development of neurological manifestations in pSS patients, followed for 12 months.

Methods: We performed a retrospective study in a single center, with a total of 265 patients (131 pSS patients and 134 healthy controls). Clinical examinations, complete blood count, inflammatory and immunological parameters were registered at baseline, 6 months and 12 months, for 131 pSS patients.

Results: In pSS patients, cellular count, complement fractions, and Vitamin B12 values are significantly decreased compared to healthy subjects (p < 0.001), while, cellular ratio–NLR, PLR, inflammatory and immunological parameters were significantly increased (p < 0.001) in the pSS patients. Likewise, the comparison at baseline and at every 6 months of cellular ratio, total proteins, and gammaglobulins and disease scores revealed exponentially increased values, in pSS patients with PN. The occurrence of PN was positively correlated with neutrophils and platelets (p < 0.05), and negatively correlated with lymphocytes (p < 0.05). NLR and PLR also revealed significant positive correlations with the emergence of PN in pSS (p < 0.05), while for total proteins, and Vitamin B12 the correlation was negative (p < 0.05). The multivariate analysis confirmed the independent predictive character for PN emergence in pSS for NLR (CI95% 0.034 to 0.254, p < 0.010), gammaglobulins (CI95% -0.409 to -0.114, p < 0.001) and vitamin B12 (CI95% -0.001 to 0.001, p < 0.001).

Conclusion: High values for hematological and immunological parameters were identified at baseline, while their persistent modifications during the follow-up period were observed in pSS patients with PN. NLR, gammaglobulins and vitamin B12, parameters that could become predictors for the early detection of patients at risk for the development of PN.

M. Flurie1, I. Alezivos2, C. Baldwin3, M. Converse4, K. Davidson5, B. LaMoreaux6, A. Amato7, J. Massengale7, J. Taylor8, W. Li9, C. DeFelice5, M. Picone5, E. R. Wassman1. 1TREND Community, Real-World Evidence, Philadelphia, United States of America; 2Horizon Therapeutics, Deerfield, United States of America; 3Horizon Therapeutics, Patient Advocacy, Deerfield, United States of America; 4Horizon Therapeutics, Rheumatology, Deerfield, United States of America; 5Horizon Therapeutics, Medical Affairs, Deerfield, United States of America; 6Horizon Therapeutics, Commercial Training, Deerfield, United States of America

Background: To obtain a comprehensive understanding of the needs of individuals in a particular community, it is essential to actively listen to and interpret the patient experience. A proprietary artificial intelligence (AI) analytics engine was applied to social media conversations from an online community for those living with Sjögren’s disease (SjD). Sjögren’s disease is an autoimmune disease characterized by inflammation of exocrine glands, most often presenting with dryness of the eyes and mouth (sicca). Some women with SjD also report vaginal dryness and discomfort (1) through individuals with SjD have an increased risk for poor mental health outcomes (e.g., anxiety, depression), the unique role of vaginal dryness and the resulting mental health impact are not well understood.

Objectives: The objective of the current study was to identify specific mental health impacts associated with vaginal dryness in SjD. We also aimed to explore common topics shared by community members discussing these symptoms to understand their impact on daily living.

Methods: We performed exploratory analyses on 3779 users and 41,406 posts/comments from October 2012 to March 2022. The proprietary AI engine used for analysis leverages natural language processing techniques to analyze text-based social media data sources. First, the engine used entity recognition to identify the most frequent clinical findings mentioned across all posts/comments. Anxiety and depression were among the most frequently mentioned mental health symptoms in conversations. The engine then extracted the most frequent dryness-related symptoms from the data, which included dry eyes, mouth, throat, and vagina. We then fit 2 logistic regression models where dryness mentions (e.g., ‘dry eyes’, ‘vaginal dryness’) predicted mentions of ‘anxiety’ (model 1) or ‘depression’ (model 2). For our exploratory analysis, we used a guided topic modeling approach to extract conversations about vaginal dryness. This involved providing a list of seed terms (e.g., ‘vaginal dryness’, ‘vaginal pain’) around which the model could converge in identifying word clusters.

Results: In total, topic modeling revealed 563 posts/comments from 345 users regarding vaginal dryness. “Vaginal dryness” was a significant predictor (P < 0.001) in both regression models, with adjusted odds ratios between 2.2 and 2.8 (95% CI, 19-4.2), suggesting that users mentioning vaginal dryness are 2 to 3 times more likely to mention a negative mental health outcome. Our guided topic modeling approach yielded 3 subtopics within the primary vaginal dryness topic. These included conversational topics about ‘sexual discomfort’, ‘lubrication’, and ‘marital impacts’ across 141 users.

Conclusion: These findings suggest that vaginal dryness and sexual dysfunction in SjD are prevalent and associated with specific negative mental health symptoms. Potential daily impacts were illuminated when topic modeling showed common topics centered on the emotional impact of vaginal dryness and the adverse impacts on marriage/relationships. This social listening approach also revealed management techniques (e.g., lubrication) for individuals experiencing sexual discomfort. Interrogating social media conversations can be invaluable to elucidating patient-reported mental health challenges in rare diseases. It remains unknown how these conversational references to negative mental health symp- toms directly translate to specific mental health diagnoses (e.g., anxiety disorder) or treatment challenges in patients with SjD. Future work should comprehen- sively explore these symptoms so clinicians, caregivers, and patients can better understand and manage mental health in the context of chronic disease.

SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN ISRAEL: GENDER DIFFERENCES IN MANIFESTATIONS, MANAGEMENT AND COMORBIDITIES

Keywords: Descriptive Studies, Systemic lupus erythematosus, Epidemiology, T. Eviatar1,2, V. Rosenberg3, G. Elkayam1,2, G. Chodick4, D. Paran1,2.1 Tel Aviv Sourasky Medical Center - Ichilov, Rheumatology, Tel Aviv, Israel, 2Tel Aviv University, Faculty of Medicine, Tel Aviv-Yafo, Israel, 3Maccabi Health Services, Kfar-Saba-Maccabi Research and Innovation Institute, Tel Aviv, Israel, 4Tel Aviv University, Faculy of Medicine, Tel Aviv-Yafo, Israel

Background: Prevalence, incidence, demographic and clinical characteristics of SLE are affected by race, ethnicity and socioeconomic status. The epidemiology of SLE in Israel is not well defined.

Objectives: We aimed to assess the prevalence of SLE and to describe the demographic and clinical characteristics of SLE patients.

Methods: A retrospective study using the computerized database of Maccabi Healthcare Services (MHS), a large health maintenance organization. Prevalent SLE patients on Dec 31 2020 were defined by: ICD-9 code 710.0 (>2 diagnoses by a rheumatologist/immunologist and/or ≥2 diagnoses by a primary care physician and/or ≥2 diagnoses from a hospital); ≥1 a positive antinuclear antibody (ANA) test; ≥1 dispensed hydroxychloroquine (HCQ) prescription. All SLE patients were ≥10 years-old when first diagnosed; first diagnosed before Dec 31 2018; MHS members for ≥12 months before and ≥24 months after the first diagnosis of SLE. Patients diagnosed with dermatomyositis and/or systemic sclerosis were excluded. SLE patients were matched to controls from the general population of MHS members for age, sex and socioeconomic status at a ratio of 1:5.

Results: We identified 1073 eligible SLE patients (prevalence rate of 5.6 per 100,000) and 5365 controls. The mean age on Dec 31 2020 was 50.7 (±14.9) and 942 SLE patients (87.8%) were female. Mean age at diagnosis was 37.2 (±14.4). The prevalence of SLE disease manifestations is shown in Figure 1A. Since 2015 over 90% of SLE patients had ≥1 dispensed HCQ within 12 months of diagnosis, compared to only 50-70% among those diagnosed before 2015. In 2020 only 67.5% of the patients were still treated with HCQ, 24% were not taking any SLE medication, and 3.8% were treated with systemic glucocorticosteroids (GCs) alone. GCs were prescribed at least once for 74.8% of all patients, and for 30.8% in 2020. The median cumulative prednisone dose per disease year was 283 mg (IQR 0-1297), and was higher for males than females (830 mg [IQR 452-2083], 251 mg [IQR, 0-1183], respectively, P = 0.001). Compared to females, male SLE patients had a significantly higher prevalence of comorbidities (Figure 1B). Despite a similar prevalence of osteoporosis (OP) (P=0.828), use of OP medications was lower among men (M-16.2%, F-32.3%, P=0.046).

Conclusion: The prevalence of SLE in MHS in this study was found to be 1:1790. Prescription of HCQ within the first year after diagnosis has increased since 2015, however HCQ uptake decreased in the years following diagnosis, possibly due to waning compliance. GC cumulative doses were generally low, although it was three times higher in male than in female patients. Cardiovascular comorbidity and OP were more prevalent in SLE patients than in the general population, and more prevalent in male SLE patients, who usually bear a worse prognosis. Moreover, male SLE patients may be undertreated for comorbidities as manifested by higher GC doses and less OP treatment.

IDENTIFYING THE RISK FACTORS AND INCREASING MORTALITY OF PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

**Keywords:** Prognostic factors, Systemic lupus erythematosus, Epidemiology

**Y. F. Fang**, Y. F. Chen. 1. Chang Gung Memorial Hospital, Linkou, Division of Rheumatology, Allergy and Immunology, Department of Internal Medicine, Taoyuan City, Taiwan, Republic of China

**Background:** Patients with systemic lupus erythematosus (SLE) have a risk of pulmonary arterial hypertension (PAH), which could be fatal.

**Objectives:** The goal of this study was to identify the risk factors for mortality in patients with PAH.

**Methods:** Patients with SLE treated at Chang Gung Memorial Hospital were included in this retrospective cohort study. Univariate and multivariate COX regression, as well as Kaplan–Meier survival curve analysis were conducted to investigate risks in SLE patients.

**Results:** The average age at diagnosis was 40.78 ± 15.92 years. A total of 42 (6.1%) of the 689 patients had PAH. Patients with PAH exhibited shorter follow-up duration, higher disease activities, higher incidence rates of comorbidities patients without PAH. Physicians preferred to use more Cyclophosphamide and less Hydroxychloroquine in PAH patients.

**Conclusion:** A 6.1% proportion of SLE patients have manifestations of PAH. Moreover, SLE patients with PAH have a greater risk of mortality. Therefore, these patients need intense screening and treatment of PAH.

Hokkaido University Faculty of Medicine, Department of Psychiatry, Sapporo, Japan; 3. Hokkaido University Faculty of Medicine, Global Center for Biomedical Science and Engineering, Sapporo, Japan; 4. Hokkaido University, Department of Diagnostic and Interventional Radiology, Sapporo, Japan

**Background:** Fatigue is one of the most common symptoms in patients with systemic lupus erythematosus (SLE) [1]. Resting-state functional magnetic resonance imaging (rs-fMRI) has emerged as a powerful tool for mapping large-scale networks in the human brain. To explore the neural mechanism of fatigue, several studies evaluated the functional connectivity between brain region of interests using rs-fMRI. However, there are still few reports on patients with SLE.

**Objectives:** To identify the fatigue-specific functional connectivity in patients with SLE.

**Methods:** rs-fMRI data were acquired from SLE patients with fatigue and healthy controls (HCs). Functional connectivity of SLE patients and HCs were analyzed, and compared by ANCOVA, adjusted for age and sex. On the day of rs-fMRI imaging, SLE Disease Activity Index score with the Safety of Estrogens in SLE National Assessment modification (SELENA-SLEDAI) was assessed, and the Chalder fatigue scale, fatigue assessment questionnaire, was collected. The association among SELENA-SLEDAI, the results of the questionnaire, and functional connectivity was evaluated by correlation analysis.
NODULAR MUCINOSIS AS INITIAL PRESENTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Skin, Systemic lupus erythematosus

D. Zajdman Faitelson1, M. Macedo Pérez2, P. Rodríguez Henríquez3, "Dr. Manuel Gea Gonzalez" General Hospital, Dermatology, Mexico City, Mexico; 2"Dr. Manuel Gea Gonzalez" General Hospital, Rheumatology, Mexico City, Mexico; 3"Dr. Manuel Gea Gonzalez" General Hospital, Dermatopathology, Mexico City, Mexico

Background: Cutaneous mucinoses comprise a wide group of disorders characterized by aberrant accumulation of glycosaminoglycans between collagen bundles, that share clinical and histological characteristics, and are classified as primary and secondary [1-3]. Nodular mucinosis associated with lupus is a primary mucinosis first described in 1954 by Gold [4]. It is a distinctive but unusual cutaneous manifestation, with an incidence of 1.5%, that presents as asymptomatic, skin-colored papules or nodules on the trunk and upper extremities [2]. It can occur in patients with discoid lupus, subacute cutaneous lupus or systemic lupus erythematosus (SLE) [2,5]. The temporal relationship with the development of SLE is variable, since in some cases it precedes it, while in others it occurs later or simultaneously, with clinical variations according to disease activity and antibody levels [6,7].

Objectives: Describe an infrequent cutaneous manifestation of SLE.

Methods: We describe a case of nodular mucinosis as an isolated clinical manifestation of SLE in a middle aged woman, with clinical improvement with methotrexate therapy.

Results: A 67-year-old female patient presented with an 8-month history of multiple skin-colored, asymptomatic nodules in face, trunk and extremities. Some of the nodules had a central depression (Figure 1 A and B). The clinical examination was otherwise unremarkable. Histological analysis of a biopsy specimen showed a circumscribed, non-encapsulated neoformation in the reticular dermis, composed of spindle cells in a storiform pattern, mixed with hyalinized collagen fibers (Figure 1 C). Ablan blue staining confirmed the presence of abundant interstitial, superficial and deep mucin, thus integrating the diagnosis of nodular mucinosis (Figure 1 D). Laboratory tests were positive for antinuclear antibodies (1:1000, coarse speckled pattern), anti-double stranded DNA (47.1 IU/ml), anti-nucleosome, anti-SSA/Ro, anti-RNP, anti-Sm antibodies and lupus anticoagulant, with a lymphocyte count of 3.6 cells/mm3 and hypocomplementemia (C4 of 15 mg/dl). A final diagnosis of nodular mucinosis associated with SLE was made and treatment was started with hydroxychloroquine 200 mg/day and prednisone 1 mg/kg/day. Improvement of skin lesions was observed after the addition of methotrexate 15 mg/weekly.

Conclusion: Our case presents a challenge to the clinician due to the atypical presentation and the absence of other systemic symptoms of SLE, as well as histologic findings similar or almost identical to other cutaneous mucinoses. This case demonstrates the importance of thorough dermatologic examination, high suspicion and directed complementary studies for the correct interdisciplinary approach to this entity.

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease affecting different organs and causing significant morbidity and mortality. Pulmonary arterial hypertension (PAH) is a rare manifestation of SLE. The prevalence of PAH in patients with SLE varies between 0.5 to 5% [1]. No screening algorithms have been developed in patients with SLE.

In patients with SSc, PAH is characterized by changes in the pulmonary vasculature and endothelial dysfunction. These microvascular changes are also present in patients with SLE, as observed with nailfold videocapillaroscopy (NVC) [2]. NVC findings may help to identify patients at a significant high risk of future development of PAH [3].

Objectives: The aim of our work is to analyze the clinical and demographic features and nailfold capillary changes of patients with SLE-related PAH compared to a group of SLE patients without PAH.

Methods: We identified and selected 20 patients with SLE and type I PAH and collected demographic, clinical and laboratory features from 8 rheumatology centers across Europe. We could perform NVC on 9 patients. We selected as controls 68 patients with SLE who underwent cardipulmonary screening to exclude PAH: we collected demographic, clinical and laboratory features and performed NVC. The presence of SD pattern was assessed as previously described [4]. Patients satisfied the 2019 EULAR/ACR SLE classification criteria. We excluded patients with a diagnosis of mixed tissue disease and overlap syndrome.

Results: Demographic and clinical features of patients with SLE-PAH and SLE controls are shown in Table 1. All patients with SLE-PAH were female, age and disease duration were not different between the 2 groups. LAC+ and anti-RNP+ was more prevalent in patients with SLE-PAH than in SLE controls. Raynaud’s phenomenon was more prevalent in patients with SLE-PAH than in SLE controls. In patients with SLE-PAH we observed a significantly higher prevalence of scleroderma pattern at NVC than in controls: patients with SLE-PAH showed a lower number of capillary density and a higher frequency of megacapillaries. In multivariation analysis, Raynaud phenomenon and anti-RNP are predictors of PAH in patients with SLE. The McFadden’s R-squared for the model is 0.30.

Conclusion: Our data show that LAC+, RNP+, Raynaud’s, Skin and CNS involvement and a SD pattern at NVC is more prevalent in patients with SLE-PAH than in patients with SLE without PAH. Our results point to a generalized microvascular involvement and a hypercoagulation state in patients with SLE-PAH.

Crescenz VA Medical Center, Dermatology, Philadelphia, United States of America; Brigham and Women's Hospital, Harvard Medical School, Dermatology and Immunology, Boston, United States of America; University Hospital of Bonn, Germany, Dermatology and Immunology, Bonn, United States of America; Bristol Myers Squibb, Clinical Development, Princeton, United States of America; Bristol Myers Squibb, Global Biometrics and Data Sciences, Princeton, United States of America

Background: Deucravacitinib is a first-in-class, oral, selective, allosteryc tyrosine kinase 2 (TYK2) inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis [1,2]. Deucravacitinib demonstrated efficacy across multiple outcome measures, including achievement of ≥50% reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity score (CLASI-A-50), in a phase 2 trial in patients with systemic lupus erythematosus (SLE) [3] and is being investigated in two phase 3 trials (NCT05617677; NCT05620407). Patients with discoid and/or subacute cutaneous lupus erythematosus (DLE/SCLE) have elevated expression of Type I interferons (IFN) [4]. Deucravacitinib mediates signaling of Type I IFN, IL-12, and IL-23 and may be an effective treatment for patients with DLE/SCLE [5].

Objectives: Results of this ongoing phase 2 trial (NCT04857034) will characterize the efficacy and safety of deucravacitinib compared to placebo in patients with active DLE/SCLE with or without SLE.

Methods: This phase 2, global, randomized, double-blind, placebo-controlled trial is enrolling adults (aged 18-75) with biopsy-confirmed clinical diagnosis of DLE/SCLE. Key eligibility criteria and study design are depicted below (Figure 1). Eligible patients will be randomized (1:1:1) to treatment with placebo or deucravacitinib (dose 1 or 2) for 16 weeks. At week 16, all patients randomized to placebo will be rerandomized (1:1:1) to treatment with deucravacitinib dose 1 or 2 until week 52. Patients originally randomized to deucravacitinib will continue treatment until week 52. The primary and secondary endpoints are depicted below (Table 1). This trial will also assess the safety and tolerability of 2 doses of deucravacitinib, exploratory efficacy endpoints, patient-reported outcomes, and pharmacodynamics.

Results: Planned enrollment is 75 total patients (25 per double-blind treatment group) in 8 countries in North and South America, Europe, and Asia-Pacific regions.

Conclusion: This phase 2 trial will characterize the efficacy, safety, and tolerability of deucravacitinib in patients with active DLE/SCLE with or without SLE.

Table 1. Primary and Secondary Endpoints Assessed at Week 16

Primary Endpoint
- Mean percentage change from baseline in CLASI-A score
- Percentage of patients who achieve ≥50% reduction in CLASI-A score (CLASI-A 50) from baseline
- Percentage of patients who achieve ≥4-point improvement in CLASI-A from baseline
- Mean change from baseline in CLASI-A score
- Percentage of patients who achieve a complete response (defined as a CLASI-A score of 0)

CLASI-A, Cutaneous Lupus Erythematosus Disease Area and Severity Index-Acivity

A RANDOMISED OPEN-LABEL PILOT STUDY OF PROBIOTICS AS AN ADJUNCTIVE THERAPY FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Real-world evidence, Randomized control trial, Systemic lupus erythematosus
M. S. Mohamed Said1, M. Armugam1, K. N. Muhammad Nawawi1, A. Abdul Wahab2, R. Mustafa1. 1Faculty of Medicine Universiti Kebangsaan Malaysia, Medical, HUKM, Kuala Lumpur, Malaysia

Background: SLE is a complex inflammatory multiorgan disease that leads to multiple comorbidities and mortality. Probiotics were shown to be successful in lowering the pro-inflammatory cytokines in animal SLE models.

Objectives: This study looked at probiotics’ effect on disease activity and pro-inflammatory cytokine interleukin-6 (IL-6) among SLE patients.

Methods: We performed a prospective randomised probiotic controlled analysis of those aged 18 years old and above with mild to moderate disease activity (Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) score < 13) visiting Hospital Canselor Tuanku Muhriz (HCTM) SLE clinic between December 2021 to February 2022. Patients were prescribed either twice daily probiotics (Lactobacillus spp. and Bifidobacterium spp) to ongoing therapy or maintaining ongoing treatment for three months. Baseline and post-treatment Interleukin-6, disease activity score (SLEDAI-2K, Systemic Lupus International Collaborating Clinics Arthritis Criteria System (SLICC/ACR) Damage index), and adverse effects following treatment were documented.

Results: There was a 7% reduction of the median (IQR) IL-6 concentration among the probiotic group, 2.28 (4.85)/pg/ml at baseline versus 2.12 (2.56) pg/ml at three months; this was not statistically significant (p=0.145). In control group shows increase in level of IL-6 by 48.9% at end of treatment [1.94 (3.59) vs 2.89 (2.83), p = 0.077]. There was a substantial reduction in SLEDAI 2K among the probiotic group by 64.3%, with the mean (SD) baseline of 4.94 (3.09) versus 1.76 (3.15) at three months (p<0.01), while the reduction in the control group were 23.7 %, with the mean(SD) baseline of 4.17 (3.20) versus 3.18 (2.50) at three months (p=0.077). There were no adverse effects noted among the probiotic group.

Conclusion: The use of probiotics reduced clinical disease activity, as demonstrated by the SLEDAI-2K and IL-6 reduction. The level of IL-6 reduction was insignificant statistically, however, it shows a beneficial effect of probiotics in stabilising IL-6 compared to the control group, which has increased serum IL-6 at three months. The probiotics are relatively safe to consume. These findings warrant further studies with a larger sample size, longer duration, and analysis of multiple cytokines profiles.

AB0612
THE RELATIONSHIP BETWEEN SYSTEMATIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY INDEX (SLEDAI) AND HEALTHCARE RESOURCE UTILIZATION AND COSTS IN SLE PATIENTS

Keywords: Real-world evidence, Systemic lupus erythematosus
J. Levy1, E. Alemao2, U. Sbajiria3, D. Goldman4, M. A. Petr5. 1Johns Hopkins Bloomberg School of Public Health, Health Policy and Management, Baltimore, United States of America; 2Janssen Pharmaceuticals, Global Services, Horsham, United States of America; 3Janssen Pharmaceutica NV Global Services, Beerse, Belgium; 4Johns Hopkins University, School of Medicine, Baltimore, United States of America; 5The Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America

Background: Standard sources of healthcare resource utilization (HCRU) for systematic lupus erythematosus patients lack granular clinical information and longitudinal follow-up. Due to the heterogeneous nature of SLE, in which disease activity fluctuates with time and acute events such as flares and remissions are common, little is known about the relationship between disease activity and HCRU.

Objectives: In this study, we assess the relationship between disease activity and HCRU in patients with SLE.

Methods: We combined data from the longstanding Johns Hopkins Lupus Cohort, where SLE Disease Activity Index (SLEDAI) was collected at minimum every six-months during standardized protocol visits, with health system cost data (Casemix). Patient resource utilization and registry data were included each calendar half-year where at least 1-registry visit and 1-Casemix item was observed. We computed the annual HCRU and cost of care by type of utilization: outpatient (OP), inpatient (IP), emergency room (ER) and pharmaceutical (Rx). We described the impact of disease activity (based on the worst SLEDAI score observed in each period) on utilization and costs using mixed effect generalized linear models where categorized SLEDAI score 0 (no activity), 1-5 (mild), 6-10 (moderate), 11+ (high) is used as a predictor of outcomes, adjusted for patients fixed effects and disease characteristics.

Results: 1,111 patients contributing 5,094 patient years between 2013-2019 were included in our analysis. The average annual cost of care (and SD) by type was: $5,337 (12,997), $3,896 (25,297), $215 (1,062), $3,251 (7,721) for OP, IP, ER and Rx. Regressions showed that total costs in 6-month period was 14% higher for mild, 32% higher for moderate and 76% higher for severe relative to SLEDAI score 0 of (no activity), (all p<0.001).

Conclusion: Using detailed clinical data collected via registry, combined with comprehensive utilization and costs, we have described the relationship between disease activity and HCRU over time. These estimates explain the clinical burden of the disease and can inform cost estimates in future studies of treatments that impact SLEDAI score.

ETOLOGY, OUTCOME AND PREDICTORS OF MORTALITY AMONG SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS PRESENTING TO EMERGENCY DEPARTMENT: A SINGLE CENTRE PROSPECTIVE STUDY

Keywords: Systemic lupus erythematosus
S. Kotwani1, G. Naidu2, M. Bhatia3, S. Sharda4, V. Dhir5, S. K. Sharma4, M. Rath4, A. Sharma6, N. Sharma7, S. Jain8. 1PGIMER Chandigarh, Internal Medicine, Chandigarh, India; 2PGIMER Chandigarh, Internal Medicine,
Background: Systemic lupus erythematosus (SLE) patients can present to emergency department (ED) with acute manifestations that require immediate evaluation and initiation of appropriate therapy. The reasons for ED visits could be due to disease activity or various complications arising due to therapy. However, there is paucity of data on the reasons and outcomes of SLE patients who present to ED.

Objectives: To determine the reason, 3 month outcomes and the predictors of mortality among the SLE patients who present to ED.

Methods: Single centre prospective observational study was being performed between July 2021 and December 2022. Patients of SLE fulfilling the SLICC or the 2019 ACR/EULAR classification criteria and aged above 18 years and presenting to ED were included. Written informed consent was obtained from all the subjects. Clinical and laboratory details were noted at the time of presentation to ED. The reasons for ED visits were classified into disease activity or infection or both or non-SLE related. Outcomes of death and disease activity (by SLEDAI2K) at 3 months were noted. The study was approved by the Institute Ethics Committee.

Results: A total of 61 patients were included in the study. Median age was 28 years (IQR: 24-35) and 55 (90.2%) were females. Twenty (32.8%) patients were newly diagnosed with SLE after presentation to ED, and the median duration of illness among previously diagnosed patients was 24 months (IQR: 12-48). Disease activity alone (n=41; 67.2%) was the commonest reason for ED visit followed by disease activity co-existing with infection (n=15; 24.6%), and infections alone (n=5; 8.2%). Among the 56 patients with disease activity at presentation, active disease manifestations were noted in following organs: renal (57.1%), musculoskeletal (53.6%), skin (51.8%), haematological (42.9%), serositis (39.3%), neurological (28.6%), cardiac (26.8%), gastrointestinal (14.3%) and lung (5.4%). Among the 20 patients with infections at presentation, lower respiratory tract infections were the commonest, seen in 7 (35%), followed by CNS infections (15%), UTI, skin and soft tissue, ear and sino-nasal and sepsis with un-identified focus were seen in 2 (10%) patients each. Infective colitis and bacterial peritonitis was identified in 1 (5%) patient each. At 3 months of follow up, 21 (34.4%) patients died, with majority (n=18; 85.7%) dying within 1 month of presentation. Deaths were significantly more in patients who presented with both disease activity and infection compared to patients who presented with only disease activity or infection (p=0.001). Among the remaining 40 patients, 15 (37.5%) were in remission, 13 (32.5%) were in low disease activity and 12 (30%) were in moderate to high disease activity. On multiple regression analysis, presence of hypoxia (p=0.046), serum albumin less than 2.5g/dl (p=0.006) and infection (p=0.001) at presentation predicted mortality at three months (Table 1).

Conclusion: The commonest cause of ED visit by SLE patients is disease activity alone followed by disease activity and co-existing infections. Infections were present at the time of ED admission in one-third of SLE patients. Three month mortality rate was high (34.4%) and presence of hypoxia, low serum albumin and infection at presentation predicted mortality at three months.

rheumatic diseases such as rheumatoid arthritis (RA), primary Sjögren’s syndrome (pSS) and systemic sclerosis (SSc).

**Methods:** A narrative literature review was conducted on disease activity and type 2 symptoms. A comprehensive medical subject heading (MESH) term was used for each disease and combined with the MESH terms for fatigue, depression, anxiety, pain and quality of life as well as the term “disease activity” to give the proper search keywords. Articles in English published after 2000 and related to adult patients were located on Medline via Pubmed. The selected articles had to evaluate at least one type 2 symptom and/or HRQoL using a validated scale.

**Results:** Overall, 287 articles were analysed, corresponding to 157 765 patients. For SLE (n=115 studies including 21 randomized controlled trials), we found that inflammatory activity/type 1 symptoms were mostly uncorrelated with type 2 symptoms and/or HRQoL, with several studies even showing an inverse correlation. No correlation was observed in 67.7% (64.7%), 60% (51.5%), 25% (11.2%), and 60% (53.6%) of studies (patients), and a weak correlation in 17.6% (27.9%), 16.7% (22.9%), 12.5% (61.9%), and 17.5% (34.4%) of studies (patients) for fatigue, anxiety-depression, pain, and HRQoL, respectively. These results were consistent in the other rheumatic diseases studied. Indeed, type 2 symptoms were mostly uncorrelated with disease activity/type 1 symptoms and this seemed even more pronounced for pain. There was no correlation in 45.2-92% (55.9-95%), 56.4-100% (54-100%), 66.7-100% (94-100%), 23-75% (43.4-55%) of studies (patients) and a weak correlation in 0-28.6% (0-34.4%), 0-31.2% (0-43%), 0-33.3% (0-6%), 25-28.6% (16-45%) of studies (patients) for fatigue, anxiety-depression, pain and HRQoL, respectively.

**Conclusion:** Type 2 symptoms are poorly correlated with inflammatory activity, type 1 symptoms in SLE as well as in other autoimmune rheumatic diseases. These results have important implications for clinical care and therapeutic evaluation.

**GREATER SOCIAL VULNERABILITY ASSOCIATED WITH GREATER GLUCOCORTICOID USE IN PATIENTS WITH SLE**

**Keywords:** Systemic lupus erythematosus

A. Som1, L. McMorrow1, L. Chen2, D. Sen1, A. El-Qunni1, E. Baker3, A. Kim3,  
1Washington University School of Medicine, St. Louis, Missouri, United States of America; 2Washington University School of Medicine, Biostatistics, St. Louis, United States of America; 3SLU College for Public Health and Social Justice, Behavioral Science and Health Education, St Louis, United States of America.

**Background:** Patients with SLE experience substantial health disparities. Studying the effect of spatial context on health outcomes has become a focus in health disparities research. The CDC Social Vulnerability Index (SVI) characterizes census tracts by individual dimensions of social vulnerability, which create a cumulative SVI capable of identifying communities where social determinants lead to higher levels of morbidity and mortality.

**Objectives:** We sought to understand the level of social vulnerability where patients with SLE reside and determine if specific dimensions of social vulnerability were associated with disease activity and prednisone utilization.

**Methods:** At the Washington University Lupus Clinic, 324 consented subjects who met either ACR or SLICC classification criteria for SLE were enrolled and longitudinally assessed from April 2014 to August 2020. Participant addresses were recorded for each clinic visit. The census tract code was determined for the address listed for each patient’s index visit which corresponds to a SVI available in the CDC database. Participants with addresses which did not correspond to a census tract code were excluded. SVI ranges from 0 to 1 with 1 being the most vulnerable; any tract with a SVI greater than the mean of 0.5 can be seen as a socially vulnerable area. Specific dimensions of SVI (socioeconomic status, household composition, race/ethnicity/language, and housing/transportation) are further elaborated in Table 1. Prednisone dosing was organized into four categories (none, >0-7.5 mg, 8-20 mg, >20 mg). SLE-DAI-2000 Responder Index-50 (S2K RI-50) assessed SLE disease activity (>4 indicated active SLE). A multinomial logistic regression model analysis was used to determine association.

**Results:** The number of patients with SVI and prednisone data available was 272 patients. There was no significant correlation between cumulative SVI and disease activity (OR 1.15, 95% CI=0.67-1.99, p=0.6128). When examining prednisone utilization, 175 patients were not prescribed any prednisone at their index visit while 66 were on supraphysiologic doses. Average cumulative SVI was 0.511. Compared to patients with invulnerable cumulative SVI, vulnerable patients were 2.31 times as likely to have higher dose of prednisone (95% CI 1.38-3.92; p=0.0019). Of the specific dimensions, patients vulnerable in terms of socioeconomic status (OR 2.47, 95% CI 1.43-4.27, p=0.0012) and household composition (OR 2.21, 95% CI 1.28-3.83, p=0.0047) were also more likely to have higher doses of prednisone. Patients vulnerable in terms of race/ethnicity/language (OR 1.57, 95% CI 0.92-2.68, p=0.095) and housing/transportation (1.08, 95% CI 0.65-1.80, p=0.7537) were not statistically significantly likely to have higher doses of prednisone.

**Conclusion:** Patients who live in more socially vulnerable areas are more likely to be prescribed higher doses of prednisone, specifically patients vulnerable in terms of socioeconomic status and household composition. This is worrisome as this likely will contribute to a higher burden of damage. Consistent with other findings, our work highlights that access to social determinants is associated with health inequities.

**Background:** Lupus is a heterogenous diseases which results in significant premature mortality. Most studies have evaluated risk factors for lupus mortality using regression models which considers the phenotype in isolation. Identifying clusters of patients on the other hand may help overcome the limitations of such analyses.

**Objectives:** The objectives of this study were to describe the causes of mortality and to analyze survival across clusters based on clinical phenotype and autoantibodies in patients of the Indian SLE Inception cohort for Research (INSPIRE) METHODOLOGY.

**Methods:** Out of all patients, enrolled in the INSPIRE database till March 31st 2022, those who had <10% missing variables in the clustering variables were included in the study. The cause of mortality and duration between the recruit-ment into the cohort and mortality was calculated. Agglomerative unsupervised hierarchical cluster analysis was performed using 25 variables that define SLE phenotype in clinical practice. The number of clusters were fixed using the elbow and silhouette methods. Survival rates were examined using Cox proportional
hazards: models: unadjusted, adjusted for age at disease onset, socio-economic status, steroid pulse, CYC, MMF usage and cluster of the patients.

Results: Indian patients with lupus have significant early mortality and the majority of deaths occurs outside the hospital setting. Out of 2211 patients in the cohort, 2072 were included into the analysis. The median (IQR) age of the patients was 26 (20-33) years and 91.7% were females. There were 288 (13.1%) patients with juvenile onset lupus. The median (range) duration of follow up of the patients was 37 (6-42) months. There were 170 deaths, with only 77 deaths occurring in a health care setting. Death within 6 months of enrolment occurred in 80 (47.1%) patients. Majorit y (n=87) succumbed to disease activity, 23 to infections, 24 to coexisting disease activity and infection and 21 to other causes. Pneumonia was the leading cause of death (n=24). Pneumococc al infection led to death in 11 patients and SARS-COV2 infection in 7 patients. The hierarchical clustering resulted in 4 clusters and the characteristics of these clusters are represented in a heatmap (Figure-1A-B). The mean (95% confidence interval [95% CI]) survival was 39.17 (38.45-39.90), 39.52 (38.71-40.34), 37.73 (36.77-38.70) and 35.80 (34.10-37.49) months (p<0.001) in clusters 1, 2, 3 and 4, respectively with an HR (95% CI) of 2.34 (1.56, 3.49) for cluster 4 with cluster 1 as reference (-<0.001 2.22(1.48, 3.22)

Conclusion: Indian patients with lupus have significant early mortality and the majority of deaths occurs outside the hospital setting. Disease activity as determined by the traditional activity measures may not be sufficient to understand the true magnitude of organ involvement resulting in mortality. Clinically relevant clusters can help clinicians identify those at high risk for mortality with greater accuracy.

AB0619 PREDICTORS FOR FUTURE DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN KOREAN SJÖGREN’S SYNDROME PATIENTS

Keywords: Systemic lupus erythematosus, Sjögren syndrome

B. W. Lee1, E. J. Kwon1, Y. Park1, J. J. Lee1, S. H. Park2, S. K. Kwok3, 1Seoul St. Mary’s Hospital, College of Medicine, Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Sjögren’s syndrome (SS) can occur alone or in combination with other autoimmune diseases. Systemic lupus erythematosus (SLE) is the most common autoimmune disease associated with SS. The prognosis of SS is generally better than that of SLE. However, the onset of SLE in these patients may be one of the factors that increase mortality.

Objectives: This study determined the impact of demographic factors, clinical manifestations, disease activity, and serological tests at baseline on future SLE development in Sjögren’s syndrome (SS) patients.

Methods: This retrospective study assessed 1,082 SS patients without other autoimmune diseases at baseline who visited our hospital between January 2012 and March 2021. We analyzed demographic features, extra-glandular manifestations (EGMs), clinical indices, and laboratory values at baseline between the two groups divided per future SLE development (SLE/SS group vs. SS group). The probability and predictors of SLE development in SS patients were estimated using the Kaplan–Meier method and Cox proportional hazards models.

Results: The median follow-up duration was 1083.5 days. Forty-nine patients (4.5%) developed SLE that met the 2012 Systemic Lupus International Collaborating Clinics or 2019 EULAR/ACR classification criteria. The baseline EULAR SS disease activity index (ESSDAI) score was significantly higher in the SS/SLE group (p<0.001). The SS/SS group had more lymphopenopathy and renal involvement (p=0.015 and p=0.017, respectively). Shorter SLE disease duration (<3 years) (hazard ratio [HR]=2.81, p=0.012), high ESSDAI (HR=3.04, p=0.024), leukopenia (HR=2.20, p=0.017), hypocomplementemia (HR=1.74, p<0.0001), and positive for anti-dsDNA (HR=19.93, p<0.0001), anti-ribonucleoprotein (RNP) (HR=2.96, p=0.025), and anti-ribosomal P (HR=2.74, p=0.048) at baseline were SLE development predictors in SS patients.

Conclusion: Shorter disease duration and higher disease activity of SS at baseline may be risk factors for future SLE development. Serological predictors of SLE development are hypocomplementemia, leukopenia, and positivity for anti-dsDNA, anti-RNP, and anti-ribosomal P antibodies. If the above factors are observed, close monitoring will be necessary during the follow-up period, considering the possibility of future SLE development.

AB0620 IMMUNE THROMBOCYTOPENIC PURPURA AND SUBSEQUENT DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Prognostic factors, Systemic lupus erythematosus

G. Ailes1, M. Socolnik1, V. Scaglioni1, J. F. Jaramillo Gallego1, M. A. Tobar Jaramillo1, R. N. Alvarado1, E. Soriano1, J. Rosa1, 1Hospital Italiano de Buenos Aires, Sección Reumatología, Buenos Aires, Argentina

Background: Immune Thrombocytopenic Purpura (ITP) is an immune-mediated disorder, characterized by isolated thrombocytopenia (<100,000/mm³). It is part of Systemic Lupus Erythematosus (SLE) classification criteria, and may be one of the first manifestations of the disease, often occurring years before its diagnosis.

Objectives: To assess the incidence of SLE in a cohort of patients with ITP, and to identify predictors for its development.

Methods: Retrospective cohort study. We included patients with ITP treated in a University Hospital between 2000 and 2018, with at least one year of follow-up. Patients with SLE or other secondary causes of ITP were excluded. Demographic, clinical, laboratory, and treatment data were recorded. Patients meeting SLE classification criteria (ACR 1997/ SLICC 2012) during the follow-up were identified, and incidence density of SLE was calculated. Patients with ITP were grouped according to the development or non-development of SLE, and comparisons were made. Univariate analysis was performed to identify factors associated with the future development of SLE.

Results: 186 patients were included, 64.5% women, with a median age of 272 months (IQR 63-63.9). After a follow-up of 1801.4 person-years (py), 10 patients (5.4%) developed SLE, with a median time of 22.9 months (IQR 9.8-60.9) between ITP diagnosis and development of SLE. The incidence density of SLE was 5.6/1000 py (95% CI 2.9-9.9/1000 py). Patients who developed SLE had significantly higher proportion of chronic ITP (60% vs 40.3%; p=0.01), lower proportion of complete response (10% vs 54.6%; p=0.006), and more relapses (60% vs 22.2%; p=0.02).
In this cohort of ITP patients, the more refractory course of ITP, as well as the presence of high titre - nuclear homogeneous ANA, hypocomplementemia (p<0.001), LAC (p<0.001), hypergammaglobulinemia (p<0.001), leukopenia (p<0.001), and hemolytic anemia (p<0.001) were significantly associated with the development of SLE. 

**Conclusion:** In this cohort of ITP patients, the more refractory course of ITP, as well as the presence of high titre - nuclear homogeneous ANA, hypocomplementemia, LAC, hypergammaglobulinemia and other cytopenias were associated with the subsequent development of SLE.

**DISEASE ACTIVITY PATTERNS OVER TIME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: IMPACT ON HEALTH-RELATED QUALITY OF LIFE**

**Keywords:** Patient reported outcomes, Systemic lupus erythematosus, Quality of life

**Background:** Health-Related Quality of Life (HRQoL) in patients with autoimmune systemic diseases has a multifactorial origin. In particular, data from the literature show that in patients with Systemic Lupus Erythematosus (SLE) the correlation between HRQoL and disease manifestations is quite controversial.

**Objectives:** to evaluate the impact of different disease activity patterns on HRQoL and patients’ perception of disease activity in a monocentric cohort of patients with SLE.

**Methods:** a retrospective analysis of prospectively collected data from adult consecutive patients with a diagnosis of SLE, regularly followed at the Rheumatology Unit of Pisa. For each patient, the following data were collected: demographics, disease duration, clinical and laboratory data, SELENA-SLEDAI for disease activity and SLICC-DI for organ damage, comorbidities and ongoing treatment. Three different disease patterns were defined based on disease activity status during the year before enrollment: long quiescent (LQ) if patients were in remission in each visit; chronically active (CA) if they were not in remission in each visit; relapsing-remitting (RR) if patients presented periods of remission interspersed with periods of disease activity. Only patients with at least two visits in the year before enrollment were included. We excluded patients with a major clinical event/hospitalization not SLE-related during the year before enrolment that could influence their health status. At enrollment, each patient completed the following Patient Reported Outcomes (PROs): SF-36, FACIT -F, Lupus Impact of life.

**Results:** 242 SLE outpatients were enrolled, mainly female (91.7%) and of Caucasian ethnicity (96.7%); mean age 44.2 ± 13 years, with a median disease duration of 12 years (IQR 6 – 21). 48.8% had at least one item of organ damage, 48.0% had at least one comorbidities and ongoing treatment. Three different disease patterns were defined based on disease activity status during the year before enrollment: long quiescent (LQ) if patients were in remission in each visit; chronically active (CA) if they were not in remission in each visit; relapsing-remitting (RR) if patients presented periods of remission interspersed with periods of disease activity. Only patients with at least two visits in the year before enrollment were included. We excluded patients with a major clinical event/hospitalization not SLE-related during the year before enrolment that could influence their health status. At enrollment, each patient completed the following Patient Reported Outcomes (PROs): SF-36, FACIT-F, Lupus Impact Tracker (LIT), SLAQ, Hospital Anxiety and Depression Scale (HADS).

**Conclusions:** 242 SLE outpatients were enrolled, mainly female (91.7%) and of Caucasian ethnicity (96.7%); mean age 44.2 ± 13 years, with a median disease duration of 12 years (IQR 6 – 21). 48.8% had at least one item of organ damage with a median SLICC-DI of 1 (IQR 0-1). Moreover, 15.3% of patients had a comorbid fibromyalgia. At enrollment, median SLEDAI in the entire cohort was 2 (IQR 0-4); the most frequent active disease manifestation was skin involvement (36/242); 12 patients had active arthritis and 11 active renal disease. Almost half of the cohort (51.2%) was on a low dose of glucocorticoids (mean daily dose 4.1 ± 2.9 mg of 6-methylprednisolone); 83.9% were on Hydroxychloroquine and 52.5% on immunosuppressive therapy. We applied the disease pattern definition criteria and we found that the LQ was the most represented pattern in our cohort (63.9% of patients), followed by the RR (22%) and CA (14.1%). No significant
To evaluate the inflammatory findings but also to rule out other etiologies, renal function or active urinary sediment, and is generally recommended. We demonstrate that renal histopathology confirmed other causes than LN in a significant proportion (19%) of SLE patients with signs of renal involvement. Since these patients may need other therapeutic interventions than patients with classic LN, we can conclude that the renal biopsy is important in order to guide the choice of therapeutics.

| **Intramuscular steroid** | 42 (16.9)       | 7 (9.3)       |

1. We found a relationship between the 2 DMARD combined scheme with being obese type 2 (p=0.02) and prednisone use with type 3 obesity (p=0.005). In SLE group BMI <25kg/m² was found in 16 (24%) and >25kg/m² in 5 (74%), high total fat in 45% (60%), low muscle mass in 61 (51.3%), low body water in 46 (61.3%), abdominal obesity in 51 (68%). Being obese type 3 and having high visceral fat was related with the use of 3 DMARDs combined (p=0.001) and having an older metabolic age was associated with intramuscular steroid use (p=0.012).

Background: The attribution of neuropsychiatric manifestations to systemic lupus erythematosus (SLE) or unrelated causes is often obscure.

Objectives: The attribution of neuropsychiatric events to lupus (SLE related) or other causes (non-SLE related) in a large SLE cohort.

Methods: A single-center study of 258 patients developed 345 neuropsychiatric events in total. Among them, 140 primary (SLE related) and 205 secondary (non-SLE related) events were identified. The attribution of neuropsychiatric events to lupus (SLE related) or unrelated causes was performed using a combination of multiple regression, logistic regression, and decision tree analysis.

Results: The attribution of neuropsychiatric manifestations to systemic lupus erythematosus (SLE) or unrelated causes is often obscure. A single-center study of 258 patients developed 345 neuropsychiatric events in total. Among them, 140 primary (SLE related) and 205 secondary (non-SLE related) events were identified. The attribution of neuropsychiatric events to lupus (SLE related) or unrelated causes was performed using a combination of multiple regression, logistic regression, and decision tree analysis.

Conclusion: This single-center study revealed that SLE patients with lowest dsDNA and second highest C3 trajectory had a significantly higher risk of mortality than SLE patients with lowest dsDNA and highest C3 trajectory.

DIFFERENTIALLY EXPRESSED GENES (DEGS) OVERLAP AMONG BLOOD SAMPLES DATASETS FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) THROUGH INTEGRATIVE BIOINFORMATICS METANALYSIS

Keywords: -Oomics, Biomarkers, Systemic lupus erythematosus

R. Martinez1, A. González Godínez1, I. Vasquez Tercero2, C. Elizondo Solís1, A. Montoya Rosales3, M. Salinas Carmona1, N. Macías-Segura1, 1UANL - Escuela de Medicina, Immunology Department, Monterrey, Mexico; 2Universidad Nacional Autónoma de Honduras, Department of Psychological Sciences, Tegucigalpa, Honduras; 3UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico

Background: Systemic Lupus Erythematosus is an autoimmune chronic disease mainly characterized by the presence of auto-antibodies, and periods of flares and remission [1]. Understanding the mechanisms of physiopathology is still being the aim for several researchers. In the last 20 years multiple studies tried to look for molecular mechanisms associated to the disease using molecular techniques [2]. Specifically, the gene expression patterns play an important role in the pathophysiology of this disease, in which the interferon signature has been widely found in SLE patients, but also in other autoimmune diseases like rheumatoid arthritis and Sjögren's syndrome [3]. However, there is a discordance in which genes from the interferon signature are specific biomarkers for SLE, since there are multiple studies that describe the interferon signature but with different differentially expressed genes.

Objectives: We aimed to identify differentially expressed genes that overlap across different datasets of gene expression from blood samples of SLE patients using an integrative bioinformatics metanalysis.

Methods: We design a search strategy in the Gene Expression Omnibus platform to identify data sets of gene expression profile by array from blood samples of patients with SLE. The inclusion criteria were: 1) assays performed in humans; 2) the dataset include SLE patients and healthy controls; 3) expression profile in which genes from the interferon signature are specific biomarkers for SLE.

Results: We selected 3 datasets that fulfill the inclusion criteria: GSE101174, GSE10325, and GSE154851. A total of 29 up-regulated genes were identified among datasets. Venn diagram shows 3 genes overlapped among all the datasets.

Conclusion: The selection of datasets that fulfill the inclusion criteria: GSE101174, GSE10325, and GSE154851. The tables GeneMania and DAVID will be used to identify overlapped genes among datasets and functional enrichment analysis of the differentially expressed genes.

DOI: 10.1136/annrheumdis-2023-eular.5996
A prediction analysis yielded 20 co-expressed genes, that interact with the overlapped genes. A functional enrichment analysis yielded the 3 principal biological processes involving those genes: 17 genes participate in defense response to virus; 13 genes associated to response to virus; and 8 genes involved in negative regulation of viral genome replication (Table 1). Most of the genes identified belong to the interferon signature.

**Conclusion:** We aimed to obtain upregulated genes and their co-expressed pairs through transcriptomic and functional enrichment analysis. 6 genes appeared upregulated across the 3 datasets, and 20 genes were listed as their co-expressed pairs. Those genes were involved in the processes of Defense Response to Virus, Response to virus, and Negative Regulation of Viral Genome Replication. These genes can serve as possible biomarkers for early diagnosis, and maybe even possible therapeutic targets.

**CLINICAL PROFILE OF PEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN A TERTIARY LEVEL HOSPITAL IN THE PHILIPPINES, YEAR 2015-2021**

**Keywords:** Systemic lupus erythematosus, J. Garcia 1, 2, Region 1 Medical Center, Pediatrics, Dagupan, Philippines

**Background:** Pediatric Lupus Erythematosus is a chronic systemic autoimmune disease with a higher risk of disease damage than adults with SLE.

**Objectives:** To profile the clinical and laboratory features and manifestations of pediatric SLE patients seen and admitted at Region 1 Medical Center from January 2015 to December 2021 and assess the association of the clinical profile with complications and mortality.

**Methods:** A retrospective review of medical records of all pediatric SLE patients age <18 years, admitted at Region 1 Medical Center from January 2015 to December 2021. Charts were reviewed for clinical and laboratory data extraction. Clinical data were analyzed using descriptive statistical analysis. Fisher’s exact test was utilized to analyze the association of clinical profile to morbidity and mortality. Odds ratio was used to determine the degree and direction of association among significantly associated variables in the study.

**Results:** A total of 29 patients who fulfilled the inclusion criteria were included in the study. Average age of diagnosis is 16 years with predominance of female. The most common presenting symptom is malar rash (27.6%) followed by joint pains (10.3%) and pallor (10.3%). Patients with pediatric SLE commonly manifested with acute cutaneous rash (75.3%). Thrombocytopenia (69%) is the most common laboratory finding. Complications of SLE include renal (51.7%), infection (27.6%), and cardiovascular (17.2%). Oral corticosteroid is the most common treatment which was administered to all participants. Mortality rate of 34.5% is associated to the most common cause which is SLE in activity (80%) followed by infection (60%). Neurologic manifestation and increase creatinine were found to be associated with mortality with odds ratio >1.

**Conclusion:** Malar rash is the most common clinical presentation among Filipino pediatric SLE. The most common complication is renal involvement. Neurologic manifestation and non-scarring alopecia increase mortality.

**IMPACT OF SOLAR RADIATION FROM SUN EXPOSURE AND PHOTOPROTECTION PRACTICES ON DISEASE ACTIVITY AMONG SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS IN MALAYSIA**

**Keywords:** Comorbidity, Systemic lupus erythematosus, Epidemiology

**S. S. Shaharir 1, J. H. Jaafar2, C. L. Teh3, S. A. Wan Aisak4, C. Yaw Kiet5, C. Seow Lin3, B. Sachdev Manjit Singh6, A. Jamal7, R. Mohd2, R. Mustafar2, S. Rajalingham2, M. S. Mohamed Said2, M. T. Latif7, Universiti Kebangsaan Malaysia Faculty of Medicine, Sarawak General Hospital, Cheeras, Malaysia; 1Universiti Kebangsaan Malaysia, Faculty of Medicine, Sarawak General Hospital, Cheeras, Malaysia; 2Sarawak General Hospital, Medicine, Kuching, Malaysia; Institute for Environment and Development (LESTARI), Universiti Kebangsaan Malaysia, Earth Sciences and Environment, Bangi, Malaysia

**Background:** Systemic Lupus erythematosus (SLE) is an autoimmune disease which is characterized by remission and flares. Experimental studies demonstrate that sun exposure can trigger immunomodulatory response, however, there is lacking of strong epidemiologic data regarding its role in triggering SLE flare. Malaysia has a tropical climate and hence get more exposure to the sun.

**Objectives:** To determine the correlations between disease activity with exposure to sun measured with solar radiation [1h (W/m²)] and photoprotection practices among SLE patients in Malaysia.

**Methods:** This was a cross-sectional study involving SLE patients conducted in Universiti Kebangsaan Malaysia and Sarawak General Hospital from January 2019 until December 2019. During the study visit, disease activity was measured using Modified Systemic Lupus Erythematosus Disease Activity Index (M-SLEDAI) and The British Isles Lupus Assessment Group 2004 (BILAG). Sun Exposure and Protection Index (SEPI) was used to assess their photoprotection practices, and patients who reported no change in their photoprotection practices for the last 2 years were included. A high SEPI score reflects an increased risk of sun exposure. Their medical records were also reviewed for retrospective assessments of the disease activity from the past 2 years (2017-2019). Clinical visits with presence of infection or recent change of immunosuppressive treatment for ≤ 3 months were excluded. Sun exposure was determined by calculating the average of daily solar radiation (mean) and the maximum solar radiation (max) within 30 days preceding the clinic visits. The hourly and daily solar radiation data was obtained from the Department of Environment (DOE) Malaysia. Correlations between the solar radiation mean, max and SEPI scores with M-SLEDAI and BILAG were determined using the Pearson’s correlation coefficient correlation; while their associations with severe SLE flares (presence of BILAG A or B) were performed using Student’s t-test. The associations between the effects of solar radiation and SEPI on M-SLEDAI and BILAG scores were analyzed using the generalized estimating equation (GEE) model, while considering fixed effects for repeated measures.

**Results:** A total of 87 patients were recruited with 514 clinic visits were recorded. There was significant correlation between the mean solar radiation with M-SLEDAI scores (rs=0.003, p=0.001). SEPI scores were significantly correlated with M-SLEDAI and BILAG scores (rs=0.098, p=0.03 and 0.421, p<0.001 respectively). Patients who had severe flare (BILAG A or B) had a higher exposure to the mean solar radiation (154.6 ± 35.9 vs 148.7 ± 19.1, p=0.011). In the GEE analysis, mean solar radiation and SEPI scores were still significantly correlated with M-SLEDAI scores; and significantly associated with severe flares p<0.05.

**Conclusion:** These results suggest that solar radiation has a significant impact on SLE disease activity and flare. Patients should be emphasized on the importance of photoprotection practices as this is one of the modifiable risk factors of active disease and flare.
Methods: serological characteristics of patients diagnosed with SS. Clinical signs and symptoms as well as specific tests including salivary gland involvement from one patient to another. Diagnosis of the disease is based on characteristic morfologic clinical manifestations, which can vary greatly in features and severity. Moreover; systemic manifestations may occur. The disease is characterized by pleo- cytic infiltration of the lacrimal and salivary glands. Glandular involvement and extraglandular symptoms involving various organs and systems can be seen in patients. It can be seen in all age groups, although it is most common in those aged 45-50 years. The average female/male incidence rate is 9/1.

Objectives: Our aim in this study is to present the demographic, clinical and serological characteristics of patients diagnosed with SS.

Methods: Our study included 466 patients diagnosed with SS according to the 2016 ACR/EULAR Classification Criteria. Age, gender, primary/secondary SS status of the patients; organ involvement, salivary gland biopsy and serologic features were recorded. Descriptive statistics were given as mean±standard deviation, frequency (n), and percent (%).

Results: The mean age of 466 (433 females, 33 males) patients in the study was 55.4±13.5 years. The female/male ratio was 13/1. There were 408 (87.5%) patients with primary SS diagnosis and 58 (12.5%) patients with secondary SS diagnosis. 67% of patients with a diagnosis of secondary SS had rheumatoid arthritis. The most common clinical presentation complaints were dry eye (86%) and dry mouth (67.8%). In our study, anti-nuclear antibody positivity was found to be 83.4%, rheumatoid factor positivity was 22.1%. Ro-52 antibody was positive in 56.4% of the patients. As a result of the evaluation in terms of organ/system involvement; pulmonary involvement was found in 45 patients (9.6%). Moreover; primary biliary cirrhosis in 18 (3.8%) patients, adenral insufficiency in 1 (0.2%) patient, chronic tubulointerstitial nephritis in 2 (0.4%) patients, crescentic glomerulonephritis in 1 (0.2%) patient, optic neuropathy was found in 1 (0.4%) patient, and lymphoma was found in 1 (0.2%) patient (Table 1).

Conclusion: Sjögren’s syndrome can affect almost any organ system, thus various systemic manifestations may occur. The disease is characterized by pleomorphic clinical manifestations, which can vary greatly in features and severity from one patient to another. Diagnosis of the disease is based on characteristic clinical signs and symptoms as well as specific tests including salivary gland histopathology and autoantibodies.

Background: Pregnancy in patients with systemic autoimmune diseases (SADs) are known to be at high risk for the occurrence of adverse pregnancy outcomes. Pre-conception counselling and risk stratification performed in a multidisciplinary clinical setting are essential for improving pregnancy outcomes and reducing maternal and perinatal complications in patients with SADs.

Objectives: To describe clinical, obstetric and maternal comorbidities and pregnancy outcomes in patients with SADs.

Methods: A retrospective cohort study was conducted. Inclusion criteria were patients diagnosed with SADs that were examined by the multidisciplinary pregnancy clinic department. Clinical, maternal and obstetric variables were collected. The multidisciplinary team evaluated if the risk of pregnancy was high, moderate or low. Data related to pregnancy outcomes were also collected. Mean, standard deviation and proportions were calculated.

Results: A total of 41 patients interested in getting pregnancy attended our outpatient preconception clinic, with a mean age at first visit of 35.7±4.43 years. The ethnicity of the patients was: 75.6% Caucasian, 19.5% Hispanic and 4.9% Asian. Sociodemographic, clinical, treatment data, maternal and obstetric comorbidities are summarized in Table 1. Prior to preconception counselling, history of live births occurred in 61%, pregnancy loss in 32%, preterm birth in 10.5% and low-weight at birth in 11.7% of patients. 53.66% of patients were under treatment with csDMARDs and/or bDMARDs and 19.5% with hydroxychloroquine. As much as 43.9% were taking ≤7.5 mg of prednisolone/day and 73% were taking >7.5 mg/day. After evaluation by the multidisciplinary pregnancy clinic, 51.2% of patients were classified as low risk, 39% as moderate and 9.8% as high risk for adverse pregnancy outcomes. The final assessment was conception with treatment changes for 46.3% of the patients, treatment changes before conception for 12.2%, postponement of pregnancy for 24.4% and 17% of patients were pregnant at their first visit. Of these women, 15 conceived (36.6%) after a median time of 6.2±4.5 months. Medical and obstetric complications occurred in 13% and 20% of the patients. Abortion occurred in 9.76%, preterm birth in 4.88% and low-weight at birth in 11.1% of patients.

Conclusion: 46% of patients attending our pregnancy outpatient clinic had a diagnosis of SLE. Of the 41 patients assessed, 59% were advised to conceive and 12% were discouraged. 36.6% of patients were able to get pregnant, with a reduction in maternal and perinatal complications after preconception counselling. Well-planned pregnancies, adequate treatment and pre-conception evaluation will contribute to an improved outcome, both for the mother and the child.

THE ASSOCIATION OF NEUROPATHIC PAIN WITH LOWER URINARY SYMPTOM SEVERITY IN PRIMARY SJÖGREN’S PATIENTS

Keywords: Descriptive studies, Patient reported outcomes, Sjögren syndrome

Methods: Sixty-two patients, including fifty-nine women diagnosed with Sjögren’s Syndrome at Sakarya University Faculty of Medicine, Internal Medicine Rheumatology Department, were included in the study after their informed consent was obtained. All patients fulfilled the criteria for the 2016 ACR/EULAR Classification for Primary Sjögren’s Syndrome. Neuropathic pain was divided into two groups, present and absent. International Prostate Symptom Score (IPSS) was used in the evaluation of LUTS and The Leeds Assessment of Neuropathic Symptoms Scale (LANSS) were used for the assessment of neuropathic pain. Data were analyzed using the computer program SPSS 21. Relationships between categorical variables were evaluated with Chi-square analysis. The relationship between IPSS and LANSS Pain Scale was assessed by spearman correlation analysis. p<0.05 was considered statistically significant.

Results: The mean age of the patients was 53.4±11.6 years. The median disease duration was four years (min-max: 0-40), 58 (92.1%) patients had at least one LUTS. Of the patients with LUTS, 32 (55.1%) were mild, 21 (36.2%) moderate, and 5 (8.7%) severe. Anxiety was found in 31 (49.2%) patients, and depression was found in 27 (43.5%) patients. The frequency of depression was significantly higher in patients with LUTS. Depression and anxiety were not observed in patients without LUTS. When the severity of LUTS was compared with the presence of anxiety and depression, a significant difference was found in both groups (p=0.033; p=0.032, respectively) (Table 1). There was a moderate positive correlation between the IPSS score and the Beck Depression and Beck Anxiety Scale (r=0.429 p<0.001; r=0.481 p<0.001, respectively).

Table 1. Association of LUTS severity and anxiety/depression.

PREGNANCY IN SYSTEMIC LUPUS ERYTHEMATOSUS: DESCRIPTION AND COMPARISON OF COMORBIDITIES WITH OTHER SYSTEMIC AUTOIMMUNE DISEASES FROM A RHEUMATOLOGY PREGNANCY CLINIC

Background: Pregnancy in patients with systemic lupus erythematosus (SLE) are known to be at high risk for the occurrence of adverse pregnancy outcomes. Pre-conception counselling and risk stratification performed in a multidisciplinary clinical setting with rheumatologists, obstetricians and nephrologists are essential for improving pregnancy outcomes and reducing maternal and perinatal complications in patients with SLE.

Objectives: To describe clinical, obstetric and maternal comorbidities and pregnancy outcomes in patients with SLE and patients with other systemic autoimmune diseases (SADs).

Methods: A retrospective cohort study was conducted including patients diagnosed with SLE attending our multidisciplinary pregnancy clinic. Clinical, immunological and obstetric variables were collected. Data related to pregnancy outcomes, delivery and disease activity were also collected. Description of the sample and comparison of groups were carried out. Shapiro-Wilk test was used for variable distribution.

Results: A total of 41 patients attended our outpatient preconception clinic. Description and comparison of the comorbidities, preconception counselling and pregnancy outcomes are summarized in Table 1. A total of 19 (43.2%) patients were diagnosed with SLE. Lupus nephritis was observed in 47% of the patients and 11% had received kidney transplant. Moderate SLEDAI activity (>4) was observed in 44.4%. There were 7 (37%) pregnancies after a mean time of 73.6 months since the first visit. SLE patients were significantly older when evaluated at the pregnancy clinic than patients with other SADs. Also, SLE patients exhibited a longer time since the last flare when evaluated at the pregnancy clinic. Significant differences were observed in treatment between both groups: more hydroxychloroquine, synthetic DMARDs and steroids were used in the SLE group. No significant differences in preconception counselling or adverse pregnancy outcomes were observed.

Conclusion: Patients with SLE took longer time since diagnosis and flare to seek pregnancy than patients with other SAD. No differences in pregnancy outcomes or risk profile were observed.

HAEMATOLOGICAL MANIFESTATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: REAL WORLD DATA FROM A CENTRE IN NORTHERN ITALY

Keywords: Systemic lupus erythematosus, Comorbidities, Descriptive studies

R. Borrelli1, N. Rashidy1, F. Meili1, E. Saracco1, F. Corradi1, I. Badu1, S. Nicolai1, L. Lo Sardo1, L. Brussino1, Mauriziano Umberto Hospital Emergency Room, Department of Medical Sciences, Torino, Italy

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder characterized by a variety of signs and symptoms; it mainly affects women of childbearing age, with an estimated prevalence of 24/100,000 people in Europe and North America. Among other clinical manifestations, haematological involvement is one of the most common in SLE as it includes anaemia, leukopenia, lymphopenia, thrombocytopenia, lupus nephropathy and splenomegaly; furthermore, it is usually challenging to discriminate whether such manifestations are caused by disease or by immunosuppressants. To date, few studies tried to evaluate them using real world data.

Objectives: To evaluate haematological manifestations in patients with SLE by using real world data.

Methods: A retrospective study was performed by gathering real world data. 2019 EULAR/ACR Classification Criteria for SLE were used to discern haematological involvements in patients with a diagnosis of SLE. Leukopenia, thrombocytopenia and autoimmune haemolytic anaemia (AIHA) were considered for this study. Six subgroups were formed as each condition alone and their combinations were analyzed. Logistic regression was used to calculate the odds ratio (OR) and a 95% confidence interval (CI) was chosen to assess statistical significance.

Results: One hundred and forty-two patients affected by SLE were enrolled in this study (N=142); among these, thirty met the inclusion criteria for haematological manifestations (n=30, 52 ±12.4 years, 28 F, 2 M). Three patients showed AIHA alone (10.0%), six had thrombocytopenia only (20.0%) and 8 displayed leukopenia alone (26.7%). Thirteen patients showed a combination as 6 people had both AIHA and thrombocytopenia (20.0%) and 4 manifested AIHA in association with leukopenia (13.3%); lastly, 3 patients showed thrombocytopenia with leukopenia (10.0%). The latter proved to be the most common manifestation as leukopenia was present in 15 out of 30 patients (50.0%) (Figure 4). Azathiaprine (AZA), in association with hydroxychloroquine (HCQ), was used in 8 patients (26.6%), while a combination of Myophenolate Mofetil (MMF) and HCQ was found in 5 out of 30 patients (16.7%); seven patients received either HCQ alone or a biologic drug (Belimumab). Among patients in therapy with AZA or MMF, the former proved to be more frequently associated with leukopenia vs MMF (OR=2.5); however, the result was not statistically significant (CI95% 0.77; 8.04); a similar result was observed for both patients in therapy with MMF or AZA when compared to HCQ alone or HCQ + Belimumab (OR=1.16, OR=0.46, respectively) since they did not reach statistical significance.

Conclusion: In this preliminary study, real-world data proved essential to analyze patients affected by SLE. Among many haematological manifestations, leukopenia showed to be the most frequent in agreement with data published in literature, strictly followed by thrombocytopenia and AIHA. AZA was linked with a higher percentage of leukopenia compared to MMF or other therapies but the result was not statistically significant. This study has some limitations (number of enrolled patients, possible selection bias) which require further evaluations to be properly assessed.

FREQUENCY OF TROPICAL INFECTIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN A MEDIUM INCOME COUNTRY, USING DATA ANALYTICS TECHNIQUES

Keywords: Systemic lupus erythematosus, Artificial intelligence, Infection-related RMDs

A. Beltrán-Ostos1, 2, S. Moreno1, J. S. Castro Villareal1, C. F. Valencia Arboleda1, 2, 3
1Colombia, Cundinamarca, Bogotá, Colombia; 2Riesgo de Fractura, Carey IPS, Rheumatology service, Bogotá, Colombia; 3Universidad de los Andes, Facultad de Medicina, Bogotá, Colombia; 4Universidad de los Andes, Facultad de Ingeniería Industrial, Bogotá, Colombia

Background: The co-occurrence of lupus (SLE) and tropical infections has been poorly studied, this group of infections, prevalent in the tropics could simulate or trigger disease activity, however, some studies suggest that malaria infection could confer protection from the development of SLE, that is for this reason, studies are required to characterize this population.

Objectives: The objective of our study was to estimate de frequency of tropical infections in patients with SLE using administrative databases in Colombia.

Methods: This study was carried out using databases generated based on technical studies conducted by the Colombian Ministry of health. For the present study, databases provided contained information from 2014 to 2017, and contains the information of approximately 20 million affiliates. A person in the database was considered a patient with SLE if she met the following, either if she has been classified with an ICD-10 diagnosis code which corresponds to SLE in an inpatient claim or if she has been classified at least two times in outpatient claims, with an estimated prevalence of 24/100,000 people in Europe and North America. Among other clinical manifestations, haematological involvement is one of the most common in SLE as it includes anaemia, leukopenia, lymphopenia, thrombocytopenia, lupus nephropathy and splenomegaly; furthermore, it is usually challenging to discriminate whether such manifestations are caused by disease or by immunosuppressants. To date, few studies tried to evaluate them using real world data.

Objectives: To evaluate haematological manifestations in patients with SLE by using real world data.

THE CLINICAL CHARACTERISTICS OF KOREAN PRIMARY SJÖGREN’S SYNDROME (PSS) PATIENTS WITH POSITIVE ANTI-DOPPLER-STRANDAN DNA (ANTI-DSDNA) ANTIBODY BY THE FARR METHOD

Keywords: Sjögren syndrome

E. J. Koren1, B. W. Lee2, Y. Park1, J. J. Lee1, S. H. Park1, S. K. Kwok1, 1Seoul St. Mary's Hospital, College of Medicine, Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Anti-Ro/SS-A antibody is considered to play a crucial role in distinguishing the clinical features of pSS. However, the association of anti-dsDNA antibody on the characteristics and prognosis of pSS is not well known.

Objectives: We aimed to clarify the clinical characteristics of pSS patients presenting with positive anti-dsDNA antibody.

Methods: This retrospective study assessed 1255 pSS patients, fulfilling the classification criteria proposed by the American-European Consensus Group in 2002 or American College of Rheumatology/European League Against Rheumatism (EULAR) in 2016, who regularly visited Seoul St. Mary’s Hospital between 2013 and 2021. Patients with other autoimmune diseases including SLE were excluded from this study. Of the total 1255 patients, 174 were in the anti-dsDNA positive group (measured by using Farr assay, cut-off = 7 IU/ml) and 1081 were in the negative group. Data were compared between the two groups, including demographic features, extra-glandular manifestations (EGMs), clinical indices, and laboratory values at baseline.

Results: Patients in the anti-dsDNA (+) pSS group were younger (p = 0.015), and had higher proportion of positive finding in ocular staining score (OSS) by Sjögren's International Collaborative Clinical Alliance (SICCA) method (OSS ≥ 5) and minor salivary gland biopsy (Focus score ≥ 1) (p = 0.021 and p = 0.040, respectively). Among the EGMs, more frequent lymphadenopathy, lymphoma, pulmonary, cutaneous, renal, and CNS involvement were observed at baseline in the anti-dsDNA (+) pSS group. Total EULAR Sjögren's syndrome disease activity index (ESSDAI) scores were also higher in the anti-dsDNA (+) pSS group (median value [IQR]: 5.9 [5.1-6.7] vs 3.7 [3.4-3.9], p = 0.001). More frequency of leukopenia (p = 0.001), anaemia (p = 0.001), rheumatoid factor positivity (p < 0.001), anti-Ro/SSA antibody positivity (p < 0.001), low C3 (p = 0.024), low C4 (p < 0.003) and hypergammaglobulinemia (p < 0.001) were found in the laboratory data in the anti-dsDNA (+) pSS group.

Conclusion: Korean pSS patients with positive anti-dsDNA antibody by Farr method showed distinct clinical characteristics at baseline including higher disease activity of SS, frequent several types of EGMs, and difference of laboratory data. Close monitoring for development of above clinical features in anti-dsDNA positive pSS patients is necessary.

PREVALENCE OF MACE AMONG SAUDI WITH SLE

Objectives: To estimate de prevalence of comorbidities in patients with systemic lupus erythematosus using administrative databases in Colombia.

Methods: This study was carried out using databases generated based on technical studies conducted by the Colombian Ministry of Health. A person in the database was considered a patient with SLE if she met the following operative definition: a patient who has been classified with an ICD-10 diagnosis code which corresponds to SLE in an inpatient claim or if she has been classified at least two times in outpatient claims, with a difference of minimum 30 days and less than 2 years, with a ICD-10 diagnosis code corresponding to SLE. In turn, a control group matched by age and sex was randomly selected to evaluate the difference in the frequency of comorbidities in both groups.

Results: We previously published the prevalence of patients with SLE, that ranges between 41.65 and 54.47 (cases/100 000), which is lower than other Latin American countries. Using the operative definition of SLE, 5527 patients were selected, and 22108 controls paired by sex and age, the average age was 43 years old in both groups, the average of comorbidities was 3.5 (SD 1.8) for SLE patients and 1.7 (SD 1.5) for control group, we found a higher prevalence for most comorbidities, particularly those related to cardiovascular disease, kidney disease and depressive disorders in subjects with SLE compared to the control group Table 1. Table Prevalence of comorbidities by group.

Conclusion: SLE patients had a burden of comorbidities, and the prevalence of multiple comorbidities were higher compared to matched controls.

two hospitals, and the treatment strategy, selection of steroid, initial dose of steroid and drugs used together with steroid have been quite similar. Therefore, it should be possible to clarify the background factors associated with ONF.

Objectives: The purpose of this study were to clarify the factors related to silent ONF in patients with SLE and, in case of ONF, to clarify the clinical characteristics between unilateral and bilateral.

Methods: One hundred thirty-two patients (18 males and 114 females) with SLE were selected on the basis of having been newly diagnosed and requiring high-dose prednisolone, including pulse therapy with methylprednisolone, as the initial treatment. All the patients initially underwent plain radiography and MRI at the start of corticosteroids to detect any early changes in the femoral head. Subsequently these examinations were performed three months thereafter. The laboratory parameters were evaluated at the beginning of steroid treatment and at one month thereafter. All statistical analyses were performed with SPSS v. 13 (SPSS Inc., Chicago, IL, USA). Statistical tests were considered significant at a P (two sided) < 0.05, and marginal significant at P = 0.05–0.10. Tests were 2-tailed, and differences at p < 0.05 were considered significant.

Results: By three months after the start of corticosteroid treatment, asymptomatic ONF was diagnosed by MRI in 33 patients (25.0%), being bilateral in 21 patients and unilateral in 12. Serological activity (C3, C4, CH50 and anti-ds DNA antibody), renal function (eGFR, serum creatinine and urinary protein), anti-phospholipid antibodies, and SLEDAI were not correlated with asymptomatic ONF. BMI, BSA, and the initial dose of prednisolone per unit body weight, BMI and BSA were not correlated with silent ONF. Additionally, the occurrence of IO was not related to SLEDAI.

Conclusion: Asymptomatic ONF is common in patients with SLE. Both of high triglyceride and total cholesterol levels are important risk factors for ONF. In unilateral and bilateral studies, excess steroid dosage relative to serologic activity of SLE might contribute to the development of bilateral ONF. In the pathogenesis ONF, it was suggested that SLE activity and steroids are closely related.

AB0642 ANTI-SSA POSITIVITY AND SALIVARY GLAND ULTRASOUND AS SCREENING TOOLS FOR PRIMARY SJÖGREN’S SYNDROME IN PATIENTS WITH SICCA SYMPTOMS

Keywords: Imaging, Sjögren syndrome, Ultrasound

K. Chandwari1, D. P. Misra,2, K. Kishor2, P. Dogga1, A. Wakhlu1, V. Agarwal1, R. Mino1, M. Mizusaki1, K. Chujo1, T. Kameda1, H. Dobashi1.

Background: Salivary Gland ultrasound is a sensitive point of care investigation for the assessment of salivary gland dysfunction. It can be abnormal in patients with primary Sjögren’s syndrome(pSS), Sarcoidosis, IgG4 disease, Systemic sclerosis, Infections and Tumors.

Objectives: To understand the utility of Anti-SSA, ANA and Anti-SSA/SSB and Salivary gland ultrasound for diagnosing primary Sjögren’s Syndrome in patients with Sicca symptoms.

Methods: In the current study, In patients referred to the department of Clinical Immunology and Rheumatology, King George’s Medical University, with Sicca Symptoms, a salivary Gland Ultrasound was performed and in those with abnormal ultrasound (Hoevear Score ≥1) Clinical and serological evaluation were performed. The Sensitivity and Specificity of Salivary Gland ultrasound with a Hoevear score ≥1 to diagnose primary Sjögren’s Syndrome was assessed, and the utility of ANA, Anti-SSA and Anti-SSA positivity in patients with abnormal ultrasound was assessed.

Results: A total of 78 patients with sicca symptoms and abnormal salivary gland ultrasound (Hoevear Score ≥1) were included of these, 36 were diagnosed with primary Sjögren’s syndrome and 42 with other diseases, including 12 with Rheumatoid arthritis, 8 with Systemic lupus erythematosus, 7 with systemic sclerosis, 4 with IgG4 related disease and 4 with Sarcoidosis. 7 patients did not have any autoimmune rheumatic disease after evaluation. The mean age of pSS patients was 36.42 ±11.68 and for non-pSS patients was 44.45 ±15.31. A Hoevear score ≥17 has a sensitivity and specificity of 80.56% and 78.57%, respectively. Adding ANA to the screening protocol improved the sensitivity but reduced the specificity while adding Anti-SSA to the screening protocol improved sensitivity, specificity, positive likelihood ratio, accuracy and area under curve for diagnosing pSS.

Conclusion: Anti-SSA positivity and abnormal salivary gland ultrasound in patients with Sicca symptoms can be effective screening tools for diagnosis primary Sjögren’s Syndrome.

Background: Women with systemic lupus erythematosus (SLE) have a higher risk for adverse pregnancy outcomes (APOs) including preterm birth (PB) and low birth weight (LBW) [1]. These APOs are revealed to be related to uncontrolled higher disease activity during pregnancy [2]. Currently, lupus low disease activity state (LLDDS), which is a comprehensive disease activity index, is suggested to be the treatment target to control damage accumulation. However, it is controversial whether achieving LLDDS during pregnancy can be a sufficient therapeutic target to prevent APOs.

Objectives: To understand the utility of risk factors for PB and LBW in SLE patients with or without achieving LLDDS at conception.

Methods: We used the data of SLE patients who have been treated at the planning for pregnancy from a single center cohort. We divided into LLDDS achieved

Outcomes and factors predicting mortality in patients with systemic lupus erythematosus admitted to intensive care unit

Keywords: Prognostic factors, Systemic lupus erythematosus, Descriptive studies

A. Gopalan, S. C. Veeravalli. 1Krishna Institute of Medical Sciences, Rheumatology and Clinical Immunology, Hyderabad, India

Results: Eighty-seven patients were included in the study. Mean age was 33.16 ± 12.6 years and 87% were females. Most common causes for admission were infection in 51 (58%) and disease flare-up in 31 (35%) patients; 34 (39%) patients had a combination of disease flare and infection. Mean APACHE II score at admission was 17.32 and mean SLEDAI-2k score at presentation was 15.16. The mean duration of ICU stay was 6.02 ± 6.58 days. Mechanical ventilation was needed for 45 patients (51%), inotropic support in 36 patients (41%) and dialysis in 19 patients (21%). The mortality rate was 21% (19 cases), 18/19 patients had both very high disease activity and sepsis. Factors correlating with mortality (on multivariate analysis) analyzed separately for LLDAS attained group and not-achieved LLDAS group. As for PB, mean glucocorticoid dose during pregnancy was found to be a risk factor for PB, regardless of whether or not the LLDAS was achieved at conception. As for LBW, low levels of C3 and CH50 was shown to be a risk factor even if LLDAS could be achieved at conception. Therefore, it is important to control the immunological disease activity parameters strictly for improving pregnancy outcomes, even if LLDAS, a comprehensive disease activity index, is achieved at conception.

Prevalence and description of autoimmune polyendocrine syndromes in patients with systemic lupus erythematosus: Experience of a single center

Keywords: Systemic lupus erythematosus, Comorbidities, Epidemiology

E. Pirovano 1, G. I. Gazzoli 2, P. Bizzelli 2, M. Taglietti 2, M. Fredi 2, C. Cappelli 2, F. Franceschini 2, 1ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy, 2ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy, 3ASST Spedali Civili and University of Brescia, Endocrinology and Metabolism Unit, Department of Clinical and Experimental Sciences, Brescia, Italy

Background: Autoimmune polyendocrine syndromes (APS) are a heterogeneous group of clinical conditions characterized by functional alteration of one or more endocrine glands and often associated with other systemic autoimmune diseases. In our Department and to assess the possible association between organic autoimmune diseases and SLE. The secondary aim is to describe the timing of onset of the different autoimmune diseases and the presence of associated comorbidities and/or any feature that may predict the development of APS.

Objectives: The primary objective of the work is to describe the prevalence of APS in a cohort of patients with Systemic Lupus Erythematosus (SLE) followed in our Department and to assess the possible association between organic autoimmune diseases and SLE. The secondary aim is to describe the timing of onset of the different autoimmune diseases and the presence of associated comorbidities and/or any feature that may predict the development of APS.

Methods: In this retrospective observational study we included the medical history, biochemical, and immunological data of patients older than 18 years of age with SLE who were actively followed at the Department of Rheumatology and Clinical Immunology of our hospital. Patients who, in addition to the diagnosis of SLE, had at least one other autoimmune disorder against an endocrine organ were included in the study.
Results: The total number of SLE patients examined is 423, with a mean age at the last evaluation of 53 (±13), 393 were female (93%) and 30 male (7%). Forty-eight patients (11.3%) have at least one other endocrinological autoimmune disease that would allow the diagnosis of APS. The sample examined is composed of 46 (86%) females and 2 (4%) males (F:M=23:1). The mean age of the patients is 52 (±14) years; the mean age of SLE onset is 36 (±14) years. No cases of APS-1 nor APS-2 were found; 45 (94%) patients are affected by APS-3; while 3 (6%) by APS-4. Forty-three (90%) patients presented two autoimmune diseases and 5 (10%) presented three autoimmune diseases. The mean age at onset of the first disease is 31 (±12) years; the second manifestation is 39 (±13) years and the third manifestation is 37 (±11) years. Concerning the timing of the onset, SLE was the first manifestation in 17/48 patients, the second manifestation in 25 patients, the third manifestation in 1 patient and in 5 patients the diseases were diagnosed at the same time. Figure 1 shows the different conditions according to the time of onset. The mean latency between the onset of the first manifestation and the onset of the second is 9 (±3) years. The mean latency between the onset of the second manifestation and the onset of the third is 4 (±3) years.

Conclusion: In our cohort of SLE patients, the prevalence of APS is quite high and occurs proportionally more in females than in males. Hashimoto’s Thyroiditis (HT) is the most represented disease, followed by Graves’ disease and DM1. And occurs proportionally more in females than in males. Hashimoto’s Thyroiditis is the most represented disease, followed by Graves’ disease and DM1. The study retrospectively evaluated the conformity of the 2019 EULAR/ACR classification criteria in patients discharged from a single-center tertiary university rheumatology center between February 2020 and February 2022, diagnosed with SLE according to their attending rheumatologists and identified by international classification of diseases (ICD10) codes. Normally-distributed continuous variables are reported as ‘mean ± standard deviation’; The correlation of continuous variables was studied with Spearman tests. Differences of continuous variables between nominal dichotomous subgroups were evaluated with Mann Whitney tests. Statistics were considered significant if p < 0.05.

Results: The study included 146 patients, of whom 92.5% were women, with an average age of 48.3 ± 13.3 years. Approximately 75% of patients had negative ANA (including at repeated measurements) and 12.3% had an unknown ANA status. The method for determining ANA was ELISA (enzyme-linked immunosorbent assay; 75.3%), indirect immuno-fluorescence (2.7%) or undetermined (21.9%). Men scored a significantly higher median number of classification points than women (i.e., 21 points versus 16 points; p = 0.020) and they had a higher prevalence of class 3/4 nephritis (18.2% versus 3.0%; p = 0.014), pleuritis/pericarditis (36.4% versus 14.8%; p = 0.064) and oral ulcers (27.3% versus 9.6%; p = 0.072). Only 63.7% of SLE diagnoses also met the 2019 EULAR/ACR classification criteria. The most common manifestations not complying with these classification criteria were proteinuria (59.5% discordance), thrombocytopenia (13.6% discordance) and joint involvement (9.3% discordance). The median number of classification points correlated significantly with the median titer of ANA (r = 0.301; p = 0.001) measured by ELISA.

Conclusion: Diagnostic reality includes ANA-negative SLE, which should be further investigated. In clinical practice, ANA are preferably determined by ELISA and their titer seems to be proportionally associated with more classifiable SLE clinical characteristics. Clinical trials have a maximum eligible SLE population of 63.7% of patients to whom additional inclusion/exclusion criteria could be applied.

in the study. The patients had an ophthalmologic examination and DED evaluation on the day of their routine follow-up appointments. ESSPRI scores were recorded and laboratory tests, salivary flow rate and salivary gland ultrasonography (USG) scores of the patients were recorded from the patients’ files. The ophthalmologic examination includes Schirmer’s test, BUT, ocular surface staining (Oxford score), Marx’s line, and noninvasive BUT (NIBUT) with the Scheimpflug-Placido disk system. Ocular surface disease index (OSDI) and dry eye questionnaire-5 (DEQ-5) were used for patient-reported outcomes. The relationship between the pSS-related parameters and the ophthalmologic findings was evaluated.

Results: The patient characteristics are given in Table 1. According to the TFOS-DEWSII definition and classification report, all patients have definite DED [3]. The mean Schirmer’s test, BUT, and NIBUT were 3.4±5.2 mm, 5.9±3.0 sec, and 5.9±3.9 sec, respectively. The mean OSDI score was 38.2±22.7, indicating severe DED symptoms, and the mean DEQ-5 score was 10.3±6.0. Oxford score was positive in 25 (73.5%) patients. Marx’s line grading that shows meibomian gland dysfunction was 3.2±2.3. The mean ESSPRI score for dryness, pain, and fatigue were 6.5±2.1, 5.4±3.2, and 5.3±3.1, respectively. There was a significant positive correlation between the ESSPRI-dryness score and OSDI (p=0.001), DEQ-5 (p=0.004), and Oxford score (p=0.03). Also, there was a significant negative correlation between patient global assessment (PGA) of general health and DEQ-5 scores (p=0.007).

AB0649 PERIPHERAL B CELLS IMMUNOPHENOTYPING IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Keywords: Systemic lupus erythematosus, Cell biology, Biomarkers

C. Di Mario1, V. Varriano2, L. Petricca3, A. Pagliocino4, M. R. Gigante5, B. Tosullo2, E. Gremese1,2, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Immunology Research Core Facility, Rome, Italy; Fondazione Policlinico Universitario A. Gemelli, IRCCS, Division of Clinical Immunology, Rome, Italy; Fondazione Policlinico Universitario A. Gemelli, IRCCS, Division of Rheumatology, Rome, Italy

Background: B cells play a central role in systemic lupus erythematosus (SLE) pathogenesis connecting innate with adaptive immunity.

Objectives: To investigate the peripheral blood B cell phenotype in a cohort of SLE patients with renal (LN-SLE) and non-renal (NR-SLE) involvement compared to healthy controls.

Methods: Ninety-nine SLE patients, 76 with active renal involvement (30 at disease onset-Early and 46 in whom LN occurred after the disease onset-Long) and 23 with non-renal disease (articular and/or cutaneous) were enrolled. Thirty-seven healthy controls were included. Clinical, laboratory and demographic data were collected at baseline and at 6 and 12 months of follow-up. Disease activity was recorded using SLEDAI-2K.

Results: The memory B cells immunophenotyping (IgD/CD27 classification) was analyzed in peripheral blood through flow cytometry. To clarify the role of key molecules in the B cells activation, IL-6 and BAFF serum levels were assayed by ELISA.

Conclusion: The results of this study can help in the identification of potential biomarkers that may be used to predict disease progression and treatment outcomes.

Disclosure of Interests: None Declared.

AB0650 PREVALENECE OF FATIGUE AND ITS IMPACT ON QUALITY OF LIFE IN PATIENTS WITH PRIMARY SJÖGRÖN’S SYNDROME

Keywords: Quality of life, Sjögren syndrome

D. Das1, G. Naidu1, S. Grover2, V. Dhiri2, S. K. Sharmaz2, A. Sharma2, S. Jain2, P. Deo2. 1Post Graduate Institute of Medical Education and Research, Chandigarh, Internal Medicine II, Rheumatology, Chandigarh, India; 2Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Psychiatry, Chandigarh, India

Background: Among the extra-glandular symptoms in primary sjögren's syndrome (pSS), fatigue and pain are the most common. Fatigue is a poorly understood phenomenon with multi-faceted involvement. Therefore, it is important to assess the severity of fatigue and describe its various dimensions while assessing fatigue. On the other hand, fatigue is also one of the predictors of reduced health and quality of life in pSS.

Objectives: To assess fatigue by Fatigue Severity Scale (FSS) and Profile of fatigue (ProF) questionnaires and quality of life (QoL) with Health Assessment Questionnaire- Disability Index (HAQ-DI) and to know the association between the two in patients with pSS.

Methods: Patients fulfilling AECG 2002 and/or ACR-EULAR 2016 classification criteria for pSS were included in this prospective observational study between January 2021 to June 2022. Fatigue was assessed with FSS and ProF and QoL was assessed with HAQ-DI. Depression and somatoform disorder were assessed using PHQ20 and PHQ15 respectively. Associations with fatigue were compared using multivariate regression analysis. Written informed consent was obtained from all subjects included in the study and the study was approved by Institute Ethics Committee.

Results: Out of 125 patients, 114 (91.2%) were female and 11 (8.8%) were male with a female to male ratio of 9.6:1. The median age at the time of inclusion into the study was 41(32-50) years. The median duration of the disease was 36 (12-60) months. The median ESSDAI and ESSPRI score were 2 (1-3) and 6 (2-9) respectively. Fifty seven (45.6%) patients had fatigue, defined as FSS of >4 and/ or ProF ≥2 in either of the domains. Among the patients with fatigue, 12 (21%) patients scored less than 4 on FSS, 36 (63.1%) had mild fatigue, 7 (12.2%) had moderate fatigue and only 2 (3.5%) patients had severe fatigue. The mean FSS score in the cohort was 2.9 ± 0.6 for somatic fatigue and 2.9 ± 1.3 for mental fatigue. The median HAQ-DI in patients with fatigue was significantly more compared to non-fatigue patients (0.1 vs 0.5; p <0.001; Figure 1). There was a positive correlation between fatigue score and HAQ-DI score (pb=0.36, n= 125, p <0.001). The prevalence of depression and somatoform disorder was 15.2% and 28% respectively. The ESSPRI pain score, ProFAD Ocular & Oral dryness score and PHQ-9 score were positively associated with higher fatigue score.

Conclusion: Fatigue was seen in nearly half of the patients with pSS and patients with fatigue had impaired QoL as assessed by HAQ-DI. The pain, dryness and presence of depression are the predictors of fatigue in patients with pSS.

AB0651 INDIRECT HEALTH RELATED COST IN PSS PATIENTS IN RELATION TO SYMPTOM BASED ENDOTYPES

Keywords: Patient reported outcomes, Work-related issues, Sjögren syndrome

L. Derou1,2,3, H. Achten1,2,3, K. De Boeck2,2, F. Van den Bosch1,2,2, D. Elewa1,2,3, I. Peere1,2,3,4, Ghent University, Faculty of Medicine and Health Sciences, Department of Internal Medicine and Pediatrics, Ghent, Belgium; 2Ghent University, Center for Inflammation Research, VIB-UGent, Ghent, Belgium; 3Ghent University Hospital, Department of Internal Medicine and Pediatrics, Rheumatology, Gent, Belgium; 4AZ Sint-Jan, Rheumatology, Brugge, Belgium
Background: Primary Sjögren’s Syndrome (pSS) is characterised by oral and ocular dryness, possible development of systemic manifestations, increased lymphoma risk, and a highly diverse patient burden. To address this heterogeneity Tarn identified four endotypes based on patient-reported symptoms of dryness, fatigue, pain, anxiety and depression: low symptom burden (LSB), pain dominant with fatigue (PDF), dryness dominant with fatigue (DDF) and high symptom burden (HSB).(1)

Objectives: The aim of this study was to explore indirect health related costs in relation to symptom-based endotypes in a cohort of patients with definite and suspected pSS.

Methods: Data from the Belgian Sjögren’s Syndrome Transition Trial (BeSSTT) were used in which patients positive for at least one of the 2016 ACR/EULAR classification criteria, were enrolled. Patients were considered ‘definite pSS’ when fulfilling these criteria, and ‘suspected pSS’ otherwise. The Newcastle Sjögren’s Stratification Tool (NSST), developed and provided by Tarn et al., was applied to stratify the cohort into endotypes. Patients reported their current work status and sick leave in the past year and completed the Work Productivity and Activity Impairment questionnaire (WPAI).

Results: Application of the NSST tool resulted in 4 endotypes, both in definite (LSB n=23, DDF n=33, PDF n=82, HSB n=30) and suspected pSS (LSB n=14, DDF n=22, PDF n=48, HSB n=21). The majority of definite pSS patients were female (158, 88.8%) with a means±SD age of 53.4±14.7, with no significant differences between endotypes (p=0.365 and p=0.415). Definite pSS LSB patients reported significantly less invalidity (p=0.020). A numerically higher proportion of working PDF and HSB patients reported part time employment due to health (p=0.063), however, reported working hours did not differ between endotypes. In contrast, HSB pSS patients reported significantly more productivity loss during their job than those with LSB and DDF endotypes (p=0.001), which led to a significantly higher total work impairment (p<0.001). In addition, definite pSS patients with HSB endotype reported significantly more productivity loss during daily activities besides their job (69%, p<0.001). No significant differences concerning job characteristics were observed between definite and suspected pSS patients with the same endotype.

Conclusion: Definite pSS patients with a HSB endotype encounter significantly more work impairment than those with other endotypes, which is due to a significantly higher productivity loss while working. In addition, these patients report significantly more productivity loss during daily activities besides paid work, which entails large indirect health related costs as pSS is a predominantly female disease. Moreover, the burden associated with the HSB endotype appears to influence work ability independent of a definite pSS diagnosis.

HISTOLOGICAL RENAL FEATURES AND CYTOKINES ASSESSMENT AS POSSIBLE BIOMARKERS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND LUPUS NEPHRITIS

Keywords: Biomarkers, Cell biology, Systemic lupus erythematosus

V Varriano1, C Di Mario2, A Pagliionico1, L Petricca1, M R Gigante3, B Toloso4, E Gremese1,2, Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Clinical Immunology, Rome, Italy;2 Fondazione Policlinico Universitario A. Gemelli IRCCS, Immunology Research Core Facility, Rome, Italy;3 Fondazione Policlinico Universitario A. Gemelli IRCSS, Division of Rheumatology, Rome, Italy

Background: Lupus Nephritis (LN) management remains a challenge for the inadequacy of the traditional parameters in identifying more severe disease and preventing renal damage.

Objectives: To identify a multipanel biomarkers matrix, from histological to molecular level, aiming to improve prognostic stratification and therapeutic protocol of LN patients.

Methods: 45 SLE patients with active disease (age: 40.5 ± 11.0 years) at disease onset or at disease flare were enrolled. 6 patients with LN in persistent remission (R-LN) (age: 43.5 ± 11.9 years) were included as controls. 28 patients had active LN and underwent ultrasound-guided renal biopsy while 15 patients with non-renal SLE (NR-SLE) displayed cutaneous or articular manifestations. Laboratory, immunological and disease activity data were collected at baseline and then at 6(T6) and 12(T12) months. Renal biopsies were evaluated according to ISN/RPS classification, assessing the activity and chronicity indexes and the active intersistial infiltrate (II) using the BANFF score system. Serum level of BAFF, IL-2, IL-6, IL-17 and IFN-γ were assayed in the study cohort by ELLA panel at each timepoint.

Results: Considering LN cohort, 66% of the renal biopsies belonged to class III and IV; 71.8% of LN patients had a II>5%. Performing univariate analysis for each renal outcome, focusing on histological assessment, a significant association between higher activity index and worse renal prognosis in terms of remission achievement at 12 months (p= 0.04), proteinuria and chronic renal damage development (p= 0.04 and p= 0.03 respectively) was observed. Through the ROC curve analysis, a cut-off value of activity index of 7.5 was identified (sensitivity 72.7%, specificity 66.7%) [AUC: 0.77; 95% CI, 0.56-0.98; p= 0.04] for remission achievement within 12 months and proteinuria development. Furthermore, LN patients with presence of II>5% were not only less likely to achieve early remission (p= 0.04) as well as those with at least one antiphospholipid antibody (Apl) positivity (p= 0.05), but displayed a worse renal outcome overall, though without reaching statistical significance. The analysis of circulating cytokines revealed that serum levels of IL-6 were significantly higher in patients with active disease as compared to R-LN patients, independently from renal involvement (LN: 76 ± 10.0 vs R-LN: 2.1 ± 2.1, p=0.02; NR-SLE: 11.4 ± 17.8 vs R-LN: 2.1 ± 2.1, p=0.02). Moreover, baseline serum level of IFN-γ was significantly increased in LN patients compared to R-LN (12.1 ± 36.8 vs 1.5 ± 3.6, p=0.01). Serum levels of IL-6 in LN patients positively correlated with disease activity index (R= 0.819; p<0.001), and negatively with C3 (R= -0.608; p=0.003) and C4 (R= -0.675; p=0.01). The evaluation of cytokines serum levels in relation to outcome achievement revealed that NR-SLE patients with favorable course had baseline higher serum level of IL-2 than those with active disease (0.6 ± 0.2 vs 0.1 ± 0.1, p=0.01). Finally, LN patients with higher serum levels of IL-6 during the follow-up were less likely to reach remission (3.7 ± 1.8 vs 2.1 ± 1.4, p=0.02) as well as LN patients with higher serum level of IL-17 (3.4 ± 8.0 vs 0.9 ± 0.3, p=0.01). In particular, higher baseline serum levels of IL-17 were observed in patients who developed persistent proteinuria than those who did not (2.3 ± 2.3 vs 0.7 ± 0.5, p=0.02) and tended to remain higher also during FU, together with IL-6 serum level.

Conclusion: II>5%, higher disease activity index and Apl+ represent in our study the strongest predictors of worse renal outcome, among traditional parameters. Higher IL-6 and IL-17 serum levels, at baseline and during FU, emerge as negative prognostic factor suggesting a possible role as biomarkers of more aggressive LN. IL-2 seems to have a protective role in extra renal disease.

PRESEPSIN IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL AND SEROLOGICAL ASSOCIATIONS

Keywords: Biomarkers, Systemic lupus erythematosus

O. Iaremenko1, D. Koliadenko1, K. Iaremenko2, Bogomolets National Medical University, Department of Internal Medicine #3, Kyiv, Ukraine; 1Alexander Clinical Hospital, Laboratory Department, Kyiv, Ukraine

Background: Presepsin (soluble CD14 subtype) is a newly recognized biomarker of sepsis. Recently it has been reported that presepsin levels are elevated in patients with systemic lupus erythematosus (SLE) without infection, possibly due to phagocytosis of neutrophil extracellular traps by monocytes/macrophages [1]. However, the clinical significance of presepsin in SLE remains uncertain [2].

Objectives: This study aims to evaluate the relation between serum presepsin levels and clinical manifestations, disease activity and laboratory parameters in SLE patients.

Methods: A total of 78 SLE patients (aged 38.9±12.8 years; 87.2% females) and 16 age- and sex-matched healthy controls were enrolled. Patients with infections were not included in the study. Serum presepsin levels were determined by ELISA and were analyzed in relation to SLE organ system and involvement, routine laboratory tests, inflammatory markers, serum complement levels, autoantibody spectrum, and the overall disease activity assessed by Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). Mann-Whitney test, Spearman and Pearson correlation tests were used for statistical analysis.

Results: The median serum presepsin level was significantly higher in patients with SLE than in healthy controls (137 (95-197) pg/ml vs 66 (62-77) pg/ml; p<0.001). SLE males had higher presepsin concentration compared with females (180 (140-156) pg/ml vs 130 (90-170) pg/ml; p=0.02). Presepsin levels were significantly lower in SLE patients with involvement of skin (124 (84-157) pg/ml) and musculoskeletal system (111 (87-153) pg/ml) compared to those without such manifestations (164 (110-210) pg/ml; p=0.032 and 145 (122-175) pg/ml; p=0.041, respectively). However, SLE patients with fever (215 (170-1606) pg/ml vs 130 (93-166) pg/ml; p<0.004), nephritis (145 (110-197) pg/ml vs 102 (82-146) pg/ml; p=0.011), anemia (170 (126-280) pg/ml vs 130 (92-280) pg/ml; p=0.04) and thrombocytopenia (198 (170-280) pg/ml vs 130 (92-161) pg/ml; p=0.049) had higher presepsin levels than those without such symptoms. Significant correlation was found between presepsin concentration and estimated glomerular filtration rate (r=0.440, p=0.017). Presepsin levels did not correlate with white blood cell count, C3, C4, C-reactive protein, erythrocyte sedimentation rate and procalcitonin levels. Presepsin levels in patients with lupus nephritis significantly correlated with SLEDAI score (r=0.461, p=0.008) and anti-dsDNA levels (r=0.545, p<0.01); no such associations were found in SLE patients without kidney involvement.

Conclusion: Higher presepsin levels in SLE patients are associated with male gender, fever, kidney involvement, anemia and thrombocytopenia. Further research focused on clinical use of presepsin in SLE is warranted.

PHOSPHATIDYLISERINE PROTHROMBIN COMPLEX ANTIBODIES UTILITY IN PLACENTAL INSUFFICIENCY MANAGEMENT: A CASE CONTROL STUDY IN A GENERAL OBSTETRIC CARE UNIT

Keywords: Diagnostic tests, Pregnancy and reproduction, Anti-phospholipid syndrome

A. Danza1, J. Sorriso2, M. Devillers2, C. d’Agostino2, F. Barad2, D. Jorquera1, 2. University Hospital of Buenos Aires, Buenos Aires, Argentina; 1Hospital Italiano, Buenos Aires, Argentina

Background: Antiphospholipid antibodies (aPL) are associated with a variety of obstetric complications, such as preterm delivery, placental abruption, and fetal growth restriction. The role of anti-phosphatidylserine-prothrombin complex antibodies (aPLPC) in placental insufficiency (PI) in obstetric patients with lupus anticoagulant and anti-phospholipid antibodies (aPL) is unclear.

Objectives: To assess the performance of antibodies against the phosphatidylserine prothrombin complex (IgM and IgG), onwards “anti-PS/PT” in preeclampsia or fetal growth restriction.

Methods: A case control study was performed in a private maternal general care unit. Cases were patients with preeclampsia or fetal growth restriction developed before the 37th weeks of gestation. The full sample was calculated in 92 cases and 192 controls. Controls were patients who were hospitalized in the third trimester of gestation, with age +/- 5 years old respect to the controls, without known autoimmune diseases or history of adverse obstetric outcomes. All patients were studied with general laboratory, doppler, classical antiphospholipid antibodies and anti-PS/PT IgG and IgM. We present demographic characteristics and media comparisons which were performed with T test. Categorical variables were compared with Chi square test or Fisher test if applicable. The statistical significance was established in 5% (p<0.05). Informed consent from the patients as well as approval from the institutional ethics committee were obtained.

Results: Two hundred and eighty-four pregnant women were included (192 controls and 92 cases). Demographic and clinical data of the groups are presented in Table 1. The median (IQR) anti-PS/PT IgM titles were 8 (6) MLP U/ml in cases and 9 (9) MPL U/ml in controls, p>0.05. Regarding to anti-PS/PT IgG test, the median (IQR) titles were 5.5 (3) GPL U/ml in cases and 5.5 (5) GPL U/ml in controls, p>0.05

Conclusion: We did not find association between anti-PS/PT both IgG or IgM in cases of foetal growth restriction or preeclampsia. It is worth to note that this study was performed in a general care maternity, therefore, high risk cases were not included. Further analysis may show the utility of this biomarkers in obstetric adverse pregnancy outcomes management, particularly in other contexts as recurrent pregnancy loss, foetal death, or early severe preeclampsia.

PREVALENCE AND RISK FACTORS ASSOCIATED WITH THROMBOCYTOPENIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT HOSPITAL DEL MAR

Keywords: Descriptive studies, Anti-phospholipid syndrome, Systemic lupus erythematosus

J. Corrubeda Lema1, 2, I. Carrion Barbera2, F. Garcia Pallarols2, B. Sanchez Gonzalez2, T. C. Salmon Monte1, 2. Universitat Pompeu Fabra, School of Medicine, Barcelona, Spain; 1Universitat Autònoma de Barcelona, School of Medicine, Bellaterra, Spain; 2Hospital de Mar, Rheumatology, Barcelona, Spain

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with a variety of manifestations, one of which is immune thrombocytopenia (ITP). Immune thrombocytopenia has been reported in 7–40% of SLE patients [1,2].

Objectives: To determine the prevalence of ITP in SLE patients and identify risk factors that correlate with ITP.

Methods: Retrospective case-control study. 407 medical records of SLE patients were reviewed: 34 patients were diagnosed with ITP (cases) and were age- and
sex-matched with 2 controls with SLE without ITP. Differences between cases and controls were analysed as well as factors associated with ITP. For the association of sex and SLE without ITP versus SLE with ITP, p-value of 0.045 was found. The results indicated that females with SLE were more likely to develop ITP with a higher disease activity score (SLE-DAS) in a cohort of Egyptian juvenile-onset SLE patients.

(*) Indicates statistically significant differences between cases and controls (level of confidence 95%), *Clinical and biochemical parameters at SLE diagnosis. Immunologic parameters along SLE course. Indicates mean and range. SLE-DASI in cases. Treatments along SLE course. Anti-β2GPI: Anti-β2-Glycoprotein 1. SLEDAI: SLE disease activity index. SLICC: SLE damage index.

**Conclusion:** Patients with SLE that develop ITP seem to have a different phenotype than those without ITP presenting less arthritis and more haemolytic anaemia at SLE disease onset, and more APS syndrome and APS antibodies along the disease. In addition, ITP was associated with a higher SLEDAI and with more frequent use of mycophenolate and azathioprine, possibly indicating a more severe disease, which would warrant the need of a more careful follow-up on these patients in the patients with the previously described associated characteristics.

**Performance of Conventional Cardiovascular Risk Scores in Identifying Subclinical Atherosclerosis in Systemic Lupus Erythematosus**

**Keywords:** Autoantibodies, Cardiovascular disease, Systemic lupus erythematosus

**Background:** Cardiovascular disease (CVD) is a major cause of mortality in systemic lupus erythematosus (SLE) with a standardized mortality ratio of 2.4, that is underestimated by conventional CVD risk scores. Subclinical atherosclerosis, a major predictor of cardiovascular morbidity is an important target for primary prevention.

**Objectives:** Perform a systematic review and meta-analysis of studies on the association of conventional CVD risk scores with subclinical atherosclerosis in SLE and healthy controls. Assess the predictive value of conventional CVD risk scores in SLE and healthy controls. Calculate the prevalence of subclinical atherosclerosis in SLE and healthy controls.

**Methods:** This is a single centre cross-sectional analytical study. Seventy-nine patients with SLE without CVD and 76 age and gender matched healthy controls were enrolled. CVD risk was calculated by QRISK3, SCORE and WHO scores. Sensitivity, specificity, positive and negative predictive values were assessed. Agreement between scores was determined using the kappa coefficient. Presence of subclinical atherosclerosis was compared with SLE disease manifestations. Positive predictive value of conventional CVD scores in detecting subclinical atherosclerosis was very poor in SLE with QRISK3 and WHO score having a sensitivity of 0% and 10% respectively. SLE disease parameters were comparable among those with and without subclinical atherosclerosis. Anticardiolipin IgG (14.6% vs 2.6%) and any APLA positivity (41.5% vs 21%) were numerically higher in SLE with atherosclerosis but not statistically significant (p=0.05).

**Conclusion:** Sensitivity of conventional CVD scores in detecting subclinical atherosclerosis was very poor in SLE with QRISK3 and WHO score having a specificity of 100% and 10% respectively. Hence further scores are needed, validated for screening for subclinical atherosclerosis using carotid ultrasound remains gold standard.

**Validity of the SLE Disease Activity Score (SLE-DAS) in a Cohort of Egyptian Juvenile-Onset SLE Patients**

**Keywords:** Systemic lupus erythematosus

**Background:**
1. M. Medhat1, M. Behiry2,3, Y. Farag4, A. Afifi1, H. Ramadan2, W. A Hassan5, N. Mostafa1. Faculty of Medicine Kasr Al-Ainy, Cairo University, Rheumatology and Rehabilitation Department, Cairo, Egypt; 2. Faculty of Medicine Kasr Al-Ainy, Cairo University, Internal Medicine and Rheumatology Department, Cairo, Egypt; 3. Armed Forces College of Medicine, Internal Medicine Department, Cairo, Egypt; 4. Faculty of Medicine Kasr Al-Ainy, Cairo University, Pediatric Rheumatology Department,
Background: Juvenile-onset SLE patients (JSLE) are commonly characterized by a more severe and deleterious disease. Hence, treating-to-target is crucial to attain favorable outcomes, and it relies on several factors including optimal disease activity assessment. However, data about evaluating disease activity in JSLE patients is mostly extrapolated from adult-onset patients, with data about the validity of the SLE-DAS among JSLE patients lacking, to the best of our knowledge.

Methods: This cross-sectional study included 108 JSLE patients (≤16 years) managed at the rheumatology departments of Cairo University in November 2022. Adult patients with juvenile onset were not included. The SLEDAI-2K was set as the gold standard. The SLE-DAS was measured through its online designed calculator (http://sle-das.eu/). Validity and agreement between the SLE-DAS and the SLEDAI-2K were assessed through Spearman’s rho correlation and Bland-Altman plot, respectively. The correlation between both scores was evaluated among patients with and without high disease activity (HDA ≥10).

Results: Of 108 patients, 95 (87.9%) were females. Age at onset and assessment duration was 43.8 ± 28.1 months (Median: 36). The most common cumulative manifestations included constitutional (71.8%), renal (65%), hematologic (55.1%), and mucocutaneous (47.6%) involvement. Serositis, arthritis, and neuropsychiatric manifestations were present in 35.5%, 27.3%, and 24.5% patients, respectively. The mean SLEDAI-2K was 14.4 ± 6.8 (Median: 14), whereas the mean SLE-DAS was 25.3 ± 14.4 (Median: 23.3). 80 (74%) patients demonstrated HDA. There was a significant correlation between both the SLE-DAS and SLEDAI-2K (rho = 0.24; p = 0.001). There was a significant, yet lower, positive correlation (rho = 0.24; p = 0.03) between the two scores among patients with HDA, whereas there was no significant correlation between those with low disease activity (rho = 0.2; p = 0.19). The mean difference of agreement between both scores was 9.3 ± 1.02 (Average-of-Scores [Bland-Altman plot (Figure 1]). Cross-sectionally, there was a significant correlation between the SLEDAI/SDI and both the SLEDAI-2K (p = 0.001) and SLE-DAS (p < 0.0001).

Conclusion: Our preliminary findings denote that the SLE-DAS could be utilized to assess disease activity among JSLE patients. Yet, its implementation among JSLE patients with lower levels of disease activity should be carefully interpreted.

PREVALENCE AND ASSOCIATION OF AUTOANTIBODIES WITH LATEX TUBERCULOSIS IN FIRST-DEGREE RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Autoantibodies, Systemic lupus erythematosus

Q. Me1, A. Narayanan2, C. Kavadiachinda3, M. M. Thabahi1, S. Sarkar1, P. B. Narasimhan1,1. JIPMER, Clinical Immunology, Pondicherry, India;2,3.JIPMER, Preventive and Social Medicine, Pondicherry, India

Background: Systemic Lupus Erythematosus (SLE) patients have a higher risk of tuberculosis (TB). Detection of latent TB (LTB) by mycobacterium tuberculosis (TB) IFN-γ release assay (TB-IGRA) is an important step to retard progression to overt TB. Among IGRA positive persons, studies have noted a dose-response relationship, where those with lower baseline levels IFN-γ have lesser risk of progression to overt TB. A family history of SLE exerts an increased risk of other autoimmune diseases. Although several studies reported autoantibodies in first-degree relatives (FDR) of SLE patients, association between LTB and antibodies is not clear. The current study focused on the role of antibodies and LTBI in FDRs of SLE.

Objectives: Study the prevalence of autoantibody levels and LTBI in FDRs of SLE. Evaluate whether seropositivity of autoantibodies confers any risk of TB.

Methods: This is a single centre cross sectional study. FDRs of SLE with no past h/o TB were recruited (n=167). Demography, comorbidity and various autoantibodies were measured by Enzyme Linked Immunosorbent Assay. LTBI was assessed using TB-IGRA. Based on the results of TB-IGRA and seropositivity to antibodies, FDR were divided into 4 groups- Autoantibody positive and negative groups with and without LTB. Basal IFN-γ and Mtb antigen specific IFN-γ levels were assessed in the unstimulated and Mtb antigen stimulated tubes.

Results: In FDRs, prevalence of autoantibodies and LTBI were 24.5% (n=41) and 25.7% (n=43) respectively. Seropositivity of various autoantibodies were comparable between those with and without LTBI. Among the antibody positive FDR, prevalence of LTBI was 34%, which is higher than the general population cohort. Next, we measured the basal IFN-γ levels in the 4 groups, where the IGRA and autoantibodies positive group had significantly (p=0.014) reduced levels of basal IFN-γ compared to IGRA positive antibody negative group. In the Mtb specific antigen tubes also, the antibody and IGRA positive group showed significantly reduced response compared to the IGRA positive and autoantibody negative group.

Conclusion: The present study showed higher prevalence of LTBI (34%) in the antibody positive FDRs of SLE. Basal and stimulated levels IFN-γ were lower in antibody positive group in contrast to SLE patients who have higher basal IFN-γ. Further longitudinal studies would be required to see the effect of these autoantibodies on LTBI and the risk of progression to TB.

AB0659 EXTREMELY LOW FREQUENCY OF CHRONIC HEPATITIS B INFECTION IN SYSTEMIC LUPUS ERYTHEMATOUS

Keywords: Clinical trials, Systemic lupus erythematosus

Z. Ademolu1, U. Ilgen1, K. Erol Kalkan1, N. S. Yasar Bilge2, T. Kajiloglu2, H. Emumungu1,1,1Trakya University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Edirne, Turkey; 2Eskişehir Osmangazi University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Eskişehir, Turkey

Background: There are few studies evaluating the frequency of chronic hepatitis B virus (HBV) infection in systemic lupus erythematosus (SLE) patients (1).

Objectives: Aim of this study is to determine the HBV seroprevalence in SLE patients and to compare it with normal population and patient control groups (rheumatoid arthritis and spondyloarthritis).

Methods: HBV serology tests [hepatitis B surface antigen (HBsAg), hepatitis B surface antibody (HBsAb), hepatitis B core antibody (HBcAb)] were performed during the diagnosis of 278 SLE patient and the control group [consist of 125 rheumatoid arthritis (RA) and 125 spondyloarthritits patient (SpA)] were analyzed retrospectively between 2005-2022 in two different centers. Patients with SLE responding to the 2019 ACR/EULAR criteria were included. HBV serology characteristics of SLE patients were compared with those of the normal population and control groups. The categorical data were presented as numbers (in percent). The chi-square test or Fisher’s exact test was used to analyze the categorical variables.

Results: HBsAg was positive in 2/278 (0.7%) in SLE patients, 6/125 (4.8%) in RA patients, and 9/125 (7%) in SpA patients. HBsAb positivity rate in SLE patients was lower than two different national normal population analysis [%4, 218/5960, (%4,57, p=0,008] and RA (p=0,019) and SpA patients (P=0,003) (2,3).

HBcAb positivity rate in SLE patients (%15) was significantly lower than both (218/5960), %4,57 , p=0,008] and RA (p=0,019) and SpA patients (P=0,003) (2,3).

</tbody>
</table>

Conclusion: The positivity rate of HBsAg and HBcAb was lower in SLE patients than both normal population and other inflammatory disease subgroups such as SpA or RA. Lower HBsAg and HBcAb seroprevalence in SLE patients compared to normal population and also to other inflammatory diseases (SpA and RA), maybe due to specific protective mechanisms in SLE pathogenesis (like the association of familial mediterranean fever and persistence). This mechanism can be explained with the high interferon levels in SLE patients. To properly understand these mechanisms we need more prospective and molecular studies.

**PERIPHERAL PLATELET-GENERATING MEGAKARYOCYTE REDUCED IN PRIMARY SJÖGREN’S SYNDROME**

**Keywords:** Sjögren syndrome

J. W. Hao1,2, Y. Qiao1,2, J. Y. Chen1,2, J. Qiao1,2, S. X. Zhang1,2, X. Li1,2, C. Wang1,2, 1Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China

**Background:** Primary Sjögren’s Syndrome (pSS) is a complex and heterogeneous systemic autoimmune disease characterized by dysfunction of the salivary and lacrimal glands following chronic inflammation of lymphocytic infiltration. 1 Megakaryocytes (MKs), the precursor cells responsible for platelet production, act across the immune continuum. 2 However, the underlying pathogenesis of pSS involving megakaryocytes (MKs) is still to be fully elucidated.

**Objectives:** This study aimed to determine the changes in megakaryocyte subsets in pSS patients and to explore the role of different subsets in the pathogenesis of pSS.

**Methods:** The scRNA-seq dataset of five patients with pSS and five HCs were obtained from the GEO database to identify megakaryocytes (MKs) among PBMCs and further define the subpopulations. Then, cellular identity was determined by identifying the DEGs for each cluster using the Wilcoxon rank-sum test with the FindAllMarkers function and comparing the markers to known cell-type-specific genes from previous datasets. Finally, to investigate the hierarchy and developmental relationship between MK subpopulations, the monocle3 analysis was used to reconstruct pseudotime trajectories.

**Results:** First, four putative subpopulations (MK1-MK4) of MKs were identified by sub-clustering (Figure 1A). MK3 referred to as platelet-generating MKs, expressed key genes involved in hemostasis, cell-extracellular matrix interactions and so on. (Figure 1B) MK2 shared the same marker as MK3, but exhibited lower expression, which means MK2 may be an early stage of MK3, known as proplatelet-generating MKs. Then, compared with other MKs, MK2 and MK3 had the highest platelet activation-related and platelet aggregation-related pathways scores generated by ssGSEA (Figure 1F). Remarkably, the inflammatory response subpopulation (MK4), consisting of MKs expressing LSP11 and CDS3 at high levels, was enriched in Immune system development and T-cell activation (Figure 1D). And, the proportion of the MK1, MK2, and MK4 subpopulations increased and that of the MK3 subpopulation was reduced in patients with pSS vs. HCs (Figure 1C), indicating the impaired maturation of platelet-generating MKs in pSS patients. Finally, with the trajectory analysis, we inferred that MK4 could exist independently of other MK subpopulations, and MK1 may characterize the point of initiation of a developmental trajectory (Figure 1E).

**Conclusion:** In summary, we have presented evidence for the reduction of peripheral platelet-generating MKs in patients with pSS, and identified changes in platelet-generating MKs via scRNA-seq analyses. The findings provide clues to the impaired maturation of platelet-generating MKs in the pathogenesis of pSS.

FOLLOW-UP FREQUENCY IN PATIENTS WITH SLE, ‘ONE SIZE DOES NOT FIT ALL’

Keywords: Systemic lupus erythematosus, Health services research, Real-world evidence

S. Snoeck Henkemans1, A. Berden2, G. Waverijn3, I. Verberk-Jonkers4, M. Kok5, E. Zirkzee2. 1Erasmus MC, Rheumatology, Rotterdam, Netherlands; 2Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; 3Maasstad Hospital, Business Intelligence, Rotterdam, Netherlands; 4Maasstad Hospital, Internal Medicine, Rotterdam, Netherlands

Background: The recommended frequency of follow-up for SLE patients ranges from monthly to yearly, although once every 3 months seems common practice. Recommendations are based on expert opinion; data on frequency of follow-up in SLE patients and its impact are very scarce. (1,2,3)

Objectives: To assess the frequency of follow-up visits in SLE patients and its relation to clinical and sociodemographic characteristics.

Methods: Patients with SLE based on the ’97 ACR criteria (4), who were treated at our regional teaching hospital between 2012 and 2021, were included in the study. Frequency of follow-up was defined by the frequency at which blood tests (Hb as a key indicator) were performed for disease assessment. This frequency was related to clinical characteristics. Kruskal–Wallis and Fisher’s exact test were performed.

Results: 238 SLE patients were included in the cohort; 117 patients (49%) had follow-up at an average of three months (interval 60-120 days), 59 patients (25%) had follow-up at a low intensity (interval >120), and 62 (26%) at a high intensity (interval <60 days). Characteristics of these groups are shown in Table 1. The patients with high intensity follow-up were younger, more often non-white and had more severe disease at diagnosis. Upon evaluation, these patients had a more severe disease course as demonstrated by more treatment intensifications, hospitalizations, ER visits, a higher SLICC damage index and more frequent renal involvement. Conversely, the patients that were monitored at a low intensity were older had longer disease duration and showed a more quiescent disease with less negative health outcomes. Figure 1 shows the linear relationship between the frequency of tests and the number of abnormal results in Hb.

Conclusion: This study shows that the frequency of follow-up varies substantially between SLE patients. A majority of patients had follow-up at a frequency of 3 months, patients that differed from this norm had distinct features. At this moment frequency of follow-up depends on clinical judgment of the physician. Potentially, this process might be captured in prognostic modelling. Patients at high risk should be identified and have a high frequency of follow-up, while in other patients resources could be spared.

COMORBIDITIES IN PRIMARY SJÖGREN’S SYNDROME: A CROSS-SECTIONAL STUDY

Keywords: Comorbidities, Sjögren syndrome

J. Mousse1, D. Dghiehm2, R. Faddoul2, M. J. Okais3, F. Fayad3, "Université Saint Joseph - Campus des Sciences Médicales, Université, Beirut, Lebanon; 2Hôpital-Dieu de France, Rheumatology, Bayrut, Lebanon; 3Saint Joseph University of Beirut, Statistics, Bayrut, Lebanon

Background: Patients suffering from autoimmune diseases have a higher risk of developing comorbidities compared to the general population. The screening of these comorbidities is important, for it affects the patient’s quality of life as well as the physician’s therapeutic decisions. The epidemiological data concerning the comorbidities associated with the primary Sjögren syndrome pSS are heterogeneous, and to our knowledge, no such study exists on the scale of the Lebanese population.

Objectives: The aim of this study is to expand the knowledge around the comorbidities associated with the pSS, in a cohort of Lebanese patients. This goal is achieved by analyzing the frequency of these comorbidities and their association with the patients’ biological profile.

Methods: It’s a cross-sectional study conducted on a population of 61 Lebanese patients, followed in a rheumatology clinic inside of Hôtel Dieu de France University Hospital in Beirut. The mean age of this population is 54 years, and 60 out of 61 participants are women. All of these patients meet the pSS classification criteria of the American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR), established in 2016. On the one hand, the prevalence of each comorbidity is calculated, and on the other hand, the association between the patient’s biological profile and the existing comorbidities has been analyzed.

Results: The most common comorbidities are: dyslipidemia (34.34%, 95% CI 23%-46%), hypertension (32.79%, 95% CI 21%-45%), obesity (26.23%, 95% CI 15%-37%), and hypothyroidism (18.03%, 95% CI 8%-28%). A significant correlation exists between hypocomplementemia (C3 and/or C4) and diabetes (p-value = 0.0026), as well as between hypocomplementemia and hypothyroidism (p-value = 0.0254). Another significant correlation is noted between the presence of the rheumatoid factor and each of the following comorbidities: dysplasia (p-value = 0.0005), diabetes (p-value = 0.0026), hypertension (p-value = 0.005), and hypothyroidism (p-value = 0.0037).

Conclusion: The Lebanese patients followed for pSS in our cohort form a population who is at risk of developing a metabolic syndrome alongside a thyroid disorder. In the light of these findings, these patients should benefit from a close cardiovascular risk factors and thyroid dysfunction screening and management, especially those presenting a particular biological profile like the presence of hypocomplementemia or the positivity of the rheumatoid factor.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2023-eular.1682
Background: Musculoskeletal inflammation is a frequent and debilitating feature of Systemic Lupus Erythematosus (SLE) that can involve all components of the joint, including extra-synovial sites such as the enthesis. In previous reports, enthesis could be clearly demonstrated by musculoskeletal ultrasound (US) in small cohorts of patients with SLE. However, SLE-enthesitis remains frequently overlooked and its prevalence in real-life cohorts as well as its clinical significance for disease classification and therapy remain to be determined.

Objectives: To assess the prevalence of US-confirmed enthesis in a monocentric cohort of patients with SLE and to analyze the clinical associations to enthesis during the course of disease.

Methods: Ultrasound examinations of SLE patients presenting with tender and/or swollen joints at the Lupus Unit of the Careggi University Hospital in Florence (Italy) were retrospectively analyzed to assess the presence of enthesitis. Only patients with US-proven enthesis were compared with SLE controls who showed no US-evidence of enthesis. Clinical features and therapies were compared between the two groups at disease onset and throughout follow-up.

Results: We assessed 400 patients fulfilling EULAR/ACR classification criteria for SLE. In 106 of them, an US examination of the joints was performed. Evidence of enthesis was found in 31/106 (29.2%) patients. Four participants were excluded due to lack of follow-up data. The remaining 71 patients without US-enthesitis were included as control group (Figure 1). At disease onset, all clinical features were comparable between enthesis cases and controls. Clinical manifestations and therapy from disease onset to the last available follow-up are reported in Table 1. The median follow-up was of 10.0 (IQR 8.3-23.3) years for cases and 12.4 (IQR 7.2-13.3) years for controls. Patients with enthesis were less likely to develop renal involvement (22.6% vs 46.5%, p<0.05), had more arthritis (100.0% vs 81.7%, p=0.01) and failed B-cell depleting therapies more frequently (75.0% vs 0%).

Conclusion: In SLE patients with tender or swollen joints, enthesis is a fairly common finding. Enthesis in SLE could be the hallmark of a distinct disease subset with less frequent renal involvement, more arthritis, and poor response to B-cell depletion, potentially requiring alternative treatments.

AB0688 BENEFITS OF ANA SCREENING FOR NPSLE IN PATIENTS ADMITTED TO THE DEPARTMENT OF PSYCHIATRY

**Keywords:** Systemic lupus erythematosus, Diagnostic tests, Autoantibodies

Y. J. Lee1, S. M. Ahn1, S. Hong1, J. S. Oh2, C. K. Lee1, B. Yoo1, Y. G. Kim1, 1Asian Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Asian Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)

Background: Neuropsychiatric systemic lupus erythematosus (NPSLE) presenting with mood disorder, headache, psychosis, and cognitive impairment appears within 1 year of SLE diagnosis in more than half of cases (1, 2). Most studies have focused on the epidemiology of neuropsychiatric manifestations in patients with established SLE (3). Therefore, diagnosing NPSLE in patients who have visited the hospital with psychiatric symptoms is challenging. Although some studies have conducted anti-nuclear antibody (ANA) screening in psychiatric patients, none have occurred in an Asian population (4, 5).

Objectives: We aimed to determine the benefits of ANA screening for NPSLE in patients admitted to the department of psychiatry in Korea.

Methods: We investigated patients admitted to the department of psychiatry who underwent ANA testing between January 2015 and December 2021 at a single tertiary center in Korea. Patients diagnosed with SLE before admission were excluded from this study. Electronic medical records, including ANA titer, extractable nuclear antigen (ENA), complement, brain magnetic resonance imaging, electroencephalogram, and cerebrospinal fluid analysis, were reviewed retrospectively. Diagnosis at psychiatric hospitalization was classified according to the International Classification of Diseases (ICD)-10.

Results: Throughout the study period, 2523 patients were hospitalized, 1355 of whom underwent ANA testing. Three patients with SLE were excluded. The median age of all patients was 40 (27–58), and 897 (66.2%) were female. Of the 1355 patients, 96 (7.1%) were positive with a titer of ≥1:80, and 61 (4.5%) were positive with a titer of ≥1:160. Among the 17 patients who underwent ENA testing, 1 was positive for anti-Ro and anti-La, eventually diagnosed with Sjögren's syndrome. According to the diagnostic classification of admission, there was no significant difference in the ANA positivity rate (p=0.205).

Conclusion: There was no difference in the positivity rate of ANA in the general population when testing was performed for screening purposes on patients admitted to the psychiatric department. Additionally, none of the 1355 patients were diagnosed with NPSLE after undergoing ANA screening. Thus, the benefits of performing routine screening appear to be limited.

AB0669  CUTANEOUS LUPUS ERYTHEMATOSUS OVER THE COVID MAJOR PANDEMIC PERIOD, INCIDENCE AND CLINICAL CHARACTERISTICS

Keywords: Systemic lupus erythematosus, COVID

M. Ferrario1, P. Congiglio1, C. Bonini1, S. Ferrigno1, M. Teoli2, C. Pagani2, V. Maffe2, M. Galluzzo3, M. Talamonti3, A. Bergamini3, M. S. Chimenti3

1Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy; 2Porphyria and Rare Diseases Unit, San Gallicano Dermatological Institute - IRCCS, Rome, Italy; 3Dermatology Unit, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy

Background: Cutaneous Lupus Erythematosus (CLE) is a chronic inflammatory autoimmune disease with a broad spectrum of clinical manifestations and a variable course, often induced by exogenous factors. CLE is classified in specific and non-specific manifestations with the former divided in acute cutaneous LE (ACLE), subacute cutaneous LE (SCLE), chronic cutaneous LE (CCLE) and intermittent cutaneous LE (ICLE).

Objectives: To assess clinical features of CLE patients over the major pandemic period and its impact on disease characteristics.

Methods: Multi-center retrospective study conducted on consecutive CLE outpatients referring to the Rheumatology and Dermatology Units of Tor Vergata Hospital and San Gallicano Institute (Rome, Italy). Inclusion criteria: diagnosis of CLE, age ≥ 18 years, and 4 years continuous follow-up from Mar 2018. Data from every visit performed between Mar '18 - Feb '22 were registered for each patient, including: number of visits performed/skipped, demographics, therapy and clinical characteristics.

Results: 80 patients were enrolled, 65 females, aged 55.2±14.3 with a disease duration of 32.1±19.8 (Tab 1). In the 1st period 398 visits were performed while only 180 resulted in 2nd with a number of visits/patient/year of 1.9 vs 1.1. Skipped and telemedicine visits amounted to 11 and 1 in the 1st period to 31 and 21 in 2nd period respectively.

Statistical significant differences emerged in number of documented cutaneous flares: 28 (8.8%) in the 1st period vs 42 (23.3%) in 2nd (p=0.03). A higher incidence in the 2nd period of ACLE (15% vs 30%, p<0.01), cutaneous calcinosis (0% vs 10%, p<0.01) and livedo reticularis (10% vs 12%, p=0.03) and a lower incidence of CCLE (13% vs 2.5% (p=0.02) were observed compared to the 1st pre-pandemic period.

Although mean SLEDAI-2K resulted significantly lower in the 2nd period (2.67 vs 2.13, p=0.02) compared to the 1st one, SLEDAI-2K score related to skin was higher in the 2nd period compared to the 1st (0.8 vs 1.1 (p=0.04). A significant reduction in the percentage of patients treated with topical therapy was registered in 2nd period (p=0.008) while other medications remained stable.

AB0670  MYOSITIS IN PRIMARY SJÖGREN’S SYNDROME: DATA FROM A MULTICENTRE COHORT

Keywords: Sjögren syndrome, Epidemiology, Myositis

K. Chandw1, S. Pandya2, K. N. Thomas1, P. Srivastava3, A. Wakhlu4, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India; 2Vedanta Institute of Medical Science, Clinical Immunology and Rheumatology, Ahmedabad, India; 3Star Clinics, Clinical Immunology and Rheumatology, Ahmedabad, India; 4Apollo Speciality Hospitals, Clinical Immunology and Rheumatology, Lucknow, India

Background: Primary Sjögren’s syndrome (pSS) is a multisystem autoimmune disease characterised by lymphocytic infiltration of the exocrine glands and their resultant dysfunction. Muscle involvement has been given the highest weightage in the ESSDAI score.

Objectives: The aim of this study was to describe the prevalence of myositis in a multicentre Indian pSS cohort and to address the clinical manifestations and therapeutic strategies.

Methods: Clinical and serological data from a pSS cohort of patients were retrospectively collected and analysed. Those fulfilling the ACR/EULAR 2017 criteria for myositis and the ACR/EULAR 2012 Criteria for pSS were included. Patients with overlap features of other autoimmune rheumatic diseases were excluded.

Results: 12 (2.7%) out of 444 patients of pSS had Myositis. The mean age was 36.8±12.16 years, and the mean duration of follow-up was 5.46±5.23 years. All patients were females with a high prevalence of ANA positivity and Ro52, and Ro60 in these patients. Myositis was the presenting manifestation in 11/12 patients. Arthritis/Arthralgia (8/86%), Giandular enlargement/ Parotitis (7/58%), Lung involvement (ILD) (5/41%), and Haematological abnormalities were also common in patients with myositis and primary Sjögren’s syndrome. The 5-year survival was good, with 11/12 patients completing the 5-year follow-up. About a half patients received pulse methylprednisolone therapy followed by 1mg/kg steroid, with few patients requiring lower doses of steroids. Methotrexate was the steroid sparing drug of choice for patients with pSS myositis without lung

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2023-eular.3609
involvement and Cyclophosphamide in patients with lung involvement followed by Azathioprine or Rituximab maintenance, one patient was induced and maintained with low dose rituximab. Details of second-line therapy was not available for all patients. The mean ESSDAI and ESSPRI scores were high. None of our patients had Sjogren’s syndrome and the proportion of patients with lung involvement in pSS myositis was much higher than is usually seen in patients with pSS and should prompt the clinician to look for clinical/subclinical lung involvement in pSS myositis patients. The response to therapy was usually good. Unlike other cohorts, we didn’t find any IBM in our set of patients – this may be due to referral bias or the rarity of IBM in the Indian population.

Conclusion: pSS patients with myositis had a younger age of onset with active disease and high ESSDAI and ESSPRI scores. Myositis was the presenting manifestation in most, the proportion of patients with lung involvement in pSS myositis was much higher than is usually seen in patients with pSS and should prompt the clinician to look for clinical/subclinical lung involvement in pSS myositis patients. The Response to therapy was usually good. Unlike other cohorts, we didn’t find any IBM in our set of patients – this may be due to referral bias or the rarity of IBM in the Indian population.

DOI: 10.1136/annrheumdis-2023-eular.4287
Background: Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) is considered one of the preeminent diagnostic and therapeutic challenges for the rheumatologist, not only due to the wide clinical heterogeneity but also because of the lack of specific diagnostic tools and biomarkers. Macrophage migration inhibitory factor (MIF) is a pleiotropic inflammatory cytokine associated with inflammatory neuropathy and neuropathic pain. This protein acts as an innate immunity modulator by promoting host inflammatory responses through induction of pro-inflammatory cytokines (including TNF and IL-6), regulating cellular processes such as T-cell proliferation, apoptosis and counter regulation of the immunosuppressive actions of glucocorticoids.

Objectives: In the present study we aimed at evaluating the serum titers of MIF in SLE patients with painful disturbances, screened for neuropathic pain through a specific questionnaire (Douleur Neuropathique en Quatre Questions-DN4). Subjects were enrolled in the presence of bilateral limb pain and one of the following: hypoaesthesia at touch or prick; pain caused or increased by brushing; tingling, numbness and itching; electric shocks, painful cold or burning pain. We excluded SLE patients with other possible explanation for neuropathic pain including diabetes, Sjögren’s syndrome and kidney impairment (eGFR <30 ml/min). For each patient the following data were collected: demographics, medical history (focusing particularly on other NPSLE manifestations), treatments, disease activity (SLEDAI-2K) chronic damage (SLICC damage index), clinical and laboratory main disease data. Each patient enrolled underwent different tools specific for neuropathic pain (DN4, Neuropathic Pain Symptoms Inventory Questionnaire, Composite Autonomic Symptom Score-31 and Small Fiber Neuropathy-Symptoms Inventory Questionnaire). A concomitant fibromyalgia (FM) was evaluated by different tools including FIRST, FibroDetect and ACR 2016 criteria. MIF levels were determined by ELISA, following manufacturer’s instructions in SLE patients and 38 HC matched for age and gender (Quantikine ELISA, Human MIF Immunoassay, Catalog Number DMP008-R&D Systems).

Results: We excluded 58 subjects because of confounding factors and 29 declined the study. Therefore we enrolled 34 patients (M/F 2/32, median age 50.5 years, IQR 21.0; median disease duration 150.0 months, IQR 190.5; median SLEDAI-2K 0; IQR 2 and median SDI 1, IQR 2). MIF levels were not different between SLE and HC, median 42.8 ng/ml (IQR 49.3) and 38.3 ng/ml (IQR 46.4), respectively. FM was identified in 79.4% of SLE patients according to ACR criteria. Neuropathic pain was diagnosed according DN4 (>3) in 58.8% of SLE patients as a group had higher levels of 25(OH) vitamin D than the controls (64.2 nmol/L vs 59.4 nmol/L respectively, p<0.0021). Among SLE patients using vitamin D supplementation, those on corticosteroids had lower serum levels of 25(OH) vitamin D; this difference was not present in the supplementation naïve group. (p=0.02; p=0.69 respectively). In the SLE and control groups, not taking supplementation, serum 25(OH) vitamin D levels did not differ according to menopausal status (p=0.22). Nephritis status (ever yes/no) did not affect 25(OH) vitamin D levels. Patients taking corticosteroids had lower serum vitamin D levels (p<0.037 , Figure 1).

Conclusion: This study suggests that MIF could be a potential biomarker in NPSLE patients, however further studies are warranted to confirm this preliminary result.

Discriminating variables: MIF, Smoking ever, Disease duration, Disease severity, Corticosteroid treatment

Figure 1. MIF serum titers in NPSLE patients compared with patients without neuropsychiatric involvement. Legend: MIF: Macrophage Migration Inhibitory Factor; NPSLE: Neuropsychiatric Systemic Lupus Erythematosus

* P < 0.05, ** P < 0.01 *** P < 0.001, ª excluding osteoporosis items, not significant; ni, not included in the model; R², coefficient of determination; Std B, standardized regression coefficient; BMD, bone mineral density.
supplements with higher disease activity (SLEDAI≥4, SLAM≥6) and more damage (SLICC/ACR Damage Index (SDI)≥1) had lower serum 25(OH) vitamin D levels than those with lower disease activity/damage (p = 0.029, p = 0.045, p = 0.002). Prenomenopausal SLE patients had higher T-scores than the postmenopausal in all measured locations (lumbar spine p = 0.0002, femoral neck p < 0.0001, total hip p < 0.0001). Neither T-scores in the whole group, nor Z-scores in the group <40 years were correlated to serum 25(OH) vitamin D levels (p = 0.05 in all locations). Variables affecting body mass index (BMI) were presented in Table 1, stratified for menopausal status.

Conclusion: Serum 25(OH) vitamin D levels are affected mainly by supplements, corticosteroid treatment, and organ damage in SLE patients. We found no correlation between serum 25(OH) vitamin D levels and BMI. Low BMI was in multivariable analyses associated with low BMI, older age, smoking, longer disease duration, and higher damage.

Background: Anticentromere antibodies (ACA) have been reported in primary Sjögren syndrome (pSS) at lower frequencies but have recently been suggested to be clinically important in this disease. Although several papers have been published on ACA-positive pSS, the results have been conflicting. Differences in patients and SLE related factors, complications, treatment and other comorbidities.

Conclusion: The prevalence of ACA in our pSS cohort was 13%. ACA-positive patients were older, had more frequent RP and digital ulcers. In our cohort, ACA - positivity had little impact on the severity of extraglandular manifestations in pSS patients. Although there were no significant differences, use of vasodilators and immunosuppressants agents was more common. This study is the first to investigate the impact of ACA positivity on the vascular manifestations of Romanian pSS patients.

Bojic1,2, D. P. Predeteanu1,2, F. B. Bergea1,2, V. V. Vlădi1,2, I. Saulescu1,2, S. D. Dială-Iliescu1, D. M. Maziul1,2, A. A. Borangiu1,2, C. C. Coblianschi1,2, M. M. Negru1,2, C. L. C. Constantinescu1,2, D. M. Mardale1,2, M. Duna1, M. A. Abobului1,2, R. Ionescu1,2, A. Balanescu1,2. St Mary Hospital; Internal Medicine and Rheumatology; Bucharest, Romania; Carol Davila University of Medicine and Pharmacy; Internal Medicine and Rheumatology; Bucharest, Romania

Background: Anticentromere antibodies (ACA) have been reported in primary Sjögren syndrome (pSS) at lower frequencies but have recently been suggested to be clinically important in this disease. Although several papers have been published on ACA-positive pSS, the results have been conflicting.

Objectives: To evaluate the correlation between presence of ACA and associated symptomatology, especially related to microvascular dysfunction in a Romanian cohort of patients with ACA-positive pSS.

Methods: We assessed 132 patients who met the 2016 American College of Rheumatology/European League Against Rheumatism classification criteria for pSS. For all ACA+ patients, we collected data on the presence of ACA+ pSS patients were older than the ACA-negative patients (median, 59 years [IQR, 45 to 60]; p = 0.042), with a shorter disease duration (53 months vs 260 months, p=0.073). Most patients were female (98.7%) and had ocular and oral symptoms of dryness (98.1% and 97.8%, respectively). Among the patients with pSS, 5 patients had ACA and limited cutaneous systemic sclerosis (lcSSc). Although there was no significant correlation between the two groups, ACA-positive patients were characterized by higher frequency of associated symptomatology related to microvascular dysfunction: RP (Raynaud’s phenomenon) and telangiectasia, esophageal involvement, interstitial lung disease, digital ulcerations/ pitting scars, pulmonary hypertension and nailfold capillaroscopy findings.

Results: The prevalence of ACA in our pSS cohort was 13%. ACA-positive pSS patients were older than the ACA-negative patients (median, 59 years [IQR, 48 to 62] vs median, 50 years [IQR, 45 to 60]; p = 0.042), with a shorter disease duration (53 months vs 260 months, p=0.073). Most patients were female (98.7%) and had ocular and oral symptoms of dryness (98.1% and 97.8%, respectively). Among the patients with pSS, 5 patients had ACA and limited cutaneous systemic sclerosis (lcSSc). Although there was no significant correlation between the two groups, ACA-positive patients were characterized by higher frequency of associated symptomatology related to microvascular dysfunction: RP (Raynaud’s phenomenon) and telangiectasia were present in 50% of the patients (5/10), scleodactyly and digital ulcerations (DUs) in 33% (3/10); digital gangrene was not found. 60% (6/10) of ACA+ pSS patients had abnormal findings on nailfold capillaroscopy, which were nonspecific in 2 patients (crossed capillaries), while in the remaining 1 patient had an early-pattern, 1 had an active-pattern and 2 patients had late scleroderma-pattern. The presence of ACA was positively correlated with the presence of RP (p = 0.024). DUs (p = 0.034). In our study, patients showed similar severities in extraglandular manifestations compared to the ACA-negative group. Nonetheless, we noticed that even if not statistically significant, the use of vasodilators was more common in the ACA-positive pSS patients (66.7% vs 12.2%, p = 0.911) thus supporting the hypothesis of a symptomatic microvascular dysfunction. A higher proportion of ACA+ pSS (64% vs 42%) was treated with immunosuppressive agents. No differences in mortality were found between the groups.

Conclusion: Patients in the ACA-positive group were older, had more frequent RP and digital ulcers. In our cohort, ACA - positivity had little impact on the severity of extraglandular manifestations in pSS patients. Although there were no significant differences, use of vasodilators and immunosuppressants agents was more common. This study is the first to investigate the impact of ACA positivity on the vascular manifestations of Romanian pSS patients.

AB0675 AVASCULAR NECROSIS IN A COHORT OF SLE PATIENTS IN AN AFRICAN CONTEXT?

Keywords: Pain, Systemic lupus erythematosus

S. N. Thalhalimshai1, R. Du Toit2, F. Moosajee2, S. Vlok3,4, J. Tygerberg Hospital, Rheumatology, Cape Town, South Africa; J. Tygerberg Hospital, Rheumatology, Cape Town, South Africa; Cape Town, Radiology, Cape Town, South Africa; Tygerberg Hospital, Radiology, Cape Town, South Africa

Background: There is lack of recent data in South Africa describing the burden of AVN among SLE patients. Joint replacement in South Africa remains a challenge with more than 500 days of delay in some cases hence identification of potential clinical associations for AVN development among SLE patients is an important undertaking for prevention, early detection and treatment.

OBJECTIVES: 1.To determine the current prevalence of AVN among SLE patients at Tygerberg Hospital. 2.To determine associations between the development of AVN in SLE patients and SLE related factors, complications, treatment and other comorbidities. 3.To assess the outcomes of AVN in SLE patients.

Methods: This was a retrospective case-control study. All SLE patients (N=755) seen at Tygerberg Hospital, Rheumatology Clinic over a 8 years period (2013 – 2020) were screened for inclusion. The inclusion criteria consisted of patients of age 18 years and a known diagnosis of SLE using the 2019 EULAR/ACR classification criteria, and a radiological diagnosis of AVN. The clinical data, radiological data and blood investigation data were collected for analysis. The radiological data (x-rays, MRI and CT scans) were reviewed by a radiologist for the diagnosis and grading of AVN using the Ficat and Ariet method.

Results: The prevalence of AVN among the SLE population at Tygerberg Hospital was 3.4%. The median SLEDAI-2K score 6 months prior to the radiological diagnosis of AVN (p = 0.001) and the SDI (p < 0.001) scores were individually found to be statistically significant between the two groups. The MRI Ficat and Ariet grading (p=0.013) was found to be more advanced when compared with x-ray grading of the same joints, although done at different points in time with a median delay of 2 months (IQR:1-5). Only 26.3% of affected joints underwent a joint replacement with a median delay of 23 months (IQR:13-52).

Conclusion: The prevalence of AVN among SLE patients at Tygerberg Hospital is slightly lower than the international and the previously reported local data. High SLEDAI-2K and SDI scores were associated with AVN development in SLE. The delay in the acquisition of MRI scan for AVN diagnosis and grading, and that of joint replacement remain as significant challenges that require special attention in the state healthcare sector.

DELAYS IN CARE SEEKING AND DIAGNOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS IMPACT ON DISEASE ACTIVITY AND DAMAGE

Keywords: Systemic lupus erythematosus, Epidemiology, Organ damage

G. Serna-Peña1, D. P. Flores-Gutierrez1, O. E. Alvarez-González1, G. García-Arellano1, J. A. Cardenas-de la Garza1, A. G. Rodriguez Flores1, M. F. Ortiz Nuño1, I. D. J. Hernandez-Galarza1, D. A. Galarza-Delgado1, 1Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that presents with heterogeneous manifestations, some of which can delay access to specialized attention and according to the symptom, also lead to greater damage. (1)

Objectives: Compare initial symptoms/signs and disease damage or activity in patients with SLE with medical attention or diagnostic delays.

Methods: We performed a cross-sectional study in the lupus clinic in Hospital Universitario Dr. José Eleuterio González. Patients over 15 years old with an SLE diagnosis according to the EULAR/ACR 2019 criteria and a disease duration > 1 year were included in this study. Data from current EULAR/ACR 2019 disease classification, SLE Disease Activity Index (SLEDAI), and SLICC Damage Index were collected from patient files. Delay was defined as ≥ 6 months to request medical assistance or disease diagnosis. The timeline studied was divided into time from symptom onset to first medical assessment, and time from first medical assessment to SLE diagnosis. We compared demographics and initial symptoms, SLEDAI, and SDI scores between groups with and without delays.

Results: Fifty-five patients were evaluated, 96.4% were female, mean age at diagnosis was 30.44 years +/- 12.48, and the mean disease duration was 7.25 years. The most frequent symptom in both groups was arthritis/arthralgia, followed by mucocutaneous manifestations (Table 1). Mean time for requesting medical assistance was 483.4 days +/- 959.741 and for diagnosis 91.67 days +/- 194.417. 41.98% had a delay in medical attention, 52.72% had a delay in diagnosis, and 60% (33) of all patients presented some type of delay ≥ 6 months. No statistical difference was found in SLEDAI score (mean of 2.42 +/- 3.699) (p = 0.740) or SLICC score (mean of 0.57 +/- 0.902) (p = 0.587) between groups. In the group with a delay in diagnosis, the patients were older, and in the group without a delay in diagnosis lupus nephritis was more prevalent.

Conclusion: Two out of 3 patients report delay ≥ 6 months in seeking medical assistance and/or a definitive diagnosis, although no statistical difference was found in disease activity or damage scores. Younger age and renal involvement were related to a prompt diagnosis.

Hamza1,5, 1Faculty of Medicine, University of Bahrain, Internal Medicine, Karboum, Sudan; 2Ziyab Research Group, President, Karboum, Sudan; 3Sudan Medical Specialization Board, Internal Medicine, Karboum, Sudan; 4Faculty of Medicine and Health Sciences, Omdumman Islamic University, Internal Medicine, Karboum, Sudan; 5Ziyab Research Group, Financial Office, Karboum, Sudan

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease with high heterogeneity. SLEDAI is the standardized method to determine disease activity, neutrophils to lymphocytes ratio emerge as new method to detect disease activity. The study aim is to study the neutrophil-to-lymphocyte ratio as a marker of active disease in SLE patients.

Objectives: This study aimed to assess cut off point of neutrophil-to-lymphocyte ratio as a marker of disease activity in systemic lupus erythematosus.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2023-eular.425
Methods: A cross sectional study was conducted in Haj Al-Safi hospital. A 53 patients were studied using pretested questionnaire, a SLEDAI assessment was conducted to each patient's individually. NLR were measured from CBC at the time of the study. Inclusion criteria were: people aged 18 or older, SLE patient diagnosed and confirmed by new 2019 criteria, and exclude any patients with infections, malignancies, and other inflammatory diseases recorded in registry. Data were collected and analyzed using SPSS.

Results: The mean age of patients was (± SD) 39.85 (± 14.07), SLEDAI score assessment was conducted for the patients, 48 (90.6 %) scored > 4 and were considered active disease according to the score, 5 (9.4 %) scored <4 and were inactive. The NLR was calculated and the mean was 2.9 (± 2.08). Receiver Operating Characteristic (ROC) was conducted, cut-off (COV) was 2.48. Area Under Curve (AUC) and was AUC=0.402 (95% CI: 0.232 to 0.572. (p=0.475). The sensitivity was 47%, and the specificity 51%.

Conclusion: This findings indicated that the Neutrophil-to-lymphocyte ratio, with a cut-off value (COV) of 2.48, could be utilized to identify the disease activity of systemic lupus erythematosus. Furthermore, by applying this NLR COV.

AB0678 INTERLEUKIN-18 AS A PREDICTOR OF SUBCLINICAL CARDIOVASCULAR AFFECTION AND DISEASE ACTIVITY IN SYSTEMIC LUPUS PATIENTS

Keywords: Biomarkers, Systemic lupus erythematosus

S. A. A. Tabra1, M. H. Abu-Zaid1, D. Maria2, R. Elsharaby2, 1Tanta University Faculty of Medicine, Rheumatology and Rehabilitation, Tanta, Egypt; 2Tanta University Faculty of Medicine, Cardiology, Tanta, Egypt; 3Tanta University Faculty of Medicine, Clinical Pathology, Tanta, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease which has variable clinical manifestations and causes severe organ damage (1). Interleukin-18 (IL-18) is a pro-inflammatory cytokine which plays a key role in many inflammatory and cardiovascular diseases (2). 

Methods: Evaluation of plasma level of IL-18 in SLE patients and correlate it with the subclinical cardiovascular affection and disease activity.

Methods: Thirty lupus patients (G I), and 30 healthy age and sex matched volunteers as control group (G II) were recruited for this case control study. All participants were subjected to complete history taking and clinical assessment, lupus disease activity was measure using SLE disease activity index 2000 (SLEDAI-2K), Serum IL-18 level, CRP, C3, C4, anti dsDNA, and lipid profiles were measured. Cardiovascular assessments were done using echocardiography, flow mediated dilatation of the brachial artery (FMD), and carotid intima-media thickness (cIMT). Plasma levels of IL-18 were measured and correlated with different parameters.

Results: There were no significant differences between the patients and controls regarding demographic data (P>0.05). The mean SLEDAI-2K was 3.5±2.1. The mean plasma level of IL-18 was 432.85±165.37 pg/ml in lupus patients, while IL-18 was 195.65±82.91 pg/ml in healthy volunteers, there was significant elevation of IL-18 level in lupus patients in comparison with controls. There were significantly lowering levels of C3, & C4 in lupus patients. Regarding cardiovascular assessment: SLE patients showed significantly higher lipid profile, & cIMT measures and revealed lower FMD as well as detecting echocardiographic abnormalities compared to controls. (These date were summmarized in Table 1).

Serum IL-18 was positively correlated with cIMT and SLEDAI-2K, also IL-18 was negatively correlated with FMD, C3 & C4.

Conclusion: IL-18 was an independent predictor of cardiovascular events in SLE patients, also it was correlated with lupus activity.

AB0679 OPHTHALMOLOGICAL FINDINGS BY STRUCTURAL SPECTRAL DOMAIN OPTICAL COHERENCE TOMOGRAPHY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Autoantibodies, Descriptive studies, Systemic lupus erythematosus

M. E. Ventura Valenzuela1, V. González Díaz1, G. Martínez-Bonilla1, A. G. Bernard Medina1, J. F. Uribe Martínez1, C. A. Rosal Arteaga1, S. Perez-Totpe1, J. Salazar García1, S. Sánchez Sánchez2, S. Cerpa-Cruz3

Background: Systemic Lupus Erythematosus represents the prototype of autoimmune systemic disease, its etiology involves aberrant interactions between genetic, immunological and environmental factors, affecting multiple organs and systems; about a third of patients present ocular alterations, with a variable degree of severity from mild clinical manifestations involving external and anterior ocular segments, to severe sight-threatening disease involving posterior eye segments.

Objectives: Describe and correlate ocular and clinical findings, as well as the positivity of autoantibodies in patients with Systemic Lupus Erythematosus using structural Spectral-Domain Optical Coherence Tomography (SD-OCT).

Methods: Cross-sectional single-center study, descriptive statistics and correlation analysis were performed using Spearman's test of the ocular findings determined by (SD-OCT) and serological determinations of antiphospholipid autoantibodies, anti-nuclear antibodies, anti-DNAs and anti-Smith antibodies in patients with Lupus during the months of January 2020 to December 2020, performing general ophthalmological examination and structural Spectral-Domain Optical Coherence Tomography.

Results: 29 patients were included, 26 women and 3 men, positive antiphospholipid antibodies in 56% of the population, lupus nephritis was found by renal biopsy in 49% of the population, disease activity was determined by MEX-SLEDAI, finding >9 points in 11 patients and >9 points in 89% of the population. Maculopathy was found in 24% of patients; the correlations between autoantibodies and ophthalmological abnormalities determined by SD-OCT were: Lupus anticoagulant/Maculopathy p=0.008, anti-cardiolipin antibodies/maculopathy p=0.026, anti Smith/choriocapillaritis p=0.014, decreased capillary perfusion/choriocapillaritis p=0.003 and choroiditis p=0.012, decreased perfusion by quadrants/maculopathy p=0.043. A decrease in retinal thickness was found in 65% of the population, also in the density of ganglion and macular cells and in the density of the optic nerve head.

Conclusion: Findings in our study were predominantly choroidal, macular and capillary alterations; a specific serological correlation was found between maculopathy and chorioretinitis with positive Lupus Anticoagulant, as well as alterations in capillary perfusion in patients with positive antiphospholipid and anti-Smith antibodies. The use of SD-OCT can provide valuable and early information on the ocular microstructure and biological system in SLE and other autoimmune diseases affecting the eyes.

THE EFFECT OF DEPRESSION, ANXIETY, AND FIBROMYALGIA ON SEXUAL DYSFUNCTION IN FEMALE PATIENTS WITH SJÖGREN’S SYNDROME

Keywords: Fibromyalgia, Sjögren syndrome

S. M. Türk1, D. Karataş1, N. Erdek1, G. Yavuzbilge1, A. Karakut1, S. B. Açıkgöz1, Z. Öztürk1, C. Arslanlardı Güneyş1, E. Gönoğull1, Y. Türk2, Sakarya University Hospital, Rheumatology, Sakarya, Turkey; 2Sakarya University Hospital, Internal Medicine, Sakarya, Turkey; 3Adaptap Hospital, Gynecology, Sakarya, Turkey

Background: Sjögren’s Syndrome is a systemic autoimmune disease that mainly affects the exocrine glands. The most common clinical symptoms of Sjögren’s syndrome are dry mouth and eyes. Vaginal dryness and dyspareunia may be seen in the disease, as the female genital mucosa is also affected.

Objectives: To compare the results by using the female sexual function scale in patients with Sjögren’s Syndrome with and without depression, anxiety, and fibromyalgia and to evaluate the patients in terms of sexual dysfunction.

Methods: Twenty-five female patients diagnosed with Sjögren’s Syndrome, according to the 2016 ACR-EULAR criteria, followed in the Internal Medicine, Rheumatology Clinic of Sakarya University Faculty of Medicine, were included in the study after their consent was obtained. Beck Depression Inventory, Beck Anxiety Inventory, and Female Sexual Function Scale were administered simultaneously to the patients. The presence of fibromyalgia was evaluated according to the 2016 Modified ACR diagnostic criteria. The relationship between depression, anxiety scale scores, the presence of fibromyalgia, and female sexual function was investigated.

Results: The mean age of the patients was 49±8.1 years, and the median duration of the disease was four years. 15 (60%) patients were primary school graduates, 2 (8%) patients were secondary school graduates, 4 (16%) patients were high school graduates, and 4 (16%) patients were university graduates. 11 (44%) of the patients were in menopause. Sexual dysfunction was found in 21 (84%) patients diagnosed with Sjögren’s Syndrome. There was no statistically significant difference in sexual function scale scores between those with and without menopause. No statistical difference was found in disease duration, age, and scale scores in the presence of fibromyalgia. Sexual dysfunction was more pronounced in those with depression and anxiety (p<0.003, p=0.045, respectively) (Table 1).

Table 1. Comparison of depression and anxiety and sexual function scale scores

Conclusion: Depression and anxiety cause lower sexual function scores in female patients diagnosed with Sjögren’s syndrome. The effect of fibromyalgia has not been demonstrated, but due to the limited number of patients, studies with a larger population will be more enlightening.

Keywords: Systemic lupus erythematosus, Real-world evidence, Outcome measures

R. Khandker¹, E. Igho-Osagie¹, J. Hetherington², E. Goddard², J. Milligan²

¹Merck & Co. Inc., Center for Observational and Real World Evidence (CORE), North Wales, United States of America; ²Adelphi Real World, Bollington, United Kingdom

Background: Unmet medical need continues to be significant in patients with systemic lupus erythematosus (SLE) despite the use of advanced therapies (AT) to control active disease. Fatigue, end-organ damage, and low health-related quality of life (HRQOL) remain characteristic of the disease even among those treated with AT.

Objectives: In this analysis we measured the burden of unmet medical need in SLE patients prescribed AT for ≥12 months in real-world clinical settings.

Methods: Data were drawn from the Adelphi Real World Lupus Disease Specific Programme™, a cross-sectional survey with elements of retrospective data collection of rheumatologists and their consulting patients with SLE in France, Germany, Italy, Spain, the United Kingdom, and the United States in 2021.

Rheumatologists provided information on patient demographics, clinical status, and treatment history for their next six consulting SLE patients. The same patients completed the EQ-SD-5L, Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-Fatigue), and Work Productivity and Activity Impairment questionnaire (WPAI) instruments. Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) scores were derived through physician assessment of patients’ current clinical manifestations. AT was defined as biologic or off-label Janus kinase inhibitors. All data were analysed descriptively.

Results: The sample included 234 patients seen by 125 physicians. Most patients (85%) were female and the mean participant age was 45.8 (SD:13.2) years. Mean duration since diagnosis was 6.6 (5.3) years and mean duration on their current regimen was 3.3 (3.0) years.

Despite receiving AT for ≥12 months, patients continued to have moderate-high levels of disease activity. Nearly half (48%) had SLEDAI scores ≥ 10 (Mean SLEDAI = 11.4 (11.2)). Many (37%) were assessed by physicians to have moderate/severe disease. Most (62%) continued to receive steroids, with 41% of patients prescribed oral/subcutaneous steroids receiving prednisone or equivalent doses of ≥7.5 mg/day. The majority of patients (56%) were currently experiencing musculoskeletal symptoms including joint tenderness and swelling; while 37% and 19% respectively, were currently experiencing mucocutaneous and renal symptoms.

Mean EQ5D-5L score was 0.70 (0.27). Mean FACIT-Fatigue score was 32.4 (12.4), compared to US general population norm of 43.6 (9.4)¹. Overall work impairment and mean daily activity impairment measured by the WPAI were 27.4% (20.4%) and 34.9% (25.3%) respectively.
SLE, Sjögren’s and APS – clinical aspects (other than treatment)

AB0683 USEFULNESS OF A MONOGRAPHIC CONSULTATION RHEUMATOLOGY - PNEUMOLOGY

Keywords: Lungs, Work-related issues

M. Pavia Pascual1, N. DE LA Torre Rubio1, M. Machattou1, P. Navarro Palomo1, M. Alonso de Francisco2, C. Navarro Joven1, C. Barbadillo Mateos1, C. Merino Arguménez1, M. Fernandez Castro2, B. Garcia-Magallon1, J. Sanz1, L. F. De Villa1, J. Campos Esteban1, J. L. Andreu Sanchez1, H. Godoy1, 1Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Madrid, Spain

Background: Some rheumatological diseases may involve the lungs. This is something that the rheumatologist and pneumologist must take into account in their clinical practice.

Objectives: To describe the characteristics of a group of patients with diffuse interstitial lung disease (ILD) that are being followed-up in a Rheumatology-Pneumology monographic consultation and study the usefulness of this consultation.

Methods: We reviewed the medical records of patients with a diagnosis of ILD that were being studied by both services in a monographic consultation in a tertiary hospital. A descriptive study was performed.

Results: A total of 46 patients were studied: 16 with nonspecific interstitial pneumonia (NSIP), 15 with usual interstitial pneumonia (UIP), 5 with fibrotic NSIP, 2 with cryptogenic organizing pneumonia (COP) and 2 with undefined ILD. 60% were women and the mean age was 64 years (40-80 years). Twenty patients with ILD were referred from pneumology to rheumatology. The primary reason for referral was the determination of positive antibodies (60%). Other reasons were arthritis (15%), other symptoms suggestive of connective tissue disease (15%) or the screening for collagenopathy in patients with poor outcome (10%). Ninety-five percent of patients with ILD referred to rheumatology were diagnosed with a connective tissue disease (Graph 1 and Table 1), which led to a change in treatment in 68.4% of them, with mycophenolate being the most prescribed drug, followed by rituximab. Twelve patients followed up in rheumatology with diagnosis of systemic sclerosis (n=6), rheumatoid arthritis (n=3), Sjögren’s syndrome (n=2) and anti-synthetase syndrome (n=1) were referred to pneumology. The reasons for referral were the appearance of a pattern of interstitial involvement in imaging tests (chest X-ray or CT) and/or the alterations in respiratory function tests requested routinely (in the case of scleroderma) or due to respiratory symptoms (cough, dyspnea or crackles on chest auscultation). Follow-up by the pulmonologist implied a modification in the treatment in 5 out of 12 patients (41.7%) which consisted in the addition of an antifibrotic, Nintedanib in all cases. The reason for initiation was a decline in lung function demonstrated by pulmonary function tests. In 8 patients, the diagnosis of ILD and rheumatologic disease had been made in another center and they were referred for follow-up.

Conclusion: Ninety-five percent of patients with ILD referred to rheumatology were diagnosed with a connective tissue disease, which led to a change in treatment in 68.4% of them, with mycophenolate being the most frequently prescribed drug, followed by rituximab. The diagnosis of ILD in patients with rheumatologic disease was possible thanks to pulmonary auscultation, anaemia on respiratory symptoms and the performance of imaging and functional tests. Referral of these patients to pneumology service allowed a better characterization of their pulmonary disease and the initiation of antifibrotic drugs in those with progressive fibrosing disease.

AB0684 RETROSPECTIVE STUDY ON SENSITIVITY AND SPECIFICITY OF VARIOUS CLASSIFICATION CRITERIA IN EARLY DIAGNOSIS OF SYSTEMIC LUPUS ERYTHEMATOSUS AND LINK TO DISEASE OUTCOMES

Keywords: Outcome measures, Systemic lupus erythematosus, Descriptive studies

M. S. Mohamed Said1, S. Chu Ee1, R. Mustafa1, 1Faculty of Medicine Universiti Kebangsaan Malaysia, Medical, HUKM, Kuala Lumpur, Malaysia

Background: Systemic lupus erythematosus (SLE) is a multisystem inflammatory disease with heterogeneous clinical manifestations, making the diagnosis of disease challenging. To date, study on comparison of sensitivity and specificity of various SLE classification criteria among multiracial Malaysians is limited.

Objectives: To compare the sensitivity and specificity of various SLE classification criteria among multiracial Malaysians.

Methods: A retrospective study on data obtained from medical records of SLE and control cases. The sensitivity and specificity of 1997 American College of Rheumatology (ACR) revised criteria, Boston Weighted (BW) criteria, 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria, and 2019 European League Against Rheumatism (EULAR)/ACR classification criteria was calculated at baseline and at one year follow up. The link of diagnostic criteria to disease outcomes five years after diagnosis [disease damage, cardiovascular (CV) outcomes, and mortality] was studied.

Results: 420 SLE cases and 420 control cases were recruited. At baseline, the sensitivity and specificity of 1997 ACR criteria, BW criteria, 2012 SLICC criteria, and 2019 EULAR/ACR classification criteria were 69.3% and 99.3%, 89.5% and 96.7%, 94% and 97.6%, 96.4% and 96.5%, respectively. At one year follow up, sensitivity and specificity of the1997 ACR criteria, BW criteria, 2012 SLICC criteria, and 2019 EULAR/ACR classification criteria improved to 72.9% and 99.3%, 91.4% and 96.7%, 97.1% and 97.6%, 100% and 96.9%, respectively. There is statistical correlation between the 2019 EULAR/ACR classification criteria and SLICC/ACR damage index (DI), and disease relapses.

Conclusion: 2019 EULAR/ACR classification criteria demonstrated the highest sensitivity to diagnose SLE, with comparable specificity to other diagnostic criteria.

**DESCRIPTIVE STUDY OF A COHORT OF PATIENTS WITH NEUROPSYCHIATRIC MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN A TERTIARY HOSPITAL.**

**Keywords:** Systemic lupus erythematosus

P. J. Gil Velaz1, L. Mendez Diaz1, I. Madroño Garcia1,1. Virgen del Rocio Hospital, Rheumatology, Seville, Spain

**Background:** Systemic lupus erythematosus (SLE) affects 0.1% of the world population and its neurological expressions include, from vascular headache, mood disturbances to cognitive and other severe disorders such as transverse myelitis. It represents a diagnostic challenge, since none of the syndromes is exclusive of SLE and up to 40% is attributed to other causes; specifically it is necessary to rule out central nervous system infection, uremia, thrombotic thrombocytopenic purpura, posterior reversible encephalopathy, steroid psychosis and hypeension.

**Objectives:** To describe the neurological/neuropsychiatric manifestations in patients with systemic lupus erythematosus, diagnostic tests used and therapeutic possibilities in a cohort of patients in a tertiary level hospital.

**Methods:** Retrospective descriptive study of a cohort of patients with neuropsychiatric manifestations in the context of SLE in the Rheumatology Department of the Hospital Universitario Virgen del Rocio Sevilla (2017-2022).

**Results:** 12 patients with neuropsychiatric manifestations were included in our study. 8 (66.6%) women, 4 (33.4%) men, with a mean age of 30 ± 6 years and mean time of diagnosis of systemic lupus erythematosus of 3.5 years. Nine (75%) SLE with joint/cutaneous involvement and 3(25%) SLE with renal involvement (focal proliferative glomerulonephritis and segmental). In 9 (75%) of the cases imaging studies both cranial MRI and PET showed inconclusive lesions and as for specific antibodies: 4 (33.3%) anti-NMDAR, 3 (25%) anti-ribosome P. Among the most frequent clinical manifestations 6 (50%) presented persistent headache, 3 (25%) psychosis, 3 (25%) memory and mood disturbances. 9 (75%) of the cases responded to anti-CO20 (rituximab) and 3 (25%) to intravenous immunoglobulin infusion.

**Conclusion:** The data obtained from the clinical histories were conclusive with current scientific publications. It is an entity whose diagnosis is a challenge for the clinician, and both analytical tests and imaging studies are usually non-specific. The most frequent manifestations are headache, cognitive manifestations and mood alterations (anxiety attacks, panic, euphoria). Further studies are needed to classify the risk of this entity and the relationship with specific neuromoral antiablodies.

**THE NEUTROPHIL-TO-C3 RATIO (NC3R) WAS AN INFLAMMATORY MARKER IN THE ASSESSMENT OF LUPUS NEPHRITIS AND OCULAR VESSEL DENSITY IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS.**

**Keywords:** Biomarkers, Systemic lupus erythematosus, Kidneys

M. Maitiayar1, P. Li1, H. Li, X. Yang1, C. Chen1, J. Zhang3, W. Huang1, Z. Liu1, S. L. Yu2,3.1. The Second Affiliated Hospital of Guangzhou Medical University, Department of Rheumatology, Guangzhou, China; 2. The Second Affiliated Hospital of Guangzhou Medical University, Ophthalmic Center, Guangzhou, China; 3. The Second Affiliated Hospital of Guangzhou Medical University, E.N.T. Department, Guangzhou, China

**Background:** Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE). An increased neutrophil to C3 ratio (NC3R) may reflect LN. NC3R is a promising predictor of LN and ocular involvement in SLE patients.

**Objectives:** To explore the relationship between NC3R and LN patients and ocular vessel density in SLE patients.

**Methods:** This retrospective study included 53 patients with LN and 80 SLE patients without kidney involvement. The differences in NC3R between patients with and without LN were evaluated. Correlations between NC3R and other variables in SLE patients were assessed. Receiver operating characteristic curves (ROC) was constructed in NC3R to predict LN. Multivariate logistic regression analysis was used to analyze the independent factor of LN. We also investigated the impact of NC3R on ocular involvement in SLE patients.

**Results:** NC3R was increased significantly in the LN group as compared with those SLE patients without LN(7.7 vs 4.5, P=0.002). NC3R were positively correlated with 24-hour proteinuria (r=0.437, P<0.001), and negatively correlated with C3(r=-0.346, P<0.001) and C4(r=-0.293, P=0.001). Multiple regression analysis suggested that NC3R was an independent risk factor of LN(OR: 4.41 (1.64~11.91), P=0.003). NC3R [AUC: 0.642, 95%CI (0.540~0.744)] was useful in differentiating LN patients, and the optimal cutoff was 4.56 (sensitivity: 79.6%, specificity: 49.2%). In the high NC3R group patients, there was increased superficial vessel density.

**Conclusion:** NC3R was a plausible indicator to predict LN and ocular involvement. Therefore, evaluating NC3R before treatment could help clinicians to identify potential organ involvement in patients with SLE.

**CHRONIC SCLEROSING SIALADENITIS, IS IT A SJOGREN’S SYNDROME OR NOT?**

**Keywords:** Sjogren syndrome, Epidemiology, Descriptive studies

E. J. Kwok1, 2, B. W. Lee1, Y. Park1, J. J. Lee1, S. H. Park, S. K. Kwok1.1. The Catholic University of Korea Seoul St. Mary’s Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2. The Catholic University of Korea - Songjei Campus, Department of Medicine, Graduate School of Medical Science, Seoul, Korea, Rep. of (South Korea)

**Background:** The Sjogren’s syndrome (SS) is a chronic autoimmune disease. The classification criteria of SS have been evolved through the decades. Recent in 2016, American college of rheumatology (ACR)–European Alliance of Associations for Rheumatology (EULAR) classification requires at least one positive finding in either the labial salivary gland biopsy or anti-Ro (SSA) serology for the confirmation of SS. Chronic sclerosing sialadenitis (CSS) is unusual, under-recognized condition that affects the salivary gland, reported by H. Kutter at first. [1] Though the CSS already has been eliminated from the diagnostic criteria of SS, there is controversy in the meaning of CSS in SS. And that makes it difficult to determine whether the patient who suffers from sicca symptom is SS or not.

**Objectives:** Investigating the clinical meaning of CSS in association with SS by comparing the clinical and laboratory findings, we provide the extent of under-recognized condition that affects the salivary gland, reported by H. Kutter at first.

**Methods:** This study is a single center retrospective study, including patients confirmed as CSS via biopsy in Seoul St. Mary’s Hospital from 2000 to 2022. [1] Patients with history of head and neck radiation, (2) graft-versus-host disease (GVHD), (3) IgG4-RD, (4) positive biopsy result in IgG4 immunohistochemistry
(IHC) staining, and (4) insufficient pathologic result to distinguish IgG4-RD from CSS were excluded. 1 of 27 CSS patients were eligible to our analysis. 4 of positivity with IgG4 in IHC staining positivity, 1 of GVHD, and 1 of prior head and neck radiation were excluded. We assessed 239 patients from 341 of the Korean Initiative of primary SS (KISS) prospective cohort study as SS control group, eligible to 2016 classification.

**Results:** In CSS group, only 1 of 21 was diagnosed as SS. Table 1 summarizes the result. ‘CSS as SS’ consisted of CSS patients meeting 2016 criteria, assuming that the CSS could be a part of SS pathology.

**Table 1.** The clinical characteristics of chronic sclerosing sialadenitis.

**Background:** Quality indicators (QI) for patients with SLE were developed based on the 2019 EULAR recommendations [1]. Measuring quality of care (QOC) may provide recognition of gaps and challenges in clinical practice. Improving QOC may relate to high satisfaction with care. Satisfaction might be considered a valuable indicator to measure the success of provided care. Evidence about the relationship between quality of care and satisfaction perceived by SLE patients is scarce.

**Objectives:** To correlate adherence to QIs based on the 2019 EULAR recommendations and satisfaction with care in SLE patients.

**Methods:** We conducted a cross-sectional and retrospective study in a Lupus Clinic in Northeast Mexico. We included patients at least 18 years old who met the ACR/EULAR 2019 classification criteria for SLE. Consecutive patients were interviewed by the researchers on their last visit to assess the adherence to quality indicators developed by Chavatza et al., based on 2019 EULAR recommendations. Medical records were revised to assess demographic data, disease activity, treatment, organ involvement, and cumulative damage. Adherence was achieved if the patient met all components of the QI. We calculated adherence as the number of fulfilled patients divided by the number of eligible patients per indicator. Satisfaction with care was evaluated with the satisfaction domain of the LupusPRO 1.7 version. The distribution was assessed with Kolmogorov-Smirnov. The Spearman correlation coefficient was obtained to determine the relationship between quality of care and satisfaction with care.

**Results:** Seventy patients were included with a median age of 33 (IQR, 23-48), and 90% were female. Global adherence to the 18-QIs and Satisfaction with Care score revealed no correlation using the Spearman correlation coefficient (r = 0.064, p = 0.599). Overall adherence was 62.29%. The median satisfaction with care was 100. The results of each indicator are shown in Table 1.

**Conclusion:** In conclusion, we did not find a correlation between satisfaction with care and QOC. The areas of quality of care that performed the lowest were the measurement of the SLEDAI-2K and the SLICC/ACR damage index, which was an area of opportunity for improvement.

**REFERENCES:**

Background: Dietary habits and Physical Activity (PA) are two pivotal features of healthy life in terms of the prevention and treatment of metabolic and chronic disease [1]. Few data are available concerning these issues in isolated Sjögren’s syndrome (SS) patients [2].

Objectives: Aim of the study was to assess the level of PA, the adherence to Mediterranean diet (MD) and the nutritional status of Italian patients with SS.

Methods: Consecutive patients with SS (AECG criteria 2002) were enrolled. For each patient ESSDAI, ESSPRI, SSDDI were calculated. The value of focus score was obtained in the minor salivary gland biopsy (MSG), when performed. The International Physical Activity Questionnaire (IPAQ) was administered to assess the level of physical activity; the Mediterranean Diet (MDiet) score [3] was employed to analyse adherence to Mediterranean diet (the More Mediterranean diet the better). BMI was higher in older patients (R 2 0.96, p < 0.02). 16 out of the 26 subjects of the subgroup (61%) showed a reduction in muscle strength (HGT and/or CST) and therefore a condition of probable sarcopenia, a muscle failure that accrue across a lifetime, was identified by a diagnostic algorithm [4] with age-differentiated cut-offs; the Hand Grip test (HGT) and the Chair Stand test (CST) were used as screening tests, the Dual Energy X-ray Absorptiometry (DEXA) was employed to analyse adherence to Mediterranean diet (the More Mediterranean diet the better) and to quantify bone mineral mass (ASM, kg/m²). The muscular performance (6-minutes Walking Test – 6MWT) was measured to grading sarcopenia. Statistical analysis was performed with SPSS.

Results: The 130 pSS patients enrolled showed a moderate adherence to the Mediterranean diet (median MDiet = 33, third quintile) and played a moderate role of PA in the Italian population [5]. In a subgroup of 26 patients, the dietary habits were evaluated with a daily food diary. Sarcopenia, a muscle failure that accrue across a lifetime, was identified by a diagnostic algorithm [4] with age-differentiated cut-offs; the Hand Grip test (HGT) and the Chair Stand test (CST) were used as screening tests, the Dual Energy X-ray Absorptiometry (DEXA) was employed to analyse adherence to Mediterranean diet (the More Mediterranean diet the better) and to quantify bone mineral mass (ASM, kg/m²). The muscular performance (6-minutes Walking Test – 6MWT) was measured to grading sarcopenia. Statistical analysis was performed with SPSS.

Conclusions: This preliminary study considering Italian women with SS shows a moderate adherence to the MD similar to what previously reported in the general female population in Europe (32.5 ± 5 DS) [6]. Moreover, considering the obtained results in the subgroup, SS patients seem to have an unbalanced diet because of an intake of fat foods higher than that recommended in the Mediterranean Diet. A possible explanation for the higher fats intake may be a lubricating effect aiding mastication and swelling. It can be hypothesized that an unbalanced diet might be partly responsible for increasing chronic damage and the associated reduction in muscle mass.

Results: Fifty females were enrolled. Clinical characteristics during the disease course and serological and clinimetric scores at the time of enrollment are reported in Table 1. Group 1: US detected synovitis (grade 1–3) in 7 (35%) patients, mainly wrists and hands. Group 2: US detected synovitis (grade 1–3) in 5 (26.3%) patients mainly hands, elbows and wrists. Group 3: US detected synovitis (grade 1–3) in 7 (83.3%) patients, mainly knees elbows Achilles tendon, hands.

Conclusion: Our study confirmed that the musculoskeletal involvement in SLE is underestimated. Although not statistically significant, the groups showed differences in synovitis involvement. The percentage of asymptomatic patients with ultrasound signs of synovitis, especially of the hands and wrists, is higher than expected and almost comparable with symptomatic arthralgia patients. No association with clinimetric and laboratory tests were highlighted. As expected, the group of patients with known arthritis more frequently had ultrasonographic changes and signs of systemic disease activity. Our study suggests how necessary and interesting it is to prospectively evaluate in the future how the joint disease will progress in asymptomatic patients, and who will develop, for example, bone erosions or Jaccoud’s arthropathy.

Restless leg syndrome among patients with systemic lupus erythematosus: a common neurologic manifestation

Keywords: Quality of life, Systemic lupus erythematosus, Comorbidities

K. Parperis1, S. Philippou1, C. Christofi2, S. Psarelis2, 1University of Cyprus, Medical School, Nicosia, Cyprus; 2Cyprus University of Technology, Biostatistics and Epidemiology, Limassol, Cyprus; 2Nicosia General Hospital, Rheumatology, Nicosia, Cyprus

Background: Restless leg syndrome (RLS) is a common neurologic condition, affecting 5 to 10 percent of adults, that can be seen in patients with autoimmune diseases, like rheumatoid arthritis; however, data in patients with systemic lupus erythematosus (SLE) are scarce. Sleep disturbances are common in the SLE population, but few studies, with a small number of patients, investigated RLS. A deeper understanding of the relationship between SLE and RLS will allow us to promptly diagnose and manage RLS.

Objectives: The aim of this study is to determine the prevalence of RLS among patients with SLE, describe the clinical characteristics of RLS, examine its impact on health-related quality of life (HRQoL), and evaluate its association with depression.

Methods: We recruited SLE patients who met the SLICC-2012 criteria from September 2020 to September 2022. Demographic data, clinical characteristics, and pain level based on a visual analogue scale (0-10) were recorded. RLS diagnosis was based on the international restless leg syndrome study group criteria, and depression was assessed by the patient health questionnaire (PHQ)-9, with scores ≥10 indicating major depressive disorder (MDD). Patient global assessment was scored from 0 to 10, with higher numbers indicating active disease. HRQoL was assessed by a disease-specific validated questionnaire, the LupusQoL; scores ranged between 0-100, with higher scores indicating better QoL. These variables were compared between SLE patients with RLS and without RLS using t-tests or Wilcoxon non-parametric tests for continuous variables, as appropriate, and the chi-square test of independence for categorical variables. A p-value ≤ 0.05 was considered statistically significant and all tests performed were two-sided.

Results: Among the 144 SLE patients included in the study, 108 were women (87.1%), with a mean age of 49 ± 19 years (range 19 - 80) and a mean disease duration of 14 ± 12 years. Forty (32%) of them met the criteria for RLS and were more likely to experience a delay in diagnosis (mean 4.8 vs 2.2 years; p=0.019) and were less likely to work (65% vs 45%, p=0.040) compared to non-RLS patients. RLS patients were more likely to have coexisting MDD (45% vs 24%, p=0.019), higher level of pain (mean 3.9 vs 2.5, p=0.007) and disease activity based on patient global assessment (mean 4.2 vs 3.2, p=0.025). Further, all the domains of LupusQoL were significantly lower in the RLS patients group suggesting worse HRQoL (Table 1).

Conclusion: One of every three SLE patients had RLS, which negatively impacted the patient’s HRQoL. In addition, RLS was associated with depression, higher levels of pain, and worse perceived disease activity. Therefore, clinicians should be vigilant to recognize and manage RLS in SLE patients.

Ab0682
Serum interferon α (IFNα) levels and systemic lupus erythematosus (SLE) disease activity in SLE patients in Estonia: A prospective cohort study of 40 SLE patients in Estonia

Keywords: Systemic lupus erythematosus, Real-world evidence, Descriptive studies

S. Meisalu1, K. Kisand1, L. Haljasma2, 1East-Tallinn Central Hospital, Rheumatology, Tallinn, Estonia; 2University of Tartu, Biomedicine, Tartu, Estonia

Background: SLE is a rare chronic autoimmune disease with polymorphic clinical manifestation. It has been found that the interferon signature is detectable in 80% of SLE patients. With the implementation of measuring IFNα levels, additional method to evaluate SLE has been provided.

Objectives: The aim of the present study is to characterize a sample of Estonian SLE patients.

Methods: Consecutive outpatient and inpatient patients with rheumatologist diagnosed SLE (≥20 years) were enrolled in East-Tallinn Central Hospital. Two study visits were done with 6 months apart to evaluate disease activity, current treatment, organ involvement, immunological findings and comorbidities. In addition, data from medical records were collected: organ involvement and immunological findings at the time of diagnosis and initial treatment. SLE disease activity was measured using SLEDAI-2K (Systemic Lupus Erythematosus Disease Activity Index 2K) score. Blood tests were taken to measure interferon levels using Simoa (Single Molecul Array) method. To evaluate the extent of the deviation of IFNα levels in patients with SLE compared to non-autoimmune individuals, age and gender matched control group was used. Interferon score was calculated according to interferon induced gene expression in blood cells collected to RNA stabilizing tubes. Spearman correlation was used for correlation analyses and chi-square and Fisher test for the group comparison.
Results: Among 40 patients (mean age 50 (standard deviation ±12.4) years, mean disease duration 12 (±9.9) years, mean SLEDAI 2K at diagnosis 10 (±3.9)) 92.5% were females. Mean SLEDAI 2K value at entering into the study was 4 (±3.4) similar to the value after six months 4 (±5.0). Median IFNα levels during first and second study visits were respectively 133 fg/ml (IQR=560) and 117 fg/ml (IQR=477). At first and second study visit respectively 48% and 45% of patients had low IFNα levels (<100 fg/ml), 35% and 37% had high IFNα levels (>1000 fg/ml) and 18% of patients had very high IFNα levels (>10000 fg/ml). IFNα levels correlated poorly or not significantly in either time point with SLEDAI 2K (r=0.3280, p=0.04 and r=0.5460, p=0.0004), organ involve ment (for joints r= 0.2352, p=0.14 and r=0.3433, p=0.03; for skin r=0.0216, p=0.89 and r=0.0352, p=0.76), Rituximab treatment (r=0.20 and r=0.3201, p=0.05). IFNα levels correlated strongly with IFN score (r=0.9325, p<0.0005) and 76% of patients had elevated IFNα levels compared to 98 percentile of healthy controls (median IFNα level 0.5605 fg/ml, IQR=1.77). There was no statistical difference in regards of Rituximab treatment during the study in low and in high IFNα level group, respectively 16% and 38% (p=0.22) at first study visit and 12% and 43% (p=0.07) at second study visit. 

Conclusion: The first analysis of Estonian SLE patients' IFNα levels and disease activity shows that measuring IFNα levels can give additional information in some SLE patients in the light of new treatments targeting IFNα, although the general correlation with disease activity and available treatment so far is low. Further studies are in progress to evaluate IFNα levels in larger Estonian SLE population to better understand possible pathogenetic mechanisms in different SLE subpopulations.

Background: Vaccines are widely credited for their role in reducing the incidence and the severity of various infections. Although the safety profiles of vaccines have been proved, there still remain gaps between healthy individuals and patients with autoimmune diseases in the efficacy and adverse events of vaccinations.

Objectives: The aim of the COVID-19 and Influenza Vaccination In Lupus (CIVIL) study was to compare the perception and safety profile between COVID-19 vaccine and influenza vaccine in Korean patients with systemic lupus erythematosus (SLE).

Methods: We conducted a cross-sectional study based on a 34-question web-based survey on COVID-19 and influenza vaccination in 207 medically confirmed SLE patients. Patients were recruited from 13 academic hospitals affiliated with Korean society of SLE research (KSSR) from DEC 2022 to JAN 2023. The primary outcome was the perception of patients and physicians on the vaccines, and the occurrence of side effects including flare.

Results: 94.1% of two hundred respondents were females aged in 20's (19.8%), 30's (24.3%), 40's (27.7%), 50's (16.8%), and 52% was treated more than 10 years. More than 50% of patients were in stable condition for recent 6 months (below 20mm in 100mm visual analogue scale with lower than 10mg prednisolone equivalent dose). COVID-19 vaccine (Pfizer, Moderna, AstraZeneca, Novavax) and influenza vaccine were in 77.7% and 87.6% of SLE patients, respectively. Reasons for willing not to vaccinated included fear of lupus flare (56.3% vs 24.5%), worried about side effects (52.1% vs 26.6%), and not recommended from physicians (35.4% vs 7.4%) on COVID-19 and influenza vaccines, respectively. Adverse events (AEs) occurred much higher in COVID-19 vaccine (65.8%) than influenza vaccine (12.4%). However, only 4.4% of patients experiencing AEs from COVID-19 vaccine had a worse perception and higher adverse events compared to influenza vaccine in Korean SLE patients.

IS AUTONOMIC DYSFUNCTION MORE COMMON IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME WITH FIBROMYALGIA THAN IN PATIENTS WITHOUT FIBROMYALGIA?

Keywords: Fibromyalgia, Sjögren syndrome

D. Kantar1, N. Erdik1, G. Yavuzilige1, S. B. Acıkgöz1, S. M. Türk1, C. Anıslantürk Günüyüz1, Z. Öztürk1, E. Gönülloğlu1, 1Sakarya University Faculty of Medicine, Rheumatology, Sakarya, Turkey; 2Ankara Atlıat Sıçan Sanatçılık ve Araştırma Hastanesi, Rheumatology, Ankara, Turkey

Background: Primary Sjögren’s syndrome (pSS) is an autoimmune disease that primarily affects the exocrine glands, but other organs, including the nervous system, may also be affected [1]. Many studies provide evidence of autonomic dysfunction in pSS [2,3]. Although the etiology of fibromyalgia (FM) is not fully understood, data suggest that FM may be caused by autonomic nervous system dysfunction [4].

Objectives: In this study, we aimed to reveal the incidence of autonomic dysfunction in patients with pSS compared to those without fibromyalgia.

Methods: In this cross-sectional study, 64 patients who admitted to our Sakarya University Faculty of Medicine rheumatology outpatient clinic between November 2021 and August 2022 were followed up with the diagnosis of pSS were included. The patients were divided into two groups 35 (54.7%) with fibromyalgia and 29 (45.3%) without fibromyalgia. Patients were evaluated with the Composite Autonomic Symptom Score-31 (COMPASS-31), which consists of 6 subsections including autonomic dysfunction, orthostatic, vasomotor, secretomotor, gastrointestinal, bladder and pupillomotor functions. Mann-Whitney U test and Chi-square test were used to compare the groups.

Results: The mean age of the patients was 53.8±11.3 years. There was no difference between the groups regarding sex and age (p = 0.586 and p = 0.580, respectively). The median disease duration (IOD) was 4(6) years. The mean total COMPASS-31 score was significantly higher in patients with fibromyalgia than in those without fibromyalgia (0.014). Among its subgroups, secretory dysfunction was significantly higher in patients with fibromyalgia (p=0.001). Vasomotor dysfunction is more common in patients with FM (p=0.016) (Table 1).

Conclusion: In our study, patients with pSS with fibromyalgia had a higher COMPASS-31 score than those without FM, and especially the secretory dysfunction score was higher. Since both diseases can cause autonomic dysfunction separately, it seems reasonable to have a high total COMPASS-31 score in patients with both. In addition, vasomotor dysfunction is more common in patients with FM.

HISTOPATHOLOGICAL FINDINGS IN RENAL BIOPSY OF PATIENTS WITH LUPUS Nephropathy as the Initial Manifestation of Systemic Lupus Erythematosus and Long-Term Renal Outcome in Mexican Population

Keywords: Systemic lupus erythematosus, Epidemiology, Descriptive studies

F. Pazo1, E. Garduño2, N. K. Cruz2, C. E. Mendez2, 1Colonia Cuauhtémoc, Nephrology, Mexico City, Mexico; 2Colonia Cuauhtémoc, nephrology, Mexico City, Mexico; 3Mexican Social Security Institute, Nephrology, Mexico City, Mexico

Background: Renal biopsy is essential in Lupus nephritis (LN) to guide treatment of lupus nephritis and provides information on classes and prognosis of lupus nephritis. Activity and chronicity index can be used as a guide for lupus nephritis treatment although little has been considered the percentage of fibrosis and tubular atrophy in the renal prognosis.

Objectives: Describe the histopathological findings in biopsies performed in patients with LN as an initial manifestation of SLE and the long-term renal outcome.

Methods: Retrospective descriptive observational study. Data on baseline demographic, biopsy records, laboratory results and treatment regimen were extracted from the case notes. Normality tests were applied, the frequencies and percentages were calculated for the categorical variables and the means with their standard deviation or medians with minimums and maximums for the continuous variables depending on their distribution.

Results: Of the 61 patients who presented LN at the diagnosis of SLE, renal biopsies were performed in 80% (n=54). The median age was 30 (19-66) years, females predominated (77%). The frequencies of different classes of lupus nephropathy as well as their index of activity and chronicity and treatment used are described in Table 1. Only 30% of renal biopsies (65%) described tubulo-interstitial findings and 60% had no immunofluorescence. Another additional finding found in the renal biopsy were fibrocellular crescents, membranoproliferative pattern and podocytopathy. At the diagnosis of LN, median serum creatinine (CrS) was 0.8 (1-6) mg/dl and proteinuria 1355 (90-9450) mg/24 hrs. The remission induction treatment frequently used was the combination of mycophenolate and prednisone. Three of them progressed to end-stage renal disease (25%), loss of social security (19%) and poor adherence (19%).

Conclusion: Frequency of class IV LN in our population is like that reported worldwide, however a higher percentage of mixed forms (IV+V) is reported. Combination of mycophenolate and prednisone was used as remission induction treatment. Although the complete remission rates are much lower than those reported (33% vs 58%). Presence of fibrosis in more than 25% is associated with progression to end-stage renal disease.

PERFORMANCE OF DRAFT 2022 ACR/EULAR CLASSIFICATION CRITERIA IN A TURKISH COHORT OF APL ANTIBODY POSITIVE PATIENTS

Keywords: Epidemiology, Anti-Phospholipid Syndrome, Autoantibodies

R.C. Kardas1, D. Yildirim1, B. Özkızılaş1, İ. Vasi1, R. Duran1, H. Karadeniz1, A. Avanoğlu Guler1, A. Erden1, H. Kocük1, B. Göker1, A. Tutun1, M. A. Ozturk1, 2Gazi University, Department of Medicine, Division of Rheumatology, Ankara, Turkey

Background: Revised Sapporo classification criteria is the most commonly used criteria set for the classification of antiphospholipid syndrome (APS) patients [1]. Since its revision in 2006, various other clinical and laboratory manifestations have been reported in the literature. Among these are livedo reticularis (race-mosa), cutaneous ulcers, thrombocytopenia, cardiac, pulmonary and renal involvement [2]. In 2022 American College of Rheumatology Congres meeting, new draft classification criteria have been presented [3].

Objectives: Comparing the performance of the new draft classification criteria for antiphospholipid syndrome with the revised Sapporo criteria in a Turkish cohort of antiphospholipid antibody positive patients.

Methods: Patients with a positive antiphospholipid antibody (LAC, aCL IgM or IgG, aB2GPI IgM or IgG) followed since 2016 in our institution have been included. Demographic, clinical, laboratory and radiological features of the patients were recorded retrospectively. All parameters were evaluated with reference to the 2006 revised Sapporo and 2022 draft criteria.

Results: 40 patients were included in our study. 80% (N=32) of the patients were female. Average age of the patients at diagnosis or first antibody positivity was 33.9 years. 27.5% of patients (N=11) were screened for hereditary thrombophilia, with only one patient having heterozygous factor V Leiden mutation. 37% of patients (N=13) had ever smoked prior to their inclusion in the cohort. 57.5% of patients (N=23) had secondary APS, 12.5% had primary APS, 30% had isolated antiphospholipid antibody positivity. Among the secondary APS patients, vast majority had SLE (N=20), 47.5% of the patients (N=19) had a history of vascular thrombosis. 16 patients had venous and 5 patients had arterial thrombosis. Among the 32 female patients, 62.5% (N=20) had an obstetric morbidity associated with APS. 20.5% of patients (N=8) had a skin finding consistent with APS, the most common one being livedo racemosa (N=7). 50% of patients had thrombocytopenia. 20% of patients (N=4) had developed autoimmune hemolytic anemia. Only a single patient had a history of catastrophic APS. 17.5% of cases (N=7) had a positive lupus anticoagulant. Most commonly positive aPL antibody was anti-cardiolipin IgG (55%, N=22), followed by anti-B2GPI-IgG (28%, N=11). 82% of patients (N=33) had a positive ANA test, 62.5% (N=25) had low C3 and C4. Overall, 42.5% (N=17) of patients fulfilled 2006 revised Sapporo criteria, whereas 40% (N=16) ultimately fulfilled the 2022 draft criteria for classification. There was a large level of agreement between the two criteria sets, with one patient not fulfilling 2006 criteria fulfilling 2022 criteria and two patients fulfilling 2022 criteria without fulfilling 2006 criteria.

Conclusion: Our cohort of patients had a high prevalence of thrombocytopenia, as well as a significant minority having livedo racemose and autoimmune thrombocytopenia. None of the patients with isolated aPL antibody positivity were classified as APS, despite many of the fulfilling the initial screening step of the draft criteria. Longer term follow-up of patients fulfilling 2022 screening criteria may yield additional information in the future.

Vasculitis - large vessel vasculitis

**AB0702**

THE INCIDENCE OF LARGE VESSEL VASCULITIS IN NORFOLK, UK

**Keywords:** Epidemiology, Vasculitis, Real-world evidence

C. Mukhtar\(^1\), C. Beardsmore\(^2\), F. Coath\(^3\), G. Ducker\(^4\), K. Sisson\(^5\), R. Watts\(^6\), \(^{1}\)Norfolk and Norwich University Hospital NHS Foundation Trust, Rheumatology, Norwich, United Kingdom; \(^{2}\)Norfolk and Norwich University Hospital NHS Foundation Trust, Radiology, Norwich, United Kingdom; \(^{3}\)Norfolk and Norwich University Hospital NHS Foundation Trust, Pathology, Norwich, United Kingdom; \(^{4}\)University of East Anglia, Norwich Medical School, Norwich, United Kingdom

**Background:** There are no data on the collective incidence of the large vessel vasculitides. The data of incidence of GCA and Takayasu arteritis in the UK has been based on clinical coding in routine administrative datasets. There are no data on the incidence of these diseases based on clinically verified diagnoses. We studied the incidence of the large vessel vasculitides in a stable population with a predominant Northern European ancestry.

**Objectives:** To report the incidence of large vessel vasculitis and its subsets in Norfolk, UK

**Methods:** Individuals attending a secondary care hospital with a clinically verified diagnosis of primary systemic vasculitis made between 2011-2020, who lived within the NR postcode districts of Norfolk County borders were included if they met classification criteria (ACR 1990 or ACR/EULAR 2022) for GCA/Takayasu arteritis [1-4], or had definite tissue or imaging evidence of large vessel vasculitis. The population data from the 2011 census, available from the office of national statistics was used as the denominator. If classification criteria for both GCA and TAK were met, a clinical decision was taken to decide on the subtype.

**Results:** 272 individuals were diagnosed with a large vessel vasculitis in a population of 454,316 above the age of 18. The annual incidence of large vessel vasculitis in Norfolk is 59.9/1million in population above the age of 18. The annual incidence of giant cell arteritis is 9.8/100,000 in population above the age of 50 using the ACR 1990 criteria and 10.6/100,000 using the ACR/EULAR 2022 criteria. There is a marked rise in the incidence from 2017 onwards as a fast-track pathway was formally established (Table 1). There is a dip in the incidence in 2020 when services were suspended during the SARS-COV2 pandemic. The annual incidence peaks at 168.5/1million in the 9th decade of life and is commoner in females (12.3/100,000) than males (73/100,000). The annual incidence of Takayasu arteritis is 3.3/1million in population above the age of 18 using the ACR 1990 criteria and 1.1/1million using the ACR/EULAR 2022 criteria.

**Conclusion:** This is the first study that reports the incidence of all objectively diagnosed large vessel vasculitis from a secondary centre which provides services to a stable large population in the East of England. The incidence of GCA rose with the establishment of a fast-track pathway and its peak may have been affected by the SARS-COV2 pandemic. GCA is commoner in females and peaks in the 6th and 9th decades.

TOWARDS TREAT-TO-TARGET PATIENT CENTRED CARE: DEVELOPMENT OF MULTIDIMENSIONAL DISEASE SPECIFIC PATIENT REPORTED OUTCOME MEASURES QUESTIONNAIRE FOR GIANT CELL ARTERITIS

**Keywords:** Remission, Patient reported outcomes, Vasculitis

Y. El Miedany\(^1\), D. Palmer\(^2\), M. Toth\(^3\), M. Elgentaly\(^4\), S. Bahlas\(^5\), S. A. Mahran\(^6\), \(^{1}\)Norfolk, \(^{2}\)Medway, \(^{3}\)London, \(^{4}\)Washington, \(^{5}\)London, \(^{6}\)King’s College London - Darent Valley Hospital, General Medicine, Dartford; \(^{1}\)Submitted for publication; \(^{2}\)Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt; \(^{3}\)King Abdul Aziz University, Rheumatology, Jeddah, Saudi Arabia; \(^{4}\)Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt; \(^{5}\)Faculty of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; \(^{6}\)Faculty of Medicine Benha University, Rheumatology and Rehabilitation, Benha, Egypt; \(^{7}\)Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt

**Background:** Giant Cell Arteritis (GCA) is the commonest form of systemic vasculitis in people over the age of 50. In 2017, the OMERACT Vasculitis Working Group published a core set of domains and outcome measures for use in clinical trials in large vessel vasculitis [1] and highlighted the lack of a disease-specific patient reported outcomes (PROs) for GCA. The OMERACT group proposed a draft core set of domains for GCA, including disease specific domains, organ and arterial function, psychosocial impact and physical function biomarkers, fatigue, pain, as well as death.

**Objectives:** To assess the validity, reliability and responsiveness to change of a patient self-reported questionnaire to assess for the construct outcome measures, co-morbidities and the impact of GCA and its treatment on health-related quality of life in GCA patients.

**Methods:** The PROMs-GCA was conceptualized based on frameworks used by the WHO Quality of Life tool and the PROMIS. Initially, cognitive interviews were conducted to identify item pool of questions. Item selection and reduction was achieved based on patients as well as an interdisciplinary group of specialists. Rasch and internal consistency reliability analyses were implemented. The questionnaire included the GCA specific physical and psychological symptoms, sense of self, symptoms severity using numerical visual analogue scale (0-10) in addition to assessment of functional disability, quality of life (QOL), review of the systems, glucocorticoids benefit:risks, comorbidities as well as motivation [2]. In addition, every patient completed HAQ and EQ-5D questionnaires.

**Results:** A total of 52 GCA patients completed the questionnaire. The PROMs-GCA questionnaire was reliable as demonstrated by a high standardized alpha (0.8670-941). Content construct assessment of the PROMs-GCA/functional disability and QOL revealed significant correlation (p < 0.01) with both HAQ and EQ-5D. Changes in functional disability, QOL showed significant (p < 0.01) variation with diseases activity status in response to therapy.

**Conclusion:** The developed PROMs-GCA questionnaire is a reliable and valid instrument for assessment of patients living with GCA. A phased treatment regimen depending on the severity of GCA as well as the patient's preferences and comorbidities are the best approach to tailored patient management.

**AB0704**

EVALUATION OF THE OF THE 2022 ACR/EULAR CLASSIFICATION CRITERIA FOR GCA IN A GERMAN PATIENT COHORT

**Keywords:** Diagnostic tests, Ultrasound, Vasculitis

R. Bernge\(^1\), P. Schultz\(^2\), J. Friedrich\(^3\), \(^{1}\)Klinikum der Stadt Ludwigshafen am Rhein gGmbH, Medizinische Klinik A, Ludwigshafen am Rhein, Germany; \(^{2}\)Klinikum der Stadt Ludwigshafen am Rhein gGmbH, Zentrum für diagnostische und interventionelle Radiologie, Ludwigshafen am Rhein, Germany
Background: In 2022, the ACR and the EULAR proposed new classification criteria for Giant Cell Arteritis (GCA). While the previous classification criteria from 1990 were based on clinical and histological findings only, the new classification criteria also consider several types of imaging.

Objectives: To assess and compare the sensitivity and specificity of the ACR 1990 (1990CC) and the ACR/EULAR-2022 classification criteria (2022CC) for GCA.

Methods: In a retrospective analysis, we classified 210 patients (33 % males, median age 68 years) with suspected GCA according to the 1990CC and 2022CC. All patients attended the Klinikum Lüdwigshafen between 2018 and 2022 and were examined with either ultrasound, MRI, or PET-CT. The results were compared with the final clinical diagnosis made by the attending physician.

Results: Of 210 patients under consideration, 94 had GCA. Of these 94 patients, 54 met the 1990CC, while 90 met the 2022CC (Table 1). Of the 116 non-GCA patients, 110 did not meet the 1990CC and 112 did not meet the 2022CC, amounting to a sensitivity and specificity of 0.57 and 0.96 for the 1990CC versus 0.96 and 0.97 for the 2022CC, respectively (Table 1). Overall, the correct classification proportion was 0.78 for the 1990CC and 0.96 for the 2022CC (Table 1). It was noticeable that 21 GCA patients had no cranial symptoms like temporal headache, jaw claudication, or striking temporal arteries. 18 of these patients were correctly classified by the 2022CC, but all of them were misclassified by the 1990CC. Moreover, 81 of 94 patients showed a typical ultrasound halo in at least one vessel section, which increased the sensitivity of the 2022CC.

Conclusion: Our results demonstrate that the inclusion of imaging methods increase the sensitivity of the 2022CC compared with the 1990CC, while the specificity of > 0.95 remains similar. The 1990CC were primarily developed for the classification of giant cell temporal arteritis, causing a frequent misclassification of patients with isolated extracranial large vessel vasculitis. Moreover, the 1990CC classified GCA patients without cranial symptoms only accurately in case of a positive temporal biopsy.

Table 1. Sensitivity and specificity of the 1990-ACR-Classification Criteria and 2022-ACR/EULAR-Classification criteria for GCA compared with the final clinical diagnosis of GCA.

DOt: 10.1136/annrheumdis-2023-eular.2102
Background: Cluster analysis is a data-driven approach to identify natural patterns of disease which may help better understand the phenotype of Takayasu arteritis (TAK), a rare large vessel vasculitis.

Objectives: From a retrospective cohort of TAK, agglomerative hierarchical clustering using Ward method was performed using clinical features. Optimal number of clusters were identified using elbow method and silhouette method. The hitherto identified clusters were compared for differences in clinical features, vascular involvement, and Hata’s angiographic subtypes using odds ratios (OR, with 95% confidence intervals), and for survival (crude, using Kaplan-Meier curves; adjusted for gender and age of disease onset using Cox regression analyses) using STATA 16.1 I/C.

Results: Optimal number of clusters was two [Ward agglomerative coefficient 0.989; Cluster 1: 111 TAK, mean (SD) age 25.06 (9.97) years, 80.2% females; Cluster 2: 89 TAK, mean (SD) age 25.54 (10.38) years, 65.2% females]. Carotidynia, pulse or BP inequality, pulse loss, vascular bruits, upper limb claudication, lower limb claudication, and chest pain were more common in cluster 1, whereas, hypertension, renal failure, and stroke/TIA were more common in cluster 2 (Table 1). Involvement of subclavian and vertebral arteries, left vertebral, brachiocephalic, ascending aorta, arch of aorta, descending thoracic aorta, abdominal aorta, carotid, superior mesenteric, inferior mesenteric, left and right renal arteries were similar in both clusters. Hata’s angiographic subtype V was more common in cluster 1 (OR 0.45, 95%CI 0.25 – 0.80), whereas, subtype IV was more common in cluster 2 (OR 6.16, 95%CI 1.70 – 22.33). Over 687 person-years of follow-up (193 patients), cluster 1 had worse survival than cluster 2 (log-rank test: 0.027, Figure 1), even after adjustment for gender and age of onset (adjusted Hazard ratio cluster 2 vs cluster 1 1.09, 95%CI 0.01 – 0.78).

Conclusion: Clinical features corresponded to vascular territories which were more common in cluster 1. Hypertension and renal failure were more common in cluster 2, which correspond to more frequent Hata’s subtype IV in this cluster. Clusters based on clinical features could predict well the patterns of vascular involvement. Higher adjusted mortality rate in cluster 1 requires validation in other cohorts of TAK.

Background: Tocilizumab (TCZ) is the only biologic therapy approved for giant cell arteritis (GCA). Clinical trials with TCZ in GCA was performed with intravenous (iv) TCZ in a phase 2 trial [1], and with subcutaneous (sc) TCZ in the phase 3 GIACTA [2]. There is general agreement on the initial maintenance dose, but duration of TCZ therapy is not well established. In GIACTA trial, after one year on TCZ, most patients had GCA relapse after withdrawal.

Objectives: To assess the predictive factors of relapse in GCA in a clinical practice scenario.

Methods: Multicentre observational study of 471 patients with GCA. The diagnosis of GCA was performed between 2016 and 2021 according to: a) ACR criteria, and/or b) temporal artery biopsy, and/or c) imaging techniques. Relapse was defined according to EULAR consensus definition [3].

From the 471 patients, we selected the patients who had available the data on relapse during follow-up. Multivariable study was conducted to identify the best set of predictors for the appearance of a relapse.

Results: GCA relapses were observed in 63 of 405 (15%) patients for whom such data was available (Table 1). No significant differences were observed between the two groups in demographic, clinical and laboratory characteristics or in prednisone dose at initiation of TCZ. The set of variables associated with GCA relapses were prior use of synthetic conventional disease-modifying antirheumatic drugs (sDMARDs), use of iv TCZ, shorter time on TCZ therapy and optimization of TCZ dose (Figure 1).

Conclusion: GCA relapse seems related mainly to TCZ schedule and was associated with iv TCZ, and a shorter treatment time and optimization.

PHYSICAL ACTIVITY AND POLYMIALGIA RHEUMATICA RISK: A MENDelian RANDOMIZATION STUDY

Keywords: Fibromyalgia, Non-pharmacological interventions, Genomics/epigenetics

Y. Chen1, Z. Jing1,2, Q. Feng1,2, Y. Feng1,2, Q. Yu1,2, R. F. He1, X. L. Zhang1,2,4, X. Zhang1,2,4,1 Shaxi Provincial Key Laboratory of Rheumatism Immune Microbiology, Shanxi Medical University, Taiyuan, Shanxi Province, China; 2Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, Shanxi Province, China; 3Shaxi Key Laboratory of Big Data for Clinical Decision Research, Shanxi Medical University, Taiyuan, Shanxi Province, China; 4The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China

Background: Polymyalgia rheumatica (PMR) is a chronic inflammatory disorder characterized by pain and long-term morning stiffness of the neck, shoulders, hips, upper arms, and thighs [1]. Prolonged unaccustomed exercise involving muscle lengthening (eccentric) movements can lead to ultrastructural muscle destruction, impaired excitation-contraction coupling, inflammation, and muscle protein degradation to produce muscle pain [2]. This muscle pain due to exercise may be associated with muscle pain in PMR.

Objectives: This study aims to discover whether physical activity affects PMR. Methods: We obtained GWAS data for sedentary: Time spent watching television (n=91,084), time spent using a computer (n=360,895), and time spent driving (n=310,555). Types of physical activity included moderate physical activity 10+ minutes (n=440,266), vigorous physical exercise 10+ minutes (n=440,512), tachometer-based physical activity, Vigorous physical activity, and moderate to vigorous physical activity (UK Biobank). GWAS of PMR included 213,145 European individuals. Single-nucleotide polymorphisms (SNPs) that were independent (p < 5×10-8, FDR 0.05) were selected as instrumental variables. The inverse-variance weighted (IVW) method was the primary method, to evaluate the causal association. The weighted median, and MR-Egger were applied for further MR analysis. Cochran’s Q test, MR-Egger intercept analysis, the funnel plot, and the leave-one-out analysis were used for sensitivity analysis.

Results: There was an inverse association between time spent using a computer with PMR (IVW OR: 0.32, 95% CI: 0.15–0.70, p = 0.004). No directional pleiotropy was revealed by the MR-Egger intercept analysis (p = 0.797). On the flip side, tachometer-based physical activity, vigorous physical activity, moderate to vigorous physical activity, moderate physical activity 10+ minutes, vigorous physical activity 10+ minutes, time spent watching TV (TV), and driving time were not associated with PMR (p>0.05). (Figure 1)

---

**Conclusion:**
Computer time spent is a protective factor for PRM. Conversely, excessive exercise may be a risk factor, providing new insights into the pathogenesis of PRM.

**Methods:**
Real-world, retrospective clinical practice study of patients with GCA treated with JAKI. Outcomes assessed included disease relapse and safety. A literature search for other JAKI-treated GCA cases was conducted in PubMed, Embase and the Cochrane library from inception to 12/31/2022. We compared results of the previous baricitinib study [1] and the baricitinib patients in our series.

**Results:**
We present 32 patients (27 females [84%], mean age 72.4 years, relapsing disease 32 [100%]) that received JAKI. The initial JAKI was baricitinib (n=12), tofacitinib (n=10) and upadacitinib (n=10) (Table 1 and Figure 1). After a median [IQR] follow-up of 6 [3-15] months, 23 (72%) achieved and maintained remission, and 9 (28%) remained in disease activity. The patients failing the initial JAKI were switched to an alternative [JAKI (n=4) or to another immunosuppressant (n=5)]. The literature review identified another 21 GCA patients (17 females, mean age 74.2 years) treated with JAKI, mostly with baricitinib (n=18). Most of these patients benefited from JAKI therapy (Table 1). Patients in our series receiving baricitinib had longer disease duration (median [IQR] 36 [24-48] months, vs 9 [7-21] months; p=0.001) and had received biologics (83% vs 6.7%; p<0.001) less frequently than those in the previous baricitinib study [1]. Remaining baseline features were similar.

**Conclusion:**
This real-world analysis suggests that JAKI could be effective in GCA, including patients failing other immunosuppressive therapies. The results of an ongoing phase 3 randomized controlled trial are awaited to confirm or rule out this observation.

Background: Treatment of patients with Takayasu arteritis (TAK) is challenging in patients with refractory TAK.

Objectives: To assess the efficacy and safety of tofacitinib in Indian patients with TAK.

Methods: In this retrospective study, medical records of consecutive patients with TAK being treated with either originator or generic tofacitinib at 4 centres in India were studied. Details regarding demographics, clinical presentation, disease duration, Indian Takayasu Activity score (ITAS), laboratory markers angiography treatment and response to treatment were recorded. The disease was considered active if the patient had evidence of activity in any two of the following three domains: new clinical symptoms as evidenced by ITAS >1; persistently raised C-reactive protein (CRP) for 2 consecutive visits; new areas of arterial wall thickening or active uptake in angiography or 18FDG PET-CT respectively. Good response was defined as the absence of activity in at least 2 of the 3 above-mentioned domains. In contrast, presence of carotid or any new areas of arterial narrowing were considered as standalone indicators of disease activity. In the absence of follow up imaging, a rise in CRP from baseline visit on 2 consecutive occasions was also considered as active disease. The data is presented as mean± SD or median (Interquartile range) according to distribution of data. Fisher’s exact test or Mann Whitney test was used to compare the parameters between patients with good response and no response to treatment.

Results: Twenty-seven patients (24, 88.9% females; age 30.4 ± 8.13 years) with median disease duration 48 (20-72) months were included. At diagnosis, 13 (48.1%), 6 (22.2%), 15 (55.6%) and 7 (25.9%) patients presented with constitutional symptoms, carotidynia, ischemia features and aortic regurgitation respectively. Four patients discontinued the drug due to side effects while one patient had sudden death within 3 months of initiation on tofacitinib.

Conclusion: The response to tofacitinib was modest in Indian patients with difficult to treat TAK. Further multi-ethnic studies are required to ascertain its effectiveness in TAK.

VASCULAR CALCIFICATIONS IN LARGE VESSEL VASCULITIS

Keywords: Imaging, Vasculitis

C. Marvici1, R. Fari2, G. Besutti3, L. Spaggiari2, P. Mancuso3, F. Muratore4, E. Galli5, P. Pattacini6, C. Salvarran1.* Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Rheumatology Department; Reggio Emilia, Italy; 2Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Radiology Department; Reggio Emilia, Italy; 3Azienda Unità Sanitaria Locale IRCCS di Reggio Emilia, Epidemiology Department, Reggio Emilia, Italy

Background: Arterial wall calcifications are a hallmark of atherosclerosis and represent an important cardiovascular risk factor. Accelerated atherosclerosis and vascular calcifications have been reported in large vessel vasculitis (LVV), but data are scarce about the amount and localizations [1].

Objectives: The aim of this study was to compare the prevalence, amount, and local distribution of arterial wall calcification evaluated on CT scan in LVVs versus lymphoma patients matched for age, sex, and year of diagnosis.

Methods: All consecutive patients diagnosed at our institution with LVVs from 2007 to 2018 with an available baseline PET-CT scan were included. Lymphoma patients were matched based on age, sex, and year of baseline PET-CT. CT images derived from baseline PET-CT scans of both patient groups were retrospectively reviewed by a single radiologist who, after setting a threshold of minimum 130 HU, semi-automatically computed vascular calcifications in three separate sites (coronaries, thoracic and abdominal arteries), quantified as Agatston, volume and mass scores. Calcifications in the two groups were compared for each site by using paired T-test. The effect of patient group was evaluated on the prevalence of calcifications in each site by means of adjusted conditional logistic regressions, and on the score of thoracic calcifications by means of adjusted regression.

Results: 258 patients were enrolled, including Takayasu’s arteritis n=57, giant cell arteritis n=72 and lymphoma n=129. Thoracic artery calcifications were more represented in LVV patients, when compared with lymphoma patients (mean volume 2026 in LVVs vs 1014 in lymphomas, p=0.054). Coronary calcifications were higher in lymphoma patients (mean volume 104 in LVVs and 198 in lymphomas, p=0.13), whereas abdominal artery calcifications were equally distributed (mean volume 3220 in LVVs and 2712 in lymphomas). A diagnosis of LVV was associated with the presence of thoracic calcifications after adjusting by age and year of diagnosis (OR=4.13, 95% CI=1.35-12.66; p=0.013), and with the volume score in the thoracic arteries (p=0.048).

Conclusion: When compared with lymphoma patients matched by age, sex, and year of diagnosis, LVV patients have higher calcification in the thoracic arteries, but not in coronary and abdominal arteries.

AB0712

INFLUENCE OF GLUCOCORTICOID THERAPY ON TEMPORAL ARTERY BIOPSY. EXPERIENCE IN A REFERRAL HOSPITAL

Keywords: Best practices, Vasculitis, Tapering

J. Sanchez-Martín1, J. Medina-Del Valle1, J. Loricer1, C. Gonzalez-Vela1, M. F. Garcia-Reija1, R. Blanco1.*Hospital Universitario Marqués de Valdecilla, IDIVAL, University of Cantabria, Santander, Spain, Rheumatology, Santander;
Background: The relationship between corticosteroid (GCs) treatment prior to temporal artery biopsy (TAB) and a negative result in giant cell arteritis (GCA) is controversial.

Objectives: To assess whether cumulative GCs dose and time of steroid exposure influence in TAB result.

Methods: Observational study of 191 patients diagnosed with GCA from a clinical practice of a referral center between January 2016 and December 2022 who underwent TAB. The diagnosis of GCA was made according to a) ACR criteria, and/or b) temporal artery biopsy, and/or c) EULAR/ACR2022 criteria, and/or d) imaging techniques. The biopsies were transversally sectioned into pieces and were cut from paraffin blocks and stained with hematoxylin-eosin. A comparative study between patients with positive TAB and those with negative TAB was performed.

Results: The 191 GCA patients were divided into 2 subgroups: a) patients with positive TAB (n=52), and b) patients with negative TAB (n=139) (Table 1) of whom 26 (13.6%) had not received prior corticosteroid therapy versus 165 (86.4%) patients who did. Patients with positive TAB had more frequently visual symptoms and/or jaw/lingual claudication, while polymyalgia rheumatica (PMR) was less frequent. The median dose [interquartile range (IQR)] of the negative TAB group was 40 [25-40] mg/day and also 40 [35-60] mg/day in the positive TAB group. The median duration [IQR] of treatment in the first group was 11 [4-24] days, while in the second group it was 7 [3-13] days. The percentage of positive TAB was higher the shorter the delay between GCs treatment onset and the TAB, decreasing after 15 days from GCs therapy onset.

Table 1. Main characteristics of patients with GCA according to biopsy result.

| Age (years), mean±SD | 77±8 | 74.2±10 | 0.11 |
| Sex, female/male (% females) | 28/24 (54) | 92/47 (66) | 0.12 |
| Length of TAB (mm), mean±SD | 17±6 | 16.±6 | 0.36 |
| Number of biopsy slices, mean±SD | 29±7 | 28±7 | 0.44 |
| Ischemic manifestations, n (%) | Headache | 45 (87) | 107 (77) | 0.15 |
| Abnormal examination of TA | 30 (58) | 61 (44) | 0.06 |
| Visual symptoms | 32 (62) | 44 (32) | <0.001 |
| Jaw/lingual claudication | 21 (40) | 107 (77) | 0.15 |
| Systemic manifestations, n (%) | PmR | 20 (38) | 93 (67) | <0.001 |
| Fever | 7 (13) | 20 (14) | 0.50 |

Dose (mg/day), median [IQR] 40 [25-40] 40 [25-40] 0.053
Cumulative dose (mg), median [IQR] 760 ± [360-2185] 484 ± [225-1295] 0.36
Time (days) from GC onset and TAB, median [IQR] 7± [3-13] 11± [4-24] 0.13

Conclusion: Longer exposure to GCs increases the likelihood of a negative TAB, especially in patients who did. Patients with positive TAB had more frequently visual symptoms and/or jaw/lingual claudication, while polymyalgia rheumatica (PMR) was less frequent. The median dose [interquartile range (IQR)] of the negative TAB group was 40 [25-40] mg/day and also 40 [35-60] mg/day in the positive TAB group. The median duration [IQR] of treatment in the first group was 11 [4-24] days, while in the second group it was 7 [3-13] days. The percentage of positive TAB was higher the shorter the delay between GCs treatment onset and the TAB, decreasing after 15 days from GCs therapy onset.

Figure 1. Positivity of TAB according to time from GC onset and TAB. 164 patients were treated with GCs prior TAB. All data are in % (n).
AB0714 CLINICAL CHARACTERISTICS AND RISK FACTORS ANALYSIS IN PATIENTS OF TA WITH CORONARY ARTERY CALCIFICATION

Keywords: Cardiovascular disease, Vasculitis
S. Yang1, L. Pan1, 2Beijing Anzhen Hospital, Capital Medical University, Beijing, Rheumatology and Immunology, Beijing, China

Background: Takayasu arteritis (TA) is a chronic inflammatory disease mainly involving large vessels, including the aorta and its main branches, pulmonary arteries and coronary arteries, which can usually lead to stenosis, occlusion, expansion, or aneurysm formation of the affected vessels [1-2]. Studies have shown that 10-20% of patients with TA have coronary lesions detected by angiography. In fact, this situation is still underestimated, because most TA patients do not complete the coronary angiography examination due to the lack of cardiac symptoms, such as palpitations and chest pain [3]. Coronary artery involvement is a serious adverse factor of poor prognosis and increases mortality in TA patients, specifically showing coronary artery stenosis, occlusion, and coronary artery calcification (cac) [4]. Patients with high coronary calcification scores have an extensive coronary plaque burden, with a high risk of stress-induced ischemic events [5].

Objectives: The aim of our study is to investigate the risk factors of cac in TA patients.

Methods: This retrospective study enrolled a total of 120 TA patients. All patients were divided into two groups according to the absence or presence of cac in TA patients (90 vs 30). We measured the Agatston score and compare clinical characteristics and ancillary findings between the two groups. A logistic model was applied to determine the risk factors associated with the incidence of cac in TA patients.

Results: A total of 30 patients with TA (25%) had cac. Age, medical history of hypertension and type of Numano V are the independent risk factors for developing cac in TA patients [OR (95% CI)]. 0.080 (1.020-1.143), p = 0.008; 5.457 [1.818-16.379], p = 0.002; 7.827 [1.822-33.615], p = 0.006. However it's not associated with disease activity and clinical symptom. We counted the number of risk factors for each patient and measured the integral value of the cac, and found that the integral value of cac increased with the number of risk factors. We also counted the medication status of patients before admission, and found that patients with cac had a greater proportion of statin (50% vs. 28.9%), fibrate (20% vs. 7.1%), and found that the integral value of cac increased with the number of risk factors.

Conclusion: Age, hypertension and Numano V type are risk factors for developing cac in TA patients. It is recommended that arterial coronar scree n in TA patients with Numano V type should be actively treated as early as possible. The severity of cac will increase with the number of risk factors, and TA patients should be actively treated and strictly controlled with blood pressure levels.

REFERENCES
[4] A total of 30 patients with TA (25%) had cac. Age, medical history of hypertension and type of Numano V are the independent risk factors for developing cac in TA patients [OR (95% CI)]. 0.080 (1.020-1.143), p = 0.008; 5.457 [1.818-16.379], p = 0.002; 7.827 [1.822-33.615], p = 0.006. AB0715 THE LONG-TERM PROGNOSTIC VALUE OF THE “2022 ACR/EULAR CLASSIFICATION CRITERIA FOR TAKAYASU ARTERITIS” DATA FROM A LARGE MONOCENTRIC COHORT

Keywords: Vasculitis, Real-world evidence, Prognostic factors
A. Tomelleri1, C. Campochiaro1, E. Rinaldi1, N. Viapiana1, E. Baldissera1, L. Dagni1, IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

Background: The ‘2022 classification criteria’ for Takayasu arteritis (TAK) have been developed for the purpose of classifying patients with TAK. These criteria provide a score from 0 to 22; a score ≥5 allows to classify a patient.

Objectives: To investigate whether the ‘2022 classification criteria’ score correlates with long-term outcomes of patients with TAK.

Methods: Data of patients with TAK followed up for ≥1 year and evaluated at least once within the last year at our Vasculitis Clinic were reviewed. For each patient, the score provided by the “2022 classification criteria” at baseline was calculated and the following outcomes at 24, 60, 120 months were evaluated: glucocorticoid (GC) suspension, introduction of a conventional disease-modifying anti-rheumatic drug (cDMARD), introduction of a biologic DMARD (bDMARD), need for vascular procedure, total number of bDMARDs received. Correlation of these outcomes with the score and with different thresholds (scores ≥5, ≥6, ≥7) was evaluated. Statistical tests were performed as appropriate.

Results: 120 TAK patients were included (103 women, 87.3%); mean follow-up duration was 154±113.8 months (24 months, n=110, 60 months, n=88, 120 months, n=60). Mean age at diagnosis was 37±13.6 years. 112 patients (93%) were classified as having TAK (mean score, 9.5±3). Seven patients (5.8%) were only treated with GC; 110 patients (91%) received at least one cDMARD (mean, 1.6±1); after a mean of 33±6.11 months, 80 patients (66.7%) received at least one bDMARD (mean, 1.2±1.5), after a mean of 40.1±6.45 months. GCs were suspended in 44 patients (36.7%), after a mean of 102.3±93.7 months. Forty-four patients (36.7%) underwent at least one vascular procedure (mean, 0.9±1.5). No significant correlation between the five outcomes and the score was found at all three timepoints (Table 1). No significant correlation between GC suspension, introduction of a cDMARD or a bDMARD, need for a vascular procedure and a score ≥5, ≥6, or ≥7 was found at all three timepoints (Table 1). A significant correlation between the total number of bDMARDs received at 120 months and both scores ≥6 and ≥7 was found (1.3±1.5 vs 0.6±0.8, p=0.045, and 1.3±0.6 vs 0.6±0.7, p=0.035, respectively).

Conclusion: Although the “2022 classification criteria for TAK” do not seem to correlate with the long-term prognosis, in our cohort we found that a higher base-line score (≥6) is associated with a higher number of bDMARDs received during follow-up. This suggests that the score might allow to identify TAK patients with a higher risk of poor prognosis and increases mortality in TA patients, specifically showing coronary artery stenosis, occlusion, and coronary artery calcification (cac).

Background: Giant cell arteritis (GCA) typically affects cranial vessels, but it can also affect large vessels in a high percentage of patients. Vascular inflammation of the aorta and/or its main branches can cause complications of high morbidity and mortality such as aneurysms, dissection, thrombosis and/or require aortic surgery. The analysis of the different clinical and imaging patterns in patients with GCA and aortitis and their relationship with the prognosis requires more investigation. Early identification of patients with the highest risk of mortality could help predict deaths and vascular complications.

Objectives: To evaluate the clinical characteristics of patients with giant cell arteritis (GCA) who present vascular complications.

To evaluate prognostic factors associated with vascular complications in patients with GCA.

Methods: A retrospective cohort study was carried out including patients diagnosed with GCA by a multidisciplinary expert committee in aortic pathologies. A total of 71 patients followed between the years 2011-2021 who had a PET-CT at onset before receiving treatment were included. Other causes of aortitis were excluded. Vascular complication was defined as the presence of aneurysm, dissection, thrombosis, or aortic surgery during the disease. Demographic, clinical, analytical and imaging variables were collected. A descriptive study of the sample and a groups comparison, according to the presence of vascular complication, was carried out. The Shapiro-Wilk test was used to test the normality of the variables. Univariate logistic regression was performed to assess predictive factors.

Results: A total of 71 patients were included, 73.2% were female and the mean age was 79.3 (±6.7) years. During the disease, 13 patients presented aortic vascular complication. Jaw claudication (p=0.014) were associated with a greater appearance of unknown origin, anemia and constitutional syndrome, and the use of glucocorticoids (p=0.035) was associated with the presence of vascular complication. The univariate analysis to identify predictive factors showed that anemia (OR: 0.11 [0.02-0.48], p=0.003) was a protective factor against the occurrence of vascular complication.

Conclusion: Occurrence of new vascular complications was observed in 18.3% of patients with GCA included in our study. Jaw claudication, fever of unknown origin, anemia and constitutional syndrome, and the use of pulses glucocorticoids as treatment were associated with a greater appearance of complications, while ischemic stroke with fewer complications. Anemia proved to be a protective factor against the occurrence of vascular complications.

Results: After IL-6 stimulation, we found a lowered proportion of pSTAT3 in CD4+ memory T-cells of GCA patients and INF controls compared to HCs. In GCA patients, proportion of pSTAT3 in CD4+ memory T cells was negatively associated with ESR at diagnosis (p=0.001, r=-0.729). Considering the link between IL-6 and ESR, we stratified GCA patients according to high (>15.5 pg/ mL) and low (≤1.5pg/mL) serum IL-6 levels and found that that the decrease in pSTAT3 in CD4+ memory T cells was especially found in GCA patients with high serum IL-6 levels. Importantly, we found that GCA patients with low ESR and high pSTAT3 at the time of diagnosis significantly predicted long-term glucocorticoid requirement. Levels of pSTAT3 in patients with high serum IL-6 levels at diagnosis normalized after 1 year of treatment.

Conclusion: We demonstrate a relation between serum IL-6 levels and in vitro pSTAT3 expression in GCA. Importantly, our results suggest that pSTAT3 can be an important prognostic marker in GCA.

Figure 1. A flowchart to diagnose c-GCA using v-US and imaging methods.
in 11, aneurysm in 4 and some other in 18. Thirteen patients (8 males and 5 females, mean age 59.69 years) showed positive aortic uptake. Among them, 6 patients underwent examination for a suspected vasculitis and 7 (53.8%) for other clinical conditions (e.g. neoplasm, FUO, polymyalgia rheumatica). Of all the patients who underwent 18FDG-PET for a suspected vasculitis, 7/25 (28%) showed abnormal vascular uptake. Moreover, among the 13 positive patients, three showed aortic uptake while the others also presented other large vessel involvement. Interestingly, in none of the isolated aortic vasculitis was the clinical question for the examination (arthritis, FUO, myocarditis).

Conclusion: the actual prevalence of aortic uptake may be underestimated and further wide-scale studies, which are currently ongoing, are expected to better identify the characteristics of CIA patients and their long-term course.

ACKNOWLEDGEMENTS: NIL.

The characteristics of CIA patients and their long-term course.

According to our results, 18FDG-PET may result positive despite the absence of clinical vasculitis-related manifestations, especially in case of CIA. For this reason, the actual prevalence of aortic uptake may be underestimated and further wide-scale studies, which are currently ongoing, are expected to better identify the characteristics of CIA patients and their long-term course.

Background: Giant cell arteritis (GCA) is the most common form of large vessel vasculitis. While remission and relapse are common primary endpoints in randomized clinical trials (RCTs), a definition of response is missing. We conducted a systematic literature review (SLR) to inform an international task force developing new response criteria in GCA.

Objectives: To identify descriptors used to measure response to treatment and change of disease activity in GCA in RCTs and longitudinal observational studies (LOS).

Methods: An SLR was conducted using Ovid Medline, Embase, and Cochrane Central. The research question was formulated according to the PICO framework: the population included patients with GCA, any intervention or comparator was considered, and the outcomes addressed were active disease, improvement/response, remission, worsening, relapse, flare, or recurrence. RCTs and LOS with >20 subjects and studies on qualitative research were included. Titles screening and full data extraction were performed by 2-3 reviewers. Discordant cases were discussed among reviewers until final consensus; if not achieved, a methodologist was consulted. In case of multiple publications from the same trial and LOS, they were only considered if separate, pre-specified outcomes were reported.

Results: 10,593 studies were retrieved in the search, of which 116 were finally included. The descriptors identified were incorporated in future phases of an international task force for the development of response criteria for GCA.

CHARACTERISTICS AND LONG-TERM OUTCOME OF DISEASE PHENOTYPES IN TAKAYASU ARTERITIS WITH SUPRA-AORTIC INVOLVEMENT

Keywords: Vasculitis, Cardiovascular disease

Y. Sun1,2,3, L. Wang1, H. Chen1, X. Dai1, L. Ma1, X. Kong1, L. Jiang1,2
1Zhongshan Hospital Fudan University, Rheumatology, Shanghai, China

Background: Supra-aortic involvement was most commonly seen in Takayasu arteritis (TA), ranging from 40% to 84%. [1, 2]. The clinical manifestations were heterogeneous and prognosis differed greatly in TA with supra-aortic involvement [3, 4].

Objectives: To explore the characteristics and long-term outcomes in different phenotypes of the East China Takayasu arteritis (ECTA) cohort with supra-aortic involvement.

Methods: Patients with supra-aortic involvement were enrolled from the ongoing ECTA cohort from July 2009 to December 2021 and followed up until June 30, 2022. Patients were assigned to four phenotypes: asymptomatic (AS), constitutional symptoms (CSs), vascular-associated symptoms (VAs), and neurological severe ischemic events (SIEs). Pattern differences in clinical features were analyzed, and the cumulative incidence of severe adverse events (SAEs) was evaluated. We performed multiple logistic regression analysis to compare the phenotypes.

Results: Six hundred fifty-seven TA patients with supra-aortic involvement were included: 54 (8.2%), 72 (11.0%), 303 (46.1%), and 228 (34.7%) patients with AS, CSs, VASs, and neurological SIEs, respectively. Compared to other phenotypes, CSs had significantly higher levels of inflammatory indicators. Neurological SIEs experienced poor treatment response including lower 6-month clinical remission rate and higher drug change rate. The median follow-up period was 3.0 (1.5–13.3) years. The 5-, and 10-year cumulative SAEs incidence rates in neurological SIEs (26.0% [18.7–32.1%], and 61.5% [30.3–78.7%]) were significantly higher than those in other patients (Figure 1). The occurrence of SAEs was 5.9 folds (3.4–10.1; p < 0.001) in patients with neurological SIEs history.

Conclusion: Our findings provide new insights into the characteristics and prognosis of different phenotypes in TA with supra-aortic involvement, which may be critical for early detection strategies and stratification management of heterogeneous diseases.

AB0722 ULTRASOUND HALO COUNT IN THE DIFFERENTIAL DIAGNOSIS OF ATHEROSCLEROSIS AND LARGE VESSEL GIANT CELL ARTERITIS

Keywords: Vasculitis, Cardiovascular disease, Ultrasound

I. Monjo1, E. Fernández-Fernández2, J. M. Mostaza3, C. Lahoz2, J. Molina Collada1, E. De Miguel3, La Paz University Hospital, Rheumatology, Madrid, Spain; 1Hospital Carlos III, Internal Medicine, Madrid, Spain; 2Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain

Background: Giant cell arteritis (GCA) is the most common vasculitis in the elderly and large vessel involvement occurs in up to 50% of cases. Otherwise, atherosclerosis is frequent in older patients; therefore, ultrasound (US) diagnosis of GCA in these patients may be challenging.

Objectives: To determine the diagnostic discriminant validity between large vessel giant cell arteritis (LV-GCA) and atherosclerosis using US with intima-media thickness (IMT) measurements.

Methods: We included 44 patients, paired by age and sex, with LV-GCA and 42 with high-risk atherosclerosis. US examinations of the axillary, subclavian and common carotid arteries (CCA) were systematically performed using a MylabX8 system (Genoa, Italy) with a 4-15 MHz probe. IMT ≥1mm was accepted as pathological.

Results: The LV-GCA cohort included 24 females and 20 males with a mean age of 72.8±6.7 years. The atherosclerosis group included 25 males and 17 females with a mean age of 70.8±6.5 years. Mean IMT values of all arteries included were significantly higher in LV-GCA than in atherosclerosis. The frequency and localization data are shown in Table 1. Among LV-GCA patients IMT ≥1mm was seen in 31 axillary, 30 subclavian and 28 CCA. In the atherosclerotic cohort, 17 (38.6%) had IMT ≥1mm with axillary involvement in 2 patients, subclavian in 3 patients, carotid distal in 14 patients (5 bilateral) and isolated carotid proximal affection in 1 case. A cut-off point of at least 1 pathological vessel in the summative count of axillary and subclavian arteries or at least 3 vessels in the count of six vessels, including CCA, showed a precision upper 95% for GCA diagnosis in front of atherosclerosis.

Conclusion: The IMT is higher in LV-GCA than in atherosclerosis. The proposed US halb count achieves an accuracy >95% for the differential diagnosis between LV-GCA and atherosclerosis. The axillary and subclavian arteries have higher discriminatory power, while carotid involvement is less specific in the differential diagnosis. "This study was presented in November 2022 at the ACR Convergence.

Background: There are few studies comparing clinical, laboratory, and imaging characteristics, and treatment of LV-GCA and TAK [1-3].

Objectives: To compare clinical and imaging characteristics in patients with Takayasu arteritis (TAK) and large vessel-giant cell arteritis (LV-GCA) in an Italian population.

Methods: We conducted a retrospective monocenter study comparing characteristics and outcomes of a cohort of 59 patients with TAK and a cohort of 127 patients with LV-GCA diagnosed between 1996 and 2016 and followed up for at least 24 months at Reggio Emilia Hospital (Italy).

Results: LV-GCA patients had a higher prevalence of males (p=0.003), and more frequently presented with cranial symptoms (p=0.001), fever>38°C (p=0.007), polymyalgia rheumatica (p=0.001), and hypertension (p=0.001), and they had higher ESR levels at diagnosis (p=0.0001). Differently, TAK patients had longer delay to diagnosis from the beginning of symptoms (p=0.048), they presented more frequently with loss of pulses (p=0.0001), vascular bruits (p=0.001), limb claudication (p=0.003), myocardial infarction/angina (p=0.03), and hypertension induced by renal artery stenosis (p=0.001). Regarding treatment, TAK patients received a higher total and at 1 year cumulative prednisone doses (0.0001 and 0.001, respectively), they had a longer duration of prednisone therapy (p=0.008), and received during follow-up more frequently traditional immunosuppressants (p=0.0001) and biological agents (p=0.0001). Flares were more frequently observed in TAK patient (p=0.001), while no differences were observed for long-term remission. New vascular procedures during the follow-up were more frequently performed in TAK patients (p=0.0001). Regard-
Conclusion: Our study revealed persistent vascular uptake on repeated 18F FDG PET/CT scan in over 1/3 of LVV patients with clinical and biological con- trolled disease. The significance of this residual uptake and its prognostic value is currently unknown. Therefore the routine use of 18F FDG PET/CT alone in monitoring disease activity and treatment response may be not appropriate and therapy should not be modified based on scan results only. Further research is needed in order to place the correct use of imaging in the long term monitoring of LVV.

BARICITINIB FOR THE TREATMENT OF REFRACTORY VASCULAR BEHÇET’S DISEASE: A PILOT STUDY IN CHINA

Keywords: Targeted synthetic drugs, Vasculitis, Behçet's disease
Z. Wang1, X. Wang2, J. Liu1, L. Zhang1, W. Zheng1. 1Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Major vessel involvement in Behçet's Disease (BD) profoundly affects morbidity and mortality. Monoclonal anti-TNF antibodies are recom- mended for severe and (or) refractory vascular BD (VBD) beyond glucocorticoids (GCs) and immunosuppressants (IS), while some patients are still struggling due to inadequate response and relative contraindications. Our group has previously reported the efficacy of JAK1/JAK3 inhibitor tofacitinitab for treating VBD[1]. We hypothesized that the JAK1/JAK2 inhibitor baricitinib might be a potential ther- apeutic choice in VBD patients through a broader panel of cytokine inhibition.

Objectives: This is a single-center, one-arm, self-controlled, open-label pilot study aimed at evaluating the effectiveness and safety of the JAK1/JAK2 inhibitor baricitinib in BD patients with refractory vascular involvement.

Methods: We consecutively enrolled refractory VBD patients who received baricitinib treatment (2mg/ day) at Peking Union Medical College Hospital between Mar 2020 and Jan 2022. Efficacy assessment mainly depends on the proportion of clinical remission after 3-month treatment. Other outcomes include disease activity, organ damage evaluation, GCs and IS-sparing effects, and side effects.

Results: A total of 17 patients (12 males) were included, with a mean age of 37.9 ± 11.9 years and a mean follow-up of 10.5±4.4 months (Table 1). Before enrollment, all patients had insufficient response or intolerance to conventional therapies and (or) biologics (five patients failed first-line anti-TNF mAb using infliximab/ adalimumab/golimumab, and two patients had second-line therapy with other anti-TNF mAb, but still responded inadequately). At the 3-month follow-up, 13 (76.5%) patients achieved a complete response and the proportion increased to 88.2% (15/17) at the last visit. Laboratory parameters ESR (13 IQR 7−40.5) vs 8 (IQR 2–17.5) mm/h, p<0.01) and CRP (11.8 (IQR 2.5–18.5) vs 1.2 (IQR 0.6–5.2) mg/L, p<0.0001) decreased significantly 3 months after baricitinib use (Figure 1), as well as the Behçet's Disease Current Activity Form (BDCF) score during follow-up.

Figure 1. Outcomes of baricitinib treatment. Change in (a) ESR, (b) hsCRP, and (c) BDCAF score during follow-up.

Background: Previous studies have reported that four functional C-reactive protein (CRP) gene polymorphisms, namely rs1417938, rs1800947, rs1205, and rs3093059 variants, were associated with plasma CRP levels, but not with clini- cal manifestations of giant cell arteritis (GCA) (1)

Objectives: Aim of our study was to investigate potential associations between two other functional variants of CRP gene at position 3872GA (rs2015) and 4741G>C (rs3093068) with susceptibility to biopsy-proven GCA, baseline clinical and laboratory findings, treatment, and disease outcomes.

Methods: 164 patients with biopsy-proven GCA, resident in Reggio Emilia area (Italy), and 198 healthy controls from the same geographic area were genotyped for 3872GA (rs2015) and 4741G>C (rs3093068) CRP gene polymorphisms by molecular methods. Data collected for all cases included comprehensive infor- mation about clinical findings, laboratory tests, historiologic data, imaging, thera- pies, and flares. Long-term remission was defined as permanent discontinuation
of glucocorticoids without flares for at least 1 year. All patients were followed according to a standardized predefined follow-up and therapeutic protocol. At the end of the follow up period, we evaluated for each patient the number of flares, long term remission, the duration of steroid treatment and the cumulative glucocorticoid dose.

**Results:** Association analysis of 3872G>A polymorphism showed that allele A homoyzosity was significantly more frequent in cases than in healthy controls (OR =2.32, 95% CI: 1.26-4.27, p=0.006). Association analysis of 4741C>G polymorphism showed that allele G carried by CG and GG genotypes was significantly lower in GCA patients than in controls (OR =0.35, 95% CI: 0.17-0.70, p=0.002). No significant associations were found between these 2 polymorphisms and baseline clinical manifestations. Patients homozigous for the allele A had a significantly lower frequency of CRP values >5mg/dl at diagnosis compared to patients carrying GA or GG genotypes (44.5% vs 72.4%, p=0.018, OR 0.31, 95% CI: 0.11-0.85). Considering 4741C>G CRP gene polymorphism, patients carrying G allele had at diagnosis significantly higher levels of CRP (13.2±5.5 vs 8.9±6.3 mg/dl, p=0.037) and ESR (105±30.6 vs 86.6±29.0 1st hour, p=0.040), and lower levels of Hb (10.3±1.2 vs 11.3±1.5 mg/dl, p=0.044). At histological examination of temporal artery biopsy (TAB), patients homozigous for the allele A had significantly more frequent eosinophilic infiltration of the arterial wall (21.4% vs 6.0%, p=0.010, OR 4.28, 95% CI: 1.31-13.98) than patients carrying allele G. Furthermore, patients carrying the allele A had lower steroid treatment duration (52±56 vs 79±78 months, p=0.041), lower cumulative steroid dose (11146±7162 vs 18520±19659 mg, p=0.017), higher frequency of steroid treatment withdrawal (61.5% vs 39.6%, p=0.016) and of longterm remission (60.3% vs 39.6%, p=0.024). Survival analyses demonstrated a significant difference for the duration of steroid treatment and the frequency of long term remission between the three AA, AG and GG genotypes (p=0.033 and p=0.031 respectively).

**Conclusion:** Single nucleotide polymorphisms of PCR gene at position 3872G/A (rs2015) and 4741C>G (rs3090368) have impact on susceptibility and outcomes of biopsy-proven GCA.

A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PARALLEL GROUP STUDY TO EVALUATE THE EFFICACY OF METHOTREXATE AS REMISSION MAINTENANCE THERAPY AFTER REMISSION-INDUCTION THERAPY WITH TOCILIZUMAB AND GLUCOCORTICOIDS IN SUBJECTS WITH GIANT CELL ARTERITIS (METEORITICS TRIAL): STUDY PROTOCOL

**Keywords:** Disease-modifying drugs (DMARDs), Vasculitis, Clinical trials

**Authors:** L. Kreiß1, W. A. Schmidt2, N. Venhoff3, C. Dejaco4, V. Schäfer1.

1University Hospital Bonn, Department of Internal Medicine III - Oncology, Hematology, Immunology and Rheumatology, Bonn, Germany; 2Immanuel Krankenhaus Berlin, Medical Centre for Rheumatology Berlin-Buch, Berlin, Germany; 3University of Freiburg, Faculty of Medicine, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; 4Medical University Graz, Graz, Rheumatology, Graz, Austria

**Background:** Giant cell arteritis (GCA) is the most common systemic vasculitis found in adults over 50 years of age and affects medium and large vessels. The standard treatment is glucocorticoids (GC). Because of the negative side effects of GC and the high prevalence of relapses GC should be combined with other immunosuppressive or immunomodulatory agents. Since the GIACTA Trial and other randomized controlled trials (RCT) assigned tocilizumab (TCZ) a GC-sparing effect, higher remission rates compared to placebo and the potency to maintain remission even without GC this biologic is a promising option to treat GCA. Due to the high costs of the TCZ treatment and the increased risk of infections, other treatment options are needed in the long term. An RCT published by Adler et al. showed that only 55% of patients remained in remission after discontinuation of intravenous TCZ therapy. It highlights the need for options to maintain remission after discontinuation of TCZ. The combination of methotrexate (MTX) and GC was also effective in reducing relapse rate and the cumulative GC doses in new or relapsing GCA.

**Objectives:** The primary objective of the study is to investigate whether MTX is useful for maintaining remission after remission-induction with TCZ and GC in patients with GCA. In addition, we evaluate patient and investigator reported outcomes, prevalence of aortitis, number of vasculitic vessels and change of intima-media-values during the study.

**Methods:** This monocentric, randomized, double-blind, placebo-controlled study estimates the efficacy of MTX through a treatment period of 12 months and a six-months follow-up. Patients who are in stable remission after treatment with GC and at least six months of treatment with TCZ for new-onset or relapsing giant cell arteritis are eligible for inclusion. Forty participants will be randomly assigned to the treatment arm (N=20) and the placebo arm (N=20). The treatment consists of 17.5 mg MTX subcutaneous weekly for 12 months as a monotherapy. In case of intolerance, elevated liver enzymes or low glomerular filtration rate a dose reduction is possible. In event of relapse an escape treatment with GC on a tapering regimen is added to the study medication. Assessments are conducted eight times during the treatment period and twice during the follow-up. An ultrasound examination takes place on every study visit to measure the intima-media-values of several arteries. Magnetic resonance imaging is performed on baseline, month 12 and 18 to detect aortitis. The primary endpoint is the time to first relapse during the 12 months therapy.

**Figure 1. Study design**

Arrows indicate study visits mg, milligram; SC, subcutaneous; BSL, baseline; M, month; GC, glucocorticoids; ULN, upper limit of normal.

**Results:** No results are available yet.

**Conclusion:** This is the first study that evaluate MTX as remission maintenance therapy after stable remission has been induced by GC and TCZ in GCA. MTX could be an effective, safe, inexpensive therapy agent after discontinuation of TCZ.

AORTITIS SPECTRUM. STUDY OF 82 PATIENTS FROM A SINGLE REFERRAL CENTER

**Keywords:** Real-world evidence, Vasculitis

1Hospital Universitario Marqués de Valdecilla, IDIVAL, Rheumatology, Santander, Spain; 2Hospital Universitario Marqués de Valdecilla, Cardiovascular Surgery, Santander, Spain;

**Background:** Aortitis is the inflammation of the aortic wall, and can be idiopathic or associated with a cluster of infectious and non-infectious diseases. Giant-cell arteritis (GCA) and Takayasu arteritis (TA) are the most common underlying [1,2].

**Objectives:** To assess the causes and the main features of patients with aortitis. Methods: Observational study of patients with aortitis from a large-vessel vasculitis monographic consultation at a referral hospital from June 2022 to December 2022. Aortitis was diagnosed by imaging techniques. We present 82 patients (52 female/30 male) (mean±SD age; 60.2±12.6 years). The different subtypes of aortitis were: GCA (n=69), Takayasu arteritis (n=6), other inflammatory autoimmune diseases (n=3), IgG4-related disease (IgG4-RD) (n=2), syphillis (n=1) and isolated aortitis
(n=1). The imaging techniques used for the diagnosis of aortitis were: PET/TAC (n=81), TAC (n=23), RMN (n=20) and arteriography (n=10). The main features of the patients are summarized in Table 1. Aortitis was most frequent in women. 50% of patients had high blood pressure and dyslipidaemia. Polymyalgia rheumatica and asthenia were more frequent manifestations. The underlying diseases in the group of aortitis related to other inflammatory autoimmune diseases were: ulcerative colitis (n=1), idiopathic retroperitoneal fibrosis (n=1), and polyarteritis nodosa (n=1). The ascending thoracic aorta and the supraaortic trunks were the most frequently involved segments (Figure 1).

Conclusion: Aortitis is an entity which can be isolated or secondary to infectious and non-infectious process. Among the non-infectious causes, GCA and TA are the most frequent, being common the presence of PMR and asthma. The ascending thoracic aorta and the supraaortic trunks seems to be the most frequently involved segments.

DOI: 10.1136/annrheumdis-2023-eular.5317
Results: The study included 31 TAK patients (age 28 [21-48], 87% female) exposed to a total of 52 treatment regimens (n=4 GC monotherapy, n=17 cDMARDs, n=5 anti-TNF, n=20 cDMARDs+anti-TNF, n=6 TCZ). Overall clinical remission rate during the follow-up was 75% in GC treated patients, 70.6% in cDMARDs-treated, 100% in anti-TNF-treated, 80% in cDMARDs+anti-TNF-treated and 100% in TCZ-treated. Persistence of treatment was 19[8-30.75] months in GC group, 10[5.5-26.5] in cDMARDs group, 15[12-44] in anti-TNF group, 21[17.5-81.75] in cDMARDs+anti-TNF group and 4 [17-64.5] in TCZ group. Treatment with cDMARDs+anti-TNF and TCZ led to a significant reduction of acute phase reactant levels (C-Reactive Protein: cDMARDs+anti-TNF 31[9-193] vs2[9-4.6] mg/L, <0.001; TCZ 31.5[10.5-59] vs2[9-2.8-7.5] mg/L, 0.009) (Erythrocyte Sedimentation Rate: cDMARDs+anti-TNF 43[14-84] vs17.5[10-25.75] mm/h, 0.017; TCZ 15[5-55] vs5.5 [2-11.75]). Daily GC dose at last follow-up was 0 in cDMARDs+anti-TNF group (25vs0 mg, p<0.001) and TCZ (11.25vs 0 mg, p<0.007). All the therapeutic regimens led to a significant reduction of disease activity at last follow-up (ITAS2010 in GC-treated 0 [0-1.5], in cDMARDs-treated 0 [0-1], in anti-TNF treated 0 [0-1], in cDMARDs+anti-TNF 0 [0-0], in TCZ 0 [0-0].) LVVID did not significantly increase during follow-up in patients treated with cDMARDs, anti-TNF, cDMARDs+anti-TNF and in TCZ. Imaging data shown an improvement in metabolic activity at LFU in 33.3% of TCZ-treated patients and in 40% of cDMARDs+anti-TNF treated patients.

Conclusion: Anti-TNF, cDMARDs+anti-TNF and TCZ led to a statistically significant reduction in GC dosage, allowing steroid sparing. Compared to monotherapy, treatment regimens with cDMARDs+anti-TNF and TCZ could lead to a better disease control in terms of clinical activity and inflammatory markers and overall is the only therapeutic lines that provides an improvement in metabolic activity on imaging.

TOCILIZUMAB TREATMENT IN SEVERE AND REFRACTORY BEHÇET’S SYNDROME: A CASE SERIES

Keywords: Behçet's disease, bDMARD

Z. Toker Dinçer1, 2, B. Yurttas1, 2, S. N. Esatoglu1, 2, D. Ucar2, 3, S. Ugur1, 2, 3, Y. Ozguler2, 3, E. Seyahi1, 2, M. Melikoglu2, 3, I. Fresko1, 2, V. Hamuryudan1, 2, A. Siva, G. Hatem1, 2, 3, 4, Istanbul University–Cerrahpaşa, Cerrahpaşa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 1Istanbul University–Cerrahpaşa, Cerrahpaşa Medical Faculty, Behçet Syndrome Research Center, Istanbul, Turkey; 1Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey; 1Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Istanbul, Turkey

Background: Tocilizumab may be an alternative for patients with Behçet's Syndrome (BS) refractory to conventional immunosuppressives and TNF inhibitors.

Objectives: We aimed to report our experience with tocilizumab in patients with BS.

Methods: We identified BS patients who were treated with tocilizumab for eye, nervous system and arterial involvement, and amyloidosis, using our hospital's electronic medical records. Demographic and clinical features, previous therapy, treatment response, outcomes, and adverse events were retrieved from patient charts.

Results: Of 12 patients with BS (M/F: 9/3, mean age 44.4±10.3 years) were treated with tocilizumab for uveitis (n=6), parenchymal nervous system involvement (n=2), aortitis (n=2) and amyloidosis (n=2) between 2014-2022. Previous treatment modalities and treatment response for uveitis are shown in Table 1. Only 2 of the 6 patients with uveitis obtained remission with tocilizumab. Both patients with neurological involvement were refractory to tocilizumab treatment. They had previously used colchicine, steroids, azathioprine, interferon-alpha, infliximab, and adalimumab. Additionally, one had used cyclophosphamide and the other methotrexate and mycophenolate mofetil.

Conclusion: BS patients with aortitis obtained remission with tocilizumab voluntarily, and the other due to dyslipidemia. Overall, tocilizumab was discontinued in 10/12 patients after 10.1±7.8 months. Adverse events were increased mucocutaneous lesions in one and dyslipidemia in another patient.

CUTANEOUS AND ARTICULAR MANIFESTATIONS OF BEHÇET’S DISEASE

Keywords: Behçet's disease

Y. Abdi1, R. Amri1, H. Tounsi1, S. Wafa1, I. Chaabane1, Z. Alaya1, 1Regional Hospital Mohamed Taher Al Maamouri, Internal Medicine, Mreza, Tunisia

Background: Behçet's disease is a chronic inflammatory disease evolving by relapses whose etiopathogenesis remains poorly elucidated. It is characterized by polymorphism and a clinical heterogeneity associating oral and genital aphthae with systemic manifestations and cutaneous and articular manifestations.

Objectives: The aim of this study is to describe the epidemiological and clinical aspects of the articular and cutaneous-mucosal manifestations during Behçet's disease.

Methods: This was a monocentric, retrospective, and descriptive study. It was conducted over a period of 30 years and included all patients with Behçet's disease followed at the internal medicine department and meeting the international criteria for Behçet's disease.

Results: We collected 98 patients. A male predominance was observed (sex ratio of 2.5) with an average age of onset of the disease of 31 years. Familial forms were observed in 5.1%. Oral aphthae was constant. The different localization were on the inner side of the lip in 17 cases (88%), the inner side of the cheek in six cases (24%), the tongue in two cases (8%), and the gums in one case (4%). Genital aphthae was found in 81 cases. Other manifestations were pseudofolliculitis (61 cases), erythema nodosum (7 cases), cutaneous aphthosis (4 cases), acneform lesions (2 cases), cutaneous vasculitis (2 cases), and erythema multiforme (1 case). The pathergy test was performed in 30 cases. It was positive in 23 cases (76%). Joint involvement was present in 47 patients. The average age of diagnosis of joint involvement was 34 years. The mean time to diagnosis was 25 months. The involvement was peripheral in the majority of cases (95.7%), with the predominant site being the knees (67%). It was in the form of inflammatory arthralgias in 45 patients, associated with arthritis in 14 cases. Other manifestations were: low back pain (2 cases), sacroiliitis (1 case), bone erosion involving the hand (1 case), and popliteal cyst (1 case).

Conclusion: In Behçet's disease, the clinical manifestations are very polymorphic. Its polymorphic and non-specific clinical presentation can be a source of confusion with other pathologies. Cutaneous and articular manifestations are the most frequent.

Vasculitis - large vessel vasculitis

OUTCOMES OF PERCUTANEOUS TRANSLUMINAL ANGIOPLASTY IN TAKAYASU ARTERITIS: A SINGLE CENTER EXPERIENCE

Keywords: Vasculitis

A. Ciotean1,2, C. Pamfil1,3, M. M. Tamas1,3, L. Damian1,3, S. Rednic1,3, I. Iuliu Hatelagaru1 University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania; 2Emergency County Hospital, Rheumatology, Satu Mare, Romania; 3Clinical Emergency County Hospital, Rheumatology, Cluj-Napoca, Romania.

Background: Revascularization endovascular techniques have been used with success in Takayasu arteritis (TA), but relapses sometimes appear. (1) There is much debate regarding optimal management and outcomes of patients who underwent these procedures. (2,3)

Objectives: The aim of the study was to investigate the long-term efficacy of percutaneous transluminal angioplasty (PTA) in patients with TA from a Romanian tertiary rheumatology center and factors that might influence it.

Methods: Data from clinical charts of patients with a diagnosis of TA established in the last 15 years who underwent interventional revascularization procedures were retrospectively studied. Symptoms, laboratory investigation results, data about treatment and outcome were analysed at baseline and follow-up.

Results: There were 11 interventions of PTA in 6 patients with a diagnosis of TAK, all of them in women. The mean follow-up period was 59 months. Cardiologists were the ones who diagnosed the disease in 83% of the patients included. The mean delay in diagnosis was 74 months, while the biggest delay was of 242 months. Hypertension was the first sign of disease in 3 of the patients, while the rest complained of limb claudication (2 patients) and acute limb ischemia phenomenon (1 patient). The average disease duration until PTA was 65 months and most of them were done at the time of diagnosis (54%). PTA was performed while the disease was active in 100% of cases and biological inflammatory syndrome was present in 45% of cases. Symptoms relief was seen in all patients. Restenosis was seen in 3 cases – two of them in patients with lack of treatment adherence and one in a patient who wasn’t given immunosuppression (due to delay in diagnosis). Restenosis was experienced 52 months after PTA, on average. Symptoms included relapse of limb claudication in 2 patients and hypertension and renal failure in a patient with renal artery restenosis. Inflammatory markers were raised in two cases. Clinical improvement was seen in all the patients after reintervention.

Conclusion: PTA is a valuable intervention in TA patients that significantly improves clinical symptoms. Relapses may appear especially in patients with deficient immunosuppression, and they may need revascularization interventions.

CONCORDANCE BETWEEN THE 1990 ACR CLASSIFICATION CRITERIA AND THE NEW 2022 ACR/EULAR 2022 CRITERIA IN GIANT CELL ARTERITIS

Keywords: Diagnostic tests, Vasculitis, Epidemiology

J. Sanchez-Martín1, J. Medina-Del Valle1, J. Loricera1, M. F. García-Reija2, R. Blanco1, 1Hospital Universitario Marqués de Valdecilla, IDIVAL, University of Cantabria, Santander, Spain, Rheumatology, Santander, Spain; 2Hospital Universitario Marqués de Valdecilla, IDIVAL, University of Cantabria, Santander, Spain, Oral and Maxillofacial Surgery Service, Santander, Spain.

Background: Classification criteria for vasculitis, including giant cell arteritis (GCA) are under constant revision. In 2022, the American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria were presented, renewing those published by ACR in 1990. They include wider range of clinical criteria and imaging tests, such as ultrasonography (US) and Positron emission tomography (PET), which has contributed to the diagnosis of a higher number of cases.

Objectives: To assess the concordance between recent 2022 ACR/EULAR giant cell arteritis classification criteria and the criteria of ACR 1990 [1,2].

Methods: Observational study of patients diagnosed with GCA who underwent temporal artery biopsy (TAB) between 2016 and 2022 in an university hospital. Concordance between both sets of criteria were analyzed with Cohen's kappa index.

Results: We present 191 patients (120 female/71 male) (means±SD: 75±10 years). The main characteristics of the patients are shown in Table 1. The Kappa index between both criteria weighted by prevalence and bias was 0.654 (moderate-high degree of agreement). Global agreement of 83% was observed, with a higher specific agreement for negative results (88%) than for positive results (67%).

Disagreement was observed in 16% of patients who were considered negative for ACR 1990 criteria but positive for ACR/EULAR 2022 criteria and in 2% who were considered positive for ACR 1990 criteria but negative for ACR/EULAR 2022. 2022 ACR/EULAR showed a higher sensitivity, and 27 additional patients were classified as GCA with these classification criteria.

Conclusion: Moderate-high concordance was found between 2022 ACR/EULAR and 1990 ACR classification criteria. However, the 2022 ACR/EULAR criteria consider a wider range of factors than the 1990 ACR criteria by introducing US and PET findings, thus increasing sensitivity and allowing a larger number of patients to be diagnosed. Cranial GCA was the most frequent phenotype observed.

POLYPHARMACY AND COMORBIDITIES ARE NOT INCREASED AT DIAGNOSIS IN PATIENTS WITH POLYMYALGIA RHEUMATICA

Keywords: Malignancy, Comorbidities

M. A. Cimmino1, E. Hysa1, P. Cini1, D. Camellino2. 1Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Genova, Italy; 2Division of Rheumatology, La Colletta Hospital, Azienda Sanitaria Locale 3, Arenzano, Italy

Background: Polypharmacy, the prescription of multiple drugs for an individual patient, is increasing especially in ageing individuals with comorbidities. Polymyalgia rheumatica (PMR) is an inflammatory disease of the elderly causing pain and stiffness in the girdles. A recent systematic review showed that cardiovascular disease and lymphoproliferative disorders could be possibly increased in PMR patients, but the quality of the included studies was relatively poor. In addition, some comorbidities could be caused by PMR treatment and not by the disease itself.

Objectives: Our study is concerned with an evaluation of polypharmacy and comorbidities in PMR patients at diagnosis.

Methods: Patients were enrolled if they fulfilled the 2012 EULAR/ACR provisional criteria for PMR. Sex and age-matched controls were patients with hand OA diagnosed according to the 1990 ACR clinical criteria and seen in the same private outpatient clinic as patients. Both groups were interviewed at the time of diagnosis for the type and number of assumed drugs and comorbidities by the same investigator. The rheumatic diseases comorbidity index (RCDI) was used.

Results: 83 PMR patients (median 75 years, range 50-88 years, 65.1% women) and 83 controls (median 72 years, range 53-90 years, 65.1% women) were studied. Median disease duration was 2 months (0.3-8 months) and median glucocorticoid dose before assessment was 0 mg (0-750 mg). The mean number of drugs assumed by PMR patients was 2.5±2.1 in comparison with 3.0±2.2 of controls (p=0.129). PMR patients with hip pain assumed less drugs (2.1±1.8 vs. 3.7±2.3, p=0.008) and those with morning stiffness >45 minutes assumed more drugs (2.8±2.1 vs. 2.8±2.1, p=0.001). The mean RCDI was 1.58±1.29 in PMR patients and 1.45±1.36 in controls (p=0.52). The frequency of the individual comorbidities in PMR patients and controls is reported in Table 1. No difference was observed in cancer type. Number of assumed drugs and RDCI significantly correlated (r=0.58; p<0.001), and both were directly associated with age (p<0.001). At multiple logistic regression, with number of assumed drugs as dependent variable and variables which showed in univariate analysis p<0.1 as independent ones, age (p=0.007) directly, whereas hip pain (p=0.006) and fever (p=0.014) indirectly predicted number of assumed drugs. With RDCI as dependent variable, age (p=0.04) and WBC (p=0.02) directly, whereas fever (p=0.019) indirectly predicted RDCI.

Conclusion: When considered at the time of diagnosis, PMR patients do not show an increased comorbidity index nor number of assumed drugs in comparison with OA controls. Only gastric disease was lower, possibly due to the increased NSAIDs use in OA patients.

THE EFFECT OF NEW CLASSIFICATION CRITERIA ON THE DIAGNOSIS OF LARGE VESSEL VASCULITIS

Keywords: Vasculitis, Rare/orphan diseases, Epidemiology

C. Mukhtyar1, C. Beadsmoore2, F. Coath1, G. Ducker1, K. Sisson1, R. Watts1. 1Norfolk and Norwich University Hospital NHS Foundation Trust, Rheumatology, Norwich, United Kingdom; 2Norfolk and Norwich University Hospital NHS Foundation Trust, Radiology, Norwich, United Kingdom

Background: GCA and Takayasu arteritis are the two recognised forms of LVV. In addition, there is recognition of LVV which are not easily classified into the two forms. Classification criteria have been proposed since 1990 and have been recently updated. Classification criteria should be able to minimise the number of cases that are unclassifiable and the number of cases that are classified into more than one set. We used both sets of criteria to test their performance in our cohort.

Objectives: To study the performance of large vessel vasculitis classification criteria in a real world cohort.

Methods: Between January 2011 to December 2020, 270 individuals were diagnosed as having LVV by virtue of having either a positive biopsy, ultrasonography, or PET scan. The ACR 1990 and the ACR/EULAR 2022 classification criteria were applied on our cohort.

Results: The mean age was 74, 181 were female. Using the 1990 criteria, 2 individuals met both classifications and 30 did not meet either. Using the 2022 criteria, 3 individuals met both classifications and 24 did not meet either. The numbers classified as having TAK has reduced from 13/270 to 2/270. The numbers classified as GCA have increased from 225/270 to 241/270. (Figure 1)

Conclusion: The new classification criteria have expanded the phenotype recognised as having Takayasu mostly by declassifying it as not meeting any criteria. Overall, the new criteria improve classification for 5/270 (1.8%) cases.

EPILOGUE OF CLINICALLY ISOLATED AORTITIS: A POPULATION-BASED STUDY

**Keywords:** Vasculitis, Epidemiology

M. Kaymakci1, M. Elfishawi1, H. Langenfeld2, C. S. Crowson2, W. Cornelia2, M. Koster1, K. J. Warrington1. Mayo Clinic, Division of Rheumatology, Department of Medicine, Rochester, United States of America; 2Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America

**Background:** Clinically isolated aortitis (CIA) refers to inflammation of the aorta without signs of systemic vasculitis or infection [1]. The diagnosis of CIA generally relies on histopathologic evaluation of aortic tissue obtained during thoracic aortic aneurysm surgery making the diagnosis more challenging. Recent studies suggest that CIA might be a limited presentation of giant cell arteritis [2]. Population-based data on the epidemiology of CIA in North America is lacking.

**Objectives:** The objectives of this study were to evaluate the epidemiology, clinical characteristics, and outcomes of patients with CIA.

**Methods:** In a defined geographical area, all possible subjects were screened for thoracic aortic aneurysm procedures with current procedural terminology (CPT) codes between January 1, 2000, and December 31, 2021. The medical records of all patients were manually reviewed. CIA was defined as histopathologically confirmed active aortitis diagnosed by evaluation of aortic tissue obtained during thoracic aortic aneurysm surgery in the absence of any infection, rheumatic disease, or systemic vasculitis. Incidence rates were age and sex adjusted to the 2020 United States total population. Mortality rates were estimated using the Kaplan-Meier method and were compared with expected mortality rates for persons of the same age, sex, and calendar year estimated using Minnesota population life tables.

**Results:** Eight incident cases of CIA were diagnosed during the study period (Figure 1); 6 (75%) of them were female. Median (IQR) age at diagnosis of CIA was 78.3 (70.2–78.9) years; all were diagnosed following ascending aortic aneurysm repair. The overall age and sex adjusted annual incidence rate of CIA was 8.9 (95% CI, 2.7–15.1) per 1,000,000 individuals over age 50 years. Histopathologic evaluation demonstrated giant cell aortitis in 7 (88%) patients and lymphoplasmacytic aortitis in 1 (13%) patient. Five (63%) patients were seen by a rheumatologist and 2 (25%) were treated with glucocorticoids after the diagnosis. CIA was defined as histopathologically confirmed active aortitis diagnosed by evaluation of aortic tissue obtained during thoracic aortic aneurysm surgery in the absence of any infection, rheumatic disease, or systemic vasculitis. Incidence rates were age and sex adjusted to the 2020 United States total population. Mortality rates were estimated using the Kaplan-Meier method and were compared with expected mortality rates for persons of the same age, sex, and calendar year estimated using Minnesota population life tables.

**Conclusion:** This is the first population-based epidemiologic study of CIA in North America. CIA predominantly affects older women and is quite rare. In this small cohort, survival following a diagnosis of CIA was not significantly different than the general population.

FAST TRACK PATHWAY: A GIANT STEP FOR THE DIAGNOSIS AND MANAGEMENT OF GIANT CELL ARTERITIS

**Keywords:** Vasculitis, Patient reported outcomes, Validation

Y. El Miedany1, D. Affam2, S. Rahman2, M. Toth3. 1Canterbury Christ Church University Medway Campus - Medway Foundation Trust, Dartford, United Kingdom; 2Darent Valley Hospital, General Medicine, Dartford, United Kingdom; 3King’s College London - Darent Valley Hospital, General Medicine, London, United Kingdom

**Background:** Giant cell arteritis (GCA), a medium and large vessel vasculitis remains a formidable disease. Through feed-forward loops and a multitude of vascular complications, GCA impacts seriously negatively on both the patient’s vision as well as life. In 2018, Darent Valley Hospital published its GCA management pathway [1] and launched a fast track GCA clinic in 2019. This included clinical assessment along with US examination in the rheumatology outpatient clinic. The pathway enabled direct access to both general practitioners in primary care as well as health care professionals in secondary care to this service. Education sessions for both the primary and secondary care teams were carried out to inform them of the referral criteria and the service pathway.

**Objectives:** To evaluate the impact of implementing the GCA-fast track pathway on prompt diagnosis and treatment of GCA.

**Methods:** Retrospective cohort analysis of patients referred to the Fast Track GCA clinic. A cohort of patients with new suspected diagnosis of GCA along with acute flare ups of diagnosed GCA cases were referred to the clinic according to a set up referral criteria. All the patients referred to the clinic were offered an appointment within 24-hours and had blood tests for inflammatory markers and basic rheumatology blood profile done prior to their assessment. Diagnosis of GCA was made based on clinical examination, laboratory results and US assessment [2]. Presence of ‘halo’ sign, which is a non-compressible hypo-echoic ring around the artery lumen reflecting inflammation of the vessel wall was considered as a positive US finding. Steroid therapy was commenced on the same day of the diagnosis. If steroid infusion is indicated, the patient is referred to the AEC/ AMU to have the steroid infusion on the same day. Outcomes of management were assessed by GCA-patient reported outcomes as well as US assessment. The service was audited twice.

**Results:** During the evaluation period, 56 patients were referred to the Fast track GCA clinic. Age range 57-87 years old. 78.6% of these patients were females. 85.7% (48/56) of these patients were offered an appointment and assessed within one working day (24-hours), whereas the remaining 14.3% (8/56) were reviewed within 24-72 hours. All the patients (100%) had US examination of the temporal artery within the targeted time of maximum 72-hours from the referral date and less than 2-weeks of presenting with the temporal headache. Six patients were diagnosed as non-GCA, 5-patients migraine, 1-patient trigeminal neuralgia, 2-patients with large vessel vasculitis, 3-patients with PMR and 2-patients had flare of their previous PMR. 37-patients (66.1%) were diagnosed with GCA. No biopsies were performed. 9-patients (24.3%) required IV steroid infusion, whereas 28-patients (75.7%) started oral steroids. None of the patients included in the study suffered GCA related sight loss. No hospital admissions were required for these patients. There was significant improvement in the GCA patient reported outcomes in response to therapy, US measures as well as the inflammatory markers.

**Conclusion:** The developed Fast Track GCA clinic has significantly facilitated early and prompt diagnosis as well as management of GCA. Majority of the patients were reviewed within 24-hours with immediate initiation of steroid therapy. The fast-track referral pathway, combined with GP education, resulted in a significant reduction of incidences of permanent sight loss attributed to GCA (which would have resulted in loss of independence and mobility which subsequent increase health care use) and has proven to be a cost-effective practice as number of admitted patients was reduced.

ELEVATED PLATELET COUNT IS A RISK FACTOR FOR REFRACTORY TAKAYASU ARTERITIS

Keywords: Biomarkers, Vasculitis

X. Shi1, L. Pan1, 1Capital Medical University, Rheumatology, Beijing, China

Background: Takayasu arteritis (TAK) is a chronic systemic vasculitis that mainly affects the aorta and its major branches. This chronic relapsing disease is relevant to significant morbidity and treatment remains challenging [1]. Early identification of refractory TAK is helpful to improve the long-term prognosis of the disease. In recent years, platelets have been recognized as important markers for various types of diseases [2]. Platelet counts may indicate the activity of autoimmune disease as well as responsiveness to anti-inflammatory therapy and presence of various comorbidities [3]. Multiple studies have demonstrated that platelet count of TAK patients was significantly increased, especially in the active phase, which was significantly higher than that in the inactive phase [4-8].

Objectives: Platelets have been recognized as important markers for various types of diseases. The aim of our study was to investigate whether platelet count could be the risk factor of refractory Takayasu arteritis (TAK).

Methods: In this retrospective study, 57 patients were divided into groups with or without refractory TAK. We compared the clinical manifestations, laboratory parameters, and medication between the two groups. The logistic regression analysis was used to identify the risk factors of refractory TAK.

Results: Among the 57 patients, 18 cases (31.6%) were considered to have refractory TAK within 1 year of initiation of medication in our hospital. Refractory TAK patients had higher level of platelet (PLT) than non-refractory TAK patients (305.5 vs. 272.0, 10^9/L, P=0.043). PLT was positively correlated with ESR (r=0.502, p<0.001), IgA (r=0.322, p=0.016), IgG (r=0.419, p=0.010), C3 (r=0.554, p<0.001). For PLT, the area under the ROC curve was 0.668 (95% CI 0.515 to 0.822, p=0.043) and the best cut-off value was 296.5±10^9/L. The level of PLT greater than 296.5×10^9/L was found to be statistically related to refractory TAK (OR [95%CI] 4.000 [1.233-12.974], p=0.021).

Conclusion: Clinicians should pay close attention to platelet levels in patients with TAK. For TAK patients with elevated platelet levels, earlier and more aggressive treatment is needed, and antiplatelet therapy is recommended as appropriate.

AB0739 PERFORMANCE OF THE 2022 AMERICAN COLLEGE OF RHEUMATOLOGY/EULAR CLASSIFICATION CRITERIA FOR GIANT CELL ARTERITIS IN A COHORT OF PATIENTS WITH SUSPICION OF HAVING GIANT CELL ARTERITIS

Keywords: Vasculitis

A. Hemmig1, M. Aschwanden2, S. Imfeld2, C. Berge2, T. Daikeler1,3
1University Hospital Basel, Department of Rheumatology, Basel, Switzerland; 2University Hospital Basel, Department of Angiology, Basel, Switzerland; 3University Hospital Basel, University Center for Immunology, Basel, Switzerland

Background: The new ACR/EULAR 2022 classification criteria for giant cell arteritis (GCA) use weighted items and incorporate findings from vessel imaging to reflect the current clinical standard. Although intended to define homogenous patient populations for research purposes when a diagnosis of medium- or large-vessel vasculitis has been made, the 2022 criteria were developed including non-vasculitis comparators. Hence, in the absence of a sensitive diagnostic gold standard, the criteria bear potential to be used for GCA diagnosis.

Objectives: To evaluate the performance of the new 2022 ACR/EULAR classification criteria for GCA when used for GCA diagnosis.

Methods: Retrospective analysis of a cohort of patients suspected of having GCA who underwent ultrasound between 12/2006 and 05/2021. GCA was diagnosed if temporal artery biopsy was positive, if the 1990 ACR criteria were fulfilled, or if at least 2/5 ACR criteria were fulfilled in combination with vasculitis on imaging.

Results: 276 patients were diagnosed with GCA, and 400 patients had a condition that mimics GCA. When applying the 2022 criteria as diagnostic criteria, sensitivity remained high with 87.3% (95% CI 82.8%-91.0%), whereas specificity was lower with 70.3% (95% CI 65.5% to 74.7%). In 35 patients (12.7%) with GCA, the criteria were not met (Table 1). These were mainly patients without cranial symptoms but having typical imaging findings in vascular territories not considered in the criteria. 119 non-GCA patients (29.8%) scored ≥6 points. Polymyalgia rheumatica (PMR) (31.9%) followed by non-vasculitic ophthalmologic diseases (15.1%) were the most frequent diagnoses among those.

Conclusion: The inclusion of polymyalgia symptoms and heavy weighting of sudden visual loss in the score led to false classification of patients with PMR and ophthalmologic diseases as GCA. For diagnostic purposes, the scoring of the criteria could potentially be adapted by applying a higher cut-off for the diagnosis of GCA or a lower weighting for polymyalgia and visual symptoms.

REFERENCES:
Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in individuals ≥50 years of age. It typically affects cranial vessels, but it can also affect large vessels in a high percentage of patients. Vascular inflammation of the aorta and/or its main branches can cause complications of high morbidity and mortality, and the presence of relapses is associated to more complications. The analysis of the different clinical and imaging patterns in patients with GCA and aortitis and their relationship with the prognosis needs more investigation. Early identification of patients with the highest risk of mortality could help predict deaths and vascular complications.

Objectives: To evaluate the demographic and clinical characteristics of patients with giant cell arteritis (GCA) who present a relapse. To evaluate prognostic factors associated with GCA relapse.

Methods: A retrospective cohort study was carried out including patients diagnosed of GCA by a multidisciplinary expert committee in aortic pathologies. A total of 71 patients followed in the vasculitis clinic between 2011-2021 who had a PET-CT at onset before receiving treatment were included. Other causes of aortitis were excluded. Relapse was defined as a new episode of vasculitis confirmed by analysis and/or imaging test. Demographic, clinical, analytical and imaging variables were collected. A descriptive study of the sample and a groups comparison, according to the presence of vascular complications was carried out. The Shapiro-Wilk test was used to study the normality of the variables. The relapse-free survival was analyzed using the Kaplan-Meier method. Univariable logistic regression was performed to assess predictive factors.

Results: A total of 71 patients were included, 73.2% were female and the mean age was 79.3 (±6.7) years. During the follow-up of the disease, 22 (30%) patients presented a relapse. Scalp tenderness (p<0.0001) and the complications prior to or at onset (aortic surgery [p=0.0003], ischemic stroke [p=0.0001], aneurysm/dissection/thrombosis [p=0.012]) presented a significant association with relapse. Cardiovascular risk factors and acute phase reactants were not associated with relapse during the disease, and either the diagnostic delay and start of treatment. Details of the demographic and clinical characteristics of the sample are described in Table 1. The relapse-free survival time in patients with GCA is shown in Figure 1. The median time (months) in relapse was 14-4 (IQR 36.1).

The univariate analysis to identify prognostic factors showed that the use of synthetic or biological disease-modifying anti-rheumatic drugs (sDMARD, bDMARD) was a protective factor against the occurrence of disease relapse, presenting a risk of relapse in untreated patients versus treated 64% higher (RR=0.64).

Conclusion: Disease relapse was observed in 30.9% of patients with GCA included in our study. Scalp tenderness and the presence of vascular complications prior to or at onset of the disease were associated with greater occurrence of relapse. Our study suggests a possible protective effect of immunosuppressive drugs against relapse in GCA patients.

CAN NORMAL ERYTHROCYTE SEDIMENTATION RATE AND C-REACTIVE PROTEIN LEVEL BE A REASON FOR DIAGNOSTIC DELAY IN POLYMIALGIA RHEUMATICA?

Keywords: Vasculitis, Diagnostic tests, Real-world evidence

M. Kara1, G. Alpi2, 1Republic of Turkey Ministry of Health University of Health Sciences Izmir Bozyaka Education and Research Hospital, Rheumatology, Izmir, Turkey; 2Republic of Turkey Ministry of Health Izmir Katip Celebi University Izmir Atatürk Education and Research Hospital, Rheumatology, Izmir, Turkey

Background: Polymyalgia Rheumatica (PMR) is an inflammatory disease which does not have specific diagnostic tests or pathological symptoms and is defined with clinical characteristics. Among the acute phase reactants (APR), erythrocyte sedimentation rate (ESR) and C-Reactive Protein (CRP) are laboratory findings used in the diagnosis and follow-up. Although abnormal ESR and CRP levels are included in the criteria for the classification of PMR, ESR and CRP can be observed as normal in 13% of PMR patients.

Objectives: In the study, it was aimed to determine the incidence of normal APR rates in patients diagnosed with PMR and to identify the distinguishing characteristics of these patients.

Methods: PMR patients who were clinically diagnosed at a single center were reviewed. After the presence of bursitis was demonstrated with ultrasonography (USG) in patients with normal ESR and CRP rates, they were accepted to have PMR. Patients with normal rates of ESR and CRP were compared against patients with high levels of ESR and/or CRP.

Results: In all 54 patients who were diagnosed with PMR (63% female, and mean age 65.39±13.9 years), >45 minute morning stiffness was present. Symptom duration median (IQR) was 3.5 (3) months, and ESR and CRP were found to be high in 72.2% and 83.3% of the patients, respectively. ESR and CRP were normal in 8 patients (14%), and serum amyloid A (SAA) was determined to be high in all these patients. At the time of the diagnosis, 51 patients (94%) had shoulder pain, and 41 patients (75%) suffered from hip pain. At the time of the diagnosis, median (IQR) ESR was found as 58.3 (49) mm/hour and CRP as 18.25 (38) mg/L. In 20 patients, SAA median (IQR) was 36 (26) U/L. The initial median (IQR) steroid dosage at the beginning of the treatment was prednisolone 20mg/day. As steroid sparing therapy, methotrexate was started in 27 patients, and azathiprine was started in 4 patients. In the group with normal levels

The relapse-free survival in patients with GCA is shown in Figure 1. The median time (months) in relapse was 14-4 (IQR 36.1).
of ESR and CRP, diagnosis median (IQR) ESR was 28.4 (4) mm/hour and CRP was 3.9 (1) mg/L, while in the group with high levels of ESR and CRP, diagnosis median (IQR) ESR was 76.5 (26) mm/hour, and CRP was 35.5 (60) mg/L. When the groups with normal and high levels of ESR and CRP were compared, it was found that diagnosis age was lower (p=0.027) in the normal ESR and CRP group, while the symptom duration was longer (p<0.001). When the patients were evaluated in terms of presence of at least one comorbidity, comorbidity was determined to be significantly lower in this group (p=0.01). Rheumatoid factor positivity, presence of anemia, and platelet count at the time of diagnosis and PMR exacerbation and giant cell arthritis development in the follow-up were similar. In the multiple regression analysis, when diagnosis age, symptom duration, and comorbidity were evaluated together, long symptom duration was independently associated with PMR with ESR and CRP normal levels (OR=0.045, 95% CI 0.03-0.676, p=0.025).

### Methods

Retrospective multicenter descriptive study of patients diagnosed with polymyalgia rheumatica in three hospitals in Madrid (Spain) treated with methotrexate as a corticosteroid-sparing agent. Clinical and demographic characteristics of the sample were analyzed and laboratory data evolution were evaluated by collecting positive acute phase reactants (ARF) (erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)) at baseline, at 6 and 12 months of treatment. Descriptive statistics were used for data presentation. The Wilcoxon test for paired data was used to contrast statistical significance, with a p<0.05 being considered significant.

### Results

Overall, 58 patients were included: 26 men (44.83%) and 32 women (55.17%), with a mean age of 78.58 (±7.3) years, mean disease duration of 7.46 (±5.78) years. The mean values of CPR, ESR, dose of prednisone and MTX at baseline, at 12 months of treatment are shown in Table 1. In 52 (89.66%) patients it was possible to reduce the dose of prednisone to <5mg/24h after 12 months of treatment. No significant liver function abnormalities were observed in any of the patients.

# Conclusion

As a therapeutic option in steroid-resistant polymyalgia rheumatica, methotrexate seems to offer a steroid-sparing effect at 6 and 12 months of treatment. The treatment is well tolerated.

<th>STEROID-SPARING EFFECT OF METHOTREXATE IN PATIENTS WITH STEROID-RESISTANT POLYMYALGIA RHEUMATICA: MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY</th>
</tr>
</thead>
</table>

#### Background

Polymyalgia rheumatica is a common inflammatory rheumatic disease affecting people older than 50. It is characterized by symmetrical pain and stiffness of the neck, shoulder, and pelvic girdle and associated with an increase in the concentration of positive acute phase reactants. The diagnosis is based on a clinical picture. Initial treatment consists of corticosteroids, and initial doses of 15 to 20mg of prednisone or equivalent are usually adequate in most cases. The subgroup of patients that responds only partially to corticosteroids or develops corticosteroid resistance usually requires the introduction of a corticosteroid-sparing drug, methotrexate being the most widely used in routine clinical practice.

#### Objectives

To evaluate the efficacy and safety of methotrexate in patients with steroid-resistant polymyalgia rheumatica in real clinical practice.

#### Methods

Retrospective multicenter descriptive study of patients diagnosed with polymyalgia rheumatica in three hospitals in Madrid (Spain) treated with methotrexate as a corticosteroid-sparing agent. Clinical and demographic characteristics of the sample were analyzed and laboratory data evolution were evaluated by collecting positive acute phase reactants (ARF) (erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)) at baseline, at 6 and 12 months of treatment. Descriptive statistics were used for data presentation. The Wilcoxon test for paired data was used to contrast statistical significance, with a p<0.05 being considered significant.

#### Results

Overall, 58 patients were included: 26 men (44.83%) and 32 women (55.17%), with a mean age of 78.58 (±7.3) years, mean disease duration of 7.46 (±5.78) years. The mean values of CPR, ESR, dose of prednisone and MTX at baseline, at 12 months of treatment are shown in Table 1. In 52 (89.66%) patients it was possible to reduce the dose of prednisone to <5mg/24h after 12 months of treatment. No significant liver function abnormalities were observed in any of the patients.

*Table 1. Baseline, 6 months and 12 months values of ESR, CRP, Prednisone and Methotrexate in patients with GCA and PMR.*
PROMs at diagnosis and during follow-up. We found that weight loss at diagnosis was associated with particularly low PROM scores, whereas inflammatory markers did not (PMR) or only moderately (GCA) associate with PROMs. Surprisingly, the physician general disease assessment (GDA) score showed no association with PROMs at diagnosis or at the 2-year visit. PROMs at the 2-year visit did correlate with the Fatigue score and patient GDA. Equivalent to the baseline visit, laboratory markers such as CRP correlated with PROMs in GCA, but not PMR patients. Finally, at the 2-year visit the use of glucocorticoids in GCA patients associated with worse PROMs, but in PMR patients with better scores on the SF-36. MTX use was associated with better PROMs, but only in GCA patients. **Conclusion:** GCA and PMR patients experience both short-term and long-term impact on their frailty, daily functioning and quality of life. Medication use appears to be important in determining the patient’s quality of life, although surprisingly, glucocorticoid and methotrexate use appear to affect GCA and PMR patients differently. Importantly, the physician GDA or inflammatory markers do not associate strongly with PROMs, particularly in PMR patients, indicating a need for better understanding of the disease and treatment impact on patient’s life.

**Data, expressed as median and interquartile range, are compared to age and sex-matched HCs. Scores range from 0-100; a score of 100 indicates the most healthy outcome.**

**Methods:** We identified 128 patients with GCA diagnosed between 2011 and 2021 in our Center. All patients were older than 50 years of age, met the 1990 ACR criteria for GCA or had a positive temporal artery biopsy or ultrasound. Medical records of all patients were reviewed and demographic, clinical, and laboratory data were collected.

**Results:** Fifty-five patients (43%) presented at diagnosis visual ischemic manifestations: blurred vision in 6 pts, diplopia in 6 pts, amaurosis fugax in 5 pts, partial visual loss in 23 pts and complete vision loss in 1 or 2 eyes in 12 and 3 pts respectively. Out of 38 patients with partial or complete visual loss, 36 presented Anterior Ischemic Optic Neuropathy (AION), and 2 presented Central Retinal Artery Occlusion (CRAO). Patients with visual manifestations had a median age of 77 (IQR 73-81) years, significantly older if compared to patients without ocular symptoms (72 (67-76) years, p<0.001). Patients with ocular involvement presented more often hypertension (67 vs 44%, p: 0.009) and chronic kidney disease (7 vs 0%, p: 0.031) as comorbidity at diagnosis, while no differences were found in diabetes, cancer, coronary heart disease and dyslipidemia incidence comparing patients with and without visual manifestations. No associations between visual impairment and other cranial symptoms (headache, jaw claudication, scalp tenderness) were found, but peripheral arthritis was negatively associated with ocular manifestations. No laboratory variables were associated with ocular involvement.

**Conclusion:** In this large cohort of patients with GCA, partial or complete visual loss were the most frequent visual manifestations. No associations between ocular involvement and other cranial symptoms were found, while patients with peripheral arthritis had a lower risk of developing visual impairment. Age and hypertension at disease onset seem to be the most important risk factors for visual ischemic manifestations in GCA patients.

Methods: We reviewed our internal database for [18F]-FDG PET/CT among patients with LVV (GCA, Takayasu). Were selected [18F]-FDG PET/CT with available blood inflammatory markers and a CTA performed during the same period (permitted a range of 7 days for blood tests or 30 days for CTA), patients were all out of therapy or on stable therapy. As controls were taken ten patients under going PET/CT for oncologic diagnostics. The SUV maximum (SUV max) was considered that in the aortic arch or in the vascular region with higher levels of SUV. Target-to-background ratio was calculated considering average SUV in the right hepatic lobe (SUV max/SUV liver ratio). Non parametric test for correlation analyses were performed between SUV max, SUV max/SUV liver ratio and CRP (mg/dl). According previous data a cut-off of SUV max/SUV liver ratio >1.2 was considered and was then compared with CRP, for disease activity, and with CTA, to find agreement with vessel wall thickness and contrast enhancement.

Results: 33 [18F]-FDG PET/CT from 21 patients, 4 Takayasu and 17 GCA, 9M/12F, mean age 61.2 years were available for analysis, 13 out of them had at least one CTA to compare (total 21 CTA). SUV max and SUV max/SUV liver ratio in LVV resulted statistically higher than controls (Mann-Whitney test respectively U= 21, p = 0.00001 and U=76, p=0.027). Linear correlation between SUV max and CRP resulted highly significant (Spearman: r = 0.51 p = 0.006) but also correlation for SUV max/SUV liver ratio resulted significant (Spearman: r = 0.47, p = 0.011). Applying a cut-off for SUV max/SUV liver >1.2 we found a statistically significant agreement with CRP (Mann-Whitney U=43 p =0.0015). Less correlation was found when [18F]-FDG PET/CT SUV was compared with contrast enhancement and vessel wall thickness of CTAs, probably, because of the increased vessel thickness remains even in the inactive disease stages.

Conclusion: Although further studies are expected, semi-quantitative [18F]-FDG PET/CT scoring methods and simple cut off scores based on TBR analysis seems to correlate with disease activity and they could be used in the clinical practice, together with inflammation indices and other radiological imaging techniques, to offer a reliable and repeatable tool to help clinicians in managing LVV.

AB0746 CHANGES IN DIAGNOSING GIANT CELL ARTERITIS OF THE TEMPORAL ARTERY OVER A 7.7 YEAR PERIOD

Keywords: Vasculitis, Imaging, Clinical trials

M. H. Röchter1, S. Thiesbrummel2, H. Marchi2, C. Fuchs2, M. Rudwaleit3.

1Bielefeld University, Department of Internal Medicine and Rheumatology, Bielefeld, Germany; 2Bielefeld University, Faculty of Business Administration and Economics, Bielefeld, Germany; 3Bielefeld University, Department of Internal Medicine and Rheumatology, Bielefeld, Germany

Background: Temporal artery biopsy (TAB) was the diagnostic reference standard for decades in giant cell arthritis (GCA). Evidence-based EULAR recommendations regarding the use of imaging techniques in diagnosing GCA have been published in 2018 [1]. According to the use of colour Doppler Ultrasonography (CDUS) could "complement the clinical criteria for diagnosing GCA, assuming high expertise and prompt availability of the imaging technique" [1]. However, sensitivity and specificity of CDUS showed substantial variation between studies (2), with the investigator’s expertise assumed to be a major contributing factor [1].

Objectives: To study changes in the use of CDUS and TAB as diagnostic procedures for suspected GCA of the temporal artery over a period of 7.7 years in a single rheumatological centre.

Methods: Patients who presented to our rheumatological department between 10/2014 and 06/2022 were retrospectively identified either via a final diagnosis of GCA (ICD-10 codes M.31.4, M31.5, M31.6) or by the coded procedure of TAB (OPS 1-587 .0 or 1-587 .x). CDUS was performed by rheumatologists using GE Healthcare S5 machine from 2014 until spring 2016, and thereafter GE Healthcare LogiqE9 machine. A positive CDUS was defined by a non-compressible halo sign and hypoechoic thickened vessel wall in any of the temporal arteries. We compared the frequency of use and results of CDUS and of TAB for confirming a clinical diagnosis of GCA of the temporal artery in three time periods of 2-3 years each (2014-2016, P1; 2017-2019, P2; 2020-2022, P3). Statistical significance of changes in relative frequencies was assessed via Fisher’s exact test.

Results: Of 158 patients, we excluded 48 patients for the following reasons: diagnosis of aortitis or Takayasu vasculitis by other diagnostic means (n=16), final diagnosis other than GCA but undergoing TAB (n=24), already existing diagnosis of GCA with affection of the temporal artery prior to first presentation (n=7), and incomplete data sets (n=1). Of 110 GCA patients analysed, the mean age was 76.2 yrs (range 55 to 91 yrs), and 72 patients (65.5%) were female. All but one patient underwent CDUS (99.1%). Over the entire study period, the proportion of positive CDUS findings increased from 45.8% in P1 to 80.6% in P3. Conversely, the proportion of TAB evaluations decreased from 88% in P1 to 71.4% in P2 to 16.7% in P3. In all three time periods, conducted TAB evaluations were largely positive: 77.3% in P1, 74.3% in P2, and 83.3% in P3 (Figure 1).

In P3, 29 out of 36 (80.6%) GCA patients had a positive CDUS and were diagnosed based on CDUS alone, of them without consecutive TAB. Only 6/36 patients (16.7%) underwent TAB: 5 patients received a positive TAB after doubtful CDUS, 1 patient received a doubtful TAB after negative CDUS. The proportion of patients who were diagnosed with GCA after positive CDUS and without TAB among all GCA-diagnosed patients that underwent CDUS of the temporal artery significantly increased when comparing P3 vs. P1 (p<0.001) and P3 vs. P2 (p<0.001), but not for P1 vs. P2 (p=0.2). Due to small sample size and involvement of several rheumatologists who gained experience in CDUS over the study period, an independent effect of changing the ultrasound machine could statistically not be assessed.

Conclusion: A significant change in using CDUS alone for diagnosing GCA of the temporal artery has taken place between 2014 and 2022, with substantial reduction of TAB evaluations especially after having obtained positive CDUS results. This change is likely due to increased expertise and confidence of the examining rheumatologists in CDUS evaluations on appropriate ultrasound machines over time. Yet, data from the most recent time period indicate the ongoing need for TAB as an effective diagnostic tool in the few cases of inconclusive CDUS and high clinical suspicion of GCA.

AB0747 NON-INFECTIONOUS AORTITIS: CLINICAL AND HISTOLOGICAL CORRELATION

Keywords: Imaging, Vasculitis

1Complejo Asistencial Universitario de León, Rheumatology, León, Spain; 2Hospital de Logroño, Spain; 3Hospital Universitario de La Princesa, Madrid, Spain; 4Fundación Jiménez Díaz, Madrid, Spain; 5Asistencial Universitario de León, Rheumatology, León, Spain; 6Hospital de Logroño, Spain
Background: Isolated aortitis is considered a single organ vasculitis in the latest 2012 International Chapel Hill Consensus Conference revision. Despite being an increasingly diagnosed condition thanks to imaging tests, given the difficulty in completing the histological study, it is frequently unknown whether it is an isolated entity or a clinical manifestation of other vasculitis or rheumatologic entities.

Objectives: To describe the histological findings in samples of inflammatory aortic aneurysms and correlate them with their clinical presentation.

Methods: A descriptive cross-sectional study was performed. Aortic biopsies from elective aortic aneurysm surgery performed at a university hospital from 2019 to 2021 were reviewed. The samples with a non-infectious inflammatory pattern were selected. Cases of aortitis secondary to infection and/or atherosclerosis were excluded. The samples were reviewed again by a pathologist specialized in vascular wall disease and classified according to the 2015 consensus on surgical pathology of the aorta of the Society for Cardiovascular Pathology and the European Association of Cardiovascular Diseases in granulomatous pattern, lymphoplasmacytic pattern and mixed inflammatory pattern. Likewise, the pathologist, taking into account the previous classification and the findings, assigned a diagnostic orientation, only taking into account the histological findings. Demographic, clinical, laboratory data and the diagnostic orientation of the pathologist were collected.

Results: Of the 116 aortic tissue samples reviewed, inflammatory findings were observed in 10 (9%) of the biopsies. Characteristics of the patients whose biopsies were included are shown in Table 1. 80% of the samples came from the proximal aorta, 10% from the aortic arch, and the remaining 10% from the abdominal aorta. The mean diameter of the aneurysm was 61.7 ± 21 millimeters. The rheumatologist’s clinical diagnosis for the patients included was: 1 patient with Giant Cell Arteritis, 1 patient with Takayasus disease, 1 patient with Behcet’s disease, 1 patient with HLA-B27-associated spondyloarthropathy, and 6 patients with idiopathic aortitis. Histologically, 8 patients presented a lymphoplasmacytic pattern, 1 patient a granulomatous pattern, and 1 patient a mixed inflammatory pattern. The diagnostic orientation of the pathologist coincided with the clinician in 9/10 of the cases. The most frequent final diagnosis was nonspecific isolated aortitis (7/10), followed by Giant Cell Arteritis (1/10), Takayasu’s arteritis (1/10) and Behcet’s disease (1/10). There is a concordance between the histological pattern and the diagnostic orientation of the pathologist with the diagnostic orientation of the clinician in 9 of the 10 cases.

Conclusion: There is a high concordance between histopathologic and clinical diagnosis in the patients included in this study. Despite this, there is a high prevalence of non-specific aortitis, yet to be identified. Non-granulomatous lymphoplasmacytic pattern is the most reported in our series of cases.

AB0748 COGNITIVE FUNCTION IN POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS

Keywords: Vasculitis, Cognitive Function, Patient reported outcomes

P. Harkins 1, S. Cowley 2, D. Kane 3, R. Conway 3. 1St James Hospital, Rheumatology, Dublin, Ireland; 3Galway University Hospital, Rheumatology, Dublin, Ireland

Background: In the past decade our understanding of the prevalence, and indeed impact of cognitive impairment in rheumatic diseases has increased [1, 2]. An aging population, coupled with systemic inflammation have been postulated as key drivers of increased cognitive decline in these conditions. Intact cognitive function is imperative not only for quality of life and maintenance of one’s functional capacity, but also for successful therapeutic management of disease, namely the adherence to treatment regimens. Both giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) occur in those over 50 years of age, and are associated with a significant systemic inflammatory response. [3] To date, the prevalence of cognitive impairment in these conditions has not been studied.

Objectives: To explore the prevalence and possible predictors of cognitive impairment in those with PMR and/or GCA.

Methods: Participants from a multicentre longitudinal cohort study of PMR and/or GCA participated in a study visit that included an assessment of cognitive function. Cognitive function was evaluated using the Montreal Cognitive Assessment (MoCA) test which was conducted by trained interviewers. Demographic, clinical and laboratory data related to disease activity (PMR-Activity Score), neuropsychiatric symptoms (DASS-21) and patient reported outcomes (Visual analogue scale (VAS) and health assessment questionnaire (HAG-DII) were collected. Cognitive impairment was defined by the previously validated MoCA cut-off score of <26. A two tailed t-test, and independent chi squared test were used to analyse continuous and categorical variables respectively. A multivariate linear regression analysis was then performed.

Results: A total of 55 participants with a mean age of 70.5 (SD 7.61) were suitable for inclusion. 29 (52.7%) were female. 29 (52.7%) had isolated PMR, 8 (14.5%) had subclinical GCA with PMR, and 18 (32%) had isolated GCA, 34...
Background: Giant Cell Arteritis (GCA) is the commonest large and medium artery vasculitis affecting patients aged 50 or above. It is a multisystem, inflammatory condition that can result in significant comorbidity, even mortality. Corticosteroids form the mainstay in remission induction and maintenance therapy. Complications can arise either due to the timing of steroid commencement; one could not be scanned due to technical reasons, so a TAB was requested. Crucially, this was the only TAB requested during this period. GCA diagnosis was comfortably made for 21 out of the 42 patients scanned (50%). We ruled out GCA in the rest of the scanned patients (50%).

Conclusion: A pilot Fast Track clinic at EDGH facilitated prompt diagnosis of GCA with the use of USS. In a period of six months, we were able to confidently diagnose or rule out GCA in 100% of our scanned patients, without the need for a TAB. Such a set up enables prompt diagnosis of GCA and timely commencement of the appropriate steroid-weening regimen, thus avoiding any future complications. Crucially, it allows the timely discontinuation of GP-commenced steroid therapy in patients with excluded GCA, thus minimising side effects of an unnecessary treatment. Typically, it takes more than three weeks to arrange a TAB. USS use also avoids an invasive procedure with potential for surgical complications. Additionally, from a Healthcare System point of view, there are certain cost-saving implications in using USS for GCA diagnosis. These range from reduced OPD clinic time and diminished demand for theatre slots and staff, to minimisation of future complications from timely commencement or discontinuation of steroid management. We also observed improved patient experience. This study confirms the integral role of USS in a Fast Track GCA Service.

PREGNANCY DURING TAKAYASU VASCULITIS: ABOUT 24 PREGNANCIES

Keywords: Vasculitis, Pregnancy and reproduction

H. Khibri1, F. Bourik El Idrissi1, A. Meghraoui1, M. Obtel2, C. Yasmina1, N. Mouattassim1, W. Ammour1, M. Maamar1, H. Harmouch1, M. Adnaoui1, Z. Tazi Mezalek1, Souissi, Department of Internal Medicine-Clinical Rheumatology, Rabat, Morocco, 2Faculty of Medicine And Pharmacy of Rabat, Clinical Epidemiology Service, Rabat, Morocco

Background: TAKAYASU vasculitis is a vasculitis of the large trunks mainly affecting women of childbearing age. Pregnancy during TAKAYASU disease may be associated with maternal and/or mater-mono-fetal complications as well as a flare-up of this vasculitis. Adequate management of TAKAYASU disease as well as regular monitoring of pregnancy is necessary.

Methods: We conducted a descriptive, analytical and observational retrospective study, spanning 36 years (1984–2020) at the internal medicine department of the UHC Ibn SINA 102 patients were being followed up for TAKAYASU disease. We have detailed the pregnancies carried out in patients during their follow-up for TAKAYASU disease.

Results: During their follow-up for TAKAYASU’s disease, 10 patients carried out 24 pregnancies. Their mean age was estimated at 31.78 ± 12.2 years (16-51 years). 2 patients had taking oral hormonal contraception. Hypertension is found in 5 patients at the time of diagnosis of TAKAYASU’s disease. It was secondary to bilateral stenosis of the renal arteries in one patient. 53% pregnancies were term without fetal complications in 5 patients with inactive TAKAYASU vasculitis during their pregnancies, 23% were complicated by fetal death in utero, 15% termination of pregnancy (voluntary and therapeutic and spontaneous), and 12.5% growth retardation in utero. 3 (33%) patients presented with pre-eclampsia, and one (10%) patient presented with pregnancy-induced hypertension and another patient (10%)
had a hemorrhagic stroke. Only one premature delivery was performed in front of a fetal distress by caesarean section. The vaginal delivery was ensured in 45.83%, and the caesarean in 8.3%. Fetal extraction was performed vaginally for death feat in utero and pregnancy terminations. The pregnancy was responsible for a flare-up of TAKAYASU’s vasculitis which went from an inactive status (NIH stage 1-2) to an active status (NIH stage 3-4) in 2/10 (20%) of the patients and was statistically linked to relapse with a significant p (p=0.009). TAKAYASU vasculitis type I was predominated (50%) followed by type V (30%). Statistical analysis showed a statistically significant link between pregnancy and carotid artery disease (P=0.01). 8/10 patients (80%) were treated by corticosteroids and platelet aggregation inhibitor during 13/24 pregnancies (54.16%). Before the pregnancies, 7 patients had received immunosuppressive treatment such as methotrexate, cyclophosphamide in one patient and another was treated by adalimumab. Only 5 patients needed recourse to immunosuppressive therapy during their pregnancies (azathioprine). Statistical analyzes objectified a significant link between pregnancy and the use of azathioprine (p=0.02). 4 patients received antiplatelet treatment; one patient had undergone vascular surgery for bilateral stenosis of the renal arteries.

Conclusion: TAKAYASU’S vasculitis does not affect the fertility of patients with this disease. But a pregnancy carried out during the progressive form of this vasculitis can be responsible for serious maternal and fetal complications. Our study suggests links between pregnancy and relapse of TAKAYASU vasculitis, TAKAYASU’s type I provocative factor, and the interest of using azathioprine during pregnancies evolving on active TAKAYASU vasculitis. We propose an internist-obstetrician collaboration in order to better manage this delicate medical situation on the maternal and fetal medical strategy.

AXIAL SPONDYLOARTHRITIS IN PATIENTS WITH GASTROINTESTINAL INVOLVEMENT OF BEHÇET SYNDROME

Keywords: Gastrointestinal tract, Behçet’s disease, Spondyloarthritis

M. Ozturk1, S. N. Esatoglu2,3, I. Hatemi4, A. F. Celik5, E. Yilmaz2, D. Ucar6, M. Melikoglu2,3, H. Yazici7, G. Hatemi2,3.

1Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Beyeh Syndrome Research Center, Istanbul, Turkey; 4Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey; 5Academic Hospital, Department of Rheumatology, Istanbul, Turkey

Background: Despite attempts to lump Behçet syndrome (BS) with spondyloarthritis, controlled studies have shown that radiographic sacroiliitis is not increased in BS (BS). However, gastrointestinal involvement of Behçet syndrome (GIBS) shares common features with inflammatory bowel disease which, in turn, can be associated with spondyloarthritis.

Objectives: To test whether GIBS patients have an increased frequency of radiographic sacroiliitis or non-radiographic axial spondyloarthritis (nr-AxSpA) compared to BS patients without major organ involvement who have only mucocutaneous and/or joint involvement.

Methods: We included 67 GIBS patients and 55 consecutive BS patients without major organ involvement. Patients were screened for axial spondyloarthritis (axSpA) using the Assessment of Spondyloarthritis International Society (ASAS) criteria. First they were questioned for chronic back pain, defined as ASAS as the presence of chronic back pain for more than 3 months with an age at onset of <45 years. Patients with chronic back pain were questioned for other spondyloarthritis features and underwent HLA-B27 testing, C-reactive protein testing, and X-ray and magnetic resonance imaging of the sacroiliac joints.

Results: Chronic back pain was reported by 24 (35%) GIBS patients and 16 (29%) BS patients without major organ involvement. Eight (12%) GIBS patients and 4 (7%) controls met ASAS criteria for axSpA (p=0.39). Four (6%) GIBS patients and 1 (2%) patient in the control group had radiographic axSpA (also termed ankylosing spondylitis), whereas 4 GIBS patients and 3 patients among the controls had nr-AxSpA. HLA B27 was positive in 2 (8%) of the GIBS patients and in 3 (19%) of the controls (p=0.33) (Table 1).

Conclusion: There was some, statistically insignificant increase in the frequency of axSpA among the GIBS patients. While the frequency of ankylosing spondylitis was consistent with previous studies, the frequency of axSpA according to the more recent ASAS criteria was found in 9.8% of the total group of BS patients.

To the best of our knowledge ASAS criteria have not previously been tested in BS. They, perhaps need to be studied in a larger group of BS patients, including those with acne associated arthritis- previously shown to be associated with ankylosing spondylitis (1) - together with healthy and diseased controls.

REMAINING UNMET NEEDS FOR THE TREATMENT AND MANAGEMENT OF GIANT CELL ARTERITIS

Keywords: bDMARD, Vasculitis, Disease-modifying drugs (DMARDs)

E. Hettel1, M. Yarnall1, K. Murray1, 1Spherix Global Insights, Market Research, Exton, United States of America

Background: Rheumatologists face significant challenges in the management of giant cell arteritis (GCA), with a limited armamentarium of treatment options. Physicians are largely dependent on the use of glucocorticoids, with tocilizumab being the only available advanced systemic agent for the treatment of giant cell arteritis.

Methods: An independent market analytics firm collaborated with 102 US rheumatologists to conduct an analysis of the GCA market. Data were collected via an online survey and supplemented with 8 qualitative interviews, all fielded June 16 through July 13, 2022. Research stimuli included physician demographics, patient management, use and perceptions of current treatments, as well as perceptions of potential new assets in development for GCA.

Results: The desire to minimize use of glucocorticoids is currently the greatest treatment challenge in the management of GCA. Although rheumatologists recognize the benefits of initiating newly diagnosed patients on glucocorticoids for the prevention of disease progression, including blindness caused by GCA, the negative side effects caused by long-term use gives physicians concern. While tocilizumab is used in patients with and without cerebral or ocular symptoms, most rheumatologists still rely heavily on the use of glucocorticoids, accounting for 89% of patient prescriptions in GCA, an aspect largely driven by a lack of availability for other advanced therapies. Of patients prescribed tocilizumab, 65% of patients were initiated on the drug in combination with glucocorticoids. Interviewed prescribers indicate difficulty in tapering glucocorticoids for patients on combination therapy, aiding in the desire for more steroid-sparing treatment options.

Figure 1.
Rheumatologists are excited to see new agents in development for GCA. Preference is highest for an IL-17A inhibitor, making secukinumab the leading drug of interest. Physicians also perceive secukinumab to be more of an advance over tocilizumab than upadacitinib or guselkumab.

**Conclusion:** With rheumatologists continuing to use tocilizumab in GCA, there is still a high need to reduce the use of steroids and for new mechanisms of actions to become available for this patient population. Physicians are eager to expand the current GCA armamentarium and anticipate these potential new agents to make have a positive impact on their management of GCA.

**AB0753 Efficacy and Safety of Tocilizumab in Patients with Vasculitis**

**Keywords:** Systematic review, bDMARD, Vasculitis

J. Luo1,2, Q. Y. Su1,2, Q. Li1,2, Y. Zhang1,2, X. Y. Li1,2, X. Zhang1,2, Y. Ren1,2, O. Yu1, P. F. He1, X. Li1,2, S. X. Zhang1,2, 3Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, Shanxi, China; 4Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 5The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi, China; 6Ministry of Education, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

**Background:** Vasculitis is characterized by inflammation of blood vessels, leading to potential long-term sequelae, including vision loss, aneurysm formation, and kidney failure. Large vessel vasculitis encompasses Takayasu arteritis and giant cell arteritis, which cause inflammation of the aorta and its major branches. Tocilizumab, a humanized monoclonal antibody against the interleukin-6 receptor, has been associated with rapid induction and maintenance of remission in patients with vasculitis.

**Objectives:** This study aimed to systematically evaluate the efficacy and safety of tocilizumab therapy in vasculitis.

**Methods:** Eight databases (PubMed, Web of Science, Embase, Cochrane Library, Web of Knowledge, MEDLINE, Clinical Trials.gov, and FDA.gov) were searched for studies on tocilizumab treatment of vasculitis published from the date of establishment of the database to January 1, 2023. We used Stata 12.0 software to conduct a meta-analysis of the efficacy and safety of tocilizumab in patients with vasculitis.

**Results:** A total of 8 studies with a total of 823 patients were included. Either doses 162mg/week or 8mg/kg/4weeks, compared with placebo, tocilizumab significantly both promoted remission of vasculitis (RR=0.909, 95%CI: 0.768-1.075, P<0.001; RR=0.639, 95%CI: 0.410-0.984, P=0.042)(Figure 1A). No significant difference was observed in the probability of disease relapse in subgroup analysis based on different diseases(Figure 1B). In subgroup analysis based on dose, 8mg/kg/4 weeks doses significantly reduced the probability of disease relapse (RR=0.639, 95% CI: 0.410-0.984, P=0.047)(Figure 1C). The results of subgroup analysis about the rate of adverse events (AE) and serious adverse events (SAE) according to different diseases and different doses, our meta-analysis found that there was no statistical significance between tocilizumab and placebo(Figure 1E-H). It demonstrated the safety of tocilizumab therapy in vasculitis treatment.

**Conclusion:** Tocilizumab treatment was effective and well-tolerated in vasculitis patients.

**AB0754 Cluster Analysis of Arteries Involved in Takayasu Arteritis**

**Keywords:** Vasculitis

H. Liao1, L. Pan2, 1Beijing Anzhen Hospital, Capital Medical University, Departments of Rheumatology and Immunology, Beijing, China; 2Beijing Anzhen Hospital, Capital Medical University, Departments of Rheumatology and Immunology, Beijing, China

**Background:** Takayasu’s arteritis (TAK) is a chronic, large-vessel vasculitis that mostly affects young Asian women[1-4]. Vascular inflammation in TAK primarily invades the aorta and its major branches and often leads to arterial stenosis and aneurysms. At present, there is no relevant research report on how to identify the vascular lesions of organs in the early stage and the relationship between the affected vessels.

**Objectives:** To investigate the correlation of arterial involvement sites in Takayasu arteritis.

**Methods:** We retrospectively investigated data of 144 TAK patients. The clinical and image data of the patients were analyzed. We performed cluster analysis according to the affected artery.

**Results:** Cluster analysis revealed five clusters of patients. In cluster one was named “abdominal aortic type”. It was characterized by the involvement of arteries in the abdominal aorta, renal artery, coeliac trunk, superior mesenteric artery. In cluster two was named “cardio-cerebral arteries type”. It was characterized by the involvement of arteries in the intracranial artery, coronary artery. In cluster three was named “thoracic aorta type” it was characterized by the involvement of arteries in the thoracic aorta and pulmonary artery was observed. In cluster four was named “vertebral artery type”. It was characterized by the involvement of arteries in the left vertebral artery, right vertebral artery. In cluster five was named “carotid artery type”. It was characterized by the involvement of arteries in the right common carotid artery, left common carotid artery, right subclavian artery, left subclavian artery, innominate artery.

**Conclusion:** Cluster analysis of the involved sites of Takayasu arteritis could be divided into 5 categories. It is abdominal aortic type, cardio-cerebral arteries type, thoracic aorta type, vertebral artery type and carotid artery type.

INVESTIGATING CYTOGLOBIN IN GIANT CELL ARTERITIS: ITS ROLE IN THE PATHOGENESIS AND POTENTIAL AS A BIOMARKER

Keywords: Diagnostic tests, Biomarkers, Vasculitis

L. Farnah1, M. Felix2, A. Ibrahim3, R. Peredo-Wende4, D. Jourd’heuili5, F. Jourd’heuili5, Albany Medical Center, Internal Medicine, Albany, United States of America; 2Yale School of Medicine, Rheumatology, New Haven, United States of America; 3Albany Medical Center, Pathology, Albany, United States of America; 4Albany Stratton VA Medical Center, Rheumatology, Albany, United States of America; 5Albany Medical College, Department of Molecular and Cellular Physiology, Albany, United States of America

Background: Cytoglobin (CYGB) is a non-erythroid globin that is found in medial smooth muscle cells (SMCs) of human vessels. Recent studies have postulated that CYGB act as a pro-survival factor during conditions associated with increased oxidative stress, by upregulating anti-apoptotic factors and antioxidant pathways. In this study, we hypothesized that CYGB regulates the inflammatory and antioxidant response associated with GCA pathogenesis.

Objectives: The purpose of this study is to evaluate giant cell arteritis (GCA) vascular lesions for the expression of CYGB and its association with specific molecular markers of cellular damage. We would also like to investigate the association of CYGB with GCA pathogenesis, symptomatology, degree of systemic inflammation, patient demographics, and response to treatment.

Methods: We obtained 29 temporal artery biopsy samples, 14-biopsy positive and 15-biopsy negative, from patients who underwent temporal artery biopsy for GCA diagnosis (Table 1). Inclusion criteria for the experimental group included patients over the age of 18 who had histologic evidence of GCA and met the ACR 1990 classification criteria. The control group included patients who were biopsy negative for GCA. Immunofluorescence staining for CYGB will be done on all samples to assess differential expression across the experimental and control groups. Proximity ligation assays (PLA) will be done to assess binding between cytoglobin and known pro-inflammatory markers to establish mechanistic insights for CYGB in the pathogenesis of GCA. We will also obtain clinical data including signs and symptoms at presentation, levels of serum inflammatory markers, treatment, clinical course, and outcomes.

Results: We are currently conducting validation studies of the immunofluorescence and PLA staining for specific molecular markers on temporal artery biopsy samples. Thus far, we were able to validate the immunofluorescence staining for CYGB (Figure 1) and the PLA for CYGB and HMGB2. Once we have established robust and reliable staining protocols for other markers, we will implement these protocols in our control and GCA groups and move forward with the analysis.

Conclusion: We previously demonstrated that overexpressing CYGB in smooth muscle inhibits apoptosis and regulates vascular remodeling. "Cytoglobin at the crossroads of vascular remodeling." Arteriosclerosis, thrombosis, and vascular biology 37.10 (2017): 1803-1805.

Background: Although temporal artery biopsy (TAB) is the gold standard in the diagnosis of giant cell arteritis (GCA), the specific histopathological findings and their relationship with clinical diagnosis have not been well discussed. In recent 2022 ACR/EULAR GCA classification criteria, the presence of giant cells, predominantly mononuclear cell infiltration, and fragmentation in the internal elastic lamina have been defined for the interpretation of definitive vasculitis. [1]

Objectives: To re-evaluate TAB histopathological findings of patients with GCA recruited from 4 tertiary centres in Ankara according to the2022 ACR/EULAR Classification criteria and compare frequencies of these items with DCVAS study [2].

Methods: TAB reports of patients with GCA from 4 tertiary centres between March 2004 and February 2022 were retrospectively reviewed according to the histopathological items defined in the updated criteria. TAB reports were classified by the local physicians as normal, nondiagnostic, consistent with vasculitis but not definite, and definite vasculitis.

Results: Totally, TAB histopathologic reports of 88 patients with GCA were reviewed. The mean age of the patients at the time of TAB was 69.7 (s=8.5) years and 46(52.2%) were female. Twenty-eight reports without microscopic details were excluded and reports of 60 patients were reanalysed. Of the 60 patients,
Results: We collected 109 files. The sex ratio (F/M) was 7.3 (96 women/13 men). 11.92% of patients were male. The mean age was 34.8 ±11.9 (12 – 62 years). Patients who had juvenile takayasu diagnosed before 20 years of age were 11 (10%) and patients who had late-diagnosed takayasu to over 50 years of age were 14 (12.88%). HTA was present in 44 (40.7%) of patients at diagnosis, 11 (10.1) of patients were taking oral contraceptives. Inflammatory syndrome was associated in 72 (66.1%) with no statistically significant difference with a P=0.6. Vascular symptomatic presentation was present in 103 (95.4%) of the cases of vascular murmur (66.1%), pulse suppression (62.4%), intermittent claudication (49.5%), and ischemia (10.1%). Extravascular symptoms were present in 47.6% of the patients dominated by inflammatory arthralgia (18.3%). Only one patient had asymptomatic TAKAYASU vasculitis discovered by chance during ultrasound examination for a thyroid nodule. Cardiac involvement occurred in 36 (33%) of patients and consisted mainly of valvulopathy (20.2%) and cardiomyopathy (17.4%). Central neurological involvement was present in 17 patients, 15.6% of patients with complicated HA in 13 patients. Renal impairment was present in 35 patients (32.11%), Ophthalmologic involvement in 26 (23.9%) of patients was mainly represented by retinal vasculitis and optic nerve involvement. In addition, 10 patients had 24 pregnancies, 4 patients had preeclampsia, we recorded 9 abortions and half of our patients had full term pregnancies. The type of injury in our series was mainly stenosis and was found in 73 (67%) of cases. Occlusion was recovered in 21 (19.3%) patients. Thrombosis was found in 26 (23.9%) of patients and aneurysms in 19 (17.4%) of patients. TAKAYASU vasculitis was Type I in 42 (38.5%) patients, followed by Type V in 39 (35.8%). Type IIa was present in 7 patients (6.4%), type IIb in 4 patients (3.7%), type III in 2 patients (1.8%), and type IV in 14 patients (12.8%). Most patients 104 (95.4%) received corticosteroids and 77 (70.6%) received immunosuppressive therapy including one on mycophenolate mofetil. Two patients received anti-TNF therapy (adalimumab), and 1 patient received Tocilizumab. At the surgical level; 9 (8.3%) of patients had angioplasty; A further 6 (8.3%) underwent cardiac surgery (5 aortic valve replacement and closed-heart commissurotomy) and 15 (13.8%) had vascular surgery. The outcome was favourable in the majority of patients. Late relapses > 6 months were reported in 25 (23.1%) patients. There was only one death from global heart failure. We analyzed several associations such as vascular and cardiac disease, vascular and neurological disease. None returned significant with P ranging from 0.3 to 1.

Conclusion: The results of our study are consistent with the literature and confirm the predominance of women and the stenosing nature of this vasculitis. Early diagnosis and management of the disease significantly improves the progression profile of the disease.

AB0758 TAKAYASU DISEASE IN JUVENILE FORM: ABOUT 11 CASES

Keywords: Vasculitis

F. Ibourk El Idrissi1, H. Khiri1, A. Meghraoui1, M. Oted1, C. Yasmina1, N. Mouattassim1, W. Ammour1, M. Maamari1, H. Harmouch1, M. Adnaoui1, Z. Tazi Mezalek1, 1Sousssi Rabat, Department of Internal Medicine-Clinical Hematology, Rabat, Morocco; 2Faculty of Medicine And Pharmacy of Rabat, Clinical Epidemiology Service, Rabat, Morocco

Background: Takayasu disease is a non-specific inflammatory vasculitis of the large and medium caliber arteries occurring during the 2nd or 3rd decade. Attachment before the age of 20 is rare.

Methods: This is a retrospective descriptive study including patients with aged less than 20 years with Takayasu disease out of a series of 109 patients between 1984 and 2022 in a department of internal medicine and vascular surgery at the CHU INB SINA of Rabat.

Results: We identified 11 cases of patients under 20 years of age with a Takayasu disease with a sex ratio of 1 man to 2.6 woman (8 women/3 men) The mean age of patients was 17 years ±2.8 (12 - 20 years). (45.5%) had hypertension at diagnosis, 10 patients (90.9%) had symptomatology type of vascular murmur (54.5%), pulse suppression (63.6%), lameness. Intermittent (36.4%), no ischemia (23.1%) and one patient had extravascular: headache, fever, altered general status, peripheral symptoms and an inflammatory syndrome was present at diagnosis in 8 of our patients (72.7%). Aortic involvement was found in 7 patients (63.6%) predominantly due to abdominal aorta (6 patients). We identified 4 cases (36.36%) of arterial damage. 3 cases of cerebral arteries (27.27%). The most common arterial disorders were stenosis (72.7%), thickening (54.5%), thrombosis (9.1%) and aneurysm (9.1%). 6 patients (54.54%) had heart disease as part of the study. Takayasu disease dominated by cardiomylopathies (4 cases), 2 cases of valvulopathy, and 1 only case of pericarditis. Associated in two cases with rhythm disturbances. 3 patients

NA: Not applicable* defined histopathologic features are giant cells, predominantly mononuclear cell infiltration, and fragmentation in the internal elastic lamina for definitive vasculitis

Conclusion: Even giant cells were reported less in our study, updated histopathological definitions for GCA seem an excellent option to diagnose vasculitis definitively.

AB0757 TAKAYASU DISEASE: ABOUT 109 CASES

Keywords: Vasculitis

H. Khiri1, F. Ibourk El Idrissi1, A. Meghraoui1, M. Oted2, C. Yasmina1, N. Mouattassim1, W. Ammour1, M. Maamari1, H. Harmouch1, M. Adnaoui1, Z. Tazi Mezalek1, 1Sousssi Rabat, Department of Internal Medicine-Clinical Hematology, Rabat, Morocco; 2Faculty of Medicine And Pharmacy of Rabat, Clinical Epidemiology Service, Rabat, Morocco

Background: TAKAYASU disease is an inflammatory vasculitis of the means and large caliber, which affects th aorta and its main branches, and which leads to the formation of arterial stenosis, thromboses and aneurysms. Touching preferably young women, it may be responsible for complications severe vascular events that may be life-threatening.

Methods: We conducted a 38-year, single-centre retrospective study (1984 and 2022) in patients followed for TAKAYASU vasculitis at the department of internal medicine and the department of vascular surgery of the Ibn Sina Hospital in Rabat. Statistical data were analyzed using SPSS 20.0 software and KHI-DEUX analytical test.
(27.28%) had stroke-type neurological disease, which accounted for 18.75% of cases (16 cases/109 cases) in the global series and 3 patients had (27.3%) two cases of blindness and one case of optic nerve damage. TAKAYASU vasculitis was type V in 5 patients (45.5%), followed by type I in 4 patients (36.4%). Type II and IV were present in 1 patient each; type I and IV have not been described in any of the patients. All patients received corticosteroid therapy; 9 patients (81.8%) were initiated immunosuppressant and one patient received adalimumab, five of the patients received a. angiplasty and/or one or more vascular surgeries; two complicated cases of restenosis, stent artery and 1 complicated case of aorto-abdominal fistula. Four patients (45.5%) had had one or more relapses during their evolution. We also noted a case of tuberculosis meningencephalitis associated with bilateral blindness in a 16-year-old patient and, two concepts of coartation of the non-dilated aorta in a 12-year-old patient and in a 18-year-old patient.

Conclusion: Our study is consistent with the literature and illustrates the seriousness of the juvenile takayasu as the common combination with severe heart disease, neurological and ophthalmological.

**Background:** Inflammatory granulomatosis with polyangiitis (EGPA), formerly called Churg-Strauss syndrome, is an ANCA-associated vasculitis which is mainly mediated by eosinophils. Mepolizumab (MPZ) is an anti-interleukin-5 monoclonal antibody that reduces the total number of eosinophils in peripheral blood and tissues, and its use has been approved in EGPA.

**Objectives:** To analyze the effectiveness and safety of MPZ in EGPA in a real-life multicenter Spanish cohort.

**Methods:** We retrospectively analyzed the epidemiological data, comorbidities, clinical evolution and adverse effects of patients who have received MPZ in 13 Rheumatology Spanish services, through electronic medical records up to November 2022.

**Results:** A total of 27 patients with EGPA treated with MPZ have been analyzed. Median age at diagnosis was 53 years old, fifteen were men (55.6%). 21 (77.8%) were Caucasian, 5 (18.5%) Arab and 1 Hispanic. At diagnosis, 3 (11.1%) patients had arterial hypertension and 4 dyslipidemia (14.8%); ten patients were or had been smokers (37%). A total of 14 (51.8%) patients were ANCA positive. The Five Factor Score (FFS) was calculated just in 20 patients, and from them, 14 had a 0 result (70%) and 6 a 1 result (30%). The mean Birmingham Vasculitis Activity Score (BVAS) at diagnosis was 15. EULAR severity index was 0 in 2 patients (7.7%), 1 in 10 patients (38.5%), 2 in 9 (34.6%) and 3 in 5 patients (19.2%). Up to 23 patients (85.2%) had rhinosinusosal symptoms and 19 (70.4%), had lung involvement of which 16 patients had interstitial lung disease. Sixteen (59.3%) patients had general symptoms 14 (51.8%) skin involvement and 11 (40.7%) peripheral nervous system involvement. Nine (33.3%) patients had musculoskeletal symptoms, 5 eye involvement and 5 cardiac involvement (18.5%). Regarding treatments, the mean starting dose of daily prednisone was 45mg, 9 patients received intravenous methylprednisolone pulses (33.3%) and 16 (59.3%) required an immunosuppressant for induction, of which in 11 it was cyclophosphamide. The mean disease duration of the EGPA when MPZ was started was 51 months, and the mean follow-up during the treatment with MPZ was 16 months. The mean Birmingham Vasculitis Activity Score (BVAS) before MPZ was 9, after one month of MPZ, it dropped down to 5.4, and three months later to 4.6. The mean C reactive protein (CRP) before treatment with MPZ was 19.9mg/L, and three months later, it was 3.3mg/L. Before MPZ, the patients had a mean eosinophils number per microliter of 753, and after three months of treatment, it was 59 eos/μL.

The mean Vasculitis Damage Index (VDI) before treatment with MPZ was 4.5 and after treatment with mepolizumab, it worsened only in 5 patients (11%). Twenty patients achieved a 50% clinical response according to global physician criteria (74.1%) and 12 achieved clinical remission (44.4%). The mean final prednisone dose was 2.5mg/d. No patients had serious infections during treatment, one developed a neoplasm, and one of them withdrew MPZ due to musculoskeletal pain, switching to benralizumab (anti-IL5-receptor). Only one patient died from causes unrelated to the disease or the disease.

**Conclusion:** Our data about the use of MPZ in EGPA in real world practice suggest that it is a quite effective and safe drug, allowing to save corticosteroids. Moreover, it seems to prevent the progression of the damage associated with the disease.

**AB0762** DIAGNOSTIC YIELD OF BIOPSIES IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: A SINGLE CENTRE EXPERIENCE

**Keywords:** Descriptive Studies, Diagnostic Tests, Vasculitis

**R. Ríos-Garcés**, **J. Hernández-Rodríguez**, **S. Prieto-González**, **C. Cid**, **G. Espigol-Frigolé**, **Hospital Clínico de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain;** **Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vasculitis Unit, Barcelona, Spain;** **Universitat de Barcelona, Facultat de Medicina, Barcelona, Spain;** **Hospital Cliníic de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain;** **Hospital Clínico de Barcelona, Internal Medicine, Barcelona, Spain**

**Background:** Recently published classification criteria for eosinophilic granulomatosis with polyangiitis (EGPA) [1] require, to be applied, a diagnosis of small- or medium-vessel vasculitis, without specifying how that diagnosis should be made. Histologically, EGPA is characterized by eosinophil-rich and necrotizing granulomatous inflammation together with necrotizing vasculitis, predominantly affecting small to medium vessels. Some of these features are not specific for EGPA and may be seen in other forms of ANCA associated vasculitis (AAV).

**Current guidelines on the management of AAV recommend biopsies to assist in establishing a new diagnosis and for further evaluation of patients with suspected relapse [2]. Therefore, biopsies are essential tools for the diagnosis, classification and management of these diseases.**

**Objectives:** To describe the histopathological findings, diagnostic yield and the most common localizations of biopsies performed to assist in the diagnosis and follow-up of patients with EGPA.

**Methods:** Medical charts of patients with EGPA regularly followed at our department were reviewed to retrieve the number and localization of biopsies, as well as biopsy findings including proportion of a) eosinophil-rich extravascular inflammation, b) granulomas and/or c) necrotizing vasculitis. Biopsies were performed if patients presented symptoms in any given and most accessible localization (at diagnosis) or if they were necessary to confirm active disease (during follow-up).

**Results:** Among 59 EGPA patients regularly controlled at our department, a total of 163 biopsies were performed on 54 of them. In 44 patients (81.5%), 89 biopsies were performed at diagnosis and in 27 (50%), 74 biopsies were performed during follow-up. A total of 37 biopsies in 26 patients (48.1%) had proven vasculitis. A total of 7 biopsies in 5 patients (9.3%) had proven granuloma. A total of 67 biopsies in 42 patients (77.8%) had proven eosinophil-rich extravascular inflammation. The main localizations were: ear, nose and throat (ENT, 49 biopsies), respiratory (31), skin (25), gastrointestinal (GI, 18), muscular (14), nerve (12), bone marrow (8), renal (4) and temporal artery biopsy (TAB, 2). Among them, at least 1 typical histological feature detailed above was found in: ENT 38/49 biopsies (sensitivity of 77.8%), respiratory 15/31 (48.4%), skin 23/25 (92%), GI 10/18 (55.6%), muscular...
4/14 (28.6%), nerve 5/12 (41.7%), bone marrow 6/8 (75%), renal 4/4 (100%) and TAB 1/2 (50%). A total of 57 biopsies performed in 29 patients (53.7%) showed none of the typical findings described above, although only 6 patients had all their biopsies without abnormal findings. These results are summarized in Table 1.

Conclusion: Multiple tissues are biopsied in clinical practice to assist in the diagnosis and evaluation of patients with EGPA, according to the multi-organ nature of this disease. Biopsies are more frequently obtained from accessible sites such as ENT or skin and usually dictated by clinical manifestations. In our cohort, the highest sensitivity was obtained from kidney, skin, ENT, bone marrow? and GI tract.

CHARACTERISTICS OF RELAPSES IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS. A SINGLE CENTRE EXPERIENCE

Keywords: Descriptive Studies, Outcome measures, Vasculitis

R. Ríos-Garcés1,2, J. Hernández-Rodríguez1,2, S. Prieto-González3,4, M. C. Cid1,2, G. Espigol-Frigolé1,2,3,1 Hospital Clínic de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain; 2Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vascularis Unit, Barcelona, Spain; 3Universitat de Barcelona, Facultat de Medicina, Barcelona, Spain; 4Hospital Clínic de Barcelona, Internal Medicine, Barcelona, Spain

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a heterogeneous disease with a variable, relapsing course. Real-world data regarding specific characteristics of relapses in this patients are scarce.

Objectives: We aim to describe and analyse the relapses presented in a single-center cohort of EGPA patients.

Methods: Medical charts of EGPA patients regularly controlled at our department were reviewed to describe demographics, clinical characteristics at diagnosis and at relapse, number of relapses, disease activity at relapse, treatment of the relapses, damage accrual, and laboratory results. The definition of relapse was the same used in the MIRRA trial: a) active vasculitis (BVAS >0), b) active asthma or active nasal or paranasal sinus disease leading either to an increase in the dose of prednisone >4mg/day, initiation of or increase in immunosuppressive therapy, or hospitalization [1].

Results: A total of 59 EGPA patients were followed regularly at our department. All fulfilled either ACR 1990 and/or MIRRA trial inclusion criteria for EGPA. The mean age at diagnosis was 51.6 years, 59.3% were female and 91.5% were Caucasian. Among them, 76.3% were ANCA positive and 23.7% were ANCA negative. The mean time of follow-up was 10.7 ± 8.2 years. During the follow-up, a total of 324 relapses were diagnosed in 47 patients, with 12 patients experiencing no relapse. A relapse-free survival analysis showed that 36% of patients had a relapse in the first year, 51% at 2 years, 59% at 3 years and 64% at 5 years. The main clinical symptoms at relapse were asthma (in 248 flares, 76.5% of them), followed by rhinitis (100, 30.9%), sinusitis (60, 18.5%), skin involvement (19, 5.9%), fever (18, 5.6%), arthralgia (16, 4.9%), lung infiltrates (15, 4.6%), myalgia (12, 3.7%), peripheral nervous system involvement (11, 3.4%), cardiac involvement (6, 1.9%), arthritis (3, 0.9%), weight loss (2, 0.6%), alveolar hemorrhage (2, 0.6%), gastrointestinal involvement (2, 0.6%) and central nervous system involvement (2, 0.6%). No renal involvement was seen at flare. Median BVAS at relapse was 2 (IQR 2-4, range 0-28). When determined, median blood eosinophils at relapse were 500 cells/mm3 (IQR 100-1000) and in 73% of the measures eosinophils did not reach 10% of the total leucocyte count. Median CRP was 0.6mg/dl (IQR 0.2-2.4) and median ESR 14 mm/h (IQR 8-32). ANCA were measured in 37 relapses only, being positive in 14 of them. The median prednisone dose at relapse was 6.25mg/day and the median increase for treating the relapse was 30mg/day. In 53 relapses, patients were already taking azathioprine. In 47, mepolizumab. In 36, methotrexate. In 11, mofetil mycophenolate. When comparing patients who relapsed vs. those who did not, and those who relapsed less than 1 time every 2 years vs those who relapsed more than 1 time every 2 years, no predictive factor of relapse was seen.

Conclusion: After a mean follow-up of 10.7 years, 324 relapses were diagnosed in 59 patients. First relapse occurred in 35% of patients at 1 year and in 64% at 5 years. The clinical spectrum of relapses was predominantly asthma, followed by ear, nose and throat, being vasculitic manifestations much less frequent. No predictive factors of relapse were identified.

EVALUATION OF THE APPLICABILITY OF THE 2022 AMERICAN COLLEGE OF RHEUMATOLOGY-EUROPEAN ALLIANCE OF ASSOCIATIONS FOR RHEUMATOLOGY CLASSIFICATION CRITERIA FOR ANTEINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS TO AN ASIAN POPULATION

Keywords: Organ damage, Vasculitis
Steady Background: The 2012 Chapel Hill Consensus Conference (CHCC) definitions and the 2007 European Medicines Agency (EMA) algorithm have been commonly used for the diagnosis of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) as a conventional and reliable method. Recently the 2022 American College of Rheumatology (ACR)-European Alliance of Associations for Rheumatology (EULAR) classification criteria for AAV have been released. It is well-known that patients with granulomatosis with polyangiitis (GPA) are predominantly proteinase 3 (PR3)-ANCA-positive in the U.S. and Europe, but myeloperoxidase (MPO)-ANCA-positive patients with GPA are more prevalent in Japan. However, very few studies have been available on the evaluation of the applicability of the new criteria to an Asian population.

Objectives: This study aimed to assess the applicability of the 2022 ACR/EULAR classification criteria to AAV patients from an Asian background.

Methods: This study included a total of 415 patients (mean age = 64.2 years, standard deviation [SD] = 16.3 years) diagnosed with AAV by the conventional method at three medical institutions in Japan between 2000 and 2022. Only Asians accounted for the whole population comprising 139, 128, and 148 patients (mean age = 65.2 years, SD = 15.7 years; mean age = 70.8 years, SD = 13.8 years; mean age = 56.1 years, SD = 15.8 years) diagnosed with eosinophilic granulomatosis with polyangiitis (EGPA), GPA, and microscopic polyangiitis (MPA) by the conventional method, respectively. The applicability of the new criteria to AAV patients in Japan was assessed through the verification of the consistency with the conventional diagnoses. Additionally, phenotypes of organ involvement were analyzed in each reclassified group from the conventionally-diagnosed GPA population.

Results: The patients diagnosed with EGPA and MPA by the conventional method were significantly more likely to be reclassified into the same AAV subphenotype 138 out of 139 patients [99.3%] and 145 out of 148 patients [98.0%], respectively. On the other hand, the patients diagnosed with GPA by the conventional method were less likely to be reclassified into the same AAV subphenotype (91 out of 128 patients [71.1%]). In the conventionally-diagnosed GPA population, 71 patients were reclassified as GPA, not as MPA, 20 were reclassified not only as GPA but also as MPA, and 36 were reclassified not as GPA but rather as MPA. In the group reclassified only as GPA, there were 59 patients with sinusitis, including ten patients with orbital mass lesions. In the group reclassified both as GPA and MPA, there were 20 patients with severe organ involvement, including 15 patients with pauci-immune glomerulonephritis (PIGN).

Conclusion: The new criteria gave more weight to ANCA serology than histology and surrogate markers compared with the conventional method, which kept diagnostic consistency in the conventionally-diagnosed EGPA and MPA populations. At the same time, the new criteria occasionally led to a big diagnostic contradiction in the conventionally-diagnosed GPA population from an Asian background. In the conventionally-diagnosed GPA population, the new criteria were likely to reclassify MPO-ANCA-positive patients as MPA. However, it is noteworthy that the new criteria were still beneficial in extracting GPA patients with recurrent or severe organ involvement, including orbital masses and PIGN.

**STEP-DOWN TREATMENT WITH MEPOLIZUMAB FOR EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA). REAL-LIFE EXPERIENCE OF A SINGLE-CENTER COHORT**

Keywords: Vasculitis

V. Batani, B. N. Germinario, M. Lanzillotta, A. Cariddi, L. Moroni, L. Dagna,
1San Raffaele University Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases –, Milano, Italy; 2San Raffaele University Hospital, Internal Medicine, Milano, Italy

**Background:** Mepolizumab is an anti-interleukin-5 (IL-5) agent approved for EGPA at the dose of 300 mg every 4 weeks. However, from real-life studies, evidence is accruing of its comparable effectiveness at “asthma-dose” of 100 mg every 4 weeks. The preferred approach at our center is to start mepolizumab 300 mg/4 weeks and to reduce to 100 mg/4 weeks once remission is achieved (Birmingham Vasculitis Activity Score – BVAS=0), asthma is controlled (Asthma Control Test – ACT >20), eosinophil count is normalized and glucocorticoids are withdrawn (step-down approach).

**Objectives:** To assess the long-term efficacy of step-down treatment with mepolizumab in EGPA.

**Methods:** We reviewed medical charts of patients with EGPA treated with mepolizumab from April 2014 to December 2022. We divided patients by homogenous dosing schedule and compared disease activity and characteristics at baseline and over time.

**Results:** We treated 38 patients for a median follow up of 38 months (IQR 29-93). Seven patients underwent a step-up approach (starting with mepolizumab 100mg/4w and subsequent switching to mepolizumab 300 mg/4w in case of failure). Among them, only 1 patient (17%) needed a dose increase due to uncontrolled respiratory symptoms. Mepolizumab 300mg/4w was started in 31 patients allowing a step-down in 9 (29%), without any patient having to increase the dose again. Both subgroups of the step-down strategy showed significant reduction in terms of BVAS, ACT, serum eosinophils and daily prednisone dose at last follow-up. At the same time presented a high proportion of nasal exacerbations (33 vs. 9% p=0.31).

**Conclusion:** In our experience, a step-down approach with mepolizumab in EGPA is reasonable and allows to safely reach the low-dose regimen in a great proportion of patients. Nasal polyps are the new challenge for physicians treating EGPA in an age where a steroid-free remission is an achievable target.

**Background:** Systemic vasculitides are rare autoimmune diseases that can lead to multiple organs and systems involvement. ANCA-associated vasculitis presents characteristics that differentiate them from other vasculitides. There is evidence that infection by (SARS-CoV-2) impacts differently in patients with various underlying diseases and different comorbidities, even generating differences in the morbidity and mortality of the viral infection.

**Objectives:** To describe the clinical characteristics and outcomes of SARS-CoV-2 infection in patients with systemic vasculitis.

**Methods:** Observational, multicenter, cross-sectional analytical study in patients 18 or older diagnosed with systemic vasculitis with confirmed SARS-CoV-2 infection (RT-PCR or serology) included in the SAR-COV registry. Patients were evaluated from July 2020 to February 2022. Patients diagnosed with ANCA-associated vasculitis (AAV), other systemic vasculitides (Giant cell arteritis, Takayasu), and a control group of patients with other rheumatological diseases matched by age, sex, comorbidities, and date of SARS-CoV-2 infection. The survival curve of the groups was studied by Kaplan-Meier and compared through the Log-Rank Test. A Cox regression model will be performed to adjust survival for different variables (sex, age, treatments for underlying disease, treatments for viral infection, smoking, obesity, d-dimer level, and disease activity).

**Results:** A total of 282 out of 2694 patients in the SAR-COV registry were included. 574 women with a mean age of 55.7 years (SD 14.1). Fifty-four patients in the AAV group, 32 in the other vasculitis group, and 196 controls were studied. In 51.1% of the cases, one or more comorbidities were observed. We found caucasian ethnicity at 50.7%, mestizo at 39.7%, and other ethnic groups at...
Conclusion: We can mention that patients diagnosed with AAV presented a worse evolution of the disease caused by SARS-CoV-2 with a more frequent requirement for invasive mechanical ventilation. Likewise, these patients showed lower survival compared to other autoimmune diseases.

Scientific Abstracts

9.6%. PCR made the diagnosis of COVID-19 in 81.2% of the cases. The controls had treatment with corticosteroids before the onset of symptoms in 30.1% of the cases, while 64.8% and 68.8% in the AAV group and other vasculitides, respectively (p < 0.001). Hospitalization was required in 32.7% of the AAV group, 37.5% in other vasculitides, and 26.2% in the control group. 5.6% of patients in the control group died from COVID-19, 9.4% from other vasculitides, and 27.8% in the AAV group (p < 0.001). We found a lower survival in the AAV group compared to the control group (p < 0.005). In the multivariate Cox regression model, we can see that older age (HR: 1.05 IC95%: 1.01-1.09 p=0.01), BMI ≤ 40 (HR:13.2 IC95%: 14.53-18.31 p<0.001), and high activity of the underlying disease (HR:16.95 IC1.3-7.69 p<0.005) were associated with lower survival.

In conclusion, we can mention that patients diagnosed with AAV showed a lower survival compared to other autoimmune diseases.

Background: IgA vasculitis (IgAV) is a rare autoimmune disease affecting small vessels. It is well established that the incidence is higher in children (5-12 per 100,000 children/year) than in adults (0.1 to 1.6 per 100,000, individuals/year) [1]. However, others epidemiological data and impact of the COVID-19 on IgAV remained overlooked [2].

Objectives: To collect and analyze epidemiological data on IgAV in both adults and children in France.

Results: During this 12-year period, 1988 patients with IgAV were reported (1498 children; 490 adults). The male to female ratio was 1.57 for adults and 1.05 for children. The median IgAV annual incidence was 15 cases/year [IQR 9-30] and 82 cases/year [IQR 72-86] for adult and children cases respectively. Time to diagnosis was less than 1 month for both. Compared with other patients reported in the same expert centers, IgAV was more frequently reported in the southern part of France than in the north (OR 4.88 [95% confidence intervals: 4.17 - 5.74] in adults and OR 1.35 [1.35 - 1.68] in children). IgAV was also more frequently observed in winter than during the rest of the year in both adults (OR 1.60 [1.39 - 1.82]) and children (OR 1.22 [1.01 - 1.48]). The incidence of IgAV decreased during the COVID-19 pandemic period (from March 2020 to September 2022) in children (OR 0.62 [0.47 - 0.81]) but not in the adult population (OR 0.90 [0.76 - 1.06]).

Conclusion: Our study confirms the winter seasonality and sex ratio in IgAV [4,5], but suggests that the incidence or the reporting of IgAV decreased in children during the COVID19 pandemic, possibly due to barrier measures [6]. The observed north/south gradient need confirmation. The main limitation of this study is a possible IgAV under-reporting as this study rely only on cases addressed in expert centers.

AB0769 CARDIAC AND PULMONARY INVOLVEMENTS IN BEHÇET’S SYNDROME: A CASE SERIES OF 93 PATIENTS

Keywords: Cardiovascular disease, Behcet’s disease, Lungs

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.5618
Background: Behçet syndrome (BS) is a multisystemic vasculitis of unknown etiology, frequently observed in the Mediterranean region and the Middle East. Pulmonary involvement (PI) and cardiac involvement (CI) are rarely described in BS, with a prevalence of less than 5%. However, they are entailed to high morbidity and mortality. Objectives: Our work aims to describe the profile and outcomes of BS patients presenting with cardiopulmonary lesions.

Methods: We retrospectively conducted a descriptive and monotopic study, between 2020 and 2022, including 576 BS patients.

Results: 93 patients were enrolled (16%). The sex ratio (M/F) was 4.8 and the mean age was 3 ± 6 years (19-51). Cardiovascular risk factors comprised smoking (26%), high blood pressure (10%), and diabetes (9%). Patients were the mean age was 3 ± 6 years [19-51]. Cardiovascular risk factors comprised smoking (26%), high blood pressure (10%), and diabetes (9%). Patients were the mean age was 3 ± 6 years [19-51]. Cardiovascular risk factors comprised smoking (26%), high blood pressure (10%), and diabetes (9%). Patients were the mean age was 3 ± 6 years [19-51]. Cardiovascular risk factors comprised smoking (26%), high blood pressure (10%), and diabetes (9%). Patients were the mean age was 3 ± 6 years [19-51]. Cardiovascular risk factors comprised smoking (26%), high blood pressure (10%), and diabetes (9%). Patients were the mean age was 3 ± 6 years [19-51].

Conclusion: PI and CI are serious complications of BS, often lately discovered and underdiagnosed, due to their discrete evolution. Systematic screening should thus be considered in at-risk patients, especially young males presenting with mucocutaneous lesions and venous thrombosis. Prompt and adequate immunosuppressive therapy is usually linked to favorable outcomes.

AB0770 MANAGING MEDICATION WITHDRAWAL IN ANCA ASSOCIATED VASculitis, A Single CENTRE STUDY

Keywords: Vasculitis, Tapering, Safety

A. Abdalla1,2, S. Skeoch1. 1Royal National Hospital For Rheumatic Diseases, Rheumatology, Bath, United Kingdom; 2Mater Misericordiae University Hospital, Rheumatology, Dublin, Ireland

Background: While ANCA-associated vasculitis (AAV) can be a life-threatening condition, once patients achieve sustained remission, it is possible to withdraw glucocorticoids (GC) and immunosuppressive therapy successfully. British [1] and European [2] guidelines advocate withdrawal of therapy in sustained remission. However, robust definitions of remission and risk of relapse on drug withdrawal are active research areas within the vasculitis community. Therefore, we took the opportunity to review & compare the clinical practice at our Tertiary Vasculitis Centre to guidelines published by the British Society for Rheumatology (BSR) [1].

Objectives: To describe the proportion of patients in remission and rates of drug withdrawal in line with BSR guidelines and evaluate if any characteristics were associated with GC-dependent remission.

Methods: We conducted a retrospective reviews record of all AAV patients (clinical diagnosis regardless of classification criteria) in our centre who attended for their routine care between July 2015 – August 2020. Those who lost or lacked significant follow-up information were excluded. Approval by the local clinical audit department was granted. Remission was defined per BSR guidance as a well-controlled disease by physician assessment on drug or drug-free remission. SPSS v25 was used for statistical analysis.

Results: Sixty-five patients were included, 58% female, mean (SD) age at diagnosis of 60.7 (13.2), and 92% were Caucasians. The median (range) disease duration was five years (0.5 – 43). 33.8% were classified as GPA, 29.2% as EGPA. 55.4% had life or organ threatening disease, and 50.8% with a relapsing disease (table 1). At the time of the study, 60% of patients remained on GCs and 89% on immunosuppressive therapy. 48/65 (74%) were in clinical remission, of whom 19/48 (39.6%) were on GC plus immunosuppression, 21/48 (43.8%) were on immunosuppression alone, and 5/48 (10.4%) were in drug-free remission. In those with disease duration > 10 years (n=14), 50% were deemed high relapse risk or poorly controlled and remained on a median dose of 10mg prednisolone. On univariate and multiple logistic regression analysis (reference=GC-dependent), skin involvement and a positive biopsy (83.3% non-renal) were associated with a statistically significant lower odds (OR 0.127 P=0.006, OR 0.207 P=0.04 respectively) of remaining on long term GC. In contrast, the relapsing disease was associated with increased odds (OR 4.006, P=0.026) of GC-dependent remission (figure 1).

Conclusion: Withdrawing treatment in AAV is challenging and achievable in a minority of patients, while the vast majority remain on long-term treatment. Skin involvement and non-renal positive biopsy may carry a positive prospect toward GC-free remission. Age, gender, disease type, ANCA status or persistent ANCA did not significantly influence the potential to stay on GC. Having a relapsing disease is the single most crucial factor significantly associated with long term treatment.

**AZATHIOPRINE VERSUS METHOTREXATE AS INDUCTION AND MAINTENANCE THERAPY IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA): A MONOCENTRIC RETROSPECTIVE STUDY**

**Keywords:** Vasculitis, Disease-modifying Drugs (DMARDs), Outcome measures

**Methods:** We collected data from 57 retrospective patients divided in 4 groups according to the treatment received (MTX/AAAZ as 1st line agents in patients with non-severe EGPA or as 2nd line agents in patients with severe EGPA previously treated with cyclophosphamide or rituximab). We analysed the data collected during five years of follow up from the initiation of AAZA/MTX and compared non-severe EGPA vs AAV.

**Background:** Despite the clinical differences between EGPA and the other AAVs, treatment guidelines are mostly based on the evidence available for patients with MPA and GPA, due to the lack of enough randomized controlled trials on patients with EGPA [1].

**Objectives:** The aim of our study is to analyse the efficacy, safety and steroid-sparing effect of azathioprine (AZA) and methotrexate (MTX) as induction and maintenance therapy in EGPA.

**Methods:** We collected data from 57 retrospective patients divided in 4 groups according to the treatment received (MTX/AAAZ as 1st line agents in patients with non-severe EGPA or as 2nd line agents in patients with severe EGPA previously treated with cyclophosphamide or rituximab). We analysed the data collected during five years of follow up from the initiation of AAZA/MTX and compared non-severe EGPA vs AAV.

**Methods:** We collected data from 57 retrospective patients divided in 4 groups according to the treatment received (MTX/AAAZ as 1st line agents in patients with non-severe EGPA or as 2nd line agents in patients with severe EGPA previously treated with cyclophosphamide or rituximab). We analysed the data collected during five years of follow up from the initiation of AAZA/MTX and compared non-severe EGPA vs AAV.

**Background:** Despite the clinical differences between EGPA and the other AAVs, treatment guidelines are mostly based on the evidence available for patients with MPA and GPA, due to the lack of enough randomized controlled trials on patients with EGPA [1].

**Objectives:** The aim of our study is to analyse the efficacy, safety and steroid-sparing effect of azathioprine (AZA) and methotrexate (MTX) as induction and maintenance therapy in EGPA.

**Methods:** We collected data from 57 retrospective patients divided in 4 groups according to the treatment received (MTX/AAAZ as 1st line agents in patients with non-severe EGPA or as 2nd line agents in patients with severe EGPA previously treated with cyclophosphamide or rituximab). We analysed the data collected during five years of follow up from the initiation of AAZA/MTX and compared non-severe EGPA vs AAV.

**Background:** Despite the clinical differences between EGPA and the other AAVs, treatment guidelines are mostly based on the evidence available for patients with MPA and GPA, due to the lack of enough randomized controlled trials on patients with EGPA [1].

**Objectives:** The aim of our study is to analyse the efficacy, safety and steroid-sparing effect of azathioprine (AZA) and methotrexate (MTX) as induction and maintenance therapy in EGPA.

**Methods:** We collected data from 57 retrospective patients divided in 4 groups according to the treatment received (MTX/AAAZ as 1st line agents in patients with non-severe EGPA or as 2nd line agents in patients with severe EGPA previously treated with cyclophosphamide or rituximab). We analysed the data collected during five years of follow up from the initiation of AAZA/MTX and compared non-severe EGPA vs AAV.
the patient groups according to time to first relapse, percentage of patients in remission (defined as R1: BVAS=0, R2: BVAS=0 with prednisone ≤3mg/day, R3: BVAS=0 with prednisone ≤3.75mg/day – following the MIRRA definition), persistence on therapy, percentage of patients with side effects and average cumulative steroid dose.

**Results:**
There were no significant differences in the time-to-first relapse. No statistically significant differences were found in R1 remission analysis; a higher percentage of patients receiving MTX as 1st line therapy obtained R2 remission (median time of suspension was >60 months vs 12 months, p=0.03). The average cumulative steroid dose was lower in patients receiving MTX as a maintenance therapy compared to those receiving AZA (6g vs 10g at 5 years follow-up, p=0.039).

**Conclusion:**
This study shows that MTX as 2nd line therapy has a better steroid sparing effect and allows a better persistence on therapy, while as 1st line therapy it allows an earlier remission on lower prednisone dose.

**REFERENCES:**

**Implications:**
The final tool will be translated into different languages and will be validated in a pilot study. The results of the pilot phase will be discussed and the tool will be translated into 8 languages and launched across Social Media. Ad hoc surveys were created in co-design with the different stakeholders to capture the different dimensions, barriers and needs related to treatment adherence. The survey was translated into 8 languages and launched across Social Media. The objectives of IMPACT_BD are to explore the unmet needs in treatment adherence and the main reasons for low- or non-adherence, to create a tool aimed at identifying and monitoring the reasons of low treatment adherence and to plan specific actions aimed at improving treatment adherence in BD.

**Methods:**
The methodology includes 5 phases. Phase A. Panel creation - The first step created a multi-stakeholder panel that included clinicians, BD patient’s representatives, BD caregiver representatives and other experts (economists, psychologists, pharmacists, etc.). Phase B. Co-design process – Ad hoc surveys were created in co-design with the different stakeholders to capture the different dimensions, barriers and needs related to treatment adherence. The survey was translated into 8 languages and launched across Social Media. Phase C. Launch of the survey. Phase D. Data analysis, workshop and agreement – Answers to the survey questions will be elaborated to identify the main barriers and unmet needs in treatment adherence. An online workshop will be organized to co-design a tool that will enable the identification and the monitoring of BD treatment adherence during the clinical follow-up of BD patients. Phase E. Pilot phase for validation – The final tool will be translated into different languages and will be adopted in a pilot study. The results of the pilot phase will be discussed and evaluated.
refined within the panel. A list of future actions aimed at improving treatment adherence in BD patients will also be produced with the support of members of the co-design panel.

Results: The main results of the study will be represented by: the identification of the main barriers and unmet needs related to treatment adherence in BD patients, caregivers and families; the co-creation of a co-designed tool aimed at assessing the causes and barriers of low- or non-adherence in BD patients; and the planning of future initiatives aimed at improving treatment adherence in BD patients.

Conclusion: Assesing the barriers causing low or non-adherence in BD will provide relevant information that will support the clinicians and the other health care professionals caring for BD patients, by improving the clinical management of the disease; by taking tangible actions aimed at increasing adherence to treatment; and therefore by improving the wellbeing of BD patients, caregivers and families.

URINARY INTERLEUKIN (IL)-16 IN ANTI–NEUTROPHIL CYTOPLASTIC ANTIBODY (ANCA)-ASSOCIATED VASCULITIS WITH KIDNEY INVOLVEMENT

Keywords: Biomarkers, Vasculitis, Kidneys

A. Juto1,2, F. Faustini1,2, A. Häyry1, A. Larsson9, V. Malmström5, A. Bruchfeld4,5,6, A. Antonic1,2, V. Oike1,2, L. Gunnansson1,2, Karolinska Institutet, Department of Medicine, Division of Rheumatology, Solna, Stockholm, Sweden; Karolinska University Hospital, Rheumatology, Stockholm, Sweden; Uppsala University, Department of Medical Sciences, Clinical Chemistry, Akademiska Hospital, Uppsala, Sweden; Karolinska Institutet, CLINTEC, Stockholm, Sweden; Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden; Karolinska University Hospital, Department of Renal Medicine, Stockholm, Sweden; Academic Specialist Center, Center for Rheumatology, Stockholm, Sweden

Background: The pro-inflammatory interleukin (IL)-16 can be released by different immune cells and has shown to be an inflammatory mediator in rheumatic diseases. Urinary (u-) IL-16 has recently been found to be associated with proliferative nephritis in systemic lupus erythematosus (SLE) and is expressed in inflammatory foci in the kidney. However, data on u-IL16 in other immune-mediated kidney diseases including Anti-neutrophil Antibody Associated Vasculitis (AAV) is lacking.

Objectives: To investigate levels of u-IL16 in AAV patients with kidney involvement compared to controls and to assess associations of u-IL16 with clinical variables.

Methods: Urine samples from 43 AAV patients were collected at the time of kidney biopsy on clinical indication. The biopsies were classified according to Berden: Focal (n=20), Crescentic (n=8), Mixed (n=6), and Sclerotic (n=3). The pro-inflammatory interleukin (IL)-16 can be released by different immune cells and has shown to be an inflammatory mediator in rheumatic diseases. Urinary (u-) IL-16 has recently been found to be associated with proliferative nephritis in systemic lupus erythematosus (SLE) and is expressed in inflammatory foci in the kidney.

Results: In the AAV group, there were 25 males (58.1%), the median age was 61 years, and 22 (51.2%) were anti-PR3 positive while 21 (48.8%) were anti-MPO positive. There were 25 (58.1%) patients with GPA and 18 (41.9%) with MPA in the study. Median BVAS was 16 (interquartile range 13-21). Thirty-seven kidney biopsies were classified according to Berden: Focal (n=20), Crescentic (n=8), Mixed (n=6), and Sclerotic (n=3). There was a significant difference in u-IL16 levels between these groups (H (3)=8.68, p =0.034) with the highest proportion of patients with detectable u-IL16 in the sclerotic (66.7%) and crescentic (62.5%) classes. Levels of u-IL16 were not statistically significantly different between patients with or without ongoing treatment. The sensitivity for u-IL16 to correctly classify occurrence of kidney involvement in AAV patients was 38% (specificity 100%, PPV 100%, NPV 14%).

Conclusion: Urinary IL-16 was detectable in a significant proportion of AAV patients with kidney involvement and reflected disease activity and severity. As similar findings have been described in SLE, u-IL16 may be a marker of kidney inflammation in systemic immune-mediated kidney diseases. Further research is warranted to evaluate the pathogenic role of IL-16, the possible use of u-IL16 as a biomarker in clinical practice, as well as its potential as treatment target.

AB0775 EFFECTIVENESS AND SAFETY OF NON-MEDICAL SWITCH FROM RITUXIMAB ORIGINATOR TO AND AMONG BIOSIMILARS IN SMALL VESSEL VASCULITIDES PATIENTS: REAL WORLD DATA FROM A RETROSPECTIVE MONOCENTRIC STUDY

Keywords: bDMARD, Safety, Vasculitis

S. Stanz1, L. Colodanato1, A. Capuano1, M. Lavista1, V. Spedicato1, M. Formaro2, F. Iannone3, F. Cacciapaglia3, University of Bari ‘Aldo Moro’; Rheumatology Unit - Department of Regenerative and Precision Medicine, Ionian Area (DimPre-J), Rheumatology, Bari, Italy

Background: Rituximab (RTX) is indicated for treatment of severe small vessel vasculitides (SVV), namely granulomatosis with polyangiitis (GPA) microscopic polyangiitis (MPA) and cryoglobulineic vasculitis (CV). Currenty available RTX molecules include the originator drug (RTX-Or) and two biosimilars, CT-P10 and GP2013. SVV are rare and only few studies evaluated safety and efficacy of non-medical switch (NMS) from RTX-Or to and among biosimilars.

Objectives: The aim of our study was to obtain real world data about effectiveness and safety of different RTX molecules, and to evaluate switching strategies between RTX biosimilars in these conditions.

Methods: We retrospectively evaluated clinical and laboratory data of patients affected by GPA, MPA, and CV according to specific classification criteria, and treated with RTX based on expert rheumatologist indication between 2018 and 2022. Specifically, C-Reactive Protein (CRP), Erythrocyte Sedimentation Rate (ESR), gamma globulins, C3, C4, Five Factor Score (FFS), Birmingham Vasculitis Activity Score version 3 (BVASv3) and concomitant rheumatologic therapy were recorded. Autoimmunity was assessed as anti-neutrophil cytoplasmic antibody (ANCA) positivity for GPA and MPA and as presence of cryoglobulins in CV. All patients were followed-up for at least 12 months and received at least two cycles of therapy with RTX-Or, CT-P10 or GP2013. NMS to RTX biosimilars was performed when clinically feasible and accepted by the patient. Any safety issue associated with RTX treatment was recorded. Clinical and laboratory data were analyzed using appropriate statistical tests with SPSS.

Results: Data on 29 patients (female No. 19 - 65.5%; mean age 56.3±15.7 years old; mean disease duration 52.3±20.1 months) were available. Ten patients started therapy with RTX-Or, and all accepted NMS to CT-P10. Nine patients were treated with CT-P10 and six accepted NMS to GP2013. Twelve patients started treatment with GP2013. At baseline and during follow-up no significant differences among laboratory and clinical data of patients treated with any RTX molecule was highlighted. All patients achieved a statistically significant reduction of mean corticosteroid dose used from 20.4±12.8 mg/day of prednisone equivalents at baseline to 5.0±2.8 mg/day at 12 months (p<0.0001), and of mean BVASv3 from 20.0±4.5 at baseline to 4.7±2.3 after 12 months (p<0.00001). On average, a reduction of CRP and ESR levels, despite a small decrement of gamma globulins level was also observed. Mean C3 and C4 level resulted normal over time. ANCA positive patients decreased from 83.3% at baseline to 35.3% after one year (p=0.0059). Cryoglobulins were still detectable in 36.4% of patients after one year of RTX treatment (p=0.0039). No severe AEs were recorded, and only two CV patients treated with CT-P10 presented mild AEs: moderate lymphopenia, resolved after temporary drug withdrawal in one subject, and mild urticaria after infusion, with no new AEs after CT-P10 retreatment in the other. Of note, no AEs were observed in our cohort after NMS. Conclusion: Our study demonstrated comparable effectiveness and safety of RTX-Or and its two biosimilars both for induction and maintenance of remission. The effectiveness and safety of NMS for RTX in SSV is confirmed, and our results grant first time evidence for safety and maintained effectiveness of treatment in such patients also after NMS between biosimilars. This practice allows economic sustainability for healthcare systems and represents a hot topic in clinical practice.

REAL-WORLD EVIDENCE ON THE LONG-TERM USE AND DRUG SURVIVAL OF MEPOLIZUMAB IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA)

Keywords: Vasculitis, Descriptive Studies, Real-world evidence

C. Koutsianas1, T. Karageorgas2, C. Tsaiaplaki1, E. Mavrea1, A. Panagiotopoulos1, B. Bourpas1, D. Vassilopoulos1,2, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, School of Medicine, Hippokration General Hospital, Athens, Greece; Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 4th Department of Medicine, National and Kapodistrian University of Athens, School of Medicine, Attikon General Hospital, Athens, Greece

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare form of ANCA-associated vasculitis in which it is frequently difficult to achieve glucocorticoid (GC) tapering without relapse. Mepolizumab (MEPO) is an approved anti-IL5 agent for EGPA but real-world evidence of its long-term efficacy and survival is scarce.

Objectives: To study the efficacy, safety, and survival of MEPO for EGPA in daily clinical practice.

Methods: Retrospective study of all patients with EGPA who received MEPO in two academic Rheumatology centers up until January 10, 2023. Demographic and clinical data were recorded at baseline (start of MEPO) and at last follow up visit.

Results: 16 patients with EGPA treated with MEPO (females: 87.5%; mean age 52.4 years, mean disease duration at MEPO start: 4.4 years, ANCA+: 25%) were included in the study. At baseline, the median (IQR) BVASv3 was 6 (7) and the history of EGPA systemic involvement was: lung 94%, ENT 94%, musculoskeletal 50%, heart 50%, peripheral nervous system 37.5%, skin 25% and gastrointestinal 25%. The median number of EGPA relapses before MEPO use was 2, while 11/16 (69%) had previously failed various immunosuppressive (IS) (MTX, AZA, MMF, CYC) and 3/18 (16%) omalizumab treatment. At MEPO start, all patients were on GCs (median prednisone dose: 12.5 mg/day), while 62.5% were on IS (MMF=6, MTX=2, RTX=2). During follow-up (median [IQR]=12 [9] months), there was a statistically significant reduction in GC dose (median, from 12.5 to 2.5 mg/day, p=0.002), while 3/16 (19%) patients discontinued GCs, absolute eosinophil count (mean, from 1603±163 to 84±42, p<0.001) and BVASv3 (median, from 6 to 0, p=0.007). The cumulative drug survival at 6, 12 and 18 months was 100%, 100% and 83% respectively (Figure 1). MEPO was discontinued in 2 patients due to relapsing disease, while it was well tolerated in all patients without withdrawals for safety issues. Of note, in 3 subjects (19%) MEPO was used concurrently with rituximab (RTX) with good tolerability.

Conclusion: In this real-world study of EGPA patients, MEPO was efficacious and safe, with a high retention rate and significant GC-sparing effects. Furthermore, in almost one out of five patients it was used successfully in combination with RTX. These findings confirm the RCT data in real-life, difficult to treat patients.

Background: External validation of the 2022 ACR/EULAR GPA, EGPA and MPA Classification Criteria is recommended by the DCVAS study group [1-3].

Objectives: Turkish Vasculitis Study (TRVaS) prospective cohort is an electronic database including 15 centres from all over Turkey. We aimed to test performance of the recent criteria sets in TRVaS cohort.

Methods: Patients diagnosed according to physicians’ decisions have been recruited prospectively in TRVaS (in total 3730 patients by January 2023). 2022 ACR/EULAR and 1990 ACR Classification Criteria sets were applied to all of the patients with AAV [n=533], EGPA [n=112], MPA [n=105], and unclassified AAV (n=70)], poliarteritis nodosa (PAN, n=47) and IgA Vasculitis (n=76). Performances were analysed using sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy.

Results: For the patients with GPA, 2022 criteria had higher sensitivity and specificity compared to 1990’s (83.6% vs. 71.0%, p=0.001), whereas no significant difference was observed between 1990 and 2022 criteria for EGPA and MPA.

Conclusion: Using 2022 ACR/EULAR Classification Criteria, improved sensitivity and specificity for GPA and sensitivity for EGPA were observed. Additionally, half of the unclassified AAV patients could be classified as either GPA or MPA. These criteria functioned well for the discrimination of patients with AAV from other small/medium vessel vasculitides such as PAN and IgA vasculitis. Total, over 80% of the patients with AAV were accordingly classified in parallel to the other small/medium vessel vasculitides of PAN and IgA vasculitis. Total, over 80% of the patients with AAV were accordingly classified in parallel to the clinical diagnosis in each GPA/EGPA/MPA.

GPA = granulomatosis with polyangiitis; EGPA = eosinophilic granulomatosis with polyangiitis; MPA = microscopic polyangiitis; AAV = ANCA associated vasculitis; PR3 = Proteinase 3; MPO = Myeloperoxidase
Background: Accuracy of diagnosis and prompt therapeutic intervention are the mainstay in patients with ANCA-associated vasculitis (AAV) suffering from life-threatening complications [1]. However, there is no definition of therapeutic window in vital AAV, nor its impact on patient outcome regarding length of hospital stay, intensive care unit (ICU) admission or survival.

Objective: The aim of this study is to analyze the process of care from the perspective of time management in vital organ involvement AAV patients and to identify potential risk factors for ICU admission.

Methods: A retrospective multicenter study identified AAV patients with life-threatening organ involvement, defined as alveolar hemorrhage, rapidly progressive renal failure, myocarditis, and showed no relationship to the type of severe organ involvement. The need for aorta was most frequently involved. Glucocorticoids (36/36), rituximab (19/36), and methotrexate (18/36) were the most frequent treatments. During the study period 8 patients died (4 in TA-AAV, 3 in A-AAV, and 1 in PA-AAV). There was no difference in mortality between this cohort of L-AAV patients and the general population (standardized mortality ratio: 0.98; 95% CI, 0.42-1.93).

Conclusion: This is the largest single-center cohort of patients with L-AAV to date. Clinicians should consider L-AAV in the differential diagnosis of vasculitis especially in the context of positive ANCA and atypical organ manifestations.

RISK FACTORS FOR SERIOUS INFECTION IN PATIENTS WITH MICROSCOPIC POLYANGITIS: RESULTS FROM THE REVEAL COHORT

Keywords: Real-world evidence, Vasculitis

Background: Many studies have reported risk factors for infection in ANCA-associated vasculitis, but the consistency of these risk factors varies between studies [1-5]. In addition, few reports have focused specifically on patients with microscopic polyangiitis (MPA) or have focused on the impact of glucocorticoids (GC) reduction on the risk of infection.

Objectives: In this study, we aimed to examine risk factors of serious infections (SI) in patients with MPA in the REVEAL cohort, a Japanese multicenter cohort. As one of the risk factors, we also focused on the pace of GC reduction.

Methods: 181 MPA patients hospitalized for induction therapy and followed for at least three months were recruited from the REVEAL cohort. We evaluated the demographic, clinical, and laboratory findings, and treatments. To assess the pace of GC reduction, GC doses at 3, 12, and 24 months were extracted, and the ratio of each to the initial dose was calculated. Univariate analysis and COX regression analysis were performed to identify risk factors for SI, defined as infections requiring hospitalization in these patients. Gray test was performed for the comparison of the cumulative incidence of SI between groups.

Results: There were 115 patients without SI and 66 patients with SI. Univariate analysis showed that age, smoking index, CRP, and GC dose ratio (3 months/initial dose) were associated with SI. In the COX regression analysis (shown in Table 1), age, CRP, and GC dose ratio (3 months/initial dose) were identified as significant risk factors (p values are <0.005, <0.005, and 0.04, respectively). In addition, the group with GC dose ratio (3 months/initial dose) ≥ 0.4 had significantly higher cumulative incidence of SI than the other group (p=0.032) (shown in Figure 1).

Conclusion: Age, CRP, and GC dose ratio (3 months/initial dose) were identified as risk factors for SI in MPA patients.

DO: 10.1136/annrheumdis-2023-eular.1057
Results: Of 68 patients with HSP nephritis, diagnosed by kidney biopsy, 41 (60.29 %) were male and 27 (39.71 %) - female. Age of onset was between 18 and 66 years (mean 37.28 ± 9.34). Duration of follow-up was between 2 and 28 years. Of 293 patients, 65 patients had histories of infection preceding presentation. At onset all patients had palpable purpura and urinary abnormalities (only hematoma - in 16.18 %; mild proteinuria ± hematuria - in 44.12 %; moderate or severe pro-
teinuria and hematuria – in 39.70 %). Arthralgias were present in 49 patients (72.06 %), gastrointestinal involvement – in 32 patients (47.05 %). Renal function was impaired in 28.47 % of patients, and 51.47 % were hypertensive. Mesan-
gi hypercellularity lesions were found in most patients (97.60 %), endocapillary proliferation – in 20.58 %, segmental sclerosis – in 32.35 %, tubular atrophy, intetral fibrosis – in 38.32 %. Corticosteroids and cyclophosphamide were pre-
scribed in patients who presented with severe clinical and histological features and/or rapidly progressing renal disease. During follow-up classical extra-renal organ diseases were seen in 55.88 % of patients, and hematoma and/or pro-
teinuria – in 77.94 %. At final review 26.47 % had progression of renal failure. Risk factors for renal failure were moderate or severe proteinuria during follow-up (p<0.001), renal impairment at presentation (p<0.001), hypertension at presenta-
tion and during follow up (p<0.05), crescents, interstitial fibrosis and tubular atro-
ysis (p<0.001). No significant difference in renal outcome was observed between patients who had relapses in extra-renal organs versus in those who did not.

Conclusion: Our results indicated that lower GFR, nephrotic syndrome, nephrit-
ic-nephrotic syndrome and crescentic nephritis were risk factors for unfavorable outcomes.

AB0784
SKULL BASE INFECTION AS A MANIFESTATION OF GRANULOMATOSIS WITH POLYANGIITIS

Keywords: Rare/orphan diseases, Organ damage, Vasculitis

A. Masak1, Z. Zdrojewski1. 1Medical University of Gdansk, Department of Rheumatology, Clinical Immunology, Geriatrics and Internal Medicine, Gdansk, Poland

Background: Although upper respiratory symptoms are the most frequent local-
izations of granulomatosis with polyangiitis (GPA) [1], infiltration of the skull base is rare.

Objectives: The aim of this analysis was the clinical characteristic of GPA patients’ skull base involvement.

Methods: The retrospective analysis was performed on patients diagnosed in tertiary academic referral center (Medical University of Gdansk, Poland) between 1990 and 2022 due to GPA. Medical database of 232 GPA vasculitis patients were retrospectively reviewed, and demographics, serological, and clinical fea-
tures of the patients presenting skull base infiltration throughout the disease course were recorded. Comparisons of disease characteristics and long-term outcomes were performed between patients with and without this manifestation.

Results: Among 232 patients (121 males, median age 52.5 years, 87% ANCA positive, 12.5% localized, 87.5% systemic), seven patients presented skull base infiltrations as a manifestation of GPA. It was 4 women and 3 men, aged between 27 and 72. Four patients were cANCA positive, 1 patient had atypical pANCA and 2 patients were ANCA negative. In six of them it was a first manifestation of vasculitis. Clinical characteristic of patients is summarized in table. Statistical analysis showed that patients with skull base involvement and those without this manifestation differed only in the frequency of ocular involvement - in patients with skull base infiltration, ocular involvement occurred in all cases, while among patients without infiltration it occurred in only 34.54% of subjects. In terms of other parameters, there were no statistically significant differences between the groups.

Conclusion: Skull base infiltrations presenting mainly as cranial nerve palsies is rare presentation of GPA. In most of patients it is one of the first symptoms of vasculitis. It can occur in both ANCA positive and ANCA negative cases.

ASSOCIATED FACTORS TO REMISSION IN PATIENTS WITH UVEITIS RELATED TO BEHÇET DISEASE TO THE FIRST THERAPEUTIC SCHEME

Keywords: Behçet disease, Uveitis, Remission

M. Cosentino1, I. Gandino2, C. Pena3, M. C. Baretto4, A. Testi1, B. M. Virasoro5, L. Garcia1, M. Scolnic5, A. Ringer5, C. Siegrist2, B. Abdala6, S. Chulibert4, M. Dalpiaz7, G. Rodriguez8, A. Schlaen9, C. Vanegas8, C. Alanez5, M. Heredia5, M. Garcia1, H.I.G.A. SAN MARTIN LA PLATA, Reumatología, La Plata, Argentina; 1Hospital General de Agudos Dr. Fernández, Reumatologia, Buenos Aires, Argentina; 2Consultorio de enfermedades autoinmunes, autonomidad, Buenos Aires, Argentina; 3Hospital Italiano de Buenos Aires, reumatologia, Buenos Aires, Argentina; 4Clinica de medicina y laboratorio inmunológico especializado, autonomidad, Santa fe, Argentina; 5Hospital Provincial del Centenario, reumatologia, Santa Fe, Argentina; 6Chumica, oftalmologia, JCP, Argentina; 7Austral University Hospital, oftalmologia, Pilar Centro, Argentina

Background: Behçet’s disease (BE) is a systemic venous and arterial vas-
culitis of unknown etiology [1]. Oral ulceration is common, affecting 40-70% of patients [2], and is the main cause of morbidity. Uveitis is the most frequent common ocular clinical presentation, with a prevalence that can reach up to 90% of cases, affecting the anterior and posterior segments of the eye. Among 16-25% of the cases end in blindness, so early detection and treatment are essential [3].

Objectives: To describe the characteristics of uveitis in EB, extracellular manifesta-
tions, therapeutic lines used, and to compare the factors associated with uveitis remission to the first therapeutic scheme. In addition, evaluate the adherence to the EULAR 2018 recommendations.

Methods: Multicenter, observational, retrospective cohort study. Patients over 18 years of age with EB according to the 2014 ICBD criteria and uveitis according to the Uveitis Nomenclature Standardization Working Group (SUN). Disease remission was defined if the patient met the SUN criteria for ocular remission and if the rheumatologist did not have to change the immunosuppressant due to ocular involvement.

Results: Fifty-five patients were included, 69.1% were men, with a mean age at diagnosis of 33.7 (SD 11.4) years old, mean age at uveitis presentation
of 37.1 (SD 19.6) years old, and a median follow-up of 2.5 (IQR 7.2) years. HLA-b51 was positive in 13/15 (86.7%). The most frequent presentation was panuveitis (49%), bilateral (69.1%) and chronic (59.6%) affection; the first-line treatment was azathioprine (45%). According to the variables studied, acute presentations responded better to the initial therapeutic scheme (41% vs 8.3%, p = 0.01) and a history of thrombosis was associated with greater refractoriness (16.7% vs 0%, p = 0.03). Table 1 shows the comparison in terms of remission or refractoriness to the first therapeutic line. In relation to the year of uveitis diagnosis, 21 cases occurred after the publication of the recommendations, and adherence to the first line was observed in 66.7%. Also, a comparison was made to find out if the physician who adhered to the EULAR recommendations had a higher probability of remission, but this was not statistically significant (66.7% vs 42.9%; p = 0.99). Sequelae were observed in 11/44 patients: 1 glaucoma, 3 retinal scars, 3 blindness, and 4 cataracts. The mean visual acuity of the right eye and left eye at the first visit was 6.8 (SD 3.6) and 6.6 (SD 3.7); and in the last visit, 7.4 (DE 5.5) and 7.1 (DE 3.4), respectively.

</tbody>
</table>

Conclusion: In this multicenter cohort of patients with uveitis associated with EB, the most frequent form of presentation was panuveitis, as well as bilateral involvement and chronic forms. Approximately half of the patients achieved remission with the first therapeutic scheme line, regardless of the selected immunosuppressant. The acute forms could be associated with a higher probability of remission, while the history or presence of thrombosis would seem to be related to greater refractoriness. The therapeutic management presented high consistency with the current recommendations.

Disclosure of Interests: None Declared.
Results: A total of 71 patients were enrolled; 30(42%) in RTX group and 41(58%) in non-RTX group. Baseline characteristics were comparable between two groups as shown in Table 1. The median age was 74 vs. 76 years with the PR3-ANCA positivity rate of 23% vs. 17%, and the median BVAS score was 11 vs. 12 points, respectively. The CR rate at week 24 was higher in the RTX group than in the non-RTX group [24(80.0%) vs 19(46.3%), p = 0.004] (shown in Figure 1), with comparable doses of concomitant glucocorticoids. The adjusted odds ratios of RTX use for CR at week 24 and 48 were 1.09 (95%CI 0.39-3.10) and 4.01 (95%CI12.9-12.30). The incidence of serious infection was similar in both groups: [4(13.3%) vs 4(9.8%), p=0.638].

Conclusion: RTX may be superior, with well tolerability, to the other conventional immunosuppressive therapies as an induction therapy in elderly patients with relapsed AAV.

FLOW CYTOMETRY ANALYSIS OF IMMUNE CELLS IN PATIENTS WITH BEHCET'S SYNDROME: A REAL-WORLD STUDY IN CHINA

Keywords: Real-world evidence, Behcet's disease

J. Li1, F. Sun1, W. Zhou1, T. Liu1. 1Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China

Background: Behcet's syndrome (BS) is an autoimmune disease characterized by recurrent mucocutaneous ulcerations, vascular and nervous system involvement. While there have been a lot of researches proving that immune cells play a vital role in rheumatic disease, opinions on the effect of different immune cell subsets on BS is inconsistent. Therefore, we performed this real-world study to explore the role of immune cells in the pathogenesis of BS.

Objectives: To investigate the changes in the levels of several immune cell subsets in BS, and the correlation between the levels of different immune cell subsets and clinical features in patients with BS.

Methods: This is a retrospective, single-center study conducted in Beijing. 136 patients diagnosed with BS in rheumatology and immunology department of Peking University People's Hospital from 2018 to 2021 and 114 healthy controls (HCs) were enrolled. All patients met the International Criteria for Behcet's Disease (ICBD). We utilized flow cytometry to test the levels of CD4+ T cells, CD8+ T cells, B cells, NK cells and several subsets of CD4+ T cells. Wilcoxon rank test and student's t-test were used and a P-value <0.05 was considered statistically significant.

Results: Compared to HCs, there is a decrease in the count of CD4+ T cells, B cells and NK cells in BS patients. A significant increase in the frequency of IFN-γ, IL-2 and IL-4 producing CD4+ T cell in BS patients were observed, which accompanied by a decreased frequency of Naïve CD4+ T cells. The frequency of Foxp3+ Treg cells was notably increased while the proportion of CLA+ Treg in T cells was significantly decreased in BS patients. BS patients’ frequency of follicular helper T cells were apparently lower than HCs. There was a significant reduction of the frequency of Treg in patients with vascular involvement. The frequency of follicular helper T cells were positively correlated with joint involvement and negatively correlated with nerve involvement in BS patients. Patients with gastrointestinal involvement had a increased frequency of TNF-α, IFN-γ, IL-2 and IL-4 producing CD4+ T cells and a decreased level of B cell count. Elevated level of NK cell count and decreased frequency of TNF-α, IL-2 producing CD4+ T cells were found in patients with skin-mucosa involvement alone.

Conclusion: Our study confirmed that Th1 cells, Th2 cells, Treg cells, follicular helper T cells, B cells and NK cells contribute a lot to the pathogenesis of BS.

AVACOPAN IN THE REAL-LIFE PRACTICE: EVALUATION OF EFFICACY, SAFETY, AND IMPACT ON QUALITY OF LIFE IN THE EARLY STAGES OF TREATMENT

Keywords: Safety, Vasculitis, Remission

1Clinic of Rheumatology, Department of Medicine, University of Udine, Udine, Italy; 2Department of Biomedical and Clinical Sciences, Sacco and Fatebenefratelli Hospitals, Milano, Italy; 3Nephrology Unit, University of Brescia, ASST Spedali Civili, Brescia, Italy; 4Rheumatology Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy; 5Centre for Inflammatory Diseases, Monash University Department of Medicine, Monash Medical Centre, Clayton, Victoria, Australia

Background: Avacopan is a new approved treatment for granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA). Compared with glucocorticoids (GCs) added to standard immunosuppressive therapy (IST) with cyclophosphamide (CYC) or rituximab (RTX), avacopan proved to be non-inferior for treatment response at 52 weeks, whereas it was superior to GCs for sustained remission at 52 weeks compared with a prednisone tapering schedule of 20 weeks [1].

Objectives: The aim of this prospective multicenter study was to assess efficacy and safety of avacopan in the real-life practice in GPA or MPA patients in the setting of a compassionate use program. A secondary objective was to describe the impact on the perceived quality of life before and during treatment.

Methods: We prospectively collected clinical and laboratory data of GPA and MPA patients who started treatment with avacopan from May 2022. Patients were recruited from 9 Italian Rheumatology/Nephrology Units belonging to the Vasculitis Study Group of the Italian Society of Rheumatology (SIR). At least 3 months of follow-up from the start of treatment were required for data analysis. Clinical remission was defined as BVASv3 equal to 0. Patients self-completed the Italian version of the AAV-PRO questionnaire (AAV-PRO_it) at baseline and after 3 months [2].

Results: A total of 12 patients (7 females, 5 males) with a median age of 64 (IQR 48-66.3) were recruited. 9 patients had GPA (4/12, 33.3%) and 3 patients had MPA (5/12, 25%). The relapsed patients had a median disease duration of 12 (IQR 4.3-15.3) years and had been previously treated with other immunosuppressants, including RTX (5/8, 62.5%), CYC (5/8, 62.5%), AZA (3/8, 37.5%), MTX (2/8, 25%), and MMF (1/8, 12.5%). At the start of avacopan treatment, the median BVASv3 and VD were 12 (IQR 8.20-8.2) and 2.5 (IQR 1.5-3.3), respectively. 9 out of 12 (75%) patients had renal involvement, of which 5/9 (55.6%) had rapidly progressive glomerulonephritis. Other disease involvements were EN (5/12, 41.7%), and pulmonary (5/12, 41.7%), of which 3/5 (60%) patients had alveolar haemorrhage. Treatment was initiated with a median steroid dose of 50 (IQR 4.9-50) mg prednisone equivalent (PN-eq) and in combination with RTX at a dose of 1 gram every 2 weeks (9/12, 75%) or 375 mg/m2 weekly for 4 consecutive weeks (3/12, 25%). Two patients also received 1 gram of CYC before RTX. After month 3, 10/12 (83.3%) patients were in clinical remission and the median steroid dose had decreased from 5 (IQR 2.2-10.6) mg PN-eq (Figure 1). The median value of creatinine did not differ from the prednisone tapering schedule (10.1 mg/dL). In all three patients the vasculitic process was confined to the same cerebral hemisphere, while the other two had cerebral lesions with gadolinium enhancement. All had multiple flares (from 4 to 10) and were treated with different traditional immunodepressive drugs and RTX (RTX) for the steroid-resistance. They received long-term treatment (more than 2 years) with fixed high-dose prednisone (PDN) in one patient (40 mg/daily, in the other two 20 mg/daily) because the vasculitic process flared when the PDN dose was reduced. One patient had at PRF prominent leptomeningeal enhancement, while the other two had cerebral lesions with gadolinium enhancement. In all three patients the vasculitic process was confined to the same cerebral hemisphere.

Conclusion: Our study described the real-life practice of avacopan in GPA and MPA patients, especially relapsing patients. The clinical added value of avacopan as steroid sparing strategy can be observed already in the early stages of treatment. Overall, avacopan appears to be an effective and safe adjunctive therapy in the active AAV.

REFERENCES:

Figure 1.
hemisphere at diagnosis and during the flares, and at the last available brain MRI performed 35 months, 167 months, and 65 months after the diagnosis, respectively. All 3 patients at last follow-up had slight disability with mild cognitive impairment; one case also had mild left hemiparesis. Spinal fluid examination at diagnosis was normal in 2 patients.

Conclusion: Unilateral relapsing involvement represents a rare subset of PCNSV with peculiar characteristics and can be observed in all neuropathological patterns.

AB0791 EVALUATION OF THE EFFICACY AND COMPLICATIONS OF PLASMA EXCHANGE IN ANCA-ASSOCIATED VASCULITIS: RESULTS OF PROPENSITY SCORE MATCHING ANALYSIS IN HIGH-RISK PATIENTS

Keywords: Vasculitis

B. Inci1, M. Bektas1, B. Celik2, S. Yuce2, Y. Yalcnkaya3, B. Artim-Esen1, A. Gu1, S. K. Bessisk1, M. Inanc1, 1Istanbul University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Istanbul University Faculty of Medicine, Department of Public Health, Istanbul, Turkey; 3Istanbul University Faculty of Medicine, Department of Internal Medicine, Division of Hematology, Istanbul, Turkey

Background: Therapeutic plasma exchange (PE) is applied in addition to standard induction therapy for patients with severe organ or system involvement in ANCA-associated vasculitis (AAV). However, prognostic significance of this approach is questioned.

Objectives: We aimed to evaluate both short- and long-term efficacy and safety of PE in our established single center cohort.

Methods: In this study, we evaluated the clinical and laboratory data of 128 patients diagnosed with AAV between 2011 and 2021. Data of patients with GFR <50 ml/min with or without diffuse alveolar hemorrhage (DAH) at the time of admission were included into the analysis. Disease activity, laboratory and follow-up data of patients who underwent PE were compared with those who did not. The analyses were repeated in the groups formed after the propensity score matching (PSM) performed according to the presence of DAH, age, gender, baseline GFR and BVAS scores.

Results: Seventy-one (55.5%) patients (F/M: 32/39, mean age± SD: 54.6±12.9) were included into the study. Thirty-nine (54.9%) patients had C-ANCA/PR3, 29 (40.8-%) patients had p-ANCA/MPO positivity. The mean age, gender, baseline GFR and BVAS scores.

AB0792 ADULT-ONSET IGA VASCULITIS WITH RENAL INVOLVEMENT

Keywords: Vasculitis, Kidneys, Prognostic factors

F. Yildirim1, M. E. Kutu2, Y. Calik3, S. Celik6, C. Bes7, 1University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Rheumatology, Istanbul, Turkey; 2University of Health Sciences, Baskoey Dr Sadi Konuk Training and Research Hospital, Rheumatology, Istanbul, Turkey

Background: Systemic Immunoglobulin A vasculitis (IgAV) often presents glomerulonephritis accompanying palpable purpura. Unlike children, renal involvement can be severe in adults. Especially, in the chronic period, renal involvement determines the prognosis. A significant proportion of the patients initially have pathological renal findings, while pathological renal findings may occur later in some patients.

Objectives: It was aimed to compare the clinical features of patients with renal involvement at the beginning and those with subsequent renal involvement, to determine the predictors of renal involvement and to determine the factors affecting renal prognosis.

Methods: A total of 42 adult patients with IgA vasculitis nephritis with followed between January 2018 and August 2022 in two tertiary hospitals were included in the study. The patients were divided into 2 groups as those with and without IgA vasculitis nephritis findings at the beginning. Patients’ clinical and laboratory data were collected at baseline and at follow-up, and were analyzed retrospectively.

Results: Thirty (%71) of 42 patients had signs of IgA vasculitis nephritis at baseline and 12 (%29) patients, signs of nephritis appeared later. The median time between first visit and development of nephritis was 18 [IQR:6-44] days in patients whose nephritis findings appeared later. In the binary logistic regression analysis, it was determined that gastrointestinal involvement at the baseline predicted the later development of renal involvement [OR:6.399, 95% CI=1.800-49.079, p = 0.008]. Comparative results of the 2 groups with and without IgA vasculitis nephritis findings at baseline in terms of clinical features are presented in Table 1.

**Results:**

A total of 158 patients (low C3: 28, normal C3: 90, high C3: 40 patients) were included when variates were categorical. Analysis of variance or the Kruskal–Wallis test was used when variates were categorical.

**Conclusion:** Low C3 levels are associated with severe disease and renal dysfunction, while high C3 levels are associated with elevated CRP levels. Serum C3 levels are closely associated with disease pathology.

**SERUM C3 LEVELS ARE ASSOCIATED WITH DISEASE PATHOLOGY IN MICROSCOPIC POLYANGITIS: RESULTS FROM THE REVEAL COHORT**

**Objectives:**

1. The ANCA-associated vasculitides (AAV) are systemic autoimmune diseases affecting small and medium-sized blood vessels. Upper airways, lungs, and kidneys are variably involved in the different types of AAV, and the consequences of a missed or delayed diagnosis of renal vasculitis are potentially life-threatening. AAV may be classified into clinical syndromes or based on their serology (Anti-PR3 or Anti-MPO). Patient survival and the risk of end-stage renal disease are closely associated with renal functional status.

2. This study was undertaken to study the disease characteristics and outcomes in patients of AAV based on the presence or absence of renal involvement.

**Methods:**

A prospective study was undertaken to study the disease characteristics and outcomes in patients of AAV based on the presence or absence of renal involvement.

**RESULTS:**

A total of 112 patients were included in our study, with a median age of 51.5 years. 74 (66%) patients had renal involvement either in the form of Nephritic (P<0.001), and serum CRP levels (P=0.002) were significantly lower in the low C3 group, while serum creatinine levels (P=0.001), BVAS (P=0.039), and five factor scores (P<0.005) were significantly higher in the low C3 group. Notably, the proportion of patients who fulfilled the 2022 revised ACR/EBULAR classification criteria for MPA was significantly lower in the low C3 group (P=0.039). Initial prednisolone dose and survival did not differ between the three groups.

**Conclusion:** Low C3 levels are associated with severe disease and renal dysfunction, while high C3 levels are associated with elevated CRP levels. Serum C3 levels are closely associated with disease pathology.

**A PROSPECTIVE STUDY ON RENAL INVOLVEMENT IN INDIAN PATIENTS WITH ANCA-ASSOCIATED VASCUITIS**

**Objectives:**

1. The ANCA-associated vasculitides (AAV) are systemic autoimmune diseases affecting small and medium-sized blood vessels. Upper airways, lungs, and kidneys are variably involved in the different types of AAV, and the consequences of a missed or delayed diagnosis of renal vasculitis are potentially life-threatening. AAV may be classified into clinical syndromes or based on their serology (Anti-PR3 or Anti-MPO). Patient survival and the risk of end-stage renal disease are closely associated with renal functional status.

2. This study was undertaken to study the disease characteristics and outcomes in patients of AAV based on the presence or absence of renal involvement.

**Methods:**

A longitudinal, observational study conducted at a tertiary care hospital in Northern India. Between February 2020 and December 2021, all consecutive adult patients diagnosed with AAV based on their autoantibody profiles (using indirect immunofluorescence and Line ImmunoAssay) and clinical features were included in this study after taking their informed consent. Demographic details, clinical features, laboratory parameters, disease activity, and mortality or morbidity outcomes of patients were analysed prospectively. All outcomes were compared between patients with and without renal involvement.

**RESULTS:**

A total of 112 patients were included in our study, with a median age of 51.5 years. 74 (66%) patients had renal involvement either in the form of Nephritic...
syndrome, Nephrotic syndrome, RPRF (Rapidly progressive renal failure), Nephritic nephrotic syndrome, or Asymptomatic Urinary Sediments. c-ANCA and PR3 positivity were seen in more than two-thirds of our population, without any significant correlation with organ involvement. Patients with renal disease had a significantly higher proportion with diffuse alveolar haemorrhage (32.4% vs 10.5%, p=0.05) and palpable purpura (19.6% vs 7.9%, p=0.025), but significantly lower occurrences of nasal pathology (14% vs 42%, p=0.001) and subglottic stenosis (1.4% vs 18.4%, p=0.001). Mean BVAS at enrolment was significantly higher in the renal group (20.9 vs 12.89). Remission was achieved in 50% and 47.4% of patients with and without renal involvement respectively. Rates of relapse (19/74 vs 14/38), refractory disease, and mortality were not significantly different among the two subgroups. The commonest organ involvement in disease flare was pulmonary involvement. 21.6% of the patients developed CKD over a median follow-up period of 18 months.

Conclusion: Kidney involvement is one of the commonest manifestations of AAV. Patients with renal involvement may have higher mean BVAS scores and an increased risk of developing alveolar haemorrhage and purpuric skin rash; while nasal pathology and subglottic stenosis occurred more frequently in patients without renal disease. Rates of remission, refractory disease, and mortality were almost similar, regardless of renal involvement, while relapses were numerically more in the non-renal AAV patients.

MPO-ANCA ANTIBODIES: ASSOCIATED DISEASES, SPECIFICITY, AND RELATION WITH SEVERITY AND PROGNOSIS OF UNDERLYING VASCULITIS. STUDY FROM A SINGLE UNIVERSITY HOSPITAL

Keywords: Autoantibodies, Vasculitis

S. Al Fazazi1, V. Calvo-Rio2, M. Renuncio García3, M. Rodriguez Vidriales4, C. Escagedo Cagigas5, J. Iruve-Ventura6, L. Martin-Penagos6, M. Lopez-Hoyos6, R. Blancom7, Hospital Universitario Puerta del Mar, Renumatology, Cadiz, Spain; 2Marques de Valdecilla University Hospital, Rheumatology, Santander, Spain; 3Marques de Valdecilla University Hospital, Immunology, Santander, Spain; 4Marques de Valdecilla University Hospital, Nephrology, Santander, Spain

Background: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) include Granulomatosis with polyangiitis GPA), Microscopic polyangiitis (MPA), and Eosinophilic granulomatosis with polyangiitis (EGPA). Anti-myeloperoxidase (anti-MPO) or anti-proteinase 3 are the two main ANCA subtypes. Anti MPO specificity and correlation with the severity and prognosis of underlying vasculitis is contradictory [1].

Objectives: To assess in patients with positive anti-MPO, a) associated diseases, b) specificity in diagnosing AAV and c), relation with severity and prognosis of vasculitis in a single university hospital.

Methods: Study of patients with positive anti-MPO from a University Hospital, from 2003 to 2022. ANCA was determined by standard immunochromotest. The specificity of anti-MPO for diagnosis and relation with severity and prognosis of underlying vasculitis were evaluated with Receiver Operating Characteristics (ROC) curves. At diagnosis severe AAV were considered cases with renal disease (hematuria and/or proteinuria) and pulmonary involvement. In follow-up, vasculitis was considered if the patient needed dialysis, a transplant of died.

Results: We study 101 patients with positive anti-MPO. Table summarizes the prevalence of these antibodies in vasculitis and non-vasculitis diseases. Most of them (76.23%) had an underlying AAV, being the most frequent MPA (33.7%). The non-vasculitis disease more frequent was neoplasm (4,9%). For anti-MPO antibodies with a diagnosis of AAV (n=77), an area under the curve (AUC=0.8084), and a cut-off point of 41.5 IU/ml was determined (Figure). When the analysis was restricted to exclusively MPA (n=34), the cut-off point was 36.5 IU/ml with an AUC of 0.6435. For severity of AAV, there were significant differences in anti-MPO levels between patients with renal or pulmonary dysfunction (n=85) versus those without them (n=36) (p=0.0003), and a cut-off threshold of 60 IU/ml was established. Finally, after evaluating the illness’s progression, an AUC= 0.5546 was found, being no significant differences between those patients who had a worse disease progression (n=19) and those who did not (n=82) (p=0.4643).

Conclusion: MPO antibodies levels, at the moment of diagnosis, may be associated to AAV diagnosis (specificity) and severity but not with disease outcome.

CANCAN VASC CONSENSUS RECOMMENDATIONS FOR THE USE OF AVOCANAD IN ANTEINEUTROPHIL CYTOPLASMA ANTIBODY-ASSOCIATED VASCULITIS: 2022 ADDENDUM

Keywords: Vasculitis

Background: In 2020, the Canadian Vasculitis Research Network (CanVasc) published their updated recommendations for the management of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV). Since then, clinical data have accumulated on the complement C5a receptor inhibitor avacopan (formerly, CCX168) has continued to expand.

Objectives: The current addendum provides further recommendations regarding the use of avacopan in AAV based on a review of newly available evidence.

Methods: An updated systematic literature review on avacopan using Medline, Embase, and the Cochrane Library was performed for publications up to 30 September 2022. New recommendations were developed and categorized according to the EULAR grading levels, as done for previous CanVasc recommendations. A modified Delphi process and videoconferences were used to reach >80% consensus on the inclusion, wording, and grading of each recommendation.

Results: Three new recommendations were developed. They focus on avacopan for therapy indication and duration, as well as timely glucocorticoid tapering.

Conclusion: These 2022 addended recommendations provide rheumatologists, nephrologists, and other specialists caring for patients with AAV with guidance for the use of avacopan, based on current evidence and consensus from Canadian experts.

R. H A Mohammed1, D. Hassan Attia1. 1School of Medicine- Cairo University, Rheumatology and Rehabilitation, Cairo, Egypt

Background: Systemic Vasculitides are a heterogenous group of immune mediated vascular inflammatory pathologies that contributes to vessel wall necrosis and damage. Ocular manifestation with systemic vasculitides isn’t uncommon as an initial presentation. Identifying the patterns of ocular involvement associated with a specific diagnosis of vasculitis might guide the diagnosis at early encounter, while if underdiagnosed or improperly treated might contribute to devastating complications [1-3].

Objectives: To survey the patterns of ocular manifestations as the initial presentation in a population of patients with systemic vasculitides.

Methods: This is an observational cohort study in which data regarding ocular involvement were retrieved from medical records. The inclusion criteria: medical records of adult patients > 18 years with the diagnosis of any form of vasculitides according to the internationally recognized criteria having ocular involvement as confirmed by an expert ophthalmologist. Exclusion Criteria: patients with additional diagnosis whether endocardial, metabolic, neoplastic and infectious diseases.

Results: The study included a total of 328 patients with the different diagnoses of vasculitis (68.9% males and 31.1% females, their mean ages were 38.58±11.96 years, mean disease duration of 65.35±75.84 months). Figure 1 Ocular involvement was reported in 46% of the included cases with vasculitis at initial encounter, uveitis was diagnosed in 31.1% (7.3% anterior uveitis, 10.7% posterior uveitis, 13.1% pan uveitis), optic neuritis in 3.5%, retinal vasculitis in 17%, retinal artery thrombosis was reported in 1.8%, retinal vein thrombosis in 5.4%, orbital pseudotumor in one patient with granulomatosis with polyangiitis, scleritis one patient and episcleritis one patient with granulomatosis with polyangiitis. Ocular involvement was found in 61.3% of cases with BD (uveitis in 48.2%, retinal vasculitis in 18.4%) at initial encounter with uveitis being the most common.

Figure 1: The Frequency of the different diagnoses of vasculitis in the Study population.
Conclusion: The patterns of ocular involvement at initial presentation might guide the diagnosis of one form of vasculitis over the other especially with incomplete forms.

AB0798 PREVALENCE AND CLINICAL SPECTRUM OF CARDIAC INVOLVEMENT IN BEHÇET’S SYNDROME: A SINGLE CENTER RETROSPECTIVE STUDY

Keywords: Cardiovascular disease, Behcet’s disease, Heart

E. Bettiol1, A. Bettiol1, E. Silvestri1, D. Malandrinò1, A. Palermo1, M. L. Urban1, R. Mazzotta1, I. Costanzo1, I. Matioli1, G. Emmi1. University of Florence, Experimental and Clinical Medicine, Firenze, Italy

Background: Behçet’s Syndrome (BS) is a systemic vasculitis, which main clinical features include mucocutaneous manifestations, pan-uveitis, non-deforming arthritis, thrombosis, central nervous system (CNS) and gastrointestinal (GI) involvement [1]. Despite being increasingly recognized as part of the clinical spectrum in BS [2,3,4], cardiac involvement has not been systematically described.

Objectives: To investigate the prevalence and clinical spectrum of cardiac manifestation in a cohort of BS patients.

Methods: Three hundred and twelve patients were retrospectively studied. All patients fulfilled the International Classification Criteria for BS [5]. Demographic, clinical, therapeutic features, and specific data on cardiac involvement were collected.

Results: Cardiac involvement was observed in 46 out of 312 patients (13.2%). The mean age at cardiac involvement diagnosis was 43 years (SD ± 13.2). Mean BS duration before cardiac manifestation onset was 5.35 years (SD ± 6.86). Female to male ratio was 1.42. Among 46 patients with cardiac involvement, 37 (80.4%) displayed a single manifestation, while 9 (19.5%) showed two or more cardiac events. BS related cardiac lesions included arrhythmias (n=12; 26%), pericarditis (n=12; 26%), ischemic heart disease (n=7; 15%), acute myocarditis (n=5; 10.8%), valvular abnormalities (n=6; 13.3%), and pulmonary hypertension (n=2; 4.3%) (Figure 1). Thirteen patients (28.2%) had cardiac abnormalities classified as “other”, which included patent foramen ovale, Takotsubo syndrome, cardiac amyloidosis, and aortic root aneurysm (Figure 1). After the first event, remission of cardiac manifestations was achieved by all patients. Cardiac relapse occurred in 9 patients (19.5%), due to recurrent pericarditis (n=7), myocarditis (n=1), and arrhythmic manifestation (n=1). Overall clinical manifestations of BS are shown in Table 1. Muco-cutaneous manifestations were present in almost all patients, specifically oral aphthosis was present in 45/46 (98%), genital aphthosis in 26/46 (56.5), and skin manifestations in 35/46 (76%). A significant proportion of patients displayed vascular involvement (n=20; 43.4%), CNS involvement (n=20; 43.4%), and GI involvement (n=32; 69.5%). At the time of cardiac events 21/46 (45.6%) patients were receiving oral corticosteroids, 16/46 (34.7%) were receiving colchicine, 13/46 (28.2%) were receiving a traditional DMARD, while 19/46 (41.3%) were receiving a biologic DMARD (Table 1).

Conclusion: Our study indicates that cardiac events are a fairly common manifestation in BS patients, pointing out the need for a routine screening of such involvement. As previously described [2], our study suggests the association between cardiac abnormalities and vascular involvement in BS. Furthermore, we found a significant proportion of patients presenting with other major organ manifestations, such as CNS and GI involvement, suggesting that cardiac involvement may reflect a more severe and systemic disease course.

AB0799 ASSOCIATION BETWEEN MUSCLE QUALITY AND MORTALITY IN PATIENTS WITH ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Keywords: Vasculitis

J. W. Ha1, S. S. Ahn1, Y. Park2, S. Lee2. Yonsei Severance Hospital, Yonsei University College of Medicine, Internal Medicine, Yonsei, Korea, Rep. of (South Korea); 2Yonsei University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Decreased muscle mass is frequently observed in patients with autoimmune rheumatic diseases; however, the relationship between muscle quality and patient outcomes has not been well understood.

Objectives: This study evaluated the influence of muscle quality on the outcomes of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV).

Methods: Records of patients with AAV (microscopic polyangiitis, granulomatosis with polyangiitis, and eosinophilic granulomatosis with polyangiitis) at the Severance Hospital having computed tomography (CT) images at disease diagnosis were retrospectively reviewed. For muscle quality measures, normal attenuation muscle area (NAMA), low attenuation muscle area (LAMA), and intramuscular adipose tissue (IMAT) in the axial muscles of the middle third lumbar vertebra level was calculated. Correlations between NAMA, LAMA, and IMAT and patient characteristics and outcomes were assessed.

Figure 1. Spectrum of cardiac lesions in a monocentric cohort of BS patients

Table 1. Demographic and clinical features of BS patients with cardiac involvement
Results: A total of 136 patients with CT images at AAV diagnosis were identified. Correlation analyses revealed that age, female sex, total cholesterol, and alanine aminotransferase were significantly associated with NAMA. LAMA was associated with age, body mass index (BMI), five-factor score (FFS), and C-reactive protein, while a relationship between IMAT and age and BMI was observed. Co-proportional hazard analysis demonstrated that NAMA/TAMA > 0.46 (odds ratio [OR] 5.612, 95% confidence interval [CI] 1.758-17.909, p = 0.004), female sex (OR 0.228, 95% CI 0.075, 0.684, p = 0.008), dyslipidemia (OR 3.819, 95% CI 1.380, 10.571, p = 0.010), and FFS (OR 2.160, 12.983-3.595, p = 0.003) were independent factors associated with mortality. Conclusion: Higher mortality was observed in patients with AAV with NAMA/TAMA ≤ 0.46, indicating that cautious monitoring is required in these patients.

EOSINOPHILIC GRANULOMATOSIS WITH POLYANGITIS: CLINICAL MANIFESTATIONS AND OUTCOMES: A RETROSPECTIVE COHORT ANALYSIS OF 38 PATIENTS FROM RUSH UNIVERSITY MEDICAL CENTER CHICAGO, IL, USA

Keywords: Prognostic factors, Organ damage, Vasculitis

M. Orentas1, Y. Zhang2, J. Fair1, A. Bukiej1. 1RUSH University Medical Center, Rheumatology, Chicago, United States of America; 2RUSH University Medical Center, Biostatistics, Chicago, United States of America

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is the rarest anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis according to incidence and prevalence reports in the literature [1]. Typical manifestations include obstructive airway disease, nasal polyps, mononeuritis multiplex, eosinophilia, and eosinophilic-predominant inflammation on biopsy [2]. Studies have been published that describe the clinical manifestations and disease outcomes but these are limited [3]. Further studies are necessary to better understand this disease.

Objectives: This study characterized the clinical manifestations and outcomes of a cohort of Rush University Medical Center (RUMC) patients with EGPA.

Methods: Retrospective cohort analysis of EGPA patients at RUMC from 1/1/2010-12/31/2021. Clinical characteristics, treatment, and outcome were analyzed, using Fisher’s Exact Test and Chi-Square Test to perform comparisons.

Results: This cohort included 38 patients with EGPA. 55% were female, 68% were Caucasian, and mean age at diagnosis was 57.7 (+/- 16.3). 95% had pulmonary involvement. 37% were (ANCA) positive. There was no statistically significant difference in clinical characteristics, treatment strategies, or outcomes when comparing ANCA positive to ANCA negative patients.

Conclusion: This analysis describes the clinical characteristics, treatment, and outcomes of a cohort of RUMC patients with EGPA. Prevalence of pulmonary involvement and ANCA positivity was similar to that reported in the literature. Unlike previous studies which reported higher prevalence of neurologic and kidney involvement in ANCA positive EGPA patients our study did not find a statistically significant difference in characteristics of ANCA positive patients when compared to ANCA negative patients.

NEW DIAGNOSTIC TOOL IN BEHÇET’S DISEASE

Keywords: Behcet’s disease

C. Soliz1, J. Bragiant1, J. Reba2, L. L. Holguin Arias1, S. Sorrentino2, G. Gómez2, A. Hamau2, D. Dubinsky2, S. Sanatório Guemes, Rheumatology, Buenos Aires, Argentina; S. Sanatório Guemes, Rheumatology, Buenos Aires, Argentina

Background: Behcet’s disease (BD) is characterized by oral, genital, and gastrointestinal manifestations. The pathergy test is used as a diagnostic tool, but this is not specific to BD, since it can be found in other diseases and can equally be negative even having the disease. Another characteristic of BD is the vascular compromise, predominantly venous. In a study, the measurement of the thickness of the common femoral vein (CFV) proved to be a diagnostic test with sensitivity and specificity greater than 80% for the cut-off value of 0.5 mm.

Objectives: To evaluate the diagnostic performance of the thickness of the posterior wall of the common femoral vein, measured by Doppler ultrasound for the diagnosis of Behcet’s disease.

Methods: A multicenter pilot study was carried out to evaluate a diagnostic test. Data were collected by reviewing medical records collected from patients who met the 2014 International Criteria for Behcet’s Disease (ICBD), and healthy controls. Venous Doppler ultrasound of the lower limbs was performed in both groups using an ultrasound evaluation protocol, considering posterior wall thickness of the CFV > 0.5 mm as positive.

Results: 19 patients with EB and 19 healthy controls were included. The mean age of patients with DB was 47 (SD 12.6), and the median age of healthy patients was 41 years (IQR 36.5-48.5). 57.89% were mestizo in the BD group and 68.42% in the control group. The median delay in diagnosis was 19 months (IQR 11-36). The presence of HLA B51 was 63.15% and the positive pathergy test was found in 31.57%. At the time of the study, 42.10% had disease activity and a mean of 8.8 years of disease. The ultrasound was positive in 89.4% of patients with BD and 10.5% in the healthy group, observing a sensitivity of 94.1% and a specificity of 94.7%, with an area under the curve 0.89 (p < 0.0001), PPV 94.1% and NPV 94.7%. (Fig. 1) We observe a post-test probability of 0.059. The test presents LR + 17.8 (95%CI 2.5-127) and LR - 0.06 (95%CI 0.008-0.4)

Conclusion: The diagnosis of Behcet’s disease is difficult because it is based mainly on clinical manifestations, so this ultrasound test has a good capacity to be used as part of the diagnosis in patients with clinical suspicion, since it has a good sensitivity and specificity profile, low cost and simplicity.

**Background:** Eosinophilic granulomatosis with polyangiitis (EGPA) is included in anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV). It mainly affects patients with asthma, sinusitis, allergic rhinitis, and nasal polyposis. **Objectives:** To assess a) prevalence of clinical features of EGPA in patients with clinical history of nasal polyps and asthma, and b) proportion of positive ANCA (+ANCA) test in those patients.

**Methods:** Retrospective study of patients with clinical history of asthma and nasal polyps with histologic study from a referral center between 2021 and 2022. The measurement of ANCA were performed by chemiluminescence assay using IO-FLASH (Inova, San Diego, CA). Diagnosis of EGPA was based on ACR/EULAR 2022 criteria. Disease activity was assessed with Birmingham Vasculitis Activity Score (BVAS). All biopsies of nasal polyps were examined by the same expert pathologist to assess the presence of eosinophil aggregates. **Results:** A total of 123 biopsies with eosinophil aggregates were studied between 2021 and 2022. Twenty-three patients (19%) had history of asthma. Of them, we objectified EGPA criteria in 12 patients (10% of the series of 123 patients). General features of these 12 patients are summarized in Table. Seven patients had more than 20 eosinophil aggregates per field in polyp biopsy. The median [IQR]
Results: Renal disease was observed in 82 of 132 (62.1%) AAV (38 men/44 women), median age 61.37 years (24-87 years). Table reflects the main clinical findings and outcomes. Renal biopsy was performed in 44 patients (36 patients showing a pauci-immune crescentic glomerulonephritis). The remaining 38 patients were not biopsied due to patient disagreement, mild renal disease or contraindication for biopsy. The most frequent ANCA antibody specificity was MPO (64.6%) followed by PR3 (28.8%) and double positivity in 3 patients (2 MPO and PR3 and 1 MPO and MBG). 43 patients were classified as MPA (52.4%), of those, 18 patients (21.9%) had renal limited vasculitis, 27 GPA (32.9%), and 4 EGPA (4.9%). The rest of the patients had other renal disease (5 microhematuria, 1 amyloidosis, 1 diabetes nephropathy and 1 nephroangiosclerosis). Nephritic syndrome was the most common renal manifestation when the vasculitis was fully established (56.1%). The most frequent therapies used were corticosteroids (68.3%), Cyclophosphamide (46.3%), Azathioprine (35.4%), Rituximab (34.1%) and mycophenolate mofetil (23.2%). After a median follow-up of 6.23 years (7 days-22.9 years) the last median creatinine and glomerular filtration rate (GFR) was 1.4 mg/dl and 43.3 ml/min, respectively. Renal function worsened compared to baseline in 78.3% of MPO positive and only in 33% of PR3 positive (p=0.005). During the first 12 months follow-up, stabilization or normalization GFR (median GFR at 1 year: 50 ml/min) was observed in 47.1% with no statistical differences among ANCA groups (p=0.303). Renal outcome at the end of follow-up was poorer in MPA than GPA or EGPA (76.3%, 47.4% and 50% respectively worsened GFR from baseline). 16 patients (19.5%) needed dialysis at any moment. Total remission was achieved in 25 patients (30.5%) while relapses were observed in 17 patients (20.7%). Severe infections was the main severe side-effect, reported in 26 patients (31.7%).

Conclusion: Most AAV patients had some grade of renal disease during follow-up and almost 20% ended up needing dialysis. Therefore this multi-systemic disease should be managed in a multidisciplinary way to establish an early diagnosis and adequate treatment, limiting chronic disease.

Cutoio5, Ghent University Hospital, Department of Rheumatology, Ghent, Belgium; 2Ghent University Hospital, Department of Internal Medicine, Ghent, Belgium; 3Vlaams Instituut voor Biotechnologie (VIB), Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium; 4Ghent University, Biostatistics Unit, Department of Public Health and Primary Care, Ghent, Belgium; 5University of Genova, IRCCS San Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, Genova, Italy

**Background:** Description of flow, measured by laser speckle contrast analysis (LASCA), in 'early' systemic sclerosis (SSc) versus clinically overt SSc (diffuse cutaneous SSc (dCSSc) and limited cutaneous SSc (lcCSSc)) has not yet been described.

**Objectives:** To investigate in an unselected, SSc cohort if baseline LASCA PBV-measurements differ between 'early' SSc and 'clinically overt' SSc.

**Methods:** Between September 2019 and December 2022, patients with SSc (as defined by the 2013 ACR/EULAR criteria and/or the 2001 LeRoy and Medsger criteria) were included [1,2]. A group of 20 consecutive 'early' SSc, lcCSSc and dCSSc patients were recruited. Vasoactive medication was continued. LASCA was performed at baseline in standardized instrumental and environmental conditions [3]. PBV was assessed by marking regions of interest (ROI's) with fixed 1 cm diameters at the fingertips of the 2nd through 5th digit volarly bilaterally. The adjusted mean PBV was calculated (expressed in perfusion units [PU]). A linear mixed model was fit with a random intercept per patient, together with a linear covariance structure to capture the residual correlations between fingers. Fixed effect terms included subset, side, finger, vasoactive medication, active smoking, history or presence of digital trophic lesions (DTL), and disease duration. Significance level was set at 0.05 and no correction for multiple testing was applied.

**Results:** Sixty patients with SSc (75% female, mean age 53 years, mean disease duration 73.1 months) were enrolled (table 1). Comparing the adjusted mean PBV at baseline in 'early' versus 'clinically overt' SSc, no statistical significant difference was found (144 ± 150 PU, p=0.77) (figure 1A). Additionally within the 'clinically overt' group no significant difference was perceived between dCSSc and lcCSSc (157 vs. 141 p=0.53). A wide variability was noted when observing the individual measurements of each subset (figure 1B).

**Conclusion:** This study with an unselected day-to-day SSc population, where patients were allowed to continue their vasoactive medication, showed there was no difference in PBV at baseline between 'early' SSc and 'clinically overt' SSc when corrected for subset, vasoactive medication, active smoking, history or presence of DTL and disease duration. Interestingly a wide variation of individual datapoints was noted in each subset, which emphasizes the heterogeneity of SSc. In conclusion, individual and subset variation between the different subsets, as measured with LASCA. Future investigation is needed to enlighten us about the intra-individual changes over time.

**THE LONG-TERM COURSE OF THE HEALTH ASSESSMENT QUESTIONNAIRE IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**Keywords:** Systemic sclerosis, Patient reported outcomes

S. Liem1, S. A. Bergstra1, J. Cialli2, C. Van der Meulen1, D. Ueckert1, R. Schreiner1, T. Huizinga1, T. M. Vliet Vlieland1, J. De Vries-Bo{returnいただきました}{ achiever}rastra1, 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Rizzoli Orthopedic Institute, Rheumatology Unit, Department of Medicine, Bologna, Italy; 3Leiden University Medical Center (LUMC), Physical Therapy, Leiden, Netherlands; 4NVLE, NVLE, Utrecht, Netherlands; 5Leiden University Medical Center (LUMC), Orthopedics, Physical Therapy and Rehabilitation Medicine, Leiden, Netherlands

**Background:** Functional disability in patients with systemic sclerosis (SSc) greatly influences quality of life. The Health Assessment Questionnaire-Disability Index (HAQ-DI) is an important outcome reflecting functional disability, but knowledge on its course over time in SSc is scarce.

**Objectives:** To describe the long-term course of functional disability in SSc patients, most importantly to investigate which patients have a worsening functional ability, and investigate its associations with disease characteristics.

**Methods:** SSc patients, fulfilling the ACR/EULAR 2013 criteria, were included from the Leiden CCISS cohort with annual assessments including the Scleroderma HAQ. The Scleroderma HAQ consists of the HAQ-DI (range: 0 [no difficulties] to 3 [maximum difficulties]) and five SSc-related VAS scores: Raynaud’s Phenomenon, digital ulcers, gastrointestinal, pulmonary and general disease burden (range: 0 to 100). The HAQ-DI course was evaluated over the total follow-up (baseline to last available HAQ-DI) and between yearly visits. Based on a minimal clinical important difference of 0.22, patients were categorized into stable, or improving. Baseline SSc characteristics were compared between patients with a worsening or improvement of the HAQ-DI using logistic regression. The change of the HAQ-DI and the SSc-related VAS scores over time was evaluated with linear mixed models.

**Results:** 517 SSc-patients were included (Table 1). The median follow-up duration was 7 years (IQR:4; 9). The mean baseline HAQ was 0.77 (SD:0.65). On group level, the HAQ-DI increased sexually with 0.019 (95% CI:0.011; 0.027). Patients ≥65 years (0.27%, 95% CI: 0.1; 0.4) and patients who died were physically not able to come during follow-up (0.34, 95% CI: 0.2; 0.5) had a significantly higher HAQ-DI over time than respectively patients younger than 65 years old and patients who did not die (Figure 1). Between baseline and the last follow-up, the proportions of patients with a worsening, stable or improved HAQ-DI were 35%, 42% and 23%, respectively. Logistic regressions, adjusted for age, sex and disease duration, revealed that, at baseline, the use of immunosuppressive medication (OR: 0.5, 95% CI: 0.3; 0.9) and gastrointestinal involvement (OR: 0.6, 95% CI: 0.4; 0.9) decreased the chance of a worsening overall HAQ-DI course, whereas presence of anti-centromere autoantibodies (OR: 1.4, 95% CI: 0.8; 2.3) and pulmonary arterial hypertension (OR: 2.3, 95% CI: 0.3; 20.8) increased this. For all the VAS scores, the p of the longitudinal course for the total group was stable. Over time, most importantly, patients who died/were physically not able to come during follow-up had a 18.8 point higher pulmonary VAS (95% CI: 12.9; 24.8) and a 13.3 higher general burden of SSc VAS (95% CI: 6.5; 20.2) compared to patients who survived.

**Conclusion:** Over time, the average course of the HAQ-DI is stable in SSc-patients, but individual trajectories vary, with worsening occurring in one third. Importantly, use of immunosuppressives decreased the chance of worsening while presence of anti-centromere antibodies increases the chance of worsening.

PATIENT-REPORTED OUTCOMES ABOUT QUALITY OF LIFE IN PATIENTS WITH IDIOPATHIC INFLAMMATION MYOPATHY

Keywords: Quality of life, Patient reported outcomes, Work-related issues

Z. Peng1, Y. Wang2, N. Liu3, S. Zhou1, J. L. Zhao1, D. Xu1, M. Li1, C. Wu1, X. Zeng1, Q. Wang1, Z. Peng1, Y. Wang2, N. Liu3, S. Zhou1, J. L. Zhao1, D. Xu1, M. Li1, C. Wu1, X. Zeng1, Q. Wang1,1 Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing, 1 Institute of Basic Medical Sciences Chinese Academy of Medical Sciences & School of Basic Medicine Peking Union Medical College, Department of Epidemiology and Biostatistics, Beijing, China; 2 The University of Hong Kong-Shenzhen Hospital, Division of Rheumatology, Department of Medicine, Shenzhen, China

Background: Idiopathic inflammation myopathy (IIM) defines a group of chronic autoimmune-mediated diseases that most commonly affect the skin, muscles, and lungs [1]. Despite considerable advances over the past decades in improving life expectancy compared with the general population, IIM patients still experience substantially impaired health-related quality of life (HRQoL) [2].

The value of incorporating patient-reported outcomes in clinical trials is increasingly appreciated. The 36-item Short-Form Health Status Survey (SF-36) has been proposed to evaluate HR-QoL in IIM patients. However, because it is very time-consuming, the actual completion rate of the questionnaire is extremely low, and the SF-36 cannot be used directly in cost-effectiveness analyses. The EuroQol 5-Dimension (EQ-5D) is another tool for assessing HR-QoL and has been used extensively for chronic diseases. Wolfe et al. [3] verified the association between EQ-5D and SF-36 in rheumatic diseases. Moreover, workforce losses in patients with IIM are underestimated, and even health-related absenteeism imposes an economic burden on society [4].

Objectives: To explore the feasibility and validity of the EuroQol 5-dimension (EQ-5D) and Work Productivity and Activity Impairment (WPAI) surveys as patient-reported outcomes of health-related quality of life (HRQoL) in idiopathic inflammatory myopathy (IIM). Methods: This cross-sectional study surveyed patient’s outcomes using the Manual Muscle Testing-8 (MMT-8), Myositis Disease Activity Assessment Visual Analog Scale (MYOACT), Myositis Damage Index (MDI), Disease Activity Score (DAS), and Physician/Patient Global Assessment (PGA/PtGA). HR-QoL was determined using EQ-5D, 36-item Short-Form Health Status Survey (SF-36), and WPAI questionnaire. The relationship between IIM-related parameters and HR-QoL was assessed using ordinal logistic and quantile regression.

Results: We enrolled 189 patients with IIM. Decreased MMT-8 and increased MYOACT, DAS, MDI-global, and PGA/PtGA were associated with higher EQ-5D values. For the 25 th– 75 th percentile of WPAI, greater activity impairment was associated with lower MMT-8 and higher age of onset and PGA. Poorer overall working productivity impairment was associated with higher MYOACT (cutaneous and skeletal), MDI-global and PtGA were associated with increased activity and overall working productivity impairment in most quantiles (P < 0.05).

Conclusion: The EQ-5D and WPAI may be valid patient-reported outcomes to evaluate HR-QoL in ambulatory patients with IIM.

A PROOF OF BIOLOGICAL CONCEPT TRIAL OF CM101 TO TARGET CCL24 IN SYSTEMIC SCLEROSIS: A BIOMARKER INFORMED, PRECISION MEDICINE APPROACH

Keywords: Systemic sclerosis, Biomarkers, Clinical Trials

F. Del Galdo1, D. Khanna2, C. Crater3, R. Aricha4, J. Lawler3, A. Mor4, I. Vaknin4, M. Frankel5, M. Matsuoki-Cerinich6,7. University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2 University of Michigan, Rheumatology, Ann Arbor; United States of America; 3 Chemomab Therapeutics, Ltd, Clinical Development, Tel Aviv, Israel; 4 Chemomab Therapeutics, Ltd, R&D, Tel Aviv, Israel; 5 University of Florence, Rheumatology, Florence, Italy; 6 IRCCS Ospedale San Raffaele, Rheumatology, Milan, Italy

Background: Systemic sclerosis (SSc) is an inflammatory and fibrosing autoimmune disease of unknown etiology. However, it has been established that endothelial cells, immune cells, and fibroblasts play important roles in SSc initiation and progression. CCL24 (eotaxin-2) is a chemokine secreted by fibroblasts and endothelial cells, which promotes trafficking of profibrotic immune cells through the CCR3 receptor. Levels of CCL24 and CCR3 in the skin and serum of patients with SSc were found to be upregulated compared with healthy controls [1].

Serum CCL24 levels have been shown to correlate with extracellular matrix turnover biomarkers, to predict decline in forced vital capacity (FVC) and the diffusion capacity of the lungs for carbon monoxide (DLCO), and to be associated with a worse digital ulcer burden in patients with SSc [1]. Blockade of CCL24 with fusion capacity of the lungs for carbon monoxide (DLCO), and to be associated with higher MYOACT (cutaneous and skeletal), MDI-global and PtGA were associated with increased activity and overall working productivity impairment in most quantiles (P < 0.05).

Conclusion: The EQ-5D and WPAI may be valid patient-reported outcomes to evaluate HR-QoL in ambulatory patients with IIM.

Background: Anti-synthetase syndrome (ASS) is an inflammatory myositis with autoantibodies against one of the aminoacyl transfer RNA synthetase. Interstitial lung disease (ILD) is a main clinical feature which dictates the prognosis and treatment. Since there are no randomized controlled trials to guide therapy, treatment strategies are extrapolated from other connective tissue diseases-related ILD (CTD-ILD), mainly systemic sclerosis (SSc).

Objectives: Our aim was to evaluate the effect of immunosuppressive treatment (IS) on ASS-related ILD, compared with SSc-related ILD.

Methods: A multicenter observational registry, including 45 patients with CTD-ILD (ASS (n=18) and SSc (n=27)) from 3 medical centers in Israel, between 2017-2021. During follow up, 12 patients did not receive any IS, while 17 patients started IS treatment shortly after the 1st visit and 16 after a period of follow up. We compared the monthly change in diffusion capacity for carbon monoxide (DLCO) and forced vital capacity (FVC) percent predicted between ASS and SSc. Further analysis included a comparison between non-IS and IS treated patients, Mann-Whitney test was used to compare medians, with a p value of <0.05 considered significant.

Results: The mean±SD age was 62.9±10 and 36% were females. ILD as the presenting disease feature was more common in ASS, compared with SSc (61% vs. 11%, p<0.001). DLCO% was lower at baseline among ASS patients (44±13 vs. 57±14, p=0.004), while other lung function measures were not significantly different (table 1). Overall, 32 patients (71%) received an IS therapy. As expected, glucocorticoid treatment was more prevalent in the ASS group (n=14) compared to the SSc group (n=8) (78% vs. 30%, p=0.002). The most prevalent non-steroidal IS was mycophenolate mofetil (MMF) (96%). Two ASS and one SSc received azathioprine. There was a trend towards a lower rate of decline (-0.17 vs. -0.29, p=0.853) (figure 1). When comparing CTD-ILD treated with IS, with non-treated patients among patients with ASS, IS was associated with a monthly increase in DLCO% (0.3 vs. -0.27 without IS, p=0.001), and in SSc – a lower rate of decline (-0.17 vs. -0.29, p=0.041); However, the positive change of FVC% in both ASS (0.12 vs. 0.32, p=0.217) and SSc (-0.38 vs. 0, p=0.79) patients was not statistically significant.

Conclusion: Immunosuppressive therapy, and specifically MMF, was associated with an improvement in DLCO% in patients with ASS and lower rate of decline in SSC. ILD in the context of ASS may respond better to immunosuppressive treatment compared to ILD in SSC. These encouraging results need to be validated in larger scaled randomized prospective studies to assess the role of MMF in ILD related to ASS.

AB0810 PERFORMANCE OF CIRCULATING BIOMARKERS FOR PREDICTING PROGRESSION OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Biomarkers

K. Yomonono1, M. Kuswana1, Nippon Medical School; Department of Allergy and Rheumatology, Tokyo, Japan

Background: In patients with systemic sclerosis (SSc), progression of interstitial lung disease (ILD) is associated with an increased risk of mortality. Since the course of SSc-ILD is variable, it is critical to predict progression of ILD in clinical practice as well as in designing clinical trials. Risk factors for ILD progression include, but are not limited to, smoking, male, elevated inflammatory markers and Krebs von den Lungen-6 (KL-6), and progression of skin thickness in diffuse cutaneous SSc (dcSSc).

Objectives: To investigate if inflammatory markers and KL-6 at baseline are useful to efficiently capture patients who subsequently experience ILD progression in patients with dcSSc or SSc-ILD using a single-center cohort.

Methods: Patients with dcSSc or SSc-ILD were selected from the prospective SSC registry. C-reactive protein (CRP) ≥5 mg/L and erythrocyte sedimentation rate (ESR) ≥28 mm/hour were used as inflammatory markers [1], and a cutoff level of KL-6 was provisionally set at 1,000 U/ml. ILD progression was defined as the first event developing progressive fibrosing ILD (PF-ILD) [2] or progressive pulmonary fibrosis (PPF) [3]. Receiver operating characteristic curve (ROC) analysis was used to determine the sensitivity, specificity, and area under the curve (AUC) values of individual biomarkers and their combinations for predicting ILD progression. Cumulative rates free from ILD progression were assessed using Kaplan-Meier analysis and were compared using log-rank test.

Results: We enrolled 109 patients with dcSSc and 136 patients with SSc-ILD. The median disease duration at baseline was 15 and 17.5 months for dcSSc and SSc-ILD, respectively, and 87 patients with SSc-ILD (64%) had dcSSc. During median of 27 months of follow-up of dcSSc patients, 27 (25%) and 22 (20%) developed PF-ILD and PPF, respectively; and during median of 44.5 months of follow-up of SSc-ILD patients, 43 (31%) and 36 (26%) developed PF-ILD and PPF, respectively. As shown in Table, specificity of CRP, ESR and KL-6 for predicting ILD progression was favorable (73.6-88%), but sensitivity of CRP and ESR was low (9.1-16%). KL-6 provided better sensitivity (29.2-45.2%). The combination of CRP/KL-6 showed the AUC value of 0.57-0.60, with sensitivity of 38.1-52.4% and specificity of 69.1-77.6%. Kaplan-Meier analysis found that ILD progression occurred more frequently in patients with increased KL-6 than in those without irrespective of definition of ILD progression (P = 0.0001-0.03). The same trend was observed when combination of CRP/KL-6 was used (P = 0.001-0.14).

Conclusion: Increased KL-6 at baseline is the best biomarker for predicting ILD progression in patients with dcSSc or SSc-ILD. When KL-6 was combined with CRP, sensitivity was increased by maintaining acceptable specificity, proposing use of this combination as inclusion criteria for enriching an “at risk” patients in clinical trials for dcSSc or SSc-ILD.

AB0811 NAILFOLD CAPILLAROSCOPY FINDINGS IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES AND ITS ASSOCIATION TO AUTOANTIBODIES: A CASE-CONTROL STUDY

Keywords: Biomarkers, Autoantibodies, Myositis

C. Seire Santos1, J. L. Tandaapán2, A. Mariscal1, S. Lainz Cornas3, H. Codes4, P. Moya5, B. Magallarres1, L. Martinez-Martínez1, A. M. Millán Arciniegas6, H. Park1, C. Díaz-Torné1, A. Laiz3, S. P. Fernandez-Sanchez3, S. Ros1, H. Corominas2, E. Diez Alvarez1, I. Castellvi7, 1Complejo Asistencial Universitario de León, Rheumatology, León, Spain; 2Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 3Hospital Universitari de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of acquired muscle diseases, which have distinct clinical, pathological, and histological features. Autoantibodies are clinically useful biomarkers to help the diagnosis of IIM. Raynaud’s phenomenon is very frequent and the presence of microvascular changes in IIM have been described however, the role of nailfold videocapillaroscopy (NVC) for diagnosis and prognosis in IIM is not clearly established.

Objectives: The aim of this study was to study the relationship between clinical and immunological characteristics and nailfold videocapillaroscopy (NVC) abnormalities in patients with idiopathic inflammatory myopathies (IIMs).

Methods: We performed a retrospective study of IIM patients followed in a University Hospital. Patients underwent a NVC at 200x magnification. Epidemiological, clinical data and antibody status, including myositis and scleroderma antibody panel of all patients were retrieved. NVC findings including loss of capillary density, enlarged and giant capillaries, ramified capillaries, haemorrhages, thrombosis, avascular areas, disorganization of capillary architecture and sub-papillary venous plexus presence were recollected, if present. For the comparison of qualitative and/or quantitative variables Fisher’s exact Test or T-test was performed when necessary.

Results: 85 patients with NVC performed during the follow-up were included (66% female) with a median age at inclusion of 55.3±24 years. Median IIM duration was 6.8±7 years. 39% had Raynaud’s phenomenon at first clinical evaluation and 58% of them showed NVC pathological findings. Table 1 summarizes the epidemiological, clinical, and autoantibody status of the patients. We found an association between the presence of dysphagia and avascular areas (p=0.02) or abnormal capillary organization (p<0.01) on NVC. IIM was associated with capillary loss (p=0.04) and avascular areas (p=0.004). Anti-MDA5+ was associated with capillary loss (p=0.03), thrombosis (p=0.02) and ramified capillaries (p=0.04). Anti-Mi2+ and anti-Th/To was associated with abnormal capillary organization (p=0.017 and p=0.001). The presence of haemorrhages was associated with anti-Ku+ (p=0.048) and anti-PL12+ (p=0.046). The presence of enlarged capillaries was associated with anti-RNA-poly III (p=0.04) and anti-NXP2 (p=0.044). A significant association between anti-Ro52 (OR 2.69 CI95% 1.05-6.8, p=0.03) and anti-Jo1 (OR 7.03 CI 95% 1.46-33.7, p=0.01) with ILD was found. Anti-PML (OR 4.32 CI 95% 1.35-10.42, p=0.038) and anti-Th/To (OR 5.82 CI 95% 1.89-13.24, p=0.04) were associated with dysphagia. Anti-MDA5+ (OR 5.85 CI 95% 1.92-14.21, p=0.044) was associated with skin involvement.

Conclusion: The presence of certain autoantibodies is related to the degree of microangiopathy in IIM and associates with capillaroscopic changes. Studying the association between capillaroscopic changes with diagnostic and pathogenic autoantibodies in IIM can provide useful information regarding the current knowledge about pathogenesis, classification, and prognosis of the disease.
Background: Gastrointestinal tract (GIT) is the second most common organ involved in Systemic Sclerosis (SSc) after the skin, and is responsible for alterations of quality of life and SSc-related mortality.

Objectives: Since early development of organ failure is associated with poor outcomes, we need to identify risk factors associated with severe GIT involvement to prevent appearance of severe form of the disease.

Methods: We conducted an observational prospective and monocentric study which included 90 patients followed for SSc, from 26 December 2019 to 14 September 2021.

Results: We included 90 patients in this study, with 76 female sex (84.4 %) and a median age of 55.7 years (IQR 44.3-64.4). 64 had a limited cutaneous SSc ( lcSSc) (71.1%) and 26 had a diffuse cutaneous SSc ( dcSSc) (28.9%). We observed 28 patients (31.1%) with malnutrition and 9 patients (10%) with at least one episode of digestive hemorrhage or small intestinal bacterial overgrowth or chronic intestinal pseudo-obstruction. The patients with malnutrition had less limited cutaneous SSc form (53.6 % vs 79 %, p = 0.027), more interstitial lung disease (57.1 % vs 27.4 %, p = 0.013) and more cardiac disease (39.3 % vs 11.3 %, p = 0.05). No patient without malnutrition died at the end of the follow-up whereas 4 patients with malnutrition died (p = 0.013). Clustering of individuals on the basis of the selected variables yielded a number of 3 clusters. Cluster 1, “Limited cutaneous systemic sclerosis” (n = 25) was only composed of lcSSc patients, presenting more frequently anti-centromeres antibodies (n = 22, 88 % vs n = 9, 34.6 %, p = 0.001) and n = 2, 6.1 %, p = 0.001 in cluster 1 and 2 respectively). They had less frequently intestinal (n = 11, 44 %) or anorectal involvement (n = 1, 4 %) than cluster 2 (n = 24, 88.9 % and n = 16, 59.3 %, p = 0.003 and p = 0.01, respectively). They also had a better diffusing capacity for carbon monoxide (median [IQR]: 78.50 [70.25, 84.00], p < 0.001). Cluster 2 “SSc with cardio-digestive involvement” (n = 27) was composed of 20 patients with lcSSc (74.1 %), less frequently than cluster 1 (n = 25, 100 %, p = 0.02) and tends to be more frequently than cluster 3 (n = 19, 50 %, p = 0.09). They had more frequently intestinal (n = 24, 88.9 %) or anorectal involvement (n = 16, 59.3 %). Regarding heart status, patients from cluster 2 had more frequently heart involvement (n = 12, 44.4 % vs n = 1, 4 %, p = 0.002 and n = 5, 13.2 %, p = 0.01 vs cluster 1 and 3 respectively) with higher BNP levels (median [IQR]: 91.0 [27.0, 244.5] vs 44.0 [20.0, 85.0], p = 0.03 and 27.0 [19.0, 42.0], p = 0.01 vs cluster 1 and 3 respectively). They also had more frequently statin (n = 1, 2.6 %, p = 0.01 in cluster 1 and 3 respectively) and more frequently pericardial effusion (n = 7, 26.9 % vs n = 0, 0.0 %, p < 0.01). Regarding treatment, they had more frequently aspirin (n = 7, 26.9 % vs n = 0, 0 %, p = 0.02 and n = 1, 2.6 %, p = 0.01 in cluster 1 and 3 respectively) and more frequently statin (n = 9, 34.6 % vs n = 1, 4 %, p = 0.02 and n = 1, 2.6 %, p = 0.01). Cluster 3 “SSc with cutaneous and pulmonary involvement” composed of 28 patients, including 10 patients (50 %) with diffuse cutaneous systemic sclerosis. They had higher modified Rodnan score (median [IQR]: 10.0 [8.0, 17.0] vs 3.0 [3.0, 6.0], p = 0.001) and 7.0 [3.0, 15.0], p = 0.04 in cluster 1 and 2 respectively). They had more interstitial lung disease according to the CT scan compared to cluster 1 (n = 24, 61.1 % vs n = 5, 20 %, p = 0.001) and tends to have more compared to cluster 2 (n = 24, 61.1 % vs n = 11, 40.7 %, p = 0.095). They also had more frequently immunosuppressive treatments than cluster 2 (n = 26, 68.4 % vs n = 10, 37 %, p = 0.02) but less frequently biotherapy (n = 3, 7.9 % vs n = 9, 34.6 %, p = 0.02)

Conclusion: This study reported the gastrointestinal manifestations in a cohort of 90 patients with SSc, with a predominance of gastro-esophageal involvement and in particular for the first time described a cluster analysis allowing classification of various clinical GIT phenotypes.

independent parametric or non-parametric tests, multivariate logistic regression of the significant variables in univariate analysis and sensitivity calculation of each radiographed site for the diagnosis of acro-osteolysis were performed.

Results: We included 165 patients, of whom 167 (85.6%) were female, with a median [min, max] age of 64 [20, 90] years-old and a median [min, max] disease duration of 11.2 [2, 57] years. Regarding disease classification, 146 (75.3%) patients had limited SSC, 32 (16.5%) had diffuse SSC, 9 (4.6%) had sine scleroderma SSC and 7 (3.6%) had early SSC. Acro-osteolysis was present in 62 (31.8%) patients, with the hands (n=49, 25.1%) being more frequently affected than the feet (n=22, 11.3%). The most sensitive location to detect acro-osteolysis was the hand (79.0%). The presence of overall acro-osteolysis was significantly associated with digital ulcers (p=0.001), flexion contractures (p=0.031), oesophageal (p=0.006), gastric (p=0.014) and lung (p=0.004) involvements, higher mRSS score (p=0.001), anti-topoisomerase I positivity (p=0.034) and radiological calcinosis (p=0.018). Patients with hand acro-osteolysis had longer disease duration (p=0.02) and were more often affected by digital ulcers (p=0.004) and flexion contractures (p=0.041), oesophageal (p=0.001), gastric (p=0.015) and lung (p=0.001) involvements, higher mRSS score (p=0.001), anti-topoisomerase I positivity (p=0.004) and radiological calcinosis (p=0.008). No significant differences were found between patients with and without feet acro-osteolysis. In multivariate analysis, anti-topoisomerase I positivity (OR 4.6, 95%CI 1.3-16.4, p=0.017) was predictor of hand acro-osteolysis.

Conclusion: The prevalence of acro-osteolysis found in Portuguese SSC patients is within the range found in the literature (20-40%) [1]. The hands were the most sensitive location to detect acro-osteolysis – a novel aspect since, to our knowledge, this is the first study evaluating acro-osteolysis in the feet besides the hands. Our data replicated some previously reported associations between acro-osteolysis and other hand involvements (digital ulcers, calcinosis and flexion contractures) and systemic complications (esophagogastric and pulmonary systems) [2-4]. Anti-topoisomerase I positivity appears to increase the risk for hand acro-osteolysis.

CLINICAL PHENOTYPE AND ANTIBODY CORRELATIONS USING IMMUNOPRECIPITATION IN INDIAN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES FROM THE MYOCITE COHORT

Keywords: Myositis, Epidemiology, Autoantibodies

A. Logananthan1,2, A. Rudge3, H. Lu2, E. Bowler2, F. McMorrow2, N. R. Ravichandran4, A. K. Anuja4, V. Agarwal4, L. Gupta4,5,6,7, N. Mchugh2, L. G. Gupta4,5,6,7, N. Mchugh2, L. G. Gupta4,5,6,7, N. Mchugh2, L. G. Gupta4,5,6,7, N. Mchugh2, L. G. Gupta4,5,6,7, N. Mchugh2

Background: There is a lack of epidemiological studies in idiopathic inflammatory myositis (IIM) to identify geographical and clinical disease variations between populations. Reviewing disease prevalence in different populations and clinical presentations may help improve our understanding of rare diseases.

Objectives: We reviewed the clinic-serological profile of 148 patients from a well-characterised MyoCite cohort of juvenile and adult patients with IIM from Lucknow, India, to determine significant clinical characteristics associated with different myositis-specific antibodies (MSA).

Methods: The MyoCite cohort is a retro-prospective dataset of adult and juvenile IIM patients (2017 ACR/EULAR criteria or diagnosed by two rheumatologists) enrolled in Lucknow, India, between 2017-2020. To characterise the well-characterised MSA detected, followed by MDA5 (9.5%) (figure 1), and 43.5% of patients were seronegative. Mechanic’s hands were associated with anti-Jo1 (OR 20.5 95%CI 5.77-77) and ARS antibodies (OR 11.9 95%CI 3.8-36.9). Heliotrope rash (OR 6.4 95%CI 1.5-26.7) and Gottron’s sign (OR 9.5 95%CI 1.2-20.9) were associated with anti-MDA5 (Table 1). ARS antibodies were negatively associated with weakness and heliotrope rash. NX2 was associated with dysphonia (OR 29.1 95%CI 3.5-243), while M2 was associated positively with a V-sign rash (OR 7 95%CI 1.4-34.7) and negatively with fever. SAE antibodies were associated with dysphagia (OR 9.3 95%CI 1.1-76.6). Seronegative IIM was associated with hyperpigmentation (OR 4.3 95%CI 1.6-11.7) and erythematous changes (OR 2.8 95%CI 1.2-6.5) and was negatively associated with arthritis and fatigue.

Conclusion: Autoantibodies are present in nearly two-thirds of Indian patients with IIM, commensurate with other populations (Figure 1), although the prevalence of individual MSA differs. The frequency of ILD is closer to those previously reported in European cohorts than in East Asian populations. Most MSAs exhibited association with prominent cutaneous manifestations, including mechanics hands, heliotrope rash, Gottron’s sign, V-sign, hyperpigmentation and erythematous changes. These differences in antibody profile and clinical characteristics from the MyoCite cohort compared to that of different geographical and ethnic populations previously reported suggest the potential influence of genetics and/or environmental factors.

TREATMENT OF A PATIENT WITH SEVERE DIFFUSE SYSTEMIC SCLEROSIS (SSc) USING CD19-TARGETING CAR-T-CELLS

Keywords: Systemic sclerosis, Autoantibodies

C. Bergmann1, F. Müller1, D. Jörg2, D. M. H. Györfi3, S. Völkl1, M. Aigner2, T. Harrer1, N. Bayer1, A. Atzinger2, J. Taubmann2, S. Boeltz1, J. Wacker1, M. Uder4, T. Kuwert5, M. Andreae6, G. Schett1, University Hospital Erlangen, Department Medicine II, Erlangen, Germany;1University Hospital Erlangen, Department Medicine V, Erlangen, Germany;4University Hospital Düsseldorf, Rheumatology, Düsseldorf, Germany;5University Hospital Erlangen, Radiology, Erlangen, Germany;6University Hospital Erlangen, Nuclear Medicine, Erlangen, Germany

Background: Several data suggest a role of B-cells in SSc-pathogenesis: disturbed B-cell homeostasis with expansion of naive and decrease of memory B-cells (1), increased levels of B-cell stimulating factors (2) and anti-fibrotic effects of B-cell-depletion in murine fibrosis models (3). Although first randomized controlled trials show promising effects of the CD20-targeting antibody rituximab (RTX) in SSc (4,5), the role of B-cell targeting treatments remains controversial. A possible explanation is the limited B-cell repertoire reported by CD20-depleting antibodies in the highly polar early B-cell precursors, which are particularly expanded in SSc, as well as plasmablasts responsible for autoantibody production. Hence, deeper and wider B-cell-depletion may be effective in SSc treatment. Recently, CD19-targeting CAR-T-cells, that are used to deeply deplete B-cells in refractory lymphoma and leukemia, showed remarkable effects in refractory systemic lupus erythematosus patients, suggesting the principle feasibility to interrupt autoimmune disease via CD19-targeting CAR-T-cells.

Objectives: To test the feasibility of treating severe SSc with CD19-targeting CAR-T-cells. Outcomes: B-cell -, absolute and relative CAR-T-cell counts, ANA-titer, SSc-specific antibodies, <sup>18</sup>Fa-FAPi-04-uptake, carpal MRI, EUSTAR activity index, mRSS, TJC, forced vital capacity (FVC), diffusion coefficient (DLCO).

Methods: This is a case study of compassionate use of CD19-targeting CAR-T-cells in a 40-year old old patient suffering from severe, diffuse SSc (year of diagnosis 2020). A non-Raynaud manifestation, mRSS 24 at baseline, with diffuse myofibroblastic lung fibrosis, Raynaud’s phenomenon and carpal arthritis who previously failed several standard therapies including methotrexate and mycophenolate. CAR-T-cell infusions were performed upon lymphodepletion with fludarabine (25 mg/m² on days -5, -4, -3) and cyclophosphamide (1g/m² on day -3) in August 2020 as single infusions. Immunosuppressive treatment was stopped before. Main outcomes were assessed before baseline and three months after CAR-T-cell infusion.

Results: CAR-T-cells expanded remarkably and fast in vivo from day 3 (0.3 cells/μl; 0.1% CARs of CD3+ T-cells) until day 9 (0.30.19 (1275/μl; 66.35% of CARs of CD3+ T-cells) and were measurable until day 51 after infusion. B-cells were completely depleted by day 7 and were not detectable until day 77. Serum IgG levels endured above 6000 mg/dl. CAR-T-cell therapy was well tolerated without signs of cytokine release syndrome or cell-associated neurotoxicity syndrome. ANA titers (before baseline: 1:320) and SSc-specific antibodies (anti-RNP III antibodies, antigen RP11) were no longer detectable three months after CAR-T-cell infusion. In parallel, myocaridal tracer uptake was reduced by 30% in <sup>18</sup>Ga-FAPi-04-PET-CT imaging, a novel imaging technique that allows the molecular assessment of fibroblast activation in vivo. The extent of lung fibrosis on CT scan and pulmonary function test parameters was stable or slightly improved. As analyzed by contrast supported high-resolution computed tomography (HRCT), one case diagnosed with both conditions. Most patients had Raynaud’s phenomenon (81%), with a median age at the onset of 60.5 years (Interquartile range, IQR, 48.71) and a median follow-up of 96 months (IQR 48-180). ANA were positive in 23 patients (88%), and the 2 most observed pattern were anticytometric (10; 38%) and nucleolar (9; 35%); 6 patients (23%) had cytoplasmic positivity of the ANA test. Six patients (23%) were concomitantly anti-La positive. Anti-Scl/70 were found in 2 cases (8%). Other systemic sclerosis associated antibodies were positive in 6 cases (23%); anti-RNA polymerase III antibodies, and anti-Ku antibodies, in 2 cases (8%), (anti-Th/To, and anti-Pm-Scl100 in one case (4%)). Patients had mainly limited cutaneous SSc subset (13; 50%), 5 had diffuse cutaneous SSc (19%), and the remaining 8 (31%) had no scleroderma. SSc was in overlap with other rheumatic diseases in the 50% of the cases. The overlap was with Rheumatoid arthritis (RA) in 4 cases (15%), and with Sjögren syndrome (SjS) in 10 cases (38%), with one case diagnosed with both conditions. Most patients had Raynaud’s phenomenon (RP) (24; 96%). The 2 patients without RP had puffy finger (PF), that were observed in 9 cases (35%). All patients performed nailfold capillaroscopy (NVC), showing scleroderma pattern in 22 cases (85%; early, 13, 50%; active 7, 27%; late 2, 8%), and ILD was observed in 12 patients (46%); the HRCT pattern was mainly NSIP (10, 83%), with a cellular phenotype in the 50% of cases. Only 2 patients (17%) had UIP pattern. Ten patients (38%) had an history of smoke, but only 3 had ILD. PAH was identified in 7 patients (27%), in 3 cases concomitantly to mild ILD. Four patients (15%) had myocarditis.

CLINICAL ASSOCIATION OF AUTO-RO52 ANTIBODIES IN SYSTEMIC SCLEROSIS: A SINGLE CENTRE COHORT PRELIMINARY ANALYSIS

Keywords: Autoantibodies, Systemic sclerosis

I. M. Bianchessi1, 2, C. Bochichio1, 2, A. Bartoletti1, 2, D. Giorgi1, 2, F. Cuzzocrea1, 2, M. Di Lemnia1, 2, B. Donotrio1, 2, G. Zanfrandomo1, 2, A. Biglia1, 2, C. Montesico2, 3, V. Codullo1, 2, L. Cavaglia1, 2, Universiti di Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy; 1RCCS Policlinico San Matteo Pavia, Division of Rheumatology, Pavia, Italy

Background: Anti-RO52 antibodies may be detected in several Rheumatic disorders, with different clinical significations. They may occur also in systemic sclerosis (SSc), but with clinical correlates not completely established, with some reports showing their association with pulmonary arterial hypertension (PAH), and other with interstitial lung disease (ILD).

Objectives: To evaluate the clinical characteristics of anti-Ro52 positive SSC patients

Methods: Patients aged more than 18 years, satisfying the 2017 ACR EULAR criteria for SSc referring to our SSc Unit and with at least one follow-up visit between October 2021 and October 2022 were evaluated for study participation. All patients positive for anti-Ro52 antibodies by ELISA were then included. Clinical characteristics were retrospectively collected and analysed. Pulmonary arterial hypertension (PAH) was defined by right heart catheterization, and ILD by chest high resolution computed tomography (HRCT).

Results: Between the 420 SSc patients assessed, we identified 76 patients (18%) positive for anti-Ro antibodies. Only 29 patients were characterized for anti-Ro52 antibody, and 26 were positive. These patients were in prevalence females (21; 81%), with a median age at the onset of 60.5 years (Interquartile range, IQR, 48-71) and a median follow-up of 96 months (IQR 48-180). ANA were positive in 23 patients (88%), and the 2 most observed pattern were anticytometric (10; 38%) and nucleolar (9; 35%); 6 patients (23%) had cytoplasmic positivity of the ANA test. Six patients (23%) were concomitantly anti-La positive. Anti-Scl/70 were found in 2 cases (8%). Other systemic sclerosis associated antibodies were positive in 6 cases (23%); anti-RNA polymerase III antibodies, and anti-Ku antibodies, in 2 cases (8%), (anti-Th/To, and anti-Pm-Scl100 in one case (4%)). Patients had mainly limited cutaneous SSc subset (13; 50%), 5 had diffuse cutaneous SSc (19%), and the remaining 8 (31%) had no scleroderma. SSc was in overlap with other rheumatic diseases in the 50% of the cases. The overlap was with Rheumatoid arthritis (RA) in 4 cases (15%), and with Sjögren syndrome (SjS) in 10 cases (38%), with one case diagnosed with both conditions. Most patients had Raynaud's phenomenon (RP) (24; 96%). The 2 patients without RP had puffy finger (PF), that were observed in 9 cases (35%). All patients performed nailfold capillaroscopy (NVC), showing scleroderma pattern in 22 cases (85%; early, 13, 50%; active 7, 27%; late 2, 8%). ILD was observed in 12 patients (46%); the HRCT pattern was mainly NSIP (10, 83%), with a cellular phenotype in the 50% of cases. Only 2 patients (17%) had UIP pattern. Ten patients (38%) had an history of smoke, but only 3 had ILD. PAH was identified in 7 patients (27%), in 3 cases concomitantly to mild ILD. Four patients (15%) had myocarditis.

SCLERODERMA RENAL CRISIS TREATMENT WITH C5 INHIBITOR ECULIZUMAB – A REVIEW OF LITERATURE

Keywords: bDMARD, Systemic sclerosis, Targeted synthetic drugs

L. Farnab1, H. H. Waqaar1, S. Mehta3, L. Shapiro3, A. Albany Medical Center, Internal Medicine, Albany, United States of America; 2A Albany Medical Center, Nephrology, Albany, United States of America; 3A Albany Medical Center, Rheumatology, Albany, United States of America

Background: Scleroderma renal crisis (SRC) occurs in about 10% of SSC patients and is characterized by abrupt onset of hypertension, thrombotic microangiopathy (TMA), and acute kidney injury. Although prognosis has improved with the use of angiotensin-converting enzyme inhibitors (ACE-i), 40% of SRC patients still require dialysis, and 20-25% die within 1 year. The pathogenesis of SRC remains poorly understood but a growing body of evidence suggests that activation of the complement system may be involved in the disease [1]. It is hypothesized that injury to the endothelium due to persistent stimulation by the complement system creates a pathological loop responsible for thrombotic microangiopathy and target organ injury. Several case reports have shown that Eculizumab (humanized recombinant immunoglobulin G2/monoclonal antibody directed against the complement component C5) is effective in treating patients with SRC who presented with symptoms of thrombotic microangiopathy [2,3].

Objectives: In this study, we aimed to characterize the presentation and outcome of patients with SRC who were treated with C5 inhibitor, Eculizumab.

Methods: A literature search was conducted on PubMed and Cochrane from inception to December 2022 using MeSH terms for ‘scleroderma’, ‘systemic sclerosis’ ‘scleroderma renal crisis,’ Eculizumab; and ‘Soliris’. We included case reports, case series, observational studies, and literature reviews. We included patients with treatment refractory SRC: who did not show improvement with ACE inhibitors or patients who had evidence of thrombotic microangiopathy (SRC-TMA).

Results: The initial search revealed 27 articles. After exclusion of non-relevant articles, data was included from 11 articles and 16 patients. The median age was 51 years, sex distribution was 4 males (33.3%) and 12 females (66.6%). Treatment with ACE-i was reported in 11 (68.75%), plasmapheresis (PLEX) in 8 (50%), steroids in 5 (31.25%), cyclophosphamide (CYC) in 3 (18.75%), calcium channel blockers (CCB) in 2 (12.5%) and Rituximab (RTX) in 2 (12.5%) of the patients. Renal replacement therapy (RRT) was required in 10 patients (62.5%). 8 out of 10 patients (80%) were reported to have clinical improvement with Eculizumab (Eculi) therapy (Table 1).

Conclusion: Recent clinical studies have focused on the role of complement activation in the pathogenesis of SRC and results suggest the use of C5 inhibitor in the treatment of refractory SRC. Serum complement levels and renal histological findings could help us identify patients who could benefit from Eculizumab.

THE RISK OF MALNUTRITION IS A PROBLEM ASSOCIATED WITH SYSTEMIC SCLEROSIS

Disclosure of Interests: None Declared.

Background: Malnutrition is a serious health problem that worsens comorbid processes, increases hospital stays, infections and mortality. In addition, in chronic patients, it increases the complexity of the processes and the fragility of the patient who suffers from it.

Objectives: To describe the prevalence of malnutrition and malnutrition risk and its associated factors in a series of patients with Systemic Sclerosis (SSc).

Methods: Design: Cross-sectional descriptive study. Participants: consecutive recruitment of patients with SSc (ACR/EULAR 2013 criteria) followed up in our unit. Follow-up of these patients is usually carried out every 3 to 6 months in consultation and all patients were registered in a database. 90% of the patients accepted and signed the consent, the rest refused due to travel or work difficulties.

Variables: The main variable was malnutrition or risk of malnutrition defined according to the Mini Nutritional Assessment (MNA) questionnaire, malnutrition was defined with a score less than or equal to 7, risk of malnutrition with scores between 8 and 11, and normal nutrition with values greater than 11. Clinical data, anthropometric and laboratory values were collected, as well as sarcopenia according to the European Working Group on Sarcopenia in Older People (EWGSOP II) and Short Physical Performance Battery (SPPB) criteria.

Statistical analysis: descriptive, bivariate and a multiple linear regression model to identify factors associated with malnutrition and risk of malnutrition.

Results: 52 patients were included, of whom 51 (98.1%) were women, with a mean (SD) age of 60.8 (11.0) years. 17/52 patients (32.7%) were at risk of malnutrition and 1/52 patients (1.9%) were malnourished (Table 1). Patients at risk of malnutrition and malnutrition compared with patients with normal nutritional status, more frequently had mild skin involvement (38.8% vs 14.7%, p = 0.05), sarcopenia (44.4% vs 11.8%, p<0.01), severe sarcopenia (27.8 vs 2.9; p=0.01), weight loss (100.0 vs 55.6%; p<0.001) and polypharmacy (23.1 vs 9.2; p=0.05). Calcium levels (8.7 [2.1] vs 9.2 [0.2]; p=0.05), circumference lesser left calf (32.8 [3.0] vs 35.4 [6.0]; p = 0.03), and in the SPPB functional grade (8.1 [4.2] vs 9.8 [2.9]; p = 0.06) and higher PCR values (10.5 [11.1] vs 7.1 [7.0]; p = 0.06). In multivariate analysis, the only factor associated with malnutrition in SSC was sarcopenia (B 95% CI), -2.521 [-4.867, -0.175]; p=0.036) (R2=0.115).

Conclusion: Malnutrition has serious consequences for the health of people with SSc, including the development of sarcopenia, a condition that predicts disability, hospitalization, and premature death.

VALIDITY AND RELIABILITY OF MEASUREMENT OF PERIPHERAL OXYGEN SATURATION DURING THE 6-MINUTE WALK TEST IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Lynggaard Riis1, E. Naeser1, K. T. Aaen1, H. Hovgaard2, P. Juhl-Olsen2, E. Bengtsson3, K. Soendergaard3, 1Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 2Aarhus University Hospital, The Department of Anaesthesiology and Intensive Care, Aarhus, Denmark; 3Aarhus University Hospital, Centre for Rare Lung Diseases, Department of Respiratory Diseases and Allergy, Aarhus, Denmark

Background: The 6-Minute Walk Test (6MWT) is a standardised method routinely used to screen for and monitor interstitial lung disease and/or pulmonary arterial hypertension in patients with systemic sclerosis (SSc). Studies shows that esaturations during the 6MWT are associated with severity of pulmonary manifestations in patients with SSc [1]. Digital sensors are commonly used to measure peripheral oxygen saturation (SpO2) during the 6MWT. However, digital-based sensors may have important limitations in patients with SSc due to disease-related microangiopathy, Raynaud’s phenomenon, sclerodactyly and motion artifacts during the 6MWT [2]. Sensors located at more central body positions may therefore be more accurate as these as less prone to Raynaud attacks.

Objectives: To determine the validity and re-test reliability of peripheral oxygen saturation measured at the finger, forehead, and earlobe during the 6MWT in patients with SSc.

Methods: 82 patients with SSc had an arterial line placed while performing the 6MWT. Peripheral oxygen saturation was simultaneously measured by finger, forehead, and earlobe sensors and compared to the arterial oxygen saturation (SaO2) measured before and after the 6MWT. 40 patients repeated the 6MWT one week later. We used Bland-Altman plots to display the agreement between SpO2 and SaO2, and between the minimal SpO2 (minSpO2) one week apart.

The intraclass correlation coefficient (ICC, 95% confidence interval 95% CI) for repeated measurement of minSpO2 was calculated.

Results: The mean difference (SpO2 - SaO2 ± standard deviation [SD]) after the 6MWT was –3.3% (±4.82), 0.15% (±1.55), and 1.36% (±1.93) for the finger, forehead, and earlobe, respectively (Table 1). The finger minSpO2 also demonstrated the poorest re-test reliability: The mean difference in minSpO2 (vis22-vis1, ±SD) was 1.28% (±5.3), 0.74% (±4.36) and –1.10% (±2.87). The ICC (95% CI) showed good agreement using the ear and forehead probe (ICCforehead = 0.89 [0.80; 0.94]; ICCearlobe = 0.88 [0.80; 0.87]), while a modest reliability was found using the finger probe (ICCFinger = 0.65 [0.43; 0.80]).

Conclusion: Peripheral oxygen saturation should be measured using either the earlobe or forehead during the 6MWT in patients with SSc.

AB0822 SYSTEMIC SCLEROSIS ASSOCIATED ANTIBODIES POSITIVITY IN SYSTEMIC SCLEROSIS PATIENTS: SINGLE VS. COMBINATION

Keywords: Systemic sclerosis, Biomarkers, Autoantibodies

Institut Mar d’Investigacions Mèdiques, Investigació cellular en inflamació y cartílago, Barcelona, Spain; Hospital del Mar, Rheumatology, Barcelona, Spain; Hospital Vall d’Hebron, Rheumatology, Barcelona, Spain; Hospital de Bellvitge, Rheumatology, Barcelona, Spain

Background: Autoantibodies (abs) are one of the most widely used tools currently in systemic sclerosis (SSc) as biomarkers. It has been described that 95% of patients with SSc have at least one ab and >5% >1. When looking only at abs associated with SSc (SSc-abs) that prevalence is reduced to 2.6%. The combination usually confers different clinical characteristics compared to those with positivity for a single ab.

Objectives: To determine the prevalence of the combination of SSc-abs in a series of patients diagnosed with SSc, and to analyze the clinical differences between those with positivity for a single vs multiple SSc-abs.

Methods: Retrospective study of 134 patients with SSc in whom the SSc-abs profile was systematically determined by an immunoblot (Euroimmun®) which included anti-topoisomerase (ATA), anti-centromere (ACA), anti-RNA-Polymerase III (ARA), anti-U3-RNP (U3), anti-Th/To (Th/To), anti-Ku (Ku), anti-PmScl (PmScl), anti-U1 RNA (U1), anti-U1-RNP (U1), anti-RNAPolymerase III (ARA), anti-ribonucleoprotein (RNP), anti-U1 (U1), anti-U3-RNP (U3), anti-U1-RNP (U1), anti-U1 (U1), anti-U3-RNP (U3).

Results: Table 1 shows the SSc-abs profile of our patients: 128/134 (96%) were ANA+, 111 (82%) had 1 SSc-ab, 8 (6%) had 2 and 3 (2.3%) had 3 concomitant SSc-ab. Ku was found in combination with other ab in all patients and was present in the 3 patients with 3 ab. When analyzing patients with combined vs sole abs, we found the following statistically significant differences: the limited cutaneous SSc subtype associated with ACA was lost in the combinations ACA-U1-Ku and ACA-Ku+, being 0/1 patients (0%, p=0.038) and 0/1 patients (0%, p=0.039, respectively). Patients with ATA-ARA+ had a higher modified Rodan skin score vs ATA- (18.33 ± 2.08 vs 9.67 ± 5.59, p=0.036). No other statistically significant differences were found in any other characteristics in the patients with ≥1 vs 1 ab, although a trend toward some clinical differences was seen in ACA-U1-Ku+ patients, with more digestive symptoms and interstitial lung disease, and less myositis than ACA+.

Conclusion: The concomitant presence of more than 1 SSc-ab is more frequent in our cohort than initially described (8%), likely due to the systematic detection carried out in our study. Anti-Ku was the most frequent ab in combination to others. The combination of abs may change the characteristic clinical phenotypes associated to them when found in isolation. We saw some differences in our study, although conclusions cannot be drawn due to the limiting sample size. The implementation of routine immunobLOTS as ab screening to achieve a better characterization of patients could be a helpful tool for medical professionals, as these combinations of SSc-ab may have prognostic implications.

DOI: 10.1136/annrheumdis-2023-eular.3762
Objectives: To assess the effectiveness of a therapy with OACs on DUs in patients with SSc.

Methods: This study used prospectively collected data from the European Scleroderma Trials and Research group (EUSTAR) registry. Patients fulfilling the 2013 ACR/EULAR SSc classification criteria with complete longitudinal data on the presence of DUs and OACs were included in the analysis. The Bayesian prior probability distribution was created by capturing SSc experts’ opinions on the probability of absence of DUs with and without OACs and their degree of uncertainty using a questionnaire. In addition, participants ranked factors that influence the presence or absence of DUs as confounding factors using a numeric rating scale. The outcome was the absence of DUs at the last follow-up visit in SSc patients from the EUSTAR cohort, after one year of exposure to OAC. A nearest neighbor matching algorithm using Bayesian Additive Regression Trees with uniform priors generated two balanced groups of patients (treated and non-treated with OACs), which were balanced for age, sex, anti-Scl-70 antibody positivity, joint contractures, use of placebos, and the presence of any endopeptidase inhibitors or phosphodiesterase type 5 inhibitors. The matching algorithm generated two balanced groups of treated and untreated patients (imbalance < 10%). A Bayesian logistic regression model was implemented to estimate the effect of OACs on DUs. This model incorporated the priors elicited from experts’ beliefs and was adjusted for the above-mentioned factors that influence the absence of DUs, as well as modified Rodnan skin score, duration of disease, season, left ventricular ejection fraction, presence of pulmonary hypertension, C-reactive protein elevation, arterial hypertension and any previous DUs.

Results: Of the 6,424 patients enrolled in the EUSTAR registry, 663 (10.3%) had current digital ulcers, 2556 (39.8%) had previous DUs and 143 (2.2%) were exposed to OACs at their last follow-up visit. Mean age was 59 (SD: 13.6) years, 933 (14.5%) were males, mean disease duration was 13.1 (SD: 8.7) years, 4,454 (69.3%) had a limited cutaneous SSc and 1510 (23.5%) had C-reactive protein elevation. The median probability for the absence of DUs after exposure of one year to OACs was 70-75%, the pessimistic and optimistic probability were 70-75% and 80-85% respectively. After incorporation of the priors experts’ opinion, the unadjusted analysis revealed that the use of OACs was associated with absence of DUs at the last follow-up visit (OR 2.05, 95% CrI 1.63 to 2.46). In the adjusted analysis, the effect of OACs was slightly stronger (OR 2.15, 95% CrI 1.71 to 2.52). The results of the analysis where the priors from experts were withheld (and uniform priors were set) are illustrated in figure 1.

Conclusion: This study indicates with incorporation of Bayesian priors that represent experts’ beliefs, a positive effect of OACs on the absence DUs related to SSc at the last follow-up visit.

AB0825
EFFICACY OF AUTOLOGOUS PLATELET RICH PLASMA ON MORPHEA: A COMPARATIVE CLINICAL AND ULTRASONOGRAPHIC FOLLOW UP STUDY

Keywords: Ultrasound, Skin, Systemic sclerosis

E. Elnasar1, M. Makki2, M. Mansour3, A. Moshrif4, 1Ras Eltin General Hospital, Dermatology, Alexandria, Egypt, 2,3, Al-Azhar University, Dermatology, Assiut, Egypt, 4, Al-Azhar University, Rheumatology department, Assiut, Egypt

Background: Morphea is a subtype of limited scleroderma characterized by affects to the skin. There are multiple treatment modalities for morphea, but all have limited success to restore atrophy.

Objectives: To evaluate the efficacy and safety of platelet rich plasma (PRP) to restore skin changes in morphea such as skin atrophy, dyspigmentation and adnexal destruction) by ultrasound and Localized Scleroderma Cutaneous Assessment Tool (LoSCAT).

Methods: Nine morphea patients (21 lesions) were diagnosed clinically and by histopathology. Intradermal PRP was injected into morphea lesion once weekly for 12 sessions. The disease severity and damage were evaluated at baseline, after the last session (3 months later) and at 6 months follow up using (LoSCAT).

Echogenicity and skin layer thickness were measured by musculoskeletal ultrasound with high frequency linear probe.

Results: The mean age of our patients was 21.8 ± 8.4 years (range: 11 to 36 years). The mean duration of morphea lesions was 5.96 ± 2.4 years (range: three months to 20 years). The LoSCAT score showed a significant improvement with a mean reduction from 13.73 ± 7.33 ± 6.8 after therapeutic endpoint (at 3 months) reaching to 6.44 ± 7.1 after 6 months follow up with p-value = 0.008 and 0.014 respectively. The activity index (LoSAI) also showed a significant lowering in the score at both timepoints with p-value <0.02 and 0.04 respectively. The significant difference in size between morphea lesions and healthy control areas by US (1.77 ± 1.13 vs 3.29 ± 1.72; p = 0.007) has been vanished after treatment (at 3 month); p< 0.17 and at 6 month; p=0.53. There was a significant positive correlation between the duration of the lesion and the improvement assessed by ultrasound with p-value = 0.01. As regard adverse effects all patients reported having pain during PRP injection, transient edema of face reported by 4 patients (45%) and only 2 patients showed transient erythema, fig 1.

Conclusion: Autologous PRP is a safe technique with great aesthetic outcomes, as filling up of contour defects and correction of both hyper and hypopigmenta- tion in addition to softening of the indurated lesions.

Disclosure of Interests: None Declared.
DOI: 10.1136/annrheumdis-2023-eular.4158

AB0826
EXPLORING THE POTENTIAL GENDER DIFFERENCE IN MYOSITIS: DISEASE PHENOTYPE AND ANTIBODY PROFILE FROM A SINGLE-CENTER ITALIAN COHORT

Keywords: Autoantibodies, Myositis, Gender/diversity issues

E. Cela1, P. Triggianese1, B. Kroegler1, A. D’antonio1, P. Conigliaro1, S. Modica1, E. Greco1, A. Bergamin1, M. S. Chimenti1,1Rheumatology and Clinical Immunology, University of Rome “Tor Vergata”, ROMe, Italy

Background: Idiopathic inflammatory myopathies (IMM) include a heterogeneous group of rare autoimmune diseases with a large spectrum of muscular and systemic manifestations, mainly involving skin and lung [1,2]. Myositis specific antibodies (MSA) and myositis associated antibodies (MAA) have been described in IMM patients potentially correlating to disease outcome [3]. As well documented, autoimmune diseases present with a clear gender bias with a greater prevalence among women. To our knowledge, no studies has explored the potential gender difference in IMM patients.

Objectives: The aim of the study was to explore differences in disease features, clinical outcome, antibody profile, and treatments in IMM patients according to the gender.

Methods: In an observational study, we included patients with a defined IMM diagnosis who were referred to 3rd level Rheumatology Unit “Tor Vergata” University Hospital in Rome (Italy) for the past 5 yrs (to Dec 2022). Inclusion criteria were i. a defined diagnosis of dermatomyositis (DM), polymyositis (PM), and anti-synthetase syndrome (ASS), in accordance with the 2017 EULAR/ACR criteria, ii. age ≥ 18 yrs, iii. availability of medical records and consent to study. Data comprised: disease duration and diagnostic delay, clinical phenotype, treatments, and autoantibodies including anti-nuclear antibodies (ANA), MSAs (anti-MDA5, -NXP2, -SAE, -Mi2, -TIF1, -Anti-IRNA synthetase, -Jo1, -PL7, -EJ), and MAAs (anti-PM/Scl, -Pod2, -Ru, U1RNP).

Results: The study cohort comprised 31 patients with IMM who met the inclusion criteria, with a similar gender distribution [n= 17 (54.8%) females and n=14 (45.2%) males]. The median age at symptoms onset was similar in both groups (59.13± 3.5 vs 56.6± 12.6 yrs) while males experienced slightly longer diagnostic delay (10.7± 14.4 vs 8.7± 8.6 months) and disease duration (30± 9.7 vs 21± 20 months) than females (P <0.05 for both). No significant difference in the distribution of IIM occurred between the two groups with a half of patients affected mostly by DM (75.5% vs M 50%). However, both PM (6.5% vs M 21.4%) and ASS (F 6.5% vs M 26.8%) were moderately prevalent in males. Skin involvement occurred similarly in both groups while lung disease occurred about twofold in males (57.1%) than females (29.4%). Most patients in the cohort showed ANA titre 1:160, with a comparable rate in females and males (64.7% vs 64.3%), and a positivity for at least one MSA and MAA. A double positivity of MSA occurred in 6.5% of the cohort, all females (MDA5/anti NXP2 and MDA5/EJ). The whole cohort had undergone steroids as 1st line therapy; as steroid-sparing agents, the main difference on treatments occurred for the mycophenolate mofetil which resulted significantly more administered in males (57.1%) than females (6%, P 0.002). Furthermore, among patients with lung involvement (n=13), the need to treat the progression of interstitial lung disease, by using the antibacterial agent (mometasone, resulted only in males (15%).

Conclusion: Our preliminary findings suggest that IMM can present a gender difference in disease outcome by showing a longer diagnostic delay and a higher respiratory involvement in male patients. These data might highlight a possible gender-oriented approach in accordance with a different disease profile and treatment strategies but require further investigations in a larger cohort.

AB0827
CLINICAL SIGNIFICANCE OF SERUM FERRITIN IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis

S. Markovich Sholomon1, Y. Braun-Moscovici2, A. Balbir-Gurman2, 1Rappaport Faculty of Medicine, Technion, Rheumatology Institute, Rambam Health Care Campus, Haifa, Israel; 2Israel, Rheumatology Institute, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion, Haifa, Israel

Figure Ultrasound (grey scale; transverse view) (a) before treatment shows morphea lesion in between two healthy areas. The lesion shows dermal and subcutaneous atrophy at end-stages with Loss of the border between dermis and subcutaneous tissue. (b) after treatment shows marked increase in dermal and subcutaneous thickness (c) remained remanent after 6 months of the end of treatment (d & e: photos for the same patient before treatment & at six-month follow up).

REFERENCES: NIL.
Acknowledgements: NIL.
Background: The main systemic sclerosis (SSc) manifestations are skin thickening, microangiopathy and ischemic changes in tissues, fibrotic damage to the lungs, heart, kidneys, and digestive system, arthritis, and myopathy. Acute phase reactants (APR) like erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) reflect inflammation activity in various inflammatory conditions. Ferritin is a protein bound to iron; low serum ferritin indicates iron deficiency and/or anemia. Instead, high ferritin levels are associated with inflammatory and non-inflammatory conditions such as dermatomyositis, pulmonary fibrosis, lupus, systemic COVID-19, vasculitis, tissue damage, thromboembolic complications, and metastatic cancer. The possible role of ferritin in SSc as APR is unclear.

Objectives: We aimed to assess whether ferritin levels can reflect the severity of SSc and predict the outcome.

Methods: 241 files of SSc patients with information on serum ferritin level (ferritin over 300 mg/dL is considered elevated) who visited the Rambam Rheumatology Institute in the years 2004-2021 were used for retrospective analysis. Patients’ demographic, clinical, laboratory, imaging, and radiographic function data were collected from electronic hospital files. Statistics included Student’s T-test, Pearson’s chi-squared test, and Kaplan-Meier curve; statistical significance was determined as p<0.05.

Results: 36 patients (FerEl-SSc) had elevated ferritin values; the rest (n=205) represented the second group (FerNor-SSc). Significant differences were seen in gender (male 44.4% - 15.6%), disease duration (4.56 - 7.7 years), modified Rodnan skin score (12.3 - 6.9), as well as in incidence of lung (65.7% - 38.7%), heart (51.4% - 21.1%), and renal (28.6% - 5.9%) involvement. Increased ferritin correlated with elevated ESR, CRP, creatine, creatine kinase, troponin, and reduced hemoglobin, impaired pulmonary function tests and reduced left ventricular ejection fraction on echocardiography. Patients with elevated ferritin had a significant increase in mortality rates (52.8% and 35.1%) and non-significant reduction in survival.

Conclusion: Our study demonstrated that ferritin has a potential as a sensitive marker for SSc severity in term of skin thickening, vital organ complications, and mortality. The ferritin test is simple and inexpensive, it can add to the complex SSc assessment and contribute to treatment decision-making in complicated SSc.

THE DIAGNOSTIC AND PROGNOSTIC VALUE OF COMMERCIAL LINE BLOT ASSAY IN TAIWANESE PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Autoantibodies, Diagnostic Tests

T. H. Yen1, W. N. Huang1, Y. M. Chen1. 1Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China

Background: Emerging evidence has demonstrated the clinical utility of sclerodera-specific autoantibodies in systemic sclerosis (SSc) [1]. However, the diagnostic performance and prognostic value of line dot assay (LIA) in Taiwanese patients was unknown.

Objectives: Our aim is to evaluate the diagnostic performance of a commercial LIA and the prognostic value of SSc-specific antibodies and anti-Ro52 in Taiwanese population.

Methods: We retrospectively enrolled all individuals tested by the LIA with 13 antigens between 2020 and 2021 in Taichung Veterans General Hospital. The diagnosis of the sclerodera was based on the 2013 ACR/EULAR classification criteria. The positive result of the semi-quantitative test was presented as +, ++ and +++ based on the signal intensity. If multiple antibodies were detected, the patient will be categorized according to the antibody with the highest signal intensity. Multivariable logistic regression was used to evaluate the association between autoantibody subtype and clinical phenotype.

Results: A total of 896 patients (209 SSc, 293 non-SSc CTD, 394 non-CTD) were retrospectively analyzed. ROC analysis of LIA showed numerically higher AUC excluding anti-Ro52 in comparison with whole panel. After excluding anti-Ro52, the LIA exhibited sensitivities of 79.9%, 65.1%, 56.0% and specificity of 44.8%, 65.2%, 72.8% for diagnosis of SSc at different cutoff values respectively (signal intensities 1+, 2+ and 3+). An overall diagnosis performance of AUC 0.674, 65.36% accuracy, 36.36% positive predictive value (PPV), 86.18% negative predictive value (NPV), 1.89 positive likelihood ratio (LR+), 0.53 negative likelihood ratio (LR-) was determined at the optimal cutoff of 2+. For SSc patients, we observed significantly higher risk of diffuse-type scleroderma in participants with negative autoantibodies, anti-Scl-70, anti-RNA polymerase III and anti-Ro52 positive (OR: 12.28, 95% CI: 3.19-47.19, p<0.001; OR: 33.56, 95% CI:8.91-126.51, p<0.001; OR:18.32, 95% CI:4.16-80.71, p<0.001**; OR:3.62, 95% CI:1.05-11.83, p=0.036 respectively, Table 1) as compared to counterparts. Anti-Ro52 positive was also associated with PAH and GI tract involvement (OR 3.26, 95% CI: 1.18-8.99, P=0.023; OR: 2.86, 95% CI: 1.28-6.39, p=0.011). In addition, we found combination of anti-Scl-70 and anti-Ro52 positive was associated with the highest rate of ILD (Figure 1).

Conclusion: We demonstrated the diagnostic performance of LIA in Taiwanese patients with optimal cutoff defined and also the prognostic values of autoantibodies. Moreover, anti-Ro52 was associated with higher risk of various organs involvement including ILD, PAH and GI tract involvement.

PROGRESSION OF ILD (INTERSTITIAL LUNG DISEASE) IN PFT (PULMONARY FUNCTION TEST) AND HRCT (HIGH RESOLUTION COMPUTERIZED TOMOGRAPHY) ACCORDING TO CTD (CONNECTIVE TISSUE DISEASE) IN 12 MONTHS

Keywords: Systemic sclerosis, Rheumatoid arthritis, Lungs

Background: ILD is an important cause of morbidity and mortality in CTD. Moreover, it can be the first clinical feature of a CTD.

Objectives: To evaluate progression of ILD in 12 months through HRCT and PFT according to the kind of CTD (systemic sclerosis, myositis, Sjögren’s syndrome, rheumatoid arthritis, mixed connective tissue disease, systemic lupus erythematosus), vasculitis, sarcoidosis and interstitial pneumonia with autoimmune features (IPAF).

Methods: A retrospective single tertiary center cohort study in CTD-ILD outpatients seen between 2012 and 2022. Sociodemographic, clinical and serological data, PFT and HRCT results were collected. ILD patterns were classified into usual interstitial pneumonia (UIP), inconsistent UIP, nonspecific interstitial pneumonia (NSIP), fibrosing NSIP, organizing pneumonia (OP), interstitial lymphoid pneumonia and associated to sarcoidosis. Progression of ILD was defined in PFT as: decline ≥ 10% in FVC ≥ 15% in DLCO. Progression of ILD in HRCT was considered according to radiologists’criteria.

Results: Data regarding 83 ILD-CTD patients is shown in Table 1. 54.1% of the patients complained of dyspnea at diagnosis of ILD. Immunosuppression prescribed was shown in Table 1. Treatment was not required in all cases at diagnosis of ILD. Pulse steroids, mycophenolate and rituximab are some of the most prescribed treatments. UIP was the most prevalent pattern in 40% of the patients of ILD. More studies must be done to identify best treatments and predictors to avoid progression of ILD.

EXAMINATION OF EXERCISE STRESS ECHOCARDIOGRAPHY AND BIOMARKERS IN SYSTEMIC SCLEROSIS PATIENTS FOR THE EARLY DETECTION OF PULMONARY ARTERIAL HYPERTENSION AND MYOCARDIAL INVOLVEMENT

Keywords: Systemic sclerosis

D Ladoеczky-Hullu1, B Morvai-Illes2, P Bencsik2, L Kovács1, G Ágoston2,
1Albert Szent-Györgyi Medical School, University of Szeged, Department of Rheumatology and Immunology, Szeged, Hungary; 2Albert Szent-Györgyi Medical School, University of Szeged, Department of Family Medicine, Szeged, Hungary; 3Albert Szent-Györgyi Medical School, University of Szeged, Department of Pharmacology and Pharmacotherapy, Szeged, Hungary

Background: The leading causes of death in patients suffering from systemic sclerosis are interstitial lung disease, malignancy and pulmonary arterial hypertension, but several other cardiovascular complications affect their quality of life.

Objectives: Our investigation aimed to examine biomarkers relating to active fibrotic changes in the myocardium and pulmonary vasculature and to find potential correlations with pathological findings detected by exercise stress echocardiography.

Methods: 28 consecutive systemic sclerosis patients attending our outpatient clinic underwent complete physical examination and routine blood tests. At the same day, resting and stress echocardiography were performed with supine bicycle exercise stress, and serum NT-proBNP, galectin-3 and soluble suppression of tumorigenesis-2 (sST-2) levels were measured. Patients with defined cardiological disease (systemic sclerosis-related manifestation or co-morbidity), interstitial lung disease, overt pulmonary hypertension or severe muscularoskeletal disorder (active myositis, arthritis and severe lower limb osteoarthrosis) were excluded from the cohort.

Results: 27 female and 1 male patient participated in the study, aged 55.09±13.05 years. Median serum galectin-3 level was 58.57±31.48 ng/ml, in 24 patients, it was found to be elevated (normal range: >22.1 ng/ml, 85.71%). The sST-2 median level was 108.39±44.06 ng/ml, increased in 27 patients (normal range: >35 ng/ml, 96.43%). Elevated levels of NT-proBNP were found in 24 patients. On echocardiography performed at rest, normal pulmonary arterial pressure was calculated in all 28 patients, while in the majority of them (in 23 patients), stress-induced pulmonary arterial hypertension (SIPAH) occurred at different grades of bicycle exercise. In those patients, the NT-proBNP level was also significantly higher (161.4±85 vs 93.5±61 ng/ml).
Clinical Phenotype of Antinuclear Antibody Negative Systemic Sclerosis in a Cohort of Systemic Sclerosis Romanian Patients

Keywords: Autoantibodies, Systemic sclerosis, Organ damage

Objective: To identify systemic sclerosis patients with a higher risk of progressive pulmonary arterial involvement. Our ongoing project is to follow up these patients with annual examinations.

Methods: A single-center retrospective study which enrolled 270 SSC. The presence for both circulating SSc-related autoAbs and ANA was assessed. Demographic and clinical features, symptoms, and parameters related to a specific organ involvement according to MEDS evaluation sheets, were evaluated.

Results: We identified a population of 32 (12%) patients who had neither SSC-related autoAbs nor ANA. The group comprised 27 females and 5 males, with a mean age of 59.7 ± 14.3 years, most of whom had diffuse subset (25/32). ANA/SSc-related autoAbs negative patients had a significantly younger disease onset (48 ± 6 vs 60 ± 20-81 years, P < 0.05), lower disease duration (6 ± 1.5-50 vs 2 ± 0-2.5 years, P < 0.01), lower mRSS (7 ± 2-21 vs 9 ± 1-25, P < 0.01) but higher European Scleroderma Study Group (ESSG) activity index (5.3 ± 1-50 vs 2.9 ± 1-25, P < 0.001), higher proportion of synovitis (42% vs 16%, P < 0.01) and calcinosis (42% vs 17%, P < 0.01). For organ involvement, although the absence of SSC-related autoAbs was positively correlated with presence of digital ulcers (P < 0.001), heart and severe pulmonary involvement (P < 0.001), we didn’t find a statistically significant difference between the two groups. Patients negative for ANA/SSc-related autoAbs had significantly higher in seronegative SSc patients, no difference in mortality were found between the groups.

Conclusion: Our data revealed that ANA/SSc-related autoAbs negative patients are younger and have more frequently diffuse skin involvement, inflammatory arthritis, and calcinosis. Although digital ulcers, severe pulmonary and heart involvement were more common, there was no statistically significant difference between the two groups. Even though overall disease activity index was significantly higher in seronegative SSc patients, no difference in mortality were found between the groups. Whether the absence of detectable autoAbs persists and is to be viewed as a favorable prognostic factor are questions to be addressed by future studies.

Chronic Intestinal Pseudo-Obstruction in Patients with Systemic Sclerosis

Keywords: Gastrointestinal tract, Systemic sclerosis, Diet and Nutrition

Objective: To analyze the clinical variables, the period between the diagnosis of SSC and CIPO, the received therapies, and the clinical outcome.

Methods: All the seven cases we studied were women, with a median (interquartile range, IQR) age at SSC diagnosis of 46.2 years (34-52). All of them met the ACR/EULAR 2010 classification criteria for SSC. Five (71.4%) of the patients presented diffuse cutaneous SSC (dcSSc), while the other two had the limited cutaneous SSC (lcSSc) subset. The median period between the SSC diagnosis and CIPO was 71 years (1.84-15.96). Considering basal characteristics, 4 (57.1%) patients presented cardiac involvement, 3 (42.8%) arthritis, 3 (42.8%) interstitial lung disease, and 1 (14.3%) pulmonary arterial hypertension. Regardless of specific SSC autoAbs, anti-centromere antibodies were detected in 2 (28.6%) patients, anti-U1RNP in 2 (28.6%) and anti-RNA polymerase III in 1 (14.2%). Six (85.7%) had concomitant small intestinal bacterial growth (SIBO), with positive response to courses of antibiotics. Regarding CIPO treatment, all of them received dietetic recommendations, 6 (85.7%) probiotics (cinapride, prucalopride or erythromycin) and 4 (57.1%) the somatostatin analogue octreotide sc or octreotide. At CIPO onset, 3 (42.8%) patients had serious oral enemas, two of them required parenteral nutrition (PTN), while the other received intravenous immunoglobulins (IVIG) and percutaneous endoscopic gastrostomy. During the first year of follow-up after an adequate initial response to treatment, 5 (71.4%) patients had a relapse into CIPO symptoms. Among them, one improved after initiating octreotide sc, 3 required PTN, 2 IVIG and 1 case was treated with adalimumab. Four (57.1%) patients died during the follow-up, three of them as a consequence of gastrointestinal complications related to CIPO, and the fourth because of sudden death.

Conclusion: CIPO is a gastrointestinal manifestation of SSC, that despite its low prevalence, represents a high morbi-mortality. Patients with dcSSc might have a higher susceptibility for CIPO. There is a substantial variability period between the SSC onset and the appearance of CIPO related symptoms. Diet recommendations, probiotics and octreotide are common initial therapies, reserving IVIG and PTN for refractory cases or with more aggressive onset. Notwithstanding, the mortality related to this gastrointestinal involvement is certainly significant.

rheumatoid arthritis and subsequently validated in many cultures and various rheumatic patient groups [1].

Objectives: The aim of the study was to investigate the validity and psychometric properties of DHI in patients with systemic sclerosis (SSc).

Methods: Patients diagnosed with SSc according to the EULAR/ACR 2013 system were included [2]. Demographic and clinical characteristics of the patients were recorded. Functional assessments of the hands were evaluated with DHI. Kelter Functional Index (KFI), visual analog scale (VAS) for disability, VAS-Handicap for handicap, and Health Assessment Questionnaire (HAQ). Short Form-36 (SF36) was used for assessing quality of life. Disease activity was assessed with European Scleroderma Study Group (EScSG) activity index and VAS doctor’s opinion for activity. Modified Rodnan skin score (mRSS), VAS-hand pain, VAS-Raynoud, swollen joint count (SJC), tender joint count (TJC), Pittsburgh sleep quality index (PSQI), and CRP levels were also noted. For the reliability analysis, internal consistency (Cronbach’s alpha) and test-retest reliability (ICC), and for the validity analysis face, content, convergent, and divergent validities were applied. Face and content validities were evaluated via cognitive debriefing interviews with the patients. The correlations of the DHI with KFI, VAS-disability, VAS-Handicap, and HAQ were analyzed for convergent validity. The correlations of the DHI with other measurements (non-functional) were analyzed for divergent validity.

Results: Seventy-three patients with a mean age of 48.6 (SD 12.8) years were recruited and 57 of them were women. Cognitive debriefing showed the DHI to be clear, understandable, and relevant. It was easy to complete and calculate, with the 5 minutes and 30 seconds, respectively. The Cronbach’s alpha coefficient for internal consistency was 0.973 and ICC for test-retest reliability was 0.993 (95%CI 0.981-0.997). DHI showed good to moderate correlations with the functional measurements indicating its convergent validity and moderate to divergent validities were applied.

Conclusion: DHI is a quite practical, reliable, and valid instrument to assess hand function in patients with SSc.

AB0835 CAPILLAROSCOPIC FINDINGS IN PATIENTS WITH SJÖGREN’S SYNDROME, SYSTEMIC SCLEROSIS, AND PRIMARY RAYNAUD’S PHENOMENON IN A HIGH-COMPLEXITY CENTER IN MEDELLÍN, COLOMBIA 2016-2022

Keywords: Sjögren syndrome, Real-world evidence, Systemic sclerosis

S. Hoyos-Patitó¹, A. Arango-Martínez², L. M. Rodríguez Padilla³, A. Chavarriaga Restrepo¹, C. J. Velásquez-Franco⁴, Universidad Pontificia Bolivariana, Internal Medicine, Medellín, Colombia; ¹Universidad Pontificia Bolivariana, School of Health Sciences, Medellín, Colombia; ²Universidad Pontificia Bolivariana, Associate Professor, School of Health Sciences, Medellín, Colombia; ³Clínica Universitaria Bolivariana, Clínica CES, Rheumatology, Medellín, Colombia; ⁴Universidad Pontificia Bolivariana, Rheumatology, Medellín, Colombia

Background: In Sjögren’s syndrome (SSS), it has been suggested that capillaroscopy could be useful to identify patients with characteristics of overlap syndromes and risk of evolving into another connective tissue disease, in addition to determine extraglandular systemic involvement. The published information is scarce, as its comparison with systemic sclerosis (SSc) and primary Raynaud’s phenomenon (pRP); in addition, different optical instruments other than the videocapillaroscope with 200x magnification have been used.

Objectives: To assess capillaroscopic findings in patients with SSS compared to subjects with SSc and pRP at a national capillaroscopy reference center in Medellín, Colombia, between 2016 and 2022.

Methods: An analytical cross-sectional observational study was carried out. Patients over 18 years who met 2016 ACR/EULAR, 2013 ACR/EULAR, and 2014 international criteria for SS, SSc, and pRP, respectively, confirmed by a rheumatologist, were included. Capillaroscopic variables were analyzed (number of capillaries per millimeter, dilated capillaries, megacapillaries, abnormal capillaries, microhemorrhages, avascular zones, arbor- escent capillaries, capillary disorganization, and capillaroscopic pattern). Qualitative variables were expressed by absolute and relative frequencies and the quantitative by the median and interquartile range (IQR) due to the heterogeneous distribution of data.

Results: In total, there were 195 patients, of which 181 (92.8%) were female; the median age was 53 years (IQR:39-61). The most frequent capillaroscopic finding in SS was the presence of dilated capillaries (n=36; 55.4%). A higher frequency of global capillaroscopic abnormalities was observed in the SSS group compared to the other groups (p<0.0001 in all comparisons). There was no difference in the frequency of arbor capillaries between the SS and SSc groups. In the SS group, either scleroderma pattern was found in 18.5% (n=12) (Table 1).

AB0836 ANTI-SAE ANTIBODY-POSITIVE DERMATOMYOSITIS: CLINICAL CHARACTERISTICS FROM AN ITALIAN COHORT

Keywords: Myositis

R. Depascuale¹, A. Ghirardello¹, E. Zanatta¹, M. Gatto¹, M. Zen¹, L. Iacarino¹, A. Doria¹, University of Padua, Rheumatology, Padua, Italy
Background: Anti-small ubiquitin-like modifier-1 activating enzyme (anti-SAE) antibodies are rare myositis-specific antibodies, which are mainly associated with cutaneous involvement in inflammatory myositis (IIM).

Objectives: To analyse clinical characteristics of anti-SAE positive Dermatomyositis (DM) patients in a monocentric cohort. We focused on clinical manifestations and type of organ involvement.

Methods: In a monocentric cohort of 169 patients with IIM, anti-SAE antibody-positive patients were included in the study. Anti-SAE antibodies were investigated by immunoblotting. We considered the presentation symptoms at disease onset and during follow-up, focusing on musculoskeletal, cutaneous and pulmonary domains. Muscular involvement was evaluated by Manual Muscle Test-B and creatin kinase (CK) levels. To determine intestinal lung disease (ILD), high-resolution computed tomography (HRCT) was performed at diagnosis and during follow-up and evaluated by an expert radiologist. Skin and joint involvement was evaluated by clinical judgment. Therapeutic approach was also considered.

Results: Of the 169 patients with IIM, 6 were positive for anti-SAE antibodies (3.5%). Among them, five were female and one male. The mean age at onset of symptoms was 46.3 years (range 5-78 years). Cutaneous manifestations were the most prevalent clinical features at disease onset. Indeed, all of the patients had photosensitive rash, heliotrope rash and Gottron papules. Mechanic’s hands were noted only in one patient with ILD. Four (70%) had arthritis. Muscular involvement, which was mostly mild, was evidenced by muscular weakness and high levels of CK (mean value 358 U/l) in 30% of patients (n=2). Three patients (50%) had radiological evidence of ILD at onset or during follow-up. Non-specific Intestinal Pneumonia (NSIP) was the main pattern found. Story of malignancy was noted only in the male patient. Half of the patients (n=3) were treated with methotrexate (MTX). Because of drug intolerance, MTX was substituted by mycophenolate mophetil (MMF) in two of them. One patient received intravenous immunonoglobulin (IGIV) and cyclophosphamide (CYC) for persistent cutaneous disease activity.

Conclusion: In our small cohort of patients, anti-SAE antibodies were strongly associated with skin disease, in one case severe. Lung involvement was another common clinical feature described and malignancy was noted in one case.

AB0837  EFFECTIVENESS AND SAFETY OF RITUXIMAB AND MYCOPHENOLATE MOFETIL COMBINATION THERAPY FOR IDIOPATHIC INFLAMMATORY MYOPATHIES: A MONOCENTRIC REAL-LIFE STUDY

Keywords: Myositis, bDMARD, Lungs

C. Campochiaro1, G. De Luca1, G. Trignani1, A. Tomelleri1, M. Matucci-Cerinic1, L. Dagna1. 1IRCCS San Raffaele, Vita-Salute San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

Background: Due to a lack of robust clinical evidence, no defined recommendations for the treatment of refractory idiopathic immune myopathies (IIMs) exist. Hence, management of IIMs is still challenging.

Objectives: To assess the real-life effectiveness and safety of rituximab (RTX) and mycophenolate mofetil (MMF) combination therapy in severe and refractory IIMs.

Methods: Adult patients with IIMs (*2017 EULAR/ACR classification criteria1*) followed up at our Myositis Clinic and treated with a combination of RTX and MMF were identified. IMACS six core set measures (i.e., VAS physician; VAS patient; MTX; HAQ; muscle enzymes; extramuscular assessment, including MITAX, MYOACT scores) were recorded at three different time points (baseline, 6-month, and 12-month after first RTX infusion). Subgroup analyses according to the involvement of specific organs (heart, lung) were performed. Safety was assessed.

Results: We identified 20 IIM patients (ASS, n=12; dermatomyositis, n=2; polymyositis, n=2; immune-mediated necrotizing myopathy, n=1; overlap myositis, n=3). Median age was 61 (48-71) years; 14 patients were women (70%). Myocarditis and interstitial lung disease (ILD) were identified in 7 (35%) and 15 (75%) patients, respectively; 6 patients (30%) had arthritis and 3 (15%) had dysphagia. MMF was started after a median of 2 (0-76) months since diagnosis. RTX was always started after MMF (after a median of 22.5 (10-122) months), and administered at a dose of 1 g 2-week apart repeated 6 monthly. MMF dose was reduced in all patients (to 1 g daily, n=3, 15%; to 2 g daily, n=17, 85%) after RTX introduction. Adjunctive treatments were glucocorticoids (n=17), hydroxychloroquine (n=5), intravenous immunoglobulins (n=3). At 6 months, IMACS core set measures significantly improved all but MTM8 (Figure). A significant reduction of CPK and CRP levels and of prednisone (PDN) daily dose was observed (Table). In addition, a reduction in troponin T levels in patients with myocarditis and a stabilization of functional parameters in patients with ILD were observed (Table). At 12 months, a further reduction in the PDN dose and a further significant reduction in troponin T levels in patients with myocarditis were observed (Table). No patient had severe infections; 10 patients (50%) had mild infections (the most common upper respiratory tract infection, n=6).

Conclusion: Combination treatment with RTX and MMF could represent an effective and safe option in patients with severe and refractory IIMs.

*only among patients with cardiac involvement; **only among patients with ILD
**Results:**

The mean age at diagnosis was 50.3 ±14.5 years and a mean disease duration 10.2 ±9.0 years. Leaving aside Raynaud's phenomenon and sclerodactyly, gastrointestinal involvement (71.4%), ulcers (46.2%) and arthritis (45.1%) were among the most prevalent clinical manifestations. Mean baseline FEV1 and FVC values were normal (83.4%±16.8 and 84.4%±18.5 respectively, while mean baseline DLCO was pathological (82.6±18.9). All patients underwent a high-resolution CT early at diagnosis and upon rheumatologist's/pulmonologist's judgement afterwards. Eighty-one patients (89.0%) were diagnosed with interstitial lung disease (76.0% had NSIP pattern, 24.0% UIP pattern). Patients with NSIP had better scores in lung function tests than those with UIP pattern (Mean difference in scores in lung function tests than those with UIP pattern (Mean difference in FEV1, FVC and DLCO were 13.3%, 17.7%, and 12% respectively, p<0.05 for all comparisons). Positivity for anti-topoisomerase antibody (ScI-70) presented an OR=24.9 (p=0.001) for ILD, while ACA and anti-CEP-B were negatively associated (OR=0.114, p=0.003 and OR=0.164, p=0.024, respectively). Pulmonary hypertension based on echocardiogram findings was reported in 19 patients (19.8%), however PAH based on right heart catheterization (RHC) was confirmed in 11 of them (12.1% of total patients). Anti-Ro52 positivity was associated with PH (OR=4.45, p=0.005) and PH-ILD coexistence (OR=5.18, p=0.002), however no association was found for ILD presence in this cohort. There was also a trend for PAH-RHC, but it did not reach statistical significance. Cardiac MRI was performed in 24 patients, and non-ischemic myocardial fibrosis (compatible with SSc involvement) was identified in 18/24. The mean disease duration in MF group was longer (8.7 ±7 vs 3.3 ±4.3, p=0.040). Gastrointestinal involvement seems to confer an increased risk for this complication (OR=10.0, p=0.038).

**Conclusion:**

The estimated ILD prevalence in our study is significantly higher than the one reported in the literature. As a referral centre, the patients reaching to our department probably have worse organ involvement than the average patient of primary care setting. In addition, universal screening with a baseline HRCT and close monitoring lead to an earlier identification of this population. Anti-Ro52 has been recently reported as an independent risk factor for PAH. Our results could not verify this observation, probably due to the relatively small number of PAH patients in our study. Cardiac MRI availability and radiologist's experience are essential for MF diagnosis. It is our belief that larger studies are necessary to evaluate this population.

**PULMONARY AND CARDIOVASCULAR MANIFESTATIONS IN SYSTEMIC SCLEROSIS: RESULTS FROM A SSc PATIENTS COHORT AT A TERTIARY CENTRE OF NW GREECE**

**Keywords:** Lungs, Cardiovascular disease, Systemic sclerosis

**N. Gerolymatou**1, N. Koletsos2, M. Karakosta1, T. E. Memi1, A. Drosos1, P. Voulgaris1, University Hospital of Ioannina, Rheumatology Clinic, Ioannina, Greece

**Background:** Systemic Sclerosis (SSc) is a connective tissue disease affecting multiple systems, including the respiratory and cardiovascular systems. Among the various disease complications, interstitial lung disease (ILD), pulmonary arterial hypertension (PAH) and lately recognized- myocardial fibrosis (MF), are those mainly related to reduced life expectancy.

**Objectives:** We aimed to evaluate the prevalence of SSc complications and to investigate possible associations with patients' clinical and serological characteristics.

**Methods:** Patients fulfilling the ACR/EULAR 2013 Scleroderma criteria, who were followed at our tertiary rheumatology centre between January 2018 and December 2022, were included in our cohort. Demographic, clinical, and serological characteristics, as well as imaging data (high-resolution chest CT, cardiac MRI) were collected and the CV risk factors, instrumental and laboratory assessments were collected and the CV risk [4]. The publication of 2022 EULAR Recommendations on cardiovascular (CV) involvement in rheumatic diseases asserting that “the use of ASA in SSc is not recommended for primary prevention” because of “data about this topic were not found” caused uncertainty to justify the use of this drug [5].

**Objectives:** Aim of our study was to evaluate the safety of ASA in a cohort of pts affected by SSc.

**Methods:** We retrospectively analyzed data from patients with SSc, fulfilling the 2013 ACR/EULAR classification criteria [6], followed in our Scleroderma Clinic, receiving ASA. Analysis included data from subjects that were not treated with ASA, as control group. Exclusion criteria were CV disorders and/or major bleeding occurred before the evaluation, treatment with ASA started before the diagnosis of SSc, Helicobacter pylori-related gastritis or other causes of gastritis not SSc-related, tumors, anticoagulant or other anti-platelet therapies. Demographic, clinical, ongoing therapies data were examined; conventional cardiovascular risk factors, instrumental and laboratory assessments were collected and the CV risk was calculated using the SCORE2 and/or SCORE2-OP [7]. All data were collected for a follow-up time variable from 2 to 10 years since ASA was prescribed (for cases) and since the first rheumatologic visit after diagnosis was done for controls (TO). Safety data included the following variables:

- major bleeding (requiring blood transfusion and/or leading to death)
- minor bleeding
- intracranial hemorrhage
- ocular hemorrhage requiring immediate treatment
- gastroenteric tract hemorrhage
- gastroenteric tract neoplasm
- gastric ulcer

**SAFETY OF LOW-DOSE ACETYL SALICYLIC ACID IN PATIENTS WITH SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY**

**Keywords:** Safety, Cardiovascular disease, Systemic sclerosis

G. Pellegrino1, M. D’orsio1, M. Caldera1, I. Bisconti1, D. M. Reza Beigi1, F. R. Di Ciommo1, S. Truglia1, F. Conti1, V. Ricci1, Sapienza University of Rome, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy

**Background:** The low-dose acetyl salicylic acid (ASA) is often used among patients with Systemic Sclerosis (SSc) in clinical practice since its use is not mentioned in any official document concerning the management of SSc [1]. Recently, a study from EUSTAR database demonstrated that anti-platelet therapy is a protective factor for digital ulcers onset, while Valentini et al associated the use of ASA with a lower incidence of primary cardiac involvement in Ssc patients [2,3]. On the other hand SSc has been shown to be one of the autoimmune diseases with the highest CV risk [4]. The publication of 2022 EULAR Recommendations on cardiovascular (CV) involvement in rheumatic diseases asserting that “the use of ASA in SSc is not recommended for primary prevention” because of “data about this topic were not found” caused uncertainty to justify the use of this drug [5].

**Objectives:** Aim of our study was to evaluate the safety of ASA in a cohort of pts affected by SSc.

**Methods:** We retrospectively analyzed data from patients with SSc, fulfilling the 2013 ACR/EULAR classification criteria [6], followed in our Scleroderma Clinic, receiving ASA. Analysis included data from subjects that were not treated with ASA, as control group. Exclusion criteria were CV disorders and/or major bleeding occurred before the evaluation, treatment with ASA started before the diagnosis of SSc, Helicobacter pylori-related gastritis or other causes of gastritis not SSc-related, tumors, anticoagulant or other anti-platelet therapies. Demographic, clinical, ongoing therapies data were examined; conventional cardiovascular risk factors, instrumental and laboratory assessments were collected and the CV risk was calculated using the SCORE2 and/or SCORE2-OP [7]. All data were collected for a follow-up time variable from 2 to 10 years since ASA was prescribed (for cases) and since the first rheumatologic visit after diagnosis was done for controls (TO). Safety data included the following variables:

- major bleeding (requiring blood transfusion and/or leading to death)
- minor bleeding
- intracranial hemorrhage
- ocular hemorrhage requiring immediate treatment
- gastroenteric tract hemorrhage
- gastroenteric tract neoplasm
- gastric ulcer

**REFERENCES:**

**Acknowledgements:** NIL.

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/nnrheumdis-2023-eular.5554
**Methods:** Data were collected from 121 SSc pts, 71 cases and 50 controls. From the analysis of gastrovascular involvement at T0 control pts showed more frequently endoscopic gastrovascular lesions of the upper gastrovascular tract respect to cases (N-% controls vs cases: 8.16% vs 4.6%; p-value 0.0039). Among traditional CV risk factors we found that cases were more frequently smokers than controls (N-% cases vs controls: 15.21% vs 2.4%; p-value 0.007), but no difference was found with either of the other traditional CV risk factors or with the CV risk scores, calculated with SCORE2, between cases and controls. Our analysis didn’t reveal any significant difference on the occurrence of adverse events concerning ASA safety between the two groups; after 1 year of treatment with ASA, 4 subjects showed minor bleeding and in one case a gastric neoplasm was diagnosed, after 2 years of treatment 2 pts reported minor bleeding, while just 1 case showed minor bleeding after 5 years of treatment. Among controls, the onset of gastric ulcers in one subject only was reported after 2 years of follow-up.

**Conclusion:** Despite the long period of ASA treatment, we didn’t find a significant increase in the frequency of related adverse events in our pts. ASA seems to be a manageable therapy and, since the high CV risk associated with SSc [4], very similar to that showed by pts with diabetes mellitus where in some cases the use of ASA in primary prevention is recommended, we suggest a reassessment of EULAR Recommendations together with other studies on larger cohort of SSc pts. In order to confirm the safety of ASA.

**AB0840 ACUTE VASCULAR EFFECTS OF INTRAVENOUS ILOPROST IN SCLERODERMA PATIENTS CAN BE DETECTED BY POWER DOPPLER EXAMINATION OF THE FINGER SUBCUTANEOUS TISSUE**

**Keywords:** Systemic sclerosis, Imaging

S. Testoni1, L. Magnani2, A. Spinnelli3, C. Salvanari1,2, D. Giuggioli1, P. Macchioni2. Università degli studi di Modena e Reggio Emilia, Rheumatology Unit, Modena, Italy; 1IRCSS Santa Maria Nuova, Rheumatology Unit, Reggio Emilia, Italy

**Background:** Intravenous iloprost (ILO) is used in the treatment of refractory Raynaud phenomenon and scleroderma (SSc) digital ulcers. To date, there are no recommended imaging modalities to monitor ILO vascular effects. So far few studies explored ultrasound (US) as a tool to assess vascular subcutaneous involvement in patients affected by SSc.

**Objectives:** We aim to evaluate the acute vascular effects of intravenous ILO infusion by power Doppler US (PDUS) examination at periungal (PU) and finger pulp (FP) subcutaneous areas in a consecutive series of SSc patients.

**Methods:** Ten consecutive SSc patients who met the ACR/EULAR criteria for SSc referring to our tertiary center for ILO infusions were enrolled in the study. FP and PU vascularization of the 1st, 2nd and 3rd finger of the dominant hand were evaluated before and after ILO infusion (dosage 0.5-2.0 ng/kg/min for 4-6 hours) using an Esaote MylabClassC (Genoa, Italy) machine equipped with a 22-8 MHz multifrequency linear probe. All the exams were performed after at least 30 minutes of acclimation in a room with an ambient temperature ranging from 20 to 22°C by the same operator (PM). All the images with the highest presence of PD signal were stored for subsequent examination by a rheumatologist (ST) blind to the sequency of the images. The presence of PD signal in every image was scored according to a semiquantitative 0-3 scale (grade 0 no vessels; grade 1: 1-2 visible vessels; grade 2: 3 to 5 vessels, and grade 3 more than 5 vessels). The value of each finger (FP & PU) were summed up to obtain a total patient PD score and values before and after ILO treatment were compared by T-test for paired samples. Single fingers PD improvements after infusion were summed obtaining total improvement respectively for the PU and FP areas.

**Results:** Clinical and laboratory features of the enrolled patients are reported in Table 1. Mean total PU PD score was 4.2±2.2 at T0 and increased to 7.3±2.5 after treatment (p=0.012). Mean total FP PD score was 2.2±1.8 at T0 and remained unchanged (2.8±1.68) at T1 (p= 0.475). The median number of fingers/patient with PU PD improvement after treatment was 2 (1-3), while the median number of fingers/patient with FP PD improvement was 0.5 [0-3].

**Conclusion:** PDUS examination of the PU area could demonstrate an ILO acute effect in SSc patients with long-lasting disease.

**AB0841 CONCORDANCE AND PROGNOSTIC RELEVANCE OF DIFFERENT DEFINITIONS OF SYSTEMIC SCLEROSIS INTERSTITIAL LUNG DISEASE PROGRESSION**

**Keywords:** Systemic sclerosis, Lungs, Outcome measures

E. De Lorenzi1,2, G. Natalello3, S. Di Donato4, L. Verardi2, P. G. Cerasuolo2, V. Kakkar1, M. A. D’Agostino2, F. Del Galdo1, S. L. Bosello3, Scleroderma Program, Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Leeds Institute of
Rheumatic and Musculoskeletal Medicine University of Leeds, Leeds (United Kingdom), Leeds, United Kingdom; Università Cattolica del Sacro Cuore, Policlínico Universitario Agostino Gemelli IRCCS, Roma, Italy, Rheumatology Department, Roma, Italy

Background: Interstitial lung disease (ILD) is a common complication of systemic sclerosis (SSc) with a variable natural history and prognosis. Several definitions of SSc-ILD progression have been proposed including minimal clinical change, worsening of forced vital capacity (FVC) MCIW, European Scleroderma Trials and Research group (EUSTAR) progression, Outcome Measures in Rheumatology Clinical Trials (OMERACT) progression, and Erie ILD working group progression. The aim of the study was to assess concordance and prognostic value of these different definitions in SSc-ILD patients overall and specific clinical subsets.

Objectives: Progression status was assessed in consecutive SSc-ILD patients over a period of 24 months and the mortality related to SSc-ILD was compared between progressors and non-progressors according to different definitions in the subsequent 60 months. Severe baseline pulmonary functional impairment was defined for a combination of FVC<80% and alveolar diffusion of CO (DLco) <50% of predicted.

Methods: Progression status was assessed in consecutive SSc-ILD patients over a period of 24 months and the mortality related to SSc-ILD was compared between progressors and non-progressors according to different definitions in the subsequent 60 months. Severe baseline pulmonary functional impairment was defined for a combination of FVC<80% and alveolar diffusion of CO (DLco) <50% of predicted.

Results: The retrospective analysis included 245 SSc-ILD patients (age 54.6±13.2 years, male 18.8%) with a 54.7% prevalence of diffuse cutaneous variant and a median disease duration of 4 years (IQR 2-8). Disease duration ≤3 years, severe pulmonary functional impairment, and pulmonary artery systolic pressure (PASP) 40 mmHg were reported in the 43.8%, 18.0% and 17.1% of patients, respectively. Twenty-six deaths were reported among enrollees diagnosed and progression according to FVC MCIW (HR 2.27, 95% CI 1.03 - 4.97, p=0.041), OMERACT (HR 2.90, 95% CI 1.28 - 6.57, p=0.011), and Erice criteria (HR 11.02, 95% CI 2.38 - 51.08, p=0.002) were associated with mortality in the whole cohort. Prognosis prediction, considering the 4 different definitions of progression status, was challenging (independently from the adopted criteria) in patients with disease duration >3 years, mild pulmonary function test impairment, and PASP ≤40 mmHg. Erice criteria performed better in patients with disease duration ≤3 years, limited cutaneous variant, and PASP ≤40 mmHg, while OMERACT criteria in patients with diffuse cutaneous variant, and severe baseline pulmonary functional impairment.

Conclusion: The proposed progression definitions of SSc-ILD are not interchangeable, since up to one third of progressors could be misdiagnosed using different criteria. Regardless of the criteria used, progressor patients presented more frequently a diffuse skin variant of the disease, a shorter disease duration and worse baseline functional impairment of the lung.

AB0843 THE EXPRESSION PROFILING OF CIRCULATING MIRNAS IN SYSTEMIC SCLEROSIS

Keywords: Genetics/Epigenetics, Systemic sclerosis

S. Machhul1, R. Minz1, S. K. Sharma1,2, Y. Kumar1, S. Singh1, S. Anand1, S. Handa1,2 Post Graduate Institute of Medical Education & Research, Chandigarh, Immunopathology, Chandigarh, India; 3Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India; 3Post Graduate Institute of Medical Education & Research, Chandigarh, Department of Dermatology, Venerology and Leprosy, Chandigarh, India

Title: The expression profiling of circulating miRNAs in systemic sclerosis.

Background: Systemic sclerosis (SSc) is a rare chronic disease of unknown etiology. Genetics plays an important role in SSc's pathogenesis; however, considering genetic factors alone does not explain the disease's occurrence, epigenetic influences are also believed to contribute to SSc development [1]. miRNAs are reportedly to be aberrantly expressed in SSc patients and, therefore, potential contributors to its pathogenesis. The role of miRNAs in SSc is just beginning to unravel [2].

Objectives: To investigate the expression profile of circulating miRNAs in SSc. Method: Whole blood miRNA (84 miRNAs involved in human fibrosis) transcripts were identified by miScript miRNA PCR Array using RT-qPCR.

Results: Fourteen miRNAs (6 upregulated -hsa-mir-145-5p, hsa-mir-150-5p, hsa-mir-18a-5p, hsa-mir-195-5p, hsa-mir-223-3p, hsa-mir-29c-3p; 8 downregulated- hsa-mir-211-5p, hsa-mir-217, hsa-mir-31-5p, hsa-mir-328-3p, hsa-mir-335-5p, hsa-mir-382-5p, hsa-mir-449a, hsa-mir-661) showed differential expression compared to controls. IPA (Ingenuity Pathway Analysis) predicted miRNA-mRNA targets gene (hsa-mir-145-5p, hsa-mir-18a-5p, and hsa-mir-449a- TGFβ1), were validated through qRT-PCR and found to be dysregulated in the SSc patients, DIANA-Mir Path v3.0 pathway analysis showed dysregulated miRNAs were associated with pathways implicated in SSc's pathogenesis (Figure 1).

Conclusion: The differentially expressed miRNA and their putative mRNA targets and associated pathways may provide diagnostic biomarkers as well as potential therapeutic targets for SSc treatments.

ARTERIAL ISCHEMIC EVENTS AND VENOUS THROMBOSIS IN SYSTEMIC SCLEROSIS: DATA FROM A MONO-CENTRIC STUDY

Keywords: Cardiovascular disease, Comorbidities, Systemic sclerosis
A. Dellal1, O. Fain2, A. Mekinian3.
1Intercommunal Hospital Group Le Raincy; 2Montfermeil, RHEUMATOLOGY, Montfermeil, France; 3Hospital Saint-Antoine Ap-Hp, Internal medicine, Paris, France; 4Hospital Saint-Antoine Ap-Hp, INTERNAL MEDICINE, Paris, France

Background: Systemic sclerosis is a systemic autoimmune disease characterized by vasculopathy (Raynaud phenomena), pulmonary arterial hypertension (PAH), and renal crisis, fibrosis of skin and visceral organs (notably the gut, heart, and lungs), and musculoskeletal inflammation (joints, muscles, and tendons) [1]. Inflammation drives atherosclerosis and contributes to cardiovascular (CV) disease [2]. A few studies have examined the incidence of individual macrovascular manifestations such as myocardial infarction, stroke, peripheral artery disease, and venous thromboembolism [3-4-6].

Objectives: Our aim was to assess the incidence and the arterial ischemic events and venous thrombosis rates of SSc in our database. We also investigated underlying the classical risk factors for venous thromboembolism (VTE) unprovoked (deep venous thrombosis and pulmonary emboli not associated with cancer, recent surgery, hospitalization, fracture and pregnancy) and ASCVD (myocardial infarction and stroke).

Methods: We performed a retrospective analysis of 212 patients (86% female) with a diagnosis of SSc. We identified a total of 7 (3%) and 26 (12%) patients respectively with arterial ischemic events or venous thrombosis, and 6 (3%) additional patients had both arterial and venous thrombosis, with an event duration of median 10(5-34) and 6 (0-55) years of follow-up. Venous thrombosis (VT) is present in 26 patients (12%), active or historic neoplasia is present in 4 patients (15%) of VT. In comparison with patient without VT, 20 patients (11%) have a neoplasia. Arterial ischemic events are also most frequent in female sex n=6 (66%) with all patients (100%) have a limited sclerosis, antinuclear antibodies and Raynaud phenomena, but no difference with the control group without thrombotic events. The prevalence of most cardiovascular disorders was found to be higher in the SSC with limited sclerosis than in diffuse sclerosis. The tobacco use, alcohol is not associated of increase risk of thromboembolic events. The presence of other autoimmune tissue disorders is not significant (p=0.0003) associated of increase rate among patients with SSc with thrombotic events than without. Further adjustment for medications (aspirin, NSAIDs, glucocorticoids, statins, oral anticoagulants, and platelet inhibitors) and comorbidities yielded results similar to the main analyses, except for ischemic stroke.

Conclusion: In this monocentric study, SSc was associated with greater risks of venous thrombosis and ischemic events, with a mortality rate in group with arterial ischemic events. There is no significant statistic difference associated of the classical risk factors of venous thromboembolism, comorbidity and the arterial ischemic events and venous thrombosis in systemic sclerosis.

A NOVEL MARKER IN SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: PEROXIREDOXIN-4

Keywords: Biomarkers, Systemic sclerosis, Lungs
G.T. Alp1, H. Karadeniz2, V. Vasi3, A. Avanougu Guler4, A. Erden2, H. Küçük2, O. Gubashar5, A. Tulat2, M. A. Öztürk6. 1Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey; 2Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 3Gazi University Faculty of Medicine, Medical Biochemistry, Ankara, Turkey

Background: Krebs von den Lungen-6 (KL-6) and surfactant protein D (SP-D) are suggested as useful markers for the evaluation of systemic sclerosis associated interstitial lung disease (SSc-ILD) [1-3]. Increased expression of Peroxiredoxin-4 (PRDX-4) mRNA had been demonstrated in the lung tissue of patients with ILD [4]. PRDX-4, a member of peroxidases family, has not been studied as a marker in SSc-ILD before.

Objectives: Aim of this study was to assess the clinical significance of serum PRDX-4 as a viable alternative to KL-6 and SP-D in patients with SSc-ILD.

Methods: The serum PRDX-4, KL-6 and SP-D levels were determined by ELISA in 61 patients with SSc(34 with ILD and 27 without ILD) and 28 healthy controls. Lung function parameters were assessed, the extent of ILD was measured by a HRCT score.

Results: PRDX-4 levels were significantly higher in patients with SSc-ILD than in SSc without ILD patients and controls (14.27(26.14) vs. 10.17(3.22) vs. 9.68(2.06) ng/ml, median(IQR), p=0.001). KL-6 levels were also remarkably different between groups [134.25(224.28) vs. 103.90(34.81) vs. 92.84(28.26) U/ml, median(IQR), p=0.002]). Moreover PRDX-4, KL-6 and SP-D levels in patients with progressive ILD were significantly higher in stable ILD patients >0.001. PRDX-4, KL-6 and SP-D were correlated each other(p<0.01). Receiver operator characteristic curve analysis demonstrated high sensitivity and specificity of PRDX-4 for the determination of SSc-ILD and progressive pulmonary fibrosis. (AUC=0.705, p=0.01 and AUC=0.936, p<0.001).

Conclusion: PRDX-4 is more sensitive and specific than KL-6 and SP-D and it is a potentially useful marker in assessing intestinal lung disease and progressive pulmonary fibrosis in patients with SSc.

AB0846 EFFICACY OF RITUXIMAB IN IDIOPATHIC INFLAMMATORY MYOPATHIES. EXPERIENCE ON 36 PATIENTS FROM A PROSPECTIVE MONOCENTRIC COHORT

Keywords: Myositis

A. Gamba1, L. Iacarino2, E. Cocconcelli3, E. Zanatta2, R. Depascale2, L. Iennari, E. Balestri3,3, M. Zen2, M. Gatto2, A. Doria2.1 Padova University Hospital, Department of Rheumatology, Padova, Italy; 2 Padova University Hospital, Department of Rheumatology, Padova, Italy; 3 Padova University Hospital, Department of Pneumology, Padova, Italy

Background: Idiopathic inflammatory myopathies are a heterogeneous group of autoimmune disorders characterized by muscle inflammation frequently associated with the involvement of other organ systems. Due to variety of presentations and severity degree, treatment of inflammatory myopathies is challenging. Considering the immunopathogenic role of B cell in myositis, Rituximab (RTX), as B cell depleting agent, could be an effective therapy in patients refractory to others immunomodulatory drugs.

Objectives: The aim of the present study is to demonstrate the efficacy of RTX for the treatment of idiopathic inflammatory myopathies in multi refractory patients. We also considered the effectiveness of a low-dose RTX as a remission-maintenance therapy.

Methods: From a monocentric cohort of patients with inflammatory myopathies, we considered all patients who have been treated with RTX (2 infusions of 1 gram, week 0-2). We also considered low-dose RTX as a single dose of 1g every 6 months. The response to RTX was considered based on physician judgement (complete CR, partial PR, no-response NR), focused on muscle and lung manifestations. Improvement in muscle involvement was based on reduction of 30% of creatine kinase levels and/or an increase in Manual Muscle Test score (MMT-8) of 20%. Intestinal Lymphatic disease (ILD) was evaluated by pneumologist judgment based on chest computer tomography and spirometry. A response was considered partial if it was maintained less than 6 months from RTX administration and complete if it persisted more than 6 months.

Results: Thirty-six patients were included, 15 with diagnosis of polymyositis, 13 with antisynthetase syndrome, 6 with dermatomyositis, 1 with inclusion body myositis and 1 with necrotizing myopathy. Anti-Jo1 autoantibodies were found in 12 patients, anti-SSA in 9, anti-SSB in 5, anti-PM/Scl 75 in 2, anti-Mi2 in 2, anti-PL1 in 1, anti-PL2 in 1, anti-PL in 1, anti-SSB in 1, anti-TIF1 in 1, anti-Ku in 1 and anti-Sp100 in 1. Most patients (50 %, n=18) were treated with RTX for muscle involvement, 17 % (n=6) for ILD, 33 % (n=12) for both muscular and lung disease. All patients received oral glucocorticoid before starting RTX administration. The others previous therapies were: methotrexate in 72% of patients, myophenolate motefil in 50%, IVIG in 27%, azathioprine in 22%, hydroxychloroquine in 14%, cyclosporine in 14%, leflunomide in 11%, tacrolimus in 3%, cyclophosphamide in 3%. We observed CR to RTX in 70% of patients, PR in 19%, NR in 11%. In the subgroup treated for muscle involvement (n=18), we found a CR in 10 patients, a PR in 5 and NR in 3. In patients with ILD, 8 patients got a CR and 1 PR. In the group of patients with both lung and muscle manifestations, we observed 10 CR, 1 PR and 1 NR. Five patients were treated with a low dose maintenance therapy after having achieved remission with standard dose. Three patients had a diagnosis of polymyositis, one of dermatomyositis and one of antisynthetase syndrome. Patients received a minimum of 3 infusions and a maximum of 5 infusions of low dose RTX. Therapy was administered for an average of 3 years. All of them maintained a CR to RTX.

Conclusion: In our cohort, RTX was effective in 89% multi-drug refractory patients and the low-dose was efficacious as a maintenance therapy in all cases.

AB0847 COMORBITIES IN IDIOPATHIC INFLAMMATORY MYOPATHIES: DATA FROM THE MYOCITE COHORT

Keywords: Autoantibodies, Myositis, Comorbidities

E. Conticini1, T. Khursheed2, A. K. Anuja3, V. Agarwal3, L. Gupta4,5,6.1 University of Siena, Rheumatology Unit, Department of Medicine, Surgery & Neurosciences, Siena, Italy; 2Pakistan Institute of Medical Sciences, Rheumatology, Islamabad, Pakistan; 3Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India; 4Royal Wolverhampton Hospitals NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom; 5City Hospital, Sandwell and West Birmingham Hospitals NHS Trust, Department of Rheumatology, Birmingham, United Kingdom; 6Centre for Musculoskeletal Research, School of Biological Sciences, The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom

Background: Patients affected by idiopathic inflammatory myopathies (IIM) may suffer from comorbidities such as cancer and cardiovascular diseases, calling for optimized evaluation and additional management.

Objectives: We aimed to explore the prevalence and profile of comorbidities in a cohort of Indian patients diagnosed with IIM, and to explore their association with a disease subtype and autoantibodies.

Methods: Information on demographics, disease subtype and autoantibodies in Indian patients with IIM were extracted from the MyoCite dataset. Comorbidities were classified as autoimmune, cardiovascular, cancer, infections, Diabetes Mellitus and others. Pearson's chi-square and Fisher’s exact test were used to assess differences in the occurrence of any comorbidity between the various IIM subtypes and antibodies.

Results: Of 250 patients (F:M 3.9:1, median age 36.0 ± 15.4), the majority (110, 44.0%) were diagnosed with dermatomyositis (DM), followed by overlap myositis (OM) (59, 23.6%) and anti-synthetase syndrome (ASS) (45, 18.0%). Patients with comorbidities had a higher median age (40 ± 13.9 years) compared to patients without comorbidities (35 ± 16 years) without any statistical significance. A statistically significant increase (P<0.001) in female to male ratio was observed in patients with comorbidities (10.5:1) compared to patients without comorbidities (2.3:1). Female gender was associated with higher odds of any comorbidity (OR = 4.58; 95 CI = 2.17-9.65). Comorbidities were identified in nearly half (115, 46.0%) of the patients, with autoimmune comorbidities being the most common (72/115, 62.6%) followed by cardiovascular (38/115, 33.0%) and infections (24/115, 20.9%). Hypertension was identified as the most common comorbidity (38/115 33.0%) overall, followed by thyroiditis (26/115, 22.6%) and mixed connective tissue disease (23/115, 20.0%). Statistically significant differences (P<0.001) in frequency of comorbidities was observed in DM (OR = 0.21; 95 CI = 0.12-0.36) and OM (OR = 136.3; 95 CI = 18.44-1008.45).

Conclusion: Despite younger population with IIM, comorbidities are frequently reported in nearly half of Indian patients with IIM. It is noteworthy that autoimmune comorbidities and infections are fairly common with substantial cardiovascular risk calling for optimized assessment and care.

### DISEASE BURDEN IS ASSOCIATED WITH POOR PATIENT-REPORTED OUTCOMES IN WOMEN'S HEALTH-RELATED DOMAINS OF QUALITY OF LIFE IN SYSTEMIC SCLEROSIS: A STUDY ON 100 PATIENTS BY A MULTIDIMENSIONAL QUESTIONNAIRE

**Keywords:** Systemic sclerosis, Quality of life, Gender/diversity issues

M. G. Lazzaroni1, L. Moschetti1, E. Pedretti1, A. Lojacono2, S. Zatti3, F. Ramazzotto2, A. Tincani1, F. Franceschini, P. Airò1, L. Andreoli1.

**Background:** Systemic Sclerosis (SSc) affects mostly women, with a significant impact on different domains of their quality of life (QoL).

**Objectives:** We aimed to identify clinical and demographic features of SSc women associated with impairment in specific QoL domains related to women's health (gynecological issues, sexual dysfunction, family planning), by means of a multidimensional ad hoc-created questionnaire.

**Methods:** The questionnaire was administered to consecutive SSc female patients attending our Unit over one year (May 2021-January 2022). The Female Sexual Function Index (FSFI) questionnaire was also administered. Clinical and demographic data were retrieved from clinical charts.

**Results:** One hundred women were enrolled, with a median [IQR] age of 59 [43-67] years, median disease duration of 11 [6-17] years; 75% had limited cutaneous involvement (lcSSc); 43% had anti-centromere antibodies; 48% had received diagnosis during reproductive age (<45 years). Non-regular gynecological follow-up visits were reported by 40% of patients. They were older at diagnosis and at questionnaire, more frequently post-menopausal (p=0.003, OR 4.96, 95%CI 1.68-16.6) and required immunosuppression more frequently (p=0.006, OR 2.37, 95%CI 1.02-5.50) than those regularly attending visits (Table 1). A negative impact on SSc on sexual function was reported by 60% of patients. Among the 39 patients who compiled the FSFI questionnaire, 51% displayed sexual dysfunction (score ≤26.55). These women were older and more treated (p:0.013, OR 4.6, 95%CI 1.69-13.3) as compared to patients with normal sexual function (Table 1). Among 48 patients who were diagnosed during reproductive age, 54% wished for a pregnancy after diagnosis and 30% did not reach the desired family size. These were more frequently affected by digital ulcers (p=0.045, OR 10.5, 95%CI 1.03-103) as compared to those who satisfied their family plan (Table 1).

**Conclusion:** Older age at diagnosis, digital ulcers, and immunosuppressive treatment were associated with a negative impact on women's health-related domains of QoL in SSc patients. The disease burden impairs sexual function and adherence to regular gynecological visits and receiving diagnosis during reproductive age increases the likelihood for a reduced family size. Clinicians caring for SSc women should be aware of the relevance of these domains of QoL, not usually considered in everyday practice as treatment targets.

Keywords: Descriptive Studies
C. Kavadichanda1, P.2, M. Gorijavolu1, S. K. Dunga1, S. Kar2, JIPMER, Clinical Immunology, Pondicherry, India; JIPMER, Preventive and Social Medicine, Puducherry, India

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of diseases manifesting with involvement of the musculoskeletal, mucocutaneous and pulmonary domains. Studies have shown that the health-related quality of life (HRQoL) in IIM is poorer than that in the general population with decreased muscle strength being associated with low HRQoL [1]. However, major-ity of the studies are cross sectional and the data on the use of EQ5D-5L based health utility measures in myositis is sparse.

Objectives: To quantify the EQ5D-5L based health utilisation scores and QALY in a cohort of IIM. To identify the determinants of gain in QALY in IIM.

Methods: This was a single center prospective study involving patients with IIM classified using the 2017 EULAR/ACR classification criteria. Patients were recruited between 2018 February and July 2022. All the patients were evaluated at 3 and 6 months with Manual muscle testing of 8 muscle groups (MMT-8), Functional index 3(FI3) and 2 minute walk distance (2MWD). The baseline and change in the core set measures. EQ5D-5L was administered to all the patients during each of their visits. The health utility scores for EQ5D-5L health states specific for Indian population was used (Table 1). The baseline and change in health-related quality and the impact of achieving early disease response was represented in Figure 1. Upon linear regression modelling with change in health utility scores at 0-3 months and 6 to-12 months the severity of disease at baseline determined the change. Improvement in MMT-8 and FI3 had significant predictability between 0-3 months but only change in MMT-8 had significant effect on improvement in health utility score between 3 and 6 months when adjusted for age and baseline disease status (Table 1).

Conclusion: The health-related quality of life at baseline and its improvement on follow up is extremely low in individuals with severe IIM. Achieving inactive disease status within 3 months results in significant QALY gain. Improvement in muscle power significantly determines improvement in health related quality of life when adjusted for other factors.

AHSCCT is based on the ablation of the immune-reactive system with high doses of chemotherapy and a subsequent regeneration of the immune system. **Objectives:** Study of the efficacy of AHSCCT in a multicentric cohort of patients with SS.

**Methods:** Descriptive study of patients with SS (ACR/EULAR 2013 criteria) treated with AHSCCT between 2002 and 2022. These clinical variables were reviewed (Raynaud’s phenomenon, pulmonary interstitial involvement, digital ulcers, presence of scleroderemic renal crisis) and activity index variables (Modified Rodnan Score, HAQ-DI).

**Results:** We included 11 patients with a mean age of 43±12.1 years, with a mean time of disease of 17±12.6 months. In all cases but one, the initial diagnosis was diffuse cutaneous SS, refractory to corticosteroids and at least one DMARD (Methotrexate n=7, Rituximab n=4, Azathioprine n=3, Tollicublum n=1). One patient had a limited cutaneous SS and was treated with AHSCCT due to a concomitant Hodgkin lymphoma. All patients (100%) had positivity for anti-nuclear antibodies and & (72.7%) for anti-ScI/0. 11 patients (100%) presented Raynaud’s phenomenon and sclerodactylly and 9 (81.8%) suffered from skin ulcers. 7 patients (63.6%) had interstitial lung disease and 1 patient had history of scleroderemic renal crisis. The conditioning treatment for the AHSCCT was cyclophosphamide and anti-thymocyte globulin with the exception of 1 patient who developed an infusion reaction (in which the globulin was stopped) and 1 patient with Hodgkin lymphoma (who received a different chemotherapy schedule). After the AHSCCT, 1 patient (9.1%) died of cardiorespiratory arrest after acute pulmonary edema the day +65. Other adverse events observed were febrile neutropenia (n=8, 72.7%), mucositis (n=4, 36.4%), confirmed infection (n=3, 27.3%) and serum sickness (n=3, 27.3%). The response of AHSCCT is summarized in table. An improvement in Modified Rodnan Score, skin ulcers and HAQ-DI was observed.

**Conclusion:** AHSCCT can be a therapeutic option in refractory and severe SS. These hopeful data must be ratified in larger studies.

**AB0853 ENDOTHELIAL DISFUNCTION MARKERS CAN BE REDUCED IN SYSTEMIC SCLEROSIS PATIENTS BY BETA-ADRENERGIC TREATMENT**

**Keywords:** Systemic sclerosis, Diet and Nutrition

A. Wolteczek1, Z. Zdrojewski2, M. Malgorzaczewicz2. 1Medical University of Gdańsk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland; 2Medical University of Gdańsk, Department of Clinical Nutrition, Gdańsk, Poland

**Background:** Systemic sclerosis is a chronic autoimmune disease which is represented by progressive fibrosis, vascular impairment and immune abnormalities. In recent years metabolic and endothelial factors were reported as elements which play role in pathogenesis of systemic sclerosis (SSc). Adipokines, mediators secreted by adipose tissue, depends on fat mass and nutritional status. Ghrelin, a gut hormone, is a key regulator of metabolism of glucose, meal initiation and appetite. Another metabolic factor myostatin, is a myokine produced by muscles and is negative regulator of muscle growth. Endothelial factors such as endothelin 1 (endothelin 1) or endogenous vasosonstriclor (endothelin 3) and asymmetric dimethylarginine (ADMA, endogenous nitric oxide inhibitor) are important markers for vascular dysfunction.

**Objectives:** The aim of the study was to evaluate serum concentration of ghrelin, myostatin, adiponectin, wsistatin, chemerin, leptin, interleukin 6 (IL-6), endothelin 1 and ADMA in relation to the nutritional status of patients with SSc, and impact different treatment on these levels.

**Methods:** Study population consisted of 56 SSc patients (47 females, 9 males) and 49 healthy persons (42 females and 7 males). Demographic and clinical...

Keywords: Autoantibodies, Myositis, Epidemiology

J. Kim 1, 3Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: The idiopathic Inflammatory Myositis (IIM) are heterogeneous with different clinical profiles associated with various myositis autoantibodies. Among the Myositis specific antibodies (MSA) antibodies against aminoacyl-tRNA synthetases(ARS) is related to the clinically unique IIM subsets, Antisynthetase syndrome(ASS). Objectives: The aim of this study was to identify the prevalence and clinical features of patients with ARS autoantibodies compared with other myositis antibodies in a single center cohort of IIM in Korea.

Methods: Adult patients diagnosed with IIM and positive for myositis antibodies were recruited in the myositis cohort from January 2020 to December 2022. Retrospective analysis was performed based on the clinical data including clinical features, laboratory data, high-resolution CT (HRCT) findings, and pulmonary function manifestations.

Results: Among 82 patients, 25 patients were positive for ARS autoantibodies and 57 patients had other myositis antibodies. The most common ARS antibody was anti-SSA/Ro (n=10) followed by anti-PL-7 (n=8), MSA other than ARS antibodies included anti-SRP (n=6), anti-TIF1γ (n=11) and anti-MDA-5(n=19). Anti-Ro52 was detected in 48 patients and 79.2% of which were accompanied by other antibodies. The most common clinical manifestations of patients with ARS antibodies were respiratory symptoms, more commonly experienced than patients with other myositis antibodies (84% vs. 47.4%, p=0.002). Meanwhile, muscle weakness (32.0% vs. 61.4%) and dysphagia (8.0% vs. 33.3%) were less frequently compared with patients with other myositis antibodies. In regard to laboratory findings, the ARS antibodies positive group showed higher inflammatory markers than other myositis antibodies group, the mean (SD) of erythrocyte sedimentation rate (ESR) was 53.6±34.56 and 33.7±24.3, respectively. Anti-Ro52 and anti-nuclear antibodies (ANA) cytoplasmic pattern were more detected in the ARS antibodies positive group. Interstitial lung disease (ILD) was also more commonly detected in patients with ARS antibodies than other myositis autoantibodies group (88.0% vs. 59.6%) and non-specific interstitial pneumonia (NSIP) was the most frequent pattern of ILD. However, there were no significant differences in the baseline pulmonary function between the two groups.

Conclusion: Patients with ARS antibodies experienced more respiratory symptoms while muscle weakness is less common clinical manifestations than patients with other myositis antibodies. Moreover, higher inflammatory markers and ANA cytoplasmic pattern along with Anti-Ro52 were more commonly detected in the ARS antibodies positive group.
Conclusion: There were no major differences in the baseline demographics such as disease duration, sex and age, and no major differences in disease severity as well as the percentage of use of immunosuppressants among the regions although some variation in SSc autoantibody specificity were observed.

Background: Proton Pump Inhibitors (PPIs) are widely used in the management of gastro-oesophageal problems in SSC. However, there is little evidence to support their empirical use in SSc, and long-term safety concerns have been highlighted in the general population [1,2].

Objectives: To examine clinicians' perspectives concerning PPI use in patients with SSc.

Methods: An online survey in the English language targeting healthcare providers (HCP) involved in the care of patients with SSc was developed and distributed through international networks and SSC associations. The survey was launched on 27th November 2022 and kept open for 3 weeks.

Results: Responses from 227 HCP from 36 countries were obtained. The majority (86.3%) were between 30-70 years old. Female and male gender were equally represented (M:48%, F:52%). Most respondents practiced in a university hospital (86%), the most common specialties represented were rheumatology (70.5%), internal medicine (10.6%), and gastroenterology (71%).

Conclusion: Overall, 68.8% of physicians agreed that gastroesophageal reflux disease (GERD) is a major cause of morbidity in SSc. Lifestyle modifications/non-pharmacological approaches alone were seldom (16%) considered as effective in controlling GERD symptoms. Only half of responders either ‘agreed’ (43%) or ‘strongly agreed’ (11%) that solid evidence supports PPI efficacy in SSC. PPIs were prescribed by 93% of HCP with the most commonly reported indications being: 1) dyspepsia, 2) GERD, 3) heartburn, and 4) other indications (5.2%), (0-10, where 10 is ‘very concerned’). There was no clear consensus whether PPI dose and/or frequency should be reduced in patients with refractory calcinosis: ‘disagree’ = 25.3%, ‘neutral’ = 48.4%, and ‘agree’ = 22.6%. In addition, around half of responders considered that patients should be on high-dose PPI long-term after lung transplantation (‘agree’ or ‘strongly agree’ = 49.8%) or were ‘neutral’ (42.9%). There were many confusions and misunderstandings about the use of PPIs in SSC, which led to poor understanding of the complications.

**ANTI-THYMOCYTE GLOBULIN EXPOSURE IS ASSOCIATED WITH TREATMENT RESPONSE IN PATIENTS WITH DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS UNDERGOING AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION**

**Keywords:** Biomarkers, Systemic sclerosis

Y. H. Chiu1,2, A. Djiver1, R. Admiraal3, A. Van Rheneren4, S. Nierkens5, J. M. Van Laar6, J. Spierings1,1. University Medical Centre Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands; 2. Tissue Service General Hospital, National Defense Medical Center, Division of Rheumatology/Immunology/Allergy, Taipei, Taiwan, Republic of China; 3. Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands; 4. University Medical Centre Utrecht, Department of Haematology, Utrecht, Netherlands; 5. University Medical Centre Utrecht, Center for Translational Immunology, Utrecht, Netherlands

**Background:** Autologous haematopoietic stem cell transplantation (HSCT) ameliorates event-free survival, skin thickening and lung function in patients with progressive diffuse cutaneous systemic sclerosis (dcSSc). Anti-thymocyte globulin (ATG) is a key lymphoablative constituent of conditioning protocols and is administered in a body weight-based dose. Response to HSCT and occurrence of infections is still highly variable across dcSSc patients. Studies in haematopo-oncological patients suggest that ATG exposure varies across subjects and impacts outcomes [1].

**Objectives:** To explore the relation between rabbit-derived ATG exposure, lymphocyte reconstitution and clinical outcomes in patients with dcSSc undergoing autologous HSCT.

**Methods:** We retrospectively analysed patients with dcSSc undergoing autologous HSCT between 2014 and 2020. ATG levels were measured in cryopreserved serum samples at four time points (day 1 and week 1, 2 and 4) after stem cell reinfusion. ATG exposure was estimated using population pharmacokinetics models [1]. Treatment response was defined as pulmonary stabilisation (with no decline more than 10% in forced vital capacity and 15% in diffusing capacity for carbon monoxide) and/or skin improvement (modified Rodnan skin score reduction of more than 30%). Differences between groups were examined with Wilcoxon rank-sum test for continuous variables and Fisher exact test for categorical variables.

**Results:** Fifteen patients were included in this study with median age 43 years-old (IQR 37–50). During a median follow-up of 45 months (IQR 19—66), 73% (n=11) of patients had a treatment response, and 27% (n=4) were non-responders. Eight (73%) responders achieved long-term remission and three (27%) responders had progressive disease in the follow-up, at a median time of eight months (IQR 5—17) post-HSCT. Although all patients received the same weight-based ATG dosage (75 mg/kg), ATG exposure varied across patients. ATG exposure was higher in responders than non-responders (p = 0.026, Table 1) but was not correlated with lymphocyte reconstitution or infection rate.

**Conclusion:** In our study, ATG exposure highly varied across dcSSc patients undergoing HSCT despite the same weight-based dosage. Responders had a higher ATG exposure than non-responders. More research into optimal ATG dosing is needed to improve HSCT outcomes.

**PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: A NATIONAL INPATIENT ANALYSIS**

**Keywords:** Lungs, Systemic sclerosis

F. Sami1, S. A. Sami2, S. Arora3, V. Reyes Pinzon1, L. Farrukh4, R. Attili5, 1. John H. Stroger Hospital of Cook County, Internal Medicine, Chicago, United States of America; 2. Trinity Health Oakland Campus, Internal Medicine, Pontiac, United States of America; 3. John H. Stroger, Jr. Hospital of Cook County, Rheumatology, Chicago, United States of America; 4. John H. Stroger, Jr. Hospital of Cook County, Internal Medicine, Chicago, United States of America; 5. Albany Medical Center, Internal Medicine, Albany, United States of America; 6. John H. Stroger, Jr. Hospital of Cook County, Internal Medicine, Chicago, United States of America

**Background:** Pulmonary arterial hypertension (PAH) is a chronic, progressive, and eventually fatal complication of Systemic Sclerosis (SS), affecting the prognosis and quality of life. Risk of PAH in SS is substantially high, and it causes early mortality. Non-specific manifestations of PAH can result in delayed diagnosis and result in poorer outcomes.

**Objectives:** We aim to study the prevalence and epidemiology of pulmonary arterial hypertension in SS, and impact of PAH on adult scleroderma hospitalizations in the United States population. We also aim to estimate the effect of PAH in SS on utilization of healthcare resources.

**Methods:** We utilized the National Inpatient Sample (NIS) to obtain pertinent data. Total adult hospitalizations with primary diagnosis of SS and consistent comorbidity of PAH were extracted from 2016-2019. We studied the demographic and epidemiological differences as well as mortality outcomes. Healthcare burden was estimated from total hospital charges (THC) and length of stay (LOS). Secondary outcomes including pulmonary embolism, atrial flutter/fibrillation, pneumonia, sepsis, cardiac & renal failure and ventilator requirements were also studied. Statistical analysis performed on STATA, with linear and logistic regression analysis. **Results:** Out of 128,685 adult scleroderma hospitalizations between 2016-19, 21930 (17%) presented with concurrent pulmonary hypertension. Females were significantly more in this group compared to patients with SS without PAH, representing approximately 85% of total admissions. Patients with PAH had a higher mean age (64.85±13.29 vs 62.56±14.51, P <0.000) as well. In terms of racial demographics, there was a significantly higher proportion of African American and significantly less Asians in the study group. Charlson comorbidity index was also higher in the PAH group. PAH was associated with higher adjusted odds ratio (aOR) for mortality (aOR: 1.39, p<0.001), increased LOS (6.64 vs 6.0 days, p<0.001) increased THC ($38313 vs $71016, p<0.001). It was also associated with significantly higher odds for cardiac failure (aOR 3.13) and ventilator requirement (aOR 2.15). Secondary outcomes of kidney failure, Pulmonary embolism, atrial flutter/fibrillation, and pneumonia recorded a significantly higher aOR for patients with PAH. No significant difference in cardiac arrest, sepsis, or respiratory failure was noted.

**Conclusion:** Pulmonary arterial hypertension in scleroderma is associated with worse overall outcomes in terms of mortality and morbidity, as well as much higher healthcare burden compared to SS without PAH. Also, PAH disproportionately affects African-American & Asian populations. Although advancements have been made in the treatment of PAH in SS, there still remains room for efforts directed towards early diagnosis and management to further improve outcomes for scleroderma patients.

**CLINICAL COURSES AND PREDICTORS OF LEFT VENTRICULAR SYSTOLIC DYSFUNCTION IN SYSTEMIC SCLEROSIS**

**Keywords:** Cardiovascular disease, Systemic sclerosis, Prognostic factors

J. Wanakit†, B. Pussadhamma†, A. Mahakkanukrauh, S. Suwannaroj, C. Foocharoen*. 1Khon Kaen University, Department of Medicine, Faculty of Medicine, Khon Kaen, Thailand

**Background:** Left ventricular systolic dysfunction (LVSD) is a cardiac involvement, resulting in its being the leading cause of death among patients with systemic sclerosis (SSc). Currently, no predictor of LVSD has been defined by longitudinal data for follow-up among SSc patients.

**Objectives:** We aimed to define the clinical course and predictors of LVSD among SSc patients.

**Methods:** We conducted a cohort study among adult SSc patients who were followed up at the Scleroderma Clinic, Khon Kaen University, between 2013 and 2020. Semi-parametric Cox regression analysis with robustness clustering by cohort identification number was used for evaluating the predictors of LVSD.

**Results:** Among the 55,056 person-years, LVSD was defined in 35 of 419 SSc patients for an incidence of 0.31 per 100 person-years. The majority were female (23 cases) with diffuse cutaneous SSc (dcSSc) (26 cases), and the median duration of the disease was 8.5 (IQR 4.9-12.9) years. Every 1-point increase in the modified Rodnan skin score (mRSS) and salt and pepper skin were strong predictors of LVSD, with a respective adjusted hazard ratio (HR) of 1.05 and 3.17. During follow-up, 26 cases (74.3%) had worsening LVSD. The strong predictors of the worsening of LVSD were every 1-point increase in mRSS (HR 1.05), every 1 mg increase in prednisolone treatment (HR 1.00), and every 1 U/L increase in creatine kinase (CK) (HR 1.001). Meanwhile, mycophenolate treatment was a protective factor against the worsening of LVSD in SSc (HR 0.15).

**Conclusion:** LVSD was frequently found in dcSSc, and most cases worsened during follow-up. The severity of skin thickness increases the risk of LVSD. High mRSS, steroid use, and high CK were predictors of worsening LVSD, while mycophenolate treatment might prevent the progression of LVSD. Steroids should be prescribed with caution to patients with longer disease duration.

**REFERENCES:**

[4] Foocharoen C, Pussadhamma B, Mahakkanukrauh A, Suwannaroj S, Nanagara R, and the lack of portability make them uncommon tools in clinical practice. In conclusion, HGS was positively associated with VM (r= 0.435, p = 0.003) and SPPB was negatively correlated with disease activity (y), modified Rodnan skin score (mRSS), the European Scleroderma Trials and Research Group (EUSTAR) SSc activity index (EScSG-AI), and the health assessment questionnaire (HAQ) were assessed. The muscle thickness was assessed by a real-time ultrasound device (Esaote S.p.A MyLab 50 X Vision; SãoPaulo, Brazil). An experienced ultrasound evaluator analyzed the muscle thickness of vastus lateralis (VL, cm), rectus femoris (RF, cm), vastus intermedius (VI, cm), and vastus medialis (VM, cm). Muscle strength was assessed by handgrip (HGS,kg) and physical performance was assessed by short physical performance battery (SPPB,points). Frequency analysis and Pearson’s or Spearman’s correlation coefficients were explored. The appropriate significance was considered when p<0.05. **Results:** We included 45 patients with SSc, 32 (71.1%) with diffuse disease. The median age was 62.00 (54.50-66.50) years and the disease duration was 4.00 (2.00-8.00) years. The mean of muscle thickness was 4.00 (2.00-8.00) and the HAQ was 0.62 (0.25-1.06). The mean of muscle thickness was 1.38 ± 0.32 cm, RF 1.06 ±0.35 cm, VM 1.16 ±0.47 cm, and VI 1.17 ±0.33 cm. The mean of HGS was 18.64 ±9.71 kg and the median SPPB was 10.00 (9.00-11.50) points. The disease activity by EScSG-AI was negatively associated with VL (r = -0.410, p = 0.016) and VI (r = -0.394, p = 0.021). In addition, HGS was positively associated with VM (r = 0.435, p = 0.003) and SPPB was positively associated with VL (r = 0.354, p = 0.017).

**Conclusion:** Low quadriceps muscle thickness is associated with higher disease activity. As expected, our findings suggest that there are positive associations between muscle thickness with strength and physical performance in SSc women. Our findings highlight the importance of aiming for disease activity control because it may indirectly influence the muscle mass of SSc women.

Keywords: Organ damage, Prognostic factors, Systemic sclerosis

C. Steiro Santos1, P. Pérez-García1, J. Ordas Martinez1, C. Moriano1, C. Álvarez Castro1, J. González Fernández1, 2 Complejo Asistencial Universitario de León, Rheumatology, León, Spain

Background: Nailfold capillaroscopy (NFC) has been suggested as a potential biomarker of disease severity in systemic sclerosis (SSc). Several studies report the association between capillary loss and disease severity however, the association of NFC abnormalities with novel severe organ involvement/progression in SSc has not been evaluated.

Objectives: We aim to evaluate the association of nailfold capillaroscopy (NFC) with novel major organ involvement/progression in SSc.

Methods: Follow-up data from patients with SSc registered between 2000 and 2022 were analysed. Patients underwent NFC at baseline. Novel severe organ involvement/progression was defined as new or progressive involvement of peripheral vasculature, lungs, heart, skin, gastrointestinal, kidney, musculoskeletal at 12 and 24 months of follow-up. The following NFC parameters were evaluated: capillary density, haemorrhages, enlarged and giant capillaries, avascular areas, organization of capillary architecture and scleroderma pattern (ear/active/late). Logistic regression modelling was run to assess associations between NFC parameters and the occurrence of novel severe organ involvement and/or progression and risk factors.

Results: 113 patients with SSc were included, 70 patients (61%) developed novel overall severe organ involvement/progression: 39 patients (56%) during the first 12 months and 31 patients (44%) from 12 to 24 months of follow-up. 11% of patients developed novel peripheral vascular involvement, 21% developed novel interstitial lung disease (ILD), 11% had progression of known ILD, 6% had novel pulmonary hypertension, 11% had skin progression, 10% had novel heart involvement, 10% had novel gastrointestinal involvement, 6% had scleroderma renal crisis and 13% had novel musculoskeletal involvement. Table 1 summarises the significant associations between NFC and novel severe organ involvement/progression during follow-up. Loss of capillary density was associated with overall severe organ involvement (p = 0.002), peripheral vascular involvement (p = 0.03), new ILD (p = 0.04) and skin progression (p = 0.01); avascular areas were associated with overall severe organ involvement (p = 0.03), new ILD (p = 0.03) and scleroderma pattern was associated with overall severe organ involvement (p = 0.03), peripheral vascular involvement (OR p = 0.04), new ILD (p = 0.004) and skin progression (p = 0.04).

Conclusion: NFC may be a potential biomarker in SSc for predicting novel severe organ involvement and/or progression. Abnormal capillary density, avascular areas and scleroderma pattern are predictors of overall severe organ involvement, peripheral vascular involvement, novel progression of ILD and skin progression.

Clinical Immunology, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy

Background: Cancer-associated myositis (CAM) remains a clinical challenge and established risk factors include older age, male sex, dermatomyositis (DM), and specific antibodies, including anti-TIF1gamma and -MJ/NXP2 [1]. However, a recent report suggests a lower risk of malignancy in -TIF1gamma positive patients with other concurrent autoantibodies (2,3), whereas the protective role against malignancy of antisyntathetease or anti-Mi-2 antibodies is being questioned [1].

Objectives: To describe the demographic, clinical, and serological characteristics of a cohort of patients with CAM in a specific autoantibody profile.

Methods: Retrospective cohort analysis on electronic clinical charts, autoantibody analysis by serum immunoprecipitation and ELISA.

Results: Malignancy was observed in 17 (76%) patients with IIM, in 13/17 (76%) within 5 years before or after IIM diagnosis and cancer relapse or progression in 7 cases; 2/17 were men with a median age of 56 years. Breast cancer was the most frequent, followed by lung, thyroid, ovarian, and lymphoma. Four patients died, three for cancer-related complications and one for severe refractory IIM. Muscle injury was observed in 17/17 (76%) while 2/17 experienced dysphagia. Skin lesions were present in 14/17 (82%) patients, while ILD (24%) and arthritis (18%) rarely occurred; no cases of myocardial involvement were described. Anti-Ro52 was the most common antibody (5/17 – 29%) in our cohort, detected as the only specificity in 2/5 cases. Anti-TIF1gamma was described in 4/17 (24%), one case with concurrent -Ro52, followed by antisyntathetease (3 – 18%), -Mi-2 (2 – 12%), -MJ/NXP2, -SAE1, -SRP (1 each – 6%). Combined, anti-EB2/E3 PDH (AMA) and anti-Ro positivity was found in a patient who developed lymphoma and cholangiocarcinoma within two years from IIM. We compared CAM patients with (n=4) and without (n=13) serum anti-TIF1gamma (Table 1). Although not reaching statistical significance, dysphagia and skin disease were more frequently observed with anti-TIF1gamma, whereas arthritis, Raynaud’s phenomenon, and capillaroscopy alterations were rarer in such group. Prevalence of early-stage cancer seemed more frequent with anti-TIF1gamma, 3/13 patients without anti-TIF1gamma died due to cancer-related causes; the only death observed in the TIF1gamma positive group was due to progressive IIM, and occurred in a patient with complete cancer remission.

Conclusion: We observed that DM remains the most common clinical subset of CAM, but other myositis phenotypes can also be observed. Anti-TIF1gamma remained the more prevalent autoantibody in CAM along with anti-Ro52. The role of AMA positivity may warrant further investigation, particularly in patients with seronegative CAM.

IODIOPATHIC INFLAMMATORY MYOPATHIES AND CANCER RISK STRATIFICATION

Keywords: Myositis, Malignancy

A. Hoeve,1 M. Tomsic1, K. Perdan-Pirkmajer1,1 University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia

Background: Patients with idiopathic inflammatory myopathies (IIMs) are at increased risk of cancer, particularly in the first ±3 years of the disease, and a cancer risk stratification was proposed recently [1], to improve cancer screening in IIMs.

Objectives: The aim of our retrospective study was to determine the frequency, temporal relations, and cancer types, as well as to evaluate the performance of proposed cancer risk stratification tool in our well-defined IIM cohort.

Methods: We analyzed medical records of IIM patients diagnosed between January 2005 and December 2020 and followed at our rheumatology centre of a median (IQR) 72.6 (35.1; 126.9) months. The development of cancer, its location and temporal relationship to IIM diagnosis were extracted. We applied the proposed cancer risk stratification [1] in a cohort of our patients.

Results: In a cohort of 175 IIM patients (122 females, 69.7%), 38 patients (21.7%; 24 females (19.7%) and 14 males (26.4%)) developed 41 cancers. Fifteen cancers (39.5%) were diagnosed or were active/relapsing within the two years prior to diagnosis of IIM, 10 cancers (26.3%) were diagnosed concurrently with IIM, and 16 (39.0%) cancers were diagnosed during the IIM follow up (9 (22.0%) of them during the first 3 years of the follow up) (Figure 1, Panel A). The most frequently diagnosed cancers were breast and gynaecologic cancer in females (20.0% each), and urogenital cancers in men (43.8%). The cancer location (overall and sex stratified) is presented in Table 1. The Figure 1, panel B shows the stratification of patients to their estimated risk of developing cancer, and the actual proportion of patients who develop cancer. Based on the estimated risk, 6.3%, 46.3% and 47.4% IIM patients were allocated into low-, intermediate- and high-risk group, respectively. While there were no episodes of cancer from -2 years to +3 years of follow up in the low-risk group, 12.5% patients in the intermediate-risk group, and 31.3% in the high-risk group developed cancer during this time interval.

SEASONAL VARIATION OF SERUM KL-6 LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED WITH INTERSTITIAL LUNG DISEASE

Keywords: Systemic sclerosis

H. Hirose1, T. Higuchi1,2, K. Takagi2, A. Tochimoto1, Y. Kawaguchi1, M. Harigai1.
1Tokyo Women’s Medical University Hospital, Division of Rheumatology, Department of Internal Medicine, Shinjuku-ku, Japan; 2Tokyo Women’s Medical University, Division of Multidisciplinary Management of Rheumatic Diseases, Division of Rheumatology, Department of Internal Medicine, Shinjuku-ku, Japan;

Background: Recent studies have shown that serum KL-6 levels were useful for diagnosing and estimating prognosis in patients with systemic sclerosis-associated with interstitial lung disease (SSc-ILD) [1-4]. Additionally, KL-6 has the potential for assessing the activity of SSc-ILD; however, it may fluctuate irrespec- tive of disease activity [5]. Identifying the reasons for fluctuation will lead to the utilization of this non-invasive tool. Based on our clinical experience, serum KL-6 levels may have seasonal variations.

Objectives: We aimed to evaluate whether serum KL-6 levels are affected by season in patients with SSc with ILD (SSc-ILD).

Methods: This is a single-center, retrospective observational study. The diagnos- is of SSc was according to the 2013 ACR/EULAR classification criteria, and the presence of ILD was confirmed by computed tomography (CT) or high-resolution CT (HRCT). We defined summer as July to September and winter as December to January. SSc-ILD patients with data of serum KL-6 levels in the 2015 winter (from December 2014 to January 2015), 2015 summer, and 2016 winter were included. Patients with comorbidities that could affect serum KL-6 levels, such as malignancy, pneumocystis pneumonia and alveolar proteinosis, and patients who did not confirm the change in the extent of ILD by chest CT during the observational period were excluded. The extent of ILD was calculated as the average of CT images at the five predefined levels [6], and scoring was blinded. Differences in serum KL-6 levels between summer and winter were analyzed by the Wilcoxon signed-rank test, followed by the Bonferroni correction for adjusting multiple comparisons.

Results: Sixty patients with SSc-ILD were included. 53 (88%) patients were female. At baseline, the median age was 61 (interquartile range [IQR]: 44–66) years, and the median disease duration was 7.7 (IQR: 4.2–13) years. 34 (57%) patients had diffuse cutaneous SSc (Table 1). Regarding the extent of ILD, 15 (25%) patients had a lesion area greater than 20%, 8 (13.3%) patients had changed in the extent of ILD, and 52 (84.6%) patients were unchanged. Serum KL-6 levels were significantly higher in the winter than in the summer (2015 summer vs 2015 winter: 585 IU/L vs 648 IU/L, p < 0.0001; 2015 summer vs 2016 winter: 585 IU/L vs 690 IU/L, p < 0.0001). However, there was no difference between the 2015 winter and 2016 winter (p=0.62) (Figure 1). Regarding 52 patients with stable ILD, similar results were obtained (2015 summer vs 2015 winter: 736 IU/L vs 860 IU/L, p < 0.0001; 2015 summer vs 2016 winter: 736 IU/L vs 815 IU/L, p < 0.0001; 2015 winter vs 2016 winter: 815 IU/L vs 860 IU/L, p=0.63).

Conclusion: Serum KL-6 levels may fluctuate regardless of the activity of SSc-
ILD. The result of our study may aid the interpretation of serum KL-6 testing.

LOW STARTING DOSE AND TITRATION OF NINTONANDBIN FOR SSC-ILD: ANALYSIS OF TOLERABILITY IN A SINGLE-CENTER COHORT

Keywords: Systemic sclerosis, Real-world evidence, Lungs

E. Fiorentini1, F. Bonomi1, L. Cometi1, G. Lepri1, S. Bellando-Randone1, S. Guiducci1, 2Careggi University Hospital, Rheumatology, Firenze, Italy

Background: Interstitial lung disease (SSc-ILD) is a common manifestation of Systemic Sclerosis (SSc) and to date few therapies are available [1]. Nintendanib (NTD) is a promising drug, but its use is often limited by intolerance, mainly by gastrointestinal adverse events (GI AEs). As reported in the SENSCIS trial [2] GI AEs related to NTD treatment (150mg bid) occur in >70% of cases, in particular diarrhea (75.7%), nausea (36.7%), vomiting (24.7%), weight loss (11.8%), abdominal pain (11.5%) and alterations of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) (13.9%).

Objectives: We investigated the safety and tolerability of an up-titration strategy of NTD until the maximum tolerated dose (max 150mg bid) in our cohort of SSC-ILD patients.

Methods: Evaluation of SSc patients followed at our Rheumatology Unit, treated with NTD according to clinical indication with a dose escalation regimen: 100mg die for 7 days, then 100mg bid for 7 days, then 150mg + 100mg/die for 7 days, and finally 150mg bid. At baseline, demographic, clinical and disease features were collected, NTD GI tolerability was clinically evaluated at 1 (T1), 3 (T3) and 6 (T6) months from the beginning of the treatment.

Results: 12 SSC-ILD patients were enrolled, all females, with a mean age of 62.5 ± 12.7 years and disease duration of 9.2 ± 8.8 years (from the first non-Raynaud symptom). The more frequent disease specific antibody was anti-topoisomerase I (50%) followed by anti-centromere (8.3%). ILD pattern at HRCT was non-specific interstitial pneumonia (NSIP) in 25% of the patients, fibrosing NSIP in 50% and usual interstitial pneumonia (UIP) in 25%. The mean FVC % predicted was 66.7%, dysmotility, vomit, and dyspepsia in 8.3% each. Table 1 shows GI AEs at T1, T3 and T6 from NTD beginning. At T6 50% of patients had nausea, 50% diarrhea, 37.5% abdominal pain and 25% referred weight loss. No one showed vomit and AST/ALT alterations. Only 3 patients reached 150mg bid (Figure 1), while 4 got at least to 100mg bid and 1 patient suspended the drug after 3 months due to vomit.

Conclusion: These data, although limited to a small cohort, suggest that a gradual dose escalation of NTD in SSC-ILD may improve the tolerability of the drug, with a lower incidence of GI AEs (≤50%) and AST/ALT elevation. Although only 3 patients reached the maximum dose, most of the cohort managed to do not exceed 100mg bid. This approach can be a good compromise in the management of ILD in SSc patients, knowing that the dose reduction to 100 mg bid does not significantly compromise the efficacy of NTD in reducing disease progression [3]–[5]. Studies of larger populations are needed to support these data.

IMMUNE CHECKPOINT INHIBITOR-ASSOCIATED MYOPATHY

Keywords: Myositis, Targeted synthetic drugs

M. Pavia Pascual1, N. De La Torre Rubio1, M. Machattou1, P. Navarro Palomo1, C. Navarro Joven1, M. Alonso de Francisco1, C. Barbadillo Mateos1, C. Merino Argumánez2, H. Godoy1, M. Fernandez Castro1, B. Garcia-Magallon1, J. Sanz1, J. F. De Villa1, J. L. Andrés Sánchez1, J. Campos Esteban2, Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Madrid, Spain

Background: In recent decades, immunotherapy has changed the management and prognosis of cancer patients. Immune checkpoint inhibitors, such as those targeting PD-1 and PD-L1, are used for some types of cancer; however, their use has been associated with the appearance of immune-mediated adverse events. Among these, those related to the field of rheumatology are relatively frequent, joint involvement being the most common, followed by muscle involvement (myalgias 4%, myositis 1%).

Objectives: To describe oncologic patients who developed immune checkpoint inhibitors-related myositis.

Methods: All patients from the oncology department of a tertiary hospital, referred to rheumatology and diagnosed with immune-mediated myositis due to immune checkpoint inhibitors were collected. A descriptive analysis was performed.

Results: Five patients were analyzed, 60% male, with a mean age of 65.8 years (56-78 years). The types of cancer were: melanoma (n=2), gastroesophageal...
juncti(c=1), cavum cancer (n=1) and pancreatic cancer (n=1); in all advanced stages with lymph node and/or metastatic involvement. The immuno-therapy employed was: Nivolumab (PD-1 inhibitor) in three patients, Pembrolizumab (PD-1 inhibitor) in one patient and Darvulamab (PD-L1 inhibitor) in one patient; all at standard doses. Mean time from onset of symptoms was 4 months from the day of drug initiation (1-10 months). In all 5 cases, the drug was discontinued with the onset of clinical symptoms and oral prednisone was prescribed at a dose between 10 and 20 mg per day. The symptom present in all patients was pain and weakness of proximal limbs (100%). In addition, one patient had ankle arthritis and another had dermatomyositis with typical cutaneous involvement (heliotrope erythema, V sign). In 3 patients there was an elevation of CK levels that resolved one month after discontinuation of the drug. Also, 3 patients, developed myositis-specific antibodies (AntiPM75 and Anti Mi2, anti-PL7 and anti-TIF1gama) that disappeared with drug withdrawal. One patient had anti-Ro52 and Ro60 antibodies that remain positive. Two patients underwent muscle MRI: one showed fatty infiltration in the gluteus medius and atrophy with fatty infiltration in the right rectus femoris (image); in the other patient, signs of inflammatory myositis in the bilateral adductor group and in the right gluteus medius and gluteus minimus and fibrosing myositis in the iliac muscle was described. In both cases, the signs of myositis had disappeared in the control PET scan 5 months after drug discontinuation. In 4 patients, symptoms subsided in less than one month. One patient required the association of methotrexate to achieve corticosteroid withdrawal.

Conclusion: In our hospital, a total of 5 patients undergoing oncological treatment with immune checkpoint inhibitors have developed, in a mean time of 4 months from the start of the drug, a myopathy associated in 60% with the appearance of myositis-specific antibodies. This represents 1.6% of the total number of patients treated with these three drugs in our hospital.

Withdrawal of the drug and treatment with prednisone at intermediate doses allowed clinical remission and normalization of laboratory and imaging tests.

AB0870 ANTI-HMGCR AUTOANTIBODY LEVELS IN THE FOLLOW-UP OF STATIN-INDUCED IMMUNE-MEDIATED NECROTIZING MYOPATHY. MULTICENTRIC STUDY OF 24 PATIENTS

Keywords: Myositis, Autoantibodies, Diagnostic Tests

D. Martínez-López1, D. Prieto-Peña2, C. Corrales-Selaya2, P. Szczypa3,4, A. Notarincola5,6,7, M. López Hoyos8, R. Blanc9,10, I. E. Lundberg11,12, M. Dastmalchi11,12, Hospital de Sierrallana, Rheumatology, Torrelavega, Spain; 2Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain; 3National Institute of Geriatrics, Rheumatology and Rehabilitation, Rehabilitation, Rheumatology, Warsaw, Poland; 4Medical University of Warsaw, Neurology, Warsaw, Poland; 5Department of Medicine, Karolinska Institute, Rheumatology, Stockholm, Sweden; 6Karolinska University Hospital, Department of Gastro, Dermatology and Rheumatology, Stockholm, Sweden; 7Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden; 8Hospital Universitario Marqués de Valdecilla, Immunology, Santander, Spain

Background: Statin-induced immune-mediated necrotizing myopathy (IMNM) is associated with anti-3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR) autoantibodies. It is characterized by elevated creatine kinase (CK) levels, and severe muscle weakness. Measuring disease activity is problematic, since it is challenging to differentiate it from damage. The utility of the quantitative analysis of anti-HMGCR autoantibodies during the follow-up has not been thoroughly studied.

Objectives: To assess the usefulness of measuring the levels of anti-HMGCR autoantibodies in relation to response to treatment.

Methods: We included patients with a consecutive patients diagnosed with statin-induced IMNM according to the definition of the European Neuromuscular International Workshop 2016 (1) and positivity for anti-HMGCR autoantibodies in two centers from Spain and Sweden from January 2017 to November 2022. All patients were followed for at least 3 months to be included. Clinical data was extracted retrospectively from the patients' medical records. Remission was defined as no disease activity assessed by expert rheumatologists according to the 2016 ACR/EULAR response criteria. This study was not a randomized controlled trial.

Results: Patients were followed for a median of 2.5 years. At the last follow-up, 60% of patients were in remission. In 60% of the patients, CK levels improved or normalized. Anti-HMGCR autoantibodies were detected in 95% of the patients at diagnosis, and their levels varied with disease activity. Anti-HMGCR autoantibodies were not detected in remission patients, indicating a correlation between disease activity and autoantibodies levels.

Conclusion: Anti-HMGCR autoantibodies level measures can be useful in the follow-up of patients with statin-induced IMNM, although further studies are necessary to confirm these results.

REFERENCES: NIL.
Results were obtained using the chemiluminescence immunossay (CLIA) method. Negative anti-HMGCR was considered as levels lower than 20 U/ml.

**Results:** Our group combined of 24 patients. Main features of the patients are summarized in the **TABLE 1**. 21 (87.5%) patients reached clinical remission or low disease activity. However, 3 patients (12.5%) remained with moderate activity of the disease. None of the patients had high disease activity. Anti-HMGCR levels at diagnosis were higher than 100 U/ml in 23 patients (95.8%) and above 200 in 11 patients (45.8%). However, anti-HMGCR levels after treatment were significantly lower in patients in remission (p=0.035). Numeric levels in patients at diagnosis of the disease and after treatment are shown in the **FIGURE 1**. Most of the patients at diagnosis (with high activity of the disease) had high anti-HMGCR levels (22 patients, 91.7% had levels above 100 U/ml). After treatment, most patients in remission had low (n=3, 14.3%) or negative (n=9, 42.9%), while patients with moderate activity had higher levels (n=2, 66.7% with levels above 100 U/ml). However, 6 patients in remission (28.6%) still had levels above 10 U/ml.

**Conclusion:** Anti-HMGCR autoantibodies levels evaluation can be used in parallel with other tools to accurately measure disease activity in patients with statin-induced IMNM. However, more studies are needed to confirm these results.

Treatment was assigned to the patients considering the current recommendations and contraindications of the therapies available. In patients with comorbidities that limit the use of glucocorticoids, a steroid-free regime was agreed through a shared decision between the physician and the patient.

**Results:** We included 24 anti-HMGCR positive patients. Main features and treatment of the patients are summarized in [TABLE 1](#). A GC-free regimen based on the use of IVIG 2g/kg every month for at least 3 months was used in 5 (20.8%) patients. The remaining received standard treatment including GCs at baseline. General demographic data, MMT-8 and CK levels were similar in both groups. Comorbidities were higher in patients treated with the GCs free protocol. Remission or low disease activity was achieved in 21 patients (87.5%), including all 5 patients who did not receive GCs (after a mean of 4.1 ± 1.1 months). However, 3 (15.8%) of the 19 patients receiving glucocorticoids did not achieve remission or low disease activity. The time to remission or CK normalization was similar in both groups.

**Conclusion:** In our series of patients with anti-HMGCR positive IMNM, we found that patients can achieve remission without glucocorticoid treatment.

**AB0872 RELAPSES OF 129 PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES**

**Keywords:** Disease-modifying Drugs (DMARDs), Prognostic factors, Myositis

**J. Choi**, J. Kim², B. Bang³, B. Yoo³. 1.Jeju National University School of Medicine, Student, Jeju, Korea, Rep. of (South Korea); 2.Jeju National University School of Medicine, Jeju National University Hospital, Jeju, Republic of Korea, Rheumatology, Jeju, Korea, Rep. of (South Korea); 3.University of Ulsan College of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea)

**Background:** A high dose of glucocorticoid is suggested as initial management of Idiopathic inflammatory myopathies (IMMs), and immunosuppressive agents are added in severe cases [1]. However, since the diseases are rarely diagnosed, few studies have addressed the issue regarding the use of immunosuppressive agents with limited evidence [2]. The treatment of IMMs largely relies on empirical evidence and small studies [3]. As a result, The immunosuppressive has been indeed administered at the discretion of the physicians in practice. The initial glucocorticoid treatment usually leads to a stable phase for IMMs where the use of immunosuppressants during a period of tapering glucocorticoid in the initial treatment would help reduce the risk of relapse of IMMs.

**Methods:** The factors associated with the relapse of IMMs were investigated by Cox proportional hazards analysis. The factors associated with the relapse of IMMs: histopathologic features consistent with IMMs (model 1; HR, 1.69; 95% CI, 1.01-2.83, P = 0.0453) and the use of immunosuppressants before relapse (model 2; HR, 0.50; 95% CI, 0.29-0.86, P = 0.0132). Doubling of ANA titer showed a trend toward an association with relapse albeit without statistical significance (model 1; HR, 1.13; 95% CI, 1.00-1.27, P = 0.0517).

**Conclusion:** The use of immunosuppressants during a period of tapering glucocorticoid in the initial treatment would help reduce the risk of relapse of IMMs.

**AB0873 WHOLE BODY INSULIN SENSITIVITY IS INCREASED IN SYSTEMIC SCLEROSIS**

**Keywords:** Diet and Nutrition, Cardiovascular disease, Systemic sclerosis

**J. Ciafalì**, P. Ruscitti², I. Di Cola³, V. Pavlocý, N. Italiano², M. Gentile³, M. Tommasetti³, T. Huizinga³, J. De Vries-Bouwstra³, F. Ursini¹, P. Cipriani¹. ¹IRCCS Istituto Ortopedico Rizzoli, Medicine & Rheumatology Unit, Bologna, Italy; ²University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy; ³Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; ⁴Alma Mater Studiorum - Università di Bologna, DIBINEM, Bologna, Italy

**Background:** The prevalence of type 2 diabetes (T2D) is increased in rheumatoid arthritis (RA) and other inflammatory diseases, while the available evidence suggests that in systemic sclerosis (SSc) it is lower than in the general population [1]. Insulin resistance and β-cell dysfunction are the main mechanisms in the pathophysiology of T2D. However, mechanisms underlying the negative association between SSc and T2D have not been elucidated.

**Objectives:** We aimed to evaluate whole-body insulin sensitivity in SSc patients and to compare the results with controls with no autoimmune rheumatic disease (non-ARD) and with patients affected by RA. Additionally, we investigated whether insulin sensitivity was associated with SSc characteristics.

**Methods:** The study population was composed of consecutive adult SSc patients. For comparison, non-ARD and RA patients were included. All were screened for T2D before inclusion. Individuals with a diagnosis of diabetes and those using corticosteroids or insulin-sensitizing agents were excluded. The whole-body insulin sensitivity index (ISI) was estimated from glucose and insulin concentrations obtained during the oral glucose tolerance test (OGTT) using the equation proposed by Matsuda [2], which is validated against euglycemic insulin clamp and provides reliable estimates of glucose homeostasis. Insulin resistance (HOMA-IR) was calculated.

**References:**

Results: A total of 41 SSc patients, 41 individuals with RA and 82 non-ARD control patients were recruited. SSC patients were significantly older and had lower BMI than controls with RA, but had comparable characteristics with non-ARD patients (Table 1). The BMI was significantly higher in RA patients when compared with SSC patients [8.01 (4.85 – 12.62) vs 3.99 (1.93 – 6.14), p < 0.001] and with non-ARD patients [8.01 (4.85 – 12.62) vs 4.38 (3.39 – 6.37), p < 0.001]. Significant differences emerged also when analysing the HOMA-IR, which was lower in SSC patients than in RA [0.98 (0.66 – 1.52) vs 2.02 (1.36 – 3.63), p < 0.001] and non-ARD [0.98 (0.66 – 1.52) vs 1.74 (1.28 – 2.28), p < 0.001]. In normal weight individuals (BMI from 18.5 to 24.9), median ISI was higher in the SSc group than in RA (p = 0.007) and non-ARD controls (p < 0.001). In overweight and obese cases (BMI ≥ 25) ISI was also higher in the SSc group than in RA (p = 0.003) and non-ARD controls (p = 0.017) (Figure 1). In the SSc group, patients with diffuse cutaneous disease had significantly higher ISI than individuals with limited cutaneous SSc [11.60 (8.59 – 20.13) vs 6.58 (4.91 – 11.63), p = 0.027]. In univariate analysis, ISI was significantly correlated with BMI (r = -0.468, p = 0.002), fasting insulin (r = -0.715, p < 0.001), and modified Rodnan skin score (r = 0.422, p = 0.006. In multiple linear regression model adjusted for BMI and fasting plasma insulin, the association between ISI and modified Rodnan skin score was lost (r² = 0.27, p = 0.095).

Conclusion: The findings of our study suggest that patients with SSc are more insulin sensitive than those with RA and even than individuals without inflammatory diseases. This is the first time that whole-body insulin sensitivity is assessed in SSc using a validated and reliable method, contributing unique data to the knowledge about glucose homeostasis in SSc.

EPIDIOLOGICAL AND CLINICAL FEATURES OF IDIOPATHIC INFLAMMATORY MYOPATHIES IN SINGLE REGION IN NORTHERN SPAIN

Keywords: Descriptive Studies, Myositis, Epidemiology

C: Corrales-Selaya1, D. Martinez-Lopez2, D. Prieto-Peñal, J. L. Martin-Villar,1, R. Blanco1. 1Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 2Sierallana Hospital, Rheumatology, Torrelavega, Spain; 3Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of disorders characterized by proximal muscle weakness and inflammation. The main subtypes of IIM are dermatomyositis (DM), polymyositis (PM), inclusion body myositis (IBM), immune-mediated necrotizing myopathy (IMNM) and antisynthetase syndrome (ASS). Prevalence and incidence vary depending on the geographic location.

Objectives: To describe the epidemiological and clinical features of IIM in a single region in northern Spain.

Methods: We included all consecutive patients diagnosed with IIM in the region of Cantabria, excluding IBM, from January 2000 to December 2022. IIM was diagnosed by expert rheumatologists according to a) EULAR/ACR 2017 classification criteria of IIM in PM and DM, b) Definition of the European Neuromuscular International Workshop 2016 in IMNM and c) Connors criteria in ASS.
was no difference in terms of muscle damage, skin lesions (heliotrope rash, Gottron's papules, periangual erythema), and Raynaud's phenomenon according to the presence of IIM. Dysphagia and heart disease at MRI were more prevalent in patients with ILD. Patients with ILD also had lower prevalence of malignancy. Anti-Ro52 and antisynthetase antibodies were significantly associated with ILD. Anti-Mi/NXP2 antibodies were observed only in the group without ILD, but such association was not statistically significant. The prevalence of anti-TIF1gamma antibodies did not differ between the two groups; 3/5 (60%) patients in the group without ILD developed malignancy vs only 1/4 (25%) in patients with ILD.

Conclusion: There is a higher prevalence of dysphagia and heart involvement in patients with IIM and ILD, a highly prevalent manifestations of IIM, thus suggesting dedicated therapeutic strategies. ILD correlates with antisynthetase and -Ro52 positivity, with a negative association with malignancy, particularly in anti-TIF1gamma positive patients.

* p=0.026, ^p=0.026 compared to ACA(+) patients, Log Rank (Mantel-Cox)test.

Conclusion: Although ACA(+) patients are considered to have a better prognosis, some patients may develop new or worsening manifestations after a longer time period. The prognosis of ANA or anti-Sc70(+) patients was shown to be more severe and most patients had new organ involvement within the first 5 years of the disease, warranting a careful evaluation and efficacious treatment at this period.

AB0877 TARGETING VASCULOPATHY TO SLOW FIBROSIS IN SYSTEMIC SCLEROSIS (SSC): DESIGN OF A PHASE II STUDY WITH A SOLUBLE GUANYLATE CYCLASE ACTIVATOR (sGC)

Keywords: Systemic sclerosis, Biomarkers, Randomized control trial

D. Khanna1, M. Flack2, T. Litzenburger3, N. Fagan4, O. Distler2. 1University of Michigan Scleroderma Clinic, Department of Internal Medicine, Ann Arbor, United States of America; 2Boehringer Ingelheim Pharmaceuticals, Inc., TA Inflammation Medicine, Ridgefield, United States of America; 3Boehringer Ingelheim Pharma GmbH & Co. KG, TMCP Therapeutic Areas, Biberach, Germany; 4Boehringer Ingelheim Pharmaceuticals, Inc., Global Biostatistics & Data Sciences, Ridgefield, United States of America; 5University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland

Background: The pathophysiology of SSC involves a complex interplay between immune dysfunction, vasculopathy, and fibrosis. The soluble guanylate cyclase (sGC) pathway has been shown to improve vascular endothelial function. We designed a Phase II study to test whether treatment of vasculopathy with an sGCa could slow the progression of fibrosis in patients with early progressive SSC and vasculopathy.

Objectives: To design a randomized, double-blind, placebo-controlled trial to evaluate the progression of fibrosis in patients with SSC treated with an sGCa.

Methods: We reviewed criteria used in published clinical trials to define early progressive disease, as well as clinical and biomarker features from existing studies and registries that are predictive of more rapid progression of fibrosis [1, 2]. Specifically, we looked for features of vasculopathy associated with progression of skin and lung fibrosis [3]. We performed a rigorous review of investigator- and patient-reported outcomes to test the hypothesis that amelioration of vascular symptoms could slow the progression of fibrosis in patients with SSCs.

Results: Progressive disease was defined as having diffuse cutaneous SSC with evidence of active disease as defined by clinical and biomarker criteria. The clinical criteria were similar to those used in previous trials, but we developed a novel biomarker strategy using KL-6 in addition to C-reactive protein (CRP) and erythrocyte sedimentation rate. These biomarkers identify additional patients at risk for progressive lung fibrosis. Significant vasculopathy was defined as having digital ulcers or a history of digital ulcers and/or Raynaud’s phenomenon requiring medical treatment or associated with elevated CRP. We developed a hierarchy of primary, key secondary, and secondary endpoints, including forced vital capacity, modified Rodnan skin score, revised Composite Response Index in Systemic Sclerosis, Health Assessment Questionnaire-Disability Index, digital ulcer burden, and Raynaud’s symptom scoring, to investigate whether amelioration of vascular symptoms could slow decline in lung function over 48 weeks and reduce the progression of skin fibrosis and other disabilities associated with SSCs. We determined that a sample size of 100 patients was sufficient to obtain 80% power to observe changes in lung and skin fibrosis.

Conclusion: We designed a 48-week randomized, double-blind, placebo-controlled Phase II trial enrolling 200 patients with early progressive SSCs and significant vasculopathy to test whether targeting vasculopathy with a novel sGCa can slow the progression of fibrosis in patients with SSCs. The trial is now active, and additional details are available at NCT05559580.

AB0878 SAFETY AND EFFICACY OF MESENCHYMAL STEM CELLS TRANSPLANTATION IN SYSTEMIC SCLEROSIS

Keywords: Safety, Systemic sclerosis, Clinical Trials

N. Krivurochko1, L. Zaripova1, M. Askarova1, A. Baijenzhin2, T. Karibekov3, G. Shaimardanova2, S. Bekturganova3. 1National Scientific Medical Center, Institute of fundamental and applied medicine, Astana, Kazakhstan; 2National Scientific Medical Center, The Chairman of the Board, Astana, Kazakhstan; 3National Scientific Medical Center, Deputy Chairman of the Board, Astana, Kazakhstan; 4National Scientific Medical Center, Pathological department, Astana, Kazakhstan; 5National Scientific Medical Center, Department of therapy and cellular technologies, Astana, Kazakhstan

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease characterized by vasculopathy and tissue fibrosis of the skin and various internal organs. Currently available treatments for SSc have limited efficacy, and the disease still has poor prognosis. New therapeutic approaches such as mesenchymal stem cell (MSC) transplantation are of great interest. MSCs are known as multi-potent progenitor stromal cells that self-renew and differentiate toward multiple mesenchymal cell lineages [1, 2].

Objectives: to evaluate the efficacy and safety of bone marrow MSCs transplantation in SSc.

Methods: Twenty-five patients with a reliable diagnosis of SSc refractory to classical immunosuppressive therapy were divided between main and control group. Patients from the main group underwent transplantation of MSCs in combination with high-dose immunosuppressive therapy (HIST) (n=14), while the control group was observed on the background of traditional immunosuppressive therapy without cell transplantation (n=11). Both groups were comparable in age, gender
of patients, duration and severity of the disease. The degree of induration of the skin was evaluated using the modified Rodnan skin score (mRSS). The disease activity was assessed using the ESScSSG scale. Anti-nuclear antibodies (ANA), anti-SCL-70 were examined in indirect immunofluorescence, cytokines (IL-1β, IL-6, IL-10, TNF-α) by ELISA. All patients underwent CT scan of the thoracic segment, echocardiography with determination of mean pulmonary artery pressure (mPAP) and spirometry. Statistical analysis was carried out by GraphPad Prism version 8.

**Results:** Before MSC transplantation, SSC patients in both groups demonstrated an increase in ANA, C-reactive protein (CRP), IL-1, IL-6, TNF-α, with the background of severe skin induration. After transplantation of MSCT with HIST a pronounced clinical effect was noted: induration and dense swelling of skin, muscle contractures, vasospasm attacks (Raynaud syndrome) significantly decreased, dysphagia was relieved. In addition, a significant decline in skin density according to mRSS was observed (from 22.13±8.3, 52 to 9.8±0.93, p<0.003). A significant reduction in EScSG was registered from 3.21 to 2.48 points (p=0.05). Six months after transplantation, patients with SSC demonstrated a decrease in CRP from 10.14±5.21 to 3.28±1.31. Parameters of the cytolyn profile with a moderate decrease for IL-1, IL-6 and TNF-α (p<0.05). According to the results obtained patients who underwent BM-MSCs transplantation demonstrated 54% decrease in mPAP, from 41.4±10.87 to 26.8±3.27. In SSC patients in the control group high levels of cytokines, mRSS, and mPAP were recorded during the observation period. No cases of death or severe complications associated with MSCs transplants have been registered.

**Conclusion:** The conducted research demonstrated the therapeutic effect of MSC transplantation consisted in the decrease of the induration of skin, the activity of SSC and the severity of pulmonary hypertension, as well as normalizing the levels of proinflammatory cytokines.

**CORRELATION BETWEEN THE RESULTS OF NAIL FOLD CAPILLAROSCOPY AND OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**Keywords:** Systemic sclerosis, Diagnostic Tests

1. Medical University of Warsaw, Department of Biophysics, Physiology and Pathophysiology, Faculty of Health Sciences, Warsaw, Poland; 2. National Institute of Geriatrics, Rheumatology and Rehabilitation, Department and Polyclinic of Systemic Connective Tissue Diseases, Warsaw, Poland; 3. Military Institute of Aviation Medicine in Warsaw, Poland, Department of Ophthalmology, Warsaw, Poland

**Background:** Vascular pathology of blood vessels are, apart from immunological disorders, an important component of the pathogenic link of dangerous organ complications in systemic sclerosis (SSc). Endothelial damage is one of the mechanisms leading to disorders of vascular hemostasis, platelet activation, thrombosis causing coagulopathy and microangiopathy. Nailfold capillaroscopy (NC) is a non-invasive diagnostic tool for the detection and monitoring patients with SSc and current methods of the assessment of microcirculation and capillary structure within the nail folds. Although vascular pathologies can occur in other organs including the organ of vision. Coherence tomography angiography (OCTA) is a noninvasive imaging method of microvasculature of the retina and choroid providing the diagnosis of retinal perfusion.

**Objective:** The aim of the study was to evaluate the correlation between the optical coherence tomography (OCT) and optical coherence tomography angiography (OCTA) parameters and capillaroscopic results.

**Methods:** 31 patients (pts) with SSc diagnosed were included to the study. Mean age of the patients was 35.1 (8.3). Capillaroscopy was performed. The modified Rodnan Skin Score (mRSS) examination was taken by one assessor at the time of the study. There were measured HcrcT, prbnp, echocardiography. Finger ulcers were observed in physical examination. OCTA scans were collected from 31 patients. 61 eyes were included to the study to assess changes in retinal microcirculation. Foveal avascular zone (FAZ) in superficial plexus and deep plexus, paravascular mean superficial vessel density and paravascular mean vessel density were correlated to NC findings and other parameters used in OCTA examination. The statistical procedures were performed by using STATGRAPHICS Centurion, version 19.4 (Statgraphics Technologies, Inc., The Plains, Virginia, USA).

**Results:** In our study group 74% has diffuse Scc, 26% has limited SSc. IncNC: 5 pts has early pattern, 12 has active pattern,9 pts has late pattern. Only one person has pulmonary arterial hypertension (PAH) and 8 pts have active finger ulcers. Interstitial lung disease was present in 46% patients (idiopathic interstitial pneumonia (NSIP) and 32% usual interstitial pneumonia (UIP)). Elevation prbnp were detect in 17.8% The paravascular mean superficial vessel density correlated positively and statistically significantly with mRSS (p=0.0460). Patients with early sclerosis pattern in capillaroscopy showed larger superficial FAZ (0.4±0.07mm²) than pts with active (0.2±0.09mm²) and late (0.22±0.08mm²). There was correlation between deep FAZ area and sclerodema pattern showing larger FAZ in pts with active (0.46±0.14mm²) than pts with active arthritis.
Background: Hand function deterioration is a major multifactorial driver of disability in Systemic Sclerosis (SSc) whose rate has been poorly described.

Objectives: The aim of this study is to describe incidence and risk factors of hand functional worsening in a longitudinal, multicenter, observational SSc cohort.

Methods: Hand involvement and disability were evaluated in consecutively enrolled patients for 24 months. Patient-reported hand impairment was captured with Cochin Hand Disability Score (CHFS) and the corresponding minimal clinical important differences (MCID) and patient acceptable symptom state (PASS). Clinical association with CHFS change over time and clinically meaningful worsening (MCID-Worsening) were investigated.

Results: Three-hundred-ninety-six patients from 10 centres were evaluated and 201 SSc (age 55.7±12.2 years, male 13.4%) were included in the final analysis. Median (IQR) disease duration was 5 (2-11) years while the proportion of patients with diffuse cutaneous variant was the 29.9%. Fifty-six (27.8%) patients had a CHFS ≥PASS at baseline. CHFS increased over time 35.8% of patients reaching CHFS >PASS (p<0.001), and 52.2% of patients reporting MCID-Worsening at 24 months. A LASSO model simultaneously exploring the effects of multiple baseline clinical variables showed that MCID-Worsening was associated with male gender, LeRoy diffuse variant, late capillaroscopy pattern, shorter disease duration, absence of digital ulcers, presence of tenosynovitis, pain, Raynaud's phenomenon, and global and hand disability severity, together with treatment with immunosuppressants, vasoactive medications, and second-line analogics.

Conclusion: Hand function tends to deteriorate over time in one SSc patient in two despite available therapies and clinical assessment support risk stratification. These results pave the way to inform design of intervention studies aimed at improving the outcome of this major driver of disability in SSc.

AB0881 - ADVANCED GLYCATION END PRODUCTS IN SYSTEMIC SCLEROSIS

Keywords: Prognostic factors, Organ damage, Biomarkers

L. Trigerer,1, L. Tio,2, I. Carrion,3, A. Guillen-Del-Castillo,4,5, A. Ribes,6, L. Valencia Muntalà,6, J. Montfort,6, T. C. Salamanca,7, J. A. Pros,7, J. R. Navarrete,7, C. P. Simeon Aznar,1,2,4,5, IDIBELL, Unitat Funcional de Malalties Autoinmunoses Sistèmiques (UFMAS), Barcelona, Spain;1 IMM (Hospital del Mar Medical Research Institute), Barcelona, Infammation and Cartilage Cellular Research Group, Barcelona, Spain;2 Hospital del Mar, Servei de Reumatologia, Barcelona, Spain;3 Hospital Universitari Vall d’Hebron, Department of Internal Medicine, Barcelona, Spain;4 VHIR, Systemic Diseases, Barcelona, Spain;5 Hospital Universitari de Bellvitge, Department of Rheumatology, Barcelona, Spain;6 Barcelona, Servei de Reumatologia, Barcelona, Spain

Background: Studies have postulated that advanced glycation end products (AGEs) could have a relevant role as inducers in the chronic inflammatory pathway present in various diseases – including systemic sclerosis (SSc). Similarly, that the concentration of AGEs maybe related to nailfold capillaroscopy SSc changes, the diffuse skin subtype, or calcinosis. Validation studies have shown that skin autofluorescence is strongly related to AGEs levels in skin biopsies.

Objectives: To characterize and identify association between the concentrations of AGEs, measured by cutaneous autofluorescence, and disease parameters in SSc patients.

Methods: AGEs concentrations were measured by skin autofluorescence (Age Reader Mu Connect from Diagnostics Technologies BV®) in 179 SSc patients and correlated with demographic and clinical data. Cumulated AGEs were distributed in tertiles. Categorical data was described with frequencies, whereas continuous variables were displayed as mean (standard deviation). ANOVA tests were conducted to explore the linear association of demographics and clinical features with the cumulated AGEs value. Regression models were adjusted by skin autofluorescence.

Results: Table 1 shows the distribution and correlation of the most relevant patients characteristics studied according to AGEs levels classified in tertiles. Male gender (p-value M1=0.008, M2=0.003) and anticitrulline antibodies (ACA) (p-value M1=0.010, M2=0.034) were statistically significant associated with higher AGEs levels. In addition, AGEs levels were inversely correlated with age (p-value M1=0.039, M2=0.022). Although not statistically significant, there was a trend towards higher values of AGEs (p-value 0.05 - 0.1) in patients with esophageal involvement and skin manifestations (either diffuse or limited cutaneous subtype) and lower prevalence of anti-topoisomerase antibodies (ATA). No associations with other characteristics were found.

Conclusion: Higher AGEs levels were independently associated to male gender, ACA positivity and inversely with obesity. AGEs might be involved in the...
aetiopathological pathways leading to skin and esophageal manifestations. Finally, the disease mechanism in obese SSC patients might indicate a milder disease, as they present lower AGEs values, opposing to what has been described in healthy subjects. This could indicate less severe gastrointestinal disease leading to malnourishment.

AB0883 IDIOPATHIC OPHTHALMIC MYOSITIS: CLINICAL PRESENTATION, THERAPEUTIC APPROACH AND IMAGING DIFFERENTIATION FROM GRAVES OPHTHALMOPATHY

Keywords: Myositis
S. Ziaragkali1, O. Argyropoulou1, G. Boutzi1, S. Chatzi1, E. Papadaki2,3, A. Karantanas2,3, A. Tzioufas1, M. N. Manoussakis1.
1School of Medicine, National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece; 2Heraklion University Hospital, Department of Medical Imaging, Heraklion, Greece; 3Medical School, University of Crete, Department of Radiology, Heraklion, Greece

Background: Idiopathic ophthalmic myositis (IOM) represents a rare autoimmune ophthalmoplegia of unknown etiology, that may mimic predominantly Graves’ ophthalmopathy (GO). IOM is characterized by pronounced inflammatory infiltration of extraocular muscles leading to fibrosis and eye-threatening complications, if remains untreated [1,2]. The rarity and clinical heterogeneity of the disease pose diagnostic and therapeutic challenges.

Objectives: To describe the clinical phenotype, therapeutic interventions and clinical course of IOM and to define the distinct imaging features that differentiate IOM from GO.

Methods: This is a single-center, retrospective, observational study of 14 consecutive patients with IOM followed up between 2017 and 2022. Cumulative clinical, laboratory and imaging data from the medical records until last follow-up were analyzed. The detailed orbital magnetic resonance (MRI) findings of 11 IOM patients were compared to those of 16 age- and sex-matched GO patients.

Results: IOM patients studied (men: 9/14, median age at disease onset: 46 years, median follow-up time: 15.5 months), presented subacute clinical course in 57%, whereas 75.0% of GO and RA patients, respectively, whereas tendon involvement was observed exclusively in IOM patients (18.2%). In all patients, the mainstay of therapy, was steroids. IOM patients were treated with various combinations of corticosteroids and c-DMRI/d-DMRI (methotrexate, mycophenolate-mofetil, azathioprine, rituximab, tocilizumab), whereas GO patients mainly received corticosteroids with/ or without tocilizumab.

Conclusion: IOM is a potentially severely organ-specific disease with heterogeneous clinical presentation. Early diagnosis and aggressive immunosuppressive treatment are required to prevent permanent eye-threatening complications. IOM should be considered in the differential diagnosis of exophthalmos, while MRI-imaging may help in differentiating IOM from GO. Studies are underway to delineate tissue-specific alterations of the inflamed extraocular muscles and involving larger series of patients.

AB0884 THE IMPORTANCE OF RENAL IMPAIRMENT IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Kidneys
L. Božić Majstorović1, J. Ojević1. 1University Clinical Centre of the Republic of Srpska, Department of Rheumatology, Banjaluka, Bosnia and Herzegovina

Background: Systemic sclerosis (SS) is an autoimmune disease characterized by fibrosis and vascular abnormalities. Studies have shown that renal impairment is increased in SS, but this fact is neglected during diagnostic evaluation [1]. As a control group, patients with rheumatoid arthritis (RA) were selected because the renal involvement was as high as 9% although the kidneys were not the target organs in the disease [2]. Comparison of renal function (RF) between patients with SS and RA have not yet been described.

Objectives: The main goal was to detect correlation between clinical features and renal impairment in SS and to compare the renal impairment in patients with SS to patients with RA.

Methods: The 30 patients diagnosed with SS were included in the study. The demographics, modified Rodnan skin score (mRSS), EUSTAR DAI, diffusing capacity for carbon monoxide (DLCO) and immunology parameters were collected. Evaluation of RF was done by using: serum creatinine (SC), creatinine clearance (CC), proteinuria from 24h urine specimen and renal parenchym thickness (RPT) with abdominal ultrasound. To compare the renal impairment, the 30 patients diagnosed with RA without history of glomerulonephritis, diabetes mellitus, hypertension or urinary tract infection were enrolled as a control group.

Results: The 86.7% patients were female, mean age was 57.07±10.41 and mean disease duration was 73.6±68.73 months. Raynaud phenomenon had 93.3% patients, digital ulcers (DU) 43.3% and the mean of mRSS was 21.4±39.5. Antinuclear antibodies had 83.3% patients, 46.7% had anti-Scl-70 antibodies and 43.3% had anticientromere B antibodies. The mean of EUSTAR DAI was 4.86±2.56 and DLCO 60.57±16.80. Regarding RF, the mean value of SC was 70.67±16.20, CC 83.08±2.60, proteinuria 0.17±0.19 and RPT was reduced in 46.7% patients. We correlated clinical features with RF parameters in patients with SS. Significantly reduced RPT was observed in patients with higher mRSS (p=0.035) and in patients with DU (p<0.05). No association was observed between RF and other clinical features. Our results showed significant difference in all RF parameters, between patient and control group. SC (p=0.004) and proteinuria (p=0.03) were significantly higher in SS compared with RA. CC was significantly higher in RA than in patients with SS (p=0.005). RPT was significantly reduced (p=0.000) in SS compared to patients with RA. The results are displayed in Table 1.

RF-rerenal function; SS-systemic sclerosis; RA-rheumatoid arthritis.
High resolution impedance manometry in dermatomyositis allows the characterization of esophageal dysmotility and the profiling of different clinical and serological subsets.

**Background:** Esophageal involvement is common in dermatomyositis (DM), occurring in up to 54% of patients [1]. It can lead to severe complications, such as malnutrition and aspiration pneumonia. Therefore, esophageal assessment is of foremost importance to drive patients management. Recently, high-resolution impedance manometry (HRiM) has emerged as a promising technique to assess esophageal motility and has already been tested in systemic sclerosis [2].

**Objectives:** To evaluate esophageal motility by HRiM in DM and correlate the alterations to clinical and serological disease domains.

**Methods:** We analyzed HRiM findings in 15 consecutive DM patients enrolled in our clinic between December 2021 and December 2022. All patients received a rheumatological assessment, including screening questions for dysphagia, and underwent HRiM. All HRiM parameters (Integrated relaxation pressure (IRP), percentage of LES relaxation, distal contractile integral (DCI), distal latency (DL), upper esophageal sphincter (UES) pressure) were studied, coupled with impedance findings (esophageal clearing and bolus transit time). The report followed the Chicago Classification v.4.0 for esophageal motility disorders. The associations between HRiM findings and DM features were evaluated.

**Results:** DM patients were divided according to their serological status: 5 M2 (33%), 6 MD45 (40%), 2 Ku (13%), 1 NXP2 (6.6%), 6 Ro52 (40%). Asymptomatic patients presenting at least one HRiM alterations were 4 (26.7%). Among HRiM parameters, 83.3% MD45 patients and 50% Ro52 patients showed high UES pressure (Figure 1), in contrast to the other serological groups. Among impedance findings, incomplete bolus clearance was detected in MD45 (67%) and in Ro52 patients (50%). Notably, the only NXP2 patient showed 100% of incomplete bolus clearance. Considering the Chicago classification v.4.0, only 16.7% of MD45 patients had a normal esophageal motility, the rest presenting absent contractility (33.3%) and ineffective esophageal motility (IEM) (50%). Distal esophageal spasm was evidenced only in M2 patients (40%). All patients with concomitant manometric and impedance alterations were MD45 positive. DM patients with high UES, IEM or impedance abnormalities presented higher rate of lung involvement and active Raynaud's phenomenon (Table 1). No relation with ongoing treatment emerged.

**Conclusion:** Raynaud's phenomenon (Table 1). No relation with ongoing treatment emerged.

**Scientific Abstracts**

**Conclusion:** Presence of DU and high values of mRSS can be associated with renal damage and that indicates the need for evaluation of the RF. The renal impairment in our study was more significant in patients with SS than in those with RA. More studies are necessary to establish this correlation.

**AB0886 PROGRESSIVE INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE**

**Keywords:** Systemic sclerosis

G. Cuomo1, C. Di Vico1, D. Perretta1, C. Iandoli1, R. Ciaburri1, P. Adamo1,2

1Seconda Università degli Studi di Napoli, Precision of Medicine, Caserta, Italy

**Background:** A subset of patients with systemic sclerosis associated interstitial lung disease (SSc-ILD) develop progressive ILD, which is associated with higher mortality, but the prevalence of progressive ILD and the overall disease course and patterns of SSc-ILD are unknown. Current clinical practice emphasises treatment initiation. Of SSc-ILD patients with progressive ILD.

**Objectives:** To identify progression patterns and risk factors predictive for progressive interstitial lung disease (ILD) in patients with systemic sclerosis-associated ILD (SSc-ILD)

**Methods:** Within our database, patients included since 2000 aged ≥18 years fulfilled the SSc classification criteria and had lung imaging data available and had measurements of forced vital capacity (FVC) at baseline and after 12±3 months. A decline in FVC of ≥10%, or a decline in FVC of 5% to 10% along with a decline in DLCO of 15%, is a proposed definition of progressive fibrosis.

**Results:** From our database of the 813 patients included 210 (25.8%) had evidence of SSc-ILD on imaging, 134 (63.8%) at basal and 76 (36.2%) over time. The proportion of
patients with SSc-ILD who experienced progressive ILD during the initial 12±3-month period was 30.9% (65 pt) (FVC), either moderate 35 pts 53.8% (FVC decline 5% to 10%) or significant 30 pts 46.2% (FVC decline >10%), 76 (36.2%) were stable and 69 (32.8%) had improvement. In our population, the strongest predictive factors for FVC decline over 12 months were higher modified Rodnan skin score at basal. Conclusion: Novel treatment concepts, with treatment initiation before FVC decline occurs, should aim for prevention of progression to avoid irreversible organ damage in SSc-ILD that shows a heterogeneous and variable disease course, and thus monitoring all patients closely is important.

AB0887 THE EFFECTIVENESS AND SAFETY OF MESENCHYMAL STEM CELLS IN TREATMENT OF SYSTEMIC SCLEROSIS: SYSTEMATIC REVIEW

Keywords: Systemic sclerosis, Systematic review

L. Zariapova1, Z. Bekniyazova2, E. Insibayeva2, A. Kambar2, N. Imanbaeva2, S. Tuganbekova3, National Scientific Medical Center, Department of Scientific and Innovation Management, Astana, Kazakhstan; Astana Medical University, Department of Internal Diseases №4, Astana, Kazakhstan

Background: Systemic scleroderma, or systemic sclerosis (SSc) is an autoimmune disease with high morbidity and mortality, characterised by fibrosis of the skin and internal organs. In the last decade, alternative methods of treatment of SSc resistant to standard immunosuppressive therapy have been actively studied. Of interest are the data about mesenchymal stem cells (MSCs) with their immunomodulatory properties, the ability to self-renew and differentiation.

Objectives: to evaluate the safety and effectiveness of MSCs transplantation in SSc refractory to standard therapy by a systematic review.

Methods: The search was conducted on PubMed and Google Scholar platforms using the following strategy: “Systemic sclerosis” + “Mesenchymal stem cells”. All articles presented in the public domain published before 12.12.2022 in the format of case descriptions, clinical and multicenter studies (Case Reports, Clinical Studies, Clinical Trials, Multicentre Studies) were analyzed. The effectiveness of MSCs was evaluated using the index of systemic sclerosis activity and the modified Rodnan skin score (mRSS), diffusing Capacity of the lungs for carbon monoxide (DLCO), the Mouth Handicap in Systemic Sclerosis (MHISS), the Cochlin Hand Functional Disability Scale (CHFS),left ventricular ejection fraction (LVEF), EASTAR 2017 Disease Activity Index, visual analog scale (VAS), manifestations of Raynaud’s syndrome, laboratory parameters (ESR, CRP), immunological parameters (ANA, Scl-70). The safety assessment included the registration of various adverse events during and after transplantation.

Results: For the period from 2010-2022, fifty publications were found on the topic of MSCs transplantation in SSc, of which 15 publications met the above criteria and were included in the study. The data of 417 patients who underwent transplantation of MSCs obtained from various biological sources (bone marrow - 7, adipose tissue - 5, umbilical cord - 1) were analyzed. The average age of the patients was 42.42 ± 10.79 y.o. The results obtained suggested that there was a significant decrease in the activity of SSc compared to the baseline level of mRSS scale from 21.8±1.72 to 4.5±5.4, the number of finger ulcers decreased, there was an improvement in mouth opening assessed by the MHISS scale, 2.5 fold decrease in the level of Scl-70, and 2-fold decrease in VAS (p<0.05). The assessment of all patients (n=417) who underwent MSCs transplantation revealed a few side effects, such as postoperative consequences (bruising, swelling and soreness of the donor site, resolved within 14 days), a superficial wound infection (1 patient), which succumbed to oral antibacterial therapy and no further surgical intervention was required. Pulmonary hypertension was diagnosed in 5 patients 24 months after MSCs transplantation; ventricular arrhythmias requiring treatment with carvedilol was observed in 1 patient four months after MSCs transplantation. Restrictive cardiomypathy and chronic fibrosing myocardiitis developed in 1 patient. 6 patients who underwent liposuction had transient paresthesia, which was completely eliminated after a few weeks; 1 patient dropped out due to dizziness after lidocaine injection. 2 patients complained about digital ulcers developed within 24 months. No tumor-related events were observed. The mortality rate consisted in 1.19%, the survival rate was 98.81%. Cause of death (5 cases in total): pneumonia- 1, lung cancer- 1, unknown – 2 patients. One patient died from sudden cardiac arrest due to ventricular fibrillation.

Conclusion: According to the analysis of data from different up-to-date research, MSCs transplantation in SSc patients improved the degree of skin thickening, lung function and mouth opening, as well as relieved ulcers and finger pain without serious side effects. Thus, MSCs can be suggested as an effective and promising therapeutic approach for patients with SSc resistant to standard immunosuppressive therapy.

Background: Immune Mediated Necrotizing Myopathy is a type of autoimmune myopathy which is commonly associated with the use of statins. Common antibody detected in these patients would be HMGCoA reductase antibodies. Significant muscle necrosis with paucity of cellular infiltration is the characteristic histological feature.

Objectives: To describe clinical and therapeutic characteristics of anti HMGCoA reductase antibody positive necrotizing myopathy.

Methods: Cohort of patients with myositis were selected. The myositis antibody panel was assessed and patients with HMGCoA reductase antibody were selected. Diagnosis was made based on the 2017 EULAR/ACR criteria [1]. Clinical manifestations, statin use, investigations, treatment offered, and outcome were described.

Results: Of the selected 5 cases, all the patients were middle aged with 3 males and 2 female patients. All 5 patients were on statins and 3 of them were on statins for many years prior to development of myopathy. None of the cases had other systemic involvement including dermatological or cardiac involvement. All 5 patients were positive for HMGCoA reductase antibodies. One patient had CLL which never required any specific treatment and another was incidentally found to have an atypical lipoma which was managed conservatively. All patients required steroids with either Methotrexate and Mycophenolate molitin. Three of the patients received intravenous immunoglobulin therapy with good response. All of the other patients had a complete recovery through 2 of them required prolonged rehabilitation.

Conclusion: Statin induced necrotising myopathy patients could develop the disease after many years of statin therapy. It is possible that changes in the drug or the dose could act as a precipitant. This cohort of patients tend to be treated with intravenous immunoglobulin in addition to other conventional treatments. In spite of having very severe disease at the onset, with timely and appropriate immunosuppressant and rehabilitation patients appeared to have a good outcome.

AB0889 FILGOTINIB FOR THE TREATMENT OF SYSTEMIC SCLEROSIS OVERLAP RHEUMATOID ARTHRITIS: DATA FROM OUR PRELIMINARY EXPERIENCE

Keywords: Targeted synthetic drugs, Systemic sclerosis, Rheumatoid arthritis

M. De Pinto1, A. Spinellia, L. Gavioli, G. Arnati, A. Rai, F. Goatelli, P. Macri1, F. Lumetti1, O. Secchi1, G. Sandri1, C. Salvarani2,2, D. Giuggioli1,4

1University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy; 2AUSL-IRCCS of Reggio Emilia, Rheumatology Unit, Reggio Emilia, Italy; 3University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Research, Modena, Italy; 4University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy

Background: Systemic sclerosis is a connective tissue disease characterized by endothelial dysfunction and fibrosis of the skin and internal organs. JAK inhibitors have shown efficacy in reducing cutaneous and pulmonary fibrosis in mice models of SSC, but only few case reports and no RCTs are reported in literature. SSC is frequently associated with other autoimmune diseases and SSC- Rheumatoid arthritis (RA) is one of the most common SSC-Overlap Syndrome. Filgotinib is an oral selective JAK1 inhibitor, recently approved for the treatment of RA.

Objectives: The aim of our work was to assess efficacy and safety of Filgotinib for the treatment of cutaneous, visceral and articular involvement in patients affected by SSC overlap RA.

Methods: Prospective, open-label, monocentric study in which 5 patients affected by SSC overlap RA (M/F 0/5, age 57,80±16,62DS years, disease duration 11,6±7,89 DS years, limited/diffuse subset 3/2) referring to the Scleroderma Units of Modena and Reggio Emilia between October 2021 and July 2022, were enrolled. All patients satisfied both ACR/EULAR criteria for SSCs and RA and were already in treatment with standard therapy (prostanoids, calcium-channel blockers and/or endothelin-receptors inhibitors a/o phosphodiesterase type 5 inhibitors) and had an inadequate response or were intolerant or had contraindication to one or more DMARDs or bDMARDs. Patients received Filgotinib 200 mg once daily for a period of 24 weeks. Articular, cutaneous and visceral involvement were assessed according to clinical practice at the baseline and at 12th and 24th week after the start of the treatment.

Results: All patients showed a significant improvement in articular involvement at 24th week, in particular a significant reduction in tender joint count (TJC, p=0,003), SDAI/SDAI (p=0,012/0,008) and pain numerical rating scale (NRS, p=0,035) was reported. A trend of improvement of DAS28 (p=0,055) was also observed. Notably a significant reduction in TJC (p=0,023) and a trend of improvement of SDAI/SDAI (p=0,059/0,051) was already seen at 12th week. The extent and severity of skin involvement assessed through modified Rodman Skin Score (mRSS) remained stable during follow-up (p=0,918). No improvement or worsening of exertional dyspnea measured by means of Borg scale was reported. No drug-related side effects were recorded during follow-up and none of the patients discontinued the treatment. No deaths were reported.

Conclusion: According to our preliminary data, Filgotinib was effective, safe and well tolerated in the treatment of articular involvement in patients affected by SSC overlap RA. Further analysis on a larger number of patients and control group are needed to confirm our data. Patients’ enrolment with assessment of efficacy on skin and lung involvement is currently ongoing.

AB0890 EARLY SYSTEMIC SCLEROSIS PATIENTS SHOW A SLOW DISEASE COURSE

Keywords: Systemic sclerosis, Epidemiology

M. Käyä1, S. Kortelanen1, J. Palta1, L. Pirilä2, H. Vähälkikä3, R. Kaarteenaho1,4, J. Huhtakangas1, Oulu University Hospital, Division of Rheumatology, Oulu, Finland; 2Turku University Hospital, Rheumatology and Clinical Immunology, Turku, Finland; 3University of Oulu, Faculty of Medicine, Oulu, Finland; 4University of Oulu, Research Unit of Biomedicine and Internal Medicine, Oulu, Finland; 5Oulu University Hospital, Center of Internal Medicine and Respiratory Medicine and Medical Research Center (MRC) Oulu, Oulu, Finland; 6Kuopio University Hospital, Division of Rheumatology, Kuopio, Finland

Background: Systemic sclerosis is a heterogeneous immune-mediated connective tissue disease characterized by vasculopathy and progressive tissue and organ fibrosis. [1]

Objectives: Our aim was to determine characteristics of Finnish patients with systemic sclerosis (SSc) and early SSc that were followed during 1996-2018 in two university hospitals in Finland.

Methods: The data of patients with SSc with ICD-10 diagnostic code (M34) were collected retrospectively from medical registers. The patients were reclassified into different subsets based on the ACR/ EULAR (American College of Rheumatology and European League Against Rheumatism) 2013 classification criteria of the SSc. Early SSc was defined as a condition that did not fulfill the classification criteria (less than 9 points). Diffuse (dcSSc), limited (lcSSc), overlap and skin sclerosis subsets were differentiated by their clinical phenotype.

Results: 336 patients were obtained after re-evaluation of data. Out of 336 patients 40 (11.9%) patients had dcSSc, 222 (66.1 %) lcSSc, 16 (4.8%) SSc-overlap syndrome, 2 (0.6%) SSc sine sclerosis and 56 (16.7%) early SSc. The early SSc group did not develop any of the most severe manifestations such as interstitial lung disease (ILD), the incidence of which was 32.7/1000 patient years in the whole SSc group, n=280, pulmonary arterial hypertension (PAH) 14/3/1000 patient years), renal crisis (RC) 3.5/1000 patient years), myositis 12/1000 patient years) during the 4.3 [IQR 1.9-6.7] years of follow-up. The SSc group had significantly more other manifestations as digital ulcers (41.1 vs. 6.7/ 1000 patient years, p<0.001, SSc and early SSc, respectively), reduced mouth opening (44.3 vs. 10.1, p<0.001) and manometry positive oesophageal dysmotility (21.1 vs 10.3, p=0.007) than patients with early SSc. ILD was diagnosed 2.8 (SD 0.7) years and RC 0.2 (SD 0.3) years after the onset of the first non-Raynaud’s phenomenon symptom in SSc patients. The patients with dcSSc had worse survival than IcSSc patients (after 5 years 81.9% vs 91.6%, 05/13/23 4 Color Fig(s):0 22:36 Art: 28_EUROAB-2023-P027-28

Children and Adults, Modena, Italy

University of Modena and Reggio Emilia, Department of Engineering

University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy

Background: Despite the positive impact of assistive devices (ADs) on the daily lives of people with disabilities, many of them are initially adopted and then regrettably abandoned. Even though the AD of an individual patient might fit his/her needs, up to 7 out of 10 people stop using it. On the one hand this may be linked to an improvement in their health, on the other, the devices may not be ergonomically suitable for long-term use. Previous studies have highlighted the possibility that co-designed and customised 3D printed assistive devices can benefit patients with rheumatic diseases which impair daily activities, especially manual ones. Among the 29 patients with Systemic Sclerosis who took part in the joint prevention clinic workshop at the University-Hospital of Modena (Italy), in 2019 4 patients actively joined the 3D printing project for the co-designing of ADs.

Objectives: This work has two main goals: firstly, to check whether in the short term the co-design approach is able to guarantee better acceptance of ADs and a lower abandonment rate. Secondly, to check during follow-ups, if the patients are satisfied and regularly use their ADs and if their daily activities remain unchanged.

Methods: The development of the ADs begins with co-design sessions which involve the patient, an Occupational Therapist and a designer. The AD is digitally modelled and 3D printed. Subsequently it is delivered to the patient following a number of training sessions. Using standardized tests such as PIADS (Psychosocial Impact of Assistive Devices Scale) and QUEST (Quebec User Evaluation of Satisfaction with assistive Technology) at the time of delivery of the ADs, then after 3 years, we assessed the level of satisfaction of the 4 patients enrolled, the condition of the ADs and their actual use.

Results: In 2019 each of the 4 patients received at least one AD, which they used on a regular daily basis [i.e. a device to open a moka pot (an Italian coffee machine); a token for a shopping trolley; a pen grip handle; a multiple key turner]. The results of the PIADS following delivery and in the 3-years follow-up were positive. The QUEST results were also positive. After 3 years the ADs were still being used regularly. Moreover, in 2022, 2 patients co-designed and 3D printed new ADs in response to new or altered needs.

Conclusion: In both the long and short term, ADs are still being used regularly and patients are still enjoying the benefits. After 3 years none of the ADs displayed any significant wear or breakage, thus their effectiveness was not compromised. Finally, the satisfaction of the patients with the co-designed ADs remained unaltered over time. Co-designed 3D printed devices have therefore proven to effectively reduce the AD abandonment rate.

Background: A proinflammatory and immunosuppressive role of cigarette smoking has been suggested in rheumatic and autoimmune conditions, with former and current smokers having increased susceptibility to the development of several diseases [1]. Conversely, a study from the United States showed that ever-smoking was not associated with a significant risk to develop systemic sclerosis (SSc) [2]. Up to date, no other study addressed smoking as a possible risk factor for developing SSc.

Objectives: The aim of our study was to investigate whether smoking is a risk factor for disease susceptibility in SSc in the Dutch population.

Methods: At Leiden University Medical Center, the prospective Combined Care in Systemic Sclerosis (CCISS) cohort was initiated in 2009 and, as of January 2022, 708 SSc patients have been included. Information about smoking history was collected at time of enrolment in the cohort, allowing patients to be categorised into never-smokers and ever-smokers. Data about smoking habits in the Dutch population from 2014 to 2021, stratified for sex and age (12-25; 25-45; 45-65; >65 years) are accessible from the Dutch Central Bureau of Statistics website (https://opendata.cbs.nl/file/83385NED/table?dl=6A354). The prevalence of ever-smokers in the CCISS cohort was compared with the prevalence of ever-smokers in the general Dutch population using chi-square tests. Due to the limited number of young SSc patients, only individuals aged 25 or above were included in the analysis. In order not to miss potentially relevant differences attributable to changes in smoking habits during time, two index years were chosen for the current analysis, 2015 and 2021. Age of the SSc patients who were enrolled in the CCISS cohort at the time of the index years was calculated. Patients who had died before each index year were excluded from the relative analysis. Official data about the Dutch population size and age composition were retrieved from the Dutch Central Bureau of Statistics website (https://www.cbs.nl/visualisaties/dashboard-bevolking/bevolkingspiramide).

Results: Details about the population size in each age range and the number of patients included in the study are reported in Table 1. No statistically significant differences emerged in the comparison of ever-smoking rates between SSc patients and the general Dutch population both in men and women and in each of the three age categories (all p-values > 0.05).

Conclusion: Our study demonstrates that the percentage of ever-smoking individuals is comparable in SSc patients and in the Dutch population. Although the stratification might have decreased the statistical power of our analysis, we can conclude that smoking does not confer an increased risk for the development of SSc in the Netherlands.

AB0893 CORRELATIONS BETWEEN CT SCAN, CLINICAL AND RESPIRATORY FUNCTIONAL DATA IN SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Systemic sclerosis, Imaging, Lungs

H. Abida1, Z. Meddeb1, C. Abdelkefi1, A. El Ouni1, S. Toujani1, S. Hamzeoui1, T. Larbi1, K. Bouslama1.

Background: The role of computed tomography (CT) in the assessment of pulmonary involvement in systemic sclerosis is witnessing constant updates with the development of scores and tools.

Objectives: The aim of our study was to look for a correlation between CT scan, clinical and respiratory functional data and to evaluate the severity of diffuse infiltrative lung disease using the Goh score.

Methods: It was a retrospective and descriptive study carried out at the Internal Medicine Department of Mongi Slim Hospital. It included data of patients with SSc with pulmonary involvement. We used the Goh CT score and the modified Goh score (with 6 levels) to assess the severity of lung involvement.

Results: 31 patients were included. The mean age of our patients was 50 years. The predominant elemental lesions on chest CT were ground-glass opacities (78%), septal thickening (77%) and traction bronchiectasis or bronchiolectasis (70%). The most common type of interstitial lung disease was non-specific interstitial pneumonia (65%) followed by usual interstitial pneumonia (23%). The statistical analysis showed associations between clinical, respiratory functional and imaging data. Decreased forced vital capacity was statistically associated with honeycomb (p=0.04) and non-specific interstitial pneumonia (p=0.05). It was also associated with the extent of lesions according to Goh score (p=0.031) and the modified 6-level Goh score (p=0.024). Crackles at the bases of lungs were associated with the degree of the reticulation extent according to the modified Goh score (p=0.022). A statistically significant relationship was also noted between cough and the extent of ground-glass opacities according to the modified Goh score (p=0.022).

Conclusion: Chest CT allows the assessment of the severity of lung involvement in SSc using semi-quantitative CT scores. We have concluded that the modified Goh score correlates better with clinical abnormalities.

SYMPTOMS OF GASTROINTESTINAL INVOLVEMENT IN PATIENTS WITH LIMITED AND DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS EVALUATED WITH TWO DIFFERENT SELF-ASSESSMENT TOOLS

Keywords: Gastrointestinal tract, Systemic sclerosis, Patient reported outcomes

M. Vujovic1, I. Paviлови2, M. Sefik Bukilica3,2, G. Gradinovici2,3, P. Ostojić2,3,1
1Institute of Rheumatology, Rheumatology, Belgrade, Serbia; 2Institute of Rheumatology, Rheumatology, Belgrade, Serbia; 3School of Medicine, University of Belgrade, Belgrade, Serbia

Background: Gastrointestinal (GI) tract is the second most affected organ in systemic sclerosis (SSc).

Objectives: This study aims to analyze the frequency and severity of GI symptoms and their impact on health-related quality of life among patients with limited cutaneous (lcSSc) and diffuse cutaneous systemic sclerosis (dcSSc), as well as in patients with anti-centromere autoantibodies (ACA) and anti-topoisomerase I autoantibodies (ATA).

Methods: Eighty-six consecutive patients with SSc (mean age 59.5 yrs, mean disease duration 11.7 ± 7.9 yrs) were included in this study. lcSSc have had 65 (75.6%) of patients, whilst 21 (24.4%) had diffuse form of the disease. ACA were detected in 48 patients (55.8%), ATA in 25 patients (29.1%), two of them had both ACA and ATA (23%) and 11 (12.5%) of them had positive antinuclear antibodies (ANA) without specific autoantibodies. We used two self-assessment questionnaires to evaluate the presence and severity of GI symptoms: UCLA-SCTC-GIT 2.0 (1) and the SAQ [2].

Results: There was no difference in percentage of patients with lcSSc and dcSSc who used proton pump inhibitors (41.5% vs 52.3%), as well as in patients with positive ACA or ATA (45.8% vs 52%). Symptoms of gastrointestinal reflux (lcSSc: dSSc = 70.7%: 71.4%), distension/bloating (lcSSc: dSSc = 72.3%: 61.9%), diarrhea (lcSSc: dSSc = 27.7%: 42.8%), constipation (lcSSc: dSSc = 44.6%: 33.3%) and fecal soiling (lcSSc: dSSc = 9.2%: 14.3%) were found equally frequent (p>0.05) in patients with lcSSc and dcSSc. GI symptoms were equally common (p>0.05) in patients with ACA and ATA as follows: reflux (ACA: ATA = 70.8%: 80%); distension (ACA: ATA = 77.1%: 64%); diarrhea (ACA: ATA = 33.3%: 28%); constipation (ACA: ATA = 47.9%: 40%); and fecal soiling (ACA: ATA = 8.3%: 16%). Reflux and distension were most frequently present categories, with the highest mean index scores, implicating that these symptoms were most common and severe in our patients. We did not notice significant difference in prevalence and severity of GI symptoms in patients with lcSSc and dcSSc, as well as in patients with ACA and ATA (Table 1). Total GIT score correlated positively with all SAQ indices. Interestingly, index of reflux correlated with the Index of respiratory status (IRS), a distinct domain within the SAQ questionnaire, related to respiratory symptoms, implicating that patients with severe reflux have more serious respiratory symptoms.

Conclusion: Gastrointestinal impairment is very frequent and affects the quality of life in patients with SSc, with no difference regarding the disease subtype or autoantibodies, emphasizing the importance of early diagnosis and treatment. These questionnaires may be helpful in early detection of GI involvement.

Table 1. Severity of GI symptoms in different disease subtypes and autoantibodies present. Differences among the groups were not statistically significant (p>0.05).

SUBCUTANEOUS IMMUNOGLUBULINS IN IDIOPATHIC INFLAMMATORY MYOPATHIES: IS IT TIME FOR A THERAPY DISCONTINUATION SCHEDULE?

Keywords: Myositis, Outcome measures, Quality of care

C. Cardelli1,2, S. Barsom1,2, E. Laurino1, M. Diomedi1, F. Fattorini1, A. Tripodi1, L. Carli1, M. Mosca1,1
1University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy; 2University of Siena, Department of Medical Biotechnologies, Siena, Italy; Ospedale di Livorno, Medicina Interna, Livorno, Italy; Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy

Background: Subcutaneous immunoglobulins (SCIG) therapy is effective in patients with Idiopathic Inflammatory Myopathies (IMI), especially in severe and refractory forms of the disease; however, its use is burdened by high costs. Although it is now known that the dosage to be used for the immunomodulatory effect is 2g/kg per month, there are no standardised tapering or discontinuation schemes to date.

Objectives: The aim of the study was to assess whether there are differences in terms of clinical outcomes and patient Quality of Life (QoL) between two different SCIG treatment regimens, involving discontinuation of therapy after the first six months or continuation of the drug for a further six months.

Methods: Within the cohort of IMI patients (2017 EULAR/ACR criteria) followed at our Myositis Clinic, we selected those who were treated with SCIG and, dividing them into two groups according to whether they discontinued therapy after the first six months, we performed a retrospective analysis on data prospectively collected. For each patient, demographic and clinical data (age, sex, disease subset and duration, organ involvement, comorbidities, treatment) were collected from medical charts. The International Myositis Assessment & Clinical Studies Group Disease Activity Core Set Measures (IMACS-CSMs) [Physician Global Activity (PhGA), Patient Global Activity (PGA), 8-items Muscle Affecting Treatment Monitoring Tool (MAMT), Health Assessment Questionnaire (HAQ), serological muscle enzymes values] were used to assess the disease activity at baseline and to evaluate the clinical outcomes after six and twelve months from the start of SCIG therapy. Patients’ perspective was evaluated also by administration of Patient Reported Outcomes (PROs) not included in the IMACS-CSMs: Short-Form 36 Items Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACT-F), Hospital Anxiety and Depression Scale (HADS). We then compared the delta of IMACS-CSMs and PROs between the 12-month (12m) and 6-month (6m) assessments to detect any significant changes in patients’ health status following the discontinuation of SCIG therapy.

Results: We included 18 patients (12 dermatomyositis, 6 polymyositis; 61.1% female) with a mean age at the beginning of SCIG therapy of 63.8±14.8 years. Of these, 10 (55.6%) discontinued SCIG therapy after 6 months of treatment while 8 (44.4%) continued it for at least one year. We found no differences between the two groups in terms of disease activity and patients’ QoL at baseline. At 12 months evaluation, there were no statistically significant differences in PhGA (2.9±1.7 vs 2.5±1.7), HAQ (6759±80.6 and 751±61.1) and serum values of muscle enzymes (CPK, LDH, aldolase) between those who had discontinued SCIG after the first 6 months and those who continued the treatment. Patients’ QoL was also found not to differ between the two groups, as no statistically significant differences emerged between the scores of HAQ, all SF-36 domains, FACT-F and HADS anxiety and depression subscales. The delta 12m-6m of QoL assessment parameters showed no differences between the two groups, while there was a worsening of mean PhGA (1.5±1.4 vs -0.5±1.8, p=0.026) and MMT8 (-5.3±6.6 vs 3±3.2, p=0.010) in those who discontinued therapy compared with those who continued SCIG.

Conclusion: Although preliminary and with the limitations inherent to the retrospective nature of the study, these data seem to suggest that there are no significant differences in outcomes assessed by IMACS-CSMs and in patient’s perception of the disease between different treatment regimens concerning the discontinuation of SCIG. If our findings will be confirmed by future studies on larger cohort of IMI patients, although it appears that there may be a slightly deterioration in muscle function, discontinuing SCIG therapy after the first six months of treatment could reduce health costs, without the risk of significantly compromising patients’ quality of care.

BEYOND CLINICAL TRIALS: EFFICACY AND SAFETY OF NINTEDANIB IN IFP AND PROGRESSIVE FIBROSING INTERSTITIAL LUNG DISEASES IN CLINICAL PRACTICE

Keywords: Organ damage, Lungs, Real-world evidence
A. I. De Gracia¹, C. Bea¹, E. Fuertes¹, A. De Castro¹, L. Navarro¹, C. Prades¹, D. Ruiz¹, P. Abioli², M. J. Forner¹, S. Vela-Bernal¹. Hospital Clinic Universitari, Medicina Interna, València, Spain

Background: Since publication of clinical trials regarding the efficacy of nintedanib in fibrosing ILD, including the ILD associated with autoimmune diseases, its clinical use has increased but not enough real-world data has been published.

Objectives: The aim of our study was to evaluate the efficacy and safety of nintedanib in patients with interstitial lung diseases (ILDs) progressively fibrosing of several etiologies in a spanish third-level hospital.

Methods: A retrospective study was designed to collect clinical and radiological data of 31 patients under treatment with nintedanib, followed up by Internal Medicine, Rheumatology, or Pneumology specialists since 2016.

Results: Characteristics of the study population are collected in Table 1. The indications for nintedanib were a fibrosis progression in the previous 24 months, determined as a decrease of Forced Vital Capacity higher than 10% in 25 patients (41,67%) or a decrease of 5-10% in 5 patients (8,33%). The increase of fibrosis in CT in 17 patients (28,33%) and a clinical worsening in 25 patients (41,67%) were also indications for treatment, as in pivotal trials. The mean time with nintedanib was 12,58 months (± 13,20). The drug was stopped in 9 patients (29%), 1 of them due to progression and 8 due to adverse effects, none of them severe, being the most frequent gastrointestinal. 12 patients died during follow-up. 7 (58,33%) were diagnosed with IPF, 4 with progressive fibrosis ILD, and 3 with ILD associated with systemic sclerosis. No significant differences between groups were found. Spirometric values were collected before treatment as well as at 3, 6, 12, and 24 months after starting treatment to compare the mean values of FVC (ml), FEV1 (ml), Tiffenau index and DLCO (%). The evolution of spirometric parameters is shown in graph 1. No significant differences were found between them at baseline and after treatment, in accordance with the expected slowing of the progression to fibrosis. Regarding the evolution in radiological studies, fibrosis progression was only observed in a small percentage of patients.

Conclusion: Nintedanib was one of the first anti-fibrotic drugs with indication in fibrosis ILD. Not only for IPF but also for ILD of diverse etiology, including those associated with autoimmune diseases, after the publication of clinical trials. Therefore, its use is increasing despite limited inclusion criteria in trials and scarce real-life clinical data. Our real-world study, even with its limitations, shows that the benefit of nintedanib in the fibrosis ILD not only for IPF but also for ILD of diverse aetiology, including the ILD associated with autoimmune diseases, after the publication of clinical trials. Therefore, its use is increasing despite limited inclusion criteria in trials and scarce real-life clinical data. Our real-world study, even with its limitations, shows that the benefit of nintedanib in the fibrosis ILD not only for IPF but also for ILD of diverse aetiology.

**AB0897 THE PRESENCE OF ANTI-U1-RNP ANTIBODY HAS A MILD BUT APPARENT IMPACT ON INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS**

Y. Itsuki, H. Fujimoto, Y. Yamamoto, A. Nakajima. ¹Mie University Hospital, Center for Rheumatic Diseases, Tsu, Japan; ²Mie University Graduate School of Medicine, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Tsu, Japan

Background: Interstitial lung disease (ILD) is the leading cause of systemic sclerosis (SSc)-related death[1]. With the availability of antifibrotic agents to slow the progression of SSc-ILD[2], it is important for clinicians to be aware of the antibody profile predicting the severity and progression of SSc-ILD.

Objectives: To determine the impact of anti-U1 ribonucleoprotein antibody (αRNPab) in addition to anti-topoisomerase 1 antibody (ATA) on SSc related interstitial lung disease (ILD).

Methods: Patients with SSc who visited Mie University Hospital between December 2020 to December 2021 were consecutively registered. The severity and progression of ILD on chest computed tomography (CT) were assessed based on the ILD and traction bronchiectasis (TBE) scores, evaluated by using established method[3] with minor modification. We hypothesized that ATA had the greatest impact on ILD, followed by αRNPab, and accordingly stratified patients into three groups: group 1, ATA-positive; group 2, αRNPab-positive; and group 3, double-negative. At registration, patient characteristics were compared according to the presence of ILD, and the severity of ILD were compared among three groups. For patients who had earlier CT scans available, ILD progression was assessed.

Results: Among 48 patients (ILD/non-ILD; n=25/23), αRNPab positivity was significantly higher in the ILD than in the non-ILD group (32%, 0%, p<0.01). In 47 patients, the percentage of patients whose ILD score ≥ 20% was 83.3, 28.5 and 5.8% in groups 1, 2 and 3 (n = 67/34), respectively (p<0.01). In 25 patients, the percentage of patients with progressive ILD whose ILD score increased by ≥ 5% was 80.0, 50.0 and 14.3% in groups 1, 2 and 3 (n = 5/6/14), respectively (p<0.01).

Conclusion: The presence of αRNPab significantly affects the presence, severity and progression of SSc-ILD, although the effect is milder than that of ATA.

LUNG ULTRASONOGRAPHY FOR THE SCREENING AND PROGNOSTIC STRATIFICATION OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Systematic review, Ultrasound, Systemic sclerosis

A. Alunno1, N. Piconi2, E. Pintus3, J. Schooners5, M. Matucci-Cerinic2,4, S. Bellando Randone2, Internal Medicine and Nephrology Division, University of Udine, Department of Life, Health and Environmental Sciences, Udine, Italy;2Division of Rheumatology, AOUC, Dept. Experimental and Clinical Medicine, University of Florence, Florence, Italy;3Leiden University Medical Center, Directorate of Research Policy (formerly Walaeus Library), Leiden, Netherlands;4IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy

Background: Intestinal lung disease (ILD) affects almost all systemic sclerosis (SSc) patients and is the major cause of morbidity and mortality. Chest high resolution computed tomography (HRCT) is today the gold standard imaging method to diagnose and disclose the characteristic SSc ILD features. More than 71% of SSc patients has ILD present, n (%) 5 (83.3%) 7 (100%) 12 (35.2%) <0.01*

Methods: A systematic literature search in several databases was conducted following the PICO framework on July 2022. Two researchers independently screened abstracts and titles and full texts were subsequently reviewed to determine eligibility (original research articles enrolling adult SSc patients undergoing lung US and HRCT). Data from eligible articles were extracted and risk of bias and/or level of evidence were assigned. In 3 studies, a very good reproducibility (intraclass correlation coefficients=0.95-0.96 and Cohen's k=0.72) was detected. The concordance between US and HRCT in identifying ILD pathological findings was around 80%.

Results: Out of 1656 retrieved articles, only 95 were selected for full text evaluation. The design, execution, and interpretation of results for this study were entirely independent of these companies.gements to declare.

**NINTEDANIB DOES NOT IMPROVE NAILFOLD CAPILLARY ABNORMALITIES IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**Keywords:** Lungs, Imaging, Systemic sclerosis

T. Sugimoto1, H. Watanabe1, Y. Yoshida1, S. Mokuda1, S. Hirata1. 1Hiroshima University Hospital, Clinical Immunology and Rheumatology, Hiroshima, Japan

**Background:** The pathogenesis of SSc consists of three aspects: fibrosis, angiopathy, and immune abnormalities. Nintedanib has been shown to be effective against interstitial lung disease (ILD) as an antifibrotic drug, but it may also have effects on vascular disorders due to its inhibitory effects on FGF, PDGF, and VEGF. While nailfold capillary abnormalities in patients with systemic sclerosis (SSc) may improve with immunosuppressive therapy, no reports have evaluated whether nintedanib improves nailfold capillary abnormalities.

**Objectives:** To clarify whether nintedanib improves nailfold capillary abnormalities in patients with SSc complicated by ILD.

**Methods:** This study is a prospective observational study. Among patients diagnosed as having SSc according to the 2013 ACR/EULAR classification criteria, those who started to treat with nintedanib for ILD at our hospital from March 2020 to July 2022 were consecutively registered. The nailfold capillaries were evaluated using a nailfold videocapillaroscopy (NVC), capable of observing at 200x magnification. The evaluation was carried out using the current standardized method. [1] NVC was performed before drug induction and 1 year after drug induction. Only patients who had NVC testing up to 1 year later were included in the evaluation. At the same time, blood tests such as KL-6, SP-A, and SP-D, and respiratory function tests were evaluated. This study has been pre-approved by the Hiroshima University Hospital Ethics Committee. (OySteR study: Optimal strategy in SSc Treatment for Recovery, approval number: E-1940-1)

**Results:** Eight patients were analyzed. The mean age was 59 ± 17 years. Female patients (7/8, 87.5%) were positive for anti-Scl-70 antibodies. Details of other cases are described in Table 1. Seven patients (87.5%) had a history of treatment with immunosuppressive therapies. The disease duration was less than 6 years in 5 patients, and 6 years or longer in the remaining 3. Five patients were able to continue nintedanib for 52 weeks: 1 patient discontinued nintedanib after 1 month due to abnormal liver function, 1 patient with diabetes discontinued after 10 months. All of the patients who were able to continue oral administration were also reduced to 200mg/day due to diarrhea. Baseline mean FVC, KL-6, SP-A, and SP-D are described in Table 1. The results by NVC pattern were Normal in 1 case, Early in 2 cases, Active in 1 case, Late in 3 cases, and Non-specific in 1 case. Quantitative baseline results for the NVC tests were capillary density (number of capillaries) 5.8 ± 2.1/mm, enlarged capillary score 0.91 ± 0.85, giant capillary score 0.31 ± 0.30, and hemorrhage score 0.26 ± 0.30. Mean FVC, KL-6, SP-A, and SP-D after 1 year are also shown in Table 1. Conclusion: Nintedanib tended to improve ILD biomarkers and pulmonary function test results in patients with SSc, but did not improve nailfold capillary abnormalities. Based on this result, combination therapy is preferable to nintedanib alone for improving the pathology of SSc.

**FUNCTIONAL CAPACITY, BODY COMPOSITION AND DISEASE ACTIVITY ARE ASSOCIATED WITH QUALITY OF LIFE IN PATIENTS WITH MYOSITIS**

**Keywords:** Outcome measures, Quality of life, Myositis

K. Y. Jensen1, P. Aagard2, C. Sueta2, J. Nielsen2, H. D. Schroder2, C. Gronset2, L. P. Diederichsen1, 1The Copenhagen University Hospital - Righospitalat, Copenhagen Research Center for Autoimmune Connective Tissue Diseases (COPEACT),
Background: Idiopathic inflammatory myopathies – or briefly myositis – has cardinal traits of muscle weakness [1] and decreased muscle endurance [2] in addition to reduced quality of life (QoL) [3]. However, QoL is complex, and it is unclear which factors affect QoL in patients with myositis. Knowledge of these factors and potential associations to QoL is of importance for evoking changes to a better life for patients with myositis.

Objectives: To investigate the influence of functional capacity, muscle strength, body composition and disease activity and damage on QoL in patients with myositis.

Methods: Measures of functional capacity (functional index 3, 2-minute walk test, timed-up-and-go and 30-s sit-to-stand), muscle strength (5 repetitions maximum strength in leg press, bench press, cable row, knee extension, biceps curl and static handgrip strength; all expressed relative to body mass), leg extensor power (Nottingham Power Rig, relative to body mass), body composition (height adjusted appendicular lean mass and fat mass) and IMACS (International Myositis Assessment & Clinical Studies Group) disease activity and disease damage core set measures were analysed to investigate the impact on QoL (physical and mental component summary in the Short Form 36 questionnaire (SF-36)).

Results: All functional capacity measures were positively correlated with the physical component summary (PCS); functional index 3 ($r^2=0.15$, $p=0.03$), 2-minute walk test ($r^2=0.26$, $p=0.003$), timed-up-and-go ($r^2=0.14$, $p=0.03$) and 30-s sit-to-stand performance ($r^2=0.15$, $p=0.03$). Only leg press ($r^2=0.15$, $p=0.04$) showed a positive correlation with PCS for measures of muscle strength and power. For body composition, height adjusted fat mass correlated negatively with PCS ($r^2=0.20$, $p=0.01$). Of the IMACS disease activity and disease damage core measures, Health Assessment Questionnaire ($r^2=0.40$, $p=0.0001$), Physician Global Assessment of Disease Damage ($r^2=0.44$, $p<0.001$), Patient Global Assessment of Disease Damage ($r^2=0.18$, $p=0.02$) were negatively correlated with PCS. In contrast, none of the investigated outcome parameters were correlated with the mental component summary of SF-36.

Conclusion: In the present group of patients with myositis, functional capacity and muscle strength had positive associations with the physical component summary of the QoL, indicating that future interventions should be directed to improve these factors to ultimately improve QoL. The Health Assessment Questionnaire and Patient/Physician Global Assessment of Disease Damage revealed strong correlations with PCS, supporting that both patient-reported outcome parameters and clinician-reported outcomes are highly relevant QoL-related monitoring parameters in patients with myositis.

LEFT VENTRICULAR SYSTOLIC DYSFUNCTION IS RARE BUT PROGNOSTICALLY IMPORTANT IN SYSTEMIC SCLEROSIS

Keywords: Cardiovascular disease, Systemic sclerosis, Heart

J. Fairey1,2, D. Hansen3, S. Proudmant4, J. A. Saha4,6, G. S.Ngian1,6, J. Walker1, L. Host1, A. La Gerche1,6, D. Prior2, K. Morrisroe1,2, W. Stevens2, M. Ninkou1,2, L. Ross1,2,1 The University of Melbourne, Department of Medicine, Dentistry and Health Sciences, Melbourne, Australia; 2St. Vincent’s Public Hospital, Melbourne, Department of Rheumatology, Fitzroy, Australia; 3The University of Adelaide, Department of Medicine, Adelaide, Australia; 4Royal Adelaide Hospital, Department of Rheumatology, Adelaide, Australia; 5Monash Health, Department of Rheumatology, Clayton, Australia; 6Melbourne University School of Medicine, Clayton, Australia; 7Fiona Stanley Hospital, Department of Rheumatology, Murdoch, Australia; 8Baker Heart and Diabetes Institute, Sports Cardiology, Melbourne, Australia; 9St. Vincent’s Public Hospital Melbourne, Department of Cardiology, Fitzroy, Australia

Background: Reduced left ventricular ejection fraction (LVEF) occurs in only around 5% of unselected SSC cohorts [1]. Subclinical LV systolic dysfunction (LVSD) defined by advanced echocardiographic measures including global longitudinal strain (GLS) may be more prevalent [2].

Objectives: To quantify the frequency of LVSD in SSCs as measured by LVEF and LV GLS, and its impact on survival and physical function.

Methods: Included participants in the Australian Scleroderma Cohort Study met ACR/EULAR criteria for SSCs and had ≥1 echocardiographic LVEF measurement. Those with secondary causes of LVSD (ischaemia, valvular disease and PAH) were excluded. Chi squared tests, two sample t-tests or Kruskal Wallis tests were used for between group comparison as appropriate. Generalised estimating equations were used to model longitudinal data. Survival analyses were performed using Kaplan-Meier and Cox proportional hazard models.

Results: Of 1145 participants, 2.5% recorded a reduced of LVEF<50% during follow up; 14% had borderline LVEF of ≥50% but <55%; and 83% always a LVEF ≥55%. Only 0.6% ever had a LVEF<40%. LVREF returned to normal in 66% of those who had recorded a LVEF<50%. Compared to those with normal LVEF, those with reduced LVEF were similar in age, more frequently male (p=0.01), with SSCs (p<0.001), SSC renal crisis (p=0.02), synovitis (p=0.04) and higher inflammatory markers (p=0.02). Those with reduced LVEF more commonly had myositis (p<0.01), muscle atrophy (p=0.01) and proximal weakness (p<0.01). Use of prednisolone (p=0.03), IVIG (p=0.01), and cyclophosphamide (p=0.01) were more common in those with reduced LVEF. Survival was worse in those with reduced LVEF (Figure 1). Reduced LVEF was associated with a 2.8-fold increased risk of death (95% CI 1.3-6.3, p=0.01; Table 1). Physical function and quality of life were worse in those with reduced LVEF. Multivariate analyses identified shorter six minute walk distance (p=0.01), higher Health Assessment Questionnaire Disability Index scores (p<0.01) and lower Short Form 36 Physical Component Summary scores (p=0.02) in those with reduced LVEF. Participants with reduced LVEF were 3.9-times more likely to record WHO Class III/IV dyspnea (95% CI 1.8-8.1, p<0.01). LV GLS data were available for 90% of participants at one centre (n=219). Abnormal LV GLS (<-18.3%) was seen in 30% of those with normal LVEF and 53% with borderline LVEF. LV GLS was lowest in those with reduced LVEF (-17.2%; IQR -14.9 - -18.0%) compared to those normal (<-19.5%; IQR -18.0 - -20.8%) or borderline LVEF (-18.3%; IQR -16.9 - -19.5%; p<0.01). Worst recorded GLS was associated with increased mortality (HR 1.3, 95%CI 1.0-16, p=0.02), although this association was attenuated in multivariate analyses (HR 1.2, 95%CI 1.0-1.5, p=0.10).

Conclusion: After excluding secondary causes, reduced LVEF in SSCs is rare. Despite the relative infrequency, LVEF<50% is associated with a specific SSC phenotype, worse survival and physical function. Abnormal LV GLS is more prevalent in SSCs, seen in 30%-50% of those with persistent LVEF<50%. Further data are required to define the threshold of LVDSD in SSCs, and to explore the utility of measures of subclinical LVSD such as LV GLS.

Background: There is a breadth of evidence supporting a key role for abnormal B-cell function in the pathogenesis of systemic sclerosis and associated interstitial lung disease (SSc-ILD) [1,2]. A previous pilot study investigated the efficacy of belimumab, a recombinant human immunoglobulin G1 lambda (IgG1λ) monoclonal antibody that binds to and neutralises B-lymphocyte stimulator (BLYS) subsequently inhibiting the survival of B cells [3], in reducing modified Rodnan skin score (mRSS) in 20 patients with SSc [4]. Belimumab is well tolerated and is approved for the treatment of patients with active systemic lupus erythematosus and active lupus nephritis receiving standard therapy [5]. We hypothesise that by reducing the number of B cells and dampening B-cell effector functions in the lung, skin, and other tissues, belimumab will not only improve inflammation and fibrosis in regions affected by abnormal B-cell function, but may also have a broader effect of improving lung function decline and skin thickening in SSc, and/or reduction in, lung function decline and skin thickening in SSc, andactive lupus nephritis receiving standard therapy [5]. We hypothesise that 

Objective: To present the design of a randomised controlled trial that will evaluate the efficacy and safety of subcutaneous (SC) belimumab versus placebo in adult patients with SSc-ILD.

Methods: In this global, parallel-group, Phase 2/3, randomised, double-blind, placebo-controlled, two-arm, 52-week study (GSK Study 218224), eligible adult patients with a documented diagnosis of SSc and ILD (as confirmed by high-resolution computed tomography) will be randomised 1:1 to receive either belimumab 200 mg SC weekly (Arm 1), or matching SC placebo weekly (Arm 2), for 52 weeks (Figure 1). Participants will be permitted to continue their stable doses of standard therapy throughout the study. The primary endpoint of the study is absolute change from baseline in mRSS, absolute change from baseline in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score, and SSc progression or death. Patient-reported outcomes (listed in the Figure 1) will also be assessed. A comprehensive biomarker approach will be implemented to evaluate the belimumab modulating effects on key biological processes involved in SSc pathogenesis (fibrosis and inflammation) in circulation and in skin biopsies. Safety will be monitored throughout the study.

Results: Target sample size is planned to be approximately 300 patients, with 150 patients per arm.

Conclusion: We present the design of a global Phase 2/3 study that will test the efficacy and safety of SC belimumab in patients with SSc-ILD. Together, the study endpoints enable the assessment of the efficacy of belimumab on a broad range of disease manifestations, disease progression, and impact on patient burden.

Figure 1. Study design

An open-label extension will be performed. FVC, forced vital capacity; R, randomisation
Background: Inflammatory muscle diseases are systemic inflammatory disorders that affect not only muscles but also skin, joints, lungs, and heart. Dermatomyositis (DM) and polymyositis (PM) are characterized by the production of antibodies. Measurement of these antibodies is useful for diagnosis, classification of disease type, evaluation of disease activity, prognosis prediction, and determination of therapeutic strategy. However, the sensitivity and specificity vary depending on the measurement method, and some autoantibodies can only be measured in limited laboratories.

Objectives: We developed a novel comprehensive assay kit for myositis-associated antibodies with the aim of developing a rapid and simple detection method for myositis-specific or related autoantibodies. We used a proteome-wide antibody screening and quantification with wet protein arrays consisting of proteins synthesized from proteome-wide human cDNA library (HuPEX). We examined whether this assay kit is clinically useful compared to enzyme-linked immunosorbent assay (ELISA).

Methods: Sera from 47 patients diagnosed or suspected of inflammatory muscle disease were used to measure myositis-specific autoantibodies (anti-ARS, anti-MDA5, anti-TIF1-γ, anti-Mi2, and anti-SRP, antibodies) and myositis-related autoantibodies (anti-U1RNP, anti-Ku, and anti-PM-Scl, anti-mitochondria antibodies) were measured using a proteome-wide antibody screening and quantification with wet protein arrays consisting of proteins synthesized from proteome-wide human cDNA library (HuPEX) and compared with the results of ELISA, which is commercially available and immunoprecipitation with some autoantibodies (anti-OJ, anti-Zo antibodies). Autoantibodies that were undetectable by the ELISA and positive only on the array were subjected to immunoprecipitation. In immunoprecipitation, primary antibody added to a solution containing an antigen to form an antigen-antibody complex in the solution. Next, a secondary antibody immobilized on the beads is added to adsorb the antigen-antibody complex to the beads. Finally, the antigen was eluted from the beads using SDS and analyzed using SDS-PAGE.

Results: In the 47 cases, the clinical diagnosis was DM in 26 cases, PM in 20 cases, and inclusion body myositis in 1 case. In the ELISA commercially available, 20 cases of anti-ARS antibody (17 cases of DM, 3 cases of PM), 5 cases of anti-MDA5 antibody (Amyopathic DM), 1 case of anti-TIF1-γ antibody (DM), 2 cases of anti-Mi2 antibody (1 case of DM, 1 case of PM), 2 cases of anti-RNP antibody (PM), and 2 cases of anti-mitochondria antibody (PM). Compared with the results measured by the ELISA commercially available, eight of the 20 cases were positive for anti-ARS antibodies using the proteome-wide antibody screening system and all other autoantibodies were 100% concordant. In addition, 1 case of DM in which autoantibodies could not be detected by the ELISA was positive for anti-OJ antibody by the proteome-wide antibody screening system. Of the 6 PM cases whose autoantibodies could not be detected by the ELISA, 1 was anti-HMGCR antibody-positive and 1 was anti-Zo antibody-positive, consistent with the clinical diagnosis. Furthermore, among the 4 PM cases which were positive only for anti-SS-A antibody by ELISA, 2 were anti-SRP antibody positive, 1 was anti-Ku antibody positive, and 1 was anti-Ki antibody positive by the proteome-wide antibody screening system. Those samples that could be detected by the array were also confirmed to be positive by immunoprecipitation.

Conclusion: Collectively, proteome-wide screening of antibodies using the in vitro proteome can reveal the myositis-associated antibodies of patients and may provide novel clinical biomarkers.

Objectives: understand the pathogenesis of the disease.

Background: Dermatomyositis (DM) patients with anti-melanoma differentiation-associated protein 5 (MDA5) antibodies (Ab) are likely to have rapidly progressing interstitial lung disease and a poor prognosis. Thus, it is important to understand the pathogenesis of the disease.

Methods: Twenty-eight cytokines in the serum of patients with anti-MDA5 Ab+ DM patients were screened and compared with the results of patients with other collagen vascular diseases. We also performed an immunohistochemical analysis of skin rashes (Gottron’s signs) from two patients.

Results: Serum levels of interferon gamma-induced protein 10 (IP-10, CXCL10), one of CXCR3 chemokines, were significantly higher in anti-MDA5 Ab+ DM patients than in SLE and anti-MDA5 Ab- DM patients. Moreover, serum interferon (IFN) α/2 levels were also higher in anti-MDA5 Ab+ DM. Patients. After initiation of immuno-suppressive therapy, IP-10 and IFN-α/2 levels decreased rapidly, whereas those of IFN-γ and CXCL9, another CXCR3 chemokine, did not substantially decrease. Skin samples revealed that the IP-10 positive cells in the dermis were positive for CD68 antigen, a monocyte/macrophage marker. In contrast, they contained a few CD8+ cells and almost no CD4+ cells. We also stimulate monocytes from healthy controls with type I and II IFNs in vitro and demonstrated that IP-10 was produced in the culture supernatant in a dose-dependent manner.

Conclusion: Our results indicate that IP-10 is highly produced in DM patients with anti-MDA5 Abs. The levels of type I IFN were also high and even exceeded those of SLE. Several reports have shown that not only type II IFN but also type I IFN induces IP-10. Thus, type I IFN/IP-10 axis may play an important role in the pathogenesis of anti-MDA5 Ab+ DM. Our immunohistochemical analysis of the skin also revealed that IP-10 released from macrophages may prompt infiltration of macrophages themselves, constituting a positive feedback loop in the skin inflammation. Further analyses are required to prove the usefulness of IP-10 as a disease activity and/or prognostic marker of DM with anti-MDA5 Abs.

SCREENING AND ANALYSIS OF POSSIBLE DRUGS BINDING TO PDGFR: A MOLECULAR MODELING STUDY

Keywords: Targeted synthetic drugs, Systemic sclerosis, Disease-modifying Drugs (DMARDs)

M. Mozziacafreddo1, D. Benfaremo2, C. Paolini1, S. Agarbati1, S. Svegliati Baroni1, G. Moroncini1,3, Marche Polytechnic University, Department of Clinical and Molecular Sciences, Ancona, Italy; Marche University Hospital, Department of Internal Medicine, Ancona, Italy

Background: The platelet-derived growth factor receptor (PDGFR) is a membrane tyrosine kinase receptor involved in several metabolic pathways, mainly in tumor progression [1, 2], immune-mediated diseases [3-4], and viral diseases [5].

Objectives: Considering this macro-molecule as a druggable target for modulation/inhibition of these conditions, the aim of this work was to find new ligands or new information to design novel effective drugs.

Methods: We performed an initial interaction screening with the human intra-cellular PDGFRα of about 7200 drugs and natural compounds contained in five independent databases/libraries and implemented in the MTL/openScreen web server. After selection of 27 compounds, a structural analysis (in particular, molecular docking and molecular dynamics analysis, using SwissDock based on EADock DSS algorithm [6, 7] and GROMACS [8], respectively) of the complexes obtained was performed. Three-dimensional quantitative structure–activity relationship and ADMET analyses were also performed to understand physicochemical properties of that compound to increase affinity and selectivity.

Results: Among these 27 compounds, the drugs Bafetinib, Radotinib, Flutamib and Imatinib showed the higher affinity for this tyrosine kinase receptor, lying in the nanomolar order, while the natural products, such as curcinum, luteolin and EGCg, included in this group showed submicromolar affinities. All these compounds, obtained through the QSAR and ADMET analysis, provided physicochemical information about an ideal best ligand for PDGFRα.

Conclusion: Although experimental studies are recommended, the structural information obtained could provide useful insight into the future development of PDGFRα inhibitors.

IMMUNOEXPRESSION OF TGFβ1 IN SKIN IN SYSTEMIC SCLEROSIS

Keywords: Prognostic factors, Systemic sclerosis, Diagnostic Tests

K. Romanowska-Prochnicka1, A. Wajda2, M. Grabowska3, M. Legatowicz-Koprowska1, A. Paradowska-Gorycka1, M. Olesińska1,2, Medical University of Warsaw, Department of Biophysics, Physiology and Pathophysiology, Faculty of Health Sciences, Warsaw, Poland; National Institute of Geriatrics, Rheumatology and Rehabilitation, Department and Polyclinic of Systemic Connective Tissue Diseases, Warsaw, Poland; National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Molecular Biology, Warsaw, Poland; Pomeranian Medical University, Department of Histology and Developmental Biology, Faculty of Health Sciences, Szczecin, Poland; National Institute of Geriatrics, Rheumatology and Rehabilitation, Department and Polyclinic of Systemic Connective Tissue Diseases, Warsaw, Poland

Background: TGF-β1 pleiotropic functions in inflammation, fibrosis, and vascular remodeling suggest that TGF-β1 signaling could play a central role as a link between fibrosis and vasculopathy characteristic of SSC. Moreover high mRNA level of TGF β1 in whole blood and high immunoreexpression in tissues in SSC patients confirms its role in the SSC pathogenesis.

Objectives: The aim of this study was to determine TGFβ1 immunoreexpression in the skin in patients with systemic sclerosis.

Methods: Skin biopsies from 14 patients with SSC (7 female and 7 male) at median age 60 years (19-69) were analyzed by immunohistochemistry method using anti-TGFβ1 primary mouse monoclonal antibody IgG (Abcam, Cambridge, UK, ab190503). Morphological analysis has been conducted by Hematoxylin and eosin (H&E) staining and Masson trichrome staining. The sections were examined using a light microscope Olympus BX 41 (Olympus, Hamburg, Germany). Patients. Women and men in the study group did...
not statistically differ in age. Men were characterized by significantly higher CRP (p=0.03) but not ESR (p>0.99). In the study group, women were more often characterized by irreversible fibrotic lesions in lungs (HRCT-T), but the frequency of occurrence was not statistically significant (p=0.56). Men were characterized by higher mRSS than women, but the difference was not statistically significant (p=0.14).

**Results:** Histological analysis of the human skin biopsies from patients with systemic sclerosis revealed perivascular edemas, flattening of the dermal papilla and excessive accumulation of collagen in the papillary and reticular layers of the dermis (Figure 1A, B). The fibrosis of the dermis was manifested by the presence of numerous bunches of irregularly distributed collagen fibers (Figure 1B). Moreover, perivascular focal infiltrations of inflammatory cells and reduction of blood vessel density were observed. In the human skin biopsies from patients with systemic sclerosis TGFβ1-positive cells were observed (Figure 1C, D, E). The cells showed various cytoplasmic immunexpression of TGFβ1 (brown-stained cytoplasm) in keratinocytes (mainly in the basal layer of epidermis) and in fibroblasts of the dermis.

**Conclusion:** High immunexpression of TGFβ1 is correlated with mRNA level observed in whole blood in patients with SSC. Patients with limited SSC are characterized by weaker staining in skin biopsy than patients with diffuse SSC. Determination of mRNA TGFβ1 level in whole blood seems to be a good diagnostic marker of SSC.

**GASTRIC DYSRHYTHMIAS IN PATIENTS WITH EARLY SYSTEMIC SCLEROSIS PROSPECTIVE CROSS-SECTIONAL STUDY**

**Keywords:** Systemic sclerosis, Gastrointestinal tract, Descriptive Studies

D. Seelmann1, M. P. Poble1, S. Saavedra2, A. M. Madrid3, C. Von Muhlenbrock4, C. Estay5, A. Goecke6, 1Hospital Clínico de la Universidad de Chile, Reumatología, Santiago, Chile; 2Hospital Clínico Grau, Dr Raúl Y zigí, Reumatología, Santiago, Chile; 3Hospital Clínico Universidad de Chile, Gastroenterología, Santiago, Chile; 4Universidad de los Andes, Medicina Interna, Santiago, Chile

**Background:** Systemic sclerosis (SSc) is an autoimmune disorder characterized by vasculopathy and fibrosis of skin and internal organs. Gastrointestinal (GI) system is affected in up to 90% of patients and dysmotility is the primary abnormality [1]. Gastric dismotility contributes to esophageal symptoms and causes nausea, vomiting, abdominal bloating, and early satiety. It also impacts quality of life and when severe is associated with increased mortality [2]. GI dysmotility can be evaluated with Electrogastrography (EGG), a non-invasive and safe test. It measures gastric myoelectrical activity, and when impaired it predicts delayed gastric emptying with an accuracy of 85% [3]. To the date gastric involvement in patients with early SSC has not been directly studied.

**Objectives:** Describe the prevalence of gastric dysrhythmias in early SSc and the association between GI symptoms and GI dysmotility.

**Methods:** SSc patients fulfilling the 2013 ACR/EULAR classification criteria with early disease (≤ 3 years from the first non-Raynaud symptom) were included and cross-sectionally assessed. Pregnancy and Diabetes Mellitus were exclusion criteria. All patients signed informed consent. GI symptoms were assessed using the UCLA GIT 2.0 questionnaire [4]. Gastric myoelectrical activity was measured using surface EGG and informed as preprandial, postprandial and continuous brady or tachygastria. Continuous bradygastria was considered a severe abnormality. It was informed by an expert gastroenterologist blinded to patient characteristics. Statistical analyses: Categorical variables were described as frequencies and percentages, and quantitative variables as mean, SD and IQR. The associations between variables were analyzed using the Fisher exact test. Statistical significance was defined as p < 0.05.

**Results:** 30 patients were included. 96.6 % were female, with a mean age of 48.7 years (25–72 years), SSc was limited in 76.6%. 14/28 patients had an anti-centromere antinuclear antibody pattern and 6 had anti Scl 70. Organ involvement was interstitial lung disease in 7/28, altered echocardiogram in 10/25 and erosive esophagitis in 11/15. Half of the patients were under immunosuppressive treatment, 43% on methotrexate and 50% mycophenolate. EGG was abnormal in 28/29 patients, 71.4% had bradygastria, 10.7% tachygastria an 17.8% mixed. Bradygastria was mostly preprandial (45%) and continuous (50%). According to the UCLA GIT 2.0 questionnaire, two thirds of the patients had a moderate to severe GI involvement. Other score items are described in Table 1. There was no correlation between symptoms and severity of the gastric motility disorder, but the presence of bradygastria was associated to a worse social functioning score (p=0.018).

**Conclusion:** Gastric dysrhythmias, especially bradygastria occurs early in systemic sclerosis. Bradygastria was associated with a worse social functioning score.

**EFFICACY OF LOW-DOSE IL-2 IN PATIENTS WITH MYOSITIS**

**Keywords:** Cytokines and chemokines, Myositis

X. M. Wang1,2, J. X. Zhang1,2, P. H. Chai1,2, Y. Z. Li1,2, Q. Y. Su1,2, Q. Yu1, P. F. He1, X. L. Zhang1,2, S. X. Zhang1,2, 1Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 2Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China; 3Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 4Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

**Background:** Idiopathic inflammatory myopathies (IMs) are a group of rare and heterogeneous muscle inflammatory diseases characterized by disturbances of regulatory T(Reg) cells. Interleukin (IL)-2 has been rediscovered as a pivotal cell population in the control of autoimmunity, which effectively relieves idiopathic inflammatory myopathies(IMs) such as polymyositis(PM) and dermatomyositis (DM).

**Objectives:** This study aimed to systematically evaluate the efficacy of low-dose IL-2 therapy in PM, DM, and IMs.

**Methods:** Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM, and Technology Journal Database were performed. Original case reports, case series, observational studies, and clinical trials reporting the changes in the numbers of lymphocyte subsets on
PM, DM, and IIMs patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I², and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

**Results:** A total of 5 studies comprising 401 patients were identified. Table 1 shows the CDASI scores were significantly decreased after IL-2 treatment [SMD=−1.146, 95%CI (−1.591;−0.700), P=0.001]. Besides, the number of Tregs cells was significantly increased [SMD=−1.146, 95%CI (−1.591;−0.700), P=0.001], and the subgroup analysis was performed based on the dose of IL-2 (Figure 1).

**Conclusion:** Low-dose IL-2 was promising in the treatment of DM, PM, and IIMs, which could promote the proliferation and functional recovery of Tregs.

**Table 1. Available evidence including patients with DM, PM, and IIMs treated with low-dose IL-2.**

Mortality and Associated Factors in 44 Patients with Systemic Sclerosis Associated Pulmonary Arterial Hypertension from Turkey

Keywords: Systemic sclerosis

S. Amikishiyev1, Y. Yağcı2, K. Mammadova2, N. Aliyeva3, G. Durak4, B. Artim-Esen1, A. Gül1, A. K. Bilge4, G. Okumuş1, M. İnanç1, Istanbul Faculty of Medicine, Istanbul University, Division of Rheumatology, Istanbul, Turkey; 2Istanbul Faculty of Medicine, Istanbul University, Department of Chest Diseases, Istanbul, Turkey; 3Istanbul Faculty of Medicine, Istanbul University, Department of Radiology, Istanbul, Turkey; 4Istanbul Faculty of Medicine, Istanbul University, Department of Cardiology, Istanbul, Turkey

Background: Pulmonary arterial hypertension (PAH) is a severe complication of systemic sclerosis with high mortality. Although new drugs and treatment strategies developed in the last years, the prognosis of prevalent patients has not been sufficiently improved.

Objectives: We aimed to analyze the prevalence, mortality, and prognostic factors in patients with SSc-PAH from our single-center SSC cohort.

Methods: We retrospectively evaluated the association between mortality and demographics, transthoracic echocardiography, right heart catheterization (RHC) and pulmonary function parameters at baseline, and treatment modalities in patients with SSc-PAH that have been assessed and followed up by a multi-disciplinary team.

Results: Forty-four (10.6%) out of 415 patients with SSC were diagnosed as SSc-PAH in 2008-2022. The mean age was 56.6±13.5 years, and 23 (52.3%) patients were deceased during a median follow-up of 45 months. The survival rates were 91% for the first year, 75% for 2 years, 68% for 3 years, and 43.1% for 5 years. The available causes of death were a cardiopulmonary failure in 6 (26.1%), infection in 6 (26.1%) including one with COVID-19, and malignancy in 3 (13%) patients. Clinical and hemodynamic findings of the patients were given in Table 1.

Table 1. Demographic, serologic, clinical, and hemodynamic findings of SSc-PAH patients.

The initial ePASP was significantly high, and cardiac output (CO), and FVC values were significantly lower in deceased patients. The patients who died had significantly lower survival rates warranted the need for early and effective treatment modalities.

Cardiovascular Risk Factors are Associated with Increased CRP Levels in Patients with Systemic Sclerosis

Keywords: Cardiovascular disease, Comorbidities

M. G. Abdelzaher1, D. Feldmann1, U. Heilmeier2, J. Andova3, F. Kollert4, R. Voel2, S. Pinel1, University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; Mansoura University, Department of Rheumatology and Immunology, Mansoura, Egypt; Krankenhaus Porz am Rhein, 3-Department of Anesthesiology, Cologne, Germany; University of Bern, Department of Rheumatology and Immunology, University Hospital Bern Bern, Bern, Switzerland

Background: Patients with systemic sclerosis (SSc) are known to have an elevated risk for cardiovascular diseases. Approximately 20-25% of all SSc patients have permanently elevated C-reactive protein (CRP) levels [1,2]. Higher CRP levels are known to be associated with metabolic syndrome and diabetes mellitus (DM) (3), two factors that contribute to cardiovascular risk.

Objectives: To investigate if permanently elevated CRP levels are associated with higher cardiovascular risk in a cohort of 65 patients with SSc.

Methods: Data analysis was carried out in R 4.1 using the packages dplyr, ggplot2, mice and MASS. 65 patients were enrolled in the study; 20 had permanently elevated CRP levels over two years before enrollment (CRP+ group), and 45 had normal CRP levels over 2 year prior enrollment (CRP- group). The following cardiovascular risk factors were selected as candidate predictors of CRP status: The Framingham Score, left and right carotid intima-media thickness (CIMT) on bilateral carotid ultrasound, pathological status of both carotids, presence of plaques in both carotids, number of plaques (0 if none), extent of largest plaque (0 if none), height, weight, body mass index (BMI), presence of arterial hypertension, history of smoking, packyears, DM type 2, chronic kidney disease, and a positive family history (cardiovascular event before the age of 65). We tested each variable as a bivariate predictor of CRP status in a logistic regression model. Subsequently, we used stepwise logistic regression based on the Akaike Information Criterion (AIC) to determine the optimal set of predictors. AIC evaluates model deviance in relation to the number of variables in the model, i.e., it can be used to find the optimal trade-off between model performance (predictive accuracy) and model complexity (number of predictors). Prior to logistic regression analysis, missing values in the dataset were replaced by means of multiple imputation.

Results: In the bivariate logistic regression analyses (Table 1), only the Framingham Score and DM2 were identified as significant predictors, both with a positive weight, i.e., a higher Framingham Score and the presence of DM2 in a given patient were predictive of permanently positive CRP status, respectively. However, due to relatively low sample size, model sensitivity was 65%, and specificity was 86.7%.

Figure 1: Kaplan-Meier survival curve of treatment in SSc-PAH patients.

Characteristics from table 1:

Title: Results of bivariate logistic regression analyses. For each candidate predictor variable, the odds ratio (OR) along with its t-value and p-value are given. An OR greater than 1 indicates that a higher value in the respective candidate predictor variable (or response ‘yes’ for categorical candidate predictor variables) is associated with a higher probability of belonging to CRP-positive group.

AB0915 A STUDY ON THE ASSESSMENT OF CARDIOVASCULAR RISK AND CIMT IN PATIENTS OF SYSTEMIC SCLEROSIS AND CORRELATION OF CIMT WITH QRISK 3 AND DISEASE SEVERITY SCORE

Keywords: Comorbidities, Systemic sclerosis, Autoantibodies

P. Dogga1, K. Chandwar2, K. Kishor1, D. Ekbote1, J. Dixit2, U. Dhakad1, P. Kumar1, 1King George Medical University, Clinical Immunology and Rheumatology, Lucknow, India; 2SGPGI, Clinical Immunology and Rheumatology, Lucknow, India

Background: Accelerated atherosclerosis is well-known in connective tissue disease however is less reported in Systemic Sclerosis. There is evidence that atherosclerosis occurs prematurely in Systemic sclerosis. The micro vascular disease is characteristic of SSc, but there is growing evidence of macro vascular disease in SSc patients. Several studies have evaluated the prevalence of atherosclerosis in carotic arteries in patients with SSc by ultrasonography. Increased CIMT and conventional CVD risk factors have well known association with future events of stroke and coronary heart disease.

Objectives:

1. To study the Cardiovascular risk and Carotid Intima medial thickness in patients of Systemic sclerosis and their correlation
2. To assess the Disease Severity by using MEDS score and its correlation with CIMT

Methods: Data of 72 patients including clinical, serological profile and treatment were recorded. Cardiovascular risk by QRISK 3 calculator, CIMT by Ultrasonography are used. Correlation between Cardiovascular profile with CIMT and disease severity were seen. Medsger disease severity score was used to estimate the disease severity. Thirty-four age comparable controls were included.

Results: A total of 72 SSc patients (lcSSc -27, dCSSc -45) were included in the study. The median duration of disease enrolled was 2.9 years and time to referral to a specialist was 128 years. On patient in our study developed Scleroderma renal crisis and one patient was diagnosed with Adenocarcinoma of lung. Lipid profile showed low HDL, high LDL, TG, Cholesterol as compared to controls. The mean CIMT of the patients showed a significant difference when compared to controls (0.58a ± 0.09 vs 0.56 ±0.10; p =<0.01). The mean mRSS was 23.99±10.44 and mean MEDS score was 8.89±2.76. Forty-three patients (59.7%) out of 72 had ILD documented by HRCT. NSIP in 22 (30.36%) and UIP in 21 (29.2%) patterns on HRCT were observed. The Severity of PAH (Mpad >20mm Hg) is greater in lcSSc vs dCSSc (30.33±10.50 vs 28.42 ± 7.38). Cyclophosphamide, MMF were used as induction therapies mainly for treatment of ILD. The mean CIMT (0.58±0.09) showed a significant positive correlation with QRISK3 however it is weak with rho=0.45 and p value 0.224.

Conclusion: CIMT had positive correlation with PAH (significant, p=0.034) and QRISK3 (significant, p=<0.01). CIMT had negative correlation with mRSS. The mean CIMT showed no correlation with MEDS score.

A RANDOMIZED CONTROLLED PROSPECTIVE SINGLE-CENTER FEASIBILITY STUDY OF RHEOPHERESIS FOR RAYNAUD’S SYNDROME AND DIGITAL ULCERS IN SYSTEMIC SCLEROSIS (RHEACT) - PRESENTATION OF FIRST INTERIM RESULTS

Keywords: Randomized control trial, Systemic sclerosis

J. G. Rademacher1, V. Korendovych1, A. Borisch1, T. Asendorf2, P. Korsten1, J. G. Rademacher1, V. Korendovych1, A. Borisch1, T. Asendorf2, P. Korsten1.

1University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany; 2University Medical Center Göttingen, Department of Medical Statistics, Göttingen, Germany

Background: Raynaud’s phenomenon (RP) and digital ulcers (DU) are frequent manifestations of Systemic Sclerosis (SSc). There are very few available approved drugs with varying efficacy. Rheopheresis (RheoP) is an extracorporeal apheresis technique used to treat microcirculatory disorders by improving blood viscosity. The effect of RheoP in SSc is currently unknown, and here, we report the interim results of the first patients.

Objectives: To determine the efficacy of RheoP compared to Standard of Care (SoC) intravenous iloprost on RCS and DU healing.

Methods: A randomized controlled prospective single-center feasibility study of Rheopheresis for Raynaud’s syndrome and Digital Ulcers in Systemic Sclerosis (RHEACT) aims to investigate the efficacy of RheoP on the Raynaud Condition Score (RCS) as the primary outcome measure after 16 weeks from baseline. A planned number of 30 patients will be randomized in a 1:1:1 ratio to one of two RheoP treatment groups or assigned to the SoC control group.

Results: We here report the results of the first seven patients. The patient assigned to the RheoP1 group had a baseline Raynaud Condition Score (RCS) of 8.6, which improved to 0 after 16 weeks (the primary endpoint). The two patients randomized to the RheoP2 had a baseline RCS of 8 and 6, respectively, which improved to 4 and stayed unchanged at 6 in the second patient. The four patients assigned to SoC had only minimal improvement. RheoP1 had a significantly lower RCS compared to RheoP2 and SoC at week 16 (*p<0.05). Furthermore, DU completely healed in patients with DU at baseline with either RheoP therapy and avoided amputation in one patient. Exemplary images are shown in figure 2 (A, baseline; B, at week 16).

Conclusion: RheoP improved the RCS and DU better than SoC (iloprost) treatment alone and avoided amputation in one patient.

DOI: 10.1136/annrheumdis-2023-eular.5632
Currently, acral vasculopathy is assessed in clinical practice by nailfold capillary microscopy. However, nailfold capillary microscopy is limited to the nailfold and cannot assess the deeper vascular plexus, changes in dynamic perfusion, or inflammatory and fibrinotic disease manifestations. These limitations do not occur with dynamic optical coherence tomography (D-OCT). D-OCT is an imaging technique based on an infrared laser. It allows simultaneous three-dimensional, high-resolution imaging of fibrinotic and inflammatory changes as well as vasculopathy in systemic sclerosis [1].

**Objectives:** The aim of this study was to characterize vascular alterations in the skin of patients with systemic sclerosis and to assess dynamic changes in skin perfusion under vasoactive therapies.

**Methods:** Twenty-six patients diagnosed with systemic sclerosis according to ACR/EULAR classification criteria 2013 were included in this study. Patients diagnosed with systemic sclerosis received a treatment with iloprost infusion for a duration of five days. Alterations in dynamic perfusion were assessed daily in six locations (nailfold, finger, hand, lower arm, upper arm, ear) using VivoSight OCT. Moreover, alterations in dynamic skin perfusion were assessed under topical treatment with diltiazem (n=13) as well as warm (n=17). Dynamic perfusion was characterized by the parameters vessel density and vessel diameter. In addition, patients filled questionnaires to assess the severity of vasculopathic disease symptoms and to assess subjective treatment response to iloprost infusion.

**Results:** Patients were mainly female (73.1%) and of a mean age of 53.6 ± 12.6 years. The majority of the patients were characterized as limited cutaneous systemic sclerosis (76.9%). Seven patients had digital ulcers at the time of study inclusion. Moreover, patients reported that Raynaud’s phenomenon occurred with a median frequency of 3.5 attacks per day and the mean duration of Raynaud’s phenomenon was 36.9 minutes per day. On a visual analogue scale ranging from 0 to 100, patients rated limitations in daily life due to Raynaud’s phenomenon with 48.3 ± 37.3. Whereas the majority of patients (83.3%) reported a subjective benefit, 8.3% reported no change and 8.3% of patients a worsening of acral perfusion under treatment with iloprost infusions. Wilcoxon matched pairs signed rank test did not reveal a significant increase in vessel diameter (p=0.4609) and vessel density (p=0.0681) after topical application of diltiazem. Application of warm led to a significant increase in vessel diameter (p < 0.0001) and vessel density (p < 0.0001). Interestingly, therapeutic efficacy assessed by increase in vessel diameter and vessel density differed markedly between individual patients. Prospective assessment of vessel diameter and vessel density under therapy with iloprost infusions yielded heterogeneous regarding the therapeutic efficacy at different sites and timepoints for individual patients.

**Conclusion:** D-OCT might be a valuable tool to assess vasculopathic alterations and response to vasoactive therapies in the skin of patients with systemic sclerosis. Further studies are required to investigate whether D-OCT might be a technology enabling individual vasoactive treatment in systemic sclerosis in the direction of precision medicine.

**Figure 1.** Linear regression analysis revealed a reduced therapeutic efficacy in patients with low baseline vessel density.
The MDAS Antibody and Its Relationship with Amyopathic Dermatomyositis

Keywords: Myositis, Autoantibodies

C. Arciniega Larios1, D. Fernandez Lozano1, M. Y. Orellana Gómez2, R. Veroz Gonzalez2, S. M. Rojas Herrera1, E. Chamizo Carmona1. 1Hospital de Mérida, Rheumatology, Mérida, Spain

Background: The antibody directed against the protein encoded by melanoma differentiation-associated gene 5 (anti-MDAS) is associated with a subgroup of rare inflammatory myopathies characterized by skin lesions typical of classic dermatomyositis with no or minimal involvement of the proximal musculature. The importance of early diagnosis and treatment lies in the rapidly progressive interstitial lung disease that can develop in 50-100% of cases. This can lead to a poor prognosis with a mortality rate between 33 and 66% six months after diagnosis. In less than 5% of cases it is associated with neoplastic disease.

Objectives: To describe the clinical and evolutive characteristics of patients presenting positivity against MDAS antibody in our hospital.

Methods: An active search for positive MDAS antibodies in the service of Rheumatology in a 3th level Hospital was performed by collecting epidemiological, clinical and radiological data between the years 2021-2022.

Results: We identified 10 patients with a mean age of 56.5 years (32-86 years), 60% being female (6) and 40% male [4]. Of the total number of patients, only 30% were diagnosed with dermatomyositis. Three patients presented other autoimmune rheumatologic diseases (two of them were diagnosed with systemic lupus erythematosus and one with rheumatoid arthritis), two exclusively with pulmonary involvement, and in two cases no pathology was found. For the patients diagnosed with dermatomyositis, 100% presented diffuse interstitial lung disease (DIDP) and classic dermatomyositis skin involvement. Arthritis was present in 66.6%, 33.3% were related to incipient breast carcinoma, and 33.3% presented muscular involvement. In all cases treatment was started early with intravenous methylprednisolone boluses associated in 66.6% of cases with intravenous cyclophosphamide and in 66.6% of cases with Tacrolimus. One death was reported due to respiratory failure, probably secondary to progression of the pulmonary disease related to the disease. The rest of the cases presented favorable evolution with remission of skin and joint involvement, as well as stabilization of the pulmonary disease in the cases treated with Macitentan 10mg/daily. Total of patients who didn't discontinue the treatment was 3.9 (IQR 2.4-5.7) years. 78% (7/9) of patients had a sustained complete response and 22% (2/9) had a partial response.

Conclusion: The frequency of hypo- or amyopathic dermatomyositis with positive MDAS is low. 100% of the cases presented pulmonary involvement at diagnosis, only 30% presented muscular involvement and 30% were associated with neoplasia. One third of the patients with MDAS-positive dermatomyositis died.

Efficacy and Safety of Macitentan in Refractory Digital Ulcers

Keywords: Systemic sclerosis, Safety, Real-world evidence

M. Retuerto-Guerrero1, C. Moriano1, I. Castellvi2, B. Atienza-Mateo3, E. Diez Alvarez1, 1Hospital de León, Rheumatology, León, Spain; 2Hospital Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 3Hospital Marqués de Valdecilla, Rheumatology, Santander, Spain

Background: Raynaud’s phenomenon (Rp) is used to describe a symptom complex caused by digital vascular involvement. The presence of digital ulcers (DU) should prompt further evaluation for secondary causes of Rp. Among the conditions that may be associated with Rp are Systemic Autoimmune Rheumatic Diseases (SARDs), especially Systemic Sclerosis (SSc). DU are a major cause of morbidity and have a high recurrence rate in most patients and may be refractory to multiple treatments. Macitentan is a dual endothelin receptor antagonist authorized to treat pulmonary hypertension. Its efficacy in the treatment of DU associated to SSc has been assessed in two clinical trials (DUAL-1 and DUAL-2), without any visible effects on their prevention or reduction. However, these trials have been criticized on the methodology and profile of the patients included.

Objectives: To assess efficacy and safety of Macitentan in patients suffering from SARDs and refractory DU.

Methods: Spanish observational multicentric study. Data were retrospectively obtained from medical records of 10 patients suffering from SARDs and refractory DU secondary to severe Rp treated with Macitentan 10mg/daily. Total response was defined as the complete healing of DU and partial improvement as the reduction of the number or size of ulcers. Patients with ischemic ulcers caused by other factors were excluded.

Results: We identified 10 patients who has received treatment with Macitentan for DU, median age 59 years (IQR 51-68), 80% female, with a median Rp and DU duration of 56 (IQR 14-214) and 25 (IQR 9-215) months (Table 1). Eight patients were diagnosed with limited SSc; anti-nuclear abs, anti-centromere abs and anti-phospholipidic abs were positive in 90%, 80% and 20% of the patients. Most patients (90%) had received previously treatment with Bosentan, and the reason for withdrawal was inefficacy in 4 cases (44%) and adverse effects (liver toxicity) in 5 (56%). 8 patients had received Intravenous prostanoids with no response. In the beginning of Macitentan the number of DU was 5.5 (IQR 2.3-6) and digital gangrene was reported in one case. Two patients were treated with Macitentan in monotherapy, 6 in combination with calcium antagonists and 2 received triple therapy (Macitentan + Calcium antagonists + PDE5 inhibitor). Just one patient stopped the treatment for adverse effects (lower limb edema). Median follow-up of patients who didn’t discontinue the treatment was 3.9 (IQR 2.4-5.7) years. 78% (7/9) of patients had a sustained complete response and 22% (2/9) had a partial response.

Conclusion: Our data show that Macitentan is an effective agent for ischemic digital refractory ulcers in patients suffering from SARDs with a favorable safety profile in clinical practice.

**CLINICAL CHARACTERISTICS AND CLINICAL OUTCOME OF SYSTEMIC SCLEROSIS OVERLAP SYNDROME (SSC-OS) IN TURKISH PATIENTS WITH SYSTEMIC SCLEROSIS**

**Keywords:** Lungs, Systemic sclerosis, Epidemiology

I. Vasi1, R. C. Karda2, R. Duran2, B. Özkıztılay3, D. Yıldırımlı3, G. T. Alp4, A. Avanoglu Guler4, H. Karadeniz5, H. Kıcık6, A. Erden6, B. Göker7, A. Tufan7, M. A. Oztürk8, Gazi University, Department of Medicine, Division of Rheumatology, ANKARA, Turkey; 2Gazi University, Department of Medicine, Division of Rheumatology, Ankara, Turkey; 3Gazi University, Department of Medicine, Division of Rheumatology, Ankara, Turkey; 4Gazi University, Department of Internal Medicine, Ankara, Turkey

**Background:** Systemic sclerosis (SSc, scleroderma) is a systemic autoimmune connective tissue disease (CTD). Disease subsets specific to the extent of skin sclerosis subdivides SSc into the three following main subtypes: (1) limited cutaneous SSc (lcSSc); (2) diffuse cutaneous SSc (dcSSc) and (3) sine scleroderma SSc (ssSSc). Any SSc subgroup can also have features of one or more other CTDs [1]. When a patient has features of any two CTDs, this satisfies the criteria for SSc-overlap syndrome (SSc-OS) [2].

**Objectives:** The aim of this study was to determine the clinical, serological features and clinical outcome of systemic sclerosis (SSc) and SSc-overlap syndromes (SSc-OS).

**Methods:** This study included patients enrolled in the Gazi University Systemic Sclerosis Cohort registry during January 2005 to December 2022. SSc-OS was defined as SSc patients who also met criteria for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), dermatomyositis (DM), polymyositis (PM) and Sjögren syndrome. Baseline and last follow-up characteristics were compared between SSc and SSc-OS.

**Results:** 41 patients (age 54.0 ± 15.8 years, 90% female, disease duration 8.2 years, 43.9% diffuse cutaneous subset, 26.8% limited cutaneous subset, 41.4% anti-Scl-70 positivity) were included. SSc-OS were classified 29.2% of patients and 43.9% diffuse cutaneous subset, 26.8% limited cutaneous subset, 41.4% polyarthritis/arthralgia (p=0.029) and SSc had a higher prevalence of interstitial lung disease (p=0.014). SSc-OS had a higher prevalence of arthralgia/arthritics. SSc-Sjögren syndrome is the most common overlap syndrome. Primary diffuse SSc patients had a greater decrease DLCO compared with the SSc-overlap patients.

**Conclusion:** Alginic acid plus PPI does not represent good value for money compared to the standard treatment among such SSc patients in Thailand unless its price is reduced significantly.

**COST-EFFECTIVENESS OF ALGINIC ACID IN COMBINATION WITH PROTON PUMP INHIBITOR FOR THE TREATMENT OF GASTROESOPHAGEAL REFUX DISEASE IN SYSTEMIC SCLEROSIS PATIENTS**

**Keywords:** Gastrointestinal tract, Systemic sclerosis

C. Foocharoen1, P. Kingkaew2, Y. Teerawattananon2, A. Mahakkanukrau1, S. Suwannaroj1, W. Manasirisuk1, J. Chaiyarat1, A. Sangchan1, Khon Kaen University, Department of Medicine, Faculty of Medicine, Khon Kaen, Thailand; Ministry of Public Health, Department of Health, The Health Intervention and Technology Assessment Program (HTAP), Nonthaburi, Thailand; Khon Kaen University, Department of Statistics, Faculty of Science, Khon Kaen, Thailand; Khon Kaen University, Special Medical Center, Sirirajrd Hospital, Faculty of Medicine, Khon Kaen, Thailand

**Background:** Systemic sclerosis (SSc) patients often become refractory to proton pump inhibitor (PPI)—a standard treatment for gastroesophageal reflux disease (GERD)—and intolerant to PPI in combination with domperidone. PPI with alginic acid is an alternative treatment option, but alginic acid is costly.

**Objectives:** We compared the costs and effectiveness of alginic acid plus proton pump inhibitor (PPI) versus standard treatments (PPI with/without antacids as needed and lifestyle modifications) for gastroesophageal reflux disease (GERD) in systemic sclerosis (SSc) patients unsuitable for, or intolerant to, domperidone.

**Methods:** An economic evaluation using the Markov model was conducted among SSc and patients between 40 and 65 with GERD, having a partial or non-response to 4 weeks of standard-dose omeprazole (40 mg/d) and being unsuitable for or intolerance to domperidone. Using a societal perspective, we computed the incremental cost-effectiveness ratios (ICERs) in terms of Thai baht (THB) per quality-adjusted life-years (QALY) between a combination of alginic acid plus PPI and standard treatment for GERD. The lifetime time horizon was used.

**Results:** The ICER for alginic acid plus PPI versus standard treatments was 377,101THB/QALY. According to the one-way sensitivity analysis, the cost of alginic acid was the most impactful parameter. If the market prices of alginic acid plus PPI were reduced by 61%, this treatment option would become cost-effective at the willingness-to-pay threshold of 160,000THB/QALY (34.71 THB/USD data on 3 December 2022). Furthermore, if alginic acid were included in the public health insurance program, the national budget would be increased by 66,313THB per patient resulting in an overall budget increase of 5,106,101 to 8,885,942THB compared to the standard treatment.

**Conclusion:** Alginic acid plus PPI does not represent good value for money compared to the standard treatment among such SSc patients in Thailand unless its price is reduced significantly.

**SMART PILL TECHNOLOGY PROVIDES SAFE AND EFFECTIVE ASSESSMENT OF GASTROINTESTINAL FUNCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**Keywords:** Gastrointestinal tract, Systemic sclerosis

I. Baruš1, H. Fretheim1, H. Didrikson1, M. N. Carstens1, M. Pessenov2, V. Sarna3, O. Midthvedt4, O. Molberg5, A. M. Hoffmann-Vold6, 1Oсло universitetssykehus HF, Rikshospitalet, Department of Rheumatology, Oslo, Norway; 2Oslo
Background: Gastrointestinal dysmotility is a common complication in systemic sclerosis (Sc) patients including slow colonic transit leading to gastrointestinal tract (GIT) symptoms. Fecal microbiota transplantation (FMT) with ACHIM did not improve lower or total GIT symptoms in SSc patients compared to placebo enrolled in the Norwegian multicenter, double-blind, randomized, placebo-controlled ReSScne trial. It is unclear if transit times were impacted by FMT. The SmartPill wireless motility capsule (SmartPill®), measures transit times and peristalsis in patients and was given to a subgroup of patients in the ReSScne trial.

Objectives: To estimate gut transit time and safety of SmartPill® in patients with SSc and predominant lower GIT symptoms.

Methods: Ten patients from the ReSScne trial were included in this SmartPill® substudy. The patients followed the required diets and procedures prior swallowing a pH calibrated SmartPill capsule. Two infusions of ACHIM or placebo at week 0 and 2 were given to all participants. SmartPill was given by all participants at week 0 and 11. The primary outcome of this study was the change of transit times in patients with ACHIM and placebo from week 0 to week 11 and safety.

Results: Ten patients were enrolled to receive a SmartPill®, six patients in the placebo group and four patients in the ACHIM group. Baseline characteristics in the placebo and ACHIM groups were comparable, with 2 (20%) males and 8 (80%) females, 90% with limited systemic sclerosis and a median age of 51 and 53, respectively. At week 0 the placebo group had a whole gut transit time (WGT) 35.8 hours ± 13.2 (mean ± SD) compared to 40 hours ± 8.1 in the ACHIM group. At week 12 the WGT for the placebo group was 38.1 hours ± 7.2 compared to 73.5 hours ± 49.8 in the ACHIM group. There was no significant difference in the change of estimated gut transit time between placebo and ACHIM group regarding whole gut transit time, p = 0.158 for week 0 and p = 0.752 for week 12. (Figure 1). One patient experienced a delayed transit time after receiving ACHIM, with 254 hours from ingestion to body exit for the SmartPill®. In four cases, the activation of the capsule failed. These patients were included in the trial with new, functional capsules. The reason for the malfunction remained unclear.

Conclusion: FMT with ACHIM did not improve gastrointestinal transit times in patients with SSc and lower GIT symptoms. Our study demonstrates that the SmartPill® is safe to use for patients with SSC, but we experienced a high number of malfunction.

Keywords: Myositis, Malignancy, Imaging

A. Younas1, R. Asif2, R. Davies1. 1University Hospital of Wales, Rheumatology, Cardiff, United Kingdom; 2Aneurin Bevan UHB, Rheumatology, Newport, United Kingdom

Background: Dermatomyositis (DM) has a strong association with Malignancy, with one study showing risk up to five times that of the general population and is the leading cause of death [1]. Occult cancer can result in resistant disease, and early diagnosis can improve patient outcomes. We report a case of occult tonsillar cancer associated with severe DM.

Methods: A 60-year-old usually fit and well gentleman presented with a 4-month history of progressive proximal muscle weakness of upper and lower limbs and a characteristic erythematous rash suggestive of DM. Investigations showed a CK of 6813 U/L typical myositis changes on MRI and positive myositis specific Anti-NXP ab. An initial malignancy screen, including CT TAP, was negative for underlyying malignancy. He was commenced on oral Prednisolone at 1mg/kg and was discharged with urgent rheumatology follow-up. However, he was admitted a week later with severe dysphagia and ongoing muscle weakness. An urgent OGD excluded a structural upper GI lesion, and Nasogastric feeding was commenced. He was administered IV methyl Pred 500 mg over three days along with IVIG (2g/kg) but failed to respond with ongoing muscle weakness and dysphagia. A subsequent PET scan showed a right tonsillar mass, later confirmed as tonsillar cancer on biopsy. Following this, the ENT team proceeded with robotic surgery and radical surgical resection of tonsillar cancer. We repeated IVIG every four weeks along with IV Methyl pred 50 mg OD and a PEG tube inserted to meet his nutritional needs.

Methods: A 60-year-old usually fit and well gentleman presented with a 4-month history of progressive proximal muscle weakness of upper and lower limbs and a characteristic erythematous rash suggestive of DM. Investigations showed a CK of 6813 U/L typical myositis changes on MRI and positive myositis specific Anti-NXP ab. An initial malignancy screen, including CT TAP, was negative for underlyying malignancy. He was commenced on oral Prednisolone at 1mg/kg and was discharged with urgent rheumatology follow-up. However, he was admitted a week later with severe dysphagia and ongoing muscle weakness. An urgent OGD excluded a structural upper GI lesion, and Nasogastric feeding was commenced. He was administered IV methyl Pred 500 mg over three days along with IVIG (2g/kg) but failed to respond with ongoing muscle weakness and dysphagia. A subsequent PET scan showed a right tonsillar mass, later confirmed as tonsillar cancer on biopsy. Following this, the ENT team proceeded with robotic surgery and radical surgical resection of tonsillar cancer. We repeated IVIG every four weeks along with IV Methyl pred 50 mg OD and a PEG tube inserted to meet his nutritional needs. Gradually he started to show signs of improvement with improved mobility, muscle strength, and normal CK levels. He received six cycles of IVIG, and azathioprine was commenced with the weaning of prednisolone to 10 mg after discharge. 6 months after the initial presentation, he mobilized independently with improved swallowing to liquids and a soft diet.

Results: Head and neck cancers are rarely associated with Dermatomyositis with tonsillar cancer extremely rare. To our knowledge, this is the first reported case of occult tonsillar cancer associated with treatment-resistant DM. Detecting occult cancer can be difficult, especially in cases where the DM symptoms precede cancer diagnosis. The usual first-line cancer screening in inflammatory myopathies includes CT TAP, which can miss a malignancy of the head and neck region. Current evidence does not show a definite benefit of PET scanning over conventional CT for cancer identification [2]. But PET scanning can be very useful in selected patients with a high index of clinical suspicion. Recently published BSR guidelines recommend considering PET scanning for cancer screening [3].

Conclusion: Increased vigilance is required to look for occult cancer, including head and neck cancers, especially in patients with treatment-resistant DM.

LA DISFAGIA EN LA ESCLEROSIS SISTÉMICA SE ASOCIA CON PROBLEMAS NUTRICIONALES Y MALA CALIDAD DE VIDA

Keywords: Sistemaico, enfermedad, paciente, resultados, trastorno gastrointestinal

L. Cano García1, A. García Studer2, F. Ortiz-Márquez2, I. Ureña3, N. Mená-Vázquez2, S. Manrique Arjía1, Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA), Rheumatology, Málaga, Spain

Background: Digestive involvement is one of the most prevalent manifestations of systemic sclerosis (SSc) with great significance for the health and quality of life of patients.

Objectives: To describe the prevalence of dysphagia and the nutritional status of a series of patients with SSc.

Methods: Design: Cross-sectional descriptive study. Participants: consecutive recruitment of patients with SSc (ACR/EULAR 2013 criteria) followed up in our unit. Follow-up of these patients is carried out every 3 to 6 months in consultation and all patients were registered in a database. 90% of the patients accepted and signed the consent, the rest refused due to travel or work difficulties. Variables: The main variable was dysphagia, defined according to the EAT10 questionnaire (positive ≥3). The dysphagia risk factors evaluated were: malnutrition according to the Mini Nutritional Assessment (MNA) (continuous: 0-14, considering 14 better nutritional status), sarcopenia defined according to the European Working Group on Sarcopenia in Older People (EWGSOP) criteria, prealbumin, polypharmacy (if they take ≥5 drugs), weight loss of at least 1 kg in the last 3 months, quality of life according to EQ-SD and Steinbrocker functional status. Statistical analysis: descriptive and logistic regression (VD: dysphagia) to identify associated factors.

Results: 52 patients were included, of whom 51 (98.1%) were women, with a mean (SD) age of 68.0 (±11.0) years. 32/52 patients (61.5%) had dysphagia (EAT≥3) and 12/52 patients (23.1%) were referred to endocrinology for severe dysphagia (EAT≥20). Table 1. Patients with dysphagia compared with the rest had sarcopenia more frequently (37.5% vs 0.0%; p = 0.001), weight loss (65.6% vs 20.0%, p = 0.004) and more polymedicated (67.5% vs 60.0%, p = 0.022). Likewise, patients with dysphagia (EAT≥3) had lower values (mean ±SD) of nutrition per MNA screening (11.0 ±12.1 vs 13.1 ±2.3; p = 0.001), of EQSD (0.5 ±0.2 vs 0.7 ±0.2; p = 0.004), EVA-EQSD (48.6 ±22.3 vs 62.5 ±17.8; p = 0.023) and in Steinbrocker’s functional grade (2.3 ±1.0 vs 1.3 ±0.6; p = 0.001). The multivariate analysis identified that MNA screening (0-14) (OR [95% CI] 0.511 [0.317;0.824]; p=0.006) and EQSD (OR [95% CI] 0.965 [0.932-0.998]; p=0.036) (R2=0.397) were independently associated with dysphagia (EAT≥3).

Conclusion: Dysphagia is a common problem in systemic sclerosis and is associated with poorer quality of life and a lower probability of reaching a normal nutritional status. The serious nutritional implications associated with dysphagia must be diagnosed in order to intervene nutritionally in these patients.

DOI: 10.1136/annrheumdis-2023-eular.2832
**Background:** Systemic sclerosis (SSc) is often difficult to treat and the evidence in support of many of the usual therapies is limited. Abnormalities in B-cell function in SSc are thought to play a role in disease pathology. Furthermore, B-cell infiltrates have been demonstrated in both the skin and lung specimens in SSc. Rituximab (RTX) is a chimeric monoclonal antibody inhibiting CD20-mediated B-cell proliferation and differentiation that has shown promising results for pulmonary and cutaneous involvement of SSc.

**Objectives:** Our aim was to assess RTX for pulmonary and diffuse cutaneous involvement in real-life patients diagnosed of SSc.

**Methods:** Retrospective observational study of a wide and unselected series of patients diagnosed as SSc from a single university hospital from 2011 to 2022. Patients were classified as SSc following 2013 ACR/EULAR classification criteria. We reviewed pulmonary function through conventional spirometry and diffusing capacity of lung for carbon monoxide (DLCO). Pulmonary involvement was also assessed by high-resolution chest-CT test. Cutaneous involvement was assessed by modified Rodnan skin score (MRSS).

**Results:** We included 15 patients with a median [range] age (at the onset of RTX) of 53 [41-78] years (80% women; 20% men). The median [range] of time since diagnosis and treatment onset was 3 [0-12] years. At the diagnosis of SSc, no one of our patients evidenced a restrictive ventilatory pattern. DLCO was below normal limits in 12 patients (80%). Small airway obstruction expressed according decreased maximal (mid-) expiratory flow (MMEF) 25-75 was present in 1 patient (6.7%). Regarding cutaneous involvement, median MRSS at diagnosis was 18.3 [range 4-26]. RTX intravenous treatment regimen employed was 1000mg (Day 1, followed by 1000mg on day 15), with a repeat cycle every 6 months if required. After a median [range] follow-up period of 31 [6-100] months, 12 (80%) patients completed a total of 4 RTX cycles. An analysis of the pulmonary function showed that, after RTX, DLCO decreased in 2 of 15 patients (13.3%) and none presented worsening of MMEF 25-75. In all patients there was also assessed by high-resolution chest-CT test. Cutaneous involvement was assessed by modified Rodnan skin score (MRSS).

**Conclusion:** In our experience, RTX seems to be a great option in real-life for those patients with pulmonary and diffuse cutaneous involvement due to SSc. However, cardiovascular, infectious and neoplastic complications should be assessed.

**THE VALUE OF THE DIAGNOSTIC TOOLS IN THE DIAGNOSIS OF INFLAMMATORY MYOPATHIES: A MULTICENTRE STUDY**

**Keywords:** Diagnostic Tests, Myositis, Biomarkers

E. Kaltsounoudi, E. Pelekasis, T. Zoi, M. Migkas, T. Dimitroulas, N. Koukla, A. Drosos, P. Voulgaris, University of Ioannina, Medical School, Rheumatology, Ioannina, Greece; Aristotle University of Thessaloniki, Rheumatology, Thessaloniki, Greece

**Background:** Traditionally, the diagnosis of inflammatory myopathies has been based on clinical signs and symptoms (muscle weakness and characteristic skin involvement, especially in dermatomyositis), increased muscle enzymes, electromyographic findings, skin or muscle biopsy, as well as anti-Jo1 antibodies (antisynthetase syndrome). However, this approach has led to significant diagnostic gaps in atypical cases such as in those of pure lung involvement.

**Objectives:** To evaluate the diagnostic yield of each procedure in a sample of 61 patients who were diagnosed, followed-up and treated in two tertiary university rheumatology clinics in Greece.

**Keywords:** Myositis

**CLINICALLY AMYOPATHIC DERMATOMYOSITIS (CADM) WITH ANTI-Melanoma Differentiation-Associated Gene 5 Antibody Positive: Understanding Its Clinical Presentation and Extent of Lung Involvement**

**Keywords:** Myositis
Methods: serum samples tested using a myositis panel (Mi-2α, Mi-2β, Ku, PM-Sc100, PM-Sc75, SRF, Jo-1, PL-7, PL-12, OJ, EJ, Ro-52, TIF1γ, MDAs5, NXFP2, SAE1) and muscle enzymes (CK, aldolase, LDH, SGOT, SGPT). Electromyography has been carried out in all patients, whereas in 27 with elevated muscle enzymes or muscle weakness an MRI-guided muscle biopsy has been done. In addition, in 8 patients, a skin biopsy has been performed and in all patients a detailed examination (determination of muscle strength) has been performed in all muscle groups.

Results: in 42 cases the diagnosis has been made after a positive myositis panel, while in 20 cases there was also a histological confirmation. In 8 cases, the diagnosis has been made on the grounds of positive clinical features and characteristic findings on the electromyogram. Only 4 patients have been diagnosed on the basis of histological findings in the absence of other laboratory and clinical findings (table 1). The most common autoantibodies in patients with lung involvement were Jo-1, PL-12 and PL-7.

Conclusion: based on the aforementioned results, a myositis panel seems a reasonable and reliable diagnostic strategy as it improves significantly the diagnostic yield of an inflammatory myopathy. In addition, it gives a diagnostic “alibi” for the therapeutic approaches that otherwise can be administered only by histological confirmation. Finally, in patients with atypical signs and symptoms such as lung fibrosis that cannot be attributed elsewhere, a myositis panel should be performed.

LONG-TERM CORTICOSTEROID THERAPY WAS ASSOCIATED WITH SIGNIFICANT LIVER FIBROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis
1Seconda Università degli Studi di Napoli, Precision of Medicine, Caserta, Italy; 2Seconda Università degli Studi di Napoli, Dipartimento di Scienze Mediche e chirurgiche Avanzate, Caserta, Italy

Background: Fibrotic changes of the internal organs, such as lungs, heart, kidneys, and gastrointestinal tract, characterize the clinical course of both limited (lcSSc) and diffuse cutaneous SSc (dcSSc), potentially leading to organ dysfunction. However, liver involvement is less defined.

Objectives: In a cross-sectional study we investigated the prevalence and predictors of significant liver fibrosis in patients with systemic sclerosis (SSc) who had no evidence of liver diseases due to heavy alcohol consumption, viral infection, drug.

Methods: A total of 65 SSc patients were recruited, satisfied the 2013 ACR/EULAR classification. In addition to the clinical and laboratory data, modified Rodman skin score (mRSS), and activity index, video-capillaroscopy, echocardiography, and lung function were analysed. Liver stiffness (LS) was measured using transient elastography to assess the degree of liver fibrosis and 7.4 kPa was adopted as the cut-off value for significant liver fibrosis and liver steatosis with CAP values ≥ 248 dB/m were considered consistent with mild steatosis (S1), ≥286 dB/m with moderate steatosis (S2) and ≥280 dB/m with severe steatosis (S3).

Results: The median age of patients (60 women) was 50.5 years (range 20-80) and the median disease duration was 5.5 years (range 1-10). The median LS value was 4.65 kPa (range 3.1-8.3); the median CAP value was 220.5 (164-327). By Spearman Rank Correlation we related the clinical variables with liver stiffness (LS) and liver steatosis with CAP values ≥ 248 dB/m were considered consistent with mild steatosis (S1), ≥286 dB/m with moderate steatosis (S2) and ≥280 dB/m with severe steatosis (S3). By Spearman Rank Correlation LS value vs age has a p value 0.02 (CI 95% 0.290-0.64), vs corticosteroid use has a p value 0.0032 (CI95% 0.179-0.731). On the contrary CAP value vs age has a p value 0.026 (CI 95% 0.04-0.64). Forty-six

RAYNAUD’S PHENOMENON AND RELATED SYNDROMES CLINIC: CHARACTERIZATION OF NEWLY REFERRED PATIENTS AND DIFFERENCES BETWEEN PRIMARY AND SECONDARY RAYNAUD’S PHENOMENON

Keywords: Autoantibodies, Systemic sclerosis, Diagnostic Tests

A. M. Gomes Correia1, C. Campinho Ferreira1, E. Costa1, D. Esperança1, Almeida1, J. Silva1, J. Neves1, J. Redondo Costa1, A. R. Ribeiro1, M. Cerqueira1.
1Hospital de Braga, Rheumatology, Braga, Portugal

Background: The Raynaud’s Phenomenon (RP) and Related Syndromes Clinic was created in the Rheumatology Department at Hospital de Braga in order to provide differentiated health care to the population with RP, emerging as a unique outpatient clinic in the country. The aim of this Clinic is to evaluate patients who present with this clinical manifestation in a prompt and multidisciplinary approach, considering the differential diagnosis between the primary and secondary etiology. In this way, adequate monitoring can be carried out, such as performing a Nailfold Videocapillaroscopy (NVC) and early and targeted therapy instituted.

Objectives: Characterize the individuals evaluated in first RP and Related Syndromes Clinic appointments and determine predictive factors allowing to distinguish primary and secondary RP.

Methods: Retrospective, single center study, including patients who were evaluated in first RP and Related Syndromes appointments between February 2021 and December 2022. Sociodemographic variables, clinical data and the results of the complementary study such as anti-nuclear antibodies (ANA) profile and NVC pattern were analyzed. Statistical analysis of the data was performed using SPSS, using the Chi-square and the t-Test independent samples tests, as appropriate.

Results: Fifty-four patients were included (female 88,89%, male 11,11%; mean age 52,48±17,06 years), referred to this clinic with the following main clinical manifestations: Raynaud’s phenomenon in 38 cases (60%), of which 4 cases had PAH, one case of pericarditis and one case of systemic sclerosis. In half of the cases. Pulmonary involvement was present in 6 cases (60%). Joint involvement was present in 9 cases (90%). Telangiectasias in 3 cases respectively. Joint involvement was present in 10 cases (10%). In 1 case, the skin involvement was made of diffuse sclerosis in 3 cases. Achenbach Syndrome (1,85%), Systemic Sclerosis (SSc) (31,48%), and early scleroderma pattern in 19,05%. The diagnosis established in the 54 patients evaluated were: acrocyanosis (1,85%), erythema pernio (7,41%), frostbite (1,85%), Achenbach Syndrome (1,85%), Systemic Sclerosis (SSc) (31,48%) - 11,76% Very Early Diagnosis Of SSc; 5,88% SSc diffuse cutaneous form; 82,35% SSc limited cutaneous form -, unclassifiable CTD (3,70%), primary RP (22,22%) and secondary RP non-CTD (22,22%) - includes patients with RP secondary to tobacco, betablockers, SARS-CoV2 infection or autoimmune thyroiditis. 7,42% of the patients didn’t have RP or a rheumatic disease. Ten patients were discharged, with the remaining patients being followed regularly. Table 1 summarizes the characterization of patients with primary and secondary RP. Comparing patients with primary RP with patients with secondary RP, we found that older age, ANA’s positivity, taking betablockers and an altered NVC pattern was statistically significantly associated with the diagnosis of a secondary RP.

Conclusion: With this work, we emphasize the importance of RP investigation in order to establish a definitive diagnosis and an adequate follow up, showing a higher probability of secondary RP in patients with older age, positive ANA’s and who were taking betablockers. It reinforces, as well, the importance of NVC in the evaluation of patients with RP, as significant differences are found between primary and secondary RP, with scleroderma pattern raising the hypothesis of a secondary RP.

SYSTEMIC SCLERODERMA IN MEN: A CASE REPORT OF 10 PATIENTS

Keywords: Epidemiology, Rare/orphan diseases, Systemic sclerosis

A. Touih1, W. Ammour1, F. Ibourk el Idrissi1, W. Chawad1, M. Noutassim1, K. Khiti1, M. Maamar1, H. Harmouch1, Z. Tazi Mezalek1, M. Adnaoui1.
1Mohamed V university, Souissi Rabat, Department of Internal Medicine-Clinical Hematology, RABAT, Morocco

Background: Systemic sclerosis is a connective tissue disease that is common in women and characterized by vascular alterations associated with skin fibrosis and visceral manifestations. Several particularities of this connectivitis in men are discussed. We propose to show these particularities in men through 10 cases.

OBJECTIVES:

Methods: We identified 10 cases of systemic scleroderma in men among 60 cases of systemic scleroderma collected for our descriptive retrospective study in the internal medicine department of the IBN SINA University Hospital in Rabat. The search for clinical or subclinical visceral involvement was performed in all our patients.

Results: The average age of the patients was 61 ±14.1 years (extremes: 28-74 years) with a delay in diagnosis of 8 months. General signs were found in 3 patients (30%), the skin involvement was made of diffuse sclerosis in 6 cases (60%) and limited in 4 cases (40%); Raynaud’s phenomenon was noted in 7 cases (70%). Pulpar ischemia and digital ulcer were noted in 1 and 3 cases respectively. Telangiectasias in 1 case. Joint involvement was present in half of the cases. Pulmonary involvement was present in 6 cases (60%). Pulmonary fibrosis was found in 1 case. Cardiac involvement was found in 6 cases (60%), of which 4 cases had PAH, one case of pericarditis and one case
of heart failure. Esophageal involvement was found in 4 cases (40%). Biologically, an inflammatory syndrome was noted in 4 patients (40%). Antinuclear antibodies were positive in 7 cases (70%). Anti-Scl70 was detected in 4 cases (40%). Capillaroscopy showed lesions suggestive of organic microangiopathy in 2 cases (20%). 4 of our patients were treated with colchicine. Corticosteroids were prescribed in 2 cases. Half of our patients received immunosuppressive treatment, including 3 cases who received monthly courses of cyclophosphamide with relay by Imurel, and 3 patients received treatment by myophenolate mofetil, stopped in one patient due to hepatic cholestasis. The association with autoimmune diseases was noted in 2 patients, including one with rheumatoid arthritis and one with primary biliary cholangitis. 2 cases of neoplasia were observed in our series, the first one was a marginal zone lymphoma and the second one was a pulmonary adenocarcinoma. 3 deaths were reported, one by pulmonary embolism, and the 2 patients who presented a neoplastic pathology.

**Conclusion:** Despite the small number of our patients, our results agree with those of the literature. The male sex seems to be associated with more severe forms with a shorter diagnostic delay, diffuse skin involvement, severe Raynaud's phenomenon, and early and severe pulmonary involvement.

**THE MIMIC THAT CAUGHT EVERYONE BY SURPRISE!**

**Keywords:** Skin, Systemic sclerosis, Rare/orphan diseases

**K. Kishor1, P. Dogga1, S. Mukherjee2, A. Krishnan2, A. Wakhlu2. 1King George’s Medical University, Clinical Immunology and Rheumatology, Lucknow, India; 2Apollomedics Superspeciality Hospitals, Clinical Immunology and Rheumatology, Lucknow, India

**Background:** 57-year-old gentleman, a previous smoker, presented with a 12-month history of gradually progressive anaasarca that started initially with bilateral lower limbs and involved face, abdomen and entire body over 3-4 months. Four months into his illness, the patient noticed skin changes in the form of hyperpigmentation initially over anterior chest that progressed to involve the face, bilateral upper limbs, abdomen, and lower limbs over next 3 months. It was associated with increased friability, subcutaneous oedema, and spontaneous ecchymosis. Gradually he developed progressive motor weakness, initially in both upper limbs proximally which progressed to involve distal, bilateral lower limbs and trunk with sparing of bowel and bladder functions severely limiting his activities of daily living. Over the next 15 days patient became breathless with rapidly worsening dyspnoea of exertion, dry cough and left sided pleuritic chest pain. There was history of loss of appetite and significant loss of weight 18 kgs over 4 months. General physical examination was suggestive of pallor, diffusely hyperpigmented and fragile skin over the face, neck, upper limbs, hands, back, anterior abdomen, lower limbs with multiple ecchymotic spots and subcutaneous edema with anaasarca. Breath sounds were decreased bilaterally over intrascapular, axillary, infra-axillary areas and JVP elevated on Cardio-Respiratory system examination. CNS examination revealed bilateral external ophthalmoplegia with pure motor quadripleasis involving limbs and trunk without sensory, cranial nerve or autonomic involvement. Generalised wasting with asymmetric swelling over right shoulder was seen with reduced active and passive range of movements.

**Objectives:**

- Differentials:
  1. Scleredema
  2. Diffuse cutaneous systemic sclerosis

**Methods:**

**Results:**

Final diagnosis: POEMS syndrome with primary amyloidosis. International Myeloma Working Group criteria fulfilled:

- Mandatory criteria-
  - Polyneuropathy
  - Monoclonal plasma cell proliferative disorder
  - Atleast 1 major criteria:
    - Elevated VEGF levels
  - Minor criteria:
    - Organomegaly
    - Extravascular volume overload
  - Skin changes
  - Hematological involvement

**Conclusion:** The patient was started on treatment after Clinical haematology reference but died due to cardiogenic shock. This interesting case highlights POEMS as a great mimic of changes associated with various autoimmune disorders including scleroderma, SLE and vasculitis syndromes.

**IMPACT OF DIFFERENT BDMARDS ON PATIENT REPORTED OUTCOMES IN AXIAL Spondyloarthritis: A SYSTEMATIC REVIEW OF THE LITERATURE AND META-ANALYSIS**

**Keywords:** bDMARD, Pain, Spondyloarthritis

**F. Gadon**, T. Loupret, C. Lemaçon, P. Bertini, P. Vergne-Salle, CHU Limoges, Rheumatology, Limoges, France

**Background:** Pain, fatigue and altered quality of life are frequent complaints in axial spondyloarthritis (axSpA), with an impact on disease activity evaluation, regardless of radiographic or non-radiographic phenotype. No study compared face to face the effects of biologic DMARDs (bDMARDs) on patient reported outcomes (PROs).

**Objectives:** To evaluate the impact of biologic DMARDs (bDMARDs: anti-TNF and anti-IL17) on three PROs (pain, fatigue, quality of life) in patients with axial spondyloarthritis (axSpA).

**Methods:** A systematic review was performed in PubMed, Embase until May 2022, and abstracts from EULAR and ACR meetings for the past 3 years. The search included all randomized controlled trials of bDMARDs with outcomes reporting data on pain ("total back pain," "nocturnal back pain"), fatigue (FACT-F) and quality of life (ASQoL and SF36 PCS and MCS) in patients with axSpA. Statistical analysis used the inverse variance method to obtain results as mean differences, which were visualized by forest plot. Variation between studies was assessed by calculating the heterogeneity (I²) with Cochran's Q test.

**Results:** A total of 25 studies were included in the final analysis, with a total number of 8457 patients. Compared to placebo, treatment with bDMARDs was associated with a significant improvement in pain, fatigue and quality of life. The mean differences were -1.47 (95% CI [-1.72, -1.22]) for total back pain, -1.67 (95% CI [-2.06, -1.28]) for nocturnal back pain, 4.47 (95% CI [3.23, 5.72]) for FACT-F, -2.59 (95% CI [-2.86, -2.49]) for ASQoL, 3.68 (95% CI [3.21, 4.15]) for SF36 PCS and 2.79 (95% CI [1.83, 3.75]) for SF36 MCS. For the subgroup analysis comparing the different bDMARDs, the effects on pain were numerically superior with anti-TNF, but the difference was not significant because of the confidence intervals overlapping. There was no difference for the other PROs between anti-TNF and anti-IL17. Heterogeneity was weak except for the "nocturnal back pain" scale. For the subgroup analysis comparing axSpA phenotypes, the improvement of PROs on bDMARDs between radiographic and non-radiographic axSpA was not different, except for the mental component of the SF36 score less improved in the non-radiographic axSpA.

**Conclusion:** bDMARDs (anti-TNF and anti-IL17) significantly improve pain, fatigue and quality of life compared to placebo in patients with axSpA. No significant difference was observed between anti-TNF and anti-IL-17 nor between radiographic and non-radiographic axSpA, except for the mental component of the SF36.

**TOFACITINIB EFFICACY AND SAFETY IN PATIENTS WITH ANKYLOSING SPONDYLITIS BY BASELINE C-REATIVE PROTEIN LEVELS: A POST HOC ANALYSIS**

**Keywords:** Randomized control trial, Targeted synthetic drugs, Spondyloarthritis

**A. Decodhar**, X. Baraliakos, M. Magrey, L. S. Gensler, A. V. Thorat, C. Kinch, S. Pemmaraju, J. M. Cadatat, P. Nash, Oregon Health & Science University, Division of Arthritis and Rheumatic Disease, Portland, OR, United States of America; 2Rheumazentrum Ruhrgebiet Herne, Ruhr-University, Internal Medicine and Rheumatology, Bochum, Westphalia, Germany; 3Case Western Reserve University/University Hospitals, Division of Rheumatology, Cleveland, OH, United States of America; 4University of California at San Francisco, Department of Medicine, Division of Rheumatology, San Francisco, CA, United States of America; 5Pfizer Inc, Infectious and Immunology, Melbourne, Australia; 6Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada; 7Pfizer Inc, Biostatistics, Bengaluru, Karnataka, India; 8Pfizer Inc, Clinical Affairs, City of Makati, Luzon, Philippines; 9Griffith University, School of Medicine, Brisbane, Queensland, Australia

**Background:** Elevated baseline (BL) C-reactive protein (CRP) levels can predict treatment response in patients (pts) with ankylosing spondylitis (AS). Tofacitinib is a Janus kinase inhibitor for the treatment of AS.

**Objectives:** To evaluate the impact of BL CRP levels on tofacitinib efficacy and safety in pts with AS.

**Methods:** Post hoc analysis of pooled data from placebo (PBO)-controlled, randomised, double-blind trials (NCT01786668, Phase [P] 2, 16 weeks; NCT03502616, P3, 48 weeks) in pts with AS on ≥1 dose of tofacitinib or PBO (P3: PBO-treated pts switched to tofacitinib after Week [W]16), by BL CRP: normal (NML) ≤5 mg/L; elevated (EVL) ≥5 mg/L. Tofacitinib 5mg twice daily (BID) efficacy was assessed to W12/W16–48 (P3). Endpoints: Assessment of Spondyloarthritis international Society (ASAS) 20/40, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) 50, AS-Disease Activity Score-CRP inactive disease (ASDAS-CRP ID), least squares mean change from BL (Δ) in nocturnal pain and Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F).

**Safety:** was assessed to W16 and W48.

**Results:** Of 372 pts, 30.4/69.6% had NML/EVL BL CRP. Both groups had generally similar BL characteristics; more pts with EVL CRP were male, current smokers and had prior biologic disease-modifying antirheumatic drug use. At W12, ASAS20 response was greater for tofacitinib vs PBO in both groups (Figure 1); efficacy maintained to W48. At W12, the difference in response from PBO for tofacitinib was numerically greater for ELV vs NML CRP for ASAS20 (44.7% vs 19.5%), ASAS40 (34.6% vs 17.3%), BASDAI50 (33.8% vs 15.3%), ASDAS-CRP ID (9.5% vs 8.2%), nocturnal spinal pain (-2.1 vs -1.4) and ΔFACT-F (5.2 vs 3.5). For tofacitinib, rates of treatment-emergent adverse events (TEAEs) and infections to W16 trended numerically higher for tofacitinib vs PBO in pts with NML CRP, but were similar to PBO in pts with ELV CRP (Table 1). There were few serious AEs (SAEs), serious infections (SIs) or herpes zoster (HZ) across groups and no deaths. Limitations: small sample size, differences in BL characteristics.

**Conclusion:** Regardless of BL CRP at W12, tofacitinib was more efficacious vs PBO; and across endpoints, the differences in response from PBO for tofacitinib were numerically greater in pts with ELV vs NML CRP. Tofacitinib safety rates were consistent with PBO in pts with ELV CRP, but trended higher for tofacitinib vs PBO in pts with NML CRP.

</table>
Methods: Joints, bone mineral density (BMD), vertebral fractures (VF) and serum markers is still limited. In this explorative study, consecutive AS outpatients from the GLAS cohort who were treated with secukinumab for 2 years were included. Standardized follow-up visits were performed at baseline (before start of secukinumab) and after 3/6 months, 1 and 2 years of treatment. Bone-related outcome was assessed at baseline and after 2 years, with little change during 2 years of treatment. Serum BTM levels reflecting the actual bone turnover process corrected for normal influence of age and gender showed high BALP at baseline, indicative for mineralization, which decreased during 2 years of secukinumab treatment.

Background: IL17 inhibitors have proven to reduce disease activity in patients with ankylosing spondylitis (AS). AS is an intriguing disease which is characterized by both excessive bone formation and bone loss. Data on the effect of IL17 inhibitors on the different aspects of bone formation as well as bone resorption is still limited.

Objectives: To evaluate radiographic progression of the spine and cervical facet joints, bone mineral density (BMD), vertebral fractures (VF) and serum markers of bone resorption, formation, and mineralization during 2 years of secukinumab treatment in AS patients in daily clinical practice.

Methods: In this explorative study, consecutive AS outpatients from the GLAS cohort who were treated with secukinumab for 2 years were included. Standardized follow-up visits were performed at baseline (before start of secukinumab) and after 3/6 months, 1 and 2 years of treatment. Bone-related outcome was assessed at baseline and after 2 years. Radiographs were blinded for patient characteristics and scored in chronological time order by 2 independent trained readers. Spinial radiographic damage was assessed using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS; 0-72) and cervical facet joint involvement according the ‘de Vlam’ method (0-15). Radiographic VF were assessed using the Genant method and bone mineral density (BMD) with DEXA. Serum levels of BTM reflecting collagen resorption, collagen formation and facilitation of bone mineralization (sCTX, PINP and BALP, respectively) were measured at all visits. BTM Z-scores were calculated using a healthy reference population to correct for the normal influence of age and gender. Bone-related outcomes were explored using descriptive statistics. Generalized estimating equations were used to analyze BTM over time within patients.

Results: In total, 17 AS patients were eligible for analyses; 53% were male, mean age was 46.6±14.6 years, 82% were HLA-B27 positive, mean ASDAS at baseline was 3.9±1.2, median CRP was 5 (IQR 3 - 26) mg/L, 53% were biologic naïve, and median time between diagnosis and start of secukinumab was 5.0 (IQR 1.5-12.0) years. After 2 years of secukinumab treatment, median sCTX, PINP and BALP Z-scores were +0.0, -0.60 and +1.2 SD, respectively. The course of sCTX and PINP did not change significantly during follow-up, BALP Z-scores, however, significantly decreased at 2 years compared to baseline (Figure 1).

Conclusion: This explorative study in daily clinical practice with assessments of both new bone formation and bone resorption in AS patients treated with secukinumab showed that there was low radiographic damage at baseline, with little change during 2 years of treatment. Serum BTM levels reflecting the actual bone turnover process corrected for normal influence of age and gender showed high BALP at baseline, indicative for mineralization, which decreased during 2 years of secukinumab treatment.

Figure 1. The effect of 2 year of secukinumab treatment on markers of bone turnover sCTX (A), PINP (B) and BALP (C) in patients with AS (n=17). Bar indicates median value.

Disclosure of Interests: This study was supported by an investigator initiated research grant from Novartis.

BONE-RELATED OUTCOME DURING TWO YEARS OF SECUKINUMAB TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RADIOGRAPHIC SPINAL AND FACET INVOLVEMENT, BONE MINERAL DENSITY, VERTEBRAL FRACTURES AND BONE TURNOVER MARKERS

Keywords: Outcome measures, Bone diseases, Spondyloarthritides

M. A. Ozturk1, S. Arends1, F. Wink2, A. Spoorenberg1, 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands

Background: Following the failure of initial biological treatment in spondyloarthritides, switching to an alternative biological drug is possible. However, the data regarding the choice of the drug is limited. ASAS/EULAR guideline on axial spondyloarthritides does not make a distinction between TNFi, IL-17i or JAKi, with certain precautions regarding JAKi [1]. On the other hand, ACR/SAA/SPARTAN guideline recommends IL-17 over a different TNFi in primary failure, based on the assumption that TNFi is not the key inflammatory mediator in these patients [2].
Objectives: Our main objective was to compare and contrast the clinical and laboratory features of the patients who received either a TNFi or IL-17i following the failure of the initial biologic treatment in our cohort of spondyloarthritis patients.

Methods: Spondyloarthritis patients followed in our institution between 2014 and 2022 who received a secondary bDMARD following primary or secondary biologic failure were included in our study. ASAS criteria were used to classify patients as having axial or peripheral SpA. Failure was defined as lack of clinical improvement following at least 12 weeks of therapy. Demographic, clinical, laboratory and radiological features of the patients, along with clinical and laboratory response following the second line bDMARD treatment were recorded.

Results: 90 patients were included in our study. 51% were female (N=46), mean age at diagnosis was 35 (SD: 11.9, %95 CI: 32.5-37.6), median duration of disease was 9 years (IQR: 10; minimum: 2 years, maximum: 38 years). 76% (N=68) of patients were classified as axial SpA, remaining 22 were classified as peripheral SpA. 68% (N=58) were HLA-B27 positive. Median ASDAS-CRP before the initial bDMARD was 3.7 (IQR: 13; min-max: 2.6-5.9). Adalimumab was the most used initial TNFi (48%, N=43). Most common reason of treatment switch was secondary failure (51%, N=41), followed by primary failure (25%, N=20) and side effects (19%, N=15). Following initial treatment failure, 30% of patients (N=27) were switched to a drug with an alternative pathway, with most of them being secukinumab (N=22). Median ASDAS-CRP after initial treatment failure was 3.8 (IQR: 1.0, min-max: 2.5-6.0).

There was no difference in type of spondylarthritis, HLA-B27 positivity, ASDAS-CRP after initial bDMARD treatment. The rate of clinical remission was 5% for TNFi and 75% for bDMARDs switching. The reasons for bDMARDs switching were PF (50%), secondary failure (25%), SF (16%) and SE (8% - mostly infections). In the bDMARDs group, the most common current therapy was ADA (53%) followed by etanercept (ETA) (28%), golimumab (GOL) (9%), ustekinumab (UST) (1%), and secukinumab (SEC) (4%). During a follow-up of five years, the comparison between survival curves of these bDMARDs showed significant differences (p=0.015) (figure 1 A). The reasons for bDMARDs switching were primary failure (PF), secondary failure (SF), side effects (SE - 20% - mostly infections). In the PM group, the most common current therapy was ADA (44%) followed by ETA (33%), SEC (12 %), GOL (6%), UST (5 %). As shown in figure 1 B, no significant differences (p=0.49) in drug survival were found among patients treated with these bDMARDs. The reasons for bDMARDs switching were PF (38%), SF (38%), SE (8% - mostly infections).

Conclusion: In our experience, ADA was the most frequently prescribed bDMARDs as the first choice in patients with axSpA and pSpA. Despite PF and SF being the main causes of treatment discontinuation, a second anti-TNF agent was the preferred option in most cases.

AB0942 ANTI-IL17 TREATMENT AND INCIDENCE OF INFLAMMATORY BOWEL DISEASE: SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL TRIALS

Keywords: Psoriatic arthritis, Spondyloarthritis, bDMARD

R. Dos-Santos1,2, I. Alcántara3, D. Fernández Fernández4, I. González Fernández5, P. Castro-Santamaría5, M. Sanchez-Wonenburger7, A. Mata1, J. L. Puga Guzmán5, I. Álvarez1, V. Bustos5, J. R. Maneiro5, A. Souto Vilas4, A. Mera Varela1,2, E. Perez-Pampín5,6, Clinical University Hospital in Santiago de Compostela, Spain, Rheumatology Department, Santiago de Compostela, Spain; Universidad de Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain; Clinical University Hospital in Ourense, Spain; Rheumatology Department, Ourense, Spain; Clinical University Hospital in Pontevedra, Rheumatology Department, Pontevedra, Spain

Background: A warning about appearance or worsening of inflammatory bowel disease (IBD) during treatment with anti-IL17 agents has been launched by regulatory agencies in the last years. This caution is based on the relationship between bowel (IBD), joint (spondyloarthritis [SpA]) and skin (psoriasis [Ps]);

AB0941 REAL-LIFE ANALYSIS ON SURVIVAL TO TREATMENT AND REASONS FOR SWITCHING OF BIOLOGICAL DMARDS IN PATIENTS WITH SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, bDMARD

L. Di Sanzo1, E. Molteni1, C. Castellani1, G. Bevignani1, G. Sciarra1, M. Di Franco1, V. Ricci1, G. Alessandrini1, R. Scivo1, F. Corsi1, Polyclinico Umberto
regarding immune aspects. As well, anti-IL17 drugs have been proved ineffective in IBD treatment.[1,2]

Objectives: To analyze the incidence of IBD in patients with SpA or Ps treated with anti-IL17 drugs.

Methods: A systematic review of clinical trials has been performed using 4 databases (Medline, Embase, Web of Science, Cochrane Library). There were identified papers assessing the appearance of IBD in clinical trial's participants, previously diagnosed of Ps or SpA, treated with anti-IL17 drugs. A global incidence rate (IRR), incidence rate ratio (IRR) and relative risks (RR) were estimated in this population, in parallel and crossover studies. Heterogeneity and risk of bias were also evaluated.

Results: 53 papers were finally selected for performing this meta-analysis. A global IR of IBD diagnosis in Ps/SpA patients under treatment with anti-IL17 was 0.3/100 patients-year (95% CI 0.24-0.37). An IRR of IBD diagnosis in Ps/SpA patients under treatment with anti-IL17 was 0.56 (95% CI 0.34-0.9, p=0.01). A RR of IBD diagnosis in Ps/SpA patients under treatment with anti-IL17 in crossover trials was 0.73 (95% CI 0.27-1.99, p=0.54) (Figure 1).

Conclusion: We cannot affirm that anti-IL17 agents increase the global risk of IBD appearance in Ps or SpA patients. Anti-IL17 drugs may not be avoided in clinical practice concerning Ps and SpA patients, due to IBD prevention.

AB0943 EVALUATION OF THE EFFECT OF TUMOR NECROSIS FACTOR - A THERAPY ON 24-HOUR AMBULATORY BLOOD PRESSURE MEASUREMENT AND SLEEP QUALITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Cardiovascular disease, Spondyloarthropathy

K. Moral1, E. Bilgin2, O. Karadag2, U. Kalyoncu2, A. Akdoğan2, S. Kiraz2, A. I. Ertënil2, T. Yildirim2, L. Kılıç2, 1Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; 2Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 3Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Nephrology, Ankara, Turkey

Background: Increased cardiovascular mortality has been reported in AS patients. There are studies showing the positive effects of anti-TNF-α therapy on both cardiovascular mortality and sleep quality. (1,2)

Objectives: To determine the changes in sleep quality and 24-hour blood pressure measurements in AS patients with-axisSpA treated with anti-tumor necrosis factor TNF-α therapy.

Methods: Patients with axisSpA who were admitted to Hacettepe University Hospital Rheumatology Outpatient Clinic between 01.03.2021 and 01.12.2021, anti-TNF-naive and without a history of cardiovascular disease were included. Disease activity assessment (ESR, CRP, BASDAI and BASFI), ambulatory blood pressure measurement (ABMP) and sleep quality evaluated by pittsburgh sleep quality index questionare (PSQI) were assessed before anti-TNF therapy (0.month) and after anti-TNF-α therapy (3.month).

Results: Totally 28 patients with axisSpA (SD age 40.0 (10.4) years, female:16/57.1% patients) were included in to this study (table-1). The 0th and 3th month ABPM measurements of the patients in our study were within the normotensive limits. Both disease activity scores and median PSQI scores [8.5 (4.0-12.8)] were high and sleep quality was poor in 71% of the patients. Although there was a significant decrease in disease activity scores and a significant improvement in sleep quality at the 3. month after anti-TNF-α therapy, no significant changes were observed in ABPM parameters such as Ambulatory Arte- rial Stiffness Index (AASI), Average real Variability (ARV), Pulse Pressure Index (PPI), Sleeppoughsure and Prewaking surge compared to pre-treatment. While after anti- anti-TNF-α therapy the percentage of patients with dipper phenomena increased in the 3. month, this increase was not statistically significant (46.4% (0. month) vs. 60.7% (3. month); p=0.388). Furthermore, the change in nighttime systolic blood pressure reduction was statistically significant respectively (4.8% (7.9- 9.2) (0. month) vs. 9.2% (7.4-11.1) (3. month); p=0.020), while there was no statistically significant difference in the change in nighttime diastolic blood pressure reduction respectively (6.4% (1.5-14.7) vs. 9.6% (5.0-15.8); p=0.112) (table-2).

Conclusion: This study shows that anti-TNF-α treatment has positive effects on modifiable cardiovascular risk factors by increasing sleep quality and increasing nighttime blood pressure reduction. Prospective and long-term studies are needed.

Background: The treatment of Spondyloarthritis (SpA) has enormously improved thanks to bDMARDs, which are usually safe but they still require some caution because of their interference with the immune system homeostasis. ATE is a still evolving method designed to study the causal relationship between treatment and outcome.

Objectives: We endeavoured to investigate the impact of TNF-inhibitors (TNFi), anti-interleukin12/23 monoclonal antibodies (anti-IL) on comorbidities among SpA patients enrolled in the Italian GISEA Registry, using an average treatment effect (ATE) analysis.

Methods: SpA patients from the GISEA Registry were divided into groups according to pharmacological exposure: no treatment (G0), TNFi (G1) and anti-IL (G2). In each group, the prevalence and incidence of infectious, cardiopulmonary, endocrinological, non-inflammatory gastrointestinal disease (NIGID), oncologic, renal and neurologic comorbidities were evaluated. Thus, each comorbidity was fitted for ATE and baseline features were evaluated for importance.

Results: This multi-centre Italian GISEA study comprised 4458 SpA patients (G0=495 patients, G1=3113 patients, G2=815 patients). Cardiovascular disease was the most prevalent and incident comorbidity in all groups, with no significant difference between groups. ATE showed no increased risk of solid cancer in G1 and G2 (G1 vs. G0 = 0.42 95% CI 0.20-0.85; G2 vs. G0 = 0.26 95% CI 0.08-0.71), but significantly higher prevalence in G0 (14.07/1000 patient-years, p=0.0001). Conversely, a significantly higher risk of NIGID and fibromyalgia was found in G1 and G2 vs. G0 (NIGID: G1 vs. G0 = 1.56 95% CI 1.06-2.33, G2 vs. G0 = 1.91 95% CI 1.05-3.24; fibromyalgia: G1 vs. G0 = 1.69 95% CI 1.05-2.68, G2 vs. G0 = 2.13 95% CI 1.14-3.41). No treatment risk modification was observed concerning haematological malignancies, cardiovascular events and endocrinological comorbidities.

Conclusion: Overall, this study reveals that bDMARDs have only a slight interference of the occurrence of comorbidities in SpA patients, underlining the appropriateness of the use of bDMARDs in current clinical practice. Some caveats pertain to NIGID and fibromyalgia. Importantly, causality may yield more reliable and relevant clinical information, flattening the imbalance between observational data and clinical trials.

A META-ANALYSIS TO EVALUATE THE EFFICACY AND SAFETY OF IGURATIMOD ON ACTIVITY AX-SPA

**Keywords:** Spondyloarthritis, Disease-modifying Drugs (DMARDs)

Y. Li1, L. Hu1, Z. Zhao1, Z. Hu1, J. Zhang1, J. Zhu1, F. Huang1.1 The First Medical Center, Chinese PLA General Hospital, Department of Rheumatology and Immunology, Beijing, China

**Background:** Iguratimod is a newly-developed small molecular anti-rheumatic drug, which can inhibit the effects of prostaglandin E2, TNF-α and IL-17. Iguratimod had been reported to be effective in the treatment of SpA. Iguratimod was implied to be of potential efficacy on ax-SPA.

**Objectives:** This study was designed to demonstrate the efficacy and safety of Iguratimod on activity ax-SPA (ASDAS≥2.1).

**Methods:** We performed a meta-analysis to systematically evaluate the efficacy and safety of Iguratimod by gathering the published RCTs about the treatment of Iguratimod in ax-SPA, mean differences (MD) and 95% CI of the change of back pain, morning stiffness, PGa, ASDAS, BASDAI, BASFI and concentration of TNF-α, ESR and CRP were calculated. Besides, the odds ratio (OR) and 95% CI of the ASAS 20, ASAS 40, partial remission of ASAS, ASAS 5/6 were calculated as well.

**Results:** 7 RCTs were admitted into the meta-analysis, including 186 cases in the control group and 208 cases in the Iguratimod group. The control group was treated with NSAIDs monotherapy or NSAIDs combined with DMARDs, and the range of follow-ups was 12-24 weeks. The improvement of back pain (MD -1.76, 95% CI: -2.33 to -1.20, P <0.001), morning stiffness (MD -1127.95, 95% CI: -13.57 to -9.96, P<0.001), PGa (MD -2.86, 95% CI: -5.45 to -0.26, P<0.05), ASDAS (MD -0.8, 95% CI: -1.26 to -0.33, P<0.001), BASDAI (MD -1.19, 95% CI: -1.59 to -0.78, P<0.001), BASFI (MD -0.92, 95% CI: -1.29 to -0.55, P<0.001), ASAS 20 (OR 1194, 95% CI: 5.30 to 26.91, P<0.001), ASAS 40 (OR 4.46, 95% CI: 1.95 to 10.16, P<0.001), partial remission of ASAS (OR 1769, 95% CI: 4.06 to 77.08, P<0.001) in the Iguratimod treatment group were better than those in the control group, as well as for concentration of ESR (MD -8.77, 95% CI: -15.37 to -2.18, P<0.001), CRP (MD -4.44, 95% CI: -6.66 to -2.23, P<0.001) and TNF-α (MD -6.98, 95% CI: -7.72 to -6.24, P<0.001). There was no significant difference in the reported adverse events between the two groups.

**Conclusion:** Iguratimod is effective and well-tolerated during the treatment and thus could be a new pharmaceutical option for activity ax-SPA patients.

EFFECT OF UPADACITINIB ON REDUCING PAIN IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS AND INADEQUATE RESPONSE TO BIOLOGIC THERAPY

**Keywords:** Spondyloarthritis, Pain, DMARD

X. Baraliakos1, M. Magrey2, L. Bessette3, K. De Vlam4, T. Gao5, A. Shmagel6, Y. Li1, L. Hu1, Z. Zhao1, Z. Hu1, J. Zhang1, J. Zhu1, F. Huang1.1 The First Medical Center, Chinese PLA General Hospital, Department of Rheumatology and Immunology, Beijing, China

**Background:** Pain is a debilitating symptom of ankylosing spondylitis (AS) that negatively affects patients’ lives. Upadacitinib (UPA), a Janus kinase inhibitor and IL-17α and IL-17 inhibitor, has been reported to be effective in the treatment of AS. Upadacitinib was implied to be of potential efficacy on ax-SPA, and much better improvement (MBI, defined as ≥2 point reduction and ≥33% reduction from baseline), and non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19 was used.

**Results:** A total of 211 patients received UPA 15 mg QD and 209 patients received PBO. Higher proportions of patients receiving UPA vs PBO achieved ≥30% and ≥50% reductions in PGA of pain, total back pain, and nocturnal back pain as early as week 2 that were sustained at all time points through 14 weeks (nominal P<0.05; Figure 1a-c). Achievement of ≥70% reductions in PGA of pain and nocturnal back pain were higher at week 4 and sustained thereafter (Figures 1a and 1c), and achievement of ≥70% reduction in total back pain was higher at week 2 and week 8, but not week 4, and sustained thereafter (Figure 1b). Results were similar for the proportion of patients achieving MCID and MBI, with improvements in PGA of pain, total back pain, and nocturnal back pain for UPA vs PBO as early as week 1 (MCID) or week 2 (MBI) that were sustained through week 14 (all nominal P<0.001; Table 1).
