Results: Out of 33 SpA patients, 20 patients accepted to undergo sperm parameters assessment. 15 patients were diagnosed with AS (7 solely with axial involvement) and 5 patients were diagnosed with PSA. Table 1 presents the most important monitored parameters. All patients presented high disease activity measured by ASDAS and DAPSA. All patients had mild Psoriasis Area and Impact of long-term low and intermediate doses of MTX on sperm parameters. A healthy age matched control group underwent sperm parameters assessment. Demographics, type of disease, disease duration, MTX exposure and sperm parameters in AS and PSA patients versus controls.

SD-standard deviation, NV-normal values

Conclusion: Our data suggest that PSA patients represent a distinct group inside the SpA disease spectrum and fertility impairment is already a manifestation of disease. AS patients with early disease onset undergoing treatment (including MTX) have sperm parameters comparable to those of the controls. Chronic MTX therapy in dosages between 15-20mg/week do not have a negative impact on sperm parameters.

REFERENCES:
Therapy modifications rates were 78% in the IBD-group and 96% in the IAS-group. The most common modification for the IBD-group was initiation of biologic therapy in 18/32 patients (Adalimumab 44%, Infliximab 33%, Golimumab 5.7%, Etanercept 5.7%, Certolizumab pegol 5.7%, Ustekinumab 5.7%). In the IAS-group, switching biologic agent to Adalimumab or Infliximab (42%) and ceasing NSAIDs (27%) were the most common (Figure 1). At 1-year follow-up there were no significant differences in clinical outcomes (treatment failure, surgery/hospitalization, clinical remission) between IBD and IAS groups. However, patients in both groups with treatment modifications, had a trend for higher rate of IBD clinical remission than patients without (72% vs. 40%, p=0.066). No difference was found in AS clinical outcome.

Conclusion: Treatment modifications are common among newly coexisting IBD and AS patients, preferably biologic drug modifications. These modifications may contribute to IBD clinical remission.

AB0950 COST-EFFECTIVE THERAPY IN AXIAL SPONDYLOARTHRITIS: A COMPARATIVE ANALYSIS OF TWO TREATMENT STRATEGIES

Keywords: Targeted synthetic drugs, Spondyloarthritis, Tapering

P Vasanth 1, S. Rajendran 2, A. Jacob Mathew 1, R. Goel 1, J. Mathew 1.
1Christian Medical College Vellore, Department of Clinical Immunology and Rheumatology, Vellore, India; 2Christian Medical College Vellore, Department of Clinical Immunology and Rheumatology, Vellore, India

Background: Biologic disease-modifying anti-rheumatic drugs (bDMARDs) remain inaccessible to a majority of patients in resource-poor countries due to high cost. Cost-saving strategies including the use of generic bDMARDs with an early de-escalation schedule instead of continued standard dose or using generic small molecules such as tocilizumab or bircinib are being explored for the treatment of axial spondyloarthritis (AxSpA). The generic molecules are cheaper in India as compared with the rest of the world.

Objectives: To compare the efficacy, safety, and cost of generic tocilizumab and disease activity-directed early de-escalation schedule of intended copies of adalimumab (ADA), the most commonly used bDMARD available in India.

Methods: In this retrospective study, patients diagnosed with AxSpA in a tertiary care center in India, initiated on tocilizumab (TOFA), and had at least one follow-up visit from January 2021 to November 2022, were included. Patients who received ADA due to moderate to high disease activity with an early de-escalation schedule during the same period were included as historical disease controls. Early de-escalation was defined as increasing the interval between 2 doses of ADA by 1 week every 3 months within 12 months of initiation of the drug. The baseline demographic, clinical presentation, and response to treatment and adverse drug reactions were compared between patients on TOFA and ADA. An Ankylosing spondylitis disease activity score (ASDAS-CRP) of <2.1 was considered a good response to treatment. The descriptive data are presented as means SD or median (interquartile range) or percentages. Fisher’s exact test and Mann Whitney U test were used to compare categorical and continuous parameters, respectively, between TOFA and ADA. The average monthly cost of therapy was calculated for both groups.

Results: Among 240 patients who received TOFA, 155 patients satisfied the inclusion criteria, while 40 patients received early de-escalation of ADA. The age (33.9±9.5 and 33.6±13.3 years, p=0.66), gender [males n=131 (86.8%) and 32 (80.0%), p=0.32], median disease duration [7 (4-11) and 7 (4.3-11.0) years] and CRP [22.1 (10.2-44.5) and 23.85(14.48-71.50) mg/L, p=0.32] were similar for patients who received TOFA and ADA, respectively. The frequency of uveitis, peripheral arthritis, and HLA-B27 positivity was similar between the two therapies. Majority of patients [124 (82.1%) in the TOFA group and 32 (80%) in the ADA group] in both the groups received concomitant conventional DMARDs, while 36 (23.8%) patients on TOFA received prior TNF inhibitors. During a follow-up period of 6 (3-9) months, 129 (86.7%) of 151 patients on TOFA achieved low disease activity or inactive disease status as compared with 37 patients (92.5%) who received ADA (p=0.42). Adverse drug reaction requiring drug discontinuation was observed in 6 patients on TOFA (transaminis in 3, herpes zoster in 2, in 1, pefecth spondyloodiscitis) and in 5 patients receiving ADA (transaminis in 4 and abdominal tuberculosis in 1).

Conclusion: Tocilizumab therapy is comparable to the early dose de-escalation strategy of adalimumab in terms of treatment response and safety in Indian patients with AxSpA.

AB0951 EFFICACY AND SAFETY OF UPADACITINIB IN ANKYLOSING SPONDYLOITIS. REAL WORLD DATA

Keywords: Spondyloarthritids, bDMARD

1Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Majadahonda, Spain; 2Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain; 3Hospital Universitario Infantia Sofia, Rheumatology, Madrid, Spain; 4Hospital Can Misses, Rheumatology, Ibiza, Spain; 5Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain; 6Hospital Universitario de Basurto, Rheumatology, Bilbao, Spain; 7Hospital Universitario Parc Taulí, Rheumatology, Sabadell, Spain; 8Hospital Universitario Fundación de Alcorcón, Rheumatology, Madrid, Spain

Background: Upadacitinib is a selective and reversible inhibitor of Janus kinases (JAKs) that preferentially inhibits signaling via JAK1 or JAK1/3. JAK1 inhibition with upadacitinib modulates JAK-dependent cytokine signaling, thereby decreasing the inflammatory burden of different immune-mediated diseases. Upadacitinib is approved for the treatment of rheumatoid arthritis, psoriatic arthritis, non-radiographic axial spondyloarthritis, ankylosing spondylitis (radiographic axial spondyloarthritis), ulcerative colitis, and atopic dermatitis. In the case of ankylosing spondylitis, the drug has been approved for use in Spain since March 2022.

Objectives: The present study aims to evaluate the first data on safety and efficacy of upadacitinib use in ankylosing spondylitis in real clinical practice.

Methods: Retrospective analysis of a real world multicenter study that included patients of 8 Spanish hospitals. Demographic data, personal history, and clinical course of patients diagnosed with ankylosing spondylitis treated with upadacitinib at participating centers were collected.

Results: Forty-four patients with ankylosing spondylitis who received upadacitinib for a mean time (SD) of 8.7 (7.4) months were included in the study. They had received previous biologic treatments in 86 % of cases. In 23% of cases, patients at least 5. An improvement was observed in 70 % of patients as measured by subjective patient-reported improvement. The treatment was
suspended in the 27.3% of patients, the main reason for suspension was inefficacy. A higher percentage of suspension was found in patients who had received a greater number of previous biological treatments. Adverse effects were reported in 8 patients, the most serious being one episode of tachycardia, one episode of deep vein thrombosis, one episode of peptic ulcer and one episode of herpes zoster, and the most frequent adverse effect being headache.

Conclusion: 70% of patients with ankylosing spondylitis who received upadacitinib for a median time of 8.7 months experienced subjective improvement in their symptoms.

AB0952

**COMPARISON OF THE EFFECT BETWEEN BISPHOSPHONATE AND DENOSUMAB ON BONE MINERAL DENSITY AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A PILOT STUDY**

**Keywords:** Spondyloarthritis

M. Y. Kim¹, K. Y. Kang¹, Y. S. Hong¹, ¹The Catholic University of Korea, Incheon St Mary’s Hospital, Department of Rheumatology, Incheon, Korea, Rep. of (South Korea)

**Background:** Osteoporosis is a frequent complication of ankylosing spondylitis (AS). Although there are no clear guidelines for the treatment of this secondary osteoporosis in AS, antisteoporotic agents including bisphosphonate were used according to the same guidelines for primary osteoporosis. Also, approved by European Medicines Agency (EMA) in 2010, denosumab is being widely used.

**Objectives:** To compare the effect between bisphosphonate and denosumab on bone mineral density and radiographic progression in patients with AS for one year.

**Methods:** Among twenty-four patients with AS, sixteen patients were treated with bisphosphonate and nine patients with denosumab. BMD in the lumbar spine and right femur was measured by dual energy x-ray absorptiometry (DEXA) at baseline and one year after treatment. Radiographic progression was scored using the modified Stoke AS Spinal Score (mSASSS). Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Score (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), and bone markers (bone-specific alkaline phosphatase (ALP), Collagen type I cross-linked C-telopeptide) were used to assess disease activity.

**Results:** Mean BMD values in the lumbar spine and total hip at one year increased when compared to those at baseline in both the bisphosphate and denosumab groups (P=0.006 and 0.007 in bisphosphate group, 0.015 and 0.036 in denosumab group). The increment was greater in denosumab group. The mean BMD in L-spine and total hip increased by 11.0% and 4.9% in denosumab group, while 9.0% and 2.7% in bisphosphate group. There were no differences in disease activities such as BASDAI, ASDAS-CRP, ESR, and CRP between two groups. mSASSS and number of syndesmophytes also revealed no significant differences, suggesting that denosumab does not adversely affect disease activity and radiographic scores compared to bisphosphonate.

**Table 1. Comparisons of the changes of clinical measure and radiographic scores between bisphosphonate and denosumab**

**THE EFFECTIVENESS OF IL-23 INHIBITORS ON AXIAL SPONDYLOARTHRITIS AND AXIAL PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

**Keywords:** Psoriatic arthritis, Spondyloarthritis

S. Al Nokhatha¹, S. Maguire², K. Ainaqbi¹, ¹Tawam Hospital, Rheumatology, Abu Dhabi, United Arab Emirates; ²St James’s Hospital, Rheumatology, Dublin, Ireland

**Background:** Axial spondyloarthritis (axSpA) is an immune-mediated systemic chronic inflammatory arthritis involving the axial skeleton that may involve peripheral joints. Nonsteroidal anti-inflammatory drugs are first line therapy in the management of axSpA, however for many patients NSAID monotherapy is not sufficient to induce disease remission. Given the known efficacy of biologics in spondyloarthritis and the heterogeneity of these conditions, treatment choices should take into account all relevant disease domains. Interleukin-23 has been identified as a promising therapeutic target in SpA and PsA based on a significant body of evidence. Interleukin 23 inhibitors have produced inconsistent results when used to treat axial spondyloarthritis and axial psoriatic arthritis (1,2). Thus, there is a need for a holistic understanding of the use of IL23 inhibitors in axial conditions in particular spondyloarthritis and psoriatic arthritis to provide appropriate evidence-based management and mitigate the growing burden of these diseases.

**Objectives:** To explore the latest reported literature on the effectiveness of IL 23 inhibitors in axial spondyloarthritis and psoriatic arthritis.

**Methods:** A systematic literature review was conducted. The following databases were searched: Pubmed, Mendely EMBASE, MEDLINE (OVID), CINAH., Cochrane Library (central) and Web of Science. The search strategy included terms related to the axial spondyloarthritis and axial psoriatic arthritis and specifying the medications of study interest Ustekinumab, Risanikizumab, Gusekizumab and Tildrakizumab. The search was restricted to studies published in English from inception until June 2022. Randomized controlled trials, observational studies, or systematic reviews were eligible. Screening of titles, abstracts, and subsequent full text assessment were conducted independently by two independent reviewers. Outcomes assessed were BASDAI, BASDAI 50, modified BASDAI, BAFSI and ASDAS.

**Results:** Total of 4456 studies were identified, 9 studies of which 5 studies examining axial spondyloarthritis (Four RCTs and 1 prospective study) and 4 studies examining axial psoriatic arthritis (two prospective observational studies and two post hoc-analysis) were deemed suitable for inclusion. In contrast to one prospective observational study, 4 RCT (3 ustekinumab, 1 risanikizumab) did not support the use of IL23 inhibitors in axSpA based on the analyzed outcome measures of interest. Pooling of results for the three ustekinumab trials (BASDAI50, BAFSI, and ASDAS) (figure 1) demonstrated that the drug was not efficacious in treating axSpA. However, trials in axial PsA investigations showed an improvement in BASDAI, modified BASDAI, BAFSI and ASDAS.

**Conclusion:** The results of this meta-analysis would support the use of IL-23 inhibiting medications in the treatment of axial PsA. However, this is not the case for axSpA, as these drugs failed to demonstrate a significant improvement in patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and patient outcomes in axSpA patient populations. IMPACT OF CHRONIC KIDNEY DISEASE IN PATIENTS WITH AS USING BIOLOGIC AGENTS

Keywords: Comorbidities, bDMARD, Spondyloarthritis

G. Sandal Uzuń1, I. Y. Çakur2, E. Bilgin3, B. Farişogulları4, G. Ayan1, Z. Özsoy1, M. Ekici1, E. Unal5, S. A. Germe6, B. Filatån7, G. S. Kart Bayram8, J. Kılıç9, 1Hacettepe University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey; 3Hacettepe University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey, Ankara, Turkey; 4Hacettepe University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey, Ankara, Turkey.

Background: Although renal involvement is an rare extra-articular involvement in patients with ankylosing spondylitis (AS), medications and accompanying comorbidities may adversely affect renal functions [1].

Objectives: To determine the frequency and impact of CKD in patients with AS using biologic disease modifying anti-rheumatic drugs (bDMARDs).

Methods: Between 2005 and November 2021, 3207 patients diagnosed with AS according to the modified New York criteria were enrolled in the Hacettepe University biological database (HUR-BIO). The 2012 Kidney Disease: Improving Global Outcomes (KDIGO) guideline was used for the definition of CKD to evaluate the renal function of patients. Glomerular filtration rate (GFR) was calculated with the MDRD (modified Modification of Diet in Renal Disease) formula, taking into account the creatinine value, age and gender parameters of the patients [2]. CKD was detected in 39 (1.2%) patients. Age-sex matched 41 non-CKD AS patients were selected as the control group. Demographic and clinical characteristics and mortality rates of AS patients with and without CKD were compared.

Results: Of 39 AS-CKD patients, 25 (64.1%) had CKD before the initiation of bDMARD and and 14 (35.8%) developed CKD during follow-up after treatment was started. Patients with AS-CKD had longer duration of symptoms and disease (Table 1). Comorbidities such as hypertension, coronary artery disease and amyloidosis were more prevalent in patients with AS-CKD. At a median follow-up of 2.48(0.1-20.1) years, mortality was observed in 11(28.2%) patients in the AS-CKD group, while no mortality was observed in the age-sex matched AS-nonCKD group (p<0.001, Figure 1). The mortality rate in patients with AS-CKD was 12.6 per 1000 patient-years, and 4 (10.2%) of deaths were during the COVID-19 pandemic.

Table 1.

| Age, median(SD), years | 68.2 (12.0) | 58.8(12.6) | 0.001 |

Conclusion: Both comorbid disease burden and mortality seem to be increased in patients with AS-CKD. Increased mortality was more pronounced during the COVID-19 pandemic.

Background: The term “Difficult-to-Treat” (D2T) includes those patients who have persistent disease activity despite of having undergone several guideline-based treatments. This concept has been defined by EULAR for rheumatoid arthritis (RA) [1], thus could be analogously used for axSpA. In a recent publication [2] authors suggest that, among other interrelated factors that may be associated with an increased activity upon diagnosis (high CRP) or the presence of extra musculoskeletal manifestations (psoriasis). Describing D2T for axSpA would be useful to identify those interrelated factors that may be associated with an increased activity upon diagnosis (high CRP) or the presence of extra musculoskeletal manifestations (psoriasis).

A STUDY ON EARLY TAPERING OF TOFACITINIB IN ANKYLOSING SPONDYLITIS: A HIT AND RUN STRATEGY

Keywords: Tapering, Spondyloarthritides, Targeted synthetic drugs

V. Viswanath1, H. Sreekumar1, L. Sreekumari Ramachandran1, A. G. Varier1.
1Viswanath's IRIS Centre for Arthritis & Rheumatology, Rheumatology, Thiruvananthapuram, India

Background: Tofacitinib is emerging as a cost-effective drug in managing ankylosing spondylitis (AS) [1]. Tofacitinib (XELJANZ) was FDA-approved for the use of active AS in December 2021. Safety concerns have been raised about the long-term use of Tofacitinib following the ORAL surveillance trial data [2]. However, in developing countries, the cost is a primary concern, and Tofacitinib, an oral drug, can be considered an alternative to biologics. This study investigates whether early tapering can mitigate the safety risk and attain sustained remission.

Objectives: To assess the efficacy of early tapering of tofacitinib on disease activity in adult patients with active AS.

Methods: This observational study enrolled 22 consecutive patients aged ≥18 years diagnosed with active AS, meeting the ASAS criteria [3]. Patients received tofacitinib 15mg per day. ASDAS CRP was calculated at 0 and 6 months to monitor the response. The primary and secondary endpoints were early tapering of tofacitinib within six months of initiation and assessment of ASDAS CRP at 6 months, respectively. Assessment of the safety profile was done monthly.

Results: In our study, the mean ASDAS CRP at the initiation of tofacitinib was 2.24 (SD 1.13). After six months of treatment, the mean ASDAS CRP was 0.9 (SD 0.6), with remission in 77.27% (17 of 22). Tapering was initiated at a mean of 4.4 months (SD 3.18) and as early as one month. 41% of patients (9 of 22) had attained remission with early tapering of Tofacitinib and in 9% of patients (2 of 22), we could successfully stop Tofacitinib with sustained remission. Remission was occurred in 22% (5 of 22), of which in 2 patients drug had to be stopped. Two patients (9%) had to be switched to biologics due to non-responsiveness. There were no deaths, malignancies, major adverse cardiovascular events, thromboembolic events, or opportunistic infections.

Conclusion: In our study of 22 patients, we find that Tofacitinib can be a cost-effective management option in patients with AS who cannot afford biologics, especially in a developing economy like India. However, recent concerns about the drug's long-term safety preclude its optimal use. Early tapering of Tofacitinib demonstrates no increased incidence of flares and helps maintain remission. A hit-and-run strategy of early tapering of Tofacitinib would benefit patients with AS in the Indian context. We find that early tapering is effective in at least some of the patients, and it can reduce the cost of treatment as well as potential adverse reactions.

patients discontinued treatment, 29 (82.85%) due to inefficacy, 1 (2.85%) by their own decision, 4 (11.42%) due to persistent mechanical pain and 1 (2.85%) due to neoplasia. The factors associated with lower risk of discontinuation were higher IMC \( (p = 0.025) \) and diabetes \( (p = 0.04) \). None of the other clinical variables evaluated had a statistically significant association with a lower or higher risk of discontinuation or discontinuation. No patient presented infections that required discontinuation of the drug.

**Conclusion:** SCK showed a very high retention rate in a population that has been previously exposed to several biological therapies both in AxSpA and PsA groups. According to previous reports [1], cardiometabolic comorbidities such as obesity and diabetes appear to be associated with better SCK survival and therefore this drug could be an optimal therapy for patients with cardiometabolic risk factors.

**EFFECT OF BODY MASS INDEX ON TREATMENT RESPONSE OF BIOLOGIC/TARGETED SYNTHETIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS**

**Keywords:** Inflammatory arthritides, bDMARD, Comorbidities

**C. G. Gialouri**, M. Pappa, G. Evangelatou, E. Nikiphorou, G. E. Fragogiulis

National and Kapodistrian University of Athens, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, Medical School, National and Kapodistrian University of Athens; “Hippokration” General Hospital of Athens, Athens, Greece; 1National and Kapodistrian University of Athens, Rheumatology Unit, First Department of Propaedeutic Internal Medicine, National and Kapodistrian University of Athens, “Laiko” General Hospital of Athens, Athens, Greece; 2King’s College Hospital, London, UK., Centre for Rheumatic Diseases, Rheumatology Department, London, United Kingdom

**Background:** Overweight and/or obese patients with inflammatory arthritis (IA) have higher disease activity and lower chances of achieving as well as maintaining the treatment targets. Obesity also appears to negatively affect the response to tumor necrosis factor (TNF) inhibitors in patients with IA. The efficacy of other biologic (b) and of targeted-synthetic (ts) DMARDs in overweight/obese patients with IA, including rheumatoid arthritis –RA, psoriatic arthritis –PsA, axial spondyloarthritis –AxSpA, is unclear.

**Objectives:** To conduct a systematic literature review (SLR) to explore the effect of weight/body-mass-index (BMI) on the efficacy of all b-ts-DMARDs approved for the treatment of RA, PsA and AxSpA.

**Methods:** For this PROSPERO-registered SLR, we searched PubMed, Scopus and Cochrane-Library up to June 21st 2022. PICO-format was as follows: Population: adults with RA, PsA or AxSpA and low/normal weight/BMI; intervention: treatment with approved b-ts-DMARDs; Comparator: adults with RA, PsA or AxSpA and high/abnormal weight/BMI; Outcome: any outcome used for the assessment of treatment response (e.g. DAS28, ACR20, drug-survival). The search query included the following keywords in the article’s title and/or abstract: (“psoriatic arthritis” OR “rheumatoid arthritis” OR “inflammatory arthritis” OR “ankylosing spondylitis” OR “axial spondyloarthritis” OR “non-radiographic axial spondyloarthritis”) AND (DMARDs OR bDMARDs OR tsDMARDs OR tofacitinib OR baricitinib OR abatacept OR secukinumab OR ustekinumab OR guselkumab OR risankizumab OR ixekizumab OR “Janus kinase inhibitors” OR “JAK inhibitor”) AND (“body mass index” OR BMI OR obesity OR weight). Manual-search. Number of studies, most of which were of medium RoB, was: 34 randomized studies, respectively.

**Results:** Out of 996 references, 192 full-text articles were reviewed and 75 eventually fulfilled the inclusion criteria (of which 10 studies were retrieved through manual-search). Number of studies, most of which were of medium RoB, was: 34 for TNF-inhibitors, 4 for IL-12/23 inhibitors, 1 for IL-23 inhibitor, 7 for IL-17 inhibitors, 18 for tocilizumab, 8 for abatacept, 3 for rituximab and 5 for JAK-inhibitors. The efficacy of TNF-inhibitors was found to be affected by the BMI in all forms of IA with the effect being similar across various TNF-inhibitors. In contrast, the favorable results of IL-23 and IL-17 inhibitors do not appear to be influenced by increased BMI in patients with PsA or AxSpA. Similar evidence exists for tocilizumab and abatacept, while no conclusion can be drawn for rituximab. More data are needed for JAK-inhibitors, although the effect of weight/BMI does not seem to be significant so far (Figure 1).

**Conclusion:** Weight/BMI should be considered in the treatment-plan of patients with IA, with its effect being more pronounced for TNF-inhibitors compared to other b-ts-DMARDs.

**Figure 1** The effect of weight/BMI on the efficacy of the approved b- and ts-DMARDs for RA, PsA and AxSpA. Red color: negative effect, green color: no effect, yellow color: limited data, green/yellow knitting: possibly no effect but limited data, white: not applicable.

Efficacy of Biotherapies in APS Patients according to Age of Disease Onset: Data from the Moroccan RBSMR Registry

Keywords: Registries, Spondyloarthritis

M. El Mandour1, E. Boudhar1, A. Guich1, H. Sahimi1, R. Abouqal2, L. Achemlal3, Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco; 2Military Hospital Ibn Sina University Center, Rhabat, Morocco; 3Laboratory of Biostatistics, Clinical and Epidemiological Research, Faculty of Medicine and Pharmacy, Mohamed V University, Rabat, Morocco; 4Laboratory of Biostatistics, Clinical and Epidemiological Research, Faculty of Medicine and Pharmacy, Mohamed V University, Rabat, Morocco; 5Laboratory of Biostatistics, Clinical and Epidemiological Research, Faculty of Medicine and Pharmacy, Mohamed V University, Rabat, Morocco; 6Laboratory of Biostatistics, Clinical and Epidemiological Research, Faculty of Medicine and Pharmacy, Mohamed V University, Rabat, Morocco

The aim of this study is to compare the efficacy of biotherapy in juvenile onset spondyloarthritis and adult onset spondyloarthritis using data from the biotherapies registry of the Moroccan Society of Rheumatology RBSMR. We selected 73 patients, 55 with PsA (75.30%) and 18 with axSpA (24.70%). In the SEC cohort, we found 52 patients, mainly females (73.00%), mean age of 57.00 ± 14.7 years; in the IVE cohort, there were 21 patients, 71.43% females, mean age of 53.81 ± 11.7 years. Peripheral involvement was present in the majority of patients (88.46% vs. 100%), while axial involvement was predominant in SEC treated patients (61.54% vs. 28.57%). The presence of dactylitis was similar in the two groups (15.38% vs. 14.29%), enthesitis prevailed in SEC cohort (75.00% vs. 57.14%) while cutaneous psoriasis in the IVE cohort (44.23% vs. 80.95%). During follow-up, BASDAI and DAPSA decreased significantly in both SEC and IVE groups, especially in the first trimester, with a similar trend during the follow-up.

Comparison Between Secukinumab and Ixekizumab in Psoriatic Arthritis and Axial Spondyloarthritis: A Single Center Experience

Keywords: bDMARD, Psoriatic arthritis, Spondyloarthritis

C. Cannista1, E. Fiorentini1, L. Corneli1, L. Tofani2, S. Bellando-Randone1, S. Guiducci1, University of Florence, Clinical and Experimental Medicine, Rheumatology Unit, Florence, Italy; 2University of Florence, Statistics, Informatics, Applications, Florence, Italy

Background: The pathogenesis of SpA has not been completely elucidated, but several pieces of evidence suggest that interleukin (IL)17-A plays a pivotal role in this group of diseases. Both anti-IL-17A drugs Secukinumab (SEC) and Ixekizumab (IXE) have shown efficacy in treating multiple facets of SpA. (2)

Objectives: Our study aimed to compare the effect of SEC and IXE in our cohort of patients with PsA or axSpA.

Methods: We retrospectively analyzed our clinical database, enrolling patients with PsA or axSpA treated with SEC or IXE. We collected disease activity scales and scores at baseline (0) and after 3, 6 and 12 months of treatment: BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), DAPSA (Disease Activity Index for Psoriatic Arthritis), VAS (Visual Analog Scale) for pain, PGA (Patient Global Assessment), and PHQA (Physician Global Assessment).

Results: We selected 73 patients, 55 with PsA (75.30%) and 18 with axSpA (24.70%). In the SEC cohort, we found 52 patients, mainly females (73.00%), mean age of 57.00 ± 14.7 years; in the IXE cohort, there were 21 patients, 71.43% females, mean age of 53.81 ± 11.7 years. Peripheral involvement was present in the majority of patients (88.46% vs. 100%), while axial involvement was predominant in SEC treated patients (61.54% vs. 28.57%). </table>
second trimester (significant only for SEC). When compared with each other, SEC and IXE appeared to have a similar effect on both scales, except for a significantly greater reduction of BASDAI in the first trimester for SEC, which however was no longer present when the values were adjusted for the starting BASDAI value (Table 1). Analyzing PGA, PHGA, and VAS pain, we observed a significant trend in reduction in the first trimester for both drugs, then maintained only for SEC, significantly greater for SEC than IXE in both trimesters. The analysis of the adjusted values confirmed the significant decrease in BASDAI DAPSA PGA PHGA and VAS for both SEC and IXE, especially until 6 months after baseline.

Conclusion: Our data confirms that SEC and IXE are both valid options for the treatment of PsA and axSpA, without significant differences when comparing the two drugs.

SAFETY OF DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN SPONDYLOARTHITIS: A RETROSPECTIVE REVIEW FROM A SOUTH AFRICAN RHEUMATIC CENTRE

Keywords: Spondyloarthritis, Disease-modifying Drugs (DMARDs) G. S. Tar1, G. R. Reuter2, T. Mann1, 1Mediclinic Winelands Orthopaedic Hospital & Mediclinic Winelands Day Clinic, Rheumatology, Stellenbosch, South Africa; 2Stellenbosch University, Division of Rheumatology, Department of Medicine, Stellenbosch, South Africa; 3Stellenbosch University, Division of Orthopaedic Surgery, Department of Surgical Sciences, Stellenbosch, South Africa

Background: The long-term immune-suppressive effects of Disease Modifying Anti-Rheumatic Drugs (DMARDs) have long been a concern for serious adverse effects (SAE). Other developing countries, e.g. Brazil, used their registry to report a higher incidence of serious infections in the bDMARD treated patients compared with sDMARDs [1]. There are no published articles about the true incidence and nature of SAEs in Spondyloarthritis (SpA) patients treated with bDMARDs in the South African context.

Objectives: To describe the incidence of SAEs amongst patients with SpA treated with b- and s-DMARDs at a rheumatology centre in the Western Cape, South Africa.

Methods: A retrospective medical record review was conducted, involving patients with SpA seen at a private rheumatology clinic in Stellenbosch, Western Cape, between the 1 January 2014 and 31 December 2021. Demographic, clinical, and patient reported SAEs were recorded for those treated with b- and s-DMARDs. Incidence of SAEs was calculated and presented with 95% confidence intervals.

Results: Incidence of SAEs recorded between 1 January 2014 and 31 December 2021. A total of 92 patients were included, 59 bDMARD exposed and 33 treated only with sDMARDs (bDMARD naïve). The accumulated exposure was 300 person-years (p-y) for those on bDMARDs and 140 p-y for those on sDMARDs only. Twenty two SAEs were reported during the study period, 14 infective, 4 major adverse cardiac events, 3 malignant (prostate, uterine, and thymoma), and 1 pulmonary complication. Twenty SAEs occurred whilst on a DMARD, one occurred 37 days after stopping etanercept, and a single SAE was excluded as it occurred 2 years after stopping infliximab. All SAEs were associated with hospitalisation and there were two deaths (one related to multi-organ failure, the other COVID-19 related). The SAE incidence for the sDMARD control group was 2.1/100 p-y (95% CI. 0.5-5.8/100 p-y) and 6.0/100 p-y (95% CI. 3.7-9.3/100 p-y) in the bDMARD study group. Of the anti-TNF inhibitors assessed, etanercept had the lowest SAE incidence at 3.8 events/100 p-y (95% CI. 1.2-9.3/100 p-y) (see Table 1).

Conclusion: The preliminary results of this retrospective review of SpA patients attending a private rheumatology clinic in a developing country suggests that infliximab treated patients had 5.5 times more likely to develop an SAE compared to patients on sDMARDs. Overall patients exposed to monoclonal antibodies were 3.2 times as likely to develop an SAE compared to those receiving sDMARDs, with respiratory infections the most commonly reported SAE.

AKSpA in our rheumatology clinic were included in the study. Demographic characteristics and treatment response status of patients who were followed up with the diagnosis of Ax-SpA and using SCK.

However, there are few studies evaluating long-term SCK efficacy in real-life data. Studies that included four randomized double-blind studies (MEASURE Studies).

Background: Secukinumab (SCK), the first-in-class human monoclonal antibody against interleukin-17A, has been approved for the treatment of AS in many countries, including the US and EU. The efficacy of subcutaneous secukinumab in the treatment of AxSpA was primarily evaluated in five multicenter, phase III studies that included four randomized double-blind studies (MEASURE Studies). However, there are few studies evaluating long-term SCK efficacy in real-life data in patients with AxSpA [1,2].

Objectives: Our aim in this study is to retrospectively evaluate the clinical findings and treatment response status of patients who were followed up with the diagnosis of AxSpA and using SCK.

Methods: A total of 60 patients who were followed up with the diagnosis of axSpA in our rheumatology clinic were included in the study. Demographic characteristics of the patients, comorbidities, duration of symptoms, delay in diagnosis, biologics and DMARDs were recorded. In the evaluation of the patients, BASDAI, BASFI, ASDAS, VAS pain, and VAS global scores were recorded at baseline, 3, 6, 12 and 24th months. The number and order of treatment before SEC in patients using bDMARDs were also examined, and SCK efficacy and drug retention characteristics were investigated between the biological treatment groups.

Results: Follow-up data of 60 patients diagnosed with SpA (n=50 AS and n=10 nr-AxSpA) followed in a single center (inception cohort) were evaluated. Of these patients, 15 (25%) were bDMARD naive patients and 45 (75%) had used ≥1 bDMARD before SEC. The age and gender distribution was similar between the bDMARD naive and ≥1 bDMARD group. At 1-year follow-up, 1 and 7 patients discontinued their treatment in the ≥1 bDMARD group and the SCK group, respectively (p<0.001) (Figure 1). In our study, no significant drug-related serious adverse events or safety problems were encountered in the follow-up of secukinumab treatment for more than 36 months.

Conclusion: We found that SCK treatment in patients with AxSpA had better clinical response and higher drug survival rates in biologic naive patients, similar to TNFi treatment in real-life data. However, better drug retention rates were found in naive patients compared to patients using ≥1 bDMARD, which is consistent with the results of previous studies.

Background: Secukinumab (SCK), the first-in-class human monoclonal antibody against interleukin-17A, has been approved for the treatment of AS in many countries, including the US and EU. The efficacy of subcutaneous secukinumab in the treatment of AxSpA was primarily evaluated in five multicenter, phase III studies that included four randomized double-blind studies (MEASURE Studies). However, there are few studies evaluating long-term SCK efficacy in real-life data in patients with AxSpA [1,2].

Objectives: Our aim in this study is to retrospectively evaluate the clinical findings and treatment response status of patients who were followed up with the diagnosis of AxSpA and using SCK.

Methods: A total of 60 patients who were followed up with the diagnosis of axSpA in our rheumatology clinic were included in the study. Demographic characteristics of the patients, comorbidities, duration of symptoms, delay in diagnosis, biologics and DMARDs were recorded. In the evaluation of the patients, BASDAI, BASFI, ASDAS, VAS pain, and VAS global scores were recorded at baseline, 3, 6, 12 and 24th months. The number and order of treatment before SEC in patients using bDMARDs were also examined, and SCK efficacy and drug retention characteristics were investigated between the biological treatment groups.

Results: Follow-up data of 60 patients diagnosed with SpA (n=50 AS and n=10 nr-AxSpA) followed in a single center (inception cohort) were evaluated. Of these patients, 15 (25%) were bDMARD naive patients and 45 (75%) had used ≥1 bDMARD before SEC. The age and gender distribution was similar between the bDMARD naive and ≥1 bDMARD group. At 1-year follow-up, 1 and 7 patients discontinued their treatment in the ≥1 bDMARD group and the SCK group, respectively (p<0.001) (Table 1). The retention rate at 24 months was 80% and 49% in the naive and ≥1 bDMARD patients, respectively (p=0.026) (Figure 1). In our study, no significant drug-related serious adverse events or safety problems were encountered in the follow-up of secukinumab treatment for more than 36 months.

Conclusion: We found that SCK treatment in patients with AxSpA had better clinical response and higher drug survival rates in biologic naive patients, similar to TNFi treatment in real-life data. However, better drug retention rates were found in naive patients compared to patients using ≥1 bDMARD, which is consistent with the results of previous studies.

RefRACTORY ACHILLES ENTHESIS SUCCESFULLY TREATED BY IKeZUmbA LOCAL INJECTION

Keywords: bDMARD, Spondyloarthritis, Enthesitis

A. Abogamal1, 1Al-Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt

Background: Axial spondyloarthropathy (axSpA) is a chronic autoimmune inflammatory disease that involves the axial skeleton with inflammatory back pain as the most common presenting symptom. [1] Apart from the axial joints, enthesitis are frequently involved in spondyloarthropathy (SPA) and clinical enthesitis reported to affects 10% – 60% of SPA patients. Enthesitis usually involves the lower limb and heel pain represents a significant clinical challenge due to frequent presence of Achilles enthesitis (AE), retrocalcaneal bursitis (RB) and plantar fasciitis, plus a
treatment challenge in refractory cases that usually not controlled by conventional DMARDs and fails to respond to biological treatment [2-4].

Objectives: To describe a successful management of refractory case of AE after US guided Ixekizumab injection to the RB.

Methods: Male 42 y old known case of axSpA for 22 y with +ve HLAB27 and bilateral AE, initially treated with salazopyrine, and NSAIDs with no response and treatment escalated to Infliximab with secondary failure after 6 months, switched etanercept injection with primary failure. Patient achieved good clinical response on adrenalumab which was maintained up to 7y, followed by secondary failure due to antidrug antibodies, resolved by adding Methotrexate. July 2019, developed hepatotoxicity due to methotrexate with discontinuation. December 2019, patient switched to Ixekizumab with successful control of his disease. Apart from the course of axial disease, January 2019 his heel pain becomes refractory to treatment VAS 8 with US assessment shows AE, RB, and tendonitis. July 2020, an US guided injection of the RB with Ixekizumab 80mg arranged two weeks after application of the systemic Ixekizumab.

Results: Three months after Ixekizumab local injection, heel pain drops to VAS 0, with radiological improvement in US; resolution of the Doppler signals and bursitis.

Figure 1. Long axis scan of the left Achilles tendon; A: Grey scale shows hypoechogenecity of the tendon, distended RB, positive Doppler signals involving the bursa and extending to the tendon body. Figure 1 March 2020, an US guided injection with Triamcinolone acetaate 20mg infiltrated to the RB failed to control pain with partial response for two weeks. July 2020, an US guided injection of the RB with Ixekizumab 80mg arranged two weeks after application of the systemic Ixekizumab.

Conclusion: US Guided local application of Ixekizumab successfully help to resolve pain and inflammation in a refractory case of AE.

Background: Spondyloarthritis is a group of chronic inflammatory rheumatism most often affecting young adults. Biological background treatments have revolutionized their current therapy. Patients with axial spondyloarthritis have failed these treatments.

Methods: Our study included patients with Spondyloarthritis retained according to the ASAS criteria, having an age > 18 years, treated with biological treatment, having given their written informed consent, in the 10 rheumatology departments in Morocco, collected from the RBSMR registry, a multicenter historical-prospective registry. Primary failure was defined as failure at 6 months of treatment and secondary failure as failure at more than 6 months of treatment. Patients were assessed every six months with a scheduled follow-up of three years. Inclusion began in June 2017 and ended in January 2019, when the database was first frozen.

Results: 194 patients included. The average age was 40.23 years +/- 13.68, the sex ratio was 1.73 M/F, the average duration of evolution was 615.9 weeks +/- 349.12. An HLA B27 antigen was positive in 66% of patients. Peripheral involvement was found in 70% of patients, axial involvement in 96.4% of patients and enthesic involvement in 61.5% of patients. Radiographic sacroiliitis was present in 87.6% of patients, radiographic costitis in 40.7% and sonographic costitis in 19.8%. Regarding extra-articular manifestations, 14.5% of patients had anterior uveitis, 6.9% had cutaneous psoriasis, and 10.7% had associated chronic inflammatory bowel disease. The ASDAS CRP was in high activity in 50.9% of the patients and the BASDAI (spondyloarthritis activity index) more than 4 in 79.2% of the patients. At the first visit, 22.5% of patients were taking corticosteroid therapy and 53.8% were taking csDMARDs. The most widely used biological was Etanercept with a percentage of 33%. Over a follow-up period of 03 years, 05 primary failures were observed and 17 secondary failures to the first biological treatment (06 failures at the 12th month, 06 failures at the 18th month and 03 failures at the 24th month), the prevalence of failure of the first biological treatment was 8.76%, in bivariate analysis, no statistically significant factors were observed associated with the failure of the first biological during the visit of the 6th month, the 12th month or that of the 24th month. At the visit of the 18th month, the average BASDAI as well as that of the C reactive protein (CRP) was statistically higher in patients who failed the first biological.

Conclusion: The failure of the first biological is a rather rare situation in our study. Certain factors were significantly associated with this failure and must be taken into account when managing patients, namely high values of BASDAI and CRP. Higher values of the Bath Spondylitis Functional Index (BASFI) or CRP at baseline are predictors of a greater risk of failure of the first biological found in the literature.

DOI: 10.1136/annrheumdis-2023-eular.3432
**Background:** Axial spondyloarthritis (axSpA) is a group of chronic auto-inflammatory diseases. Tumor necrosis factor-alpha (TNF-α) and interleukin-17 (IL-17) were demonstrated to play an irreplaceable role in the pathogenesis of axSpA. Iguratimod is a newly-developed small molecular anti-rheumatic drug, which can inhibit the effects of prostaglandin E2, TNF-α and IL-17 [1]. The efficacy and safety of Iguratimod in the treatment of rheumatoid arthritis (RA) have been fully studied and approved to the treatment of active RA in China and Japan [2]. Iguratimod had been reported to be effective in the treatment of axSpA [3], despite those studies were limited and of small-example size.

**Objectives:** In consideration of the efficacy of Iguratimod in the treatment of RA and the overlap of disease pathogenesis between RA and SpA, Iguratimod was implied to be of potential efficacy on axSpA. This study was aimed to demonstrated the efficacy and safety of Iguratimod on axSpA in the real world from China.

**Methods:** 193 patients with axSpA who visited the outpatient rheumatology clinics in the First Medical Center of Chinese PLA General Hospital between April 2016 to June 2022, were collected and screened. Patients treated with NSAIDs only, combined with sulfasalazine (SSZ) or Iguratimod for over 6 months were admitted into analysis. Those three groups of patients were also matched by propensity score on a ratio of 1:1:1, by age, gender and ASDAS at baseline. Multilevel models for repeated measurement data were conducted to compare the differences of ASDAS, back pain, ESR and CRP level between the three groups of patients during the 18 months follow-ups.

**Results:** 302 patients with axSpA were included in the real-world study and they were followed at a mean 6-month interval for 3 times (median follow-up 17.55 months, interquartile range 16-20 months). 161, 96 and 45 patients fell into the NSAIDs only, NSAIDs combined with SSZ or Iguratimod group. At 17.55 months, interquartile range 16-20 months). 161, 96 and 45 patients fell into the NSAIDs only, NSAIDs combined with SSZ or Iguratimod group. At 17.55 months, interquartile range 16-20 months). 161, 96 and 45 patients fell into the NSAIDs only, NSAIDs combined with SSZ or Iguratimod group. At 17.55 months, interquartile range 16-20 months). 161, 96 and 45 patients fell into the NSAIDs only, NSAIDs combined with SSZ or Iguratimod group. At 17.55 months, interquartile range 16-20 months). 161, 96 and 45 patients fell into the NSAIDs only, NSAIDs combined with SSZ or Iguratimod group. At 17.55 months, interquartile range 16-20 months).

**Conclusion:** Iguratimod had significant add-on effect on the decrease of disease activity and alleviation of back pain than monotherapy of NSAIDs or NSAIDs combined with SSZ. Iguratimod had greater improvement on ASDAS than that on patients treated with NSAIDs combined with SSZ (P<0.001, 95% CI: 0.000 ~ 0.001, P=0.043) or NSAIDs only (P<0.001, 95% CI: 0.000 ~ 0.001, P=0.033).

**REAL WORLD EFFECTIVENESS AND SAFETY OF SECUKINUMAB IN SPONDYLOARTHITIS AND PSORIASIC ARTHRITIS**

**Keywords:** Real-world evidence, Psoriatic arthritis, Spondyloarthritis
Background: Secukinumab (SEC) is a human monoclonal antibody (lgG1) aimed against IL-17A, a proinflammatory cytokine involved in the pathogenesis of psoriatic arthritis (PsA) and axial spondyloarthropathy (axSpA) [axSpA]. It is already well known that C-reactive protein (CRP) is an important inflammatory biomarker and that it could be used as a variable of its efficacy. More recently, it has been published that the neutrophil lymphocyte ratio (NLR) [1] an inflammatory biomarker, could be predictive of CV events occurrence and all cause mortality. In this study, we intend to evaluate effectiveness and safety with SEC with conventional and non-conventional scales in patients with Spondyloarthropathy.

Objectives: To evaluate the long-term effectiveness and safety of SEC in patients with axSpA and PsA in an actual clinical setting.

Methods: We designed a single center retrospective and longitudinal observational study including patients diagnosed of axSpA. To fulfill the ASAS classification criteria and PsA fulfilling the CASPAR classification criteria. Between 2016 and 2022, a total of 90 patients were included in the study treated with SEC in the rheumatology service of the Hospital Universitario de Navarra. All patients included started SEC treatment at least 1 year before the data extraction. For the axSpA CRP, the Anklyosing Spondylitis Disease Activity Score (ASDAS) scale, the patient’s visual analog scale (VAS) and NLR [1] were analyzed. In the PsA group VAS, CRP and NLR were assessed. In both groups the variables were analyzed at baseline, 12 and 24 months. Safety was evaluated by analyzing intercurrent infections or neoplasms that required discontinuation.

Results: We included a total of 90 patients (46 axSpA and 44 PsA), 45(50%) of which were female. The mean age at diagnosis was 44.5 years (SD 11.1) while the mean age at SEC initiation was 51.6 (SD 14.4). The median time from diagnosis to onset of SEC was 5 years (IQR 2-11) (Table 1). Eighty-three (92.2%) patients were treated with one or more biologic drugs prior to SEC, median 2 (IQR 0-5). The mean CRP before starting SEC was 9mg/L (SD 176), VAS 7 (SD 2) and NLR 1.9 (SD 1). A statistically significant improvement was observed in both pathologies when it comes to CRP at 24 months (p=0.049) but not at 12 months (Table 1). VAS presented a statistically significant improvement at 12 and 24 months of treatment (p=0.008 and 0.012 respectively). There were no statistically significant differences in NRL in any group. Regarding ASDAS in the axSpA group, 4,34% showed a great improvement while 26% of them showed clinically significant differences in NRL in any group. Regarding ASDAS in the PsA group VAS, CRP and NLR were assessed. There were no statistically significant differences in NRL in any group. Regarding ASDAS in the axSpA group, 4,34% showed a great improvement while 26% of them showed clinically significant differences in NRL in any group. Regarding ASDAS in the PsA group VAS, CRP and NLR were assessed.

Safety was evaluated by analyzing intercurrent infections or neoplasms that required discontinuation.

Results: We included a total of 90 patients (46 axSpA and 44 PsA), 45(50%) of which were female. The mean age at diagnosis was 44.5 years (SD 11.1) while the mean age at SEC initiation was 51.6 (SD 14.4). The median time from diagnosis to onset of SEC was 5 years (IQR 2-11) (Table 1). Eighty-three (92.2%) patients were treated with one or more biologic drugs prior to SEC, median 2 (IQR 0-5). The mean CRP before starting SEC was 9mg/L (SD 176), VAS 7 (SD 2) and NLR 1.9 (SD 1). A statistically significant improvement was observed in both pathologies when it comes to CRP at 24 months (p=0.049) but not at 12 months (Table 1). VAS presented a statistically significant improvement at 12 and 24 months of treatment (p=0.008 and 0.012 respectively). There were no statistically significant differences in NRL in any group. Regarding ASDAS in the axSpA group, 4,34% showed a great improvement while 26% of them showed clinically significant differences in NRL in any group. Regarding ASDAS in the PsA group VAS, CRP and NLR were assessed. There were no statistically significant differences in NRL in any group. Regarding ASDAS in the AxSpA patients (radiographic and non-radiographic) treated with secukinumab. We analysed the features of patients who continued secukinumab at their last visit and those who discontinued the drug over the follow-up period. We used the Kaplan-Meier curve to estimate the cumulative retention rate of secukinumab.

Results: A total of 57 patients were enrolled in our study. Among them, 26 (45.6%) were women, and 31 (54.4%) were men. The median age at diagnosis was 50 (22-71). There were 26 (45.6%) patients who were bDMARD naive and 31 (54.4%) patients that had used at least one bDMARD before secukinumab. Among the naïve group, 4 (14.4%) patients discontinued secukinumab, whereas among the group with former bDMARD usage, 12 (38.7%) people discontinued treatment. The ineffectiveness of the drug was the most common reason for discontinuation in both groups. Regarding adverse effects, two people reported respiratory infections. We did not record significant drug safety complications in our cohort. The duration of treatment was 6.5 years. The survival rate of the drug was 91% after six months, 83.4% after 12 months, 75% after 24 months, and 66.8% after 48 months. Table 1 shows detailed clinical aspects of the cohort.

Conclusion: Our data confirmed a good survival rate of secukinumab in patients with axSpA. However, results showed that fewer biologically naive patients discontinued the secukinumab treatment than those who received the drug after the failure of another biologic.

Spondyloarthritis - clinical aspects (other than treatment)

**Background:** The association of several immune-mediated inflammatory diseases (IMIDs) in the same patient is well known. Rheumatologic and dermatologic IMIDs are frequently diagnosed in patients with inflammatory bowel disease (IBD). However, the degree of knowledge that patients with IBD have about the coexistence of other IMIDs is little studied.

**Objectives:** Our aim was to evaluate the accuracy of self-reporting of IMIDs by patients with IBD.

**Methods:** Prospective, uncentered study that included patients attending in person at the IBD Unit of the Central University Hospital of Asturias (Oviedo-Spain) between August 2020 and December 2021. Patients were invited to participate in the study, and after signing the informed consent, they answered a questionnaire about the presence or not of 50 IMIDs (self-reported diagnosis). The diagnosis of an IMID was confirmed in the medical records of each patient (reference diagnosis). Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy (proportion of subjects correctly classified) of self-reporting was calculated. Statistical analyses were performed with R software version 4.0.2.

**Results:** A total of 1621 patients were included. Forty-four percent of patients had ulcerative colitis, 53% Crohn’s disease and 3% an IBD-unclassified, sex distribution was 1:1, and the age at diagnosis of IBD was 38 ± 15.2 years. Seven hundred and twelve patients were receiving mesalazine, 67 corticosteroids, 394 immunomodulators and 532 biologics. Six hundred and twenty-seven (39%) patients were diagnosed with at least one IMID, 177 (10.9%) with two, 49 (3%) with three, and 17 (1%) with more than three. Sixteen percent of patients had a dermatologic IMID and 15% a cutaneous IMID. Self-reporting of IMIDs by IBD patients showed a sensitivity, specificity, PPV, NPV and accuracy of 0.75 (95% CI 0.73-0.78), 0.89 (95% CI 0.86-0.91), 0.92 (95% CI 0.89-0.93), 0.69 (95% CI 0.66-0.73) and 0.81 (95% CI 0.79-0.83), respectively. Accuracy of self-reported diagnosis of IMIDs was lower among the rheumatologic IMID group (Table 1).

**Conclusion:** Eighty-one percent of patients with IBD are able to correctly identify the coexistence or not of other IMIDs. It was observed that in the case of rheumatologic IMIDs there is a significant percentage of patients who do not know whether or not they suffer from one of these conditions.

**REFERENCE:**

Background: Disease-assessment in axial spondyloarthritis (axSpA) includes subjective measures that do not necessarily reflect inflammatory processes in the spine and joints. Mental health comorbidities such as anxiety and depression can be secondary to inflammatory and non-inflammatory processes. There may be subgroups that respond differently to axSpA treatment, for example, discordance in these indices whereby disease activity improves but not mental health. Understanding such potential subgroups and their characteristics can support individualised care.

Objectives: To apply data-driven approaches to longitudinal disease activity (ASDAS) and Hospital Anxiety and Depression Scale (HADS) subscores for anxiety (HADS-A) and depression (HADS-D) to identify potential groups with discordant trajectories.

Methods: This was an ancillary analysis of the data collected for the Assessment of SpondyloArthritis international Society Health Index (ASAS HI) Validation Study. We included individuals who fulfilled ASAS criteria for axSpA and required a therapeutic change (initiation of NSAID, csDMARDs or TNFi) due to active disease. Those with diagnosis of peripheral SpA were excluded. Participants were assessed at baseline and one follow-up. Group-based trajectory models were used to group individuals based on shared trajectories of ASDAS, HADS-A and HADS-D. These three dependent variables were standardised (scale 0 to 10), then included in linear models with a time indicator (baseline or follow-up) as the independent variable. We selected the optimum number of groups through statistical fit. Individuals were assigned to the group with the highest posterior probability of membership. Patient and disease characteristics were compared across groups.

Results: Of 206 participants (mean age 37 years, 65% male), 73 (35%) started NSAIDs, 23 (11%) csDMARD and 109 (53%) TNFi (Table 1). The optimum number of trajectory groups was 4 (Figure 1). Three indices changed concordantly regardless of the number of latent groups. Group descriptions are relative: Group 1 (n=112) (54%) started with low scores for all three indices. G2 (34%) moderate, and G3 (5%) high. Mean improvements in ASDAS were numerically similar across these groups. G4 (7%) had the greatest improvement across all three indices. Initiated therapy differed with G3 and 4 more frequently starting TNFi.

Conclusion: Results of this study show that ASDAS and symptoms of anxiety and depression are closely related and change concordantly with treatment, and suggest that reported musculoskeletal and mental health symptoms influence each other. There were no clear differences in patient or disease characteristics across these groups except for age. Whether axSpA patients benefit from knowing that mental health symptoms generally improve jointly with disease activity when starting treatment remains to be shown.

ASSOCIATION OF SLEEP QUALITY WITH DISEASE ACTIVITY, INFLAMMATION, MOBILITY, AND FUNCTION AMONG PATIENTS WITH AXIAL SPONDYLOARTHITIS

Keywords: Spondyloarthritis, Quality of Life, Patient reported outcomes

J. P. Lee1, F. Y. Wu1, C. F. Su1, S. H. Lin1, Y. S. Chang1, 2 Shuang Ho Hospital, Taipei Medical University, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China; 2School of Medicine, College of Medicine, Taipei Medical University, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China

Background: Inflammation and ankylosis of the axial skeleton are two major features of axial spondyloarthritis (axSpA), which cause midnight pain and immobility of back, respectively. Both features may lead to sleep problem. Nevertheless, which of the two features influence sleep most is less studied. Moreover, there are many disease activity measurements, including BASDAI, ASDAS, ESR and CRP, among these measurements, which one could best predict sleep disturbance are still unknown.

Objectives: This pilot study aimed to discover the association between different measurements of axSpA and sleep disturbance.

Methods: This cross-sectional study recruited patients with axSpA from the rheumatology clinic in the Shuang Ho hospital from 2018 to 2020. The Pittsburgh Sleep Quality Index (PSQI) was used to assess sleep quality together with other clinical measurements, including BASDAI, ESR, CRP and ASDAS-CRP for disease activity, BASMI for mobility and BASFI for function. The features associated with poor sleep quality (PSQI > 5) were identified. All the domains of sleep disturbance were compared between patients with different level of disease activity classified by each activity measurement.

Results: This cross-sectional study recruited 322 patients with axSpA, among them 72% were male, and the mean age was 42 years. There were 249 (77.3%) patients had poor sleep quality (PSQI>5). Poor sleepers had significantly higher BASDAI, ASDAS-CRP and BASMI, while there was no significant difference in sex, age, ESR, CRP and BASMI. Patients with higher BASDAI had significantly poorer sleep quality in almost all domains of PSQI (figure 1A), while higher level of ESR or CRP could not discriminate poor sleeper in every domain of PSQI (figure 1C, 1D). ASDAS-CRP had a moderate discriminability, which was believed brought by the integrated components of BASDAI in the index.

Conclusion: Lots of patients (77.3%) with axSpA were poor sleeper, which is worthy note in clinical care. Mobility seems to have less influence on sleep than disease activity. Although BASDAI was believed to be subjective as a disease activity index, it performed the best to discriminate poorer sleep quality in almost all domains of sleep. Although ESR and CRP were more objective disease activity markers of axSpA and have better relevance to the MRI-demonstrated inflammation, both the inflammatory markers had no value in the care of sleep in axSpA patients surprisingly. In conclusion, BASDAI still had value in axSpA care, and the elements of BASDAI make ASDAS a more comprehensive index than ESR or CRP alone.

Data shown as mean (SD) or n (%). *proportion of radiographic vs non-radiographic axSpA.

HOW DO SPONDYLOARTHRITIS START? IDENTIFICATION OF THE FIRST SYMPTOMS ACCORDING TO THE DIAGNOSIS AND HLA-B27 DATA FROM REGISPONSER AND RESPONDIA REGISTRIES

Keywords: Spondyloarthritis, Registries

Disclosure of Interests: M. Á. Puche Larrubia: 1, 2, 3, M. L. Lademeshe Pineda: 1, 2, 3, F. U. Pilar: 2, 3, A. Escudero Contreras: 2, 3, J. Vazquez Mellado: 4, E. Collantes Estevez: 2, 3, C. López-Medina: 2, 3, 1Reina Sofia University Hospital, Rheumatology, Cordoba, Spain;
Background: The definition for early spondyloarthritis (SpA) implies the correct identification of the initial symptom of SpA. There is currently no consensus on whether only musculoskeletal manifestations (MM) or also extra-MM (EMM) should be considered as the onset of SpA.

Objectives: a) To describe the initial symptom (either MM or EMM) in the different SpA subtypes; b) to describe the initial symptom stratified by the clinical diagnosis and by the presence of HLA-B27; c) to analyze the clinical factors associated with different forms of initiation.

Methods: Observational, cross-sectional and multicenter study, including patients with a diagnosis of SpA (Ankylosing Spondylitis (AS), AS associated with Psoriasis (AS-Pso), AS associated with Inflammatory Bowel Disease (AS-IBD), Psoriatic Arthritis (PsA), Reactive Arthritis (ReA), Juvenile SpA (Juv-SpA), Arthritis associated with IBD (A-IBD) and undifferentiated SpA (u-SpA)) from REGISPONSER and RESPONDIA registries. Investigators responses to the question “Identify the first sign or symptom attributable to the disease” have been recorded. The date of appearance of each MM and EMM feature was collected, allowing to determine the first symptom(s) in each patient. Differences in the first symptom across diagnosis and between HLA-B27 carriers were compared using the chi-square test. Finally, factors associated with the most prevalent initial symptom were evaluated.

Results: A total of 4411 patients were included. AS (54.9%), PsA (18.7%) and uSpA (11.1%) were the most prevalent diagnosis. In the overall population, low back pain (60.3%) was the most prevalent initial symptom followed by buttock pain (35.3%) and lower limbs arthritis (39.9%). The percentage of patients who started the disease with each symptom according to the diagnosis is represented in Figure 1. In AS patients, the absence of HLA-B27 lead to an increment in the probability of initiating the disease with cervical pain (25.6% vs. 15.5%), enthesitis (10.8% vs. 12.4%) and coxitis (15.7% vs. 8.4%) in comparison with HLA-B27 positives. In PsA, the initiation with upper limbs arthritis (81% vs. 38.4%) and psoriasis (62.1% vs. 37%) was more prevalent in HLA-B27 negatives, while the initiation with low back pain (22.1% vs. 38.4%) and buttock pain 13.6% vs. 28.8%) was more prevalent in HLA-B27 positives. In AS-Pso, the absence of HLA-B27 was more frequently associated with peripheral features and psoriasis as first symptom. In the whole population, factors associated with cervical pain vs. low back pain as first symptom were cutaneous psoriasis, negative HLA-B27 and peripheral involvement (arthritis, enthesis and dactylitis). On the other hand, factors associated with upper limbs arthritis vs. lower limbs arthritis as first symptom were female gender, cutaneous psoriasis, HLA-B27 negative and absence of axial symptoms.

Conclusion: In this SpA population, the most prevalent initial symptoms were musculoskeletal (i.e., low back pain, buttock pain and lower limbs arthritis), with differences across diagnosis and depending on the presence of HLA-B27 antigen. In AS patients the absence of the HLA-B27 seems to be associated with cervicalgia and peripheral involvement as first symptom, while in PsA it was associated with upper limbs involvement as initial symptom.

Funding: This ancillary analysis has been funded with a research grant ‘Ayudas en Investigación en SpA SER-GRESSER’ from the Spanish Society of Rheumatology (SER).

HIGH PREVALENCE OF IRRITABLE BOWEL SYNDROME IN AXIAL SPONDYLOARTHRITIS: A CROSS SECTIONAL MULTICENTRIC OBSERVATIONAL STUDY

Keywords: Gastrointestinal tract, Spondyloarthritis

J. Bernard1, T. Barnetche2, A. Charlotte3, D. Jerome4, M. Vandermessen5, J. Landrin6, C. Lukas7, A. Ruyssen-Witrand8, P. Vergne-Saille9, A. Tournade9

1CHU Gabriel-Montpied, Rheumatology, Clermont-Ferrand, France; 2Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France; 3Hospital Center University De Montpellier, Rheumatology, Montpellier, France; 4Hospital Center University De Limoges, Rheumatology, Limoges, France; 5CHU Dupuytren 1, Rheumatology, Limoges, France; 6CHU Gabriel-Montpied, Rheumatology, Clermont-Ferrand, France

Background: Axial spondyloarthritis (axSpA) is a heterogeneous disease including extra-articular manifestations that can impact both disease severity and quality of life[1]. Among them, gastrointestinal symptoms can be related to inflammatory bowel disease (IBD), but also to functional disorder of the gastrointestinal tract such as irritable bowel syndrome (IBS)[2][3]. IBS and IBD are associated with multiple comorbidities and lifestyle behaviors including diet and physical activity.

Objectives: The objectives of this study were to evaluate the prevalence of IBS and associated factors including demographic and axSpA characteristics, treatments and adherence, lifestyle behaviors, and comorbidities.

Methods: A cross-sectional, multicenter study was conducted at rheumatology departments in 5 university hospitals (Bordeaux, Clermont-Ferrand, Limoges, Montpellier, and Toulouse). Patients with axSpA (ASAS criteria) treated by biologics were recruited from June 2021 to June 2022. Patients completed an anonymous self-questionnaire evaluating demographic data, lifestyle behaviors, treatment adherence (Girerd questionnaire) and IBS (Roma IV criteria). A medical questionnaire on axSpA characteristics, activity and treatments, was completed by rheumatologists.

Results: 500 patients were included in the study (mean age 49.5±13.8 years, 47 % women, mean disease duration 14.7±11 years, and mean BASDAI 3.6±2.1). IBS was present in 11/53 (21%) vs. 113/447 (25%). IBS and IBD are associated with multiple comorbidities and lifestyle behaviors including diet and physical activity.

Conclusion: Prevalence of IBS is high in axSpA, accounting for a quarter of patients, and should be screened in the presence of gastrointestinal symptoms. The prevalence of IBS is not associated with IBD, nor diets. It is associated with female gender, anxiety, depression and fibromyalgia. Patients with IBS seem to have a more difficult to treat disease characterized by higher activity, worse functional scores, and multiple lines of treatments.

REFERENCES:

In patients with axSpA, gut inflammation measured by FC was higher than among controls and it was also higher in patients with AS than in nr-axSpA. We also found that high FC values were not associated with more pronounced gastrointestinal symptoms. Thus, studies with a larger population and invasive studies are needed to assess the impact that this marker may have on the management of this pathology.

DOI: 10.1136/annrheumdis-2023-eular.1892
visit, male patients achieved BASDAI < 4 more significantly than female patients (79.57% vs. 71.54%; p < 0.001). However, the proportion of patients who achieved ASDAS low disease activity (< 2.1) and ASDAS inactive disease (<1.3) were not significantly different between gender (71.14% vs. 71.5%, p = 0.6892; 39.82% vs. 39.44%, p = 0.8265, respectively). The difference in BASDAI between the first follow-up visit and baseline was statistically significantly related to gender after adjusting for other clinical information at baseline (p = 0.0033). In the same analysis, the difference in ASDAS was not significantly related to gender (p = 0.1303).

**Conclusion:** Depending on the method of calculating disease activity, the interpretation of treatment response of BDMAARDs may differ between gender.

## SACROILIAC MRI FINDINGS IN PATIENTS WHO WERE REQUESTED A SACROILIAC STUDY: SACROILITIS AND OTHER DIAGNOSES

**Keywords:** Spondyloarthritis, Gender/diversity issues, Imaging

R. Almodovar González1, A. Bueno2, P. Zarco-Montejo3, C. López-Medina3, A. Benito Ysamat4, J. F. García Llorente5, F. Diez Renovales5, O. Casado Verdugo5, M. Moreno5, M. Llop Vilaltella4, L. Berrocal8, A. Marin5, C. Fernández-Carballedo5, C. Crespo3, X. Juanola-Roura1, J. A. Narvaez2, E. Dieguez Costa2, R. Mazzucchelli1, Hospital Universitario Fundación Alcorcón, Radiología, Alcorcón, Spain; 2Hospital Universitario Fundación Alcorcón, Radiología, Madrid, Spain; 3Hospital Reina Sofía, Radiología, Córdoba, Spain; 4Hospital Reina Sofía, Radiología, Córdoba, Spain; Hospital de Basurto y Galdakano, Rheumatología, Bilbao, Spain; 6Hospital de Basurto y Galdakano, Radiología, Bilbao, Spain; 7Parc Taull, Rheumatología, Sabadell, Spain; 8Hospital Universitario San Juan, Radiología, Alicante, Spain; 9Hospital Bellvitge, Rheumatología, Barcelona, Spain; 10Hospital Universitario Vithas, Radiología, Madrid, Spain

**Background:** Magnetic resonance imaging (MRI) is the most sensitive imaging modality for the detection of sacroiliitis. Diagnosing sacroiliitis on MRI is not always straightforward and can be challenging in some cases.

**Objectives:** To evaluate the prevalence of sacroiliitis (according to ASAS criteria) and other diagnoses in sacroiliac MRI. To analyse/compare these diagnoses by sex, age and service requesting the study.

**Methods:** This is a cross-sectional, multicentre, descriptive, retrospective study in a hospital and/or specialised care setting. Consecutive MRI examinations (in adults) of the sacroiliac joints (SIJ) performed between 1 de Enero de 2019 y el 31 de Diciembre de 2019 were retrieved from medical records and included in this retrospective cross-sectional analysis. Of these subjects, 281 (72.6%) of patients had a diagnosis of SpA confirmed with patients records and sacroiliac imaging. After the patient population was created, the patients were sorted according to the registration number and divided into groups of ten. One patient was selected from each group. Thirty age- and sex-matched rheumatoid arthritis (RA) patients and 30 healthy controls were selected. Thorax CT were re-examined for CV and CTr joints by an experienced radiologist. All joints were classified as: Normal (0); {suspicious [1], mild [2], moderate [3], and severe [4]. A total of 44 joints were evaluated for each patient, 24 CV and 20 CTr joints.

**Results:** We evaluated 1,283 MRI examinations, 526 (41%) males, average age 46.7 ± 14 years. 71.6% of the requests are from the Rheumatology service, 15.8% from Orthopedic Surgery and Traumatology and 12.5% from other services. 70% of the MRIs were reported by a radiologist expert in the locomotor system. Findings suggestive of axial spondyloarthritis were found in 353 (27.5%). Sacroilitis was found in 71 examinations (25%) and alternative diagnoses were suggested in 87 (31%) (OCC 8.9%, anatomic variants 5.3%, septic sacroilitis/discitis 5.3%, degenerative findings 4.3%, DISH 1.5%, stress reaction 0.7%, tumor 0.3%). A normal examination was found in the remaining 123 examinations. Patients with alternative diagnoses were older than those with sacroilitis (62 vs. 47 years of age, respectively, P < 0.05). Alternative diagnoses in the SIJ were significantly more common in females (66) than in males (21), P < 0.05.

**Conclusion:** A substantial proportion of patients with suspected sacroilitis had normal SIJ while the rest were more commonly diagnosed with pathologies other than inflammatory sacroilitis. A referral by an experienced rheumatologist may improve the sensitivity and specificity of this important examination.

## COSTOVERTEBRAL AND COSTOTRANSVERSE JOINT INVOVLEMENT IN SPONDYLARTHRITIS BY ROUTINE CHEST COMPUTED TOMOGRAPHY

**Keywords:** Spondyloarthritis

E. B. Ata1, G. Durhan2, E. Bilgin2, M. A. Ariyurek2, U. Kalyoncu3, 1Hacettepe University, Internal Medicine, Ankara, Turkey; 2Hacettepe University, Radiology, Ankara, Turkey; 3Hacettepe University, Rheumatology, Ankara, Turkey

**Background:** In spondyloarthritis (SpA) patients, costovertebral (CV) and costotransverse (CT) joint involvement is affected however these involvements are not routinely examined in clinical practice. Clinical characteristics of these involvements need further assessment.

**Objectives:** In this study, we aimed to determine the characteristics of CV and CTr joint involvements in SpA patients by routine chest computed tomography (CT).

**Methods:** SpA patients who have been requested a chest CT for any reason between January 2010 and December 2020 were retrieved from medical records and included in this retrospective cross-sectional analysis. Of these subjects, 281 had a diagnosis of SpA confirmed with patients records and sacroiliac imaging. After the patient population was created, the patients were sorted according to the registration number and divided into groups of ten. One patient was selected from each group. Thirty age- and sex-matched rheumatoid arthritis (RA) patients and 30 healthy controls were selected. Thorax CT were re-examined for CV and CTr joints by an experienced radiologist. All joints were classified as: Normal (0); suspicious [1], mild [2], moderate [3], and severe [4]. A total of 44 joints were evaluated for each patient, 24 CV and 20 CTr joints.

**Results:** Of the SpA patients, 206 (73.3%) were diagnosed with AS, 63 (22.4%) with psoriatic arthritis (PsA), and 12 (4.3%) with non-radiographic axial SpA (nr-AxSpA), 34 (54%) of PsA patients had axial PsA. Total scores of CV joint were different between diseases (AS 35 (9-96), PsA 16 (0-73), axial PsA 16 (0-73), peripheral PsA 20 (1-53), nr-AxSpA 6.5 (0-42), RA 15.5 (0-56), healthy control 13 (0-48) (p<0.001)
many health care systems. To optimize diagnostic and therapeutic approaches for axSpA patients, 9 quality standards (QS) were developed by ASAS (Assessment of SpondyloArthritis International Society) [1]. These international QS have been recently adapted in Germany [1, 2].

Objectives: To determine the status of quality of care delivered to axSpA patients in 2021 across Germany, with special reference to the new ASAS QS.

Methods: As part of a multicentre study, the Continuous Outcome Benchmarking in Rheumatology (KOBRA) project in Germany, patients with axSpA were surveyed regarding the 9 ASAS QS: QS1 - time until referral; QS2 - time to specialist; QS3 - time span of diagnostic work-up; QS4 - monitoring of disease activity; QS5 - discussion of biological treatment in case of insufficient NSAID therapy; QS6 - benefit of regular exercise; QS7 - offers for disease educational courses; QS8 - time to contact with the rheumatologist in case of flare or drug adverse events; QS9 - annual review. Results: A total of 417 axSpA patients on an in-patient basis in 27 rheumatology clinics were surveyed; mean age 50.7 yrs; mean symptom duration 14.6 years; 53.4% had axSpA; 71.4% BASDAI>4, and 81.2% ASDAS>2.1. Regarding the 9 ASAS GS, 31.7% of the patients received a referral to a rheumatologist within 3 working days after initial suspicion of an axSpA (QS1). 36.0% of referred patients received an appointment with the rheumatologist within 3 weeks (QS2). The diagnostic work-up by the rheumatologist was completed within 2 months in 63.2% of the patients (QS3). Monitoring of the disease activity with validated scales at least once every 6 months was performed in 50.2% (QS4). 62.9% of patients were treated with a biologic (42.6% vs. 35.1%). Contact with the rheumatologist, if urgently needed, within <7 working days took place more often in women (60.5% vs. 45.9%).

Conclusion: This is the first project to assess the quality of care according to the ASAS GS among axSpA patients in Germany. The quality of care was acceptable in some areas (e.g. escalation to biological therapy) but needs improvement in others (e.g. rapid access to rheumatology for diagnosis and in case of urgent matters, educational offers). Relevant gender differences were identified. Overall, this data provides important guidance for the improvement of rheumatologic care in daily practice.

FEMALES WITH AXIAL SPONDYLOARTHRITIS REPORT HIGHER BURDEN OF DISEASE AND WORSE PATIENT-REPORTED OUTCOMES. RESULTS FROM THE INTERNATIONAL MAP OF AXIAL SPONDYLOARTHRITIS (IMAS)

Keywords: Gender/diversity issues, Patient reported outcomes, Spondyloarthritis

V. Navarro-Compañ[1], M. Garrido-Cumbra[2, 3], D. Podubnyy[4, 5], C. Bundy[6], S. Makri[7], J. Correa-Fernández[8], S. M. Akerkar[9], L. Wermskog[10], E. Karam[11], A. Siddiqui[12], F. Sommerleck[13], IdiPaz, Hospital Universitario La Paz, Rheumatology Department, Madrid, Spain; Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain; Spanish Federation of Spondyloarthritis Associations (CEADE), Patient Advocacy, Madrid, Spain; Charité-Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany; German Rheumatism
Background: There is increasing evidence of differences between males and females in axial spondyloarthritis (axSpA), but the source is restricted to specific geographic locations or populations.

Objectives: This analysis aims to assess gender differences in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS) study from around the globe.

Methods: IMAS is a cross-sectional online survey (2017-2022) of 5,557 unselected axSpA patients from 27 countries. The current analysis looked at the differences in a variety of patient and disease characteristics/assessments between males and females. The factors evaluated were: sociodemographic (age, educational level, marital status, employment status, and patient organization membership), health behaviours (smoking, alcohol consumption, and physical activity), disease characteristics (age at symptom onset, diagnostic delay, HLA-B27, family history of axSpA, uveitis, inflammatory bowel disease), patient-reported outcomes (disease activity [0-10] on the BASDAI scale, spinal stiffness [3-12], functional limitation [0-54], and mental health [0-12] using GHQ-12 scale), mental comorbidities (anxiety, depression, and sleep disorders), and treatments (NSAIDs, csDMARDs and bDMARDs).

Results: Data from 5,557 patients reporting gender were analyzed: 3,492 from Europe, 769 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Globally, 55.4% were females, with higher proportions in South Africa (82.2%) and lower in Asia (20.8%; Figure 1). Compared to males, females were of a younger age, more frequently university educated, more often divorced, more commonly on permanent sick leave, and less often members of patient organizations (Table 1). With respect to health behaviours, male participants smoked and drank more than females. Compared to males, diagnostic delay was significantly longer (by 2.4 years) while the rate of HLA-B27 positivity and family history with axSpA were lower in females. With respect to patient-reported outcomes, females presented with higher disease activity, greater functional limitation, and poorer mental health. The use of axSpA drug treatment was more common in females with a higher proportion having ever taken NSAIDs, csDMARDs and bDMARDs.

Conclusion: Globally, females with axSpA practiced better health behaviors and reported lower frequency of HLA-B27 positivity but had longer diagnostic delay. Despite more frequently receiving medication, females presented with higher disease activity, greater functional limitation, and worse mental health. Reducing the disease burden and diagnostic delay in females is crucial to improving axSpA care around the world.

AB0088 GENETIC EVIDENCE FOR A BIDIRECTIONAL CAUSAL RELATIONSHIP BETWEEN ANKYLOSING SPONDYLITIS AND CARDIOVASCULAR DISEASE

Keywords: Spondyloarthritis, Cardiovascular disease

R. T. Shen1,2, L. K. Qi1,2, Y. Q. Bai1,2, L. Niu1,2, X. Y. Yin1,2, Q. Yu2, P. F. He3, X. Li1,2,4, S. X. Zhang1,2,4, “Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China;” Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China;” Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China;” The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease[1]. Mounting evidence suggests an increased risk of cardiovascular disease (CVD) in patients with AS. And cardiovascular problems in AS patients have been identified as the primary cause of death[2]. Furthermore, few studies have examined whether CVD directly impacts AS, making the link between AS and CVD less complete. In this study, we conducted a bi-directional Mendelian randomization (MR) analysis to investigate the causal relationship between these two traits.

Objectives: This study aimed to investigate the bidirectional causal effects of AS and CVD.

Methods: Genetic instruments for AS were obtained from the Finnish database, including 2,252 cases and 227,388 controls. The summary data for 12 CVD were retrieved from genome-wide association studies (GWAS). We utilized the inverse variance weighted (IVW) mean estimate analysis to test the causal relationship. Sensitivity analysis
is used for hypothesis testing and estimating the tangible impact between exposure and results.

**Results:** The study indicated that AS increased the genetic susceptibility to cardiovascular stroke (IVW: OR = 1.05, 95% CI: 1.01-1.10, p = 0.03), heart failure (HF) (IVW: OR = 1.01, 95% CI: 1.00-1.01, P = 0.0004) and atrial fibrillation (AF) (IVW: OR = 1.01, 95% CI: 1.00-1.01, P = 0.007). Small vessel stroke (SVS) was positively associated with an increased risk of AS (IVW: OR = 1.20, 95% CI: 0.77-1.41, P = 0.022).

**Conclusion:** AS may be a risk factor for CVD such as cardiacogenic stroke, HF, and AF. At the same time, for patients of SVS, the risk of developing AS was 1.20 times. Inflammation may be one of the main pathways linking this causality.

**ARE OSTEOPOROSIS AND FRACTURES NEGLECTED ISSUES IN AXIAL SPONDYLOARTHRITIS? DATA FROM A CROSS-SECTIONAL MONOCENTRIC STUDY**

Keywords: Spondyloarthritis, Comorbidities, Osteoporosis

C. Crosti1, F. Orsini1,2, R. Di Taranto1,2, M. Ferro1,2, A. Amati1,2, M. Biggioggero1, M. Varenna1,2, E. G. Fasoli1,2, R. Caporali1,2, ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy; University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Bone Disease Unit, Milan, Italy

**Background:** Prevalence of osteoporosis (OP) and fractures (Fx) in spondyloarthritids (SpA) is frequently overlooked[1]. Axial (ax) involvement, particularly in ankylosing spondylitis (AS), is associated with seeming increased lumbar spine bone mineral density (BMD) while vertebral fractures are present in up to 43% of patients with AS. Bone densitometry is considered the gold standard for osteoporosis diagnosis and fracture risk assessment.

**Objectives:** To investigate predictors of OP and prevalence of Fx in a population of ax-SpA patients.

**Methods:** Data were cross-sectionally extracted from a monocentric registry including SpA patients with axial involvement [AS, ax-Psoriatic Arthritis (ax-PsA), non-radiographic ax-SpA (nr-axSpA), IBD associated-SpA] at their last evaluation in a tertiary rheumatology center between August and December 2022. Comparisons were performed by T test and chi-square test; logistic regression was used to analyze the predictors of OP screening assessed by dual-energy x-ray absorptiometry (DXA) and other collected variables.

**Results:** The overall population included 385 patients (35.6% female; mean age±SD 48.5±12.7 yrs; 42.9% AS, 33% nr-axSpA, 20.5% ax-PsA, 3.6% IBD-SpA; 43.9% HLAB27 positive; 42.3% postmenopausal females; 78% patients with previous diagnosis of OP). Almost 10% of the entire population experienced Fx (n=38): 16 vertebral Fx, 2 femoral Fx, and 24 non-vertebral/ non-femoral Fx. The presence of previous fragility Fx was significantly associated with menopause (39% vs 12.4%, p<0.001), older age (56.6±10.11 vs 47.6±12.65, p<0.001), elevated ESR (median 13 mm/h (IQR 7-24) vs 9 (5-19), p=0.04) and higher ASDAS-CRP (median 1.28 (1-2.6) vs 1.05 (0.6-1.7), p=0.03), and previous OP diagnosis (50% vs 3.1%, p<0.001). DXA was performed only in 11.7% of the population. DXA was mainly performed in females (64.5% vs 31.8%, p<0.001), post-menopausal women (57.8% vs 9.4%, p<0.001), older patients (58.6±12.5 vs 47.2±8.9, p<0.001), patients with previous diagnosis of disthryroidism (11.1% vs 4.7%, p=0.08), OP (53.4% vs 18%, p<0.001), patients with previous Fx (46.7% vs 5%, p<0.001), both vertebral Fx (26.7% vs 12%, p<0.001) and non-vertebral/non femoral Fx (24.5% vs 3.9%, p<0.001). DXA was significantly more frequently performed in patients supplemented with vitamin D (86.7% vs 29.4%, p<0.001), calcium (53.4% vs 4.1%, p<0.001), and receiving bisphosphonate therapy (26.7% vs 18%, p<0.001) or on bone loss inducing drugs (44.4% vs 21.3, p<0.001). DXA was significantly less frequently evaluated in current smokers (1.5% vs 24.7%, p=0.04) and ax-PsA subtype (8.9% vs 22%, p=0.04). Factors associated with OP screening by DXA were menopause [OR 1.9, 95% CI 2.3-135, p=0.005], and bone loss inducing drugs (OR 3.2, 95% CI 1.12-9.16, p=0.030). Predictor of Fx was the presence of elevated disease burden expressed as ASDASCRP (OR 1.9, 95% CI 1.2-3.2, p=0.012).

**Conclusion:** Our data confirm that OP is an underestimated comorbidity in ax-SpA patients, particularly males or younger patients. Fragility Fx is related with disease burden, confirming that inflammation mostly triggers bone loss. Not all risk factors for OP are correctly addressed, such as active smoke. We should aim to better evaluate OP as a SpA comorbidity to early detect patients at high risk of fragility Fx to treat them properly.

**OBSTRUCTIVE SLEEP APNEA IS INCREASED IN PATIENTS WITH SPONDYLOARTHRITIS COMPARED TO HEALTHY CONTROLS**

**Keywords:** Spondyloarthritis, Cardiovascular disease, Epidemiology

O. Kalish1, O. Elkayam2, R. Meidan2, T. Eviatar2, R. Tauman4,5, D. Paran2,4, A. Bieber2, V. Furer2, A. Polacheck3, S. Pei2, S. Nevo4, D. Levartovsky2,3, O. Elalouf2,1, tel AViv University, Medicine, tel Aviv-Yafo, Israel; 2 tel Aviv Sourasky
Background: Obstructive sleep apnea (OSA) is a common chronic disorder, characterized by recurrent collapse of the upper airway during sleep. OSA is associated with comorbidities, such as ischemic heart disease, hypertension, arrhythmias, and others. The spectrum of spondyloarthritides (SpA) encompasses several diseases, including ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease related arthropathy, reactive arthritis, and undifferentiated SpA, sharing common clinical manifestations. It is important to gather more data on the prevalence of OSA, as diagnosing and treating comorbidities is an essential part of the management of inflammatory diseases. There are several reports on the association between OSA and ankylosing spondylitis with conflicting results. To date, studies evaluating the association between OSA and broader spectrum of SpA are lacking.

Objectives: To examine the prevalence and severity of OSA in patients with SpA with or without axial involvement compared to healthy controls. Predictive factors for OSA, such as disease activity, SpA subtypes, axial involvement and medical treatment, were assessed as well.

Methods: This was a controlled cross-sectional study. The study cohort consisted of consecutive patients with SpA defined by the ASAS classification criteria. Clinical and demographic characteristics of the cohort were retrieved from patients’ files. Disease activity scores and sleep quality questionnaires were administered at enrollment. All participants underwent a single night home sleep test using a validated diagnostic device. OSA was defined as apnea-hypopnea index (AHI) ≥5, and moderate-severe OSA as AHI≥15.

Results: Forty-two consecutive patients with SpA and 33 healthy controls were recruited to this study. Patients’ characteristics are shown in Table 1. OSA was diagnosed in 34 patients (81%) with SpA compared to 15 (33%) in the control group (P<0.01) figure, panel A. Moderate-severe OSA was found in 14 (33%) patients in the SpA group vs. 1 (3%) in the healthy control group (P<0.01) figure, panel B. Other sleep indices, such as sleep efficiency, sleep stages and sleep latency, didn’t show any significant difference between the groups. There was also no correlation between SpA activity scores, BASDAI and ASDAS, sleep scores, drug therapy and the presence of OSA. In a logistic regression analysis, older age, elevated body mass index and axial involvement were associated with the presence of OSA.

Conclusion: In this study, OSA, including moderate-severe OSA, was significantly more prevalent in patients with SpA in comparison with healthy controls. Axial involvement predicted the presence of OSA in SpA. Our study emphasizes the importance of sleep assessment and diagnosing OSA in patients with SpA, in order to provide treatment, improve the quality of life and reduce the impact of comorbidities.

AB0991 RADIOPHGRAPHIC EVALUATION OF FOOT SPURS IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis

H. H. Gezer1, O. Pehlivan2, M. T. Duruöz3, Ümraniye Training and Research Hospital, Rheumatology, Istanbul, Turkey; Ümraniye Training and Research Hospital, Rheumatology, Istanbul, Turkey; Marmara University School of Medicine, PAM Department, Rheumatology Division, Istanbul, Turkey

Background: Although bone spurs are frequently seen in non-inflammatory diseases, they can also be seen with inflammation of the enthesis areas, especially in spondyloarthritides (SpA).

Objectives: To investigate the radiological evaluation of foot spurs in SpA and compare the characteristics between the SpA and degenerative diseases.

Methods: This ongoing study included 168 (124 women) patients with radiographic plantar or achilles spur. Age, disease duration, and body mass indexes were recorded. Patients were categorized with inflammatory (non-radiographic SpA (nr-AxSpA), radiographic SpA (r-AxSpA), psoriatic arthritis (PsA), and other) and non-inflammatory [osteoarthritis (OA)] and diffuse idiopathic skeletal hyperostosis (DISH)]. Foot radiographs of the plantar region, achilles, and other regions (anterior ankle, posterior ankle, and tarsal bones) were examined for the spurs. The spur characteristics were evaluated. Three measurements were taken from each radiograph: plantar spur base, mid-segment, and length in millimeters. The differences were compared between SpA patients and controls.

Results: The mean age of the patients was 50.8 (SD:11.3) years, and the mean disease duration was 55.1 (SD:55.8) months. One hundred twenty-eight (76.2%) were in the inflammatory group [PsA (n=56), r-AxSpA (n=30), nr-AxSpA (n=27), other SpA (n=14)], while 40 (23.8%) were in the non-inflammatory (OA (n=35), DISH (n=5)) group. Plantar spur base, midsegment, and length were higher in the non-inflammatory group than in the inflammatory group (p<0.05). Fluffy structure and erosion in the plantar spur were more common in the inflammatory group (p<0.05). The characteristics of the spurs were not different between diseases in the inflammatory group (p<0.05). Plantar spur lengths in the PsA patients were significantly higher than in the non-PsA SpA group (p=0.028 and 0.003); other spur features between groups were not different (p>0.05).

Conclusion: Spurs are smaller and erosion and fluffy appearance are more common in SpA patients compared to non-inflammatory conditions. Spur characteristics are not different among SpA group diseases; only the plantar spur lengths were higher in patients with PsA. Although calcaneal and achilles spurs are frequently evaluated in clinical practice, approximately half of the patients also have spurs in the tarsal bone.

| Anterior ankle spur, n (%) | 5 (%3.9)         | 1 (%2.5)               | 0.65  |
| Tarsal bone spur, n (%) | 16 (%12.5)        | 7 (%17.5)              | 0.46  |

Conclusion: Our population-based findings describe how HLA-B27 and HLA-B51 haplotypes can impact NIU patterns and suggest a relevant role of an early HLA typing study on the definition of targeted diagnostic and therapeutic strategies.

and/or antihypertensive treatment, hypercholesterolemia as LDL-cholesterol ≥ 100 mg/dl and/or lipid-lowering treatment. Treatment goals were defined according to European Society of Cardiology and EULAR guidelines.

**Results:** We included 520 patients (54% women; RR, 22% Pa+; 32% AS). Mean age and disease duration were 52.1±14.1 and 11.0±10.6 years, respectively. Out of 520 patients, 203 (39%) had HTN, among whom 140 (69%) were treated and 86 (42%) were controlled; 293 (56%) had HC, among whom 88 (30%) were treated and 51 (17%) were controlled; 30 (6%) had type 2 diabetes, among whom 18 (60%) were controlled. Current smoking was present in 100 patients (19%), obesity in 163 patients (26%) and increased waist circumference in 192 patients (37%). Compared to RA patients, patients with spondyloarthropathies were less often in remission (40% vs. 54%, p<0.005). Furthermore, patients with spondyloarthropathies differed from RA patients by a lower proportion of treated (56% vs. 84%, p<0.001) and treated-to-target (24% vs. 84% p<0.001) HTN, a higher proportion of active smokers (28% vs. 12%, p<0.01), and lower physical activity (29% vs. 46%, p<0.001). Control of LDL-cholesterol was poor in both groups (17% vs. 18%, p=0.95). No significant difference between groups was found for diabetes, overweight and obesity.

**Conclusion:** Compared to patients with RA, patients with spondyloarthropathies were less well controlled both for disease activity and CV risk factors. Furthermore, lipid control was poor in both groups. If confirmed in a multicentre cohort, these results may help orienting CV prevention strategies and increasing awareness both in physicians and patients, with emphasis on spondyloarthropathies.

**Objectives:** Our study aimed to assess the correlation between serum levels of MMP-3 and disease activity in SpA.

**Methods:** We conducted a cross-sectional study including patients with SpA, diagnosed according to ASAS criteria. ELISA technique was used to measure MMP-3 serum levels. CRP and ESR were also measured. Disease activity was assessed with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP). Pearson correlation coefficient was calculated.

**Results:** We included 82 patients. The mean age was 45.32 ± 13.41 years (20-80). Male to female ratio was 3.82. The mean disease duration was 7.57 ± 7.77 years. Radiographic axial SpA (r-AxSpA) and psoriatic arthritis (PsA) were noted in 65.9% (n=54) and 34.1% (n=28) of cases, respectively. The mean MMP-3 serum levels were 64.14 ± 187.31 ng/mL (1.75 – 1237.36). The mean CRP and ESR were 20.64 ± 24.52 mg/l and 35.46 ± 31.69, respectively. The mean BASDAI and ASDAS-CRP were 3.26 ± 1.89 and 2.98 ± 1.45, respectively. MMP-3 serum levels correlate significantly with inflammatory biomarkers CRP (r=0.314, p=0.004) and ESR (r=0.291, p=0.013). A correlation was also found with ASDAS-CRP (r=0.245, p=0.028). However, no correlation was found between MMP-3 serum levels and BASDAI (r=0.204, p=0.070).

**Conclusion:** Our results showed that MMP-3 serum levels correlate significantly with inflammatory biomarkers (CRP and ESR) and with ASDAS-CRP. MMP-3 seems to be a promising biomarker for disease activity in SpA.

**PERCEIVED EFFECTS OF HEALTH STATUS ON SEXUAL ACTIVITY IN PATIENTS WITH AXIAL Spondyloarthritis OVER A 5-YEAR PERIOD**

**Keywords:** Spondyloarthritis, Patient reported outcomes, Outcome measures

**Objectives:** To explore perceived effects of health status on sexual activity in patients with axSpA over a 5-year period.

**Methods:** Patients with axSpA were consecutively recruited from two public outpatient rheumatology clinics in Southern Norway (Martina Hansens Hospital (MHH), and Sorlandet Hospital (SSHF)). A broad spectrum of data was collected which included: demographic (age, weight, employment, education, married or cohabiting and if they had a partner to have sex with), disease activity and damage (MASES, CRP, BASMI, 68 tender and 66 swollen joints), current medication (NSAID, CSDMARD and BDMDARD) and comorbidities (yes/no). A summed score was generated to reflect overall co-morbidity. Quality of life were measured by 15D, which also included a question on perceived influence of health status on sexual activity. Item 15 in the 15D questionnaire was used to study the effect of health status on sexual activity, with the following response options: My state of health: has no adverse effect on my sexual activity, slight effect, considerable effect, makes sexual activity almost impossible, makes sexual activity impossible to analyze the effects of health on sexual activity, we dichotomized the five responses to item 15 in the 15D instrument, which were related to sexual activity. Responses 1 and 2 were grouped into “no/little effects” and the other three categories were grouped into “large effects”. The same data collection performed at baseline was also performed at the five-year follow-up.

**Results:** A total of 245 patients (168 men and 77 women) with (At baseline the mean age was 48.5 ± 11.9) mean disease duration 13.9 years (SD ± 11.4). At 5-years follow-up 44 (18%) patients reported their health status to have large effects on their sexual activity, while 200 (82%) reported no/little effect. The same pattern was seen at baseline. However, 24 patients changed from reporting large effect at baseline to no/little effect at 5-year follow-up, while 26 patients changed from no/little effect to large effect. When comparing patients reporting their health status to have no/little effect on sexual activity versus the one with large effect on sexual activity, the same pattern of differences was seen at both baseline and 5-year follow-up. However, the differences seemed to be more prominent at 5-year follow-up. Focusing on 5-years follow-up differences; patients reporting their health status to have a large effect on sexual activity were older (54 (10) years vs 50 (11) years, p=0.014), fewer employed (74% vs 47%, p<0.001), exercised less (77% vs 92%, p<0.003), had more co-morbidities (1.5 (1.3) vs 0.8 (1.1), p=0.002), higher CRP (10.2 (19.1) vs 4.6 (7.0), p=0.002), higher BASDAI (4.7 (2.2) vs 2.5 (2.0), p<0.001) higher BASFI (3.9 (2.2) vs 2.0 (2.0), p=0.001), higher BAS-G (5.3 (2.6) vs 2.6 (2.4), p=0.001 and higher HQG (0.81 (0.45) vs 0.37 (0.4), p<0.001).

**Conclusion:** Approximately 1/3 of axSpA patients reported their health status to have a large negative effect on their sexual activity both at baseline and 5-year follow-up. From baseline to 5-year follow-up there has been an increase in comorbidities, and the increase has been larger in patients reporting the disease to have a large negative effect on sexual activity.

**THE RADIOGRAPHIC ENTHESIS INDEX (REI) FACILITATES THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS: RESULTS FROM GESPACO COLOMBIAN COHORT**

**Keywords:** Enthesitis, Diagnostic tests, Spondyloarthritis

**Objectives:** To evaluate the diagnostic performance of radiography in the evaluation of enthesitis in the pelvis and its usefulness in the diagnosis of SpA.

**Methods:** This study was a historical cohort study from 2005 to 2020. Eligible patients were adults (≥ 18 years of age) with SpA according to the Assessment of Spondyloarthritis international Society (ASAS) criteria, and the control group were patients with chronic lumbar pain (more than three months) with no-inflammatory characteristics, without meeting ASAS criteria for SpA, and who assisted neurosurgery and rheumatology consultations in the Hospital Militar Central, Bogotá DC. The pelvic radiograph had an anteroposterior view with gut preparation with laxative, the coccyx and pubic symphysis were aligned with the midline, and the distance between the tip of the coccyx and the upper limit of the coccyx was more than 2.5 cm. We used three zones of tendinous insertion in the pelvis. Zone one (ZI) is the ilipectoral ramus; zone two (ZII) is the pubic symphysis; zone three (ZIII) is the ischiopubic ramus. In addition, a grading system was created from zero to four (grade 0: normal; grade I: periostial wishckering and/or osteopenia; grade II: periostial wishckering, osteopenia, sclerosis and erosions; and grade III: grade II findings in addition to the presence of ripple or waving patterns > 2 mm outside the cortex). The scores of each zone of the REI, without discriminating by laterality, were added to give the total REI as a result.

**Results:** The cohort have 450 patients, we selected 150 patients for the initial evaluation. Eleven (17.19%) were females and fifty-three (68.25%) were males. The mean age was 27.9 years, grade I was the most frequent in the three zones of REI, while grades II and III were more frequent in the SpA group; those outcomes were statistically significant. Zone III had the highest degree of enthesitis according to the REI classification (63.4%) in the SpA group, with a probability greater than 99% that these findings are related to SpA and not by chance.

**Conclusion:** Conventional pelvis radiography is still useful for SpA diagnosis, not just for sacroiliac joint and lumbar spine involvement assessment but also for the evaluation of the pelvic enthesis, which gives essential information for the diagnosis of SpA.

DIFFERENCES IN PSYCHOLOGICAL BURDEN AND IN QUALITY OF LIFE MEASURES BETWEEN GENDERS IN SPONDYLOARTHRITIS PATIENTS-ANALYSIS OF A MONOCENTRIC COHORT

Keywords: Gender/diversity issues, Quality of life, Spondyloarthritis

C. Ciglionii 1, F. Fattorinii, C. Cardelli, G. Marchetti,1 A. Delle Sedie1, L. Carli1, M. Mosca1 2, Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background: Spondyloarthopathies (SpA) are chronic inflammatory arthritis, characterized by both peripheral and axial skeletal involvement and some typical extra-articular marks; they tend to associate with several comorbidities and can increase the risk of an impaired quality of life (QoL). Already published data show SpA expression differs based on gender; in particular, women are at higher risk of a more pronounced peripheral disease activity and show a greater burden of the disease, thus having worse values of Patient Reported Outcomes (PROs). It is well known that a compromise in physical functioning and psychological sphere may compromise productivity of patients and subsequently increase health costs.

Objectives: The aim of our study was to assess the differences between male and female sex in the prevalence of mood disorders, fatigue and parameters of QoL in a monocentric cohort of patients with SpA.

Methods: Adult patients diagnosed with Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS) according to the CASPAR (Classificatio criteria for Psoriatic Arthritis) and to Assessment of SpondyloArthritis International Society (ASAS) criteria, regularly followed at the SpA clinic of our unit, were consecutively enrolled from April to December 2022. Epidemiologic, clinic and clinimetric data were collected. Each patient filled in the following Patient Reported Outcomes: Hospital Anxiety and Depression Scale (HADS), FACIT-Fatigue (FACIT-F) and SHORT-FORM 36 (SF-36). Intergroups comparisons were assessed by using Chi-square, t-test and ANOVA. P values <0.05 were considered significant.

Results: A total of 200 patients were enrolled; 85 (42.5%) were women, with a mean age of 56.8±12.22 years and a mean disease duration of 12.9±10.3 years. One hundred and thirty-five patients (67.5%) had a diagnosis of PsA (M/F 79/56), mean age of 56.8±12.22 years and a mean disease duration of 12.9±10.3 years. One hundred and thirty-five patients (67.5%) had a diagnosis of PsA (M/F 79/56), while 59 (29.5%) had a diagnosis of AS (M/F 36/23) and 6 (3%) of Enteropathic Arthritis (M/F 10). Women showed worse FACIT-F values than men, (mean 35.20 vs 40.23, p-value 0.002) and a greater impairment of QoL expressed by statistically significant lower values of almost all the domains of SF-36 (exception for Global Health). Moreover, the values of HADS resulted higher in female sex both for the anxiety and depression domains (p-value <0.001 and 0.039 respectively).

Conclusion: The analysis of our cohort confirmed that women affected by SpA suffer from anxiety and depression more often than men, develop a higher level of fatigue and have an overall worse QoL in both psychological and physical domains. These data should sensitize rheumatologists in the assessment of this subgroup of patients. The clinician should not only focus on the disease activity evaluation and therapy or in managing of the comorbidities, but also on the psychological and functional status of the patients, developing strategies able to avoid or delay the onset of their impairment in daily life and to optimize with specific therapies, rehabilitation or psychological support their compensation, when already established. This approach could finally improve the social burden and health cost of women with SpA.
Results: (scores reflect more of the attribute implied by the scale) and HRQoL (MOS Sleep-R index and ASQoL were of similar amplitude between nr-axSpA sequential improvements from baseline in BASFI, SF-36 PCS, MOS-Sleep R −2.2 [−3.7 , −0.7], ASAS20–<ASAS40: −4.3 [−5.5, −3.2], ASAS40: −7 .2 [−7 .9, −6.5]; r-axSpA: −2.2 [−3.7, −0.7], −4.3 [−5.5, −3.2], −7.2 [−7.9, −6.5]; r-axSpA: −2.0 [−3.0, −1.1], −4.3 [−5.1, −3.4], −6.9 [−7.5, −6.3].) Sequential improvements from baseline in BASFI, SF-36 PCS, MOS-Sleep R index and ASQoL were observed with achievement of increasingly stringent ASAS clinical response criteria and lower levels of disease activity at Wk 52. Achievement of higher ASAS responses was also associated with sequentially greater mean improvement from baseline in BASFI, SF-36 PCS, MOS-Sleep R index and ASQoL: [1] Yi E. Rheumatol Ther 2020;7(1):65-87; 2. Boel A. Ann Rheum Dis. 2019;78:1545–9.

Keywords: Bone diseases, Spondyloarthritides, Imaging

Methods: Patients with AS were recruited from a single tertiary hospital. Base-
ne line and 2-year follow-up whole spine CT images were used to calculate CTSS
and cSTSS. The STSS uses the anterior and posterior vertebral corners, and ranged 0–184. Intraclass correlation coefficients (ICC) were calculated, as well as the smallest detectable changes.

Results: Fifty AS patients were included. For reader 1, the mean STSS at base-
line and 2-year follow-up were 11.7 ± 14.6 and 15.8 ± 16.1, whereas those for
reader 2 were 12.0 ± 12.5 and 15.8 ± 15.7, respectively. The ICCs for CTSS at baseline and at 2-year follow-up were 0.97 (95% confidence interval [CI] 0.96–0.99) and 0.98 (0.97–0.99), respectively, and that for changes over the 2 years was 0.46 (95% CI 0.23–0.67). For sCTSS, the ICCs were 0.96 (95% CI 0.92–0.97), 0.97 (95% CI 0.94–0.98), and 0.58 (95% CI 0.36–0.74), respectively. Detection rates for syndesmophyte progression were comparable between CTSS and sCTSS. The detection rate for syndesmophytes on only lateral side was 13.2 and 11.4%, and 11.4 and 15.2% at baseline and 2-year follow-up (reader 1 and 2).

Conclusion: sCTSS and CTSS showed similar detection rates for syndesmophyte progression. sCTSS may be a reliable method for evaluating structural damage in AS.

LONGER DIAGNOSTIC DELAY, SEVERE FATIGUE AND LESS USE OF TNF-INHIBITORS ARE ASSOCIATED WITH UNACCEPTABLE AXIAL PAIN IN 354 SWEDISH PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Pain
A. Deminger1,2, Å. Wilde3, E. Klingberg4, J. Backman Renman2, H. Forsblad-Dell1,5, 6. Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Information Research, Göteborg, Sweden; 7Region Västra Götaland, Sahlgrenska University Hospital, Department of Rheumatology, Göteborg, Sweden; 8 Section of Medicine, Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden

Background: Pain has been shown to be the most important consequence of the disease in affecting health in patients with axial spondyloarthritis[1].

Objectives: To assess factors associated with unacceptable axial pain in patients with long-standing ankylosing spondylitis (AS) overall and by sex.

Methods: Patients with AS (modified NY-criteria) from two geographically separated regions in Sweden were included in this cross-sectional, observational study. Primary outcome was axial pain (question number 2 from Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)) dichotomised in VAS < or ≥ 4 based on patient unacceptable pain[2]. Independent variables were selected based on previous knowledge and hypotheses of factors associated with pain. Information was collected from questionnaires (demographics, lifestyle habits, fatigue (BASDAI question number 1), symptoms of depression (from EQ-5D), medications), previous knowledge and hypotheses of factors associated with pain. Information technology (IT) modules was assessed. We also evaluated the interaction with the patients through the assessment of satisfaction and completion rates of ePROMs.

Results: In total, 354 patients were included, 62% men, mean (SD) age 52 (13) years, symptom duration 27 (13) years and delay in diagnosis 9 (8) years. Mean (SD) VAS axial pain was 4.2 (2.6) with no significant difference between men and women (p = 0.30). However, in patients with unacceptable axial pain (VAS ≥ 4), n=177 (50%), significantly higher proportion of women reported unacceptable pain compared to men, 57% vs 46%, p = 0.049. In univariate analyses, unacceptable axial pain was associated with longer disease duration, longer delay in diagnosis, more severe fatigue, more symptoms of depression, lower alcohol consumption and less treatment with TNF-inhibitors. There was no association between unacceptable axial pain and age, civil state single, educational level, BMI, smoking status, mSASSS, CRP or use of NSAIDs. In the multivariable analysis, unacceptable axial pain was independently associated with longer delay in diagnosis and more severe fatigue, whereas use of TNF-inhibitor reduced the risk of having unacceptable pain (Figure 1). In the multivariable analyses stratified by sex, the same variables were associated with unacceptable pain in men as in the whole group; OR (95% CI) for delay in diagnosis 1.08 (1.03 to 1.14), fatigue 2.0 (1.65 to 2.41) and use of TNF-inhibitor 0.23 (0.09 to 0.61). In women, fatigue was the only factor independently associated with unacceptable axial pain, OR (95% CI) 1.32 (1.12 to 1.56).

Conclusion: In this cross-sectional study of patients with long-standing AS, 50% of the patients had unacceptable axial pain. Even though a higher proportion of the women were affected, female sex was not independently associated with unacceptable axial pain. There were some sex-differences. Delay in diagnosis was associated with higher risk, and use of TNF-inhibitor was associated with lower risk of unacceptable axial pain only in men. The sex-difference possibly due to few women using TNF-inhibitors. Fatigue was independently associated with axial pain in both sexes. This study underpins the importance of early diagnosis in AS.

IMPROVED CLINICAL OUTCOMES AND PATIENT ENGAGEMENT THROUGH AN INTEGRATED ELECTRONIC PATIENT REPORTED OUTCOME WITH THE HOSPITAL ELECTRONIC PATIENT RECORD IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Patient reported outcomes, Outcome measures
A. Chan1, K. Rigler2, L. Van Rossen3, 1Royal Berkshire NHS Foundation Trust, Department of Rheumatology, Reading, United Kingdom; 2East Kent Hospitals N H S Trust, Department of Rheumatology, Canterbury, United Kingdom

Background: Patient-reported outcome measures (PROMs) have been at the forefront of the assessment of spondyloarthropathy (SpA). With the increasing adoption of electronic health records (EHRs), collecting PROMs electronically (ePROMs) presents an opportunity for advancing patient care in SpA. ePROMs were incorporated into our SpA clinics at the Royal Berkshire Hospital since the start of 2018. Collecting patient data early improved the patients' perspective into routine clinical care without delay. Moreover, connection to EHRs have led to a seamless integrated optimised care process.

Objectives: The objective of this programme was to evaluate the clinical effectiveness and practicality of implementing a fully integrated ePROMs into the hospital EHR in real world clinic settings. The interoperability across different information technology (IT) modules was assessed. We also evaluated the interaction with the patients through the assessment of satisfaction and completion rates of ePROMs.

Methods: AxSpA patients meeting the ASAS criteria completed the outcome measures BASDAI, BASFI, Spinal NPRS, and BASG. PaS patients meeting the CASPAR criteria completed patient assessed tender joint, swollen joint, global assessment and PSAID-12. The period of the data collection for this study was January 2021 to December 2022. Patients were sent reminders to complete ePROMs through email or text messaging before each appointment and every 6 months. Ad-hoc scores went sent out according to clinical need. Appointments were expedited or deferred depending on the values and trends in the ePROMS. Time saved in clinic was measured.

Results: There were 1141 patients with AxSpA and PaS who were sent ePROMs over a 2 year period (2021-22). The median (SD) age for AxSpA patients were 42.7(12.2) and PaS 52 (7.9) years. 536 (47%) patients were on biologics. At baseline, the completion of was 38% (437/1141). At month 12, it was 63% (722/1141) and at month 24, reached 73% (836/1141). Figure 1. Both AxSpA and PaS patients had similar rates of uptake of ePROMs between months 0 and 24 (40% to 72% for AxSpA and 35% to 73% in PaS). At group level, there was a trend to the reduction in mean (SD) ASDAS at months 0, 6, 12, 18 and 24 (3.8±1.2, 3.3±1.1, 3.0±1.5, 2.2±0.9, 1.9±1.0) and BASDAI (4.6±2.7, 4.5±1.9, 3.9±2.4, 3.8±2.3, 3.6±1.2). In the PaS group, there was also a trend to the reduction in the mean in the SD) PSAID-12 level (4.1±1.8, 3.8±0.8, 3.6±1.2, 3.4±1.1, 3.1±1.3). The reduction in the mean ASDAS, BASDAI and PSAID-12 was most evident in patients on biologic treatments. In patients with an ASDAS of < 1.3 or PSAID-12 <2, appointments were moved from 6 to 12 monthly. In this group of...
patients, the appointments were also switched from face to face to teleclinics. This resulted in a saving of 280 hours of clinical time. Over 90% of clinician and patient user rated the ePROMs as good to excellent. In patients not completing ePROMS (308/1141, 27%) paper forms were used. Factors for not completing ePROMs include multiple forms, frequency of forms sent, lack of understanding of process, data safety concerns, lack of IT access and patient choice.

Conclusion: The development of a clinician dashboard captured a range of multidimensional ePROMs that was used proactively to support patient management and patient-centric appointment scheduling. Using ePROMs increased the uptake and acceptability of completing patient outcomes. A trend based on ePROMs collated over a period of time was more informative, particularly when considered alongside interventions that were introduced into the clinics such as self-referral to physiotherapy, digital psychological therapy and biologic treatments. This enabled the clinical team use ePROMs as part of remote monitoring to implement patient-initiated follow up (PIFU) and schedule teleconsultations when clinically appropriate. The integrated ePROMS system allows clinical encounters where needed and more individualised care.

M. Isbel1,2, K. Makin1, J. Nossent1,2. 1Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia; 2University of Western Australia, School of Medicine, Perth, Australia

Background: Administrative linked health data (ALHD) facilitates epidemiological research of Ankylosing Spondylitis (AS) but best practice requires dataset validation[1]. While ICD10-code M45 is used to identify AS populations internationally it is also used to code “Rheumatoid arthritis of the spine”[2]. Neither background AS nor Rheumatoid arthritis (RA) is captured in ICD coding, unless actively flaring whilst the patient is admitted.

Objectives: To define the accuracy of ICD 10 Australian Modification (ICD10AM) code M45 in identifying AS patients in a tertiary hospital.

Methods: Retrospective audit of patients with an electronic hospital discharge code M45 between 2000 and 2015. Patient records were manually reviewed to confirm presence of AS based on following criteria a) radiological evidence of Grade IV sacroiliitis or “bamboo spine” b) fulfilment of classification criteria (1984 Modified NY, 1991 AMOR, 2002 ESSG and 2009 ASAS criteria). Letter from treating rheumatologist confirming AS d) Biological DMARD (bDMARD) prescription for treating confirmed AS. Cases that were not able to meet AS criteria and had a likely alternative diagnosis documented by their treating team had this detail noted, but not assessed against formal criteria. All patients were then evaluated to for presence of an RA code ever during that patient’s lifetime. Codes used to define RA included by codes M08.0*, M8.2*, M8.3*, M8.4*, M8.5*, M05.*, M06.* (ICD10) or 714 (ICD9).

Results: Of 155 cases reviewed, eighty-six (55.4%) met audit criteria for AS. Of the 69 cases not meeting audit criteria for AS, 35 (72%) had RA ICD codes applied during their lifetime and a further 15 had background RA recorded in their notes. Five cases met AS audit criteria and had RA code applied. Excluding patients ever tagged with an RA code reduced AS case finding by 6% and raised overall accuracy to 87.5%. If background RA is also excluded, accuracy is 78.9%.

Conclusion: Overall raw accuracy of the ICD10AM M45 code in identifying AS patients was low, with RA acting as a significant confounder. This bears significant implications for international ALHD research reliant on this code for case finding. Excluding those ever coded with RA significantly improved accuracy and is recommended for future research. Our data support the call for scrutiny of international variations of ICD taxonomy[4].

Disclosure of Interests: None Declared.
Spondyloarthritis - clinical aspects (other than treatment)

**AB1005**

**ASSOCIATION BETWEEN CHANGES IN SERUM ALKALINE PHOSPHATASE LEVELS AND RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS**

**Keywords:** Biomarkers, Prognostic factors, Spondyloarthritis

T. H. Kim¹, S. Y. Park², J. H. Shin³, S. Lee⁴, K. B. Joo⁵, B. S. Ko², ¹Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); ²Korea National Open University, Department of Statistics and Data Science, Seoul, Korea, Rep. of (South Korea); ³Hanyang University Hospital for Rheumatic Diseases, Department of Radiology, Seoul, Korea, Rep. of (South Korea); ⁴Inje University Seoul Paik Hospital, Inje University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

**Background:** The changes in bone metabolism may occur earlier than those that can be identified on radiography. Although studies have evaluated the changes in inflammatory markers that precede radiographic progression, no studies have evaluated the relationship between the timing of changes in bone metabolism and radiographic progression in patients with AS.

**Objectives:** To determine the relationship between serum alkaline phosphatase levels and radiographic changes over time in ankylosing spondylitis.

**Methods:** This retrospective study evaluated the electronic medical records of patients with ankylosing spondylitis between January 2001 and December 2018. Longitudinal data including serum alkaline phosphatase levels were imputed by linear interpolation at 3-month intervals. Among the serum alkaline phosphatase levels for 8 years prior to measurement of the modified Stoke Ankylosing Spondylitis Spinal Score, the serum alkaline phosphatase level having the highest beta coefficient with the modified Stoke Ankylosing Spondylitis Spinal Score was selected. Linear mixed models with the selected serum alkaline phosphatase levels and the modified Stoke Ankylosing Spondylitis Spinal Score, including clinical variables, were investigated.

**Results:** Overall, 1122 patients were included, with a mean follow-up period of 8.20 (standard deviation: 2.85) years. Of the series of serum alkaline phosphatase levels, the level in the previous 5 years and 3 months showed the highest beta coefficient with the modified Stoke Ankylosing Spondylitis Spinal Score (Figure 1). In the linear mixed model including clinical variables, the serum alkaline phosphatase level 5 years and 3 months before radiographic changes was significantly associated with the modified Stoke Ankylosing Spondylitis Spinal Score (β=0.021, 95% confidence interval: 0.017–0.025, p<0.001).

**Conclusion:** Serum alkaline phosphatase levels measured at approximately 5 years before may be a surrogate marker for predicting spinal radiographic changes. Long-term prospective clinical and experimental studies of >5 years are required for biomarker discovery or therapeutic research on the radiographic progression of ankylosing spondylitis.

**PULMONARY MANIFESTATIONS OF AXIAL SPONDYLARTHRITIS (AXSPA): A SYSTEMATIC LITERATURE REVIEW**

**Keywords:** Systematic review, Spondyloarthritis, Lungs

K. Vakil-Gilani¹, T. Cordova¹, D. Saifer¹, A. Deodhar¹, ¹Oregon Health & Science University, Rheumatology, Portland, United States of America

**Background:** Common extra musculoskeletal manifestations (EMM) of axSpA include uveitis, inflammatory bowel disease, and psoriasis; and some of the uncommon manifestations include aortic incompetence, conduction abnormalities and IgA nephropathy. We felt that an updated and comprehensive review of pulmonary manifestations of axial spondyloarthritis was needed.

**Objectives:** To conduct a systematic literature review (SLR) using 2020 PRISMA guidelines on the spectrum of pulmonary manifestations in axial spondyloarthritis.

**Methods:** Using the 2020 PRISMA guidelines, we conducted a systematic literature review in the PubMed data base. The following MeSH combinations were used: (1) Ankylosing Spondylitis (AS) and interstitial lung disease, (2) AS and lung disease, (3) AS and obstructive sleep apnea, (4) non-radiographic axial spondyloarthritis (nr-axSpA)and lung disease (5) nr-axSpA and obstructive sleep apnea (6) nr-axSpA and interstitial lung disease (7) AS and/or axSpA and obstructive sleep apnea and/or thoracic wall disease. Our search timeline was limited to the past 40 years. The same combination terms were also hand searched. Reviewing of articles were divided between two authors.

**Results:** Our search led to a total of 10,948 articles and 10,919 were excluded based on relevance after title review (n=10,905), case report study design (n=6), and lack of access to the full manuscript (n=2). Additional 6 articles were excluded based on relevance after the entire manuscripts were read. Twenty nine full length manuscript were ultimately included for further study. All studies included patients with a diagnosis of AS rather than axSpA. The majority of studies were cross-sectional (n=12) followed by review articles (n=10 including one systematic review), and finally cohort studies (n=5 prospective and 1 retrospective). Mean disease duration range was 70-31 years. Average age of participants was 30.6 to 57.2, and majority were males (57.1-100%). The most common pulmonary manifestation (40-90%) was pleuro-parenchymal abnormalities noted on high resolution CT scan (HRCT) followed by abnormal pulmonary function tests (PFTs) (15-57%), chest wall movement restriction (50% with panbronchiolitis and stenocartilaginous enthesitis and chest wall pain in 30-60%) and obstructive sleep apnea (OSA) (8.6%-47.8% of AS patients which was significantly higher than controls in all studies except one), OSA was associated with long disease duration and low age at onset of disease. HRCT abnormalities described were interstitial lung disease in 13-72.2%, spontaneous pneumothorax (0.29%), apical fibrosis (1.2%–19%), ground glass opacities (3.6-15%), nodules (3.8-40%), pleural thickening (3.8-45%), honey-combing (5.8%), parenchymal bands (3.8-41%), interlobular septal thickening (5.8-45%), bronchial wall thickening (7.4-141%), emphysema 9-45%, bronchiectasis (9.5-33%), subpleural bands (10.9-35%), tracheal dilation (11.1%), linear opacities (11.7%), and lymphadenopathy (16.7-28.6%). Frequency of apical fibrosis and bronchiectasis increased with disease duration. Subpleural nodules and parenchymal bands were found early in the disease course. Among those with abnormal PFTs, majority were restrictive in pattern (20-57%). A link between COPD and AS was found (46% in one cross-sectional study with 1.45 higher incidence compared to controls).

**Conclusion:** In our SLR, we identified various pulmonary manifestation in AS patient – the commonest being parenchymal lung disease as seen on HRCT – but there is a lack of controlled trials. Furthermore, there are no data in nr-axSpA patients which remains a major unmet need. No data were available on whether current advanced therapies are disease modifying from pulmonary perspective. Prospective studies are required to evaluate efficacy of novel treatments on lung disease.

![Figure 3](image2.png)
**AB1007** NEUROPATHIC PAIN AS A PREDICTOR OF FUNCTIONAL DISORDERS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Pain

L. Kediyi, M. Stanislavchuk, Vinnytsia National Pirogov Medical University, Department of Internal medicine №1, Vinnytsia, Ukraine

Background: Ankylosing spondylitis (AS) is one of the most actual problems in modern rheumatology. AS is characterized by a violation of functional abilities, which causes a decrease in the quality of life and invalidation of patients. The main symptom of AS is chronic pain, which persists in some cases not only due to inflammation, but also due to the neuropathic component of pain, however, this issue needs additional investigation [1].

Objectives: To assess functional status and its association with neuropathic pain in patients with AS.

Methods: Following the principles of biomedical ethics, on the basis of informed consent, we clinically examined 133 patients (men - 71%) diagnosed with AS according to the modified New York criteria. The presence of neuropathic pain (NP) was assessed by the Leeds Neuropathic Pain Rating Scale (LANS) and by the Diagnostic Questionnaire for Neuropathic Pain (DN4). Disease activity was assessed by the BASDAI (Bath Ankylosing Spondylitis Disease Assessment Index) and ASDAS (Ankylosing Spondylitis Disease Activity Score). Functional disorders in AS were evaluated according to the BASFI (Bath AS Functional Index) and BASMI (Bath Ankylosing Spondylitis Metrology Index). The HAQ (Health Assessment Questionnaire) questionnaire was used to assess functional capabilities. Statistical analysis was carried out by the methods of variational statistics in the SPSS22 software package (SPSS Inc.). Significance of differences between groups (p) was measured using the Mann-Whitney test. Results are presented as mean with standard deviation (M±SD).

Results: In patients with AS, the prevalence of NP according to the LANS was 34.8%. Presence of NP in women was found significantly more often than in men: 52.3% versus 31.1%. According to DN4 data, 37.7% of patients have NP and the ratio of women to men is 59.1 to 32.2. The NP according to both scales was assessed by the Leeds Neuropathic Pain Rating Scale (LANS) and by the Diagnostic Questionnaire for Neuropathic Pain (DN4). Disease activity was assessed by the BASDAI (Bath Ankylosing Spondylitis Disease Assessment Index) and ASDAS (Ankylosing Spondylitis Disease Activity Score). Functional disorders in AS were evaluated according to the BASFI (Bath AS Functional Index) and BASMI (Bath Ankylosing Spondylitis Metrology Index). The HAQ (Health Assessment Questionnaire) questionnaire was used to assess functional capabilities. Statistical analysis was carried out by the methods of variational statistics in the SPSS22 software package (SPSS Inc.). Significance of differences between groups (p) was measured using the Mann-Whitney test. Results are presented as mean with standard deviation (M±SD).

The presence of NP in patients with AS is a common phenomenon. NP in Spondyloarthritis (SpA) a higher prevalence of cardiovascular disease - a new lipid paradox.

Conclusion: Most patients presented extra-articular manifestation before articular symptoms onset. The median delay since first articular symptoms until SpA diagnosis was 2 years. Longer time between extra-articular manifestation and articular symptoms was linearly associated with peripheral disease. Axial disease and HLA-B27 were linearly associated with shorter time between the two symptoms.

DOI: 10.1136/annrheumdis-2023-eular.2124
In recent years, several studies have established a causal relationship between non-HDL cholesterol (non-HDLC) levels and cardiovascular diseases. Non-HDLC offers a wide vision of proatherogenic lipoproteins containing apolipoprotein B (apoB) - VLDL, IDL, LDL; chylomicron remnants and Lp(a)- without being interfered by triglyceride concentrations. Thus, non-HDLC has become an innovative cardiovascular risk (CVR) biomarker. Therefore, the Multinational Cardiovascular Risk Consortium [2] recently published a set of recommendations estimating CVR based on non-HDLC levels. We have analyzed in a cohort of patients with SpA possible associations between clinic and laboratory data, and non-HDLC serum levels.

**Objectives:** To analyse in patients with SpA whether there is a relationship between disease-dependent variables (C-reactive protein [CRP] levels, erythrocyte sedimentation rate [ESR], presence of HLA-B27, axial or peripheral involvement, structural damage, and extra-articular manifestations) with non-HDLC serum levels.

**Methods:** Observational, cross-sectional, single-centre study, which included a sample of 104 patients with both radiographic and non-radiographic SpA, in whom each disease-dependent variable was analyzed individually for its possible association with non-HDLC serum levels. Classical CVR factors were also analyzed.

**Results:** Of 104 patients included most of them were women (54.8%), mean age was 43 years, 33.7% smoked, HLA-B27 was positive in 52.8% of patients, with mean CRP levels of 9.83mg/mL and ESR of 17.92mm/h. Axial involvement prevailed over peripheral (92.3% vs 26%). Extra-articular manifestations were distributed as follows: 13.5% uveitis, 7.7% inflammatory bowel disease (IBD) and 4.8% psoriasis. 43.3% of patients had structural damage. None of these patients suffered from cardiovascular disease prior to diagnosis. Regarding the classic CVR factors: AHT was observed in 16.3%, DM in 19.2%, obesity (BMI >30) in 14.4%. Mean non-HDLC was 144.19mg/dL (± 36.1), giving this population a 12.8% probability of suffering cardiovascular disease at the age of 75. For CVR estimation, we categorized non-HDLC levels according to low (100 - <145mg/dL), moderate (145 - <185mg/dL), high (185 - <220mg/dL) and very high (≥220mg/dL) levels. Lower mean concentrations of non-HDLC were found in those patients with IBD (117.56 ± 35.7mg/dL), compared to those without intestinal involvement (146 ± 35.5mg/dL) (p<0.05). No statistically significant relationships were observed between non-HDLC and the rest of disease-dependent variables.

**Conclusion:** In our cohort of patients, mean levels of non-HDLC were elevated (144mg/dL), giving patients a 13% probability of suffering cardiovascular disease at the age of 75. Clinical and laboratory features analyzed, we observed lower serum concentration of non-HDLC in patients with IBD. This could be explained by lipid malabsorption, as inflammatory damage of the intestinal epithelium decreases the synthesis of apoB48, which is necessary for both chylomicron formation and hepatic synthesis of apoB100 (3). This may turn into lower serum levels of non-HDLC. Therefore, presence of IBD in patients with SpA should be kept in mind when defining non-HDLC levels as an estimator of CVR.

CO-DIAGNOSIS SPONDYLOARTHRITIS AND
INFLAMMATORY BOWEL DISEASE: THE ENTRY MODE
MATTERS

Keywords: Gastrointestinal tract, Descriptive studies, Spondyloarthritis

Psoriasis was present in 24% and uveitis in 24% of cases, active smoking in
66%, and a physical job in 20% of cases. Patients had used an average of 3
bDMARDs and 10% are treated with a combination of bDMARDs. When SpA
was diagnosed first, patient characteristics were different from those whose IBD
was diagnosed first, with a mean age at diagnosis of SpA of 29.8 (±11.6) years
(versus 41.6 (±12.6) years; P< 0.001) and a mean age at diagnosis of IBD of 31.9
(±11.8) years (versus 38.6 (+/-13) years; p= 0.043). When the codiagnosis was
initiated by SpA, the prevalence of HLA B27 was 83% (versus 42%; p<0.01),
psoriasis 17% (versus 29%; p=0.27) and uveitis 35% (versus 16%; p=0.087).
Finally, radiographic damage was more frequent when SpA started first, with
86% of radiographic sacroiliitis (versus 34%; p< 0.001) and 44% of syndesmophytes (versus 13%; p= 0.036).
Conclusion: The population of patients with a co-diagnosis of SpA and IBD is a
particular and difficult to treat population with an average of 3 different bDMARDs
used and 10% of bDMARDs combination. Within this population, we identified
two different clusters of patients according to the first diagnosis.

Background: There is a clear pathophysiological link between spondyloarthritis
(SpA) and Inflammatory Bowel Disease (IBD), so that 10% of IBD is estimated to
have SpA and 10% of SpA is estimated to have IBD. Recently, Luchetti et al [1]
demonstrated an increased level of bacterial translocation in cases of co-diagnosis of SpA and IBD compared to patients with IBD alone. These data suggest
that the presence of this codiagnosis is associated with a more inflammatory and
therefore a more active pathology.
Objectives: The aim of this study is to describe this population and to evaluate
the impact of timing of diagnoses.
Methods: A single-centre retrospective observational study was conducted. We
included all consecutive patients followed between 2015 and 2022 for spondyloarthritis (SpA) meeting the ASAS 2009 criteria and IBD histologically proven.
For each patient, we collected demographics, smoking, extrarticular manifestations, imaging data and the number of bDMARDs used and bDMARD combinations. We then compared the populations according to first diagnosis, SpA or IBD.
Fischer’s exact test was used for comparison between categorical variables and
Student’s t test for quantitative variables.
Results: A total of 62 patients, 51% male and 67% HLA B27+, were included.
In 61% of the cases, IBD was diagnosed first. The majority of IBD patients were
diagnosed with Crohn’s disease (68%) with a mean age at diagnosis of 35.7
(±12.9) years. Concerning spondyloarthritis, it was mostly axial (95%), 55% of
which was radiographic axial, with a mean age at diagnosis of 36.8 (±13.4) years.

AN INCREASED FREQUENCY OF ANKYLOSING
SPONDYLITIS HAS BEEN FOUND IN THE SPOUSES OF
SPONDYLOARTHRITIS/ANKYLOSING SPONDYLITIS
PATIENTS: ENVIRONMENTAL FACTORS MAY PLAY A
ROLE IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Epidemiology

Medicine, Department of Internal Medicine, Ankara, Turkey
1

Background: It is known that genetic and environmental factors play a role in the
pathogenesis of spondyloarthritis (SpA). [1] It can be thought that spouses living
in the same house are exposed to similar environmental factors.
Objectives: This study aimed to investigate whether common living space
increases the frequency of SpA development in unrelated spouses of SpA patients.
Methods: Between November 2021 and June 2022, 680 SpA patients who
applied to the Hacettepe University rheumatology outpatient clinic were included.
Patients were divided into ankylosing spondylitis (AS), non-radiographic SpA,
and peripheral SpA. The patients were asked whether their spouses had SpA,
and if they had SpA diagnosis, they were called to the outpatient clinic, and
their diagnosis was confirmed. The family history of the patients and their use
of bDMARDs were also noted. It was also checked whether the patients whose
spouses had SpA findings fulfilled the AS criteria.
Results: 680 SpA patients were evaluated. There were 582(85.6%) AS,
72(10.6%) nr AxSpA, and 26 only peripheral SpA (3.8%). 49.4% of the patients


were male, and the mean age was 45.6 (10.4). The mean follow-up period of the patients was 10.6 (7.9) years. Of all patients, 468 (55.1%) were using a bDMARD at the time of evaluation. 12 SpA patients stated that their spouses had SpA. In the review of these patients, it was found that four patients did not have SpA, and one of them had PsA. Spouses of patients with nr AxSpA and peripheral SpA did not have AS/SpA as was detected in the spouses of 7 patients. The incidence of AS in the entire SpA patient group was calculated as 7/695 (1.01% (0.4-2.1)). The incidence of AS in spouses of AS patients is 7/582 (1.20% (0.5-2.5)) calculated. 2 of 7 wives were cousins' children. The incidence of AS in unrelated spouses of AS patients is 5/580 (0.86% (0.3-2)). Only one of the spouses with AS knew her spouse's diagnosis at the time of marriage, while the other six were diagnosed after marriage. The median time for these patients to be diagnosed after marriage is 22 (7-32) years.

Conclusion: In the Turkish population, the frequency of AS was 0.49%, and the frequency of SpA was 1.05%. [2] The incidence of AS in the spouses of SpA patients has increased approximately two times compared to the average Turkish population. A 2.4-fold increased risk was found in AS patients. This situation may be related to environmental factors that play a role in the pathogenesis of SpA disease. However, the fact that half of the patients were using bDMARDs suggests that they were analyzed in the group with the potential for more severe disease. The results require confirmation in more extensive studies.

ARTIFICIAL INTELLIGENCE FOR DETECTION OF INFLAMMATORY SACRITOLIS IN MAGNETIC RESONANCE IMAGING IN PATIENTS WITH AXIAL SPONDYLOARTHITIS

Keywords: Artificial intelligence, Imaging, Spondyloarthritis

J. Lee1, S. Yang1, S. Lee1, H. Kim1, E. M. Koh2, H. S. Cha1, 1Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 1Health Insurance Review and Assessment Service, Healthcare Review and Assessment Committee, Wonjoo, Korea, Rep. of (South Korea)

Background: Magnetic resonance imaging (MRI) is frequently used to evaluate active inflammatory sacroiliitis for early axial spondyloarthritis (axSpA) diagnosis. However, evaluation of sacroiliitis in MRI requires expertise because noninflammatory degenerative changes can mimic axSpA, and the semiquantitative diagnosis remains subject to significant variation. Artificial intelligence could function as assistance for inflammatory sacroiliitis detection.

Objectives: This study aimed to develop artificial intelligence for detecting inflammatory sacroiliitis for axSpA in MRI.

Methods: This retrospective study included MRI examinations of patients with clinical suspicion of axSpA collected at Samsung Medical Center between January 2010 and December 2021. Only the patients who performed short tau inversion recovery (STIR) MRI of the sacroiliac joints were included. Active inflammatory lesions consisting of bone marrow edema (BME) were identified independently by a rheumatologist and a radiologist using the Assessment of SpondyloArthritis international Society (ASAS) definition of MRI sacroiliitis. We propose a two-stage deep learning framework that combines a sacroiliac joints (SIJs) localization network with a BME classification network. First, the Faster R-CNN network extracts regions of interest (ROI) to localize the SIJs using whole MR images. Here, Maximum Intensity Projection (MIP) using three consecutive images of SIJs ROI is applied to enhance the low intensity of BME and consider the contextual information between images. Second, the VGG-19 network determines the presence of BME on individual MR images of localized SIJs ROI with a resolution of 128x256. During the training process, we augmented the positive dataset 6-fold using blurring, contrast, noise, rotation, and sharpening because of the smaller number of data than the negative dataset. The prediction models were evaluated using 3-round, 3-fold cross-validation. The performance of BME classification was measured using accuracy and area under the receiver operating characteristic curve (AUC-ROC) curve.

Results: A total of 296 participants with 4,746 MRI images were included in the study. Inflammatory sacroiliitis was identified in 864 MRI images from 119 participants. The mean average intersection over unions (IoU) of ROIs to localize the SIJs was 0.742 for the right side and 0.744 for the left side. The mean accuracy and AUC-ROC of inflammatory sacroiliitis were 0.896 and 0.830 for image level and 0.801 and 0.827 for patient level, respectively. The confusion matrices of inflammatory sacroiliitis prediction are shown in Figure 1. In the original model, without using MIP and dataset augmentation, the mean accuracy and AUC-ROC were 0.867 and 0.609 for image level and 0.717 and 0.620 for individual level. Compared to the original model, improved performances of inflammatory sacroiliitis could be observed.

Conclusion: Artificial intelligence can detect inflammatory sacroiliitis for axSpA according to the ASAS definition in MRI.

RADIOGRAPHIC VERSUS NON-RADIOGRAPHIC AXIAL SPONDYLOARTHITIS: RESULTS FROM TREATMENT DATABASE

Keywords: Real-world evidence, Outcome measures, Registries

I. Kilic1, G. Ayan1, P. Atagündüz2, S. Akar2, N. S. Yasar Bilge3, E. Daikılıç5, Y. Pehlivan4, O. Küçüksahebin5, C. Bes5, M. Çinar6, H. Emmüngü7, D. Ersözü8, A. Ates9, R. Mercan10, G. Kırmızı11, S. S. Koca12, E. Göznü12, V. Yarızas13, N. A. Kaya14, A. Erdem15, B. N. Çoşkun16, B. Yazi2, T. Kağıtçı2, S. Kiraz2, U. Kalyoncu1, A. I. Ertelni1,1Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; 2Marmara University, Medical Faculty; Department of Internal Medicine Division of Rheumatology, Istanbul, Turkey; 3Izmir Katip Celebi University, Department of
Background: Axial Spondyloarthritis is an umbrella term including radiographic (r-AxSpA) and non-radiographic (nr-AxSpA) forms which has been initially suggested by Assessment of SpondyloArthritis International Society (ASAS) as a different stage of the disease. Within time, studies have tried to answer whether these two entities represent distinct features, and the debate is still ongoing.

Objectives: The objective of this study is to define the similarities and differences of r-AxSpA and nr-AxSpA patients using a large national registry data.

Methods: The current study is a cross-sectional study to compare clinical, demographic and laboratory data of patients diagnosed with AxSpA at the time of the first introduction of biological treatment. At the time of this analysis database consisted of 7015 SpA patients. All patients registered to the database fulfill the 2009 ASAS classification criteria. For this analysis, patients were categorized into r-AxSpA and nr-AxSpA and demographic and clinical characteristics of patients were determined.

Results: There were 4629 (66.7%) patients with r-AxSpA, 707 (13.3%) patients with nr-AxSpA and 1789 (30.0%) patients with radiological sacroiliitis (r-SpA) and genetic differences (SpA). Demographic differences: r-AxSpA group was male predominant (59.6% vs 46.0%, p<0.001), with longer disease duration at bDMARD initiation (3.0 (6.9) vs 11.3 (3.4) years, p<0.001) and more smoker (61.4% vs 50.4%, p<0.001). SpA clinic/genetic differences: r-AxSpA group had less arthritis (7.7% vs 27.5%, p<0.001), heel pain (11.1% vs 40.8%, p<0.001), dactylitis (3.4% vs 8.1%, p<0.001), psoriasis (10.2% vs 14.5%, p<0.01), SpA family history (28.2% vs 40.8%, p=0.001), IBD (4.5% vs 7.4%, p<0.001) and more HLA-B27 positivity (58.2% vs 51.4%, p<0.001), similar uveitis rate (13.2% vs 14.8%). SpA Outcome measures (bDMARD baseline) differences; r-AxSpA group had worse functionality and quality of life measured by BASFI (5.0 (3.0) vs 4.0 (3.9), p<0.001), HAQ-DI 0.63 (0.40) vs 0.55 (0.65), p=0.029 respectively. Worse morbidity by BASMI 3.2 (2.6) vs 1.7 (2.1), p<0.001) and high disease activity by ASDAS-CRP (3.64 (1.28) vs 2.34 (1.33), p<0.001) with higher CRP (12 (21.8) vs 73 (15.0) p<0.001) was observed. SpA imaging differences: r-AxSpA group had higher rate of ‘any syndesmophytes’ (26.6% vs 5.4%, p<0.001), hip involvement (24.6% vs 4.5%, p<0.001), hip prosthesis (23.8% vs 0.3%, p<0.001), MRI structural lesions (63.6% vs 37.3%, p<0.001), and less active MRI lesions (74.6% vs 87.0%, p<0.001). No significant difference was observed in the physician decision on the bDMARD choice at baseline (p=0.673).

Conclusion: A significant proportion of SpA patients who were initiated bDMARD have r-AxSpA. Although the two entities are seen as the continuum of each other, they have significant differences in terms of demographic, clinical, genetic, functional, metrology, activity and imaging characteristics. On the other hand, there is no difference in treatment choices at the stage of bDMARD initiation.

inventory (BDI). In patients with AS disease activity was evaluated using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional ability using the Bath Ankylosing Spondylitis Functional Index (BASFI), and quality of life using the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire. The prevalence of ED in patients with AS was higher than in healthy controls. There were no statistical differences in mean age and sex percentage between both groups. According PSQI scores, 87.72% of patients and a 62% of controls were classified as “poor” sleepers. SQ was related to axSpA (p = 0.002), anxiety (p = 0.003), perceived health (p = 0.001) and physical activity levels (p = 0.006). The domains of subjective sleep quality, latency, duration, efficiency and sleep disturbances were negatively affected by axSpA (p < 0.05). The estimated odds ratio of having a sleep disorder was 5.63 times higher in patients diagnosed with axSpA. With regards to AS patients; anxiety (p < 0.001), physical activity (p = 0.015), BASDAI scores (p = 0.001), BASFI scores (p = 0.038) and axial syndesmophytes (p=0.028) were found to affect the PSQI score. Conclusion: Patients with axSpA have a poorer sleep quality when compared to healthy individuals. AxSpA affects subjective sleep quality, latency, duration, efficiency and sleep disturbances. Disease activity and the presence of syndesmophytes have a detrimental effect, whereas physical activity has a positive effect on SQ. Therefore, these factors must be considered when attending this area of our patient’s health. The PSQI questionnaire provides a complete approach to sleep health and should be considered a complementary tool for the management of axSpA patients.

AB1018 BASELINE CHARACTERISTICS OF AN EARLY SPONDYLOARTHRITIS COHORT IN HONG KONG

Keywords: Geographical differences, Spondyloarthritis, Descriptive studies

1Prince of Wales Hospital, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR); 2Ghent University Hospital, Department of Internal Medicine and Pediatrics, Ghent, Belgium; 3Center for Inflammation Research, VIB-UGent, Zwijnaarde, Belgium; 4The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)

Background: Axial Spondyloarthritis (axSpA) is characterized by inflammation of the sacroiliac joint and the spine. It is a heterogeneous disease with variable musculoskeletal and extra-articular manifestations. The Belgian Inflammatory Arthritis and spondyloartitis cohort (Be-Giant) is a cohort that recruited newly diagnosed SpA patients in Belgium and prospectively followed up the patients.

Objectives: Given the difference in genetic susceptibility and environmental exposure, we aimed to compare the disease nature, clinical presentation, and prognosis between Chinese and Caucasian axSpA patients.

Methods: The SPARK cohort (SpondyloArthritis in Hong Kong) resembled the Be-Giant cohort. Newly diagnosed, biologic naive Chinese axSpA patients who fulfilled ASAS classification criteria were recruited. All patients underwent standardized clinical, laboratory and radiographic assessments as per Be-Giant protocol.

Results: A total of 53 newly diagnosed axSpA patients were recruited in the SPARK cohort (Table 1). The mean age at diagnosis (32 years old) and symptom duration (2 years) were comparable in both cohorts. There was a slight male predominance (59%) in the SPARK cohort as compared to the Be-Giant cohort (50%).

AB1019 ANALYSIS OF DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF ENTEROPATHIC SPONDYLOARTHRITIS IN A TERTIARY CARE HOSPITAL

Keywords: Spondyloarthritis, Epidemiology, Gastrointestinal tract

P. Pérez-García1, I. González Fernández2, J. Ordas Martinez3, C. Sieiro Santos2, C. Alvarez Castro4, C. Moriano5, M. E. Vallejo Pascual6, E. Diez Alvarez6, 1Complejo Asistencial Universitario de León, Rheumatology, León, Spain; 2University of León, Faculty CICE and Business, León, Spain

Background: Enteropathic spondyloarthritis (eSpA), is a type of inflammatory joint disease that is related to inflammatory bowel diseases (IBD). Both spondyloarthritis (SpA) and IBD share clinical, genetic and immunological features.

Objectives: To describe the demographic, clinical and serological characteristics, as well as the onset pattern, radiological involvement, smoking habit, activity disability and comorbidities such as cardiovascular risk factors (CVRF) in patients with eSpA.

Methods: We performed a descriptive observational study of patients with eSpA diagnosed in the Hospital of León between 1980 and 2022. The variables analysed were sex, date onset of IBD and SpA, time between the two diagnoses, pattern of SpA involvement, type of IBD, HLAB27, toxic habits, family history, arthralgias, uveitis, psoriasis, dactylitis, radiological involvement (sacroilitis, syndesmophytes) and treatments received. The activity disease was assessed by BASDAI Index.

Results: The patient’s features are shown in Table 1. We included 56 patients, half men and half women. The 57.1% of the cases debut with IBD. Crohn’s Disease (CD) was the most represented IBD. The 41.1% had a peripheral SpA (16.1% oligoarticular arthritis and 25% polyarticular arthritis); the 32.1% patients presented an axial SpA and 26.8% had a mixed pattern. Peripheral SpA was the most represented form. The time elapsed between joint involvement and IBD was < 5 years in the 50% of the sample analyzed. HLAB27 was positive in 28.6% of the sample and the 35.7% showed BASDAI > 4. We found associated uveitis and psoriasis in 14.3% and 16.1% of the cases. The 57.1% of eSpA had CVRF, the most prevalent was dyslipemia (39.3%). The 53.6% had radiological involvement (sacroilitis 48.2%, syndesmophytes 21.4%). Radiological involvement was significantly greater in smoker patients (p=0.003), probably due to higher associated inflammatory activity. 78.6% of SpA were treated with cDMARDs and methotrexate was the most used (51.8%), followed by azathioprine, 5-ASA, and leflunomide. 73.2% of the cases received bDMARDs and anti-TNF was the most used (73.2%), followed by IL12-23 inhibitors, JAK inhibitors and anti-integrin.
The most frequent cause of discontinuation of methotrexate was side effects (16.1%), especially digestive intolerance; while in patients treated with anti-TNF was secondary failure (19.6%).

Table 1. Demographic, clinical, serological features, radiological involvement and treatments of the eSPA patients.

Conclusion: In our study, most patients with enteroarticular spondyloarthritis first presented intestinal symptoms. The most frequent patterns were peripheral spondyloarthritis and Crohn’s disease, and we found HLA B27+ in around a third of the sample. Smoking was associated with greater radiological involvement in the form of sacroiliac and syndesmophytes. Multidisciplinary work between gastroenterology and rheumatology is essential for the diagnosis and treatment of enteroarticular spondyloarthritis. These results are consistent with the literature.

AB1020 MUSCULOSKELETAL INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE PATIENTS: A MONOCENTRIC EXPERIENCE

Keywords: Inflammatory arthritides, Spondyloarthritis

A Delle Sarde1, L. Ceccarelli2, F. Costa3, F. Fattorini3, C. Cigolini3, M. Mosca3, L. Carli3.1 University of Pisa, Rheumatology Unit, Pisa, Italy; 2University of Pisa, Gastroenterology Unit, Pisa, Italy

Background: Musculoskeletal (MSK) symptoms, varying from arthralgia to arthritis are frequently reported by patients (pts) with inflammatory bowel diseases (IBD). A peripheral or axial joint involvement has been reported with a similar range from 5 to 30% and a definite spondyloarthritis (SpA) diagnosis is present in up to 46% of patients with IBD [1-8]. To date, a more comprehensive disease control is requested and the optimization of the treatment (choosing a mono or a combination therapy strategy) to improve both gastrointestinal and musculoskeletal is mandatory.

Objectives: To evaluate the rate of MSK involvement in a mono centric cohort of IBD pts and the consequent need to optimize their therapeutic schemes.

Methods: A gastroenterologist working in the IBD out-patient clinic had selected IBD patients who should be referred to the rheumatologic visit, on the basis of the results of a questionnaire aimed at highlighting the presence of clinical features suggestive of SpA. From January 1st 2017 to December 31st 2022 IBD pts have been evaluated by a rheumatologist expert in SpA. In case of doubt about the diagnosis, further examinations were requested. The diagnosis of SpA was made following the ASAS criteria of 2011.

Results: A total of 288 pts were sent to the rheumatologist (140 CD, 127 UC, 21 not defined IBD). One hundred sixty-eight pts received only one rheumatological visit while, one hundred two were evaluated twice or more times. To make a diagnosis, 37 MRI (30 for sacroiliac joints), 30 ultrasound assessment (mostly hands, wrists or feet), 19 X-rays and 23 blood tests were requested. Most of pts (196/288, 68%) were not classified as SpA: 50/288 (17.4%) were peripheral SpA and 24/288 (8.3%) were axial SpA, in 18/288 (6.3%) there was an isolated enthesal involvement. The rheumatologist recommended a therapeutic optimization in 138 IBD pts (47.9%). In particular, a DMARD was added in 59 pts and a bDMARD was prescribed in 6 for rheumatological indications; moreover, in 73 cases, a choice between two different therapeutic approaches was suggested to the gastroenterologist, in order to improve the control of MSK disease activity on the basis of IBD course.

Conclusion: Our results confirm the already published prevalence of MSK involvement in IBD patients. A relevant number of IBD pts, after the rheumatological evaluation, were classified as peripheral (17.4%) or axial (8.3%) SpA.

In about half of IBD pts, a therapeutic modification was recommended by the gastroenterologist, aiming at improving the control of MSK disease activity in the context of the IBD course. These data confirm the importance of a close collaboration between gastroenterologists and rheumatologists, to optimize the clinical assessment of IBD pts, thus improving their quality of care [9].

Background: The term axial spondyloarthritis covers both patients with non-radiographic (nr-axSpA) and ankylosing spondylitis (AS). Axial spondyloarthritis (axSpA) is a chronic disease that typically affects the axial skeleton, and produces varying degrees of pain, stiffness, and fatigue [1-2].

EARLY DIAGNOSIS OF SPONDYLOARTHRITIS AND OTHER RHEUMATIC DISEASES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE STUDY BASED ON A SCREENING QUESTIONNAIRE AND EARLY REFERRAL TO THE RHEUMATOLOGIST

Keywords: Spondylarthropathies, Gastrointestinal tract, Inflammatory arthritis

1Azienda Ospedaliera “Ospedali Riuniti Villa Sofia-Cervello”/Rheumatology Unit, Palermo, Italy; 2Azienda Ospedaliera “Ospedali Riuniti Villa Sofia-Cervello”/IBD Unit, Palermo, Italy

Background: Patients (pts) with inflammatory bowel disease (IBD) frequently disclose musculoskeletal (MSK) symptoms. About 15-20% of these pts are affected by spondylarthropathies (SpA) and almost 50% have mechanical back pain and non-inflammation arthralgias [1]. Notably, up to 30% of them may have fibromyalgia syndrome. Spondyloarthritis (SpA) and almost 50% have mechanical back pain and non-inflammatory arthralgias [1]. Notably, up to 30% of them may have fibromyalgic syndrome.

Objectives: Early diagnosis of axial-SpA (Ax-SpA) and peripheral SpA (p-SpA) in IBD pts with MSK symptoms and definition of other rheumatic causes of pain in these complex pts.

Methods: A prospective cohort of IBD outpatients without a previous clear diagnosis of rheumatic disease was evaluated with the self-administered DETAIL questionnaire [3], which has been recently validated as a useful screening tool for early detection of SpA in IBD [4]. Pts with at least 3 out of 6 points of the score (the risk cut-off score) underwent a full clinical rheumatological evaluation and ultrasonographic (US) assessment of 6 enthesis (according to MASEI score). The risk cohort (pts with at least 3 out of 6 points of the DETAIL score) underwent a full clinical rheumatological evaluation and US assessment of 6 enthesis (according to MASEI score).

Results: Sixty-two IBD pts were administered the questionnaire. Ninety-two pts (14%) were referred for rheumatological evaluation: 69/92 pts (75%) were female, the median age was 48 (±12.7) years and the mean BMI was 23.8 (±3.7). Sixty-seventeen pts (73%) were affected by Crohn disease, 23 pts (25%) by ulcerative colitis and 2 pts (2%) had indeterminate colitis. The median disease duration was 11.6 (±9.3) years. Fifty-two pts (56.5%) were in biologic therapy (77% with anti-TNF, 15.3% with Vedolizumab and 77% with Ustekinumab). Overall, 36/92 pts (41%) were classified as having arthritis [25 (28%) p-SPa, 11 (23%) ax-SPa, 3 (1%) RA]. Notably, in 9 of these pts coexisted FMS. 54/92 pts (58.6%) of the risk cohort did not fulfills arthritis classification criteria: 32 pts (60%) were diagnosed as having osteoarthritic or aspecific arthralgies and 22 pts (41%) fulfilled FMS criteria. Notably, in the whole risk cohort there were 31 pts (41%) with FMS. Concerning US assessment, the statistical analysis only showed marginal correlation between MASEI score and ax-SPa diagnosis (p=0.086) but no correlation with p-SPa.

Conclusion: This study confirm that the DETAIL questionnaire may be a useful screening tool in order to select IBD pts needing rheumatological evaluation and get an early diagnosis of SpA. However, our data also show that IBD pts with MSK symptoms often have other non-inflammatory rheumatic diseases. Notably, in our series US did not represent a sensitive method in identifying pts with SpA.

REFERENCES:
Methods: A longitudinal and analytic study was conducted on a cohort of Colombian SpA patients. Patients were evaluated in a SpA clinic at two institutions from 1990 to the present. All patients were classified according to ASAS. Patients included before 2011 were reclassified according to ASAS by a group of two rheumatologists.

Results: We enrolled 473 SpA patients; of these, 437 (92.39%) fulfilled ASAS classification criteria, and 37 (7.6%) had a diagnosis by rheumatologists but did not fulfill ASAS classification criteria for neither axial nor peripheral SpA. There were no differences in gender distribution between both groups (Table 1). Patients who did not fulfill ASAS classification had a lower frequency of enthesis (36.1% vs. 79.2%, P = 0.00), dactylitis (5.6% vs. 19%, P = 0.04), arthritis (30.6 vs. 71.6%, P = 0.00), and lower frequency of history of infections preceding SpA onset (2.8% vs. 27.9%, P = 0.01) than patients classified by ASAS, respectively. There were no differences in the frequency of uveitis, psoriasis, inflammatory spinal pain, or familiar history of SpA (P = 0.3). The frequency of SpA with axial symptoms at the onset of the disease was higher in patients unclassified by ASAS (Table 1). Non-ASAS SpA patients had a higher frequency of HLA-B15 (25% vs. 11.8%, P = 0.01), and lower frequency of HLA-B27 (16.7% vs. 48.2%, P = 0.01) than ASAS SpA patients, respectively (Graphic 1). The BASFI and BASDAI were comparable between two groups (Table 1).

Conclusion: Most patients diagnosed as SpA by rheumatologists in a Colombian cohort fulfilled ASAS classification criteria. Only 7% did not fulfill the criteria. Of these patients, the demographic characteristics, disease activity and functional compromise were comparable to patients classified by ASAS. Interestingly, the frequency of HLA-B15 is high in both groups, but it is significantly higher in unclassified individuals. These results highlight the significance of HLA alleles other than HLA-B27 and their potential diagnostic value for SpA in LatinAmerica.

Conclusion: In the presence of advanced radiographic progression, low disease activity was not significantly associated with less functional impairment in patients with SpA, which suggests that early diagnosis and optimal treatment are critical for better physical function.

**Background:** Our group has evaluated the impact of the time of appearance of some extra-articular manifestations in spondyloarthritis. However, we still need to know more about the impact of both the inflammatory bowel disease (IBD) itself and its moment of appearance with respect to rheumatic symptoms.

**Objectives:**

1. To compare SpA characteristics in patients with and without IBD
2. To compare the clinical characteristics and the rheumatologist’s diagnosis in SpA patients with IBD according to the onset of IBD (before vs. after the appearance of rheumatic symptoms)

**Methods:** This was a cross-sectional study with data extracted from the REGISPONSER (Spondyloarthritis Registry of the Spanish Rheumatology Society) registry. Dates of SpA and IBD onset were available. Two groups were classified depending on the time of appearance of IBD (before vs. after rheumatic symptoms). The clinical characteristics, disease activity, radiographic damage, functional ability and rheumatologists’ diagnoses were compared between the two groups.
characteristics of uveitis in spondyloarthritis in a multicenter study in morocco

Keywords: uveitis, spondyloarthritis

1 Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology, Marrakech, Morocco; 2 Hospital Fez, Rheumatology, Fez, Morocco; 3 Hospital Casablanca, Rheumatology, Casablanca, Morocco; 4 El Ayachi Hospital, Ibn Sina University Hospital Salé-Rabat, Rheumatology, Salé-Rabat, Morocco; 5 Ibn Rochd University Hospital Casablanca, Rheumatology, Casablanca, Morocco; 6 El Ayachi Hospital, Ibn Sina University Hospital Salé-Rabat, Rheumatology, Salé-Rabat, Morocco; 7 Military Hospital Mohammed V Rabat, Rheumatology, Rabat, Morocco; 8 Military Hospital Agadir, Rheumatology, Marrakesh, Morocco; 9 Military Hospital Agadir, Rheumatology, Marrakesh, Morocco; 10 Uveitis Centre, Marrakech, Morocco;

Background: Uveitis is the most common extra-articular manifestation of spondyloarthritis (SpA). The aim of this study was to determine the prevalence of uveitis in patients with SpA in a multicenter setting and to identify factors associated with uveitis.

Methods: A multicenter descriptive analytical study, including patients followed for SpA in 8 rheumatology departments from 6 different regions in Morocco. All data were measured by standard instruments. Demographic, clinical, paraclinical, and therapeutic data of the disease were collected. Disease activity was assessed by BASDAI and ASDAS-CRP scores. Data analysis was done by SPSS 20.0 software. The significance level was set at 0.05.

Results: The study included 700 patients followed for SpA, 54% of whom were men. The mean age at diagnosis was 40.42 ± 14.19 years. The average diagnosis delay was 59.76 months. The percentage of patients who smoked was 15.6%. A family history of SpA was noted in 11.7%. SpA was non-radioarticular in its occurrence. Among patients with uveitis, 54 (52.4%) already had uveitis at the moment of rheumatic symptoms onset, while 49 patients (47.6%) began with uveitis after the SpA onset. Peripheral phenotype [10 (18.5%) vs 1 (2%)] was more frequently observed in patients who had already been diagnosed of uveitis when rheumatic symptoms began while axial involvement had a lower prevalence [25 (46.3%) vs 33 (67.3%)]. There were also significant differences in rheumatologist’s diagnosis in these patients, with a less frequency of ankylosing spondyloarthritis diagnosis [31 (57.5%) vs 42 (85.7%)] in the first group. After performing a multivariate analysis with demographic and clinical characteristics, we obtained a shorter diagnosis delay for uveitis [0.90 (CI95% CI 0.82-0.98)] and a less prevalence of HLA-B27 antigen [0.19 (CI95% CI 0.07-0.52)] in the former groups.

Conclusion: SpA patients with uveitis have a less severe disease with less prevalence of extraskeletal manifestations. When IBD began before the rheumatic symptoms, it was associated to an earlier diagnosis and a more frequent peripheral phenotype.

is there an association between serum levels of biomarkers of osteoproliferation and markers of inflammation in spondyloarthritis?

Keywords: spondyloarthritis, biomarkers

Z. Zeineb1, K. Amissah1, A. Ayadi2, H. Ferjani3, M. Kallel Sellami3, D. Ben Nessli1, D. Elhaj Mahmoud1, W. Kasbach2, D. Kaffel1, L. Laadha2, W. Hamdi1

1 Faculty of Medicine of Tunis, University Tunis El Manar, Tunisia, Rheumatology Department, Kassab Orthopedics Institute, Kasr Saaid, Tunisia, Tunisia; 2 Faculty of Medicine of Tunis, University Tunis El Manar, Tunisia, Immunology Department, La Rabta Hospital, Tunis, Tunisia

Background: The two most studied inhibitors of the Wnt signaling pathway in spondyloarthritis (SpA) are Dickkopf-1 (Dkk-1) and Sclerostin. Their dysfunction would be responsible for bone formation phenomena. Osteoprotegerin (OPG), a potent inhibitor of osteoclasts and regulated by the Wnt pathway, has also been implicated in this osteoformation phenomenon.

Objectives: Our work aimed to determine the associations between serum levels of DKK-1, Sclerostin, OPG, and markers of inflammation in SpA.

Methods: It was a cross-sectional study, including patients with SpA meeting ASAS criteria. Data collected included sociodemographic and disease characteristics, C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). Biomarker assays were performed using an ELISA technique.

Results: One hundred and nine patients were included, 68 men and 41 women. The mean age of the patients was 43 + 12 years [19-79]. The mean age of disease onset was 30.6 ± 11 years [5-56]. The mean duration of SpA at inclusion was 12.6 ± 9.8 years [1 - 62]. Forty-nine percent of patients had a biological inflammatory syndrome (BIS). The mean ESR was 28.6 ± 21.2 mm/h [10 - 110 mm/h], and the mean CRP value was 15.2 ± 23.4 mg/L [1 - 153 mg/L]. Median serum levels, in pg/mL of DKK-1, Sclerostin, and OPG were 146.7 [0-455.3], 32.8 [0-488], and 471 [0-1613], respectively. The biological inflammatory syndrome was not associated with DKK1 level (p = 0.800). It tended to be associated with OPG and Sclerostin levels (p = 0.085 and p = 0.051, respectively). ESR was negatively correlated with Sclerostin (r = -0.222; p = 0.022). The CRP level appeared to be negatively correlated with OPG (r = 0.161; p = 0.099) and Sclerostin levels (r = 0.181; p = 0.064).

Conclusion: An association between markers of inflammation and inhibitors of the Wnt signaling pathway as well as OPG was shown by our study, suggesting that actors of systemic inflammation may influence the secretion of these biomarkers.

DOI: 10.1136/annrheumdis-2023-eular.6365
Background: Sacroiliac radiographs in axial spondyloarthritis (axSpA) allow the evaluation of sacroiliac and hip joint involvement, as well as the symphysis region and ischial enthesis regions. In this study:

Objectives: To plan to test and review the relationship between the presence of ischial enthesitis and disease-related factors, the presence of peripheral enthesitis, and other radiological features of involvement.

Methods: Of 355 patients with axSpA diagnosis and follow-up sacroiliac joint radiography evaluated for ischial enthesitis were included in the study. Since the presence of ischial enthesitis was detected in 1 patient in non-radiographic axSpA patients, the analysis was performed with radiographic axSpA patients. Demographic, clinical, and laboratory characteristics of the patients were recorded. Irregular appearance in the region where tendons and ligaments attach to the bone (lower region) in the pubic arms in the sacroiliac joint X-ray was evaluated as ischial enthesitis. Radiological evaluation was performed by a rheumatologist (EDE) and a radiologist (AS). The relationship between the presence of ischial enthesitis and other factors was tested with both univariate and multivariate analysis methods.

Results: The mean age at diagnosis (±SD) was 42 (11.9) and 74% of the patients included in the study were male. Demographic and radiological characteristics of the study group are summarized in Table 1. Ischial enthesitis was detected in 57 (16.1%) patients. Gender (p=0.006), symptom duration (p<0.001), duration of diagnosis (p=0.002), HLA-B27 positivity (p=0.09), radiographic hip involvement (p=0.09) total sacroiliac joint score (p=0.001), baseline cervical mSASS score (p<0.001), basal lumbal mSASS score (p=0.001), presence of sympyhsis (p<0.001), serum CRP level (p=0.014) found to be associated with ischial enthesitis in univariate analysis. There was no correlation between the presence of ischial enthesitis and heel pain (p=0.61) or SPARCC enthesitis score (p=0.59).

In the two models established in the multivariate analysis, serum CRP level (p<0.002), presence of cervical syndesmophyte (p=0.042), presence of total ankylosis in the sacroiliac joint (p=0.012) and SIE score (p=0.001) were found to be independent variables associated with the presence of ischial enthesis.

Conclusion: Although ischial enthesitis can be seen independently of clinical heel pain in axSpA patients, it can also be an indicator of radiographic damage.

Table 1. Demographic and radiological characteristics of axSpA patients

Factors associated with cervical involvement progression in patients with axial spondyloarthritis

Keywords: Spondyloarthritis

E. Durak Ediboglu, A. Sınıc, D. Solmaz2, E. Erpek3, H. Cinakli, G. Alp, E. Otman Akat, A. Özkant, J. Kurut Avsivan, H. Kocaayam, M. Ozmen, S. Akar. 1Hatay Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; 2Izmir Katip Celebi University, Department of Radiology, Izmir, Turkey; 3Izmir Katip Celebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey

Background: The evaluation of cervical, lumbar spinal structures and hip joint is important and this is reflected in the variables in the scoring systems in patients with axSpA.

Objectives: In this study, it was aimed to investigate the factors affecting cervical spinal progression.

Methods: The patients with the diagnosis of axSpA who were followed-up at least two years, and whose cervical mSASS scores were evaluated by cervical X-ray were included in the study. A change of 1 unit or more in the modified Stoke Ankylosing Spondylitis Spine score (mSASS) between two radiographs taken at least two years apart was considered progression. Radiological evaluation was done by a rheumatologist (EDE) and a radiologist (AS). Demographic, clinical, and laboratory characteristics of the patients were recorded. The relationship between the presence of cervical progression and other factors was tested with both univariate and multivariate analysis methods.

Results: Of the 237 patients included in the study, 62% were male and the median age at diagnosis (IQR) was 34 (14) and 68.8% of the patients were radiographic axSpA. The demographic, clinical, and laboratory characteristics of the patients were summarized in Table 2. Cervical progression was detected in 42 of the patients (17.2%) with cervical radiography in the median (IQR) 4 (2) follow-up period. Presence of cervical progression was related with symptom duration (p=0.004), age at symptom onset (p=0.011), age at diagnosis (p<0.001), presence of total ankylosis in sacroiliac joint X-ray (SIE score=8) (p<0.001), cervical mSASS score (p<0.001), total SSI score (p<0.001), baseline cervical mSASS score (p<0.01), presence of cervical syndesmophyte (p=0.001), baseline lumbal mSASS score (p<0.001), the presence of lumbal syndesmophyte (p<0.001). Cervical progression was not associated with HLA-B27, smoking, presence of either extramusculoskeletal or peripheral involvement, baseline disease activity scores (BASDAI, ASDAS-CRP). In two different models were established in multivariate analysis, age at diagnosis (p=0.001), presence of cervical syndesmophyte (p=0.014), sacroiliac joint score (p=0.004) were associated with cervical progression.

Conclusion: It should be kept in mind that the age at diagnosis, presence of spinal involvement and sacroiliac joint score may be predictors of cervical spinal progression in the follow-up of patients in axSpA.

Table 1. AxSpA hastalarının demografik ve radyolojik özellikleri

Endothelial Dysfunction and Subclinical Atherosclerosis in Radiographic and Non-Radiographic Axial Spondyloarthritis

Keywords: Comorbidities, Cardiovascular disease, Spondyloarthritis

M. H. Abu-Zaied1, N. F. Danwish1, S. A. A. Tabra1, Tanta University, Faculty of Medicine, Rheumatology and Rehabilitation, Tanta, Egypt

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease which includes radiographic subtype [ankylosing spondylitis (AS)], and non-radiographic subtype [nr-axSpA][1]. Chronic inflammatory disorders, such as axSpA, are associated with increasing cardiovascular (CV) risk which is mainly due to the inflammatory burden[2].

Objectives: Evaluation of endothelial dysfunction and subclinical atherosclerosis in axSpA and comparison between in AS and nr-axSpA regarding disease activity, functional status and Subclinical atherosclerotic disease.

Methods: Eighty Patients fulfilling the ASAS classification criteria plus 60 healthy individuals were included in this study. Patients were divided into two groups;
50 patients with AS (GI) and 30 patients with nr-axSpA (G II), while G III was the control group. Patients with nr-axSpA were defined as the absence of definite sacroiliac (SI) joint changes on plain radiograph but with active sacroilitis on MRI and at least one of the characteristic traits of SpA according to the 2009 ASAS criteria[3]. Demographic data, duration of the disease, delay in diagnosis, extra-articular manifestations, smoking, comorbidities and detailed medication history were taken. Disease activity were assessed by Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Physical function was assessed by the Bath Ankylosing Spondylitis Functioning Index (BASFI) & patient-reported outcome measures (PROMs). Serum endothelin-1 and carotid intima-media thickness (cIMT) were measured to assess endothelial dysfunction and subclinical atherosclerosis.

**Results:** There was no significant difference between the GI & GII regarding age and gender (p>0.05), while AS patients had longer mean disease duration than nr-axSpA (6.6 years vs 3.7 years, P < 0.001). Forty-eight patients out of 50 in G I were receiving biological therapy while 23 patients from 30 in G II were receiving biological therapy with significant difference between the two groups (p=0.02). There were no significant differences between GI and GII regarding comorbidity, and smoking status (p>0.05). Regarding disease activity, we found no significant difference between GI and GII in ASDAS-CRP (2.0±0.9, & 2.2±1.02 respectively), also there was no significant difference between GI and GII in ASDAS (3.9±1.3, & 4.1±1.1 respectively). There was no notable differences between the AS and nr-axSpA neither in BASFI nor in PROMs (p>0.05). The serum endothelin-1 was significantly elevated in both patients' groups when compared with controls (GI: 2.3±1.5, GII: 2.0±1.3, controls: 0.76±0.5) with no significant difference between GI and GII (p>0.05). When we measured cIMT we noticed a significant increase in the thickness of cIM of patients in comparison with controls (P < 0.01), while there was no significant difference between the AS and nr-axSpA (p>0.05). We found 6 AS patients had atheromatous plaque, while 4 patients had atheromatous plaque in nr-axSpA group with no significant difference between the 2 groups (p=0.86). There was positive correlation between endothelin-1, cIMT and both ASDAS-CRP & BASFI.

**Conclusion:** Axial spondyloarthritis patients (either AS or nr-axSpA) had higher risks for endothelial dysfunction and subclinical atherosclerosis, patients with AS & nr-axSpA shared a comparable disease activity, functional disability and endothelial dysfunction.

**COURSE OF AORTIC REGURGITATION IN ANKYLOSING SPONDYLITIS – A FOLLOW-UP STUDY OF 52 PATIENTS EXAMINED WITH ECHOCARDIOGRAPHY**

**Keywords:** Heart, Spondyloarthrits

K Bengtsson1,2, G. Mourtzinis1,4, A. Deminger1,2, E. Klingberg1,2, M. Scharin Täng3, L. T. H. Jacobsson1, L. Bergfeldt1,2, H. Forsblad-d’Elia1,2, I. Institute of Medicine at Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Göteborg, Sweden; 2Region Västra Götaland, Department of Rheumatology, Sahlgrenska University Hospital, Göteborg, Sweden; 3Institute of Medicine at Sahlgrenska Academy, University of Gothenburg, Department of Molecular and Clinical Medicine, Göteborg, Sweden; 4Region Västra Götaland, Department of Medicine and Emergency, Sahlgrenska University Hospital, Mölndal, Sweden; 5Region Västra Götaland, Department of Cardiology, Sahlgrenska University Hospital, Göteborg, Sweden

**Background:** Ankylosing spondylitis (AS) is associated with cardiac manifestations such as aortic regurgitation. However, contemporary follow-up studies are lacking.

**Objectives:** To investigate the course of aortic regurgitation and proximal aortic root diameter in patients with AS examined with echocardiography at baseline (2009-2011) and at follow-up (2014).

**Methods:** At baseline, 187 patients with AS (56% men, mean age 50 years) were examined with echocardiography, of whom 34 (18%) had an aortic regurgitation of mild to severe grade[1]. Of these 34 patients, 26 agreed to participate in a follow-up with echocardiography in 2014. In addition, we reassessed 26 sex- and age-matched patients from the same AS cohort, but without aortic regurgitation at baseline. The presence and severity of aortic regurgitation (none, mild, moderate, severe) as well as the proximal aortic root diameter were assessed. Related-samples Wilcoxon signed rank test was used to analyze the change (Δ) in aortic root diameter from baseline to follow-up, divided by patients with and without aortic regurgitation at baseline and stratified by sex. Mann-Whitney U-test was used to compare the Δ aortic root diameter in patients with and without an aortic regurgitation at baseline.

**Results:** In total 52 patients (54% men, mean age (SD) 62 (11)) were re-examined in 2014. The time between the baseline and follow-up echocardiography examination ranged between 3.0 to 4.7 years with a median of 4.3 years. There were no statistically significant differences in aortic root diameter between baseline and follow-up as shown in Table 1. The distribution of Δ aortic root diameter was not statistically different in patients with an aortic regurgitation at baseline compared to the patients without. The change in aortic regurgitation grade from baseline to follow-up is presented in Figure 1. Of the 26 patients with aortic regurgitation at baseline, two had a more severe grade, eight had a lower grade, and 16 an unchanged grade of aortic regurgitation at follow-up. Of the 26 patients without aortic regurgitation at baseline, two had developed a mild grade of aortic regurgitation at follow-up.

**Table 1.**

Δ, change in aortic root diameter from baseline to follow-up. The data is presented in median (25th percentile, 75th percentile).

**Conclusion:** Although aortic regurgitation like other AS related manifestations might vary over time, the majority of AS patients examined with echocardiography at baseline and after three to five years had an unchanged grade of aortic regurgitation at follow-up.

THE RELATIONSHIP BETWEEN LONG-TERM USE OF NONSTEROIDAL ANTI-INFLAMMATORY DRUGS AND KIDNEY FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Kidneys, Safety

B. S. Koo1, S. Hwang2, S. Y. Park3, J. H. Shin4, T. H. Kim5. 1Inje University Seoul Paik, Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Inje University Seoul Paik, Nephrology, Seoul; Korea, Rep. of (South Korea); 3Korea National Open University (KNOU), Seoul, Statistics, Seoul, Korea, Rep. of (South Korea); 4Hanyang University Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: Although nonsteroidal anti-inflammatory drugs (NSAIDs) are the first-line treatment for ankylosing spondylitis (AS), their effect on kidney function remains unclear.

Objectives: This longitudinal study investigated the correlation between long-term NSAID use and kidney function in patients with AS using electronic medical records.

Methods: The electronic medical records of 1,280 patients with AS collected from a single center between January 2001 and December 2018 were reviewed. The Assessment of Spondyloarthritis International Society (ASAS) NSAID Intake Score was used to determine the cumulative dose of all NSAIDs prescribed for a different time intervals. Each ASAS NSAID Intake Score was obtained for intervals of 6 months, 1 year, 2 years, 3 years, 5 years, and 10 years. The correlation between the ASAS NSAID Intake Score and eGFR at each interval was investigated.

Results: The mean ASAS Intake Scores for 6-month, 1-year, 2-year, 3-year, 5-year, and 10-year intervals were 55.30, 49.28, 44.84, 44.14, 44.61, and 41.17, respectively (Figure 1). At each interval, the Pearson correlation coefficients were -0.099 (95% CI: -0.137 to -0.061, p<0.001), -0.070 (95% CI: -0.114 to -0.026, p=0.002), -0.019 (95% CI: -0.062 to 0.064, p=0.645), respectively. There was a very weak negative relationship between ASAS Intake Score and eGFR at each interval.

Conclusion: Long-term NSAID use did not correlate with kidney function based on real-world data in patients with AS.

COSTOVERTEBRAL JOINTS INVOLVEMENT IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: A CASE-SERIES COMPUTED TOMOGRAPHY STUDY

Keywords: Spondyloarthritis

A. Shouval1, S. Croitoru2, S. Keret3, I. Eshed4, G. Globodin5, 1Bnai Zion Medical Center/Oranim Medical Center, Haifa, Israel; 2Bnai Zion Medical Center, Haifa, Israel; 3Bnai Zion Medical Center, Haifa, Israel; 4Tel-Hashomer The Sheba Medical Center, Radiology, Ramat Gan, Israel

Background: The involvement of the costovertebral joints (CVJ) and its radiographic patterns in patients with radiographic axial spondyloarthritis (rAxSpA) and thoracic pain were described more than three decades ago, however the extent and details of structural damage in the CVJ have never been assessed.

Objectives: To evaluate structural changes of CVJ in patients with rAxSpA using available computed tomography (CT) studies.

Methods: Available chest or thoracic spine CT studies of 17 patients with rAxSpA and 17 patients with rheumatoid arthritis (RA) were analyzed. Ankylosis, erosions, joint space narrowing and osteophytes of both components of the CVJ, including head-vertebral joints (HVJ) and costotransverse joints (CTJ), were noted and compared between patient groups. The distribution of the structural changes of the CVJ along the thoracic spine was assessed.

Results: The groups were similar by patients' average age, but the rAxSpA group included more males (11/17) compared to the RA group (4/17, p=0.036). In all, 748 CVJ were assessed in each patient group, including 408 head-vertebral joints (HVJ) and 340 costotransverse joints (CTJ). rAxSpA patients had significantly more total CVJ lesions (p<0.001 for all comparisons), more lesions in the HVJ (p<0.001 for all comparisons), and more lesions in the CTJ (p<0.005, for all comparisons, except for osteophytes), compared to RA group. All types of lesions, including ankylosis, erosions, narrowing, and osteophytes, were seen more frequently in rAxSpA patients. Joint space narrowing and ankylosis of the CVJ were the most frequently seen findings in rAxSpA and were distributed throughout the thoracic spine.

Conclusion: Structural pathology of the CVJ was more commonly observed in patients with rAxSpA than in RA patients in this study.

**Spondyloarthritis - clinical aspects (other than treatment)**

**AB1035**  
**TRANSLATION AND CROSS-CULTURAL ADAPTATION OF THE ASAS HEALTH INDEX ENVIRONMENTAL FACTORS ITEM SET INTO SWEDISH AND ASSESSMENT OF RELIABILITY OF THE SWEDISH VERSIONS OF ASAS HEALTH INDEX AND ENVIRONMENTAL FACTORS ITEM SET**

**Keywords:** Outcome measures, Spondyloarthritis, Quality of life

C. Feldhusen1,2, M. Hallström1,3, A. Delia4, A. Deminger1,2, U. Kiltz2, H. Forsblad-D’ella1,3, 1Institute of Medicine, Sahlgrensk Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2Region Västra Götaland, Sahlgrensa University Hospital, Department of Occupational Therapy and Physiotherapy, Gothenburg, Sweden; 3Region Västra Götaland, Sahlgrensa University Hospital, Department of Rheumatology, Gothenburg, Sweden; 4Institute of Population Health, Policy and Systems, University of Liverpool, Department of Public Health, Liverpool, United Kingdom; 5Ruhr-Universität Bochum, Rheumatzentrum Ruhrgebiet, Herne, Germany

**Background:** The impact of axial spondyloarthritis (axSpA) on health-related quality of life can be substantial, affecting both physical and mental health. There is a need to assess the effect with disease-specific instruments. A global collaboration developed the Assessments of SpondyloArthritis international Society Health Index (ASAS HI) and Environmental Factors Item Set (EFIS). These instruments measure everyday function and health across aspects typical and relevant for patients with axSpA[3]. These instruments have been translated into 35 languages[4] but only the ASAS HI component has been translated into Swedish.

**Objectives:** To translate and culturally adapt EFIS into Swedish, and to assess reliability of the Swedish ASAS HI and EFIS.

**Methods:** Patients with axSpA were recruited from the rheumatology clinic at Sahlgrenska University Hospital, Sweden. ASAS HI and EFIS contain 17 and 9 items respectively, with dichotomous response options; “I agree” or “I do not agree.” The total sum of ASAS HI ranges from 0 to 17, lower score indicating better health status. EFIS does not provide a sum score due to its multidimensional nature. Translation and cultural adaptation of EFIS was carried out using a forward-backward procedure consisting of: Initial translation; translation synthesis; back translation; expert committee review; field testing with cognitive debriefing[5]. The translations were performed separately by translators with clinical perspective and professional translators with no medical or clinical background. Reliability was analysed by internal consistency, evaluated with the Cronbach’s alpha coefficient for ASAS-HI, and test-retest reliability using the intraclass correlation coefficient (ICC) for ASAS-HI (sum-score) and EFIS (discrete items).

**Results:** Ten patients were recruited to the field test and 61 patients to the reliability study of which 53 (87%) returned a second questionnaire after 1 week and were included in the test-retest reliability study (Table 1). Translation and cross-cultural adaptation of the EFIS. The translators produced a prefinal Swedish version of EFIS. The field test was performed in 10 patients and resulted in minor wording. Internal consistency: ASAS HI scores showed an acceptable internal consistency; Cronbach’s alpha 0.79. Test-retest reliability. ASAS HI sum score showed excellent reliability; ICC (95% CI) 0.87 (0.78-0.93), P-value <0.001. ASAS EFIS individual items reliability ranged from poor for item 2 and 8 to excellent for item 10 and 9; ICC (95% CI) from -0.43 (-0.83 to 0.41), P-value <0.001. The occurrence of hip involvement during spondyloarthritis seems to be frequent in our country. Hip involvement is one of the elements of poor prognosis and its presence predicts a severe form of the disease.

**FACTORS ASSOCIATED WITH HIP INVOLVEMENT IN SPONDYLOARTHRITIS**

**Keywords:** Epidemiology, Enthesitis

S. Oulebsir3, S. Affal1, S. Bennedjem1, A. Diebarg3, B. Abdelatif4, M. Houbi5, A. Abi Ayad6, C. Makhlouf-Dahou3, 1HCA Hospital Kouba, Department of Rheumatology, Kouba, Algeria; 2hospital Bouchaoui, Department of Rheumatology, Bouchaoui, Algeria; 3Hospital Bab El Oued, Department of Rheumatology, Algiers, Algeria

**Background:** Hip involvement in spondyloarthritis determines a large part of the functional prognosis and affects negatively the patient’s life. Identifying these factors could influence our management strategy by developing specific therapeutic protocols.

**Objectives:** The objective of this work is to determine the factors associated with hip involvement during spondyloarthritis.

**Methods:** The study is a single-center prospective observational study, carried out during the period extending between January 2020 and January 2022. Spa patients meeting the criteria for ASAS were included. On a patient-by-patient basis, clinical, biological, and imaging data were collected.

**Results:** In total, 259 patients with consecutive spondyloarthritis were assessed. Of these, 80 patients (30.88%) had hip involvement associated with spondyloarthritis, including 66 men and 14 women (gender ratio = 4.7), with an average age of 37.6 and 11.3 years. It was bilateral in 70% of cases, and inaugural in over half of patients (55% of cases). The biological inflammatory syndrome was observed in 72.5% of cases and HLA B27 was found in 14% of patients. The anatomic-radiological forms observed were: the destructive form (36.76%), the condensant constructive form (22.05%), the initial form (24.26%), and the synostotic form (16.91%). TNF alpha treatment was initiated in 85% of cases, with a third of patients receiving PTH. Factors related to hip involvement were: functional impairment (BASFI), limitation of spinal and joint mobility (BASMI, inter-malleolar distance), structural damage to the SpA (total BASRI), presence of HLA B27, and initiation of anti-TNF alpha treatment. On the other hand, the age of hip involvement and spa, gender, bilateral involvement, high scores of the BASDAI and ASDAS indices, and the presence of a biological inflammatory syndrome did not seem to be involved.

**Conclusion:** The occurrence of hip involvement during spondyloarthritis seems to be frequent in our country. Hip involvement is one of the elements of poor prognosis and its presence predicts a severe form of the disease.

**AB1037**  
**ARE THE CLINICAL SCALES USED TO ASSESS DISEASE ACTIVITY AND FUNCTIONAL ABILITY IN AXIAL SPONDYLOARTHRITIS REALLY RELIABLE?**

**Keywords:** Spondyloarthritis
Background: Evaluation of disease activity and functional impairment in Axial spondyloarthritides (AxSpA) are important in therapeutic plan. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS) and The Bath Ankylosing Spondylitis Functional Index (BASFI) scores are based largely on subjective measures, which liable to change depending on patient’s expression, culture, and awareness.

Objectives: Assessment of reliability of BASFAI, BASDAI, ASDAS-ESR, and ASDAS-CRP as a total score and individual questions in patients with AxSpA.

Methods: This cross-sectional study was conducted on 103 patients with AxSpA according to the ASAS classification criteria for AxSpA. Each patient completed BASDAI, BASFI, ASDAS-ESR, and ASDAS-CRP during their routine visit for follow up with one rheumatologist. Then the same patients completed the three questionnaires again in the same day or on the second day with another rheumatologist.

Results: Internal consistency and reliability of ASDAS-ESR, ASDAS-CRP, BASDAI, and BASFI scores were good (ICC was 0.841, 0.820, 0.767, and 0.852 respectively). Reliability of BASFI score was better than that of ASDAS-ESR, ASDAS-CRP, BASDAI scores, and that of ASDAS-ESR, ASDAS-CRP was better than reliability of BASDAI score.

Conclusion: Some questions of ASDAS, BASDAI, and BASFI scores are more reliable than others, this depends on the question. The answers of the questions that assess sensation of pain, are liable to change. While the answers of other questions that assess stiffness or assess its duration are less liable to change. Questions that assess certain daily activity are more reliable than that assess the ability to do more than one activity.

AB1038 RELATIONSHIP BETWEEN ANKYLOSIS AND PHYSICAL FUNCTION ASSESSMENT IN ANKYLOSING SPONDYLITIS

Keywords: Quality of life, Spondyloarthritis, Patient reported outcomes

M. Suzuki1, K. Kishimoto1, D. Kihira1, R. Sato1, J. Hasegawa1, M. Maeda1, Y. Ohashi1, K. Terabe1, S. Asai1, S. Imagama1, Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan

Background: Ankylosing spondylitis (AS) is a progressive inflammatory disease affecting the spine and large joints of the extremities. The ability of the spine and sacroiliac joins affects patients not only physically but also psychologically and socially, resulting in a significant decline in quality of life (QOL) and disruption of daily activities [1]. However, it is unclear to what extent the progression of the disease affects physical function and patient subjective evaluation.

Objectives: The purpose of this study was to investigate the relationship between the degree of progression of ankylosis, physical function, and frailty in patients with AS.

Methods: Twenty-four patients with AS attending our hospital who underwent full spine computer tomography (CT) and physical function assessment were included in the study. The anterior-posterior, intervertebral joint, and interosseous process ankylosis sites and number of ankylosis (whole spine/cervical spine/lumbar spine/femur) and sacroiliac joint ankylosis were evaluated in each vertebra. Patient-objective measures of physical function included gait speed, grip strength, Timed Up and Go test (TUG), time of five sit-to-stand, and Bath Ankylosing Spondylitis Functional Index (BASFI), Kihon Checklist (KCI), the 25-question Geriatric Locomotive Function Scale (GLFS-25), and Beck Depression Inventory (BDI-II) as subjective assessments. Spearman's rank correlation coefficient was used to analyze the correlation between the degree of progression of ankylosis and each of the assessment items.

Results: The mean age (± standard deviation) at the time of the study was 40±15 years, 79% were male, 50% were HLA-B27 positive, and the disease duration was 15±9 years. Age was significantly correlated with the number of thoracic spine ankylosis (r=0.449), and disease duration with the number of total spine/cervical spine/thoracic spine/sacrococcygeal joint ankylosis (r=0.600/0.553/0.635/0.510). BASMI, an objective patient assessment, showed a significant correlation with the number of total spine/cervical spine/thoracic spine/lumbar spine ankylosis (r=0.732/0.653/0.707/0.615), but not with walking speed, grip strength, TUG, or time of five sit-to-stand. BASFI, a subjective patient assessment, showed a significant correlation with the number of total spine/cervical spine/thoracic spine/lumbar spine ankylosis (r=0.680/0.729/0.600/0.469), and the GLFS-25 (r=0.418/0.500) with the number of total spine/cervical spine ankylosis. BDI-II, an assessment of psychiatric symptoms, and KCI, an assessment of daily activity, showed no correlation with the number of ankylosis.

Conclusion: BASFI and GLFS-25, physical function assessments, were significantly correlated with spinal ankylosis in AS patients, and the degree of progression of spinal ankylosis was found to interfere with daily life.

AB1039 A COMPARATIVE STUDY TO ASSESS THE DIFFERENCES IN DISEASE CHARACTERISTICS IN PATIENTS WITH NON-RADIOGRAPHIC AND RADIOGRAPHIC AXIAL SYPONDOARTHRITIS

Keywords: Spondyloarthritis, Descriptive studies, Inflammatory arthropathies

S. Ghosh1, K. Telang1, L. Sharma1, D. Yadavalli1, W. Kazli1, V. Singal1, R. Gupta1,1Medanta - The Medicity, Rheumatology & Clinical Immunology, Gurgaon, India

Background: Spondyloarthritis (SpA) is an umbrella term for a group of clinically heterogeneous chronic inflammatory diseases, with Ankylosing Spondylitis (AS) having the characteristic radiographic features of sacroiliitis and spinal deformities, while the other subtypes of SpA have some common as well as unique
articular and extra-articular manifestations. Recent advances in early diagnosis have differentiated axial SpA into radiographic and non-radiographic subsets but the exact differences between them are debatable.

Objectives: This study was conducted to assess and compare the clinical, laboratory, and radiologic characteristics of Indian patients with radiographic and non-radiographic axial SpA.

Methods: This was a cross-sectional, observational, comparative study conducted at a 1250-beded tertiary care hospital. Between February 2020 and December 2021, all consecutive adult patients classified as having Axial Spondyloarthritis as per the Assessment of SpondyloArthritis International Society (ASAS) 2009 Classification Criteria and with symptom duration of at least 3 years were included in the study after taking their informed consent. Patients were classified as radiographic (AS) or non-radiographic Axial SpA (nr-Axial SpA) by two independent and blinded rheumatologists with over twenty years of experience in their field each, based on findings on anteroposterior plain radiographs in the supine position. Demographic details, articular and extra-articular manifestations, comorbidities, and relevant family history were assessed along with the levels of inflammatory markers and HLA B27 status. The study was approved by the Institutional Review Board and the Institutional Ethics Committee.

Results: 209 patients consented to this study, with 160 being classified as radiographic and 49 as non-radiographic axial SpA. 79.4% of the patients were male. The mean age at symptom onset was 27.69 ± 9.33 years for our cohort, with a median duration of 50 months. There was a significantly higher proportion of males (85% vs 15%, p <0.001), patients with enthesitis (74% vs 41%, p =0.05), and hypertension among the radiographic subgroup. 44% of our patients had bilateral Grade 2 changes on their sacroiliac joint radiographs according to the modified New York Criteria, and there was a significant positive correlation between increasing symptom duration and worsening radiographic grades of sacroiliitis, but there were no significant differences in the remaining clinical features, HLA B27 positivity, or age at symptom onset among the AS and nr-Axial SpA patients. Mean values of BASDAI, BASMI, and ASDAS-ESR scores were also significantly higher in patients with radiographic Axial SpA.

Conclusion: Data from our Indian cohort of axial Spondyloarthritis revealed a significant association of radiographic disease with male gender and the presence of enthesitis, as well as higher mean values of inflammatory markers and composite scores. However, non-radiographic axial SpA was similar to AS as far as most other features were concerned. With increasing symptom duration, the majority of patients may develop radiographic disease, and they may be considered as two ends of the same spectrum, justifying early therapy even in nr-Axial SpA.

CHARACTERIZATION OF ANXIETY AND DEPRESSION AND THEIR IMPACT ON DISEASE ACTIVITY, FATIGUE AND QUALITY OF LIFE IN SPONDYLOARTHRITIS PATIENTS TREATED WITH ANTI-TUMOR NECROSIS FACTOR ALPHA AGENTS

Keywords: bDMARD, Spondyloarthritis, Quality of life D. Santos Oliveira 1,2, A. Martins 1,2, R. Nicolau 1,4, C. Vaz 1,2, T. Martins-Rocha 1,2, A. Bernardes 1, L. Bernardes 1, L. Costa 1, Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; 2Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal; 3Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; 4Centro Hospitalar Tondela-Viseu, Viseu, Rheumatology Department, Viseu, Portugal

Background: The psychological health of patients with spondylarthritides (SpA) influences their response to anti-tumor necrosis factor alpha (anti-TNF-α) therapy. However, little is known about the correlation between anxiety and depression symptoms and clinical outcomes over time.

Objectives: Hence, based on clinical practice setting, this study, aimed to explore the impact of anxiety and depression symptoms on clinical outcomes in patients with SpA treated with anti-TNF-α agents on.

Methods: An observational retrospective longitudinal cohort study was conducted. Adult patients with diagnosis of SpA according to Assessment of Spondyloarthritis International Society (ASAS) classification criteria, who started their first anti-TNF-α agent between 2002 and 2022 were included. Sociodemographic, clinical and laboratory data were obtained from the national register Reuma.pt at the time of initiation of the first anti-TNF-α agent and after 12 months. (M). Anxiety and depression symptoms were assessed by Hospital Anxiety and Depression Scale (HADS). A score ≥8 on the HADS-Anxiety and HADS-Depression indicates the presence of clinically significant anxiety and depression symptoms, respectively. Ankylosing Spondylitis (AS) Disease Activity Score Activity Score with CRP (ASDAS-CRP) and Bath AS Disease Activity Index (BASDAI) were assessed to measure disease activity. Pain Visual-Analogue-Scale (VAS), Bath AS Functional Index (BASFI) and Bath AS Metrorlogical Index (BASMI) were also collected to assess pain severity and disability. To evaluate enthesitis the Maastricht AS enthesitis score (MASES) was performed. Clinical response was evaluated by ASDAS response. Fatigue was evaluated using Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue: score ≥39 indicates the presence of clinically significant fatigue and health-related quality of life with EQ-5D. In order to correlate anxiety and depression with clinical outcomes, Pearson coefficient was used. Linear regression models adjusted for age, gender and disease duration were used to assess the impact of anxiety and depression symptoms on clinical outcomes.

Results: A total of 130 patients with SpA (mean age of 40.6±10.8 years old; 85.4% female; 74% with AS) with a median disease duration of 7 [4-14] years were included. Nearly half (50.6%) of patients had anxiety, 33.8% depression and 30% had both anxiety and depression symptoms. At the baseline, the median of anxiety and depression symptoms was 8 [4.5-12] and 6 [3-8], respectively. At the baseline, there were statistically significant correlations between anxiety and depression symptoms and pain-VAS at night (r =0.47, p=0.03 and r =0.6, p=0.004, respectively); between depression symptoms and BASMI (r =-0.34, p=0.006) and between anxiety and depression symptoms and EQ-5D (r =-0.56, p=0.04 and r =-0.65, p=0.011, respectively). At 12M, there were statistically significant correlations between anxiety symptoms and BASDAI (r =-0.23, p=0.03), FACIT-Fatigue (r =-0.68, p<0.001) and EQ-5D (r =-0.51, p=0.001); and between depression (r =-0.65, p<0.001) and EQ-5D (r =-0.59, p<0.001). In the multivariable regression models, depression symptoms at baseline moment predicted VAS at night (β =0.6, p=0.06). At 12M anxiety symptoms predicted BASDAI (β =0.2, p=0.027), FACIT-Fatigue (β =0.7, p=0.001) and EQ-5D (β =-0.5, p=0.002); depression symptoms also predicted EQ-5D (β =-0.6, p=0.001).

Conclusion: Anxiety and depression are common conditions in patients with SpA treated with anti-TNF-α agents. After 12M of treatment, anxiety and depression symptoms predicted worse quality of life and anxiety also predicted higher disease activity and fatigue. Our results encourage the assessment and monitoring of anxiety and depression symptoms over time in these patients in order to design more individualized multidisciplinary approaches. Further longitudinal research is needed to explore the impact of anti-TNF-α agents on anxiety and depression symptoms.

AUTOMATED VERTEBRAL FRACTURE ASSESSMENT AS A SCREENING TOOL IN PATIENTS WITH AXIAL SpondyloArthritis

Keywords: Outcome measures, Imaging, Spondyloarthritis M. Siderius 1, L. Bares 1, N. Littmann 1, G. Richter 1, Y. Van der Knaap 2, R. Slart 3, A. Spoorenberg 1, S. Arends 1, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Nuclear Medicine and Molecular Imaging, Groningen, Netherlands; 3University of Twente, Biomedical Photonic Imaging, Enschede, Netherlands

Background: Bone loss reflected by low bone mineral density (BMD) is common in axial spondyloarthritis (axSpA) and often already noticed at early stages of disease. Severe bone loss may lead to vertebral fractures (VF). Prevalent VF, low BMD and older age are well-known risk factors for the development of new VF. Manual assessment of VF according to the method of Genant et al. is considered as the gold standard, however, this is time consuming in research and clinical settings. Nowadays, when performing BMD measurements an automated screening method for detecting VF in patients with axSpA.
Objectives: To investigate the performance of aVFA in comparison to manual assessment of radiographic VF according to Genant method in patients with axSpA.

Methods: In this pilot study, we included axSpA patients from the GLAS cohort who underwent DEXA with aVFA and had spinal radiographs available within 1 year. Two independent trained readers assessed the vertebral bodies on the lateral view of the thoracic and lumbar spine for radiographic VF. Anterior, middle, and posterior heights of the 4th thoracic vertebra (Th4) to the 4th lumbar vertebra (L4) were exactly measured. VFA scans were analyzed from T4 to L4 by using a viewer (QDR, Hologic) with software supplied by the manufacturer and in which a computer-aided fracture assessment semi-automatically performs total vertebral assessment for each vertebra (T4-L4) on a lateral VFA image. In both methods, radiographic VF were defined according to the method of Genant et al.[1]. A prevalent VF was defined as ≥20% reduction in any vertebral height. Vertebrae were categorized as grade 0 (normal, <20% height reduction), grade 1 (mild, ≥20-<25% reduction), grade 2 (moderate, ≥25-<40% reduction) or grade 3 (severe, ≥40% reduction) fractures. Agreement was compared at vertebral level.

Results: In total, 40 axSpA patients were included; 58% were male, mean age was 46.2±14.2 years, mean symptom duration was 18.0±12.4, 80% were HLA-B27 positive, mean ASDAS was 2.1±1.0 and mean mSASSS (n=35) was 5.2 (IQR 1.2-18.3). At group level, median BMD T-score and BMD Z-score of the lumbar spine was -0.5 (-1.3-0.8) and -0.1 (-1.0-0.7), respectively. Osteoporosis was found in 1 (2.6%) patient and 15 (38.5%) patients had osteopenia, of these 56% were male and mean age was 46.7±14.1 years. In 477 (91.7%) vertebrae, there was absolute agreement on the aVFA and manual assessment (missing, normal or fracture and accompanying grade and fracture shape). In total, manual assessment detected 2 radiographic VF in 2 patients and aVFA detected 10 VF in 6 patients. The 2 fractures found with the manual method were seen in the lumbar spine, both grade 2 and wedged or biconcave shaped. The 10 aVFA fractures were found in the thoracic (n=5) and lumbar (n=5) spine; grade 1 (n=5), grade 2 (n=4) or grade 3 (n=1) and wedged (n=4) or biconcave (n=6) shaped. The fractures detected with manual assessment were both also detected with aVFA, but the fracture grading was different for one of these fractures (manual grade 2 vs. aVFA grade 3). 8 fractures detected with aVFA were not found with manual assessment. In 6 of these cases, the patient had extensive radiographic damage. X-ray quality was low in the 2 remaining cases. Regarding vertebrae defined as missing; aVFA could not assess 26 (5%) vertebrae compared to 8 (1.5%) for manual assessment.

Conclusion: In this pilot study using data from our observational cohort, aVFA seems a good first screening tool for the detection of radiographic VF in axSpA. Agreement was compared at vertebral level. The fractures detected with manual assessment were both also detected with aVFA, but the fracture grading was different for one of these fractures (manual grade 2 vs. aVFA grade 3). 8 fractures detected with aVFA were not found with manual assessment. X-ray quality was low in the 2 remaining cases. Regarding vertebrae defined as missing; aVFA could not assess 26 (5%) vertebrae compared to 8 (1.5%) for manual assessment.

PATIENT CHARACTERISTICS AND SPA FEATURES IN RECENTLY DIAGNOSED AXIAL SPONDYLOARTHRITIS PATIENTS STRATIFIED FOR CLINICAL DIAGNOSIS AND ASAS CLASSIFICATION CRITERIA; RESULTS FROM STANDARD-OF-CARE COHORT

Keywords: Gender/diversity issues, Spondyloarthritis, Epidemiology

J. M. Nijmeijer1, S. Kieskamp1, F. Wink2, S. Arends1, A. Spoorenberg2

1 University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2 Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands

Background: In axial spondyloarthritis (axSpA), besides the characteristic symptoms of chronic (inflammatory) back pain and stiffness, patients may suffer from peripheral and extra-skeletal manifestations. Within axSpA patients, patients can be diagnosed with ankylosing spondylitis (AS) or non-radiographic axSpA (nr-axSpA) based upon the presence or absence of radiographic sacroiliitis. Furthermore, patients can be classified as axSpA according to the ASAS criteria into the imaging arm for which radiographic sacroiliitis and/or sacroiliitis on MRI is mandatory or into the clinical arm for which the presence of HLA-B27 is mandatory. Until now, little is known about patient characteristics in these subgroups of axSpA with recent axSpA diagnosis.

Objectives: To explore patient characteristics and SPA features in recently diagnosed axSpA patients diagnosed as AS or nr-axSpA and in patients fulfilling the imaging or clinical arm of the ASAS classification criteria.

Methods: This cross-sectional analysis included consecutive axSpA patients between 2009 and 2019 diagnosed no more than 1 year before inclusion in the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort. Demographic data and all SPA features based on the ASAS classification criteria (sacroiliitis on pelvic radiograph according to the modified New York criteria, sacroiliitis on MRI according to the ASAS criteria, inflammatory back pain (IBP) according to the ASAS criteria; peripheral manifestations (peripheral arthritis, enthesitis and dactylitis); extra-skeletal manifestations (uveitis, psoriasis, inflammatory bowel disease); good response to a NSAID; family history of SpA; HLA-B27 status and CRP level) were collected at the GLAS baseline visits. Characteristics and features of the following axSpA subgroups were analyzed: clinical diagnosis AS vs. nr-axSpA, imaging arm vs. clinical arm of the ASAS classification criteria, only axial disease vs. axSpA with ≥1 peripheral manifestation.

Results: In total, 319 axSpA patients were included, with a mean age of 38.2 ± 12.0 years, 175 (55%) were male, mean symptom duration was 25 (19-34) years and 242 (76%) were HLA-B27 positive. 177 (55%) patients were diagnosed with AS and 142 (45%) with nr-axSpA. AS patients were more often male (65% vs. 42%, p<0.001), had more often IBP (89% vs. 78%, p=0.004), more often a SpA family history (38% vs 22%, p=0.002) and higher CRP (median 5 vs. 2, p=0.001) compared to patients diagnosed with nr-axSpA. The number of SPA features was not significantly different between patients diagnosed with AS or nr-axSpA (median 3.7 vs. 3.7, p=0.73). 265 (83%) axSpA patients fulfilled the imaging arm and 54 (17%) patients fulfilled the clinical arm. Patients fulfilling the clinical arm were per definition all HLA-B27 positive (100% vs. 71%, p<0.001), had more often IBP (92% vs. 80%, p=0.040) and a positive SpA family history (51% vs. 25%, p<0.001) compared to patients fulfilling the imaging arm. Furthermore, patients from the clinical arm showed a higher CRP (median 4 vs. 2, p=0.028) and had more SPA features (median 4.1 vs. 3.6, p=0.019). 200 (64%) axSpA patients had only axial involvement without peripheral manifestations and 111 (36%) axSpA patients had ≥1 peripheral manifestations, of which 69% had a history of peripheral arthritis, 37% enthesitis and 17% dactylitis. Accordingly, axSpA patients with peripheral manifestations presented significantly more SPA features than patients with only axial involvement (median 4.5 vs. 3.2, p=0.001).

Conclusion: In this large cross-sectional study of recently diagnosed (<1 year) axSpA patients, the presence of IBP, positive family history and higher CRP occurred significantly more often in patients diagnosed with AS compared to patients diagnosed with nr-axSpA and in patients fulfilling the clinical arm compared to patients fulfilling the imaging arm of the ASAS classification criteria.

DOI: 10.1136/annrheumdis-2023-eular.3641
(16.6 ± 11.7 vs 13.6 ± 9.4; p=0.045), higher body mass index (26.7 ± 4.6 vs 26.0 ± 4.8; p=0.043) and psoriasis (13.1% vs 3.8%; p=0.001) were more frequent in familial cases. HLA B27 positivity was higher tendency without statistical significance in patient with family history (66.4% vs 56.7%; p=0.60). In terms of structural damage, basal syndesmophyte, basal mSSASS, mSSASS progression and new syndesmophyte development could not differ between the groups. Family history was found in 30% of nr-axSpA patients. HLA B27 positivity, higher baseline mSSASS and basal syndesmophyte frequency were found more frequently in patient with family history among nr-axSpA. And also more mSSASS progression was detected in the same group (Table 1). In the nr-axSpA group, there was no difference in structural damage or radiological progression, except for longer symptom duration in those with a family history.

Conclusion: There was a significant frequency of family history in AxSpA and it might be contribute to the disease phenotype at different rates. The presence of family history in both baseline and follow-up data, especially in radiographic, seems to increase severity in disease subgroups.

Background: The absence of categoric radiographic evidence of structural changes in the sacroiliac joints serves to distinguish AS from nr-axSpA. Both groups of patients are characterized by active inflammatory changes, established by magnetic resonance tomography (MRT) of the sacroiliac joints, which, with the progression of the disease, are structurally progressive. Objectives: To determine whether it is possible to detect erosions, subchondral osteosclerosis, and bone marrow metaplasia on a magnetic resonance imaging of the sacroiliac joints in patients with non-radiographic axial spondyloarthritis and symptom duration less than 3 years.

Methods: A cross-sectional survey was conducted with rheumatologists and their consulting patients in Bulgaria from February 2012 through April 2019. Patients who had a rheumatologist confirmed diagnosis of nr-axSpA were eligible to participate. All patients met ASAS criteria for IBD with duration from 3 months to 2 years. All patients had no changes reported after the conventional X-ray of the sacroiliac joints and a performed subsequent MRI. Sacroiliac joint inflammation was assessed using the Canadian Spondyloarthritis Research Consortium (SPARCC). The SPARCC scores of sacroiliac joint inflammation and sacroiliac joint structural damage (SSSD) (erosions, bony bone metaplasia and subchondral osteosclerosis) were evaluated by both - a radiologist and a rheumatologist.

Results: A total of 98 patients with non-radiographic were included in this analysis. A higher proportion of patients were male patients (51% vs 37%). The mean age was 33.8±7.71 with mean symptoms duration 0.76±0.26 years. MRI showed bone marrow edema (BME) in all 98 patients and at least 1 structural lesion in 32 patients (92.5%). The most prevalent chronic lesions were erosive changes in 7.14% (n = 7) and narrowed joint space in 7.14% (n = 7). Fat metaplasia was found in 5.10% (n = 5) in the patients with nonradiographic axial spondyloarthritis. The mean values of SPARCC score in patients with the different arm of nr-axSpA is 22.42 ± 15.18. The burden of disease activity measured by BASDAI, ASDAS-CRP and VAS as well as ASQoL did not differ in patients with SSSD compared to those with BME only (p>0.05).

Conclusion: Patients with nr-axSpA are characterized by a short duration of symptoms. Regardless of this recent onset and initially normal X-ray image of the sacroiliac joints, in some patients there are objective data of previous inflammation of the sacroiliac joints that may have not been detected on X-ray. That arise raised question of low sensitivity of conventional radiography as well as the presence of risk factors for rapid structural damage and progression in some patients with nr-axSpA.

shown at Figure 1. FM patients were associated with a higher median tender joint count [1.0 vs 0, p=0.020] and swollen joint count [1.5 vs 0, p=0.037], BAS-DAI=14/10 [75.8%] vs 34/16.5%, p=0.002], mean ESSD index [0.6 vs 0.88, p=0.001], median overall work impairment [65 vs 10%, p=0.002], and activity impairment [50 vs 10%, p=0.001] than those without FM.

Figure 1. Pain areas and symptoms according to the 2016 Revisions fibromyalgia diagnostic criteria comparing participants with fibromyalgia and without fibromyalgia.

Conclusion: The prevalence of FM among Thai patients with SpA is low. However, it is important to identify and treat because it is associated with reduced productivity and poor quality of life. Active inflammation is associated with FM. Controlling SpA disease can also help to control FM.

Structural thickness: χ² = 1.5 p = 0.22

Conclusion: MASEI score and PD US positivity at entheseal level are possible predicting factors for the development of SpA in IBD patients. Further investigations from long term prospective studies need to confirm these preliminary data.

REFERENCES:
HCs [SMD = -0.324, 95% CI (-0.971, 0.323), P = 0.327]. Because of a significant statistical heterogeneity observed [p < 0.1, I^2 = 89.2%], we conducted sub-analyses based on individual definitions of Breg cells. We found that the proportions of CD19^+CD24^+CD38^- Breg cells have no significant difference between AS and HCs [SMD = -0.965, 95% CI (0.339, 1.590), P = 0.003] with no publication bias based on the Egger tests (t = 1.35, p = 0.236).

Conclusion: The levels of CD19^+CD24^+CD38^- Breg cells were significantly increased in AS patients, suggesting that the abnormalities of Breg cell numbers and function are the critical causes in the development of AS.

Conclusion: The fact that fCal level in the NSAID group is higher than the anti-TNF Group supports the literature that NSAIDs cause leaky gut syndrome by adversely affecting the gut microbiota. Higher fCal level in the NSAID group makes us think that in addition to intestinal inflammation caused by the disease, it is originated by the NSAID treatment [1]. In our study, the reason why the level of IL-23 in the NSAID group is lower may be the underlying mechanism through PGE2, and the reason why it is higher in the anti-TNF group may be that anti-TNF treatment has not had enough effect on the IL-17/23 pathway [2,4]. Especially the relationship of IL-17 level with MASES using for the clinical evaluation of the enthesitis areas, clinically shows us the role of the IL-17/23 pathway in the enthesal inflammation as well [5].

**PREGNANCY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

**Keywords:** Spondyloarthritis, Pregnancy and reproduction
Background: There is limited information available on the course of axial spondyloarthritis (AxSpA) during pregnancy, in contrast to other chronic inflammatory disorders. AxSpA poses a special set of challenges because it has anatomical and inflammatory consequences on pregnancy.

Objectives: The aim of this study was to evaluate the course of AxSpA during pregnancy.

Methods: In order to evaluate the course of AxSpA during pregnancy, an observational descriptive retrospective study was carried out at a private rheumatology clinic. Data were gathered using a self-administered questionnaire from 70 women who were diagnosed with AxSpA prior to pregnancy.

Results: The average age at disease onset was 23.6 years. Approximately one-third (35.7%) of patients said their AxSpA symptoms were worse during pregnancy, compared to 64.2% who said their symptoms got better. The postpartum flare was reported by 52.5% women. The mode of delivery was by cesarean section in 76% patients. Back pain and stiffness during pregnancy were the most prevalent symptoms. None of the patients had extra-articular manifestations during pregnancy or postpartum. Adverse pregnancy outcomes were reported by 15.7% patients. In our study, we found that the majority of women avoided using drugs even when they felt the need to do so out of concern for the foetus.

Conclusion: A large number of patients reported ease of symptoms during pregnancy. Due to the significant risk of flare, patients should be followed up during postpartum period. AxSpA females have an increased prevalence of cesarean sections.

COMPARISON OF HIP INVOLVEMENT IN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLARTHRITIS: A RETROSPECTIVE STUDY

Keywords: Spondyloarthritis

AB1053

MATRIX METALLOPROTEINASE-3: A BIOMARKER OF SPONDYLARTHRITIS

Keywords: Biomarkers, Spondyloarthritis, Diagnostic tests
Background: Several studies reported that matrix metalloproteinase 3 (MMP-3), an enzyme of the proteolytic system, is implicated in the pathogenesis and progression of several rheumatic diseases [1].

Objectives: We aimed to compare MMP-3 serum levels between spondyloarthriti s (SpA) patients and healthy controls.

Methods: We conducted a case-control study, including 164 subjects divided into two groups, all matched for age and gender: G1 including 82 SpA patients, diagnosed according to ASAS 2009 criteria, and G0 including 82 healthy controls. ELISA technique was used to measure MMP-3 serum levels. Statistical analyses were carried out using SPSS software, fixing a P value of <0.05.

Results: Each group included 65 men. The mean age was 45.32 ± 13.41 years. The mean disease duration was 757 ± 779 years. Radiographic axial SpA (r-AxSpA) and psoriatic arthritis (PsA) were noted in 65.9% (n=54) and 34.1% (n=28) of cases, respectively. In G1, axial manifestations were noted in 81.7% (n=67). A peripheral syndrome was associated in 45% (n=18); arthritis in 42.7% (n=35) and enthesis in 14.6% (n=12). The mean MMP-3 serum levels were statistically higher in G1 than in G0 (G1: 64.14 ± 187.31 [1.75 – 1237.36] versus G0: 12.06 ± 10.99 ng/mL [2.98 – 58.94], p=0.01). MMP-3 serum levels were significantly higher in PsA than in r-AxSpA patients (141.65 ± 366.33 [2- 1238] ng/mL versus 23.95 ± 31.67 [3- 149] ng/mL, p=0.006). The cutoff of 10.43ng/mL could discriminate G1 from G0 with a sensitivity and a specificity of 67.1% and 61% respectively (AUC: 0.647, p=0.001).

Conclusion: Our study showed that MMP-3 serum levels were significantly higher in SpA patients compared to controls. This finding suggests that MMP-3 plays a role in the pathogenesis of SpA. However, MMP-3 did not have high sensitivity and specificity in discriminating patients from healthy controls. Thus, MMP-3 was not a good biomarker for the diagnosis of SpA.

AB1054 - SPONDYLOARTHRITIS IN FIRST DEGREE RELATIVES OF ANKYLOSING SPONDYLITIS PATIENTS

Keywords: Imaging, Spondyloarthritis, Genetics/epigenetics

K. Bubov1, L. Hasikova1, M. Gregova1, K. Mintalova1, S. Forejtova1, L. Senoil1
1Institute of Rheumatology, Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic

Background: Ankylosing spondylitis (AS) is a relatively common inflammatory rheumatic disease with strong familial risk and heritability. The aim of this study was to examine first-degree relatives of patients diagnosed with AS to determine the presence of active spondylitis, fulfillment of Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axial and/or peripheral spondyloarthritis (SpA), and the clinical diagnosis of SpA.

Methods: One hundred subjects without a previous rheumatological diagnosis with a first-degree relative treated for AS were included in the study. Clinical data were collected and rheumatological examinations were performed by trained rheumatologists. Magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) was read by a trained rheumatologist who was blinded to all patient data. Subjects were further divided into both SpA (according to ASAS classification criteria and clinician opinion) and non-SpA subgroups.

Results: A total of 26 subjects met ASAS classification criteria for SpA, of which the diagnosis of SpA was confirmed in 14 subjects (13 subjects met ASAS classification criteria for axial and 1 subject for peripheral SpA). In addition, 12 individuals met the clinical arm of the ASAS classification criteria for axial SpA, but were not diagnosed with axSpA in the clinicians’ opinion. Active spondylitis as defined by MRI was present in all 13 individuals diagnosed with axSpA, 7 (54%) of whom also had advanced radiographic changes on conventional radiographs of the SIJ. In addition, active spondylitis as defined by MRI was also present in 4 individuals who did not have back pain. The data are shown in Figure 1. Analysis of clinical characteristics showed a significant difference in CRP and BASDAI between the SpA vs. non-SpA subgroups (6.8 ± 10.5 vs. 23.3 ± 14.1 mg/L, P<0.0048, and 3.1 ± 1.8 vs. 1.76 ± 1.78, respectively). Individuals diagnosed with SpA were more likely to be HLA-B27 positive and had inflammatory back pain compared to the non-SpA subgroup (87% vs. 43%, p=0.0069 and 57% vs. 9%, p=0.0002, respectively). Individuals who were not diagnosed with SpA but met the clinical arm of the ASAS classification criteria for axSpA were excluded from the analysis. Other clinical characteristics and differences between subgroups are shown in Table 1.

Conclusion: In this cross-sectional study, a quarter of the relatives of patients with AS met the ASAS classification criteria for SpA, and 14% were diagnosed with SpA based on physician opinion. These individuals had a significantly higher prevalence of HLA-B27, inflammatory back pain, and disease activity indices. It should be kept in mind that in a small proportion of individuals, active spondylitis may be present in relatives with first-degree AS even in the absence of back pain.

AB1057 INTERPRETATION OF DISEASE-SPECIFIC QUESTIONNAIRES ON DISEASE ACTIVITY, FUNCTIONAL CAPACITY AND QUALITY OF LIFE IN DAILY PRACTICE IN AXIAL Spondyloarthritis

Methods: Patients were recruited through a cohort study in a tertiary care university hospital. Participants were asked to complete a disease-specific questionnaire on disease activity, functional capacity, and quality of life at each visit. The questionnaire used was the Ankylosing Spondylitis Disease Activity Index (ASDAS) and the Health Assessment Questionnaire (HAQ).

Results: A total of 100 patients were included in the study. The mean age of the patients was 45.2 years, and 80% were male. The mean ASDAS was 1.6, and the mean HAQ was 0.6. The questionnaire showed good discriminative power, with higher scores indicating worse disease activity and lower functional capacity.

Conclusion: The disease-specific questionnaires used in daily practice were found to be reliable and valid tools for measuring disease activity, functional capacity, and quality of life in axial spondyloarthritis. Further research is needed to determine the impact of these measures on patient outcomes and to identify optimal cutoffs for clinical decision-making.
Background: Spondyloarthritis (SpA) are a group of autoimmune diseases, mainly affecting the musculoskeletal system, with typical axial or peripheral forms. Recent data from the literature show significant differences in SpA subsets, levels of disease activity, drug efficacy and quality of life between male and female sex. [1, 2] It is well known how disease activity and comorbidities could compromise physical function and quality of life of SpA patients.

Objectives: To describe the clinical characteristics of women with SpA in our single-centre cohort compared to men, in relation to clinical characteristics, disease activity, therapy and comorbidities.

Methods: Adult patients with a diagnosis of Psoriatic Arthritis (PsA) and Axial Spondyloarthritis (AxSpA) according to CASPAR (ClASsification criteria for Psoriatic Arthritis) and Assessment of SpondyloArthritis international Society (ASAS) criteria, regularly followed at the SpA clinic of our unit, were consecutively enrolled from April to December 2022. Their epidemiologic, clinic and clinimetric data were collected. Intergroups comparisons were assessed by using Chi-square, t-test and ANOVA. P values <0.05 were considered significant.

Results: A total of 200 patients were enrolled, 115 male (57.5%) and 85 female (42.5%) with comparable mean age values (M 56.13±14.48 years, F 56.84±12.22 years; p=0.508) and with a significantly shorter disease duration in women (12.9±10.3 years vs 17.05±12.08 years; p<0.001). No differences in the distribution of PsA or AxSpA based on gender were observed. Six patients had a diagnosis of enthesopathic SpA, all of them were women. Taking into account the clinimetric evaluations, female patients show higher values of both Disease Activity Index for Psoriatic Arthritis DAPSA (15.63 vs 9.40; p=0.003), Leeds Enthesitis Index (LEI) (0.46 vs 0.16; p=0.02) and Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index (0.7 vs 0.4; p=0.05). The total number of drugs [both Biological disease modifying anti-rheumatic drugs (bDMARDs) and conventional synthetic DMARDs] taken for disease control was 4.47±2.45 for women and 3.79±2.07 for men (p=0.012); no differences were observed between the 2 groups for any specific drug. Among the comorbidities, none of them was more prevalent in men, while osteoporosis (OP) (p=0.006), mood disorders (0.009), fibromyalgia (FM) (p=0.000015), osteoarthritis (OA) (0.007) and thyroid disease (p=0.000015) were significantly more frequent in women.

Conclusion: Women of our cohort show a significantly higher risk of developing an inflammatory bowel disease than men. Female patients have also higher levels of peripheral disease activity, both on joints and enthesis; moreover, they show a significantly lower persistence in drug therapy. Besides, they have a more complex disease, suffering more frequently of OP, OA, FM and thyroid diseases than men. Finally, it is very interesting to note how women tend to develop a much more complex disease, even with a significantly shorter disease duration than male patients. These data confirm how rheumatologists should focus on the assessment of women with SpA, aiming at promoting a closer monitoring of gastrointestinal symptoms, peripheral arthritis and enthesis and at preventing the development of comorbid conditions, thus optimizing also their quality of life and physical functioning.

AB1059

NETRIN-1 IN SPONDYLOARTHRITIS: A NOVEL MARKER TO PREDICT DISEASE ACTIVITY?

Keywords: Biomarkers, Real-world evidence, Spondyloarthritis

F. Baykal1, S. Erten2, B. C. Güven3, A. Kor4, F. Eren4, S. Neşeliolu4, B. Polat5, K. Gök6, B. Armagan7, I. Dogan8, Y. Mara8, S. Bayer9, O. Erel9. *Yildirim Beyazit University Medical School, Internal Medicine, Ankara, Turkey; **Yildirim Beyazit University Medical School, Internal Medicine, Rheumatology, Ankara, Turkey; *Ankara City Hospital, Rheumatology, Ankara, Turkey; **Yildirim Beyazit University Medical School, Biochemistry, Ankara, Turkey

Background: Netrin-1 is a chemorepellent and inhibits the migration of monocytes, neutrophils and lymphocytes by activation of its receptors. It has been revealed that netrin-1 can limit the inflammatory response, reduce tissue damage due to hypoxia and simultaneously suppress apoptosis. Due to this immune regulatory role, it has been hypothesized that netrin-1 can be used as a biomarker in rheumatic diseases.

Objectives: To compare plasma netrin-1 levels in axial spondyloarthritis (SpA) patients with the healthy subjects and to evaluate its relationship with disease activity and other clinical and laboratory parameters.

Methods: Patients with axial SpA between the ages of 18-65 who applied to Ankara City Hospital Rheumatology outpatient clinic between November 2021 and January 2022 were consecutively enrolled upon acceptance to participate. Pregnant patients, patients with systemic disease other than axial SpA and patients who were taking regular medication other than axial SpA treatment were excluded. A control group was formed from healthy volunteers with similar age and gender characteristics. In both groups, in addition to regular laboratory tests netrin-1 level was measured by an Enzyme Linked ImmunoSorbent Assay (ELISA) kit with an analytical unit of pg/mL (Elabscience, Texas, USA, Catalog No: E-EL-K3238; Lot No: GZWTKZ5SWSK).

Results: A total of 60 axial SpA patients and 56 healthy controls were included in the study. There was no statistically significant difference between the groups in terms of age, gender and netrin-1 levels between patients and controls (Table 1). Data regarding clinical characteristics, HLA-B27 positivity, acute phase reactants at the time of evaluation and disease activity scores of the axial SpA group was presented in Table 1. No significant differences were observed in netrin-1 levels in any comparison among all axial SpA patients, in ankylosing spondylitis (AS) and nonradiographic axial spondyloarthritis (nr-ax SpA) patient subgroups, and in healthy controls (all axial SpA vs control p=0.361, AS vs nr-axSpA p=0.790, AS vs control p=0.360, nr-axSpA vs control p=0.700).

Netrin-1 levels had a significant positive correlation with BASDAI (r=0.301 p=0.032), ASDAS CRP (r=0.320 p=0.022), VAS pain (r=0.340 p=0.015). Our results demonstrated a positive correlation between netrin-1 levels and disease activity in axial SpA patients, implying that netrin-1 may come to the forefront as a novel biomarker to predict disease activity in axial SpA.

Spondyloarthritis - clinical aspects (other than treatment)

**AB1060**

**EXPLORING DISEASE ACTIVITY AND PATIENT CHARACTERISTICS IN ANKYLOSING SPONDYLITIS (AS) IN EUROPE**

**Keywords:** Spondyloarthritis

D. Baldock1, M. Thoo2, R. Connolly3, E. Baynton1.1 United Kingdom, Ipsos Healthcare, London, United Kingdom; 2Kuala Lumpur, Ipsos Healthcare, Kuala Lumpur Malaysia; 3New York, Ipsos Healthcare, New York, United States of America

**Background:** Ankylosing Spondylitis (AS) is a form of arthritis that primarily affects the spine. It causes inflammation of the spinal joints that can lead to severe, chronic pain and discomfort[1]. The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is the most frequently used patient-reported outcome to measure disease activity in axial spondyloarthritis. There is no validated definition for disease remission using BASDAI, although a threshold of ≤3 has been used in clinical trials for low disease activity[2].

**Objectives:** The objective of this study was to examine AS patient characteristics of those with low disease activity (LDA) (BASDAI score ≤3), highlighting any nuances in treating these patients.

**Methods:** A multi-centre online medical chart review study of patients with AS was conducted between July 2022 – September 2022 among UK, FR, DE, IT & ES rheumatologists practicing across hospital and private practices. Physicians were screened for practice and patient volume. Charts of patients pre-scribed with biologics were included in the analysis.

**Results:** 262 sampled physicians collectively reported 524 AS patients. From the reported AS patients, 277 were recorded as having achieved LDA (‘LDA’) and 165 were recorded as not having achieved LDA (‘not LDA’). Among not LDA reported patients, a higher proportion were female vs the LDA cohort (32% vs 19%). Reported not LDA patients were more likely to suffer any additional co-morbidities vs LDA cohort (63% vs 44%). When analysing disease severity (physician-defined) status between these two patient groups, reported not LDA patients were more likely to be recorded as ‘mild’ at diagnosis vs LDA (14% vs 4%). In contrast, current (i.e. at time of consult) disease severity was more likely to be recorded as moderate/severe for the not LDA cohort vs the LDA cohort (76% vs 20%). In addition, reported not LDA patients recorded with higher mean disease and haematology scores.

**Table 1. Reported patient disease and haematology scores (mean)**

<table>
<thead>
<tr>
<th>Reported AS patients</th>

</thead>
<tbody>
<tr>
<td>Achieved LDA</td>
<td>0.8</td>
<td>0.4</td>
<td>10.7</td>
<td>3.6</td>
</tr>
<tr>
<td>Not achieved LDA</td>
<td>3.4</td>
<td>2.2</td>
<td>28.9</td>
<td>15.5</td>
</tr>
</tbody>
</table>

The most prominent biologic therapy class used to treat both patient groups are still TNFis; notable JAKI usage is more prominent in the not LDA cohort vs the LDA cohort (5% vs 5%).

**Conclusion:** From the sample submitted, it appears the not achieved LDA group are milder at diagnosis but show a greater disease severity/activity on their most recent consultation compared to the LDA cohort – it could be inferred that initial mild severity resulted in a lesser need to treat earlier and, as such, disease progression ensued. There may therefore be an argument to treat early with advanced therapies, regardless of initial disease severity. Further investigation using comparator cohort is warranted.

**RENAIINVOLVEMENT IN SPONDYLOARTHRITIS**

**Keywords:** Descriptive studies, Spondyloarthritis, Kidneys

S. Boude1, M. Ben Messaoud1, O. Saidane1, L. Rouached1, A. Ben Tekaya1, I. Mahmoud1, R. Tekaya1, L. Abdelmoula1.1 Hospital Charles Nicolle, Rheumatology, Tunisia, Tunisia

**Background:** Spondyloarthritis (SpA) encompasses a group of inflammatory diseases characterized by enthesitis, axial and eventually peripheral skeletal involvement. Extra-articular manifestations are common and important systemic features of SpA. The most common extra-articular manifestations are represented by uveitis, bowel disease, skin, heart, lung and kidney involvement. Renal complications are frequent among patients with SpA.

**Objectives:** The aim of the present study was to assess the epidemiological, clinical, biological and histological features of renal diseases in SpA.

**Methods:** A retrospective monocentric study was performed including patients diagnosed with SpA according to the ASAS criteria. Baseline data were obtained during the period from 2002 to 2022. We reviewed sex, age, disease duration and results of laboratory examination and uroanalysis in order to detect renal abnormalities.

**CORRELATION OF SUBFATIN, CTHRC1, CTRP3, CTRP6 LEVELS WITH DISEASE ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

**Keywords:** Prognostic factors, Spondyloarthritis

I. M. Baytarolu Uçar1, G. Sarg1, A. Tuzcu2, S. Cildag1, T. Senturk1. 1Usak Training & Research Hospital, Rheumatology, Usak, Turkey; 2Adnan Menderes University, Rheumatology, Aydin, Turkey; 3Adnan Menderes University, Biochemistry, Aydin, Turkey; 4Aydın Rheumatology, Aydın, Turkey

**Background:** It has been determined that biological treatments affect the serum concentration of these biomarkers independently of disease activity. As current adjuvants and known modulators of inflammation, it may play a role in evaluating the efficacy of treatment, especially in cases using biologic agents.

**Objectives:** To analyze novel biomarkers from the C1q TNF superfamily and their function in autoimmune inflammatory rheumatic disorders, as well as to look for a biomarker capable of evaluating both the clinical disease activity and aiding in the evaluation of therapy efficacy.

**Methods:** Sixty-one AxSpa patients and 30 healthy controls were enrolled in the study. Serum biomarkers subatlin, CTHRC1, CTRP3, CTRP6, IL-6, IL-17, TNF-α and disease activity indexes BASDAI, BASFI, MASES, ASDAS-ESR-CRP were evaluated and compared. Patients were then classified, and their serum biomarkers were also assessed according to their disease activity scores, and further according to their treatment regimens.

**Results:** None of the examined biomarkers revealed a discernable difference between patients and healthy controls. Although the difference was not statistically significant, healthy controls were found to have lower median concentrations of serum subatlin, CTHRC1, CTRP3, CTRP6, IL-6, IL-17, and TNF-α, Furthermore, no association between the research biomarkers and clinical disease activity was seen once the patients were categorized according to the severity of their disease. Finally, it was discovered that biological therapies had an impact on these biomarked serum concentrations (Table 1) regardless of the disease's activity.

**Conclusion:** Circulating levels of subatlin, CTHRC1, CTRP3, CTRP6, IL-6, IL-17, and TNF-α, which are novel adipokines and well-known inflammatory mediators, may be important for determining treatment effectiveness, particularly in patients receiving biologics. We were unable to prove a connection between serum bio-marker levels and clinical disease activity, though.

PREDICTORS OF ACTIVITY OF ANKYLOSING SPONDYLITIS DURING PREGNANCY

Keywords: Spondyloarthritis, Pregnancy and reproduction

M. Ajdynan1, N. Melkonyan1, E. Guryanova2, N. Zhuravleva2, V. Diodimova2, 1Yerevan State Medical University, Department Internal Diseases, Yerevan, Armenia; 2Chuvash State University by I. N. Ulianov, Department Internal Diseases, Cheboksary, Russian Federation

Background: The ratio of men and women suffering from ankylosing spondylitis (AS) approaches 1:1. Many women aged 30-40 think about motherhood, which makes it important to study the problem of pregnancy in AS.

Methods: The study included 38 pregnant women who met the New York criteria for ankylosing spondylitis, 1984. The average age of patients was 32.6±6.8 years, age at the onset of the disease was 22.8±12.9 years, disease duration was 132.9±67.3 months The BASDAI index for 1-3 months before conception, in the I, II and III trimesters averaged 2.2±1.85; 2.7±1.72; 3.3±1.87 and 3.4±2.15, respectively. 11 (28.9%) patients received genetically engineered biological preparations (GEP) 1–3 months before pregnancy, 8 (21.05%) patients in the month of conception, 4 (10.5%) and 1 (2.6%) women, respectively. Non-steroidal anti-inflammatory drugs (NSAID) were used in 71 cases (76.1%) and 16 (42.1%) women, respectively. 25 (65.7%) women planned an ankylosing spondylitis pregnancy, 7 - in the II, 1 - in the III trimester. The visits were carried out at 10-11, 20-21 and 31-32 weeks of pregnancy.

Results: In the first trimester of pregnancy with the level of activity according to BASDAI 92 patients with SpA who met the ASAS criteria were included in this study. Most patients with SpA complain of chronic pain during the course of the disease. Chronic pain can be explained by central sensitization (SS). Objectives: Our aim was to investigate the relationship between disease activity and SS in patients with SpA receiving biologic therapy.

Methods: 92 patients with SpA who met the ASAS criteria were included in this retrospective study. Demographic characteristics of patients, comorbidities, drug treatments, used Bath Ankylosing Spondylosis Metrology Index (BASMI), Bath Ankylosing Spondylitis Functional Index (BASFI), visual analog scale (VAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Index (ASDAS-CRP), Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), Central Sensitization Scale (SS) were calculated. Patients were divided into 2 groups according to BASDAI score <4 low disease activity and >4 high disease activity. Correlation parameters between groups were compared. ROC analysis was performed to estimate the disease activity of SS value and the optimal threshold value was determined.

Results: The proportion of patients with high disease activity was 41.3% (n=38 patients). There was no statistically significant difference between the low disease activity (group 1) and high disease activity (group 2) groups in terms of age, gender, body mass index, comorbid diseases, and the medical treatment (NSAID, steroid, methotrexate, sulfasalazine). There was no statistically significant difference between the groups in ESH, CRP and vitamin D levels. SS, MASES, BASFI, and ASDAS-CRP were found to be significantly higher in group 2 patients, respectively (40.87±12.26 vs 26.78±11.81, p<0.001; 6.32±3.60 vs 3.69±3.05, p<0.001; 5.77±2.12 against 2.90±1.33, p<0.001, 3.35±0.70 versus 2.43±0.45, p<0.001). A moderate correlation was found between the SS scale and ASDAS-CRP (r=0.421; p<0.001) and BASDAI (r=0.581; p<0.001). ROC curve analysis showed that the optimal threshold value of the SS scale score for high disease activity was 31.5% with 78.3% sensitivity and 78.1% specificity (AUC: 0.802, 95% CI: 0.687-0.917, p<0.001) (Figure 1).

Conclusion: It has been shown that the central sensitization scale, which is a simple and applicable scale, can be used to evaluate disease activity in SpA patients receiving biologic therapy.

AB1065 BERTOLOTTI SYNDROME: AN UNDER RECOGNIZED CAUSE OF INFLAMMATORY BACK PAIN?

Keywords: Spondyloarthritis, Pain, Quality of life

S. Stebbings1, C. White2, T. Doyle2. 1University of Otago, Department of Medicine, Dunedin School of Medicine, Dunedin, New Zealand; 2University of Otago, Department of Medicine, Dunedin School of Medicine, Dunedin, New Zealand

Background: Bertolotti syndrome describes a lumbosacral transitional vertebra (LSTV) which causes symptoms, usually low back pain. LATV is a congenital anomaly where the L5 vertebra has an unusual morphology. Bertolotti syndrome is an under-recognised condition by clinicians.

Objectives: To clarify the presentation of Bertolotti syndrome, whether there are features of inflammatory back pain (IBP) and the effect on quality of life.

Methods: In this pilot study, 62 patients with LSTV were identified on imaging (plain x-ray). Imaging was performed for a variety of indications, predominantly for back pain. In total, 34 patients agreed to take part, with 18 returning questionnaires. Questionnaires were selected for face validity and included: Calin IBP Questionnaire, EQ-5D Questionnaire, Visual analogue pain scale (VAS-P).

In view of Covid restrictions all contact was by phone and questionnaires were completed online or returned via post. Plain X-rays visualising the lumbar spine (LSTV) which causes symptoms, usually low back pain. LATV is a congenital anomaly where the L5 vertebra has an unusual morphology. Bertolotti syndrome is an under-recognised condition by clinicians.

Results: Seventeen (94%) of the participants (n=18) recorded a VAS-P score >3, indicating a clinically significant level of pain. The mean VAS-P score was 6 (range of 2-9). 89% of respondents scored at least 3/5 in the Calin questionnaire. Of the 5 features of inflammatory back pain in the Calin questionnaire, 4 out of the 5 were reported by most respondents. The exception was 'improvement on exercise', which was only reported by 18% of respondents. Quality of life was impaired-EQ-5D (mean: 0.503, range -0.074 to 0.796). The commonest radiological abnormality was enlarged aortic root (33%). Presence of sclerosis and/or osteoarthritis at the pseudoarticulation transverse process (100%) followed by pseudoarticulation with the sacrum (83%) and scoliosis (16.5%).

Conclusion: These results suggest Bertolotti syndrome is associated with pain in the majority of patients and affects quality of life. The character and site of the pain suggests that Bertolotti syndrome should be considered in the differential diagnosis of spondyloarthritis.

AB1066 DISEASE DURATION, AGE AND CLINICAL FEATURES RELATED TO AORTIC VALVE SCLEROSIS IN PATIENTS WITH SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Heart, Epidemiology

A. García-Alía1, P. Moya Alvarado2-3, H. S. Park2-3, A. Laiz2-3, C. Marco Pascual1, A. Casals Urquiza2, C. Pitarqu Grau1, C. Diaz-Tome1-3, B. Magallanes2-3, I. Castelvi2-3, S. P. Fernandez-Sanchez5, S. Ros1, A. Garcia-Gullien1, J. L. Tandapan1,4, A. M. Millán Arciniegas1, H. Codes1, L. Sainz Comas1, H. Corominas2,3,4. 1Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 2Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 3Universitat Autònoma de Barcelona, Medicine, Barcelona, Spain; 4Hospital Dos de Maig, Rheumatology, Barcelona, Spain

Background: Valve degeneration is prevalent in Spondyloarthritis (SpA) patients according to descriptive studies, but it is also common in general population. Disease burden may be a key factor for valve degeneration in SpA.

Objectives: Compare clinical, radiographic and laboratory parameters between patients with spondyloarthritis (SpA) with aortic valve sclerosis (AVS) with SpA without aortic valve sclerosis (AVS) compared disease duration since onset of symptoms, diagnosis, and age in patients with AVS and patients without AVS.

Methods: A retrospective cohort study was conducted. Eligible patients were 219 SpA patients that met ASAS criteria visited the SpA clinic between July – October 2022. A total of 75 patients that had an echocardiography carried out after SpA diagnosis were included. Aortic valve surgery, rheumatic valve disease, endocarditis and bicuspid valves were excluded. Missing information about SpA were collected prospectively. Comparison between groups was conducted using t test or U-Mann Whitney test according to variable distribution. Proportions were compared using risk difference (RD) or odds ratio (OR).

Results: AVS was observed in 30 (39.5%) patients. Description and comparison of the sample is summarized in Table 1. Age had an OR of 1.17 (95% CI 1.1-1.3) with minor increase of risk for AVS. Duration of disease and delay in diagnosis were similar in both groups. Smoking had a protective effect for AVS with OR for former smoker 0.36 (95% CI 0.12-1.11) and OR smokers 0.13 (95% CI 0.03-0.61). Other echocardiographic findings of the patients were: mild aortic insufficiency in 15 (19.5%) and moderate in 3 (3.9%). Mean aortic root diameter was 34.4±7.0mm.

Conclusion: Age showed small but statistically significant association with AVS. Disease duration measured since diagnosis or onset of 1st symptom did not show significant association. Surprisingly, smokers showed less AVS.

AB1067 OPTIC NEURITIS IN SPONDYLOARTHRITIS NAIVE TO TNFA INHIBITORS: A SYSTEMATIC LITERATURE REVIEW

Keywords: Spondyloarthritis

Gullien4, J. L. Tandaipan1,4, A. M. Millán Arciniegas1, H. Codes1, L. Sainz Comas1, H. Corominas2,3,4. 1University of Otago, Department of Medicine, Dunedin, New Zealand; 2University of Otago, Department of Medicine, Dunedin School of Medicine, Dunedin, New Zealand

Background: Optic neuritis (ON) is an under-recognised condition by clinicians.

Objectives: To assess the prevalence of ON in patients with spondyloarthritis (SpA) and to compare disease duration since diagnosis, age, sex, smoking history and extra-articular manifestations (EAM) among patients with and without ON.

Methods: A retrospective cohort study was conducted. Eligible patients were 219 SpA patients that met ASAS criteria visited the SpA clinic between July – October 2022. A total of 75 patients that had an echocardiography carried out after SpA diagnosis were included. Aortic valve surgery, rheumatic valve disease, endocarditis and bicuspid valves were excluded. Missing information about SpA were collected prospectively. Comparison between groups was conducted using t test or U-Mann Whitney test according to variable distribution. Proportions were compared using risk difference (RD) or odds ratio (OR).

Results: AVS was observed in 30 (39.5%) patients. Description and comparison of the sample is summarized in Table 1. Age had an OR of 1.17 (95% CI 1.1-1.3) with minor increase of risk for AVS. Duration of disease and delay in diagnosis were similar in both groups. Smoking had a protective effect for AVS with OR for former smoker 0.36 (95% CI 0.12-1.11) and OR smokers 0.13 (95% CI 0.03-0.61). THE ROLE OF HEPcidin IN THE FORMATION OF ANEMICAL SYNDROME IN PATIENTS WITH ANKYlosing SPONDYlitis AND ITS SIGNIFICANCE IN THE DIFFERENTIATION OF ANEMIA OF CHRONIC DISEASE, IRON DEFICIENCY ANEMIA AND THEIR COMBINATION

Keywords: Spondyloarthritids, Diagnostic tests

O. Zviahina, S. Shevchuk, O. Pavlik
National Pirogov Memorial University, Vinnytsya, Internal Medicine Chair # 2, Vinnytsya, Ukraine

Background: Anemia is a frequent comorbid condition in ankylosing spondylitis (AS) patients. Anemia of chronic disease (ACD), iron deficiency anemia (IDA) and their combination are most often found in patients. The differential diagnosis between ACD and IDA is important because they require different treatment and at the same time is complicated due to the presence of an inflammatory component. Objectives: To establish the role of hepcidin in the formation of anemic syndrome in AS patients and its significance in differentiating anemia of chronic disease, iron deficiency anemia and their combination.

Methods: The study included 76 patients diagnosed with AS according to the modified New York criteria (1984) and 26 controls. Among them, there were 47 patients without anemia and 29 patients with anemia (IDA, n=7; ACD with iron deficiency, n=6; ACD, n=15, folate deficiency anemia, n=1). The diagnostic list included a complete blood count, serum iron, total iron-binding capacity, transferrin saturation, serum ferritin, soluble transferrin receptors (sTfR), and hepcidin. In the literature, there are no clear criteria for gradation of hepcidin levels, therefore, for further analysis, a percentile comparison was performed and indicators corresponding to P25 (up to 25 ng/ml), P25 - P75 (25-35 ng/ml) and P75 (above 35 ng/ml) were selected control group. The statistical processing of the obtained results was carried out using the Microsoft Office Excel 2007 statistical software package.

Results: In the group of AS patients, 41 patients (54%) had hepcidin levels >P75, 16 (21%) <P25, and 19 (25%) within P25 - P75. Hepcidin levels in patients with anemia were 1.4 times higher (51.77 ± 4.62 ng/ml) than in people without anemia (36.08 ± 2.57 ng/ml). The level of hepcidin (35.84±7.50 ng/ml) in patients with IDA is practically comparable to the group of patients without anemia. The level of hepcidin (62.78±5.94 ng/ml) is 1.7 times higher in people with ACD than in people with IDA (p<0.05). Patients with ACD and iron deficiency in terms of hepcidin level occupy an intermediate place (48.53±9.50 ng/ml), which may indicate an important role in the pathogenesis of ACD and can be used as a diagnostic marker for the differential diagnosis of ACD and IDA. In the group of patients without anemia, we found no significant relationship between hepcidin and indicators of red blood and ferrokinetics. While in individuals with anemia we found the relationship of hepcidin with serum iron (r=0.26; p<0.05), soluble transferrin receptors (r=-0.15; p<0.05) and transferrin saturation coefficient (r=0.17; p<0.05). Conclusion: For AS patients, for the early differential diagnosis of the types of anemia (ACD, IDA, and ACD with iron deficiency), in addition to traditional methods, the complex of laboratory tests should include determination of the hepcidin level in blood serum. A high level of hepcidin indicates the presence of ACD.

Objectives: Few studies have explored the male and female disease features in Latin American population. The aim of this study was to examine the clinical presentation, disease onset characteristics, metrology, HLA frequency, and clinical characteristics of male and female SpA patients.

Methods: We used a cohort of Colombian SpA patients from 1990 to the current day. Patients were evaluated by rheumatologists, filled out validated questionnaires, and were classified according to the Assessment of SpondyloArthritis International Society (ASAS) classification criteria at the time of diagnosis. Using the available data, patients enrolled before 2011 were reclassified according to ASAS. We compared the features of both genders and used SPSS 26.0 to conduct statistical analysis.

Results: In this study, 469 SpA patients from a Colombian SpA cohort were included. There were 164 (34.9%) females and 305 (65.1%) males total. There were no statistically significant differences in ASAS classification; 61.2% of females and 50.6% of males had AxSpA, P = 0.3. However, nr-AxSpA was more prevalent among females (20.6%) than males (15.1%), P = 0.01. In all groups the frequency of HLA-B27 was comparable (15.9% vs. 11.2%, P = 0.1). And the prevalence of HLA-B27 was greater in men than in women (52.4% vs. 33.3%, P < 0.01). The symptoms at the onset of the disease had similar distribution in both sexes (table 1). Enthesopathy was more prevalent among women than males (82.4% vs. 72.4%, P = 0.02), but no arthritis, uveitis, psoriasis, and inflammatory bowel disease (table 1). In males, disease onset was more acute (40.7% vs. 27.3%, P = 0.04). Age at beginning of the disease was 32 (24.5 – 41.1) years for females and 24.9 (20.5 – 31.7) years for males (P < 0.01). The time to diagnosis (in months) was 39 (11.5 – 126) for females and 13 (3 – 71) for males (P < 0.01). Women had more functional impairment measured by BASFI and en, and men showed a higher C-reactive protein (CRP) (P < 0.01) (Table 1).

Conclusion:_nr-AxSpA is more frequent in women than in men, although radiographic disease is more prominent in men. The prevalence of HLA-B27 is higher in men with SpA. Males are older at the onset of the disease and were diagnosed sooner than females. Females had more disease activity as measured by BASDAI and functional impairment as measured by BASFI, whereas males have lower CRP levels.

ASAS: Assessment of Spondyloarthritis international Society; CRP: C-reactive protein; BASFI: Bath Ankylosing Spondylitis Functional Index; BASDAI: Bath ankylosing Spondyloarthritis Disease Activity Index.

CERVICAL SPINE INVOLVEMENT IN AXIAL SPONDYLOARTHRITIS. RADIOPHOTIC CHARACTERISTICS AND ASSOCIATED FACTORS

Keywords: Imaging, Spondyloarthritis, Descriptive studies

L. Berbel Arcobie1, X. Michelenia, J. A. Narvaeza2, J. M. Nolla1, J. Palacios Olí2, P. Maymo Paituvi1, X. Juanola-Roura1, Bellsviague University Hospital, Rheumatology, L’Hospitalat de Llobregat, Spain; Vall d’Hebron University Hospital, Rheumatology, Barcelona, Spain; Bellvitge University Hospital, Radiology, L’Hospitalat de Llobregat, Spain

Background: The study of the cervical spine (CS) in axial spondyloarthritis (axSpA) and its radiographic characteristics including the zygapophyseal joints (ZJ) may be helpful for early diagnosis, establishing a prognosis and sharpening treatment choices.

Objectives: To describe the prevalence and characteristics of CS involvement in a cohort of patients with axSpA and its associated factors, which have been followed up in the Rheumatology Department of a third level university hospital.

Methods: Descriptive, retrospective and unincentric study. Patients with an axSpA diagnosis based on the ASAS classification criteria, from March 2011 to December 2022, retrieved from a dedicated axSpA database were included.

Sociodemographic, clinical, radiographic and therapeutic variables were gathered. They were separated into two groups according to CS involvement; “CS group” as patients with BASRI≥2 in CS and/or a score ≥3 in ZJ measured by De Vlam method[1]; and “no CS group” as controls.

Results: A total of 340 patients were included (71.8% men; mean age 57.4 ± 14.9 years). CS involvement is common among axSpA (n=182; 53.5%). ZJ involvement was observed in 99 patients (29.1%), and of those, 21 did not show concomitant structural damage in the vertebral bodies. A total of 83 patients (24.4%) had damage in the vertebral bodies exclusively, and 37 (10.9%) had CS involvement without radiographic involvement of the lumbar spine (LS) (29.7% women). Patients from the CS group were predominantly men, older, had a higher BMI and higher prevalence of smoking (Table 1). They also showed a higher disease activity (BASDAI and ASDAS CRP), worse function in CS and LS, as well as more structural damage in both LS and sacroiliac joints. No differences were found between groups for positive HLA B27, age at diagnosis, familiar history of arthritis, enthesitis, dactylitis or extra musculoskeletal manifestations (uveitis, psoriasis or IBD).

Conclusion: The radiographic evaluation of the CS is relevant in axSpA, and it should be performed routinely, as well as the evaluation of the ZJ, as they are commonly involved in axSpA and related to higher disease activity and worse function.

1. University of Rome Tor Vergata, Rheumatology Allergology and Clinical Immunology, Rome, Italy; 2. University of Rome Tor Vergata, Gastroenterology Unit, Rome, Italy

Background: Micronutrient deficiency (MND) is common among patients with chronic inflammatory diseases. MND is associated with a pro-inflammatory status and co-morbidities. Recent evidence documented a relevant prevalence of MND in Spondyloarthritis (SpA) and its interplay with gender and inflammatory-ry-dependent dysmetabolism[1]. MND in patients with Enteropathic Spondyloarthritis (ESpA) has not been analyzed even though the concomitant occurrence of Inflammatory Bowel Disease (IBD) and SpA might strongly impact MNDs.

Objectives: In this study, we aimed at comparing for the first time the occurrence of anemia and deficiencies of ferritin (Fe), vitamin B12 (B12), folic acid (FA), and vitamin D [25(OH)D] in patients with ESpA, IBD without SpA, and isolated SpA.

Methods: In a prospective case-control study, consecutive subjects were enrolled among ESpA (Cases), IBD (Controls-1), and SpA (Controls-2) patients referring to one gastro-rheumatologic outpatient clinic at the “Tor Vergata” University Hospital (Rome, Italy). Each Case (ESpA) was retrospectively matched (1:1) for IBD type with one IBD subject from Controls-1 group. Inclusion criteria: 1) age ≥18 years; 2) follow up (≥2 visits/year); 3) recent (<3 mos) micronutrients data. Additional inclusion criteria for Cases: 1) diagnosis of SpA, 2) diagnosis of IBD. Additional inclusion criteria: 1) for Controls-1: diagnosis of IBD; 2) for Controls-2: diagnosis of SpA. Exclusion criteria: 1) for Controls-1: diagnosis of SpA; 2) for Controls-2: diagnosis of IBD. The disease activity was evaluated by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and C-reactive protein (CRP) levels in patients with Ankylosing Spondylitis. Magnetic Resonance Imaging (MRI) of the sacroiliac joints was performed on all patients using coronal oblique T1, T2 and STIR weighted sequences. Active sacroilitis was defined as the presence of inflammatory lesions according to the ASAS (Arthritis Research and Therapy) criteria. CRP was considered high if it was greater than or equal to 6 mg/L. The statistical analysis was performed using the Fisher and Chi-Squared test and a p-value of 0.05 was considered as the level of significance.

Results: One hundred ESpA (Cases) were enrolled and matched with 100 IBD (Controls-1, n=58 Crohn's Disease - CD, n=42 Ulcerative Colitis - UC), and 100 SpA including 81% psoriatic-SpA (Controls-2). The mean age was 38.5 ±25.7 (pg/ml), 23.7± 9 (ng/ml), 0.57± 0.32(ng/ml), respectively. The mean 25(OH)D deficiency (≤20 ng/ml) was more frequent in Controls-2 than in Controls-1 (15% and 19%, respectively) than in Controls-2 (7%) while Fe deficiency (>15 ng/ml) was similar between Cases and Controls-1 and significantly prevalent in both Cases and Controls-1 than Controls-2 (P=0.001 for both). The B12 deficiency (≤200 pmol/l) was similar between Cases and Controls-1 but it resulted more frequent in Controls-1 than Controls-2 (P=0.04). The rate of folate defect (≤4 ng/ml) was similar between Cases and Controls-1 but it resulted less frequent in Controls-2 than in both Cases (P=0.002) and Controls-1 (P=0.0001). The 25(OH)D deficiency (≤200 ng/ml) was more frequent in Controls-2 than Cases (P=0.02).

Conclusion: In this study, the results of this study did not demonstrate a significant association between CRP levels and active sacroilitis on MRI in patients with AS. However, the study suggests that MRI may allow for an early diagnosis of AS in the absence of biological inflammation, and that young onset may be a risk factor for active sacroilitis in AS patients. Further studies are needed to validate these findings and to better understand the relationship between CRP levels, imaging, and sacroilitis activity in AS patients.

IS THERE A RELATIONSHIP BETWEEN BONE TURNOVER MARKERS AND DISEASE ACTIVITY IN TUNISIAN SPONDYLOARTHRITIS PATIENTS?

Keywords: Spondyloarthritis, Vitamin D

S. Rekki1, S. Rahmouni1, K. Zouaoui1, S. Boussaid2, H. Aljani2, H. Sahli1, M. Elleuch1, 1 La Rabta hospital, Rheumatology, Tunis, Tunisia; 2 Yasminette Ben Arous Hospital, Rheumatology, Ben Arous, Tunisia

Background: It has been reported that disease activity was correlated to the alterations in vitamin D metabolism and increased bone resorption in patients with spondyloarthritis (SpA) [1].

Objectives: To investigate the relationship between bone turnover markers, Vitamin D levels and disease activity in SpA patients.

Methods: In this cross-sectional study, we included patients with SpA. In addition to the routine blood and urine tests, serum 25-(OH)D3, bone turnover markers (osteocalcin and Alkaline phosphatase (ALP) for formation, and serum C-terminal telopeptide (CTX) for resorption) of all participants were also measured. The disease activity was evaluated by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and AS disease activity scores (ASDAS-CRP) and the functional status by Bath Ankylosing Spondylitis Functional Index (BASFI).

Results: We included 79 patients (56 males, 23 females; mean age: 46.3 ± 19 years). The mean 25(OH)D3, Calcium, Phosphor, ALP, PTH, Osteocalcin, CTX values were 17.7 ± 9.8 ng/ml, 90.70 ± 12 (ng/ml), 36.10 ± 5.5 (mg/l), 94.6 ± 25(U/l), 38.5 ± 25.7 (pg/ml), 23.7 ± 9 (ng/ml), 0.57 ± 0.32(nmol/l), respectively. The mean

BACKGROUND

Axial spondyloarthritis (AxSpA) is a chronic inflammatory disease of the axial skeleton and peripheral joints that affects approximately 0.5% of the population. It is characterized by low back pain and stiffness, and in some cases, peripheral arthritis. The diagnosis of AxSpA is often delayed, and the correct utilization of MRI is essential for early detection and management. The purpose of this study is to assess adherence to the OMERACT/ASAS recommendations for MRI protocol in axial spondyloarthritis.

METHODS

We conducted a retrospective chart review of patients with axial spondyloarthritis (AxSpA) who underwent MRI at our institution. The MRI protocol was assessed to determine if it was fully compliant with the OMERACT/ASAS recommendations. The study included 102 patients with an average age of 39.3 years and a male-to-female ratio of 1.2:1. The MRI protocol was assessed for adherence to the OMERACT/ASAS recommendations.

RESULTS

The MRI protocol was not fully compliant with the OMERACT/ASAS recommendations in 45% of the patients. The most common deviations were the absence of short T1 inversion recovery (STIR) and T1-weighted sequences. These sequences are crucial for the detection of early bone and cartilage changes, which can be missed in non-compliant MRI protocols.

CONCLUSION

Axial spondyloarthritis is a chronic inflammatory disease that affects approximately 0.5% of the population. The diagnosis of AxSpA is often delayed, and the correct utilization of MRI is essential for early detection and management. The results of this study highlight the importance of adhering to the OMERACT/ASAS recommendations for MRI protocol in axial spondyloarthritis.

SPECTRUM OF AXIAL SPONDYLOARTHRITIS IN COLOMBIAN PATIENTS: NON-RADIOGRAPHIC VS RADIOGRAPHIC AXIAL SPA. RESULTS FROM GESPA COLOMBIAN COHORT

Keywords: Epidemiology, Spondyloarthritis

J. Rueda, G. Rodríguez Salas, A. M. Santos, M. J. Mantilla, J. C. Santacruz Devia, E. Calvo, J. G. Ballesteros, S. Arias, J. Rueda, M. Cardiel, C. F. Pacheco Tená, V. Navarro-Compán, J. Londono, Universidad de La Sabana, Cundinamarca, Chía, Colombia; Hospital Militar Central, Bogotá, Colombia; Universidad Nacional de Colombia, Medicine, Bogotá, Colombia; Clínica de Morelia, Michoacan, Michoacan, Mexico; Universidad Autónoma de Chihuahua, Medicine, Chihuahua, Mexico; La Paz University Hospital, Medicine, Madrid, Spain
Background: Spondyloarthritis encompasses several diseases with similar clinical, biochemical, and imaging features. Since 2009, these characteristics have allowed this disease to be classified into axial and peripheral, with the presence of chronic spinal pain and the age of onset of the disease being important criteria for the classification of axial spondyloarthritis[1]. Interest in non-radiographic axial spondyloarthritis has recently increased [2], but this information is limited in our population.

Objectives: To differentiate the clinical, biochemical, and imaging characteristics of one Colombian cohort of patients with radiographic and non-radiographic axial spondyloarthritis.

Methods: Patients with axial spondyloarthritis were consecutively recruited at a reference institution in Colombia from 2002 to 2015. A structured survey was conducted at the time of the diagnosis of the disease, which included sociodemographic, clinical, biochemical, and imaging variables. The presence of sacroiliitis was evaluated by local radiologist. Patients and disease characteristics were compared in sex, the age of onset, the duration of the disease, initial symptom, number of swollen joints, duration of morning stiffness, number of painful entheses. Compared with r-axSpA, patients with nr-axSpA had greater presence of HLA-B15 (P=0.04), presence of inflammatory spinal pain (P=0.01), history of relatives with spondyloarthritis (P=0.03), longer duration of enthesitis (P=0.001), low back pain (P=0.007) and gluteal pain (P=0.003) in the first episode, and greater back chest expansion (P=0.001) and distance in the Schober test (P=0.001) in non-radiographic axial versus radiographic axial patients.

Conclusion: Colombian patients with non-radiographic axial spondyloarthritis have higher presence of HLA-B15, higher frequency of inflammatory spinal pain, family history of spondyloarthritis, low back pain, and gluteal pain during the first episode of the disease, greater chest expansion and distance on the Schober test than patients with radiographic axial spondyloarthritis.

CLINICAL, RADIOLOGICAL AND BIOLOGICAL CHARACTERISTICS OF SPONDYLOARTHRITIS WITH COXITIS

Keywords: Spondyloarthritis, Prognostic factors
Spondyloarthritis (SpA) is the most common chronic inflammatory rheumatic disease with hip involvement, which is a marker of disease severity, given its major functional impact.

Objectives: Determine the clinical, biological and radiological characteristics of SpA with coxitis, and to determine the factors associated with its occurrence.

Methods: Retrospective and analytic study including patients with SpA. Clinical demographics, biological radiological data, and activity scores were collected. The significance threshold was set for a value of p < 0.05.

Results: These were 333 patients, of which 54.1% were men. The mean age at onset was 40.52 ± 15.05 years, and the mean age at onset was 32.02 ± 15.42. The percentage of smoking patients was 11.1%. HLA-B27 was positive in 57% and uveitis was present in 7.2% of patients. Coxitis was present in 25.52% of patients, it was inaugural in 10.5% and bilateral in 71.76% of cases. Coxitis was more common in men; the male gender accounted for 76.47% in SpA with coxitis versus 46.37% without coxitis (p < 0.001). The mean age of SpA onset was lower in patients who developed coxitis (24.4 ± 13.75 years versus 34.6 ± 15.14 years; p = 0.014). Pure axial form and low back and buttock pain were more noted in patients with coxitis (18.8% versus 13.3% p = 0.022, 31.7% versus 18.9% p = 0.018 respectively). Enthesopathy was more common in SpA without coxitis (56.86% versus 35.3%, p = 0.001). There was no significant difference between the two groups for CRP and erythrocyte sedimentation rate (p = 0.91; p = 0.35), nor for ASDAS and BASDAI (p = 0.95; p = 0.38 respectively). Also a frequency not modified by the presence or absence of coxitis was noted, in particular for the family history of SpA, smoking, HLA-B27, uveitis, the existence of radiographic sacroilitis.

In multivariate analysis, coxitis was associated with male gender, early age of onset, and pure axial form.

Conclusion: Our study showed that the presence of coxitis was associated with early disease onset, male sex and pure axial form of SpA.

IS HLA-B27 ASSOCIATED WITH BIOMARKERS OF OSTEOFORMATION IN SPONDYLOARTHRITIS? RESULTS OF A STUDY FROM NORTH AFRICA

Keywords: Biomarkers, Spondyloarthritis

K. Maatallah1, Z. Zeineb1, I. Ayadi2, H. Ferjani1, M. Kallel Sellami2, D. Ben Nessib1, D. Elhaj Mahmoud2, W. Kaabachi2, D. Kaffel1, L. Laadhar2, H. Arabi1, F. Idrissi Zaki1, H. Teba1, A. Mougui1, I. El Bouchti1.

Background: The Wnt signaling pathway is a signaling pathway regulating bone metabolism. Dickkopf1 (DKK-1) and Sclerostin are potent inhibitors of osteoblasts, which regulate bone turnover.

Objectives: To investigate the association between the presence of these biomarkers (DKK-1; p = 0.744), (Sclerostin; p = 0.870), (OPG; p = 0.835).

Methods: One hundred and nine patients were included, with a mean age of 43 ± 19 years and a sex ratio M/F of 1.65. The mean age of SpA diagnosis was ± 11 years. Seven patients had a juvenile onset of the disease. HLA-B27 allele was present in 30 patients (27.5%). The respective medians [range] of serum levels, in pg/mL, of DKK-1, Sclerostin, and OPG were 146.7 [40-553], 32.8 [0-488], and 471 [0-1613]. HLA-B27 was not associated with any of these biomarkers (DKK-1: p = 0.744), (Sclerostin; p = 0.870), (OPG: p = 0.835).

Conclusion: Our study suggests that there is no association between inhibitors of the Wnt signaling pathway as well as OPG and HLA B27.

Background: Sacroiliac joint radiographs allow the evaluation of the symmetry region and ischial enthesis regions as well as the evaluation of the sacroiliac and hip joints in patients with axial spondyloarthritis (axSpA).

Objectives: In this study, it is planned to test and review the relationship between the presence of symphysis and disease-related factors and other radiological involvement factors.

Methods: Of 384 patients with axSpA and whose sacroiliac joint radiographs were evaluated for symphysis were included in the study. The presence of symphysis was not detected in non-radiographic axSpA patients.

In multivariate analysis, coxitis was associated with male gender, early age of onset, and pure axial form.

Conclusion: Our study showed that the presence of coxitis was associated with early disease onset, male sex and pure axial form of SpA.

**Background:** Improvement in health-related quality of life (HRQoL) is a key goal of psoriatic arthritis (PsA) therapy.¹ Here, we assess whether early clinical response predicts long-term improvement in HRQoL for patients (pts) with PsA and inadequate response to 1–2 tumour necrosis factor inhibitors (TNF-IR).

**Objectives:** Assess the association between early clinical response across various PsA domains and HRQoL at Week (W)48, as well as identify baseline (BL) characteristics that could predict early response in gusekumab (GUS)-treated TNF-IR PsA pts in the Phase 3b COSMOS trial.

**Methods:** In the randomized controlled COSMOS trial (NCT03796858),[3] adults with active PsA (swollen/tender joint counts [SJC/TJC] each ≥3) and TNF-IR were randomized: 2:1 to receive subcutaneous injections of either GUS 100 mg (at W0, W4, W4, every 8 weeks through W44) or placebo (at W0, W4, W12, W20, followed by GUS at W16 [early escape] or at W24 [planned], W28, W36, W44). Only pts randomized to GUS were included in this analysis. Long-term improvements in HRQoL were defined as clinically significant changes from BL to W48 in 36-item short-form survey (SF-36) physical and mental component summary (PCS and MCS) and Dermatology Life Quality Index (DLQI) scores. Early clinical response was defined as achievement of the following criteria at W4 or W8: American College of Rheumatology (ACR)20, pt pain on a visual analogue scale (VAS) ≤15, SJC ≤1, skin VAS ≤20, and health assessment questionnaire – disability index (HAQ-DI) ≤0.5. In addition, Psoriasis Area and Severity Index (PASI) ≤1 was considered at W16 – the earliest PASI assessment. Analyses were restricted to pts not meeting the respective early response criteria at BL. Long-term HRQoL improvements were compared between pts achieving vs not achieving early response criteria by means of Student's t-test and by multivariate linear regression model including BL for demographic and BL pt disease characteristics. Results from the multivariate linear regression analyses are presented here. Demographic and BL pt disease characteristics predicting early clinical response were investigated using multivariate logistic regression.

**Results:** Overall, 189 pts were randomized to GUS, with a mean age of 49.1 years, and 45.5% were male. Among pts not meeting the respective early response criteria at BL, GUS led to 2.7–19.0% and 4.3–38.4% of pts achieving one of the clinical responses of interest as early as W4 and W8, respectively. SF-36 PCS improvement from BL to W48 was significantly associated with ACR20 response, SJC ≤1 and HAQ-DI ≤0.5 achievement at W4 as well as at W8. There were no significant findings for SF-36 MCS. DLQI improvement from BL to W48 was significantly associated with ACR20 and skin VAS ≤20 at W8 (Figure 1). Improvements in SF-36 PCS, SF-36 MCS and DLQI at W48 were all significantly associated with achievement of PASI ≤1 at W16. Multivariate logistic regression identified significant (P<0.05) associations between males and early clinical response at W8 (ACR20: odds ratio [OR]=1.98; HAQ-DI ≤0.5: OR=3.71), BL SJC and SJC ≤1 at W8 (OR=0.84), BL HAQ-DI and HAQ-DI ≤0.5 at W8 (OR=0.23), and BL skin VAS and skin VAS ≤20 at W8 (OR=0.98).

**Conclusion:** For early clinical GUS, ACR20 response at W4 and W8 was positively associated with SF-36 PCS improvement from BL to W48, and also at W8 with DLQI improvement from BL to W48. Therefore, early clinical response is relevant for HRQoL improvements over time. These results may help in shared decision-making processes.

HALF OF THE PSORIATIC ARTHRITIS PATIENTS IN A GERMAN CLAIMS DATA CENTER EXPERIENCE POLYPHARMACY

**Keywords:** Psoriatic arthritis, Comorbidities, Health services research

K. Albrecht², A. Regierer², A. Strangfeld¹, U. Marschall³, J. Calhoff²,²German Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin, Germany; ³Charité-Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; ²BARMER, Institute for Health System Research, Wuppertal, Germany; ³Charité-Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany

**Background:** Psoriatic arthritis (PsA) therapy and comorbidity almost inevitably lead to the issue of polypharmacy (intake of ≥ 5 medications daily), which may further challenge the management of the disease. There is a lack of data on polypharmacy in PsA.

**Objectives:** To assess polypharmacy in women and men with PsA.
Methods: From the German BARMER health insurance database, 11,984 persons with PsA and DMARD therapy in 2021 were included and compared to sex and age matched controls without inflammatory arthritis. Medications were grouped by Anatomical Therapeutic Chemical groups. Polypharmacy (≥5 concomitant drugs) was compared by sex, age and comorbidity using the Rheumatic disease comorbidity index (RDCI, range 0-9) and the Elixhauser comorbidity index (range 0-31). The mean difference in the medication number between persons with PsA and controls was estimated with a linear regression model.

Results: From all adult persons insured in 2021 (n=7.4 Mio.; 190,000 (2.6%) had a diagnosis of psoriasis (ICD-10-GM Code L40). Of those, 20,245 (11%) had a PsA diagnosis (L40.5 + M07.0-3) and 11,984 received any DMARD therapy. A total of 119,840 persons without diagnoses of inflammatory arthritis were included as controls. A total of 63% of all persons with PsA and DMARD therapy were women and the overall mean age was 60 years (Table 1).

Polypharmacy was significantly higher in PsA (49%) compared to controls (17%), more frequent in women (52%) compared to men (45%) and strongly increased with age (15% in 18 to 30 yrs., 76% in >80 yrs.) and comorbidity. Comorbidity was more frequent in PsA compared to controls (mean Elixhauser comorbidity score 3.6 vs. 2.2 in controls, table 1). This applies to the conditions of the metabolic syndrome: hypertension (57% vs. 42% in controls), dyslipidemia (32% vs. 27%), diabetes (21% vs. 13%) as well as to all other comorbidities, in particular osteoarthritis (35% vs. 15%) and depression (28% vs. 16%). Compared to controls, all ATC drug classes were significantly more frequent in persons with PsA, most commonly drugs for the musculoskeletal system (81% vs. 30%), immunomodulating agents (66% vs. 26%), cardiovasculars (62% vs. 48%), alimentary tract metabolism (57% vs. 31%) and nervous system (50% vs. 31%) (frequencies for PsA see Figure 1). For each unit increase of the RDCI, the age-adjusted number of prescribed medications increased by 0.98 (95% CI 0.95; 1.01) units in men and 0.90 (0.96) units in women. Compared to controls, the number of prescribed medications (mean 4.9 (2.8)) was 2.4 (2.34; 2.43) units higher in women and 2.3 (2.21; 2.39) units higher in men.

Conclusion: Polypharmacy commonly presents in PsA and is composed of PsA-specific medication as well as medication for frequent comorbidities, equally affecting women and men. While DMARD therapy is essential to prevent subsequent damage, systemic GC should be avoided in PsA and analgesics might be dispensable if PsA is well controlled. With regard to the elderly, more frequent therapy with bDMARDs should be discussed which may result in reduced use of analgesics, opioids, and other secondary-induced co-medication.

Acknowledgements: The study was supported by the Federal Ministry of Education and Research within the network TARISMA (01EC1902A). The authors thank the BARMER for providing access to data via their data warehouse for this study. We thank the patient partners in the TARISMA project for dedicating their time to add the patient view to this project.

Methods: This post hoc analysis evaluated 1120 adults with active PsA despite standard therapies from DISCOVER-1 (D1) (swollen & tender joint counts [SJC/TJC] ≥3 each, CRP ≥0.3mg/dL, 1-2 prior TNF inhibitors [TNFi] in 31% of pts) and D2 (SJC/TJC ≥5 each, CRP ≥0.6mg/dL, biologic-naive). Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO)—GUS 100mg Q4W at W24. Time to MCII in outcomes of interest, i.e., in SJC/TJC ≥5.7, Joint Visual Analogue Scale [VAS] ≥15mm, Pain ≥15mm, HAQ-DI ≥0.35, PASDAS ≥0.8, PGA ≥15mm, Skin VAS ≥15mm, FACIT-F ≥4, SF-36 PCS ≥3, was compared between GUS vs PBO with Cox regression adjusting for baseline (BL) levels of respective outcome, treatment group, prior TNFi use, and BL DMARD use. MCII achievement was determined using non-responder imputation and compared between GUS and PBO using logistic regression adjusting for the above covariates. The association between MCII achievement at W4/W8 and stringent clinical response at W24/W52 amongst GUS-treated pts was assessed with logistic regression adjusting for prior TNFi use and BL DMARD use.

Results: Time to achieve MCII in all studied outcomes was significantly shorter (hazard ratio range: 1.3-2.5; all p<0.01) for both GUS Q4W and Q8W vs PBO, including cDAPSA as a representative example (Figure 1), with curve separation occurring at the first timepoint assessed. MCII rates also were significantly higher with GUS vs PBO at the first timepoint assessed, i.e., W4 for cDAPSA, Joint VAS, Pt Pain, and HAQ-DI and W8 for PASDAS, PGA, Skin VAS, FACIT-F, and SF-36 PCS (Table 1).

Background: The Group for Research and Assessment of Psoriasis and PsA advocates addressing all aspects of disease, including optimizing functional status and improving health-related quality of life (HRQoL).[1] Gusekumb (GUS) has demonstrated robust efficacy across key PsA domains at week (W) 24, with effects sustained or further enhanced through 2 years.[2-4] Timing of clinically meaningful improvement in disease activity (DA), functional status, and HRQoL is of interest to PsA patients (pts) and providers.

Objectives: 1) Evaluate effect of GUS on time to minimally clinically important improvements (MCII) in pt reported outcomes and composite measures of DA; 2) Assess association between W4/W8 MCII achievement and later disease control (W24/W52).

Methods: From the German BARMER health insurance database, 11,984 persons with active PsA despite standard therapies from DISCOVER-1 (D1) (swollen & tender joint counts [SJC/TJC] ≥3 each, CRP ≥0.3mg/dL, 1-2 prior TNF inhibitors [TNFi] in 31% of pts) and D2 (SJC/TJC ≥5 each, CRP ≥0.6mg/dL, biologic-naive). Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO)—GUS 100mg Q4W at W24. Time to MCII in outcomes of interest, i.e., in SJC/TJC ≥5.7, Joint Visual Analogue Scale [VAS] ≥15mm, Pain ≥15mm, HAQ-DI ≥0.35, PASDAS ≥0.8, PGA ≥15mm, Skin VAS ≥15mm, FACIT-F ≥4, SF-36 PCS ≥3, was compared between GUS vs PBO with Cox regression adjusting for baseline (BL) levels of respective outcome, treatment group, prior TNFi use, and BL DMARD use. MCII achievement was determined using non-responder imputation and compared between GUS and PBO using logistic regression adjusting for the above covariates. The association between MCII achievement at W4/W8 and stringent clinical response at W24/W52 amongst GUS-treated pts was assessed with logistic regression adjusting for prior TNFi use and BL DMARD use.

Results: Time to achieve MCII in all studied outcomes was significantly shorter (hazard ratio range: 1.3-2.5; all p<0.01) for both GUS Q4W and Q8W vs PBO, including cDAPSA as a representative example (Figure 1), with curve separation occurring at the first timepoint assessed. MCII rates also were significantly higher with GUS vs PBO at the first timepoint assessed, i.e., W4 for cDAPSA, Joint VAS, Pt Pain, and HAQ-DI and W8 for PASDAS, PGA, Skin VAS, FACIT-F, and SF-36 PCS (Table 1).

References:

Methods: In DISCOVER-2, biologic-naive adults with active PsA (swollen joint count ≥5, tender joint count ≥5, C-reactive protein [CRP] ≥0.6 mg/dL) were randomized 1:1 to GUS 100 mg every 4 weeks (Q4W) or placebo (PBO) for 52 weeks. Blood samples from consenting GUS-treated pts (Q4W and Q8W pooled) were assessed for serum cytokine levels (N=100), including TNF-α, IL-1β, IL-6, and other serum cytokine levels through Week 24 (W24) of GUS treatment are associated with clinical response through 2 years.[4] Objectives: Further assess effects of GUS on serum cytokine and collagen turnover biomarkers from W24 through W100 (2 years) and explore associations between biomarker changes and improvements in PsA activity (measured by changes in Disease Activity Score in Psoriatic Arthritis [DAPSA] score, Psoriasis Activity Disease Activity Score [PASDAS], Psoriasis Area and Severity Index [PASI] score) assessed. Associations between biomarker changes and achievement of American College of Rheumatology (ACR)50 response at W100 were also assessed. Results: Continued treatment with GUS led to significant and sustained reductions in serum cytokines from W24 through W100. Reductions in CRP and IL-6 were associated with changes in DAPSA score; with a similar trend observed for PASDAS. Reductions in CRP and IL-6 were associated with improved responses in the PASI score, and reductions in collagen turnover biomarkers correlated with changes in the PASDAS (Table 1). Continued disease improvement with long-term GUS treatment, assessed clinically using ACR50 response, was supported by the further reductions in CRP, AA, IL-6 and collagen turnover biomarkers in ACR50 responders at W100 who were ACR50 nonresponders at W24 (Figure 1). These results provide molecular evidence that sustained reductions in serum acute phase proteins and collagen turnover biomarkers may contribute to the continuous, durable improvements in joint symptoms and that reductions in Th17-related effector molecules contribute to improvements in skin symptoms seen in PsA pts receiving GUS.

## Discussion

COVID-19 was among the most frequently reported AEs during the 2-year period of the pooled POETYK PSO-1, PSO-2, and LTE trials due to the temporal overlap of the pandemic with the trials. However, COVID-19 infection and death rates did not differ from those observed in the reference population.

**Background:** The IL-23p19-subunit inhibitor guselkumab (GUS) demonstrated clinically meaningful improvements in fatigue through one year of treatment1 independent of its effects on American College of Rheumatology 20% (ACR20) improvement criteria and Minimal Disease Activity (MDA) achievement2.

**Objectives:** In this post-hoc analysis, the Functional Assessment of Chronic Illness Fatigue (FACIT-F) scale was used to evaluate the long-term effect of GUS in maintaining or further improving fatigue between week (W) 52 and W100, and to identify potential early (W8) predictors, in terms of fatigue, of GUS treatment were further enhanced through 2 years, at which time nearly a third of GUS-treated pts reported normative FACIT-F levels. Early targets in FACIT-F levels achieved with GUS were identified to aid in guiding treatment decisions in routine clinical practice.

**Conclusion:** The clinically meaningful improvements in fatigue seen after 1 year of GUS treatment were further enhanced through 2 years, at which time nearly a third of GUS-treated pts reported normative FACIT-F levels. Early targets in FACIT-F levels achieved with GUS were identified to aid in guiding treatment decisions in routine clinical practice.
Background: Patients (pts) with psoriatic arthritis (PsA) experience lower quality of life than both the general population and pts with psoriasis alone.[1,2] Recent PsA treatment recommendations highlight the importance of maximizing long-term (LT) health-related quality of life (HRQoL) and social participation as primary goals of therapy.[3]

Objectives: To determine whether early clinical improvement with gusekumab (GUS) predicts future attainment of enhanced HRQoL.

Methods: DISCOVER-2 enrolled adults naïve to biologics/JAK inhibitors who had active PsA defined as swollen joint count (SJC) ≥20, tender joint count (TJC) ≥20, and C-reactive protein (CRP) ≥0.3 mg/dL. 739 pts were randomized (1:1:1) and treated with GUS 100 mg every 4 weeks (W4), GUS 100 mg at W0, W4, then Q8W (n=248); or placebo (PBO) (n=246). In this post hoc analysis, pts treated with GUS Q4W and GUS Q8W were pooled. Early (W8) clinical improvement was defined as any of: (i) ≥20% improvement in SJC, TJC, pt pain, pt skin visual analog scale (VAS), and Health Assessment Questionnaire-Disability Index (HAQ-DI); (ii) ≥4-point improvement in the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score; (iii) minimally clinically important improvement (MCII) in clinical disease activity in PsA (cDAPSA; ≥5.7 points); (iv) change in Leeds enthesis index (LEI) and dactylitis severity score (DSS) at W8 among pts with baseline (BL) enthesis and dactylitis, respectively. Time-averaged changes in HRQoL estimates from BL to W52-100 were determined for Dermatology Life Quality Index (DLQI), EQ-5D Index & VAS, and SF-36 mental (MCS) and physical (PCS) component summary scores. The association between early clinical improvement at W8 and LT HRQoL among GUS-treated pts was assessed with mixed models.

Results: Clinical improvement by W8 was significantly greater among GUS-treated patients compared with PBO. Early clinical improvement with GUS was associated with greater increase in HRQoL (EQ-5D) at W52 through W100, with the exception of SJC on EQ-5D VAS (Figure 1; LEI & DSS results not shown). Similarly, pts achieving early clinical improvement in any domain except DSS and SJC experienced significantly greater benefits in physical function (SF-36 PCS) at W52-W100. Early improvements in skin disease and fatigue were associated with greater improvement in mental health (SF-36 MCS) at W52-W100, while for early clinical improvement, benefits in HRQoL were also observed in pts without clinical improvement at W8.

Conclusion: Clinical response at W8 with GUS was associated with significantly greater improvements in HRQoL from W52 through W100. Although pts without early clinical improvement demonstrated benefits in LT HRQoL, early response in distinct PsA domains differentially impacted more specific aspects of HRQoL over 2 years. In contrast, significantly greater improvements in overall and physical HRQoL were observed among responders across several PsA domains.

BIMEKIZUMAB EFFICACY IN HIGH-IMPACT AREAS FOR PATIENTS WITH MODERATE TO SEVERE PLAQE PSORIASIS: POOLED RESULTS THROUGH TWO YEARS FROM THE BE SURE AND BE RADIANT PHASE 3 TRIALS

Keywords: Skin, Outcome measures, Clinical trials

J. F. Merola, 1. A. Bettlie, 2 A. Morita, 3 J. M. Carracciosca, 4 E. Elewski, 5 I. Tif, 6 S. Wiegartz, 7 K. Wixted, 8 U. Mrowietz, 9 Harvard Medical School, Brigham and Women's Hospital, N/A, Boston, Massachusetts, United States of America; 10 The Icahn School of Medicine at Mount Sinai, Department of Dermatology, New York, New York, United States of America; 11 Nagoya City University Graduate School of Medical Sciences, N/A, Nagoya, Japan; 12 Hospital Universitari Germans Trias I Pujol, UAB, IGT/N, Badalona, Spain; 13 University Hospitals of Cleveland, Case Western Reserve University, Department of Dermatology, Cleveland, Ohio, United States of America; 14 UCB Pharma, N/A, Slough, United Kingdom; 15 UCB Pharma, N/A, Monheim, Germany; 16 UCB Pharma, N/A, Raleigh, North Carolina, United States of America; 17 Psoriasis Center, University Medical Center Schleswig-Holstein, Department of Dermatology, Campus Kiel, Germany

Background: High levels of complete clearance of plaque psoriasis in high-impact areas such as the scalp, nails, palms and soles have been reported in patients (pts) after 1 year (yr) of bimekizumab (BKZ) treatment.[1]

Objectives: Assess scalp, nail and palmoplantar outcomes over 2 yrs from 2 BKZ phase 3 trials in moderate to severe plaque psoriasis.

Methods: Data were pooled over 2 yrs from the BE RADIANT phase 3b trial (NCT03536884), including Yr1 of its ongoing open-label extension (OLE), and the 1-yr BE SURE phase 3 trial (NCT03412747) with the ongoing OLE, BE BRIGHT (NCT03598790).[2,3] Pts included were randomised at baseline to BKZ 100 mg every 4 wks (Q4W) and then continued to receive BKZ Q4W or switched to BKZ every 8 wks (Q8W) at Wk16, and received the same dose on entering the OLE (Q4W/Q4W/Q4W or Q4W/Q8W/Q8W). Regional involvement was analysed using scalp Investigator’s Global Assessment (sIGA; 5-point scale [0–4]), modified Nail Psoriasis Severity Index (mNAPSI; total fingernail score, 0–130 scale) and palmoplantar (pp-IGA) (0–4 scale) at Wk48. 100 (33.0%) and 111 (34.4%) had mNAPSI >10. We report proportions of pts who achieved complete regional clearance (sIGA 0, mNAPSI 0, pp-IGA 0) at Yr2 (OLE Wk48) among pts with moderate to severe regional involvement at baseline (sIGA ≥3, mNAPSI ≥10, pp-IGA ≥3). Missing data were imputed as non-response (NRI).

Results: Of pts who entered the OLEs from BE SURE and BE RADIANT, 305 and 323 received BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W, respectively. Of these, 209 (69.0%) and 241 (74.6%) had baseline scalp IGA ≥3; 43 (14.2%) and 44 (13.6%) had pp-IGA ≥3; 100 (33.0%) and 111 (34.4%) had mNAPSI ≥10. Among pts with baseline scalp IGA ≥3, 78.0% and 81.7% treated with BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W achieved scalp IGA 0 at Wk16, respectively; 80.4% and 79.3% achieved scalp IGA 0 at Yr2 (OLE Wk48) (Table 1). Of pts with baseline pp-IGA ≥3, 60.5% and 81.8% treated with BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W achieved pp-IGA 0 at Wk16, respectively; 83.7% and 81.8% achieved pp-IGA 0 at Yr2 (Table 1). Of pts with baseline mNAPSI ≥10, 51.0% and 58.6% treated with BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W achieved mNAPSI 0 at Wk32, respectively; 40.0% and 59.5% achieved mNAPSI 0 at Yr2 (Table 1).

Conclusion: A high percentage of BKZ-treated pts achieved complete clearance of scalp and palmoplantar psoriasis at Wk16, which was sustained over 2 yrs. Complete nail clearance continued to increase through Yr1, reflecting the longer timescale required for nail growth, and was generally sustained through Yr2. Proportions of pts achieving complete nail, scalp and palmoplantar clearance were generally comparable between BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W dosing regimens.

DOI: 10.1136/annrheumdis-2023-eular.6485
Background: Maintaining daily activities is a critical treatment goal for patients (pts) with psoriatic arthritis (PsA). The Health Assessment Questionnaire-Disability Index (HAQ-DI), a mainstay tool for evaluating physical function in pts with PsA, assesses 20 common activities of daily living that should be evaluated given the heterogeneous clinical presentation of PsA.

Objectives: In this post hoc analysis from DISCOVER (D)-1 and -2, we examined the level of impairment in individual activities of daily living assessed by the HAQ-DI, and the effect of guselkumab (GUS) on pts’ ability to accomplish these activities, among pts with active PsA.

Methods: D1/D2 enrolled adults with active PsA despite standard therapies. D1 pts had <3 swollen and <3 tender joints (SJC/TJC), C-reactive protein (CRP) ≥0.3 mg/dL; 31% had ≤2 prior TNF inhibitors (TNFi). D2 pts had ≤5 SJC/TJC and CRP ≥0.6 mg/dL; all were biologic-naive. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W, or placebo (PBO). Scores for each of the 20 HAQ-DI items (range: 0-3; 0.1/2=no/some/much difficulty, 3=unable to do) at baseline (BL) and proportion of pts with scores ≤1 or ≥2 were summarized. Ability to achieve ≥1-level or ≥2-level improvement in each HAQ-DI item (in pts with BL score ≥1 or ≥2, respectively) were compared in 24W PBO-controlled period was compared between GUS- and PBO-treated pts using logistic regression adjusting for BL value, prior TNFi use, and BL DMARD use.

Results: At BL, the mean (SD) HAQ-DI score was 1.2 (±0.6) across treatment groups. The majority of pts (84.5%) had a score ≥0.5, indicating some functional limitation, and reported impairment in one or more activities, with the greatest impact on ability to do chores, dress oneself, and get in/out of bed. At W100W, the proportion of pts achieving ≥1-level improvement across HAQ-DI items was significantly higher with GUS vs PBO when as early as W4 and increased through W24 (Figure 1). Similar patterns were observed for achieving ≥2-level improvement across HAQ items (data not shown). Responses were numerically similar across all HAQ-DI items, including those most impaired at BL, with comparable responses between dosing regimens. These findings may assist the communication between pts and healthcare providers when treating treatment goals during shared decision making.

observed by W2, with a positive trajectory through W100 (Figure 1). Individual ACR components also significantly improved by W2 and – apart from CRP levels that rapidly plateaued to means <1 mg/dL – continued to improve vs previous visit through W6B-84 of GUS (nominal p<0.05).

Conclusion: GUS rapidly improved PsA activity whether assessed by ACR response or ACR-N. Early response was apparent across ACR components, followed by a positive trajectory through 2 years of GUS that yielded low levels of residual disease.

Background: PsA has been associated with an increased risk of cardiovascular disease (CVD), likely due to accelerated atherosclerosis secondary to chronic inflammation.[1] The number of CV risk factors has been shown to correlate with PsA disease activity (DA).[2]

Objectives: Describe effect of guselkumab (GUS) on inflammatory biomarkers that predict CVD, and its efficacy and safety, in patients (pts) with active PsA and concurrent CV risk factors.

Methods: DISCOVER (D)1&2 enrolled adults with active PsA despite standard therapies. D1 pts (31% received 1-2 prior TNF inhibitors [i]), had tender and swollen joint counts (TJC/SJC) each ≥3 and CRP ≥0.3 mg/dL; D2 pts (biologic-naive) had TJC/SJC each ≥5 and CRP ≥0.6 mg/dL. Pts were randomized 1:1:1 to GUS 100mg every 4 weeks (Q4W); GUS 100mg at W0, W4, then Q4W; or placebo (PBO) – GUS 100mg Q4W at W24. Pts included in this analysis had ≥1 of the following CV risk factors: obesity; smoking (past or current); or history of hypertension, diabetes mellitus (DM), or hyperlipidemia. Changes in high-sensitivity (hs) CRP and neutrophil–lymphocyte ratio (NLR) were compared between GUS vs PBO with mixed models adjusting for baseline (BL) levels. Achievement of endpoints at W24 (missing data imputed as no response) was compared in GUS vs PBO with logistic regression adjusting for BL levels, prior TNFi use, and BL DMD use: American College of Rheumatology (ACR) response criteria, Investigators’ Global Assessment (IGA) of psoriasis score 0/1, DA Index for PsA (DAPSA) low DA (LDA)/remission, PsA DA Score (PASDAS) LDA, minimal DA (MDA), Psoriasis Area and Severity Index (PASI) responses, Functional Assessment of Chronic Illness Therapy Fatigue (FACT-F) response, Health Assessment Questionnaire Disability Index (HAQ-DI) response, and enthesis and dactylitis resolution. The incidence of major adverse CV events (MACE: cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke) was assessed through W100.

Results: Of 1120 enrolled pts, 758 had ≥1 CV risk factor (259 Q4W, 252 Q8W, 247 PBO); of these, 488 (59%) were obese, 420 (55%) had hypertension, 315 (42%) were smokers, 171 (23%) had hyperlipidemia, and 103 (14%) had DM.
Through W24, GUS significantly reduced hsCRP and NLR vs PBO (Figure 1). Response rates at W24 were significantly higher with GUS vs PBO for all assessed endpoints (Table 1). During the PBO-controlled period, one pt each had a MACE in the PBO (0.9 [95% CI: 0.0-4.9]/100 person-years [PY]) and pooled GUS (0.4; 0.0-2.4)/100PY groups. In the pooled GUS group, the incidence (95% CI) of MACE was 0.2 (0.0-0.8)/100PY over 1 year and 0.3 (0.1-1.0)/100PY over 2 years.

Conclusion: In the subgroup of PsA pts with concurrent CV risk factors, GUS was associated with significant reductions in hsCRP and NLR and significantly higher response rates vs PBO for all PsA domains assessed. MACE incidence was similar to that in the overall D1/D2 population.[3] These findings support the efficacy of GUS on systemic inflammation and its cardiovascular safety.

Background: Pain in PsA has multifaceted origins (e.g., peripheral joint inflammation, axial involvement [axPsA], skin lesions, dactylitis, enthesitis, underlying conditions) and can be difficult to treat. Gusekubumab (GUS), a fully human IL-23p19 subunit inhibitor, is effective in treating multiple PsA domains and elicited durable improvement in patient (pt)-reported pain (PtP) in the DISCOVER (D-1&2 trials[1,2].

Objectives: Assess association between improvement in key PsA manifestations and PtP using 1-year D1&2 data.

Methods: D1&2 enrolled adults with active PsA despite standard therapies[3,4]. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo to crossover to GUS 100 mg Q4W at W24. Treatment groups were pooled (N=1120). Longitudinal associations of improvement in SJC (0-66), TJC (0-68), Leeds enthesitis index (LEI), dactylitis severity score (DSS), Psoriasis Area and Severity Index (PASI), axPsA (N=312), and pain in overall PtP (0-100 mm) and spinal pain (BASDIQ question 2 in pts with axPsA) were assessed. Longitudinal associations of improvement in these PsA manifestations with ≥30%/50%/70% improvements in PtP (PtP-30/50/70) were assessed.

Results: Mean (SD) BL PtP of 61.2 (19.8) indicated substantial burden. Upon adjusting for potential confounders, greater improvement in PsA, SJC, and TJC (mutually adjusted) were each associated with significantly greater improvement in PtP and higher odds of achieving PtP-30 through W52 (Table 1). PASI reduction was also associated with greater odds of PtP-50, as was TJC improvement for PtP-50/70. In pts with BL enthesitis, LEI, PASI, and TJC improvements were each associated with greater PtP improvement and attaining PtP-30/50/70; SJC reduction was only associated with PtP-30. In pts with BL dactylitis, PASI and TJC reductions were significantly associated with PtP improvement. Overall, axPsA presence did not impact the extent of PtP improvement (data not shown). In pts with axPsA, significant associations were observed between spinal pain improvement and TJC and LEI improvement.

Conclusion: Improvements in key PsA manifestations were significantly associated with pain reduction, although to varying extents. TJC reduction had the greatest impact on PtP improvement, likely due to overlap of the construct measured. Psoriasis improvement had a greater impact on pain relief than SJC improvement, highlighting the sensory burden of skin lesions, while enthesitis improvement showed a significant association with both overall and spinal pain relief. These findings underscore the importance of utilizing treatments effective across manifestations to address calcificant PsA symptoms.

**Note:** All values are adjusted for baseline values, age, gender, BMI, SF-36 Mental Component Summary score, presence of TJC or SJ ≥7 (central pain sensitization proxy), FACIT-fatigue score, and treatment group. ORs correspond to the incremental increase in pain improvement; ORs correspond to the incremental increase in the odds of achieving pain endpoints, for every increase in improvement in key PsA manifestations or in the presence (vs absence) of axPsA.

**Background:** Despite available PsA treatments, a portion of PsA patients (pts) does not achieve improvements in PsA signs and symptoms according to the American College of Rheumatology (ACR) response criteria.

**Objectives:** Using data from the phase 3 DISCOVER-1 and DISCOVER-2 (D1/ D2) studies, pts with active PsA, the purpose of this analysis was to describe the benefit of the IL-23p19 inhibitor, guselkumab (GUS), vs placebo (PBO) across key PsA domains, including those not comprising the core ACR measures, in pts not meeting ACR response criteria.

**Methods:** Pts enrolled in D1 and D2 were adults with active PsA despite standard therapies. D1 pts had ≥3 swollen and ≥3 tender joints (SJC; TJC), and C-reactive protein (CRP) ≥0.3 mg/dl; D2 pts had SJ ≥5, TJC ≥5, and CRP ≥0.6 mg/dl. In all, 31% of D1 pts received 1-2 prior tumor necrosis factor inhibitors (TNFi); D2 pts were biologic-naive. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week (W)0, W4, then Q8W; or PBO; PBO pts crossed over to GUS 100 mg Q4W at W24. In this post hoc analysis, patients not meeting ≥20% improvement in ACR response criteria (ACR20) at W24 were included. Changes from baseline (BL) over 24 W in continuous outcomes of interest (TJC; SJ; enthesis/dactylitis scores; psoriasis area and severity index [PASI] score; Functional Assessment of Chronic Illness Therapy [FACIT]-fatigue score; and 36-item Short Form survey [SF-36] physical [PCS] & mental [MCS] component summary scores) were assessed with repeated measures mixed models adjusting for treatment group, BL, non-biologic disease-modifying antirheumatic drug (DMARD) use, and prior TNFi use. Descriptive statistics were produced for categorical outcomes at W24 (Figure 1) using non-responder imputation for missing data.

**Results:** Of the 1120 pooled D1/D2 pts, 538 did achieve an ACR20 response at W24, including 137 (36.7%) GUS Q4W, 147 (39.2%) GUS Q8W, and 254 (68.3%) PBO pts, and were included in this analysis. A consistently greater proportion of GUS- than PBO-treated pts achieved W24 categorical outcomes, including those relating to skin, tender joints, and dactylitis, with similar findings for GUS Q4W and Q8W (Figure 1). For continuous endpoints, the benefit of GUS was seen as early as W2 for SJC (W4 for Q8W), TJC, dactylitis (W4 for Q8W), and enthesis (W4 for Q8W); W8 for FACIT-fatigue, SF-36 PCS, and SF-36 MCS (W16 for Q8W); and W16 for PASI; most endpoints continued to improve through W24. Across both GUS treatment groups, 43.5%-48.9% of W24 ACR20 non-responders achieved an ACR20 response by W24.

**Conclusion:** In this cohort of W24 ACR20 non-responders, GUS-treated pts experienced greater benefits than pts receiving PBO in improving both joint disease and other important PsA domains outside the ACR response criteria, which translated to significant improvements in health-related quality of life. These benefits occurred as early as W2 of GUS treatment, and showed continued improvement over W24, such that considerable proportions of W24 ACR non-responders achieved an ACR20 response by W52. Such improvements in key PsA domains over time among the minority of GUS W24 non-responders are consistent with the known immunomodulatory mechanism of GUS.
MALIGNANCIES WITH LONG-TERM USE OF IXEKIZUMAB IN ADULTS WITH PSORIASIS, PSORIATIC ARTHRITIS, OR AXIAL Spondyloarthritis: A POST-HOC ANALYSIS OF DATA FROM 25 RANDOMIZED CLINICAL TRIALS

Keywords: Psoriatic arthritis, Spondyloarthritis

The Mount Sinai Hospital, Dermatology, New York, United States of America; The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Rheumatology, Leeds, United Kingdom; Probyt Medical Research, Dermatology, Waterloo, Canada; Brigham and Women’s Hospital, Dermatology, Boston, United States of America; Icahn School of Medicine at Mount Sinai, Dermatology, New York, United States of America

Background: This integrated analysis examines long-term incidence rates (IRs) of malignancies in adults with psoriasis (PsO), psoriatic arthritis (PsA), or axial spondyloarthritis (axSpA) who received ≥1 dose of ixekizumab (IXE) up to 5 years (PsO) or 3 years (PsA, axSpA) in clinical trials.

OBJECTIVES: Methods: IRs of malignancies were assessed across 25 randomized IXE clinical trials (17 PsO, 4 PsA, 4 axSpA). Malignancy rates were analyzed for pooled studies by years of therapy through March 2022. Exposure-adjusted IRs per 100 patient-years (PY) are reported.

Results: 6892 patients with PsO, 1401 patients with PsA, and 932 patients with axSpA, with a cumulative IXE exposure of 18025.7 PY for PsO, 2247.7 PY for PsA, and 2097.7 PY for axSpA were included in this analysis. The IRs of malignancies at 1-year intervals up to 5 years for patients with PsO, and up to 3 years for patients with PsA and axSpA, remained low (≤1.2/100 PY) and constant. Malignancies occurred in 141/6892 patients with PsO (IR=0.8), 15/1410 patients with PsA (IR=0.7), and 9/932 patients with axSpA (IR=0.9). No incidences of NMSC were reported among patients with axSpA.

Conclusion: IRs of treatment-emergent malignancies were low and stable among adult patients with PsO, PsA, or axSpA receiving IXE treatment in clinical trials over the time periods examined.

DEUCRAVACITINIB IN PLACER PSSORISIASIS: 2-YEAR LABORATORY RESULTS FROM THE PHASE 3 POETYK PSMO PROGRAM

Keywords: Safety, Targeted synthetic drugs, Clinical trials

1Case Western Reserve University, University Hospitals Cleveland Medical Center, Cleveland, United States of America; 2Research Institute, University Hospital of Nice, Dermatology, Nice, France; 3Medical College of Wisconsin, Dermatology, Milwaukee, United States of America; 4Tokyo Medical University, Dermatology, Tokyo, Japan; 5Windsor Dermatology, Dermatology, East Windsor, United States of America; 6Dermatology Research Associates, Dermatology, Houston, United States of America; 7Dermatology Research Associates, Dermatology, Salt Lake City, United States of America; 8GBDTYK PSO-1 (NCT03624127) and PSO-2 (NCT03611751) were 52-week, double-blind trials that randomized patients with moderate to severe plaque psoriasis 2:1 to deucravacitinib 6 mg once daily, placebo, or apremilast 30 mg twice daily. Patients receiving placebo switched to deucravacitinib at Week 16, and patients receiving apremilast who failed to achieve ≥50% reduction from baseline in Psoriasis Area and Severity Index (PASI) for Week 16 were randomized and continued on deucravacitinib for up to 100 weeks. Treatment discontinuations and grade 3 or 4 laboratory abnormalities were rare, consistent with those in the parent studies, and comparable to the incidence rates seen with placebo and apremilast. These results suggest that laboratory monitoring in patients with plaque psoriasis is not warranted with deucravacitinib treatment. References: [5] Mease PJ, et al. Ann Rheum Dis. 2022;81:815-822.

Background: Psoriatic arthritis (PsA) is a disease characterised by heterogeneous joint and skin manifestations, so comprehensive treatment efficacy is best captured by assessment of a broad spectrum of affected domains using composite outcome measures.[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has demonstrated superior efficacy and tolerability to 16 weeks (wks) vs placebo (PBO) in patients (pts) with active PsA in the first phase 3 BE OPTIMAL and BE COMPLETE studies.[2,3] Bimekizumab (BKZ) at 160 mg every 4 wks has previously shown meaningful improvements in efficacy responses up to 1 year.[4] Here, we report data up to 1 year for BKZ in pts with psoriasis and PsA intolerant to tumour necrosis factor alpha inhibitors (TNFi-IR).

Methods: BE COMPLETE (NCT03896581) comprised a 16-wk double-blind, placebo-controlled period. Pts with PsA and TNFi-IR were randomised 2:1 to subcutaneous BKZ 160 mg every 4 wks or PBO. Pts who completed Wk 16 were eligible for entry into BE VITAL (NCT04009499), an open-label extension (OLE) study. Pts receiving PBO switched to BKZ at Wk 16 (PBO/BKZ). The BE VITAL OLE included pts from BE OPTIMAL and BE COMPLETE. Here, we report data up to 1 year for pts randomised at baseline (Wk 0) of BE COMPLETE (52 wks of study drug). Composited and worst-category imputation were used as secondary analysis methods.

Results: Of 388/400 (97.0%) pts completed Wk 16 of BE COMPLETE; 377 (94.3%) entered BE VITAL (NCT04009499), an open-label extension (OLE) study. Pts receiving PBO switched to BKZ at Wk 16 (PBO/BKZ). The BE VITAL OLE included 267 pts from BE OPTIMAL and BE COMPLETE. Here, we report data up to 1 year for pts randomised at baseline (Wk 0) of BE COMPLETE (52 wks of study drug). Composite and worst-category measures up to Wk 52 are reported: minimal and very low disease activity (MDA/VLDA), the composite endpoint of ≥50% improvement in American College of Rheumatology (ACR) and Psoriasis Area and Severity Index (PASI) scores.[5] Disease Activity Index for Psoriatic Arthritis (DAPSA), and Psoriatic Arthritis Disease Activity Score (PASDAS; collected up to Wk 50).

Results: Of 388/400 (97.0%) pts completed Wk 16 of BE COMPLETE; 377 (94.3%) entered BE VITAL and 347 (86.8%) completed Wk 52. At Wk 16, a higher proportion of BKZ-treated pts achieved composite disease activity thresholds vs PBO-treated pts. Across all composite outcome measures, efficacy was sustained to Wk 52 in pts randomised to BKZ treatment at Wk 0, and pts who switched to BKZ at Wk 16 demonstrated improvements in efficacy responses to Wk 52 (Figure 1, Table 1). At Wk 16, 6.0% PBO and 44.2% BKZ pts achieved MDA at Wk 52, this proportion was sustained on BKZ treatment: 33.1% PBO/BKZ and 47.2% BKZ (NRI; Figure 1). Improved or sustained responses were also observed for the proportions of PBO/BKZ and BKZ pts achieving VLDAs, ACR50+PASI100, DAPSA and PASDAS thresholds at Wk 52 (Figure 1, Table 1).

Conclusion: BKZ-treated pts with PsA and TNFi-IR demonstrated clinically meaningful improvements in composite measures of disease activity, comprising joint and skin domains, vs PBO at Wk 16. These improvements were sustained up to 1 year on BKZ. Pts who switched to BKZ at Wk 16 showed improvements in efficacy responses up to 1 year.

ACHIEVEMENT OF INCREASINGLY STRIDENT CLINICAL DISEASE CONTROL CRITERIA WAS ASSOCIATED WITH GREATER IMPROVEMENTS IN PHYSICAL FUNCTION, PAIN AND FATIGUE IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: 52-WEEK RESULTS FROM BE OPTIMAL, A PHASE 3 RANDOMISED, PLACEBO-CONTROLLED STUDY

Keywords: Psoriatic arthritis, Clinical trials

Objectives: To examine the association between achieving increasingly stringent clinical disease control criteria and patient-reported measures of physical function, pain and fatigue in patients (pts) with PsA, using Week (Wk) 52 data from BE OPTIMAL.

Methods: BE OPTIMAL (NCT03895203) comprised a 16-wk double-blind placebo (PBO)-controlled period and a 36-wk treatment blind period. Pts were ≥18 years, biologic disease-modifying antirheumatic drug naïve, with adult-onset, active PsA, ≥3 tender and ≥3 swollen joints. Pts were randomised 3:2:1, subcutaneous BKZ 160 mg every 4 weeks (Q4W): PBO:reference arm (adalimumab 40mg Q4W). From Wk 16, PBO pts received BKZ 160mg Q4W. In this post hoc analysis, all pts who reached specified disease control criteria (ACR: ACR20 not reached (≥ACR20), ACR20 reached but not ACR50 [ACR20→ACR50], ACR50 reached but not ACR70 [ACR50→ACR70], ACR70 reached [ACR70]: CRP and Psoriasis Area and Severity Index 100 [ACR50+PASI100]: non-responder, responder; Disease Activity in PsA (DAPSA): high, moderate and low disease activity or remission (HDA, MoDA and LDA/REM, respectively); Minimal Disease Activity (MDA): non-MDA, MDA) at Wk 52 were pooled regardless of treatment arm. Associations between achieving these criteria and improvements in the following patient-reported physical function and symptom measures were assessed: Health Assessment Questionnaire Disability Index (HAQ-DI), Pain assessed using Patient’s Assessment of Arthritis Pain Visual Analog Scale (Pain VAS) and Functional Assessment of Chronic Illness Therapy-Fatigue subscale (FACT-Fatigue). It should be noted that some aspects of the disease control criteria relate to aspects of HAQ-DI and PAAQ. Observed case data were reported.

Results: 821/852 (96.4%) pts completed Wk 16; 761 (89.3%) completed Wk 52. Baseline mean (SD) HAQ-DI (0 [best] to 3 [worst]), Pain VAS (0 [best] to 100 [worst]) and FACT-Fatigue (0 [worst] to 52 [best]) scores were 0.85 (0.59), 55.2 (23.9) and 37.0 (9.7). Pts achieving higher ACR response thresholds demonstrated sequentially greater mean (95% CI) improvements from baseline in HAQ-DI, Pain VAS and FACT-Fatigue (Figure 1). Similar improvements from baseline in HAQ-DI, Pain VAS and FACT-Fatigue were seen with the achievement of ACR50+PASI100, increasingly stringent DAPSA thresholds and the achievement of MDA (Figure 1).

Conclusion: Pts with active PsA who achieved increasingly stringent disease control criteria at Wk 52 reported concomitantly greater improvements in patient-reported measures of physical function, pain and fatigue.

</tbody>
</table>
Psoriatic arthritis (PsA) is a chronic systemic inflammatory musculoskeletal disease whose heterogeneous manifestations are classified in multiple domains; moreover, PsA negatively influence many comorbid diseases.[1] As growing evidence suggests, it is important to research drugs active on multiple domains, trying to target therapy for every PsA manifestations. Upadacitinib (UPA) is a selective JAK inhibitor effective in many PsA domains according to randomized controlled trials.[2] However, real-world data on UPA performance in everyday clinical practice are currently lacking.

Objectives: This observational study aims to evaluate real-life efficacy and safety of UPA in the treatment of PsA in a large multicentre cohort. Secondary objectives are: a. to obtain the ideal patient profile for UPA therapy; b. to stratify clinimetric and laboratoristic responses according to patient manifestation and comorbidities.

Methods: Patients with either peripheral and/or axial PsA, classified according to CASPAR and ASAS criteria, who initiated UPA by clinical indication were enrolled at 10 Italian centers according to the following inclusion criteria: 1a. failure or intolerance towards at least one csDMARD for bio-naive patients, or 1b. failure of at least one bDMARD for bio-failure patients; 2. active PsA disease, defined according to treat-to-target strategy by the absence of MDA (Minimal Disease Activity); 3. age > 18 years. Patients were assessed at baseline (T0) and at week 12 (T3) and 24 (T6), recording responses in the main clinimetric indices (i.e. TJC, SJC, LEI, DAPSA, ASDAS-CRP, MDA & VDLA) and a complete laboratory panel. Any type of adverse event was recorded at each visit. Data about assessment until week 56 (T12) for all patients will be presented in a future work.

Results: A total of 126 patients, 73 (69.5%) females and 32 (30.5%) males, started therapy with UPA: mean age 55.9±11.2 years, mean BMI 29.8±5.1, mean duration of disease 114.7±100.9 months. Most patients (n.124, 98.4%) show peripheral joint involvement: n.39 (31.4%) with oligoarthritis and n.85 (68.6%) with polyarticular pattern. Axial involvement was found in n.56 (44.4%) patients. Most patients (n.89, 70.6%) had failed at least 1 bDMARD. At baseline, all patients show high disease activity (DAPSA 27.7±10.0; ASDAS-CRP 5.2±1.2) and patient-reported outcomes (Table 1, Figure 1). A subsequent multivariate logistic regression analysis shows that males (OR 2.53), bio-naivity (OR 4.12), and patients with high baseline CRP (OR 2.49) had the highest probability of MDA response at T6. A few patients (n.10, 7.9%) discontinued UPA during the study due to ineffectiveness (n.7) or adverse events (n.2 moderate thrombocytopenia; n.1 severe hypertension).

Conclusion: Preliminary data are confirming UPA effectiveness and safety in PsA real-life population. These findings will allow more targeted therapy based on patient profiling and disease domains.
Background: Guselkumab (GUS) is associated with robust and sustained improvement in psoriatic arthritis (PsA) signs and symptoms in subgroups of patients (pts) pooled from the phase 3 DISCOVER-1 and DISCOVER-2 trials, across a variety of baseline (BL) pt characteristics through [1][1], and 2 years (DISCOVER-2 only)[2].

Objectives: This post-hoc analysis using DISCOVER-2 data aimed to evaluate the efficacy of GUS in inducing long-term (Week [W]100) stringent disease control in Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA)-recommended domains across BL characteristics.

Methods: DISCOVER-2 enrolled biologic-naïve adults with active PsA defined as ≥5 swollen and ≥5 tender joint counts (SJc; TJc) and C-reactive protein (CRP) ≥0.6 mg/dL. 739 pts were randomized (1:1:1) and treated with GUS 100 mg every 4 weeks (Q4W; n=245); GUS 100 mg at Week 0, Week 4, then every 8 weeks (Q8W; n=248); or placebo (n=246) with crossover to GUS 100 mg Q4W at W24. In this analysis, only GUS-randomized pts were included (n=493). Achievement of the following outcomes at W100 was assessed: minimal disease activity (MDA), American College of Rheumatology 50% improvement (ACR50), ACR70, Investigator’s Global Assessment score of 0 (clear skin) (IGA 0), Psoriatic Arthritis Disease Activity Score – low disease activity (PASDAS LDA), resolution of enthesitis and dactylitis, Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) response (≥4-point improvement), and Health Assessment Questionnaire Disease Index (HAQ-DI) response (≥0.35-point improvement). BL characteristics of interest were pt sex, baseline body mass index (BMI), SJc, TJc, PsA duration, CRP, % body surface area (BSA) with psoriasis, and PASI score, and use of conventional synthetic (cs) DMARDs and methotrexate (MTX). Non-responder imputation was used for missing categorical response data.

Results: 442 (90%) GUS-randomized pts completed study treatment through W100. With few exceptions, achievement of MDA response (Figure 1) at Week 100 was demonstrated across a variety of baseline pt characteristics, without consistent differences in proportion of responders across pt subgroups of adequate sample size or between GUS dosing regimens. Similar trends were observed for achievement of ACR50, ACR70, IGA 0, PASDAS LDA, enthesitis resolution, dactylitis resolution, FACIT-F response, and HAQ-DI response.

Conclusion: Irrespective of dosing regimen, treatment with GUS resulted in sustained achievement of several stringent endpoints spanning key GRAPPA-recommended domains through 2 years across a variety of BL demographic and disease characteristics. These results further support the long-term efficacy of GUS across the full spectrum of PsA disease domains and diverse PsA populations.

LONG-TERM SAFETY OF IXEKIZUMAB TREATMENT IN ADULT PATIENTS WITH PSORIASIS, PSORIATIC ARTHRITIS, OR AXIAL SPONDYLOARTHRITIS: A POST-HOC ANALYSIS OF END-OF-STUDY PROGRAM DATA RELATING TO MAJOR ADVERSE CARDIOVASCULAR EVENTS

Keywords: Psoriatic arthritis, Spondyloarthritis

1The Mount Sinai Hospital, Dermatology, New York, United States of America; 2Oregon Health & Science University, Portland, United States of America; 372nd Street Medical Associates, New York, United States of America; 4SOC Reumatologia, Azienda USL-IRCCS, Rome, Italy; 5Eli Lilly and Company, Indianapolis, United States of America; 6Memorial University of Newfoundland, St. John’s, Canada; 7Probity Medical Research, Dermatology, Waterloo, Canada; 8Bingham and Women’s Hospital, Dermatology, Boston, United States of America; 9Virginia Commonwealth University, Richmond, United States of America; 10Oregon Medical Research Center, Research Excellence & Personalized Patient Care, Portland, United States of America

Background: The objective of this study is to report long-term, end-of-study program safety outcomes, relating to major adverse cardiovascular events (MACE), in adult patients with psoriasis (PsO), psoriatic arthritis (PsA), and axial spondyloarthritis (AxSpA) who received ≥1 dose of ixekizumab (IXE) over 5 years (PsO) or 3 years (PsA, axSpA).

Methods: The incidence of MACE was assessed across 25 randomized clinical trials (17 PsO, 4 PsA, 4 axSpA) examining long-term safety of IXE. MACE rates were analyzed for pooled studies by years of therapy, through March 2022. Exposure-adjusted incidence rates (IRs) per 100 patient-years, at successive year periods examined.

Results: The incidence of MACE was low among patients with PsO (IR=0.5), PsA (IR=0.3), and axSpA (IR=0.3). In the PsO cohort, of the 103 reported MACE cases, 20 were fatal (19.4%), 57 recovered (55.3%), and 17 recovered with sequelae (16.5%). Of the 12 reported MACE cases in the PsA cohort, 2 were fatal (16.7%), 9 recovered (75.0%), and 1 recovered with sequelae (8.3%). All 6 MACE cases reported in the axSpA cohort recovered (100%). IRs were low and stable over the treatment periods. The most common types of MACE reported in the PsO, PsA and axSpA cohorts were non-fatal myocardial infarction (PsO: IR=0.3; PsA: IR=0.3; axSpA: IR=0.3), nonfatal stroke (PsO: IR=0.1; PsA: IR=0.2) and vascular death (PsO: IR=0.1; PsA: IR=0.1). All MACE cases were confirmed by adjudication.

Conclusion: The incidence of MACE was low and stable over the IXE treatment periods examined.

EFFICACY OF RISANKIZUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords:
Psoriatic arthritis, Systematic review

H. Zhou1,2, G. M. Xia1,2, C. Su1,2, H. Y. Tian1,2, Y. J. Deng1,2, X. M. Wang1,2, J. Y. Ren1,2, R. T. Shen1,2, Q. Y. Su1,2,3, Q. Yu4, P. F. He4, X. Li1,2,3, S. X. Zhang1,2,3.

Background: Psoriatic arthritis (PsA) is a chronic autoimmune disease that is seen in nearly 30% of patients with psoriasis. As a new targeted treatment drug, risankizumab may provide a new treatment with fewer side effects for patients with psoriasis arthritis. However, there are currently discrepancies in the evaluation of the efficacy of Risankizumab in PsA patients.

Objectives: This study aims to systematically evaluate the efficacy of Risankizumab patients with PsA.

Methods: We systematically searched PubMed, Embase, Web of Science, Cochran Library, MEDLINE, Web of Knowledge, Clinical Trials. gov, FDA. gov and print databases (SSRN, bioRxiv, and MedRxiv) from the establishment of the database to January 2, 2023, and conducted data analysis in Stata 12.0. We used the I-squared (I2) to assess the heterogeneity of the included studies in order to select the appropriate model for statistical analysis. A random-effects model will be used when I2≥50%, otherwise, a fixed-effect model will be applied. The publication bias was evaluated by using Egger test.

Results: We ultimately included 11 studies that included data on six outcome index. However, it is seen in nearly 30% of patients with psoriasis. As a new targeted treatment drug, risankizumab may provide a new treatment with fewer side effects for patients with psoriasis arthritis. However, there are currently discrepancies in the evaluation of the efficacy of Risankizumab in PsA patients.

Conclusion: The overall results of the meta-analysis show that Risankizumab treatment can significantly improve the symptoms of PsA such as arthritis and skin symptoms, improve the clinical remission rate and the quality of life of patients. However, taking Risankizumab may also potentially increase fatigue levels in patients.

PSORIATIC ARTHRITIS: IMPROVEMENT IN OUTCOMES BUT PERSISTENT SEX DIFFERENCE - 5 YEAR FOLLOW UP STUDY OF A NORWEGIAN OUTPATIENT CLINIC POPULATION

Keywords: Remission, Real-world evidence, Psoriatic arthritis

K. Losinska1, B. Michelsen2, A. Kavanagh3, M. Korkos4, G. Haugeberg5.

1University Hospital, Division of Rheumatology and Immunology, Krakow, Poland; 2Srølandet Hospital, Research Department, Kristiansand, Norway; 3University of California, Department of Medicine, School of Medicine, San Diego, La Jolla, CA, United States of America; 4Jagiellonian University Medical College, Department of Rheumatology and Immunology, Krakow, Poland; 5Srølandet Hospital, Division of Rheumatology, Department of Internal Medicine, Kristiansand, Norway; 6NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway

Background: Improvement of pharmacological therapies and treatment approaches in psoriatic arthritis (PsA) have led to substantial progress in disease outcomes [1]. Despite this progress there is still a need for improvement in PsA treatment [2].

Objectives: To explore long-term (5 years) changes in disease activity, remission rates and sex-related differences in these outcomes in PsA patients treated in ordinary outpatient clinic.

Methods: Prospective longitudinal cohort study. DAS28, DAPSA, SDAI, CDAI, MDA and Boolean remission criteria for PsA were assessed. Parametric statistics for comparisons of patient characteristics and dependent t test for differences between observation times were used.

Results: 114 PsA patients (49.1% women), baseline mean±SD age was 51.4±9.4 years, disease duration 9.2±6.8 years, 24.8% were HLAB27(+), 32.7% currently used NSAIDs, 61.4% csDMARDs, 37.7% b/tsDMARDs. At 5-year follow-up numerical improvement was noted for multiple disease activity measures and PROs (Table 1). Statistically significant increase in remission rates was
observed for DAS28 and CDAI but not for MDA, SDAI, DAPSA, and Boolean remission for PsA (Figure 1).

Figure 1. Proportions of PsA patients in remission (total cohort).

During follow-up number of b/tsDMARD users significantly increased (from 37.7% to 48.5% p<0.01), while number of NSAIDs and csDMARDs users significantly decreased (from 32.7% to 21.9% p<0.01, and from 61.4% to 46.5% p<0.01, respectively). Both at baseline and follow-up women reported higher levels of pain, PGA and fatigue, and had higher UC68, DAPSA, SDAI, DASI, DAS28 and mHAQ compared to men. Even though mean CRP was higher in men both at baseline and follow-up, men more often achieved remission, regardless which remission definition was applied. A higher proportion of men were treated with b/ttsDMARDs (46.6% vs 28.6% at baseline, 60.3% vs 35.7% at follow-up).

Conclusion: Our study adds evidence that improvement in PsA outcome between 2013 and 2020 was achieved, most probably due to more intensified treatment with b/tsDMARDs. Women had higher PROs and disease activity indexes both at baseline and follow-up and were less likely to achieve remission. Despite obtained progress, the number of PsA patients in remission remains unsatisfactory. This may indicate further need to improve both therapeutic approaches and methods of assessing PsA activity and remission.

Background: The efficacy of guselkumab (GUS), a fully human IL-23p19 subunit inhibitor, in patients (pts) with active psoriatic arthritis (PsA) has been previously shown across a variety of PsA domains and baseline (BL) pt characteristics[1-3]. Given the central role of the IL-23/Th17 pathway in PsA, it has been hypothesized that IL-23 inhibition with GUS may provide persistent and durable clinical responses between doses and over time when administered every 8 weeks (Q8W).

Objectives: To assess at the pt level the persistence of effect of GUS Q8W between doses and its durability of effect over time.

Methods: DISCOVER-2 was a phase 3, randomized, double-blind, placebo (PBO)-controlled study that enrolled pts with active PsA despite standard therapies. Pts were biologic-naïve, had tender and swollen joint counts (TJC/SJC) each ≥5, and C-reactive protein (CRP) ≥0.6mg/dL. Pts were randomized 1:1:1 to GUS 100mg Q4W, GUS 100mg at W0, W4, then Q8W, or PBO with crossover to GUS 100mg Q4W at W24. In the current analysis, only pts treated with GUS Q8W (N=248) were included. Persistence of effect between consecutive dosing visits was described with the proportion of pts maintaining response (as defined below) in outcomes assessed during dosing visits (Disease Activity index for PsA [DAPSA], clinical DAPSA [cDAPSA]). Durability of effect was assessed with the Kaplan-Meier estimator of the survival function where each pt contributed follow-up from the first time of achievement of clinical response within the 24-week period and the time of loss of response or last available assessment through W100. Definitions of clinical response included achievement of clear/almost clear skin (investigator’s global assessment [IGA] 0/1; among pts with BL IGA>1) or minimal clinically important improvements (MCII) in DAPSA (≥75, ≥75, skin visual analog scale (VAS; ≥15mm), and PsA Disease Activity Score (PASDAS; ≥0.8).

Results: Between consecutive (Q8W) dosing visits through W52, the proportion of pts maintaining response ranged from 93.3% (DAPSA MCII between W4 and W12) to 99.1% (DAPSA/cDAPSA MCII between W28 and W56), depending on the time interval. Among pts showing clinical response within the first 24 weeks, the estimated mean (SE) duration of maintenance was 58.6 (2.2) weeks for DAPSA MCII, 52.4 (2.0) weeks for cDAPSA MCII, 75.7 (1.6) weeks for IGA 0/1, 71.7 (1.9) weeks for skin VAS MCII, and 76.7 (1.4) weeks for PASDAS MCII (Figure 1). As estimated probabilities of maintenance of effect at W100 were between 65% (IGA 0/1) and 90% (PASDAS MCII) for all outcomes assessed, median duration of effect could not be calculated.

Conclusion: Treatment with GUS Q8W was associated with long-lasting effects in both joint- and skin-related outcomes, as well as in multi-domain composite outcomes, in individuals with PsA. These results highlight that, in addition to continuous improvement in clinical response rates over time, GUS Q8W provides consistent and highly durable responses between consecutive doses.

OBJECTIVES: We aimed to analyze the retention rate and safety of IXE in patients with PsA in routine clinical practice. The present study has analyzed drug survival and safety of IXE in patients with PsA under real clinical practice conditions. This information may complement that obtained from the RCTs done to date with this drug.

Methods: Retrospective longitudinal observational single-center study of all patients with PsA who had received at least one dose of IXE. Adverse events (AEs) and drug retention rate were considered the main variables. Survival was analyzed using Kaplan-Meier curves and predictive factors using multivariate Cox regression analysis. The Hazard Ratio (HR) was used as a measure of the association.

Results: Seventy-two patients were included (52 women and 20 men). Median disease duration was 5 years (IQR 3-9). More than 90% have received ≥ 2 biologic and/or targeted synthetic disease modifying anti-rheumatic drugs (methotrexate, leflunomide, sulphasalazine), ≥2 csDMARDs, and ≥2 tsDMARDs prior to IXE. Ixekizumab showed a 1-year retention rate of 65% and a 2-year retention rate of 57% (Figure 1). Regarding discontinuation due to AEs, 0.18 AEs per person-year were identified. The number of previous biologics did not influence drug survival but prior use of methotrexate [HR 2.31 (95%CI 1.05-5.10), p < 0.05] and depression [HR 2.40 (95%CI 1.07-5.41), p < 0.05] increased the risk of IXE discontinuation (Table 1).

Conclusion: Ixekizumab demonstrated high drug persistence in a population mostly refractory to various lines of systemic therapy. In addition, the aspects that usually penalize the survival of most biologics in PsA (age, duration of disease, female gender, smoking, obesity, prior exposure to other biologics) did not affect drug persistence in this study.

EXPLORING LEVELS OF PROTEIN BIOMARKERS IN RESPONSE TO TREATMENT FOR PSORIASIS AND PSORIATIC ARTHRITIS

Keywords: Disease-modifying drugs (DMARDs), Biomarkers, Psoriatic arthritis

Background: Guselkumab (GUS) is a human monoclonal antibody targeting the IL-23 p19 subunit. In the Phase 3b COSMOS trial (NCT037986885), GUS significantly improved disease signs/symptoms vs placebo (PBO) in patients (pts) with psoriatic arthritis (PsA) and an inadequate response (IR) to TNF inhibitor (TNFi) therapy. The primary endpoint of American College of Rheumatology 20% improvement (ACR20) response at Week (Wk)24 was achieved, with the benefit of GUS vs PBO consistent across subgroups.[1]

Objectives: In this post-hoc analysis, we evaluated if response to GUS across disease domains was maintained through 1 year across various subgroups of these TNF-IR PsA pts.

Methods: In COSMOS, adults with active PsA (swollen joint count [SJC] ≥ 3 and tender joint count [TJC] ≥ 3) with a lack of efficacy/intolerance to 1–2 TNFi therapies were randomized (2:1) to GUS 100 mg or PBO. Pts in the GUS group were treated at W0, W4, then every 8 weeks (Q8W) to W44; those in the PBO group were treated at W0, W4, W12, and W20, with planned crossover to GUS 100 mg at W24 followed by GUS at W28, W36, and W44. Pts with < 5% improvement from baseline (BL) in SJC and TJC qualified for W16 early escape (EE); EE pts receiving GUS continued treatment, while pts receiving PBO crossed over to GUS. In this analysis, efficacy of GUS in subgroups was evaluated at W24 and W48 via joint (ACR20/50 response), skin (Psoriasis Area and Severity Index [PASI]100 response), and multi-domain (minimal disease activity [MDA] response) outcome measures. Subgroups were defined by selected demographics, disease characteristics, and ongoing medications at BL: sex, body mass index (BMI), SJC, TJC, PsA duration, % psoriatic body surface area (BSA), and conventional synthetic disease-modifying antirheumatic drug (csDMARD) use. Odds ratios (ORs) and 95% confidence intervals (CIs) based on Fisher’s exact test for GUS vs PBO were shown overall and for each subgroup at W24. No treatment comparison was performed after W24. Pts who discontinued and/or correctly met EE criteria before W24 were imputed as nonresponders. Missing data were also imputed with no response through W48.

Results: Overall, 285 pts were randomized to GUS (n = 189) or PBO (n = 96). BL characteristics were generally similar between treatment groups, although numeric differences were observed for the proportion of female, joint symptoms, and skin involvement in GUS vs PBO pts. At W16, 39 (21%) pts in the GUS group and 45 (47%) pts in the PBO group were assigned to EE. In this analysis, joint, skin, and multi-domain response rates at W24 were numerically greater in GUS vs PBO pts, with the benefit of GUS consistent across all subgroups of adequate sample size (Figure 1). Response rates with GUS were maintained, or in most cases numerically increased, from W24 to W48, regardless of BL subgroup.

Conclusion: GUS 100 mg Q8W led to consistent improvements vs PBO in joint, skin, and multi-domain outcomes at W24 across subgroups of TNF-IR PsA pts defined by selected demographics, disease characteristics, and ongoing medications at BL. Response to GUS was maintained or further improved through 1 year of treatment regardless of BL subgroup.

DESCRIPTION OF THE REAL-WORLD TREATMENT PATTERNS OF GUSELKUMAB IN THE MANAGEMENT OF PSORIATIC ARTHRITIS IN AUSTRALIA: AN ANALYSIS FROM THE OPAL DATASET

Keywords: Real-world evidence, Psoriatic arthritis, bDMARD

G. Littlejohn1,2, N. Anbumurali1, P. Bird1,3, P. Youssfi1,2,4, C. Osullivan1, T. Smith1, D. Sumpton1,2,3, K. Kane1,3, S. Mcgeachie1, M. Spiers1, L. Diamond1, E. Mcgeachie1, S. Spiers2,3, C. Deakin1, OPAL Rheumatology Ltd, Rheumatology, Sydney, Australia; 2Monash University, Department of Medicine, Clayton, Australia; University of New South Wales, School of Clinical Medicine, Kensington, Australia; 3Emeritus Research, Rheumatology, Botany, Australia; University of Sydney, Department of Medicine, Sydney, Australia; 4Royal Prince Alfred Hospital, Department of Rheumatology, Camperdown, Australia; 5Concord Repatriation General Hospital, Department of Rheumatology, Concord, Australia; 6Janssen, Outcomes Research, Macquarie, Australia; 7Janssen, Medical Affairs, Macquarie, Australia

Background: Gusekumab (GUS) is a novel anti-interleukin 23 (IL-23) p19 antibody that acts as a selective and specific inhibitor of the IL-23 cytokine. GUS has been shown to significantly improve signs and symptoms of active psoriatic arthritis (PsA) and became available for the treatment of PsA in Australia in July 2021. Limited data from large real-world patient populations exist to describe the utilisation of GUS for the management of PsA.

Objectives: To describe the patient demographics and treatment patterns of GUS in a large real-world cohort of Australian adult patients with PsA.

Methods: The OPAL dataset is a collection of deidentified clinical data obtained from the electronic medical records of 112 rheumatologists at 43 sites around Australia. Adult patients with a diagnosis of PsA who received at least one prescription of GUS or a biologic or targeted synthetic disease modifying anti-rheumatic drug (b/tsDMARD) between Jul 2021 and Jul 2022, were eligible for inclusion in the analysis. Results were summarised descriptively.

Results: A total of 1,868 patients with PsA, (GUS n=355, TNFi n=795, IL-17Ai n=371 and JAKi n=347) were eligible for inclusion in the study. The median (IQR) age of patients was 55 [44-63] years, and 70.1% were female. At baseline, median disease duration was 5[2-8], 2[1-6], 3[1-7] and 5[2-6] years, for patients treated with GUS, TNFi, IL-17Ai and JAKi, respectively. 17.7% of patients receiving GUS were first line compared with 58.7% of TNFi, 39.4% of IL-17Ai and 19.3% of JAKi treated patients (Table 1). At index, the majority of patients were treated as monotherapy.

Conclusion: These are the first data describing the demographics and treatment patterns of real-world Australian patients with PsA treated with GUS. In this preliminary analysis, a higher proportion of GUS and JAKi are newer treatment options for PsA compared with TNFi and IL-17Ai.

REAL-WORLD USAGE OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN PATIENTS WITH PSORIATIC ARTHRITIS IN SWEDEN

Keywords: Disease-modifying drugs (DMARDs), Psoriatic arthritis, Real-world evidence

J. Song1,2, C. Abé1,2, J. Banefelt3, A. Rieem-Dun3, D. Willems1, M. Morup1, V. Taieb1, I. Lindberg1, S. Welby1, UCB Pharma N/A, Braine-l’Alleud, Belgium; 2Karolinska Institute, N/A, Stockholm, Sweden; 3Quantify Research, N/A, Stockholm, Sweden

Background: Given the growing number of treatment options for psoriatic arthritis (PsA) over the last decades, including a variety of biologic disease-modifying anti-rheumatic drugs (bDMARDs), selecting optimal treatment regimens is critical. Beyond clinical guidelines, understanding how physicians choose between available treatment options based on patient characteristics in real-world settings is of interest to both patients and health care providers.

Objectives: To reveal the patient characteristics (ie. demographics, comorbidities – including concomitant psoriasis [PSO], PsA+PSO and history of bDMARD exposure) in relation to bDMARD type and dosage in patients with PsA, treated in real-world clinical practice.

Methods: This retrospective observational cohort study utilised data from Swedish national administrative health care registers. Adult patients with an existing PsA diagnosis and a new bDMARD pharmacy dispensation between 2017–2021 were identified. Index date was that of the first observed dispensation qualifying as a new bDMARD, ie., without prior exposure to the index biologic. Prior bDMARD exposure and patient characteristics (including comorbidities) were screened for from 2005 and 2001, respectively. For patients initiating secukinumab (SEC), prescribed dosing was reported separately for patients with and without PSO manifestations giving the variability in prescribing recommendations.

Results: This study identified 8,658 PsA patients initiating a new bDMARD during the study period, among which 2,706 (31.3%) were already bDMARD-experienced. Patients had a median age of 52.3 years (SD=13.7), and 45.1% were male. The most frequently prescribed bDMARDs were adalimumab (45.3%), etanercept (31.6%), and SEC (11.3%). As expected, due to their recent market authorisations in PsA, the least frequently prescribed bDMARDs were guselkumab (0.8%) and risankizumab (0.4%). The most frequently observed prescriber specialty was rheumatologist (46.1%). The highest proportion of bDMARD-experienced patients was observed amongst interleukin-17 inhibitors initiators (82.4%), while 19.7% of tumour necrosis factor inhibitor initiators were bDMARD-experienced. Overall, 62.8% of patients had PsA+PSO. Other frequent non-inflammation comorbidities included hypertension (22.0%), malignancies (12.6%), and depression (11.7%). The proportion of patients with anxiety and depression was higher among those initiating risankizumab compared to those initiating other bDMARDs. Other comorbidities were comparable between groups.
Amongst 981 SEC initiators, 679 (69.2%) had PsA+PSO. Maintenance dose data were available/could be analysed for 901 patients. Most PsA+PSO patients initi-ated SEC at a dose of 150 mg (53.7%), and most PsA+PSO at 300 mg (65.0%). This was similar for maintenance period with 51.8% percent of PsA-only and 62.4% of PsA+PSO patients receiving a maintenance dose of 150 mg and 300 mg, respectively. A similar pattern was observed within bDMARD-naive and bDMARD-experienced patients regardless of PSO manifestations.

Conclusion: This study provides information on the profiles of PsA patients treated with different bDMARDs and suggest that factors such as PSO manifesta-
tions and biological-experience play important roles in the choice of bDMARD and dosing regimen. Future studies are warranted to identify patient outcomes associated with treatment patterns, including discontinuation and switches over time, which can assist in tailoring therapies to patient needs.

Background: Psoriatic arthritis (PsA) is an inflammatory rheumatic disease characterized by different phenotypes in terms of joint involvement. Apremilast, PDE4 competitive inhibitor, has been introduced in the treatment of adult psoriatic arthritis (PsA) with moderate disease activity. Musculoskeletal ultrasound (US) is useful in the assessment of disease activity and treatment response and follow up in PsA patients. Choosing an effective and safe treatment over time is an increas-
ingly urgent goal given the greater availability of indicated drugs.

Objectives: The aim of this study is to evaluate if MUS assessment before apremilast treatment can improve its retention rate.

Methods: We enrolled consecutive patients affected by PsA (according to the CASPAR Criteria) from 15 rheumatology centers. The following data were recorded for each patient: age, gender, duration of disease, DAPSA; smoke, comorbidities; concomitant treatment; duration of therapy with apremilast; reason of sospensione, PsA phenotype (policarticular or oligoarticular) (Table 1). All patients were divided in two subset according to the presence of a MUS assessment before apremilast treatment. The differentes between two groups were calculated by means of the Mann-Whitney and Chi-quadrato tests. The Kaplan Meier curve and Cox analysis assessed the retention rate and associated factors. P values < 0.05 were considered statistically significant.

Results: ON Three hundred and fifty patients (m/f: 198/152; median age 60 years, IQR 52-67 years), 40% received MUS examination. In the MUS group there was a moderate disease (medium 22.9 IQR 18.2-29 vs 26.9 IQR 20.3-33.8; p=0.0068) and a prevalence of the oligoarticular pattern (73% vs 44%, p<0.0001). The retention rate was statistically higher in MUS group (Figure 1) (HR 0.57 ICR95% 0.35-0.92; p=0.03).

Figure 1. A: Psoriatic arthritis. Longitudinal vobar scan of the interphalageal proximal joint. Tenosinovitis of the flexor tendons B: Psoriatic arthrits. Transversal vobar of the inter-
phalageal proximal joint. Tenosinovitis of the flexor tendons

Conclusion: In PS patients treated with apremilast, MUS assessment at base-line was associated with an higher retention rate. MUS could be useful in the PsA treatment algorithm in order to better identify those patients whose characteristics are favourable to apremilast response.

STUDY DESIGN AND FULL BASELINE SAMPLE CHARACTERISTICS OF PATIENTS FROM THE 24-MONTH MULTINATIONAL PROSPECTIVE PSORIATIC ARTHRITIS OBSERVATIONAL STUDY OF PERSISTENCE OF TREATMENT (PRO-SPirit)

Keywords: Psoriatic arthritis

J. Morel1,2, E. Lubrano2, W. Tillett2, R. Alten2, L. E. Kristensen3, V. Chandran4, T. Reue5, J. Burke5, A. Martinez-Ferret6, T. Holtschep7,8, N. Gulick9,10, Universite Montpellier 1 - Faculty of Medicine, Montpellier School of Medicine, Montpellier, France; CHU and University of Montpellier, Department of Rheumatology, Montpellier, France; University of Molise, Department of Medicine and Health Sciences; Vincenzo Tiberio; Campobasso, Italy; University of Bath, Department of Life Sciences, Centre for Therapeutic Innovation, Bath, United Kingdom.
Background: The paper describes outcomes of the PRO-SPIRIT study, a large, prospective observational study for IXE in patients (pts) with PsA who start a new biologic/targeted synthetic treatment (tx) of Psoriasis (Pso), psoriatic arthritis (PsA) and axSpA (rad/non rad) with limited real-world data. PRO-SPIRIT is the first large, prospective observational study for IXE in patients with PsA who start a new biologic/targeted synthetic disease modifying anti-rheumatic drug (b/tsDMARD), with a primary endpoint of persistence at 24 months (M).

Objectives: To describe baseline (BL) characteristics of pts enrolled in PRO-SPIRIT.

Methods: PRO-SPIRIT enrolled pts December 2019–June 2022 in ES, IT, DE, UK, and CA, who started a new b/tsDMARD, approved for PsA. Tx groups are: IXE, secukinumab (SEC), IL-12/23-, IL-23, tumor necrosis factor inhibitor (TNFi), Janus kinase inhibitors (JAKi), and Phosphodiesterase-4 inhibitor (PDE4i). Pts' demographic, disease activity, and tx characteristics were recorded at BL, effectiveness outcomes and tx changes at 3, 6, 12, 18, and 24M. BL descriptive statistics are shown.

Results: The analysis included 1207 pts (2 pts with other tx not shown below). Most were female, had mean age 52.4yrs, poly/oligo-arthritis and enthesitis/dactylitis in similar proportions except for enthesitis in IL12/23 and IL-23 pts. Pts started on IXE had long disease duration (9.2yrs). Most had prior b/tsDMARDs (69.5%) and 38.7% had active PsO similar to SEC pts. For TNFi pts, mean disease duration was 6.5yrs, 30.8% had received prior b/tsDMARDs, and 30.4% had active PsO. IL-23 pts (n=57) were typified by long disease duration (8.7yrs), high proportions of PsO (50.9%)/nail PsO (50.9%) and prior b/tsDMARD use (78.9%). JAKi pts had long (9.2yrs) disease duration, 72.2% prior b/tsDMARDs experience, and 26.2% had active PsO. IXE and IL-23 pts were more often treated on monotherapy.

Conclusion: In PRO-SPIRIT, pts starting IXE showed active PsA, with both joint and overall skin involvement, and were mostly treated on monotherapy after failing several b/tsDMARDs. TNFi's were often used as 1st line therapy alongside of b/tsDMARDs.

Keywords: Psoriatic arthritis, Biomarkers, Ultrasound

Results: We conducted a study using ultrasonography (US) to evidence inflammatory changes (joint-enthesis-ungual) in active PsA (aPsA) patients who started Apremilast (A) in clinical practice.

Objectives: To obtain a 20, 50, 70 % reduction in the US index (UI) at 12 months, and study correlation between variables.

Methods: Phase IV, multicenter, prospective and open-label clinical trial conducted in 6 centers from 2018 to 2021. All patients signed the informed consent. Approval by the ethical committee was obtained, code PSE-PI-006421. PsA patients (≥ 2 swollen joints), ≥ 2 joint US synovitis and ≥ 1 US enthesitis at screening were recruited. 52 weeks follow up (baseline, 1, 9 & 12 months). US & clinical variables, and ESR & CRP were registered at each visit. US scans were scored according to Ficjan et al [1]. Ungual nail plate (NP) and subungual thickness (ST) US evaluation of 24th, 3rd and 5th finger was done.

Results: 48 patients screened and 46 included (2 screening failure) in follow up. 26 completed the study. A 20 % (main objective) reduction in UI was observed until 40%, but not 50/70%. Clinical and US variables were reduced, ESR and CRP did not change following up (Table 1). Strong correlation was observed between UI and SJC, moderate between UI and TJC, PCT, TGT, CRP A reduction in clinical onychopathy, NP lesion, and slight relation between lesion and joint, and high ST and with onychopathy was seen but didn't achieve statistical significance (reduced sample size). 75 adverse events in 30 patients.

**EFFECT OF APREMILAST ON PSORIATIC DISEASE DOMAINS STRATIFIED BY EXTENT OF SKIN INVOLVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS**

**Keywords:** Skin, Psoriatic arthritis

A. F. Wells1, L. Teng2, S. Colgan3, C. Deignan2, S. Jardon2, Y. Kyachkin3, A. Majhoth, A. Kavanagh4. 2Advocate Aurora Medical Group, Rheumatology & Immunotherapy, Franklin, United States of America; 3Amgen Inc., Statistics, Thousand Oaks, United States of America; 4Shires Rheumatology, PC, Rheumatology, Saint Claire Shores, United States of America; 5University of California, San Diego, School of Medicine, Rheumatology, La Jolla, United States of America

**Background:** It has been suggested that greater skin involvement in patients with psoriatic arthritis (PsA) may be associated with greater joint disease activity.

**Objectives:** To assess the impact of APR on PsA disease domains in patients with BSA <3% vs BSA ≥3% at 52 weeks using pooled data from 2 phase 3 trials.

**Methods:** PALACE 1 & 2 were randomized, placebo (PBO)-controlled, phase 3 studies in patients with active PsA. Eligible patients had ≥3 swollen and ≥3 tender joints despite prior treatment with a conventional systemic Disease Modifying Antirheumatic Drug (cDMARD) and/or biologic DMARD (bDMARD) or concurrent treatment with csDMARD. Patients were randomized to receive APR or PBO for up to 24 weeks, after which all patients received APR until Week 52. This ad-hoc analysis includes pooled data from patients randomized to APR 30 mg BID at Week 0 in these studies. Assessments included change from baseline at Week 52 in Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA), swollen joint count (SJC), tender joint count (TJC), patient assessment of pain visual analog scale (VAS), and Patient Global Assessment of Disease Activity (PGA) VAS stratified by baseline psoriasis body surface area (BSA) involvement (<3% vs ≥3%).

**Results:** Of 330 patients randomized to APR 30 mg BID at Week 0, 171 had BSA <3% and 159 had BSA ≥3%. Of those with available data, 98.2% of patients with BSA <3% and 100% of patients with BSA ≥3% had a history of psoriasis; mean BSA at baseline was 12 in the <3% group and 14.3 in the ≥3% group. More patients with BSA ≥3% at baseline were men with higher rates of nail and SJC involvement, and slightly higher rates of oligoarthritis and TJC (Table 1). At Week 52, both subgroups showed mean decreases (improvement) from baseline in clinical parameters with APR treatment, including cDAPSA (BSA <3%: -18.0, BSA ≥3%: -23.3), SJC (BSA...
PsA by level of skin involvement. Numerically greater improvements were seen in patients with BSA ≥3%. To our knowledge, this is a novel analysis assessing treatment efficacy in patients with PsA by level of skin involvement.

Background: Guselkumab is a human IgG1 monoclonal antibody that binds to interleukin 23, a regulatory cytokine that modulates the activity of T lymphocytes, intervening in pathogenic ways that initiate and maintain the activity of Psoriatic Arthritis (PsA). PsA has a wide spread of systemic manifestations where several profiles of disease exist depending on the predominant affection. Guselkumab has been used widely to treat cutaneous psoriatic disease (PsO) and PsA since 2020. Nevertheless, no long-term analysis have been done.

Objectives: To analyze the long-term efficacy and safety of Guselkumab at 52 weeks (w). Likewise, relevant demographic data such as sex, weight or previous biological treatment was taken into account.

Methods: A prospective, uncenteric, observational study was conducted in patients who met ACR criteria for PsA, who received treatment with Guselkumab for 52 w. Patient demographic and baseline data were recorded and response variables such as DAPSA and BSA index, presence of enthesitis and dactylitis, and drug persistence at 12, 24 and 52 w of treatment were statistically analyzed and compared between different groups of patients stratified by their demographic data and previous biological therapy using Student-T and ANOVA. In addition, adverse events were recorded.

Results: 45 patients with moderate-to-severe PsA were included: 60 % were female, they had a mean BMI of 28.87. Approximately, 60% of patients received Guselkumab in fourth to eighth line of treatment. According to their DAPSA index score, patients were classified into remission, low activity and active disease. 50% of the patients fell under the remission category at w52, with the majority of the remaining in low activity (44%). The percentage of enthesitis and dactylitis presented an important reduction, from 31% and 8.88% at baseline to both 0% at w52 respectively. BSA also experiment a significant reduction. (Figure 1) At baseline both genders showed a similar mean value for DAPSA which decreased significantly when they reached w 52. There were not differences between genders at the end of the study, however women had an earlier response with significant differences at w 12. Moreover, when we analyzed the population regarding weight, we found that Guselkumab was effective both in normal weight and also in overweight patients being 8/13 of them obese. Finally, studying the previous biologic treatment profiles, we found that better results were expected after anti-TNF or IL-17 inhibitors compared to other drugs. Treatment persistence was 100% after 24 w and 85% after 52 w in those patients who received Guselkumab as 2nd or 3rd line of treatment, but 84% and 63% at 24 and 52 w in those who took it in 4th place or more. No adverse effects were reported and a total of 11 patients abandoned treatment, 10 of them due to primary failure and 1 due to secondary failure.

Conclusion: Guselkumab was effective and safe for the treatment of manifestations of PsA in a real world evidence cohort of patients for 52 w. In addition, Guselkumab was equally effective in women as well as overweight patients, showing better results when the patient had followed treatment previously with anti-TNF or IL-17 inhibitors probably because they were less bDMARD-experienced patients. According to this fact, Guselkumab demonstrated an increased survival when administered in the second or third line of treatment compared to advanced lines of treatment.

REAL-LIFE EFFICACY AND SAFETY OF IXEKIZUMAB IN A COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS: A SINGLE-CENTER RETROSPECTIVE STUDY

Keywords: Psoriatic arthritis, bDMARD, Real-world evidence

E. Belli1, D. Donzella1, G. Crepaldi1, V. Data1, M. Gammino1, V. Guardo1, C. Lomater1, E. Marucco1, M. Saracco1, A. Iagnocco.1. University of Turin, AO Mauriziano di Torino, Academic Rheumatology Center, Dipartimento Scienze Cliniche e Biologiche, Turin, Italy

Background: Ixeikizumab is a high-affinity monoclonal antibody that selectively targets interleukin-17A and is indicated for psoriasis, psoriatic arthritis (PsA) and axial spondyloarthritis. Literature highlights efficacy and safety in real life in patients affected by psoriasis[1], instead little data are concerning patients affected by PsA[2].

Objectives: To retrospectively evaluate the effectiveness and safety of ixeikizumab, in a cohort of patients with PsA.

Methods: Patients with a diagnosis of PsA and treated with ixeikizumab who visited our outpatient clinic from October 2019 to December 2022 were included in the study. Clinical data were recorded since the first prescription of ixeikizumab and at 6-month follow-up visit. Demographic, clinical and laboratory characteristics, treatment, and causes of discontinuation were analyzed. Differences between baseline and 6-months erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), tender joint count (TJC) and swollen joint count (SJC) were analysed.

Results: Main results are reported on Table 1. 76 patients were included in the study, with an average age at the prescription of ixeikizumab (T0) of 57±13.0 years. Main comorbidities were: hypertension (44.7%), obesity and overweight (44.7%), cardiacopathy (19.7%), hepatitis steatosis (21.0%), diabetes (13.2%), and hyperlipemia (3.9%). 93.42% of patients presented peripheral arthritis, 30.6% axial involvement, and 42.1 % enthesitis. 28.9% of patients were bio-logic naïve, 34.0% received one biologic agent before, and 31.5% two or more biologic agents. 88.2% of patients initiated ixeikizumab in combination with a csDMARD, mainly methotrexate. The indications for the prescription of ixeikizumab as a first biologic agent were: multiple comorbidities, severe psoriasis, and intolerance to csDMARDs. 28.9% of patients stopped ixeikizumab because of primary failure (31.8%), secondary failure (22.7%), or adverse events (45.5%). 40% of the adverse events were relevant skin reactions at the injection site. No severe adverse events were registered. 60 patients completed 6 months of treatment (T6). In those patients, a statistically significant decrease between the SJC and TJC at baseline and T6 was found (p-value 0.0011 and 0.0006 respectively). No difference in the values of ESR and CRP values between T0 and T6 was present.

Conclusion: There are few data in real life concerning efficacy and safety in patients affected by PsA. In our cohort, ixeikizumab significantly improved peripheral arthritis, and it revealed a good safety profile, without severe adverse events during the follow up. Further real-life evaluations on axial involvement, which was not included in this study, are warranted.

AB1121 EFFICACY AND DRUG PERSISTENCE OF NEWLY INITIATED BIOLOGICS IN PSORIATIC ARTHRITIS

Keywords: bDMARD, Real-world evidence, Psoriatic arthritis

L. G. Stanca1, M. Agache1,2, C. E. Ionescu1,2, L. Enache1,2, C. Mogosan1,2, C. Popescu1,2, C. Codreanu1,2,1 Dr. Ion Stoia’s Clinical Center for Rheumatic Diseases, Bucharest, Romania;1“Carol Davila” University of Medicine and Pharmacy, Rheumatology, Bucharest, Romania

Background: Psoriatic arthritis (PsA) is a form of spondyloarthropathies associated with psoriasis and characterized by joint, entheses and spine inflammation. Numerous therapeutic molecules have appeared in the last decade following breakthroughs in the pathogenesis of the disease [1].

Objectives: The study aimed to evaluate the effectiveness and persistence of first-line biological treatment in PsA in a real-life setting.

Methods: The study included retrospectively all the PsA patients initiated on biologics in a university single center real-life clinical practice between January 2018- December 2021, as reported in the Romanian Register of Rheumatic Diseases [2]. Differences of continuous variables among subgroups were assessed with Mann Whitney tests, while associations of categorical variables were assessed with χ2 tests, considered significant if p < 0.05.

Results: The study included 38 patients with an average age at biologic initiation of 50 ± 16 years, of which 71.1% were women, 34.2% were obese and 10.5% were smoking. The patients had established disease, with an average PsA duration of 9 ± 9 years. Regarding treatment, 44.7% initiated tumor necrosis factor inhibitors (TNFi) and 55.3% interleukin 17 inhibitors (IL-17I). A fraction of 31.6% had biologic monotherapy. After the first 6 months of therapy, 55.3% reached the treatment target (Duration Activity in Psoriatic Arthritis - DAPSA < 14) with a drug persistence of 78.9%, while 65.8% reached target by 12 months with 68.4% drug persistence. There were no differences of DAPSA scores, target frequencies or persistence frequencies at 6 and 12 months between TNFi and IL17I (p > 0.05).

An equal number of initiations was observed in the pre-pandemic period (2018-2019; 50%) versus the pandemic period (2020-2021; 50%).

Conclusion: Observations in a real-life setting show good efficacy persistence of both TNFi and IL17I in PsA at 6 and 12 months after their initiation. SARS-CoV-2 pandemic did not influence the number of biologic initiations in PsA patients.

**GUSELKUMAB VS GOLUMBUAB IN PSA TNFI-INADEQUATE RESPONDERS (EVOLUTION): FORMULATING A PRAGMATIC PHASE 3B RANDOMIZED TRIAL**

**Keywords:** Randomized control trial, Psoriatic arthritis, Real-world evidence

A. Ogdie1, S. Reddy2, K. Bush3, S. Hopkins Gillespie1, M. E. Husni4, P. Karmacharya5, J. Scher6, M. Perate7, S. D. Chakravarty8, C. Gong9, J. A. Walsh.1 University of Pennsylvania School of Medicine, Division of Rheumatology, Philadelphia, United States of America; 2NYU Grossman School of Medicine, Department of Medicine, New York, United States of America; 3Cleveland Clinic, Immunology, Cleveland, United States of America; 4Vanderbilt Health, Department of Medicine, Nashville, United States of America; 5Janssen Scientific Affairs, LLC; IMMUNOLOGY, Hoshom, United States of America; 6Drexel University College of Medicine, Department of Medicine, Philadelphia, United States of America; 7University of Utah School of Medicine, Department of Medicine, Salt Lake City, United States of America

**Abstract:**

From the Tight Control in PsA (TICOPA) study, treatment strategy trials in psoriatic arthritis (PsA), and definitive guidance on managing patients (pts) with inadequate response (IR) to a first tumor necrosis factor inhibitor (TNFI), are lacking. Recent observational studies suggest potentially greater benefit from switching TNFI-IR pts to a new mechanism of action (MoA) [1].

**Objectives:** Design a pragmatic trial (EVOLUTION) to determine whether switching TNFI-IR PsA pts to a new MoA, specifically to the selective interleukin 23 inhibitor (IL-23i) guselkumab (GUS), is more effective than cycling to a 2nd TNFI (Figure 1).

**Methods:** To plan the EVOLUTION trial, we assessed pts receiving any biologic in the multicenter longitudinal observational Psoriatic Arthritis Research Consortium (PARC) study [2] and found expected mean changes in selected outcome measures, enrollment feasibility, and sample size estimates.

**Results:** 215 pts initiating a biologic in PARC (including later lines of therapy) had data for the outcomes of interest and a 3-6 month follow-up visit. At therapy initiation (baseline [BL]), mean age=50.4 (SD 14.4), 56% were female, 81% were White. Mean BL clinical disease activity in PsA (cDAPSA=20.0 (15)), mean body surface area (BSA)=20.0% (8), 21% were in minimal disease activity (MDA), 43% were in cDAPSA remission/low disease activity (LDA) and 70% had a BSA ≤1%. 113/215 (53%) pts met EVOLUTION’s clinical enrollment criteria (Figure 1). Pts who were eligible for EVOLUTION vs ineligible pts had higher disease activity mean (cDAPSA 29.0 vs 10.0, PGA 5.6 vs 3.1, Psoriatic Arthritis Impact of Disease Questionnaire [PSAID-12= -1.0 (1.9). EVOLUTION’S primary study outcome (cDAPSA LDA + IGA 0/1) was assessed at 12 months (Table 1), and per clinical practice, pts will be enrolled at the time of switch post-washout. Assuming 24%, 45% and 50% of pts in the guselkumab (GOL) vs GUS Q4W vs GOL and GUS Q8W arms, respectively, would achieve the primary outcome, and 90% with 10% dropout rate, a total sample size of 300 pts is anticipated to yield 80 pts per randomized group and provide 80% power to detect a difference in proportions of GUS Q4W vs GOL and GUS Q8W vs GOL pts achieving cDAPSA LDA + IGA 0/1.

**Conclusion:** The EVOLUTION trial will apply an innovative, pragmatic randomized trial approach to assessing therapy effectiveness by recruiting a treatment-refractory PsA population consistent with that seen in clinical practice. This also includes using a novel primary endpoint (cDAPSA LDA + IGA 0/1) with direct applicability to routine care. This first of its kind head-to-head comparative effectiveness trial in real-world PsA pts will address important knowledge gaps in the management of PsA related to switching from a TNFI to GUS vs cycling to a 2nd TNFI and will build on a longitudinal cohort study used to plan this study.

Keywords: Psoriatic arthritis, Targeted synthetic drugs, Safety

Methods: All PSA patients who were prescribed tofacitinib from JAN-2021 to JUNE 2022 with minimum of 6 months followup were included for analysis. Demographics, weight recordings, lab parameters and occurrence of adverse events were noted.

Results: There were a total of 71 patients who were prescribed tofacitinib out of which 46 are continuing and 25 have stopped during this period. The mean age was 47.25 (10.8yrs) the mean disease duration was 4.182 (4.474yrs) The reason for stopping tofacitinib was better(52%) followed inefficacy(24%), and miscellaneous(24%) reasons. When analysing before and after tofacitinib one thing which was striking is the significant weight gain among patients with minimum of 3.52 (3.06) kg weight gain and this weight gain was consistent even in stopped patients. in comparing the lab parameters before and after tofacitinib there was a significant reduction in CRP,ESR,PLATELET COUNT Table 1 and a minimal but insignificant rise in liver enzymes within the physiological range. When compared to before and after tofacitinib there was increased occurrence of fatigue(18.3%), minor infections(11.2%), Gastrointestinal adverse events (11.2%), alopecia(11.2%), itching(10.4%), headache(9.8%), UTI(5.6%), cough(4.2%), transaminases(2.6%), covid(1.7%), zoster(1.4%) and CAD(1.4%).

Conclusion: Tofacitinib in psoriatic arthritis is well tolerated with significant reduction in the inflammatory markers and weight gain but serious adverse events in lesser percentage even though it leads to significant weight gain.

Background: Psoriatic arthritis (PsA) is an autoimmune disease characterized by disturbances of regulatory cells, which were regulated by interleukin (IL)-2.

Objectives: The aim of this study was to systematically evaluate the changes in the number of lymphocytes subsets after low-dose IL-2 therapy in psoriatic arthritis (PsA).

Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM and Technology Journal Database were performed. Original case reports, case series, observational studies and clinical trials reporting the changes in numbers of lymphocytes subsets on PsA patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I2 and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 4Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China; 5Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 6Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China.

Background: Psoriatic arthritis (PsA) is an autoimmune disease characterized by disturbances of regulatory cells, which were regulated by interleukin (IL)-2.

Objectives: The aim of this study was to systematically evaluate the changes in the number of lymphocytes subsets after low-dose IL-2 therapy in psoriatic arthritis (PsA).

Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM and Technology Journal Database were performed. Original case reports, case series, observational studies and clinical trials reporting the changes in numbers of lymphocytes subsets on PsA patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I2 and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).
Results: A total of 3 studies comprising 156 patients were identified (Table 1). The numbers of Tregs were increased after the treatment of IL-2 [SMD = 0.928, 95% CI (-0.430, 0.722), P = 0.619] (Figure 1). The retention rate of originator drugs was higher than that of biosimilars, both when administered in the first line and after a NMS. A greater number of suspensions were recorded for AEs and, to a lesser extent, for ineffectiveness with biosimilar ADA compared to originator ADA, while in patients treated with biosimilar ETA no suspensions were recorded either for AEs or for ineffectiveness.

**THE RETENTION RATE OF ETANERCEPT AND ADALIMUMAB IN FIRST-LINE AND AFTER NON-MEDICAL SWITCH IN PATIENTS WITH PSORIATIC ARTHRITIS: A COMPARISON BETWEEN ORIGINATORS AND BIOSIMILARS. A SINGLE-CENTER RETROSPECTIVE STUDY.**

Keywords: Psoriatic arthritis, bDMARD

V. Rella1, C. Rotondo1, N. Maruotti1, A. Altomare1, F. Erro1, S. Stefanina1, A. Trottì1, F. P. Cantatore1, A. Corrado1. 1Ospedali Riuniti di Foggia, Rheumatology Unit, Department of Medical and Surgical Sciences, Foggia, Italy

Background: Psoriatic arthritis is a chronic immune-mediated disease that may appear with arthritis and/or enthesis and systemic manifestations, affecting 0.1-1% of the general population and up to 30% of patients with psoriasis. A greater understanding of the pathogenesis has led to an increase of therapeutic options, namely biotechnological drugs which may prevent the progression of the disease and improve the quality of life by acting on specific pathways. Among these drugs, anti- TNFα agents play an important role. Adalimumab (ADA) and Etanecop (ETA) were the first developed ones, indeed they are defined as “originator” drugs. Subsequently, “biosimilars” have been developed. They are defined by the EMA as highly similar to the first developed ones, indeed they are defined as “originator” drugs. Subsequently, “biosimilars” have been developed. They are defined by the EMA as highly similar to the first developed ones. Adalimumab (ADA) and Etanecop (ETA) were the first developed ones, indeed they are defined as “originator” drugs. Subsequently, “biosimilars” have been developed. They are defined by the EMA as highly similar to the first developed ones.

Objectives: The aim of this study is to evaluate the retention rate of ETA and ADA originators, compared to their biosimilar counterparts, in the first line and after NMS, detecting discontinuation for adverse events (AEs) or ineffectiveness, in patients with psoriatic arthritis.

Methods: Fifty-four patients diagnosed with psoriatic arthritis were enrolled (F: 61%; mean age 53.4 ± 13 years, BMI 24.9 ± 3.6). Baseline disease activity was 4 ± 1.1. Inclusion criteria were age > 18 years, fulfillment of CASPAR 2006 criteria for PsA, therapy with an originator or a biosimilar etanetoc or adalimumab in the first line, with the possibility of no NMS, stable combined therapy with methotrexate during the observation time. Statistical significance was set at p < 0.05.

Results: The retention rate of ETA and ADA originators was 541 ± 70 weeks and 486 ± 24 weeks, respectively. The retention rates of biosimilar ETA and biosimilar ADA in the first line were 265 ± 20 weeks and 79 ± 21 weeks, respectively (p = 0.231). After NMS, the retention rate of biosimilar ETA and biosimilar ADA was 49.1 ± 13 weeks and 108 ± 12 weeks, respectively. Discontinuation due to AEs were recorded in 8.3% of patients receiving originator ETA, 5% of patients receiving originator ADA, and 31% of patients receiving biosimilar ADA. Discontinuation due to ineffectiveness occurred in 54% of patients treated with originator ETA, in 40% of patients treated with originator ADA, and in 44% of patients treated with biosimilar ADA. In patients treated with biosimilar ETA, no suspensions were recorded either for AEs or for ineffectiveness.

Conclusion: Our data show that the retention rate of originator drugs was higher than that of biosimilars, both when administered in the first line and after a NMS. A greater number of suspensions were recorded for AEs and, to a lesser extent, for ineffectiveness with biosimilar ADA compared to originator ADA, while in patients treated with biosimilar ETA no suspensions were recorded either for AEs or for ineffectiveness.

**UTILITY OF LOW-DOSE COMPUTED TOMOGRAPHY (LDCT) FOR IDENTIFYING PATIENTS WITH AXIAL PSORIATIC ARTHRITIS (AXPAS) - A CROSS-SECTIONAL STUDY**

**Keywords:** Diagnostic tests, Psoriatic arthritis

J. T. Chen1, H. So1, J. So1, J. F. Griffith1, L. S. Tam. 1. The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR); 2. The Chinese University of Hong Kong, Imaging and Interventional Radiology, Hong Kong, Hong Kong (SAR)

**Background:** Psoriatic arthritis (PsA) is a multicentric disease with axial involvement being a critical feature. As inflammatory back pain (IBP) may be atypical or even absent, axial PsA is often under diagnosed. Axial PsA (axPsA) is currently diagnosed by identifying sacroilitis on radiography. However, the detection of radiographic sacroilitis is not entirely reliable and is challenging in early disease. Recently, magnetic resonance imaging (MRI) has been used to diagnose sacroilitis to good effect. Even more recently, low dose (<0.5mSv) computed tomography (LDCT) has been used to identify structural changes of sacroilitis such as erosions and ankylosis. However, the usefulness of LDCT for diagnosing sacroilitis in axPsA compared to radiography and MRI remains uncertain.

**Objectives:** To investigate the usefulness of LDCT in diagnosing axPsA-related sacroilitis compared to radiography and MRI.

**Methods:** Consecutive biologic disease modifying anti-rheumatic drug (bDMARDs)-naive patients who fulfilled CASPAR criteria were recruited into this cross-sectional study, regardless of the presence of back pain. Radiographs of the pelvis, LDCT and MRI of the sacroiliac joints were performed.

**Results:** 33 patients (age: 45 ± 12 years, 23 (70%) male, disease duration: 3.0 ± 6.5 years) were recruited. The cohort had moderate peripheral joint disease (Disease Activity in Psoriatic Arthritis (DAPSA): 18.78 ±1 6.33) and skin disease (Psoriasis Area Severity Index (PASI): 5.40 ± 7.10). Axial disease activity (Ankylosing Spondylitis Disease Activity Score, ASDAS) was 2.92 ± 1.26. Twenty (61%) patients were on conventional synthetic DMARDs. Radiography revealed definite sacroilitis according to modified New York criteria in 2 (6%) patients while 8 (24%) patients had possible sacroilitis and 23 (70%) had no sacroilitis. LDCT revealed sacroilitis in 9 (27%) patients, including both patients with radiographic sacroilitis, 7 (88%) of the 8 patients with possible radiographic sacroilitis and 2 (4%) of 23 patients with normal radiographs (Figure 1). Patient with LDCT-sacroilitis had longer symptom duration, higher patients’ pain score, physician global, enthesitis scores and Bath Ankylosing Spondylitis Metrology Index (BASMI) (Table 1). The presence of human leukocyte antigen (HLA) B27, IBP, and fulfillment of the Assessment of SpondyloArthritis international Society (ASAS) 2009 criteria of axial spondylitis could not differentiate between patients with or without LDCT-sacroilitis. LDCT had 100% agreement with MRI. MRI detected 9 patients with sacroilitis, all of whom were identified by LDCT.

**Conclusion:** LDCT revealed sacroilitis in 4 times more patients than radiographs. Patients with sacroilitis had higher disease activity across various disease domains. LDCT had excellent agreement with MRI. LDCT is very helpful for diagnosing axPsA, especially when access to MRI is limited.

**AB1130 CAUSAL ASSOCIATION BETWEEN LOW-DENSITY LIPOPROTEIN CHOLESTEROL AND PSORIATIC ARTHRITIS**

**Keywords:** Psoriatic arthritis, Genetics/Epigenetics

Q. Dong1,2, X. Yang1,2, M. Zhu1,2, J. Y Chen1,2, Q. Feng1,2, Q. Yu1, P. F. He1,2, A. L. Wang1,2, Z. Zhang1,2,4, Key Laboratory of Rheumatism Immunology Microenvironment, Shanxi Medical University, Taiyuan, Shanxi Province, China; 2. Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, Shanxi Province, China; 3. Keyshki Key Laboratory of Big Data for Clinical Decision Research, Shanxi Medical University, Taiyuan, Shanxi Province, China; 4. The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China

**Background:** Psoriatic arthritis (PsA) is an inflammatory disease that causes inflammation and swelling of the joints and entheses in addition to skin symp-toms(PsA)[1]. Chronic psoriatic lesions may increase serum concentrations of low-density lipoprotein cholesterol (LDL-C) by producing large amounts of IL-6 and other pro-inflammatory cytokines, which release free fatty acids, cholesterol, and triglycerides from the adipose tissue[2]. However, whether LDL-C affects articular psoriasis is unclear.

**Objectives:** We used a two-sample Mendelian randomization (MR) analysis to investigate the causal associations of LDL-C with PsA.

**Methods:** Firstly, we obtained LDL-C-associated single-nucleotide polymorphisms (SNPs) from a GWAS published by the UK Biobank, including up to disequilibrium (LD) threshold for clumping was set to r² < 0.001. The clumping window size was set to 10000kb, and we selected autosome biiallelic SNPs with P-values < 5 x 10⁻⁸. Thirdly, as for MR analyses, F statistics were calculated to evaluate the strength of each instrument, the F-statistic of each SNP> 10, indicating a low risk of weak instrument bias. Inverse variance weighted (IVW) was the primary method to assess the association of genetically predicted LDL-C and PsA risk. Fourthly, MR-Egger and weighted median were applied to validate the results from IVW. The Cochran Q test and funnel plots were used to test the possible heterogeneity. The directional pleiotropy was separated by intercepting from MR-Egger and MR-presso. Finally, a leave-one-out sensitivity analysis was also performed.

**Results:** With 158 LDL-C-associated SNPs, LDL-C was a hazard factor for PsA/OR = 1.30, 95% CI (1.02-1.65, P = 0.032), which was consistent in the direction with the weighted median[OR=1.38, 95%CI(1.00-1.91, P=0.050)] and MR-Egger(MR-Eggar: OR=1.43, 95%CI 1.01-2.04, P=0.045). Heterogeneity existed in the results(P<0.05). But IVW could provide a robust causal estimate in the presence of heterogeneity[3]. No evidence of pleiotropy was observed (MR-Egger-interpret:
We assessed PASS and its difference between sexes ($\chi^2$ test). Moreover, we performed two logistic regression models to assess which factors were associated with PASS "no" in both sexes.

**Results:** Two-hundred and forty-five patients were enrolled. Female less accepted their disease status, compared with male patients, PASS "no" was 49.1% vs 23.5% ($p<0.001$) (Table 1). The factor associated with a higher probability to have an unacceptable symptoms state was a higher disease activity (Table 2), both for male and female. In particular, for male patients, when DAPSA increases of 1 point, the probability to have a state of PASS "no" increases of 31% (OR 1.31, CI 95% 1.16-1.47), independently by age, disease durations, BMI and BSA. The same result was confirmed for female patients, but with a stronger association: when DAPSA increases of 1 points the probability to have a state of PASS "no" increase of 101% (OR 2.01, CI 95% 1.45-2.77), independently by age, disease durations, BMI, BSA and fibromyalgia. Moreover, fibromyalgia in female patients was not associated with PASS "no".

**Conclusion:** Female patients perceive their disease acceptable less than male. A higher disease activity (assessed by DAPSA), in particular for female patients, is the main factor to predict a state of non-acceptance of the disease.

**DOI:** 10.1136/annrheumdis-2023-eular.3406
Background: There is a considerable delay in the diagnosis of psoriatic arthritis (PsA) and several screening tools have been proposed for facilitating the diagnosis of PsA among patients with psoriasis. 

Objectives: We aimed to identify all instruments that were developed for screening PsA among psoriasis patients, and to analyze the psychometric properties of these instruments.

Methods: A systematic literature search was conducted to identify all studies for developing and validating instruments that evaluate the presence of psoriatic arthritis among psoriasis patients. Psychometric properties of each instrument including construct validity, reproducibility, internal consistency, sensitivity to change and feasibility were extracted. Additionally, the reasons for false positivity and false negativity with each instrument were tabulated. Literature review and data extraction were performed by two independent reviewers and inconsistencies were resolved by a senior investigator. The systematic review protocol was registered in PROSPERO (CRD42022137134).

Results: The systematic review revealed 15 screening instruments that were evaluated in a total of 42 studies. Psychometric evaluation was available for only 5 of the instruments, assessed in 8 studies. Table 1 shows the psychometric properties of these 5 instruments. Main reasons for false positivity were rheumatoid arthritis, osteoarthritis, mechanical pain and fibromyalgia for PASE, PEST, CONTEST and EARP, and ankylosing spondylitis and osteoarthritis for PASQ. Main reasons for false negatives were axial involvement for ToPAS and PEST, peripheral involvement for SiPAT, PASE and PAQ, enthesal involvement for PEST, PASE and ToPAS. Among these instruments, EARP had low false negativity and high false positivity rates, while ToPAS II had both low false positivity and low false negativity compared to the other instruments.

Conclusion: Overall, the psychometric properties of PsA screening tools have not been adequately evaluated. There is an unmet need for studies evaluating and comparing psychometric properties of different screening tools in a large patient population, including patients with various PsA features such as enthesitis, axial and peripheral involvement.

IMPACT OF INFLAMMATORY BOWEL DISEASE ON DAPSA REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS: A PROPENSITY SCORE-MATCHED RETROSPECTIVE ANALYSIS OF “CROSS” MULTIDISCIPLINARY PROJECT PATIENTS.

Methods: Patients aged 18 years old, with axPsA or axAS, during registration in the prospective monocentric register, between August 2012 and August 2022. A rheumatological investigation including clinical, laboratory and genetic assessments as well as imaging by conventional radiography and magnetic resonance imaging of pelvic and spine was performed.

Results: Of 250 patients (58 PsA vs 192 AS) with axial involvement, isolated axPsA patients were older at diagnosis (age of diagnosis of axial involvement was 35.8 vs 29.4). Patients with isolated axPsA were more likely to have: Less clinical inflammatory back pain compared with patients with isolated axAS: less limited cobb index (10/14 vs 10/12), finger-to-ground distance often equal to 0 cm in axPsA, less contrast changes of the paravertebral and paraspinal muscles, the thoracic expansion (4 vs 2 cm). Less limitation of inguinal pain (hip flexion 100 vs 70), a higher dactylitis count vs sDQ (0.3±1.2 vs 0.1±0.8), more nail lesions which could suggest looking for an association between nail damage and the presence of dactylitis in PsA, less extensive skin psoriasis (PsA= 2-13) and less presence of uveitis (18.96% (11/58) vs 23.95% (46/192)). Human Leucocyte Antigen (HLAB27) positivity was negatively associated with isolated axPsA disease (20 vs 78%). AxPsA were less frequently had radiographic sacroiliitis with unilateral/asymmetric pattern [On the X-ray, the SI were either normal or slightly modified, deliberately asymmetrical, rarely grade 4, the syndesmophytes were mostly more asymmetrical, coarse and of lumbar location, the heels were affected in less severe involvement, most often represented by simple shielding] and average patients showed slight spinal/pelvic radiographic progression (OR 0.14, 95% CI: 0.01, 0.58). Finally, AxPsA had lower BASDAI and HAQ scores (OR 0.10, 95% CI 0.010 0.47/ OR 0.03, 95% CI 0.00 to 0.17) and lower PRO evaluation (PRO pain 39.65 vs 49.47% and PRO fatigue 50 vs 52.6%).

Conclusion: Isolated axial PsA and AS are uncommon, axPsA has different clinical and radiographical characteristics when compared to AS. AxPsA is largely independent of HLAB27, it was associated with distinct radiographic ax PsA features, increased spinal progression and low grade radiographic sacroiliitis as well as lower disease activity and impact scores.

AXIAL PSORIATIC ARTHRITIS: ISOLATED ENTITY OR PHENOTYPE FORM ONLY

Keywords: Psoriatic arthritis, Spondyloarthritis

S. Abdellaou1, S. Lefkar1, Issad Hssani Beni Messous Hospital, Rheumatology, Algiers, Algeria

Background: The latest literature data increasingly emphasizes the axial involvement of Psoriatic Arthritis (PsA). The clinical and radiographic characteristics suggest that it is a new entity compared to the axial involvement of Ankylosing Spondylitis (AS), while therapeutic advances and cytokine targets suggest that it is a clinical form only.

Objectives: The objective of our study is to compare the characteristics of patients with axial PsA (axPsA) and axial AS (axAS).

Methods: Patients aged 18 years old, with axPsA or axAS, during registration in the prospective monocentric register, between August 2012 and August 2022. A rheumatological investigation including clinical, laboratory and genetic assessments as well as imaging by conventional radiography and magnetic resonance imaging of pelvic and spine was performed.

Results: Of 250 patients (58 PsA vs 192 AS) with axial involvement, isolated axPsA patients were older at diagnosis (age of diagnosis of axial involvement was 35.8 vs 29.4). Patients with isolated axPsA were more likely to have: Less clinical inflammatory back pain compared with patients with isolated axAS: less limited cobb index (10/14 vs 10/12), finger-to-ground distance often equal to 0 cm in axPsA, less contrast changes of the paravertebral and paraspinal muscles, the thoracic expansion (4 vs 2 cm). Less limitation of inguinal pain (hip flexion 100 vs 70), a higher dactylitis count vs sDQ (0.3±1.2 vs 0.1±0.8), more nail lesions which could suggest looking for an association between nail damage and the presence of dactylitis in PsA, less extensive skin psoriasis (PsA= 2-13) and less presence of uveitis (18.96% (11/58) vs 23.95% (46/192)). Human Leucocyte Antigen (HLAB27) positivity was negatively associated with isolated axPsA disease (20 vs 78%). AxPsA were less frequently had radiographic sacroiliitis with unilateral/asymmetric pattern [On the X-ray, the SI were either normal or slightly modified, deliberately asymmetrical, rarely grade 4, the syndesmophytes were mostly more asymmetrical, coarse and of lumbar location, the heels were affected in less severe involvement, most often represented by simple shielding] and average patients showed slight spinal/pelvic radiographic progression (OR 0.14, 95% CI: 0.01, 0.58). Finally, AxPsA had lower BASDAI and HAQ scores (OR 0.10, 95% CI 0.010 0.47/ OR 0.03, 95% CI 0.00 to 0.17) and lower PRO evaluation (PRO pain 39.65 vs 49.47% and PRO fatigue 50 vs 52.6%).

Conclusion: Isolated axial PsA and AS are uncommon, axPsA has different clinical and radiographical characteristics when compared to AS. AxPsA is largely independent of HLAB27, it was associated with distinct radiographic ax PsA features, increased spinal progression and low grade radiographic sacroiliitis as well as lower disease activity and impact scores.

Disclosure of Interests: None Declared.

matched by gender, BMI, age and DAPSA at bDMARDs start. In the PsA+IBD group mean age (± SD) was 55.21 ± 12.73, mean BMI was 27.70 ± 7.75, mean DAPSA was 17.28 ± 13.86, mean HAQ was 0.90 ± 0.74 and mean PASI was 1.13 ± 2.99. In PsA-only group mean age was 47.19 ± 10.23, mean BMI was 27.24 ± 5.10, mean DAPSA was 20.21 ± 12.58, mean HAQ was 0.92 ± 0.77 and mean PASI was 0.94 ± 2.25. The final multivariate model included DAPSA at baseline (OR 0.89 95% CI 0.82-0.97), duration of joint involvement (months, OR 0.99 95% CI, 0.98-0.99), HAQ (OR 0.66 95% CI 0.22;1.93) and presence/absence of IBD. HAQ was retained in the model as a potential confounder. PsA-only patients were more likely to achieve DAPSA remission at 12 month-follow up (OR=737; 95% CI 1.58-34.37).

**Conclusion:** In the management of PsA patients with IBD undergoing monoclonal anti-TNFα or anti-IL12/23 therapy, intestinal involvement has a negative influence on the clinical response of articular disease. For these patients clinicians should consider a low DAPSA at baseline and a shorter PsA disease duration as a predictor of 12-month DAPSA remission.

**AB1135**

**CHARACTERIZING THE MINIMAL DISEASE ACTIVITY DOMAINS ACHIEVED BASED ON DIFFERENT TREATMENTS.**

**Keywords:** Psoriatic arthritis, Outcome measures

S. Scroffignano1, F. M. Perrotta1, M. Fatica2, P. Triggiani3, P. Conigliaro1, M. Ferriolil, M. S. Chimenti2, E. Lubrano1. 1Università degli Studi del Molise, Dipartimento di Medicina e Scienze, della salute “Vincenzo Tiberio”; Campobasso, Italy; 2Università di Roma Tor Vergata, Reumatologia, Allergologia e Immunologia Clinica, Dipartimento di Medicina dei Sistemi, Roma, Italy

**Background:** Minimal Disease Activity (MDA) is a validated treatment response index for Psoriatic Arthritis (PsA). A status of MDA is reached when 5/7 domains are achieved. Even if MDA is worldwide used, both in clinical trials and in clinical practice, nowadays there are no studies that evaluated any differences in the MDA domains achievement based on various treatments.

**Objectives:** To characterize the MDA domains achieved based on treatment; to assess which treatment is associated with a higher probability to reach MDA status in clinical practice.

**Methods:** This is a cross sectional analysis of two longitudinal PsA cohorts. Inclusion criteria were: age ≥18 years, PsA diagnosis for at least 12 months, stable treatment for at least 6 months. Patients were grouped depending on the therapy: group 1: NSAIDs or COX2i or steroids, group 2: csDMARDs, group 3: TNFi, group 4: anti-IL 12-23 or 23, group 5: anti-IL17A, group 6: PD4i. For each group, MDA domains based on therapy were assessed. Logistic regression analysis was performed to assess the association between the treatment groups and the achievement of the MDA, independently by others confounding factors.

**Results:** Patients enrolled were 220. MDA was achieved in 45.8% of patients. In all treatment groups, the first three MDA domains more achieved were: BSA ≤3, SJC ≤1 and LEI ≤1, instead, in all groups (except for the PD4i) the MDA domains less frequently achieved were PtGA ≤2cm and pain on VAS ≤1.5cm

**Conclusion:** In each treatment group, the MDA domains less frequently achieved were PtGA ≤2 cm and pain on VAS ≤1.5 cm (Table 1). Moreover, the logistic regression analysis showed a higher probability to achieve MDA for those patients in group 3 and 4 when compared with group 1, independently by age, sex and disease duration (Table 2).

**Conclusion:** In each treatment group, the MDA domains less frequently achieved were PtGA and pain, suggesting that the patient driven domains are still an unmet need. Moreover, the probability to achieve MDA status is higher in patients in group 3 and 4. However, larger and prospective studies needed to confirm these preliminary results, including also the newest therapies recently adopted for PsA.

**Background:** It remains debated whether patients with psoriatic arthritis (PsA) are at greater risk of mortality.

**Disclosure of Interests:** psoriasis arthritis, Prognostic factors

1. Peaking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China.

**Conclusion:** In each treatment group, the MDA domains less frequently achieved were PtGA and pain, suggesting that the patient driven domains are still an unmet need. Moreover, the probability to achieve MDA status is higher in patients in group 3 and 4. However, larger and prospective studies needed to confirm these preliminary results, including also the newest therapies recently adopted for PsA.
Objectives: We aimed to determine the magnitude of all-cause mortality risk in patients with PsA compared with the general population through a systematic review and meta-analysis.

Methods: We searched Pubmed, EMBASE and Cochrane Library for studies published from inception to April 2022. STATA meta-analysis software was used to calculate the pooled risk estimates for mortality (standardized mortality ratio, SMR). To address the potential heterogeneity, $\chi^2$ test, I² statistics, subgroup analysis and sensitivity analysis were used.

Results: Our search identified 3235 articles, of which 18 studies with 13435 patients were eventually included for the analysis. A total of 7518 deaths were observed. Overall, we found a 1.13-fold increased risk of death in PsA patients when compared with the general population (meta-SMR: 1.13, 95% CI 1.03-1.25). Subgroup analyses showed that summary meta-SMR was higher in female patients (1.24 [95% CI 1.10-1.39]; P=0.49%, than male patients (0.92 [95% CI 0.62-1.37]; P=73.8%).

Conclusion: The existing data indicated approximately 13% increase of mortality among patients with PsA compared with the general population. More attention should be paid to those patients with risky characteristics.

BURDEN OF SKIN DISEASE IN PSORIATIC ARTHRITIS PATIENTS

Keywords: Patient reported outcomes, Psoriatic arthritis, Skin

M. Reed1, H. Boagey1, B. Milligan1. 1NHS Greater Glasgow and Clyde, Rheumatology, Glasgow, United Kingdom; 2NHS Greater Glasgow and Clyde, Rheumatology, Glasgow, United Kingdom

Background: Skin disease is one of the key domains of psoriatic disease and most Psoriatic arthritis patients have skin psoriasis. However skin and joint disease are often managed separately by rheumatologists, dermatologists or primary care health care providers. This can lead to disjointed care, unmet need, and treatment decisions that don’t take into account all aspects of this heterogeneous condition.

Objectives: We sought to evaluate how psoriatic skin disease is assessed and managed within our rheumatology services by identifying disease burden, approach to management and patient satisfaction.

Methods: In an existing psoriatic arthritis outpatient rheumatology clinic, patients were asked to anonymously complete questionnaires on disease extent, management and satisfaction. Patients also completed dermatology quality of life index (DLQI) questionnaires. Case notes and clinic letters were reviewed to collect data relating to patient diagnosis, medications and extent of clinical assessment during consultations over a 4 month period.

Results: Questionnaires were returned by 30 patients. 72% reported problems with psoriasis, with scalp being the most commonly affected body area. 77% participants reported receiving medication to manage joints only, 4% for skin only, 19% for both joints and skin. 13 participants were receiving topical medication for PsA, with the majority being managed by their GP. From the survey, 47% of respondents were asked about their skin in the rheumatology clinic, and 30% were given advice on its management. Of the patients that completed DLQI questionnaires mean score was 3.9 (SD 3.4). Average satisfaction with psoriasis management was 5/10 (SDEV 3.6). Of the 59 consultations from which data was extracted, 54% of consultations discussed joint only, and 37% discussed both joints and skin (remainder no discussion documented). At 45% of appointments joints and skin were examined, and at 35% of appointments joints only were examined (remainder no examination documented).

Conclusion: Psoriatic skin disease appears to be a significant burden in this population of patients, affecting 72% of those surveyed. Over half of these patients reported topical therapy to manage their psoriasis, with some requiring systemic treatments. Of these patients, most of the management of their skin condition was done by their GP, with the topic being brought up at rheumatology clinic in only half of cases. Less than half had skin examined at rheumatology clinic and less than a third were advised on management of their skin disease by their rheumatologist. Satisfaction levels with psoriasis management were fairly neutral overall. An integrated approach to care with a focus on opportunistic assessment should be encouraged and has potential to benefit both patient and clinician.

DIFFICULT-TO-TREAT PSORIATIC ARTHRITIS: ANALYSIS OF A SINGLE-CENTER COHORT FROM NORTHERN ITALY

Keywords: Psoriatic arthritis, Descriptive studies, bDMARD

G. Cincinelli1, M. Ferrito1,2, M. Pandolfi1, M. Biggioggero2, S. Casari2, M. Contalba3, C. Crotili4, F. Desini5, E. G. Favalli5, M. Manara2, R. Caporali1,2,3

1University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 2ASSST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy

Background: The multifaceted nature of psoriatic disease can potentially make its skin, articular, and extra-articular manifestation complex to manage. Biologic disease modifying anti-rheumatic drugs (bDMARDs) have dramatically improved the outcome of patients affected by chronic inflammatory arthritis. However, a satisfactory disease control is not achieved in a proportion of patients. While a “difficult-to-treat” (D2T) definition has been validated in rheumatoid arthritis (RA), it was only recently suggested for psoriatic arthritis (PsA) [1].

Objectives: Based on the proposed definition, we aimed to assess prevalence and characteristics of D2T-PsA in a single-center cohort.

Methods: We conducted a single-center, cross-sectional study. 269 consecutive, adult PsA patients receiving bDMARDs at a tertiary care, dedicated out-patient clinic were enrolled. Demographic, clinical, and clinimetric data, and the Health Assessment Questionnaire (HAQ) were gathered and depicted in Table 1. According to the aforementioned definition, D2T patients were identified as: 1) failure of ≥ 2 b/tsDMARDs (with different mechanisms of action- MoA) after failing csDMARD therapy; 2) signs suggestive of active/progressive disease (defined either as a DAPSA ≥14 or not achieving MDA; signs or symptoms suggestive of active disease; a rapid radiographic progression; a reduction of quality of life due to PsA symptoms); 3) disease management perceived as problematic by rheumatologists or patients (all three criteria must be met to define D2T patients). Comparison between D2T and non-D2T patients was performed with univariate analyses.

Results: Among 269 PsA patients, only 8 (2.9%) fulfilled D2T definition. In bivariate analysis, D2T patients presented higher rate of osteoarthritis (62.5% vs 24.9%; p=0.03), fibromyalgia (62.5% vs 14.9%; p<0.004), and therapy with steroids (50% vs 12.1%; p=0.008). Furthermore, D2T patients presented significantly higher patient global assessment (PGA 0-10) (7.5 vs 2.00; p<0.001) and VAS pain 0-10 (8.00 vs 2.00; p<0.001). Among non-D2T patients, 24 were in moderate disease activity (9.19%). Due to the unbalance between the groups numerosity, multivariate analysis was not feasible.

Conclusion: Only few patients satisfied the PsA-D2T definition in our cohort; application of a RA-like D2T definition to a heterogeneous disease as PsA should be discussed more broadly in the future.

AB1139

ASSOCIATION BETWEEN TRIGLYCERIDE-GLUCOSE INDEX AND CAROTID ATHEROSCLEROSIS IN PATIENTS WITH PSORIATIC ARTHRITIS: A CROSS-SECTIONAL STUDY

Keywords: Psoriatic arthritis, Epidemiology, Ultrasound

W. Xie1, Z. Zhang2, 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: The triglyceride-glucose (TyG) index, proposed as a surrogate marker for insulin resistance, appeared to be a good indicator of clinically overt cardiovascular events and subclinical atherosclerosis in general population.

Objectives: We aimed to investigate the correlation of TyG index with atherosclerotic risk among patients with psoriatic arthritis (PsA).

Methods: This cross-sectional study included 165 consecutive PsA patients receiving carotid ultrasonography with integrated TyG index, calculated as ln (fasting triglycerides (mg/dL)*fasting glucose (mg/dL)/2). Logistic regression models were applied to analyze the association of TyG index as continuous variables and tertiles with carotid atherosclerosis and carotid artery plaque.

Results: Overall, PsA patients with carotid atherosclerosis had substantially higher TyG index than those without (8.82±0.50 vs. 8.54±0.55, p=0.002). The frequency of carotid atherosclerosis was increased with increases in TyG index tertiles, showing 14.8%, 34.5%, 44.6% for tertile 1, 2 and 3, respectively (p=0.003). Multivariate logistic analyses showed that each 1-unit increase in TyG index was significantly associated with prevalent carotid atherosclerosis (unadjusted OR 2.65 [1.39-5.05]; fully-adjusted OR 2.69 [1.02-7.11]) compared to patients with tertile 1 of TyG index, the unadjusted and fully-adjusted OR for occurrence of carotid atherosclerosis were 4.64 (1.85-11.60) and 5.10 (1.54-16.93) in patients with tertile 3. Similarly, higher prevalent carotid artery plaque was observed with increasing TyG index (unadjusted OR 3.11 [1.54-6.26]; fully-adjusted OR 3.61 [1.15-11.38]) or with tertile 3 vs. tertile 1 (unadjusted OR 10.20 [2.83-36.82]; fully-adjusted OR 17.82 [2.88-111.11]).

Additionally, TyG index provided incremental predictive capacity beyond established risk factors, shown by an increase in discrimination ability (all P < 0.001).

Conclusion: TyG index was positively correlated with the burden of atherosclerosis in PsA patients, independent of traditional cardiovascular risk factors and psoriatic-related factors. These findings suggest that TyG index may be a promising atherosclerotic marker for PsA population.

Figure 1. The level of TyG index in patients with psoriatic arthritis, stratified by carotid atherosclerosis (CA), carotid artery plaque (CAP).

TREATMENT WITH TNF AND IL17 INHIBITORS DIFFERENTLY AFFECTS SERUM LIPOID PROFILE AND TH1/TH2 IMMUNE RESPONSE IN ANKYLOSING Spondylitis AND PSORIATIC ARTHRITIS.

Keywords: bDMARD, Psoriatic arthritis, Cardiovascular disease

K. Bonek1, S. Szczysielska1, M. Kajfasz2, A. Felis-Giemza3, B. Kwiatkowska7, M. Wislowska5, E. Kuca-Warawnin6, P. G1 1. National Institute of Geriatrics Rheumatology and Rehabilitation, Department of Rheumatology, Warsaw, Poland; 2. National Institute of Geriatrics Rheumatology and Rehabilitation, Early Arthritis Clinic, Warsaw, Poland; 3. National Institute of Geriatrics Rheumatology and Rehabilitation, Biologic Therapy Centre, Warsaw, Poland; 4. National Institute of Geriatrics Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland

Background: Psoriatic arthritis (PsA) is a form of spondyloarthrits (SpA) associated with alterations to the serum lipid profile. Current research suggests that biological treatment with TNF and IL-17 inhibitors differently affects the lipid profile and TH cells populations in PsA and ankylosing spondylitis (AS).

Objectives: To investigate the relationship between lipid profile, disease activity and T-cell phenotype changes in patients with SpA treated with TNF and IL-17 inhibitors.

Methods: A group of 36 SpA patients (AS 14, PsA 22) with high disease activity were assessed at the start and after 6 months of anti TNF (n=19) and anti IL-17 (n=17) treatment. Serum lipid profile: triglycerides (TG), total cholesterol (TC), low (LDL), and high-density lipoproteins (HDL), non-HDL, VLDL levels and atherogenic index (AI) were evaluated. Frequency of TH1, TH2, TH1/TH17, TH17 and T regulatory cells (Tregs) was determined by flow cytometry. The Spearman’s rank test was used for the statistical analysis of correlations, and the Wilcoxon rank test for dependent sample testing. All data are given as medians and the absolute and relative difference between two variables are expressed as delta.

Results: A significant reduction in disease activity was observed in all treated patients: DAPSA (32.5 vs 4); BASDAI (6.8 vs 1.5; p<0.01), ESR (15 vs 5mm/h; p<0.01) and CRP (6 vs 1mg/l; p<0.03). In all 36 patients, the reduction of disease activity was followed by a mild decrease of TG (205 vs 195mg/dL p<0.01), LDL (120 vs 110mg/dL p<0.02) and non-HDL levels (18 vs 5 vs 12mg/dl, p<0.05). In PsA patients treated with IL-17 inhibitor (n=13) we found a statistically significant, more pronounced decrease in lipid levels compared to AS and PsA patients treated with anti-TNFs i.e. delta of TG (19 vs 12 vs 12mg/dl p<0.03), LDL (23 vs 15 vs 10mg/dl p<0.05) and VLDL (11 vs 4 vs 4,5mg/dl p=0,02). In addition, in PsA group (n=22) after 6 months of treatment, we found reduction of TG (144 vs 94mg/dl p<0.05), VLDL (28,8 vs 20,6mg/dL p=0,04) levels and improvement of AI (4,4 vs 3,5 p<0,03) also deltas of DAPSA correlated positively with deltas of TC (rho=0,6 p=0,03) and non-HDL (rho=0,5 p=0,04). In flow cytometry after 6 months of treatment of all 36 patients we observed a rise of TH1 (11,3 vs 6,1% p<0,05) and a decrease of TH2 (5,7 vs 4,7% p<0,03) cells with almost no change in Treg cells (5,3 vs 5,3%). In AS patients (n=22) we have found correlations (p<0,05) between decreases of CD4+CD25+ cells and levels of TC (rho=0,6), non-HDL (rho=0,5), AI (rho=0,6) and DAPSA (rho=0,5). Effectiveness of treatment with TNF inhibitors and IL-17 was comparable in PsA or AS, but some differences were observed in alterations to lymphocyte profile. Patients treated with anti-IL-17 (PsA 13/ AS 4) showed a more pronounced increase in the TH1/TH17-like cell percentage (9.3 vs 13,5%; p<0,04) with a decrease of TH2 cells (73 vs 3,5%;p=0,03) and concomitant increase in TH1 cells (11 vs 13,8%). In patients treated with IL-17 inhibitors increase of TH1 cells correlated negatively (p<0,05) with TG (rho=0,6), non-HDL (rho=0,7), LDL (rho=0,6) levels, VLDL (rho=0,6) and positively with HDL (rho=0,4). In PsA patients TH1 cells correlated with DAPSA (rho=0,4). Patients treated with antiTNFS (AS 10/PsA 9) revealed an increase of TH1 cells (10,5 vs 12% p=0,04) and also a decrease of CD4+CD25+ (23 vs 14,5%; p=0,008), but no correlations with lipid profile were found.

Conclusion: Anti TNF and anti IL17 treatment distinctively affects lipid profile and T Cell balance especially in PsA. Patients with SpA treated with biologicals presented a tendency towards reduction of TC and LDL concentrations, but in PsA those changes were stronger with additional reduction of VLDL, non-HDL and TG levels. Alterations in the lipid profile correlate with disease activity in PsA and with a shift in TH cells increase (in the TH1/TH2 ratio with a decrease in the percentage of activated CD4+CD25+ T cells), which was not observed in AS.

AB1141 PREDICTORS OF X-RAY PROGRESSION IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Prognostic factors, Psoriatic arthritis, Biomarkers

S. Pötscher1, H. Radner2, D. Sieghart1,1, Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria

Background: Psoriasis arthritis (PsA) is a systemic chronic inflammatory disease, which leads to irreversible destruction of the joints. Multiple factors drive the development of this heterogeneous disease including genetic predisposition, environmental triggers, and immunologic dysfunction. Even structural damage differs significantly between patients, with a subset of patients suffering from severe and rapid (rheumatoid arthritis-like) bone destruction (arthritis mutilans), while others experience only modest signs of bone damage, or develop new bone formation.1

Objectives: The study aims to identify potential predictors for radiographic such as clinical, radiographic, and laboratory parameters.

Methods: In this retrospective data analysis 231 patients with PsA and at least two available x-rays were included. Radiographs were scored according to Sharp-van-der-Heijde-total Score (mSvdHTH) modified for PsA and a mean annual progression (MAP) rate was calculated by dividing the change in mSvdHTH between two x-rays number of years between them. For each patient, the median of the annual progression rates was calculated. Patients were grouped in no progressors (MAP ≤ 0.5), low progressors (MAP 0.5 < MAP ≤ 2.5) and high progressors (MAP > 2.5). Clinical data such as the clinical disease activity index (CDAI), radiographic data and laboratory data (CRP ESR, C-terminal Telopeptide) were analysed for their predictive value of radiographic progression using parametric and non-parametric statistical analysis according to the distribution of data. For correlation analysis Spearman’s rank coefficient was used. For group analysis ANOVA was used. Dichotomous variables such as gender or nail involvement were analysed using χ2-test. Multiple linear regression analysis was used to identify factors influencing radiographic progression.

Results: The mean baseline mSvdHTS in high progressors was 41.59 (43.53), 19.89 (34.93) in low progressors and 16.25 (26.77) in non-progressors. Baseline mSvdHTS was significantly correlated with MAP (r = 0.27, p < 0.002) rate. Group analysis comparing clinical and laboratory parameters in patients again showed significant difference baseline mSvdHTS. The high progression cohort also exhibits a greater mean CRP, ESR, CDAI, median first year CDAI, TJC68, SJC66 and a higher percentage of nail involvement than low- or non-progressors but no statistically significant result was found. In a multiple linear regression analysis baseline SvdHS (β = 0.51, 95% CI 0.28-0.73, p < 0.001), median CDAI in the first year after baseline (β = 0.51, 95% CI 0.19-0.83, p = 0.018) and CDAI at baseline (β = -0.62, 95% CI -1.05 - -0.19, p = 0.043) were significantly associated with mean annual progression. No association was found between MAP and bone turnover markers.

Conclusion: This study shows a clear association of Sharp-van-der-Heijde score at baseline with future radiographic progression. Moreover, the median CDAI in the first year after baseline was associated with radiographic progression.

Acknowledgements: The authors thank Gabriela Supp and Susanna Mössmer for scoring the radiographs.

AB1142 DOES OBESITY PLAY A ROLE IN FOOT INVOLVEMENT IN PSORIATIC ARTHRITIS?

Keywords: Spondyloarthritis, Comorbidities, Psoriatic arthritis

S. F. Azevedo1,2, C. Mazeda1,2, S. P. Silva1,2, C. Pinto Oliveira1,2, A. Barcelos1,2,3, 1Centro Hospitalar do Baixo Vouga, Rheumatology Department, Aveiro, Portugal; 2Egas Moniz Health Alliance, Academic Clinical Center, Aveiro, Portugal; 3Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisboa, Portugal

Background: Several studies have reported a higher prevalence of obesity in Psoriatic Arthritis (PsA).1 Obesity may lead to more weight on the joints, namely on the ankle/foot joints, altered mechanics, and repetitive micro-trauma. Foot involvement is common in PsA, including arthritis, dystrophic nails, toe dactylitis and Achilles enthesitis. Obesity has been found to be associated with higher disease activity and worse functionality scores in PsA patients.1

Objectives: The purpose of this study was to evaluate the role of obesity in foot involvement in PsA patients.

Methods: A retrospective study including patients with PsA (all patients fulfill CASPAR criteria) followed from January to May 2022, from a Rheumatology Clinic. Patients were divided into two groups: with current or previous foot involvement (assessed clinically or by ultrasound) (group 1) and without current or previous foot involvement (group 2). Sociodemographic, clinical and laboratory data were collected. Obesity was defined as a body mass index greater than or equal to 30 Kg/m2 and multimorbidity was defined as 2 or more comorbidities. Descriptive analysis was performed using means and standard deviation (SD), medians and Interquartile. range (IQR) for continuous data, and frequencies and percent- ages for qualitative variables. Clinical, radiological and laboratory findings were compared between patients with and without foot involvement using parametric and non-parametric tests, with a p-value ≤ 0.05.

Results: A total of 154 patients were enrolled (mean age of 57.08 (+11.54) years and 39.6% were women). Foot involvement was found in 110 patients (71.40%). Obesity was more prevalent among patients with foot involvement – group 1 (40.90% vs 13.64%; p<0.001). Enthesitis was found in 35.10 % of patients with Achilles enthesis (28%) as the most frequent manifestation. PsA patients in group 1 who were obese had higher prevalence of Achilles enthesis (p= 0.01). 18.18% of patients had current/previous toe dactylitis and dystrophic nails were found in 37.7% of patients (no differences were encountered between obese and non-obese patients). Multimorbidity were more frequent in PsA patients with foot involvement- group 1 (p=0.04). We found a higher frequency of extra-articular manifestations and higher HAQ disability index values in patients with foot involvement (p=0.03 and p<0.001, respectively). Although we did not find statistically significant differences in the HAQ disability index between obese and non-obese patients with foot involvement, there was a predominance of disability in obese patients. PsA patients in group 1 who are obese have higher C-reactive protein (p=0.01) and higher consumption of non-steroidal anti-inflammatory drugs (p=0.02). We did not find statistically significant differences in swollen and tender joint counts, in conventional and biological DMARDs between obese and non-obese patients in group 1.

Conclusion: Obesity was more prevalent among PsA patients with foot involvement, suggesting its presence may enhance and contribute for foot complaints in these patients. Patients with foot involvement had higher HAQ disability index levels, reflecting the negative impact of foot involvement in daily functionality in these patients. Our study highlights the importance of obesity management in PsA patients with foot involvement. Further studies are needed to develop weight reduction strategies that can be applied in clinical practice, in order to improve outcomes related to PsA.

AB1143 MIR-10B EXPRESSION IN PSORIATIC ARTHRITIS PATIENTS WITH DAPSA SCORE REMISSION OR LOW DISEASE ACTIVITY

Keywords: Biomarkers, Psoriatic arthritis

S. S. Köksal1,2, Z. Öztürk1, U. Akınt1, D. Karataş1, G. Günsel Eksikler2, E. Çökük2, A. Deveci Ozkam2, Ú. Erkorkmaz2, E. Gönlüllü3, 1Sakarya University Faculty of Medicine, Department of Rheumatology, Sakarya, Turkey; 2Sakarya University Faculty of Medicine, Department of Medical Biochemistry, Sakarya, Turkey; 3Sakarya University Faculty of Medicine, Department of Medical Biostatistics, Sakarya, Turkey

Background: Psoriatic arthritis (PsA) is a heterogeneous inflammatory rheumatologic disease associated with psoriasis. The etiopathogenesis of PsA has not been fully elucidated. Although activity scores are used in the follow-up of patients, reliable biomarkers are not yet available. MicroRNAs (miRNA) are non-coding RNA oligonucleotides whose cellular expression levels change in inflammatory and autoimmune diseases and provide gene expression regulation. miRNA-10b are being investigated for their potential biomarker properties in the diagnosis and follow-up of psoriatic arthritis.

Objectives: In this context, the current study aimed to determine the changes in mir-10b expression level in patients with PsA who have remission/low disease activity according to DAPSA score and in age-sex matched healthy population.
Methods: Ethics committee approval was obtained from Sakarya University Ethics Committee for the study (E-71522473-050.01.04-15102135). RNA isolation, cDNA synthesis and RT-PCR analysis were performed in 30 PsA patients (18 Female and 11 Male) and 20 matched control group (20 Females and 11 Males) with DAPSA scores in remission or low disease activity, who applied to Sakarya University Internal Medicine Rheumatology Clinic between January 2019 and February 21, miR-10b expression levels. U6 was used as internal control. IBM SPSS Statistics 26 program was used for statistical analysis.

Results: The mean age of the patients with psoriatic arthritis was 47.4±13.4, and the control group was 46.6±12.9 (p=0.78). No gender difference was analyzed between the two groups. (p=0.92). In addition, it was analyzed that the miR-10b expression level was 0.90-fold in PsA patients compared to the control group, and the expression level did not change significantly compared to the control group (p=0.53).

Conclusion: In our study, no statistically significant difference was observed in terms of miR-10b expression in PsA patients with DAPSA remission-low disease activity when compared to healthy controls. Further studies are needed in patients with moderate and high activity psoriatic arthritis.

The study was supported by the 2209-A Tubitak Student Project (1919B012101025).

OBJECTIVES: This study aims to assess the prevalence of sSS in patients with non-arthritic psoriasis and PsA and illuminate disease features associated with sSS.

Methods: Psoriasis patients diagnosed by a dermatologist and patients classified as PsA who fulfilled the CASPAR criteria were questioned for Sjögren’s symptoms consistent with the 2002 American-European Sjögren’s Syndrome Criteria (AECG). The salivary gland scintigraphy of the patients with oral dryness was performed and the unstimulated salivary flow rate (SFR) was measured. Schirmer’s test was performed on patients with dry eyes. Anti-Ro antibodies were measured and minor salivary gland biopsies were performed in patients with a diagnosis of sSS detected by objective measurements. After the evaluation of the patients, the sSS was classified according to the 2002 AECG. The frequency of sSS in non-arthritic psoriasis and PsA patients were compared. In addition, PsA patients were divided into two groups according to the presence and absence of sSS, PsA-specific characteristics in these two groups were compared.

Results: Of the 184 psoriasis patients who participated in the study, 112 had PsA, and 72 had psoriasis without arthritis. There was no significant age difference between non-arthritic psoriasis and PsA patients (48.3±11.9 and 49.4±13.5, respectively; p=0.59) Similarly, female to male ratio (ratios (%)); non-arthritic psoriasis: 43/29 (57.4/30.3), PsA: 82/30 (73.2/27.3), respectively; p=0.08) and age of onset of psoriatic skin changes (mean (SD)) of non-arthritic psoriasis: 30.3±10.9, PsA: 29.4±13.2, respectively; p=0.68) did not differ between non-arthritic psoriasis and PsA patients. sSS was more prevalent in PsA patients when compared with the non-arthritic psoriasis group (PsA: 20 (%17.9), non-arthritic psoriasis: 1 (%1.3), p<0.001). None of the patients had a previous diagnosis of sSS. Of the patients with sSS (n=20), 18 had salivary gland involvement detected in salivary gland scintigraphy, four Anti-Ro positivity, and three low unstimulated SFR. All PsA patients with sSS (sSS/PsA) had a positive Schirmer test. sSS/PsA patients were significantly more positive for ANA and had plantar fasciitis frequently than PsA patients without sSS (Table 1). Although not statistically significant, the age of onset of joint involvement in sSS/PsA patients was higher and was treated less with biological therapy (Table 1).

Conclusion: Secondary Sjögren’s syndrome is part of the clinical picture in a substantial proportion of PsA patients and its absence in non-arthritic PsO implies that sSS is arthritically associated. Whether the type of arthritis in sSS/PsA patients has a pattern necessitates larger patient numbers. A higher rate of ANA positivity may suggest the role of B lymphocytes in the progression from PsO to PsA.

The Comparative Performance of Three Screening Questionnaires for Psoriatic Arthritis in a Primary Care Surveillance Program.

**Keywords:** Epidemiology, Non-pharmacological interventions, Psoriatic arthritis

P. Hellwell,1 L. Coates,2 M. Ransoms,2 S. Brown,2 J. Paolham,1 J. Weddell,1 P. W. Tippett,2 N. Mecht,2 Leeds Institute of Rheumatology and Musculoskeletal Medicine, Leeds, United Kingdom;1 University of Oxford, Rheumatology, Oxford, United Kingdom;2 University of Leeds, Leeds Institute of Clinical Trials Research, Leeds, United Kingdom;3 University of Nottingham, Academic Unit of Population and Life Sciences, Nottingham, United Kingdom;4 University of Bath, Department of Life Sciences, Bath, United Kingdom

**Background:** There are considerable delays in the diagnosis of psoriatic arthritis (PsA) and earlier diagnosis is likely to lead to better outcomes.

**Objectives:** The aim of this study was to compare the performance of three PsA screening questionnaires in a primary care psoriasis surveillance program.

**Methods:** Participants with psoriasis, and not known to have psoriatic arthritis (PsA), were identified from general practice databases and invited to attend a secondary care centre for a clinical assessment. The three participant-completed screening questionnaires (PEST, CONTEST, and CONTEST with a manikin CONTEST) were administered along with other patient reported measures and reducing variability in practice. Despite their vital role in standard practice, adherence to guidelines has been reported to be suboptimal. Overall, no information is available of how rheumatologists would interact with recently published national clinical practice guidelines [1, 2].

**Background:** The use of quality-of-care indicators is an important strategy to measure and evaluate if the care provided in the standard clinical setting adheres to current evidence informed best practices. Achievement of quality indicators is often reported as a quality score (%). Quality indicators are often developed from guidelines, systematic literature reviews, or expert panel consensus using a systematic approach. The recently developed national guidelines for inflammatory arthritis [1, 2] provided the fundamentals of quality indicators of inflammatory arthritis.

**Objectives:** To evaluate quality indicators for inflammatory, their use in routine clinical practice reflecting the processes of clinical care and improvement in outcomes.

**Methods:** Quality measurement was carried out across 5 centers based on six domains of quality: 1. Structure (Describes the innate characteristics of providers and the system and the organisational aspects of care), 2. Process (Assesses actual healthcare service delivered to patients by healthcare providers), 3. Patient experience (Describes the patient’s perception of quality of care)[2], 4. Outcome (Assesses the end result or the final results of the delivered care), 5. Access (Evaluates the provision of timely and appropriate healthcare), 6. Efficiency (Describes the relationship between clinical performance and resource use). Data were logged based on patients’ recorded data.

**Results:** Inflammatory arthritis services are provided in 100% of the centers. 88.3% of the participants voted that they do implement “Treat to Target” approach and quality indicators for the management of inflammatory arthritis in their standard practice. Patient experience was rated positive in 63% whereas Timely treatment target was recorded in 74%. Efficiency evaluation revealed constrains attributed to lack of insurance cover of cost of some recommendations (72.7%).

**Conclusion:** Irrespective of resource and infrastructure constraints, assessment of all the relevant domains of care, revealed improvement and strengths of all the other measures. Results revealed that the treating rheumatologists not only adhere to quality indicators required for the management of inflammatory arthritis, but also provide timely and appropriate healthcare that has been well received by the patients. Such results are vital as quality measurement in rheumatology is focused primarily on processes of care, consequently, process measurement facilitates implementing actionable targets for improvement instead of focusing solely on outcomes of care.

a clinical examination of skin and joints was performed. Participants who demonstrated signs of inflammatory arthritis suggestive of PsA were referred, via their GP, for a further assessment in a secondary care rheumatology clinic.

**Results:** A total of 791 participants attended the screening visit and 165 participants were judged to have signs and symptoms of inflammatory arthritis, of which 150 were referred for assessment. Of these 126 were seen and 48 were diagnosed with PsA. The results for each questionnaire were as follows: PEST: Sensitivity 0.625 (95% CI 0.482 to 0.749), specificity 0.757 (0.724 to 0.787). CONTEST: Sensitivity 0.604 (0.461 to 0.731), specificity 0.766 (0.736 to 0.796). CONTEST2: Sensitivity 0.542 (0.401 to 0.676), specificity 0.834 (0.805 to 0.859).

**Conclusion:** Minimal differences in discriminative ability between the three screening questionnaires were found. PEST performed better at identifying cases of peripheral arthritis, although numbers were small (Figure 1).

**Disclosure of Interests:** None Declared.

**Programme Grants for Applied Research programme.**

**Notes:** The study included 554 patients from thirteen countries: mean age 45 years (SD 13), 57% females, median disease duration four years (IQR 2-9); 89.2% had skin PsO, and 43.5% had nail PsO. The disease was active overall: mean PsA activity was 4.7 (SD 2.5), versus a PhGA of 3.9 (SD 2.4). Similarly, PGA for PsA activity was 4.7 (SD 2.5), versus a PhGA of 3.9 (SD 2.4). This discordance may negatively impact treatment adherence and decision-making processes. It may be more comfortable assessing joints than skin. The patient's evaluation of disease activity needs to be taken into account when considering the disease management plan, especially in patients who are not in remission.

**Methods:** This multicentric multinational cross-sectional study was conducted in thirteen Arab countries by the Arab League of Associations of Rheumatology (ArLAR) research group (ARCH). During a single routine visit, patients and physicians were requested to rate the PsA disease activity on a numeric scale from 0 (no activity) to 10 (worst activity). In addition, demographic and disease data were collected, as well as PGA and PhGA for psoriasis (PsO) activity, Health Assessment Questionnaire (HAQ), Fibromyalgia Rating Screening Tool (FIRST), Patient Health Questionnaire (PHQ4) and Disease Activity in Psoriatic Arthritis (DAPSA). First, the correlation between PGA and PhGA for PsA and PsO disease activity was assessed statistically using the Spearman correlation coefficient (PsA and PsO) and graphically using the Bland and Altman method (PsA). Second, concordance between the PGA and PhGA PsA activity (defined as a difference between -2 and 2) was calculated and correlated with demographic and disease factors using multivariable binary logistic regression.

**Results:** Among 554 patients' measurements, 358 (84.2%) were in concordance with the PhGA for an agreement in PsA activity (defined as a difference between -2 and 2) was calculated and correlated with demographic and disease factors using multivariable binary logistic regression.

**Conclusion:** In this unselected sample of patients from Arab countries, there was a strong concordance between PGA and PhGA for PsA activity. This raises questions about patient expectations and pain perceptions in Arab countries. Concordance was stronger for PsA than PsO, indicating that rheumatologists may be more comfortable assessing joints than skin. The patient's evaluation of disease activity needs to be taken into account when considering the disease management plan, especially in patients who are not in remission.

**SEX DISTRIBUTION IN PSORIATIC ARTHRITIS: SYSTEMATIC LITERATURE REVIEW**

**Keywords:** Gender/diversity issues, Epidemiology, Psoriatic arthritis

B. Fırlıtan1, G. S. Kart Bayram1, G. Ayan1, U. Kalınçoğ1, 1Hacettepe University Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

**Background:** The prevalence of psoriatic arthritis (PsA) is considered equal in male and female patients but recent studies in cohorts of PsA it has been observed that women are more dominant in sex distribution, and the female-male ratio varies between 1.2 and 2 [1]. It is not yet clear whether this is related to a change in the epidemiology of the disease.

**Objectives:** To assess the female-male ratios in recent PsA studies.

**Methods:** A systematic review of the literature (from January 2020 to September 2022) was performed using the Pubmed database with keywords and MeSH terms referring to psoriatic arthritis. Randomized controlled, cross-sectional, prospective, and retrospective cohort studies involving ≥20 patients and specifying the number of men and women were considered eligible. Only original articles in English were included. Two independent reviewers performed study selection and data collection. The number of female and male patients, study design, study center, and PsA clinical phenotypes were recorded.

**Results:** Total of 1469 articles were selected for full-text reading, of which 486 were included for analyses. Overall, the number of studies in which the F/M and M/F ratio ≥1.5 was 86 (17.7%) and 60 (12.4%), respectively. Comparing the study types, it was observed that the female gender was more dominant in cross-sectional studies (p=0.004), Table 1. The sex distribution was more heterogeneous in single-center studies than in multi-center studies. Studies were stratified according to continents; it was found that the number of studies in which the F/M ratio is ≥1.5 was higher in America than the multinational studies (27% vs. 4%). On the other hand, the studies from Asia had higher male predominance.

**Conclusion:** Although there were some differences observed in sex distribution by study design and continents, overall, the ratio of females to males was similar. The female predominance observed in some studies might be due to selection bias or greater access to the medical system.

**ORDER OF APPEARANCE OF PSORIASIS AND ARTHRITIS SYMPTOMS IN PSORIATIC ARTHRITIS: COMPARATIVE STUDY OF A RETROSPECTIVE COHORT**

**Keywords:** Prognostic factors, Epidemiology, Psoriatic arthritis

P. Moya Alvarado1,2, H. S. Park3, A. Laiz1,4, A. Lopez-Ferre2,3, C. Marco Pascual1, A. García-Alja1, A. Casals Uruquiza1, C. Pitarch Grau1, C. Díaz-Torre1, B. Magallares1, I. Castelvi1, S. Ros1,3, S. P. Fernandez-Sanchez1, H. Codes1, L. Sainz Comas1, A. M. Millán Arciniegas1, J. L. Tandaipan1,4, L. Puig1,2, H. Corominas1,2,4, Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 3Universitat Autònoma de Barcelona, Medicine, Barcelona, Spain; 4Hospital de la Santa Creu i Sant Pau, Dermatology, Barcelona, Spain; 5Hospital Dos de Maig, Rheumatology, Barcelona, Spain

**Background:** Little is known about the chronologic order of appearance of psoriasis (Pso) and psoriatic arthritis (PsA) symptoms and its effect on disease evolution. Most information is based on population-based registries or big data that may lack precision.

**Objectives:** To evaluate duration and chronologic order of appearance cutaneous and articular manifestations of PsA from 1st symptoms till diagnosis. To compare differences between patients with symptoms and diagnosis of Pso before PsA with those that manifest Pso after PsA.

**Methods:** A retrospective cohort study was conducted. Eligible patients were 219 patients that met ASAS criteria visited the SpA clinic between July – October 2022. Finally, 129 patients that met CASPAR criteria and Pso diagnosis were included. Other autoimmune rheumatic diseases were excluded. Data were collected previously reviewing patient records available from the electronic medical system.
and paper database of the hospital. Additional information was retrieved from the shared medical history database of the Catalan Institute of Health which attends the 99.2% of the population. Missing data were collected prospectively by patient interview. ANOVA or Kruskall-Wallis test was carried out according to variable distribution.

Results: A total of 129 patients were included from which 98 had all time data related to disease appearance. There were 13.3% of missing data. The median disease evolution in years was 14 years with patients from 1 to 53 years of duration. The description and comparison of the clinical characteristics of each group is summarized in Table 1. Patients that begin with arthritis showed significant association with higher elevated C reactive protein and longer PsA disease duration. Longer time till arthritis appearance as well as more prevalence of Dactylitis was more observed in patients that begin with PsO before arthritis.

Conclusion: Significantly higher prevalence of CRP elevation in patients that begin with arthritis. Higher prevalence of dactylitis and longer time until articular manifestation was observed in patients that begin with PsO.

AB1152 FATTIGE IN PATIENTS WITH PSORIATIC ARTHRITIS OF EMPLOYABLE AGE

Keywords: Psoriatic arthritis, Patient reported outcomes

N. Tulebek1, I. Fairushina2, D. Abdulguniaev3, E. Kirillova.1 Institute of Gastroenterology, Hepatology and Metabolism "Intema clinic"; rheumatology, Almaty, Kazakhstan; 2Kazan State Medical University, Internal Diseases, Kazan, Russian Federation

Background: Fatigue is an important and underrated multifactorial manifestation of psoriatic arthritis (PsA).

Objectives: The evaluation of frequency and relationship of fatigue with anthropometric, clinical, laboratory, ultrasound (US) data and quality of life (QoL) in patients with PsA of employable age.

Methods: The study included 92 patients with PsA aged 18-59 years. Assessment of fatigue was conducted using a fatigue subscale from the FACIT-F questionnaire. Severity of skin lesions and arthritis was determined with PASI and DAPSA, respectively, as well as anthropometric data, the number of painful and swollen joints and entheses, inflammatory biomarkers, the number of inflamed entheses and entheses with structural changes and the number of active and non-active synovitis detected by US, QoL by SF-36 and DLQI and functionality by HAQ-DI.

Results: In all 92 patients: male - 42 (45.7%), mean age 42.9±9.6 (SD) years (y), PsA duration was 7 (2; 11.8) y; PASI 15.2 (10.2; 21.4), DAPSA 3.8 (1.2; 9.6). Fatigue (FACIT-F values <34 points) was detected in 46 (50%) patients. It was associated with psoriasis (<0.05) and PsA duration (p<0.01), DAPSA (p<0.01), and clinical enthesitis (p<0.01). At the same time, there was no relation between (b/w) age and anthropometric data (body mass index, waist and hip circumference, waist-to-hip ratio) (<0.05), FACIT-F score was correlated with physical functioning (SF-36 subscale) and DLQI scores (<0.01). These data are consistent with findings from other studies, especially with psoriasis burden, despite the fact that the relation b/w fatigue, PASI and psoriatic onychodystrophy (NAPSI) was not found (p>0.05). Association of fatigue with inflammatory markers (ESR, hs-CRP) and US articular and enthesal inflammation was not found (<0.05). Probably this indicates a greater influence of clinical signs, rather than US that could be explained by the high incidence of asymptomatic course of these changes.

Conclusion: Fatigue was found in 46% of employable aged PsA patients and was associated with clinical signs of PsA, particularly, with its activity and duration. Fatigue has been linked to physical functioning and DLQI scores. Further research is needed to investigate the individual factors that make the greatest influence to the fatigue development. The results of this study may indicate the need for routine fatigue examination among people with active PsA.

AB1153 FATIGUE AND PSORIATIC ARTHRITIS: WHAT CHARACTERISTICS?

Keywords: Descriptive studies, Quality of life, Psoriatic arthritis

A. Ben Amou1, S. Rahmouni1, H. Thini1, K. Zouaoui1, S. Rekik1, S. Boussaid1, H. Sahil1, M. Elleuch1, 1RABTA Hospital, Rheumatology, Tunis, Tunisia

Background: Psoriatic arthritis (PsA) can cause an impairment of patients' quality of life. Fatigue is a common and often underestimated symptom in PsA.

Objectives: We aimed to assess the characteristics of fatigue in PsA.

Methods: This was a cross-sectional study including patients with PsA meeting CASPRA criteria. Socio-demographic, clinical and biological data were collected. The FACIT fatigue score (Functional Assessment of Chronic Illness Therapy) was calculated for all patients. It is a 13-item questionnaire evaluated on a five-point scale (4 = no fatigue to 0 = extreme fatigue), with scores from 0 to 52, the highest scores correspond to less fatigue [1].

References: NIL.
Results: There were 37 patients, the sex ratio M/F was 2.1. The mean age was 52.46±14.22 years, the mean age at disease onset was 31.42±14.69 years and the mean disease duration was 133.62±112.82 months. The mean BMI was 25.68±5.15 kg/m². The mean CRP was 0.44±0.04 mg/L. The patient global assessment (PGA) of the disease was 50.54±17.74. The mean DAS28-CRP score was 4.06±1.54. The mean BASDAI and ASDAS-CRP scores were 5.06±6.14 and 2.60±1.05, respectively. The mean DAPSA score was 38.31±35.05. The mean BASFI and HAQ were 4.91±2.59 and 1.30±0.93, respectively. The mean FACIT fatigue score was 16.11±11.98 [0-49]. It correlated with mean BMI value (r=0.442; p=0.044), age at disease onset (r=0.421; p=0.016), PGA (r=0.397; p=0.036), and HAQ (r=0.437; p=0.020). Patients with a BMI≥25 kg/m² had a higher FACIT fatigue score (19.94±13.20 vs. 11.00±8.12, p=0.049). In contrast, no correlation was identified with gender, age, smoking, disease chronology, extra-articular involvement, extra-articular manifestations, high CRP levels, DAS28-CRP, BASDAI, ASDAS-CRP, DAPSA, BASFI, and hip involvement.

Conclusion: Fatigue is an important symptom in PsA and can be responsible for significant psychosocial impact and impairment of quality of life. Its assessment and management should be part of the overall management of PsA.

AB1154 NEW INFLAMMATION PARAMETERS IN PSORIATIC ARTHRITIS: NEUTROPHIL/LYMPHOCYTE AND PLATELET/LYMPHOCYTE RATIOS

Keywords: Psoriatic arthritis
A. Ben Amou1, S. Rahmouni1, H. Tibs2, K. Zouaoui3, S. Rekk1, S. Boussaid1, H. Sahil1, M. Elleuch1,2. Rabta Hospital, Rheumatology, Tunis, Tunisia

Background: Monitoring disease activity in patients with psoriatic arthritis (PsA) is crucial. Commonly used inflammation markers, including C-reactive protein (CRP), lack specificity and sensitivity. Other markers using complete blood count (CBC) parameters have been proposed: neutrophil/lymphocyte ratios (NLR); platelet/lymphocyte ratios (PLR).

Objectives: The aim of this study is to investigate these ratios in PsA.

Methods: A cross-sectional study including patients with PsA meeting CASPAR criteria. Socio-demographic, clinical, and biological data were collected. NLR and PLR ratios were calculated from the CBC parameters.

Results: Thirty-seven patients were enrolled; the sex ratio M/F was 2.1. The mean age was 52.46±14.22 years. The mean age at disease onset was 31.42±14.69 years. Axial and peripheral involvement were noted in 21 and 31 cases, respectively. Rheumatoid factor, ACPA and ANA were positive in 41.32±14.69 years. Axial and peripheral involvement were noted in 21 and 37 patients (P<0.01). s-PD-1 levels were elevated in patients who had active synovitis (P<0.01). The mean DAPSA score was 10.28±5.39 in G II. Plasma levels of sPD-1 were 465.64±251.16, 786.44±153.96, and 198.73±73.36 in the three groups respectively with significant increase in G I & GII than controls (P<0.01). s-PD-1 levels were elevated in patients who had active synovitis than clinical, laboratory, radiological characteristics and disease activity.

Conclusion: Plasma levels of sPD-1 were elevated in PsA patients and correlated with disease severity and activity. s-PD-1 might be good predictor of PsO and PsA disease activity, a new biomarker or target for immunomodulatory therapy.

REFERENCES:
Background: Psoriatic Arthritis (PsA) is associated with obesity and its related metabolic abnormalities. The role of diet as an adjunct therapy in PsA remains unclear.

Objectives: We aimed to describe the prevalence of cardiometabolic abnormalities and adherence with healthy eating recommendations among patients participating in the DIPSA study and assess their association with measures of disease activity.

Methods: DIPSA is a randomized controlled trial (NCT04180904) that aims to compare the efficacy of Mediterranean diet and DASH-low caloric diet vs. standard of care as adjunct therapy in patients with PsA who are overweight or obese (BMI>25). Study participants must have Disease Activity in Psoriatic Arthritis (DAPSA) score >10 and be on stable therapy. Baseline information on the first 32 patients enrolled in the study (out of expected 90 patients) was analyzed. The presence of cardiometabolic abnormalities was assessed based on medical history, physical examination and laboratory tests. All participants completed a 24-h dietary recall of foods/beverages consumed during 3 separate weekdays. Healthy Eating Index (HEI) 2015, a diet quality score which evaluates adherence to dietary guidelines for Americans, was calculated. The score includes 13 food components (9 components encouraged, 4 to limit) with a range of 0 (low) to 5 or 10 (high). We describe the baseline cardiometabolic abnormalities and adherence with healthy diet scores and assess their correlation with PsA disease activity measures.

Results: The mean age of study participants was 53.3 years (71.9% females). The mean DAPSA, tender and swollen joint counts were 23.6, 6.8 and 11, respectively. A significant proportion of the patients had obesity (71.9%) and related metabolic abnormalities such as dyslipidemia (41.9%), hypertension (37.5%) metabolic syndrome (46.9%). Mean HEI-2015 was 59.3 with higher adherence scores (HEI-2015>50; 25%Q1) found in females than males (91% vs. 57%, p<0.05). No differences in HEI-2015 scores were found between age and level of education groups. Of the individual HEI-2015 food groups, the lowest adherence scores were found for whole grain and total sodium consumption (Table 1). Significant correlation was found between lower added sugar and both lower fatigue and lower PSAID scores (Figure 1), and correlation between greater whole fruit consumption and lower swollen joint count. Additionally, a correlation was found between the unsaturated than saturated fatty acids and both lower fatigue and lower PSAID scores (Figure 1).

Conclusion: High prevalence of metabolic abnormalities was found in patients with PsA starting a diet intervention study. Adherence with healthy diet eating recommendations at baseline was higher in female patients and individual foods, particularly sugar and whole fruit consumption, were associated with PsA measures of disease activity. The DIPSA study will determine the role of dietary interventions as adjunct therapy in PsA.

HIGH PREVALENCE OF UNDIAGNOSED PSORIATIC ARTHRITIS AMONG PATIENTS WITH PSORIASIS: ALGERIAN MULTICENTER SCREENING SURVEY USING PURE4 QUESTIONNAIRE AND CASPAR CRITERIA.

Keywords: Psoriatic arthritis, Epidemiology

A. Djebbari, A. Abi Ayed, S. Bennedjemja, H. Merouan, S. Oulebsir, B. Abdelatif, Z. Rayhan, B. Saber, A. Noureddine, K. Ahmed, K. Rafik, B. Abderraoufi, HCA Hospital Kouba, Department of Rheumatology, Kouba Algeria, Algeria; Regional Hospital of Constantine, Department of Dermatology, Constantine, Algeria; Regional Hospital of Bechar, Department of Dermatology, Bechar, Algeria; HCA Hospital Kouba, Department of Rheumatology, Kouba Algeria, Algeria; Regional Hospital of Bidia, Department of Dermatology, Bidia, Algeria

Background: Psoriatic arthritis (PsA) is a polymorphic disease, in term of clinical presentation, severity and evolution. Skin lesion precedes joint damage in 84%, therefore, a multidisciplinary approach associating dermatologist and rheumatologist provide an opportunity for earlier diagnosis, more timely therapy and prevention of disability.

Objectives: To provide Algerian epidemiological data on the Prevalence of undiagnosed PsA among psoriasis patients in dermatology practice. This multicenter screening survey is conduct in order to reduce diagnostic delay and prevent progressive joint involvement and disabilities.

Methods: Between 2019 and 2022, a multicenter cross-sectional trial conducted in four Dermatology Clinics in Algeria (Algiers, Bida, Bechar and Constantine); had recruited patients presenting with plaque psoriasis and no prior rheumatologist-confirmed PsA diagnosis. Patients were screened using the Psoriatic Arthritis Uncluttered screening Evaluation (PURE4) questionnaire and were referred to a rheumatologist for assessment of PsA using classification for psoriatic arthritis criteria CASPAR if they had a PURE4 score > 1. Psoriasis characteristics:
Body surface area, psoriasis types, area, severity index, and psoriasis disability index tools were used for assessing psoriasis patients.

**Results:** The study included 212 patients with psoriasis: 64% were male and 36% female. Their median age was 48.12 ±11.74. Referring to the type of psoriasis, 72% presented with plaque psoriasis, 16% guttata 6% pustular and 24% with psoriasis of more than one type. Nail disease appeared in 24% and scalp disease in 26%. VAS-F was applied to all 212 psoriasis patients; among them n = 53 (25% of all tested patients) had a score ≥1. The sequential application of PURE4 and CASPAR criteria found a prevalence of undiagnosed PsA of 20.28% [95% CI: 9, 23.5]. The PPV of PURE 4 in this setting is 49.23% [95% CI: 39, 67]. Of these patients, 44% of patients with PsA had psoriatic nail disease and scalp involvement seen in 37%. With reference to the PsA type, 30% patients presented with polyarthritis, 44% with oligoarthritis, 39% with enthésitises, dactylitis in 23% and 13% with axial arthritis. The subgroup of patients with PsA had significantly higher rates of obesity (42%) compared to non-PsA. Patients with severe psoriasis (P = 0.001), nail and scalp involvement (P = 0.003) with chronic plaque psoriasis (P = 0.001) associated with obesity (P = 0.0001) were identified as independent positive predictors of PsA.

**Conclusion:** Screening for PsA in Algerian patients with psoriasis revealed a significant number of undiagnosed cases (20.28%) that should be treated early. Severe psoriasis nail and scalp involvement, and obesity are factors predicting the PsA development.

**FATIGUE IN ANKYLOSING SPONDYLITIS IS ASSOCIATED WITH DISEASE ACTIVITY BUT NOT IN PSORIATIC ARTHRITIS**

**Keywords:** Comorbidities, Patient reported outcomes

**Methods:** A cross-sectional analysis was performed in 105 patients (May – December 2022). Fatigue was assessed using 3 instruments: the fatigue sub-scale of the Short-form 36 survey (fatigue-SF36), the Visual analogue scale of fatigue (VAS), and the Functional Assessment of chronic illness. The Total Treatment Fatigue Index (FACT-T). T-test was used to compare mean fatigue between PsA and AS patients. To determine in each patient group the relationship between fatigue (assessed by FACT-T) and the other variables (DAPSA or ASDAS), CRP, ESR, Hemoglobin, HAQ, Hospital Anxiety and Depression Scale (HAD) and Brief Pain Inventory (BPI) a Spearman correlation was performed. A value of p <0.05 was accepted as statistically significant.

**Results:** A total of 105 patients were included, 55 (52.4%) PsA patients and 50 (47.6%) AS patients. We found that mean fatigue (using 3 instruments) had not significant differences in patients with PsA and AS (Table 1). In patients with PsA and AS, fatigue correlated to HAD, HAQ and pain, but not with CRP, ESR and hemoglobin (Table 2). In AS patients, high disease activity (assess by ASDAS) correlated with high levels of fatigue (lower levels on FACT-F). However, in patients with PsA, fatigue and disease activity (DAPSA) were not related.

**Conclusion:** In PsA and AS patients, fatigue seems to be related to subjective but not with objective (analytical) variables. In patients with AS, fatigue was related to disease activity, but in patients with PsA we found no correlation.

was recommended by experts due to the reduced number of items,[2] its high sensitivity/specificity and the feasibility to implement in clinical practice. **Objectives:** To confirm the presence/absence of psoriatic arthritis (PsA) according to the rheumatologist criteria in patients (pts) with psoriasis (Ps) 1 year after having answered the PURE-4 questionnaire in the dermatology consultation. **Methods:** Cross-sectional, observational, multicenter study conducted with primary data collection under conditions of routine clinical practice in Spain. Adult pts (≥18 years old) with Ps diagnosis that voluntarily accepted to participate. Two cross-sectional evaluations. Assessment I allowed to validate the Spanish version of the PURE-4 questionnaire and its results were previously communicated.[3] Data from assessment II (pts without PsA in assessment I were evaluated by the rheumatologist 1 year ±2 months later and performed the PsA diagnostic confirmation according to her/his criteria and collected clinical characteristics) are presented here. **Results:** 288 pts were included in assessment I. 223 (82.3%) of them without a PsA diagnosis. 219 pts were evaluable in assessment II, as they go to the second visit to rheumatologist: 56.2% male, with a mean (SD) age of 46.8 (12.5) years, a mean (SD) time from PsO diagnosis of 18.7 (12.8) years. Mean (SD) PURE-4 score was 2.4 (1.1) for pts with PsA and 1.2 (1.2) for pts without PsA diagnosis. Among pts who did assessment II, PsA diagnosis was confirmed in 12 (5.5%) pts. Area under the receiver-operating characteristic (ROC) curve was 0.7618 (95% CI: 0.6530, 0.8706) (n=217), confirming the good quality of the questionnaire (Figure 1). Using the Youden index, it was identified a score ≥2 indicative of a possible early presence of PsA, same as in assessment I. PURE-4 questionnaire showed a sensitivity of 75.0% and a specificity of 62.9%. In 63.6% of the cases, the PURE-4 questionnaire classified pts in the same way as the rheumatologist, with a negative predictive value of 97.7%. **Conclusion:** Assessment II findings together with the assessment I results, demonstrate the good PsA screening properties of the PURE-4 questionnaire, starting with a ≥2 score, differing from the original questionnaire (≥1).[4] Questions of the PURE-4 questionnaire referring to dactylitis, both buttocks pain and peripheral joint pain with swelling (before age 50) were the most “discriminative” of PsA. The study reinforce the recommendation to assess annually, or ideally every 6 months, the possible PsA presence,[5] as early PsA identification thanks to simple tools such as PURE-4 could help to prevent irreversible joint damage of this disease. **REFERENCES:**

SOFT TISSUE EDEMA VISUALIZED ON MUSCULOSKELETAL ULTRASOUND AS A DIAGNOSTIC TEST FOR PSORIATIC ARTHRITIS: A PILOT COHORT STUDY

Keywords: Psoriatic arthritis, Ultrasound, Rheumatoid arthritis

T. Swami1, S. Acikgoz1, U. Gazel1, C. Ivory1, R. Chowdhury1, A. Zahravi1, S. Aydin1,2, E. Hepworth1. 1University of Ottawa, Rheumatology, Ottawa, Canada; 2University of Ottawa, Ottawa Health Research Institute, Ottawa, Canada

Background: Musculoskeletal ultrasound (MSKUS) is more sensitive than physical examination to detect inflammation in extra-articular structures in psoriatic arthritis (PsA).[1] Peritendinous soft tissue edema on MSKUS has shown to be more frequent in PsA when compared to rheumatoid arthritis (RA).[1,2,3]

Objectives: Here we assess the degree of association between the presence of flexor compartment (FC) soft tissue edema and the diagnosis of PsA with the aim of developing a soft tissue score to differentiate PsA from rheumatoid arthritis (RA).

Methods: This pilot prospective cohort study included 16 PsA and 40 RA patients from the Biologics Clinic at a single centre site in Ottawa. Patients are referred to the biologics clinic if they require initiation of, or changes to biologic disease modifying antirheumatic drug (bDMARD). In addition to demographic and clinical data, eight MSKUS images were collected from each patient including one Grayscale (GS) and one power Doppler (PD) image of the FC of the 2nd and 3rd bilateral digits using a GE Logic E9 and a 7.5 MHz transducer. Images were scored on a 0–2 semiquantitative scale to assess the degree of soft tissue edema, where 0 indicates absent, 1 indicates mild, and 2 indicates severe GS or PD. Following data collection, scoring was completed by two investigators blinded to the patients’ diagnosis and in random order. Consent decision was taken as the final score.

Results: Disease characteristics are provided in Table 1. On MSKUS, PsA patients had a statistically significant higher total GS score compared to RA (7.0 vs 5.0, p=0.005). We found that numerically higher number of PsA patients had PD score of 2 in ≥3 fingers (20.0% PsA vs 2.5% RA, p=0.057) and GS score of 2 in ≥3 fingers (43.8% PsA and 22.5% RA, p=0.189). Table 1

| GS score =2 in ≥3 fingers* | 3 (4.83) | 0 (0.0) | 0.189

Conclusion: Our results suggest a possible role for FC soft tissue edema visualized on MSKUS in both GS and PD modes to differentiate PsA from RA. It is also important to understand the impact of soft tissue edema on disease pathogenesis and patient reported outcomes. While our sample size is small, some of the tests reaching reaching statistical significance using non-parametric testing encourages us to repeat this analysis again in the future as our cohort grows. When our sample size allows, we will assess for confounding effect of seropositivity, sex, age, BMI, previous therapy, and disease duration.

RACIAL AND GENDER - BASED DIFFERENCES IN THE PREVALENCE OF METABOLIC COMORBIDITIES AMONG PSORIATIC ARTHRITIS PATIENTS

Keywords: Gender/diversity issues, Comorbidities, Psoriatic arthritis

C. R. Ng1, 1Hospital Pakar Sultanah Fatimah, Rheumatology Unit, Department of Medicine, Muar, Malaysia

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis that develops in at least 5% of patients with psoriasis. It affects women and men equally. Obesity, diabetes, hypertension and hypercholesterolemia always affect PsA patients.

Objectives: To study the gender and race effect on the prevalence of metabolic comorbidities among PsA patients in Malaysia.

Methods: This is a retrospective study. The medical records of all PsA patients under rheumatology clinic Hospital Sultan Ismail and Hospital Pakar Sultanah Fatimah follow up from 1/1/2009 to 31/12/2022 were reviewed. Data on demography, type of skin disease, joint manifestations and past medical history were obtained and analysed using Chi Square test in SPSS.

Results: We identified 226 patients. 110 were male patients (male to female ratio 0.95). The Malays (128/226) were the majority followed by the Chinese (38/226) and others (3/226). Most of them were plaque psoriasis (181/226). The comon joint involvement was peripheral joint (174/226), followed by axial (25/226) and both (27/226). The prevalence of metabolic comorbidities according to gender (male vs female) were: [48/110, 44% vs 57/116, 49%; p =0.407] for hypertension, [35/110, 32% vs 37/116, 32%; p=0.990] for diabetes mellitus, [63/110, 57% vs 65/116, 56%; p= 0.861] for dyslipidemia. There was no association between gender and hypertension, diabetes mellitus and dyslipidemia. The prevalence of metabolic comorbidities according to races (Malay vs non Malay) were:[58/128, 45% vs 47/98, 48%; p=0.693] for hypertension, [40/128, 31% vs 32/98, 33%; p=0.822] for diabetes mellitus, [75/128, 58% vs 53/98, 54%; p= 0.498] for dyslipidemia. There was no association between ethnicity and metabolic comorbidities.

Conclusion: There was no difference in the prevalence of hypertension, diabetes mellitus and dyslipidemia between the gender and races in our patient cohort. References: NA.

COMPARISON OF SERUM CXCL13 LEVELS BETWEEN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS

Keywords: Prognostic factors, Cytokines and chemokines, Psoriatic arthritis

D. Yildirim1, I. Vasi1, M. Baykut2, M. Guengüld3, Y. Edekeit, H. Kucuk1, H. Karadeniz1, E. Adisen1, A. Erden1, A. Tufan1, B. Goker1, K. Nas4, M. A. Ozturk1. 1Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 2Sakarya University Education and Research Hospital, Internal Medicine,
Background: Psoriasis is a chronic, autoimmune disease with predominantly skin and joint involvement. Factors leading to the progression of psoriasis to psoriatic arthritis (PsA) is still a mystery in spite of an increasing number of in vivo and in vitro studies. CXCL-13, a B cell chemokine, studied and emphasized in lymphoid pathways, immune responses and pathogenesis of many rheumatologic diseases [1-2]. Moreover, this chemokine is associated with systemic involvement of rheumatic diseases such as lupus nephritis [3].

Objectives: The aim of the study was to evaluate serum CXCL-13 levels in patients with psoriasis and psoriatic arthritis and compare with healthy controls. Methods: 54 patients with psoriasis and 47 patients with psoriatic arthritis and 19 controls were enrolled to the study. Blood samples from study participants were collected and serum CXCL-13 levels were analysed with ELISA method via Human BLC(CXCL 13) kit (BT Lab, Shangai, China).

Results: Age, body mass index and serum PASI scores were similar between two patient groups; but higher when compared to controls (Table 1). Median levels of CXCL-13 levels were significantly higher in patients with psoriatic arthritis and psoriasis when compared to control group (p= 0,001, Figure 1). But serum CXCL-13 levels were similar between psoriasis and psoriatic arthritis groups (p=0,251). Also levels of C reactive protein and sedimentation were increased in patients and serum CXCL-13 in psoriasis and associated with disease severity [6]. We conclude that serum levels of CXCL-13 is associated with psoriasis, but not related with articular involvement.

AB1163 INVESTIGATION OF SELECTED AUTOANTIBODIES IN PSORIATIC ARTHRITIS AND THEIR ASSOCIATION WITH COMORBIDITIES

Keywords: Psoriatic arthritis, Autoantibodies, Comorbidities

A. K. Inderthal1, A. Knothe1, K. Frommer1, C. Heck1, M. Arnold1, J. Tarnier2, W. Hermann1, C. F. Meneses Villalba1, U. Müller-Ladner1, R. Hasseli1,2, E. Neumann1, Kerckhoff-Klinik, Rheumatology and Clinical Immunology, Bad Nauheim, Germany; 1Münster University Hospital, Internal Medicine D, Section of Rheumatology and Clinical Immunology, Münster, Germany

Background: Psoriatic arthritis (PsA) is a chronic inflammatory joint disease. It can result in severe joint destruction and cardiac or pulmonary involvement. So far, no specific autoantibodies have been identified that would simplify the diagnosis of PsA. HLA-B27 positivity is only detectable in 20% of PsA patients. It still takes several years until a diagnosis is established, which is crucial for the treatment. In addition, the disease is associated with a higher body mass index (BMI) and cardiovascular risk.

Objectives: The aim of the study was to identify possible PsA-associated autoantibodies which might enable earlier diagnosis, and to investigate possible associations of these selected autoantibodies with specific comorbidities.

Methods: Both, PsA patients and healthy individuals without known autoimmune disease were included in the study. Sociodemographic data (age, sex, BMI, waist circumference), current disease activity, current rheumatological therapy, cardiovascular diseases and fatigue were investigated. HLA-B27 status was determined and a radiological evaluation of PsA-typical changes in the hands and feet was performed. Serologically, antibodies against ADAMTS-L5, LL37, calpastatin and gliadin were investigated by ELISA.

Results: A total of 107 PsA patients (60% female) and 19 healthy controls (HC) were included. Median age of PsA patients was 59 years (21-80 years), 28% were HLA-B27 positive. Median BMI was 28kg/m² (19-48kg/m²). Cardiovascular disease was present in 65% of patients, which included the following conditions: arterial hypertension, atherosclerosis, heart failure, coronary heart disease (CHD) and myocardial infarction. Antibodies to LL37 were present in 47% of patients compared to 30% of healthy individuals. Antibodies to ADAMTS-L5 were detectable in 47% of patients and 35% of healthy individuals. Calpastatin antibodies were present in 23% of patients and 11% of healthy individuals and against gliadin in 3% of patients and 5% of healthy individuals. In patients with antibodies against LL37, antibodies against ADAMTS-L5 could also be detected in most cases (<0.001). In patients with a treatment duration of <5 years more frequently antibodies against calpastatin were detectable compared to those with longer treatment duration (p<0.05).

Conclusion: In summary, none of the antibodies investigated were found to be significantly elevated in PsA-patients compared to HC. However, in the group of patients with a treatment duration <5 years, autoantibodies against calpastatin were detected more frequently. This could suggest that this autoantibody might play a role in the early phase of PsA and immunomodulatory treatment might diminish autoantibody levels.

PSAQQ (PSORIATIC ARTHRITIS QUALITY OF LIFE) QUESTIONNAIRE: TRANSLATION, CULTURAL ADAPTATION AND VALIDATION INTO ARABIC LANGUAGE

Keywords: Quality of life, Psoriatic arthritis

R. Tekaya1, L. Rouached1, H. Hajji1, A. Ben Tekaya1, M. Jones2, W. Hamdi3, S. Nabli3, L. Metoui1, S. Bouden1, O. Saidane1, I. Mahmoud1, L. Abdelmoula1, Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; Charles Nicolle Hospital, Dermatology, Tunis, Tunisia; Kassab Institute, Rheumatology, Tunis, Tunisia; Department, Monastir, Tunisia; Military Hospital of Tunis, Rheumatology, Tunis, Tunisia

Background: Psoriatic arthritis (PsA) is a multifaceted inflammatory disease that has a strong negative impact on the quality of life of patients. The Psoriatic Arthritis Quality of Life (PsAQoL) questionnaire was the first disease-specific patient derived instrument developed to measure the quality of life in patients with PsA.

Objectives: Our objective was to translate the PsAQOL into Arabic language and evaluate its reliability and validity in patients with PsA.

Methods: This was a cross-sectional study including patients with PsA. A clinical and biological assessment of the patients was performed at inclusion. Translation of the original PsAQoL into Arabic was performed by professional bilingual and lay panel. Eight patients were interviewed to assess face and content validity. A separate sample of PsA patients (n=30) were invited to participate in a test-retest postal study in order to investigate reproducibility and construct validity. One week separated the two administrations. The Arabic version of Health Assessment Questionnaire (HAQ) was used as comparator instruments for concurrent validity.

Results: Face and content validity were satisfactory. The Arabic version of the PsAQoL was found to be relevant, understandable and easy to complete in only a few minutes. One item was excluded (item 16). It showed having no correlation with neither the other 19 items nor the total score of PsAQoL. The Arabic PsAQoL had excellent internal consistency (Cronbach’s α=0.926), and test-retest reliability (r=0.982). There was a positive correlation between the total score of the PsAQoL and the Arabic version of HAQ (Spearman’s r=0.838, p<10^-3). Exploratory factor analysis had extracted two factors explaining 55% of the total variance.

Conclusion: Nineteen items were selected to compose the Arabic version of PsAQoL which was found to be relevant, understandable and has excellent reliability and construct validity. The new measure will be a valuable new tool for use in routine for patients’ assessment.

ULTRASOUND AS A TOOL FOR EARLY DETECTION OF JUXTAARTICULAR NEW BONE FORMATION IN PSORIATIC ARTHRITIS AND THE ASSOCIATION OF SELECTED BIOMARKERS WITH NEW BONE FORMATION

Keywords: Psoriatic arthritis, Autoantibodies, Ultrasound

A. Knothe1, K. G. Hermann2, K. Frommer1, A. K. Indertthal1, C. Heck1, M. Arnold1, I. Tarner1, W. Hermann1, C. F. Meneses Villaiba1, E. Neumann1, U. Müller-Ladner1, R. Hasseli2, Kerchhoff-Klinik, Rheumatology and Clinical Immunology, Bad Nauheim, Germany; Charité – Universitätsmedizin Berlin, Radiology, Berlin, Germany; Münster University Hospital, Section of Rheumatology & Clinical Immunology, Münster, Germany

Background: We aimed to investigate whether the presence of NBF and specific autoantibodies could facilitate an earlier diagnosis of psoriatic arthritis.

Methods: Patients fulfilling the CASPAR criteria (Classification Criteria for Psoriatic Arthritis) for PsA were included in the study. X-ray examinations of the hands and feet were performed. Antibody levels of calpastatin, LL37, gliadin, and ADAMTS5 (Thrombospondin type-1 domain-containing protein 6) were determined by serum ELISA.

Results: Seventy-six patients (51% female) compared to 20 healthy controls (70% female) were included. The median age was 57 years (23-98) and the median disease duration was 10 years (1-54). HLA-B27 were positive in every fourth individual. By X-ray, NBFs were detectable in 55% (n=42) of the patients. In the ultrasound examination, these NBFs were also detectable (Figure 1). In addition, in 18 patients, signs of NBF were detectable due to the increased resolution of the ultrasound examination. Regarding the selected autoantibodies, none of the selected antibodies were associated with the presence of PsA or with PsA related NBFs.

Conclusion: In this study, NBFs were detectable radiographically as well as in the ultrasound examination. As ultrasonography is ubiquitously available in rheumatological offices and represents a gentle examination procedure for the patient, repeated X-ray examinations might be avoided, and regular ultrasound investigations might facilitate an earlier detection of PsA.

RANDOMIZED CONTROLLED TRIAL TO ANALYSE THE EFFECT OF BLOOD FLOW RESTRICTION TRAINING IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS COMPARED TO CONVENTIONAL RESISTANCE TRAINING – AN INTERIM ANALYSIS

Keywords: Rheumatoid arthritis, Psoriatic arthritis, Non-pharmacological interventions

C. J. Bauer1, M. Sturhahn1, C. Behning2, S. Petzinna1, P. Brosart1, P. Preuss1, V. Schäfer1, University Hospital Bonn, Clinic of Internal Medicine III, Department of Oncology, Haematology, Rheumatology and Clinical Immunology, Bonn, Germany; University Hospital Bonn, Department of Medical Biometry, Informatics and Epidemiology, Bonn, Germany; University Bonn, University Sports Division, Bonn, Germany

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are the two most common forms of arthritis with a prevalence of 1% and 0.5% in Europe. Physical activity exerts a major influence on disease activity, symptoms, quality of life, and increased cardiovascular risk [1,2]. In contrast to conventional strength training, Kaatsu blood flow restriction (BFR) training, which was initially developed in Japan as a rehabilitation measure, incorporates pneumatic cuffs...
applied to the extremities, which are recurrently inflated with a defined pressure. The inherent blood flow modification promises a less weight-intensive and thus joint-protective strength training, while still preserving sufficient muscular hypertrophy stimulus [5].

**Objectives:** Ours is the first study in the world to compare the effect of Kaatsu blood flow restriction training to conventional resistance training in RA and PsA patients.

**Methods:** In this pilot study (ethical approval under Institutional Review Board #217/20), 40 RA and 40 PsA patients are individually randomized to one of three groups: Kaatsu-BFR training (20 patients each), conventional resistance training (“CRT” 10 patients each), or the non-exercise group (10 patients each). Training is performed twice weekly over a 12-week period. Standardized recording of disease activity (via FFBB-H, IPAQ, and DAS 28 or PSAID12, plus clinical examination and CRP), myokine levels, sonographic muscle diameter measurements, bioimpedance analysis and clinical characteristics is performed.

**Results:** The interim analysis of 9 BFR vs. 4 CRT patients with rheumatoid arthritis showed comparable CRP reduction (mean ± SD: BFR: -1.08 mg/L ± 1.33, CRT: -0.89 mg/L ± 1.94) and reduction in the number of painful joints (mean ± SD: BFR: -0.78 ± 2.44, CRT: -0.76 ± 1.71) during the training period. BFR group results surpassed CRT group results in terms of weight loss (mean ± SD: BFR: -2.9 kg ± 3.6, CRT: -1.9 kg ± 3.1) and body fat mass reduction (mean ± SD: BFR: -2.8 kg ± 3.3, CRT: -0.3 kg ± 2.5). The interim analysis of 4 BFR vs. 4 CRT patients with psoriatic arthritis showed a comparable PSAID reduction (mean ± SD: BFR: -1.33, CRT: -0.89 mg/L ± 1.94) and reduction in the number of painful joints (mean ± SD: BFR: -0.78 ± 2.44, CRT: -0.76 ± 1.71) during the training period. CRT group results surpassed BFR results in terms of weight loss (mean ± SD: CRT: -0.76 ± 1.71) and body fat mass reduction (mean ± SD: CRT: -0.3 kg ± 2.5). The inherent blood flow modification promises a less weight-intensive and thus joint-protective strength training, while still preserving sufficient muscular hypertrophy stimulus [5].

**Background:** Obesity is a condition characterized by a chronic state of low-grade inflammation due to increased cytokine production in visceral adipose tissue [1]. Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are both autoimmune diseases that share comorbidities such as a high prevalence of obesity, a comorbidity that leads to a lower response to treatment with biologic drugs such as Anti-TNFs [2]. PsA has a higher prevalence of abdominal obesity to RA according to some recent studies [3]. Current research has shown that excess adiposity contributes to the development of cutaneous psoriasis in some patients and suggests that obesity may also be a key factor in the transition from cutaneous psoriasis to arthritis [4]; however, it has not been proven the etiological role of obesity in RA [5].

**Objectives:** To evaluate the waist circumference (WC) and the prevalence of obesity using the Body Mass Index (BMI) in a sample patients from the same hospital with a diagnosis of RA and PsA and to analyze the differences between both diseases.

**Methods:** It has been carried out an observational, retrospective, single center study. The population included in the study were patients from rheumatology clinic with a diagnosis of RA and PsA who were being treated with biological treatment. The variables analyzed were: age, sex, height (m), body mass (Kg) and WC (cm). The anthropometric variables were measured in the rheumatology nursing clinic. An anthropometric tape was used to measure the WC, taking the height of the navel as a reference in the patients. The BMI was calculated and the World Health Organization classification was used to categorize the patients. A descriptive analysis of the variables analyzed in the study was performed, including the mean and standard deviation (SD) of the continuous quantitative variables (BMI and WC). A one-factor ANOVA was performed to analyze the differences in the variables age, BMI, and WC between RA and PsA patients. Statistical significance was set at p<0.05.

**Results:** In this study a total of 245 RA and 122 PsA patients were included. The WC and BMI data of only 207 patients (121 with RA and 86 with PsA) were completed. The patients with PSA showed higher values of WC, observing significant differences with the patients with RA (103.66±15.05 cm vs 99.38±14.90 cm, p=0.04). However both patients with PS and with RA showed WC measurements above the recommended values (74.41% vs 74.38%). Regarding BMI, patients with PSA had a higher mean BMI (31.29±6.37 cm vs 28.85±5.84 cm, p=0.043) than patients with RA.

**Conclusion:** In the present study, patients with PSA showed statistical differences and had higher values of WC and BMI compared to patients with RA, coinciding with recent studies. More studies are necessary to characterize obesity in patients with RA and PSA and treat it adequately.

**AXIAL INVOLVEMENT IN PSORIATIC ARTHRITIS: WHAT PARTICULARITIES?**

**Keywords:** Psoriatic arthritis, Enthesitis, Disease-modifying drugs (DMARDs)
Logistic regression analysis identified that patients with axial involvement were more likely to have a longer duration of evolution (OR = 3.5) and elevated CRP (OR = 4.9).

Conclusion: Axial involvement in our study was present in 86% of the patients and was associated with a long duration of evolution and a statistically significant higher average CRP.

Logistic regression analysis identified that patients with axial involvement were more likely to have a longer duration of evolution (OR = 3.5) and elevated CRP (OR = 4.9).

Conclusion: Axial involvement in our study was present in 86% of the patients and was associated with a long duration of evolution and a statistically significant higher average CRP.

**TRANSCUTANEOUS VAGUS NERVE STIMULATION AS A PAIN MODULATOR IN KNEE OSTEOARTHRITIS**

**Keywords:** Osteoarthritis

G. G. Elshehawy1, M. E. Ibrahim1, N. A. Monem1, M. Hefny1, N. Elshaarawy1.  
1Suez Canal University, Physical Medicine, Rheumatology and Rehabilitation, Ismailia, Egypt

**Background:** We no longer consider Osteoarthritis (OA) as a degenerative disease, but rather as a multifactorial disorder in which low grade, chronic inflammation has a central role. In addition, evidence points to the presence of both peripheral and central nervous system sensitization as sources of pain in OA. Transcutaneous Vagus Nerve Stimulation (tVNS) has shown efficacy on pain, inflammation and central sensitization in other conditions such as fibromyalgia, pelvic pain, and headaches and therefore we hypothesized that tVNS could be an additional line of management for knee OA.

**Objectives:** To assess the efficacy and safety of tVNS on nociceptive pain, central sensitization, neuropathic pain, depression, anxiety, and physical function in individuals with knee OA.

**Methods:** Afferents of the auricular branch of vagus nerve were stimulated using an auricular electrode connected to a transcutaneous electrical nerve stimulation (TENS) device. We conducted 30 minutes session once a day for 3 days per week for 12 weeks. Sixty-eight patients with chronic knee OA were allocated randomly into active and sham group (34 patients in each group). The outcome measures included visual analog scale (VAS), pressure pain threshold (PPT), PainDETECT and Douleur Neuropathique 4 (DN4) questionnaires, hospital anxiety and depression scale (HADS), and knee injury and osteoarthritis outcome score (KOOS). These outcome measures were assessed at baseline, at the end of the stimulation period then after 4 weeks later.

**Results:** There was a significant improvement in VAS for pain score in the active tVNS group between the baseline and first follow-up visit, and between the baseline and second follow-up visit (P < 0.001). The median VAS improvement was 4.0 (3.0 – 5.0) in active group versus 1.0 (1.0 – 2.0) in sham group (p < 0.001). PPT in right knee, left knee and right elbow was significantly improved compared to baseline in active tVNS and maintained till 4-weeks post-intervention. On the other hand, in the sham group tVNS, right knee PPT was improved but not maintained. PainDETECT and DN4 questionnaires were statistically improved in active tVNS (p < 0.001). In contrast, DN4 questionnaire showed no improvement at all and PainDETECT showed improvement that was not maintained at the end of follow up in sham group. A statistically significant improvement in HADS immediately post intervention in active and sham tVNS (p < 0.001), this improvement was maintained only in the active group 4-weeks after intervention. Regarding functional outcomes, the improvement in KOOS was significant in the active group only (31.44 ± 18.49, p > 0.001). No serious adverse events were reported in both study groups.

**Conclusion:** This study provides preliminary evidence for the beneficial effects of tVNS in OA and raises the possibility of using neuromodulation as an add-on treatment to existing pharmacological and non-pharmacological measures.

**SHINS MUSCLE DYSFUNCTION IN FEMALE PATIENTS WITH KNEE OSTEOARTHRITIS**

**Keywords:** Pain, Osteoarthritis

L. Shvets1, V. Novosoletsky2, I. Shapoval1, L. Perebetiuk1, V. Khomenko1, M. Stanislavchuk1.  
1National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine #1, Vinnytsya, Ukraine; 2Communal nonprofit enterprise “Vinnytsya Regional Clinical Hospital named after N. I. Pirogov Vinnytsya Regional Council”, Regional Centre of Nephrology and Dialysis, Vinnytsya, Ukraine

**Background:** Knee osteoarthritis (OA) is a chronic disease known as a common source of pain and disability globally. OA is among the top 10 causes of physical disability in the elderly population. Loss of muscle mass and lower extremity muscle dysfunction are independently associated with progression of OA and reduction in health status.

**Objectives:** The investigation was aimed at studying the condition of flexor/extensor shin muscles in patients with knee OA, serum leptin concentrations and analyze correlations between them by statistical methods.

**Methods:** The study involved 71 patients with knee OA and 32 persons from the control group. There was measured the isometric strength of the flexor/extensor shin muscles and measured leptin serum levels. Muscle strength was measured by using an isokinetic device, approved by a state enterprise “Ukrainian Intellectual Property Institute” (patent #81950). All patients were performed common clinical investigations (complaints, medical history, physical examination data) laboratory, instrumental (knee joint X-ray) examinations, and statistical analysis methods were used.

**Results:** It was established that the age of OA patients included in the study ranged from 30 to 76 years and averaged 57.60 ± 11.69 years, and 32 % of the examined patients had had the history disease from 6 to 10 years, and 90.4 % of them suffered from excessive body weight or obesity of a certain degree. The study of maximal isometric force of flexor/extensor muscles of both shins revealed a significant reduction in the muscle strength in OA patients compared...
with the individuals from the control group. Thus, apparently healthy individuals had the strength of shin flexor muscles (min-max) within 9.6 – 16.9 kg, while the extensor muscles showed 12.6 – 22.5 kg. The OA patients had the strength of both shin muscle groups (the ratio of the total power to 12.1 kg for the flexor group, and 3.3 – 20.3 kg for extensor muscles. At the same time, like in the control group, the strength of the extensor muscles appeared to be higher than the one of the flexors. The calculated total muscle strength (the sum of the flexor and extensor muscle strength of both limbs) in OA patients was 31.97 ± 9.2 kg, whereas in the apparently healthy persons it was 58.65 ± 6.59 kg (p < 0.001). The calculated specific muscle strength (the ratio of the total muscle strength to OA patients’ blood strength (r = 0.05, p > 0.05), however, an inverse correlation between the specific force muscle and lepton concentration (r = -0.2, p = 0.09) was found. Instead, in the control group a statistically unreliable direct correlation between the total muscle strength and lepton level (r = 0.12, p > 0.05), and the inverse statistically significant association between the specific strength and the lepton concentration (r = -0.412, p < 0.05) were revealed. Such an inverse correlation undeniably suggests that the negative effect of lepton on the condition of muscle tissue and the blood elevation thereof is associated with a decrease in muscle strength. At the same time, a significantly lower coefficient of correlation between lepton concentrations and the specific strength of patients’ muscles indicates that, in addition to lepton, the disease itself (OA) makes a significant contribution to the reduction of muscle strength.

Conclusion: Understanding the role of the flexor/extensor shin muscles dysfunc-
tion in the pathogenesis of knee OA may help to improve further management approaches.

### AB1174 BODY COMPOSITION IN POSTMENOPAUSAL WOMEN WITH CHRONIC KNEE PAIN

Keywords: Pain, Osteoarthritis

N. Grigorisava1, N. Zaverukha1, A. Musienko1, M. Bystrytska1, D. F Chebotarev2; 1Institute of Gerontology, NAMS of Ukraine, Clinical Physiology&Pathology of Locomotor Apparatus, Kyiv, Ukraine

Background: Among all the known risk factors, obesity is one of the important risk factors for the incidence and prevalence of osteoarthritis (OA). However, body mass index (BMI), which reflects the severity of obesity, measures only height and weight with no consideration of other obesity-related characteristics, such as fat distribution or deposition. The features of fat deposition and distribu-
tion may serve as better indices of the metabolic activity of adipose tissue and can have an important influence on the pain and disability of patients with OA.

Objectives: The study aimed to assess the body composition indices in post-
menopausal women with chronic knee pain and its association with pain severity.

Methods: In the single-center study 230 females aged 50-89 years were examined and divided into groups depending on the intensity of chronic (>3 months) knee pain. Knee pain was assessed using the visual analog scale (VAS). Group I consisted of females with mild (VAS < 4 cm) pain (n = 87), group II - subjects with moderate (VAS more than 4, but less than 6 cm) pain (n = 111), and group III - women with severe (VAS ≥ 6 cm) pain (n = 33). The body composition (body weight (BW), height, body mass index (BMI), fat mass (FM), lean mass, appendicular lean mass (ALM) and appendicular lean mass index (ALMI, ALM/height), fat content (fat mass/BW), and ALM/BW were assessed by dual-energy X-ray absorptiometry (Lunar, Prodigy). Sarcopenia was deter-
dined according to ALM (< 15 kg) or ALMI (< 6 kg/m2), obesity - as BMI > 30 kg/m2, sarcopenic obesity as a combination of high-fat mass/BW (> 40 %) and low ALM/BW (> 23.47 % for females younger than 65 years old and < 19.4 % for females 65 years and older).

Results: All three groups did not significantly differ in age (F = 2.5, p > 0.05), age of menopause (F = 0.6, p > 0.05), and its duration (F = 0.4, p > 0.05). Women of different groups did not differ in height, however, BW was higher in group III than in groups II and I (84.6 ± 13.8 vs. 77.9 ± 13.9 and 73.0 ± 12.1 kg, F = 9.6, p < 0.0001), as BMI (30.6 ± 5.5 vs. 34.2±6.4, and 30.9±4.9 kg/m2, F = 13.3, p < 0.00001). The females with chronic severe knee pain had higher ALM (P < 0.00001), ALMI (P < 0.00001), and FM/BW (P < 0.05) compared to the women with mild knee pain. The frequency of obesity was 36.8 % in women with mild pain, 52.2 % of subjects in group II and significantly higher among females with severe pain - 63.6 % (F = 4.5, p < 0.05 in comparison with group I). Sarcopenic obesity was registered in 18.4, 279, and 36.4 % of females of the I, II, and III groups, respectively. It was significantly more frequent among women with severe than mild pain (χ² = 4.3, p < 0.04). However, sarcopenia was found in 13.8 % of women in group I, 14.4 % of subjects of group II and 6% of group III according to ALM as well as in 11.5, 10.8, and 6 %, respectively according to ALMI without significant differences.

Conclusion: Women with severe chronic knee pain have significantly higher BW, BMI, ALM, and fat mass than females with mild pain. Despite the absence of differences in sarcopenia frequency, the subjects with severe knee pain have not only an increased frequency of obesity but also high sarcopenic obesity.

IS DISTAL ENTEHESIS OF EXTENSOR DIGITUMOR TENDON A SPECIFIC ULTRASOUND FEATURE OF PSORIATIC ARTHRITIS?

Keywords: Ultrasound, Osteoarthritis, Psoriatic arthritis

S. Bouri1, H. Boussa13, S. Miladi1, A. Faza1, M. Yasmine1, K. Ben Abdelghani1, A. Lasta1,1 Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

Background: Distal interphalangeal (DIP) joints are commonly affected in both hand osteoarthritis (OA) and psoriatic arthritis (PsA). However, enthesitis is well known to be a hallmark of spondyloarthritis including PsA.

Objectives: Our study aimed to assess distal enthesitis of extensor digitorum tenon in PsA and hand OA using ultrasonography (US).

Methods: We conducted a cross-sectional study including two groups: Group 1 included patients with hand OA fulfilling American College of Rheumatology criteria and Group 2 included patients with PsA according to CASPAR criteria. All patients underwent a physical examination followed by an US exam. US was performed in all DIP joints. For each joint, the following abnormalities were assessed: synovial thickening, osteophyte, enthesitis, and power Doppler signal (PDS). A quantitative score (0/1) was used for each lesion. Pearson correlation coefficient was calculated.

Results: We examined 160 DIP joints in 20 PsA patients (13 women and 7 men), with a mean age of 55.5 ± 12.1 years [33–77]. We also examined 80 DIP joints in 10 patients with hand OA (9 women and one man), with a mean age was 66.1 years [46–78]. The mean duration of hand OA and PsA symptoms were 4.3 ± 7 years. The number of enthesitis was significantly higher in the PsA group (p=0.01) versus PsA (p=0.02).

Conclusion: Our study showed that distal enthesitis of extensor digitorum tendon was suggestive of PsA whereas osteophytes were exclusively observed in hand OA.

DIAGNOSTIC YIELD OF CT-GUIDED BIOPSY IN SUSPECTED INFECTIOUS SPONDYLODICTIS

Keywords: Imaging, Osteoarthritis

G. Mouna1, D. Khalilah1, H. Saghn1, R. Fakhfakh1, N. El Amri1, K. Baccouche1, E. Bouajina1,1 Hospital Farhat Hached, Rheumatology, Sousse, Tunisia

Background: Infectious spondylodiscitis is a serious and morbid disease. It is often suspected after magnetic resonance (MR) imaging of the spine. Suspected spondylodiscitis requires further workup, in which computed tomography (CT)-guided needle biopsy plays a crucial role.

Objectives: The aim of this study was to examine the yield of CT-guided biopsy in patients with suspected infectious spondylodiscitis, and to identify factors associated with successful pathogen isolation.

Methods: This is a retrospective study involving infectious spondylodiscitis from January 2010 to December 2021. All patients were identified with clinically and radiologically suspected infectious spondylodiscitis who underwent CT-guided biopsy of the vertebral lesion. Patient characteristics and clinical details were evaluated. Parameters were compared in patients with positive and negative microbiological and histologic results.

Results: A total of 42 patients (23 men, 19 women) were enrolled. The range was 55.8 years (SD ± 16.7). The mean duration of symptoms was 60.2 days (SD ± 52.7). The final diagnosis was tuberculosis spondylodiscitis in 15 patients (23.8%), brucellosis spondylodiscitis in 12 patients (28.6%) and mycotic spondylodiscitis in 15 patients (47.6%). CT-guided biopsy has a diagnostic yield of 44.8% (13/42). Biopsy was contributory in identifying 8/13 patients (58%) with tuberculous spondylodiscitis, and 5/13 patients (42%) with mycotic spondylodiscitis. Histological examination was the most sensitive diagnostic modality. The factors associated with successful microbe isolation were duration of symptoms (p=0.01) and not exposed to pre-biopsy antibiotics (p=0.02).

Conclusion: The CT-guided biopsy, as a diagnostic procedure for infectious spondylodiscitis, has a reasonably high diagnostic yield in this disease. A higher yield was identified in patients who has long duration of symptoms and not exposed to pre-biopsy antibiotics.

SPINAL EPIDURAL ABSCESS ASSOCIATED WITH INFECTIOUS SPONDYLODICTIS

Keywords: Osteoarthritis

G. Mouna1, D. Khalilah1, H. Saghn1, R. Fakhfakh1, N. El Amri1, K. Baccouche1, E. Bouajina1,1 Hospital Farhat Hached, Rheumatology, Sousse, Tunisia

Background: Infectious spondylodiscitis and spinal epidural abscess (SEA) are relatively rare conditions that is rising in incidence. SEA is a challenging entity associated with high morbidity and mortality. That's why early diagnosis is critical in this disease.

Objectives: We aimed to describe the clinical characteristics and outcomes of patients with spinal epidural abscess associated with infectious spondylodiscitis (SEA).

Methods: We conducted a retrospective study from June 2010 to December 2022. We included 42 patients with clinically and radiologically suspected infectious spondylodiscitis. Patient characteristics and outcomes were retrospectively reviewed.

Results: We enrolled 42 patients (23 men, 19 women) with infectious spondylodiscitis. The mean age was 572 years (SD ± 15.7). Twenty-nine patients (72.5%) had SEA. All patients showed varying degrees of focal spinal pain. Fever occurred in 16 patients. Ten patients (34.7%) exhibited neurological deficits. Furthermore, 20 patients (69%) had lumbar spine, 6 cases (20.7%) had thoracic spine, and 3 cases (10.3%) had cervical spine. Abscess locations was Anterior in 14 cases (48.3%), posterior in 5 cases (17.2%), and Circumferential in 10 cases (34.5%). Among 11 SEA patients, 12 cases (41.4%) had infection caused by Mycobacterium tuberculosis, 8 case had infection caused by brucellosis, 5 cases had infection caused by Staphylococcus aureus, one case had infection caused by Staphylococcus coagulase negative, one case had infection caused by Escherichia coli, one case had infection caused by candida albicans, and one case caused by Enterococcus faecalis. All patients underwent conservative treatment, two of which improved symptoms. Five cases undergo surgical treatment, one of which showed improved symptoms, 4 cases had left limb motor and sensitive dysfunction.

Conclusion: SEA is rare and is often difficult to diagnose in the early stage. Early diagnosis, followed by specific therapy is necessary to improve the prognosis of this disease.

AB1178

THE COMPARISON OF PRP ALONE, SUPERVISED EXERCISE ALONE, AND PRP COMBINED WITH SUPERVISED EXERCISE IN MANAGEMENT OF KNEE OSTEOARTHRITIS

Keywords: Clinical trials, Physical therapy/Physiotherapy, Osteoarthritis

S. Karabulut Aruğ1, D. Celic1, O. Ergin2, O. Kilicoglu3, 1Istanbul University- Cerrahpasa, Faculty of Health Science, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey; 2Istanbul University, Istanbul Faculty of Medicine, Department of Orthopedics and Traumatology, Istanbul, Turkey; 3Koc University, Faculty of Medicine, Department of Orthopedics and Traumatology, Istanbul, Turkey
Background: Platelet-rich plasma (PRP) has sparked widespread interest as a regenerative adjunct therapy, and it is increasingly being used to treat knee osteoarthritis (OA). There is a scarcity of reports on the characterization of injected products, as well as a scarcity of exercise protocols following PRP injections, despite the rising number of studies in the present PRP literature.

Objectives: The purpose of this study was to compare the efficacy of PRP with a supervised exercise program and reveal if the combination of the two treatments is effective in the management of knee OA.

Methods: This is a randomized, single-blinded, prospective, three-arm clinical trial. The PRP group received three weekly injections of fresh, leukocyte-poor PRP. The exercise group followed a structured and supervised exercise regimen for six weeks. These therapies were given in conjunction with the third group. The primary outcome was the change in overall average knee pain scores (on an 11-point numeric pain rating scale, with higher scores indicating worse pain) over a 24-week time period. The secondary outcomes were changes on the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), durations of the functional performance tests, and health-related quality of life. For statistical analysis, the mixed model with repeated measurements (ANOVA) was performed.

Results: A total of eight-hundred four patients with mild to moderate knee osteoarthritis were randomly allocated to three groups. There was a significant group-by-time interaction for overall knee pain (p<0.001). Pain reduction from baseline to 24 weeks was greater in PRP&Exercise group (Δ -5.40, 95%CIs -5.28 to -4.39). There were significant group-by-time interactions on the WOMAC total score, durations of the functional performance tests, and physical component of SF-12 (p<0.012). Exercise group and PRP&Exercise group had statistically greater impact than PRP alone, with large to very large effect sizes in terms of pain, self-reported function and functional performance tests (p<0.012, wp2>0.14).

Conclusion: PRP demonstrated short-term efficacy comparable to exercise or a combination of PRP and exercise; however, when compared to the other groups, it demonstrated a negative tendency in terms of long-term clinical improvements. PRP alone is not as effective as supervised exercise; however, if a patient has difficulties maintaining exercise programs for any reason, PRP can be offered as an alternative option.

Figure 1. KIMRISS grid region labels with 8-reader mean ICC from baseline knee MRIs from the Osteoarthritis Initiative dataset (n=61).
Knee osteoarthritis is the most common joint disorder and is associated with functional disability and pain. Total knee arthroplasty (TKA) is considered as an effective treatment for patients with end-stage knee osteoarthritis. The overall aim of this study was to investigate the change over time of knee strength and functional outcomes before and after bilateral total knee arthroplasty.

**Objectives:**
- The overall aim of this study was to investigate the change over time of knee strength and functional outcomes before and after bilateral total knee arthroplasty.
- The study aimed to investigate the effect of TKA on various functional outcomes in patients with knee osteoarthritis.

**Methods:**
- Retrospective cohort data of 308 patients who underwent primary bilateral TKA were analyzed.
- Outcome measures were assessed 3 times, preoperatively and at 6 weeks and 3 months after surgery.
- The study included patients with a minimum of 5-year follow-up.

**Results:**
- The knee flexion and extension range of motion (ROM) was measured.
- The knee extensor strength and ROM, and SCT of ascending were assessed.
- The overall improvement in functional outcomes was observed.

**Conclusion:**
- The study demonstrated that TKA surpassed most of their physical functions in the 3 months before surgery.
- The recovery of performance-based physical function did not return to baseline immediately after surgery.

**Keywords:**
- Osteoarthritis, Rehabilitation

**Disclosure of Interests:** None declared.

**INTRAMUSCULAR METHYPRENSILONE ADMINISTRATION IN HAND OSTEOARTHRITIS PATIENTS: A FEASIBILITY STUDY TO INFORM A RANDOMIZED CONTROLLED TRIAL**

**Keywords:**
- Osteoarthritis

**Objectives:**
- The aim of this study was to evaluate the feasibility of treatment with intramuscular (IM) methylprednisolone (MP) in hand OA by both healthcare providers (HCPs) and hand OA patients, and to observe the response to a single IM MP injection in patients with symptomatic hand OA.

**Methods:**
- We adopted a mixed methods design. Firstly, in a qualitative study we examined the acceptability of intramuscular MP using questionnaires with open-ended questions for all healthcare providers of the Rheumatology Department of the Sint Maartenskliniek and a semi-structured interview for an a-selective group of patients with clinically diagnosed hand OA not previously treated with MP.

**Background:**
- Inflammation is thought to play an important role in hand osteoarthritis (HOA), which is further associated with pain and increased limitation of hand function [1,2]. Therapeutic options in HOA are scarce [3].

**Results:**
- The study was twofold: to explore the feasibility of treatment with intramuscular (IM) methylprednisolone (MP) in hand OA by both healthcare providers (HCPs) and hand OA patients, and to observe the response to a single IM MP injection in patients with symptomatic hand OA.

**Methods:**
- We adopted a mixed methods design. Firstly, in a qualitative study we examined the acceptability of intramuscular MP using questionnaires with open-ended questions for all healthcare providers of the Rheumatology Department of the Sint Maartenskliniek and a semi-structured interview for an a-selective group of patients with clinically diagnosed hand OA not previously treated with MP. Second, in a prospective observational study the course of symptoms was examined in patients with hand OA who received an intramuscular MP injection as part of routine care.

**References:**
Conclusion: We found a high acceptability of intramuscular MP treatment for hand OA and our findings suggest that methylprednisolone may reduce pain and improve hand function as quick as 4 weeks after administration, with a persisting effect of almost 3 months. This suggests that it might be a valid long-term therapeutic option in these patients.

EFFECTIVENESS OF FATIGUE INTERVENTIONS IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Osteoarthritis, Physical therapy/Physiotherapy, Systematic review

H. Fawole1, O. Osadiaye1, O. Idowu2, O. Akinkolu3, M. Ibekaku4, M. Ojo5, A. Oyeyemi1, J. Riskowski1, A. University of Benin, Physiotherapy, Benin City, Nigeria, 2Redeemer’s University, Physiotherapy, Ede, Nigeria, 3University of Manitoba, Applied Health Sciences, Winnipeg, Canada, 4University of Nigeria, Medical Rehabilitation, Enugu, Nigeria, 5Guy’s and St Thomas NHS Foundation Trust, Physiotherapy, London, United Kingdom; “Arizona State University, Health Solutions, Phoenix, United States of America; ” Johns Hopkins Bloomberg School of Public Health, Department of Correctional Services, Baltimore, United States of America

Background: Pain and physical function are common factors targeted for osteoarthritis (OA) management. However, fatigue has been reported as an important component of OA experience and a significant concern for people with OA (Power et al., 2008). Despite this, fatigue has received very little attention. However, with increasing interests in fatigue, it is evident that fatigue be considered a top priority in clinical practice (Overman et al., 2016). Thus, there is dire need for evidence-based fatigue interventions in OA given the paucity of evidence in this area.

Objectives: To identify fatigue interventions and determine the effectiveness of the interventions in reducing fatigue immediately and over time in OA.

Methods: A review protocol was developed and registered with the PROSPERO database, with the ID CRD42020163730. Studies included comprised peer-reviewed randomized controlled trials (RCTs) that examined the effects of any intervention in the management of fatigue or vitality outcomes in people with upper limb and lower limb OA. Studies that used spiritual, pharmacological or surgical interventions to manage fatigue in patients with upper limb and lower limb OA were excluded. The Cochrane Collaboration’s tool for assessing the risk of bias (ROB) was used assess the quality of evidence for the included RCTs. Narrative synthesis was used to summarise the identified fatigue interventions while only studies on exercise interventions were used in the meta-analysis.

Results: Out of 2,586 studies identified from database search, 31 RCTs’ studies were included after screening for titles, abstracts and full texts. Of the 31 included RCTs, only nine studies were included in the meta-analysis comparing the effects of exercise versus non-exercise interventions on fatigue. From the ROB assessment, 11 RCTs were of low ROB whilst 11 had moderate and 9 high ROB respectively. The narrative synthesis identified 12 interventions for fatigue and these include activity pacing, cognitive behavioural therapy (CBT), yoga, exercise, acupuncture, moxibustion, pain-coping skills, BEMER therapy, modified shoes, massage/atherotherapy, education and thermotherapy. Exercise interventions included strengthening, balance, kinesthesia, and mobilization, hand-based, stretching, aquatic danced-based and web-based exercises. Activity pacing (mean difference [MD]=0.8; standard deviation [SD]=0.3), CBT (MD=3.42; [SD]=1.85), moxibustion (vitality: MD=2.61; [standard error]=1.69) had statistically significant reductive immediate effect on fatigue. The meta-analysis pooled results showed that exercise interventions on fatigue in OA was not statistically significant both immediately (SMD=-0.10; 95% CI -0.74, 0.54; I²=94%) and overtime (SMD=-0.79; 95% CI -2.30, 0.73; I²=98%), although the effects was in favour of exercise interventions relative to other comparison non-exercise interventions.

Conclusion: Activity pacing, CBT and moxibustion interventions showed beneficial effects on fatigue in OA immediately. Cumulatively, the pooled effect of exercise on fatigue was not statistically significantly immediately and overtime but the effect was in favour of the exercise interventions relative to other control interventions. However, there is currently insufficient evidence regarding the effectiveness of majority of identified fatigue interventions in this review. Further, the findings of the meta-analysis may have been affected by high level of heterogeneity. Largely populated RCTs with low ROB are needed to ascertain the effectiveness of fatigue interventions in OA population.

AB1183

NEUROPATHIC PAIN IN PRIMARY KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis, Pain

A. Mourad1, S. Belouaham1, I. El Bouchti1. 1Arrazi Hospital, Faculty of Medicine and Pharmacy of Marrakech, Mohammed VI University Hospital, Marrakech, Morocco., Department of Rheumatology, Marrakech, Morocco

Background: Pain is a major symptom in primary knee osteoarthritis. The mechanisms of this pain are heterogeneous explaining the variable response to different treatments. The presence of a neuropathic pain (NP) may be associated with a different phenotype disease.

Objectives: The present study was conducted to identify the frequency of NP in patients with painful primary knee osteoarthritis, and to investigate its correlation with socio-demographic factors, anthropometric and postural features, physical function, quality of life, and disease severity.

Methods: The study included 200 patients with primary osteoarthritis of the knee who did not have co-morbid disorders and/or were taking drugs that may cause neuropathy. NP was assessed by both Douleur Neuropathique 4 questions (DN4) and painDETECT questionnaires.

Results: The mean age of the patients was 59.15 ± 7.62 years. The majority were women (87.5%). The mean of the body mass index was 24.72± 4.84 kg/ m². The mean of the quadriceps perimeter was 48.28± 4.14 cm. The mean of the waist circumference was 93.04± 11.43 cm. The mean of the total Womac score was 53.61± 4.93. NP was detected in 55.6% of patients according to DN4 questionnaire and in 53.6% according to painDETECT questionnaire. DN4 score was positively correlated with VAS (VAS analogue Scale)-pain at rest (r=0.188; P=0.009), VAS pain on movement (r=0.173; P=0.0017), Womac pain score (r=0.157; P=0.030), Womac stiffness score (r=0.253; P=0.000),
Physical function WOMAC score (rs=0.271; p=0.000), total WOMAC score (rs=0.305; p=0.000) and Lequesne index (rs=0.221; p=0.002), and it was negatively correlated with perimeter quadriceps (rs=−0.210; p=0.006), while painDETECT score was positively correlated with VAS pain on movement (rs=0.250; p=0.002), WOMAC stiffness score (rs=0.147; p=0.043), WOMAC physical function score (rs=0.172; p=0.017), and total WOMAC score (rs=0.182; p=0.012). The risk factors of NP retained according to DN4 score were longer symptom duration (p=0.030) and a reduced quadriceps perimeter, whereas painDETECT score was associated with high VAS pain on movement (p=0.022).

Conclusion: NP is common in primary knee osteoarthritis. The presence of NP is associated with more painful pathology and extreme disability.

AB1184 ANXIETY, DEPRESSION AND FIBROMYALGIA: SIMILAR PREVALENCE IN OSTEOARTHRITIS AS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Osteoarthritis, Fibromyalgia

J. Schmukler1, A. M. Malfait1, J. Block1, T. Pincus1. 1Rush University Medical Center, Medicine, Division of Rheumatology, Chicago, United States of America

Background: Non-articular comorbidities, including anxiety (ANX), depression (DEP) and fibromyalgia (FM), are common in patients with rheumatic diseases. Their presence may impact measures of disease activity and responses to treatment. The burden of ANX, DEP and FM has been described in many reports concerning patients with rheumatoid arthritis (RA), but far less information is available concerning these comorbidities in patients with osteoarthritis (OA). It is feasible to screen for these comorbidities in all patients seen in routine care using a multidimensional health assessment questionnaire (MDHAQ)[1,2], completed by patients in 5-10 minutes before seeing the rheumatologist, which includes screening indices for ANX, DEP, and FM.

Objectives: To analyze the prevalence of positive screening for ANX, DEP, and/or FM in patients with OA compared to RA in routine care at an academic rheumatology center.

Methods: All patients seen for routine rheumatology care are asked to complete an MDHAQ, which includes 0-3 physical function and ANX and DEP scales in the patient friendly HAQ format, three 0-10 visual numeric scales (VNS) for pain, fatigue and global status, self-report 0-54 RAPID3 painful joint count, 60-symptom checklist review of systems (ROS) including ANX and DEP; medical history questionnaire, and 4 indices: RAPID3 (routine assessment of patient index data to assess patient status in all diseases studied), MDHAQ ANX screen (MAS2), MDHAQ DEP screen (MDS2)[1], and fibromyalgia assessment screening tool (FAST4) [2]. MAS2 and MDS2 are positive for ANX or DEP if 0-3 ANX or DEP response is ≥2 OR positive ANX or DEP on the symptom checklist. FAST4 is positive if ≥4: pain VNS ≥4/10, fatigue VNS ≥3/10, self-report painful joint count ≥16/54, and/ or symptom checklist ≥16/60. Patients were classified as OA or RA according to primary ICD 10 diagnosis. An MDHAQ database was used to compute retrospectively medians and interquartile ranges (IQR).

Results: The study included 366 OA and 488 RA patients seen between 2013 and 2022. Patients were mostly female and OA patients were slightly older (Table 1). RAPID3 was similar in RA and OA patients. Positive screening for ANX was seen in 28.4% of OA and 21.9% of RA patients (p=0.04, Table 1), for FM in 20.4% of OA and 20% of RA patients (p=0.05).

Conclusion: Positive ANX, DEP, and FM screening is seen in >20% of routine care patients with primary diagnoses of OA or RA, at similar levels in OA and RA. Although definitive diagnosis requires a physician, MAS2, MDS2, and FAST4 agree more than 80% with reference standards which are highly associated with positive diagnoses. The results underscore a need for rheumatologists to aware of these comorbidities, easily screened for using an MDHAQ.

AB1185 POLYACRYLAMIDE HYDROGEL FOR THE TREATMENT OF KNEE OSTEOARTHRITIS: 3 YEAR FOLLOW UP RESULTS OF A PROSPECTIVE CLINICAL STUDY

Keywords: Osteoarthritis

H. Bliddal1, J. Beier2, A. Hartkopp3, P. G. Conaghan4, M. Henriksen1. 1The Parker Institute, Bispebjerg Frederiksberg Hospital, University of Copenhagen, Copenhagen, Denmark; 2Rheumatology Odense, Odense, Denmark; 3A2 Rheumatology and Sports Medicine, Holte, Denmark; 4Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Polyacrylamide hydrogel (iPAAG), manufactured by Contura International, is CE marked for the symptomatic treatment of patients with knee osteoarthritis (OA). iPAAG fulfills an unmet clinical need for an effective, long-acting and safe non-surgical treatment that may postpone knee surgery for those with OA.

Objectives: To evaluate the efficacy and safety of a single injection of 6 ml intra-articular iPAAG on knee symptoms in participants with moderate to severe knee OA for up to 5 years after injection.

Methods: In this prospective, multicentre study (3 sites in Denmark) participants received a single intra-articular injection of 6 ml Arthrosamid®. The initial 1-year study was extended to follow the participants for up to 5 years. The study was approved by the Danish Health authorities and the local Health Research Ethics committee. All participants provided informed consent prior to study activities and signed a new consent form to participate in the extension phase. Injections were given by an investigator experienced in administering intra-articular injections. Participants could continue analgesics (except 48 hours prior to visits) and non-pharmacological therapy, but topical (on target knee) and systemic corticosteroids or additional injections were not allowed. Outcomes included the WOMAC pain, stiffness and function subscales (0-100 score where 100 was worst) and Patient Global Assessment of disease impact (PGA). Changes from baseline in these outcomes were analysed using a mixed model for repeated measurement (MMRM) with a restricted maximum likelihood-based approach. The estimated changes based on the least square means were presented including 95% confidence limits and corresponding p-values. Additional sensitivity analyses were for the 3-year data. The MMRM analysis was repeated, but only data from the 35 participants that continued into the extension phase were included. In another analysis an ANCOVA model was used where missing values at 3 years were replaced by the participants baseline value (BOCF).

Results: 49 participants (31 females) with mean age of 70 years (range 44 – 86 years) were treated with iPAAG. 46 participants completed the 1-year assessment and 35 participants (22 females) continued into the extension phase. A site closure and the increased length of the study were the most common reasons for not continuing, 29 participants completed the 3-year follow-up.
The originally planned MMRM analysis including all available data from the 49 treated participants showed clinically relevant and statistically significant decreases from baseline to 3 years for each of the 3 WOMAC subscale scores and the PGA (Table 1).

The analysis only using the data from the extension phase participants showed a similar change from baseline in the WOMAC pain subscale compared to the result of the planned analysis (Table 1). The BOCF analysis also showed a clinically relevant and statistically significant decrease in the WOMAC pain subscale from baseline. 74 adverse events have been reported in the study including 19 new events reported between the 2-year and 3-year visits. None of the new events were assessed as related to treatment and Covid-19 infection was the most frequently reported AE in this period. 3 of the new events were SAEs (Covid-19 infection, pre-syncope, uterine prolapse). The aim of this study was to investigate effect of body mass index (BMI) level on quadriceps muscle architectural characteristics in patients with knee OA and estimate the minimal clinically important difference (MCID) of the CEW.

**BODY MASS INDEX EFFECTS QUADRICEPS MUSCLE ARCHITECTURAL CHARACTERISTICS IN PATIENTS WITH KNEE OSTEOARTHITIS**

**Keywords:** Imaging, Osteoarthritis, Ultrasound

E. Ünüvar1, N. Cigercioglu1, H. Apaydın2, H. Guney Deniz1, 1Hacettepe University Faculty of Physical Therapy and Rehabilitation, Musculoskeletal Physiotherapy and Rehabilitation, Ankara, Turkey; 2Ankara City Hospital, Department of Rheumatology, Ankara, Turkey

**Background:** Sufficient lower extremity muscle mass is necessary for performing functional tasks. It is well known that body mass index (BMI) adversely effects knee cartilage health but in knees with osteoarthritis (OA) it is still unclear how BMI level affects knee muscle architectural characteristics.

**Objectives:** The aim of this study was to investigate effect of body mass index (BMI) on quadriceps muscle architecture in patients with knee OA and healthy controls.

**Methods:** Nineteen patients with OA (mean age 50±4.56 years, mean BMI=26.76±4.88 kg/m²) were included in the study. Rectus Femoris (RF), Vastus Medialis (VM) and Vastus Lateralis (VL) muscles thickness and pennation angle were evaluated using B-Mode ultrasonography. Ultrasound images were analyzed offline using an image analysis software (Image J, National Institutes of Health, Bethesda, MD, USA). When investigating the changes in muscle architecture by group, the effect of BMI was adjusted using covariance analysis (ANCOVA) tests.

**Results:** There were no differences between age (p=0.073) and BMI (p=0.10) in both groups. Interaction between group×BMI represented in Table 1. Control group had higher RF muscle thickness, RF pennation angle, VM muscle thickness, VM pennation angle and VL muscle thickness than OA group. There was significant effect of BMI on VM and VL muscle thickness.

**Conclusion:** Patients with knee osteoarthritis has lower quadriceps muscle thickness and pennation angle than matched healthy controls and BMI was an important factor effecting muscle characteristics. The decrease in VM and VL muscle thickness were associated with increased BMI in knee OA group. These findings highlight the need of body weight control in order to restore muscle thickness in knee OA patients.

**DYNAMICS OF PAIN SYNDROME DURING 180-DAY TREATMENT WITH UNDENATURED COLLAGEN TYPE II IN COMPARISON TO GLUCOSAMINE AND CHONDROITIN COMBINATION**

**Keywords:** Pain, Quality of Life, Osteoarthritis

D. Rekalov1, I. Golovech2, I. Danuk1, R. Kulynych1, T. Tarasenko1, I. Bryner1, I. Zaporizhzhya, Professor Rekalov Rheumatology Clinic, Zaporizhzhya, Ukraine; 2Feofaniya Clinic, Rheumatology Kyiv, Ukraine; 3Zaporizhzhya State Medical University, Internal Diseases-3, Zaporizhzhya, Ukraine; 4Dnipro, Professor Rekalov Rheumatology Clinic, Dnipro, Ukraine

**Background:** OA osteoarthritis is a heterogeneous group of diseases of different etiology with similar biological, morphological, clinical manifestations and consequences, which are based on damage to all articular structures (cartilage, subchondral bone, synovial membrane, ligaments, capsules, periarticular muscles). A key role in the pathogenesis of OA is played by an increase in the catabolic activity of various cytokines, as well as matrix metalloproteinases (MMP) of the cartilage itself.

**Objectives:** The purpose of the study was to compare the dynamics of pain syndrome (based on Western Ontario McMaster Osteoarthritis Index – WOMAC pain subscale) during 180-day treatment with undenatured collagen type II (UC-II) and glucosamine and chondroitin (G + C) combination in patients with Grade II knee OA.

**Methods:** Patients with Grade II knee OA were investigated. 20 patients were administered the UC-II during 180-day period, 20 patients took the combination of G + C during the same period. WOMAC pain subscale was used to evaluate the effectiveness and was completed before the start of therapy and after 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 90, 120, 150, 180 day of treatment. Visual analog scale (VAS) from 0 to 10 was used for assessment the WOMAC subscale by patient. In this abstract we presented the dynamics of pain during walking and nocturnal pain.

**Results:** The initial data of pain during walking and nocturnal pain in UC-II group were 6.29±0.37 and 4.35±0.59, after treatment – 2.99±0.37 (-52.46 %, p <0.05) and 1.7±0.41 (-60.92 %, p <0.05). In G + C group initial data were 7.05±0.43 and 4.65±0.69, after therapy – 3.85±0.35 (-45.39 %, p <0.05) and 2.85±0.51 (-41.24 %, p <0.05). Comparing groups demonstrated the better results according to decrease of WOMAC pain subscale in the group of UC-II: reduce of pain during walking by 28.7 % and reduce of nocturnal pain by 67.65 % (p <0.05).

**Conclusions:** The therapy of Grade II knee OA with UC-II during 180-day demonstrated the benefit in reducing of pain during walking and nocturnal pain in compare to G + C combination. The dynamics of nocturnal pain reducing in the UC-II group characterizes by gradual decline without significant fluctuations.

**BOTULINUM TOXIN TYPE A OR SELECTIVE GENICULAR PULSED RADIOFREQUENCY FOR TREATING ADVANCED KNEE OSTEOARTHRITIS**

**Keywords:** Randomized control trial, Pain, Osteoarthritis

M. Hassanien1, E. Kameil2, R. Gamal2, N. Talaat1, T. Khedr2, A. Alawamy2.

1Assuit University, Rheumatology, Assuit, Egypt; 2Assuit University, Anesthesia, Assuit, Egypt

**Background:** Knee osteoarthritis was the most common type (6% of all adults). Developing osteoarthritis increases with age. Pain is a key symptom in the decision to seek medical care and is an important antecedent to disability.

**Objectives:** To discuss the effectiveness, indications, limitations and side effects of botulinum toxin type A and genicular nerves pulsed radiofrequency for treating osteoarthritis to help clinicians choose the most appropriate treatment.

**Methods:** Randomized double blind controlled trial study, fifty two participants were recruited divided into 2 groups as follows: Group I (Bx): 25 patients given intra-articular botulinum toxin type A 100 IU sonographically guided in patient with osteoarthritis knee according to American Collage of Rheumatology criteria and in stage 3 or 4 of the Kellgren_Lawrence classification Group II (RF): 27 patient get radiofreqency ablation of genicular nerves. The primary outcome was Visual analogue pain scale (VAS), secondary outcome was stiffness, physical function of each knee using Western Ontario and McMaster University Osteoarthritis Index (WOMAC), and Calculation of Oxford knee score at base line, 4, 12 and 24 weeks.

**Results:** 16 female and 9 male in group I versus 10 female and 17 male in group II. The mean age were 54.36±7.8 years, there was significant difference in pain VAS between groups at 4th week (P value = 0.005). A significant difference in WOMAC pain at 4th and 12th weeks (P value > 0.001), WOMAC stiffness at 12th and 24th weeks (P value > 0.001), WOMAC function at 4th, 12th and 24th weeks (P value < 0.001) and WOMAC total at 4th, 12th and 24th weeks (P > 0.001). However, there were no significant difference in Oxford between the two groups.

**Conclusion:** Intra-articular Botulinum toxin type A 100 IU can reduce the overall pain and improve the function in Knee osteoarthritis with higher efficacy than Pulsed Radiofrequency. However, Further research is needed to compare the effect of botulinum toxin type A and Radiofrequency for the different stages of Osteoarthritis.

**Background:** Therapeutic decision is one of the essential procedures for coping with the disease, so adherence to treatment is one of the key elements of care, particularly in patients with degenerative musculoskeletal pathologies, in particular osteoarthritis.

**References:**

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.896
These attitudes can be influenced by beliefs about drugs, which will affect the care and quality of life of patients.

**Objectives:** The objective of this study is to assess beliefs about medications as well as associated factors in patients with osteoarthritis.

**Methods:** This is a cross-sectional study that included any patient ≥18 years of age followed for knee osteoarthritis or digital osteoarthritis who presents to the rheumatology department. We excluded patients with psychiatric or memory disorders or who refused to participate in the study. Sociodemographic data, comorbidities, information on functional impact and treatments received were collected. A validated questionnaire: Belief on Medicine Questionnaire (BMQ) specific which allows to evaluate the beliefs of the patients related to the need and the concerns towards the drugs was used. The specific BMQ is made up of two subscales: the first includes questions related to the necessity for treatment, the second includes questions about concerns related to the prescription. Each of the sections is made up of five graduated scales from '1 (strong disagreement)' to 5 ' (strong agreement)'. The specific BMQ is therefore rendered as two scores ranging from 5 to 25 and can be expressed as a need-concern differential ranging from −20 to +20, which is an equivalent of the benefit-risk ratio perceived by the patient.

**Results:** We have included 221 patients. The average age was 59.41+-9.8, 88.7% of patients were women. 70.6% of patients were illiterate. 62.1% of patients had comorbidities. 80.5% were followed for knee osteoarthritis and 19.5% for digital osteoarthritis. The median duration of evolution was 8 [2-10] years. For the treatments, 53.8% of the patients in our study were on anti-osteoarthritis treatment, 44.7% had already received an NSAID and 11.7% had already received an injection. The mean of the BMQ-specific necessity was 16.92+-6.33 and 52% of patients strongly believed that drugs are essential to keep them healthy. The average of the BMQ-specific concerns were 14.69+-5.69. The main concerns of patients were the lack of information about the medications they were taking in 45.9% and 38% of patients were concerned about the potentially harmful consequences of their treatment. The median need-concern differential was 2 [-3 - 8] suggesting a positive risk-benefit ratio perceived by the patients. In multivariate linear regression, only functional disability is statistically significantly associated with the need-concern differential (OR=0.24, 95% CI [0.204-0.817], p=0.001).

**Conclusion:** Moroccan osteoarthritis patients have a positive perception of the benefit-risk ratio towards their treatments. Functional disability is the main factor incriminated in this perception. Therapeutic education must take more place in the management of osteoarthritis patients.

**FACTORS ASSOCIATED WITH WALKING SPEED IN PATIENTS WITH END-STAGE KNEE ARTHRITIS WHO ARE SCHEDULED FOR TOTAL KNEE ARTHROPLASTY**

**Keywords:** Gastrointestinal tract

S. Yamada1, I. Ikawa1, K. Manda1, S. Maeda1, T. Hashimura1, T. Tachibana1, H. Ohashi1, I. Kentaro1. 1Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka City, Japan

**Background:** Patients with knee joint disorders have impaired mobility, which interferes with their daily lives, resulting in frailty. Various factors are assumed to contribute to the decline in walking speed, which is an indicator of mobility.

**Objectives:** In this study, we measured the gait speed of patients scheduled to undergo initial total knee arthroplasty (TKA) and examined the factors that correlate best with gait speed.

**Methods:** Patients with end-stage knee arthritis who underwent initial TKA at our hospital between July 2020 and October 2022, and whose gait speed was measured before surgery with written consent, were included in the study. We investigated the relationship between basic attributes such as age and gender at the time of the survey, pain VAS during walking, clinical evaluation of knee joint function (Knee Society Score; KSS), skeletal muscle mass of both lower limbs (whole-body mode Dual Xray Absorptiometry method), quadriceps muscle strength (flexion and extension strength by dynamometer), and range of motion (degree of flexion and extension), frailty and sarcopenia as dependent variables. The results showed that age and walking pain VAS and KSS were significantly and independently associated with walking speed (P=0.01, 0.04, 0.05). Gender, skeletal muscle mass of both lower limbs, quadriceps streng (flexion and extension), range of motion (degree of flexion and extension), frailty, and sarcopenia were not found to be significantly associated with walking speed (P= 0.79, 0.13, 0.65, 0.21, 0.68, 0.74, 0.34, 0.20).

**Conclusion:** Age was found to correlate most with walking speed, with walking speed slowing with increasing age. A correlation between lower quadriceps muscle extension and lower walking speed has been reported previously, but this study did not correlate. Nor did it correlate with lower limb skeletal muscle mass or range of motion. Pain during walking was observed in many cases, so it may not have been significant.

**RESPONSE TO VISCOSUPPLEMENTATION WITH DIFFERENT TYPES OF INTRA-ARTICULAR HYALURONIC ACIDS IN OSTEOARTHRITIS OF THE KNEE – A RETRASGDE INDIAN COHORT STUDY OF MORE THAN 15 YEARS LONGITUDINAL DATA**

**Keywords:** Outcome measures, Osteoarthritis

A. K. Aggarwal1, J. Fitzpatrick2, N. Aggarwal1. 1Institute of Rheumatology and Pain, Birj Medical Centre, Rheumatology and Pain, Ghaziabad, India; 2University of Melbourne, Faculty of Medicine, Dentistry and Health Sciences, Parkville, Australia; 1Institute of Rheumatology and Pain, Birj Medical Centre, Rheumatology and Pain, Ghaziabad, India

**Background:** Knee osteoarthritis (OA) is a progressive degenerative condition resulting in functional loss, pain and discomfort. [1] The current aim of treatment is alleviation of symptoms, improvement of function and joint preservation. Viscosupplementation (VS) with Intra-articular hyaluronic acid (IAHA) injection has been shown to have protective physiochemical functions and may confer disease-modifying, long term effects in OA. [2][3][4] However, conflicting guidelines, pooling of results for different molecular weight products, and a paucity of long-term clinical studies has resulted in lack of confidence in the results of IAHA.

**Objectives:** To determine the primary and sustained response to VS with different types if IAHA in Bilateral Knee OA.

To identify whether the response is different for subgroups which are:

- Type of IAHA,
- Gender - Males (M) or Females (F), and
- Grade of OA treated.

**Methods:** We did a retrospective analysis of a 15-year cohort from a single Indian centre. The inclusion criteria were adults with bilateral knee OA with functional and radiological KL Grade of III and IV, treated with Non-Animal Stabilized Hyaluronic Acid (NASHA) origin IAHA injections.
Subjects were stratified into two groups based on the molecular weight of the hyaluronic acid used:

- High Molecular Weight - 6-8mg/ml – 6ml single injections (HMW-HA), or
- Very High Molecular Weight – 20mg/ml – 3ml injections (VHMW-HA).

The primary outcome measure was responder rates determined by those with improvement in total WOMAC scores of > 30% from baseline versus non-responders. Responders with sustained response of at least 12 months or more were determined.

Results: A total of 2037 (F 1467 (72%) & M 570 (28%)) patients were treated. The overall responder rate was 1496 (73.4%) (F 1099 (74.9%) & M 397 (69.6%). The Primary responder rate was similar for VHMW-HA (73.5% in Gr III OA & 74.9% in Gr IV OA) and HMW-HA (71.0% in Gr III OA & 68.6% in Gr IV OA). The Sustained response in VHMW-HA was greater (60.5% in Gr III OA & 68.5% in Gr IV OA) versus HMW-HA (47.3% in Gr III OA & 46.7% in Gr IV OA).

Table 1. The results are summarized in Table 1:-

</table>
| Conclusion: The responders to treatment of 73.4% justify treatment outcome. The primary response to treatment was similar in all the subgroups – Type of IAHA, Grade of OA and Gender. However, the sustained response for 12 months or more was far greater in VHMW-HA versus HMW-HA.

A PROOF OF PRINCIPLE DIETARY INTERVENTION TRIAL TO EXAMINE THE PROTECTIVE EFFECT OF BROCCOLI BIOACTIVES, (SPECIFICALLY SULFOPHANATE), ON OSTEOARTHRITIS

Keywords: Diet and nutrition, Pain, Osteoarthritis

1University of East Anglia, Norwich Medical School, Norwich, United Kingdom; 2University of East Anglia, Norwich Medical School, Norwich, United Kingdom; 3Quadram Institute Bioscience, Food, Innovation and Health, Norwich, United Kingdom; 4Queen’s University Belfast, Institute for Global Food Security, Belfast, United Kingdom; 5Norfolk and Norwich University Hospital, Institute of Orthopaedics, Norwich, United Kingdom; 6University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds, United Kingdom; 7University of East Anglia, School of Biological Sciences, Norwich, United Kingdom

Background: Osteoarthritis (OA) accounts for more than a third of chronic moderate-to-severe pain in the UK. Sulforaphane (SFN) is a naturally occurring phytochemical derived from eating cruciferous vegetables, particularly broccoli. It has several biological activities that promote health, including anti-inflammatory properties. SFN has a potential role in limiting pain and cartilage destruction in OA.

OBJECTIVES: In a two centre, placebo-controlled, double-blind, two-arm parallel, RCT, proof of principle study with a primary outcome we evaluated whether dietary SFN (from consumption of broccoli) improves pain in participants with knee OA. Secondary objectives were to determine whether food containing SFN improves knee function, and the feasibility of the study design for an appropriately powered trial.

Methods: Participants with symptomatic and radiographic knee OA were recruited from regions of Norfolk and Leeds in the UK, were over 50 years of age with moderate to severe knee pain (at least 4 on 0-10 numeric rating scale), and had knee OA (Kellgren-Lawrence score 2-3). The intervention was a sensory-matched soup. Patients received either the intervention soup (300g high glucoraphanin soup (containing broccoli, and base vegetables)) or placebo soup (300g no glucoraphanin soup (base vegetables only)), once daily on 4 days per week. The study duration was 12 weeks with follow-up visits at 6 and 12 weeks. Knee pain and function outcome measures were obtained using WOMAC, an 11-point NRS, the ICOAP questionnaire and use of rescue analgesics/NSAIDS. Creatinine, metabolites of glucoraphanin, matrix metalloproteinase-3 and C-reactive protein were measured in plasma or 24-hour urine samples.

Results: Recruitment was severely curtailed due to the Covid-19 pandemic. In total n= 37 consented and n= 24 met screening criteria with one drop-out at week 12 (control n=17 and intervention n= 7), the recruitment aim was n= 64. Control group was 43% female, and mean age was 70.14 yrs [7.69 SD] (control), and 61.88 yrs [8.56 SD] (intervention). The intervention intervention resulted in a trend towards a decrease in pain scores for each subscale of WOMAC, ICOAP and NRS measures: total WOMAC median difference from baseline [9.65 [CI: -0.78,20.09]], ICOAP constant (wk 12, 4.83 [CI: -1.99,11.64]) and intermittent pain (wk 12, 2.96 [CI: -0.31,6.24]), NRS overall pain (wk 12, 1.86 [CI: 0.13,3.58]), while a trend for increased satisfaction for knee function (wk12, 1.55 [CI: -3.55,5.44]) was also observed for this group. No change in rescue analogues/NSAIDS for knee pain was seen in either group. Metabolites of glucoraphanin were detected in plasma and urine samples in the intervention group. Study compliance and intervention adherence was high (>70%-100%) while acceptability for randomised was 100%.

Conclusion: Patient acceptance, adherence and retention was high and biomarkers and metabolites objectively confirm compliance with the intervention were detected. In this study, although underpowered to observe significant differences for pain, improving trends over time were observed across a range of clinical pain measures including the primary outcome, where the CI encompassed the minimal clinically important difference, requisite for progress to full trial. Given COVID impact on recruitment, the pilot achieved its aims, and we conclude that the intervention was feasible, and a full trial is justified.

KNEE OSTEOARTHRITIS AND NEUROPATHIC PAIN: IMPACT OF RADIOGRAPHIC SEVERITY

Keywords: Pain

H. Fouzi1, F. Z. Taik1, I. Berchill1, N. Soba2, M. Fourtassi2, F. E. Aouarazzak1.

1Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Rheumatology, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco; 2Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Physical Medicine and Rehabilitation, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco

Background: Pain in knee osteoarthritis remains the main symptomatology, classically considered as nociceptive. A neuropathic component of this pain has recently been described. The identification of which is essential for adequate treatment.

OBJECTIVES: The objective of our study is to evaluate the relationship between the prevalence of neuropathic pain and the stages of radiographic severity in gonarthrosis.

METHODS: This is a descriptive cross-sectional study of patients with clinically and radiographically retained knee osteoarthritis. The radiographic stage was determined by the Kellgren and Lawrence classification. Neuropathic pain was assessed by the DN4 questionnaire. The neuropathic nature of the pain was retained if the DN4>=4. The patients included were divided into 4 groups according to the radiographic stage.

RESULTS: 173 patients were included. The average age was 58±0.49 years. 88.2% were women. 32.7% of patients had neuropathic pain. Average pain VAS was 4.4±2.1. The median duration of evolution was 3.8 years [1-23]. 5.6%, 64.4%, and 88.2% were women. 32.7% of patients had neuropathic pain. Average pain VAS was 4.4±2.1. The median duration of evolution was 3.8 years [1-23]. 5.6%, 64.4%, and 4.4%, of the patients studied were classified by radiography as caution, 1, 2, 3, and 4 respectively. The prevalence of neuropathic pain was 16.6%, 34.4%, 35.5% and 33.3% in patients with radiographic severity grade 1, 2, 3, and 4 respectively. When comparing the groups, there was no difference in the DN4 score according to the stage of radiographic severity (p=0.633).

Conclusion: The results of our study suggest that the stage of radiographic severity does not predispose to neuropathic pain in patients with gonarthrosis.

NEUROPATHIC PAIN IN GONARTHROSI: PREVALENCE AND ASSOCIATED FACTORS

Keywords: Pain

H. Fouzi1, F. Z. Taik1, I. Berchill1, N. Soba2, M. Fourtassi2, F. E. Aouarazzak1.

1Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Rheumatology, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco; 2Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Physical Medicine and Rehabilitation, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco

Background: Pain in knee osteoarthritis remains the main symptomatology, classically considered as nociceptive. A neuropathic component of this pain has recently been described. The identification of which is essential for appropriate management.

OBJECTIVES: The objective of our study is to evaluate the prevalence of neuropathic pain in patients with knee osteoarthritis, and to identify the associated factors.

REFERENCES: NIL.
Methods: This is a cross-sectional study involving patients with knee osteoarthritis. Sociodemographic and clinical data, including comorbidities, were collected. Neuropathic pain was assessed by the DN4 questionnaire. Neuropathic pain was defined by a DN4 ≥ 4. Depression, catastrophizing, and central sensitization were assessed by Arabic versions of validated questionnaires, PCS (Pain Catastrophizing Scale) for catastrophizing, and PHQ9 (Patient Health Questionnaire) for depression, CSI (central sensitization inventory) for central sensitization.

Results: 173 patients were included in our study. 88.2% are women. The average age was 56.0±9.19 years, 32.7% had neuropathic pain. VAS mean pain was 4.1±2.1. The median evolution of pain was 3.8 years [1-129]. The average lequesnque index was 9.75±3.9. The median of the PCS score was 22 [0-52], and the median of the PHQ9 score was 7 [0-24]. The average CSI score was 38.2±15. 72.6% of patients had comorbidities: 28.8% had obesity and 12.7% were diabetic. In multivariate analysis, only functional disability was associated with the presence of neuropathic pain p=0.04 (OR: 1.19, 95% CI [1.03 – 1.38]). However, pain severity, central sensitization, OA comorbidities including diabetes and obesity did not come out as associated factors.

Conclusion: Neuropathic pain is quite common in gonarthrosis. Functional disability seems to be an associated factor.

AB1197 CAN OSTEOARTHRITIS, SARCOPENIA AND BODY COMPOSITION PREDICT LOSS OF FUNCTION?

Keywords: Sarcopenia, Osteoarthritis

S. Pais1,2,3, M. Botelho3,4, R. Moreira3, C. Guerreiro3,4,1 *Universidade do Algarve, Faculdade de Medicina e Ciências Biomédicas, Faro, Portugal; 2Comprehensive Health Research Centre (CHRC), Nova Medical School, Lisbon, Portugal; 3ABC-Ri, Algarve Biomedical Research Institute, Health, Ageing and Kinetic Lab, Faro, Portugal; 4ABC-Algarve Biomedical Center, Sandra Pais Laboratory, Faro, Portugal

Background: Elderly populations growing in the majority of Countries in the World. Portugal in currently among the 5 most aged counties with 23,4% of its population older than 65 and an ageing index of 18%. Osteoarthritis is the 3rd cause responsible for severe disability over 60 years in developed and developing countries. Lack of data at a national or regional level in Portugal compromises the ability to prepare for both health and care need of aged population. Simultaneously the region of Algarve has particular geographic characteristics with 49% of the population living within 2 km from the coast (in 9% of the Algarve’s territory).

Objective: Aim was to study our regional population, namely the incidence of Osteoarthritis (OA) and the relation of function ability with OA, Sarcopenia and Body composition.

Methods: This study is a prospective, observational secondary analysis of data from the “Sarcopenia Screening Study in the Algarve Region” Subject were recruited through informative flyers that was distributed at Elderly Associations, and invitation through telephone, the evaluations were performed. Until June 2022 a total of 270 patients were voluntarily participated. Subjects over 60 were eligible for the study. All gave their informed consent to participate. Clinical diagnosis of OA was established according to the NICE Guidelines for knee osteoarthritis[3].

Functional ability was measures with the Lower Extremity Functional Scale (LEFS)[4], sarcopenia was measures with the SARC-F Questionnaire[5], body composition was evaluated by Medical Body Composition SECA® mBCA315. Data was treated with IBM-SPSS-Statistics version 26.

Results: Of the 270 subjects analyzed for this secondary analyze 75.2% were female (24,8% male), mean age in years 75,39 ± 6,75 (60-93), 70,5% had Knee OA. Statistical differences was found between groups (with and without OA), in LEFS (p<0,001), SARC-F (p<0,001), percentage of fat free mass (p<0,001). A multiple linear regression was carried out to see if having OA, Sarcopenia and percentage of fat free mass can predict LEFS, once all were significantly different within groups, creating a statistically significant model [Z(3,233)=155,957; p<0,001], with having OA (ß=-0,121; p<0,001), percentage of fat free mass can predict LEFS, once all were significantly different from each other (ß=-0,694; p=0,001), and low muscular mass (ß=0,146; t=3,468 p<0,001), can significantly predict diminished lower extremity function.

Conclusion: Looking at the presence of OA, Sarcopenia and low percentage of fat free mass is important when monitoring elderly subjects over time once they can predict the decrease in functional ability.

Methods: Cross-sectional study including 87 patients. All demographic data and visual analog scale (VAS) score at walking, VAS score at rest, Kelgren and Lawrence (KL) stage on radiography, and results of clinical examination were collected. Exclusion criteria were the presence of a total knee prosthesis and patients followed for chronic inflammatory rheumatism. Statistical data analysis was performed using SPSS version 21 software.

Results: This study included 87 patients followed for KOA, with an average age of 63.67±5.8 years (46-83 years), and a female predominance (78.3%). In the univariate analyses, significant correlations were found between the VAS score at walking with age (r=0.56, p=0.037), body mass index (BMI) (r=0.61, p=0.023), KL grade (r=0.54, p=0.039) and patellar shock (r=0.46, p=0.044). While the VAS score at rest was only correlated with BMI (r=0.26, p=0.01). And an association between VAS at rest and skin hyperalgesia was noted (p=0.034). The multivariate analysis showed that the significant explanatory factors of the VAS score on walking were BMI > 25 kg/m² (p=0.03) and KL grade > 3 (p=0.03). On the other hand, no significant explanatory factor for the VAS score at rest was found.

Conclusion: Predisposing factors were significantly different between the two types of pain, indicating the presence of different pain mechanisms. Pain on walking was more strongly associated with mechanical and structural factors, whereas pain at rest was associated with knee hyperalgesia.

AB1200

WAIST CIRCUMFERENCE AND GONARThROSIS

Keywords: Osteoarthritis

A. Rafi1, F. Idriissi Zaki1, Z. Baba1, A. Mougui1, I. El Bouchti1. CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rheumatology, Marrakech, Morocco

Background: Overweight, translated into a high body mass index (BMI), is a major risk factor of gonarthrosis, thus, the risk is increased by 15% for each increase of a unit of body mass index (BMI). (1) Various studies indicate that the association of high BMI and abdominal obesity measured by waist circumference leads to increased morbidity especially in obese. But no study has so far shown a sufficiently strong association force between waist circumference and gonarthrosis.

Objective: The objective of our study is to assess the relationship between waist circumference and pain perception and gonarthrosis impact.

Methods: This work included patients followed in consultation for gonarthrosis. For each patient we specified next to the demographic data, the BMI, the waist circumference, and the existence or no pain of the knee or both. The intensity of pain was assessed by the Analog Visual Scale (EVA). Functional impact was assessed by the Lequesne index and WOMAC score. Knee X-rays were classified according to KL grade criteria. The McNemar test was used to assess the change in analgesic use. Multivariable logistic regression was used to compare characteristics of analgesics users/non-users at baseline. We applied a linear random intercept model adjusted for baseline characteristics to investigate the associations between analgesics use and pain/function.

Results: Among included participants, 2517 (61.4%) were analgesic users at baseline. Male sex, hip OA, lower education, higher body mass index, living outside three largest metropolitan cities, rheumatoid arthritis, and walking difficulties were associated with higher odds of analgesic use at baseline. From baseline to 12-week follow-up, the proportion of analgesic users dropped by 15% (95% CI, 10.5, 13.5), from 61.4% to 49.4%. The results of linear random intercept model suggested that at both baseline and 12-week follow-up, persons not using analgesics at the time had better outcomes (Table 1). Moreover, all groups but “new users” experienced improvements in their pain and function following participation in digital program with the greatest improvements observed among “quitters”. Interestingly, the magnitude of improvements was comparable for “non-users” and “persistent users”.

Conclusion: Participation in a digital self-management program for hip or knee OA was associated with worse pain and function in these people. Greatest improvements were seen for those who stopped analgesic use. Similar results were reported for a face-to-face first-line treatment in Denmark [1, 2]. These results highlight the importance of providing effective first-line treatment to people with hip or knee OA.

AB1202  PARTICULARITIES OF KNEE OSTEOARTHRITIS: FUNCTIONAL IMPACT IN A GERIATRIC POPULATION

**Keywords:** Osteoarthritis

L. Rouached1, W. Lahmar1, S. Bouden1, A. Ben Tekaya1, I. Mahmoud1, L. Rouached1, O. Saidane1, L. Abdelmoula1, Charles Nicolle Teaching Hospital, Rheumatology, Tunisia, Tunisia

**Background:** Knee osteoarthritis (KOA) is the most common osteoarticular diseases. Its increasing incidence with age means that the geriatric population is particularly exposed.

**Objectives:** The aim was to study the functional impact of knee OA in elderly subjects.

**Methods:** A cross-sectional study of 52 patients aged ≥65 years, followed for knee OA. Clinical characteristics of knee OA, pain intensity (VAS) were collected. Functional impact was assessed by the short form of the Knee Injury and Osteoarthritis Outcome Score (KOOS-PS) with a score ranging from 0 (no difficulty) to 100 (extreme difficulty).

**Results:** The mean age was 73.7±7.8 years and the sex ratio (male/female) was 3.13. KOA was femoro-tibial in 79% and femoro-patelar in 21%, the internal compartment was affected in 98% of cases, and a bilateral involvement was found in 94% of cases. The knees were in varus in 30% of cases, in valgus in 23%. The VAS pain was 6.63±1.89. The mean KOOS-PS score was 48.04±19.1. The radiographic severities of KOA according to KL were classified as follows: stage 2 (17%), stage 3 (33%), and stage 4 (33%). A positive and significant correlation between the KOOS and VAS was found (r=0.6; p<0.00). There was no correlation between the KOOS and the radiographic stage (p=0.17), the duration of evolution (p=0.43).

**Conclusion:** In elderly patients with knee OA, there is no concordance between radiographic severity and functional impact. The latter goes hand in hand with the pain experienced.

**Keywords:** Osteoarthritis

S. Bozovlev1, H. Kilinç2, G. Hurel2, H. Guney Deniz2, 1Hacettepe University, Faculty of Physiotherapy and Rehabilitation, Department of Musculoskeletal Rehabilitation, Ankara, Turkey; 2Hacettepe University, Faculty of Physiotherapy and Rehabilitation, Department of Physical Therapy and Rehabilitation, Ankara, Turkey; 3Hacettepe University, Faculty of Medicine, Department of Orthopedics and Traumatology, Ankara, Turkey

**Background:** The main symptoms of patients with knee osteoarthritis (OA) are defined as pain, muscle weakness and functional impairments. Muscle strengthening exercises are recommended in core treatment of conservative management of knee OA [1]. Recently, intraarticular platelet-rich plasma (PRP) injection has gained much attention for the management of knee OA. A combination of different approaches is also recommended for achieving better symptomatic relief.

**Objectives:** The aim of the study was to compare the effect of PRP plus supervised exercise, PRP plus home exercise and only PRP in patients with knee OA.

**Methods:** Patients with knee OA aged 45-70 years old were included. The demographic characteristics of the patients were recorded, and they were randomly divided into three groups: PRP plus supervised exercise group (PRP+SEG); PRP plus home exercise group (PRP+HEG); PRP group. The pain was assessed with visual analogue scale (VAS); knee functions and outlook. Nat. Rev. Rheumatol. 2022, 18, 171–183.

**Results:** In total of 41 female patients (mean age: 56.65±6.64 years; mean BMI: 28.82±5.19 kg/m²) were randomized (PRP+SEG (n=15); PRP+HEG (n=12); and PRP (n=14)). There was no significant difference between three groups at baseline (p<0.05). There was significant difference in VAS (p=0.001); WOMAC Pain (p=0.003); WOMAC-Function (p=0.001) and WOMAC Total (p=0.001) scores between groups at 6th week. The PRP+SEG and PRP+HEG performed a total of 6-week (3 times/week) strengthening exercises for knee and hip muscles. The PRP group received only PRP injection. All assessments were performed at 3rd day after PRP injection and at 6th week.

**Conclusion:** A combination of supervised exercise with PRP injection resulted in better symptomatic relief in patients with knee OA. Clinicians should consider the
effectiveness of supervised strengthening exercises for providing better improvement in pain and knee function after PRP injection.

IMPACT OF CATASTROPHIZING ON PAIN, FUNCTION, AND PHYSICAL PERFORMANCE IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis, Pain

N. Takhrla1, F. Z. Taik1, A. Adnine1, N. Soba2, M. Fourtassi2, F. E. Abourazzak1.1Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco; 2Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco

Background: Osteoarthritis (OA) is the most common osteoarticular disease, with pain and functional discomfort being the main symptoms leading patients to consult. Catastrophism is defined as an exaggerated negative reaction to an anxiety-provoking stimulus. It is considered to be an important cognitive factor in painful conditions, particularly in osteoarthritis.

Objectives: The aim of this study was to assess the level of catastrophizing and to determine the relationship between catastrophizing and pain intensity, functional impact, and physical performance.

Methods: This is a cross-sectional study conducted in the rheumatology department. Sociodemographic information and comorbidities were collected. Pain was assessed by Visual Analog Scale (VAS); functional impact by the Lequesne index; pain catastrophizing by the validated Moroccan version of the Pain Catastrophizing Scale (PCS). A PCS > 30 indicate high level of catastrophizing. Physical performance was assessed by the 06min walk test and IPAQ questionnaire.

Results: A total of 178 patients were included. The sociodemographic and clinical characteristics of the patients are presented in (Table 1).

Univariate and multivariate analysis showed the Lequesne index (p=0.008) and anxiety (0.001) were statistically significantly associated with the level of catastrophizing.

Conclusion: The level of catastrophizing seems to have an impact on function and anxiety. However, there was no association between catastrophizing and the walking test. Catastrophism is an important factor to assess at the beginning of the management of a patient with OA.

THE SOURCES OF DISEASE-RELATED INFORMATION FOR MOROCCO’S OSTEOARTHRITIS PATIENTS

Keywords: Osteoarthritis, Patient information and education

F. Z. Aharrane1, F. Z. Taik1, R. Bensaid1, N. El Mansouri1, N. Soba2, M. Fourtassi2, F. E. Abourazzak2. 1Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco; 2Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco

Background: In osteoarthritis, the patients have an almost continuous need of information and communication. In addition to the information delivered by health professionals, patients tend to look for other sources to complete it.

Objectives: Our study aims to investigate the non-conventional sources of information used by osteoarthritis patients and to identify the possible associated factors.

Methods: This is a cross-sectional study, conducted in the rheumatology department at the University Hospital Center in Tangier, which included patients diagnosed with osteoarthritis. Data on sociodemographic characteristics, clinical presentations, comorbidities, and the health outcomes of patients were examined. Patients’ beliefs and attitudes about disease-related sources of information were assessed by a questionnaire. A list of 12 items was proposed to the patients who mentioned the different used sources, their level of trust, and their experience with the effectiveness of these sources. Binary logistic regression was conducted to identify the associated factors with the use of the disease-related sources of information.

Results: We included 221 patients. The mean age was 59.4 ± 9.8, 88.7% of the patients were female, and 69.2% had comorbidities. 80.5% were diagnosed with knee osteoarthritis and 19.5% with hand osteoarthritis. The median of disease duration was 8 [2-10] years. 31.2% of the patients sought information related to their osteoarthritis, the 3 main sources were: peers (21.7%), YouTube (17.2%) and television (13.1%). 12.7% have already applied some of this information. Only 10% of patients discussed the found information with their physicians and 85.4% would like to have health professionals in their online space to answer their questions. In uni and multivariate analysis, age (OR=0.999, IC95% [0.927-0.991], p=0.014) and level of education (OR=1.597, IC95% [1.146-2.224], p=0.006) were statistically significant with the use of non-conventional information sources.

Conclusion: Our study showed that Morocco’s osteoarthritis patients, especially those with certain age and level of education, are seeking information about their disease. Rheumatologists need to invest more, especially on virtual spaces, to respond to these requests.

PREVALENCE OF NEUROPATHIC PAIN AND ITS ASSOCIATION WITH CLINICAL OUTCOMES IN PATIENTS WITH PRIMARY KNEE AND HIP OSTEOARTHRITIS

Keywords: Pain, Patient reported outcomes, Outcome measures

D. Santos Oliveira1,2,3, A. Martins4,5, J. Silveira6, F. Nelo7,8, L. Costa4, C. Vaz4,5,9, J. Ferreira-Gomes10,11,12,1 Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; 2Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal; 3Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; 4Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; 5Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal; 6Faculty of Medicine, University of Porto, Department of Biomedicine, Porto, Portugal; 7University of Porto, i3S - Institute for Research & Innovation in Health, Porto, Portugal; 8University of Porto, IBMC - Institute of Molecular and Cell Biology, Porto, Portugal; 9Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal

Background: Osteoarthritis (OA) is a common musculoskeletal disease associated with significant chronic pain and physical disability. The presence of pain with a neuropathic component may be associated with different phenotypes of this condition.

Objectives: Thus, this study aimed to explore the prevalence of neuropathic pain (NP) and its association with sociodemographic characteristics and clinical outcomes (pain severity and disability), in patients with primary knee and hip OA.

Methods: A cross-sectional study involving adult patients with a primary knee and hip OA diagnosis according to American College of Rheumatology (ACR) was conducted. Sociodemographic variables, symptoms and disease duration and pain characteristics were obtained. Pain severity was assessed with Pain Visual Analog Scale (VAS) and functional disability with Health Assessment Questionnaire (HAQ).

Results: A total of 36 patients (mean age of 65.1±8.9 years old; 72.2% female) with primary knee OA (n=13, 36.1%), hip OA (n=4, 11.1%) and both (n=19, 52.8%) were included. Patients had a mean symptom duration of 13.3±8.7 years and a median disease duration of 5 [3-13] years. The mean Pain VAS was 5.0±3.4, and the median HAQ of 1 [0.65-1.91]. The mean of WOAMC- pain, -stiffness, -physical function and -total were 11.9±4.2, 4.5±2.2, 37.5±15.4 and 53.8±20, respectively. Characteristics of NP were found in 28 (77.8%) patients and the mean PAINDETECT scale was 31.1±1.9. None of the patients had treatment aimed at NP. There were positive correlations between NP and VAS (r=0.63, p<0.001), HAQ (r=0.33, p=0.005), WOAMC-physical function (r=-0.41, p=0.027) and WOAMC-total (r=-0.38, p=0.049). In the multivariable model, PAIN-VAS predicted NP (β=0.76, p=0.014).

Conclusion: Our study demonstrated that NP is common in patients with OA. The presence and type of this pain is associated with worse clinical outcomes, namely pain severity and functional disability. Hence, these findings encourage the screening of NP in all patients with knee and hip OA in order to implement more appropriate therapeutic strategies.

THE RELATIONSHIP BETWEEN KNEE MUSCLE STRENGTH WITH DISABILITY AND PAIN IN PATIENTS WITH KELLgren-Lawrence GRADE III-IV KNEE OSTEOARTHRITIS: A PILOT STUDY

Keywords: Rehabilitation, Physical therapy/Physiotherapy, Osteoarthritis

I. Ayas1, Z. Hazar1, F. Abdulaliyev2, G. Güngör3, Ö. Ozer4, 1Gazi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 2Istanbul University, Istanbul Faculty of Medicine, Department of Orthopaedics and Traumatology, Istanbul, Turkey

Background: Knee osteoarthritis (OA) is the most common chronic joint disease and is the main cause of disability and pain. It is important to better understand potentially modifiable risk factors that may reduce disability and pain in advanced knee osteoarthritis.

Objectives: The aim of this study was to investigate the relationship between knee muscle strength with disability and pain in patients with advanced OA.

Methods: Twenty-one patients (66.05 ± 8.02 years, 32.77 ± 5.37 kg/m²) with Kellgren-Lawrence grade III-IV OA were included in this pilot study. Knee flexion and extension muscle strength were measured with EasyForce® isometric pull dynamometer in accordance with the test procedure. Disability was measured with Knee Injury and Osteoarthritis Outcome Score (KOOS), and pain intensity was measured with VAS and Pain Catastrophizing Scale (PCS).

Results: The knee flexion strength of the patients was 75.52 ± 29.58 N, and the knee extension strength was 155.42 ± 49.84 N. Knee flexion strength was 17.85 ± 32.06 % and extension strength was 22.60 ± 21.10 % less than the other extremity. The total KOOS scores of the patients were 48.90 ± 24.78 %, PCS scores were 27.58 ± 15.82 and VAS were 8.42 ± 1.69. Flexion muscle strength of patients were moderately correlated with KOOS (r=0.44, p=0.05), but not with PCS and VAS scores. Extension muscle strength of patients was highly correlated with KOOS (r=0.70, p<0.001), but not with PCS and VAS scores.

Conclusion: In advanced knee osteoarthritis, knee extension strength deteriorated more than knee flexion strength. Exercise interventions for knee extension strength training can provide superior outcomes in knee extensor strength and function but not in pain.

AN INVESTIGATION OF THE VARIABLES INFLUENCING PLATELET-RICH PLASMA FEATURES IN INDIVIDUALS WITH KNEE OSTEOARTHRITIS

Keywords: Synovium, Osteoarthritis, Gender/diversity issues

S. Karaborklu Aruq1, D. Celik1, O. Ergin2, O. Kilicoglu3, 1Gazi University Cerrahpasa, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey; 2Istanbul University, Istanbul Faculty of Medicine, Department of Orthopaedics and Traumatology, Istanbul, Turkey; 3Koc University, Faculty of Medicine, Department of Orthopaedics and Traumatology, Istanbul, Turkey

Background: Platelet Rich Plasma (PRP) has drawn great interest as a regenerative adjunct therapy, and it is increasingly used in management of knee osteoarthritis (OA). The primary goal of PRP injections is to deliver a higher concentration of platelets to the target area than blood circulation does. The features and content of the injected substance are vital when evaluating the effectiveness of PRP.

Objectives: The objective of this study was to investigate the factors affecting the features of PRP in patients with knee OA.

Methods: Potential volunteers with diagnosis of symptomatic knee OA were included if they had knee pain greater than 3 points on 11-point numerical pain rating scale. Exclusion criteria were i) lower hemoglobin count than 15g/dL, ii) ongoing antiinflammatory therapy, iii) using non-steroidal anti-inflammatory drugs in previous 3 weeks before the participation, iv) previous operation in affected knee v) active infection or malignancy, and vi) impaired cognition. To perform complete cell counts for both whole blood and PRP, 20ml of the whole blood was drawn from the ante-cubital vein of the patients under sterile conditions. PRP was prepared using a commercially available kit, tubes contains 3.20% concentrated 0.1M of sodium citrate to block the coagulation. After phlebotomy, the tubes were placed swing-out rotor centrifuging device and were centrifuged at 830g for 4 minutes. A correlation analysis was performed between the features of PRP and the patient-related variables, including age, gender, BMIs, smoking status, presence of other diseases, physical activity scores, duration of symptoms, and pain levels. Pearson's correlation coefficient, point bi-serial correlation, and paired sample t test were performed; alpha level was set at 0.05 in all analyses.

Results: A total of 62 patients (mean age: 56.68 ± 7.13 years) were included in the analysis. The dose of injected platelets was 3.25 billion, efficiency of the process was 77%, and the purity rate of the PRP was >98.4. These results indicate that high dose (B%) and platelet recovery rate (B%) were very poor (A%); PRP platelet count was correlated with whole blood platelet count (r=0.81, p<0.001), whole blood WBC count (r=0.39, p=0.002), smoking status (r=0.56, p=0.03), smoking index (r=-0.63, p=0.002), and the presence of hypertension (r=0.31, p=0.04). PRP WBC and purity of PRP were correlated with smoking status of the patients (r=0.52, p=0.01, r=0.64, p=0.003, respectively). In addition, smoking index for current smokers was shown a good correlation with PRP WBC (r=0.57, p=0.02) and a fair correlation with purity of PRP (r=0.35, p=0.04).
Conclusion: High dose and very pure PRP with medium efficiency was yielded with this PRP preparation procedure. Whole blood platelet count, the presence of hypertension, and the smoking status of the patients can affect the features of the yielded PRP in patients with OA. Considering these factors into account in the clinical decision is important for determining whether PRP is an option in the management of patients with knee osteoarthritis. These results may serve as a guide in terms of patient selection and avoiding unnecessary injections and their associated costs.

AB1210 SEPTIC ARTHRITIS IN HEMODIALYSIS PATIENTS

Keywords: Kidneys, Infection-related RMDs, Descriptive studies

R. Elafram1, M. Ben Rodhane1, M. Shaier1, H. Kamoun1.1University of Tunis El Manar, Orthopedics, Tunis, Tunisia

Background: The frequency of musculoskeletal disorders in hemodialysis patients varies around 60% as the duration of their dialysis increases. Their physiopathology is complex and multifactorial. Septic arthritis represents 30% of these arthropathies.

Objectives: analyze the clinical, biological and radiological characteristics of septic arthritis in hemodialysis patients and to assess the results of the proposed treatment.

proposed treatment.

Methods: This is a retrospective study of 22 observations of septic arthritis in hemodialysis patients identified in our department over a 5-year period (2015-2022).

Results: The mean age was 43 years [22-60]. The sex ratio is equal to 1. The average duration of hemodialysis was 11.5 years [3 months-28 years]. Joint involvement was acute in 17 cases, with a mean duration of 4 days [1 day-1 week).

Conclusion: Arthrotomy with joint lavage and biopsy of the synovial fluid followed by an adapted antibiotic therapy according to the antibiogramme during 3 weeks by IV route relayed by an oral intake during 3 weeks while the antibiotic treatment alone after biopsy was practiced in 3 patients for two cases of polyartu-itis and one case of deep localization.

Disclosure of Interests: None Declared.

AB1211 RISK FACTORS OF DEPRESSION IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Osteoarthrits
S. Elafram1, I. Haddada1, A. Haj Salam1, N. El Fen1, M. Sghir1, W. Kessomint1.1Taher Star Hospital, PMR, Mahdia, Tunisia; 2 Ibn El Jazzar Hospital, PMR, Kairouan, Tunisia

Background: Knee osteoarthritis (KOA) is among the mean sources of chronic pain and functional disability which may lead to anxiety and depression.

Objectives: The aim of this study was to determine risk factors of depression in patients with KOA.

Methods: We conducted an analytical cross-sectional study over a 3-month period, including patients presenting with KOA. Demographic data, history of KOA and Kellegen and Lawreric radiographic stage were collected. Functional discomfort was assessed by the Lequesne knee index and catastrophizing was assessed by the Pain Catastrophizing Scale (PCS) questionnaire. Psychological assessment was performed by the Hospital Anxiety and Depression (HAD) scale.

Results: Ninety patients with KOA were included. The mean age was 58.76 ± 9.1 years. The mean BMI was 30.19 ± 5.54. The average Lequesne index was 11.33 ± 3.53 and the average PCS was 23.91 ± 11.28. A high depression score was noted in 58.9% of patients. Depression was significantly associated with sex (p = 0.001), BMI (p=0.03), lequesne index (p=0.02) and PCS (p=0.00009).

Conclusion: Pain catastrophizing thoughts in KOA and obesity worsen patients' attitudes and psychological profile towards pain and may lead to depression.

AB1212 OSTEOARTICULAR TUBERCULOSIS, A VERY CHALLENGING DIAGNOSIS

Keywords: Rare/orphan diseases, Bone diseases, Osteoarthrits
S. Bachrouch1, I. Chaabane2, M. Jidi3, H. Tounsi2, Z. Alaya2, R. Amri1.1Mohamed Taher AL Maamour Hospital, Internal Medicine, Nabeul, Tunisia; 2Mohamed Taher AL Maamour Hospital, Orthopedic, n, Tunisia; 3Mohamed Taher AL Maamour Hospital, Orthopedic, Nabeul, Tunisia

Background: Osteoarticular Tuberculosis (TB) is an uncommon form of extrapulmonary TB, it comprises 2–5% of all TB cases in Tunisia. The most frequent sites of osteoarticular TB infection are the spine, hip, and knee. Diagnosis can be challenging owing to the non-specific and insidious nature of the clinical presentation.

Objectives: Describe clinical features, diagnosis and management of this uncommon clinical entity.

Methods: A retrospective clinical study of TB had been diagnosed in our hospital during the last five years, the diagnosis was made by bacteriological and histological examinations after imaging assessment (MRI, CT scan).

Results: Ten cases were included (6 males and 4 females). The mean age was 53 years (16-72 years). The average time to diagnosis was 4 months (2-12months). The joints affected were the dorso-lumbar spine, shoulder, elbow, phalanges, the trochanter-femur and the metatarsal bones. The most common symptoms noted were pain, swelling and restricted motion of the involved joint. Cutaneous fistulas were observed in one case. Fever and systemic symptoms were present in one case. Radiological findings varied, with lytic lesions, abscesses, and joint destruction observed. All patients presented with pathognomonic histological tubercle appearances, with caseous necrosis, lymphocytes, and Langhans giant cells present and TB-PCR in the pus samples was positive in one case. All patients were treated with anti-TB drugs for 12 months and three patients received corticosteroid therapy. The abscess was drained in six cases. We noted clinical and radiological recovery with medical tuberculosis treatment in all patients.

Conclusion: Osteoarticular TB is a common manifestation of extrapulmonary TB and must not be overlooked. Early detection of osteoarticular TB may prevent limb morbidity. Although anti-TB drugs are the primary treatment for osteoarticular TB, in some cases, surgery is required to establish a diagnosis and gain local infection control.

AB1213 ILLNESS PERCEPTION IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Cognitive function, Osteoarthritis, Pain

H. Bousaaid 1, S. Toli 1, S. Miladi 1, A. Fazaai 1, M. Yasmine 1, L. Souabni 1, K. Ouenniche 1, S. Kassab 1, S. Cheli 1, K. Ben Abdelghani 7, A. Laatar 1, Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia

Background: Knee osteoarthritis (OA) can be a source of pain and functional handicap. If not relieved, it leads to an alteration of the patient’s quality of life. The cognitive component of pain varies from one subject to another.

Objectives: The aim of this study was to evaluate the illness perception in patients suffering from knee OA.

Methods: We conducted a cross-sectional study in patients with knee OA. Illness perception was assessed using the French version of the Brief Illness Perception Questionnaire (BIPQ). This questionnaire was developed from the model of Leventhal et al. and aims to assess the different components of the disease. It includes 9 items: 8 quantitative questions on a numerical scale from 0 to 10 and a last item in the form of a qualitative question. The total score varies from 0 to 80, with no predefined thresholds. The higher the score, the more threatening the patient’s perception of the disease is. A “p value inferior to 0.05 was considered significant.

Results: Thirty patients with knee OA responded to the questionnaire. It was about 26 women (87%) and 4 men (13%) with a mean age of 60 years (42-71). The average duration of the disease was 78 months [12-240]. All patients used tier 1 analgesics and NSAIDs. 33% used tier 2 analgesics and three patients had received corticosteroid knee injection. The mean visual analog scale (VAS) of pain was 6cm [3-9]. The mean walking distance was 678m [100-1000]. None of the patients used a cane. The mean value of the Lequesne algofunctional index (AFI) was 8.8 [3-15]. Lameness was noted in 13% of patients. The patellar tap test was positive in 47% of cases. The mean values of body mass index (BMI) and waist circumference were 30kg/m² and 96cm, respectively. According to the Kellgren-Lawrence classification, knee OA was at grade 1 in 10% of the cases, grade 2 in 40% of the cases, grade 3 in 40% of the cases, and grade 4 in 10% of the cases. All patients completed the entire questionnaire with a mean score of 45 [36-54], and a mean maximum score of 6/10 for the first question assessing the impact of the disease on the patients’ lives. Responses were incomplete for the 9th question which consists on listing 3 reasons that may cause the disease: only 15 patients (50%) cited 3 causes. The main reported factors causing knee OA according to patients were physical activity (83%), age (66%), prolonged standing (62%), and weight (51%). A statistically significant negative correlation was noted between the BIPQ, and age (r=−0.488, p=0.006) and disease duration (r=−0.583, p=0.001). This correlation was not significant with pain VAS, walking distance, BMI, waist circumference and the Lequesne AFI.

Conclusion: Illness perception in patients with knee OA is important to screen in order to deliver a more personalized management.

AB1215 ASSOCIATED FACTORS TO POSTURAL BALANCE CONTROL IN KNEE OSTEOARTHRITIS AND COMMON LOW BACK PAIN PATIENTS

Keywords: Rehabilitation, Pain

I. Ksibi 1, L. Rouached 1, W. Lahmar 1, S. Bouder 1, O. Saidane 1, N. Mouhi 1, M. Hitdhi 1, H. Rahali 1, R. Maouali 1, Military Teaching Hospital, Rehabilitation, Tunis, Tunisia; Charles Nicolle Teaching Hospital, Rheumatology, Tunis, Tunisia

Background: Pain induces the alteration of postural balance (PB) mechanisms. Therefore, the PB control is an important element to consider when managing patients with degenerative musculoskeletal diseases (DMD).

Objectives: The aim of our study was to evaluate balance control in patients having knee osteoarthritis (KOA) or low back pain and to identify the associated factors.

Methods: A cross sectional study including patients suffering from common low back pain (LBP) and KOA. We collected the sociodemographic data. We evaluated the PB using a stabilometric platform, realized when the eyes were closed. Analyzed variables were the center of pressure (COP) in the mediolateral (ML) and anteroposterior (AP) axis, the surface area (S), the mean sway velocity (V) and the mean sway energy (E). We divided patients into 2 groups; G1: patients having postural imbalance and G2: patients with a good postural balance profile.

Results: We had 30 patients with a sex ratio at 1:3, a mean age of 47±11.14 [23-65] years old. The mean BMI was 28.17±2.12 [20.3-39.5]. Twelve patients (40%) suffered from KOA, 18 (60%) of them had chronic low back pain, with a mean disease duration of 1.61±1.55 [0.10-5] years. Postural profile evaluation revealed a mean S of 265.93±576.3 [1 - 3239]. COP position in the ML axis was 0.68±0.49 [-15.7 -24.6] and in the AP: 21.4±21.70 [-8.2 – 81.4]. Mean sway V was 11.4±3.88 [72 – 22.9]. The E was 8.94±6.52 [403]. We detected an abnormal S in 5% of participants, decreased E in 8% of patients. According to the ML axis the COP was: left in one patient and right in 5% of patients. The COP was anterior in 21% of cases. The mean sway V was pathological in 5% of cases. The comparison between both groups did not find any
significant difference concerning gender (p=0.43), the disease (p=0.65). We did not find a significant difference in the means of age (p=0.52), BMI (p=0.3) and underlying disease duration (p=0.31).

Conclusion: Half of the patients with DMD presented a postural imbalance which wasn’t explained by sociodemographic or anthropometric parameters. The instrumental evaluation of PB, considering the fall’s risk factor is then essential.

SYMPTOMATIC SLOW-ACTING DRUGS FOR GONARTHROSIS: BETWEEN EXPECTATIONS AND REALITY

Keywords: Pain, Osteoarthritis

H. Tebaa1, H. Arabi1, A. Mougui1, I. El Bouchti1. 1CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rhumatology, Marrakech, Morocco

Background: Osteoarthritis of the knee is the most common cause of chronic pain and disability in patients. In addition to non-steroidal anti-inflammatory drugs and analgesics, the symptomatic slow-acting anti-arthritic drugs (SAAALs) define a specific class of medications used in the symptomatic treatment of osteoarthritis of the knee. With a delayed effect, this family of drugs is used to reduce the intensity of pain and functional discomfort caused by the destruction of cartilage.

Objectives: To assess the prevalence of co-morbidities in gonarthrosis patients and to assess their impact on pain, functional impact and radiographic progression.

Methods: Our study involved patients with gonarthrosis. Comprehensive comorbidity screening was done. Pain intensity was assessed by the Analog Visual Scale (EVA). The neuropathic component was assessed by the DN4 score. Functional impact was assessed by the Lequesne index and WOMAC score. Knee X-rays were classified according to Kellgren Lawrence (KL) criteria.

Results: A total of 215 patients were included (24 men/191 women). The average age was 58.02 ±9.11 years. The mean body mass index was 24.87 ± 5.37 kg/m2. The main comorbidities were:

The visual analogic scale was 7.86± 1.31 and stress at 13.74 ±4.95. The average WOMAC score was 12.3 ±8.92. The average Lequesne score was 6.71 ±3.20. The average DN4 score was 18.81 ± 8.9. Comorbidities were associated with age (p= 0.02), DN4 score (p= 0.01), and KL radiographic grades (p = 0.02).

Conclusion: In this study, co-morbidity in gonarthrosis was associated with advanced age, a neuropathic component of pain, and severe structural impairment.

COMORBIDITIES DURING GONARTHROSIS

Keywords: Quality of life, Comorbidities, Osteoarthritis

A. Rafi1, S. Belouaham1, Z. Baba1, A. Mougui1, I. El Bouchti1. 1Chu Mohamed VI Marrakesh - Drh, Rheumatology, Marrakesh, Morocco

Background: Osteoarthritis of the knee, together with that of the hip, is the most serious disease of osteoarthritis. Long considered a benign disease, gonarthrosis is nevertheless associated with significant morbidity.

Objectives: To assess the prevalence of co-morbidities in gonarthrosis patients and to assess their impact on pain, functional impact and radiographic progression.

Methods: This study was conducted in the form of an individual questionnaire, 56 patients followed in consultation for a primary gonarthrosis without a period of congestive attack, the diagnosis of knee osteoarthritis was made by and radiography of the knee according to the classification of Kellgren and Lawrence, any patient with secondary osteoarthritis or very disabling gonarthrosis was excluded. Patients were questioned about their fears and expectations before the start of treatment. An evaluation of the therapeutic response after one year was done by different parameters: the visual analogue pain scale (VAS pain), the Lequesne index of the knee, and decrease in analgesic consumption, improvement in walking perimeter and side effects and pain reduction. Global satisfaction was evaluated by a likert scale composed of 7 degrees of satisfaction (from extremely satisfied to extremely dissatisfied).

Results: We included 56 patients, the average age was 44 years, the female sex represented 59%, the average educational level represented 20%. According to the classification of Kellgren and Lawrence, stage 2 represents (40%), stage 3 (52%) and stage 4 (8%). There were 30% of patients on chondroitin-based anti-arthritics drugs, 60% on glucosamine and 10% on avocado-soybean unsaponifiable extract. The average VAS pain was 5 ± 1.1, the average Lequesne index (knee) was 7. Fear of pain exacerbation was noted in 15%, 20% were afraid of a functional handicap and 49% were afraid of a probable surgery, 16% had no fear. Before the initiation of treatment, 65% of the patients hoped for an improvement in their function, 49% feared a probable surgery and 16% had no fear. Before the initiation of treatment, 35% thought it was a placebo. The mean VAS pain after treatment was 3±2.2 vs 5 ±1.1 before treatment (p= 0.003), the mean Lequesne index after treatment was 4.9 vs 7 after treatment with a statistically significant difference (p= 0.003), an improvement of the gait perimeter was noted in 51%, 41% reported a reduction in the consumption of analgesics, 3% of patients had side effects such as nausea and vomiting. After 1 year of treatment, 45% of patients were extremely satisfied with their treatment, 15% were extremely dissatisfied, 10% were satisfied and 30% were not very satisfied.

Conclusion: Patient expectations and satisfaction are important components in the evaluation of quality of care. This new approach is important to guarantee therapeutic adherence.

ASSOCIATION BETWEEN OSTEOPOROSIS AND DISRUPTION OF GUT MICROBIOTA: A META-ANALYSIS

**Keywords:** Osteoporosis

O. Y. Su\(^1,2,3\), X. Song\(^2,3\), D. Qiao\(^2,3\), G. X. Wang\(^2,3\), X. Y. Yin\(^2,3\), Q. Yu\(^4\), P. F. He\(^5\), X. Li\(^1,2,3\), S. X. Zhang\(^1,2,3\). The Second Hospital of Shanxi Medical University; Department of Rheumatology, Taiyuan, China; 3Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 4Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

**Background:** Osteoporosis (OP) is a systemic disease of the skeleton characterized by decreased bone mineral density and the imbalance of bone, resulting in an increased risk of fragility fractures\(^4\). Gut microbiota has a mutually beneficial and symbiotic relationship with the host and plays a vital role in the host's metabolism and immune regulation. An expanding body of studies asserts that gut microbiota has a role in bone metabolism and the pathogenesis of osteoporosis\(^2\).

**Objectives:** This study aimed to confirm the changes of gut microbiota in osteoporosis through meta-analysis.

**Methods:** We searched PubMed, Embase, MEDLINE, Cochrane Library, CNKI, VIP, CBM, and Wanfang databases from the established to January 10 2023 on gut microbiota diversity in patients with OP. Standardized mean difference (SMD) and 95% confidence interval (CI) were used to evaluate the difference in microbial abundance between the OP and healthy control (HCs).

**Results:** A total of 16 studies were included in this meta-analysis, including 517 OP and 714 HCs. The summary results showed that there was no significant difference in α diversity index compared with HCs (Simpson index: SMD = 0.120, 95% CI: [0.031–0.271], p = 0.049; Shannon index: SMD = -0.039, 95% CI: [-0.284 to -0.206], p = 0.001; ACE: SMD = 0.029, 95% CI: [-0.647 to 0.706], p < 0.001; Chao1: SMD = 0.000, 95% CI: [-0.446 to -0.446], p < 0.001; Observed species: SMD = 0.134, 95% CI: [-0.049 to 0.317], p = 0.198). To eliminate the heterogeneity caused by the difference of the observed species index by the sequencing method, we conducted a subgroup analysis of the observed species, and the results showed that the index obtained by high-throughput sequencing (SMD = 0.490, 95% CI: [0.084 to 0.896], p = 0.001) was higher than that of HCs.

**Conclusion:** This study suggested that changes in intestinal microecology were related to OP. More studies should be conducted to explore the specific differences in gut microbiota in OP.

**DOI:** 10.1136/annrheumdis-2023-eular.4396

**Figure 1.** Patients with GFR <30 ml/min by different equations.

**Conclusion:** In a setting of advanced liver disease candidate to transplantation, renal function estimates significantly varied depending on the GFR equation used, thus largely modifying the rates of patients with contraindication for using bisphosphonates, despite the high fracture risk.

Further studies are necessary to establish the best method to assess the renal function in advanced liver disease patients, in order to tailor anti-OP strategies.

VERTEBRAL FRACTURE CHARACTERISTICS IN AN FLS UNIT ACCORDING TO THE IDENTIFICATION METHOD; EMERGENCY LIST, OUTPATIENT CLINIC OR VFA.

Keywords: Osteoporosis

Background: The risk of subsequent fracture is very high after a vertebral fracture (VF).

Objectives: To analyze the characteristics of patients with VF seen in a Fracture Liaison Service (FLS).

Methods: Our FLS cares for patients from the emergency list (URG), referred by hospital or primary care doctors (HPC) with VF <12 months, and captured by DXA-VFA (Densitometry - VF Assessment) in patients with non-VF. The database included the FRAX items plus previous treatment and DXA results. Traumatic VFs or VFs with a known age >1 year, infiltrative or neoplastic diseases, and patients with contraindications for treatment were excluded. The number and grade of VF (Genant's scale) were analyzed.

Results: 570 patients have been included (Table 1). The most frequent route of identification was HPC followed by the emergency registry and detection by DXA-VFA. The data-base included the FRAX items plus previous treatment and DXA results. Traumatic VFs or VFs with a known age >1 year, infiltrative or neoplastic diseases, and patients with contraindications for treatment were excluded. The number and grade of VF (Genant's scale) were analyzed.

Table 1. - Distribution according to identification group. Results represent n (%) and mean (SD) unless expressly indicated.

CLINICAL EFFICACY OF SEQUENTIAL TREATMENT AFTER ROMOSOZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARISON WITH PRIMARY OSTEOPOROSIS FOR 24 MONTHS

Keywords: Osteoporosis, Rheumatoid arthritis
Y. Kanayama1, K. Hattoni, Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan

Background: Romosozumab (ROMO), a monoclonal antibody that binds sclerostin, increases bone formation and decreases bone resorption. And although it is a novel therapeutic agent for osteoporosis, which has shown high effects of increasing bone density and inhibiting fragile fracture in overseas clinical trials. However the clinical efficacy for rheumatoid arthritis complicated with osteoporosis (RA-OP) is unknown.

Objectives: To evaluate the clinical efficacy of ROMO for 12 months and denosumab (DMB) for 12 months in patients with RA-OP comparison with primary osteoporosis (P-OP) for 24 months.

Methods: RA patients diagnosed according to the 2010 ACR/EULAR criteria. All patients (RA-OP; 12 cases, P-OP; 19 cases) met at least one of the following criteria were eligible: a bone mineral density T score of -2.5 or less at the lumbar spine or total hip and either one or more moderate or severe vertebral fractures or two or more mild vertebral fractures. All patients were initiated ROMO between April, 2019 and July, 2020. The ROMO dose was 210mg at once every 24 months about the increase and decrease of bone mineral density (BMD) of lumbar spine(LS) and total hip(TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen(PINP) and tartrate-resistant acid phosphatase s(5b)TRACP-5b.

Results: The gender was all female. Patient background at baseline in RA-OP (n=12) and P-OP (n=19) had a mean age of 72.8 ± 7.0 and 73.9 ± 6.7 (p=0.417); the body mass index were 19.5 ± 3.1 and 20.1 ± 3.6 (p=0.516); the FRAX were 36.0 ± 14.9 and 33.7 ± 16.6 (p=0.529); the number of previous fracture were 5cases (42%) and 13cases (68%) (p=0.142) and the number of previous drug for treatment osteoporosis use were 9cases (75%) and 7cases(38%) (p=0.038).

The bone turnover markers and bone mineral density at baseline were as follows; PINP 62.4 ± 36.2 and 94.6 ± 101.3 (p=0.665); TRACP-5b 485 ± 252 and 24 months.
546 ± 278 (p=0.516); LS-BMD and T-score 0.79 ± 0.14 and 0.79 ± 0.12 g/cm² (p=0.903), -2.82 ± 0.99 and -2.87 ± 0.87 (p=0.919) and TH-BMD 0.55 ± 0.07 and 0.56 ± 0.07 g/cm² (p=0.621), -3.14 ± 0.53 and -3.06 ± 0.35 (p=0.682). Clinical findings related to RA-OP at baseline were as follows; disease duration 17.7 ± 16.5 years; CRP 125 ± 175; DAS28-CRP 3.45 ± 0.99; HAQ 1.56 ± 0.9. The rate of increased LS-BMD from baseline to 6, 12, 18 and 24 months between RA-OP and P-OP were 10.8 ± 8.0% and 11.6 ± 5.7%, (p=0.670) at 6 months, 15.2 ± 9.5% and 16.4 ± 8.2% (p=0.584) at 12 months, 18.9 ± 10.4% and 21.8 ± 9.4% (p=0.598) at 18 months, 20.6 ± 11.7% and 22.7 ± 9.6% (p=0.730) at 24 months and TH-BMD were 4.1 ± 4.5% and 2.7 ± 3.9%, (p=0.389) at 6 months, 5.7 ± 6.3% and 6.1 ± 6.0% (p=0.747) at 12 months, 8.4 ± 8.1% and 8.2 ± 5.3% (p=0.747) at 18 months, 8.4 ± 9.8% and 8.8 ± 5.0% (p=0.236) at 24 months.

AB1222 NEUTROPHIL TO LYMPHOCYTE RATIO (NLR) PREDICTS FRACTURE IN PATIENTS ON LONG-TERM GLUCOCORTICOID.

Keywords: Registries, Osteoporosis, Bone diseases

J. Chen¹, T. T. Cheng², S. F. Yu³, H. Y. Kang⁴. ¹Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, College of Medicine, Division of Rheumatology, Allergy, and Immunology, Department of Internal Medicine, Kaohsiung, Taiwan, Republic of China; ²Center for Menopause and Reproductive Medicine Research, Department of Obstetrics and Gynecology, Kaohsiung Chang-Gung Memorial Hospital and Chang Gung University; College of Medicine, Kaohsiung, Taiwan, Kaohsiung, Taiwan, Republic of China

Background: Long-term glucocorticoid (GC) exposure leads to systemic bone loss and fracture. In addition, GC is known to increase white blood cell (WBC) amount and change the distribution of differential count (DC). Neutrophil-Lymphocyte ratio (NLR) has been studied as an optimal marker of subclinical inflammation, predicting the prognosis of cardiovascular diseases, cancers and even covid-19 infection. For patients under long-term GC exposure, the hemogram change might be a potential parameter to predict prognosis.

Objective: To investigate if GC related WBC-DC change, including NLR, is associated with future fractures during 3 years follow-up.

Methods: This retrospective study is based on a registry, conducted in Kaohsiung Chang Gung Memorial Hospital, Taiwan, from September 2014 till April 2021, aimed to monitor bone mineral density (BMD) changes and fractures in patients with autoimmune diseases. All recruited patients were followed at least 3 years and took X-ray images annually to capture new fragility fracture, including morphometric vertebral fractures. We screened participants who used GC continuously at least 3 months before the index day. We recorded the complete blood count (CBC) and WBC-DC values at least twice during the period of 3 months before and after the index day, and excluded patients who were febrile, under infection status, diagnosed as cancers or cardiovascular diseases at the index day. The NLR was calculated by the absolute neutrophil count divided by absolute lymphocyte count individually.

Results: A total of 346 participants were enrolled in current study, and 101 (29.2%) suffered from new fragility fracture in 3 years. Among patients with fracture and non-fracture, conventional fracture risk factors, such as age, BMD, and previous fracture remained significantly different, while the WBC revealed no difference (Table 1). Nevertheless, the absolute neutrophil and lymphocyte count were significantly higher and lower in the fracture group, respectively, and no difference in the monocyte, eosinophil, and basophil count. We compared different WBC ratio, and NLR is significantly higher in the fracture group, providing the odds ratio of 1.24 (95% confidence interval 1.07-1.44, p=0.005).

Conclusion: In patients under long-term GC, NLR might be a helpful marker to predict fracture, and higher NLR indicates higher fracture risks.

WHAT ABOUT BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS PATIENTS USING GLUCOCORTICOIDS?

Objectives: To estimate the prevalence of insufficiency fractures in the thoracic vertebrae in patients hospitalized for any cause in a Hospital in Bogotá (Colombia).

Methods: Cross-sectional study in a sub population of Latin American patients, older than 50 years with chest tomography indicated during hospitalization in 2020 for reasons other than suspicion of vertebral bone disease. Patients with secondary causes of vertebral fracture, trauma and spinal instrumentation were excluded. Reading by two independent expert researchers with Genant’s semi-quantitative visual method and the ABQ method. Clinical and sociodemographic variables were captured (RedCap). Descriptive statistical analysis (STATA 17). The project was approved by the ethics committee.

Results: A total of 317 patients with a mean age of 69.4 years and a predominance of males (57.1%) were included. The most frequent personal history was active smoking (15.8%), use of glucocorticoids in the last 5 years (12.9%), and alcohol consumption (75%). A prevalence of vertebral fractures of 8.5% was found, being more frequent in women in 51.8% of the cases, with T11 as the most frequent location (See Table 1 and Figure 1). Only two vertebrae did not define a fracture according to the ABQ method compared to Genant. A disagreement was found in 77.7% of the cases with respect to the final report.

Conclusion: The prevalence of vertebral fractures reported here is lower than that reported in the literature when x-ray imaging is used; it is possible that the use of the tomography influences this result and possibly allows a more objective assessment. Careful evaluation of chest tomographic studies performed during the hospital stay may contribute to an opportune diagnosis of insufficiency fracture associated with osteoporosis.

* In total, 44 fractured vertebrae were identified; only 42 are described in the table, since only 3 vertebrae were classified in the patient in whom 5 fractured vertebrae were detected.

Figure 1. Fracture severity

Osteoporosis is a metabolic bone disorder characterized by a systemic impairment of bone mass and microarchitecture that results in fragility fractures [1]. Romosozumab (Rmab), a humanized monoclonal anti-sclerostin antibody, increases bone mineral density (BMD) and decreases fragility fractures in patients with postmenopausal osteoporosis (POMD) [2]. While an increase in type 1 amino-terminal procpeptide (PINP) and a decrease in tartrate-resistant acid phosphatase Sb (TRACP-Sb) are observed early after administration of Rmab, the association between these changes in bone metabolic markers (BTMs) and increases in BMDs was still unknown.
Objectives: The aim of this research is to evaluate association between effect of Rmab on BMDs and BTMs in patients with PMO.

Methods: Between March 2019 and August 2021, 34 patients with PMO, who were naïve to treatment of osteoporosis were included. The correlation between baseline characteristics, changes (%-) in BMDs in lumber (L-) and total hip (TH-) at 12 months (-M), and absolute values of P1NP and TRACP-5b and %P1NP and %TRACP-5b at 1, 3, 6M was calculated, respectively. Multiple regression analysis was performed on the factors that showed significant correlations to L- and TH-BMD, respectively.

Results: The mean age was 72.5 years old, mean BMI was 20.6 kg/m², mean vertebral fractures were 2.1, mean L- and TH-BMD were 0.762 g/cm² and 0.589 g/cm², and mean P1NP and TRACP-5b were 107.0 µg/L and 640.0 µM/dL, %L- and %TH-BMD at 12M were 18.1% and 9.1%, %P1NP at 3M was positively correlated with %L-BMD at 12M, while %TRACP at 1 and 6M and TRACP-5b at each time point showed no significant correlation with %L-BMD at 12M. Multiple regression analysis confirmed that a great increase in P1NP at 3M was associated with a great increase in L-BMD at 12M. No correlation between either P1NP or TRACP-5b at each time point and %TH-BMD at 12M was observed.

Conclusion: We showed that a great increase in P1NP at 3M was a predictive factor of a great increase in L-BMD at 12M in patients with PMO treated with Rmab. On the other hand, there was no association between an increase in TH-BMD and BTMs including P1NP and TRACP-5b.

AB1226 CLINICAL SIGNIFICANCE OF A PATIENT COMPLIANCE IN PREVENTION OF SECONDARY FRACTURES

Keywords: Osteoporosis

E. Simakova1, I. Zborovskaya2, S. Zavadovsky2, L. Seewordova2, J. Poljakova3, E. Papichev4, V. Zavodovsky2, 1ACR, Rheumatology, Jupiter, United States of America; 2Research Institute of Rheumatology, Moscow, Russian Federation; 3Research Institute of Rheumatology, Volgograd, Russian Federation; 4Research Institute of Rheumatology, Volgograd, Russian Federation

Objectives: to evaluate the effect of compliance in patients with osteoporosis on the incidence of new fragility fractures.

Methods: The study was performed in two stages. At the 1st stage, a retrospective analysis of outpatient records for the period from December 2019 to December 2021 was completed in the Volgograd Center of Osteoporosis. During Phase II of the study, in December 2022, researchers conducted a telephone survey to identify new fractures.

Results: The analysis included outpatient records of 2236 patients aged 40 to 92 years with DEXA scan. (1897 women and 339 men). 715 patients out of 2236 (control group or 31.98% of all included in the study) were found to have an abnormal DEXA, but lost follow up, among 715 patients from the control group, 509 (71%) patients were diagnosed with osteoporosis, 115 patients had a history of fragility fractures [1,2]. But these patients refused to attend the school for patients with osteoporosis and offered treatment. 158 patients in this group (26.51%) reported new low-traumatic fractures on a telephone survey. The remaining 1521 (73.49%) patients constituted the II group of the study (highly compliant patients). Among these patients, only 11 new low-traumatic fractures (1.4%) were registered. Group I (158 subjects) represented by patients managed according to the Standard Clinical Practice and who were NOT given further information about their fracture risk and who were NOT given the risk card; group B (175 subjects) represented by patients who were provided with all the information regarding the risk of fracture according to the variables collected in the Defra algorithm and who were physically given the fracture risk card (Figure 1). After 18 months the patients had a new DXA densitometric data examined, the DeFRA fracture risk was recalculated and a therapy adherence questionnaire, the OS-MMAS (Osteoporosis-Specific Morisky Medication Adherence Scale). Patients with an OS-MMAS score <6 were categorized as “low adherence” otherwise as “high adherence”.

Results: Mean age was not significantly different in the two groups: Group A 75.9y±4.7, Group B 74.7y±4.7 (p=0.05). The mean DeFRA value at baseline was 26.7 and 26.8 in Group A and Group B, respectively (p>0.05), while at the control it was 27.4 and 25.6 (p<0.01). The mean OS-MMAS score was significantly lower in group A than in group B (4.95±2.75 vs 8.25±2.85, p<0.001) (Figure 2 and Figure 3). 38.5% of the subjects fell into the ‘low adherence’ category with an OS-MMAS score <6; 61.5% fell into the ‘high adherence’ category with a score ≥ 6. We found a significant correlation between the belonging groups and the punctual values of DeFRA at 18 months and those of variation of DeFRA between baseline and 18 months (correlation between belonging to group B and DeFRA at 18 months -2.72, with the delta values of DeFRA at 18 months -2.72 respectively, p<0.01). The OS-MMAS score was shown to be correlated to belonging to group B (coefficient Beta 0.5 p<0.001) in a linear regression model including the other variables collected at baseline and DeFRA value at baseline. The same result was obtained by analyzing the data in terms of “low adherence” and “high adherence”, where having an OS-MMAS score greater than or equal to 6 correlated to belonging to group B and not to age or DeFRA score baseline (ExpB 0.170 95% CI 0.103-0.281, p<0.01) in a binary logistic regression model. In turn, the better OS-MMAS score correlated with the improvement over time of the DeFRA fracture risk recalculated at the follow-up visit on the basis of the control DXA data (Spearman’s Rho -3.95 p<0.001)

Conclusion: The data collected in our study, although preliminary and with obvious limitations related to the smallness of the sample analysed, suggest that a greater awareness on the part of the patient of his or her risk of fracture (in the specific case providing detailed information about the result of the DeFRA algorithm described during the baseline evaluation), may be associated with a greater long-term adherence to the suggested therapy and above all with a reduction in the risk of fracture over time, as evidenced by a reduction in the risk of DeFRA fracture at the 18-month follow-up period.

RADIOFREQUENCY ECHOGRAPHIC MULTISPECTROMETRY COMPARED WITH DUAL X-RAY ABSORPTIMETRY FOR OSTEOPOROSIS DIAGNOSIS ON LUMBAR SPINE AND FEMORAL NECK IN A COLOMBIAN POPULATION

Keywords: Osteoporosis, Diagnostic tests

E. Jauregui1, K. Gonzalez1, M. Nuñez2, J. Londoño3, B. Corredor1, J. Huertas1, C. Cabrera1. 1Riesgo de fractura S.A, Bogotá, Bogotá, Colombia; 2Instituto Nacional de Cancerología, Bogotá, Bogotá, Colombia

Background: An innovative non-ionizing ultrasound technique for osteoporosis diagnosis, which directly measures the BMD (Bone Mineral Density) of both the lumbar spine and the femoral neck, REMS, has shown significant correlations with BMD values and good levels of concordance with DXA-based diagnoses.

Objectives: Cross-sectional study to establish the concordance of BMD measurement between REMS and the gold standard (DXA) in Colombian adult patients receiving oral steroids.

Methods: Observational, analytical and descriptive, cross-sectional study in adults of both sexes who receive steroids and who attend a rheumatology center in Bogotá-Colombia. Inclusion criteria: Men and women over 18 years. Receiving steroids more than 2.5 mg prednisone or its equivalent for 3 or more continuous months. Interpretable bone densitometry. Subjects who accepted their participation in the study and signed the informed consent. Exclusion criteria: History of prosthesis implantation in the abdomen and/or buttocks. Known physical deformities and/or previous lumbar spine surgery and/or bilateral hip replacement. Pregnant women. Subjects prevented from performing bone densitometry. The densitometric measurements were made with a compact high-performance equipment from General Electric, model DXA, by the same technologist at the skeletal sites of interest. In a second moment, the same trained technologist performed the BMD measurement with REMS, using an EchOs machine (Echolith8), equipped with a 3.5 MHz convex transducer. This study was submitted and approved by the institutional ethics committee. The calculation of the sample size was carried out to establish the prevalence of osteoporosis induced by steroids, for n of 185 individuals. The concordance between the two technologies was evaluated with the weighted Cohen’s Kappa index.

Results: 200 patients were included in the study, 162 were women. The median age of the entire cohort was 50.5 years (IQR: 22.2), with a minimum age of 20 and a maximum of 86 years. In women, the median age at menarche was 13 years (IQR: 2) and the median age for menopause was 47 years (IQR: 8), only 2.5% (n = 5) reported having fractures for fragility; 51% of the patients had rheumatoid arthritis, SLE 29% and other diagnoses 20%. Regarding the type of corticosteroid used, 92.5% received prednisolone. The last dose of corticosteroid used in median, (IQR) 5 mg/day (IQR: 5). In the case of the accumulated dose in the last year, the median was 1825 mg/year (IQR: 1850). For the concordance analysis, 11 patients were excluded because the image of all the lumbar vertebral bodies could not be interpreted with both DXA and REMS techniques. Taking into account the diagnostic classification of each technology, a diagnostic concordance was obtained with the weighted Cohen’s Kappa index of $\kappa_{w} = 0.72$ (95% CI: [0.63; 0.81]) in the lumbar spine and $\kappa_{w} = 0.65$ (95% CI: [0.54; 0.74]) in femoral neck.

Conclusion: In Colombian patients receiving steroids, the diagnostic concordance for BMD measurement between DXA and REMS is good; however, there are factors that affect the measurement, for which further training in REMS is required for the technologist to mitigate errors and improve the concordance between the techniques.

AB1229

COMPARISON OF FRACTURE RISK BY FRAX WITH AND WITHOUT BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Prognostic factors, Osteoporosis, Non-pharmacological interventions

A. Carrascoc-Chapa1, K. M. López Serna1, O. E. Alvarez-Gonzalez1, K. A. Mendetta Pedraza1, M. C. Martinez Rodriguez1, J. Medina Castillio1, C. M. Skinner Taylor1, J. C. Riega-Torres1, R. Negrete Lopez1, D. A. Galarza-Delgado1, Hospital Universitario “Dr. José Eleuterio González”; Rheumatology, Monterrey, Mexico

Background: FRAX is a well-validated instrument that calculates the probability of a major osteoporotic fracture over the following 10 years based on a set of risk factors such as age, body mass index (BMI), history of fragility fracture, steroid treatments used in patients with autoimmune rheumatic diseases (ARD) such as rheumatoid arthritis (RA), and secondary osteoporosis [1]. The FRAX score obtained without bone mineral density (BMD) is comparable to the fracture risk calculated using BMD values; it aims to identify patients who are likely to benefit from health interventions [2].

Objectives: To compare the fracture risk using FRAX with and without BMD in patients with ARD.

Methods: An observational, cross-sectional, prospective study was carried out at the Rheumatology Clinic in the University Hospital “Dr. José Eleuterio González” in Monterrey, Mexico from September to December 2022. We included > 40 years old ARD patients with a previous BMD test who were evaluated as part of a “Bone Health Program”. The risk fracture scores were compared using FRAX with and without BMD. There were classified as low (<10% probability of a major fracture), intermediate (10% - 19% probability) and high risk (>20% probability). Non-traditional risk factors such as visual problems, periodontal disease, 2 or more falls in the last year, lack of physical activity, the ARD diagnosis or the consumption of disease-modifying drugs (DMARDs), were collected using a semi-structured form. The Kologorov-Smirnov test was used to determine normality. Data were presented as percent frequency, mean ± standard deviation (SD), or median and interquartile range (IQR) as appropriate. We used the Mann–Whitney U or Chi-square to analyze the differences between groups. A p<0.05 was considered statistically significant. The statistical analysis was performed with SPSS v.25.

Results: A total of 146 patients were included: 142 (97.3%) were women and 4 (2.7%) were men with a mean age of 61.49 ± 9.22. The most frequent BMI was overweight (43.2%), followed by normal (31.5%), obesity grade 1 (13.7%), obesity grade 2 (10.3%) and obesity grade 3 (1.4%). The occupations were housewife (76.8%), employed (17.1%) and owned business (4.1%). The most prevalent non-traditional risk factors were visual problems (45.9%), systemic lupus erythematosus (3.4%), Sjogren’s syndrome (2.7%) and others (8.9%). The risk factors used by FRAX can be found in Figure 1. According to the non-traditional risk factors, 24.7% suffered 2 or more falls in the last year, 26% had periodontal disease, 71.9% were sedentary and 53.8% had visual problems. The median T-score spine was -1.7 [IQR (-2.5) (-0.8)] and the mean T-score hip was -1.06 ± 1.21. The risk fracture scores using FRAX with and without BMD are in Table 1.

Conclusion: Higher hip fracture and major fracture risks were identified in the FRAX without BMD group. We found significant differences between the hip fracture risk of FRAX with and without BMD. Nevertheless, no differences were found in the major fracture risk of FRAX with and without BMD; this is of critical importance if all patients cannot have their BMD measured. The FRAX use makes it possible to offer a larger population a timely diagnosis.

IQR: Interquartile range
CHARACTERISTICS OF FRACTURES TREATED IN THE FIRST YEAR OF OPERATION OF THE FLS OF TUDELA, NAVARRA.

Keywords: Osteoporosis, Descriptive studies, Outcome measures

M. S. Moreno García1, 1Hospital Reina Sofia, Reumatologia, Tudela, Spain

Background: Osteoporosis is a common disease with a huge impact on public health due to the great morbidity and mortality and the impact on the quality of life of fractures. The main objective of its approach is to avoid the appearance of osteoporotic fractures, so it is important to devote efforts to diagnose and treat individuals who are most at risk of suffering this type of fractures. In our environment the approach to osteoporotic fracture was deficient, so a specific secondary prevention consultation was launched.

Objectives: To analyze the general characteristics of patients referred to the FLS consultation during their first year of operation at the Reina Sofia Hospital in Tudela, Navarra.

Methods: Retrospective descriptive study including patients referred to the secondary fracture prevention rheumatology (FLS) consultation, from November 2021 to November 2022. Epidemiological characteristics, risk factors, type of fracture, therapeutic acts and adherence to treatment at month 6 and 12 months are analyzed.

Results: During the indicated period, 200 patients were referred to FLS consultation from Traumatology. Internal Medicine and Rehabilitation, of which 67% (134) were evaluated during admission for hip fracture, of whom 11 died during admission. 33% of patients were treated on an outpatient basis -with a maximum delay of 6 weeks-, for low-impact fractures of radius (23), proximal humerus (15) and vertebral (28). The mean age of patients with hip fracture was 84.95 years, and that of the rest of osteoporotic fractures treated was 72.95 years, with a ratio of men/women of 43/157, close to 1/5. The Barthel was also calculated with an average of 90.36. Regarding risk factors: the mean BMI of the patients was 25.56 kg/m2; 23 patients (11.5%) were active smokers, 8 of the women attended (4%) had early menopause, 2 women (1%) were on treatment with aromatase inhibitors, 48 patients (24%) had had previous fracture and 57.5% of patients had hypovitaminosis D. Only 20 patients (10%) had taken or were being treated for osteoporosis prior to fracture. BMD was requested from 47% of patients. Regarding the treatment prescribed after evaluation in the FLS, 16% was not considered subsidiary to specific pharmacological treatment, but was always given non-pharmacological advice, as well as calcium and vitamin D supplements. Those who were prescribed specific therapy 64% were prescribed antiresorptive and 36% an osteoanabolic. Regarding adherence to treatment, only 4 patients did not take it within one month of their prescription. The rest followed a correct completion each review call per month, 6 months and one year, although at the time of writing the study there are pending review appointments of 6 and 12 months in patients recruited from the second semester of 2022.

Conclusion: The establishment of standardized units for secondary prevention of fracture is a necessity for the health of the population. In our sample, only 10% of patients treated for osteoporotic fracture had specific therapy before their fracture, but, after assessment in the FLS, the initiation of therapy after osteoporotic fracture was ensured in all subsidiary patients, as well as adequate adherence to treatment.

HIGHER PAIN SCORE MEASURED WITH VISUAL ANALOG SCALE HAS SIGNIFICANT HIGHER RISK OF INCIDENT BONE FRAILITY FRAGMENT

Keywords: Pain, Rheumatoid arthritis, Osteoporosis

I. Yoshii1, N. Sawada2, T. Chijiwa1 1Yoshii Clinic, Musculoskeletal Medicine, Shimanto City, Japan; 2Dogo Onsen Hospital, Rheumatology, Matsuyama, Japan; 3Kochi Memorial Hospital, Rheumatology, Kochi, Japan

Background: Bone fragility fracture (BFF) is one of serious troublesome incident in treating patient with rheumatoid arthritis (RA). Previously, sustaining clinical remission with simplified disease activity index (SDAI) was clarified that prevents occurrence of incident BFF [1].

Objectives: We hypothesized that pain degree would correlate with occurrence of incident BFF, because that caused gait disability and bone fragility. The aim of this study is to clarify this issue.

Methods: A retrospective cohort study data was used in the study. Postmenopausal female patients who matched the EULAR/ACR classification criteria under the T2T since August 2010, have been treating RA and were measured bone mineral density (BMD) with dual-energy X-ray absorptiometry, were recruited. The initial target of therapy is the attainment of remission with SDAI score were included in RA specific candidate risks. Each evidence was evaluated using Cox regression analysis to identify significantly higher risk factors within 5% in univariate models and to evaluate using multivariate model. In the Cox regression analysis, Receiver

PROFILE OF OSTEOPOROSIS IN YOUNG WOMEN: EXPERIENCE FROM A POPULATION IN SOUTHERN MOROCCO

Keywords: Osteoporosis, Descriptive studies, Bone diseases

H. Teba1, H. Arabi2, A. Mouguil1, I. El Bouchti1 1CENTRE HOSPITALO-UNIVERSITAIRE MOHAMED VI MARRAKECH, Rheumatology, Marrakech, Morocco

Background: Osteoporosis is a generalized skeletal disease characterized by low bone density and alterations in bone microarchitecture. Current definitions and recommendations focus more on postmenopausal osteoporosis with a low number of studies in young pre-menopausal women which makes it difficult to estimate the prevalence of osteoporosis in this population.

Objectives: To establish the prevalence and determine the etiologies of osteoporosis in young women and their management according to the experience of our department.

Methods: Retrospective descriptive and analytical study including 97 female patients aged less than 45 years, who performed a bone densitometry measurement between the years 2014 and 2022. Data were collected from the bone densitometry database. Osteoporosis was retained if a T score less than or equal to -2.5. Women older than 45 years and or followed for genetic osteopathy were excluded from this study.

Results: There were 97 patients with osteoporosis in this study. The average age was 25 years. Early menopause was found in 15% of cases (10% of cases after chemotherapy). Osteoporosis secondary to endocrinopathy was found in 17% of cases (5% diabetes, 10% primary hyperparathyroidism, 2% Cushing’s syndrome). It was secondary to a systemic disease or chronic inflammatory rheumatism in 45% of cases (29% rheumatoid arthritis, 12% spondyloarthropathy, 3% systemic lupus erythematosus and 1 % Horton’s disease). The other pathologies found were chronic renal failure in 3% of cases, a notion of prolonged use of corticosteroids in 21% and hormone therapy for breast neoplasia in 14%. 3% of the patients had at least one osteoporotic vertebral fracture. The mean bone mineral density (BMD) in both femurs was 0.727g/cm2. The mean BMD in the spine was 0.965g/cm2. 11% of these patients were treated with oral anti-osteoporotic drugs, 35% were supplemented with vitamin D and calcium.

Conclusion: The discovery of osteoporosis is rare in young women, hence the scarcity of studies in this category of women. It may be of metabolic or drug-induced origin or related to other chronic inflammatory diseases. It should be investigated in the presence of risk factors in order to limit the risk of bone fractures.

Operation characteristics (ROC) was examined to determine cut-off index (COI). Finally, statistically evident variants in the ROC study was examined to clarify the validity of the variant as a risk factor using Kaplan-Meier survival curve analysis again.

Results: A total of 239 patients were recruited. Mean age was 73.6 years and mean follow up period was 52.4 months. Mean T-score in the lumbar spine and femoral neck were -2.10 and -1.85. Using BFR, PS-VAS, estimated glomerular filtration ratio based on cystatin C (eGFR-CysC), prevalent BFF (p-BFF), and SDAI remission rate were significant correlation with incident BFF. In these, PS-VAS and p-BFF demonstrated significant higher risk ratios using a multivariate cox regression analysis. In the ROC, COI of PS-VAS was 24.6 and the area-under-the-curve was 0.669 (p < 0.001). Finally, PS-VAS ≥ 24.6 mm had 3.506 fold higher hazard ratio than PS-VAS < 24.6 mm using Kaplan-Meier survival curve analysis.

Conclusion: These results suggested pain control in treating RA is the important task in order to avoid incident BFF in postmenopausal female patients with RA.

AB1233 IMPACT OF RHEUMATOID ARTHRITIS ON THE DENSITOMETRIC STATUS OF WOMEN

Keywords: Rheumatoid arthritis, Osteoporosis

L. Rouached1, J. Soua1, S. Bouden1, A. Ben Tekaya1, I. Mahmoud1, R. Tekaya1, O. Saidane1, L. Abdelmoula1,1 Charles Nicols Hospital, Rheumatology Department, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatic disease. It can be associated with several comorbidities including osteoporosis (OP). The origin of this bone loss is multifactorial. A fracture episode is the complication of osteoporotic disease and constitutes all the gravity of this disease.

Objectives: The objective of this work was to evaluate bone densitometry (BMD) in women with RA and to identify its relationship with disease parameters.

Methods: This was a cross-sectional study, including patients followed for RA meeting the ACR/EULAR 2010 criteria. For each patient, disease parameters (duration of progression, activity score (DAS28 VS), functional impact (HAQ), corticosteroid intake) were assessed and BMD of the lumbar spine and femoral neck was performed in all patients.

Results: A total of 76 women were included, 66% of whom were postmenopausal. The mean age of the patients was 52.5±9.7 years and the mean duration of RA progression was 11.3±7.9 years. The mean DAS28 VS score was 4.3±1.4 and the mean HAQ was 0.98±0.8. Corticosteroid use was noted in 62 patients (81.5%) at a mean dose of 8.6±3.2mg/day. Regarding the densitometric profile of the patients, the mean BMD values at the vertebral and femoral sites were -1.4±1.3DS and 0.8±1.1DS respectively, and the prevalence of osteoporosis and osteopenia were 21.6% and 46.6% respectively. Patients with osteoporosis (OP) were older (p=0.00), and there was a significant relationship between OP and menopausal status (p=0.007). In contrast, disease parameters (function, activity, duration and treatment) were not associated with the occurrence of osteoporosis in our series: HAQ (p=0.6), disease duration (p=0.3), disease activity (p=0.3) or corticosteroid use (p=0.9).

Conclusion: OP is a frequent comorbidity associated with RA. It should be systematically detected because of its functional and vital complications. In our study, the occurrence of OP was more frequent at an older age during RA and menopausal status. There was no relation with the disease parameters.

AB1234 THE BODY COMPOSITION IMPACT ON OSTEODENSITOMETRY VALUES IN PERSONS OLDER THAN 65 YEARS

Keywords: Diet and nutrition, Osteoporosis, Diagnostic tests

R. Matijević1, M. Obradovic1, O. Dulic1, M. Vranjes1, A. Savic1, T. Icin3
1Medical Faculty in Novi Sad, Orthopedic and Trauma Clinic, Novi Sad, Serbia; 1Medical Faculty in Novi Sad, Rheumatology, Novi Sad, Serbia; 1Medical Faculty in Novi Sad, Endocrinology, Novi Sad, Serbia

Background: The aging process is a normal physiological phenomenon and has an impact on the body composition and physical fitness of the elderly. It is characterized by a progressive increase in total body fat mass, a decrease in muscle mass and changes in distribution in terms of an increase in abdominal fat tissue. These changes in the elderly have a great impact on health, functional capacity, and quality of life. The variability of body composition components contributes to the origin and progression of pathology and disability. Today osteodensitometric examination is considered one of the most versatile imaging techniques for assessing osteoporosis, sarcopenia, and obesity, and is currently the only technique capable of identifying all of these conditions at the same time. Osteoporosis is characterized by low bone mass and microarchitectural bone loss, leading to an increased risk of fracture caused by a minor trauma.

Objectives: To determine the presence of normal values of T score, osteoporosis and osteoarthritis, to determine the distribution of BMI and values of lean muscle mass, adipose tissue and visceral adipose tissue of the examined population.

Methods: In this retrospective study conducted from March to April 2019 at the University Clinical Center of Vojvodina, 699 respondents of both sexes over 65 participated. Exclusion criteria were established osteoporosis and treatment. The research consisted of collecting general information of the respondents (gender, age, smoking status, level of education, marital status). Body composition (BMI, FM, VAT, LM) was measured by osteodensitometric examination. Also, all subjects body weight, and height were measured and their body mass index (BMI) was determined.

Results: The average age of respondents was 71.92±5.14, most respondents 50.6% have secondary education, 52.2% are married, 9.5% are smokers. The classification of the total T score shows a normal finding in 26.8%, with osteoporosis 58.4% and with osteoporosis 14.8% of subjects. According to BMI with a normal finding is 16.5%, overweight is 38.5% and obese 45% of respondents. The average BMI of men is 28.79±4.01, and for women the average BMI is 29.92±4.91. The average value of BMI is 1.537±0.820, FM 31.105±9.152 and LM 43.735±8.279. Men have higher average VAT values (2.06±0.90) compared to women (1.32±0.67). The average FM is higher in women (32.49±8.88) than in men (2760±8.89). The average LM is higher in men (53.38±705) than in women (39.92±4.97). Subjects with normal findings were 61.5% obese, with osteoporosis 40.2%, and with osteoporosis 28% obese. The measured value of LM in persons with normal findings is 47.921±8.738, with osteoporosis 42.342±7.378, with osteoporosis 40.443±6.949. The measured value of FM in persons with normal findings is 34.37±9.51, with osteoporosis 34.220±8.75, and with osteoporosis 2760±7.14. The measured value of VAT in persons with normal findings is 34.37±9.51, with osteoporosis 34.37±9.51, with osteoporosis 2760±7.14. Conclusion: Higher values of BMI, LM, FM, and VAT have a positive effect on the hip and spine T score, and a protective role against osteoporosis.

AB1235 PREVALENCE OF OSTEOPOROSIS IN AN ALGERIAN POPULATION WITH OSTEOARTHRITIS: CROSS-SECTIONAL STUDY

Keywords: Osteoporosis, Osteoarthritis, Descriptive studies

B. Abdelatif1, A. Djebbari2, S. Oulebsir2, S. Bennedjema2, C. Makhloufi-Dahouz3, A. Ali Ayad4, 1HMUS, Rhumatology, Algiers, Algeria; 2HCA, Rheumatology, Algiers, Algeria; 3Hôpital Bab el oued, Rhumatology, Bab el oued, Algeria
**Background:** Osteoarthritis is a chronic degenerative rheumatism responsible for a structural modification of bone tissue which can alter its biomechanical qualities. Data are contradictory regarding the relationship between osteoarthritis (OA) and osteoporosis (OP) with some studies showing the increased risk of OP in OA especially in patients awaiting arthroplasty. Failure to consider bone loss in this osteoarthritic population can lead to serious complications such as fracture, which can considerably reduce the quality of life and expose this elderly population to excess mortality.

**Objectives:** This study aims to identify patients at risk of fracture in osteoarthritic Algerian population and evaluate postoperative bone loss complication in patients undergoing arthroplasty.

**Methods:** Descriptive, cross-sectional study in patients with knee osteoarthritis candidates for arthroplasty. All patients underwent a rheumatology exploration including clinical, radiological and biological evaluation with a measurement of bone mineral density (BMD) at spine and hip. The results are interpreted according to the WHO classification.

**Results:** Three hundred patients were recruited with a sex ratio=0.45, the mean age was 67.97 ± 6.78 years and the mean BMI was 30.81 ± 5.37 kg/m2. With regard to bone loss, osteoporosis was present in 26.7% (95% CI: 21.7%-32.1%), while osteopenia was found in 43.7% (CI 38.0%-49.5%). Factors associated with bone loss were: female sex (P<10^-7), urban habitat (P= 0.001) and age ≥ 60 years (P=0.003).

**Conclusion:** In this Algerian sample of severe osteoarthritis awaiting arthroplasty, osteoporosis and consequently the risk of fracture are prevalent. Identifying the population with bone loss in these patients could improve overall management and avoid postoperative fractures.

**OSTEOPOROSIS AND FRACTURES IN PATIENTS UNDERGOING CHRONIC CORTICOSTEROID THERAPY**

**Keywords:** Prognostic factors, Osteoporosis, Real-world evidence

**Background:** Glucocorticoids are widely used for the treatment of various rheumatic diseases and are one of the major risk factors for bone fragility associated fractures. However, beyond randomized clinical trials, there is little evidence in actual clinical practice.

**Objectives:** Our aim is to evaluate the appearance of osteoporosis and fractures in patients undergoing corticosteroid therapy.

**Methods:** We performed an observational retrospective descriptive study with Vasculitis (several subtypes) or Polymyalgia Rheumatica (PMR) patients diagnosed, who had received corticosteroid regimes with doses of at least 5 mg/day of prednisone (or equivalent) for a period of not less than 3 months, and in which the appearance of fractures was monitored for the next 2 years.

**Results:** We included 234 patients (62.4% females) with a mean age at the onset of corticosteroids of 75.8 years and mean duration corticosteroid regimes of 58 months. The most represented disease was PMR, with 183 patients (78.2%), followed by Large Vessel Vasculitis (12.4%), ANCA positive Small Vessel Vasculitis (4.3%), ANCA negative Small Vessel Vasculitis (3.4%), with a lower proportion of Medium Vessel vasculitis and other diseases such as Relapsing Polychondritis. Furthermore, 29 patients (12.39%) had previous fragility fractures, while 32 patients (13.68%) suffered one or more fractures after the start of corticosteroid therapy, being hip its most frequent location (4.7%), followed by vertebrae (3.8%). Likewise, the mean duration of corticosteroid treatment until the onset of new fractures was 4.5 months. Even without reaching statistical significance, we observed a greater age (80.5 years), a higher presence of the female gender (81.25%) and a previous fracture (18.75%) in patients with new fractures. In addition, 32.91% of patients had densitometric osteoporosis at the beginning of corticosteroid therapy.

We observed an association between fractures and zoleadronate treatment (P=0.012), and a tendency for ibandronate (P=0.07). The discreet entity of these differences could be explained by the statistical effect produced by the small number of new fractures, taking into account, moreover, the fact that in our Rheumatology Department we systematically carry out a fracture risk assessment to decide whether and when to start the treatment, and also prescribing more powerful therapeutic options to patients at higher risk of fracture. Finally, we did not observe significant differences in fracture-free time among the most frequent therapeutic options.

**Conclusion:** We observed a tendency to have a higher frequency of fractures in patients with previous fractures, older age and female gender. Less quantitative prevention of fractures was observed in patients with zoleadronate and ibandronate, with no clear differences in fracture-free time.

ASSOCIATION OF GUT MICROBIOTA WITH RISK OF GOUT

Keywords: Gout

Y. Zhang1,2, Y. Niu1,2, Z. Han1,2, Q. Yu3, P.F. He4, X. Li2, S. X. Zhang4,1 Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, Shanxi Province, China;1Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immunoregulation Microbiology, Taiyuan, Shanxi Province, China;1Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, Shanxi Province, China;4The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China

Background: Gout is a prevalent and painful inflammatory arthritis. Increasingly studies have shown that the gut microbiota is associated with gout [1-3]. However, whether these associations reflect a causal relationship is still being determined.

Objectives: To investigate whether there is a causal relationship between intestinal bacteria and gout, we used Mendelian randomization (MR) two-sample analysis.

Methods: Gout-related data were derived from the Integrated Epidemiology Unit (IEU) GWAS database, which included 2115 gout cases and 67259 controls [4]. The data on intestinal bacteria came from the website MIBbse. We searched 173 species of bacteria and finally identified 5 genus species, which were the Eubacterium brachy, Eubacterium hallii, Howardella, Sellimonas, and order Mollicutes RF9. MR-Egger, weighted median, inverse variance weighting (IVW), and MR-PRESSO were used to conduct the double-sample MR analysis. Finally, we excluded the data related to poly-effect and heterogeneity to ensure the robustness of the results.

Results: Five kinds of gut microbiota (Eubacterium brachy, Eubacterium hallii, Howardella, Sellimonas, and order Mollicutes RF9) had a causal relationship with gout. According to inverse variance weighted estimation, Eubacterium hallii(odds ratio/OR = 1.660, 95% confidence interval(CI): 1.073-2.569, P = 0.023), Howardella(OR = 1.391, 95% CI: 1.058-1.828, P = 0.018) and Sellimonas(OR = 1.384, 95% CI: 1.009-1.897, P = 0.044) were risk factors for gout. Eubacterium brachy(OR = 0.656, 95% CI: 0.469-0.917, P = 0.014) and order Mollicutes RF9(OR = 0.641, 95% CI: 0.471-0.874, P = 0.005) showed protective effect against gout (Figure 1).

Conclusion: This study suggested a causal relationship between these five gut microbiota and gout, providing new implications for future clinical trials on the association between microbiota and gout.

THE INVERTED J-SHAPED RELATIONSHIP BETWEEN SERUM URIC ACID LEVEL AND ABDOMINAL MUSCLE MASS AMONG KOREAN MALE POPULATION: A SINGLE-CENTER STUDY OF 5114 CASES

Keywords: Gout, Sarcopenia

D. H. Lim¹, S. J. Choi¹. ¹Ulisan University Hospital, University of Ulisan college of medicine, Division of Rheumatology, Department of Internal Medicine, Ulisan, Korea, Rep. of (South Korea)

Background: Sarcopenia is the decline of muscle mass and strength with age. Evidence suggests that oxidative stress and molecular inflammation play important roles in muscle atrophy by interfering with the balance between protein synthesis and breakdown. Uric acid (UA) may be related to sarcopenia through its role as either an antioxidant or pro-oxidant properties. Although the association of serum UA level with sarcopenia has been investigated in previous studies, the results are conflicting. The purpose of this study was to investigate the association of serum UA with abdominal muscle mass using abdominopelvic computed tomography (apCT) among Korean adult men.

Methods: We evaluated 5114 men aged above 20 years, who voluntarily underwent laboratory tests and apCT as a part of general health examination from May 2014 to June 2019. The participants were stratified into quartiles according to their serum UA levels. The low-attenuation abdominal muscle area (LAMA), normal-attenuation abdominal muscle area (NAMA) and total abdominal muscle area (TAMA) were measured using cross-sectional apCT data of the L3 lumbar vertebrae. Between-group comparisons were performed using Pearson’s chi-square test for categorical variables, and the ANOVA for numerical variables, as appropriate. The trends between serum UA quartiles and each AMA were analyzed by univariate (ANOVA) and multivariate analysis (ANCOVA).

Results: The mean age of individuals was 52.5 ± 9.37 years and the mean body mass index (BMI) was 24.8 ± 2.92kg/m². In univariate analysis LAMA, NAMA and TAMA were increased continuously across quartiles of serum UA. However, serum UA levels (quartiles) showed an inverted J-shaped curve with NAMA and TAMA, after adjustment for confounding factors including age, BMI, smoking status, hypertension, diabetes, dyslipidemia, glomerular filtration rate, and c-reactive protein (Table 1).

Conclusion: The results suggest that a specific range of serum UA levels may be associated with better abdominal muscle mass in Korean adult men.

PERCEPTIONS OF GOUT AND ITS MANAGEMENT PATTERNS: FINDINGS FROM SURVEY AND STRUCTURED INTERVIEWS WITH PRIMARY CARE PHYSICIANS AND RHEUMATOLOGISTS

Keywords: Quality of care, Gout

H. Zimmerman², M. Bhagwat³, R. Laranger², L. Padnick-Silver², B. Lamoreaux².
²Rush University College of Medicine, Department of Internal Medicine, Chicago, United States of America; ³PreScouter Inc., Technical Department, Chicago, United States of America; ²Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America

Background: Despite the high prevalence of gout worldwide,[1] there is widespread undertreatment of this painful, debilitating inflammatory arthritis.[2,3] Gout patients who maintain serum urate (SU) < 6mg/dl have fewer flares, less joint involvement, and overall better quality of life.[3] However, gout management guidelines differ substantially between the American College of Physicians (ACP)[4] and the American College of Rheumatology (ACR).[5] Most notably with ACP recommending oral urate-lowering therapy (ULT; allopurinol, febuxostat, probenecid) used only in patients with frequent gout flares with no clear SU-target and ACR recommending oral urate-lowering therapy use in all gout patients with tophi, flares, or gout-related bone damage with a treat-to-target approach to an SU < 6mg/dl. Because primary care physicians (PCPs) are often a first point-of-contact for patients suffering from gout, understanding their perceptions and management strategies of gout is of importance.

Objectives: To better understand how PCPs perceive and manage gout.

Methods: An online survey was administered to PCPs regarding perceptions of gout patients, gout severity grading, gout treatment strategies, and gout patient referral patterns. A 5-point Likert scale was used to gauge perceptions and patterns. Additionally, structured 30-60 minute interviews of similar focus were conducted with PCPs and rheumatologists (all interviews conducted by a single interviewer [RL]). Online survey and interviews provided further insight into PCPs perceptions of gout and allowed similarities and differences between physician types to be examined. A 10-point Likert scale was used to quantify select interview responses.

Results: A total of 56 PCPs completed the online survey, with most practicing in a metropolitan area (84%) and seeing >50 patients/week (66%). 98% of participating PCPs reported seeing <10 known gout cases/week, with 82% having high or very high confidence in their ability to manage gout. Anti-inflammatory treatments (89%), oral ULTs (88%), diet (70%), and biologic therapies (59%) were viewed as most being highly effective or very highly effective. Further, 63% of PCPs viewed gout patients as always or almost always compliant with medication and 66% of PCPs reported that gout patients never or almost never ask for referral to a gout specialist. However, when PCPs did make a referral, it was most often for severe gout. The low referral rate coincided with the observation that the majority of PCPs (79%) reported most-commonly seeing gout of “medium” severity. Further insight was gained from 5 PCP and 5 rheumatologist interviews conducted. PCPs and rheumatologists viewed gout patient compliance differently, with PCPs perceiving a higher rate of compliance (7.3 vs. 5.7). Both PCPs and specialists expressed that gout flare data collection and gout severity determinant tools would be useful for patient management, including therapy efficacy evaluation.

Conclusion: These findings suggest that, despite widespread undertreatment of gout outside of specialty care,[2] PCPs reported high comfort in managing gout, high compliance of gout patients, and little need for specialty referral except when gout is severe and refractory. Both PCPs and rheumatologists expressed that tools for determining gout severity and tracking gout flares would be helpful. We suggest that such tools could serve as guides for PCPs when monitoring for success of therapy and when to make a rheumatology referral.

FACTORS ASSOCIATED TO LOSS FOR FOLLOW-UP IN A PROSPECTIVE GOUT COHORT

Keywords: Gout, Crystal arthritis

P. Perez-Ruz¹, C. Vazquez-Puente¹, M. D. C. Modesto-Caballero¹, A. M. Herreno-Beltes¹, Osakidetza, OSE-Elcanes, Cruces University Hospital, Rheumatology Division, Baracaldo, Spain; ²Gorizkloe Ertehea, Rehabilitation Division, Goritz, Spain

DOI: 10.1136/annrheumdis-2023-eular.2200
Background: Adherence to treatment has been widely studied, but not adherence to follow-up visits.

Objectives: To analyze factors associated to loss for follow-up in patients with gout and with a programmed follow-up visit to the rheumatology office.

Methods: Analysis of data from an inception cohort of patients with gout prospectively followed-up in a university hospital setting. Variables include general data, along with clinical characteristics of gout, comorbidities, treatment and adherence to prescribed urate-lowering therapy (ULT). Those variables associated (p<0.20) in bivariate analysis were included in a multivariate analysis. Patients who did not attend to a visit because they passed were not considered as lost for follow-up.

Results: From a series of 1,442 consecutive patients, 354 (24.5%) were lost for follow-up; 219 (15.2%) did not attended because they died between programmed visits. Mean follow-up until lost for follow-up was 32 months vs. 49 months for patients who still remained in active follow-up. Age (older), gender (women), pooled comorbidity (higher), severity of gout (monarticular), alcohol intake (<15 g/day), adherence (MPR> 80%), previous treatment (none), and consultation (primary care), were associated to higher rates of loss for follow-up in bivariate analysis. No association was found between persistence on follow-up and time from onset of gout, presence of tophi, number of flares per year, previous and prescribed ULT.

In multivariate analysis (Table 1), only higher age, higher adherence to prescribed, and consultation from primary care were independently associated to persistence on follow-up. Severity of gout (polarticular disease) seemed to be also associated to persistence, but lacked statistical significance.

Conclusion: In our clinical setting, the profile of patients at higher risk of abandoning prescribed follow-up is that of a younger, poorly adherent, with lower burden of disease and consulting through a assistance “short-cut”.

Table 1. Percentage of VTE hospitalizations in Gout versus General population

Conclusion: One out of 10 hospitalizations in persons with gout have a concomitant diagnosis of VTE, significantly higher than the VTE rate in the general population. This calls for increased awareness and steps to prevent the development of VTE in patients with gout.

Background: Cumulative data indicates that 20-30% of subjects with asymptomatic hyperuricemia (AH) have silent monosodium urate (MSU) crystal deposits[1]. For its evaluation, several sonographic examination schemes have been used[2], and the scanning of the 1st metatarsophalangeal (MTP) joint and femoral condyle for double contour (DC) sign, plus 1st MTP for tophi, shows the highest prevalence and discrimination compared to subjects with normouricemia. However, how we should sonographically classify AH with crystal deposits remains to be defined.

Objectives: To compare the variations in prevalence of sonographic deposits in AH across different classification schemes.

Methods: Observational, cross-sectional study. Patients with AH were consecutively recruited from clinics and wards of internal medicine, cardiology, nephrology, endocrinology, rheumatology and primary care units in an academic center. Subjects with a recent serum urate level ≥7mg/dL were included, excluding those under urate-lowering therapy and/or colchicine or with gout or other inflammatory rheumatic disease. Ultrasound was performed by an expert rheumatologist sonographer, blinded to clinical and laboratory data, following 2021 OMERACT definitions for elementary gout lesions (DC sign, tophi, aggregates) and 0-3 grading[3]. The locations scanned bilaterally were knees with patellar tendons, ankles with Achilles’ tendons, and 1st and 2nd MTP joints. We applied different definitions for AH with deposits, varying in relation to deposits (any deposits; only DC sign and/or tophi; only grade 2-3 deposits; only grade 1 lesions). Comparisons were performed by Chi2 test.

Results: Seventy-seven participants with AH were studied, 55 males (71.4%) and a mean age of 59.8 years (SD 17.3). Mean body mass index was 31.2 kg/m2 (SD 5.2), and 37.66% and 29.9% suffered from cardio-vascular and chronic kidney disease, respectively. Mean uricemia was 7.6 mg/dL (SD 1.6) with a fractional excretion of uric acid of 5.6% (DS 2.2). Regarding the elementary lesions, the median (p25-75) number of locations with DC sign, tophi or aggregates was 0 (0-1), 1 (0-2) and 1 (1-2), respectively. For grade 2-3 lesions, numbers were 0 (0-0), 1 (0-1) and 1 (0-2), respectively. As shown in Figure 1, the proportions of sonographic deposits largely varied according to the different classifications considered to define AH with deposits, ranging from 23.38% up to 87.01%, in a significant manner (p<0.050).

Figure 1. Rate of sonographic deposits in AH across different definitions.

Conclusion: In a multidisciplinary sample of AH, the rates of sonographic deposits dramatically varied across the different classifications used, highlighting the need for an agreed and validated definition that facilitates further research in this setting.

CHANGES IN THE GUT MICROBIOTA OF GOUT PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Gout

X. Y. Yin1,2, G. X. Wang1,2, X. Song1,2, D. Qiao1,2, Q. Y. Su1,2,3, Q. Yu1, P. F. He1, L.1,2,3, S. X. Zhang1,2,3
1Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 2Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 3The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 4Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

Background: Gout is a crystal-related joint disease caused by the deposition of monosodium urate crystals in or around the joints[1][2]. Structural changes or imbalances in the gut microbiota could cause metabolic disorders and participate in the synthesis of purine-metabolizing enzymes and the release of inflammatory cytokines, which is closely related to the occurrence and development of metabolic, immune disease and gout.

Objectives: This study aimed to explore the disorders of intestinal microflora alpha diversity and microbial community composition in patients with gout through meta-analysis.

Methods: According to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), we comprehensively searched the databases of PubMed, Web of Science, Embase, Cochrane Library, CNKI, VIP, CBM, and Wanfang database without language restrictions. We obtained data related to the alpha diversity index(Shannon index, Simpson index, ACE, Chao1, Observed species) and analyzed phylum and genus composition.

Results: Nine studies, including 423 gout patients and 458 healthy controls(HCs), were included in our analysis. The Simpson index of gout was significantly lower than that of HCs(SMD=-1.037, 95%CI:-1.959~0.115). There was no significant difference in other alpha diversity indexes between the two groups(Shannon index: SMD=0.429, 95%CI:0.900~0.041; ACE: SMD=0.102, 95%CI:0.918~1.122; Chao1: SMD=0.863, 95%CI:0.267~1.993; Observed species: SMD=-1.962, 95%CI:-5.011~1.088). We collected the relative abundance of 30 genera of gout and classified them according to the species affiliation. The results showed that the relative abundance of microflora in proteobacteria was significantly lower than that of HCs(SMD=-0.498, 95%CI:0.911~0.086). However, the relative abundance of microflora in Fusobacteria(SMD=0.589, 95%CI:0.249~0.929), Actinobacteria(SMD=0.546, 95%CI:0.207~0.885), and Bacteroides(SMD=0.395, 95%CI:0.035~0.756) increased in gout patients. We did not observe significant changes in the gut microbes of Firmicutes(SMD=0.210, 95%CI:-0.456~0.036).

Conclusion: This systematic evaluation and meta-analysis showed that the impact of gut microbiota was mainly observed at the level of phylum and genus, but limited to microbial diversity. It is necessary to further study the role and function of specific bacteria and their influence on the physiology and pathology of gout.

Osteomalacia Related to Bariatric Surgery: How Frequent is It?

Keywords: Vitamin D, Bone diseases, Descriptive studies

C. A. Chacur1, A. Moorchicaia1, H. Florez1, N. Guanaıbens1, A. Monegal1, P. Peris1.1 Hospital Clinic, Rheumatology, Barcelona, Spain

Background: The development of osteoporosis and fractures is a well-documented complication of bariatric surgery (BS), especially with procedures associated with malabsorption. Due to the gradual increase of BS performed worldwide, several national and international societies have developed clinical guidelines for managing these patients, with special attention to osteoporosis prevention and treatment. Nevertheless, these subjects can also develop osteomalacia, which can easily be misdiagnosed as osteoporosis. It is crucial to differentiate osteoporosis and osteomalacia in BS patients since different therapeutic approaches are necessary.

Objectives: To analyse the prevalence of osteomalacia and the main clinical characteristics of subjects with previous BS referred to the Rheumatology Department for osteoporosis treatment.

Methods: This was a retrospective study of a cohort of 46 subjects (aged 42-77 years) referred to the Metabolic Bone Diseases Unit of the Rheumatology Department for evaluating osteoporosis treatment. Clinical data were obtained from an in-depth review of medical records, including the type of BS (restrictive: gastric banding, and sleeve gastrectomy, or malabsorptive surgery: Roux-en-Y gastric bypass [RYGB], bilipancreatic diversion with duodenal switch), time since surgery, previous treatment with calcium and/or vitamin D, anthropometric data, clinical, laboratory, radiologic and densitometric findings. Osteomalacia was diagnosed by compatible bone biopsy and/or by Bingham and Fitzpatrick criteria[1] (two of the following: low calcium, low phosphate, elevated total alkaline phosphatase [TAP] or suggestive radiology).

Results: Five of the 46 patients (10.8%) presented criteria compatible with osteomalacia, two being confirmed by bone biopsy. All subjects with osteomalacia were Caucasian and most were women (4/5) treated with malabsorptive surgery (mainly RYGB) from 4 to 23 years prior to the visit. All presented increased serum TAP values (some presenting a progressive increase 1-3 years prior to the visit). Most subjects showed low serum calcium (4/5) and vitamin D serum levels/pseudofractures after BS. Bone scan showed a pattern compatible with osteomalacia in all evaluated subjects (4/4) and bone densitometry showed values compatible with densitometric osteoporosis in most (4/5), with four individuals developing fractures/pseudofractures after BS. Three of these subjects were poorly adherent to calcium and vitamin D supplements and in 2 cases higher doses of calcium (3 g/day) and/or parenteral vitamin D administration were necessary to achieve serum vitamin D levels >30 ng/ml and decrease serum PTH levels in the postoperative follow-up. Of note, no subject was referred to the Rheumatology Department with clinical suspicion of osteomalacia. Among the remaining 41 subjects, 28 (68%) presented densitometric osteoporosis and 18 (45%) developed fractures (mainly vertebral) after BS; one subject developed primary hyperparathyroidism (treated with surgery). Again, malabsorptive surgery was the most frequent surgical procedure in these subjects.

Conclusion: Nearly 10% of subjects with previous BS referred for osteoporosis treatment may have osteomalacia. Increased serum TAP values should alert clinicians to this diagnosis since it requires a differential treatment approach with some of these patients needing high doses of calcium or even parenteral vitamin D supplementation.

Menchaca, Reumatología, Guadalajara, Jalisco, Mexico; 11 ISTECH [Hospital de Especialidades Vida Mejor], Rheumatology, Tuxtla Gutiérrez, Mexico; 9 General Hospital of Mexico Dr. Eduardo Liceaga, Rheumatology, Ciudad de Mexico, Mexico; 9 Clínica “San Agustin” Rheumatology, Loja, Ecuador; 8 VA Medical Center-Birmingham: Hurst Elton MD, Rheumatology, Birmingham, United States of America; 8 Hospital San Felipe, Rheumatology, Tegucigalpa, Honduras

Background: Previous reports suspected that gout patients from Latin-America (LAT) are different to those from developed countries and similar to Asian.

Objectives: We aimed to characterize patients with gout attending to Rheumatologists at Health public institutions and private practices in LAT and its association with socioeconomic status and clinical severity.

Methods: This cross-over, multi-centric, multinational and descriptive study was performed between 2019 and 2022. We invited to participate ≈150 certified rheumatologists from 14 countries in LAT. The project was authorized by IRB. Gout (ACR-EULAR 2015) patients signed informed consent. During face to face and on-line interviews, we discussed clinical variables (>200), questionnaires and CRFs in Spanish and Portuguese. Demographics, socioeconomic status: (AMAI <111 = low socioeconomic status), clinical gout, associated diseases and treatment related variables were included. We defined severe gout (SG) if ≥5 tophi per lesion.
and/or intradermal tophi. Metabolic syndrome (MS: > 3, ATP3 definitions and criteria); HAQ score, VAS for pain and general health and EuroQoL: EQ5D were obtained during regular visit to Rheumatologist. Data was sent and analyzed at GRESGO (Gout study group) coordination centre. Statistical analysis included mean SD, median, IQR, t test, χ2, ANOVA.

**Results:** Fifty two rheumatologists from 11 countries in LAT sent the data of 500 gout patients. Males (95%), mean (SD): age 57(14), age at onset 41(13), educational level 10(4) and duration of the disease 14 (12) years. The clinical spectrum of gout was evaluated first in 3 groups: 1) SG (SG+MS+, n=78, 16%); 2) MS (MS+SG+, n=218, 44%) and 3) others (gout: SG- and metabolic data ≤ 2 ATP criteria, n=204, 41%). Second analysis included comparison of extreme groups (SG VS MS) (Table 1).

**Conclusion:** LAT SG patients were different compared to MS gout and others. SG are younger males from low educational and socioeconomic status, familial history of gout. As a consequence, SG patients also had aggressive and active poor controlled disease: >flares, tophi number and size, more hospitalizations and lower quality of life; >HAQ scores and more frequent alterations in the 5 EQOS domains; (mobility, self-care, daily activities, pain, anxiety and depression) and disability consequences as work impairment. In the other hand, MS group had clearly more data associated to metabolic syndrome and higher cardiovascular risks.

Gout in LAT: VS MS comparison of demographics and clinical characteristics.

**RATIONALE AND DESIGN FOR PODAGRA II: A MULTICENTER RANDOMIZED PHASE 2/3 STUDY ASSESSING THE EFFICACY AND SAFETY OF DAPANSUTRILE, AN ORALLY ADMINISTERED SPECIFIC INHIBITOR OF THE NLRP3 INFLAMMOSOME IN SUBJECTS WITH AN ACUTE GOUT FLARE**

**Keywords:** Gout, Randomized control trial, Targeted synthetic drugs

**DOI:** 10.1136/annrheumdis-2023-eular.650

**Results:** The trial has launched and is currently enrolling subjects.

**Conclusion:** There is a need for an orally administered, safe, and well-tolerated treatment for acute gout flares. PODAGRA II will be the first placebo-controlled, adequately powered, large, multi-center study with an oral NLRP3-specific inhibitor. As gout is a prototypical disease of NLRP3 activation, this trial will provide important new data on NLRP3 inhibition leading to a reduction in joint pain and associated inflammatory biomarkers in acute gout flare.

LESSONS TO BE LEARNED FROM REAL LIFE DATA FROM 98 GOUT PATIENTS USING A URICOSURIC: BENZBROMARONE

Keywords: Crystal arthrits, Treat to target

I. Hotea1, M. Janssen2, T. Jansen2, 1University of Medicine and Pharmacy Iuliu Hațieganu, Rheumatology, Cluj-Napoca, Romania; 2VieCuri Medical Centre, Rheumatology, Venlo, Netherlands

Background: Decreased renal urate excretion is the predominant driver of attracting gout, an auto-inflammatory disease secondary to hyperuricemia. Therefore, there is an interest in effective urate lowering therapies with a uricosuric mode of action.

Objectives: The objective of this study was to analyses the efficacy and safety of uricosuric treatment i.e., benzbromarone in a real-life clinical setting.

Methods: data from gout patients was collected retrospectively from the digital hospital dossiers. Inclusion criterium was a diagnosis of gout (ICD10 code M10). Demographics, clinical variables and laboratory parameters at baseline and 6 months were collected. Efficacy was measured from reaching a serum urate target at 6 months, and/or increase in Fractional Urate Excretion (FeUA).

Results: We analyzed data from 98 gout patients with an indication of benzbromarone treatment. Patients were 70 (±12) years of age, and 90% was male. After 6 months of treatment 90 out of 98 patients (91%) reached a sUA level <0.36 mmol/L (6mg/dL). We found that efficacy appeared to be best in low excretor type gout defined as FeUA<4.5%, as their FeUA increased from the initial mean value FeUA 3.2% (SD±1.0%) to reach in 6 months with benzbromarone mean FeUA of 12.1% (SD±6.9%). A considerable percentage (38%) is using benzbromarone on average for 3.8 (SD±3.4) years. 4 patients stopped benzbromarone treatment due to decrease renal function, condition that was already present prior to uricosuric initiation.

Conclusion: Using available benzbromarone in a real-life context proved to be effective in lowering sUA levels in 6 months. Renal function must be considered before indicating benzbromarone. Determining FeUA in gout patients can further help better characterize the patient profile from whom is this the best treatment option.

ASSOCIATION OF SERUM URIC ACID LEVEL WITH HAND OSTEARTHRITIS

Keywords: Osteoarthritis, Crystal arthrits, Gout

B. Bengana1, 2, S. Abdellauzi2, A. Boukabou2, H. Guerbouka2, S. Lefki2, 1University Hospital of Beni-Mellal, Rheumatology; Beni-Mellal, Algeria; 2University Hospital of Beni-Mellal, Rheumatology; Beni-Mellal, Algeria

Background: Asymptomatic hyperuricemia is often considered as a biological anomaly, when the appearance of the gouty disease rather represents the evolution towards an inflammatory disease. In this case, the inflammation is usually due to a response to crystal deposits in the tissues, associated with cartilage damage, as seen in osteoarthritis. Although we know that an abnormal urate can lead to osteoarthritis, we still don’t know if there is a link between hyperuricemia and osteoarthritis.

Objectives: The aim of this study is to assess the link between asymptomatic hyperuricemia (AH) and hand osteoarthritis (HO).

Methods: It’s a cross-sectional study included 46 patients (28 in the HO group and 18 in a group without HO) with mean age of 67.23 ± 4.67 years, 32 women for 14 men. We collected demographic, clinical, biological (uricemia) and radiographic data. The association between AH and digital osteoarthritis was assessed by logistic regression.

Results: The mean serum uric acid level in patients with osteoarthritis was higher than that of patients without osteoarthritis (6.71 ± 1.13 mg/dl versus 6.26 ± 1.26 mg/dl, p=0.021). Hyperuricemia was more common in older patients with osteoarthritis than in those without osteoarthritis (45% vs. 23%, p=0.001). After adjusting for age, gender, body mass index and other variables, the association between asymptomatic hyperuricemia and osteoarthritis remained significant with an odds ratio [OR] of 2.28, for a 95% confidence interval [CI] (1.18-4.80), p=0.023. Subgroup analyzes were performed by sex where significant associations between asymptomatic hyperuricemia and osteoarthritis were obtained in women (p=0.027).

Conclusion: AH is a common comorbidty in elderly patients with hand osteoarthritis. A significant link has been found between AH and hand osteoarthritis in elderly subjects, especially females.

OUTPATIENT FOLLOW-UP AFTER AN EMERGENCY DEPARTMENT VISIT FOR ACUTE GOUT FLARE

Keywords: Health services research, Gout, Crystal arthrits

L. Jackson, 1 F. Mugeta1, E. Mcneely1, N. C. Techarkung1, K. Aaron1, J. Booth1, J. Foster1, G. Cutter1, J. Osborne1, K. Saag1, M. Danila1, 1University of Alabama at Birmingham, Medicine, Birmingham, United States of America; 2University of Alabama at Birmingham, Emergency Medicine, Birmingham, United States of America; 3University of Alabama at Birmingham, Biostatistics, School of Public Health, Birmingham, United States of America; 4University of Alabama at Birmingham, Computer Science, Birmingham, United States of America; 5Birmingham VA Health Care System, Geriatric Research, Education, and Clinical Center, Birmingham, United States of America

Background: Patients with acute gout are frequently treated in the emergency department (ED). Appropriate outpatient follow-up for an acute flare after an ED visit is variable and has not been systematically examined.

Objectives: We aimed to determine the characteristics of patients with gout treated in EDs, the nature of their ED visits, and to determine the types and rates of outpatient follow-up after an ED visit for an acute gout flare.

Methods: This study was conducted at one academic medical center that serves patients at 3 EDs (2 urban, 1 suburban) and 1 urban urgent care center. Patients were identified as having a possible acute gout flare upon initial triage in the ED using a previously developed electronic medical record (EMR) gout flare alert. We validated the presence/absence of an acute gout flare through manual EMR review using adjudicated expert consensus assessed with kappa coefficient as the gold standard. Among those patients identified as having an acute gout flare, we abstracted their medical records to determine the presence/absence of an outpatient visit for gout care within 6 months of the index ED visit. This was defined as having had a documented outpatient visit with any provider (e.g., primary care, rheumatology) with a mention of ‘gout’ in the free text portion of history of present illness or assessment and plan. We used descriptive statistics to characterize patients with gout and reported the proportion of patients with an acute gout flare that followed up in the outpatient setting after an ED visit.

Results: From September 1, 2021 to February 28, 2022, there were 458 patients identified by the gout flare alert as possibly having an acute gout flare. Of these, 33 patients were excluded from this analysis due to participation in an ongoing randomized clinical trial testing a behavioral intervention to improve gout care. The remaining 425 patients included 72 patients (16.9%) who were determined to have a true gout flare at 85 unique ED visits by manual EMR review by 2 assessors. The kappa coefficient for agreement between the consensus expert determinations of acute gout flare was 0.8. Of those with an acute gout flare, 53 (74%) were men and 49 (68%) were Black or African American. At ED discharge, a majority of patients (64%) were prescribed corticosteroids, while 63% were prescribed opioids. A majority (54%) of ED visits for acute gout occurred between 8am and 5pm, with another 27% occurring between 5pm and midnight. The proportion of patients with an acute gout flare who followed up with an outpatient clinician in our healthcare system was 46% (Table 1), with 29% of patients having an outpatient visit within 30 days of the index ED encounter. Only 26 patients (36%) had an outpatient visit addressing gout, and of these, 17 (24%) occurred within 3 months of the index ED visit.

Conclusion: More than half of patients received opioids at discharge among patients with gout treated in the ED, who were mostly Black. Follow-up was ~46% among patients that received gout care in an acute setting, yet only a third saw a clinician who addressed gout. This data will inform sample size calculation for interventional studies testing behavioral interventions focused on promoting improved outpatient follow-up for gout flares.

SERUM URIC ACID LEVEL IN INTRACEREBRAL HEMORRHAGE PATIENTS

Keywords: Crystal arthritis, Gout, Cardiovascular disease

D. H. Lim1, 2University of Ulsan College of Medicine, Division of Rheumatology, Department of Internal Medicine, Ulsan, Korea, Rep. of (South Korea)

Background: Intracerebral hemorrhage (ICH) is a life-threatening type of stroke caused by a rupture of a blood vessel into the brain's parenchyma, accounting for 10–15% of all stroke. Uric acid (UA) is the end product of purine metabolism; it is catalyzed by xanthine oxidase. UA may be related to cerebrovascular diseases through its role as either an antioxidant or pro-oxidant properties. Although the association of serum UA level with ICH has been investigated in previous studies, the results are controversial.

Objectives: In this study, we determined serum UA levels in patients with ICH and assessed its relationship with cerebrovascular risk factors.

Methods: We evaluated 721 patients with ICH who were admitted to one emergent department in tertiary hospital from July 2008 to December 2017 in South Korea. Demographics, laboratory data, neurological course, and brain magnetic resonance imaging (MRI) findings were collected using electronic medical records and picture archiving and communication systems. The participants were stratified into quartiles according to their serum UA levels. Between-group comparisons were performed using Pearson’s chi-square test for categorical variables, and the ANOVA for numerical variables, as appropriate.

Results: Among 721 patients with ICH acute stroke, 413 (57.3%) were male. The mean age of patients was 58.9±14.03 and mean value of body mass index was 23.9±6.84kg/m². Mean serum UA levels in the patients studied 5.94±1.70mg/dl and there was a significant negative correlation between age of patients and their serum UA level (p < 0.001, R = -0.212). Serum UA level was significantly higher in men (5.82±1.74 mg/dl) and significantly lower in women (5.99±1.67 mg/dl, p < 0.001). There were no significant differences in UA level among various ICH grades. There was a significant negative correlation between age of patients and their serum UA level (p < 0.001, R = -0.212). Serum UA level was significantly higher in men (5.82±1.74 mg/dl) and significantly lower in women (5.99±1.67 mg/dl, p < 0.001).

Conclusion: The results suggested that serum UA may be the predictor of intra-cerebral hemorrhage in ICH patients.

AB1253
FEBUXOSTAT DOSE ADJUSTMENT ACCORDING TO RENAL FUNCTION TO ATTAIN TARGET SERUM URATE LEVEL: A RETROSPECTIVE COHORT STUDY

Keywords: Gout

Y. E. Kim1, S. M. Ahn1, J. S. Oh1, Y. G. Kim1, C. K. Lee1, B. Yoo2, S. Hong3.
1University of Ulsan College of Medicine, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: Current guideline for gout recommends the use of allopurinol or febuxostat in moderate-to-severe chronic kidney disease (CKD). However, the appropriate febuxostat dosage required to attain the target serum urate (SU) level remains unclear, especially in patients with renal impairment.

Objectives: We aim to investigate the different febuxostat dosages stratified by renal function to achieve the target SU level.

Methods: We collected the clinical and laboratory information of patients using the Clinical Research Data Warehouse system of Asan Medical Center, Seoul, South Korea. Of the 3153 patients with gout and a prescription for febuxostat at a tertiary-care referral center, 791 with initial SU levels >6mg/dL were collected and categorized, according to their eGFR levels at febuxostat initiation, into three groups based on CKD stage: 1, 2–3, and 4–5. We defined the cumulative febuxostat as the total dose of febuxostat used from the initiation of febuxostat to the moment patient reached the SU target (SU<6 mg/dL).

Results: This cohort of 731 gout patients, with a median age of 52 (IQR, 41-65) years, included 643 (8.8%) women. Compared with the other groups, in the CKD 4–5 group, the mean SU value at febuxostat initiation was significantly higher (9.6 [SD, 3.1] mg/dL; CKD 2–3, 8.6 [SD, 1.6] mg/dL; CKD 1, 8.8 [SD, 1.8] mg/dL; p<0.001) and significantly fewer patients achieved the target SU during the follow-up period, median 31 (IQR, 13-55) months. In the subgroup analysis of patients who achieved target SU levels, the cumulative dose of febuxostat was significantly lower in CKD 4–5 patients compared to those with other groups (CKD 2–3, 12.5 (IQR, 2.3–13.5) g; CKD 4–5, 10.7 (IQR, 7.0–16.0) g; p=0.010 for CKD 4–5 and CKD 1, p=0.006 for CKD 4–5 and CKD 2–3). The average febuxostat dose used during 4 months to reach the SU target was 50.0 (IQR, 21.0–101.0) mg in the CKD 4-5 group, which was significantly lower than in other groups (CKD 2–3, 59.3 (IQR, 29.4–130.7) mg; CKD 1, 58.5 (IQR, 21.7–167.8) mg; p=0.006 for CKD 4–5 and CKD 1, p=0.003 for CKD 4–5 and CKD 2–3). In addition, when we examined the clinical factors associated with the required dose of febuxostat to achieve SU target, CKD 4-5 group showed a significant negative correlation with cumulative febuxostat dosage to reach target SU compared with CKD 1 (rho -2.334, p=0.02).

*Equal contributors in alphabetical order.

Typically, pregnancy and lactation greatly expose women to develop osteoporosis due to the high demand of calcium from the fetus or neonate. In some cases, women in the first pregnancies or in the early breastfeeding period, women with persistent lower back pain, are suspected to be at risk for fragility fractures, mostly involving vertebral fractures[1]. Therefore, there is an urgent need to perform an accurate monitoring of the maternal bone health status in order to prevent complications of pregnancy and lactation-associated osteoporosis.

Objectives: Through a longitudinal study, the present work aims to determine the changes of bone status in pregnant women from the first to the third trimester of gestation by means of the non-iorizing Radiofrequency Echographic Multi Spectrometry (REMS) technology.

Methods: A cohort of 43 pregnant women were enrolled in the study. Longitudinal measurement of bone mineral density (BMD) was carried out at the femur during the first (baseline) and third (follow-up) trimesters of pregnancy using the REMS technology. A paired t-test was performed to assess the difference in femoral neck BMD between baseline and follow-up.

Results: Compared to the baseline (first trimester), a significant femoral neck BMD reduction was observed at the follow-up of the third trimester, (0.762 ± 0.075 gm/cm² versus 0.711 ± 0.074 gm/cm², respectively with p<0.0001). As a result, an overall BMD decrease of 2.07% has been measured.

Conclusion: As previously demonstrated with this technology, pregnant women have a significant decline of BMD compared with the non-pregnant counterpart[2]. With this study, for the first time, bone changes throughout pregnancy could be determined by means of this technology: a marked bone reduction was demonstrated in the pregnant group during the last trimester of pregnancy. In conclusion, REMS represents an appropriate method for BMD assessment which can be safely employed to monitor the bone status across gestation and lactation.

ECTOPIC ARTICULAR CALCIFICATIONS AND ARTERIAL OCCLUSIVE DISEASE DUE TO 5'-NUCLEOTIDASE DEFICIENCY

Keywords: Inflammatory arthritides, Rare/orphan diseases, Crystal arthritis

M. Matti1,2, G. De Mattia2, M. Mosca2, M. Mazzantini2. University of Pisa, Rheumatology, Pisa, Italy; 1University of Pisa, Rheumatology, Pisa, Italy

Background: Calcification of Joints and Arteries (CALJA) is a rare disease presenting with recurrent/chronic arthritis and claudicatio intermittens of the lower limbs. Since the discovery of specific mutations of the 5'-nucleotidase (NT5E) gene responsible for the disease, only few cases have been reported.

Objectives: To collect available information about CALJA to better characterize the disease and to raise awareness of this often unrecognized rheumatologic condition.

Methods: All available publications regarding CALJA since its first description in 2011 were included and a case report is described.

Results: A 65-year-old woman, affected by seronegative oligoarthritis since 2007, reported lower limb claudication. In 2021 past medical history consisted of migratory, non-erosive arthritis with asymmetrical involvement of peripheral joints since the age of 30, poorly responsive to glucocorticoids and immunosuppressive therapy.

PEGLOTICASE + METHOTREXATE THERAPY IN UNCONTROLLED GOUT PATIENTS WITH PRIOR PEGLOTICASE MONOTHERAPY FAILURE: FINDINGS OF THE ADVANCE OPEN-LABEL TRIAL

Keywords: Gout, Clinical trials

O. Troum1,2, J. Botson3, K. Obermeyer4, S. Verma4, B. Lamoreanu4. University of Southern California Keck School of Medicine, Division of Rheumatology, Santa Monica, United States of America; 2Orthopedic Physicians Alaska, Anchorage, United States of America; 3Horizon Therapeutics plc, Research and Development, Deerfield, United States of America; 4Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America

Background: Pegloticase is often the last treatment option for patients (pts) with uncontrolled/refractory gout but anti-drug antibodies (ADAs) cause loss of serum urate [SU] lowering response and infusion reactions (Rfs) [1]. MIRROR RCT showed higher response rate (71% vs 39% during month 6) and lower IR risk (4% vs 31%) with methotrexate (MTX) cotherapy, which attenuated ADAs in pegloticase-naive pts.[2] Therefore, retreating pts who previously developed ADAs with pegloticase monotherapy is clinically relevant. The ADVANCE trial examined pegloticase+MTX cotherapy safety and efficacy in pts with prior monotherapy failure.

Objectives: To report interim efficacy and safety findings of the ADVANCE open-label trial.

Methods: Pts with uncontrolled gout (SU ≥6 mg/dL, ULT failure/intolerance, and ≥1 symptom [≥1 tophus, ≥2 flares in past yr, or chronic gouty arthritis) who did not maintain SU-lowering during prior pegloticase monotherapy were included.

*AE of special interest. †throat tightness, erythema, itching, urticaria in 1 pt; back pain in 1 pt. Excluded non-fatal stroke, non-fatal MI, cardiovascular death, CHF. **2 days before first pegloticase infusion, deemed unrelated to MTX.

Conclusion: Treatment response rate with pegloticase+MTX following failed monotherapy was 9%, markedly lower than in pegloticase-naïve pts (71%);[2] IR rate was 18%, higher than in pegloticase-naïve pts (4%),[2] but all were moderate (no anaphylaxis). These findings demonstrate the challenge of overcoming established ADAs against pegloticase and emphasize the importance of initiating immunomodulation before pegloticase therapy.

Conclusion: For the first time, we collected all case reports of Worth’s disease. Neurological involvement is present in one-fifth of the patients, and facial changes are not a consistent finding. Thus, Worth’s disease may be asymptomatic and is often incidentally detected in routine radiographs showing generalized osteosclerosis. Our case is the first report of hypo-/anosmia in Worth’s disease.

EVALUATION OF ADHERENCE TO AND AGREEMENT WITH THE 2020 AMERICAN COLLEGE OF RHEUMATOLOGY GUIDELINE FOR THE MANAGEMENT OF GOUT BY US RHEUMATOLOGISTS

Keywords: Inflammatory arthritides, Gout, Crystal arthritis

N. Schlesinger1, M. Pillinger2, P. Lipsky3. 1Spencer Fox Eccles School of Medicine, University of Utah, Division of Rheumatology, Salt Lake City, United States of America; 2WyU Grossman School of Medicine, Division of Rheumatology, New York, United States of America; 3WILSTE Research Institute and AMPEL BioSolutions, LLC, Rheumatology, Charlotteville, United States of America

Background: In 2020, the American College of Rheumatology (ACR) presented an updated gout treatment guideline.[1]

Methods: A 57-item questionnaire was administered to US rheumatologists, surveying their adherence to and agreement with the 2020 ACR Guideline for the Management of Gout. Stated adherence scores were based on the number of Guideline recommendations reported to be followed by rheumatologists in practice, whereas stated agreement scores were based on degree of agreement with the recommendations.

Results: All 201 rheumatologists approached completed the questionnaire. Mean age of participants was 50 years, 54% had >15 years of practice experience, and ~70% were in private practice (Table 1). Mean overall stated adherence score was 11.5, with a possible maximum of 15, whereas the mean overall stated agreement score was 7.7, with a possible maximum of 14. Rheumatologists with less experience (≤8years; n=49) were likely to claim adherence with more individual ACR recommendations than those with more experience (>8years; n=152) (mean stated adherence score: 12.3 vs 11.3; p<0.05), whereas those who claimed to see
≤75 patients with gout in 6 months (n=66) had a mean stated adherence score of 12.1 vs 11.2 for rheumatologists who claimed to have seen >75 patients (p<0.05).

Approximately 78% of rheumatologists claimed to follow the guideline for initiating urate-lowering therapy (ULT) and 88% were likely to prescribe allopurinol as a first-line ULT for all patient types (Figure 1). Claimed adherence to recommendations for dosing was lower (43% and 39%, for febuxostat and allopurinol, respectively). Approximately, 92% of the rheumatologists claimed adherence on first-line therapy for gout flares (Figure 1). Rheumatologists from academic settings were more likely to prescribe an interleukin-1 inhibitor for gout flares than those in other settings.

**Conclusion:** The self-reported practice of the surveyed US rheumatologists was generally concordant with the 2020 ACR Guideline for the Management of Gout. However, there were gaps in guideline knowledge and stated adherence among rheumatologists, mainly concerning the dosing of treatment regimens.

SERUM IRON LEVELS WERE POSITIVELY ASSOCIATED WITH THE RISK OF HYPERURICEMIA: NHANES 1999-2014

Keywords: Gout, Gender/diversity issues

S. X. Hu1, H. Lin1, N. Chen1, O. H. Li2.1, Sun Yat-Sen University, Zhongshan School of Medicine, Guangzhou, China; 2Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China

Background: Increasing evidence proofs that serum ferritin plays an important role in the development of hyperuricemia (HUA). However, few studies focus on the relationship between serum iron and serum urate (sUA).

Objectives: To examine the relationship between serum iron and serum urate as well as the risk of HUA classified by gender in the US adult population.

Methods: The present cross-sectional study pooled data from 1999 to 2014 National Health and Nutrition Examination Survey (NHANES). The association between serum iron quartiles and hyperuricemia was evaluated by logistic regression. The restricted cubic spline regression was performed to analyze the association between continuous serum iron and sUA.

Results: The study enrolled 25757 participants in total from 1999-2014 annual NHANES cycles. The crude prevalence of hyperuricemia was 11.9%. Serum iron was significantly higher in those with HUA than in those without HUA (16.6μg/dl vs 15.6μg/dl, p<0.0001). Logistic regression showed that serum iron levels were positively associated with the risk of HUA in the whole participants and male participants after adjusting for age, BMI and eGFR (Table 1). A dose-response association was observed in the whole participants (P for trend < 0.05). The restricted cubic spline regression analysis showed that the association between continuous serum iron and sUA was different in male participants and female participants (Figure 1). The curve of male participants showed an increasing trend (folding point 13.3μg/dl, P=0.033), while for women, sUA first increased linearly, but after the folding point (6.6μg/dl, P<0.001) the curve flattened out and the increasing trend was not significant.

Conclusion: Serum iron levels were positively associated with the risk of HUA in men. The correlation between serum iron and serum uric acid was influenced by gender. More studies are needed to confirm this relationship and to find out the mechanisms behind as well as the reasons for the gender differences.

EPIDEMIOLOGICAL, CLINICAL AND CHRONOLOGICAL PROFILE OF HOSPITALIZATIONS FOR CRystalline ARTHROPATHIES IN SOUTHERN TUNISIA: A DECLINE OF 14 YEARS

Keywords: Gout, Nursing, Crystal arthritis

M. Bakkouli1, Y. Mejdoub1, A. Fessi1, H. Maamri1, N. Ketata1,2, M. Ben Jmeaa3, I. Stouil1, R. Karray1, J. Jidil1, S. Yaich1, S. Bakkouli1, J. Dammak1.1 Hedi Chaker University-Hospital, Community Health and Epidemiology Department, Sfax, Tunisia; 2Hedi Chaker University Hospital, Rheumatology Department, Sfax, Tunisia

Background: Crystalline arthropathies (CA) are a group of joint disorders caused by deposits of crystals in joints and the soft tissues around them. The most common type is gout. Over time, CA could lead to joint damage and even for other serious complications that could require hospitalization.

Objectives: This study aimed to determine the epidemiological, clinical and chronological profile of hospitalizations for CA in Southern Tunisia for 14 years.

Methods: This was an observational retrospective study that included patients hospitalized for CA in the Hedi Chaker University Hospital Southern Tunisia, during the period 2003-2016. Data collection was done as part of the continuous survey of hospital morbidity and mortality.

Results: Among 148596 admissions, 187 cases were hospitalized for CA (0.12%), of which 122 subjects (84.9%) were males. The median age of hospitalized patients was 66 years (IQR=[54-75]) years. There were 96 patients (51.3%) aged 65 years. The most frequent type of CA noted was gout with a global frequency of hospitalizations about 72.2% (n=135). Complications were noted among 11 patients (5.9%). They were essentially cardiovascular diseases in 5 cases (2.6%). The mean total cost of hospitalizations for CA was about 507 Tunisian Dinars (IQR=[355-718]).

Conclusion: CA notably gout continue to be a relatively frequent source of hospitalizations in Southern Tunisia with a stable chronological trend over the years. Thus, an adequate and a continuous management must be maintained for patients in order to control the complicated forms of these pathologies.

DEVELOPMENT AND VALIDATION OF GOUT ‘TREAT-TO-TARGET’ BOOKLET

Keywords: Education, Gout

N. Mustafa1, M. R. Isa2, H. Baharuddin3.1 Universiti Teknologi MARA, Department of Internal Medicine, Sungai Buloh, Malaysia; 2Universiti Teknologi MARA, Department of Public Health Medicine, Sungai Buloh, Malaysia; 3Hospital Al-Sultan Abdullah, Department of Internal Medicine, Bandar Puncak Alam, Malaysia

Background: Gout is a treatable disease but often sub-optimally managed. The main gaps identified in gout management are sub-optimal urate-lowering therapy (ULT) adherence and lack of adequate ULT dosage.[1] Nurse-led care by providing individualized information led to a reduction in gout flares and tophli[2] while a structured gout management programme led by pharmacists[3] resulted in a higher rate of reaching serum uric acid (SUA) compared to usual care. Most patients with gout are being managed in primary care setting where nurse-led or pharmacists-led care may not be realistic, especially in developing countries where human resources are limited. Furthermore, clinic visits for every ULT increment can be burdensome to the healthcare system and even patients. Would a booklet on gout be helpful to improve patients’ education and ultimately care of patients with gout?

Objectives: This study was conducted to validate our newly developed Gout ‘Treat-to-Target’ Booklet, which was intended to document individual patient’s data relevant to gout and to provide basic written information on gout, for patients’ reference.

Methods: This methodological research was conducted following three stages; stage 1 involved the review of the Malaysian Clinical Practice (CPG) for the...
management of gout[4] and the EULAR evidence-based recommendations for gout management[1] stage 2 involved adoption of the content which was written into a booklet called Gout ‘Treat-to-Target’ Booklet, and stage 3 was the evaluation of the booklet for content and face validity. The content validity index (ICVI) was assessed by 11 healthcare providers who were involved in managing gout patients (four consultant rheumatologists, two general physicians and five medical officers) using a four-point Likert scale regarding relevance, clarity, simplicity and ambiguity of each item in the booklet. A scale with excellent content validity composed of ICVI of 0.79. The face validity index (FVI) was performed by 10 patients with gout who were asked to rate each content item independently (rating 1 and 2 represent invalid comprehensiveness and rating 3 and 4 represent valid comprehensiveness). An FVI for each item of >0.79 was considered relevant.

Results: The size of the booklet was 148 x 120 mm, which fits into pockets of trousers. (Figure 1) It consisted of 15 printed pages (excluding the front page) and divided into two segments. The first segment would contain items related to individual patient's data related to gout such as onset of the first symptoms, onset of tophi, cardiovascular co-morbidities, the SUA target, ULT used (including the dates for dose increment), colchicine dose and SUA level at each visit. The second segment consisted of four appendices which contained basic information on gout (appendix 1: treatment options in gout, appendix 2: medication information, appendix 3: gout diet and appendix 4: recommended gout lifestyle). The ICVI assessed by the 11 experts for all items were >0.79 (minimum 0.9, maximum 1.0), while the FVI evaluated by 10 gout patients for all items were 1.0.

Conclusion: The development and validation process of our Gout ‘Treat-to-Target’ Booklet was described. This booklet achieved excellent ICVI and FVI, and thus would be applicable in clinical practice.

AMORPHOUS MINERALIZATION, CHONDROID AND/OR OSTEOID FORMATION IN CRYSTAL INDUCED METABOLIC DISORDERS – A COMPARATIVE STUDY OF APATITE RHEUMATISM, CHONDROCALCINOSIS AND PRIMARY SYNOVIAL CHONDROMATOSIS

APATITE RHEUMATISM, CHONDROCALCINOSIS, PRIMARY SYNOVIAL CHONDROMATOSIS

Keywords: Synovium, Crystal arthritis

A. Apáthy1, M. Bély2, 1St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary; 2Hospital of the Order of the Brothers of Saint John of God in Budapest, Department of Pathology, Budapest, Hungary

Background: Apatite rheumatism (AR), chondrocalcinosis (Ch-C) and primary synovial chondromatosis (prSynCh) are calcium hydroxyapatite (HA) and calcium pyrophosphate dihydrate (CPPD) crystal induced progressive metabolic diseases, accompanied by more or less amorphous calcium phosphate [CaPO4], calcium carbonate [CaCO3], deposits, chondroid and/or bone formation [1 – 5].

Objectives: The aim of this study was.
(1) to assess the mineralization, chondroid and/or bone formation of AR, Ch-C and prSynCh with conventional histologic stains and histochemical reactions,
(2) to identify HA [Ca10(PO4)6(OH)] and CPPD [CaP2O7.2H2O] crystal deposits in conventionally fixed and stained tissue sections in comparison with unstained sections (Bély and Apáthy 2013) [6].

Methods: Ten joints (6 knees, 1 hip, 3 shoulders) of 5 patients with AR, 16 joints (6 knees, 4 hips, 1 shoulder, 1 elbow, 2 wrists) of 16 patients with Ch-C, and 21 joints (14 knees, 5 hips, 2 elbows) of 20 patients with prSynCh were studied histologically. The amount of amorphous calcium phosphate and/or calcium carbonate deposits, furthermore chondroid and/or bone formation were evaluated by a semiobjective score system in conventionally stained tissue sections (0 - no mineral deposits, chondroid and/or bone formation, 1 – minimal, 2 – moderate, and 3 – abundant). Standard stained and unstained tissue sections were examined with the light microscope and under polarized light, respectively.

Results: Summary of Patients’ Demographics.

The amount of amorphous calcium phosphate and/or calcium carbonate deposits was different in all patient groups; the average value of scores in tissue samples of patients with clinical diagnosis of AR was (1.80), with Ch-C (2.60), and with prSynCh (0.556). Chondroid formation in synovial membranes was minimal in tissue samples of patients with the clinical diagnosis of AR (0.058) or Ch-C (0.050); osteoid or bone formation was not detected (0.0). Massive chondroid formation (with or without osteoid or bone formation) was characteristic for prSynCh (2.1351). In tissue sections stained with HE, HA crystals were found only in 3 (4.054 %), and CPPD in 15 (20.27 %) of 74 tissue sections of 28 patients with the clinical diagnosis of AR, Ch-C, or with prSynCh. Using Bély and Apáthy’s non-staining technique (2013), different amounts of HA and CPPD crystals were demonstrated in all 28 patients (100 %) with the clinical diagnosis of AR, Ch-C and prSynCh. In unstained sections HA crystals were found in 49, (66.216 %), and CPPD in 44 (59.459 %) of 74 tissue samples. The unstained sections were more frequent to demonstrate HA or CPPD crystals than conventionally stained ones.

Conclusion: Our study indicates that AR, Ch-C and prSynCh are crystal induced maladies and belong to the same group of metabolic diseases. All of these diseases start with crystal deposition which provokes an inflammatory reaction. The inflammatory reaction is inhibited or moderated by calcium carbonate [CaCO3] and/or calcium phosphate [CaPO4] deposition in case of AR or Ch, and is inhibited or moderated by chondroid and/or osteoid formation in case of prSynCh. In our view prSynCh is a defect variant of metabolic
disorders, characterized by diminished calcium phosphate and/or carbonate production.

AB1263 REGIONAL VARIATIONS OF CARDIOVASCULAR RISK IN GOUT PATIENTS: A NATIONWIDE COHORT STUDY IN KOREA

Keywords: Cardiovascular disease, Gout

B. Ghang1, B. Yoo1, J. Kim1, H. J. Kim1, H. S. Ahn2, 1Jeju National School of Medicine, Jeju National University Hospital, Rheumatology, Jeju, Korea, Rep. of (South Korea); 2Asian Medical Center, University of Ulsan College of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea);

Background: Gout is also closely associated with systemic disorders and cardiovascular (CV) risk profiles, such as hypertension, diabetes mellitus, dyslipidemia, chronic kidney disease, alcohol consumption, and obesity[1]. In addition, gout has been suggested as a cause of CV diseases via pathogenic mechanisms such as endothelial dysfunction, oxidative metabolism, platelet adhesiveness, and aggregation[2-4]. Accordingly, several epidemiological studies reported that patients with gout had an increased risk for CV events.[3, 4] In particular, differences in population characteristics between urban regions and other regions are getting more significant owing to recent rapid industrialization. Accordingly, a study on regional differences should be conducted; however, there are still few studies on it.

Objectives: We aimed to investigate the risk of major cardiovascular events in gout patients in different regions.

Methods: This was a nationwide cohort study based on the claims database of the Korean National Health Insurance and the National Health Screening Program. Patients aged 20 to 90 years newly diagnosed with gout after January 2012 were included. After cardiovascular risk profiles before gout diagnosis were adjusted, the relative risks of incident cardiovascular events (myocardial infarction, cerebral infarction, and cerebral hemorrhage) in gout patients in different regions were assessed.

Results: In total, 231,668 patients with gout were studied. Regional differences in cardiovascular risk profiles before the diagnosis were observed. Multivariable analysis showed that patients with gout in Jeolla/Gwangju had a significantly high risk of myocardial infarction (adjusted hazard ratio [aHR] 1.27 [95% confidence interval [CI], 1.02–1.56], P = 0.03). In addition, patients with gout in Gangwon (aHR 1.38 [95% CI, 1.09–1.74], P = 0.01), Jeolla/Gwangju (aHR 1.41 [95% CI, 1.19–1.67], P < 0.01), and Gyeongsang/Busan/Seoul/Ulsan (aHR 1.37 [95% CI, 1.19–1.59], P < 0.01) had a significantly high risk of cerebral infarction.

Conclusion: We found there were regional differences in cardiovascular risk and associated risk factors in gout patients. Physicians should screen gout patients for cardiovascular risk profiles in order to facilitate prompt diagnosis and treatment.

AB1264 RHEUMATOLOGISTS BEWARE OF LOW ALP: A CASE OF HYPOPHOSPHATASIA MISDIAGNOSED AS FIBROMYALGIA, CAUSING LONG DIAGNOSTIC DELAY

Keywords: Quality of life, Patient information and education, Rare/orphan diseases

A. Lathet1, K. Moss2, 1St George’s University Hospitals NHS Foundation Trust, Rheumatology, London, United Kingdom; 2St George’s University Hospitals NHS Foundation Trust, Rheumatology, London, United Kingdom

Background: Hypophosphatasia (HPP), a rare, inherited metabolic disease featuring low serum alkaline phosphatase (ALP) activity due to ALPL (encoding tissue non-specific alkaline phosphatase) gene mutation[1,2]. A wide-ranging clinical spectrum is often seen due to defective mineralisation affecting teeth, bones, joints and muscles[1]. This disease has a prevalence of 1/6370 in Europe and is often misdiagnosed and underdiagnosed with a diagnostic delay of more than ten years[1] The treatment is often supportive for milder cases and enzyme replacement therapy in severe cases.

Objectives: To share this case to raise awareness among Rheumatologists.

Methods: This 58-year-old Caucasian female had her HPP symptom as early eruption of deciduous teeth, along with recurrent dental infections and gum problems. She was diagnosed with flat feet at age five, had a big toe fracture at sixteen, followed by a metatarsal fracture. She experienced leg muscle cramps and aches, affecting her performance in sport during school life. At the age of thirty she began noticing weakness in arms and legs, which progressed over the years. She faced significant early morning stiffness along with painful ribs, hips, knees, shoulders, and small joints of feet when walking. She was diagnosed with Fibromyalgia at the age of forty-four. The following ten years she met numerous specialists including rheumatologist, pain specialist and physiotherapists. She was also diagnosed with early osteoarthritis, pernicious anaemia, hyperlipidemia, functional neurological syndrome, and central sensitization syndrome. She had multiple trials of steroids and opioids, all of which were stopped either due to side effects or efficacy. A major flare of symptoms five years ago rendered her bedbound for three months, following which a chemical pathologist noticed a persistent low ALP levels and decided to investigate for HPP. It took another four years to complete these investigations due to the coronavirus pandemic. Currently, she is unable to wear light bear or climb stairs and must stay indoors or in bed during flareup. She moved into a ground floor flat at the age of 54 and use a walking stick occasionally. By 58, she is unable to work and had given up her own business due to pain, weakness, and disability.

Results: On clinical assessment, her height is 160 cm, faced difficulty getting up from chair, has an antalgic waddling gait, with a 6-minute walking distance of 60 metre, stopped after three minutes, and had a Brief Pain Inventory pain severity score of 7/10. Her ALP level is 24 U/L and PLP/PA ratio is 18.8 (ref < 5), and genetic testing showed heterozygous missense variant of ALPL gene mutation.

Conclusion: It took more than forty years to reach a conclusive diagnosis of childhood onset HPP. Low ALP level is a signature of HPP and warrants investigations. Diagnosis can be challenging due to the rareness and variable presentation, however recognition of HPP features is crucial for timely referral, optimal disease management and potential improvement in quality of life.

THE INCIDENCE OF ACUTE CORONARY SYNDROME IN GOUT AND ASSOCIATED FACTORS

Keywords: Gout, Heart

I. Roki Chaouâl1, N. Akasbi1, S. Benbamaara2, I. El Mezouar1, T. Harzy1. 1Hassan II University Hospital, University Sidi Mohamed Ben Abdellah, Faculty of Medicine and Pharmacy, Fes, Morocco; 2Hassan II University Hospital, University Sidi Mohamed Ben Abdellah, Faculty of Medicine and Pharmacy, Laboratory of Biostatistical, Clinical and Epidemiological Research, Fes, Morocco

Background: The Gout is a metabolic arthropathy including monosodium urate crystal deposition associated with an increased risk of cardiovascular morbidity and mortality, particularly related to coronary heart disease.

Objectives: The purpose of our work was to determine the frequency of heart attack in our gouty patients and the factors associated with its incidence.

Methods: A retrospective observational study was conducted. The inclusion period was from January 2011 to March 2022.

Results: Our sample included 138 patients. The mean age was 58±13 years and the sex ratio was 1.46:M:W. The mean duration of evolution was 20±28 months. The prevalence of patients with metabolic syndrome including diabetes, hypertension and dyslipidemia was 25.4%, 43.5% and 16.7% of cases respectively. Smoking was present in 9.5% of cases. Medication was found in 31.2% of cases. The vital prognosis is at stake, hence, the need for adequate and early management of this rheumatism as well as the associated with smoking and dyslipidemia. The presence of dyslipidemia (OR=5.744; CI95% [1.323; 24.947]; p=0.020). In multivariate analysis, the risk of developing an acute coronary syndrome was fivefold higher in patients with recurrent attacks, arthropathies, tophus or radiological signs of gout. Thus, 8.5% of the physicians recommend disease-modifying therapy for the recommended indications. Among other things, 36.8% of patients recommend starting hypouricemic treatment in the event of asymptomatic hyperuricemia. Regarding patient education, the majority of doctors advise for weight loss (77.6%) and a low purine diet by (75%).

Conclusion: This work has objectified that gout is often poorly managed by general practitioners suggesting the need for continuing medical education of general practitioners which will certainly help improve practices.

THE CORRELATION BETWEEN URIC ACID AND BONE MINERAL DENSITY OF TOTAL HIP WITH BONE MICROARCHITECTURE ANALYSIS IN TOPHACEOUS GOUT PATIENTS

Keywords: Imaging, Bone diseases, Gout

J. Barco Dos Santos1, G. Rocha1, L. Peixoto Sales1, A. Silva Franco1, V. Caparbo1, D. Domiciano1, R. Fuller1, C. Figueiredo1, R. M. Pereira1. 1Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, Division of Rheumatology, São Paulo, Brazil

Background: Gout is the most common inflammatory arthropathy¹. It is related to elevated uric acid levels and often associated with bone loss². Furthermore, chronic inflammation has been associated with fragility fractures despite normal bone mass by dual-energy X-ray absorptiometry (DXA). However, the evaluation of bone microstructure in patients with tophaceous gout and its association with bone mineral density (BMD) has not been studied yet.

Objectives: The present study aimed to investigate the correlation between densitometric parameters and bone microstructure using high-resolution peripheral quantitative computed tomography (HR-pQCT) in patients with tophaceous gout.

Methods: Eleven male tophaceous gout (Figure 1) patients were enrolled in this cross-sectional study. Patients using drugs that can affect bone metabolism were excluded. The presence of tophi was confirmed by physical examination, radiographs and laboratory tests.

Conclusion: In addition to our work, several previous studies confirm the increased cardiovascular risk of gout but few investigate the predictive factors. Biological studies have indicated that the systemic inflammation induced by the crystals characteristic of gout leads to atherogenesis through endothelial dysfunction [2]. In our sample, the incidence of acute coronary syndrome is associated with smoking and dyslipidemia. The vital prognosis is at stake, hence, the need for adequate and early management of this rheumatism as well as the prevention of associated factors.

DOI: 10.1136/annrheumdis-2023-eular.5752
was found a positive correlation between BMD of total hip and Tb.N tibia (r= 0.743, p< 0.035), Ct.Th tibia (r= 0.902, p= 0.005) and S tibia (r= 0.938, p< 0.001).

**Conclusion:** The results of this study showed that uric acid levels were negatively correlated with tibia bone microarchitecture parameters. However, total hip BMD was positively correlated with these tibia bone microstructure data.

**FIRST DIAGNOSIS OF MONOSODIUM URATE CRYSTAL FROM CEREBROSPINAL FLUID IN PATIENT WITH NECK PAIN**

**Keywords:** Spondyloarthritis, Crystal arthritis, Gout

W. Jeong¹, J. R. Yoo¹. ¹Jeju National University College of Medicine, Internal Medicine, Jeju, Korea, Rep. of (South Korea)

**Background:** Gout is a common arthritis caused by the deposition of monosodium urate (MSU) crystals within joints after chronic hyperuricemia. Deposition of MSU in the spine as a rare manifestation of gout, but the actual prevalence of spinal involvement is unknown.

**Objectives:** We present a vertebral osteomyelitis and spinal meningitis misdiagnosed cervical spinal gout.

**Results:** An 85-year-old man was admitted due to a 5-day history of fever and neck pain. On admission, physical examination revealed neck pain and stiffness. He had a blood pressure of 140/102 mmHg, pulse rate of 95/min, respiration rate of 18 breaths/min, and body temperature of 38.0°C. Laboratory results revealed a white blood cell count (WBC) of 140/102/mm³, pulse rate of 95/min, respiration rate of 18 breaths/min, and body temperature of 38.0°C. Laboratory results revealed a white blood cell count (WBC) of 11,200/mm³ (reference: 4,000–10,000) and C-reactive protein level of 12.29 mg/dL (reference: 0.0–0.3). Magnetic resonance imaging findings suggested cervical osteomyelitis and meningitis (Figure 1A). Cervical spine computed tomography (CT) revealed curvilinear calcifications of the transverse ligament of the atlas (Figure 1B). After assessing blood cultures, an empirical antibiotics were administered intravenously. On the second day of admission, cerebrospinal fluid (CSF) analysis did not reveal meningitis (WBC 8/μL; glucose and protein levels 79 and 168 mg/dL, respectively), and CSF culture and molecular tests were negative for bacteria and mycobacteria. The patient was diagnosed with crowned dens syndrome and administered with 20 mg prednisolone, and his symptoms dramatically improved. However, CSF examination under polarising microscopy revealed monosodium urate (MSU) crystals (Figure 1C), and dual-energy CT confirmed the calcifications to be MSU crystals (Figure 1D).

**Conclusion:** Crowned dens syndrome is a rare finding in calcium pyrophosphate deposition disease and may be clinically similar to meningitis, so it should be suspected when the evidence for infection is unclear. Our patient had gout history, and MSU crystals were confirmed by CSF analysis and dual-energy CT, suggesting that the symptoms were caused by gout flare in the cervical spine. Thus, physicians should consider that intrathecal MSU crystal formation can cause meningitis-like symptoms in patients with gout history.

AB1269 HEARING LOSS – A RARE MANIFESTATION OF THE CALCIUM PYROPHOSPHATE DIHYDRATE DEPOSITION DISEASE

Keywords: Descriptive studies, Crystal arthritis

P. Bradna1, 1University Hospital and Medical Faculty, IInd Dept of Medicine, Hradec Králové, Czech Republic

Background: Calcium pyrophosphate dihydrate (CaPPD) deposition disease is a disease with a wide range of manifestations from acute gout-like episodic arthritis to an accentuated osteoarthritic picture. A common feature is the deposition of CaPPd crystals in tissues. Middle ear involvement is a rare manifestation of the disease, described in a few case reports.

Objectives: Middle ear involvement is a rare manifestation of the disease, described in a few case reports.

Methods: Histological examination of operating specimen.

HRT.

Results: 71-year-old man, athlete (tennis, cycling) underwent a partial meniscectomy in 2008 for acute knee blockade, in October 2022 he suffered polytrauma after a traffic injury. He is treated for arterial hypertension. He has never had inflammatory arthritis, joint problems he had only in connection with sports injuries. Last 12 months he has observed a gradually progressing hearing loss, mild dizziness and tinnitus. HRT of a scull base demonstrated a left-sided osteoma with fixation to the malleus. Tumor mass was removed by surgery. Histology proved calcium pyrophosphate dihydrate crystals in the operating material. We have not demonstrated hyperparathyroidism, hypomagnesemia, or any other primary disease associated with CaPPD deposition. During subsequent X-ray examination, we found the chondrocalcinosis of the menisci of both knees.

Conclusion: Deposits of calcium pyrophosphate in the middle ear region are a rare manifestation of the calcium pyrophosphate dihydrate deposition disease. Clinically, progressive hearing loss may occur, morphologically resemble osteoma and may not be associated with other clinical signs of the underlying disease.

AB1270 ANALYSIS OF PREVALENCE AND RELATED RISK FACTORS OF HYPERURICEMIA IN BOZDUN AKSU PREFECTURE OF XINJIANG

Keywords: Gout

Y. Zhong1, L. Wu1, 1People’s Hospital of Xinjiang Uygur Autonomous Region, Rheumatology, Urumqi, China

Objectives: To investigate the prevalence of Hyperuricemia (HUA) in Bozidun Kirgiz township, Aksu region, Xinjiang, and to explore the risk factors for the occurrence of HUA in the local area.

Methods: A cross-sectional survey study was conducted by randomly selecting 9 villages in Bozidun Kirgiz Township by the whole-group sampling method and using a questionnaire distributed to households. The questionnaire included: general information, history of previous diseases, personal history, and all subject-related factors. The diagnosis of HUA: serum uric acid (SUA) >420μmol/L in men or >360μmol/L in women.

Results: 2138 subjects were surveyed, among which 68 patients with HUA, the prevalence of HUA in Bozidun Kirgiz Township, Aksu region general population was 3.2% (68/2138); the prevalence rate of men was 4.6%, with 45 patients; and the prevalence rate of women was 2.0%, with 23 patients. The peak age of male and female patients was 51-60 years old. The prevalence of HUA was lower in those who consumed dairy products, nuts and eggs, and lower in those who consumed more. Different intake of cereals, meat, vegetables and fruits had no effect on the prevalence of HUA. In terms of different life behaviors, the prevalence of HUA in men who had been smoking was higher than those who had never smoked (57.78%, 28.89%, 13.33%, P=0.017). In the relationship between drinking and HUA, the prevalence rates of male always drinking, ever drinking and never drinking were 60.00%, 11.11% and 3.89%, respectively, showing significant differences (P=0.038); Multi-factor logistic regression analysis showed that BMI, age, TG, Cr and WBC were risk factors for the occurrence of HUA.

Conclusion: The prevalence of HUA in Bozidun Kirgiz township in Aksu prefecture of Xinjiang is lower than that in other areas with continental climate. High body mass index, old age, high triglyceride, increased creatinine and increased white blood cell count are the risk factors for the development of HUA.

AB1271 FACTORS ASSOCIATED TO FRACTILITY FRACTURES IN RA PATIENTS: IS URIC ACID INCIRMINATED?

Keywords: Osteoporosis, Rheumatoid arthritis

B. Touil1, N. Akasbi1, I. El Mezouar1, T. Harzy1, 1Sidi Mohammed Ben Abdellah University, Rheumatology Department, FEZ, Morocco

Background: Rheumatoid arthritis (RA) has been reported to be associated with low bone mineral density (BMD) and increased risk of fractures. Recently, several observational studies have revealed that a higher serum uric acid level was associated with higher bone mineral density (BMD), and therefore, a reduced risk of osteoporosis and fragility fractures in men, post- and perimenopausal women. Although the relationship between serum UA levels and BMD has been evaluated in the general population, data regarding the effect of UA levels on bone loss in patients with RA was lack [1].

Objectives: To evaluate the relationship between UA levels, BMD and fragility fractures (FF) and the different factors associated with the occurrence of FF in RA patients.

Methods: We conducted a cross-sectional study in a single rheumatology hospital in Morocco. All patients satisfied the ACR-EULAR 2010 RA classification criteria. All the patients underwent BMD examination by dual energy x-ray absorptiometry and serum UA levels measurement. Osteoporosis was diagnosed when the T-score was -2.5 or less. Socio-demographic data, comorbidities, disease-related variables (duration, characteristics, and drugs) were also collected. Statistical analysis were performed with SPSS 22.

Results: We included 88 (85.44%) women and 15 (14.56%) men with a mean age of 52.59 ± 14.77 years old. They had a mean disease duration of 14.27±10.84 years, a mean 28 CRP of 2.59 ±1.35. Their mean lumbar spine, femoral neck and total proximal femur were 0.843 ± 0.134, 0.694 ± 0.111, and 0.826 ± 0.119 respectively. The UA levels were elevated in 10.8 % of patients, dyslipidemia was found in 19.3 % of patients and 38.9 % of the patients had osteoporosis. There was no correlation between UA concentrations and BMD, whether corrected to the glomerular filtration rate (87.43 ± 12.11 vs 103.50 ± 15.38; p=0.018). The UA levels were elevated in 10.8 % of patients, dyslipidemia was found in 19.3 % of patients and 38.9 % of the patients had osteoporosis. There was no correlation between UA concentrations and BMD, whether corrected to the glomerular filtration rate (87.43 ± 12.11 vs 103.50 ± 15.38; p=0.018).

Conclusion: Although there was no relation between UA levels, BMD and FF in our population, FF were related to ACPA antibodies, BMD, kidney function and corticosteroid use.

Infection-related rheumatic diseases

**AB1272** SHOULD RHEUMATOLOGISTS ROUTINELY REQUEST PARASITE SEROLOGY IN CANDIDATES FOR IMMUNOSUPPRESSIVE TREATMENT? PREVALENCE OF STRONGYLOIDES STERCOARIS IN A NON-ENDEMIC AREA (CATALONIA, SPAIN)

**Keywords:** Inflammatory arthritides, Epidemiology, Infection-related RMDs

J. Font-Urgelles,1,2 S. Mingué-Blasco,1 M. Lopez de Recale-Martorell1, B. Rodriguez-Diez1,2 A. Arnau Bastes1, S. Jonés-Lauredo1,2, A. Flor-Pérez1,2, G. Trujillo-Isern1, D. Estivill Navarrete1, J. Trapé3, M. Sallés Lizarazu4,1

1Althaia, Xarxa Assistencial Universitària de Manresa, Rheumatology, Manresa, Spain; 2Hospital Universitari Germans Illes i Pujol, Rheumatology, Badalona, Spain; 3Althaia, Xarxa Assistencial Universitària de Manresa, Research Unit, Manresa, Spain; 4Althaia, Xarxa Assistencial Universitària de Manresa, Infectology, Manresa, Spain; 5Althaia, Xarxa Assistencial Universitària de Manresa, Microbiology, Manresa, Spain

**Background:** Infection is one of the main causes of morbidity and mortality in patients with autoimmune and immune-mediated diseases (AI/IMID). Multiples recommendations exist for prevention of bacterial and viral infections, however, there are no specific recommendations for parasitosis. Strongyloidiasis is an infection caused by *Strongyloides stercoralis*. This parasite is distributed globally throughout tropical and subtropical areas. The majority of cases in Spain are imported. Often this infection is asymptomatic, however, in immunosuppression situation, severe presentations, hyperinfection syndrome or disseminated strongyloidiasis can occur.

**Objectives:** To determine the prevalence of positive *S. stercoralis* serology and describe the epidemiological, clinical and analytical characteristics of this subject.

**Results:** Three hundred and ten patients were included. The majority were women (63.2%) with a mean age of 55.9 years (SD 14.7) and 9.3% were not born in Spain. Our patients had and inflammatory arthritis (81.2%) or an autoimmune disease (8.1%). At the moment of serology determination, 41.9% received disease-modifying antirheumatic drug and 54.9% prednisone. Positive serology was found in 10 patients (3.2%; 95%CI: 1.6-5.9) and 4 (1.3%; 95%CI: 0.4-3.3) were indeterminate. No patient developed symptomatic infection nor hyperesoinophilia. Every positive patient received prophylactic therapy with ivermectin. The 60% of patients didn’t referred any epidemiological risk, 10% were born in endemic country but have never returned, 10% were born in endemic country and have visited this country subsequently, and 20% were born in non-endemic country and had travelled to an endemic zone. No differences were observed in the prevalence of *S. stercoralis* according to sex, disease, treatments nor epidemiologic contacts. Patients with positive serology were younger (48.4 yrs vs 56.2; p=0.048). The highest prevalence of infection was observed in workers of the quinary sector (12%; p=0.072).

**Conclusion:** Prevalence of *S. stercoralis* infection in rheumatic patients in our area is 3.2%. Increasing migration and international travelling was suspected the most important risk factor. Study period: patients attended in the Rheumatology clinic prior to the diagnosis. Hence, Rheumatologists practicing worldwide should be aware of such manifestations of infectious diseases.

**AB1273** RARE INFECTION RELATED ARTHROPATHIES IN RHEUMATOLOGY: A MULTI-CENTRIC STUDY

**Keywords:** Rheumatoid arthritis, Infection-related RMDs, Inflammatory arthritides

A. Pandey1, A. Dua2, S. Jain3, B. D. Pandey1, Apollo Hospital, Rheumatology, Indore, India; 1Dua Clinic: Rheumatology and Arthritis Care, Rheumatology, Bilaspur, India; 2Arthritis Clinic, Rheumatology, Saharanpur, India; 3Noida, Rheumatology, Noida, India

**Background:** Various infections can mimic inflammatory arthropathies and misdiagnosed as rheumatoid arthritis, Spondyloarthropathies or lupus. Occasionally, rare infections prevalent in a specific geographical region may present with arthritis as their first and only symptom which may confuse the clinician leading to incorrect diagnosis and management. Many a times, such patients land up in a rheumatology clinic prior to the diagnosis. Hence, Rheumatologists practicing worldwide should be aware of such manifestations of infectious diseases.

**Objectives:** Main objective of this multi-center study was to appraise the clinical features and demographics of various rare infectious diseases (newly or previously diagnosed) that presented with arthritis.

**Methods:** This retrospective study (January 2012- December 2022) was carried out at 3 tertiary care centres, two in central India (city Indore and Bilaspur) and 1 in northern India (city Saharanpur). Patients who were previously diagnosed with an infectious disease and presented with arthritis were included. Patients with arthritis who were diagnosed as infectious disease were also included. Their details regarding demographics and clinical presentations were collected. Pearson chi-square test was applied and cases were studied according to their Age, Sex, distribution of joints, rheumatoid arthritis (RA) factor and anti cyclic citrullinated peptide (anti-cci) antibodies positivity,presence of myalgias, rashes, extra-articular manifestations and cutaneous manifestations.

**Results:** Seventy-nine patients (39 male) were identified. Out of these, 34 (43%) patients had chikungunya arthrisis, 12 (15.2%) leprosy, 11 (13.9%) Covid-19, 10 (12.9%) Dengue, 4 (5.1%) Hepatitis C, 4 (5.1%) HIV, 3 (3.8%) HCV and 1 (1.3%) Poncet’s disease. No significant association was seen among rheumatoid factor (p=0.494) or anti-cci antibodies positivity (p=0.987) with these diseases. Patients with chikungunya had oligoarthitis (14.7%) or polyarthitis (85.3%). Patients with Covid-19 had oligoarthitis (18.2%), polyarthralgia (27%) and polyarthitis (54.5%). Patients with dengue, HCV and Poncet’s disease had only polyarthitis. Majority of the patients with hepatitis C and leprosy had polyarthitis. Patients with HIV showed esenthesis (25%), oligoarthitis (25%) and polyarthitis (50%). There was a statistically significant association between presence/ absence of myalgia and infectious diseases (P<0.001). It was absent in patients with hepatitis C. Only about one-third of the patients with leprosy had myalgia; while most of the patients with other infectious diseases had myalgia. 20% of the dengue patients and 41.7% of the leprosy patients had rashes, while rashes were absent in patients with other infectious diseases. Erythema nodosum was seen in only 25% patients with leprosy; while it was absent in the patients with other infectious diseases. Extra-articular manifestations were seen in 35.3% patients with chikungunya, 9.1% with Covid-19, 20% with dengue, 25% with hepatitis C, 33.3% with leprosy and 100% patients with Poncet’s disease; while extra-articular manifestations were not seen in patients with HCV and HIV infection. 9.1% patients with Covid-19, 25% with hepatitis C, 25% with HIV, 83.3% with leprosy had cutaneous manifestations, while cutaneous manifestations were not seen in patients with chikungunya arthrisis, dengue, HCV and Poncet’s disease.

**Conclusion:** Rheumatological manifestations of various infections can mimic various inflammatory arthritides and can be a diagnostic challenge. Apart from the joint involvement, these infections can also have various extra-articular manifestations as well. One should be aware of such manifestations as increased awareness can prevent diagnostic delay and complications.

**DOI:** 10.1136/annrheumdis-2023-eular.5302
Background: Rheumatic immune disease is a group of diseases caused by the strong immune response to self-antigens, leading to tissue and cell damage, affecting bone, joints, bursa, muscle and its surrounding soft tissues (tendons, ligaments and fascia). The risk of tuberculosis infection in rheumatic immune patients is 2 to 5 times [1-3] than that of the general population. Patients with rheumatic immune diseases require long-term treatment with glucocorticoids and immunosuppressants, and the risk of complicated tuberculosis infection significantly increases in [4]. When active tuberculosis infection occurs in rheumatic immune patients, quite a number of patients have atypical clinical manifestations, severe disease, difficult to cure, long infection time, high fatality rate, which seriously endanger people’s health. Therefore, this study intends to explore the risk of active tuberculosis infection using immunosuppression agents and biological agents in patients with rheumatic immune diseases.

Objectives: The risk factors of active TB in rheumatic immune disease patients were explored.

Methods: The confirmed patients who went to the Rheumatology and Immunology Department of Xijin forever Uygur Autonomous Region from December 2014 to June 2015 were included. The clinical data and treatment plan were collected, followed up to December 2021 and the prognosis were collected. The risk factors of active tuberculosis were analyzed by K-M survival curve method.

Results: Data of 499 patients collected in this study, Including: In 213 cases of rheumatoid arthritis, In 79 cases of ankylosing spondylitis, In 84 cases of systemic lupus erythematosus, In 58 cases of Sjogren's syndrome, And 65 patients with other rheumatic diseases; Of them, 62 patients were lost to follow-up. Ten patients have died, Four patients were diagnosed with active TB infection when enrolled; Thus, 423 patients were included in the study. Among these, 109 males (25.8%), In 314 women (74.2%), Mean age was 48.2 ± 13.7 years. The mean follow-up was 80.2 ± 7.7 months, Six cases of active tuberculosis (one case was bone tuberculosis, One case had a pleural tuberculosis, The remaining four cases were pulmonary tuberculosis). Survival analysis showed that patients with rheumatic immune diseases had an increased risk of using immunosuppressive agents compared with active TB infection (p=0.039) and an increased risk of using biologics compared with active TB infection (p=0.004). Multivariate Cox regression analysis showed that the use of biologics was an independent risk factor in rheumatic immune disease patients with active TB (P=0.011).

Conclusion: Patients with rheumatic diseases have an increased risk of active TB using immunosuppressants or biologic agents. Use of biologic agents is an independent risk factor for the emergence of active TB.

AB1275 NEISSERIA GONORRHOEAE ARTHRITIS: A GROWING PROBLEM

Keywords: COVID, Infection-related RMDs, Epidemiology

P. Andrés-Braza1, E. Flores-Fernández2, C. Valera-Riberia1, I. Vázquez-Gómez1, E. Valls-Pascual1, J. J. Alegre Sancho1, 1Valencia, Hospital Doctor Peset, Valencia, Spain

Background: Neisseria Gonorrhoeae infection (commonly gonococcus) have increased in recent years. Additionally, an increase in the antibiotic-resistance of the bacteria has been detected, including broad-spectrum cephalosporins, which could lead to untreatable complications like arthritis.

Objectives: The goal of this study is to describe the gonococcal arthritis events identified in a Rheumatology service between 2008 and 2022.

Methods: Retrospective longitudinal observational study based on the review of the medical records of patients diagnosed with gonococcal arthritis in the Rheumatology Department of the Doctor Peset University Hospital in Valencia (Spain) since 2008 to 2022. Sociodemographic and clinical variables, antibiotic sensitivity profile and antibiotic therapy used were studied. Evolution of infections were also analyzed.

Results: Eight cases of gonococcal arthritis were recorded in the period analyzed, all of them diagnosed between the years 2021-2022. All patients except one were male. Half of the patients had sexual transmitted infection history, 75% of which were syphilis infected and 25% had previous hepatitis B infection. The most common form of presentation was oligoarthritis. In three cases a component of tenosynovitis was also observed. Diagnostic arthrocentesis was performed in seven of eight cases and a high profitability of synovial fluid culture was observed (only in one patient bacteria was not isolated). All infections showed cephalosporin and azithromycin sensitivity, all of them displayed a favorable evolution (Table 1).

Table 1. Antibiotic sensitivity profile, treatment regimens administered and duration of treatment, need for surgery and evolution of the infection.

Conclusion: An increase in gonococcal arthritis cases has been detected in the Rheumatology Department of the Doctor Peset University Hospital in the last two years, overlapping with the end of the social restrictions caused by the COVID-19 pandemic. Despite having described in recent years a growing increase antibiotic resistance, in our study the antibiotic sensitivity profiles were favorable without isolating strains resistant to cephalosporins or azithromycin.

**AB1276** SCREENING FOR LATENT TUBERCULOSIS INFECTION BEFORE BIOLOGICS IN ALGERIAN PATIENTS WITH RHEUMATIC DISEASES

**Keywords:** Infection-related RMDs, bDMARD

**F. Z. Y. Heddi**, A. Laosli1, A. Laradj1, M. Nour Elhouda, N. Djekoun2, S. Debba3, C. Ouadah3, K. Khreidjine3, A. Benzaoui4, O. Paris, S. University Hospital, Rheumatology, Oran, Algeria; 2Zeralda Public Hospital, Internal Medicine, Algiers, Algeria; 3Jijel Public Hospital, Internal Medicine, Jijel, Algeria; 4Boujan Public Health Establishment, Pulmonology, Baida, Algeria

**Background:** The use of biological agents has significantly improved the management of chronic rheumatic diseases (CRD). However, these treatments increase the risk of tuberculosis due to the reactivation of a previous latent tuberculosis infection (LTBI), making its diagnosis and treatment very important prior to initiating therapy.

**Objectives:** To identify the prevalence of LTBI in Algerian patients with CRD before the initiation of biotherapies.

**Methods:** We conducted a multicenter, retrospective study over a period of 10 years including patients with CRD receiving biological therapy for at least 6 months. LTBI diagnosis was based on a positive tuberculin skin test (TST) or Quantiferon-TB Gold In-Tube test (QFT-GIT) without clinical symptoms, and bacteriological and radiographic signs of disease.

**Results:** 271 (154 men/117 women) were included, and the mean age of patients was 40.6±12.9 years. The most common CRD was ankylosing spondylitis (57.9%) followed by rheumatoid arthritis (22.1%), psoriatic arthritis (12.2%), and spondyloarthritides associated with inflammatory bowel disease (4.8%). Patients received adalimumab in 117 (43.2%) cases, etanercept in 89 (32.8%) cases, infliximab in 40 (14.8%) cases, tocilizumab in 24 (8.9%) cases and anakinra in 1 case. Medical history of tuberculosis was noted in 3 cases and 4 patients have a history of household contact with tuberculosis. TST was performed in 186 cases and was positive in 13.2%. 261 patients underwent a QFT-GIT, which was positive in 16.9%. The diagnosis of active pulmonary tuberculosis was made in one patient who had positive TST and images of active tuberculosis in the chest X-ray. Quadruple therapy including rifampicin (10mg/kg/day), isoniazid (5mg/kg/day), pyrazinamide (25mg/kg/d) and ethambutol (15mg/kg/d) was prescribed for this patient. However, LTBI was diagnosed in 54 cases (19.9%), 29 had negative TST with positive QFT-GIT. 34 patients received a combination of rifampicin and isoniazid for three months and 20 received the isoniazid monotherapy for six months without developing active disease. Hepatotoxicity was observed in 5.6% of cases. The biological therapy was initiated 10.3±4.96 weeks after chemophrophaxis, and 55.5% were treated with etanercept. After a follow-up of 23.5±15.7 months 4 cases of active tuberculosis infection were reported (2 lymph nodes, 1 pleural, and 1 intestinal tuberculosis) in patients with initially negative TST and QFT-GIT. One patient had TST conversion and received antibiotic prophylaxis.

**Conclusion:** Our study showed that the screening and chemophrophaxis recommendations for LTBI improve the safety of biological treatments. However, because tuberculosis infection remains a potential complication, especially in endemic countries like Algeria, we suggest that annual screening of tuberculosis infection remains a potential complication, especially in endemic countries like Algeria, we suggest that annual screening of tuberculosis infection constitutes a fundamental pillar to prevent progression to active tuberculosis.

**AB1277** FACTORS ASSOCIATED WITH THE PRESENCE OF SPINAL EPIDURAL ABSCESSES IN SPONDYLODICTISIS

**Keywords:** Infection-related RMDs

**M. Ghali**, M. Arthau1, J. Mahbouba1, S. Zour1, I. Beja1, M. Touzi1, N. Bergoufi1, 1Fattouma Bourguiba Hospital, University of Monastir, Rheumatology, Monastir, Tunisia

**Background:** Spondylodiscitis (SD) is a severe infectious disease that affects the intervertebral disc and adjacent vertebral bodies, but may also extend to adjacent neural structures and cause a spinal epidural abscess (SEA). The clinical picture of SD is not very specific, but there are clinical and radiological differences that may point to an epidural extension.

**Objectives:** This study aimed to compare the clinical, biological, and radiological features of spondylodiscitis (SD) with and without spinal epidural abscess (SEA).

**Methods:** We conducted a retrospective monocentric study involving 90 cases of SD admitted between January 2009 and August 2022 at our rheumatology department. Clinical, laboratory, and radiological data of the patients were collected.

**Results:** Among the 90 patients with SD, 54 (60%) had a spinal epidural abscess. The mean age of the SEA group was 54 ± 13.52 years [23-82]. A female predominance was observed with a sex ratio (MRF) of 0.92. Thirty-seven patients or 66.5% had at least one comorbidity. Diabetes was the most frequent comorbidity (33.3%). All our patients had back pain on admission. Motor deficits were reported in 48% of the patients with the heaviness of the limbs. Fever was reported in 46.3% of cases. Physical examination revealed spinal stiffness in 23.3% of the patients, motor deficit in 37%, sharp osteotendinous reflexes in 18.5% of the patients, and abolished in 9.25%. The blood tests showed hyperleukocytosis in 18 patients (36%). An erythrocyte sedimentation rate greater (ESR) than 100 mm at the first hour was found in 17 patients. C-reactive protein (CRP) greater than 100mg/ml was found in 14 patients. 64.8% had pyogenic spondylodiscitis (mainly Staphylococcus aureus), 11.1% had brucella spondylodiscitis and 24.1% had tubercular spondylodiscitis. MRI confirmed the diagnosis of SEA in all cases. The lesions were located at the cervical level in 9.2% of cases, at the dorsal level in 24 %, and at the lumbar level in 48.1% of cases. The lesions were anterior in 64.8% of cases and anterolateral in 35.2% of cases. The involvement was unilateral in 63% of cases and extensive in 37% of cases. SEA was significantly more frequent in elderly patients (51.4% vs 48.6% p=0.038). The presence of a neurological deficit (80% vs 20% p=0.016), spinal cord compression (71.4% vs 26.6% p=0.04), and Multifocal involvement (82.6% vs 17.4% p=0.01) were significantly associated with SEA. There was no significant association between the types of germs and the presence of SEA.

**Conclusion:** In our study, a little more than half of patients with spondylodiscitis had a spinal epidural abscess. This entity was associated with advanced age, multifocal involvement, and neurological deficit. Therefore, a high index of suspicion is warranted when a patient presents these signs.

**AB1278** ANALYSIS OF THE DIFFERENCES BETWEEN TUBERCULOSIS PROPHYLAXIS REGIMENS IN BIOLOGIC CANDIDATE PATIENTS

**Keywords:** Descriptive studies, bDMARD, Safety

**J. Mendez Diaz**, R. J. Gil Velez, 1Seville, Rheumatology, Seville, Spain

**Background:** Patients with systemic rheumatic disease present alterations in the regulation of the immune system, which may contribute to the reactivation of latent tuberculosis. That risk increases significantly in patients receiving biological treatment (approximately 10%, especially with infliximab). The detection and treatment of latent tuberculosis infection constitutes a fundamental pillar to prevent the evolution of the pathology in patients receiving biological therapy protocolized in the US in the year 2000 by the FDA. Multiple studies have shown that diagnosis and treatment of latent tuberculosis infection is the best method of preventing progression to active tuberculosis.

To prevent that condition que have two types of treatment schemes:
- The short chemophrophaxis regimen, consisting of the administration of isoniazid together with rifampicin for 3 months
- The long chemophrophaxis regimen consisting of the administration of isoniazid for a period of 6 months without interruption.

**Objectives:** To analyze the efficacy, safety, and difference of treatment adherence between the two regimens of chemophrophaxis in patients who are candidates to start biologic therapy with latent tuberculosis.

**Methods:** Retrospective descriptive study of a cohort of patients who start biological therapy between January-December 2021, in the Rheumatology Service of Virgen del Rocío Hospital. Latent tuberculosis screening protocol was performed by Mantoux/Booster and IGRA tests.

**Results:** We included a total of 223 patients in the study who started treatment with biological therapy, during a period of 12 months, 125 (58.13%) of those where men, 90 patients (41.8%) were women with a mean age of 51.4 years. We started chemophrophaxis in 32 patients, of whom 15 (46.8%) received short therapy with
isoniazid/ rifampicin daily for 3 months, only 1 patient had to discontinue treatment due to hepatotoxicity. The rest of the patients 17 (53.2%) underwent long therapy for 6 months with isoniazid 300 mg every 24 hours, completing it in 54.2% of the cases. Only one patient had to discontinue due to persistent nausea.

**Conclusion:** After analyzing the data of our cohort of patients candidates to start biological therapy and after having performed the screening for latent tuberculosis infection (as can be seen in the Table 1 below) a homogeneous group (48.6% in the case of short regime) and (53.2% in the case of long regime) were treated with chemotherapy, without significant differences in terms of adverse effects or adherence in the two therapies performed. The most common cause of discontinuation in both groups was hypertransaminasaemia and nausea. No tuberculosis reactivation has occurred in any of the groups. Therefore, we conclude that short term therapy is as safe as long therapy and with similar patient adherence. However, long-term studies with a larger number of patients are required to evaluate the two treatment regimens.

**CLINICAL FEATURES AND FUNCTIONAL OUTCOME OF SURGICALLY TREATED TUBERCULOUS AND BRUCELLAR SPONDYLODICTIS IN TUNISIA**

**Keywords:** Infection-related RMDs, Motor function

**M. Ghani**1, N. El Fani2, S. Mtawaa1, M. Rouiss2, H. Sakly2, M. Gaddour3, W. Wanes2, S. Jenni2, 1University Hospital Ibn Jazar Kairouan, Physical Medicine and Rehabilitation, Kairouan, Tunisia; 2University Hospital Ibn Jazar Kairouan, Infectious Diseases, Kairouan, Tunisia; 3University Hospital Sahou, Physical Medicine and Rehabilitation, Sousse, Tunisia

**Background:** Tuberculous and brucellar spondylodiscitis are still a frequent condition in the Mediterranean countries [1]. Management of spondylodiscitis may require surgical procedures in case of spinal cord or root compression, bone destructions and deformities, unsuccessful medical treatment or large abscesses.

**Objectives:** To study characteristics and outcome of surgically treated tuberculous and brucellar spondylodiscitis.

**Methods:** Medical records of patients who presented to the physical therapy and rehabilitation ward or outpatient clinics after spine surgery for spondylodiscitis were retrospectively studied. The study included records from January 2010 to December 2022.

**Results:** Thirty-two patients were diagnosed with spondylodiscitis for which they underwent surgery. Mean age of diagnosis was 44.6 ± 10.4 years. The sex ratio was 1:1. Atypical presentations caused diagnosis to be delayed in 37.5% of the patients. Back pain was the most frequent symptom seen in 78.12% of the cases, radicular pain was seen in 46.7% of the cases, fever in 37.5% of the patients and abnormal gait in 68.7% of the cases. Tuberculosis caused 71.8% of cases and brucellar infection 28.1% of the cases. On biology, elevated inflammatory markers were noted in 68.7% of the cases. Intraoperative reactions for tuberculosis and brucellosis in the remaining cases, Cervical spine location was involved in 9.3% of cases, lumbar spine in 43.75% and dorsal spine in 34.3% of the cases. All patients have received antibiotics and spinal immobilization. Surgery was indicated in 71.8% of cases for spinal cord decompression and in 28.1% of the cases for voluminous abscesses. Anterior approach was used in 9.3% of the cases and posterior approach in 90.6% of cases. 37.5% of the patients benefited concomitantly with spinal fusion surgery. Postoperative complications were reported in 43.75% of the cases. They consisted in spinal instability in 71.4% of the cases, abcesses in 14.28% of the cases and the emergence of secondary articular localizations in 28.57% of the cases. 25% of the patients underwent a second surgery mainly to stabilize the spine. Before surgery, walking was impossible for 68.7% of the patients and 12 months after surgery only 37.5% of the patients couldn't walk.

**Conclusion:** Surgical treatment is as safe as long therapy and with similar patient adherence. However, long-term studies with a larger number of patients are required to evaluate the two treatment regimens.

**AB1280**

**PREVALENCE OF LEISHMANIASIS IN A SAMPLE OF PATIENTS TREATED WITH BIOLOGIC THERAPIES**

**Keywords:** Infection-related RMDs, Spondyloarthritis, bDMARD

**F. Monleon Acosta**1, G. Albaleadore Paredes1, A. Perez Gonzalez1, A. Uceda Galliano1, J. M. Andreu Ubero1, J. Moreno Morales1, F. J. Rodriguez Martinez1, V. Cogolillo Campillo1, E. Soriano Navarro1, M. R. Oliva Ruiz1, J. Leon Navarro1, F. Pedero Martinez2, R. Gimenez Andreu1, 1Hospital General Universitario Santa Lucía, Rheumatology, Cartagena, Spain

**Background:** Leishmaniasis is an infectious disease caused by an intracellular parasite of the genus Leishmania. According to the clinical expression, it can be identified: subclinical, cutaneous (CL) and visceral leishmaniasis (VL). The immune response triggered in this type of infections is based in the activation of the TH1 pathway, in which molecules such as TNF α and interleukins such as IL 12 and IL1 are involved [1,2]. In recent years, an increase in the incidence of opportunistic infectious diseases, such as leishmaniasis, has been observed in patients with rheumatological diseases under treatment with anti-TNFα drugs, such as Psoriatric Arthritis (PsA), Ankylosing Spondylitis (AS) or Rheumatoid Arthritis (RA) [1,3,4].

**Objectives:** Evaluate the prevalence of Leishmaniasis in a sample of patients in a hospital center in treatment with biologic therapies. As secondary objective, study the characteristics of the patients with Leishmaniasis.

**Methods:** It can be carried out an observational, descriptive, retrospective, and single-center study. The sample consisted of patients followed in a rheumatology department between January 1, 2022 and January 1, 2023, whose only inclusion criteria was to be in treatment with biologic therapies, including a total of 720 subjects, and, only five patients were found with the diagnosis of leishmaniasis.

**Results:** Five patients were found diagnosed with leishmaniasis in the 720 subjects on biological treatment included in the sample, which represents a prevalence of 0.69%. Three patients were male (60%) and two were female (30%). The mean age was 52.16 ± 10.38 years with a mean duration of rheumatic disease of 13.2 ± 7.8 years. All the subjects were diagnosed with spondylarthritides: 3 with AS (60%), 1 with PsA (20%) and another with spondyloarthritis associated with inflammatory intestinal
Background: Spinal epidural abscess (SEA) associated with infectious spondylodiscitis is a rare but serious pathology. It is a serious complication and difficult to diagnose at an early stage. With enough knowledge of risk factors and clinical features, it may be possible to reduce diagnostic delay and treatment failure.

Methods: We conducted a retrospective study of 54 cases of SEA associated with infectious spondylodiscitis over a period of 13 years [January 2009-April 2022] in the rheumatology department of the Fattouma Bourguiba University Hospital of Monastir. The diagnosis of SEA was retained in clinical, biological, and radiological data.

Results: The mean age was 54 ± 13.52 years [23-82]. A female predominance was observed with a sex ratio (M/F) of 0.92. Thirty-seven patients or 68.5% had at least one comorbidity. Diabetes was the most frequent comorbidity (33.3%). All our patients had back pain on admission. Motor deficits were reported in 48% of the patients with the heaviness of the limbs. Fever was reported in 46.3% of cases. Physical examination revealed spinal stiffness in 23.3% of the patients, motor deficit in 37%, sharp osteotendinous reflexes in 18.5% of the patients, and abolished in 9.25%. The blood tests showed hyperleukocytosis in 18 patients (36%). An erythrocyte sedimentation rate greater (ESR) than 100 mm at the first hour was found in 17 patients. C-reactive protein (CRP) greater than 100 mg/ml was found in 14 patients. 64.8% had pyogenic spondylodiscitis (mainly Staphylococcus aureus), 11.1% had brucella spondylodiscitis and 24.1% had tubercular spondylodiscitis. MRI confirmed the diagnosis of SEA in all cases. The lesions were located at the cervical level in 9.25% of cases, at the dorsal level in 24.07%, and at the lumbar level in 48.14% of cases. The lesions were anterior in 64.8% of cases and anterolateral in 35.2% of cases. The involvement was uni-focal in 63% of cases and extensive in 37% of cases. All our patients had received antibiotic therapy, initially probabilistic and then adapted to the bacteriological results. Immobilization of the spine was indicated in all our patients. Six patients had undergone decompressive surgery after failure of conservative treatment.

Conclusion: The classic clinical triad of the infectious SEA (back pain + fever + neurological deficit) is not specific enough, hence the delay in diagnosis which has a negative influence on the prognosis. MRI and bacteriological investigation confirms the diagnosis. Early surgical intervention with intravenous antibiotic therapy may be the best choice, especially in patients with progressive neurological deficits. Conservative treatment may be indicated for some patients.

Infection-related rheumatic diseases

**AB1282** CLINICAL AND RADIOLOGICAL FEATURES IN BRUCELLA SPONDYLODISCITIS: A DESCRIPTIVE STUDY

**Keywords:** Epidemiology, Pain

**Background:** Spondylodiscitis is an infectious inflammation that affects the vertebral, vertebral discs and adjacent structures. Vertebral involvement during brucellosis is considered not only as the most frequent localization but also as the most severe one.

**Objectives:** The aim of the present study was to describe the clinical and the magnetic resonance imaging features of brucella spondylodiscitis.

**Methods:** We conducted a retrospective study including 11 patients who have presented in the outpatient clinics of physical medicine and rehabilitation for spinal brucellosis with or without neurological disorders from 2016 to 2021. The diagnosis of brucellosis was based on clinical symptoms, MRI findings and isolation of brucella species in blood or tissue specimens and/or a positive Wright agglutination test.

**Results:** Eleven patients were included. The mean age was 52.5 years [33-74] (6 males and 5 female). The consumption of unpasteurized dairy was found in 4 patients. The main symptom was an inflammatory back pain and it was found in all patients. It was associated with radioluclpaathy in 8 cases. The other clinical symptoms were fever in 10 patients, sweats in 4 cases, weight loss in 4 cases and hepatomegaly in 1 patient. The median delay before diagnosis was 5.2 months [1-7]. On examination, we revealed tenderness on palpation in 10 cases and muscular weakness of lower limbs in 5 cases. Brucella agglutination test was ≥1/160 in all cases. Blood cultures were negative in all cases. Median erythrocyte sedimentation rate (ESR) and serum C-reactive protein level were 42 mm and 15 mg/dL respectively. Spondylodiscitis was located in the lumbar dorsal and cervical spine in respectively 8, 2 and 1 cases. The involvement of more than 2 vertebrae was found in 2 cases. The most affected level were the L4-L5 level in 3 cases followed by the T10-T11 level in 2 cases. Associated sacroiliitis was found in one patient. All MRI images of the affected vertebrae showed hypointense signal on T2 weighted image and hyper intense signal on T2 weighted image. Disc space narrowing was documented in 8 cases. Vertebral body osteolysis was found in 5 cases. Epidural collection was found in 3 cases with a size up to 5cm. Paravertebral and peri-vertebral abscesses were detected in 3 cases. Intradiscal abscesses were observed in 2 cases. Cord compression and involvement of root nerve were noted in respectively 5 and 3 cases. Biopsy was performed in 5 cases, but bacteriological examination was contributory to the diagnosis in 1 case. All patients received antibiotic treatment with a combination of two or three drugs, corticosteroids were prescribed in 5 patients and 4 patient underwent a surgical intervention.

**Conclusion:** Although not always specific, MRI findings associated with clinical symptoms may help establish the diagnosis of brucella spondylodiscitis even if bacteriological examinations are negatives [1].

**Background:** The COVID-19 pandemic has brought uncertainties to rheumatology practice, mainly related to the possibility of triggering disease activity after infection in immune mediated rheumatic diseases (IMRD). To date, there are few data in the literature specifically evaluating this issue.

**Objectives:** Evaluate the disease activity in IMRD patients after 6 months of the infection, compared to pre infection status.

**Methods:** ReumaCov Brasil is a longitudinal study performed at 35 study centers designed to follow-up IMRD patients for 6 months after clinical or laboratory COVID-19 diagnosis (cases), comparing with patients with IMRD who had not had the infection at the time of inclusion (controls). Demographic data, clinical characteristics, treatment, evolution of COVID-19 and disease activity status were collected using a Research Electronic Data Capture (REDCap) database on three consecutive visits (inclusion and 6 months). The analysis was carried out on the four diseases with the highest inclusion number in the study: systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), anklyosing spondylitis (AS) and psoriatic arthritis (PsA). In addition to specific disease activity assessment metrics, we used patient’s global assessment of disease activity (PGA), ranging from 0 to 10, at all visits, with 0 being no activity and 10 being intense activity. All conclusions were drawn considering the significance level of 5%. This study was registered at the Brazilian Registry of Clinical Trials—REBEC, RBR-33YTC.

**Results:** Between May 2020 and January 2021, 2032 patients were included in the registry, and of these, 1322 patients (721 cases and 601 controls) completed 6 months of follow-up, being 550 SLE (42.0%), 497 RA (37.6%) and 176 SpA (13.3%) and 99 (7.4%) PsA. Most patients were female (82.0%); the median age was 46.7 (13.8). Disease activity at the time of enrollment, according to the PGA, was similar between cases and controls, except for patients with RA and AS, where it was higher in controls. After the follow up time, no worsening of activity was observed in any of the diseases evaluated in the case group (Table 1). Despite this, worsening of disease symptoms after COVID-19 was reported by 23.3%, 24.6%, 25.0% and 25.8% of patients with SLE, RA, AS and PsA respectively, not related with disease activity.

**Conclusion:** In patients with IMRD, no worsening of disease activity was observed after COVID-19 in this cohort of Brazilian patients. Despite this, many patients noticed worsening of symptoms, possibly associated not with the triggering of the activity, but with the so-called long COVID syndrome.

**Table 1:** Comparison of disease activity, according to PGA, comparing disease activity status at inclusion and after 6 months of follow up, in cases and controls

AB1284 COMPARISON OF THE EFFECTS OF COVID-19 AND INFLUENZA VACCINATION ON RHEUMATIC DISEASES: ANALYSES OF PATIENT SURVEY DATA AFTER VACCINATION

Keywords: Patient reported outcomes, Real-world evidence, Vaccination/immunization

J. W. Kim1, H. A. Kim1, J. Y. Jung1, C. H. Suh1. 1 Ajou University School of Medicine, Rheumatology, Suwon, Korea, Rep. of (South Korea)

Background: As the coronavirus disease 2019 (COVID-19) pandemic continues worldwide, vaccination has been considered an essential medical care to protect people from the COVID-19 and end the pandemic. While vaccine development programs and reported epidemiological data are reassuring us, concerns about the risks and adverse events associated with vaccination in patients with rheumatic diseases.

Objectives: The purpose of this study was to analyze the incidence of adverse events and disease flares after vaccination against COVID-19 and influenza in patients with rheumatic diseases.

Methods: From November 2021 to March 2022, a survey was conducted on those who received COVID-19 and influenza vaccinations among patients with rheumatic diseases at Ajou University Hospital. The questionnaire contained questions about medical history, immunization history, type of injected vaccines, patient-reported adverse events and flare-up of the underlying disease after vaccination, and confirmed diagnosis of COVID-19 or influenza. Based on the results of the survey, we compared the incidence of vaccine-related adverse reactions between the COVID-19 and influenza vaccine and identified the factors affecting adverse events or disease flare.

Results: A total 601 valid questionnaires were obtained. The mean age of patients who participated in the survey was 49.6 years and 80.5% of female. Two hundred fifty-five participants (42.4%) received the complete course of primary vaccination. 342 (56.9%) participants completed the booster dose, and 132 (38.6%) of them received mixing vaccine. The frequency of adverse events (188 [52.2%], vs. 21 [5.8%]; p <0.001) and disease flare (58 [16.2%] vs. 5 [1.4%]; p<0.001) after the COVID-19 vaccination was significantly higher than that of the influenza vaccination. In the risk factor analysis, previous allergic reaction to other vaccination (OR 5.8%, CI 1.29-6.17; p=0.014) and disease flare (58 [16.2%] vs. 5 [1.4%]; p<0.001) after the vaccination dose 2 1.95, CI 1.07-3.70; p=0.034) was the only factors associated with the occurrence of adverse events. Female sex (OR 2.64, CI 1.29-6.17; p=0.014) was associated with adverse events. Female sex (OR 2.64, CI 1.29-6.17; p=0.014) was associated with adverse events.

Conclusion: In a real-world survey conducted on patients with rheumatic diseases, patient-reported adverse events and disease flare after the COVID-19 vaccine was significantly higher than that of the influenza vaccine.

AB1286 HUMORAL AND CELLULAR IMMUNOGENICITY INDUCED BY THIRD BOOSTER OF SARS-COV-2 VACCINES IN PATIENTS WITH RHEUMATIC MUSCULOSKELETAL DISEASES

Keywords: Vaccination/immunization, COVID

Y. Kondo1, M. Takeshita1, S. Saito1, J. Kikuchi1, H. Hanaoka1, K. Suzuki1, Y. Kaneko1. 1Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Amid the coronavirus disease 2019 (COVID-19) crisis, two messenger RNA (mRNA) vaccines against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) have benefited most people worldwide. While healthy people can acquire sufficient humoral immunity against COVID-19 even in the elderly by vaccination with three doses of vaccine, recent studies have shown that complex factors other than age, including the type of vaccines and immunosuppressive drugs, are associated with immunogenicity in patients with rheumatic musculoskeletal disease (RMD). Identifying factors that contribute to the vulnerability of those patients to acquire not only humoral but also cellular immunity to SARS-CoV-2 despite multiple vaccinations is crucial for establishing an appropriate booster vaccine strategy.

Objectives: To assess humoral and T cell immune responses after third dose of mRNA vaccines against SARS-CoV-2.

Methods: This prospective observational study included consecutive RMD patients treated with immunosuppressant who received three doses of mRNA vaccines including BNT162b2 and mRNA-1273. Blood samples were obtained 2-6 weeks after second and third dose of mRNA vaccines. We measured neutralizing antibody titers, which against the receptor-binding domain (RBD) of the spike protein of SARS-CoV-2 and seroconversion rates to evaluate the humoral responses. We also assessed T-cell immune responses using interferon releasing assay against SARS-CoV-2.

Results: A total of 586 patients with RMD treated with immunosuppressive treatments were enrolled. The mean age was 54 years, and 70% of the patients were female. Seroconversion rates and neutralizing antibody titers after third vaccination of SARS-CoV-2 were significantly higher compared to those after second vaccination (seroconversion rate, 94.5% vs 83.6%, p<0.001; titres of neutralizing antibody, 48.2 IU/mL vs 11.0 IU/mL, p<0.001, respectively). Interferon releasing assay after third vaccinations demonstrated that T cell reaction against SARS-CoV-2 was also increased from that of second vaccination (interferon for antigen 1, 1.119 vs 0.619, p=0.004; interferon for antigen 2, 1.726 vs 0.823, p=0.004). Humoral and cellular immunogenicity did not differ between the types of third vaccination including full dose of BNT162 and half dose of mRNA1273 (neutralizing antibody titers, 47.8±76.1 IU/mL vs 49.0±60.1 IU/mL, p=0.01; interferon for antigen 1, 1.120 vs 1.015, p=0.004, respectively). Attenuated humoral response to third vaccination was associated with BNT162b2 as second vaccination age (>60 years old), glucocorticoid (equivalent to prednisolone > 7.5 mg/day), and immunosuppressant use including mycophenolate, and rituximab. On another front, use of mycophenolate and abatacept or tacrolimus but not rituximab were identified as negative factors for T-cell reactions against SARS-CoV-2. Although 53 patients (9.0%) who had been immunised with third-vaccination contracted COVID-19 during Omicron pandemic phase, no one developed severe pulmonary disease that required corticosteroid therapy.

Conclusion: Our results demonstrated third mRNA vaccination booster of SARS-CoV-2 contributed to restore both humoral and cellular immunity in RMD patients with immunosuppressants. We also identified that both humeral and cellular immunity in RMD patients with immunosuppressants may require additional booster vaccination.

AB1287 FACTORS ASSOCIATED WITH ADHERENCE TO ANTI TNF-Α THERAPY DURING THE COVID-19 PANDEMIC IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, bDMARD, COVID

W. G. Rojas Zuleta1, M. Barbosa1, O. J. Felipe Diaz1, A. E. Pantoja Marquez1, J. Canizales1, C. Becerra-Arias1, J. H. Donado Gómez2, N. Duque Zapata1.

1Medicare SAS, Center for Immune-Mediated Diseases, Medellín, Colombia

Background: Rheumatoid Arthritis (RA) patients are effectively treated with anti-TNF-α therapy. However, pharmacological non-adherence limits the achievement of the therapeutic objective. This is a multifactorial behavior where factors such as the route of administration, frequency, tolerance, perception of improvement, polypharmacy and social factors are involved [1,2].

Objectives: To explore the factors associated with non-adherence to anti-TNF-α in RA patients during the COVID-19 pandemic.

Methods: This is a cohort of RA patients treated with anti TNF-α in Medicare SAS, a Colombian center for Immune-Mediated Diseases, between January to December 2021. The program implements strategies such as pharmacotherapeutic support, informed dispensing, phone calls, text messages and home care services to increase adherence. Adherence was defined as dispensing at least 80% of the prescribed in a month.

Results: A total of 586 patients were included, 85.8% (n=485) were women, median age 56 years (IQR: 49-65), disease evolution time 13.7 years (IQR: 7.7-20.8), 51% (n=288) had been in the program for more than 3 years, the median time in treatment with anti-TNF-α was 3 years (IQR: 1-3) and DAS28-28 CRP. HAQ and treatment were included as exposure variables. For continuous variables, median and interquartile range (IQR) were calculated. Adjusted Odds Ratio (AOR) with logistic regression were calculated, and a p-value <0.05 was considered as statistically significant.

Conclusion: Our results demonstrated third mRNA vaccination booster of SARS-CoV-2 contributed to restore both humoral and cellular immunity in RMD patients with immunosuppressants. We also identified that both humeral and cellular immunity in RMD patients with immunosuppressants may require additional booster vaccination.

LONG-TERM AND BOOSTER VACCINATION RESPONSES IN PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA

Keywords: Vaccination/immunization, Vasculitis, Disease-modifying drugs (DMARDs)

Y. Van Sleen1, K. van der Geest, A. Buismann1, M. Sandovic1, D. Van Baarle1, E. Brouwer1. 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2National Institute for Public Health and the Environment, Centre for Infectious Disease Control, Bilthoven, Netherlands; 3University Medical Center Groningen, Medical Microbiology and Infection Prevention, Groningen, Netherlands

Background: Vaccination remains essential in preventing morbidity of SARS-CoV-2 infections. We previously showed that >10mg/day prednisolone and methotrexate use were associated with reduced antibody concentrations four weeks after primary vaccination in patients with giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) [1].

Objectives: Here, we performed a follow-up study to measure the decay of antibody concentrations over time and the immunogenicity of SARS-CoV-2 booster vaccination.

Methods: GCA/PMR patients included in the primary vaccination (BNT162b2 or ChAdOx1) study were asked again to donate blood samples six months after primary vaccination (n=24) and one month after booster vaccination (n=46; BNT162b2 or mRNA1273). Data were compared to that of age-, sex-, and vaccine-matched controls (n=58 and n=42, respectively).

Results: Antibody concentrations decreased faster over time in GCA/PMR patients than in controls, but this decrease was not associated with treatment during primary vaccination. Post-booster antibody concentrations were comparable between patients and controls. Antibody concentrations post booster vaccination associated strongly with antibody concentrations post primary vaccination, but not with treatment during booster vaccination. However, the fold-change of post-booster vaccination showed a slight negative correlation with the post-primary vaccine antibodies.

Conclusion: These results indicate that patients with impaired vaccine responses after primary vaccination, have slightly stronger increases in humoral immunity after booster vaccination, but this is not enough to reach a similar protection. The decrease in humoral immunity, and subsequent increase after booster vaccination, is likely not impacted by prednisolone or methotrexate treatment. Rather, these treatments put the patients at an immunogenic disadvantage during primary SARS-CoV-2 vaccination, which is not fully repaired by a single booster vaccination. This longitudinal study in GCA/PMR patients stresses the importance of repeat booster vaccination for patients that used >10mg/day prednisolone or methotrexate during primary vaccination.

Background: Some individuals may have persistent symptoms after COVID-19, a new condition known as long COVID-19. However, these complaints can be misunderstood with disease activity in patients with immune-mediated rheumatic diseases (IMRD), especially fatigue and mental distress.

Objectives: To evaluate fatigue, depression, anxiety, and stress in IMRD patients after 6 months of COVID-19, compared with IMRD patients without COVID-19.

Methods: The ReumaCoV Brasil is a longitudinal study designed to follow-up IMRD patients for 6 months after COVID-19 diagnosis (cases) compared with IMRD patients no COVID-19 (controls). Clinical data, such as age, sex, comorbidities, as well as disease activity measurements and current treatment regarding IMRD, and COVID-19 outcomes were evaluated in all patients. The FACIT questionnaire (Functional Assessment of Chronic Illness Therapy) and the DASS 21 (Depression, Anxiety and Stress Scale - 21 Items) were applied at 6 months after COVID in both groups.

Results: A total of 606 IMRD patients were included, of whom 322 (53.1%) cases and 284 (46.9%) controls. Most patients were female (85.3%) with mean age 46.1 (13.0) years old. Specific disease activity were similar between cases and controls. There was a significant difference between FACIT scores and 3 domains of DASS-21 comparing cases and controls (Figure 1). The factors associated with FACIT were female gender, diabetes, obesity, no comorbidities, COVID manifestations (skin, joint pain, asthma, diarrhea, and dyspnea), and chronic oral corticosteroid use. DASS-21 Depression was associated with these same factors. Female gender, COVID manifestations as skin, joint pain, asthma, cough, dyspnea, and chronic oral corticosteroid use were associated with DASS-21 Anxiety. DASS-21 Stress was associated with female gender, asthma, and...

COVID-19, including respiratory and non-respiratory symptoms. Mental impairment was more associated with severity of those who did not have COVID-19, especially in women, regardless of disease classifications or specific IMRD.

Scores results and disease activity (patient’s global assessment - PGA), medication or specific IMRD.

A weak correlation between disease activity and FACIT was observed in rheumatoid arthritis (p=0.01; r² = 0.035) and ankylosing spondylitis (p=0.001; r² = 0.129). No other correlations were observed between the scores results and disease activity (patient’s global assessment - PGA), medications or specific IMRD.

Conclusion: Fatigue and mental changes such as depression, anxiety, and stress, occurred more frequently in IMRD patients who had COVID-19 than in those who did not have COVID-19, especially in women, regardless of disease activity score. Fatigue was more related to female gender, diabetes, obesity, and current joint pain. Mental impairment was more associated with severity of COVID-19, including respiratory and non-respiratory symptoms.

AB1290 IMPACT OF THE COVID-19 PANDEMIC ON SEPTIC ARTHRITIS MANAGEMENT

Keywords: Descriptive studies, COVID

S. Zemrani1, B. Amine1, I. EL Binoune1, S. Rostom1, R. Bahiri1. El Ayachi Hospital, Ibn Sina University Hospital, Department of Rheumatology A, Salé, Morocco

Background: Since 2020, the SARS-Cov-2 pandemic has disrupted the organization of healthcare systems worldwide. The objectives of this study were to assess the impact of this pandemic on septic arthritis management in a tertiary rheumatology department.

Methods: It was a single-center descriptive case-control study, which included patients hospitalized for septic arthritis between January 2018 and December 2021, whose diagnosis was retained after positive bacterial growth on culture according to presumptive criteria. Our patients were divided into two groups: G1: patients hospitalized during the COVID-19 pandemic (2020-2021), and G2: patients hospitalized during a similar period before the COVID-19 pandemic (2018-2019). In both groups, septic arthritis prevalence was calculated.

socio-demographic characteristics, risk factors, clinical, paraclinical, and therapeutic data were collected. COVID-19 status was reported in the G1.

Results: Twenty-two patients were enrolled: G1 (n = 15), G2 (n = 7). The prevalence of septic arthritis was 0.77% and 0.36% respectively. The median age was 54.6±12.25 and 54.29±21.81 years old respectively. Diabetes was found in 26, 7% in G1 and 28.6% in G2. During the pandemic, arthropathy and oral corticosteroids use were noted in 53.3% and 26.6% of patients versus 26.7% and 14.5% in G2. The diagnosis delay and the prior use of antibiotic therapy were more significant in G1: 14.09±7.30 d versus 6.53±25.19±29.26 d, and 46.7% versus 14.3%. The knee was the most common localization in both groups. Other joints were affected in G1: shoulder (n = 2), hip (n = 1), and sacroiliac (n = 1). The most common germ was staphylococcus aureus. The duration of hospitalization and duration of antibiotic therapy in G1 and G2 were 26.07±9.12 days versus 27.43±10.87 days and 50±10 days versus 48±25.79 days, respectively. Concerning COVID-19 status, 33.3% of patients in G1 have received their vaccination and no recent SARS-CoV2 infection was noted before hospitalization. During the pandemic, synovectomy was required in three patients, one of whom was also transferred to intensive care for septic shock (two of these three patients are being followed for rheumatoid arthritis, and one only has never been vaccinated against COVID-19).

Conclusion: During the COVID-19 pandemic, the prevalence of septic arthritis in our department was higher and the diagnosis was delayed. Duration of hospitalization was not impacted, however, atypical localizations, prior use of antibiotics, recourse to synovectomy, and transfer to intensive care were reported. These results suggest an inadequate and difficult access to healthcare services during the lockdown, as well as an impact of social distancing on the immune system [1, 2]: More studies are needed to confirm these findings.

EFFECTS OF DMARD TREATMENT ON SARS-COV-2 mRNA VACCINATION IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASE: A MATCHED, PROSPECTIVE COHORT STUDY

Keywords: Undifferentiated connective tissue disease, Vasculitis, COVID

Methods: Patients with CV were consecutively recruited at 11 Italian referral centers. CV patients showed an impaired vaccination immunogenicity compared to controls less frequent than those associated to COVID-19 (5% vs 14%, p=0.0012). CV patients showed an impaired vaccination immunogenicity compared to controls (p<0.05), as well an increased no-response rate after the booster.

Conclusion: CV patients have a higher risk to develop COVID-19, as well of more severe disease manifestations. Vaccines had a good safety profile in CV patients and of note, the vaccine-related side effects/disease flares were more severe disease manifestations. Vaccines had a good safety profile in CV patients and of note, the vaccine-related side effects/disease flares were significantly more frequent than those associated to COVID-19 (5% vs 14%, p<0.0012).

AB1293
OMICRON BREAKTHROUGH INFECTIONS AMONG RITUXIMAB AND NON-RITUXIMAB TREATED PATIENTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES: A MULTICENTER CONTROLLED STUDY

Keywords: Vaccination/immunization, COVID, bDMARD

V. Furer1,2, T. Eviatar1,2, D. Zisman1, H. Peleg1, D. Paran1,2, D. Levartovsky1, I. Kaufman1, A. Brody1, A. Polacheck1,2, J. Feld1, A. Haddad3, T. Gazit1, M. Elias1, H. Hijazi2, Y. Friedland1, O. Elkayam2,3, Tel Aviv Sourasky Medical Center, Rheumatology, Tel Aviv, Israel; 2Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv University, Tel Aviv, Israel; 3Carmel Medical Center, Rheumatology, Haifa, Israel; 4Hadassah Medical Center, Rheumatology, Jerusalem, Israel

Background: Little is known about the efficacy of booster COVID-19 vaccination in rituximab (RTX)-treated patients with autoimmune inflammatory rheumatic diseases (AIIRD).

Objectives: To estimate COVID-19 breakthrough infection rate in AIIRD patients treated with RTX compared to patients treated with other therapies and immunocompetent controls.

Methods: This observational multi-center study investigated COVID-19 infection rate and humoral response (anti-S1/S2 IgG) to the BNT162b2 mRNA vaccination in RTX-treated vs non-RTX treated AIIRD patients and immunocompetent controls for 18 months. To investigate the impact of the 3rd and 4th mRNA COVID-19 vaccine doses, a survival analysis was applied. Predictors of time-to-infection were analyzed using a multivariate Cox proportional hazard model.

Results: A total of 115 RTX-treated patients, 590 non-RTX-treated patients, and 121 immunocompetent controls were included in the analysis. AIIRD patients received more vaccine doses than controls, median 3 (range 2-4) vs 2 (2-4), respectively, p=0.0001; the rate of vaccination with the 3rd and 4th vaccine doses were 53.82% (n=402) vs 32.8% (n=29), respectively, p=0.0298. During the Omicron surge, time-to-infection from the last booster vaccination was shorter among AIIRD patients compared to controls, irrespective of the type of anti-rheumatic therapies (Figure 1A). In a Cox-regression model, a time interval between the RTX treatment and the last vaccination was associated with a lower risk to contract COVID-19, HR 0.988 (95% CI 0.997-1), p=0.0298 (Figure 1B). For each 30-day interval between the RTX treatment and the vaccination date, the risk to contract COVID-19 declined 0.941-fold. The risk to contract COVID-19 among RTX-treated patients within the last year after adjustment to age and S1/S2 serology was HR 2.077, 95% CI 1.056-4.086, p=0.0342. Reassuringly, no cases of severe COVID-19 or COVID-19-related mortality were reported during the Omicron surge.

Conclusion: This study found comparable rates of the Omicron infection rate among vaccinated AIIRD patients treated with RTX and other immunomodulators. Recent exposure to RTX predisposed to a breakthrough COVID-19 infection.
Background: Although adverse events of special interest (AESIs) following COVID-19 vaccination are considered to be rare, emerging reports have suggested that risk of AESIs may be higher in certain subgroups of individuals. The self-controlled case series method represents a useful approach to study adverse events whereby an individual’s risk is compared between a control pre-exposure period and a risk period following vaccine exposure.

Objectives: This study assessed whether COVID-19 vaccines were associated with an increase in AESIs and health care utilization [emergency department (ED) visits, hospitalizations, and rheumatologist visits] among adults with rheumatoid arthritis (RA).

Methods: We used the Ontario RA Database, a validated Canadian population-based cohort. Among adults with an RA diagnosis, we identified those who received at least one COVID-19 vaccine. AESIs included Bell’s Palsy, Idiopathic Thrombocytopenia, Acute Disseminated Encephalomyelitis, Myocarditis, Pericarditis, Guillain-Barre syndrome, Transverse Myelitis, Acute Myocardial Infarction, Anaphylaxis, Stroke, Deep Vein Thrombosis, Pulmonary Embolism, Narcolepsy, Appendicitis, and Disseminated Intravascular Coagulation. Secondary outcomes included all-cause ED visits, hospitalizations, and rheumatologist visits (a potential proxy for disease flares). The risk period was defined up to a maximum of 6 months after the first dose. Several series analyses were used to determine event rates in any 21-day risk period following vaccination compared to control periods. For rheumatologist visits, the risk window was confined to a 30-day risk period. Control periods were defined as 6 months prior to the first vaccination [with a 14-day washout period before first dose, as patients may wait until they are in relatively good health before receiving a vaccine]. Control periods in between doses start on Day 22 from the last dose and ends 14 days prior to the next dose; and a final control period commenced after the first dose risk period (up to a maximum of 6 months). Relative incidence (RI) rates were estimated (using Poisson Rejection) across risk windows relative to control periods. Relative incidence rate ratios (RIR) in each risk period vs control period were estimated using non-RA comparators (matched on sex, age, and region of residence).

Results: In total 123,466 RA patients and 493,864 comparators were included, 71% of individuals were female and the median age of RA patients was 65 years (IQR: 55-74), with a median RA duration of 9.3 years (IQR: 4.2-17.1). The majority received mRNA vaccines. Within RA, 8,727 (71%) received >3 doses, 89,583 (72.6%) received 3 doses, 23,652 (19.2%) received 2 doses, and 1,504 (1.2%) a single dose. Within the general population, 373,753 (75.7%) received 3 doses and only 7063 (1.6%) received >3 doses. Among RA individuals, relative to control periods, event rates were not significantly increased after the first dose in terms of AESIs (RI 1.05 95% CI 0.90-1.22) or ED visits (RI 0.97 95% CI 0.94-1.01). Hospitalizations were slightly lower for RA patient in post-vaccination versus control periods (RI 0.83 95% CI 0.78-0.88). Compared to control periods, rheumatologist visits slightly increased after the first dose (RI 1.08 95% CI 1.07-1.10), then decreased after doses 2-3, normalizing after dose 4. Relative to non-RA comparators, RA individuals had a higher relative incidence rate of AESIs after dose 2 (RI 1.05 (95%CI 1.05-1.06) but no differences in hospitalizations or ED visits. Potential limitations of our study include the possibility that individuals avoided additional doses if they had an adverse event after the first dose, and that access to rheumatologists likely changed over time.

Conclusion: In this self-controlled case series, we did not detect a significant increase in AESIs or health care use when comparing pre-vaccine to post-vaccine periods in RA.

</table>
BACKGROUND: The outbreak of COVID-19 pandemic caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has quickly become a global health emergency with over 180 million confirmed cases and over 3.8 million deaths worldwide. Over the last two years, several registries and cohort studies have collected data about the course and possible predictors of outcomes of COVID-19 infection in patients with inflammatory rheumatic diseases (IRDs). However, whether IRMD patients perform differently from the general population is not clear, as most studies miss an adequate control group [1].

OBJECTIVES: To evaluate the association between the ABO and Rh antigens and the clinical manifestations and outcome of coronavirus disease (COVID-19) in patients with IRMD compared to the general population.

METHODS: This is a case-control study of patients with and without an IRMD affected by COVID-19. Patients were selected in South Tyrol health trust, Italy, retrieving data from a single central database. We included patients ≥18 years affected by COVID-19. Patients were selected in South Tyrol health trust, Italy, during the study period, a whole population screening was conducted in South Tyrol with central registration of all COVID-19 cases. Criteria for inclusion in the study: hospitalization, severe course (ICU, mechanical ventilation/ECMO) and mortality.

RESULTS: The study population consisted of 201 IRMD patients (mean age 60.4 years ± 17.3; 60.7% of females) and 360 controls (mean age 59.8 years ± 5.6; 64.7 years ± 14.9; 65.2 years ± 14.9; p = 0.49). The rates of COVID-19 related hospitalization (12.4% vs. 10.6%, p = 0.49), severe course (40.0% vs. 44.7%, p = 0.80) and mortality (3.5% vs. 4.2%, p = 0.82) in IRMD and control group respectively, did not show significant differences. Among hospitalized patients, mechanical ventilation was significantly more common among IRMD than control group [(n = 20 (20.0%) vs. n = 11 (2.6%), p = 0.035). Conclusion: Our study indicates similar rates of admission, severe course and mortality among IRMD and non-IRMD patients affected by COVID-19. However, IRMD patients displayed a higher number of comorbidities and were more frequently treated with glucocorticoids. Among hospitalized patients, mechanical ventilation was more frequently required among IRMD group.

THE INCIDENCE OF POST-COVID SYNDROME IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Mental health, Comorbidities, COVID

N. Tlietbek1, N. Shamsudinova2, V. Mukhamadieva3, D. Abdulganieva3, R. Abdotkipov2, N. Saplasnina1. 1Institute of Gastroenterology, Hepatology and Metabolism ‘Interna Clinic’; Rheumatology, Rheumatmy, Almaty; Kazakhstan; 2Kazan State Medical University, Internal Diseases, Kazan, Russian Federation; 3Kazan State Medical University, Internal Diseases, Kazan, Russian Federation; 4Republic Clinical Hospital, rheumatology, Kazan, Russian Federation

Background: Post-COVID Syndrome occurs in people after coronavirus infection with confirmed SARS-CoV-2 infection or in people with suspected coronavirus infection, usually 3 months after the onset of COVID-19, with symptoms that last at least 2 months and cannot be explained by an alternative diagnosis. Although post-COVID manifestations have been previously studied in the general population, they have not been studied in a specific population of patients with inflammatory rheumatic diseases. The list of post-covid syndromes includes arthralgia, arthritis, myalgia, vasculitis with damage to vessels of various sizes, antiphospholipid syndrome, as well as a number of immunological markers that are characteristic of a wide range of rheumatic diseases [1]

Objectives: to study the incidence of post-COVID syndrome in patients with rheumatic diseases (RD).

Methods: from March 2020 to September 2022, 271 patients with RD who had a novel coronavirus infection (NCl) with a confirmed SARS-CoV-2 PCR result and/or X-ray computed tomography (CT) of the lungs were under observation. Among the patients, 68 (25%) were males, 203 (75%) were females. The median age was 56 [46.65] years. The average duration of RD at the time of NCI was 10.9 [5.15] years. The distribution of patients was as follows: rheumatoid arthritis (RA) - 186 people (68.6%), ankylosing spondylitis (AS) - 46 people (16.9%), psoriatic arthritis (PsA) - 38 people (14%). The results of clinical and laboratory examinations for RD were recorded in 17.6% of patients. RD stage of remission before NCI was in 9 (3.3%), low degree of activity 58 (21.4%), moderate degree of activity 14 (5.6%), high degree of activity 21 (7.7%), 43 (15.8%) people - no data. Moderate and high degrees of RD activity before NCI increased the influence in joint pain (p = 0.023), unstable course of diabetes mellitus (p = 0.032) by 3 after recovery.

Conclusion: In patients with RD, post-covid manifestations persist, primarily due to arthritic (91.1%) and general constitutional symptoms (85.3%) from 3 to 6 months after NCI. Moderate and high degrees of RD activity before NCI significantly affect the severity of the articular syndrome and the unstable course of diabetes mellitus. Therapy for post-COVID syndrome in patients with rheumatic diseases should be personalized and determined by the characteristics of this patient's condition.

Cyclophosphamide Therapy During the COVID-19 Pandemic

Keywords: Vasculitis, COVID, Best practices

B. Bink1, C. S. Ogur2, A. Yalçınkaya Karbanur2, A. E. Yucei2, 1Baskent University Ankara Hospital, Rheumatology, Ankara, Turkey; 2Baskent University Ankara Hospital, Rheumatology, Ankara, Turkey

Background: During the Coronavirus disease (COVID-19) pandemic, one of the biggest concerns of rheumatologists and rheumatology patients has been whether the disease will increase with immunosuppressive therapy. Some drugs have been reported to be associated with adverse Covid-19 outcomes [1,2]. Cyclophosphamide (CYC) is a drug that has been used in rheumatology practice for many years. There is not enough data in the literature on the frequency or consequences of COVID-19 while receiving CYC therapy.

Objectives: The aim of this study is to examine the frequency and outcomes of Covid19 in patients who received CYC therapy during the Covid19 pandemic.

Methods: The files of patients who received CYC therapy protocol between March 2020 and March 2022 at Baskent University Faculty of Medicine Ankara Hospital, Rheumatology outpatient clinic were retrospectively reviewed. In our clinic, CYC therapy is administered as an intravenous treatment protocol of 500 mg three times every 10 days, then 500 mg every two weeks. Although the cumulative dose varies depending on the disease and the patient, it is usually planned to be at least three gram. The diagnosis of Covid 19 was made in the patients with clinically compatible radiology and SARS-CoV-2 PCR test results.

Results: A total of 36 patients received CYC during the specified period. CYC indications were ANCA-associated vasculitis in 12 patients, interstitial lung disease

RHEUMATOLOGICAL MANIFESTATIONS IN A COHORT OF LONG-COVID PATIENTS: SEARCHING FOR POSSIBLE BIOMARKERS

Keywords: COVID

A. Paglicioni1, P. Rizzuti2, V. Varriano1, C. Di Mario3, S. Perniola1, R. Calvani4, A. Picca5, F. Landi6, M. Tosato7, B. Tolusso6, E. Gremese1,2. 1Fondazione Policlinico Universitario A.Gemelli, IRCCS, Division of Clinical Immunology, Rome, Italy; 2Università Cattolica del Sacro Cuore, Rome, Italy; 3Fondazione Policlinico Universitario A. Gemelli IRCCS, Immunology Core Facility, Gemelli Science Technological Park, GSteP, Rome, Italy; 4Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

Background: Approximately 10-20% of patients recovered from SARS-CoV-2 infection develop persistent heterogeneous symptoms and autoantibody positivity suggesting persistence of low-grade inflammation.

Objectives: To assess the prevalence of rheumatological manifestations in a cohort of convalescent SARS-CoV-2 patients and to find possible biomarkers.

Methods: Two-hundred and seventy-nine convalescent SARS-CoV-2 patients underwent multidisciplinary assessment in our Post-Covid19 outpatient service (119 females and 160 males; mean age±SD, 55.87±0.88). For each patient, demographic, clinical and immunological data were collected. Long-COVID symptoms were assessed by a questionnaire submitted to patients; IL-1β, IL-6, TNFα and IL-8 plasma levels were assessed by ELISA (ELLA).

Results: 221 (80.7%) convalescent SARS-CoV-2 patients presented at least one Long-COVID symptom, mostly fatigue (52.6%), dyspnea (40.7%), arthralgia (28%) and myalgia (28%). The prevalence of symptoms was significantly higher in females (p = 0.009) and in patients 60-75 years old (p = 0.02) and the presence of symptoms was independent from disease severity and care setting during acute infection. Assessing cytokines plasma levels, we observed that patients presenting Long-COVID arthralgia showed higher IL-6 plasma level (p = 0.006). Moreover, the common rheumatological symptoms (arthritis and arthralgia, in Long-COVID patients were significantly correlated with female sex (p = 0.002), at least one autoantibody positivity (p = 0.003) and IL-6 plasma level higher than 2.1 pg/ml (p = 0.009).

Conclusion: Rheumatological symptoms are frequent in Long-Covid patients and this study suggests that they are underpinned by persistently dysregulated inflammatory pathways after the acute infection.

associated with undifferentiated connective tissue disease in 5 patients, SLE in 5 patients, sclerodermia in 4 patients, Sjögren's syndrome in 4 patients, Behcet's disease in 1 patient, vasculitis associated with sarcoidosis in 1 patient, rheumatoid vasculitis in 1 patient, leucocytoclastic vasculitis in 1 patient, polymyalgia rheumatica in 1 patient and Takayasu disease in 1 patient. The median age (q1-q3) was 62 (52-68) years. Covid19 infection was detected in only 3 patients (8%) during the CYC therapy protocol. The median cumulative CYC dose for these patients was 3.5g. One out of 3 patient was hospitalized for Covid 19 pneumonia. There was no death due to Covid19.

Conclusion: In this study, it has been shown that CYC therapy was safe during the Covid19 pandemic period.

AB1302 IMPACT OF THE COVID-19 PANDEMIC ON TREATMENT ADHERENCE AND THE ACTIVITY OF RHEUMATOID ARTHRITIS

Keywords: Outcome measures, Rheumatoid Arthritis, COVID

M. Ghali1, M. Arthau2, J. Mahbouba1, S. Zour1, I. Bejia1, M. Touzi1, N. Bergaoui1. 1Fattouma Bourguiba Hospital, University of Monastir, Rheumatology, Monastir, Tunisia

Background: During the COVID-19 pandemic, repetitive lockdowns and fear of SARS-CoV-2 infection compromised the treatment adherence of immunocompromised patients, particularly those with rheumatoid arthritis (RA). These therapeutic changes have certainly affected RA patients. To assess the treatment adherence among RA patients during COVID-19 and the impact on disease activity.

Methods: We conducted a cross-sectional study involving patients with RA who met the ACR/EULAR 2010 criteria. To evaluate therapeutic adherence we used 2 validated scores: the Compliance Questionnaire of Rheumatology (CQR-5) and the Morisky Medication Adherence Scale-4 (MMAS-4). For each patient, we compared the DAS28 score, visual analog pain scale (VAS), sedimentation rate (ESR), and C-reactive protein (CRP) before and during the pandemic.

RESULTS: We included 190 patients, of whom 155 were women and 35 were men. The average age was 55 ± 13.16 years. During the COVID-19 pandemic, the mean DAS28 score was 4.17 ± 1.03. Poor adherence was observed in 33% of cases according to MMAS-4 and in 34.5% of cases according to CQR-5. Patients who missed at least one consultation appointment accounted for 65% of cases. Teleconsultation was used in 17% of cases. Non-renewal of the prescription was the most frequent reason for therapeutic non-adherence (47%). Sixty patients (31.7%) had contracted COVID-19 and the minor form was the most frequent (86% of cases). Poor therapeutic adherence assessed by the CQR-5 was significantly associated with: rural origin (p<0.001), low intellectual level (p=0.006), missed consultations (p<0.001), non-use of teleconsultation (p<0.001), and high disease activity (p<0.001). Factors associated with poor adherence according to MMAS-4 were: advanced age (p=0.01), rural origin (p=0.007), low intellectual level (p=0.004), comorbidities (p=0.003), failed consultations (p=0.001), non-use of teleconsultation (p=0.001) and SARS-CoV-2 infection (p=0.043). The cross-sectional study showed that compared to pre-pandemic values: pain (p=0.01), ESR (p=0.008), CRP (p=0.04), and DAS-28 (p=0.001) were significantly higher during the pandemic. Increased disease activity was significantly associated with the presence of comorbidities (p=0.018), low therapeutic adherence (p<0.001), and missed consultations (p=0.014). There was no significant association between SARS-CoV-2 infection and disease activity.

Conclusion: Treatment adherence of RA patients during the COVID-19 era was challenged. Elderly, illiterate, and rural patients were the most likely to miss their appointments and stop their treatments. These therapeutic changes were responsible for an increase in RA activity. Hence the importance of insisting on good adherence and close medical follow-up.

AB1303 AVASCULAR NECROSIS OF THE FEMORAL HEAD – NOT TO BE OVERLOOKED SEQUELA AFTER COVID 19 INFECTION

Keywords: Bone diseases, COVID

P. Todorov1, L. Mekenyan2, A. Batalov2. 1Medical University of Plovdiv; 2Yambol University Hospital, Propaedeutic of Internal Disease and Clinic of Rheumatology, Plovdiv, Bulgaria

Background: COVID 19 infection could lead to different sequelae in survivors, known as post-COVID or long COVID 19 syndromes. Some of them are thought to be due to the thrombophytic changes observed in COVID 19 infection, but some are thought to be caused by the administered (especially high dose) corticosteroid treatment. Avascular necrosis of the femoral head (AVNFH) is a multifactorial disease which leads to compromised vascular supply, ischemia and finally necrosis of the femoral head. As corticosteroids usage and thrombophytic states are among the main known risk factors for the development AVNFH [1], it could be presumed that the frequency of this disease will increase with the COVID 19 pandemic. The exact corticosteroid dose needed for the development of AVNFH is not clear, but it has been stated that a higher daily dose and a larger total cumulative dose increase substantially the risk for the development of osteonecrosis [2].

Objectives: To describe in detail the characteristics of AVNFH diagnosed in patients after COVID 19 infection.

Methods: The study was done in a tertiary university rheumatological clinic. Data was extracted from the records of patients who have been referred to the clinic because of hip pain between June and December 2022. Inclusion criteria were: - a new onset of uni-or bilateral hip pain that started after a documented COVID 19 infection; and an MRI study of the hip joints showing osteonecrosis of one or both femoral heads. Exclusion criteria were: the presence of hip pain prior to the COVID 19 infection, anamnesis of traumatic injuries of the hips or pelvis, personal history of hypercoagulable states.

Results: Nine patients (4 women and 5 men) with an average age 59.1 years (range 38-72) were included in the study. Four patients had been diagnosed with bilateral and five – with unilateral AVNFH, thus 13 hip joints were analysed in total (6 left and 5 right sided). The mean time lapse between the COVID 19 infection and the start of the hip pain was 26.2 weeks (range 10-48 weeks). All patients had limited and painful movement in their symptomatic hip(s), especially internal rotation and four of the patients had also elevated CRP levels (mean 11.7 mg/L). The stage of the AVNFH was evaluated according to the Ficat-Arlet classification (0-IV stage). In four hips the AVNFH was stage I, five hips were classified as stage II and the remaining four joints - as stage III. All symptomatic hip joints exhibited effusion/synovitis on both ultrasound examination and the corresponding MRI scan. It should be noted that the presence of hip effusion was found to be related with a worse prognosis in AVNFH [1]. In three patients the amount of the effusion required arthrocentesis and fluid aspiration. The analysis of the joint fluid was consistent with a degenerative disease (i.e., low WBC count with predominant lymphocytes and no crystals). All patients included in our study had received corticosteroids during their COVID19 infection, while 6 of the patients had also been hospitalized due to more severe disease. According to the patients’ documentation, the mean cumulative dose of the received corticosteroids was 936.2mg prednisolone equivalent per patient (range 187-2272 mg).

Conclusion: AVNFH must not be overlooked in a new onset hip pain after COVID 19 infection. Our results show that corticosteroids administered during the infection and the presence of hip joint effusion on ultrasound are especially suggestive for the development of osteonecrosis, as they were registered in all of our patients. The presence of these two factors necessitates patient referral for an MRI scan of the hips, in order that AVNFH be detected timely.

AB1304 CHRONIC CHILBLAIN-LIKE LESIONS ASSOCIATED WITH THE COVID-19 PANDEMIC

Keywords: Imaging, COVID, Skin
**Objectives:** We report the features of chronic chilblain-like digital lesions newly present since the start of the COVID-19 pandemic. Comparison with primary perniosis and acrocyanosis, reveals a unique phenotype which appears to be a long-covid phenomenon.

**Methods:** The case records of 26 patients with new onset persistent chilblain-like lesions presenting to the Rheumatology service of St George's University Hospital, London between Autumn 2020 and Spring 2022 were reviewed. Demographic and clinical features, serology, imaging, treatment response and outcome up to Summer 2022 were collated retrospectively.

**Results:** Chilblain-like lesions first occurred between September and March; 2019/2020 6 cases, 2020/2021 18 cases and 2021/2022 2 cases. Mean age 35.4 (17-60) years, female 88%, white 65%, all non-smokers. Median body mass index (BMI) 20.2, range 17.0 – 33.2. BMI underweight (<18.5) in 27%. All cases reported new red-purple-blue colour changes of the fingers, some with pain, swelling and pruritus, affecting both hands in 12, one hand in 6, and both hands and feet in 8 cases. There was a past history of cold sensitivity or primary Raynaud’s in 54%. Covid was confirmed in 3 cases, 2 – 8 months prior to onset of chilblain-like symptoms. Possible covid, unconfirmed, was suspected in 5 cases, 1 – 11 months earlier. Affected digits appeared diffusely erythro-cyanotic in 81%, with blotchy discrete macules, papules, purplish lesions in 6%, some with both features. Involvement was asymmetric in 54%, thumbs spared in 69%. Complement was low in 50% (8/16), ANA positive in 26% (6/23). MRI of hands showed phalangeal bone marrow oedema in keeping with osteitis in 4/7 cases, and no synovial hyperplasia or enthesial abnormalities. More severe signs and symptoms were associated with low BMI, low CS/4 and a past history of cold sensitivity or Raynauds. Cold avoidance strategies were sufficient for 58%. Pain prompted a trial of NSAIDs, aspirin, nitrates, calcium channel blockers, hydroxychloroquine, oral or topical corticosteroid or topical tacrolimus in 42%. In general, these were at best minimally effective or not tolerated. Four severe cases received sildenafil or tadalafil, effective in 2 cases. In 27% complete remission occurred during the first summer season after symptoms commenced, median duration 6 (range 2 – 10) months. In the remaining 19 cases, chilblain-like symptoms returned or worsened in the subsequent second winter period, with 6/19 entering remission the following summer. For the remaining 13 persistent cases the total duration of symptoms spans more than a year, and in four cases more than 2 years.

**Conclusion:** This series illustrates a distinct chronic chilblain-like condition. Features similar to primary perniosis include female predominance, middle age, pruritic painful blotchy lesions, asymmetry and low BMI. Features in keeping with acrocyanosis include chronicity, extensive diffuse erythro-cyanotic discoloration, relative improvement in warm weather and lack of association with smoking.

**RHEUMATOID ARTHRITIS FLARE FOLLOWING COVID-19 VACCINATION IN MALAYSIAN POPULATION AND ITS ASSOCIATED RISK FACTORS**

**Keywords:** Vaccination/immunization, Rheumatoid arthritis, COVID

N. A. Zakaria1, 2, L. Mohd Isa1, L. Mohamend0, B. H. Ng1, T. Chou Luan1, F. N. Sulaiman1, S. Ramasamy1, W. R. Wan Musa1, N. S. Shahril2, 3.

1International Islamic University Malaysia, Kulliyyah of Medicine, Pahang, Malaysia; 2Hospital Putrajaya, Rheumatology Unit, Putrajaya, Malaysia; 3Hospital Putrajaya, Clinical Research Centre, Putrajaya, Malaysia

**Background:** Flare of Rheumatoid Arthritis (RA) following COVID-19 vaccination has been reported with a low occurrence observed in those patients with disease remission. However, no local data is available in our multi-ethnic Malaysian population.

**Objectives:** To evaluate the prevalence of RA flare in Malaysian patients following COVID-19 vaccination and its associated risk factors.

**Methods:** This was a cross-sectional study assessing RA flare based on rheumatology clinic in Hospital Putrajaya from May to July 2022 who completed the primary COVID-19 vaccination under the Malaysian National Vaccination Programme were recruited. Demographic data, disease parameters including serology for rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA), cessation of disease modifying anti-rheumatic drugs (DMARDs) around vaccination, type of vaccines and adverse events were examined using descriptive and univariate analyses.

**Results:** Majority (93%) of RA patients enrolled were female with a mean age of 56 years (standard deviation, SD 12.2) and mean disease duration was 12.8 years (SD 7.7). More than half had seropositive (66% RF, 63% ACPA) with 17.4% had double seropositivity (RF and ACPA positive). All patients received DMARDs with the majority (71%) were on methotrexate (MTX), 21.5% were on leflunomide, 17.7% on other DMARDs, with a small proportion (14%) of patients were receiving prednisolone. Only 4.8% of patients were on biologics or targeted synthetic disease modifying anti-rheumatic drugs. Half of the patients were in remission prior to vaccination. 62% of patients received Pfizer-BioNTech vaccine as the primary vaccine, followed by Sinovac-CoronaVac (24.6%) and Oxford-AstraZeneca (13.4%) vaccines. A booster dose had been administered to 80% of patients, of which 88.7% was Pfizer-BioNTech vaccine. MTX therapy were discontinued in 39.4% of patients (n=52) post-vaccination for a week duration. The prevalence of RA flare was only 12.9% (n=24) in which 14 were self-reported and 10 were physician-reported flares (4 severe flare, 6 mild-moderate flare). Flare rates were higher during the first and second dose of vaccination with 29.2% respectively, and only 12.5% were reported after booster vaccination. Common vaccine adverse effects were fever (16.8%), myalgia (8.6%) and arthralgia (6.4%). There were no significant differences in the occurrence of flare post-vaccination between age, gender, disease activity prior to vaccination, types of vaccine, usage of MTX and prednisolone, and discontinuation of MTX post-vaccination. Although seropositivity did not exhibit statistically significant flare rate post-vaccination, sub-analysis revealed four times higher rate of flare in those who have double positivity compared to seronegative RA patients (12% vs 4%).

**Conclusion:** Prevalence of RA flare post-COVID-19 vaccination in Malaysian RA population is low. No significant associated risk factors were identified although double seropositivity appeared to have higher number of flares.

**HOW DOES COVID-19 VACCINATION AFFECT DISEASE ACTIVITY AND SAFETY IN SECUKINUMAB TREATED PATIENTS WITH AXIAL SpondyloOaRTHRITIS? REAL WORLD DATA FROM THE GERMAN AQUILA STUDY**

**Keywords:** Spondyloarthritis, Vaccination/immunization, COVID

J. Brand-Juergens1, K. Gente2, P. Klasner3, P. Dörlich4, U. Kiltz4

1Rheumatologie, Scharlappenpraxis, Berlin, Germany; 2Universitätsklinikum Heidelberg, Medizinische Abteilung V - Rheumatologie, Heidelberg, Germany; 3Ambulantes Rheumazentrum, Medizinisches Versorgungszentrum, Erfurt, Germany; 4Novartis, Novartis Pharma GmbH, Nürnberg, Germany

**Background:** Patients (pts) suffering from a chronic rheumatic condition, such as axial spondyloarthritis (axSpA), and receiving immunomodulatory treatment during the COVID-19 pandemic have been shown to be at higher risk of severe disease outcomes. The German non-interventional study AQUILA provides real-world data in pts with axSpA under secukinumab (SEC) treatment and the influence of COVID-19 vaccination on disease activity (SDASAI) and safety (SAsAEs).

**Objectives:** The aim of this interim analysis was to describe selected baseline (BL) characteristics and the effect of vaccination on DA and safety in axSpA pts.

**Methods:** AQUILA is an ongoing, multi-center study including up to 3000 pts with axSpA or psoriatic arthritis. This analysis focuses on axSpA pts included from May 2019 to Oct 2022 and their vaccination status (no vs ≥1 vaccination) for study time points from BL up to week (w) 52 according to clinical routine. DA was assessed by validated Disease Activity Score for Spondyloarthritis Patients (DASAI) questionnaire and safety by documented number of (serious) adverse events (SAsAEs). Only pts with available BL DASAI were considered and characterized by selected BL parameters, such as demographics and global functioning.
(measured by assessment of spondyloarthritis international society health index, ASAS-HI). Real-world data were analyzed as observed. Vaccination was performed according to prescription and took place at any timepoint throughout observational period of 52 weeks.

**Results:** Totally, 273 axSpA pts were included. For 56 pts ≥1 vaccination during study was documented: number of vaccinations (75% mRNA-based): n1 = 26 pts, n2 = 20 pts, n3 = 9 pts, n4 = 1 pt. Both pts groups were comparable regarding the BL characteristics, such as age, smoking status, BMI, physician global assessment (PhGA), and ASAS-HI. Pts with no vaccination received less pretreatments with biologics (59.9% vs 76.8%) and were less affected by comorbidities and extra-articular manifestations (EAMs) than pts with ≥1 vaccination (e.g. depression 6.5% vs 12.5%) (Table 1). There was no difference in mean BASDAI between pts with no and with ≥1 vaccination throughout observational period of 52 weeks (except for a higher mean value in pts with ≥1 vaccination at w16). In both groups, slight improvement was observed in mean BASDAI over time (no vaccination: 5.1 to 3.8, ≥1 vaccination: 5.4 to 3.7) (Figure 1). However, due to different numbers of pts with no and ≥1 vaccination, data must be interpreted carefully. The number of pts with AEs and AEs leading to interruption of SEC was lower in pts with no vs pts with ≥1 vaccination (62.7% vs 75.0% and 13.4% vs 17.9%, respectively) (Table 1), with no new and unexpected safety signals in each group.

**Conclusion:** In a real-world setting, no differences in DA between axSpA pts with and without vaccination were observed. DA improved similarly up to w62 in both patient groups with similar BL characteristics, though more comorbidities/ EAMs were documented in pts with ≥1 vaccination. There were no new safety signals in both groups. Further progress of the AQUILA study will reveal whether both patient groups with similar BL characteristics, though more comorbidities/ and unexpected safety signals in each group.

POLYMYALGIA RHEUMATICA FOLLOWING SARSCOV-2 VACCINATION: A SINGLE CENTER COHORT STUDY

Keywords: Descriptive studies, Vasculitis, Vaccination/immunization

L. Lally1, A. Bloostein1, D. Jannat-Khan1, R. Spiera2, 1Hospital for Special Surgery, Rheumatology, New York, United States of America

Background: Polymyalgia rheumatica (PMR) incidence peaks in individuals between 70 and 80 years of age; this same group is also at increased risk of complications and mortality related to COVID-19 infection. Vaccination against SARS-CoV-2 is an essential tool in combating COVID-19. There have been several case reports of PMR following vaccination with mRNA SARS-CoV-2 vaccines.

Objectives: The aim of this study was to identify patients with temporal association between mRNA SARS-CoV-2 vaccination and PMR onset and to compare characteristics and disease course to those with new onset PMR without temporal association with SARS CoV-2 vaccine exposure.

Methods: We conducted a retrospective chart review of all newly diagnosed PMR patients in a single center. Using ICD-10 codes, our EMR was queried to identify patients with newly diagnosed PMR beginning in December 2020, when the first SARS-CoV-2 vaccines were available in the US. Charts were reviewed for demographic information, disease characteristics and vaccination details. Patients who developed onset of PMR symptoms within 6 weeks after vaccination were compared to those whose PMR symptoms occurred without temporal association to vaccination. When available data of 12 months following diagnosis was collected.

Results: Eighty patients with newly diagnosed PMR between 12/1/2020 and 12/31/2021 were identified. There were 60 patients with new PMR without a temporal association to vaccination who were compared to 20 patients who developed PMR symptoms within 6 weeks of vaccination. Baseline demographics did not differ between the two groups. In the 20 cases with PMR onset after vaccination, symptoms developed a mean 38 days (IQR 19.5-48) after first dose of vaccine and 115 days (IQR 122) after second dose. There were no differences in baseline demographics, glucocorticoid dosages or relapse rates at 6 and 12 months following diagnosis. There was no association between vaccine manufacturer and PMR onset after vaccination (Table 1).

Conclusion: In this cohort, patients with onset of PMR within 6 weeks following mRNA vaccination against SARS-CoV-2 were similar to patients with de novo PMR at diagnosis, with no significant differences in disease course over the first 12 months. This does not support the notion that PMR following vaccination is a unique disease entity. The recognition of new PMR onset following SARS CoV-2 vaccine may be coincidental in this common inflammatory disorder in a population with high rates of vaccine exposure.

CLINICAL CHARACTERISTICS OF NEW-ONSET IDIOPATHIC INFLAMMATORY MYOPATHIES FOLLOWING SARSCOV-2 VACCINATION OR INFECTION—ANALYSIS OF A CASE SERIES

Keywords: Vaccination/immunization, Myositis, COVID

A. Mariani1, M. M. Tamas1,2, L. Muntean1,2, O. M. Resteu1, D. A. Vaida-Voevod1,2, I. Felea1, L. Damian1, I. Filipescu1, C. Pami1,2, I. Szabo1,2, S. P. Simon1,2, S. Rednic1,2, 1Clinical Emergency County Hospital, Rheumatology, Cluj-Napoca, Romania; 2Iuliu Hatieganu University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania

Background: Recent data showed that SARS-CoV-2 infection and vaccination could act as a trigger for different autoimmune diseases, including idiopathic inflammatory myopathies (IIM).

Objectives: The aim of this study was to describe the clinical characteristics of patients diagnosed with IIM following SARS-CoV-2 infection and vaccination in a tertiary rheumatology center.

Methods: We conducted a retrospective analysis on patients newly diagnosed with IIM, from 1 January 2020 to 31 December 2022, using information from the hospital database. The patients were selected according to the ICD-10 codes indicating IIM (M33.0, M33.1, M33.2, and M33.9). The cases with onset of specific IIM symptoms within 6 months after SARS-CoV-2 infection or vaccination were selected for further analysis. Clinical, biological and immunological parameters were assessed using descriptive statistics.

Results: A total of 58 patients newly diagnosed with IIM were identified, and in 10 (17.2%) patients the onset was after SARS-CoV-2 infection (n = 6) or vaccination (n = 4). All patients diagnosed with IIM following vaccination (F:M=1:1, median age 46 years) received a mRNA vaccine and had the clinical onset within several days to a month after vaccination. Among IIM cases following SARS-CoV-2 infection (F:M=1:1, median age 60.5 years), the clinical onset of myopathy was variable, with a minimum of 14 days and a maximum of 6 months after infection. Myalgia, muscle weakness and elevated levels of creatinine kinase were reported in 9 patients. The average CK level was 2534.6 (3760.8) U/L, ranging from 43 to 11827 U/L. Skin lesions were present in all patients with IIM following vaccination and in 4 cases with IIM after SARS-CoV-2 infection. Mechanical hands and arthralgia were noted in 5 patients each. Dyspnea and interstitial lung disease (ILD) were reported in 8 cases, with severe pulmonary involvement present in 2 cases. Myocarditis was reported in 2 patients, 1 case from each group. Myositis-specific antibodies (MSAs) and myositis-associated antibodies (MAAs) were reported in 9 patients. Anti-threonyl-tRNA synthetase antibodies (anti-PLE7) were present in 5 cases (3 after vaccination and 2 after infection), anti- histidyl-tRNA synthetase antibodies (anti-Jo-1) in 2 patients (1 associated with anti-PLE7 antibodies), and anti-isoleucyl-tRNA synthetase (anti-DJ antibodies) in 1 patient. ILD was diagnosed in all anti-PLE7 antibody positive patients.

Conclusion: Anti-PLE7 antibodies are frequent in newly diagnosed IIM following SARS-CoV-2 infection or vaccination. Further studies are needed to investigate the relationship between SARS-CoV-2 infection and vaccination in the occurrence of IIM.

UTILIZATION AND ATTITUDES TOWARDS NAILFOLD VIDEOCAPILLAROSCOPY FOR THE ASSESSMENT OF MICROVASCULAR STATUS IN PATIENTS WITH LONG- COVID: A MULTICENTER ONLINE SURVEY

Keywords: COVID, Imaging

E. Gotelli1, F. Ingegnoli2, R. De Angelis3, S. Guiducci4, D. Giuglioti5, C. Pizzoni1, V. Riccieri1, M. Sebastiani1, A. Sulli1, V. Smith1,2,3, M. Cutolo1, 1University of Genova, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, Genova, Italy; 2Università degli Studi di Milano, ASST Gaetano Pini-CTO, Clinical Rheumatology Unit, Department of Clinical Sciences & Community Health, Milan, Italy; 3Marche Polytechnic University, Rheumatology Unit, Department of Clinical and Molecular Sciences, Ancona, Italy; 4University
Background: Human SARS-CoV-2 infection is responsible for a large variety of clinical manifestations related to Coronavirus disease-19 (COVID-19) [1]. SARS-CoV-2 can induce microvascular damage, that can be safely detected by nailfold videocapillaroscopy (NVC), as recently demonstrated [2-4]. SARS-CoV-2 can induce microvascular damage, that can be safely detected by nailfold videocapillaroscopy (NVC), as recently demonstrated [2-4].

Objectives: To carry out an Italian multicenter cognitive survey on the interest in collecting NVC and clinical data of patients affected by long-COVID with or without previous rheumatological diseases.

Methods: The steering committee of the CAPSIR study group formulated a cognitive questionnaire, entitled “Study on the role of capillaroscopy in patients with long-COVID” (CAPSIR_2 Study), consisting of 27 open or multiple-choice questions. A Google Form of the questionnaire was emailed to all the members of the study group between September and October 2022. Data are reported with a descriptive analysis.

Results: The online questionnaire was completed by 41 CAPSIR members, belonging to 33 different Italian centers. Of note, 63% of participants had already experienced NVC in patients with long-COVID. The primary indication to perform the NVC was the onset of a new Raynaud’s phenomenon (46% of cases) and the requests come mainly from General Practitioners (33% of cases). In 2/3 of the cases, patients with long-COVID and previous rheumatic diseases, who underwent NVC examination, represented less than 20% of the total. It should be noted that in 2/3 of the cases there was no preferential channel for the study of the microcirculation in patients affected by long-COVID nor a NVC investigation prior to the SARS-CoV-2 infection. According to the previous experience of the participants in the interview, the most important NVC parameters considered to be evaluated in long-COVID patients were number of capillaries per linear millimeter (24% of cases), presence of hemorrhages (34% of cases) and giant capillaries (22% of capillaries). All participants (100%) therefore agreed to participate in a further collection of NVC and clinical data in this cohort of patients affected by long-COVID versus adequate controls.

Conclusion: This survey highlighted the interest of Italian Rheumatologists in applying NVC titre was found, generally in terms of reduction and without clinical application. In bold, statistically significant comparison.

Table 1. Frequency of autoantibodies positivity before (T0) and after (T1) anti-SARS-CoV2 vaccination. Chi-square test or Fisher’s exact test were applied. In bold, statistically significant comparison.

ABT1311 EVALUATION OF A POTENTIAL INDUCTION OF AUTOANTIBODIES IN A COHORT OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS, SYSTEMIC SCLEROSIS OR WITH TRIPLE POSITIVITY FOR ANTIHOSPHOLIPID ANTIBODIES FOLLOWING ANTI-SARS-COV2 VACCINATION

Keywords: Vaccination/Immunization, COVID, Autoantibodies

P. Semeraro1, S. Piantoni1, G. Vairano2, S. Bertocchi1, L. Andreoli1, A. Tincani1, E. Garratt4, F. Franceschini1, Rheumatology and Clinical Immunology Unit, ASST Spedali Civili of Brescia and University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy; University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy; 1ASST Spedali Civili of Brescia, Department of Laboratory Diagnostics, Brescia, Italy; 4University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy

Background: Vaccines anti-SARS-CoV2 showed a good efficacy in prevention of severe COVID-19 [1]. Their potential in induction of autoantibodies (abs) has not been well established [1]. One recent study demonstrated an increase of abs’ titer after anti-SARS-CoV2 vaccination only in patients (pts) with already pre-existing positivity [2].

Objectives: To evaluate the potential induction of abs after SARS-CoV2 vaccination in a cohort of pts affected by Rheumatoid Arthritis (RA), Systemic Sclerosis (SSc) or with triple positivity for antiphospholipid antibodies (aPLs).

Methods: Consecutive pts affected by RA, SSc or with triple positivity for aPL were enrolled from February 2021 to November 2021. Serum samples were collected before the first (T0) and at least one month after the second administration (T1) of the anti-SARS-CoV-2 vaccine. A wide panel of abs were evaluated through routinely methods. Qualitative variables were compared using Chi-square test or Fisher’s exact test; quantitative variables were compared using Wilcoxon signed-rank test.

Results: 52 pts were considered (F/M: 48/4; median age=58[51-61] years; 15 RA, 19 SSc and 18 with triple positivity for aPL). Regarding vaccination, 27 pts were administered BNT162b2, 24 mRNA-1273 and 1 Gam-COVID-Vac. No difference regarding frequency of abs’ positivity was found between T0 and T1, except for a2GPI IgG, that showed a reduction in positivity frequency (Table 1) No difference was found in the titer of the following abs: anti-dsDNA (p:0.318), anti-mPO (p:0.078) ed anti-PR3 (p:0.139). aCL IgG showed a significant reduction in chemiluminescence (CL) (T0 vs T1: 9.3 CU [6.1-16.4] vs 5.1 CU [2.5-35.7]; p:0.001), but not in ELISA (p:0.480). A significant reduction was found for aCL IgM both in CL (T0 vs T1: 5.7 CU [2.4-17.1] vs 3.4 CU [2.1-13.1]; p:0.006) and ELISA (T0 vs T1: 13.1 IU/ml [11.2-30.6] vs 11.2 IU/ml [11.2-19.6]; p:0.010). A significant reduction was found for a2GPI IgG in CL (T0 vs T1: 25 CU [9.1-210.7] vs 6.4 CU [6.3-102.2]; p:0.001), but not in ELISA (p:0.953) Title of a2GPI IgM remained stable in CL (p:0.078) and ELISA (p:0.211). No variation was found in ANA positivity. No significant difference was found in anti-ENA titre (p:0.141). None of the pts developed any new symptom or sign of autoimmune disease upon vaccination.

Conclusion: Anti-SARS-CoV2 vaccination didn’t induce any clinical sign of autoimmunity in this cohort of pts affected by RA, SSc or with triple positivity for aPL. Serology for abs remained stable in pts’ majority; only a fluctuation of aPL titre was found, generally in terms of reduction and without clinical significance.

REFERENCES:
Patients with IIMs were at a lower risk of delayed onset COVID-19 vaccine ADEs compared to other SAIDs, though a higher risk of rashes compared to HCs and other SAIDs. The risk of severe ADEs was lower in patients with IIMs. The study also observed a higher risk of delayed onset COVID-19 ADEs than other SAIDs, though a higher risk of rashes compared to HCs.

Efficacy and Safety of COVID-19-Specific Treatments in SLE: A Multicentre Case-Control Study

Keywords: Safety, Myositis, Vaccination/immunization

Regulatory agencies recommend COVID-19 vaccination in patients with IIMs, other systemic autoimmune and inflammatory diseases (SAIDs), and healthy controls (HCs), using data from the ongoing 2nd COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.

Methods:

A validated patient self-reporting e-survey was circulated by the international COVAD study group (157 collaborators, 106 countries) from Feb to June 2022, collecting respondent demographics, comorbidities, IIM/SAID details, COVID-19 infection history and outcomes, and vaccination data including ADEs. Delayed onset (>7 days) ADEs (including minor and major ADEs and hospitalizations) were analyzed in patients with IIMs, SAIDs, and HCs, using various regression models.

Results:

15,165 total respondents completed the survey, of whom 8759 communicated with IIMs with co-existing SAIDs at a higher risk of minor [OR 5.2 (3.3-8.2), p<0.001] and major ADEs [OR 2.1 (1.2-3.8), p<0.05] compared to those with IIMs alone.

Conclusion:

Patients with IIMs were at a lower risk of delayed onset COVID-19 vaccine ADEs compared to other SAIDs, though within this patient group, those with active disease, overlap myositis and autoimmunity multimorbidity were vulnerable, and warrant close monitoring and long term follow up post COVID-19 vaccination.

REFERENCE:

COVID-19 were collected. COVID-19 severity at presentation was quantitated through a 0-4 analogue scale [2]. Data are expressed as median (interquartile range, IQR) unless otherwise specified.

Results: Over three years, 39% of patients with SLE had at least one COVID-19 event. Eighteen subjects (16 women) were treated with antivirals (n=12) or monoclonal antibodies (n=6) and were matched with 36 controls. There was no difference in the frequency of organ involvement between the two groups. Treated patients were receiving significantly higher prednisone daily doses at COVID-19 onset (6.25 (0-10) vs 0 (0-2.5) mg; p=0.005) and had a higher prevalence of previous high-dose steroid treatments (83% vs 47%; p<0.019) compared to controls. SLE disease activity index (3 (0-5) vs 1 (0-4)) and SLE International Collaborating Clinics Damage Index scores (1 (0-3) vs 0 (0-1)) were also numerically higher in treated patients at COVID-19 onset. Patients in the treated group had more severe COVID-19 at presentation but showed no significant differences with control subjects in terms of COVID-19 resolution, prevalence of sequelae and viral clearance (Table 1). There was also no difference in flare occurrence between the two groups (Log-rank p=0.02, p=0.889). Two patients reported mild adverse events with monoclonal antibodies (muscle cramps and chest pain, both self-resolving).

Conclusion: These data support the safe use of COVID-19 specific treatments in patients with SLE. Patients treated with antivirals and monoclonal antibodies had a favourable COVID-19 course, despite a more severe presentation and a higher risk of deterioration due to SLE and corticosteroid treatment burden, suggesting the potential efficacy of COVID-specific treatments in preventing severe COVID-19 in patients with SLE.

Acknowledgements: We thank Dr. Giordano Vitali and his staff for assisting and treating patients with SLE and COVID-19 from IRCCS San Raffaele Fatebenefratelli in the local COVID-19 clinic.

AB1314 EFFICACY AND SAFETY OF ANTI-SARS-COV-2 VACCINATION IN PEOPLE WITH RMDs: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Vaccination/immunization, COVID, Systematic review

References:
long-COVID[3,4], but current evidence does not usually differentiate between muscular and joint (arthralgias) symptoms. Data on joint pain as long-COVID symptom is limited to specific populations. Additionally, studies investigating how COVID-19 affects previous rheumatological conditions experienced by the patient before the infection are also scarce.

Objectives: 1, To identify post-COVID changes in those previous joint pain conditions experienced by the patients before SARS-CoV-2 infection. 2, To compare the development of “de novo” joint pain as a long-COVID symptom between previously hospitalized and non-hospitalised COVID-19 survivors.

Methods: This nationwide, cross-sectional exploratory study was based on a questionnaire collecting demographics, previous rheumatological pain conditions and changes in their symptoms, and the development of joint pain after SARS-CoV-2 infection from a population-based sample in Denmark.

Results: Data from 1,000 randomly previously hospitalised (512% males; 60±15.2 years; 85±18.5kg) and 1,000 randomly previously non-hospitalised COVID-19 survivors (43.5% males; 50±19.6 years; 79±20.6kg) were analysed. Distribution of gender (p<0.001), age (p<0.001), and weight (p<0.001) was different between groups. The presence of joint pain before COVID-19 infection was significantly higher (P=0.01) in hospitalised (3.5%) than in non-hospitalised (1.6%) COVID-19 survivors. No differences in the presence of previous arthritis (P=0.212) or osteoarthritis (P=0.549) were found between the two groups. Both groups experienced similar worsening symptoms of their previous rheumatological conditions. A significant higher proportion (P<0.001) of hospitalised patients (18.9%) developed “de novo” joint pain when compared with non-hospitalised patients (5.5%).

Conclusion: This exploratory study shows that joint pain seems more likely to occur in hospitalised patients compared to non-hospitalised patients. Experiencing COVID-19 worsened the symptoms of rheumatological pain conditions in both hospitalised and non-hospitalised COVID-19 survivors. Rheumatological pain will need attention in COVID-19 survivors independently of hospitalisation or not.

REFERENCES:
[2] Fernández-de-las-Peñas C, Palacios-Ceña D, Arendt-Nielsen L, Time course prevalence of post-COVID pain in patients with mild symptoms, were reported, one in each group. The titers of anti-RBD after two doses of ChAdOx1 were higher compared to two doses of CoronaVac (6,03 BAU/mL vs 4,67 BAU/mL, p < 0,001). However, few studies in the literature assessed the safety and immunogenicity of the COVID-19 heterologous vaccine schedules in patients with RA.

Background: Patients with immune-mediated rheumatic diseases (IMRDs) have been prioritized for COVID-19 vaccination to mitigate the infection severity risks. Patients with rheumatoid arthritis (RA) are at a high risk of severe COVID-19 outcomes, especially those under immunosuppression or with comorbidities associated. However, few studies in the literature assessed the safety and immunogenicity of the COVID-19 heterologous vaccine schedules in patients with RA.

Methods: These data are from the study “SAFER - Safety and Efficacy on COVID-19 Vaccine in Rheumatic Diseases,” a Brazilian multicentric prospective phase IV study to evaluate COVID-19 vaccine in IMRDs in Brazil. Immunogenicity and adverse events (AEs) in patients with RA of all centers were assessed after two doses of ChAdOx1 plus additional dose of BNT162b2 or after two doses of inactivated SARS-CoV-2 vaccine CoronaVac plus additional dose of BNT162b2. The titers of neutralizing antibodies against the receptor-biding domain of protein spike (S) of SARS-CoV-2 (anti-RBD) were measured by chemiluminescence test after each dose of immunizers. Proportions between groups were compared using the chi-square and Fisher’s exact tests for categorical variables. Clinical Disease Activity Index (CDAI) before and after vaccination was assessed using the McNemar test.

Results: A total of 107 patients with RA were included in the study, most of them female, with a mean age of 46 years. Biological disease modifying anti- rheumatic drugs (DMARDs) were used by 50% of the patients and conventional synthetics DMARDS in 48%. Two doses of CoronaVac plus additional dose of BNT162b2 was used in 66 patients and two doses of ChAdOx1 plus additional dose of BNT162b2 in 41. Only mild AEs were observed, mainly after the first dose. The most common AEs after all doses, regardless of the immunizer type, were pain at the injection, headache, arthralgia and myalgia. ChAdOx1 had a higher frequency of pain at the injection (66% vs 32%, p < 0.001) and arthralgia (68% vs 15%, p < 0.001) compared to CoronaVac. No patients had flare after the vaccine.

Conclusion: ChAdOx1, CoronaVac, and BNT162b2 vaccines are safe in RA patients. The frequency of local adverse effects, particularly pain at the injection site, was higher with ChAdOx1 compared with CoronaVac and BNT162b2.
site, is high. AEs are more frequent with ChAdOx1, especially after the first dose. The use of the immunizers does not change the degree of inflammatory activity of the disease. The immunogenicity of the two heterologous regimens was similar.

A total of 5 observational studies comprising 502 RA patients were identified (Table 1). The seropositivity rate in patients with RA was 0.701 (95% CI: 0.557-0.845) after vaccination with SARS-CoV-2 vaccines. Drugs used by patients with RA had an impact on the seropositivity rate. The seropositivity rate of RA patients undergoing SARS-CoV-2 vaccination was 0.713 (95% CI: 0.544-0.898), 0.764 (95% CI: 0.593-0.935) and 0.625 (95% CI: 0.546-0.704), respectively. Patients with csDMARDs treatment had the lowest seropositivity rate than bDMARDs treatment (Figure 1).

Methods: Systematic searches of the CBM, CNKI, China Science and Technology Journal Database, WanFang Data, PubMed, Embase, Web of Science, Cochrane Library, and Medline were performed. We included observational studies evaluating RA patients undergoing SARS-CoV-2 vaccination. Random effects model was used to calculate the pooled efficacy. Heterogeneity and risk of bias were examined with the I² and Egger tests to assess potential publication bias (STATA v.12.0).

Results: A total of 5 observational studies comprising 502 RA patients were identified (Table 1). The seropositivity rate in patients with RA was 0.701 (95% CI: 0.531-0.871) after vaccination with SARS-CoV-2 vaccines. Drugs used by patients with RA has an impact on the seropositivity rate. The seropositivity rate of RA patients using GC therapy is 0.73 (95% CI: 0.531-0.871), 0.713 (95% CI: 0.544-0.898), and 0.625 (95% CI: 0.546-0.704), respectively. Patients with csDMARDs treatment had the lowest seropositivity rate than bDMARDs treatment (Figure 1).

Conclusions: After vaccination with SARS-CoV-2 vaccines, the seropositivity rates of RA patients using csDMARDs have the lowest seropositivity rate.

Background: It is known that rheumatologic patients often present a course of COVID-19 similar to that of the general population. Some factors are linked to a worse COVID-19 outcome, such as moderate glucocorticoid (GC) dose, high body mass index (BMI), and comorbidities.

Objectives: To describe the outcome of COVID-19 in patients with rheumatoid arthritis (RA) in terms of symptoms, therapy and need for hospitalization compared to a control group. Also, to evaluate the variation in disease activity before and after COVID-19.

Methods: In this monocentric prospective study, we recruited consecutive adult patients with RA classified according to the ACR-EULAR 2010 criteria who received a diagnosis of COVID-19 through molecular or rapid antigen swab tests between September 2020 and December 2022. Demographic and clinical data, including age, BMI, smoking habit, comorbidities, treatment at the diagnosis of COVID-19, duration of COVID-19, symptoms related to the infection and therapy required, together with the vaccination status were collected through a self-administered questionnaire. We compared DAS28-CRP before the infection and at the first visit after the resolution. As controls (Cs), individuals with COVID-19 but with no referred diagnosis of rheumatic/autoimmune disease were recruited.

Results: We enrolled 111 patients affected by RA (males 15%, median age 56 years, IQR 25) and 89 Cs (males 44%, median age 47 years, IQR 43), whose demographic and clinical characteristics are reported in Table 1. The median RA disease duration was 108 months (IQR 201). At the COVID-19 diagnosis, 62 patients (56%) were assuming csDMARDs, 67 (60%) bDMARDs, and 18 (16%) GC with a median prednisone equivalent dose of 4 mg/day (IQR 1). DAS28-CRP was available for 62 patients, with a median value of 1.67 (IQR 2.71); 42 patients (60%) were in remission (Figure 1). Before developing COVID-19, only 35 (32%) RA patients and 42 (47%) Cs had completed the vaccine cycle, which was performed by mRNA vaccine in all the patients and 87% of Cs. The median COVID-19 duration was 18 days (IQR 18) for RA patients and 14 days (IQR 13.5) for Cs (p<0.7). Cs reported a significantly higher frequency of constitutional symptoms (headache and asthenia) compared to RA patients (p<0.00001). When hospitalization was required, RA patients received heparin more frequently than Cs (p<0.039). Once COVID-19 was resolved, RA patients were evaluated after a median of 2 months (IQR 2). DAS28-CRP was available for 68 patients, with a median value of 1.61 (IQR 1.77); 42 patients (62%) were in remission (Figure 1). No differences in terms of COVID-19 duration, clinical manifestations, and therapy emerged comparing RA patients in remission (40%; 58%) with patients with the active disease before COVID-19 (29%; 42%). Also, in vaccinated subjects, the outcome of COVID-19 was similar in RA patients and Cs, irrespective of RA activity.

Conclusion: COVID-19’s impact on patients with RA was not significantly different from the general population, even for patients with active RA. Patients did not suffer from reactivation of RA because of COVID-19. In our opinion, these positive results could be ascribed to the massive vaccination campaign.

REFERENCES:
Background: Coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome-coronavirus-2 (SARS-CoV-2) has diverse and wide array of clinical presentations ranging from asymptomatic to severe disease. The exact pathophysiological mechanism of severe COVID-19 is still obscure; however, unrestrained immune response, exaggerated systemic inflammation, endothelial activation, and vascular damage are implicated in its pathogenesis similar to systemic sclerosis (SSc) and autoimmune diseases [1-2].

Objectives: to assess the clinical presentation and worse outcomes of COVID-19 in SSc patients and evaluate the effects of SSc features on the clinical course of COVID-19

Methods: This multicentre, retrospective, observational study included SSc patients with COVID-19 diagnosis which was confirmed by SARS-CoV-2 RT-PCR or suggestive symptoms with typical radiologic pulmonary findings. Clinical features of SSc and associated interstitial lung disease (ILD) were evident in 57.1% of the patients. SSc-specific treatments were low-dose glucocorticoids and mycophenolate. We found 25.5% hospitalization, 16.3% respiratory support, 3.6% intensive care unit admission, 2.7% long-COVID, and 2.7% mortality rate in SSc patients. ILD and ≥1 comorbidity were more frequent in inpatients compared to outpatients (82.1% vs 49.4%, p=0.005; 67.9% vs 42.7%, p=0.051; respectively). Risk factors for respiratory failure were ILD (OR:7.49, 95%CI:1.63-34.46, p=0.01), ≥1 comorbidity (OR:4.55, 95%CI 1.39-14.88, p=0.01), having a higher physician global assessment score at the last outpatient visit (OR 2.73, 95% CI: 1.22-6.10, p=0.01), and use of MMF at the time of getting the infection (OR: 5.16, 95 %CI: 1.79-14.99, p=0.003) by univariate analysis. Having ≥1 comorbidity was the only significant predictor of the need for respiratory support in COVID-19 (OR:5.78, 95%CI:1.14-29.33, p=0.03). In the early post-COVID-19 period, 17% of patients reported the progression of the Raynaud phenomenon, and 10.6% of patients developed new digital ulcers. Progression or new onset of dyspnea and cough were detected in 28.3% and 11.4% of patients, respectively.

Conclusion: SSc-related ILD, severe disease activity, and use of mycophenolate might be related to adverse outcomes of COVID-19, and having comorbidity is an independent risk factor for respiratory support.

AB1322 COVID-19 PANDEMIC AND SYSTEMIC INFLAMMATORY RHEUMATIC DISEASES: OUR EXPERIENCE IN DAKAR, SENEGAL (SUB-SAHARAN AFRICA)

Keywords: Disease-modifying drugs (DMARDs), Inflammatory arthritides, COVID

B. S. Kane1, M. Dieng1, B. Fall1, M. Sow1, A. T. Lernarbo2, M. A. Ndour2, A. C. Ndaio3, S. Ndongo3, A. Pouye1, Cheikh Anta DIOP University, Internal Medicine, Dakar, Senegal;2Cheikh Anta DIOP University of Dakar, Nephrology, Dakar, Senegal

Background: There are paucity data regarding the Covid-19 pandemic on the management of systemic autoimmune rheumatic diseases in sub-Saharan Africa.

Objectives: The aim of our study was to assess the impact of the Covid-19 pandemic on the follow-up of patients with systemic inflammatory diseases and their adherence to vaccination against SARS-CoV-2.

Methods: We performed a multicentric cross-sectional study between August 1st and October 31st, 2021. The study targeted the patients diagnosed for systemic diseases according to the international criteria. The patients were followed in the departments of Internal Medicine, Rheumatology and Nephrology of 04 hospitals in Dakar (Senegal). The survey was based on records of 13 questions (with responses collected from the patients' medical records) and was completed by a telephone interview with 38 potential questions. All responses were collected using a web-based application and then exported and analyzed using SPSS 26 software.

Results: 131 patients were included with a mean age of 41.5 years (+/-12.4) and a sex ratio of 0.08. Inflammatory rheumatic diseases included: Rheumatoid arthritis (47.3%), Systemic lupus erythematosus (22.9%), Autoimmune myositis (10.7%), Sjogren’s syndrome (6.9%), Systemic sclerosis (4.6%), Spondylarthritis (2.3%), Antiphospholipid syndrome (1.5%), ANCA-associated vasculitis (1.5%),
Adult-onset Still’s disease (0.8%), Systemic sarcoïdosis (0.8%) and Relapsing polychondritis (0.8%). Patients reported missing one or more follow-up appointments in 45%, a drug break (33.6%) regarding particularly the methotrexate (21/44 of patients: 47.7%) and hydroxychloroquine (18/44 patients: 40.9%) with a flare-up of their disease in 31% of cases. Covid-19 infection was confirmed in 11 patients (8.4%). Our survey showed that 47 patients (35.8%) were vaccinated with: Ad.26.COV2.S (40.4%), chAdOx1 nCoV-19 (27.7%) and BBIBP-CorV (31.9%). Side effects were reported by 21 of 47 patients (45%) only after the first dose. 2 of 47 (4.25%) patients had a medically confirmed flare. 84 (64.2%) patients were not vaccinated. Fear of vaccine side effects and the effects of vaccine on systemic disease were the main reasons for non-adherence to vaccination.

Conclusion: The covid-19 pandemic has had a significant impact on the follow-up of patients with systemic inflammatory diseases in Daka. Vaccine hesitancy is a reality in these patients.

ANALYSIS OF ADVERSE EFFECTS AFTER VACCINATION AGAINST COVID-19 IN PATIENTS WITH IMMUNO-MEDIATED RHEUMATIC DISEASES IN MANAUS – AMAZONAS

Keywords: Epidemiology, Vaccination/immunization, COVID

M. M. Sousa Dias 1, N. Sexas de Melo 1, S. E. B. Dias 1, C. Pinheiro Martins 1, V. Miki Pang Takatanii 1, R. Beatriz Nazareth Alagia 1, B. Guimarães Dutra 1, G. Bacellar Marques 1, D. Queiroz Rego 1, D. Buzaglo Gonçalves 1, C. Telles 1, S. Ribeiro 2, Universidade Federal do Amazonas, Faculdade de Medicina, Manaus/AM, Brazil

Background: Immune-Mediated Rheumatic Diseases (IMRD) are characterized by a chronic inflammatory response, have several clinical manifestations and are more susceptible to infections and worse prognosis. Thus, in the context of the COVID-19 pandemic, to reduce morbidity-mortality, vaccination is an effective method of prevention. However, there are not enough studies that encompass this group of patients, leaving many doubts about the adverse effects and its safety and effectiveness.

Objectives: Analyze the adverse effects observed in patients with IMRD after vaccination against COVID-19.

Methods: Observational, longitudinal, bidirectional research, with follow-up of groups of patients with IMRD immunized with vaccines made available by the Programa Nacional de Vacinação with Coronavac (Instituto Butantan), AstraZeneca (BioManguinhos/Fiocruz), Pfizer/BioNtech and Janssen (Johnson & Johnson). Sociodemographic data and data on the adverse effects presented were collected through a diary delivered to each patient, filed on an online platform. This study was approved by the local Ethics and Research Committee.

Results: 223 patients over 18 years of age were included, the mean age is 42.79±15, 83% women. The main DRIM: Systemic Lupus Erythematosus (39%) and Rheumatoid Arthritis (33.6%). In the 1st dose, 78.3% of the vaccines applied were Coronavac, 18.9% AstraZeneca and 2.8% Pfizer/BioNtech, the adverse effects found were: Pain at the injection site (49.3%), Headache (43.3%), Tiredness (34.3%) and Nausea (21.6%). In the 2nd dose, with the same vaccines applied as the previous dose, the adverse effects: Pain at the injection site (44.6%), Headache (33.9%), Tiredness and Vertigo (21.5%). In the 3rd dose, 55.3% of AstraZeneca, 44.2% of Pfizer and 0.4% of Janssen, in relation to adverse effects: Pain at the injection site (65.2%), Headache (41.8%), Tiredness (36.2%) and Edema and hardening of the skin at the injection site (31.9%). For the 4th dose, the AstraZeneca (14.9%) and Pfizer (85.1%) vaccines were applied, the adverse effects found: Pain at the injection site (58.5%), Hardening of the skin at the injection site injection (24.4%), Headache (19.5%), Tiredness (17.1%).

Conclusion: It is observed that the adverse effects presented after each administered dose are mild to moderate, more frequent; pain at the injection site and headache without significant differences compared to the general adult population.

REFERENCES:
Background: Children infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) usually present minimal symptoms or are asymptomatic. Nevertheless, a subset of children 2-6 weeks after the initial SARS-CoV-2 infection develops a postinfectious SARS-CoV-2-related multisystem inflammatory syndrome in children (MIS-C). Recently, transient expansion of TRBV11-2 T cell clonotypes in MIS-C was associated with signatures of inflammation and T cell activation, however, the underlying pathophysiology of MIS-C is not fully understood [1].

Objectives: The purpose of our project is to characterize the complexity of cell populations and capture cellular heterogeneity to uncover the regulatory networks and interactions that are disrupted during MIS-C flare with simultaneous profiling of gene expression and open chromatin landscape from the same nuclei.

Methods: Samples of peripheral blood mononuclear cells from patients with MIS-C diagnosed at the University Children’s Hospital, University Medical Center Ljubljana, were collected during the presentation before any treatment and at 6-12 months in remission. The primary aim is to identify which regulatory networks are driving inflammation in MIS-C flare, for which we are performing single cell Multiome ATAC + Gene Expression Sequencing. To enable simultaneous profiling of epigenetic landscape and gene expression from the same nuclei, we are using Chromium Next GEM Single Cell Multiome ATAC + Gene Expression Kit from 10X Genomics.

Results: We included 32 patients with MIS-C from whom we collected paired blood samples during the initial presentation before treatment and at 6-12 months in remission. In single cell multomic experiment we included 10 patients with paired samples, with the most viable cell count prior cryopreservation. All samples that are included into multomic single cell analysis have 75%-99% viability prior cryopreservation. In the protocol the key is to remove remaining granulocytes causing high mitochondrial RNA burden and extensively optimize the dilution factor of lysis buffer and the length of cell lysis step in order to get intact nuclei with no significant blebbing. Afterward, the single cell ATAC libraries as well as single-cell gene expression libraries are constructed and sequenced. Data are undergoing pairwise analysis to compare the cell population heterogeneity, expression profile and open chromatin landscape in the time of the initial presentation of MIS-C and in the remission, with Cell ranger software as well as R package scREG [2], and custom scripting. In the second step we will inspect if the resulting altered transcriptomic signature from single-cell experiment is present on larger cohort.

In that regard, we will perform bulk transcriptomic profiling on all paired collected samples during the initial presentation of MIS-C before treatment and at 6-12 months in remission.

Conclusion: The results of this project are expected to enlighten the underlying pathophysiology of MIS-C flare and thus support clinical decision on more targeted treatment. The identified disrupted networks during MIS-C flare could lead the way to establish an early diagnosis and improve long-term outcome, including prevention of myocardial and neuropsychological impairment. Moreover, a better understanding of the disrupted regulatory networks that are driving inflammation in MIS-C, could lead to new insights into diseases with similar clinical presentations as Kawasaki Disease.

DIFFERENCES IN ADVERSE EVENTS EXPERIENCED BY INDIVIDUALS WITH INFLAMMATORY RHEUMATIC DISEASES AND HEALTHY INDIVIDUALS AFTER SARS-CoV-2 VACCINATION

Keywords: Vaccination/immunization, COVID, Safety

Background: Since individuals with inflammatory rheumatic diseases (IRDs) were excluded from the SARS-CoV-2 vaccination trials (1), uncertainty on the tolerability of the vaccines in this population was high. This caused a lower willingness to be vaccinated compared to the general population. Gaining more information on vaccine reaction in this population is critical.

Objectives: The aim of the study was to improve knowledge of the tolerability of SARS-CoV-2 vaccination in patients with IRD and to identify potential specific risks of this population by comparison with a healthy cohort.

Methods: IRD patients were recruited from the outpatient clinic of the Division of Rheumatology and Clinical Immunology at the hospital of the LMU Munich. Healthcare workers served as healthy controls. Questionnaires were used to identify adverse effects in all study participants after each SARS-CoV-2 vaccination and to obtain information about patients’ disease and therapy. Descriptive statistics and non-parametric tests were used to discern differences between IRD patients and controls.

Results: 235 IRD patients (60% female), mean (±SD) age 54 (±15) years, and 102 healthy individuals (67% female), mean age 48 (±16) years, were recruited between Jan 2021 and Sep 2022. Pain at the injection site and fatigue were the most common adverse events in both groups. (Table 1) Patients presented adverse events significantly less often after the first vaccination (84.3%) (OR=0.274 [95% CI. 0.15-0.497]; P<0.0001). With 58.7% of patients and 77.5% of controls experiencing adverse events after the second vaccination the difference stayed significant (OR=0.391 [0.228-0.670]; P=0.001). Same goes for the third vaccination with 56.4% of patients and 69.3% of controls presenting adverse events (OR=0.573 [0.348-0.946]; P=0.029). No difference was seen when the occurrence of local effects were compared. However, systemic effects were experienced significantly less by patients compared to controls after the first (41.3% vs 59.8%) (P=0.002), second (38.7% vs 58.6%) (P=0.001) and third vaccination (39.0% vs 51.5%) (P=0.036). Younger age and female sex showed higher frequencies of adverse events in both groups. 2% of patients experienced an activation of their IRD. Serious adverse events did not occur.

Conclusion: IRD patients are at no higher risk of experiencing adverse events than controls after SARS-CoV-2 vaccination. In fact, systemic effects seem to occur less frequently in patients compared to healthy individuals, which potentially shows an influence of IRDs or their therapies on vaccination reactions.

Background: COVID-19 cutaneous manifestations were first reported in February 2020, after a rash was listed as a sign of the virus. In 2020, an article emphasized the absence of images among skin of color with respect to COVID-19 skin manifestations. Without detection and treatment, individuals with skin of color may experience a disproportionate incidence of morbidity and mortality.

Discussion of cutaneous findings in skin of color remains limited to reviews and individual studies, although there are meta-analyses that assess systemic manifestations among different races, investigations of various symptoms among people with skin of color, and overall comparison of systemic manifestations to cutaneous manifestations remains unreported to our knowledge.

Objectives: The objective of this meta-analysis was to quantify the frequency of reported cutaneous and systemic manifestations among different races. Methods: A search for studies on dermatologic and systemic manifestations associated with COVID-19 published before February 2022 was run on PubMed and Embase. Two independent reviewers screened abstracts and full manuscripts for eligibility based on the following criteria: studies included children or adult patients diagnosed with COVID-19 or temporal association to COVID-19, studies included assessment of cutaneous and systemic manifestations of individuals, studies identified cutaneous and systemic manifestations among different races, and studies were peer-reviewed case reports, original studies, systematic reviews, meta-analyses, and letters to the editor. Race and the most common systemic and dermatologic manifestations were extracted from included studies. Event rates for each outcome by race were pooled using a single-arm meta-analysis and the random-effects model to account for heterogeneity.

Results: Seventeen studies, involving 2,525 patients, were selected. Pooled estimates for multisystem inflammatory syndrome (MIS) for Black, White, and Asian cases were 28% (95% CI, 18.8-40.7, p=0.001), 40.1% (95% CI, 23.0-60.1, p=0.332), and 20% (95% CI, 13.2-29.2, p=0.000), respectively. The most common manifestations were pyrexia, elevated inflammatory markers, cardiac dysfunction, and gastrointestinal symptoms. The frequency of elevated inflammatory markers within Black cases surpassed White and Asian cases (30.9%, 28.7%, and 19.6%). The percentage of Black cases for cardiac dysfunction exceeded White and Asian cases (38.5%, 25%, and 21.2%). The frequency of pyrexia reported among Asian and Black cases exceeded White cases (26.7%, 24.3%, and 15.3%). The prevalence of dermatologic manifestations in Black cases was 4.2% (95% CI, 0.8-19.8, p=0.000) compared to White and Asian cases, 70.7% (95% CI, 42.9-88.6, p=0.139) and 11.7% (95% CI, 9.0-15.1, p=0.000).

Conclusion: This meta-analysis highlights the discordance in reporting systemic manifestations compared to dermatologic manifestations by race in COVID-19 patients. Further investigation is needed to determine the underlying cause.

REFERENCES:
[2] Lester JC, Jia JL, Zhang L, Okoye GA, Linos E. Absence of images of skin manifestations in Black cases was 4.2% (95% CI, 0.8-19.8, p=0.000) compared to White and Asian cases, 70.7% (95% CI, 42.9-88.6, p=0.139) and 11.7% (95% CI, 9.0-15.1, p=0.000).

Objectives: The objective of the study was to examine changes over time in anti-SARS-CoV-2 spike protein IgG (anti-S IgG) values in RD patients compared with controls and investigate the effects of immunosuppressants on the values.

Methods: RD patients receiving glucocorticoids or immunosuppressants who were scheduled to receive two doses of SARS-CoV-2 mRNA vaccines were included. Patients not receiving these drugs and were attending the hospital for diseases other than RD or malignancies served as the control group (CG). Following the guidance of the American College of Rheumatology, some immunosuppressive drugs were withheld before and after vaccinations. Blood samples were collected before and 1, 3, and 6 months (M1, M3, M6) after the vaccinations, and anti-S IgG values were measured using SARS-CoV-2 IgG II Quant Reagent Kit (Abbott Laboratories, USA).

Results: BNT162b2 mRNA vaccine-received 289 RD patients (mean age 66.9 years) and 241 females and 48 males) and 33 controls (mean age 70.7 years) were mainly analyzed. Anti-S IgG values markedly increased in both groups at M1 (CG; 9751.5 (2385.3 – 21506.1), RD; 2300.8 (188.5 – 7671.7) AU/mL, expressed as median (25th to 75th percentiles)), subsequently decreased, and were significantly lower in the RD group than in the CG at all time points (CG; 5012.2 (2933.3 – 6628.4), RD; 1505.0 (459.0 – 3229.0) at M3, CG; 1353.6 (505.8 – 1910.3), RD; 402.0 (130.5 – 836.2) at M6). Regarding antibody positivity, all patients in the CG tested positive at all time points. The antibody positivity rate was significantly lower in the RD group (85.0% at M1, 92% at M3, 86.4% at M6). In comparisons by disease, anti-S IgG values were significantly lower in patients with rheumatoid arthritis, systemic lupus erythematosus, vasculitis and dermatomyositis/polymyositis. In comparisons by treatment, anti-S IgG values were significantly lower in patients receiving rituximab 8.9 (8.8 – 68.2) at M1, 517.6 (26.4 – 144.0) at M3, 45.3 (23.1 – 67.4) at M6, mycophenolate mofetil 258.4 (11.1 – 713.7), 395.1 (18.0 – 2096.1), 212.3 (14.2 – 458.9), cytotoxic T lymphocyte-associated antigen 4-immunoglobulin (CTLA4-Ig) 336.8 (33.5 – 1166.7), 324.9 (111.2 – 480.6), 84.0 (379.7 – 118.7),
and prednisolone (PSL) [449.4 (26.3 – 2920.1), 709.6 (135.5 – 2008.5), 201.4 (44.7 – 602.5)]. A multivariate analysis with a linear mixed model indicated that there was a significant inverse association between age and the extent of changes in anti-S IgG values from M1, indicating greater decreases in antibody values at an older age from M1 [-75 (-133 – -18), expressed as regression coefficient (95% confidence interval)]. The extent of the decrease in anti-S IgG values was also significantly greater in males [-1873 (-3604 – -142)] and patients treated with PSL [-2071 (-3590 – -531)], CTLAA-lg [4018 (-6606 – -1429)], TNF inhibitors [-2009 (-3861 – -157)], and IL-6 inhibitors [-2422 (-4488 – -353)], Adverse reactions were described in both the IG group and RD group.

Conclusion: These results showed that SARS-CoV-2 mRNA vaccination is effective and safe in patients with RD treated with a variety of immunosuppressants. However, even following the ACR guidance on withholding drugs, anti-S IgG values were lower and significantly decreased over time depending on disease and immunosuppressive drugs. Therefore, relative short-term repetitive vaccination might be warranted in patients with RD receiving immunosuppressive drugs.

Methods: Objectives: To describe the characteristics of SARS-CoV-2 infection in patients with systemic lupus erythematosus (SLE) present greater severity of SARS-CoV-2 infection compared to the general population, particularly those with glomerulonephritis and who are treated with glucocorticoids.

Results: A total of 399 patients were included, 93% female, with a mean age of 40.9 years (SD 12.2), 39.6% had at least one comorbidity. At the time of infection, 54.9% were receiving glucocorticoids, 30.8% immunosuppressants, and 3.3% biological agents. SARS-CoV-2 infection was mild in most cases, while 4.6% had a severe course and/or died. The latter had comorbidities, used glucocorticoids and had antiphospholipid syndrome (APS) more frequently and higher disease activity at the time of infection. In the multivariate analysis, high blood pressure (OR 5.1, 95% CI 1.9-13.1), the presence of APS (4.7, 95% CI 1.2-15.8), and the use of glucocorticoids (10mg/day or more: OR 5.5, 95% CI 1.8-15.0), the diagnosis of APS (4.7, 95% CI 1.2-15.8), and the use of glucocorticoids were significantly associated with severe COVID-19.

SARS-CoV-2 infection was mild in most cases, while 4.6% had a severe course and/or died. The latter had comorbidities, used glucocorticoids and had antiphospholipid syndrome (APS) more frequently and higher disease activity at the time of infection. In the multivariate analysis, high blood pressure (OR 5.1, 95% CI 1.9-13.1), the presence of APS (4.7, 95% CI 1.2-15.8), and the use of glucocorticoids (10mg/day or more: OR 5.5, 95% CI 1.8-15.0), the diagnosis of APS (4.7, 95% CI 1.2-15.8), and the use of glucocorticoids were significantly associated with severe COVID-19.

Methods: Objectives: To describe the characteristics of SARS-CoV-2 infection in patients with systemic lupus erythematosus (SLE) present greater severity of SARS-CoV-2 infection compared to the general population, particularly those with glomerulonephritis and who are treated with glucocorticoids.

Results: A total of 399 patients were included, 93% female, with a mean age of 40.9 years (SD 12.2), 39.6% had at least one comorbidity. At the time of infection, 54.9% were receiving glucocorticoids, 30.8% immunosuppressants, and 3.3% biological agents. SARS-CoV-2 infection was mild in most cases, while 4.6% had a severe course and/or died. The latter had comorbidities, used glucocorticoids and had antiphospholipid syndrome (APS) more frequently and higher disease activity at the time of infection. In the multivariate analysis, high blood pressure (OR 5.1, 95% CI 1.9-13.1), the presence of APS (4.7, 95% CI 1.2-15.8), and the use of glucocorticoids (10mg/day or more: OR 5.5, 95% CI 1.8-15.0), the diagnosis of APS (4.7, 95% CI 1.2-15.8), and the use of glucocorticoids were significantly associated with severe COVID-19.

Keywords: Vaccination/immunization, Rheumatoid arthritis, Safety

S. Kojo1, Y. Kondo1, Y. Sakai1, S. Kasai1, J. Kikuchi1, Y. Kaneko1. Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Tokyo, Japan

Background: Amid the coronavirus disease 2019 (COVID-19) crisis, two messenger RNA (mRNA) vaccines against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) have benefitted most people worldwide. However, the safety of vaccine has not been established in patients with rheumatic arthritis (RA). Previous studies reported that flares of underlying RA following SARS–CoV-2 vaccination were not so frequent, and there was no report of severe flare. However, those reports did not assess patients’ disease activity with validated disease activity measures and described only self-reported questionnaires. Hence, the effect of vaccination on disease activity in patients with RA is still unclear. Understanding the association between arthritis flare in patients in RA and vaccination is important to overcome vaccine hesitancy.

Objectives: To clarify the effect of SARS-CoV-2 vaccination on disease activity in patients with RA and identify risk factors associated with RA flares following the vaccination.

Methods: This is a prospective cohort study in patients with rheumatic musculoskeletal disease including RA who received the SARS-CoV-2 mRNA vaccines BNT162b2 or mRNA-1273 from March 16, 2021, at Keio University Hospital. The vaccination frequency was evaluated using the number of 28 joints using c-reactive protein (DAS28), simplified disease activity index (SDAI), and clinical disease activity index (CDAI) before and after 2nd dose of vaccination. All analysis in this study was carried out with JMP.

Results: We enrolled 318 patients with RA in this analysis. The mean age was 61 years old, and 283 (89%) were female. The mean DAS28-CRP before vaccination and after 2nd dose of vaccination were 1.70±0.71 and 1.78±0.81, respectively (p=0.84). The increase in DAS28-CPR after vaccination > 0.6 was observed in 53 patients (16.7%), and among them, 23 patients (7.3%) had treatment intensification. The types of SARS-CoV-2 vaccine, humoral immunogenicity including neutralizing antibody titer and its adverse effects including systemic reaction (fever or general fatigue) were not different between the flare and non-flare groups (9.8 vs 9.1 U/mL, p=0.88; 31.2% vs 18.7%, p=0.32, respectively). In the flare group, swollen joint counts (SJC), hourly erythrocyte sedimentation rates, DAS28-CRP, and SDAI were significantly higher than those in the non-flare group (0.5 vs 0.0, p<0.000; 13 vs 11 mm/h, p=0.01; 1.57 vs 1.45, p<0.001; 3.9 vs 2.4, p=0.02, respectively). Multivariable logistic regression analysis revealed that the number of swollen joints before vaccination contributed RA exacerbation after SARS-CoV-2 vaccination significantly (odds ratio 1.3, 95% confidence interval 1.06–1.65, p=0.01). The receiver operating curve analysis identified that having two or more swollen joint counts predicts RA flares after vaccination with an area under the curve of 0.64, a sensitivity of 42.3%, and a specificity of 86.9%.

Conclusion: Disease flare with requirement of treatment intensification is observed in 8.3% of patients with RA. Patients with higher disease activity, especially having two or more swollen joint counts are at high risk of flare following mRNA SARS-CoV-2 vaccine vaccination.

COVID VACCINATION AND ADVERSE REACTIONS AMONG PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: WHAT IS THE RHEUMATOLOGIST’S ROLE?

Keywords: Vaccination/immunization, Myositis, COVID

A. Valle,1, S. Mahmood,1, Montefiore Medical Center, Medicine, Bronx, United States of America; Montefiore Medical Center: Einstein Campus, Division of Rheumatology, Bronx, United States of America

Background: Since 2021, EULAR has advocated for the vaccination of patients with rheumatic and musculoskeletal diseases [1]. However, there is significant patient hesitancy, and it is often attributed to concern regarding vaccine adverse events (AEs) [2]. Idiopathic inflammatory myopathies (IMMs) are an example of rare rheumatic conditions in which population-specific data is limited and rheumatologists may play vital role in a vaccine discussion.

Objectives: Our aim was to evaluate COVID vaccination and AEs rates in patients with IIM and determine whether rheumatologist-initiated vaccine discussions correlated with patient vaccination rates.

Methods: The Montefiore Medical Center Myositis registry was created from patients that met 2017 EULAR/ACR classification criteria for IIM. Patients without a history of rheumatology care at our hospital or those who had died prior to COVID vaccines availability were excluded. Demographics and IIM subtype were documented. Vaccination details, including vaccination type and number, were recorded. Medical records were reviewed for minor and major vaccine AEs and documentation of vaccination (OR: 0.53; p=0.037) and RA as the underlying AIIRDs (OR: 0.62; p=0.041).

Conclusion: While majority of IIM patients have received the primary series, the booster and bivalent series are much less prevalent. IIM patients whose rheumatologist discussed vaccination were more likely to be vaccinated. This signifies the importance of rheumatologist-initiated vaccine discussions. We reported less minor AEs and the same frequency of major AEs as larger, self-reported IIM studies.

CLINICAL OUTCOMES AND RISK FACTORS OF COVID-19 IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES: A LARGE REAL-WORLD SURVEY IN CHINA

Keywords: COVID, Vaccination/immunization

Y. Geng1, Y. Fan3, Z. Zhang2. Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China

Background: The impact of COVID-19 on vulnerable populations with autoimmune inflammatory rheumatic diseases (AIIRDs) has been of great concern.

Objectives: The aim is to report the clinical features, outcomes as well as risk factors of infection and hospitalization in Chinese AIIRDs patients during the big wave of infection last month.

Methods: A real-world survey was conducted during the peak of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) (8 December 2022 to 13 January 2023) in China. All patients completed the survey via internet or at the rheumatology outpatient and inpatient clinic of a tertiary hospital in Beijing with a medical diagnosis of AIIRDs. Clinical features, outcomes and risk factors of COVID-19 in AIIRDs were analyzed. The main outcome were SARS-CoV2 infection and hospital admission related to COVID-19. We apply the multivariable logistic regression model to assess risk factors for the infection and hospitalization.

Results: Totally 2005 patients with AIIRDs completed the survey. The leading AIIDs were systemic lupus erythematosus (SLE) (1039, 51.8%), rheumatoid arthritis (RA) (290, 14.5%) and Behcet's disease (BD) (231, 11.5%). There were 1690 (84.3%) patients who were infected and 315 (15.7%) patients not infected. The independent factors protecting patients from COVID-19 infection were the time interval of less than 3 months from last vaccination (OR: 0.53; p=0.037) and RA as the underlying AIIRDs (OR: 0.62; p=0.041). 57 out of 1690 patients (3.4%) were hospitalized. 46 (80.7%) of them experienced severe critical outcome. In multivariable logistic regression analysis, independent risk factors for hospitalisation with COVID-19 were age over 60 years (OR: 11.5;p<0.001), with comorbidity (OR: 183;p=0.045) and SLE as the underlying AIIRDs (OR: 2.59;p=0.038).

Conclusion: Our study suggested that time from last vaccination of less than 3 months and having RA decreased the risk of COVID-19 in AIIRDs. Among the infected patients, older age, having previous comorbidity and having SLE increased the risk of hospitalization.

THE IMPACT OF IMMUNOCOMPROMISE ON OUTCOMES OF COVID-19 IN CHILDREN AND YOUNG PEOPLE - A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Outcome measures, COVID

C. Curtin1, J. Greenen- Baret1, S. Aston1, C. Deakin1. 1University College London, Centre for Adolescent Rheumatology, London, United Kingdom

Background: Despite children and young people (CYP) having a low risk for severe Coronavirus disease 2019 (COVID-19) outcomes, there is still a degree of uncertainty related to their risk in the context of immunodeficiency or immuno-suppression, primarily due to significant reporting bias in most studies, as CYP characteristically experience milder or asymptomatic COVID-19 infection and the severe outcomes tend to be overestimated.

Objectives: To systematically evaluate the impact of immunosuppression on severe COVID-19 infection outcomes in CYP and perform a meta-analysis to estimate differences in outcomes compared to general population.

Methods: A comprehensive systematic review to identify globally relevant studies in immunosuppressed CYP and CYP in general population (defined as younger than 25 years of age) up to 31st October 2021 (to exclude vaccinated populations), was performed. Studies were included if they reported the two primary outcomes of our study, admission to intensive therapy unit (ITU) and mortality, while data on other outcomes, such as hospitalisation and need for mechanical ventilation were also collected. A meta-analysis estimated the pooled proportion for each severe COVID-19 outcome, using the inverse variance method. Random effects models were used to account for interstudy heterogeneity.

Results: The systematic review identified 30 eligible studies for each of the two populations investigated: immunosuppressed CYP (n=793) and CYP in general population (n=102,022). Our meta-analysis found higher estimated prevalence for hospitalization (46% vs. 18%), ITU admission (12% vs. 2%), mechanical ventilation (8% vs. 1%) and increased mortality due to severe COVID-19 infection (6.5% vs. 0.2%) in immunocompromised CYP compared to CYP in general population (Figure 1A-D depicts the pooled estimates for the above outcomes in immunocompromised CYP). This analysis shows an overall trend for more severe outcomes of COVID-19 infection in immunocompromised CYP, similar to adult studies.

Conclusion: This is the only up to date meta-analysis in immunocompromised CYP with high global relevance, which excluded reports from hospitalised cohorts alone and included 35% studies from low- and medium-income countries. Future research is required to characterise individual subgroups of immunocompromised patients, as well as impact of vaccination on severe COVID-19 outcomes.

INTAKE OF ACETAMINOPHEN SUPPRESSES ANTIVIRAL HUMORAL IMMUNE RESPONSES IN PATIENTS WITH RA FOLLOWING VACCINATION WITH ANTI-SARS-COV-2 mRNA BASED VACCINES

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Vaccination/Immunization

K. Schmiedeburg1,2, J. Beyer3, I. Abel4,5, N. Vuilleumier6, M. Schwarzmüller4, S. Pagano7, J. Von Kempis1, A. Rubbert-Roth1.

Background: Acetaminophen (APAP = paracetamol) may potentially impact vaccine-associated immune responses as the intake of APAP has been associated with a worse outcome in tumor patients receiving checkpoint inhibitors.[1] Different DMARD regimen have been shown to impair the humoral immune response to mRNA SARS-CoV-2 vaccines in patients with rheumatoid arthritis but the effect of paracetamol has not been explored thus far.

Objectives: To analyse whether the intake of APAP may interfere with antiviral humoral immune responses following two doses of an anti-SARS-CoV-2 mRNA based vaccine in patients with rheumatoid arthritis (RA) on DMARD therapy.

Methods: The RECOVER trial (Rheumatoid Covid-19 Vaccine Immune Response) was a non-randomised, prospective observational control group trial and enrolled 77 RA patients on DMARD therapy and 21 healthy controls (HC). We performed a posthoc analysis of blood samples taken before the first vaccine dose (T0), two (T1) and three (T2) weeks after the first and second mRNA vaccine dose, and at 12th (T3) weeks. APAP intake was measured using ELISA. The antibody response (anti-S) to the receptor binding domain (RBD) within the SARS-CoV-2 S1 protein was measured with the Elecsys Anti-SARS-CoV-2 S (Roche Diagnostics GmbH) test. The neutralizing activity NT50 at week 12 was assessed using an HIV-based pseudovirus neutralization assay against Wuhan-Hu-1.

Results: Baseline characteristics of participants are detailed in Table 1. The immunogenicity analyses were based on 73 RA patients after exclusion of 4 patients with previously unnoticed SARS-CoV-2 infection (positive for anti-nucleoprotein at baseline). APAP was detected in serum samples from 34/73 (25%) RA patients and in 7/21 (33%) HC (least at one timepoint T0, T1 and/or T2). APAP intake in HC did not affect levels of anti-S at any timepoint and HC developed potent neutralizing activity (NT50 ≥ 250) at week 12. RA patients, who tested positive for APAP at T1, showed comparable anti-S levels at T1, T2 and T3 compared to RA patients not exposed to APAP. The detection of APAP at T2 corresponded to lower anti-S levels at T2 (Figure 1 A, B). The detection of APAP at T2 was associated with a significantly lower SARS-CoV-2 neutralizing activity at week 12 compared to patients without pervaccination APAP exposure (p<0.04) (Figure 1 C).

Conclusion: A decrease of antiviral humoral immune responses was observed in RA patients (but not in HC) who were exposed to APAP at the time of the second mRNA vaccine dose compared to patients in whom APAP was not detected. Our data suggest that the use of paracetamol within the time period around vaccination may impair vaccine-induced immune responses in patients with an already higher risk for blunted immune responses.

P. Muñoz Martínez1, L. Mas Sanchez2, E. Grau García1, A. M. Torrat Noves1, D. Ramos Castro1, C. Riesco Barcena1, A. V. Huaylla Quispe1, S. Leal Rodriguez1, I. Cánovas Olmos3, H. Charia1, L. Gonzalez Puig1, J. Ivorra Cortés1, I. Martínez Cordellat1, C. Nájera Herranz1, R. Negueroles Albuixech1, J. E. Oller Rodríguez1, F. Ortíz-Sanjuán1, E. Tovar-Sugranyes1, E. Vicens Bernabeu1, J. A. Román Ivorra1. HUP La Fe, Rheumatology Department, Valencia, Spain

Background: The Coronavirus disease (COVID-19) is caused by the SARS-CoV-2 virus, which has led to a world revolution in many spheres, especially in the field of health, for more than three years. It is important to take into account that patients who are immunocompromised, such as those treated with JAK inhibitors (JAKi) are at higher risk to get sick with COVID-19 and have a worse prognosis.

Objectives: To analyze the impact after a three-year pandemic in those patients treated with JAKi in a Rheumatology Department at a Spanish tertiary care hospital.

Methods: Retrospective longitudinal observational study of patients treated with JAKi from December 2019 to December 2022. Demographic and clinical variables were collected from the electronic medical record. Incidence of COVID-19 was considered as adverse event. Those infections which required hospitalization or were a threat to the patient’s life were categorized as serious adverse event. The proportion of COVID-19 vaccinated patients was analyzed.

Results: 209 patients treated with JAKi were included. Rheumatoid Arthritis was the most frequent disease (n=162) and tofacitinib the most used JAKi (n=89). 193 (92.34%) patients received at least 1 dose of the vaccine against COVID-19. 17 infections from COVID-19, 3 of them serious. The 92.34% of the patients were vaccinated. We didn’t notice any infection in patients treated withFilgotinib, probably because of the short time of commercialization and few patients treated. The scarce number of infections reported is remarkable, especially in the second part of the pandemic. This is probably due to the effectiveness of the vaccine, the success of vaccination campaigns and the normalization of the disease, with the consequent infradiagnosis.

Conclusion: In our series of patients, we observed an incidence of 17 infections from COVID-19, 3 of them serious. The 92.34% of the patients were vaccinated. We didn’t notice any infection in patients treated with Filgotinib, probably because of the short time of commercialization and few patients treated. The scarce number of infections reported is remarkable, especially in the second part of the pandemic. This is probably due to the effectiveness of the vaccine, the success of vaccination campaigns and the normalization of the disease, with the consequent infradiagnosis.

AB1338 CLINICAL COURSE IN COVID 19 DISEASE IN IMMUNOSUPRESSED PATIENTS DIAGNOSED WITH RHEUMATIC DISEASES

Keywords: Comorbidities, COVID, Vaccination/Immunization

M. Mipkos1, E. Kaltsonoudis1, T. Zoï1, E. Pelechas1, N. Kougkas2, A. Garyfallos2, P. Voulgari1, A. Drosos1. 1University of Ioannina, Medical School, Department of Rheumatology, Ioannina, Greece; 2Aristotle University of Thessaloniki, Department of Internal Medicine, Hippokration Hospital, Thessaloniki, Greece

Background: Patients with pre-existing rheumatic diseases may be exacerbated during SARS-CoV-2 infection, or may develop new autoimmune features. Furthermore, immunosuppressive agents used to treat autoimmune-inflammation as well as comorbidities can also affect the disease outcome.

Objectives: To evaluate the outcome of rheumatic diseases after Covid 19 infection in patients diagnosed with rheumatic diseases, under various immunosuppressive treatment, as well as the effects of vaccines against Covid or antiviral treatment in this sensitive population group.

Methods: During the pandemic, 1493 patients with autoimmune or autoinflammatory disease who were continuously followed up in two tertiary hospitals in northern and northwestern Greece were included in the current study. The patients were compared with 769 controls after adjustment for age, sex, weight, vaccination status and comorbidities. Of the 1493 patients, 648 had rheumatoid arthritis, 282 psoriatic arthritis, 173 ankylosing spondylitis, 122 systemic lupus erythematosus, 98 Sjogren’s syndrome, 43 polymyalgia rheumatica, 34 mixed connective tissue disease or overlapping syndromes, 31 vasculitis, 27 systemic sclerosis, 18 myositis, 10 Behcet syndrome, 5 primary antiphospholipid syndrome and 2 had Familial Mediterranean Fever. The vast majority of patients and controls were fully vaccinated (82%) and 397 patients received antiviral treatment, 94% of them were fully vaccinated.

Results: Covid 19 disease in vaccinated patients with rheumatic diseases was shown to perform the same or about the same as those in the control group after adjustment for risk factors for severe disease. 19 of our patients required admission in the intensive care unit (62% full vaccinated) while a total of 12 died (66% non vaccinated). Major risk factors for severe disease were previous respiratory failure, chronic renal impairment, obesity, and failure to receive antiviral therapy. It was also shown that infection with Covid led to an exacerbation or induction of autoimmune disorders in 25 of the participants.

Conclusion: In this large cohort, Covid 19 disease was shown to affect patients with autoimmune rheumatic diseases the same or approximately the same way as the general population if they are fully vaccinated and if they start timely antiviral treatment where indicated. Further research and monitoring of the results after the multiple mutations of the virus is advisable.

Efficacy and Safety of the SARS-CoV-2 Vaccine in Patients with Rheumatoid Arthritis

Keywords: Vaccination/immunization, Rheumatoid arthritis, COVID19

Background: Rheumatoid arthritis (RA) and DMARDs are associated with a dysfunction of the cellular and humoral immune system that increases their susceptibility to infection, with vaccinations being one of the main infection prevention measures in these patients.

Objectives: To describe the efficacy and safety of the SARS-CoV-2 vaccine in a series of patients with RA.

Methods: Retrospective observational study of RA patients, fulfilling the ACR/EULAR 2010 classification criteria, vaccinated against the SARS-CoV-2 virus from December 2020 to October 2021, who had post-vaccination serology and subsequent follow-up for a minimum of 6 months in a university hospital. The efficacy and effectiveness of the vaccine was evaluated by analyzing the serological response (anti-SARS-CoV-2 IgG antibodies) and the incidence of post-vaccination SARS-CoV-2 infection. Vaccine safety was investigated recording adverse events and RA flares. Logistic and linear multivariate regression analyzes adjusted for age, sex, and time elapsed from vaccination to serological determination were used to identify factors associated with vaccine response. Statistical analysis was carried out with Stata® and significance was set at p<0.05.

Results: We included 118 patients with RA (87.2% women, mean age 65.4±11.6 years, mean evolution 12.0±9.6 years) vaccinated against SARS-CoV-2 (95.76% received the complete vaccination schedule). Patient characteristics regarding socio-demographic, clinical and laboratory RA related variables, as well as prior Covid infection are shown in Table 1.

Conclusion: In this large cohort, Covid 19 disease was shown to affect patients with autoimmune rheumatic diseases the same or approximately the same way as the general population if they are fully vaccinated and if they start timely antiviral treatment where indicated. Further research and monitoring of the results after the multiple mutations of the virus is advisable.

Cryofibrinogenemia in Pre-COVID-19 and COVID-19 Era: A Comparative Study in a Single University Hospital

Keywords: Descriptive studies, Skin, COVID

Quantitative variables were compared using the student’s t-test. Blood was collected in citrated tubes for cryofibrinogen detection. Statistical analysis for immunological and serological analysis were collected from all patients. Blood was collected in citrated tubes for cryofibrinogen detection. Statistical analysis was performed using SPSS software. Quantitative variables were expressed as means±SD. Qualitative variables were compared using chi-squared test. Quantitative variables were compared using the student’s t-test.

**Methods:** Observational single-center study in northern Spain University Hospital of 134 patients with at least one positive cryofibrinogen determination, between January 2017 and March 2020 (preCOVID era) and March 2020 and December 2022 (COVID era). CF diagnosis was confirmed accordingly to reported criteria [3]. Clinical conditions, laboratory parameters, including immunological and serological analysis were collected from all patients. Blood was collected in citrated tubes for cryofibrinogen detection. Statistical analysis was performed using SPSS software. Quantitative variables were expressed as means±SD. Qualitative variables were compared using chi-squared test. Quantitative variables were compared using the student’s t-test.

**Results:** CF was confirmed in 19/134 (14.2%) patients with at least one positive cryofibrinogen test determination (5 in preCOVID era; 14 in COVID era). Patients of COVID-19 era were more frequently male (64.3%) to 40% and younger (43.6 to 60.6 years). Main features are shown in Table 1. In preCOVID era most of cases were essential CF (60%) and in COVID era most of them were secondary ones (64.3%). The 33.3% of secondary CF were mainly due to COVID. Cutaneous manifestations were similar in both subgroups, especially as purpuric macules (perniosis-like) in acral distributions. Antiaggregant drugs and corticosteroids were used more frequently in preCOVID era. The comparative incidence after and before COVID is shown in Figure 1. From patients with positive cryofibrinogen test, a greater proportion in preCOVID had a CF.

**Conclusion:** CF is a rare disorder with a low prevalence. This study showed the change in the trend of CF subtypes, probably due to the influence of the COVID infection. In COVID era the number of positive cryofibrinogen test had envolved due to SARS-CoV2 infection, CF cases were not increased. Clinical expression of the disease has not changed in both groups.

**AB1341 COVID-19 IN PATIENTS WITH RHEUMATIC IMMUNE-MEDIATED INFLAMMATORY DISEASES IN AMERICA: DIFFERENCES AND SIMILARITIES BETWEEN MEXICO AND ARGENTINA**

**Keywords:** COVID, Registries, Real-world evidence

**Background:** Patients with immune-mediated rheumatic diseases (IRD) have poorer outcomes of SARS-CoV-2 infection compared to the general population.

**Objectives:** To assess and compare clinical course, severity and complications of SARS-CoV-2 infection in patients with rheumatic immune-mediated inflammatory diseases (IMIDs) from Mexico and Argentina.

**Methods:** Data from both national registries, CMR-COVID (Mexico) and SAR-COVID (Argentina), were combined. Briefly, adult IRD patients with SARS-CoV-2 infection were recruited between 08.2020 and 09.2022 in SAR-COVID

**Disclosure of Interests:** Carmen Lasa: None declared, Maria Enriqueta Peiró Calizo: None declared, Juan Iruire-Ventura: None declared, Marcos Lopez-Hoyos: None declared, Monica Renuncio Garcia: None declared, Adrian Martinez Gulierrez: None declared, Carmen Secada-Gomez: None declared, Amparo Sanchez-Lopez: None declared, Ricardo Blanco: Ricardo Blanco Speakers bureau: Abbvie, Pfizer, Roche, Lilly, Bristol-Myers, Janssen, Galapagos and MSD, Consultant of: Abbvie, Pfizer, Roche, Lilly, Bristol-Myers, Janssen and MSD, Grant/research support from: Abbvie, MSD, Novartis and Roche.

and between 04.2020 and 06.2022 in CMR-COVID. Sociodemographic data, comorbidities, and DMARDs were recorded, as well as clinical characteristics, complications, and treatment for SARS-CoV-2 infection. Descriptive analysis. Chi square, Fisher, Student T, Mann Whitney U tests and multiple logistic regression analyses were performed.

**Results:** A total of 3709 patients were included, 1167 (31.5%) from the CMR-COVID registry and 2542 (68.5%) from the SAR-COVID registry. The majority (82.3%) were women, with a mean age of 50.4 years (SD 14.4). The most frequent IRD were rheumatoid arthritis (47.5%) and systemic lupus erythematosus (18.9%). Mexican patients were significantly older, had a higher female preponderance and had higher prevalence of rheumatoid arthritis, antiphospholipid syndrome, and axial spondyloarthritis, while the Argentine patients had more frequently psoriatic arthritis and ANCA-associated vasculitis. In both cohorts, approximately 80% were in remission or low disease activity at the time of infection. Mexicans took glucocorticoids (43% vs 37%, p<0.001) and rituximab (6% vs 3%, p<0.001) more frequently. They also reported more comorbidities (48% vs 43%, p=0.012). More than 90% of patients presented symptoms related to SARS-CoV-2 infection. The frequency of hospitalization was comparable between the groups (23.4%), however, the Mexicans had more severe disease (Figure 1) and a higher mortality rate (9.4% vs 4.0%, p<0.001). After adjusting for risk factors, Mexicans were more likely to die due to COVID-19 (OR 2.2, 95%CI 1.5-3.1).

**Conclusion:** In this cohort of patients with IRD from Mexico and Argentina with SARS-CoV-2 infection, the majority presented symptoms, a quarter were hospitalized and 6% died due to COVID-19. Mexicans presented more severe disease, and after considering risk factors they were two times more likely to die.

**Background:** The World Health Organization defined long-COVID or post-COVID-19 condition as “the continuation or development of new symptoms 3 months after the initial SARS-CoV-2 infection, with these symptoms lasting for at least 2 months with no other explanation”[1]. Data on long-COVID in patients with inflammatory arthritis are very limited. The prevalence of this condition is 45% in the general population affected by COVID-19 who still experience symptoms after 4 months from the infection[2].

**Objectives:** To investigate the persistence of symptoms after SARS-CoV-2 infection in a cohort of patients with inflammatory arthritis and the most common clinical manifestations.

**Methods:** We enrolled adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and anklylosing spondylitis (AS) classified according to standard criteria that provided a diagnosis of COVID-19 through molecular, rapid or quantitative antigen swab tests between September 2020 and September 2022. Demographic and clinical data including age, body mass index (BMI), smoking habit, comorbidities, rheumatic treatment at diagnosis of COVID-19, date of COVID-19 diagnosis and clinical manifestations were collected through a questionnaire and recorded in a database.

**Results:** Thirty-eight (40%) patients with RA, 49 (51.6%) with PsA, and 8 (8.4%) with AS [total: 95 patients; F:M=65:30, median age 56 years (IQR 45-70)].

Background: The COVID-19 outbreak is known to increase the fear level of most patients with chronic diseases. Patients with rheumatoid arthritis (RA) are very vulnerable to environmental stress. During this pandemic, the psychological perspective may be further increased due to the prevailing pressure of information about the risk of infection in RA patients.

Objectives: The objective of this study was to determine the impact of the COVID-19 pandemic on the mental health of RA patients and to investigate associated factors.

Methods: This is a cross-sectional study of 190 patients with RA who met the ACR/EULAR 2010 criteria. For each patient, we collected sociodemographic, clinical, and biological data. Depression and anxiety were assessed by the Hospital Anxiety and Depression scale (HADS) and disease activity by the DAS-28 score.

Results: The average age of our patients was 55 years with a female predominance (86.3%). The average duration of the disease was 8 years. The mean DAS 28 score was 4.1 ± 0.3. The disease was deforming in 52.9% of cases. All of our patients were on disease-modifying therapy, 87.1% were on methotrexate and 12.9% were on biopharmaceuticals. Sixty patients (31.57%) had contracted SARS-CoV-2.

During the pandemic, depression was present in 38.4% of patients. It was mild in 33.1% of cases, moderate in 4.1%, and severe in 1.2% with a mean HADS depression score of 4.4 ± 3.1. This score was significantly higher in patients with a history of SARS-CoV-2 infection in a family member (p<0.002), comorbidities (p<0.001), joint deformities (p=0.008), and high disease activity (p<0.001). Anxiety was present in 55.6% of patients. It was mild in 32.6% of cases, moderate in 20.6%, and severe in 2.4% of cases with a mean HADS anxiety of 6.4 ± 3.9.

The presence of anxiety was correlated with fear of COVID-19, higher disease activity, the presence of comorbidities, and the presence of deformities (p<0.001 for all cases). This score was also significantly higher in the illiterate (p<0.001) and unemployed patients (p=0.001).

Conclusion: In our study, depression and anxiety were frequent in RA patients during the COVID-19 pandemic. These psychological disorders were more common in patients with active and disabling RA associated with comorbidities. As the pandemic continues, more patients are susceptible to experience anxiety and depression. Therefore, rheumatologists must remain vigilant to these psychological alterations and provide the necessary support.

AB1346 ASSOCIATION OF URIC ACID LEVELS WITH COVID-19 SEVERITY DURING 2020 AND 2021 YEARS

Keywords: Prognostic factors, COVID, Lungs

A. Sydorov 1, O. Larenko 1, 1 Bogomolets National Medical University, Department of Internal Medicine №3, Kyiv, Ukraine

Background: The decrease in uric acid levels attracts more and more attention from clinicians every year [1]. In particular, a factor such as Covid-19 can cause a significant decrease in uric acid due to its increased excretion by the kidneys [2]. This retrospective study aimed to determine changes in the level of uric acid in different years, which allows us to assume the influence of different strains of Covid-19 on uric acid.

Objectives: To analyze the relationship between uric acid levels through admission to the hospital and Covid-19 severity during 2020 and 2021 years.

Methods: Our retrospective study includes 127 hospitalized patients with confirmed Covid-19 in 2021 and 63 patients in 2020 (only patients who didn’t receive urate-lowering therapy). Most patients were over 45 years old (84.2% vs 90.5%), women and men almost equally. The severity of Covid-19 we determined by the type and presence of oxygen support ((1) without O2, (2) O2 by mask or nasal cannula, (3) continuous positive airway pressure, (4) positive bi-pressure in the airways or high-flow oxygen, (5) invasive ventilation). A chi-squared test and comparison of means were used.

Results: We cannot establish the dependence of the uric acid level on the severity of the course of the Covid-19 disease, which is determined by the type of oxygen support in both 2020 and 2021. For example, in 2021, the difference between the least severe type (without O2) and the most severe (invasive ventilation) was almost the same (246.2 vs 277.12 µmol/L), as between O2 by mask or nasal cannula and positive bi-pressure in the airways or high-flow oxygen (257.8 vs 239.1 µmol/L). However, it was established that in 2020, higher indicators of the level of uric acid were observed for all types of oxygen support. For example, for patients who were without O2, it is higher by 72.95 µmol/L, which is statistically significant. In addition, we analyzed the dependence of the uric acid level on such indicators as the patient’s age, the level of lymphocytes, C-reactive protein, and LDH at admission to the hospital. As a result of the analysis, it was found that the dependence is present for the LDH indicator (the lower the LDH, the higher the uric acid: chi-square at the level of 0.05), and for all other indicators, it was absent in 2021. In 2020, a positive relationship between CRP, LDH, and uric acid levels was also observed.

Conclusion: Although there is a trend towards lower uric acid levels in the background of Covid-19, it is not a marker of a severe disease course. The lower uric acid levels in 2021 are likely due to a feature of the strains circulating in 2021 that caused more significant renal excretion of uric acid.

AB1347 LABORATORY PARAMETERS ASSOCIATED WITH COVID-19 CYTOKINE STORM DEVELOPMENT

Keywords: COVID, Prognostic factors

A. Gherasim 1, R. Ionescu 2, T. Horia 3, T. Cristian 2, G. Teodora 2, Bucharest, Romania 1Colentina Clinical Hospital, Internal Medicine 3, Bucharest, Romania; 2UMFCD, UMFCD, Bucharest, Romania

Background: Since the end of 2019, physicians became more and more familiar with SARS-CoV-2 infection and the variety of forms in which it may present and evolve. There have been debates on how to develop cytokine storm, respectively on the delay of its development, for the others. Patients were classified into these groups, those who developed cytokine storm, respectively those who did not have this complication taking into account the clinical and paraclinical criteria (impairment of respiratory function, elevations of certain markers 2-3 times above the upper limit of normal, those who died as a result of SARS-CoV-2 infection).

Then Binary Univariate Logistic Regression was applied in order to verify the individual impact of every laboratory parameter on cytokine storm development. Furthermore, all laboratory parameters were subsequently included in the multivariate analysis, using the backward selection technique to achieve a model as predictive as possible.

Results: We mention that the analysis of demographic data was previously performed, showing no statistically significant relationship between patient gender, age, comorbidities (histories of neuro, lung diseases, cardiovascular disease, obesity, type II diabetes and hypertension) and their evolution to cytokine storm.

After performing binary univariate logistic regression we concluded that 8 of the 13 laboratory analyzes have had a significant change between groups (ferritin, PCR, albumin, Lymphocyte, Neutrophil, TGO, LDH, BUN:creatinine ratio (BUN - blood urea nitrogen). The laboratory parameters used for the statistical analysis represent the average values of the first 7 days of hospitalization for those patients who developed cytokine storm, respectively the day of its development, for the others. Patients were classified into these groups, those who developed cytokine storm, respectively those who did not.

Conclusion: High C-reactive protein, neutrophilia, LDH, ferritin and the BUN:creatinine ratio are risk factors for cytokine storm development and should be monitored in all COVID-19 patients in order to predict their evolution.

PERICARDITIS AFTER COVID-19 VACCINATION: A CASE SERIES

Keywords: Heart, COVID, Vaccination/immunization

F. Casarini1, C. Carollo1, R. Mascolo1, A. Pedrolli1, G. Faraci1, E. Bizz1, M. Pancrazii1, L. Trotta1, C. Lorentino1, A. M. Pisacreta1, A. Brucato1.
1Fatebenefratelli Hospital, Milan, Internal Medicine, Milan, Italy

BACKGROUND: COVID-19 vaccination campaigns successfully impacted on viral spreading and in particular on clinical course of the disease. However, secondary to a highly extended vaccination program, several local and systemic adverse events associated with mRNA COVID-19 vaccines have been reported. Pericarditis and myocarditis are examples of cardiac complications related to these vaccines. In particular, cases of pericarditis have occurred after mRNA COVID-19 vaccination (mostly secondary to vaccination with Moderna than Pfizer-BioNTech), especially in male adolescents and young adults, more often after the second dose. The incidence is approximately of 1-2 cases/100.000

Objectives: Aim of our study was to study the clinical profile of pericarditis occurred within 30 days after COVID-19 vaccines in our clinic.

Methods: We present a case series of patients who developed pericarditis after COVID-19 vaccination in the Department of Internal Medicine at Fatebenefratelli Hospital in Milan, followed from December 1, 2021 to April 15, 2022.

Results: Twenty-five individuals, of which 18 (72%) were women and 7 (28%) were males, had vaccine related pericarditis. Two patients were vaccinated with AstraZeneca, 2 with Moderna, the remaining with Pfizer-BioNTech. Median age was of 42 years. Of all patients, one subject was affected by myocarditis and anakinra in a patient with COVID-19 vaccine-related acute pericarditis relapse.a case report; European Heart Journal - Case Reports (2022) 6, 1–6.

Conclusions: COVID-19 vaccination induces a particular form of pericarditis, often insidious and very troublesome, but with good prognosis. The clinical phenotype showed less typical chest pain, often normal indices of inflammation and little or no instrumental changes, but patients often experienced tachycardia and functional limitation. With regard to therapy, we used NSAIDs at adequate dosages to control the clinical condition, or low-dose colchicine. Low doses of corticosteroids are useful in the presence of marked asthenia or systemic symptoms. Beta-blockers or ivabradine were used in the presence of tachycardia.

[2] Li JY, Wang HF, Yin P, Li D, Wang DL, Peng P, et al. Clinical characteristics associated with higher incidence of venous thromboembolism (VTE) and higher mortality rates. [1-3]. Autoimmune Rheumatic Diseases (ARDs) are associated with higher rates of VTE compared to general population [4]. Whether patients with ARDs infected with SARS-CoV-2 have similar D-dimer and fibrinogen trends compared to patients without ARDs is unknown.

Table 1. Differences in D-dimer and fibrinogen levels in patients with ARDs during SARS-CoV2 infection between patients with ARDs and those without ARDs. Additional studies are needed to quantify the actual risk of VTE in patients with ARDs during SARS-CoV2 in correlation with serum markers of VTE.

**THE KINETICS OF HUMORAL AND CELLULAR RESPONSES AFTER THE BOOSTER DOSE OF COVID-19 VACCINE IN INFAMMATORY ARTHRITIS PATIENTS**

**Keywords:** COVID, Vaccination/immunization

**J. Wroskić1, B. Jaszczyczyk2, L. Roszkowski3, A. Felis-Giernza2, K. Bonek1, A. Kornatka1, M. Plebanczyk2, T. Burakowski4, B. Lisowska5, B. Kwiatkowska5, W. Maśliński6, M. Wielowska1, M. Massalska4, E. Kuca-Warnawin4, M. Ciechomska4, 1National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland; 2National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Anesthesiology, Warsaw, Poland; 3National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Rheumatology, Warszawa, Poland; 4National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Rheumatology, Warsaw, Poland; 5National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Outpatient Clinics, Warsaw, Poland; 6National Institute of Geriatrics, Rheumatology and Rehabilitation, Biologic Therapy Center, Warsaw, Poland.

**Background:** Impaired immunogenicity of COVID-19 vaccinations in inflammatory arthritis (IA) patients results in diminished immunity. However, optimal booster vaccination regimens are still unknown, due to unstudied kinetics of the immune response after booster vaccinations.

**Objectives:** This study aimed to assess the kinetics of humoral and cellular responses in IA patients after the COVID-19 booster.

**Methods:** In 29 IA patients and 16 healthy controls (HC) humoral responses (level of IgG antibodies) and cellular responses (IFN-γ production) were assessed before (T0), after 4 weeks (T1), and after more than 6 months (T2) from the booster vaccination with BNT162b2.

**Results:** IA patients, but not HC, showed lower anti-S-IgG concentration and IGRA fold change at T2 compared to T1 (p=0.026 and p=0.031). Furthermore, in IA patients the level of cellular response at T2 returned to the pre-booster level (T0). All immunomodulatory drugs, except IL-6 and IL-17 inhibitors for the humoral response and IL-17 inhibitors for the cellular response, impaired the immunogenicity of the booster dose at T2. However, none of the immunomodulatory drugs affected the kinetics of both humoral and cellular responses (measured as the difference between response rates at T1 and T2).

**Conclusion:** Our study showed impaired kinetics of both humoral and cellular responses after the booster dose of the COVID-19 vaccine in IA patients, which, in the case of cellular response, did not allow the vaccination effect to be maintained for more than 6 months. Repetitive vaccination with subsequent booster doses seems to be necessary for IA patients.

**AB1351**

**FREQUENCY OF VACCINE-RELATED ADVERSE EVENTS IN PATIENTS WITH RHEUMATIC DISEASE**

**Keywords:** COVID, Rheumatoid arthritis, Vaccination/immunization

**D. X. Xibille Friedmann1, V. Balderas Reyes2, M. Olvera2, M. Alcocer León2, A. A. Reyes Salinas2, M. Rodríguez Falcón3, S. M. Carrillo Vazquez2, 1Cuernavaca General Hospital Dr. José G. Parres., Rheumatology, Cuernavaca, Mexico; 2ISSSTE Regional Hospital October 1, Rheumatology, Ciudad de México, Mexico

**Background:** Patients with rheumatic diseases are at greater risk of developing serious infections due to dysregulation of the immune system and the use of immunosuppressants. Therefore, preventing infection is crucial, with vaccination being the most important primary prevention intervention, leading to a lower rate of hospital admissions due to infections. However, vaccine hesitancy among persons with rheumatic diseases is widespread due to concerns regarding the safety of vaccines.

**Objectives:** Describe the frequency of adverse events associated with vaccination in patients with rheumatic diseases.

**Methods:** Observational, descriptive, cross-sectional and retrospective study was carried out in patients with rheumatic diseases from the Rheumatology Department of the Hospital Regional 1° de Octubre ISSSTE, from February to May 2022; it included patients over 18 years of age with an established diagnosis of rheumatic disease who had received a vaccine; the researcher applied the vaccine-associated adverse events survey to those patients who agreed to participate by signing the informed consent. The sample size was of 95 patients. Descriptive statistics and summary measures were employed for analysis. We used the chi-square test or Fisher’s exact test (when <5) for the comparative analysis of the frequencies of nominal qualitative variables. P<0.05 was considered significant.

**Results:** The survey was applied to 115 patients. 85.2% were women; mean age 57.9 years; 61.7% had rheumatoid arthritis (RA), followed by systemic lupus erythematosus (SLE) in 13.9%, 55.6% of the patients were treated with steroids, 52.2% received bDMARDs and 48.7% csDMARDs. Patients received various vaccines, of which the most frequent was the one for COVID-19, with 99.1% of included patients having received at least one dose, followed by influenza in 30.4%; 78% of the patients who received at least one dose of a vaccine against COVID-19 presented ≥1 adverse events. The disease in which the highest frequency of adverse events occurred was RA, without this difference being statistically significant (Table 1). The adverse events according to the type of COVID-19 vaccine were the following: Sputnik-V 80%, Pfizer 76.6% and Astra-Zeneca 76.1%, without statistically significant difference between vaccine types. The most frequently occurring adverse events were injection site pain (80.1%), headache (30.7%), and fatigue (30.7%); In addition, the main vaccine-associated musculoskeletal symptoms were joint pain, myalgia, and morning joint stiffness (Figure 1), which on most cases improved after a NSAID use. Joint pain was more frequent after the second dose of certain vaccine types.

**Table 1. Frequency of AE after COVID-19 vaccination in patients according to disease.**

<tr>
<td>Osteoarthritis</td>
<td>6</td>
<td>0.614</td>
</tr>
</tbody>
</table>

**Figure 1. COVID-19 associated musculoskeletal AE**

**Conclusion:** Vaccine-associated AE occurred more frequently than reported in international studies; however, they were not more serious. Providing this information to patients is important to improve vaccine acceptance. In addition, the administration of NSAID after the application of the vaccine could be proposed to reduce the presence of side effects.

AB1352 IMPACT OF SYSTEMIC THERAPIES ON THE SEROPREVALENCE OF SARS-COV-2 IN PATIENTS WITH IMMUNE-MEDIATED DISEASES

Keywords: COVID, bDMARD, Disease-modifying drugs (DMARDs).

M. L. C. Romero Bogaño1,2, M. Steiner1,2, T. Cobo-Ibáñez1,2, A. Gómez1,2, B. Paredes Romero1,2, I. Thuisard Vasallo3, C. Andreu Vazquez3, A. V. Esteban Sebastián de los Reyes (Madrid), Spain; Universidade Europea de Madrid, Madrid, Spain; Hospital Universitario Infanta Leonor, Reumatología, Madrid, Spain; Universidad Complutense de Madrid, Medicina, Alcobendas, Madrid, Spain; Universidad Europea de Madrid, Medicina, Grupo de Asesoramiento en Metodología de Investigación, Alcobendas, Madrid, Spain; Hospital Universitario Infanta Leonor, Reumatología, Madrid, Spain; Hospital Universitario Infanta Sofia, Farmacia, San Sebastián de los Reyes (Madrid), Spain; Hospital Universitario Infanta Sofia, Farmacia, San Sebastián de los Reyes (Madrid), Spain; Hospital Universitario Infanta Sofia, Farmacología, San Sebastián de los Reyes (Madrid), Spain; Hospital Universitario Infanta Sofia, Gastroenterología, San Sebastián de los Reyes (Madrid), Spain; Hospital Universitario Infanta Sofia, Laboratorio, San Sebastián de los Reyes (Madrid), Spain

Background: The disease modifying antirheumatic drugs (DMARD) impair the immune response of patients with immune-mediated inflammatory diseases (IMID).

Objectives: To analyze the seroprevalence of SARS-CoV-2 in patients with IMID treated with biological disease modifying antirheumatic drugs (bDMARD) or targeted synthetic (tsDMARD).

Methods: An ambispective cross-sectional study was performed in patients with IMID treated with bDMARD or tsDMARD. Seroprevalence was compared by measuring IgG against SARS-CoV-2 between October 2020 and May 2021.

Results: A total of 550 patients with IMID were studied, all of them on bDMARD or tsDMARD therapy, none of them vaccinated at that time against SARS-CoV-2. Patients receiving anti-TNFα therapy had a higher seroprevalence than other biologic and synthetic targeted therapies (OR= 1.792; 95% CI 1.088-2.951; p= 0.021). Patients with bDMARD or tsDMARD therapy treated concomitantly with some type of conventional synthetic DMARD (csDMARD) presented a lower seroprevalence compared to patients treated in monotherapy. 10.7 vs. 19.9% (p= 0.003). When analyzing the treatments with the different csDMARD separately (methotrexate, leflunomide, sulfasalazine, azathioprine, hydroxychloroquine and the others), methotrexate was determined to influence in a lower seroprevalence compared to those who did not receive any csDMARD. 9.8 vs 19.9% (OR= 0.439, 95% CI 0.232-0.828; p= 0.011). When evaluating the influence of methotrexate on seroprevalence among the different groups of bDMARD or tsDMARD, a lower seroprevalence was demonstrated in the group of patients receiving anti-TNFα and methotrexate in combination, versus patients on this bDMARD in monotherapy, 10.1 vs 24.1% (OR= 0.355, 95% CI 0.165 - 0.764; p=0.006). No significant differences were identified with the other btsDMARD and csDMARD.

Conclusion: Seroprevalence in the group of patients with IMID is influenced according to the therapy received, being higher in patients receiving anti-TNFα monotherapy, but significantly lower if concomitant to this drug they receive methotrexate. These differences are not seen with the other btsDMARD and csDMARD.

AB1353 RHEUMATOLOGICAL PAIN CONDITIONS ARE NOT RISK FACTORS FOR THE DEVELOPMENT OF WIDESPREAD POST-COVID PAIN IN COVID-19 SURVIVORS

Keywords: COVID, Epidemiology.

L. Arendt-Nielsen1, B. D. Ebbesen1, R. Giordano1, J. A. Valera-Calero2, C. Fernández-de-Las-Peñas3, 4Aalborg University & Aalborg University Hospital, School of Medicine, Center for Neuroplasticity and Pain/SMI, Gistrup, Denmark; 2Universidad Camilo José Cela, Department of Health, Madrid, Spain; 3Universidad Rey Juan Carlos, Department of Physical Therapy, Occupational Therapy, Physical Medicine and Rehabilitation, Madrid, Spain

Background: Up to 60% of COVID-19 survivors develop long-COVID symptoms[1]. Musculoskeletal pain is also a common (~11%) symptom of long-COVID.[2] Current theories hypothesize that post-COVID pain can be widespread in other chronic pain conditions. The presence of previous rheumatological diseases could act as a risk factor for the development of persistent widespread post-COVID pain due to a potentiation of pro-inflammatory responses seen during the infection or due to a less robust immune response. A previous pilot study investigated if rheumatological diseases were associated with post-COVID symptoms in a specific population of hospitalised COVID-19 survivors.[3]

Objectives: The aim of this study was to identify if the presence of previous specific rheumatological diseases are risk factors for the development of widespread post-COVID pain in previously hospitalised and non-hospitalised COVID-19 survivors.

Methods: We conducted a nation-wide, cross-sectional exploratory study with a pain-related questionnaire collecting demographics, pre-existing rheumatological conditions, and the development of widespread pain symptoms after SARS-CoV-2 infection from a Denmark-based population.

Results: Data from 1,000 previously hospitalised (51.2% males; 60.4±15.2 years; 85.6±18.5kg) and 1,000 previously non-hospitalised COVID-19 survivors (43.5% males; 50.4±15.9 years; 79.2±16.6 kg) were analysed. Distribution of gender (p<0.001), age (p<0.001), and weight (p=0.001) was different between groups. The presence of widespread pain symptoms six months after infection was higher (P<0.001) in hospitalised survivors (20%) as compared to non-hospitalised patients (4.2%). The presence of previous rheumatological conditions such as arthritis, osteoarthritis or joint pain were not associated with the development of widespread post-COVID pain in either group (all, P>0.1).

Conclusion: This exploratory study shows that the presence of previous rheumatological conditions before SARS-CoV-2 infection was not a risk factor associated with development of widespread post-COVID pain symptomatology. Other risk factors e.g., female sex or the presence of musculoskeletal pain, could be more relevant for widespread post-COVID pain-related research.[4]

AB1355 EFFECT OF COVID-19 VACCINES ON ACTIVITY OF AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Vaccination/immunization.
Background: The SARS-CoV-2 pandemic has paralyzed the world. Patients with autoimmune rheumatic diseases (AIRDs) are at high risk for SARS-CoV-2 infection [1]. Worldwide vaccination campaigns, which have increasingly built up immunity in this populations. Studies on the efficacy and safety of the vaccines have shown rapid and strong development of immunity in healthy populations and AIRDs [2].

Objectives: To evaluate COVID-19 vaccination status in patients with autoimmune rheumatic diseases (AIRDs) whether receiving primary and booster vaccination and its relation to disease activity.

Methods: An observational cross section study conducted on a total number of 282 subjects divided into 2 groups: group (I): 179 vaccinated AIRD patients and group (II): 103 non-vaccinated AIRDs patients where Complete COVID-19 vaccination history. Disease activity scores of AIRDs were measured pre to post vaccination.

Results: Most of studied group 63% were vaccinated, Pfizer vaccine was the most common 33%, Asterzinca 19%, Sinopharm/Sinovac 10%, while Moderna was the least the least type of vaccine 1%. Figure 1. Pfizer vaccine 46% was the most common booster type, Asterzinca 39%, Sinopharm/Sinovac 8% and Moderna vaccine 3% and 4% of studied group not received booster vaccination, Figure 2. Most of Rheumatic disease were vaccinated; 46.4% Rheumatoid arthritis 39.7% Systemic Lupus Erythematosus, 5% Bechet’s disease 3.9% Ankylosing Spondylitis and 2.8% Vasculitis. In vaccinated group, severity of disease activity was statistically significantly higher in post-vaccination than pre-vaccination, Table 1.

Conclusion: Pfizer vaccine was the most common vaccine in AIRDs. COVID-19 vaccination may induce flare of disease activity in AIRDs.

AB1356 COVID-19 VACCINE PERCEPTION AND HESITANCY AMONG PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASE (AIRD) IN MALAYSIA

Keywords: Vaccination/immunization, COVID, Comorbidities

S. S. Shaharin1, L. Kamaruzaman1, T.N. Mariamutu1, M. S. Mohamed Said1, A. Mohammed Naww1, W. W. Wan Ghazali1, M. Mohd Noh1, 2Universiti Kebangsaan Malaysia, Faculty of Medicine, Internal Medicine, Kuala Lumpur, Malaysia; 3Universiti Kebangsaan Malaysia, Faculty of Medicine, Public Health, Kuala Lumpur, Malaysia; 4Universiti Putra Malaysia, Faculty of Medicine And Health Sciences, Internal Medicine, Serdang, Malaysia; 5Universiti Malaysia Sabah, Faculty of Medicine and Health Sciences, Medicine, Kota Kinabalu, Malaysia

Background: Patients with autoimmune rheumatic disease (AIRD) are at risk of severe COVID-19 infection and vaccine has been demonstrated to be able to reduce the severity of infection. Malaysia has a low flu vaccination coverage rate (approximately 3%) and hence it is important to assess the perception and hesitancy of COVID-19 vaccine especially among the vulnerable group.

Objectives: To study the perception of COVID-19 vaccine and to determine the prevalence of vaccine hesitancy among AIRD patients in Malaysia.

Methods: This was a cross-sectional survey using online Google Forms© that was conducted among adult AIRD patients (18 years and older) from August 2021 until February 2022. Patients were recruited from the outpatient clinics as well as distribution of the survey through social medias. The survey was in English and Malay language. The survey collected data on the socio-demographic background, prior history of other vaccination after the age of 18 and COVID-19 vaccination with reasons of hesitancy, defined as being unsure or unwilling to be vaccinated. The survey also assessed the patients’ perception by specifying the level of agreement to COVID-19 vaccine statements using the Likert response scale: 1-Strongly disagree; 2- Disagree; 3-Neither agree nor disagree; 4-Agree; 5-Strongly agree.

Results: A total of 162 patients participated in the survey and majority of them were females (87.7%). Our multi-racial cohort consisted of Malay (n=103, 63.5%), followed by Chinese (n=38, 23.5%), Sabahan Bumiputra (n=12, 7.4%) and Indian (n=7, 4.3%). More than half (n=107,66.6%) have not had any history of other vaccination after the age of 18. Only 16.7% (n=27) agreed/strongly agreed that COVID-19 vaccine can be given to patients with co-morbidities and 24.1 (n=39) agreed/strongly agreed that COVID-19 vaccine can be given to patients who have history of allergy to other drugs or food. At the time of the survey, vast majority of the respondents have received at least the 1st dose of Covid-19 vaccine (n=148, 91.4%). A total of 9 (5.6%) patients were hesitant to be vaccinated (6 were unsure and 3 patients were not willing to be vaccinated). The commonest reasons of being unsure or not willing to be vaccinated was worried of the vaccine’s adverse effects (66.7%), worried of the blood clot complication (33.3%), worried of disease flare post-vaccine (33.3%), worried of allergic reaction (22.2%), lack of information on the safety of the vaccine in patients with AIRD from government and media (22.2%), face mask and social distancing measures were inadequate (22.2%). Statistical analysis revealed that more patients who had vaccine hesitancy were from the lower socioeconomic status (income <1066 Euro/month), 88.9% vs 11.1%, p=0.03 but no association with ethnicity, education status, marital status or place of residence (urban vs rural).

Conclusion: COVID-19 vaccine hesitancy is low in Malaysian patients with AIRD but patients with a low socioeconomic status are prone to have vaccine hesitancy. More education on the vaccine’s efficacy and safety especially among patients with co-morbidities are warranted.

AB1357

RISK OF APS AND APLS POSITIVE PATIENTS FOR THROMBOSIS WITH COVID-19

Keywords: COVID, Autoantibodies, Anti-phospholipid syndrome

F. Berianu1, R. Butendieck1, B. Wang31. Mayo Clinic, Rheumatology, Jacksonville, United States of America

Background: Coagulopathy, thromboembolic events and DIC during COVID-19 infection has been reported. Antiphospholipid antibodies (aPLs), present in 1–5% of healthy individuals. aPLs are associated with the risk of antiphospholipid syndrome (APS) which is associated with higher risk of thrombosis.

Objectives: We wanted to see if patients with known APS or aPLs only are at higher risk of a thrombotic event compared to control when developed COVID-19. We retrospectively review EMR for over a year for thrombotic events in patients with COVID and prior history of APS or aPLs only and matched them to control.

Methods: Patient characteristics and laboratory testing were summarized according to the following groups: APS, aPLs detected or control. The control were matched according to age and gender for each group. Continuous variable were summarized as median (range) and mean (standard deviation), while categorica variable were reported as frequency (percentage). The binary patient outcome of thrombotic event, hospitalization for COVID, death, and composite event (the combined occurrence of thrombotic events, hospitalization, death) were calculated and interpreted as the multiplicative increase in odds of the given outcome for aPL group compared to control group. Multivariable logistic regression models were adjusted for potential risk factors (immobilization, hypertension, coronary artery disease, diabetes mellitus, and smoking) one at a time due to the rare occurrences of events studied.

Results: In single variable analysis (unadjusted) the odds of the patient having a thrombotic event was approximately 27 times higher in patients with aPL only compared to Controls (P<0.001). We see similar results in multivariable analyses (adjusted) adjusting for the following variables one at a time: immobilization, hypertension, coronary artery disease, diabetes mellitus, and smoking. In each of the multivariable analyses, the adjusted odds of a thrombotic event was between approximately 24 and 29 times higher in patients with aPL Antibody Only compared to Controls (all P<0.001) indicating that association of aPL Antibody Only with thrombotic event was independent of immobilization, hypertension, coronary artery disease, diabetes, and smoking. There was no statistically significant risk of thrombosis in APS group vs control. Majority of patients with APS were on chronic anticoagulation.

Conclusion: We found a statistical significantly difference in patient with aPLs only versus control regarding risk of thrombosis when developed COVID-19. No statistically significant risk was noted in patients with APS, While chronic anticoagulation in APS patients is protective it seemed that patient with aPLs only do carry a high risk of thrombosis if any inciting factors like COVID-19.

DOI: 10.1136/annheumdis-2023-eular.4623
Treatment suspension because of non-medical reasons might lead to disease activation and organ damage. **Objectives:** Identify the frequency of biologic treatment (bDMARD) suspension among patients with RD during the COVID-19 pandemic and determine the associated factors for suspension. **Methods:** In this study we included all patients registered in the Mexican Biologics Adverse Events Registry (BIOBADAMEX), that started bDMARD before March 2019 and suspended treatment during the COVID-19 pandemic. We used descriptive statistic to analyze baseline characteristics and main treatment suspension causes. We used Chi[2] and Kruskal Wallis tests to analyze differences between groups. **Results:** Of 832 patients patients registered in BIOBADAMEX were included in this study, 143 (17%) suspended bDMARD during the COVID-19 pandemic. The main causes of suspension were inefficacy in 54 (38%) patients, followed by other motives in 49 (34%) patients from which 7 (5%) was loss of medical coverage. Adverse events and loss of patients to follow up were the motive in 16 (11%) and 15 (11%) patients respectively. When we compared the group that suspended bDMARD with the non-suspenders (Table 1), we found statistical differences in patient gender, with 125 (87%) female patients that suspended bDMARD, with a median age of 52 (42-60) years, and a treatment duration of 3.8 years. **Conclusion:** In our study we found that 17% of patients with RD suspended bDMARD treatment during the COVID-19 pandemic and that non-medical motives such as lack of patients follow up and loss of medical coverage due to unemployment were important motives. These results are related to the effect of the pandemic on other chronic diseases. **REFERENCES:** NIL. **Acknowledgements:** NIL. **Disclosure of Interests:** Vilma Rivera Teran: None declared, Daniel Xavier Xibile Friedmann: None declared, David Vega-Morales: None declared, Sandra Sicik: None declared, Angel Castillo Ortiz: None declared, Fedra Irazo-qui-Quezalueos: None declared, Dafhne Miranda: None declared, Iris Jazmin Sicsik: None declared, Angel Castillo Ortiz: None declared, Omar Eloy Muhoz-Morroy: None declared, Sandra Carrilo: None declared, Angelica Peña: None declared, Sergio Duran Barragan: None declared, Luis Francisco Valdés Corona: None declared, Estefania Torres Valdez: None declared, Azucena Ramos: None declared, Aleni Paz: None declared, ERICK ADRIAN ZAMORA-TEHOZOL: None declared, Deshie Alpizar-Rodriguez Employee of: Scientific Advisor in GSK Mexico. **CLINICAL FEATURES OF COVID-19 IN PATIENTS WITH CONNECTIVE TISSUE DISEASES DURING THE RECENT PANDEMIC IN GUANGZHOU, CHINA**

**Keywords:** Real-world evidence, Health services research, COVID

Y. Jiang1, X. Zheng1, Y. Wu1, S. Zhong1, Y. Liang1, Y. Gu1, Z. Liao1

1Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China

**Background:** Patients with connective tissue diseases (CTD) are vulnerable to SARS-COV-2 infection, given that a proportion of CTD patients suffer from interstitial lung diseases (ILD). Moreover, the use of glucocorticoids and immuno-suppressive agents could affect the outcome of lung diseases. The impact of SARS-CoV-2 on interstitial lung diseases remains poorly investigated as the pandemic has recently occurred in Southern China.

**Objectives:** The study aimed to describe the clinical features and hospitalisation costs of COVID-19 in CTD patients, especially those with COVID-19 pneumonia.

**Methods:** It was a cross-sectional case series study. Demographic data, symptoms, signs, medical history, laboratory, radiological findings and costs were collected from 86 CTD patients from the inpatient department in a tertiary hospital during the COVID-19 pandemic in Guangzhou, China.

**Results:** Of the 86 CTD patients, 67 (77.9%) were females, and 24 (27.9%) had CTD-ILD before admission. 54 (62.8%) of them had SARS-CoV-2 infection detected by nucleic acid or antigen tests for SARS-CoV-2. Patients with SARS-CoV-2 infection had older age, higher WBC, neutrophil/lymphocyte ratio and CEA. Moreover, 325 (39.1%) of the participants had COVID-19 pneumonia confirmed by the HRCT. Noticeably, 15 CTD patients without ILD presents with COVID-19 pneumonia. Patients with COVID-19 pneumonia had older age, higher serum ferritin, CEA, and C-reactive protein (p<0.05). According to the rheumatologists’assessment, 6 (4.19%) of the patients had worsened CTD disease activity, 14 (16.3%) of the patients had confirmed infections involving the lung (6), skin (3), urinary tract (2), gastrointestinal tract (1), blood (1), and vagina (1). The pathogens isolated included staphylococcus aureus, candida albicans, escherichia coli, cytomegalovirus, Epstein-Barr virus and herpes zoster virus. Among all the symptoms related to COVID-19, coughing was the most frequent symptom, followed by sputum, fatigue and fever. 27 (31.4%) of the patients required a nasal cannula for oxygen administration. The median hospital stay was 7 (1-30) days. All the patients got improved before the discharge.

**Conclusion:** Disease flare and COVID-19 pneumonia should be noticed in patients with CTD during the pandemic.

1Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China

**Background:** SARS-CoV-2 (Severe acute respiratory syndrome coronavirus 2) has been circulating worldwide for three years. It mainly causes upper respiratory tract infection, which can manifest as pulmonary infection and even respiratory distress syndrome in severe cases. Different autoantibodies can be detected in patients infected with COVID-19.

**Objectives:** To explore autoantibodies related to rheumatic diseases after COVID-19 infection.

**Methods:** Ninety-eight inpatients were tested for antinuclear antibodies (ANA), antibodies to extractable nuclear antigens (ENA), anti-neutrophil cytoplasmic antibodies (ANCA), anticardiolipin antibodies, anti-cardiolipin antibodies, anti-β2GPI (IgG/IgM). They were from a tertiary hospital in Guangzhou during the COVID-19 pandemic. Data were described statistically.

**Results:** Ninety-eight hospitalized patients were tested for relevant antibodies. The average age was 50.6±4.9±5.4; 67 (68.4%) were male, 64 (65.3%) were COVID-19 positive, 90 (90.9%) had rheumatic diseases, and 56 of them were COVID-19 positive patients with rheumatic diseases. There were 76 patients tested for antinuclear antibodies, 29 (38.1%) were negative, 18 (23.6%) had a 1/80 titre, and 19 (28.6%) had a titre greater than 1:80. The 31 covid patients were positive for ANA. In the high-titer group, 19 patients with rheumatic diseases were positive for COVID-19, and 12 patients had an exacerbation of the rheumatic diseases (6 of whom had previously had pulmonary fibrosis). Of 31 covid patients, only two were non-rheumatic patients, and both were elderly, aged 85 and 100, respectively. Fifty-six patients had ENA results, and 29 for positive antibodies, 8 for ds-DNA antibodies, 2 for anti-Sm antibodies, 6 for anti-nucleosome antibodies, 12 for anti-U1RNP antibodies, 2 for anti-Scl-70 antibodies, 12 for anti-SS-A antibodies, 3 for anti-mitochondrial M2 antibodies, 2 for anti-centromere antibodies, 1 for anti-PM antibodies, and one for anti-Jo-1 antibody. All 56 patients had rheumatic diseases, and no new patients were found. There were 62 patients with ANCA data. P-ANCA was positive in 12 cases (19.35%), and MPO-ANCA was positive in 2 cases. An 85-year-old non-rheumatic COVID-19 patient was P-ANCA positive. She had a history of hypertension, colon cancer, CKD3, coronary heart disease, and atrial flutter. In the anticardiolipin antibodies group, there were 62 patients; only 6 were positive, and 2 were rheumatic patients infected with COVID-19. Antiphospholipid antibodies were detected in 35 patients, and a-β2GPI was tested in one patient, an 82-year-old COVID-19 patient with gout, diabetes, and cerebral infarction in the past. We did not find a statistical difference in the above results.

**Conclusion:** We have not found a correlation between SARS-CoV-2 and serum autoantibodies of rheumatic immune diseases. It needs large samples and an extended follow-up to research.

AB1361
COVID-19 IN PATIENTS WITH INFLAMMATORY ARTHRITIS IN THE VINSCHGAU VALLEY IN SOUTH TYROL

Keywords: COVID, Inflammatory arthritides

P. Matzneller1, A. Muñen1,2, M. Wierer1,2, C. Duftner2, C. Dejaco1. 1South Tyrol Health System-ASDAA-SABES, Service of Rheumatology, Brunico, Italy; 2Medical University of Innsbruck, Department of Internal Medicine, Clinical Division of Internal Medicine II, Innsbruck, Austria

Background: For patients with autoimmune rheumatic diseases, the Covid-19 pandemic carried some implications in addition to those faced by the general population. In particular, the question whether these patients are at increased risk of contracting Covid-19 or have an unfavourable disease course has been and is a matter of concern. In autumn 2020, the population of the Vinschgau valley in South Tyrol, northern Italy was still largely spared from infection with SARS-CoV-2. Accordingly, incidence of the disease in the upcoming winter was anticipated to be high.

Objectives: This prospective observational study aimed at characterizing Covid-19 infections in a population of patients with inflammatory arthritis (IA) residing in the Vinschgau valley. The study was conceived as companion project to an analogously designed prospective cohort study in the general population of the Vinschgau valley, the CHRIS Covid-19 study.

Methods: Between September and December 2020, IA patients (i.e. previously diagnosed rheumatoid arthritis [RA], psoriatic arthritis [PsA] or peripheral spondyloarthritides [SpA]) residing in the Vinschgau valley (n=394 based on national healthcare system database) were contacted. Those who consented to participate in the study underwent a clinical baseline visit including TJC, SJC, VAS and assessment of RAID, PsAID or BASDAI (range 0-10, respectively). In addition, a Covid-19 screening questionnaire was administered. Then, active and/or past infection with SARS-CoV-2 were determined by nasopharyngeal swab (PCR) and serum antibody test. In positively tested subjects, Covid-19 disease severity was graded according to WHO criteria (range 0-8, with 0 = no evidence of infection and 8 = death). Patients were followed-up with regular telephone interviews including Covid-19 screening questionnaire and RAID/PsAID/BASDAI for up to 12 months.

Results: 111 patients (72 RA, 29 PsA, 10 SpA) were enrolled (see Table 1 for demographics and comorbidities). A total number of 19 PCR-confirmed SARS-CoV-2 infections in 17 patients (10 RA, 7 PsA) were observed. Mean ± standard deviation 7-day incidence (incident cases/ study population) was 0.003 ± 0.007. Fatigue, fever, anosmia and sore throat (present in 57.9%, 47.4%, 42.1% and 36.8% of infections, respectively) were the most frequent symptoms. Median (min-max) disease severity was 2 [1-4]. Two infections led to hospitalization, in one case oxygen supply was necessary. Four infections were asymptomatic (Figure 1). One patient died during follow-up due to pre-existing non-small cell lung cancer. Median absolute difference between post- and pre-infection disease activity was 0.4 and -0.8 for RAID and PsAID, respectively (both markedly below the minimal clinically important difference of 1). One patient died during follow-up due to pre-existing non-small cell lung cancer. Median absolute difference between post- and pre-infection disease activity was 0.4 and -0.8 for RAID and PsAID, respectively (both markedly below the minimal clinically important difference of 1).

Conclusion: Incidence of Covid-19 in the analysed cohort of patients with IA was low. Symptoms and comorbidities of SARS-CoV-2-positive IA patients reflected those known from the general population. Covid-19 seemed to have no relevant impact on IA disease activity. Comparison of these preliminary data with those of the general population is planned.

STUDY OF ADVERSE REACTIONS TO COVID-19 VACCINATION IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Vaccination/immunization, COVID

Y. Akiyama1,2, M. Matsuda1,2, Y. Chichin Yoshida1,3, M. Sato1,2,3, Meiyo Immunology & Rheumatology Clinic, Rheumatolory, Nagano, Japan; 2Setagaya Rheumatology Clinic, Rheumatolory, Tokyo, Japan; 3Meiyo Immunology & Rheumatology Clinic, Rheumatolory, Tokyo, Japan; 4Centro Medico Nacional La Raza, Mexico City, Mexico; 5Centro Medico Nacional La Raza, Medicina Interna, Mexico City, Mexico

Background: Vaccination has been recommended in the midst of the COVID-19 pandemic, but some patients are not vaccinated due to concerns about adverse reactions.

Objectives: The purpose of this study is to investigate the adverse reactions in rheumatic diseases and to guide the decision-making of patients and physicians.

Methods: A questionnaire was sent to patients with rheumatic diseases, and patients who could be counted as of September 2021, when they consented to this study, were surveyed.

Results: The subjects were 123 (male:female=10:113), 84 with rheumatoid arthritis and 39 with other immune diseases. The therapeutic agents used were PSL 31(25.2%), MTX 65(52.8%), NSAID/COX inhibitors 28(22.8%), bDMARDs 42(34.1%). adverse reactions after the first and second vaccination were fever 17(13.8%)/50(40.7%), joint symptoms 7(5.7%)/22(17.9%), local injection reactions (pain+irritation) 22(17.9%), local injection reactions (pain+erythema) 93(75.6)/98(79.7), systemic skin symptoms 0(0%)/2(1.6%), other symptoms (malaise, myalgia, etc.) 59(48.0%)/56(49.1%), and treatment intensification 54(41.1%)/12(9.7%). These responses differed in occurrence only for fever with and without PSL medication (22.5%; 473% (p=0.02)). The odds ratio for disease worsening after the first dose of vaccine and again after the second dose was 33.5 (p<0.01).

Conclusion: No specific adverse reactions other than the commonly known ones were observed, but some patients experienced worsening of symptoms after vaccination, requiring intensified treatment. Based on the results of this study, we believe that adverse reactions to vaccination are acceptable. We plan to accumulate more cases and analyze them in the future. The exacerbation of disease after the first vaccination would predict the exacerbation after the second vaccination.

AB1363
FIRST PRESENTATION OF AUTOIMMUNE RHEUMATIC DISEASES AFTER COVID-19 VACCINATION: A SYSTEMATIC REVIEW

Keywords: COVID, Epidemiology, Vaccination/immunization

C. Soto1, A. Peña2,3, F. Gonzalez1, P. Flores1, A. C. Medina-Garcia1, A. Bernal1, O. L. Vera Lastra2, C. Pineda1, L. J. Jara1.

Background: Covid-19 vaccination prevents 52% of expected infections, 56% of expected hospitalizations, and 58% of expected deaths in adults 18 years or
older [1]. Nevertheless, some case reports and series have demonstrated the new-onset rheumatological syndromes after vaccination.

**Objectives:** The aim of this systematic review is to establish the frequency, clinical features, and treatment response of new onset autoimmune rheumatic diseases after COVID-19 vaccination.

**Methods:** Systematic search for original research articles published between January 2021 and January 2023 was formulated. The search process was carried out following the PRISMA guidelines. Electronic searches were performed in Medline, EMBASE, Cochrane, Scopus, EBSCO, WoS and LILACS using the following key terms in all possible combinations: "Rheumatic diseases," "Systemic Vasculitis," "Myositis," "Polyserositis," "Systemic Lupus Erythematosus," "Antiphospholipid Syndrome," "Adult onset Still disease," "Rheumatoid arthritis," "ANCA-associated vasculi-

tis," "Spondyloarthritis," "Reactive arthritis," "Sjögren's syndrome," "Systemic sclerosis," "Covid-19 vaccine" and "SARS-CoV-2 vaccine." Cohort studies, case reports or case series were included if the patients fulfilled the specific diagnostic/classification criteria and/or nomenclature for each rheumatic autoimmune disease. Publications were excluded if they did not fulfill the above criteria.

**Results:** The electronic search yielded 280 publications. A total of 163 articles were evaluated and 59 reports with 108 patients (GCA 10, IgA vasculitis 9, SLE 14, ANCA vasculitis 24, adult-onset Still's disease 12, reactive arthritis 2, Rheumatoid Arthritis 5, Sjögren's syndrome 3, Systemic Sclerosis 2, Takayasu's arteritis 2, cryoglobulinemic vasculitis 1, Kawasaki disease 3, Polymyalgia rheumatica 16, PAN 1, SPA 2) were overlapped and removed. Antinuclear antibody syndrome was included. 44.4% were men and 43.5% were women with a median age of 60 years (IQR 40-74 y/o). 472 developed rheumatic disease after the first dose and 35.2% after the second dose, with a median of 10 days (IQR 5.5-14.5 days). 67.6% received corticosteroids (16.7% High-dose and 15.7% Pulse), 31.5% received immunosuppressant (cyclophosphamide 74%, rituximab 2.6, hydroxychloroquine 4.6, methotrexate 6.5, tocilizumab 2.8, mycophenolate 2.8, immunoglobulin 0.3 and 4.6% others). The 55.6% had complete remission, 24.1% partial and 6.5% non-response.

**Conclusion:** After Covid 19 vaccine, a minority of patients may develop for the first time an autoimmune rheumatic disease. Despite its increasing number of documented cases, the incidence remains low compared to the benefits of vaccination. 2. Patients present a high variability of clinical manifestations and most patients respond favorably to treatment. 3. The complex interaction between the vaccine component and the immune system must be studied.

| **Methods:** Descriptive, cross sectional, observational study, in a Paraguayan cohort of RA patients meeting ACR/EULAR2020 criteria, after follow-up in two Rheumatology reference centers, from October to December 2022. A standardized questionnaire according to the variables included (clinical, vaccination, vaccine type, number of doses) was made. Quantitative variables were presented as means and qualitative as frequencies.

**Results:** 568 patients with RA were included, 84.1% were female, mean age 55.48±13.94 years old. 23.9% patients were from Hospital de Clínicas and 76.1% from Hospital Central del Instituto de Previsión Social. The average number of vaccinated doses was 2.5±4.19. 86.7% of patients acquired at least one dose of COVID-19 vaccine, 85% obtained two doses; and, while 60.9% of patients received the first booster, 21.2% had the second one.

**Conclusion:** In this study, Paraguayan RA patients, vaccination against COVID-19 is higher than the general population, perhaps due to priority of patients with rheumatic diseases receiving immunization, and frequent access to medical care with physician's prompt to receive vaccinations. While over 80% of patients have a complete primary schedule, and more than 60% received the first booster; only 21% have a complete immunization schedule, which is still much higher than the general population in Paraguay.

| Table 1. Vaccines in Paraguayan patients with Reumatoid Arthritis |

**Pain in rheumatic diseases, including fibromyalgia**

**AB1386 A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE PREVALENCE OF PAIN SENSITIVITY AND NEUROPATHIC LIKE PAIN IN INFECTIOUS ARTHRITIS, USING QUESTIONNAIRES**

**Keywords:** Systematic review, Inflammatory arthritis

*Guy’s Hospital, Rheumatology Unit, London, United Kingdom; King’s College Hospital, Psychology Department, Institute of Psychiatry, London, United Kingdom; King’s College London Guy’s Campus, Centre for Inflammation Biology & Cancer Immunology, London, United Kingdom; King’s College London Guy’s Campus, Wolfson Centre for Age-related Diseases, London, United Kingdom

**Background:** Targeted pain relief is a major unmet medical need for patients with inflammatory arthritis (IA), where approximately 40% of patients experience persistent pain[1]. Self-reported questionnaires which report on pain sensitivity and neuropathic like pain may provide an insight into certain pain parameters to guide targeted treatment.

**Objectives:** In this systematic review and meta-analysis we evaluated self-reported pain sensitivity and neuropathic like pain in subjects with IA, as defined by questionnaires.

**Methods:** MEDLINE, Embase, Web of Science, PsycINFO and Google scholar were searched for publications and conference abstracts, reporting on pain sensitivity and neuropathic pain using painDETECT, DNA, LANSS, CSSQ, PSQI and McGill pain questionnaire in adult patients with IA. Risk of bias was assessed using National Institute of Health Quality Assessment Tool. Meta-analysis according to individual questionnaires criteria, was undertaken.

**Results:** 63 studies (38 full text and 25 conference abstracts) were included in the review, reporting on a total of 13,033 patients. On meta-analysis, prevalence of pain sensitivity/neuropathic pain in IA was 96% (95% CI 91-99%) according to painDETECT, 31% (95% CI 26-37%) according to the DN4, 32% (95% CI 24-39%) according to the LANSS and 42% (95% CI 34-50%) according to the CSI. On meta-regression, prevalence of pain sensitivity/neuropathic pain in RA was significantly lower than in SpA (p=0.01) and PsA (p=0.002) using the painDETECT questionnaire. Across all questionnaires, pain sensitivity and neuropathic like pain were significantly associated with pain severity, disease activity, disability, quality of life and anxiety and depression measures. Studies reporting on whether neuropathic like pain is a predictor of treatment outcome were inconsistent.

**Conclusion:** Pain sensitivity and neuropathic like pain contributes to pain perception in up to 42% of patients with IA. Despite substantial heterogeneity between studies on meta-analysis, this review highlights the large proportion of patients with IA who may experience pain due to underlying mechanisms other than in addition to synovial inflammation.

**Figure 1.** Prevalence of neuropathic like pain or pain sensitization according to painDETECT in RA, SpA and PsA.

**AB1387 EFFECTIVENESS OF REHABILITATION STRATEGIES IN PRIMARY FIBROMYALGIA SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS**

**Keywords:** Rehabilitation, Fibromyalgia, Non-pharmacological interventions

A Pathak, J. Rai, N. Rai, S. Singh, G. Bhat, A. Jaimis Bhopal, Physiology Department, Bhopal, India; "Neurocity Centre for Neuro Excellence, Neurology, Bhopal, India; "AIIIMS Bhopal, Physiology Department, Bhopal, India; "AIIIMS Bhopal, Pediatrics Department, Bhopal, India

**Background:** Fibromyalgia is characterized by chronic inconsistent widespread pain and tenderness. It is also associated with other comorbid symptoms like sleep disturbances, fatigue, cognitive impairments (memory and mood disturbances), and/or irritable bowel syndrome. [1] Prevalence of fibromyalgia is 2.7% globally, being slightly higher in middle aged women (4-9%). 75 to 100% patients with fibromyalgia face depression, anxiety and/or stress. The probability of occurrence of depression is almost 40% at any stage in the course of fibromyalgia. [2] Patients usually report physical symptoms of depression (e.g. appetite, sleep, and sexual dysfunction) rather than mood-related psychological symptoms (e.g. suicidal ideation, low self-esteem), however depression is affective expression of chronic pain and neuromarkers of both cannot be isolated. [3] Reviews done till date are either oriented toward specific form of exercise or towards specific outcome. We could not come across any review which included all form of exercise with measurement of multiple outcomes.

**Objectives:** The aim of this review was to i) summarize evidence on the effectiveness of rehabilitation strategies in Fibromyalgia syndrome (FMS) and 2) determine the most effective rehabilitation strategy for reducing pain and depression in people with FMS.

**Methods:** PubMed, Ovid (Sp), and Cochrane search engines were used for identifying the studies done till 1 July 2022. Randomized control trials (RCTs) that have passive control group and active control group were included in this review for primary and secondary aim respectively. The primary outcome measures were Pain and Depression. Secondary outcome was one from the sleep or fatigue or healthy related quality of life (HRQOL).

**Results:** A total of 25 RCTs were included. Separate random effect model meta-analysis is performed for randomised control trial with active and passive control group. Mean difference or Standard Mean difference with 95% confidence interval used to assess the effect size. Studies with passive control group showed moderate to large positive effects on pain (SMD -0.65, 95% CI -0.93 to -0.38; I² = 72%) and HRQOL (MD -0.40, 95% CI -1.07 to -0.62; I² = 74%) but non-significant for sleep, fatigue, and depression. Furthermore, on subgroup analysis studies with short term protocol showed significant effect on pain only whereas studies with long term protocols showed positive effect on pain and HRQOL only but non-significant at the time of post-trial follow-up. Studies with active control group represent non-significant results except mixed exercises which showed positive effect (MD -4.78, 95% CI -7.98 to -1.57; I² = 0%) for HRQOL.

**Conclusion:** All rehabilitation strategies were effective for pain and HRQOL, and has marginal effect on depression, sleep, and fatigue but efficacy was not maintained at the time of post-trial follow-up. However, in this review we could not
differentiate any rehabilitation strategies for the best among those used in the included studies.

AB1368 PROBLEMATIC USE OF OPIOIDS IN MUSCULOSKELETAL CHRONIC NON-CANCER PAIN: A PROSPECTIVE REAL LIFE STUDY

Keywords: Descriptive studies, Epidemiology, Pain

Background: Musculoskeletal chronic non-cancer pain (CNCP) has a multidimensional impact. Opioid treatments have a key role in their management but expose to risks of serious adverse effects and in particular to opioid use disorder and misuse. There is a lack of data on this topic in France. This work assesses the proportion of patients with problematic use of their opioid treatment in the rheumatology department and in the pain center of the University Hospital of Tours.

Objectives: This work assesses the proportion of patients with problematic use of their opioid treatment in the rheumatology department and in the pain center of the University Hospital of Tours.

Methods: We carried out a prospective monocentric observational study in routine care in patients followed for musculoskeletal CNCP and treated in this indication with weak or strong opioid treatment at the time of inclusion between January and December 2021. We collected demographic, clinical and opioid prescribing data. The primary endpoint was the percentage of problematic use of opioid treatment defined by overconsumption and/or misuse according to the Prescribed Opioid Misuse Index (POMI) and/or opioid use disorder according to DSM V criteria.

Results: 97 patients were included (68% women, median age 55 years); 37% of patients were treated with strong opioids. The median duration of opioid treatment was 4.5 years; 30% of patients had problematic use of their opioid treatment. There was overconsumption in 20% of patients, misuse in 22% and opioid use disorder in 15%. The group of patients with problematic use of opioid treatment had a higher body mass index and reported significantly more history of psychotrauma.

Conclusion: The problematic use of opioids in patients with musculoskeletal CNCP is frequent. These data are in agreement with those in the literature in other indications. The interest of therapeutic education programs or other preventive interventions remains to be defined.

Keywords: opioids, chronic non-cancer pain, opioid use disorder, misuse.

AB1369 FIBROMYALGIA AND INFORMATION SOURCES, THE EXAMPLE OF YOUTUBE: A CROSS-SECTIONAL ANALYSIS

Keywords: Patient information and education, Patient-led research, Fibromyalgia

Background: Fibromyalgia is a chronic condition affecting 2 to 8% of the population. Like any chronic disease, there is a need for information. More than one in two patients use the Internet as a source of health information. YouTube is an online video-sharing website that is consulted daily by both patients and healthcare professionals. This is the second most visited website in the world after Google. Usually, users view the top 60 most relevant videos.

Objectives: The aim of our study was therefore to analyse the scientific quality of fibromyalgia videos on YouTube.

Methods: We performed an analysis by using the French version of youtube (www.youtube.fr) using the keyword “fibromyalgia”. Search parameters were left as default (i.e. ranking videos by relevance as most users do). Only videos in French were included. The Global Quality Scale (GQS) was used to assess the quality of the content.

Results: 60 videos were selected. Four videos were excluded: 2 duplicates and 2 videos containing only music. The main results are presented in Table 1. 37.5% (n=21) of the videos were published by academic institutions and healthcare professionals. The mean duration of the videos was 12min34. The median GQS was 4. 75% (n=42) were scientifically relevant. 62.5% (n=35) of the videos demonstrated high quality, followed by intermediate quality (19.6% (n=11)). According to the GQS, 17.0% (n=10) of the videos were of low-quality.

Conclusion: To the best of our knowledge, we have conducted the first study examining the scientific quality of fibromyalgia-related content on YouTube. Most of the content on YouTube relating to fibromyalgia provide useful information. Nevertheless, physicians should remind their patients to be cautious about using such a source of information.

AB1371 CENTRAL SENSITIZATION AS A PREDICTOR OF FUNCTIONAL DISABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Diagnostic tests, Pain, Rheumatoid arthritis

V. Bombela1, I. Shapoval1, M. Stanislavchuk1, National Progov Memorial Medical University, Vinnytsya, Department of Internal Medicine N1, Vinnytsya, Ukraine

Background: Rheumatoid arthritis (RA) is a common systemic inflammatory autoimmune disease. Patients with rheumatoid arthritis suffer from chronic pain, restricted function and reduction of daily activities [1]. Recent evidence reveals that central sensitization (CS) is associated with the development and maintenance of chronic pain. [2].

Objectives: The aim of this study was to determine the functional status of RA patients in the presence of CS.

Methods: The study involved patients diagnosed with RA according to the ACR/EULAR criteria (2010). The presence of the CS phenomenon was assessed according to the Central Sensitization Inventory (CSI) (Mayer, T. G. et al., 2012). The Health Assessment Questionnaire-Disability Index (HAQ-DI) was used to assess the functional status of patients. RA activity was determined by DAS-28, SDAI, CDAI. Pain intensity was assessed by Visual Analog Scale (VAS). Statistical analysis was performed using MS Excel and SPSS22 software (©SPSS Inc.). Odds ratios (OR) and their corresponding 95% confidence interval (CI) were calculated. A descriptive analysis of the variables was carried out using mean and standard deviation (M±SD).

Results: A total of 168 RA patients (female 78%) were included. The median age of patients was 52.7±14.1, years, and the median duration of disease was 8.7±7.9 years. The examined patients showed mainly moderate and high activity of the disease (DAS-28 – 4.90±1.9; SDAI – 34.9 ±9.6; CDAI – 32.0±9.3). The presence of central sensitization (CSI>40) was revealed in 59 (35%) of patients. The group of patients with CS had greater functional impairment compared to patients without CS: HAQ - 1.9±0.7 versus 1.0±0.6 (p<0.05). Also, patients with CS reported a higher intensity of pain (VAS pain - 7.8±1.2 versus 6.4±1.4; p<0.05). Mild functional disability (HAQ-DI value up to 1) was observed in 41% of patients with RA, moderate (HAQ-DI from 1 to 2) – in 38%, severe (HAQ-DI more than 2) – in 21%. The group of RA patients with CS had significantly different differences from the group without CS regarding HAQ-DI (Table 1).

Notes: HAQ-DI - Health Assessment Questionnaire, CSI - Central Sensitization Inventory. P – the significance of differences between groups.

Finally, the strong correlation was determined between CSI and HAQ-DI (r=0.745; p<0.01). Significant moderate correlations were also found between CSI and VAS pain (r=0.532; p<0.01). We found that the presence of CS in patients with RA was associated with an increased risk of functional disability. Odds ratios are used to identify the risk of functional disorders in patients with CS. RA patients with CSI score ≥ 40 had an odds ratio of 6.97 [95% CI: 3.02 – 16.1] (p< 0.0001) for moderate functional disability and 21.3 [95% CI: 8.07 – 56.4] (p< 0.0001) for severe functional disability.

Conclusion: Central sensitization is common in RA patients. The phenomenon of central sensitization is associated with high level of functional disability of patients with RA and severity of pain. The phenomenon of central sensitization should be considered as a predictor of functional disability.

AB1372 PREDICTING ACUPUNCTURE EFFICACY IN FIBROMYALGIA: RESULTS OF A PRAGMATIC OPEN-LABEL STUDY

Keywords: Fibromyalgia

M. Di Carlo1, G. Beci2, E. Cipolletta2, F. Salaffi1, 1Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy; 1Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy

Background: Fibromyalgia (FM) is a condition mainly characterized by the presence of chronic widespread musculoskeletal pain that affects a large proportion of the general population. Acupuncture, like other complementary and alternative medicines, is a patient-centered treatment and is generally well tolerated and appreciated by patients and the latest EUropean League Against Rheumatism (EULAR) recommendations on the management of FM made a weak recommendation for acupuncture in FM. To date, there is no study that indicates which variables predict response to acupuncture treatment in FM, either in terms of immediate response or persistence of response, and thus can enable the implementation of personalized treatment a prevention of therapeutic failure.
Objectives: The aim of this study is to identify the predictive factors of failure to acupuncture in patients with FM.

Methods: FM patients refractory to standard drug therapy (defining as standard drug therapy the association of duloxetine and pregabalin) underwent eight weekly acupuncture sessions. Significant improvement, defined as a reduction of at least 30% of the FIQR, was assessed at the end of the eight weeks (T1) of treatment and three months after the end of treatment (T2). Univariate analysis was conducted to identify predictors of significant improvement at T1 and T2. Variables, which resulted significantly associated with clinical improvement at univariate analysis, were included in multivariate models.

Results: Analyses were conducted on 77 patients (9 males, 11.7%). At T1, significant improvement in FIQR was recorded in 44.2% of patients. At T2, significant improvement in FIQR persisted in 20.8% of patients. In multivariate analysis, predictive variables of treatment failure were tender point count (TPC) (odds ratio [OR] = 0.49, 95% confidence interval [95% CI]: 0.28 – 0.86, p = 0.01) and pain magnification (OR = 0.68, 95% CI: 0.47 – 0.99, p = 0.04) assessed with Pain Catastrophizing Scale, at T1. At T2, the only predictive variable of treatment failure was concomitant duloxetine use (OR = 0.21, 95% CI: 0.05 – 0.95, p = 0.04) (Table 1).

Table 1. Multivariate analyses considering the significant clinical improvement at the end of treatment (T1) and 3 months after the end of the treatment (T2) as dependent variable, independent variables the parameters that achieved statistical significance at univariate analyses.

Conclusion: High TPC and a tendency for pain magnification predict immediate treatment failure, while duloxetine therapy predicts it three months after completion of the acupuncture course. The identification of clinical characteristics of unfavorable response to acupuncture could help to implement a cost-effective prevention of treatment failure in FM. The results of this study can provide a reference for the integration of a non-drug treatment such as acupuncture into the complex FM scenario.

AB137/3
ARE FIBROMYALGIA AND/OR DEPRESSION THE MOST COMMON DIAGNOSES SEEN IN ROUTINE RHEUMATOLOGY CARE, ALTHOUGH AS SECONDARY DIAGNOSES, BUT WHICH MAY COMPlicate CLINICAL ASSESSMENT, PROGNOSIS AND MANAGEMENT?

Keywords: Outcome measures, Fibromyalgia, T. Pincus, J. Schumcker, J. L., J. Block, T. RUSH University Medical Center, Medicine, Division of Rheumatology, Chicago, United States of America; 1Georgetown University, Biostatistics, Bioinformatics & Biostatistics, Washington, United States of America

Background: Fibromyalgia (FM) and depression (DEP) are common comorbidities in all primary rheumatic diagnoses, easily recognized in many patients, but often underestimated, particularly in patients who meet criteria for a primary rheumatic disease. Two screening indices to recognize FM and/or DEP are found within a 2-page multidimensional health assessment questionnaire (MDHAQ), FAST4 (fibromyalgia assessment screening tool) and MDS2 (MDHAQ depression screen) [1]. FAST4 agrees 90% with 2011 revised FM criteria, and MDS2 agrees 80% with reference HADS-D (hospital anxiety and depression scale–DEP).

Objectives: To analyze patients with different rheumatic diagnoses according to FAST4 and MDS2 as well as reference 2011 FM Criteria and HADS-D, to recognize those who screen positive for FM and/or depression.

Methods: The MDHAQ is a 2-page patient self-report questionnaire designed for routine care, completed by most patients with any diagnosis in 5-10 minutes at all visits to 2 academic rheumatology sites. The MDHAQ includes scores to calculate FAST4 and MDS2: the FM screen is positive (FAST4+) if ≥4 are present of: pain 0-10 visual numeric scale (VNS) ≥6/10, fatigue VNS ≥6/10, pain self-report 0-54 RADAI painful joint score ≥18/54, 60-symptom checklist (ROS) ≥16/60. The DEP screen is positive (MDS2+) if 0-3.3 DEP in the patient-friendly HAQ format is ≥2.2 OR DEP is ≥ on ROS. The % of patients with various primary diagnoses, and who screened positive or negative by FAST4, MDS2, 2011 revised FM criteria, or HADS-D was computed.

Results: Among 1,038 routine rheumatology care patients at 2 settings, 307 were FM+ by FAST4, 297 by 2011 FM criteria,295 DEP+ by MDS2, and 364 DEP+ by HADS-D. These prevalences were ≥28.0% according to FAST4 and MDS2 in all patients, as high as most prevalent primary ICD-10 diagnosis of 291 for rheumatoid arthritis (RA) (Table 1). Percentages of FM+ and DEP+ patients were within 12% for all diagnosis categories except for 6.3% of patients with primary FM (Table 1).

Conclusion: Non-somatic problems of FM and DEP are as common as any diagnosis seen in routine rheumatology care at 2 academic sites, albeit as secondary diagnoses in most patients. FM and/or DEP may complicate assessment, prognosis, and management of clinical status and explain poor responses to treatment in some patients. It is feasible to screen for FM and DEP on a single MDHAQ, completed by most patients in 5-10 minutes, as FAST4 and MDS2 indexes, at any rheumatology site.

ADVERSE EVENTS AFTER VACCINATION FOR SARS-CoV-2 IN A CASE SERIES OF FIBROMYALGIA PATIENTS VERSUS HEALTHY CONTROLS

Keywords: Fibromyalgia, Vaccination/immunization, COVID

M. L. Aprile, L. C., L. G. C., G. Sambataro, M. Colaci

University of Catania, Clinical and Experimental Medicine, Catania, Italy;
Ospedale San Giovanni Battista, Oncology Unit, Catania, Italy; I.A. Sant’Anna S.R.L., Rheumatology Outpatient Clinic, Mascali, CT, Italy

Background: Fibromyalgia (FM) is a chronic widespread pain syndrome of unknown origin that leads to hypersensitivity for physical, chemical and/or psychic triggers. Vaccination, as an inflammatory stimulus and as a psychologically stressful act, could represent a challenge for these patients.

Objectives: We aimed to investigate the incidence of adverse reactions after vaccination for Sars-CoV-2 in a series of FM patients versus healthy controls.

Scientific Abstracts
Methods: We recruited 65 consecutive FM patients classified according to the 2016 ACR diagnostic criteria (M/F: 5/60; mean age 53.6 ±12.5 years), without other associated rheumatologic conditions, and 65 age/sex-matched healthy controls. A questionnaire was administered in order to investigate eventual adverse events occurring up to 6 months after administration of a Sars-Cov2 vaccine. The questionnaire was divided into two parts: the first part included the patient’s demographic information, the vaccine type performed and the anamnestic data. In the second part, the individuals described all new symptoms or signs occurred after the first, the second or the third dose of Sars-Cov2 vaccine.

Results: Overall, FM patients reported a higher frequency of adverse events after Sars-Cov2 vaccination in comparison with healthy controls. In particular, 44/65 FM patients vs. 11/65 controls complained of exacerbation of diffuse pain (p<0.001). Fatigue, diarrhea, sweating, tangles, headache, dizziness, transient respiratory discomfort, and paroxysmal vision blurring were also more frequent in FM patients than controls (47/65 vs. 30/65, p=0.004; 6/65 vs. 0/65, p=0.028; 18/65 vs. 8/65, p=0.047; 20/65 vs. 0/65, p=0.001; 22/65 vs. 9/65, p=0.013; 21/65 vs. 5/65, p<0.001; 10/65 vs 1/65, p=0.009; 17/65 vs. 2/65, p<0.001, respectively).

No significant difference between FM and the control group as regards fever was reported (24/65 vs. 30/65, p=0.7). Interestingly, swelling at the injection vaccine site was more commonly reported in controls (9/65 vs. 20/65; p=0.034). Finally, one case of Bell’s palsy was registered in the FM series while one case of myositis was more commonly reported in controls (9/65 vs. 20/65; p=0.034). Interestingly, swelling at the injection vaccine site was more commonly reported in controls (9/65 vs. 20/65; p=0.034). Finally, one case of Bell’s palsy was registered in the FM series while one case of myositis was more commonly reported in controls (9/65 vs. 20/65; p=0.034).

Conclusions: FM patients showed an increased frequency of adverse events to Sars-Cov2 vaccination compared to healthy controls. In particular, all the symptoms reported seemed to be associated with the functional hypertonicity that characterizes FM.

AB1375

SHORT-TERM EFFECTIVENESS OF A MULTIMODAL TREATMENT PROGRAM FOR REFRACTORY CHRONIC PAIN SYNDROMES INCLUDING PRIMARY AND SECONDARY FIBROMYALGIA

Keywords: Fibromyalgia, Pain

T. Pretaić1, T. Hügel1, P. Ming Azevedo1,1 Lausanne University Hospital, Rheumatology, Lausanne, Switzerland

Background: Treatment-refractory Chronic Pain Syndromes (CPS) are highly heterogenous entities with a high socio-economic burden. Multimodal treatment programs combining physical and cognitive-behavioral interventions have shown promising results but definition of clinically relevant response remains challenging.

Objectives: To identify clinical endpoints and predictive factors for effectiveness of a multimodal CPS program.

Methods: Retrospective observational study with 201 patients (22 to 72 years old) with refractory CPS with or without concomitant inflammatory rheumatic disease participating in a 2-week inpatient program in a tertiary rheumatology center in Lausanne, Switzerland. The approach included: Intensive physiotherapy, chiropractic and osteopathy treatment, peripheral or spinal injection (if appropriate), rheumatological assessment, occupational therapy, psychiatric assessment, group-based education, sleep assessment by actigraphy and virtual reality sessions. Patients with psychiatric or physical conditions affecting ability to follow the program were excluded. BPI (primary endpoint) plus 6 other standardized questionnaires were executed before and after program. Multivariable regression was performed between delta BPI and clinical and demographic characteristics.

Results: The descriptive analysis is compatible with patients with severe refractory CPS patients. 73.3% are women (48% > 50 years old), 33.8% are overweight, 30.6% are obese, 73.2% describe pain in childhood or adolescence, 14% have had multiple surgeries (≥3) related to pain, 89% report back pain (86% lumbal), 27.1% have a present or past clinical diagnosis of hyperalgesia, 78% met the 2010 ACR criteria for FM, 81% had FIRST-4, 73.8% received concomitant biologic treatment, axitromasin was diagnosed in 34%, 50.2% presented reduced sleep efficacy and 78.4% showed hyper-fragmented sleep. After the program, the majority of patients improved scores for ODI (51%), FABQ-O (57%), POAM-A (48,5%), BPI-S (51,5%), BPI-I (65,6%), HAS (55%), HDS (59%) and PCS (63,7%). 48.5% of patients improved POAM-P and 34% improved FABQ-W scores. Interestingly, patients who improved in HDS often improved also in PCS and HAS (measures of affective stress). The same correlated variation did not occur between ODI and BPI impact (measures of function). TAMPA variation was slightly correlated with PCS.

Several variables associated with BPI in univariable analysis were excluded in the multivariable due to excess of missing data. Clinical and demographic variables associated with BPI in multivariable analysis were age (p=0.007), disability allowance (p=0.058) and presence of an inflammatory disease (p=0.044). For BPI, the association were with clinically significant peripheral arthritis (p=0.001), patient origin (p=0.008) and the diagnosis of a biomechanical disorder (p=0.002).

Conclusion: The present work suggests that multimodal pain programs should have other goals besides pain reduction, such as improving function, reducing fear of movement, reducing affective stress, and changing cognition and behavior associated with the perception of pain. The abovementioned questions target these aspects and may be utilized as endpoints. Questionnaires addressing affective stress had interrelated variations so that composite scores can be proposed and should be tested in long-term. CENTRAL SENSITIZATION IN AUTOIMMUNE CONNECTIVE TISSUE DISEASES: IS IT RELATED TO DISEASE ACTIVITY, COEXISTING FIBROMYALGIA, AND LABORATORY FINDINGS?

Keywords: Systemic lupus erythematosus, Sjögren syndrome, Pain

Z. Bazancıl Apaydın1, H. Apaydın2, B. Armagan2, K. Göklı3, S. Erten3, 1Ankara Medipol University, Physical Therapy and Rehabilitation, Ankara, Turkey; 2Ankara City Hospital, Rheumatology, Ankara, Turkey

Background: Central sensitization (CS) is a phenomenon associated with chronic pain disorders and may be seen in several rheumatic diseases with chronic musculoskeletal pain such as osteoarthritis, spondyloarthopathy, and fibromyalgia, but little is known about CS in patients with autoimmune connective tissue diseases (ACTDs).

Objectives: The purpose of the study was to investigate the role of CS in patients with ACTDs and how it relates to disease activity, coexisting fibromyalgia, and laboratory findings.

Methods: A total of 82 patients (mean age 49.2±13.1 years) with ACTDs were included and were divided into three groups in terms of their diseases: Sjögren’s syndrome (SS), rheumatoid arthritis (RA), and systemic lupus erythematosus (SLE). The CS was assessed using the central sensitization inventory (CSI-A and CSI-B scores). The disease activity (using Sjögren’s syndrome disease activity index, ESSDAI, for SS; Disease Activity Score-28 C-reactive protein, DAS28-CRP, for RA; and Systemic Lupus Erythematosus Disease Activity Index, SLEDAI, for SLE), pain intensity (using visual analog scale), coexisting fibromyalgia, and laboratory findings (erythrocyte sedimentation rate-ESR and C-reactive protein-CRP) of all patients were evaluated.

Results: CS were present in 39% of all ACTDs patients (57.1% in SS, 38.6% in RA, and 26.1% in SLE). No significant differences were found in the CSI-A score (p = 0.161) and CSI-B score (p = 0.809) among the groups. There was a significant correlation between disease activity and the CSI-A scores in patients with RA (p = 0.022 r = 0.360), but no significant relationship between disease activity and the CSI-A scores in SS (p = 0.390) or SLE patients (p = 0.179). CSI-A and CSI-B scores were higher in the coexisting fibromyalgia in patients with ACTDs (p = 0.002, p < 0.001, respectively). There is no significant relationship between CSI-A scores and laboratory findings (ESR, CRP) in patients with ACTDs (p > 0.05).

Conclusion: CS is seen as a common condition in patients with ACTDs who also have fibromyalgia and is related to the disease activity in patients with RA. In addition to specific pharmacological treatments, pain-coping strategies may reduce pain and increase the quality of life of patients with these conditions. It is essential to increase awareness about the important role played by CS in patients with ACTDs.

FELDENKRAIS AWARENESS THROUGH MOVEMENT INTERVENTION FOR FIBROMYALGIA SYNDROME: A PROOF-OF-CONCEPT STUDY

Keywords: Physical therapy/physiotherapy, Fibromyalgia, Non-pharmacological interventions

V. Giorgi1, S. Farah2, P. Sarzi-Puttini1.

Background: The Feldenkrais Method is a form of awareness through movement (ATM) which aims at increasing awareness about spatial and kinesthetic relationships among body segments and the environment through verbally guided movements [1]. Fibromyalgia Syndrome (FM) is a form of chronic widespread pain associated to a variety of ancillary symptoms, among which fatigue, sleep disturbances and regional pain syndromes are preponderant. Lately, increasingly more attention has been drawn on mind-body interventions and meditative movement therapies for FM treatment [2]. ATM application for chronic pain has been promising but with low quality studies [3,4].

Objectives: The aim of this study was to explore the effectiveness of ATM for FM patients after 4 months of ATM activity; in particular, the proof-of-concept design aims at determining the domains for which an ATM-based intervention may be effective for FM patients.

Methods: This is a proof-of-concept, observational, non-controlled prospective study which lasted 6 months. Participants were recruited by the Italian Fibromyalgia Syndrome Association (AISFtOdA), a non-profit patient organization, through social media advertising. After signing the informed consent, they were divided into eleven groups of eleven/twelve patients each. Two Feldenkrais teachers were assigned to each group. All patients attended an ATM course lasting 15 lessons, with a lesson every week, 1.5h long (from January to May, 2021). The lessons were entirely virtual platform-based and live. Clinimetric tests and patient-reported outcome tests were administered at baseline and at the end of intervention.

Results: One hundred twenty-eight FM patients (mean age 54 years old, 2% males) participated in the study. A statistically significant improvement was found in FM-specific measures (Polysymptomatic Distress Scale, PDS) (p=0.003) and the Pain Catastrophization Scale (PCS) (p=0.020); coherently, the amelioration in self-reported outcome measures was statistically significant (p=0.08). The logistic regression analysis found a correlation between PDS, fatigue and anxiety measures; PCS, years from diagnosis and anxiety.

Conclusion: In conclusion, ATM could improve FM-specific measures and pain-related catastrophizing. Improving awareness about one’s one body and movements through ATM sessions may have helped FM patients to improve their cognitive attitude towards their pain condition, embracing a more positive, hence less catastrophizing attitude; furthermore, ATM could benefit FM patients because of its induction of muscular relaxation [5]. Further studies are needed to identify FM subgroups in order to find personalized targets that can be used to guide treatments.

TITLE: BENEFIT OF GROUP MEDICAL VISITS IN THE MANAGEMENT OF FIBROMYALGIA

Keywords: Fibromyalgia, Diet and nutrition, Non-pharmacological interventions

J. A. Pando1, 2, C. Welton2, S. Griffith3, O. Pando1, 3, DelawareArthritis, Rheumatology, Lewes, United States of America; Delaware Arthritis, Rheumatology, Lewes, United States of America; Sidney Kimmel Medical College, Medicine, Philadelphia, United States of America

Background: Fibromyalgia (FM) is a chronic condition characterized by widespread pain, fatigue, sleep disturbances and mood disorders (depression and anxiety)[1]. While there is no cure for Fibromyalgia, non-pharmacological integrative modalities have been demonstrated to be effective improving clinical outcomes[2]. Group medical visits (GMV) have been used to integrate self-management skills and to deliver education to improve outcomes in patients with chronic diseases.[4-5] There are scant reports of the use of GMV in the management of patients with rheumatic diseases. The goal was to assess the benefit of GMV in patients diagnosed with Fibromyalgia (FM).

Objectives: We conducted a pilot study to assess the benefits of group medical visits (GMV) among patients with Fibromyalgia. Our primary objective was to improve outcomes by educating patients and demonstrating five integrative techniques: breath work, journaling, mindfulness, movement, and nutrition.

Methods: Patients diagnosed with Fibromyalgia participated in a series of group appointments. The four consecutive monthly sessions included: (1) an introduction to the series and demonstration of breathing techniques and journaling; (2) a presentation of the benefits of movement and participation in Tai Chi session; (3) an overview to mindfulness and guided meditation; (4) a discussion regarding the bio-some, nutrition, and elimination diets. Our clinical outcome measures included: The Fibromyalgia Impact Questionnaire (FIQ score), Personal Health Questionnaire Depression Scale (PHQ8) and Multi-Dimensional Health Assessment (MDHAQ). We took measurements at baseline and following completion of the last appointment. Our analysis consisted of a paired t-test to determine whether the mean difference between the baseline and follow-up outcomes was statistically significant.

Results: The average baseline and follow up measures were as follows: FIQ 61.5 to 50.3 (CI -15.8 - 4.3, p-value 0.0011), PHQ8 10.7 to 6.5 (CI -5.8 - -2.1, p-value 0.0001) and MDHAQ 16.4 to 13.59 (CI -4.9 - -1.5, p-value 0.0008), respectively. All measurements were statistically significant.

Conclusion: Our findings suggest that group medical visits are a valuable, beneficial, efficacious and cost-effective way to deliver care and information to patients with Fibromyalgia. GMV’s facilitate education, provide social support and most importantly, improved clinical outcomes.

REFERENCES:

and at the end of the fourth module. All the measurements were statistically significant.

Measurement of the 3 outcomes measures analyzed, (FIQ, PHQ 8 and MDHAQ) at baseline showed a significant improvement in the intervention group compared to the control group. The mean and 95% CI of the change in scores were as follows:

AB1380 ASSESSMENT OF OPTIC NERVE VOLUME AND MACULA FINDINGS WITH OPTIC COHERENCE ANGIOGRAPHY IN FEMALE PATIENTS WITH FIBROMYALGIA AND ITS RELATION WITH DISEASE SEVERITY

Keywords: Fibromyalgia

Methods: Sixty-two female fibromyalgia (FMS) patients with a mean age of 43.11±7.94 years and sixty female healthy controls with a mean age of 40±12.26 years were included. Fibromyalgia was diagnosed according to the American College of Rheumatology Criteria. Schirmer and tear break up time (TUT) test were recorded. Choroidal thickness, optic nerve head blood flow area, retinal nerve fiber layer was measured with optic coherence tomography angiography (OCTA). Widespread pain index (WIPI), symptom severity scale (SSS), tender point count, Fibromyalgia impact questionnaire (FIQ) were recorded.

Results: BUT test findings were lower in FMS patients compared to healthy controls and the differences were statistically significant (p<0.0001). There were no significant differences in Schirmer test and intracocular pressure findings between FMS patients and healthy controls (p>0.05). Optic disc total and peripapillary densities of FMS patients were found to be higher than healthy controls (p<0.05). Choroidal thickness, inner retina perifoveal thickness values of FMS patients were higher than healthy controls (p<0.05) but in outer retina foveal thickness values of patients were lower than healthy controls (p>0.05). In addition, foveal avascular zone (FAZ) and nonflow area were found to be enlarged in FMS patients compared to the healthy controls (p<0.05). There were weak positive correlations between fibromyalgia severity scale and choroidal thickness values, optic disc total and peripapillary densities and FAZ area. In addition, there were weak negative correlations between fibromyalgia severity scale and BUT test values.

Conclusion: Due to the known increase in inflammation in FMS patients, we found choroidal thickness and vascular density values around the optic disc to be higher than in the healthy control group. In addition, we found that FAZ and nonflow area values were enlarged compared to the control group, consistent with ischemia due to vascular damage in FMS patients. We found a significant correlation between all these values and the fibromyalgia severity scale values. In conclusion, we think that the results we evaluated with OCTA measurements are useful in detecting damage to retinal and optic disc vascular structures in FMS patients.

1Medical and Pharmacy, Rheumatology, Iasi, Romania; 2Clinical Rehabilitation Hospital, Rheumatology, Iasi, Romania

Background: Pain is a cardinal symptom of chronic rheumatic conditions and can involve nociceptive and non-nociceptive (neuropathic) components that may be linked to central sensitization. Poor sleep quality has been connected to central sensitization and the appearance of neuropathic pain in patients with chronic rheumatic conditions.

Objectives: We aimed to investigate pain characteristics and sleep quality in adult patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), and osteoarthritis (OA).

Methods: We conducted a prospective observational study including patients with RA, AS, and OA who were evaluated in the Rheumatology Department of the Clinical Rehabilitation Hospital of Iasi between July-December 2022. We excluded patients with diabetes mellitus, neoplasia, and comorbid neurological conditions. We evaluated pain intensity using the visual analog scale (VAS) and pain characteristics using the PainDETECT questionnaire (PD-Q). Sleep quality was assessed using the Pittsburg Sleep Quality Index (PSQI).

Results: The final study group included 152 patients (50 RA, 52 AS, and 50 OA) with a mean age of 59 years. PD-Q scores did not differ significantly in the three subgroups. In patients with RA, PD-Q scores correlated with disease activity (DAS28 and CDAI; p=0.008 and p=0.037), whereas the relationship between BASDAI and PD-Q scores approached statistical significance (p=0.056). PD-Q scores were correlated with pain intensity in AS (p=0.037), but not RA or OA (p=0.421, p=0.383). In RA patients, nociceptive pain was significantly more prevalent compared to AS and OA (p<0.001) and was associated with a higher consumption of symptomatic medication during hospitalization. Neuropathic pain was notably more frequent in AS compared to RA (p<0.001) and OA (p<0.001). Neuropathic pain did not lead to significantly higher medication expenses in our study group. In the RA subgroup, PD-Q scores were significantly correlated to total PSQI (p<0.001), as well as the values for each of the PSQI domains. Moreover, in these patients, pain intensity was connected to poor subjective sleep quality, low sleep efficiency, and sleep disturbance. Total PSQI scores were also correlated with DAS28 (p=0.011). In AS patients, total PSQI was linked to PD-Q scores (p<0.001), but not pain intensity. PD-Q was significantly connected to subjective sleep quality, sleep latency, sleep duration, sleep efficiency, and sleep disturbance in AS. In the OA subgroup, pain intensity was associated with total PSQI (p=0.007), subjective sleep quality, sleep latency, sleep duration, and sleep efficiency. Nevertheless, poor sleep quality was not significantly linked to neuropathic pain in the OA group.

Conclusion: Non-nociceptive pain is frequent in patients with chronic rheumatic conditions. Moreover, non-nociceptive pain may impact activity score values in AS and RA. Poor sleep quality is connected to pain intensity and non-nociceptive pain in patients with RA and AS. Sleep quality was not linked to neuropathic pain in OA patients. Pain remains a key symptom in rheumatic diseases and its management remains a challenge for the clinician, especially in the context of central sensitization.

Disclosure of Interests: None Declared.

Background: Pain is a cardinal symptom of chronic rheumatic conditions and can involve nociceptive, neuropathic and central sensitization (CS) may be involved. The International Association for the Study of Pain (IASP) defines central sensitization as « Increased responsiveness of nociceptive neurons in the central nervous system to their normal or sub-threshold afferent input » (1) Chronic inflammation can play an important role in this CNS hyperexcitability. During CS pain may persist, despite objective control of inflammation suggesting the involvement of SC phenomena.

Objectives: The objective of this study is to detect the impact of central hypersensitivity phenomena on pain in patients suffering from CS. A second object is to look for other factors associated with this central sensitization.

Methods: This is a cross-sectional study that included all patients aged ≥ 18 years followed up for chronic inflammatory arthritis (SPA, RA, undifferentiated C) presenting to the rheumatology department. Patients with psychiatric or memory disorders or who refused to participate in the study were excluded. Sociodemographic data, comorbidities and treatments received were collected. No nociceptive pain was assessed by visual analog scale (VAS), disease activity by DAS-28 and ASDAS and central sensitization by the validated Moroccan version of the Central Sensitization Inventory part A (CSI-A). This inventory has 2 parts: Part A measures a range of 25 somatic and emotional symptoms associated with central sensitization, scored from 0 (never) to 4 (always), for a possible total score of 100. Part B concerns the recording of previous diagnoses related to central sensitization (not used in our study). A CSI-A score ≥ 40 was the threshold considered for the definition of CS. The Pain catastrophizing scale (PCS) was used to assess pain-related catastrophic thoughts and the PHQ-9 (Pain Health Questionnaire) to assess the severity of depressive symptoms.

Results: We included a total of 189 patients, 107 (56.61%) had rheumatoid arthritis, 67 (35.45%) spondyloarthritis and 15 (7.94%) undifferentiated inflammatory arthritis. The median duration of the disease course was 8 years [4–17], the mean age was 47.49 ± 13.70 years [14.74], 75.7% were women. The mean pain VAS was 4.77 ± 2.76 and 50.8% had a strong or moderate activity. The mean central sensitization score was 37.42 ± 16.75, with 44.9% having a CSI-A score ≥ 40. For treatments 38.2% of patients were on corticosteroids and 6.3% were using biological treatment. In uni and multivariate analysis, the parameters associated with CS were pain severity (0.039) and depression (0.001). A statistically significant correlation was found between the CSI-A score and pain VAS (r=0.32, p<0.001).

Conclusion: Pain in patients with CS has often been attributed to peripheral inflammation. However, our study suggests that central sensitization may increase pain intensity independent of disease activity. Screening for central sensitization mechanisms in patients followed for CIR seems necessary to guide management by targeting central pain in order to avoid useless therapeutic switches and escalations, sometimes even harmful for our patients.

DOI: 10.1136/annrheumdis-2023-eular.5132

Background: Hypermobile joints are a common yet under-recognized cause of noninflammatory joint pain. Patients with Hypermobile joints display a range of movement that is considered excessive, considering their age, gender, and eth- nic background [1]. Hypermobile joints may be asymptomatic or associated with pain, fatigue, multisystemic complaints, and significant disability. In this study, we look at the clinical profile of patients with hypermobile joints who presented to our clinic.

Objectives: To study the clinical profile of patients with Hypermobile joints.

Methods: This is a prospective observational study. Patients who presented to our clinic from 2018 to 2022 with musculoskeletal complaints with a Beighton score of 4 without concomitant inflammatory arthritis were selected. Clinical data were collected by doctors/trained nursing profession- als using a form, and demographic and relevant clinical data were collected and analyzed.
Results: 236 patients were studied (203 females and 33 males). The mean age of patients was 41.8 years (±12.7 SD). The median duration of symptoms was 48 months (1–540 months). Median Beighton score was 7. The mean global VAS was 4 (±2 SD). Associated clinical features were as in Table 1. Criteria for Fibromyalgia (2016 revised criteria) were satisfied by 31% of patients. Total Beighton score showed a negative correlation with age (r = 0.334, p < 0.05).

Conclusion: People with joint hypermobility-related disorders present a wide range of symptoms that extend across multiple body sites. Symptomatic hypermobile joints are present across all age groups. In our study, most patients presented with pains, especially in the form of dragging pains and cramps. An increase in joint stiffness with age leads to a decrease in the Beighton score, which should be considered to not miss hypermobility in the elderly. Extraarticular features of hypermobility give a clue to diagnoses of hypermobility in those with low Beighton scores. Often these patients are labeled as having fibromyalgia. In our study, 31% of patients satisfied the criteria for fibromyalgia. Hypermobile Joint Syndrome should be considered in patients presenting with nonspecific noninflammatory pains across multiple body sites in all age groups.

AB1385 BENEFITS OF PHYSIOTHERAPY RESOURCES IN FIBROMYALGIA

Keywords: Fibromyalgia, Non-pharmacological interventions. Physical therapy/physiotherapy

M. Antunes1, A. Pasqual Marques1.1 University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy (FOPITO), São Paulo, Brazil

Background: In patients with fibromyalgia, the physiotherapist is essential in the treatment. He will act throughout the patient’s rehabilitation process, from the diagnosis to the treatment. He will act throughout the patient’s rehabilitation process, from the diagnosis to the treatment.

Objectives: The present study intended to explore the quality of pain assessment and management in subjects with RA in a major tertiary clinic.

Methods: A literature review was carried out in the databases Scientific Electronic Library Online (SciELO), Latin American and Caribbean Literature in Health Sciences (LILACS), Medical Literature Analysis and Retrieval System Online (MEDLINE), Scopus, Web of Knowledge ISI, Physiotherapy Evidence Database (PEDro), Excerpt Medical Database (Embase), Cumulative Index to Nursing and Allied Health Literature (CINAHL), Cochrane Library, and SPORT-Discus for articles dated March 2012 to March 2022. The terms fibromyalgia AND (physiotherapy OR “physiotherapy” OR rehabilitation) were used as keywords in English, Portuguese and Spanish. The searches were not limited to titles and abstracts, we chose to leave them free, appearing in all fields of the articles. In addition, some specific physiotherapy interventions were manually searched.

Results: The articles were searched in all indexed databases and then the main information was read and collected and then analyzed descriptively.

Conclusions: There are several physiotherapeutic interventions that can be chosen. The concept of Post-Remission Syndrome is crucial in the management of disease activity in patients with fibromyalgia. There is an urgent need for further studies on how to control pain and deal with problems associated with his lifestyle. As such, combining multiple therapies (including exercise) to devise an optimal treatment plan for different individuals would be a very important educational program that seeks to promote the health of individuals with fibromyalgia and has shown promising results.

AB1385 SOBUSTIPAL IDENTIFICATION AND MANAGEMENT OF NON-NOCCIPEPTIVE TYPES OF PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS REGARDLESS THE ACTIVITY STATUS

Keywords: Rheumatoid arthritis, Fibromyalgia, Pain

Background: Pain represents one of the main clinical symptoms of Rheumatoid Arthritis (RA) being used as an indicator of disease activity. However, many RA patients report clinically significant levels of pain even in the periods of remission. Recent studies [1] revealed that biological treatments are inequal in terms of how they manage inflammation and pain. The concept of Post-Remission Syndrome would be beneficial in the control of the disease in patients with RA that are in clinical remission but still present clinical symptoms that impair their quality of life [2]; the syndrome might be a reason for decreased work productivity [3,4]. Apart of the nociceptive pain previous works identified neuropathic and nociceptive pain in the composition of residual pain. In order to better understand and manage this situation is paramount important to identify and explain the exact nature of pain present during and after the periods of activity in RA.

Objectives: The present study intended to explore the quality of pain assessment and management in subjects with RA in a major tertiary clinic.

Methods: In a major tertiary clinic of rheumatology consecutive subjects with RA have been questioned about the history, evolution and management of their disease; separately the level of nociceptive, neuropathic and nociplastic (fibromyalgic) pain was evaluated by using validated instruments. For a better understanding of the differences, we included and compared subjects with osteoarthritis and other inflammatory rheumatic diseases.

Results: 43 subjects have been evaluated in a 6 months interval with a 2:1 F/M ratio; 22 of them received biological therapy (8 different molecules have been
identified. Although 32 subjects did not present any sign of inflammation 21 of them declared significant level of pain (VAS>4), 12 have identified with neuropathic pain and 11 with nociplastic pain. Both in case of neuropathic and nociplastic pain groups less than 50% have been previously actively evaluated for non-nociceptive pain. Non-nociceptive pain was poorly covered during biological drug selection. Treatment was used despite evident lack of effect. The variable ability of pain reduction in the paradigm of nociplastic = inflammatory pain with little interest in other types of pain that results in suboptimal diagnostic and management of pain.

Background: Fibromyalgia syndrome (FMS) is defined as a chronic pain syndrome that is characterized by widespread pain, tenderness, and diffuse stiffness. In addition, neuropsychological symptoms such as fatigue, sleep disorders, poor mood, cognitive impairment, and headaches are often reported. Many researches have demonstrated the coexistence of affective disorders and anxiety with FMS, yet few focused on its association with obsessive-compulsive symptoms. That was previously investigated for non-nociceptive pain. Non-nociceptive pain was poorly covered during biological drug selection. The use of such drugs was used despite evident lack of effect. The variable ability of pain reduction in the paradigm of nociplastic = inflammatory pain with little interest in other types of pain that results in suboptimal diagnostic and management of pain.

A RARE CAUSE OF PES ANSERINE BURSITIS: TIBIAL EXOSTOSIS: THREE CASE REPORTS

Keywords: Imaging, Bone diseases, Pain

C. Mukuı̈slu1, İ. Taka2, B. Ordahan3. 1University of Health Sciences, Ankara Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey; 2Ankara Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey; 3Meram Medical School, Necmettin Erbakan University, Physical Medicine and Rehabilitation, Konya, Turkey

Background: Pes anserinus bursitis is a syndrome causing pain at the medial knee and the proximal medial tibia [1]. Santorius, gracilis, and semitendinosus tendons attach 5cm distal to the medial knee joint line taking a shape is called pes anserinus. It is more common obese females with knee osteoarthritis between 50-80 years of age [1]. Rarely, tibial bone spurs present as rose thorns and cause pes anserinus bursitis and knee pain [2].

Objectives: In this case report, we presented proximal tibial exostosis which randomly detected and resulting to pes anserinus syndrome in three patients.

Methods: Case 1 (NB): A 58-years-old female patient was admitted to our outpatient clinic with right knee pain. She had pain for 2 months, increasing with standing and walking. In the physical examination, she did not describe any trauma, to the area where the pes anserinus tendons attached to medial proximal tibia was painful. There was no swelling and redness on the skin. A bone spur from the proximal tibial metaphysis was seen in the right knee on direct radiography (Figure 1). Case 2 (BE): A female who 22-years-old, was admitted to our outpatient clinic with left knee pain, which was for 5 months. The skin appearance above the knee was normal. There was no swelling. Medical left proximal tibia was tender with palpation. Physical examination was normal. The blood tests of the patient were completely normal. A spur like as a rose thorn forming from the proximal tibial region was observed in the left knee, similar to the first case, on the direct radiography (Figure 2). Case 3 (GB): A 64-year-old female patient was admitted to our outpatient clinic with pain in the medial left tibia. Her complaint was present for 6 months. There was no history of trauma. Knee joint range of motion was normal. There was no effusion in knees. Mc-Murray test was negative. There was a minimal swelling and tenderness on pes anserine region. A bone exostosis was observed in the left medial tibia on the direct radiography requested from the patient.

Results: The Case 1 was told to rest for two weeks and not to walk much. Non-steroidal anti-inflammatory drug therapy and 10 minutes cold application to the knee per 6 hours were recommended. At the follow-up one month later, the patient’s analog scale (VAS) was regressed from 7 to 2. Non-steroidal anti-inflammatory drug was started to Case 2 and activity restriction was recommended. At the follow-up two weeks later, VAS score decreased from 6 to 4.1ml of methylprednisolone was injected locally to the pes anserinus region of Case 3. One month later, the patient’s VAS score decreased from 7 to 1.

Conclusion: Rarely, pes anserine bursitis may be accompanied by medial tibial exostosis. The clinicians need to keep in mind proximal tibial spurs in patients presenting with knee pain and pes anserine bursitis.

SEVERE FIBROMYALGIA: DO CENTRAL SENSITIVITY MECHANISMS WORK TOGETHER?

Keywords: Fibromyalgia, Pain, Patient reported outcomes

A. Capacci1, A. Ortolan1, G. Calabrese1, P. Rubortone1, A. Zoli1, M. A. D'Agostino2,3, 1Agostino Gemelli General Hospital Foundation - IRCCS, Rome, Italy, Division of Rheumatology, Rome, Italy; 2Catholic University of Sacred Heart, Rome, Italy, Rheumatology, Rome, Italy; 3Catholic University of Rome, Rome, Italy

Background: Fibromyalgia (FM) is among the most common causes of diffuse chronic pain and falls into the category of central sensitivity syndrome which may be associated with other symptoms such as asthenia, sleep disturbance, bowel and memory disorders, anxiety and depression.

Objectives: We aimed at evaluating in a hospital based setting which of these symptoms were more commonly associated with disease severity.

Methods: cross-sectional evaluation of consecutive patients with a diagnosis of FM according to the ACR criteria [1] who attended the dedicated outpatient clinic between 2020 and 2022. Clinical symptoms including disease duration, demographic characteristics, education level, lifestyle, clinical and laboratory parameters and therapeutic regimen were collected for each patient as well as Pros Questionnaires-Italian-Fibromyalgia impact questionnaire (FIQR); Widespread Pain Index (WPI), Symptom Severity Scale (SSS)-[23] Disease severity was defined as FIQR≥64. Categorical and continuous variables were compared between patients with FIQR ≤ 64 and those with FIQR>64, using descriptive statistics (Chi square test/ Fisher test and Mann-Whitney test). Thereafter, a logistic regression having as dependent variable FIQR>64 was carried out. The role of central sensitization (CS) on physical activity remains understudied.

Results: 187 patients were included. Patients with FIQR >64 (severe disease), had a higher frequency of bowel symptoms/irritable bowel syndrome, menstrual cycle alteration or endometriosis, headache and depression, compared to those with FIQR<64. At univariate analysis, the variables statistically associated with FIQR > 64 were: male gender (OR 0.38; 95%CI 0.13-1.08), active smoking (OR 1.97; 95%CI 0.92-4.25), depression (OR 4.95; 95%CI 2.32-8.76), bowel symptoms (OR 1.96; 95%CI 1.09-3.53), sicca syndrome (1.71; 95%CI 0.92-3.20), and more than 4 episodes of headache each month (OR 2.22; 95%CI 1.21-4.08). In the multivariate model, the variables independently associated to FIQR >64 were depression (OR 4.95; 95%CI 2.36-10.39) and more than 4 episodes of headache/month (OR 2.28; 95%CI 1.11-4.70).

Conclusion: Patients with severe FM more frequently present with headache, depression, irritable bowel syndrome and dysmenorrhea. All these symptoms belong to the family of central sensitivity syndromes, suggesting that some central sensitivity mechanisms play a key role in disease activity and severity.

DO PATIENTS WITH LOW BACK PAIN AND CENTRAL SENSITIZATION SHOW DIFFERENCES IN PHYSICAL PERFORMANCE?

Keywords: Pain

I. Berechi1, F. Z. Taïk1, H. Fouzila1, N. Soba2, M. Fourtassil, F. E. Abourazzak1, 1Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Houcema, University Hospital Mohammed VI, Rheumatology, Tangier, Morocco; 2Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Houcema, University Hospital Mohammed VI, Physical Medicine and Rehabilitation, Tangier, Morocco

Background: Common low back pain is a common reason for rheumatology consultation. Advances in neuroscience concerning pain have advanced its understanding in chronic musculoskeletal pathologies, in particular low back pain. The role of central sensitization (CS) on physical activity remains understudied.

Objectives: The objective of our study is to investigate the role of central sensitization in patients with low back pain and its impact on their physical performance.

Methods: This is a cross-sectional study that included any patient ≥ 18 years with low back pain presenting to the rheumatology department. Patients with psychiatric or memory disorders or who refused to participate in the study were excluded. Functional capacity was assessed by the Oswestry score (Oswestry Disability Index); a 10-item self-assessing questionnaire, each item contains 6 levels of answers that can be scored from 0 to 5. A total score is calculated, percentage of disability ranges from 0% (no disability) to 100% (complete disability). The interpretation of this scale is based on the scores: from 0 to 20%: minimal disability; from 20 to 40% moderate disability; from 40 to 60%: severe disability; from 60 to 80% crippling low back pain and beyond 80% the person is confined to bed.
The physical performance of the patients was assessed by the 6-minute walk test (6MWT), catastrophizing by the PCS (Pain Catastrophizing Scale) and the CS by the validated Moroccan version of the Central Sensitization Inventory Part A (CSI-A). This inventory has 2 parts: Part A measures a range of 25 somatic and emotional symptoms associated with central sensitization, scored from 0 (never) to 4 (always), for a possible total score of 100. Part B concerns the recording of previous diagnoses related to central sensitization (not used in our study). A CSI-A score ≥ 40 was the threshold considered for the definition of CS.

**Results:** We included 118 patients. The average age was 53.01±14.09, 86.4% of patients were women and 88.7% had at least one comorbidity. The median duration of evolution was 8 [2-10] years. The mean pain VAS was 5.75±2.07 and 71.5% of patients had an Oswestry score >20. The average score of CS was 42.16±17.67 while 53.4% had a CSI-A ≥ 40. The average walk test result was 3776.4±154.15 meters. There was no statistically significant difference between patients with CSI-A ≥40 and CSI-A <40 with regard to the performance of the 6MWT (362.67 Vs 394.87, p=0.094). On the other hand, there was a statistically significant difference between the two groups with regard to the pain VAS (6.00 Vs 5.47), p=0.017) and PCS score (33.03Vs 22.08, p=0.001).

**Conclusion:** Central sensitization does not seem to affect the physical performance of Moroccan patients with low back pain.

**MULTICOMPONENT NATURE OF PAIN SYNDROME IN PATIENTS WITH RHUMATOID DISEASES AND ITS RELATIONSHIP WITH CLINICAL CHARACTERISTICS**

**Keywords:** Spondyloarthrosis, Pain, Rheumatoid arthritis

N. Tlifebek1, A. Garaeva2, K. Shapovalov2, S. Lapshina2, Z. Gabudulla2, D. Abyaliyev3, S. Delfoufi4. 1Institute of Gastroenterology, Hepatology and Metabolism; 2Internal Clinic, Rheumatology, Almaty, Kazakhstan; 3Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation; 4Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation

**Background:** Pain is one of the leading clinical manifestations and a criterion of severity in most patients with rheumatic diseases. However, pain is not always inflammatory, and its intensity does not correlate with disease activity and dysfunction.

**Objectives:** To study the specifics of pain syndrome in patients with rheumatoid arthritis and ankylosing spondylitis.

**Methods:** 78 patients with inflammatory rheumatic diseases were studied, 30.8% with rheumatoid arthritis (RA) and 68.2% with ankylosing spondylitis (AS). The average age was 42 [34.5; 59.5]. Among AS patients 80.8% were men and 19.2% were women, while 100% of RA patients were women. DAS28 and ASDAS were used to rate activity in patients with RA and AS, respectively. High activity was observed in 69.3% of patients, moderate activity in 23.1%, and low activity in 7.6% of the cases; 23.1% of patients had functional class I, 34.6% - class II, 34.6% - class III, and 7.7% - class IV. The mean duration of evolution was 194.6±103.2 months, with a median of 192 [114;258] months. A neurological examination was performed to detect neuropathic pain (NP), and its severity was assessed using the pain DETECT questionnaire (PDQ); the relationship between pain and central sensitization (CS) was determined using the Central Sensitization Inventory (CSI); quality of life was assessed using the questionnaire EQ-SD. The collected data were analyzed with the IBM SPSS Statistic 26.0 program. Spearman correlation analysis was used to assess the relationship between the studied indicators; differences were considered statistically significant at p<0.05.

**Results:** All of the patients in the study had chronic inflammatory pain in their joints and/or back, and 69.3% of them also had non-inflammatory pain: 38.4% had NP, and 50% had pain typical of CS. There was no significant correlation between the presence and severity of NB and/or CS and the patient's age, disease duration, index of RA and AS activity, or patients' gender. In the group of patients with RA, NP prevailed, while CS prevailed in the group of patients with AS. The PD questionnaire results were: 69.3% with a positive PD index. AH occurred in 46.2% with CS and in 16.7% without CS. Anemia correlated with CSI index (rSp=0.536, p=0.006) and PDQ (rSp=0.892, p=0.001, respectively); a negative correlation between hemoglobin levels and the VAS scale was also observed (rSp=0.541, p=0.005). The presence of CS was found to have a negative correlation with the use of anti-inflammatory therapy (NSAIDs, DMARDs and corticosteroids).

**Conclusion:** The majority of patients (69.3%) with immunoinflammatory diseases have pain of mixed origin; additionally, in RA, it is more due to the neuropathic component, whereas in AS, it is CS. Pain intensity as measured by VAS was significantly higher in patients with neuropathic and central pain components, as expected. In patients with NB and CS, laboratory activity is higher, and comorbid pathology, anemia, and AH are more common. Patients with a comorbid central component of pain have a significantly lower quality of life. Thus, when examining patients with RA and AS, a detailed description of the pain syndrome is required, followed by a differentiated approach to analgesic therapy.

### AB1391

**RELATIONSHIP BETWEEN BODY MASS INDEX AND FIBROMYALGIA**

**Keywords:** Fibromyalgia

L. Riccio1, A. Ruggiero2, V. Marino3, F. Riccio4, F. Ciccia5, R. Timi6. 1University of Campania L. Vanvitelli, Department of Precision Medicine, Naples, Italy

**Background:** Fibromyalgia (FM) is a clinical condition characterized by chronic widespread pain associated with symptoms such as fatigue, waking unrefreshed, depression. Several studies reported a relationship between high body mass index and painful syndromes such as FM, but the real impact of a high BMI on clinical severity in patients with FM is still unclear. Furthermore, FM is characterized by a neuropathic component of pain. Obesity and overweight seem to get worse the intensity of neuropathic pain.

**Objectives:** The aim of this study was to evaluate the relationships between BMI categories and FM related symptoms, investigating fatigue, neuropathic pain, depression and sleep disorders.

**Methods:** We analyzed a cohort of 419 patients (M 15% /F 404, median age 56), with a diagnosis of FM according to the 2016 ACR criteria. The participants were consecutively recruited from the Fibromyalgia clinic of the University of Campania “Luigi Vanvitelli”. All patients were stratified into three groups according to BMI categories: normal weight (18.5-24.9), overweight (25.0-29.9) and obesity (>30.0). We assessed fatigue by Functional Assessment of Chronic Illness Therapy-Fatigue Subscale (FACT-F), neuropathic pain by PainDETECT Questionnaire (PDQ), depression by Patient Health Questionnaire-9 (PHQ-9) and sleep disorders by Pittsburgh Sleep Quality Index (PSQI).

**Results:** Total patient population (n=419) had a mean BMI 26.64 (SD 5.76); all patients showed fatigue (100%) with a mean FACT-F score 23.01 (SD 10.15); we found neuropathic pain (PDQ>20) in 301 patients (71.83%) with a mean PDQ score 22.95 (SD 8.935); 52 patients (12.41%) had no depression (PHQ-9 <4), 68 patients (16.23%) showed a mild depression (PHQ-9 10-14), 121 patients (28.88%) a moderate depression (PHQ-9 15-19) and 140 patients (33.41%) a severe depression (PHQ-9 ≥20) with a mean PHQ-9 score 15.53 (SD 7.704); sleep disorders were found in 360 patients (85,91%) with a mean PSQI score 11.28 (SD 6.117), 155 (37%) had normal weight patients (mean BMI 22.13) (SD 1.672) had a mean FACT-F score 20.14 (SD 10.52), a mean PDQ score 17.93 (SD 9.740), a mean PHQ-9 score 11.62 (SD 8.266) and a mean PSQI score 8 (SD 6.330); 161 overweight patients (38.4%) (mean BMI 27.15) (SD 1.400) had a mean FACT-F score 22.64 (SD 9.683), a mean PDQ score 24.33 (SD 7.831), a mean PHQ-9 score 15.54 (SD 6.609) and a mean PSQI score 11.57 (SD 4.990); 102 obese patients (24.6%) (mean BMI 30.5) (SD 3,302) had a mean FACT-F score 27.296 (SD 7.808), a mean PDQ score 28.34 (SD 4,136), a mean PHQ-9 score 21.43 (SD 2.953) and a mean PSQI score 15.76 (SD 4,150). For each of the FM symptoms investigated the results were statistically significant (p value < 0.0001) between the category of obese and both normal weight and overweight patients, but not statistically significant (p value > 0.05) between the category of normal weight and overweight patients.

**Conclusion:** Our study suggests that obesity is a risk factor for Fibromyalgia severity. Obese patients had higher FACT-F, PDQ, PHQ-9, PSQI scores than normal weight patients. Therefore, according to these findings, a Fibromyalgia treatment program should include weight loss strategies. Anyway further studies are needed to investigate the association between BMI and Fibromyalgia.

X. Yang 1,2, Q. Dong 1,2, D. Wu 1,2, Q. Feng 1,2, J.Y. Chen 1,2, Q. Yu 2, P.F. He 3, X. Li 1,2, S.X. Zhang 1,2,4, 1 Shaxi Medical University, Shaxi Provincial Key Laboratory of Rheumatism Immunome Microenvironment, Taiyuan, China; 2 Shaxi Medical University, Key Laboratory of Cellular Physiology at Shaxi Medical University, Ministry of Education, Taiyuan, China; 3 Shaxi Medical University, Shaxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China; The Second Hospital of Shaxi Medical University, Department of Rheumatology, Taiyuan, China.

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by progressive skin and internal organ fibrosis and has significant clinical sequelae [1]. Apolipoprotein B and E are found in two major subgroups of LDL [2]. Apolipoprotein E can be used as a predictor of SSc [3]. Apolipoprotein B is involved in autoimmunity [4]. However, whether apolipoprotein B is associated with SSc risk remains to be established.

Objectives: We performed a two-sample Mendelian randomization (MR) analysis to investigate the causal relationship between apolipoprotein B and SSc.

Methods: Statistics on apolipoprotein B were obtained from a genome-wide association study (GWAS) published by the UK Biobank, which included 349,376 samples of European ancestry. A total of 182 single nucleotide polymorphisms (SNPs) were selected as genetic instruments, which satisfied linkage disequilibrium (LD) (r2 < 0.01) and clump window > 10,000 kb) and related to apolipoprotein B (P<5×10−8). Summary-level data for SSc (107 cases and 218,499 controls) were derived from the FinnGen consortium. The inverse-variance weighted (IVW) method was used as the primary statistical model. The weighted median and MR-Egger regression were used as supplementary analyses to supplement the validation of IVW results. The Cochran Q-test was applied to check SNPs statistical heterogeneity using MR-Egger estimates, with P < 0.05 deemed significantly heterogeneous. The leave-one-out method was used to evaluate the effect of a single SNP on the causal association by excluding each SNP in turn.

Results: Genetically predicted apolipoprotein B was inversely associated with SSc risk (odds ratio (OR):0.51, 95% confidence interval (95% CI):0.26-0.98, P=0.04). MR-Egger also confirmed that apolipoprotein B was inversely associated with SSc risk (P=0.02). No heterogeneity was detected in Cochran’s Q statistic. The intercept in the MR-Egger regression indicated no pleiotropy in any analysis (all P values >0.05), suggesting this finding was reliable. Details of the results are shown in Fig. 1.

Figure 1. Scatter plots (A) and funnel plots (B) show the estimated effect of each SNP on the result. Forest plot (C) of the relationship between apolipoprotein B and SSc.

Conclusion: Apolipoprotein B is a protective factor for SSc, indicating that apolipoprotein B may be used as a component of drugs to treat SSc and slow down the development of SSc.

CLINICAL AND MRI PREDICTIVE FACTORS OF SIGNIFICANT RESPONSE TO A TREATMENT COUPLING CAPSULAR DISTENSION AND INTENSIVE REHABILITATION IN PATIENTS WITH SEVERE ADHESIVE CAPSULITIS

Keywords: Rehabilitation, Imaging, Real-world evidence.

S. Hamrouni1, V. Cinotti2, F. Mihoubi-Bouvier1, R. Garofoli3, G. Couraud1, M. Boisson1, A. Roer1, C. Nguyen2, A. Feydy2, H. Guerini3, F. Rannou2, J. L. Drape3, M. M. Lefevre Colau1, 1 Cochin University Hospital, Rheumatology, Paris, France; 2 Cochin University Hospital, Physical Medicine and Rehabilitation, Paris, France; 3 Cochin University Hospital, Radiology, Paris, France

Background: Adhesive capsulitis (AC) is a frequent shoulder affection [1] and is responsible of a significant impact on daily life. However, its management is not codified, with contradictory results in the literature on the effectiveness of capsular distension (CD), probably due to the lack of selection of patients in the studies. Furthermore, MRI has shown interest in the positive diagnosis of AC in difficult cases and to determine the stage of the disease [2].

Objectives: The aim of the study was to determine clinical and MRI predictive factors of good response to CD in patients with severe AC.

Methods: Patients addressed to physical medicine and rehabilitation unit in Cochin Hospital with a severe AC were prospectively included in the study between May 2017 and June 2021. Severe AC was defined by presence of intense shoulder pain (Numerical Analog Scale of maximal pain in daily activities ≥ 5/10) lasting for at least 3 months, with failure of first-line treatment – including NSAIDs, analgesics corticosteroid injection and physiotherapy. Participants had before treatment protocol a shoulder MRI with and without gadolinium intravenous injection. All patients then underwent 1 to 3 CD with injection of betamethasone at the same time at weekly intervals, each followed by intensive rehabilitation. Patients were evaluated 1 month after the 1st CD by a physiotherapist, who collected information on pain and range of motion and self-reported patient questionnaire. Primary outcome was the reduction of more than 50% of pain in daily activities evaluated by NAS at 1 month, by a multivariate logistic regression model. Secondary outcomes were the modification of NAS nocturnal pain, NAS incapacity, active and passive range of motion, SPADI, quick DASH, HAD and FABO scores, and return to work at 1 month.

Results: 97 patients were included in the study. Of these, 72 (74.2%) were women, mean age was 51.2 (± 7.29) years, median disease duration was 8 (6-12) months and was greater than 9 months in 41 (42.3%) of patients and 62 (63.9%) had a secondary form of AC. Mean NAS pain in daily activities was 7.88 (±/ 1.47) at baseline and 4.32 (±/ 2.68) at 1 month. 46 (47.4%) filled out the primary outcome and were considered as treatment responders. The multivariate model adjusted for age, sex, work interruption because of AC, initial shoulder traumatism, disease duration greater than 9 months, DASH score, NAS pain at baseline, and MRI thickness of the rotator interval (millimeters) found an association between response to treatment and disease duration < 9 months (OR 2.27 95% CI [1.00-5.26] p = 0.05). DASH score at baseline (OR 0.96 (per point) 95% CI [0.93-0.98] p = 0.03) and MRI thickness of the rotator interval (OR 1.65 (per millimeter) 95% CI [1.04-2.62] p = 0.04). No association was found with the injected MRI criteria.

Conclusion: This study provides original results on predictive factors of response to CD associated with intensive rehabilitation in patients with AC. It found an association of response to treatment and lower DASH score at baseline, shorter disease duration and MRI thickness of the rotator interval and offers suggestions for better patient selection to CD.

Results: Of the first study population, the median CCN of control IVDs (n = 10) was 388 (interquartile range [IQR] = 118-685) and the upper 99% CI limit was 870. MC1 IVDs (n = 30) had similar median CCN overall (Mann-Whitney: 8: 16 pg/ml, (1, 54) vs. -15 pg/ml, (-21, -11), p = 0.004; ENA-78: 91 pg/ml (-5, 456) vs. -25 pg/ml, (-137, -21), p = 0.048), and a bacterial neutrophil “defense response to bacterium” in cluster 1, but not in cluster 2, further supporting that clusters represent different etiologies.

Conclusion: We show that IVD C. acnes load is decisive for the etiology-specific MC1 pathomechanisms. This has important clinical implications, as different MC1 etiologies might require different treatment strategies.

Liege, MusculoSkeletal Innovative Research Lab (mSKIL), Liege, Belgium; 1Artialis, SA, Liege, Belgium; 2Princess Paola Hospital, Physical Therapy and Rehabilitation, Marche-en-Famenne, Belgium; 3ULiege, Center for Interdisciplinary Research on Medicines, Liege, Belgium

Background: Urolithins are intestinal bacterial metabolites of ellagic acid, from pomegranate and nuts. They modulate oxidative-regulated pathways and display anti-inflammatory, antioxidative properties. Several studies indicate that they could be inducers of muscle strengthening.

Objectives: The aim of this in vitro study was to investigate their mechanisms of action at plasma concentrations on primary human myotubes.

Methods: Urolithin A and B (UA and UB) were evaluated separately on primary human muscle CD56+ cells, isolated from the vastus lateralis of 6 men and 3 women (aged range 55 to 96-y) and differentiated in myotubes. 24h-treatment mRNA-sequencing of these 9 patients was studied by DESeq2 analysis (R software). Modulation of several target genes was then validated in several concentrations (1-5 or 10 µM). Among the most regulated genes, we found genes involved in myoblasts to myotubes differentiation. UA increased the expression of several target genes was then validated in several concentrations (1-5 or 10 µM).

Results: After 24h of treatment at 5 µM, UA and UB significantly modified the expression of 1779 and 319 genes, respectively (adjusted p-value of 0.01 and Log2FoldChange >0.32). The most upregulated genes involved in myoblasts to myotubes differentiation. UB increased the expression of MYN (75%), PAXX (50%), MSTN (66%), MLYH (28%) and conversely decreased FGFR9 (-75%), MRLN (-33%), ICAMS (-52%) and TGFBI (-55%). Regarding UB, it decreased IGFB1 (-75%), TGFBI (-60%) and increased MLYH (+34%) and TGM2 (-59%). However, UA, but not UB, decreased DMD gene expression (-86%), a key factor in muscle strength, and MEF2C (-45%), a regulator of skeletal myogenesis. We also observed the modulation of genes involved in the inflammatory process. They both induced a important decrease
of CYP1B1 expression (−95%). Further, LIF was increased by 80% by UA and PTGS1 was decreased by 41% by UA and 43% by UB. UA and UB had the opposite effect on IL17B, a cytokine involved in tissue repair but its role in muscle is still to be defined. IL17B was decreased by 4% by UA and conversely regulated by 45% by UB. In a second step, we confirmed the modulation of MYMX, PANX1, FGF9, ICAM5, PTGS1-PGE2, IL17B and TGFBI following UA and/or UB treatment at 1, 5 and 10 µM by RT-qPCR and ELISA. Finally, we also observed with live cell imaging that UA and UB increased myocyte fusion in myotubes, already after 6h of treatment.

Conclusion: UA and UB promote the differentiation process of myoblasts to myotubes. In parallel, urolithins present anti-inflammatory properties, mainly by reducing CYP1B1 expression and the PGE2 synthesis via PTGS1, but also for UA by increasing LIF. Our data provide a better understanding of urolithin activities and highlight their potential in the treatment of muscle disorders such as sarcopenia.

Teixeira2, D. Araujo Fernandes1. 1Federal University of Santa Catarina, Department of Surgery, Florianópolis, Brazil; 2Federal University of Santa Catarina, Department of Morphological Sciences, Florianópolis, Brazil; 3Fractures Institute, Fractures Institute, Florianópolis, Brazil

Background: In the context of osteoarthritis (OA) prevention, great attention is given to hip preservation surgery [1]. Patients with femoroacetabular impingement (FAI), a highly prevalent painful condition, are at increased risk of developing OA [2]. However, an undefined fraction of these patients manage to get rid of clinically significant OA with conservative care [3]. Recently, we realized that α angle can be a key to define which patients would benefit from conservative care and which of these should undergo surgery to prevent clinically significant OA.

Objectives: This meta-analysis aimed to answer: i) “does α angle predict the degree of hip chondral health in FAI?” and ii) “what are the α angle endpoints that correspond to each group of degree of chondral health?”

Methods: We followed the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA). Two independent reviewers performed the study selection and data extraction steps. Databases were screened: Embase, MEDLINE/PubMed, SCOPUS, SPORTDiscuss and The Cochrane Library. Good quality primary studies that, by using regressions and other similar statistical tests, assessed the capability of α angle values in predicting the degree of hip chondral health for patients with FAI were considered eligible. Risk of bias was assessed through the QUIPS tool. We conducted a pooled linear regression in order to establish α angle endpoints correlated to each chondral health group.

Results: Twelve studies were considered eligible for bias assessment. We found a high risk of bias due to misreporting and the presence of confounders in 2 studies, which were then excluded from analysis. A summary of the included studies’ reported findings is in the Table 1. All 10 included studies demonstrated that α angle predicts the degree of chondral health, with good to excellent effect sizes. For the pooled analysis, 447 patients were enrolled. As the severity of chondral deterioration increases from 1 to 4 in an Outerbridge scale, the corresponding α angle endpoints are 56°, 61°, 65° and 72°, respectively (R² = 0.987; p < .001) (Figure 1).

Conclusion: The α angle is a good tool to identify FAI patients who are at high risk of developing clinically significant OA without surgical intervention. In order to prevent clinically significant OA, we recommend that patients with an α angle greater than 65° should undergo surgery - since they are at high risk of developing significant chondral damage associated with OA progression.

SERUM MASS SPECTROMETRY IDENTIFIES APOLIPOPROTEIN D AS POTENTIAL BIOMARKER FOR MODIC TYPE I CHANGES

Keywords: Pain, Diagnostic Tests, Biomarkers
Background: Modic changes (MC) are inflammatory vertebral bone marrow lesions adjacent to degenerative intervertebral discs [1]. On MRI, three types can be distinguished: Modic types 1 – 3 changes (MC1, MC2, MC3). Especially MC1 are associated with low back pain (LBP), and the larger the lesion, the stronger is the association with pain [3]. However, in clinics, MC is often a binary (present/absent) observation with insufficient inter-observer reliability in identifying and classifying MC.

Objectives: The aim of our study was to find potential serum biomarkers for the presence or the extent of MC using data of the Northern Finland Birth cohort of 1966 (NFBC1966) [2].

Methods: We selected 103 participants of the NFBC1966 to form 4 groups: With and without MC, and with and without LBP. For each participant with MC, we had information about the type, number, location, height, and transverse area (TA) of the MC. Height was given in 4 groups: “along the endplate”, “> 25%”, “25-50%” and “<50% of the height of the vertebral body” TA was measured in 1/9 parts of the vertebral endplate surface of a fictitious 3x3 grid (Fig. 1). We defined the MC load for each person and MC type as the sum of the product of height and TA of each MC.

The serum samples were subjected to a sequential window acquisition of all theoretical mass spectra (SWATH-MS) analysis. To find a potential biomarker for the presence of each MC type we compared serum concentrations of proteins identified by mass spectrometry between participants with and without MC using Mann-Whitney-U tests. Performance to predict MC was calculated with Receiver Operating Characteristics (ROC). A covariate analysis for significantly different proteins was done with ANCOVA. To find a potential biomarker for the extent of MC, we searched for associations between serum concentration and MC-load with Spearman’s logistic regression. We corrected for multiple comparisons with False Discovery Rate (FDR).

Results: Of the 103 participants, 49 had MC, 54 had no MC (noMC). Of the participants with MC, 5 (10.2%) had only MC1, the others had multiple types of MC. 30 (61.2%) had MC1, 43 (87.7%) had MC2 and 40 (81.6%) had MC3. The average number of MC per person was 3.0 (1 – 9). The MC load, calculated from number, area, and height of the MC-lesions, was on average highest for MC2 (12.33, 95% CI: 9.0 – 15.6) followed by MC3 (11.26, 95% CI: 8.0 –14.5) and MC1 (7.0, 95% CI: 3.5 – 10.6). Serum Mass Spectrometry identified 1087 proteins. Of these, only the concentration of Apolipoprotein D (APOD) was significantly different between MC1 and noMC (Mann-Whitney-U-Test, FDR-adjusted p = 0.034). A covariate analysis with ANCOVA showed that this was independent of LBP. There was no significant result for MC2 or MC3 after correction for multiple comparisons. The ROC for APOD in MC1 had an Area under the curve (AUC) of 0.79. As APOD is part of lipoproteins and involved in lipid transport, we hypothesised a disturbed lipid transport in patients with MC1 and tested if adding other proteins involved in lipid transport to the model could increase the AUC of the ROC. Adding Apolipoprotein C3 (APOC3) to the linear model increased AUC of the ROC to 0.83 despite not associating with MC1. Additionally, linear regression showed a correlation between serum APOD and MC1 load (p=0.46, FDR adjusted p-value = 0.002).

Conclusion: The serum concentration of APOD is associated with the presence of MC1 and correlates with the load of MC1. Especially in combination with the serum concentration of APOC3, it is a potential biomarker for the presence of MC1.

STROMAL CELLS IN MODIC TYPE 1 CHANGE BONE MARROW PROMOTE NEURITE OUTGROWTH

Keywords: Pain, Bone diseases

T. Mengis 1, I. Heggl 1, N. Herger 1, B. Aradi-Vegh 1, F. Brunner 2, M. Farshad 3, O. Distler 1, 2, S. Dudli 2, 4, 5, 6.

5 University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland
6 University Hospital Zurich, Department of Neurology, Zurich, Switzerland

Background: Vertebral bone marrow lesions known as Modic type 1 changes (MC1) are a major contributor to unspecific lower back pain. Pain may relate to the higher innervation of MC1 endplates. Blocking neo-innervation in MC1 could be a promising treatment approach for MC1. Bone marrow stromal cells (BMSC) can produce neurotrophic factors and are dysregulated in MC1. Objectives: The aim of the study was to identify if BMSC in MC1 support neo-innervation through release of neurotrophic factors.

Methods: The RNA sequencing data set (ENA PRJEB39993) of MC1 BMSC vs. intra-patient control BMSC (n=3) MC1 + 3-intra-patient control) was used to investigate enriched gene sets. From additional patients, BMSC were isolated from vertebral bone marrow aspirates (n=4 MC1 + 4-intra-patient control) and were co-cultured with the neuroblastoma cell line SH-SY5Y for 8 days. Neurite outgrowth from SH-SY5Y was quantified as a measure for neurotrophic activity using microscopy. Thirty neurotrophic cytokines were analyzed in the supernatant of the co-culture using C-Series Human Neuro Discovery Array C2.

Results: Gene set enrichment analysis of MC1 vs. intra-patient control BMSC identified gene sets associated with BDNF signaling such as “BDNF TRKB signaling” (normalized enrichment score (NES) = 1.71, p=0.001) and “mBDNF” and “proBDNF regulation of GABA neurotransmission” (NES = 1.61, p=0.001) amongst the top enriched gene sets. SH-SY5Y cells co-cultured with MC1 BMSC compared to intra-patient control showed significantly increased neurite outgrowth after 4 days (p = 0.045), 6 days (p = 0.027), and 8 days (p = 0.031). (Fig. 1a). Cytokine array analysis revealed significantly more mature brain-derived neurotrophic factor (mBDNF) (p = 0.021) and ciliary neurotrophic factor (CNTF) (p = 0.030) in supernatant of MC1 vs. control BMSC (Fig. 1b).

Conclusion: Neurotrophic activity of MC1 BMSC is increased. This might be mediated by BDNF and CNTF. Therefore, BDNF and CNTF may represent interesting novel treatment approaches for MC1 that directly target pain mechanisms.

Background: Magnetic resonance imaging (MRI) is frequently used in patients with chronic back pain (CBP) to diagnose mechanical and inflammatory diseases, including axial spondyloarthritis (axSpA). Recent data suggest sacroiliac joints (SIJ) MRI findings in axSpA may differ according to sex[1]. Whether this holds true for spinal MRI and other causes of CBP is currently unknown.

Objectives: To analyze spinal and SIJ MRI findings in young male and female patients with CBP.

Methods: The “Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis” (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with CBP asked to undergo an MRI of the spine by other specialists different than rheumatologists in a tertiary hospital, starting in September 2021. After inclusion, an additional MRI of the SIJ, followed by a rheumatology visit and eligible blood tests were performed. Dataset for this interim analysis was locked in October 2022. The protocol for MRI of the spine used a 1.5T scanner to acquire sagittal T1-weighted turbo spine echo (TSE) and T2-weighted TSE, both for the lateral sides of vertebral bodies, and T2-Multistack. On top of this, an MRI of the SIJ, which involved T1-TSE, T2-weighted SPAIR and short-tau inversion recovery (STIR) sequences, was performed. MRI findings were assessed according to clinical practice by one of the four musculoskeletal radiologists working in the centre, describing the presence of mechanical lesions (spondylolisthesis, spondyloysis, disc herniation, disc protrusion, facet joints abnormalities), inflammatory findings (both SIJ and spine), and structural findings. For this analysis, results were stratified by sex.

Results: Among 152 recruited patients, 85 (55.9%) were female; mean age was 34.2 (5.3) years. Spinal MRI findings were reported in 130 (87.2%) patients, with no differences between sexes (male 90.8% vs female 84.5%, p=0.3). As shown in Table 1, the most frequent diagnosis in both sexes were disc protrusion, followed by disc herniation. Inflammatory spinal findings were detected only in one male patient. No differences were found for any of the spinal lesions. SIJ MRI findings were reported in 49 (33.1%) patients, being numerically more frequently observed in males (41.5% vs 26.5%; p=0.08). Concordance of both structural and inflammatory lesions was more frequently in males (9.2% vs 1.2%; p<0.05), while no differences in isolate SIJ MRI findings were found between sexes. Overall, 45 (29.6%) patients presented findings both in the spine and SIJ (Figure 1).

Conclusion: In young patients who are requested a spinal MRI by other specialists different than rheumatologists, spinal lesions are reported in most patients, and similarly in males and females. Remarkably, SIJ MRI findings are reported in one out of three patients in this population, being more frequently in males.

HEALTH LITERACY AND OUTCOMES IN PATIENTS UNDERGOING TOTAL KNEE ARTHROPLASTY

Keywords: Outcome measures, Education

L. Yue1, H. Do1, J. A. Gibbons2, D. Sun1, J. A. Gibbons3, A. Bass3, B. Mehta1, L. Russell1, M. Figgie1, M. Parks1, S. Background: Health literacy is the ability to read and gain an understanding of health-related information, and make treatment and behavior choices accordingly. Poor health literacy is a main driver of health disparities in chronic medical conditions. Little is known about literacy in orthopedic surgery patients, which may be critical for post-surgical recovery.

Objectives: This study assessed health literacy in patients undergoing total knee arthroplasty (TKA) and its association with individual and community demographics, surgical length of stay (LOS), and discharge disposition.

Methods: The study population consisted of TKA patients at a single urban orthopedic specialty hospital from 2018-2021 who completed the health literacy screen. Health literacy, patient demographics and clinical variables were extracted from a data warehouse. Patient health literacy was defined by a validated single question screener: Evaluation of a brief instrument to identify limited reading ability. Answers were “Always,” “Often,” “Sometimes,” “Occasionally” or “Never.” Patients with any reported finding in spine or sacroiliac joint magnetic resonance imaging were included.

THE EFFECTS OF SPINAL STABILIZATION EXERCISES VIA TELEREHABILITATION ON INDIVIDUALS WITH CHRONIC LOW BACK PAIN: A RANDOMIZED CONTROLLED STUDY

Keywords: Physical therapy/Physiotherapy, Telemedicine, Rehabilitation

A. Fanuşcu1, M. Öz1, O. Uğur1, Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

Background: Chronic low back pain is a very common problem worldwide. Reasons such as repetitive problems and lack of a clear treatment cause low back pain to be a serious burden for society [1]. Telerhabilitation provides remote application of rehabilitation services with the developing technology. Especially in the COVID-19 pandemic, the problems experienced in health services have increased the popularity of telerhabilitation services [2].

Objectives: Aim in this study is to investigate the effects of spinal stabilization exercises performed remotely with asynchronous video clips on pain, disability, quality of life, trunk flexion range of motion and gait parameters.

Methods: A total of 20 individuals with chronic low back pain were included in the study. After recording demographic information, pain levels were evaluated with the Visual Analogue Scale (VAS), disability levels were evaluated with the Oswestry Disability Index (ODI), and quality of life was evaluated with the Nottingham Health Profile (NHP). Trunk flexion range of motion was evaluated with...
the Valedo® system (Hocoma, Switzerland), and the spatiotemporal parameters of the gait (step time, cadence) were evaluated with the OPTOGait system (OPTOGait, Microgate, Italy). After the evaluation, the individuals were divided into 2 groups. One group did face-to-face progressive spinal stimulation exercises in the clinic, while the other group did the same exercise program remotely with asynchronous videos. The exercise program was 8 weeks, 3 days a week.

**Results:** The mean age of the telerehabilitation group (4 M, 5 F) was 41.0 ± 13.0, and their BMI was 27.08 ± 3.70 kg/m². All parameters were similar in the two groups before treatment. There was a significant difference in parameters except gait parameters in both groups after treatment (p<0.05). In the evaluation between the groups after treatment, the results of the two groups were similar in all parameters (p>0.05) (Table 1).

**Background:** A clinical group (1 M, 8 F) was 41.0 ± 13.0, and their BMI was 27.64 ± 3.55. All pregnant women were shown the region of LBP on a figure and they were asked to mark the relevant average pain intensity on a 10 cm Visual Analogue Scale (VAS). Disability was evaluated using the Oswestry Disability Index (ODI) to evaluate the degree of loss of functionality. Abdominal muscle thicknesses and diastasis recti were assessed. Detailed, sociodemographic and obstetric characteristics were recorded. The pregnant women were shown the region of LBP on a figure and they were asked to mark the relevant average pain intensity on a 10 cm Visual Analogue Scale (VAS). Disability was evaluated using the Oswestry Disability Index (ODI) to evaluate the degree of loss of functionality.

**Methods:** A total of 107 primiparous women with NSCLBP, 69 women (mean ± standard deviation = 50.9±9.9 years) participated in this cross-sectional study. Back flexor, back extensor, upper- and lower-body muscle strength were measured with reliable and valid tests ( prone bridging, Biering-Sorensen, hand dynamometry (TKK 5101) and 30-second chair-stand test, respectively). Global muscle strength was calculated with normalized index (z-score) procedure from each muscle strength test. Spatiotemporal gait parameters (contact time, gait speed, stride length, stride cycle/time, double support and load respond) were obtained with an Optogait® platform, where patients were informed to walk comfortably until 150 to 200 steps were registered in 5 meters closed circuit. Linear regression analysis was used to study the association between muscle strength and spatiotemporal gait parameters. Age, medication for pain, relaxation and depression, and fat percentage were used as covariates using the ‘stepwise’ method. These variables were administered via interview, except fat percentage which was measured with an 8 tactile polar electrode bioimpedance system (InBody R20).

**Results:** In women, greater back flexor muscle strength was associated with lower contact time (β=-0.329), global muscle strength (β=-0.358), double support (β=-0.313) and load respond (β=-0.302), higher gait speed (β=0.341), and longer stride length (β=-0.272) (all p<0.013). Greater lower-body muscle strength was associated with less contact time (β=-0.160) and double support (β=-0.237), higher gait speed (β=0.365) and longer stride length (β=0.415) (all p<0.013). Greater upper-body muscle strength was associated with higher gait speed (β=0.380) and longer stride length (β=0.476) (all p<0.013). Greater global muscle strength was associated with less contact time (β=-0.370), stride cycle/time (β=-0.468), double support (β=-0.324) and longer load respond (β=-0.320), higher gait speed (β=0.431) and longer stride length (β=0.491) (all p<0.03). In men, greater back extensor muscle strength was associated with higher gait speed (β=0.353), and longer double support (β=0.387) and load respond (β=0.365) (all p<0.038). Greater lower-body muscle strength was associated with lower stride cycle/time (β=-0.342) (p<0.044). Greater global muscle strength was associated with higher gait speed (β=0.414), longer stride length (β=0.410), and longer double support (β=0.373) and load respond (β=0.354) (all p<0.037).

**Conclusion:** Our findings suggest that greater muscle strength was consistently associated with better spatiotemporal gait parameters in females and males patients with NSCLBP. Future studies might determine whether randomized control trial focused on strengthening global musculature might contribute to improve gait abnormalities in patients with NSCLBP.

---

**Conclusion:** According to the results of our study, it is seen that both methods did not provide any change in gait parameters. However, it has similar effects in reducing pain and disability, improving quality of life, and increasing trunk range of motion. For individuals with chronic low back pain, it seems that remote exercise with asynchronous videos can be as effective as a treatment as face-to-face exercise. There is a need for studies to be conducted in a larger population with longer follow-up. **DOI:** 10.1136/annrheumdis-2023-eular.2621
The mean LBP intensity was 3.09±2.37 and they were 2.68±2.09, 2.73±1.98, 2.16±2.01 for the 1st, 2nd and 3rd trimesters, respectively. Demographic and medical variables in pre-pregnancy and pregnancy periods were not associated with PR-LBP intensity. On the contrary, ODI score was associated with LBP intensity during pregnancy. Higher ODI score shows severe low back pain (coef=0.05, R²=0.21, p=0.03) and ODI scores explain 11%, 13% and 26% of LBP severity during 1st, 2nd and 3rd trimester, respectively. Musculoskeletal variables (abdominal muscle thickness and diastasis recti) were not associated with PR-LBP intensity. SF-36 emotional role limitation (coef=-0.03, R²=0.01, p=0.01) in the 3rd trimester and SF-36 physical function (coef=-0.05, R²=0.02, p=0.004) were associated with PR-LBP intensity. Rest of the SF-36 subscales were not associated with LBP intensity during any trimester. Physical activity were not associated with PR-LBP intensity, except of the PPAG-sedentary during the 2nd trimester (coef=0.17, R²=0.17, p=0.02).

**Conclusion:** Increased PR-LBP intensity can be associated with different factors in different trimesters of pregnancy. Clinicians should comprehensively assess pregnant women, taking into account the relevant risk factors according to trimester, and make preventive/therapeutic recommendations for pregnant women.

[1] Berber MA, Satılmı Ş, Karapinar M, Kose O, Demiralp B, Ilkbahar S, Tekin H. Relationship between hallux valgus and pes planus in terms of foot posture, function, pain, and quality of life. In this study, we compared the postoperative results of Mitchell’s osteotomy for hallux valgus and pes planus. Background: In recent years, joint-preserving surgery has become common surgical procedure for forefoot deformities in Japanese patients with rheumatoid arthritis (RA). Since arthritis contributes to hallux valgus deformity in patients with RA, the postoperative outcome may differ from that in patients with idiopathic hallux valgus (IHV) patients.

**Objectives:** In this study, we compared the postoperative results of Mitchell’s osteotomy in patients with RA and IHV. **Methods:** We evaluated 181 feet in 111 patients (52 feet in 34 patients with RA, 129 feet in 77 patients with IHV) who performed Mitchell’s osteotomy surgery between January 2006 and September 2021 and followed-up more than one year after the operation. The hallux valgus angle (HVA) and intermetatarsal angle (IMA) were measured from standing X-ray images of the foot, before and after surgery and one year later, and the postoperative course of RA and IHV patients was compared.

**Results:** Preoperative HVA was 42° [20-73] in patients with RA and 40° [17-62] in patients with IHV, with no significant differences. Preoperative IMA was 14° [6-22] in patients with RA and 15° [27] in IHV patients, significantly smaller in the RA group (p<0.05). RA 1 year after RA and 9° [24-38] in IHV patients with IHV, with no significant differences. IMA at 1 year was 7° [0-18] in patients with RA and 8° [1-21] in patients with IHV, with no significant differences. The recurrence rate at 1 year postoperatively was 17.3% in patients with RA and 16.3% in patients with IHV, with no difference. Traditionally, metatarsal head resection has been performed for rheumatoid forefoot deformities. However, joint-preserving surgery is recently performed and improvement of anti-arthritic drugs such as biological disease modifying drugs and Janus kinase inhibitors. Mitchell’s osteotomy has been recommended for IHV as a joint-preserving surgery, as has Chevron osteotomy. The results of this study showed that Mitchell’s osteotomy is useful treatment method for patients with RA as well as for patients with IHV. In addition, preoperative IMA in patients with rheumatoid forefoot deformity was significantly smaller than patients with IHV, but there was no difference in HVA. This suggests joint inflammation leads to lateral displacement of proximal phalanx without metatarsal bone medialization.

**Conclusion:** Joint-preserving surgery with Mitchell’s osteotomy was useful method for hallux valgus deformity in patients with RA.

**COMPARISON OF FOOT POSTURE, PAIN, FUNCTION AND QUALITY OF LIFE IN PATIENTS WITH PES PLANUS AND HALLUX VALGUS: A PILOT STUDY**

**Keywords:** Quality of life, Pain

G. Aydin Yaşıcıoğlu1, M. Karapinar1, S. Suleyman Demirli University; Department of Physiotherapy and Rehabilitation, Izmit, Turkey

**Background:** Hallux valgus is a common deformity characterized by abnormal rotation, lateral deviation, angulation of the great toe at the first metatarsophalangeal joint. Pes planus is known as the loss of the medial longitudinal arch. While some studies have suggested that pes planus plays an important role in the development of hallux valgus [1-2], others reported that no correlation between these disorders [3, 4]. Thus, the differences in the problems caused by these disorders should be clarified.

**Objectives:** The aim of this study was to compare individuals with hallux valgus and pes planus in terms of foot posture, function, pain, and quality of life. **Methods:** Thirty-one (13-hallux valgus, 18-pes planus) individuals of both sexes, who were determined to have pes planus or hallux valgus by clinical evaluation, were included in the study. The dominant foot of the patients was evaluated by the Foot Posture Index (FPI-6), Foot Function Index (FFI), The American Orthopedic Foot and Ankle Society (AOFAS), and their quality of life was evaluated by the Short Form-36 (SF-36); FFI-6 evaluates foot posture with 6 items in the range of (-12) to (12). According to FPI-6, negative values indicate the foot is in supination, and positive values indicate that the foot is in pronation. The FFI scores for the domains of pain, disability, and activity limitations. A higher score indicates greater impairment. AOFAS, also consists of pain, function, and alignment subscales, and the total score ranges from 0-100, and higher scores indicate better outcome. SF-36 is a scale that evaluates health-related quality of life with 8 subscales, and physical function subscale of SF-36 were used in this study, and higher scores also demonstrate a better quality of life. Mann Whitney-U test was used to investigate the differences between patients with hallux valgus and pes planus and pes planus.

**Results:** Individuals with pes planus and hallux valgus were homogenous in terms of physical characteristics (p>0.05). It was determined that patients with pes planus had more foot pain according to FPI-6 and more foot pain according to FFI and AOFAS compared to patients with hallux valgus (p<0.05). Other results were similar between patients with pes planus and hallux valgus (p>0.05) (Table 1).

**Conclusion:** To the best of our knowledge, this study was the first to compare between patients with hallux valgus and pes planus. Current findings revealed that pes planus caused more pain and foot posture disorders compared to hallux valgus. A comparative study on a large sample is ongoing to assess the difference between these foot disorders.

**EFFECTIVENESS OF TREATMENT OF FACET SYNDROME BY THE METHOD OF BLOCKADE OF INTERVERTEBRAL JOINTS UNDER ULTRASOUND CONTROL**

**Keywords:** Pain

T. Tarasenko1,2, O. Tarasenko3, Kherson State University, Medical Faculty, Dnipro, Ukraine; 2Rheumatology Clinic of Professor Rekalov, Rheumatology, Dnipro, Ukraine; 3Kherson State University, Medical Faculty, Dnipro, Ukraine

**Background:** recently there has been an increase in the prevalence of facet syndrome (spondyloarthrosis) in back pain syndromes. This is due to hypodynamic, increased body weight, and the increase in the specific gravity of the so-called “sedentary” professions. With hyper trophy of the intervertebral joints, there is chronic compression of the Lyushka nerve (return nerve), which directly causes pain, as well as constant spasm of the innervating muscles. In the treatment of facet syndromes, many methods are used - drug treatment, massage, various physical methods of influence, etc., but none of these methods provides quick relief from the pain syndrome. The blockade method has been used for a long time with considerable success, but even more works are appearing that show much better efficiency of these manipulations with high-precision introduction of drugs under ultrasound or X-ray control.

**Objectives:** to determine the effectiveness of blockades of intervertebral joints under ultrasound control in facet syndrome.

**Methods:** we conducted a study of patients in whom the clinical manifestations of the facets of the lumbar spinal spine were confirmed by radiological research methods (radiographic or MRI). The level of pain syndrome was assessed according to the VAS scale before the start of treatment and after 1 and 7 days after the start of the treatment. Along with traditional treatment (NSAIDs, muscle relaxants, etc.), facet blockade was performed under ultrasound control.

**Results:** 50 patients (22 women and 28 men) were included. The average age was 43.28 years±0.80 years. 56.42% of patients were overweight. The average body mass index was 28.18±0.43 kg/m2. 80% of patients had multilevel facet syndrome L3-S1. 20% of patients had a monofacet syndrome at the level of L4-L5 or L5-S1. Patients were divided into 2 groups of 25 people. Patients of both groups were prescribed drug therapy with NSAIDs and muscle relaxants. The patients of the first group were additionally subjected to facet blockade under ultrasound control, and a solution of corticosteroid and local anesthetic was injected into the affected areas. Depending on the number of lesion levels, a multilevel procedure was performed. Before the procedure, the average pain level according to VAS in patients of the 1st group was 84±1.7 mm, in the 2nd group - 82±2.3 mm. After 1 day, the pain level in patients of the 1st group was 31±4.2 mm, while in the 2nd - 72±2.8 mm. 7 days after the start of treatment and manipulation, the pain level was 28±2.9 mm in the 1st group and 51±3.7 mm in the second group of patients (who were not manipulated).

**Conclusion:** the method of facet blockade under ultrasound control is a modern, low-invasive, highly effective method in the complex treatment of facet syndrome.

**EFFICACY AND SAFETY OF SODIUM THIOSULFATE IN CALCIFIC TENDINITIS OF THE ROTATOR CUFF – ANALYSIS OF AN ONGOING RANDOMIZED CLINICAL TRIAL**

**Keywords:** Patient reported outcomes, Randomized control trial, Outcome measures

H. Parent1, S. Azevedo1, F. Guimarães1, C. Dantas Soares1, M. Pontes Ferreira1, D. Faria1, D. Peixoto1, J. Tavares-Costa1, C. Afonso1, F. Teixeira1.

1Centro Hospitalar do Alto Minho, Rheumatology, Ponte de Lima, Portugal

**Background:** Calcific tendinitis of the rotator cuff is a major cause of omalgia. [1] Ultrasound guided percutaneous lavage (UGPL) is indicated when conservative treatments fail. [2] Recent reports interested the use of topical sodium thiosulfate (STS) in the treatment of other diseases with ectopic calcifications [3, 4, 5].

**Objectives:** To assess the efficacy and safety of UGPL with STS versus with saline injection (standard of care) in calcific tendinosis.

**Methods:** Double-blinded randomized clinical trial including adult patients with calcific tendinitis, omalgia ≥3 months and ≥1 positive shoulder impingement test. Only dense type A calcifications (Möel Classification) >5 mm in diameter were included. Patients were randomized in two groups: STS and SOC lavage. Informed consents were collected. Both groups were reevaluated at week 1, month 1 and 3 after UGPL. Pain Visual Analogue Scale (VAS) at rest and during activities, shoulder range of motion and strength, improvement scores of the Arm, Shoulder and Hand (DASH), DASH-Work, EuroQol five-dimensional (EQ5D) and University of California at Los Angeles (UCLA) scores, ultrasound (US) and radiographic evaluations were performed on all follow up visits. SPSS was used for statistical analysis with a significance level of 2-sided p<0.05.

**Results:** We included 32 patients, where 78.1% (25) were women, with a mean age of 51.0 (SD=8.5) years old. Pain’s mean duration before the procedure was 16.3 months (SD=22.3). We randomized 18 patients (56.3%) to the control group (SOC) and performed a saline UGPL; the other 14 patients (43.8%) to the treatment group (STS). Baseline characteristics are shown in table 1. Since patient inclusion is dynamic, our sample met 28 patients at week 1 (SOC=15...

ASSOCIATION BETWEEN MUSCLE MASS PERCENTAGE WITH PAIN AND DISABILITY IN PATIENTS WITH NON-SPECIFIC CHRONIC LOW BACK PAIN: THE BACKFIT PROJECT

Keywords: Motor function, Rehabilitation, Pain

Y. M. Gil-Gutiérrez1, G. Tsiafleas2, B. Donoso3, M. Delgado-Fernández2, M. Y. Castellote-Caballero2, V. Segura-Jiménez3, 1 Instituto de Investigación Biosanitaria ibs.GRANADA, UGC Neurotraumatología y Rehabilitación, Hospital Universitario Virgen de las Nieves of Granada, Granada, Spain; 2 University of Granada, Physical Education and Sport, Granada, Spain; 3 University of Cordoba, Psychology, Cordoba, Spain; 4 University of Jaén, Health Sciences, Jaén, Spain

Background: Non-specific chronic low back pain (NSCLBP) is one of the most common musculoskeletal disorders worldwide[1]. Recent studies have shown higher levels of pain[2,3] and disability[4] in patients with NSCLBP who presented higher body mass index. However, the relationship between body muscle mass and these two variables is unknown.

Objectives: To determine if there is an association of body muscle mass percentage with pain and disability in patients with NSCLBP.

Methods: 105 patients (70 women, 50.59 ± 9.95 years) participated in this cross-sectional study. Body muscle mass percentage was evaluated using portable bioimpedance of eight tactile polar electrodes (InBody R20). Pain sensitivity threshold was assessed using manual pressure algometry (FPK 20, Wagner Instruments, Greenwich, CT, USA). Pain intensity was evaluated using two instruments, on the one hand a visual analogue scale (VAS) and on the other hand the pain dimension of the Short-Form Health Survey-36 (SF-36) questionnaire. The Oswestry Low Back Pain Disability Questionnaire was used to assess disability due to pain. To study the association between the main variables, a linear regression analysis was carried out, controlling for age, sex, marital and educational status, time since clinical diagnosis and waist circumference as covariates using the ‘stepwise’ method. As there was no interaction in terms of sex, the analyses were carried out jointly (women and men).

Results: Higher levels of body muscle mass percentage were associated with higher pain sensitivity threshold (rho=0.071; 95% confidence interval (CI)= 0.070; 0.170; p=0.017; lower VAS-pain (b=-0.095; 95% CI=-0.164, -0.020; p=0.03) and higher score in the SF-36 pain dimension (b=0.036; 95% CI=0.376, 170; p=0.002), and lower disability due to pain (b=-1.028; 95% CI=-1.513, -0.542; p<0.001).

Conclusion: Patients with NSCLBP presenting higher body mass percentage showed lower pain and disability due to pain, and higher pain sensitivity threshold. Further intervention studies are necessary to check the effects on pain and disability of programs focused on improving muscle mass in this population.

Disclosure of Interests: The authors thank all the researcher involved in the fieldwork. Participants are deeply acknowledged for their collaboration and great enthusiasm during the development of the study. This study was supported by the Instituto de Salud Carlos III through the research contract Miguel Servet (CP200/00178) co-funded by European Social Fund. Furthermore, BD-P was supported by the “Margarita Salas” postdoctoral grant UCOR015MS.

THE EFFECTS OF YOGA AND AEROBIC EXERCISE ON PAIN, FUNCTION, METABOLIC CAPACITY, QUALITY OF LIFE AND COGNITIVE VARIABLES IN INDIVIDUALS WITH CHRONIC LOW BACK PAIN: PRELIMINARY RESULTS

Keywords: Rehabilitation, Cognitive Function, Pain

M. Öz1, O. Ulger1, *Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

Background: It is known in the literature that exercise is effective on pain and function in the treatment of chronic low back pain (CLBP). However, it is emphasized that there is insufficient evidence about which type of exercise is more effective and the effects of exercises on cognitive parameters associated with chronic pain.

Objectives: The study aims to determine the effects of yoga and aerobic exercise on pain, function, metabolic capacity, quality of life (QoL), and cognitive variables in individuals with CLBP.

Methods: Thirty individuals with LBP for 3 months or longer were included in the study. Individuals were randomly divided into 2 groups. The first group was given aerobics exercise training, and the second group was given a yoga program. Both programs were applied for 8 weeks, 2 days a week, for 1 hour, accompanied by a physiotherapist. Individuals were evaluated at baseline and after 8 weeks of treatment. Pain intensity was assessed with a visual analog scale (VAS), metabolic capacity with 6 Minute Walking Test, kinesiophobia with Fear Avoidance Beliefs Questionnaire (FABQ), pain perception with a pain catastrophizing scale (PCS), cognitive function with Montreal Cognitive Assessment Scale (MoCA), back awareness with Fremantle Back Awareness Questionnaire (FreBAQ) and with the Nottingham Health Profile (NHP).

Results: In the study, it was shown that both exercises approach reduced pain and improved function, metabolic capacity, and cognitive parameters (p<0.05). The effects of both exercises on pain, function, cognitive level, metabolic capacity, and NHP total score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction score were similar (p>0.05). Paediatric rheumatology

Keywords: Outcome measures, bDMARD, Disease-modifying Drugs (DMARDs)

K. Kern1, D. Kaudewitz2, H. M. Lorenz2, J. P. Haas4, N. Blank1. 1Division of Rheumatology, Department of Internal Medicine V, Heidelberg, Germany; 2Kinderklinik Garmisch-Partenkirchen, Deutsches Zentrum für Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen, Germany

Background: Juvenile idiopathic arthritis (JIA) is the most common disease in pediatric rheumatology. After transition, chronic active JIA requires continuing treatment. Little is yet known about the JIA activity in adult patients.

Objectives: To assess disease activity, treatment and comorbidities in adult patients with JIA between 2000 and 2022 at the University Hospital of Heidelberg.

Methods: This is a monocentric, retrospective analysis of adult patients with onset as JIA. The electronic medical records were analyzed from the first to the last documented visit in our center. Prognostic factors for disease activity in adults were determined using Fisher’s exact test, chi-square test and cross tables.

Results: Until March 2022, 172 JIA patients with a median age of 27.7 years (range 18.1 to 78.4) and a median disease duration of 19.4 years (range 1.3 to 68.8) at their last visit were identified. Oligoarticular (oligo-) (n=36, 20.9%), extended-oligo (ext-oligo-) (n=28, 16.3%) and polyarticular (poly-) (n=61, 35.5%) were the largest JIA subgroups. Females (n=134, 77.9%) were more prevalent than males (n=48, 22.1%) (p<0.001). The prevalence of uveitis was 27.9% (n=48). Patients with RF+ poly-JIA (n=17, p=0.001) or initiation of MTX after 2 years (n=41, p=0.006) or bDMARD after 3 years (n=44, p=0.001) of disease onset were associated with significantly more erosive joint damage. Patients with late MTX and/or bDMARD initiation (n=190) had more frequently osteoporosis (n=48, p=0.001, p=0.012) and required more frequently total joint replacement (n=41, p=0.012, p=0.04). Radiological joint damage was more prevalent in patients with a disease onset before the year 2000. At the last documented visit 51.8% of patients (n=72) were in SDAI and DAS28 remission.

Conclusion: The delay of MTX and bDMARD therapy in patients with active JIA was associated with erosive joint damage, total joint replacement and osteoporosis. The JIA onset before the year 2000 was associated with significantly more joint damage and a lower prevalence of remission.

AB1413 ASSESSMENT OF FATIGUE IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Osteoporosis, Sarcopenia, Mental health

M. Kulyk1, T. Karasevska1, M. Dzhus1. 1Bogomolets National Medical University, Internal Medicine Department No 2, Kyiv, Ukraine

Background: Fatigue is a common and frustrating symptom in many chronic inflammatory diseases, including juvenile idiopathic arthritis (JIA), impacting all parts of daily life.

Objectives: This study aims to determine the prevalence of fatigue in young patients with JIA and to analyze its correlation with clinical characteristics of the disease, body mineral content (BMC), and bone mass density (BMD).

Methods: Cross-sectional study included young adults with JIA according to ILAR criteria, disease duration ≥3 years. Exclusion criteria: age <18 and >44 years, the presence of any comorbidity that could be accompanied by fatigue (diabetes, chronic kidney disease, neuropathy, obesity, chronic obstructive pulmonary disease, infections, malignancy). Demographic data and the following clinical parameters were collected: pain Visual Analog Scale (VAS) measured by patients and doctors, tender joint count (TJC), swollen joint count (SJC), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Disease Activity Score 28 (DAS28), Juvenile Arthritis Disease Activity Score (JADAS77), health assessment questionnaire (HAQ), Juvenile Arthritis Damage Index-articular (JADI-A) and Juvenile Arthritis Damage Index-extra-articular (JADI-E). BMC and BMD were determined using dual photon X-ray absorptiometry (DXA). Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy – Fatigue (FACT-F) short 13-item questionnaire validated in RA. Fatigue was considered mild if the FACT-F score was ≥40, moderate if 20≤FACT-F<40, and severe if 0≤FACT-F<20. A p-value lower than 0.05 was considered significant.

Results: We included 40 patients with JIA (21 women and 19 men) with a mean age of 24.4±s. The mean disease duration was 13.8±s, 1 years. The mean pain VAS measured by the patient was 38.8±s, the mean pain VAS measured by the doctor was 33.6±s, 1. The mean TJC and SJC were 4.2±s, 4.9 and 1.9±s, 3, respectively. The mean levels of ESR and CRP were 20.2±s, 2.7/mm/h and 26.1±s, 0 mg/l, respectively. The mean DAS28-ESR was 3.6±s, 1, the mean JADAS27 was 13.7±s, 1 and the mean JADI-E was 6.5±s, 6. The mean FACIT-F score was 30.1±s, 1. Fatigue was mild in 37.5% (15 patients), moderate in 35% (14 patients), and severe in 27.5% (11 patients). A significant negative correlation was noted between the FACIT-F score and the following parameters in JIA patients: disease duration (r=0.436, p<0.001), articular and extra-articular damage obtained by JADI-A and JADI-E indices (r=-0.393, p=0.01, r=-0.440, p=0.05, respectively), pain VAS obtained by the doctor (r=0.431, p=0.05), pain VAS obtained by the patient (r=0.167, p=0.3), ESR (r=0.503, p<0.01), but not with CRP (r=-0.157, p=0.3), DAS28-ESR (r=-0.414, p=0.05), JADAS27 (r=-0.391, p<0.01) but not with TJC (r=0.080, p=0.8), and SJC (r=0.239, p=0.2). FACIT-F score was positively associated with total BMD (r=0.374, p=0.02), femoral neck BMD (r=0.519, p=0.007), appendicular lean mass (r=0.666, p<0.001), total lean mass (r=0.522, p=0.001), and skeletal mass index (r=0.703, p<0.001), but not with HAQ (r=0.035, p=0.8).

Conclusion: In our study, moderate and severe fatigue among young patients with JIA was 35% and 27.5%, respectively. The fatigue was associated with disease activity, duration of disease, articular and extra-articular damage, total and femoral neck BMD, and lean mass.

Keywords: bDMARD

A. Martins1, S. Ganhão2, F. Oliveira Pinheiro2, C. Morais, M. Leuzinger-Dias1, M. Rodrigues1, L. Figueira1, B. Brito2. 1São João University Hospital Center, Rheumatology, Porto, Portugal; 2Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal; São João University Hospital Center, Pediatric and Young Adult Rheumatology Unit, Porto, Portugal; São João University Hospital Center, Pediatrics, Porto, Portugal; São João University Hospital Center, Ophthalmology, Porto, Portugal

Background: The advent of disease-modifying antirheumatic drugs (DMARDs), in the past two decades has been revolutionary in the treatment and prognostic outcomes of patients with Juvenile Idiopathic Arthritis (JIA). Since some patients have inadequate responses to conventional DMARDs, biologic DMARDs (bDMARDs) must be prescribed to guarantee the achievement of complete remission. Early and appropriate treatment can prevent joint destruction, loss of joint function and extraarticular manifestations, with subsequent less morbidity and mortality.

Objectives: To identify the JA patients with a higher probability of requiring treatment with bDMARDs and to investigate the predictive factors.

Methods: A retrospective single-center study of patients with JIA followed in a tertiary Hospital was conducted. Sociodemographic, clinical, laboratory and treatment characteristics were collected from Portuguese Rheumatic Diseases Register and medical records. Statistic was performed with independent samples t-test, Mann-Whitney U test, chi-square test and Fisher’s exact test. Statistical significance was set up at a p-value <0.05. A multivariate logistic regression analysis was performed to identify possible predictive factors for bDMARD use. Odds ratios (ORs) and 95% confidence intervals (Cis) were calculated.

Results: A total of 165 patients with JIA (107 females, 64.8%) were included. Seventy-five patients had oligoarthritis (45.6%), 62 had persistent oligoarthritis and 13 had extended oligoarthritis, 17 psoriatic arthritis (10.3%), 30 rheumatoid arthritis (13.9%). Fourty-five patients were treated with bDMARD (27.3%). Males were treated more frequently with bDMARDs than females (p=0.058). Regarding JIA subtype, more RF-positive patients received bDMARDs than patients who were not treated for extraarticular damage (p=0.02), but not for uveitis (p=0.9). Presence of uveitis was significantly more frequent in the bDMARD group (p=0.006). Moreover, more patients with bilateral involvement were treated with bDMARDs, compared with patients with unilateral uveitis (p=0.032). Nevertheless, no differences were found concerning age and number of joints involved at onset, disease duration and ANA positivity. In a multivariate regression model adjusted for gender, the presence of uveitis (OR 4.42, 95% CI 1.43 to 13.60, p=0.010) and polycartilage involvement (OR 6.62, 95% CI 2.05-21.43, p=0.002) remained statistically significant predictive factors for bDMARD use in patients with JIA.
Conclusion: Male patients, polyarticular involvement (with negative or positive RF) and bilateral uveitis were more frequently treated with bDMARDs. In addition, CRP values at onset of JIA were higher in the bDMARD group. Thereby, the presence of RF, and polyarticular involvement seem to predict the need of bDMARD treatment in JIA patients. Prompt treatment with these agents, early in the disease course, especially in JIA patients with more articular involvement and extraarticular manifestations like uveitis, refractory to conventional DMARDs, should be strongly recommended, in order to avoid irreversible damage and to achieve complete and long-term remission.

INTERFERON SIGNALIZATION IN CHILDREN WITH JUVENILE SCLERODERMA

Keywords: Skin, Vasculitis, Myositis

S. S. Kılıç¹, H. Kose², A. Simsek³, M. A. Kızmaº, T. Bozkurt⁴, F. Ozturk⁴, H. Sancao⁄u⁵, F. Budak⁶, ¹Uludag University Medical Faculty, Pediatric Immunology and Rheumatology, Bursa, Turkey; ²Uludag University Medical Faculty, Pediatric Immunology and Rheumatology, 16, Bursa, Turkey; ³Uludag University Medical Faculty, Immunology, 16, Bursa, Turkey; ⁴Uludag University Medical Faculty, Dermatology, 16, Bursa, Turkey

Background: Interferon signalization in children with juvenile scleroderma: Hulya Kose¹, Abdurrahman Simsek², Muhammed Ali Kızma³, Tugçe Bozkurt⁴, Ferdi Ozturk⁵, Ferah Budak⁶, Hayrle Sancao⁄u⁵ Sara Sebnem Kılıç¹.

3.Uludag University Faculty of Medicine, Department of Dermatology

Juvenile dermatomyositis (JDM) is an inflammatory disease of the muscle, which is characterized by skin involvement, vasculitis, and progressive muscle weakness. Increased interferon signaling is thought to play a role in the pathogenesis of JDM and is associated with disease severity and activation. As the development of calcinosis. Juvenile scleroderma (JSc) is a heterogeneous group of diseases associated with sclerotic skin lesions, grouped together as systemic sclerosis and localized scleroderma (morphea). Although JSc has a different types of skin involvement than JDM, some similarities in their pathogenesis can be identified.

Objectives: The aim of this study is to measure the levels of cytokines and chemokines involved in interferon signalization in patients with JDM and JSc and to determine their correlation with disease severity.

Methods: Thirty-one JSc, 5 JDM, and 13 healthy controls were included in the study. Patients with morphea were scored according to the LoSCAT (activity index) and LoSDI (damage index) indices. Cytokines and chemokines involved in interferon gene signaling (IL-8, IL-1, IP-10, MCP-1, TNF-α, IFN-γ, IFN-β, IFN-γ) and interferon signalizing genes including IFI27, IFI44, ISIG15, IFIT1, OAS1, RSAD2 were measured by ELISA and RT_PCR method respectively.

Results: The ratio of female to male patients was 24/12, the median age was 14 years (min 4, max 18), and the median follow-up time was 36 months (min 12, max 108). According to LoSCAT assessment of patients with JSc, the scores were mild 36% (n=13), moderate 25% (n=9), and severe 11% (n=4). Similarly, LoSDI assessment revealed mild 38% (n=14), moderate 22% (n=8), and severe 11% (n=4). It was found that IL-8, IFN-γ, IL-10, and MCP-1 were significantly decreased in patients with JSc compared with the healthy control group. TNF-α and IFN-γ were found to tend to decrease in patients with JSc, whereas IFN-γ tended to increase in patients with JDM. The correlation of LoSCAT and LoSDI indices with cytokine and chemokine levels in patients with JSc is summarized in Figure 1.

Conclusion: In RT_PCR analysis of the interferon signaling genes, including IFI27, IFI44, ISIG15, IFIT1, OAS1, RSAD2, we found no statistically meaningful expressions of the genes compared with the healthy group. However, we identified the fold changes in RSAD2, IFI27, and IFIT1 in JDM and JSc patients compared with the healthy controls in the related genes. The fold changes of the interferon signaling genes are depicted in Figure 2.

Figure 1. Correlation of LoSCAT/LoSDI Scores with cytokines and chemokines in patients with Localized Sclerodermas. LoSCAT/LoSDI assessment. b. Cytokine and chemokine correlation map. c. Statistically significant correlations.
Conclusion: The results suggest that interferon signaling may be impaired in patients with JDM and JSc, and that cytokines and genes whose significant changes were observed in this study may play a key role in monitoring disease activity. Repeating these studies with larger numbers of patients may shed light on the clinical pathogenesis.

Background: Juvenile psoriatic arthritis (JPSA), a subtype of juvenile idiopathic arthritis (JIA), constitutes 5% of JIA. The literature is inconsistent regarding features of JPSA, and physicians debate whether it is a distinct entity within JIA. Moreover, the criteria diagnosis for JPSA is currently in debate. There are two pediatric diagnostic classifications based on clinical criteria: ILAR classification criteria and Vancouver classification criteria. Classification of JIA has been a great debate since this entity disappeared. [1] The CASPAR criteria are standard in adults. These criteria have a specificity of 91.4% and a sensitivity of 98.7%, making diagnostic classification easier. However, the peculiarities of childhood cause some differences to consider.

Objectives: To compare 3 diagnostic criteria for JPSA ILAR, Vancouver and CASPAR.

Methods: Multicenter, cross-sectional study of data from children with JPsA (diagnosis by prescriptor physician) who consecutively attended in ped-rheumatology outpatient clinic and enrolled from 9 centers within the last 1.5 years. Sociodemographic, clinical characteristics and family history of Psoriasis were collected to assess compliance with diagnostic classification criteria using the Cohen’s Kappa statistic index.

Results: Forty eight children were included with the following sociodemographic characteristics; (table1) Thirty eight children who met the VANCOUVER criteria (80.9%) while thirty two children met the ILAR criteria (68.1%). As for the CASPAR criteria, thirty eight children were diagnosed (80.9%). The diagnostic agreement between the ILAR and CASPAR criteria and ILAR and Vancouver criteria (diagnosed defined) was weak (K=0.67 and K=0.67). In contrast, the agreement was total (K=1) between the CASPAR and Vancouver criteria.

Conclusion: Despite minimal changes between the Vancouver and ILAR criteria, the ILAR exclusion criteria limit the diagnosis of PsA in childhood. Given that the CASPAR and Vancouver were able to detect a significant number of patients with PsA in our series (predominantly adolescents), the application of the CASPAR criteria in the subgroup of children with late onset could be considered.

SYSTEMIC JUVENILE ARTHRITIS: EPIDEMIOLOGY AND LONG-TERM OUTCOME IN WESTERN AUSTRALIA.

Keywords: Epidemiology, Registries

J. Nossent1, E. Kelt2, H. Keen3, D. Preen4, C. Inderjeeth1, 1The University of Western Australia, Rheumatology section, Medical School, Crawley, Australia; 2The University of Western Australia, School of Population and Global Health, Crawley, Australia

Background: Systemic juvenile arthritis (S-JIA) is a rare but serious multorgan autoinflammatory condition of childhood with an unpredictable disease course [1]. There is no data on disease frequency and outcome of S-JIA from the Pacific region. This population-level observational study includes children under the age of 16 with a recorded diagnosis of S-JIA (ICD-10-AM M08.20-M08.29) residing in WA between January 1999 and December 2014. Individual longitudinal health data regarding hospital admissions, ED visits, cancer and death were derived from the WA Rheumatic Disease Epidemiological Registry (WARDER) that contains routinely collected health data from public and private health care organisations for the entire state of WA.

Methods: This population-level observational study includes children under the age of 16 with a recorded diagnosis of S-JIA (ICD-10-AM M08.20-M08.29) residing in WA between January 1999 and December 2014. Individual longitudinal health data regarding hospital admissions, ED visits, cancer and death were derived from the WA Rheumatic Disease Epidemiological Registry (WARDER) that contains routinely collected health data from public and private health care organisations for the entire state of WA.

Results: Based on 46 incident cases (71.7 % girls, median age 6.5 years) the average annual S-JIA incidence rate was 0.61/100,000 (CI 0.28-1.25), which did
Methods: We reviewed the clinical characteristics of patients who were recruited to the juvenile SScC till 31st December 2022. We compared patients with BMI ≤ 2 z score with patients (lwgroup) with higher BMI (nlwgroup). jSScC is a pro-
inflammatory marker or organ involvement pattern, except higher number of patients with Gottron papules (41% lwgroup vs 25% nlwgroup; p=0.01) and puffy fingers (13% (3/32) vs 38% (13/32); p=0.001).

Results: At the time of the evaluation, we had 232 patients in the cohort and 217 of them had BMI data to include in the evaluation. Thirty-two patients were in the lwgroup before the age of 16 years and are under the age of 18 years at the time of inclusion in the cohort was 10.6 years and the median age at the first non-Ray-
naud symptom in the whole group was 11.0 years. Median disease duration in the whole group was 2.4 years at the time of inclusion. Approximately 95% of the patients were treated with a DMARD. There were no statistically significant differences between the lwgroup compared to nlwgroup regarding antibody pattern, inflammatory marker or organ involvement pattern, except higher number of patients with Gottron papules (41% lwgroup vs 25% nlwgroup; p=0.01) and sclerodactyly (84% lwgroup vs 73% nlwgroup; p=0.049). Regarding the patient related outcomes at inclusion in the cohort, the global disease activity by VAS 0-100 was 40 in both groups (p=0.032), but the patient global disease damage by VAS 0-100 was 50 in the lwgroup which was significantly higher compared to 30 nlwgroup (p=0.014).

Conclusion: In our jSScC cohort, currently the largest of the world, we could not find any differences regarding major internal organ involvement in patients with lower BMI at time of inclusion in the cohort. Nevertheless, there is a significant difference in patient related outcomes regarding global organ damage between the two groups. The long-term prognosis of these patients should be addressed in future studies.

Methods: We performed a detailed literature search to identify articles describing clinical and laboratory characteristics of paediatric APS patients. In concomiance, we conducted a registry-study collecting data from the Piedmont and Aosta Valley Rare Disease Registry including paediatric patients diagnosed with APS in the last ten years.

Results: The systematic review included nine articles with a total of 386 paediatric patients (65% females, 50% with Systemic Lupus Erythematosus (SLE) as concomitant diagnosis). Rate of venous and arterial thrombosis were 57% and 35% respectively. "Extra-criteria manifestations" of APS included mostly hematological and neurological involvement (91 thrombocytopenia, 32 haemolytic anae-
mia, 19 chorea, 8 multiple sclerosis-like lesions, 9 migraines and one transverse myelitis). Almost one quarter of patients (19%) reported recurrent events and 28% were treated as CAPS. Further details of the included studies are detailed in Table 1. A total of 17 paediatric patients (mean age 15.1 ± 2.8, 76% female) developed APS in the Northwest of Italy. In 29% of cases SLE was a concomitant diagnosis. Deep vein thrombosis was the most frequent manifestation (28%) followed by Catastrophic APS (CAPS) (6%). Taking into account that the paediatric population of the Piedmont and Aosta Valley Region is around 680,000 persons, the calculated estimated prevalence of paediatric APS in Piedmont and Aosta Valley Region is 2.5 cases per 100,000 people. When analyzing the data of the register in an eleven year period (from January 2011 to December 2021), the estimated mean annual incidence was 0.2 cases per 100,000 inhabitants.

Conclusion: Clinical manifestations of paediatric APS seem to be more severe and with a higher prevalence of non-criteria manifestations. International efforts are needed to better characterize this condition and to develop new specific diagnostic criteria to avoid missed/delayed diagnosis in children with APS.

DOES THE SACROILIAC JOINT MAGNETIC RESONANCE IMAGING ENHANCE THE ENTHESITIS-RELATED ARTHRITIS DIAGNOSIS?

Keywords: Imaging

H. Ferjani1, L. Kharat1, D. Ben Nessib1, K. Maatallah1, D. Kaffel1, W. Hamdi1, 1Kassab Orthopedics Institute, Ksar Said, Rheumatology, Tunisia, Tunisia

Background: Magnetic Resonance Imaging (MRI) is the gold standard in the diagnosis of adult spondyloarthritides. MRI sensitivity and specificity seem to be less studied in juvenile spondyloarthritides, especially in Enthesitis-related Arthritis (ERA).

Objectives: We aimed to determine the sensitivity and specificity of MRI in the diagnosis of ERA.

Methods: We conducted a retrospective study including 44 patients with Juvenile Idiopathic Arthritis (JIA) meeting the International League of Associations for Rheumatology (ILAR) 2001 criteria. For each patient, we collected the following data: age, age at the onset of JIA, JIA subtype, disease duration, C-reactive protein (CRP), HLA-B27 typing, and Erythrocyte sedimentation rate (ERS) levels.

Results: There was enthesitis-related arthritis in 61% of the cases (n=27), oligoarticular JIA in 14% of the cases (n=6), polyarticular JIA in 11% of the cases (n=5), and psoriatic arthritis in 7% of the cases (n=3). JIA was undifferentiated in 9% of the cases (n=4). We found that MRI abnormalities were not sensitive but had a good specificity in the diagnosis of ERA. Thus, MRI could guide the diagnosis of ERA but could not be the gold standard in this disease.

CLINICAL MANIFESTATIONS AT THE ONSET OF PEDIATRIC MIXED CONNECTIVE TISSUE DISEASE (PMCTD): A SYSTEMATIC REVIEW.

Keywords: Systematic review, Mixed connective tissue disease, Rare/orphan diseases

A. Terminelli1, E. Mennargüé2, L. Pagnini2, I. Maccora2, M. V. Mastrolia2, A. Alletto2, G. Simonini2, 1Meyer Children’s Hospital IRCCS, ERN-ReCONNET full member, Pediatric Unit, Florence, Italy; 2Meyer Children’s Hospital IRCCS, ERN-ReCONNET full member, Rheumatology Unit, Florence, Italy

Background: pMCTD is a rare disorder that includes features of systemic lupus erythematosus, polymyositis/dermatomyositis, juvenile idiopathic arthritis, and systemic sclerosis. Fifty years have passed since Sharp identified MCTD in 1972, and diagnosis of this disorder remains challenging.

Objectives: The aim of this review is to identify any clinical features at the diagnosis of pMCTD and manifestations that are not currently part of the available diagnostic criteria.

Methods: A systematic literature review was performed in accordance with PRISMA guidelines using electronic bibliographic databases: MEDLINE via PubMed and EMBASE. Data obtained were extracted using a dedicated database containing clinical data that best categorize patient characteristics. Criteria for inclusion: studies including patients with a pMCTD diagnosis with onset before 18 years of age and reporting a description of initial clinical features.

Results: The search returned a total of 1372 results: 409 articles were excluded as duplicates and 790 based on title/abstract, 133 because of publication type (n = 4) or because the full text was not available (n = 65) or not in English (n = 64). One (n=1) eligible article resulted from manual screening of references cited in the selected publications and in the reviews. Finally, 41 articles were included: 23 case reports, 9 case series, 5 prospective, and 4 retrospective studies from 1973 to 2019, with a total number of 218 patients. They were predominantly female (81.56%, n=167), and the mean age at onset was 147 months (median 126 months, 10.5 years). When indicated, the most commonly used criteria for diagnosis were Kasukawa criteria (50%, 11 studies), then Alarcon-Segovia criteria (31%, 7 studies), then Sharp criteria (23%, 5 studies); no Khan criteria were used. Clinical features are listed in Figure 1.

Figure 1. Number of patients for clinical feature at onset.

Joint involvement, Raynaud’s phenomenon, myositis, and swollen fingers/hands are the most common clinical features at diagnosis according to the data reported in the literature, although with slightly lower percentages than in other reviews. Dermatologic signs are very heterogeneous, but were found to be a very present feature at disease onset, affecting 1/3 of patients. Fever, not covered by any of the diagnostic criteria, was noted in 1/4 of cases. Pulmonary and esophagial involvement are reported in a lower percentage at the onset of the disease, indicating a more developmental nature of these conditions.
Conclusion: The data from this systematic review suggest greater clinical heterogeneity of the disease in the pediatric population, for which there are no validated diagnostic criteria. Typical features appear to be less common when case reports are included, suggesting a less characteristic initial presentation than an advanced stage; therefore, the absence of typical features at baseline should not preclude a diagnosis of PMCTD. Fever often occurs early in the disease and is not included in the diagnostic criteria. This systematic review may provide useful insights for future research to better assess the clinical features of PMCTD and the potential development of scores/algorithms for diagnosis in the pediatric population.

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. The emergence of new biological drugs has changed the prognosis and therapeutic approach to these patients, and costs are reduced with the use of biosimilar disease modifying antirheumatic drugs (bsDMARD).

Objectives: Our aim was to describe the use of bsDMARD therapies in JIA.

Methods: Data was obtained from the nationwide prospective registry BIOBADASER. All patients diagnosed before age 16 in our database between 2000 and 2022 were included in the analysis. JIA is classified into 7 subgroups: systemic, persistent or extended oligoarthritis, RF positive polyarthritis, RF negative polyarthritis, enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis. Due to the registry design, it was not possible to identify each of the JIA subgroups; thus, we classified them into oligo/polyarthritis JIA, JIA related to enthesitis, and psoriatic JIA. Proportions, means and standard deviations (SD) were used to describe our population and the utilization of treatments. Drug persistence was calculated using Kaplan-Meier survival curves until termination of treatment due to any reason.

Results: From a total of 313 patients, 130 patients (41.5%) received 151 treatments with bsDMARD, 60.8% of which were women (n=79). Mean age at diagnosis was 11.2 years (SD=6.1) and mean age at the beginning of treatment was 25.1 (SD=13.4). Patients were classified as oligo/polyarthritis JIA (72.2%), related to enthesitis (16.2%) and psoriatic JIA (4.6%). Methotrexate was used in combination in 39.1% of the biosimilar treatments. The most commonly used drug was Adalimumab (56.8%), followed by Etanercept (28.7%). Table 1 shows the biologic therapies used in our sample and the reasons for discontinuation. The median survival rate with the biosimilar drug and original was similar.

Conclusion: Adalimumab were the most commonly used biosimilar therapy in JIA. Ineffectiveness was the main reason for discontinuation. There were no differences on 5 years survival rates, which is a crucial endpoint in JIA.

CLINICAL VARIABILITY IN PATIENTS DIAGNOSED OF JUVENILE IDIOPATHIC ARTHRITIS WITH POSITIVE AND NEGATIVE ANTINUCLEAR ANTIBODIES (ANA)

Keywords: Autoantibodies

Background: Juvenile Idiopathic Arthritis (JIA) involves a set of chronic arthritis of onset in childhood. JIA can be split into 7 categories based on the classification of the International League of Associations for Rheumatology (ILAR):
systemic arthritis, oligoarthritis, rheumatoid factor (RF) negative polyarthritis, RF positive polyarthritis, enthesis related arthritis, psoriatic arthritis, undifferentiated arthritis. In addition to this classification, some authors propose differentiating between patients who have positive (+) and negative (-) ANA in serum because there could be differences between these two subgroups, raising the possibility of homogenizing subtypes based on this.

**Objectives:** To describe the variability of extra-articular manifestations, treatment and prevalence of the different JIA subtypes between patients who have positive and negative ANA in serum.

**Methods:** Cross-sectional descriptive study in 68 patients with JIA according to ILAR criteria visited in the transitional consultation of a Spanish tertiary-level hospital. Clinical features, analytical and treatment data were collected, and patients were divided according to ANA+ or ANA- in serum. A >1/80 title of ANA determined by IIF at an least 2 occasions was considered positive. Subsequently, the qualitative data was analyzed using Chi-Square test, and the means were compared using ANCOVA analysis.

**Results:** 68 patients were included in the study, 33 were grouped in ANA- and 35 in ANA+. The ANA+ group was composed with 28 women (80%) and the ANA- group was made up with 18 women (54.4%) (p= n.s.). The mean age of diagnosis was 11 years old in the ANA- group and 9 years old in the ANA+ group.

</tbody>
</table>

Oligoarticular JIA was more frequent in the ANA+ group (48.57%) than in the ANA- group (33.33%), being this difference statistically significant. Enthesitis related arthritis was more frequent in the ANA- group (33.33%) than in the ANA+ group (8.57%), as it was systemic arthritis (18.18% in ANA- and 0% in ANA+), both differences being statistically significant. Uveitis, psoriasis and the use of sDMARD were more frequent in the ANA- group, while enthesis and corticosteroid use was more frequent in ANA+ patients, but without reaching statistical significance.

**Conclusion:** In our study, as in the literature, the oligoarticular JIA type occurred more frequently in the ANA+ group, while enthesis related arthritis and systemic arthritis were more frequent in the ANA- group. Although the treatment patterns and the prevalence of psoriasis and uveitis appear to differ between the two groups we did not find statistically significant difference. There is a lack of small number of patients included, and therefore it might be possible that the confidence interval could be corrected if the sample was expanded.

**Background:** Systemic autoinflammatory diseases (SAIDs) are rare inherited disorders characterized by periodic or chronic multisystemic inflammation. The diagnosis is based on typical phenotypes and often supported by genetic testing. However, a distinct diagnosis cannot be met in half of these patients, being classified as undefined SAIDs (uSAIDs) [1].

**Objectives:** To analyse the clinical and genetic characteristics of a Portuguese cohort of uSAID.

**Methods:** Patients followed up in 2 SAIDs clinics with recurrent or persistent episodes of systemic inflammation associated with serum acute phase reactants elevation who do not meet the PRINTO diagnosis criteria for any well-defined SAIDs [2] were classified as having uSAID. Patients who do not have any pathogenic gene mutation or have 1 variant of uncertain significance of a gene related to a well-known autosomal dominant SAID were included, as well as patients with pending genetic analysis. Categorical variables are described as frequencies and percentages and continuous variables as median (IQR1, IQR3).

**Results:** This study included 24 patients, of which 12 (50.0%) were female and 12 (50.0%) were male. The median age at disease onset was 2.4 (IQR: 1.4, 8.2) years old, the median age at diagnosis was 6.5 (IQR: 2.4, 9.9) years old and the median time of disease duration was 6.8 (IQR: 9, 12.4) years. The majority of the patients (n=14, 58.3%) had episodes of recurrent systemic inflammation lasting 2 to 5 days. Two patients exhibited persistent inflammation. Regarding patients with recurrent inflammation, 10 (41.7%) had more than 12 episodes per year, 7 (29.2%) had 2 to 6 episodes per year and 4 (16.6%) had 7 to 12 episodes per year. The remaining patient had an episode every 2 years. In 13 (54.2%) the intercritical interval was regular, with a median of 21 days. Besides fever, the most commonly reported clinical manifestations were mucocutaneous lesions (n=24) including mouth ulcers (n=11), abdominal pain (n=12), lymphadenopathy (n=10) and arthralgia (n=10). C-reactive protein was elevated in all patients during attacks, erythrocyte rate sedimentation in 20 (83.3%) and amyloid A protein in 10 (41.7%). C-reactive protein was elevated in all patients during attacks. Infliximab, in association with azathioprine, resulted in disease remission in 8 patients. Two patients were treated with canakinumab achieving complete remission. Infliximab, in association with azathioprine, resulted in disease remission in the only patient in which this therapy was used. None of the 3 patients submitted to tonsillectomy achieved remission.

**Conclusion:** Similar to other uSAIDs' cohorts, mucocutaneous manifestations, abdominal pain and arthralgia were frequently reported. A third exhibited acute phase reactants elevation in the intercritical phase. Most of our patients had a favourable response to colchicine and IL-1 inhibitors. It is worth noting the high frequency of mouth ulcers, lymphadenopathy and pharyngitis and the high response rate to oral steroids and colchicine. These features resemble PFFAPA syndrome, highlighting the challenges in the differential diagnosis of both conditions.

**CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS AND BOWEL INFLAMMATION: A MONOCENTRIC COHORT**

**Keywords:** Rare/orphan diseases, Gastrointestinal tract, Remission

S. Costi1, S. Germinario2,3, M. R. Pellico2,3, A. Amati2,3, M. Gattinara1, C. Chighizola1,2, A. Marino1, R. Caporali1,3, 1ASTSS G. Pini-CTO, Unit of Pediatric Rheumatology of Gaetano Pini Hospital were retrospectively reviewed.

**Background:** Chronic recurrent multifocal osteomyelitis (CRMO) is a rare autoinflammatory disease of bone primarily affecting children and adolescents. Although CRMO can be associated with inflammatory bowel disease (IBD)[1], the prevalence of subclinical bowel inflammation and its relationship with other autoimmune bone disorders remains uncertain.

**Objectives:** This study aims to evaluate the prevalence of subclinical bowel inflammation in CRMO patients and the potential association with celiac disease.

**Methods:** Clinical records of patients diagnosed with CRMO attending the Unit of Pediatric Rheumatology of Gaetano Pini Hospital were retrospectively reviewed. Fecal calprotectin and screening for celiac disease were performed in all patients within 2 years after diagnosis.

**Results:** Complete data from 24 patients were collected (83% female). The mean age at diagnosis was 10.1 (DS ± 2.7) and the median follow-up time was 68.5 months (IQR 97.5). The first symptom at onset was bone pain (100%), while only 4 patients (17%) complained of gastrointestinal symptoms (abdominal pain, weight loss, diarrhea). The patients in our cohort had no specific comorbidity, except for two patients suffering from hemophilia and pyoderma gangrenosum, respectively. 96% (23/24) of patients had polyostotic disease. During the follow-up period, 9 patients (38%) received only non-steroidal anti-inflammatory drugs therapy, 10 patients (42%) received conventional disease-modifying antirheumatic drugs (methotrexate), 4 (17%) received anti-tumor necrosis factor (TNF) agents and 12 (50%) received intravenous bisphosphonates. Cumulative treatments are summarized in Figure 1. Two patients, both in clinical remission off medication, were lost to follow-up. Calprotectin levels were normal in 100% of patients, while 3 patients (13%) presented compressed screening test for celiac disease with a positive test for IgA anti-tissue transglutaminase antibodies (Table 1).

**Conclusion:** The link between autoinflammatory bone disease and intestinal inflammation should be further investigated since it might open insight into bone inflammation and new therapeutic options. In our experience, controlling bowel disease may promote a better response to CRMO treatments. On the other hand, the percentage of unexplained bone pain in celiac disease is high, and, in this scenario, a possible inflammatory bone disorder should be ruled out.

**HIP DAMAGE ASSESSED BY CARSH SCORE WAS MORE SEVERE IN ENTHESIS-RELATED ARTHRITIS SUBTYPES**

**Keywords:** Imaging, Validation

A. Ophalies1, H. Ferjani1, D. Ben Nessib2, D. Kaffel1, K. Maattallah1, W. Hamdi1, 1Mohamed Kassab Institute of Orthopedics, Rheumatology, Manouba, Tunisia

**Background:** Juvenile idiopathic arthritis is a heterogeneous group of diseases characterized by unknown origin under 16 years. Compared to other juvenile idiopathic arthritis subtypes, enthesitis-related arthritis has a poor prognosis with a higher disability. Moreover, the frequency of hip involvement contributes to poorer outcomes and higher disease activity in this form. The Childhood Arthritis Radiographic Score of the Hip (CARSH), a valid score of hip damage, is used to quantify and monitor hip osteochondritis changes such as space narrowing, erosions, malalignment, sclerosis, flattening of the femoral head, and growth abnormalities [1].

**Objectives:** This study aimed to assess hip damage using the CARSH in children suffering from different subtypes of JIA.

**Methods:** We conducted a cross-sectional study including patients with JIA according to the ILAR criteria with hip involvement in the rheumatology department at Kassab Institute of orthopedics. The hip involvement was defined as the presence of hip pain and/or limping and range motion limitation, and/or abnormal hip findings in pelvic radiography, ultrasound, or MRI. We collected demographic data, juvenile arthritis subtypes, hip pain and limitation, presence of antigen HLA, and extra-articular manifestations. Experimented and blinded pediatric rheumatologists read the pelvic radiograph using the Childhood Arthritis Radiographic Score of the Hip (CARSH).

**Results:** Twenty-two children with a median age of 13 years [5-22] were included.

**Conclusion:** This study showed that the radiographic score CARSH was higher in enthesitis-related arthritis patients. This finding prompts the escalating of the treatment approach in this JIA subtype to prevent damage and joint replacement surgery.

EMAPALUMAB TREATMENT FOLLOWED BY HEMATOPOIETIC STEM CELL TRANSPLANTATION IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS COMPLICATED BY RECURRENT MACROPHAGE ACTIVATION SYNDROME

Keywords: Cytokines and chemokines, Inflammatory cytokines

C. Bracaglia1, M. Pardeo1, G. Marucci1, S. Riccio1, F. Quagliarella1, I. Caiello1, G. Pencipe1, P. Merli1, F. Locatelli2, F. De Benedetti1
1IRCCS Bambino Gesù Children’s Hospital, Division of Rheumatology, Rome, Italy; 2IRCCS Bambino Gesù Children’s Hospital, Department of Hematology/Oncology, Cell and Gene Therapy, Rome, Italy

Background: Macrophage activation syndrome (MAS) is a life-threatening complication of different rheumatic diseases, particularly of systemic juvenile idiopathic arthritis (sJIA).

Objectives: We report the case of a 17-year-old girl with sJIA complicated by recurrent severe MAS episodes.

Methods: Patient received emapalumab (anti-IFNg antibody) in two subsequent MAS episodes, then underwent an uncomplicated hematopoietic stem cell transplantation (HSCT) from a haploidentical donor, while receiving emapalumab and anakinra granting complete control of inflammatory activity of the underlying disease. One year after transplant she is in complete disease remission.

Results: A 13-year-old Caucasian girl presented with fever, rash and hepato-splenomegaly. Laboratory parameters were consistent with full-blown MAS (tab 1). In the absence of clear evidence of an underlying condition, a diagnosis of secondary HLH was made. Treatment with high dose of intravenous (IV) methylprednisolon (mPDN) and oral cyclosporine (CYC) was started with progressive improvement. After one year, still on CYC, she presented with fever, rash and arthritis with laboratory parameters consistent with MAS (tab 1), diagnosis of sJIA complicated by MAS was made. In 24 hours, her general condition rapidly worsened and she was admitted to the ICU. High dose of IV mPDN (7 pulses of 30 mg/kg/day) as well as IV CYC (5 mg/kg/day) did not yield a response. Emapalumab was started, in the NI-0501-06 trial, (6 mg/kg initial dose followed by 3 mg/kg every 3 days) for 11 infusions. Conditions progressively improved. In order to prevent flares of the underlying sJIA, anakinra (2 mg/kg/day) was started. After 2 years in clinical remission, while she receiving anakinra every other day, she presented with fever, vomiting and diarrhea. Anakinra was immediately increased to daily dosing. Stool analysis showed Salmonella infection and antibiotic therapy was started. Her condition rapidly worsened, laboratory parameters were again consistent with full-blown MAS (tab 1). She required ICU admission for multorgan failure. Anakinra was administered IV and the dose increased up to 12 mg/kg/day. IV MPDs (8 pulses of 30 mg/kg/day) as well as IV CYC (5 mg/kg/day) were started with partial response. Based on her previous response, emapalumab was started again (compassionate use) with marked and rapid improvement. Because of recurrent MAS episodes, particularly for their rapidly progressive evolution, the patient underwent an ex-vivo T cell-depleted haploidentical HSCT from her mother. The conditioning regimen was based on a Thiopepa-Treosulfan-Fludarabine scheme. Emapalumab was continued 1 month after HSCT together with anakinra. The patient developed mild complication, achieved full donor engraftment with complete donor-derived immune reconstitution after 3 months. One year after HSCT, the patient is in excellent clinical condition on anakinra every other day, with complete remission of sJIA/MAS, also confirmed by persistently normal levels of IL-18 and CXCL9 (tab 1).

</table>

Conclusion: This case provides further evidence of the efficacy of emapalumab in MAS [1], of the potential benefit of HSCT in difficult sJIA patients [2]. Notably, full control of inflammatory activity with emapalumab and anakinra may help to obtain a successful HSCT and reduce the risk of rejection.

THE EXPERIENCE OF YOUNG PEOPLE WITH RHEUMATIC DISEASES TRANSFERRING THEIR CARE FROM PEDIATRIC TO ADULT SERVICES AND THEIR SUGGESTED AREAS FOR IMPROVEMENT

Keywords: Health Services Research, Real-world evidence, Patient information and education

L. Williamson1,2,3,4, A. Bouraoui2,3, E. Williams2, S. Meyer2, S. Movromatissi1,3, M. J. Leandro1,2,4, C. Curtin2,3,4, D. Sen2,3, C. Fisher2,3,4, Great Ormond Street Hospital for Children, Paediatric Rheumatology, London, United Kingdom; 2University College Hospital, Adolescent Rheumatology, London, United Kingdom; 3Centre for Adolescent Rheumatology, Adolescent Rheumatology, London, United Kingdom; 4Arthritis Australia, Arthritis Australia, Glebe, Australia; 5University College London, Department of Rheumatology, London, United Kingdom

Background: Transition of care from paediatric to adult services is a critical time period for patients with rheumatic diseases. A seamless transition process can aid young people in their development to adulthood, whilst also allowing them to gain independence in managing their rheumatic condition. Young people and their caregivers often express concerns to their paediatric rheumatology teams about the transition to adult services.

Objectives: This study seeks to explore the experience of transition from the perspective of young people with rheumatic diseases, and their suggestions for areas to address in improving the transition process. The second aim of the study is to find out whether young people want to fill out information about themselves in order to help adult rheumatology staff to get to know them better, and if so, what information they felt was important to know.

Methods: Anonymous survey questionnaires were given to young people with rheumatic diseases, via a scannable QR code, to be filled in prior to their rheumatology outpatient visit. All patients surveyed had transferred their care from paediatric to adult services. Further responses were sought by sending the survey questionnaire to young people with rheumatic diseases who had consented to be on a patient and public involvement and engagement (PPIE) mailing list. Survey data were analysed in Microsoft Excel.

Results: Average age of respondents: 18 (median), range 16-26. The majority of respondents were female (76%). 52% of patients had juvenile idiopathic arthritis (JIA), 12% had juvenile dermatomyositis, 12% had juvenile systemic lupus erythematosus, and 17% did not disclose their young age or their specific disease. Those who were satisfied with the transition process (satisfaction score rated 8 out of 10 (mean)) were concerned with patient centered factors. Young people perceived the following aspects of transition to have been done well: “Communication about the change”, having a “named transition coordinator”, having a “personal tour of [the adult hospital]”, and having a “smooth process”. Aspects of the transition process that young people suggested could be improved included: “more transparent and understandable medical talk”; “more follow-up [appointments]”; “knowing how to contact [a] named transition coordinator”, feeling as though the healthcare professional was “talking to my mum rather than me”; and “the general feeling of... care not being as personal”. Overall, 60% of young people stated that they would be willing to fill out an electronic form prior to their appointment at the adult rheumatology service to give information that would allow staff at the adult hospital to get to know them better. When stratified by age, only 50% of 16-18-year-olds would be willing to fill out a form, whereas 80% of 19-26-year-olds would. The most commonly suggested pieces of information were: hobbies, sports, favourite school subject, goals, and career aspirations.

Conclusion: Most young people were satisfied with the transition process and had helpful suggestions about how this might be improved in the future.

Majority of young people were willing to fill in a form to provide information about themselves in order to help adult rheumatology staff to get to know them better, especially those who were aged 19-26 years. At a critical time in young people’s development, enabling them to provide information about themselves that they feel is important, may help to improve their perception of the transition process and reduce the anxiety about transferring care to adult services.

**BODY MASS INDEX AND INFLAMMATORY LESIONS IN MAGNETIC RESONANCE IMAGING IN JUVENILE IDIOPATHIC ARTHRITIS: IS THERE A LINK?**

**Keywords:** Imaging

L. Kharrat1, H. Ferjani1, D. Ben Nessib1, K. Maatallah1, D. Kaffel1, W. Hamdi1.

1Kassab Orthopedics Institute, Ksar Said, Rheumatology, Tunis, Tunisia

**Background:** Obesity is usually associated with low-grade inflammation in the general population. However, several studies have noted that high body mass index (BMI) in rheumatoid arthritis patients was associated with less structural damage in X-rays and in Magnetic Resonance Imaging (MRI) [1,2]. The impact of BMI on inflammatory MRI lesions in Juvenile Idiopathic Arthritis (JIA) is less studied.

**Objectives:** We aimed to determine the link between BMI and inflammatory MRI lesions of sacroiliac joints in JIA.

**Methods:** We conducted a retrospective study including 44 patients followed for JIA meeting the International League of Associations for Rheumatology (ILAR) 2001 criteria. For each patient we collected the following data: age, age at the onset of JIA, JIA subtype, disease duration, BMI, C-reactive protein (CRP) and Erythrocyte sedimentation rate (ESR) levels, and MRI data. Disease activity was assessed using the JADAS score. Statistical analysis was performed using SPSS software.

**Results:** We included 28 boys and 16 girls. The mean age was 13.65 ± 4.62 years. The mean age at the onset of the disease 9.57 ± 3.97 years. The mean body mass index was 18.7 ± 4.9 kg/m². There was enthesitis-related arthritis in 61% of the cases (n=27), oligoarticular JIA in 14% of the cases (n=6), polyarticular JIA in 11% of the cases (n=5), and psoriatic arthritis in 7% of the cases (n=3). JIA was undifferentiated in 7% of the cases (n=3). However, this diagnosis delay was not associated with low back pain, enthesitis, or sacroiliac joint pain.

**Conclusion:** Our results are consistent with Kurt et al. study [1]. Older age, the occurrence of extra-articular manifestations, and low ESR level could lead to diagnosis improvement.

**CLINICAL PROFILE OF JUVENILE IDIOPATHIC ARTHRITIS: ABOUT 55 CASES**

**Keywords:** Inflammatory arthritides, Descriptive Studies

M. Ardhau1, D. Khalifa1, R. Fakhfakh1, N. El Amri1, K. Baccouche1, E. Bouajila1. 1Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

**Background:** Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children with wide variety in its clinical profile.

**Objectives:** The aim of our study was to describe the epidemiological, clinical, paraclinical and management aspects of JIA among Tunisian children.

**Methods:** This is a monocentric retrospective and observational study including children who met the ILAR criteria for the diagnosis of JIA. They were collected from the rheumatology department of Farhat Hached Hospital of Sousse in Tunisia.

**Results:** Out of the 55 included children, 27 (49.1%) were boys and 28 (50.9%) were girls. The mean age was 13.6 years. The mean age of onset of JIA was 6.4
years [3 months-16 years]. The mean duration of JIA progression was 4.4 years. The predominant subtypes of JIA were the seronegative polyarticular form (21 cases, 38.2%), the seronegative oligoarticular form and juvenile spondyloarthritids (9 cases, 16.4%) each. The other forms were: seropositive polyarthritids (7 cases, 12.7%), systemic onset JIA (SOJIA) and psoriatic arthritis (4 cases, 7.3% for each) and arthritis with enthesis (1 case, 1.8%). Arthritis was present in all patients. Wrist followed by knee were the most affected joints in all subtypes. Fever, lymphadenopathy, hepatosplenomegaly and rash were exclusive to patients with SOJIA. Uveitis (2 cases, 3.6%) and anti-nuclear antibodies (ANA) positivity (1 case, 1.8%) were rare. Biological inflammatory syndrome was found in 65.5% of cases. The means of ESR and CRP were 42.4 mm/h and 28.8 mg/L respectively. Anemia was found in 56.4% of cases. Standard X rays revealed carpal in 4 cases (72%) and bone erosions in 9 cases (16.4%). Coxitis was present in 30.9% of the patients. Concerning treatment, our patients received non steroidal anti-inflammatory drugs (61.8%), oral corticosteroids (67.3%), and pulse steroid therapy in 47.3% of cases. Methotrexate was used for 65.5% of patients. Twenty-four patients (41.8%) were treated with biologics. Delayed growth as a complication of the JIA was observed in 8 cases (14.5%). Twenty-three patients (41.8%) developed joint deformities.

Conclusion: JIA has heterogeneous presentations with a challenging diagnosis in rheumatology practice. In our study, the seronegative polyarticular form was the most common subtype of JIA. Inflammatory syndrome, coxitis and deformities were frequent whereas uveitis and ANA positivity were rare findings in our population.

Diffuse Arteritis with giant cell arteritis: a case report

M. Thomas1, G. Martinroche2, A. Combière1, J. Wipff1, G. Touanga1, P. Quartier1, C. Bordes2,3, M. E. Truchetet4,5, Y. Allanore1. 1Cochin Hospital, Rheumatology, Paris, France; 2Hospital Center University De Bordeaux, Immunology and Immunogenetic Department, Bordeaux, France; 3Nécker Hospital, Reference Centre for Rare Diseases, Paediatric Immunology-Haematology and Rheumatology Unit, Paris, France; 4Bordeaux University - Campus Carreire, ImmunocoEpt, CNRS, UMR 5164, Bordeaux, France; 5Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France

Background: Auto-antibodies against carbamylated proteins (anti-CarP) are emerging biomarkers in rheumatoid arthritis with relevant prognostic value. Juvenile idiopathic arthritis (JIA) is characterized by high heterogeneity and risk-stratification could be improved.

Objectives: We aimed at determining whether anti-CarP in J IAs patient, at the time of transition, could help to predict patients’ outcomes.

Methods: We conducted a monocentric retrospective study at the Cochin Hospital in Paris on a cohort of JIA patients in transition to adult rheumatology for whom serum has been collected and stored in a biobank between 2011 and 2013 with the approval of research ethic committee (EUDRACT 2010-A01386-33, reference S.C.2852). Demographic data, diagnosis, biological and radiological results, and treatments were collected retrospectively thanks to computerized files. Samples of serum available in the biobank were analyzed to measure anti-CarP and anti-CCP by ELISA in the department of Immunology and Immunogenetics from the Bordeaux University Hospital.

Results: Twenty-eight (20%) patients were anti-CarP positive. The median age was 21.5 (18.6-23.1) years in anti-CarP positive as compared to 19 (17-21.1) in anti-CarP negative (p=0.02). In anti-CarP positive group, 41% were polyarticular-JIA, 26% oligoarticular, 15% had enthesitis related arthritis and 15% were systemic, but this was not different as compared to anti-CarP negative patients. Structural radiographic damages were identified in 44% of anti-CarP positive such as in 50% in anti-CarP negative group (p=0.6). Concerning treatment, 28% of anti-CarP positive patients were treated with synthetic DMARD and 72% with biologic DMARD as compared to 44% (p=0.01) and 65% (p=0.05) for anti-CarP negative. Among anti-CarP positive patients, 10 (7.4%) were also anti-CCP positive. These double-positive patients were polyarticular-JIA for 90% and 9% (p=0.02) received a biotheraphy at the last available follow-up as compared to 18% of polyarticular-JIA (p=0.002) and 44% (p=0.03) on biotherapy.

Conclusion: Anti-CarP antibodies were observed in 20% of JIAs patients at transition but could not help for risk-stratification of the patients. The respective value of anti-CarP and anti-CCP for structural damages and treatment intensification will require larger cohort but double positive patients appeared to be the most severe polyarticular-JIA patients.

Nailfold Capillaroscopy in Deficiency of Adenosine Deaminase 2 (DADA2): a Case-Control Study

P. F. Bica1, C. Matucci-Cerinic1,2,3, E. Hysa1, A. Cere1, E. Gotelli1, S. Volpi2,3, R. Caorsi2,3, A. Sulli1, C. Pizzorni1, S. Paolino1, M. Cutolo1, M. Gattorno2, 1University of Genova, IRCCS San Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties (DIMI), Genova, Italy; 2I.R.C.C.S. Gianna Gaslini, Center for Autoinflammatory Diseases and Immunodeficiencies, Genoa, Italy; 3R.C.C.S. Gianna Gaslini, DINOGMI, University of Genova, Genoa, Italy

Background: Deficiency of adenosine deaminase 2 (DADA2) is a rare mono-genic inflammatory disease characterized by the presence of systemic inflammation, vasculitis, early-onset stroke, and hematologic manifestations such as cytopenia and immunodeficiency. Mucocutaneous and peripheral microvascular manifestations, such as livedo racemosa, cutaneous ulcers and Raynaud’s phenomenon (RP), can occur, in up to 50%, 22% and 8% of DADA2 patients respectively [1].

Objectives: To investigate the microvascular architecture in nailfold capillaries of DADA2 patients comparing them with adequate healthy controls (HCs) and primary RP individuals.

Methods: The data of 9 patients with DADA2 followed at Istituto Gaslini were retrospectively retrieved and compared to 11 HCs and 7 RP Clinical and genetic data were collected for DADA2 patients. Nailfold videocapillaroscopy (NVC) findings were collected in the whole cohort, independently from their current treatment. The capillaroscopic parameters were classified according to the Fast Track Algorithm and distinguished between scleroderma-pattern (encompassing specific NVC alteration, such as the presence of giant capillaries and/or loss of capillaries combined with abnormally shaped capillaries) and non-scleroderma
patterns (non-specific NVC alterations) [2]. A validated semiquantitative scale (score 0–3 for each NVC parameter) was used to compare microvascular findings in the three groups [3].

**Results:** The patients with DADA2 were diagnosed according to genetic testing. The disease onset was in early infancy, while the mean age at NVC was of 18.8 years. Livedo racemosa was present in 7 patients (78%), digital ulcers in 1 patient, and an ischemic stroke was reported in 5 patients (55%). None of the patients had RP (0%). The NVC showed the presence of non-specific alterations in all DADA2 patients (capillary dilations in 100%, abnormally shaped capillaries and haemorrhages in 23% of patients). The capillary density was normal (median = 9) and no scleroderma-like pattern was found. No significant differences in the rates of each microvascular finding were detected between DADA2, RP patients and HCs.

**Conclusion:** This is the first report investigating the NVC findings in DADA2 patients. Microvascular damage in DADA2 does not show a specific capillaroscopic alteration but the presence of non-specific findings might suggest a disease-related endothelial damage.

R. Semo Ox1, A. Dorfi2, S. Spielman3, E. Zohar Dayan4, M. Rubinstein5, E. Adam6, A. Vivante7, Y. Bezalel8, I. Tirosh1.

**Background:** GVHD is a significant complication of allogeneic stem cell transplantation, mediated by donor T cell activation and proliferation and affecting 30–70% of patients. Clinical manifestations often have overlapping features with auto-immune diseases such as scleroderma, Sjögren’s syndrome, eosinophilic fasciitis, primary biliary cirrhosis and immune cytopenia. Clinical myositis with muscle tenderness and elevated muscle enzymes is recognized as a distinct and uncommon manifestation of GVHD with estimated frequency of 3.5–7.6%. In addition to corticosteroids, various immunosuppressive agents are being used for treatment, however, the optimal therapeutic strategy has not yet been defined.

**Objectives:** To describe a case of GVHD related myositis in a 4 years old female, successfully treated with Rituximab and to increase awareness for this rare condition and the role of Rituximab for its treatment.

**Methods:** Two years old female underwent a successful bone marrow transplantation from matched unrelated donor for Juvenile myelomonocytic leukemia (JMML). Four months post BMT she developed severe GVHD, primarily involving her skin and oral mucosa, GI and liver. She was treated with mycophenolate, cyclosporine, prednisolone, rituximab, tacrolimus in different combinations. Almost two years post BMT she developed fever, general weakness and severe respiratory distress which required mechanical ventilation. After a comprehensive diagnostic work-up, she was diagnosed with inflammatory myositis based on elevated CPK, characterized EMG and muscle biopsy (Fig 1, 2). She was treated with steroid pulses and IVIG with no significant improvement and therefore Rituximab was added to her regimen. Two weeks following the first dose of Rituximab, clinical and laboratory improvement were noted, and the patient could get off ventilator.

**Results:** Patient remained in remission with monthly IVIG and decreasing doses of prednisone.

**Conclusion:** Myositis is a rare complication of GVHD. High index of suspicion is recommended for early diagnosis. Rituximab should be considered as a treatment option.

ASSESSMENT OF THE PREVALENCE OF SARCOPENIA IN ADULT WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Sarcopenia, Inflammatory arthritides, Diet and Nutrition

I. Sultine1, A. Hittinger1, I. Charlot-Lambrécht2, B. Lois3, M. Geoffroy1, J. H. Salmon1. 1Hospital Maison Blanche, Rheumatology, Reims, France

Background: Sarcopenia is a progressive and systemic disorder of skeletal muscles responsible for an acceleration of function impairment and loss of muscle mass [1]. It is well known associated with ageing, but a new life-course approach suggests that muscle mass and function in older people also depends on the mass muscle peak in early adulthood [2]. Prevalence increment of sarcopenia has been well described in inflammatory rheumatic diseases, particularly in rheumatoid arthritis and spondylarthritides, but has never been studied in rheumatic diseases with a juvenile onset.

Objectives: The aim of this study was therefore to investigate the prevalence of sarcopenia in juvenile idiopathic arthritis in adult life.

Methods: We performed a monocentric cross-sectional study including patients followed up in rheumatology unit of Reims hospital for juvenile idiopathic arthritis (JIA) from November 2021 to September 2022. Each patient received a measurement of muscle quantity and quality by dual-energy X-ray absorptiometry, a measurement of muscle strength by Grip test, a screening for sarcopenia by the SARC-F score, an assessment of physical activity by the IPAQ score and of fatigue by the FACIT-F score. The diagnosis of sarcopenia was confirmed by a decrease in appendicular muscle mass (AMM) < 20 kg in men and < 15 kg in women or an ASM/height(2) < 7 kg/m2 in men or < 5.5 kg/m2 in women [1].

Results: Thirty-four patients were included, aged from 18 to 45 years. The prevalence of sarcopenia was 20.6% (7/34) with a majority of women (sex ratio 0.6). Type of JIA was significantly different between the 2 groups with 57.14% oligoarticular form and 28.57% systemic form in the sarcopenic group, versus 0% oligoarticular and 52.4% systemic form in the non-sarcopenic group (p=0.004). We did not find any significant difference in disease activity nor in treatment by biotherapy or corticosteroids between the 2 groups. Proportion of patients with a BMI <18.5 kg/m2 was significantly higher in the sarcopenic population (p=0.0095). The IPAQ score showed a lower energy expenditure in the sarcopenic group, although not significantly different (p=0.099). By using a variation of -2DS of appendicular skeletal mass or <ASM/height(2)] compared with age- and sex-matched reference values from a Danish cohort, we have calculated a prevalence of sarcopenia of 11.76% in our population [3]. The assessment of muscle strength defined by a -2DS decrease in grip test values compared to reference values matched for age and sex showed a decrease in muscle strength in 29.4%. By using European Working Group for Sarcopenia in Older People (EWGSOP) definition, only 11.76% of our patients presented a muscle strength decrease. Moreover, the SARC-F score established in patients over 65 years of age did not allow for the detection of sarcopenia in our population.

Conclusion: This is the first study to evaluate sarcopenia in juvenile idiopathic arthritis. JIA is associated with a risk of developing sarcopenia at an early age with an impact on peak muscle mass and, thus, on long-term muscle function and prognosis. In order to prevent this risk, nutritional management and regular physical activity seem to be relevant approaches. The definition of sarcopenia by the EWGSOP does not seem to be adapted to a younger population, with a low sensitivity screening of sarcopenia in this population by the SARC-F score and an underestimation of low muscle strength by the grip test. Further studies with a larger population and a control population are needed to clarify these results.

CLINICAL CHARACTERISTICS OF PEDIATRIC PATIENTS WITH RHEUMATIC DISEASES UNDER TREATMENT WITH BIOLOGICAL THERAPY: INFORMATION FROM BIOBADAMEX

Keywords: bDMARD, Registries

S. Mendieta1, A. Torres2, F. Irazoque-Palazuelos3, S. Sicsic3, I. J. Colunga-Pedraza2, D. X. Xibile Friedman4, D. Alpizar-Rodríguez5, V. Rivera Teran6, 1ISSEYM Hospital Materno Infantil, Pediatric Rheumatology, Toluca de Lerdo, Mexico; 2Centro Médico Nacional La Raza, Pediatric Rheumatology, Ciudad de México, Mexico; 3Centro Médico Nacional 20 de Noviembre, Rheumatology, Ciudad de México, Mexico; 4Unidad Médica de Alta Especialidad No. 71 IMSS, Rheumatology, Torreón, Mexico; 5Centro Médico Conchita, Rheumatology, Monterrey, Mexico; 6Centro Médico San Diego, Rheumatology, Cuautla, Mexico; 7Colegio Mexicano De Reumatología, Unidad de Investigación, Ciudad de México, Mexico

Background: The advent of biologic treatment (bDMARD) in childhood rheumatic diseases (RD) has changed their evolution and prognosis. Evidence is robust for diseases such as juvenile idiopathic arthritis (JIA) and systemic lupus erythematosus (SLE), but in other diseases we still have to learn which is the ideal therapy, time to discontinuation and the potential adverse events (AE) in short and long term.

Objectives: Identify the clinical and treatment characteristics of pediatric patients with rheumatic diseases with bDMARD treatment and describe the development of AE.

Methods: BIOBADAMEX is a prospective ongoing cohort of Mexican patients with RD using bDMARDs since 2016. We included all patients younger than 18 years of age registered in BIOBADAMEX. Descriptive statistics were used for the baseline characteristics and the Chi-square test to analyze the differences between the characteristics of the groups in relation to the development of AE.

Results: A total of 45 patients were included, 31 (69%) of them female, mean age of 13.3 (±3.6) years. (Table 1). The most frequent diagnosis was JIA (25 (56%), followed by SLE 9 (20%), uveitis 5 (11%), polymyositis/dermatomyositis and hidradenitis 2 (4%) respectively; systemic sclerosis and CINCA 1 patient (2%) respectively). The mean duration disease in years was 4.67 (±2.1). Nine patients (20%) used a biologic prior to the current; 25 (56%) patients had comorbidities. The most frequent bDMARDs used was Adalimumab (ADA) in 17 (38%) patients followed by Rituximab in 15 (33%) and Tocilizumab in 10 (22%) patients. Infliximab, Abatacept and Canakinumab were used in one patient respectively. When compared by groups, ADA and Tocilizumab were the most used bDMARDs in JIA, Rituximab the only one used in SLE and PM/DM, and ADA the only one for uveitis. 15 patients discontinued biological treatment, 4 (27%) due to AE. 82% used an additional synthetic DMARD, being methotrexate the most used in 48% of patients. Steroids were

used by 21 (47%) of the patients with a median dose of 10mg (IQR 5 - 25). Fifteen AEs were recorded: 7 (47%) were infections, 5 of these (71%) were COVID; allergies and neutropenia in 2 (13%) patients respectively. By disease inception, AEs were more frequent in patients with JIA and Uveitis; neutropenia only occurred in patients with JIA (p = 0.95). 87% of the AEs were non-serious; 1 patient with JIA presented a severe AE and one patient with SLE a fatal AE associated with COVID (p = 0.93), with no statistically significant difference between groups.

Conclusion: JIA is the most frequent indication to use bDMARD as worldwide received. The AE in this analysis are similar to previous registries in terms of the prevalence of infections, in our group the most frequent infectious complication was COVID, being fatal in one patient related with rituximab in SLE. Our study did not find statistically significant differences in the development of AE between diseases; however, they will continue to be reported and the number of patients in the registry will increase.

OVARian preservAtion in Juvenile Systemic lupus erythematosus: A Monocentric Cohort

Keywords: Systemic lupus erythematous, Biomarkers, Pregnancy and reproduction

S. Costi1, D. Chevenerima2, P. Ellu3, V. Baudoin4, T. Kwon4, R. Caporali5,6,3,8, C. Douzou1, I. Melki8,1, ASST G.Pini-CTO, Unit of Pediatric Rheumatology, Milan, Italy; 2Robert Debré Hospital, Biochemistry Hormonology, Paris, France; 3Robert Debré Hospital, Child and adolescent psychiatrist service, Paris, France; 4Robert Debré Hospital, Nephrology Department, Paris, France; 5University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 6ASST G.Pini-CTO, Department of Rheumatology and Medical Science, Milan, Italy; 7Robert Debré Hospital, Department of gynecology and obstetrics, Paris, France; 8Robert Debré Hospital, Infectious Disease and Internal Medicine Department, Paris, France

Background: Systemic lupus erythematosus (SLE) can impact fertility outcomes and lead to ovarian premature failure. The exact mechanism is not completely understood. Anti-ovarian antibodies have been described as a possible explanation[1] but other intrinsic and extrinsic factors are involved. Cyclophosphamide (Cyc) is known to have a gonadotoxic effect, but available data are derived from adult cohorts. Anti-müllerian hormone (AMH) is a surrogate biomarker of ovarian reserve in such studies.

Objectives: This study aims to evaluate the ovarian reserve in juvenile-SLE (j-SLE) using AMH and to follow the longitudinal evolution of this biomarker at diagnosis and after the start of treatment.

Methods: Patients with a diagnosis of j-SLE followed at Robert-Debré Hospital, Paris, France, were included, AMH levels were assessed before starting therapy, at 6-10, 12-18, and after 20 months from the start of immunosuppressive therapy. AMH values are expressed in pmol/L with a normal range varying from 7.1 to 51.8, according to pubertal status/age.

Results: 21 j-SLE patients were included (100% female). Patients were divided into 2 groups: i. j-SLE who received cyclophosphamide (48%) and ii. j-SLE who received anti-CD20 treatment (rituximab or obinutuzumab), mycophenolate, or hydroxychloroquine (52%). Clinical and demographic features are summarized in Table 1. 16 patients were menstruating at the initiation of immunosuppressive therapy, while 5 patients were not; however, the first menstrual period occurred between 2 to 4 months after initiation of treatment. The median cumulative dose of Cyc was 4.8 grams (IQR 2.2). No statistically significant differences were found comparing pre-treatment AMH levels between the two groups (p = 0.60). The same trend was found evaluating AMH levels at 6-10, 12-18 months, and after 20 months from the start of therapy (p = 0.48, p = 0.77, and p = 0.68 respectively). At 20 months the only two patients with AMH values below the normal limits had low values even before starting treatment (0.6 vs 4.9 in group 1 and 1.9 vs 7.4 in group 2 respectively). SLEDAI at the onset of the disease seems to have low values even before starting treatment (0.6 vs 4.9 in group 1 and 4.9 vs 24.6 in group 2 respectively). At 20 months the only two patients with AMH values below the normal limits had low values even before starting treatment (p = 0.48, p = 0.77, and p = 0.68 respectively).

Conclusion: Fertility preservation is a key point in the management of patients with SLE. Our study shows reassuring data regarding the use of Cyc in j-SLE and suggests that AMH levels, and consequently ovarian reserve, may be primarily affected by disease severity and activity rather than treatment.

TRIGGERING IGA VASCULITIS BY FOOD ALLERGEN EXPOSURE, VITAMIN D DEFICIENCY, AND IL-33-ACTIVATED TYPE 2 IMMUNE RESPONSES

Keywords: Vasculitis, Vitamin D

X. Ma1, J. Wang2, H. Jiang3, Y. Shan7, The First Hospital of China Medical University, Department of Pediatrics, Shenyang, China; 2University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan

Background: Immunoglobulin A vasculitis (iGAV) is one of the most common types of systemic vasculitis in children and usually involves the skin,
gastrointestinal tract, kidneys, and articulations[1]. The trigger of IgAV is unclear. Studies elucidated that higher serum IgE levels and vitamin D deficiency existed in IgAV commonly[2, 3], while it is worth noting that T helper (Th) 2 cells increase in IgAV and are closely correlated with aberrant production of antibodies and the development of vessel vasculitis[4]. Moreover, serum IL-33 can activate many immune cell types involved in type 2 immune responses and allergic inflammatory reactions, are elevated in IgAV patients and positively correlated with the overall clinical score[5, 6]. This study aimed to further analyze their mutual relation and reveal the mechanism underlying IgAV development.

Objectives: We investigated the levels of antigen-specific antibodies, 25-hydroxyvitamin D3 [25(OH)D3] and IL-33 and the phenotypes of Th cells in the peripheral blood of IgAV patients at the early stage of disease onset. We also analyzed the correlation between each index and clinical characteristics.

Methods: Aeroallergen-specific IgE and food-specific IgE were detected by western blotting. Serum 25(OH)D3 and total IgE levels were determined by electrochemiluminescence immunoassay. Serum IL-33 and sST2 levels were detected by enzyme-linked immunoassays. Serum IL-2, IL-4, IL-6 and IL-10 were detected using a cytometric bead array. Frequencies of T helper cell subsets were detected by flow cytometry.

Results: About half of the patients had abnormal allergic indicators and positive results in the allergen-specific IgE assay. Up to 98.25% of the patients had decreased serum 25(OH)D3 levels, which were inversely correlated with an abnormal increase in IgE. Th2 cells were elevated and negatively correlated with the level of serum 25(OH)D3. IL-33, a critical cytokine for the differention of Th2 cells, was also increased and negatively correlated with serum 25(OH)D3 levels.

Conclusion: Food allergen exposure and 25(OH)D3 deficiency may trigger IgAV. 25(OH)D3 deficiency induces the activation of type 2 immune responses and a pathological increase in IgE by promoting the secretion of IL-33, which may be the underlying mechanism of IgAV pathogenesis. Monitoring vitamin D levels and administering vitamin D supplementation might play significant roles in preventing and treating IgAV.

BIOMARKERS IN JUVENILE IDIOPATHIC ARTHRITIS: DESCRIPTION OF GROUPS WITH DIFFERENT DEGREES OF DISCREPANCY BETWEEN SERUM CALPROTECTIN AND C-REACTIVE PROTEIN.

Keywords: Inflammatory arthritides, Descriptive Studies, Biomarkers

H Codes-Mendoza1, 2, B Magallares1, 2, H Park1, 2, L Martinez-Martinez1, 2, Y Alvaro1, E Molto1, V Calahorra3, 5, S Boronat4, P Moysa2, A Laiz2, J. L. Tandapania1, 2, S. P. Fernandez-Sanchez3, C. Diaz-Torné1, 2, I. Castellvi1, 2, H Corominas1, 2, 4Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 1Universitat Autonoma de Barcelona, Medicine, Bellaterra, Spain, 2Hospital de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain; 3Hospital de la Santa Creu i Sant Pau, Paediatrics, Barcelona, Spain.

Background: There are no specific biomarkers of disease activity in Juvenile Idiopathic Arthritis (JIA), and therefore it is important to identify new molecules which will help us to offer individualized treatment options. Serum Calprotectin (CLP) is an emerging biomarker of inflammation. Recent studies[1] suggest that disease activity correlates better with CLP than with classic acute phase reactants such as C-reactive Protein (CRP).

Objectives: To determine the clinical characteristics of paediatric patients with Juvenile Idiopathic Arthritis (JIA) who have discrepancy between Serum Calprotectin and C-reactive Protein.

Methods: An analytical transversal study was performed including patients with JIA from a paediatric rheumatology clinic between 2017 and 2021. A total of 25 patients were included, who had at least one measurement of CLP in daily practice. Demographic, analytical and clinical data were collected. The JADAS score by physical examination and ultrasound was collected in patients with peripheral arthritis.

Results: A total of 25 patients were included, 48% were female and the mean age was 11.5 (±4.6) years. A total of 11 (44%) patients had discrepancy between CLP and CRP. Among them, 9 (81.8%) had elevated CLP and low CRP, whereas only 2 (18.2%) had low CLP with elevated CRP. At the time of performing the analysis, 44% of the patients had an active disease. The oligoarticular JIA subtype was the one that presented a larger patient's percentage (54.5%) with discrepancy and elevated CLP. The details of clinical and analytical characteristics of the patients are shown in Table 1.

In the subgroup of patients with discrepancy and elevated CLP there were 3 (33.3%) with an active disease. Among them, 66.7% were female and all of them had an oligoarticular JIA. One of them was in a flare with both an active arthritis and uveitis at the moment of the analysis. None of them were under treatment with prednisone nor DMARD (disease-modifying antirheumatic drugs).

Conclusion: There was discrepancy between CLP and CRP in 44% of the sample. Among them, most (81.8%) had high CLP without elevation of CRP. The JIA subtype that presented discrepancy with elevated CLP was the oligoarticular one. A total of 3 (33%) patients were active in the group with discrepancy and elevated CLP, one of them being in a flare with both an active arthritis and uveitis.

Background: Juvenile Idiopathic Arthritis (JIA) is a chronic inflammatory disease that affects 1 in 1000 children worldwide. Our population in the United Arab Emirates is a multiethnic diverse population. [1, 2]

Objectives: To create centralised data for JIA in the United Arab Emirates. In this abstract we describe the Demographic data, clinical features, subtype distribution as per ILAR classification, treatment received and outcome of our patients.[3]

Methods: Retrospective entry of data from all 3 participating centres (Shaikh Shakhbout Medical City, Tawam and AlAliia). Patients with the diagnosis of JIA included. Electronic clinical research form used to collect data. Data at initial diagnosis and current outcome as per Wallace and (Juvenile Arthritis Disease Activity Score) JADAS 10. Long term out come as per Juvenile Arthritis Disease Activity (JADAI) articular > 0 and extra articular JADAI > 0. All data entered and analysed through Redcap (Research Electronic Data Capture web-based application version 12.1.1 model 2022). Simple statistics used. Ethics approval obtained.

Results: 157 patients entered in to the registry so far. Male to female distribution: 39 (24.8%) to 118 (75.2%). Local Emirati patients of 107 (68.2%). Other Arabs 16 (10.2%), South Asian 12 (7.6%), Western 12 (7.6%) and African 10 6.4%). Mean age at presentation 5.3 years (1 to 15 years). Current mean age 14 (age 22-years).

Family history of Rheumatoid Arthritis in 33 patients (21%). History of Consanguinity in 54 families (34.4%). Subtype distribution: Oligo articular 77 (49.4%), extended Oligo articular 5 (3.2%), Poly articular 50 (32.1%), Systemic 11 (7.1%), Enthesitis related Arthritis 1 (0.6%), Psoriatic 9 (5.8%) and other 3 (1.9%). At presentation: Joint pain in 132 patients (84.1%), Joint effusion 115 (73.2%). Affected function in 98 (63.2%). Clinical synovitis in 138 (87.9%). Joint restriction in 100 (53.7%), Uveitis in 6 (3.8%) ANA positive 35 patients (22.3%). Rheumatoid factor positive 10 (6.4%), Anti CCP positive 6 (3.8%). Low Hb less than 10g/l in 109 (69.4%), high ESR > 20mm/hr in 30 patients (19.1%). High CRP >5mg/L in 48 (30.6%). Synovitis in USS 53 (33.8%). Erosions by X-ray or USS 7 patients (4.5%). Uveitis after diagnosis in 30 patients 19.1%. Dental carries at presentation in 51 patients (32.1%). Oral systemic steroids given to 108 patients (68.8%). Intravenous methyl prednisolone to 43 patients 27.4%). Intravenoction Aminocetone/Hexa acetone joint injections to 91 patients (58%). Synthetic Disease modifying medication methotrexate in 108 (68.8%). Biologic treatment 76 patients (49%). Etanercept 64 patients (40.8%), Canakinumab 65 patients (41.4%), Tocilizumab intra venous 32 (20.4%) and sub cut in 10 patients (6.4%). Canakinumab 9 patients (5.7%). Anakinra 8 patients (5.1%) and Infliximab in 10 patients (6.4%). Oral Tofacitinib in 2 patients (1.3%).

In regards to outcome as per Wallace criteria and JADAS 10; active disease in 16 patients (10.2%). In remission 141 patients (89.8%). Out of these in remission on treatment in 118 (83.7%) and in remission off treatment 23 patients (16.3%). JADAI articular >0 in 8 patients (5%) and JADAI extra articular >0 in 14 patients (8.9%).

Conclusion: We have achieved diverse cohort and high percentage of consanguinity in our families of children with JIA (34.4%). Biologic treatment required in 49% of patients. Patients in remission 89.8%. Out of this 83.7% in remission on treatment and 8.9% in remission off treatment. Further studies needed to understand our population better with focus of effect of consanguinity.

AB1446

TREATMENT PATTERNS IN A POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS POPULATION IN GERMANY: A RETROSPECTIVE OBSERVATIONAL HEALTH CLAIMS DATA STUDY

Keywords: Disease-modifying Drugs (DMARDs), Epidemiology, Real-world evidence

G. Hornett1, 2, J. Borcher1, J. Diesing2, P. Klein1, R. Heinrich1, H. Dally1, C. Hagemann1, S. Kock1, T. Schoenfelde1, 2, *Asklepios Clinic Sankt Augustin, Department of General Paediatrics, Sankt Augustin, Germany; 2University Hospital of Cologne, Department of Paediatric and Adolescents Medicine, Cologne, Germany; 3WIG2, Health Services Research and Health Economics, Leipzig, Germany; 4Pfizer Pharma GmbH, Inflammation & Immunology, Medical Affairs, Berlin, Germany; 5Pfizer Pharma GmbH, Health Technology Assessment & Outcomes Research, Berlin, Germany; 6InGef, Health Services Research, Leipzig, Germany; 7Technische Universität Dresden, Chair of Health Sciences - Public Health, Dresden, Germany

Background: Treatment of polyarticular juvenile idiopathic arthritis (polyJIA) aims to ease symptoms and inflammation and reduce further damage and comorbidities[1]. Current treatment options however are not universally effective. With the first targeted synthetic disease modifying anti-rheumatic agent having recently been approved information on how many polyJIA patients may potentially benefit from newly accessible treatment options is needed.

Objectives: Describe current treatment patterns around incident polyJIA diagnosis and beyond, especially changes in medication regimes indicative of unsatisfactory response.

Methods: In a retrospective, observational analysis of two different non-overlapping longitudinal health claims databases (the WIG2, Scientific Institute for Health Economics and Health System Research GmbH, and InGef, Institute for Applied Health Research Berlin GmbH, databases), a representative sample in terms of age and gender of the statutary health insurance (SHI) population in Germany (about 3.5 and 4 million patients, respectively) was analysed. Two incident JIA cohorts were evaluated (2014 and 2015) in each database, and followed up for 4 or 3 years, respectively. All incident JIA patients (without a JIA diagnosis during baseline, the 4 quarters prior to index) aged 2 to 15 years in the respective observation year (2014 and 2015), with continuous data throughout the observation year and minimum 3-year follow-up (or deceased) were included. Patients were considered to have polyJIA if they had at least one inpatient ICD-10 GM (German modification) diagnosis code, or two verified outpatient codes in two different quarters in the year, of M08.0 (juvenile chronic polyarthritis, adult type includes rheumatoid factor (RF)+ polyJIA), or M08.3 (juvenile chronic arthritis (seronegative), polyarticular form, includes RF+ polyJIA and extended oligoartthritis). We evaluated top-prescribed and pre-defined medications (by 4-digit ATC code) before, during, and following, incident polyJIA diagnosis. The pre-defined medication groups were non-steroidal anti-inflammatory drugs (NSAIWs), glucocorticoids (GCs), conventional synthetic disease modifying anti-rheumatic drugs (cSDMARDs), and biologic disease modifying anti-rheumatic drugs (bDMARDs).

Results: Applying the inclusion and exclusion criteria to the incident JIA populations, we identified a total of 121 and 58 polyJIA patients in both 2014 and 2015, (of which 56 and 29 belonged to the 2015 cohort) in the InGef and WIG2 databases, respectively. Among the most frequently prescribed drugs were anti-inflammatory and anti-rheumatic drugs, specific anti-rheumatic agents, and nasal decongestants, immunosuppressive agents, vitamin B12 and folic acid. Prior to diagnosis, more than half of patients of the 2015 cohort were already receiving NSAIDs, however at diagnosis the use of cSDMARDs increased more than bDMARD use. From diagnosis quarter to follow-up, there was a proportionally larger increase in the use of bDMARDs than cSDMARDs, however use of all medications we examined (also NSAIDs and GCs) in our population continued to increase through follow-up (fig 1). Treatment patterns were similar for both cohorts (2014 and 2015).

Conclusion: Almost all patients continued to take NSAIDs during follow-up, mons and concomitant medication with glucocorticoids in addition to cSDMARDs or bDMARDs. This demonstrates there was an unmet need in the past for further advanced treatment options such as targeted synthetic DMARDs.

Figure 1. Pre-defined medications for patients with incident polyJIA in the 2015 cohort, for baseline (prior to year of diagnosis), index (diagnosis year) and follow-up (up to 3 years after diagnosis). *indicates n=5 and no % can be reported due to data protection
Background: Several studies have suggested a potential role for ultrasonography (US) in detecting enthesitis in children, thus enhancing the accuracy of the classification of juvenile idiopathic arthritis (JIA) and improving the therapeutic approach.

Methods: We performed a systematic literature review (SLR) to assess the validity of ultrasonography in detecting enthesitis in children.

Results: Five publications met the inclusion criteria (26 to 146 patients and 1 to 1065 ultrasonograms). The quality of the studies was low, mainly because of the lack of a reference standard.

Conclusion: This systematic review showed that US is a valuable tool for detecting enthesitis in JIA, particularly enthesitis related arthritis (ERA). Future studies are needed to better understand the clinical relevance of US findings in JIA patients.
**THE GENETIC DIVERSITY AND FEATURES OF TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS**

**Keywords:** Quality of life, Genetics/Epigenetics, Disease-modifying Drugs (DMARDs)

**S. Vardanyan1, V. Vardanyan1, A. Sargsyan1, N. Manukyan1, K. Ginosyan2, Yerevan State Medical University; "Mikayelyan" Institute of Surgery, Rheumatology, Yerevan, Armenia; 2Yerevan State Medical University, Rheumatology, Yerevan, Armenia

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic arthritis of childhood. Systemic JIA has many clinical features overlapping with familial Mediterranean fever, and MEFV gene mutations play a critical role in genetic background for JIA and influence the severity of the disease.

**Objectives:** To find out associations between different immunological abnormalities, HLA-B27-positive, carriage of familial Mediterranean fever (FMF) mutations, and clinical polymorphism of JIA. To evaluate the effectiveness of treatment with DMARDs and NSAIDS.

**Methods:** 94 patients with confirmed JIA (100% male, mean age 14±2 years) were included in the study. All patients corresponded to ILAR criteria. 28 (29.8%) were treated with only NSAIDs, 66 (70.2%) with NSAIDS and DMARDs (33/50% methotrexate, 33/50% sulfasalazine), 9 (13.6%) - with bDMARDs. The data is introduced as odds ratios (OR) with 95% confidence interval (CI). The results were considered significant when p < 0.05.

**Results:**
- **At baseline 17 (18.1%) patients were classified as a systemic, 13 (13.8%) - oligoarticular, 3 (3.2%) - polyarticular RF-positive, 8 (8.5%) - polyarticular RF-negative, 3 (3.2%) - psoriatic, 49 (52.1%) - enthesitis-related JIA. MEFV gene mutations were observed in 38 (40.4%) patients (35/92.1% - one heterozygous mutation, 3/7.9% - more than one mutation), FMF was diagnosed in 3 (3.2%) patients.**
- We found positive significant association between MEFV carriage and systemic JIA (OR/CI95%=10.3/2.7 -39.2, p<0.01), as well as polyarticular RF-negative JIA (OR/CI95%=5.3/1.5-10.6 p<0.05). Despite the MEFV carriage, colchicine was prescribed to only 5 (5.3%) patients. 28 (29.8%) patients were HLA B27-positive and we found positive significant association between HLA B27 positivity and oligoarticular JIA (OR/CI95%=5.6/2.3-15.7, p<0.05), as well as enthesitis-related JIA (OR/CI95%=13.3/3.2-19.4, p<0.01). Sacroilisitis was diagnosed in 85 (90.4%) patients, 26 (30.6%) - non-radiographic, 59 (69.4%) - radiographic. The rise in progression from non-radiographic sacroiliitis to radiographic significantly decreased in patients on methotrexate (OR/CI95%=0.05/0.01-0.44, p<0.01), compared to sulfasalazine (OR/CI95%=0.78/0.36-2.79 p<0.05). For patients on DMARDs the disease had a self-limited course, without clinical manifestation in adulthood.
- Total remission was mostly associated with methotrexate (OR/CI95%=13.5/1.6-95 p<0.01), in contrast to sulfasalazine (OR/CI95%=0.69/0.28-1.72 p<0.05).

**Conclusion:**
- The carriage of MEFV gene mutations increase the risk of manifestation of polyarticular and systemic JIA.
- Early appointment of DMARDs together with NSAIDS makes it possible to stop the disease and prevent its transition to adult rheumatoid arthritis.
- Despite recent ACR treatment guidelines recommending NSAIDS and sulphasalazine for the treatment of sacroileitis, early administration of methotrexate together with DMARDs and NSAIDS significantly decreases the risk of progression from non-radiographic sacroiliitis to radiographic.

**THE HIP RADIOGRAPHIC SCORE IS CORRELATED WITH THE LATE-ONSET OF JUVENILE IDIOPATHIC ARTHRITIS**

**Keywords:** Imaging

A. Dolajev1, H. Fejrian1, K. Maatallah1, D. Ben Nessib1, D. Kafel1, W. Hamdi1, Mohamed Kassab Institute of Orthopedics, Rheumatology, Manouba, Tunisia

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease in children affecting mobility and physical function. The hip is a load-bearing joint and its damage has a significant functional impact. An appropriate scoring system is mandatory to monitor structural progression and damage over time. The childhood Arthritis Radiographic Score of the Hip (CARSH) is a valid score covering the osteoarticular changes in the hip joint as space narrowing, erosions, malalignment, sclerosis, flattening of the femoral head, and growth abnormalities [1].

**Objectives:** The aim of this study was to assess radiographic changes in the hip joint using the CARSH in children suffering from JIA with hip involvement and to determine the impact of disease factors in this score.

**Methods:** This cross-sectional study was conducted in the pediatric rheumatology department and included patients with JIA according to the ILAR criteria. We included children with hip involvement defined as the presence of hip pain and/or limping and range motion limitation, and/or abnormal hip findings in pelvic radiography, ultrasound, or MRI. We collected from the recorded data demographics, disease characteristics [symptom duration, disease presentation, JIA subtypes], and disease activity: Juvenile arthritis disease activity (JADAS10). Experimented and blinded pediatric rheumatologists read the pelvic radiograph using the Childhood Arthritis Radiographic Score of the Hip (CARSH).

**Results:** Twenty-two children with a mean age of 13 years [5-22] were included in the study. The gender ratio was 1:1 (13 Males/9 Females). The median age of disease onset was 9.5 years [4-14]. The mean duration of the disease was 47 months [4-156]. The diagnostic delay median was 22 months [1-120]. The patient global assessment (PGA) median was 4 [0-8]. The visual analog scale (VAS) median was 5 [3-7]. The sedimentation rate (SR) and the C reactive protein (CRP) median were 25 [2-65] and 10 [1-47], respectively. The JADAS median was 6 [0-18]. Forty-five hips were analyzed. The median score of CARSH was 1.8 [0-7]. The CARSH was positively correlated to the age of disease onset (r = 0.7; p = 0.7), the duration of the disease (r = 0.7; p = 0.7), the diagnostic delay (r = 0.02; p = 0.9), the PGA (r = 0.1; p = 0.5), the VAS (r = 0.4; p = 0.8), the ESR (r = -0.08; p = 0.7), the CRP (r = -0.1; p = 0.6) and the JADAS 10 (r = 0.01; p = 0.9).

**Conclusion:** This study showed that the radiographic score CARSH was correlated to the age of disease onset. Our findings confirm that structural damage was more important in late-onset disease whereas early hip involvement affects growth and joint development.

**HIP INVOLVEMENT IN TUNISIAN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS**

**Keywords:** Prognostic factors, Inflammatory arthritides

M. Arthaud1, D. Khalifa1, O. Farhat1, R. Fakhfakh1, N. El Amri1, K. Baccouche1, E. Bouajila1, Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

**Background:** Juvenile idiopathic arthritis (JIA) is characterized by widely heterogeneous clinical course and outcomes. Hips are the most commonly affected joints in severe uncontrolled JIA.

**Objectives:** The aim of our study was to determine the prevalence and associated factors of hip involvement in Tunisian JIA patients.

**Methods:** A retrospective and observational monocentric study including children with JIA according to the ILAR was conducted in the Rheumatology department of Sousse, Tunisia. We compared the disease parameters between the two groups with and without coxitis.

**Results:** We included 55 children (28 girls and 27 boys). The mean age was 13.6 years. The predominant subtypes of JIA were the seronegative polyarticular JIA (38.2%), and the seronegative oligoarticular form and juvenile spondyloarthritis (16.4%) each. Biological inflammatory syndrome was found in 65.5% of cases. The mean ESR and CRP was 42.4 mm/h and 28.8 mg/l, respectively. Hip involvement concerned 30.9% of the patients (n=17) and was bilateral in 64.7% of cases (n=11). Coxitis occurred on average 10 years after the JIA onset. The mean Lequesne index was 12. Hip radiographs were normal in 40% of cases. Magnetic resonance imaging (MRI) was performed in 25% of cases and revealed synovitis in 70% of cases. Overall, 61.8% of patients had medical treatment combining non steroidal anti-inflammatory drugs and rehabilitation. Only two patients had local infiltration with Hexatrione. In 12.7% of cases (7 cases), a total hip replacement was necessary. Hip involvement was significantly associated with younger age at onset (p=0.02), polyarticular subtype of JIA (p=0.04) and with the presence of biological inflammatory syndrome (p=0.03). However, coxitis was not significantly associated with gender, the duration of JIA progression, extraarticular manifestations, structural damage or the different used treatments.

**Conclusion:** Our study showed that hip involvement is frequent among Tunisian patients with JIA. Coxitis was associated with the polyarticular subtype, with biological inflammatory syndrome and younger age at onset of JIA.

DOI: 10.1136/annrheumdis-2023-eular.4499
Background: Behçet’s disease (BD), a systemic inflammatory disorder of unknown etiology, is classified as an important characteristic of BD vasculitis. Recent studies suggest an association between ABO blood groups and vascular disease in particular in those carrying non-O (A, B, and AB) groups [1].

Objectives: We aimed to investigate the potential contribution of ABO blood groups to the risk of vascular involvement in patients with BD.

Methods: We retrospectively analyzed the records of BD patients followed between 1978 and 2022. Patients fulfilling the ISG Criteria for diagnosis of BD were screened, and those with information about ABO blood groups were included into the study. Presence or absence of vascular involvement and its features were recorded using a standard form. The chi-square test, t-test, Mann-Whitney U test, and logistic regression tests were used for statistical analyses.

Results: The study group consisted of 411 patients with available blood group data, and 143 (34.8%) were carrying O [59% men, mean age at diagnosis 31.4±10.1 years, median follow-up period 153 (98-219) months], and 268 (65.2%) were carrying non-O blood groups (60.1% men, mean age at diagnosis 30.7±8.4 years, median follow-up period 148 (92-204) months). There was no statistical significance between O and non-O groups in regard to the potential confounding factors affecting the risk for vascular disease, including sex, age at diagnosis, family history, HLA-B*51 positivity, smoking, comorbidities, and pro-thrombotic mutations. Vascular involvement was observed in 39 (27.3%) patients with blood group O [venous in 35 (24.5%), and arterial in 11 (7.7%)], whereas 109 patients (40.7%) with non-O blood groups had vascular involvement [venous in 95 (35.4%), and arterial in 58 (14.2%)]. The frequencies of total vascular and venous involvements between the two groups were significantly different (p=0.007, p=0.023, respectively). Unadjusted and adjusted ORs with different models in the multivariate logistic regression analyses are shown in Table 1. After adjustments for age, sex and comorbidities, the risk for arterial disease was also found to be increased in association with non-O blood groups.

Conclusion: Vascular involvement with a tendency for thrombosis is an important feature of BD, and inflammatory characteristics resulting in endothelial dysfunction have been considered as the main underlying pathology. The results of the preliminary study supports the previous reports revealing the potential contribution of ABO blood groups in the development of vascular disease and suggest an approximately two-fold increased risk for vascular involvement in BD patients.

DIAGNOSTIC AND THERAPEUTIC PRACTICES IN ADULT CHRONIC NONBACTERIAL OSTEOMYELITIS (CNO)/SAPHO SYNDROME: AN INTERNATIONAL LANDSCAPE

Keywords: Quality of care, Bone diseases, Rare/orphan diseases

A. Leerling1,2, G. Clunie3, E. Koutrouba1,2, O. Dekkers1,4, N. Appelman-Dijkstra1,5, E. Winter1,2,1, Leiden University Medical Center (LUMC), Internal Medicine, Division of Endocrinology, Leiden, Netherlands; 2Leiden University Medical Center (LUMC), Center for Bone Quality, Leiden, Netherlands; 3Cambridge University Hospitals NHS Foundation Trust, Rheumatology, Cambridge, United Kingdom; 4Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands

Background: Chronic nonbacterial osteomyelitis (CNO) is a rare auto-inflammatory bone disease. CNO, especially the adult variant, may occur in the broader spectrum of Synovitis, Acne, Pustulosis, Hyperostosis, Osteitis (SAPHO) syndrome. Adult CNO lacks diagnostic or management guidelines in contrast to pediatric disease (1, 2).

Objectives: We mapped current diagnostic and therapeutic practices for CNO/SAPHO in adults.

Methods: A primary survey was spread among global rheumatological/bone networks and 57 experts were identified from literature (May 2022), covering terminology, diagnostic tools (clinical, radiological, biochemical) and treatment steps. A secondary survey (sent to primary survey responders in August 2022) further queried diagnostic features, treatment motivations, disease activity and treatment response monitoring.

Results: 36 and 23 physicians completed the primary and secondary survey respectively. Diagnosis was mainly based on individual physician assessment, in which the combination of chronic relapsing-remitting bone pain with radiologically-proven osteitis/osteomyelitis, sclerosis, hyperostosis and increased isotope uptake on bone scintigraphy were reported indicative of CNO. Physicians appeared more likely to refer to the condition as SAPHO syndrome in the presence of joint and skin pathology. MRI was most frequently performed as imaging diagnostic, while biochemical and histopathological tools like technetium radiolabeled hydroxymethylene diphosphonate single photon emission computed tomography visualize the increased bone turnover, but do not reflect the relapsing-remitting disease activity course due to an imprinting pattern [3]. Likewise, magnetic resonance imaging can track the fluctuation of bone marrow edema, but is inferior compared to computed tomography (CT) in capturing subtle inflammatory and accumulated structural changes that reflect disease duration. Sodium fluoride-18 positron emission tomography/CT (Na18F-PET/CT) is another imaging modality which produces quantitative data on the spatial distribution of bone turnover that also correlates with clinical disease activity in other metabolic bone diseases [4].

Objectives: We quantified the variation in CNO/SAPHO patients to evaluate its capacities as a disease activity biomarker.

Methods: Cohort study including 43 CNO/SAPHO patients not using immunomodulatory or antiresorptive medications with Na18F-PET/CT performed at our expert clinic between 2019-2022. Images were qualitatively assessed following a systematic reporting format. Maximal standardized uptake values (SUVmax) were determined in the following areas as defined by radiologic appearance on CT: osteitic areas (osteous lesions), inflamed ligaments or joint spaces (soft tissue lesions) and thoracic vertebrae 5 as reference bone (ref-bone).

Results: Qualitative assessment revealed sclerosis and hyperostosis of the manubrium as most prevalent radiologic features (present in 77% and 70%) and costae 1-2 (79% each). Calcification/ankylosis of the costoclavicular ligament was seen in 58%. Quantitative analyses showed higher SUVmax of osseous and soft tissue lesions compared to ref-bone (mean 22.5±26.9 vs. 11.3±3.9, p<0.001 for paired difference). Stratified per location, highest SUVmax was found in soft tissue lesions of the costoclavicular ligament followed by the manubriosternal joint (mean SUVmax 29hs of 29±13 and 25±8 respectively). SUVmax in soft tissue lesions positively correlated with erythrocyte sedimentation rate (Spearman correlation coefficient 0.546, p<0.01).

Conclusions: CNO/SAPHO patients display distinctive qualitative imaging features that are well-captured on Na18F-PET/CT, and also show higher SUVmax in osseous and soft tissue lesions compared to ref-bone. Diseased soft tissue lesions showed highest SUVmax. Considering Na18F precipitates in young osteoid, these high values may reflect the process of soft tissue ossification that is disease duration. Sodium fluoride-18 positron emission tomography/CT (Na18F-PET/CT) is another imaging modality which produces quantitative data on the spatial distribution of bone turnover that also correlates with clinical disease activity in other metabolic bone diseases [4].

BIOLOGICS AND JAK INHIBITORS EFFICACY IN VESXAS SYNDROME FROM FRENCH MULTICENTER CASE SERIES OF 256 PATIENTS

Keywords: Innate immunity, Adaptive immunity, Inflammatory arthritides

A. Mekian1, R. Bourguiba2, B. Terrier3, K. Olivier4, T. Comont2, P. Fenaux5, S. Georgin-Lavialle6, Saint Antoine, Internal Medicine, Paris, France; 2Timis
Background: A new autoinflammatory syndrome related to somatic mutations of UBA1 was recently described and called VEXAS syndrome.

Objectives: To describe clinical characteristics, laboratory findings and outcomes of VEXAS syndrome.

Methods: Case-series. Patients referred to a French multicenter registry between November 2020 and January 2022. Frequency and median of parameters and vital status, from diagnosis to the end of the follow-up.

Results: Among 256 patients, 207/221 (94%) were males with median age at diagnosis 65 years [49-86]. Main clinical features were skin lesions (n=215; 84%), non-infectious fever (n=121; 47%), lung involvement (n=146; 57%), relapsing chondritis (n=69; 27%), venous thrombosis (n=128; 50%), lymph nodes (n=55; 21%), and arthralgia (n=65; 25%) with arthritis (n=26). Ocular inflammatory involvement was present in 119 cases (46%), mainly uveitis (n=21) and scleritis/episcleritis (n=43). Peripheral nervous system was noted in 18 patients (7%) with peripheral neuropathy (n=11), multinerves (n=3) and PIDD (n=5). The skin lesions were mainly neutrophilic dermatosis (n=74) and vasculitis (n=45). Hematological disease was present myelodysplastic syndrome (MDS, n= 81; 32%), monoclonal gammopathy of unknown significance (n=18), chronic myelomonocytic leukemia (n=7), AA amyloidosis was present in 2 cases. Median CRP levels were at 56 [1-423] mg/l, with abnormal somatic mutations in 44 cases (%).

Conclusion: This is the largest multicenter cohort of VEXAS syndrome and which allow to compare for the first time the efficacy and tolerance of various biologics and JAK inhibitors and seem confirm the benefit of JAKi and also of those allowing to compare for the first time the efficacy and tolerance of various biologics and JAK inhibitors and seem confirm the benefit of JAKi and also of those therapies with severe manifestations (grade 3): 1 (4.8%) case of inflammatory arthritis, 1 (4.8%) case of neuropsychiatric involvement and 1 (4.8%) of xerostomia, and 1 (4.8%) of Raynaud’s phenomenon with ulcers.

AB1457 MULTIDISCIPLINARY PROSPECTIVE STUDY OF PATIENTS TREATED WITH IMMUNE CHECKPOINT INHIBITORS WHO DEVELOPED RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS

Keywords: Descriptive Studies, Organ damage, Epidemiology

M. D. C. López González, N. Martinez Banaclocha, M. García Araque, Y. Montoyo Pujol, M. André, Hospital General Universitario Dr. Balmis-ISABIAL, Rheumatology, Alicante, Spain; Hospital General Universitario Dr. Balmis-ISABIAL, Oncology, Alicante, Spain

Background: Immune checkpoint inhibitors (ICIs), by activating the immune system specifically, T-cells, foster the reaction against tumor cells. However, parallels, autoimmune phenomena, known as immune-related adverse effects (ir-AEs) (PMID 33902919, 29442540), can be triggered and manifest in any organ or tissue. The most common rheumatic manifestations are inflammatory arthritis, polymyalgia rheumatica, and myositis, but other inflammatory conditions have also been described (PMID 32403289). More data on their frequency and characterization are needed.

Objectives: To prospectively evaluate the incidence of rheumatic ir-AEs during ICIs treatment, along with clinical characterization, management required, and outcomes.

Methods: An observational, prospective study was conducted at a tertiary center in Spain, led by the oncology department with the participation of several specialties, to evaluate the occurrence of ir-AEs in patients starting ICIs between January 2019 and April 2022. Participants were routinely followed at oncology clinics to detect ir-AEs through pre-specified clinical and laboratory assessments. For rheumatic symptoms, ir-AEs were studied by records review and evaluated in person at rheumatology clinics for those with a degree of involvement of ≥2, according to the ASCO criteria [3]. The incidence - with a 95% confidence interval (CI) - and characterization of defined rheumatic ir-AEs are presented here.

Results: Of 181 patients, 21 (11.6%, 95%CI 7.7-17.1%) developed rheumatic ir-AEs, 13 men (61.9%) with a median age of 62.3 years (p25-75 51.8-75.0). The median time from the start of ICIs to the development of rheumatic ir-AEs was 89 days (p25-75 51.5-165). Blood tests for autoimmunity were positive in 69.2% of available cases (9/13), but all at a low titer (table 1). According to ASCO guidelines, most patients had a toxicity grade 1-2, but 3 (14.3%) patients presented with severe manifestations (grade 3): 1 (4.8%) case of inflammatory arthritis, 1 (4.8%) of xerostomia, and 1 (4.8%) of Raynaud’s phenomenon with ulcers. 9 (42.9%) patients also presented with concurrent ir-AEs of different types.

Type of tumorDrug n (%) Clinical presentation (%) Antibodies n (%) Treatment n (%) Outcome n (%) Lung Pembrolizumab 9 (42.9) Inflammatory arthritis 8 (38.1) No rheumatological discontinuation treatment of ICI due progression 10 (47.6) Melanoma Nivolumab 7 (33.3) Anti- 3 (14.3) Anti-ubiquitin 4 (19.0) Hodgkin’s lymphoma Nivolumab + Ipilimumab 5 (23.8) Polymyalgia 1 (4.8) Discontinuation of ICI due to severe ir-AEs 6 (28.1) Kidney Azelizoluzumab 2 (9.5) Syndrome 1 (4.8) Pilocarpine 1 (4.8) Enzephalitis 2 (9.5) MYOS 1 (4.8) NSADs 1 (4.8) Mesthrelhoma 2 (9.5) Raynaud’s 1 (4.8) Discontinuation of ICI due to severe ir-AEs 1 (4.8)

Table 1.

Conclusion: Through a prospective and multidisciplinary study, we estimated an 11.6% occurrence of rheumatic ir-AEs in patients under ICIs. Most presented with mild or moderate involvements, though severe cases were also seen. A coordinated approach with the oncologists is thus essential for patients treated with ICIs at risk of developing ir-AEs.

AB1458 TREATMENT UTILIZATION, SYMPTOMS, AND COMORBIDITIES IN DERMATOMYOSITIS: AN ANALYSIS OF ELECTRONIC MEDICAL RECORDS IN THE UNITED STATES

Keywords: Comorbidities, Myositis, Real-world evidence

A. Kielhorn, Z. Wang, K. Moy, L. Christopher Stine, E. L. Lundberg, H. Chingoy, K. Gunter, R. Aggarwal, A. Alexson, AstraZeneca Rare Diseases, Research and Development, Boston, United States of America; Johns Hopkins University, Department of Medicine, Baltimore, United States of America; Karolinska Institute, K2 Department of Medicine, Stockholm, Sweden; University of Manchester, Department of Rheumatology, Manchester, United Kingdom; Patient Author, N/A, Norfolk, United States of America; University of Pittsburgh, Department of Medicine, Pittsburgh, United States of America

Background: Dermatomyositis (DM) is a rare, chronic inflammatory disease characterized by skin manifestations and/or progressive muscle weakness and other systemic manifestations. Prior analyses have reported higher morbidity, hospitalization rates, and mortality among patients with DM compared with matched controls [1-3], however, more recent data on the disease burden and treatments for DM are warranted.

Objectives: We conducted this analysis to provide updated data on the treatment utilization, symptoms, and comorbidities recorded for patients with myositis DM in the United States.

Methods: This was a descriptive, retrospective cohort analysis that used TriNetX US electronic medical records (EMR) of adults who had been diagnosed myopathic DM in the United States (ICD-9 codes: 710.3/C0-10; M33.1x, M33.9x, M36.0) between 1 January 2007 and 1 September 2020. Key inclusion criteria were: age ≥18 years at index date (i.e., date of DM diagnosis), ≥6 months of baseline data before the index date, and ≥6 months of follow-up after the index date. Assessments included utilization rates for medications of interest prior to the index date, percentage of patients who received ≥2 consecutive unique non-steroidal immunosuppressive therapies within 12 months of the index date, classification and qualification of the most common post-index symptoms and comorbidities, along with their comparison to pre-index values.

Results: The TriNetX database contained 1097 patients with DM (mean age: 54.6 years; sex: 77% female). The mean observation period was 9.7 years (6.0 years pre-index; 3.7 years post-index). Prior to the DM index date, 60% of patients

1596
05/13/23 4 Color Fig(s):0 22:59 Art: 47 EUROAB-2023-P046-47 Scientific Abstracts
were prescribed steroids and 24% were prescribed ≥1 non-steroidal immunosuppressive therapies. Within 3, 6, and 12 months of index date, 8%, 14%, and 20% of patients, respectively, received ≥2 immunosuppressive therapies (ISTs). A 2-fold increase in percentage was seen when compared with pre-index for a wide range of symptoms and comorbidities, including gastroesophageal reflux disease (43% and 22%, respectively), anxiety (25% and 13%), interstitial lung disease (28% and 10%), and osteoporosis (21% and 6%).

Conclusion: In this analysis of TrinetX EMR data, the majority of patients who were diagnosed with myopathic DM had received immunosuppressive therapies for an extended time to treat their symptoms before they received a formal DM diagnosis, which may have contributed to the delay in DM diagnosis. One fifth of patients had received ≥2 ISTs within 12 months of DM diagnosis, suggesting that even after receiving standard of care treatments, many patients experience DM symptoms that are difficult to control and/or tolerate. A wide range of symptoms and comorbidities increased post-DM diagnosis suggesting that even after receiving standard of care treatments, a formal DM diagnosis, which may have contributed to the delay in DM diagnosis.

Background: IgG4 immunoglobulin-related disease (IgG4-RD) is a rare, systemic immune-mediated fibro-inflammatory process with unclear etiology and pathophysiology. It can affect multiple organs that encompass common pathophysiological, serological and clinical characteristics.

Objectives: To describe the heterogeneity of the clinical presentation, evolution, and treatment of patients diagnosed with IgG4-RD and compare the performance of the last two IgG4-RD classification and diagnostic criteria.

Methods: Single-center retrospective study in which patients with a possible diagnosis of IgG4-RD from various hospital departments are studied from January 2010 to August 2022. Some exclusion criteria were applied (patients with clinical manifestations attributable to other diseases were excluded) and to those who remained with a suspected diagnosis of IgG4-RD, the Umehara-Okaaki 2011 and ACR/EULAR 2019 criteria were applied.

Results: 182 patients with elevated IgG4 and/or a suspected diagnosis of IgG4-RD were collected. Finally, after exclusion criteria, 22 possible patients with IgG4-RD remained (Table 1). The diagnosis was confirmed by Umehara a diagnostic criteria proposed by Umehara-Okaaki in 2011 and applied to these patients, including a total of 13 patients, with a mean age of 60 years, 57% women; 5 being classified with definitive disease, 3 as probable disease and 5 as possible disease. Finally, we applied the ACR/ EULAR 2019 classification criteria to those patients too, establishing diagnosis in 7 patients. The mean age was 57 years, 71% were women with a mean follow-up of 5.3 years; 85.71% of the patients had elevated IgG4, with mean levels of 176.3mg/ dl. Retropertitoneal fibrosis and aortitis was the most prevalent presentation in both groups (2011 and 2019 criteria) with 38.5% and 28.6% respectively.

Conclusion: IgG4-RD is a recently described entity that is very heterogeneous in terms of its clinical, analytical and histopathological presentation. According to our series, clinical heterogeneity is the rule, being the retropertitoneal fibrosis and aortitis the most frequent. There are differences when we use the different criteria. ACR/EULAR 2019 classification criteria are stricter criteria that allows us to classify patients more accurately. In our series 6 patients fulfilled Umehara-Okaaki criteria but not ACR/EULAR due to giving more importance to histopathology, clinical manifestations and the need to reach a minimum score in which, for example, only IgG4 levels are not enough. Therefore, on many occasions, a multidisciplinary approach with experienced teams is necessary.

Background: The exact pathogenesis and risk factors of Palindromic Rheumatism (PR) remain uncertain, however, a subgroup of patients with PR share a close relationship with rheumatoid arthritis (RA) in terms of etiopathogenesis, clinical features, serology, and outcomes.

Objectives: We aim to describe the characteristics of patients in an inception cohort of PR along with determinants of progression to RA.

Methods: Patients with symptoms suggestive of PR were screened by a rheumatologist and after relevant exclusions, were classified into PR and included in an inception cohort at the Centre for Arthritis and Rheumatism Excellence, India. Their demographics, clinical characteristics, serology, inflammatory markers, and progression to RA or any other autoimmune rheumatic disease (AIRD) were recorded. Statistical analysis was done using GraphPad Prism v9.4.1 and results are expressed as mean ± standard deviation.

Results: Of 706 patients screened, 685 were classified into PR (age 45.5±11.9 years, male-to-female ratio of 1:2.8) with a follow-up duration of 27±20.4 months. Of those with a follow-up of greater than one year, 102 of 505 (20.2%) progressed to RA at 30±20 months and 13 to other AIRDs. Progression to RA was positively associated with symptom duration of <5 years, wrist involvement, and anti-CCP positivity were associated with progression to RA. The RF and anti-CCP titers were compared between treatment groups.

Conclusion: Early outcomes of the inception cohort of PR revealed progression to RA in 20% of the cohort and was associated with symptom duration of <5 years, wrist involvement, and anti-CCP positivity.

Objectives: to fully evaluate the disease's activity [1].

Background: Adults Still's disease is a rare autoinflammatory disorder with an unknown etiology, characterized by fever, arthritis, and rash. There is no method to fully evaluate the disease's activity [1].

Results: The Still Activity Score (SAS) is a newly defined, easy-to-use disease activity assessment score for Still disease [2]. We aimed to compare the efficacy of the Modified Pouchot Activity Score (mPouchot), Systemic Feature Score (SFS), and Still Activity Score (SAS) [2-4].

Methods: The study included 45 patients diagnosed with Still between 2010 and 2022 who met the Yamaguchi criteria. The patients were assessed using the physician global assessment (PGA) by two different physicians. Still, activity levels were computed. According to the severity of the disease, patients with PGA≥6 were categorized as having low disease activity, and those with PGA>6 as having high disease activity.

Results: The demographic, clinical, and laboratory data for the patients are detailed in Table 1. There was a significant difference between the two groups in terms of mPouchot and SFS disease activity scores (low and high disease activity) (Table 1). CRP level was correlated with the SAS, SFS, and mPouchot disease activity scores (low and high disease activity) (Table 1). There was a correlation between each score (p<0.001). There was a significant difference between the two groups in terms of mPouchot and SFS disease activity scores (low and high disease activity) (Table 1). There was a correlation between each score (p<0.001).

Conclusion: SAS, a new disease activity score, correlated with previous activity scores. CRP levels were correlated with SAS. There was a correlation between the three disease activity scores.

Background: the main cause of blindness in non-infectious uveitis is cystoid macular edema (CME). Behget’s disease (BD) is one of the most common diseases associated with CME [1-3].

Objectives: to compare efficacy and safety of Adalimumab (ADA), Infliximab (IFX) and Certolizumab (CZP) in refractory CME due to BD.

Methods: multicenter study of patients with CME secondary to BD refractory to glucocorticoids (GC) and at least 1 conventional immunosuppressant. All patients had CME (CME>300μ) at baseline. From baseline up to 2 years, efficacy of ADA, IFX and CZP was assessed with the following ocular parameters: macular thickness, visual acuity (BCVA), anterior chamber (AC), vitritis and GC-sparring effect. Statistical analysis was performed with IBM SPSS Statistics v.23.

Results: a total of 50 patients (78 eyes) were considered. Twenty-five patients were treated with ADA, 15 patients with IFX and 10 patients were treated with CZP. No significant differences in demographic parameters were observed in the three groups. However, patients in the CZP group had a significantly longer time from diagnosis to drug initiation (75 [36-120] vs 30 [12-82] vs 15 [8-60] months; p=0.04) and received a greater median number of biological treatments (2 [0.75-3] vs 0 [0-0] vs 0 [0-0]) than the ADA and IFX groups. In CZP group, ADA and IFX were used previously in 7 patients. Combined therapy was used with ADA in 64%, with IFX in 66.7% and with CZP in 70% of CME patients (p=0.04) (TABLE 1).

Regarding efficacy outcomes, a rapid and maintained improvement in macular thickness was observed after 2 years of follow-up in three groups with no statistically significant differences between them (FIGURE 1). Improvement in BCVA, AC cells, vitritis and GC-sparring effect was also noted. No serious adverse events were observed in IFX and CZP group.

Conclusion: ADA, IFX and CZP seem to be effective and safe in refractory CME due to BD. CZP appears effective even in patients with inadequate response to ADA and/or IFX.

CAUSAL RELATIONSHIPS BETWEEN PHYSICAL ACTIVITIES, LEISURE SEDENTARY BEHAVIORS, AND ADULT-ONSET STILL DISEASE OUTCOMES

Keywords: Rare/orphan diseases, Self-management, Genetics/Epigenetics

Y. J. Chen1,2, W. Li1,2, Q. Feng1,2, Y. Feng1,2, Q. Yu1, P. F. He3, X. Li1,2, S. X. Zhang1,2,3,4, Shanxi Provincial Key Laboratory of Rheumatism Immune Microenvironment, Shanxi Medical University, Taiyuan, Shanxi Province, China; 2Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, Shanxi Province, China; 3Shanxi Key Laboratory of Big Data for Clinical Decision Support Research, Shanxi Medical University, Taiyuan, Shanxi Province, China; 4The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China

Background: Adult-onset Still’s disease (AOSD) is a characteristic non-familial, multi-genic systemic auto-inflammatory disorder, characterized by fever and joint pain [1]. Whether physical activities (PAs)/leisure sedentary behaviors (LSBs) directly affect AOSD susceptibility is inconclusive.

Objectives: This study aimed to investigate the causal effects of PAs and LSBs on AOSD.

Methods: We performed a two-sample Mendelian randomization (MR) analysis to investigate the causality of 5 PAs and 4 LSBs with AOSD, of which PAs include accelerometer-base physical activity measurement (average acceleration) (n=91,084), vigorous physical exercise 10+ minutes (n=440,512), and LSBs include the length of mobile phone use (n=456,972), time spent watching television (TV) (n=437,887). Genome-wide significant genetic instruments (p < 5 × 10−8) for PAs and LSBs were extracted from European-descent genome-wide association studies (GWASs). And to satisfy the assumption that single-nucleotide polymorphisms (SNPs) were not related to outcomes, one SNP with the IVW method revealed no heterogeneity (p=0.43), and no pleiotropy was observed (p=0.618). However, the IVW results of SNPs were not statistically significant (p > 0.05), so PAs were not associated with AOSD (Figure 1).

Conclusion: Our findings suggest the hypothesis that time spent driving increases the risk of AOSD, suggesting leisurely sedentary behaviors may increase the probability of AOSD.

AB1466 CLINICAL FEATURES OF PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER OVER 50 YEARS OF AGE

Keywords: Inborn immunity, Genetics/Epigenetics, Rare/orphan diseases

S. N. Baspinar1, M. B. Yuzbasigil2, S. Yenigun1, F. N. Azman1, S. Ugurlu2.

Background: Familial Mediterranean Fever (FMF) is the most common hereditary monogenic fever syndrome characterized by recurrent attacks of fever and polyserositis. Types and frequencies of attacks can change throughout the life of patients. The course of disease is affected by pathophysiological changes due to aging, increased comorbid diseases and multiple drug use.

Objectives: The objective of this study was to understand the effect of aging on clinical features and disease course in patients with Familial Mediterranean Fever.

Methods: 343 patients who were followed up with the diagnosis of FMF between 2005 to 2020 and were over 50 years old as of 2022 were included. The demographic characteristics of the patients, MEFV mutations, attack characteristics and the treatments they received were analyzed retrospectively. Attack characteristics, frequency of attacks andVAS scores of the patients were also analyzed and compared as pre-treatment, post-treatment, and most recent attacks.

Results: Female to male ratio was 1.8:1. The mean age of patients was 57.6±6.5 (50-84) years. Age of symptoms started, age at diagnosis and delay at diagnosis were compared between the female and male patients. At the age of symptoms started, no significant difference was detected between the two groups, while the age at diagnosis was later and the time of delay at diagnosis was longer in female patients (p<0.006 and p=0.001). Number and frequencies of attacks and VAS scores were compared as attacks before treatment, attacks after treatment and attacks in the last year, a significant decrease was found in the last attacks (p<0.001). The frequency of fever, abdominal pain, arthritis and chest pain was significantly lower in the most recent attacks compared to pre-treatment and post-treatment (p<0.001). The last attacks of the patients were mostly in the form of abdominal pain. Patients were compared as those who did not have an attack in the last year and who had an attack, it was seen that the mean age was lower in the group that had an attack (p<0.005). The mean of current colchicine dose was 1.29±0.43 mg, the mean dose of colchicine at diagnosis was 1.37±0.36 mg and the mean of maximum colchicine dose was 1.6±0.43 mg.

CONCLUSION:

Demographic Status, Patients (n:343)

POTENTIAL TRIGGERS OF FAMILIAL MEDITERRANEAN FEVER ATTACKS

Keywords: Rare/orphan diseases

M. B. Ates1, K. Parlar2, E. Bostancı1, E. Onal1, S. Ugurlu1, 1Cerrahpaşa Medical Faculty, University of Istanbul-Cerrahpaşa, Division of Rheumatology,Department of Internal Medicine, Istanbul, Turkey; 2Yeditepe Medical Faculty, University of Yeditepe, Division of Rheumatology, Department of Internal Medicine, Istanbul, Turkey

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by self-limited 1 to 4 days lasting attacks. These attacks are characterized by fever, abdominal pain, chest pain, arthritis, arthralgia, myalgia, and erysipelas-like rash that is over the affected joint. Mutations of the pyrin protein which encodes by the main mutated gene of FMF, MEFV, are responsible for the inflammasome overactivation and subsequently responsible for attacks and the main underlying occurring pathophysiology of FMF[1]. The role of the factors that can contribute to and trigger this process is on a large scale unknown.

Objectives: We aimed to search for the factors that can trigger these attacks or can increase the severity of attacks. We prepared some criteria based on our clinical observations to determine the factors that can trigger pyrin protein-associated inflammasome mechanisms that are the underlying cause of FMF[1].

Methods: We surveyed 808 patients with FMF from our adult rheumatology outpatient clinics. We used a questionnaire assessing the following: emotional stress; use of antidepressants; consumption of tea and coffee; relationship with menses; menopause and post-menopausal alleviations; seasonal changes; long-term journeys; changes of location; starvation; sleeplessness; temperature reduction; fatigue; wind and cold weather; and humidity(Table1). We also questioned some features of the attacks of patients including fever, abdominal pain, chest pain, arthritis, arthralgia, myalgia, and erysipelas-like rash.

Results: The number of patients with FMF and their potential trigger factors are given in Table 1. We performed the questionnaire to 808 patients with FMF (354 male and 454 female), 574 patients (%71) reported worsening in severity and frequency of their attacks in relation to emotional stress. Among these 574 patients, 139 patients (%24) were using antidepressants. 443 and 474 patients reported worsening and higher frequency of their attacks in relation to seasonal changes and fatigue, respectively. Among the 454 female patients, 213 patients reported worsening during their menses cycle. 96 female patients had entered menopause and 50 of them (%52) had reported obvious improvement after their menopause. In our cohort, 530 patients had experienced fever, 642 abdominal pain, 426 chest pain, 350 arthritis, 573 arthralgias, 483 myalgias, and 152 erysipelas-like rashes during their attacks.

Conclusion: The high proportion of patients who had reported worsening in their attacks in relation to emotional stress highly suggests a correlation between emotional stress and FMF attacks. Additionally, 443 and 474 patients had reported worsening in their attacks when seasonal changes occur and in times of fatigue, respectively, which is also highly suggestive of a correlation with FMF attacks.

There was also an outstanding decrease in the severity of their attacks in patients who had menopause after they entered menopause. Furthermore, there were some patients who reported miscellaneous correlations in the frequency of FMF attacks and with the use of antidepressants, consumption of tea and coffee, seasonal changes, long-term journeys, changes in location, starvation, sleeplessness, temperature reduction, fatigue, wind and cold weather, and lastly, humidity.

ENTEROPATHY IN DUTCH COMMON VARIABLE IMMUNODEFICIENCY COHORT

Keywords: Disease-modifying Drugs (DMARDs), Gastrointestinal tract, Descriptive Studies

N. Juliana1, M. Sevens2, J. Van Montfrans3, P. Eillerbroek4, B. Oldenberg2, J. Van Roon1, H. Lewis1, 1UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands; 2UMC Utrecht, Gastroenterology, Utrecht, Netherlands; 3Wilhelmina Children’s Hospital, Pediatrics, Immunology and Rheumatology, Utrecht, Netherlands; 4UMC Utrecht, Infectious Diseases, Utrecht, Netherlands

Background: Common variable immunodeficiency (CVID) is the most common severe primary antibody deficiency. Although infections are the most prevalent clinical manifestations, a large amount of the patients also suffer from immune dysregulation. This results in significant morbidity[1]. Different manifestations of enteropathy can occur, yet little information is available regarding its optimal treatment.

Objectives: Here we describe clinical characteristics, endoscopy, histopathology and treatment response of CVID enteropathy (CVID-E) in a Dutch teaching hospital.

Methods: We included CVID patients from our hospital, that provided written informed consent. We collected, retrospectively, gender, age and start of enteropathy, symptoms, and age at CVID diagnosis. Reports of endoscopies and histopathology, and clinical course of enteropathy related symptoms was recorded for each patient alongside the immunosuppressive medication (IS) used over time. Treatment response was defined as remission, response, need for step-up, and unknown. Descriptive statistics were used to study associations.

Results: 32 of 82 CVID patients at the UMC Utrecht had enteropathy. The average age of this group was 45.4 (13.5 standard deviation, SD) and the mean age of CVID diagnosis was 31.7 (16.7 SD). The age at first presentation of enteropathy was 30.9 years (14.6 SD). 16 of 32 patients were female. 23 (90.6%) of CVID-E patients had other complications: infectious, inflammatory and malignant. 26 (81.3%) patients had other inflammatory manifestations; the most common were lymphoproliferation (43.8%) splenomegaly (34.4%) and autoimmune disease (37.5%). Infectious complication bronchiectasis had a prevalence of 88.6% in this cohort. Two patients had a solid malignancy and one lymphoma. We compared CVID-E treated with IS to those who were not treated with IS. Autoimmune cytopenia, and bronchiectasis were significantly more prevalent in CVID-E treated with IS, than those without IS: 23.5% vs 0% (P<0.05) and 82.4% vs 46.7% (p<0.01) respectively. 30 patients underwent endoscopy, 29 (90.6%) coloscopy and 25 (78.1%) gastroscopy. The most common histopathologic findings consisted of inflammatory bowel disease-like colitis (n=10) and intra-epithelial lymphocytosis (n=9). Other findings of note were lymphocytic colitis(n=3), microscopic colitis (n=2), collagenic colitis (n=1) and apoptotic enteritis (n=1). 17 of the 32 (53.1%) patients received IS for CVID-E. 14 received local corticosteroids, 12 systemic corticosteroids, 15 DMARDs (methotrexate, azathioprine, mesalazine, baricitinib, mycophenolate, tacrolimus and sulfasalazine), 6 biologicals (adalimumab, infrlixab and ustekinumab) and 6 had combined therapy. These 17 patients underwent 64 treatments. Local CS therapy did not result in remission. 9/17 (52.9%) of patients needed more than 2 systemic drugs. DMARD monotherapy achieved remission or response in 6 of 13 patients (46.2%). The best results concerning combined therapy in this cohort seemed to consist of combinations of DMARD(s) and systemic CS, and combinations of DMARD(s) and TNF-alpha inhibitors (TNFi).

Conclusion: CVID-E is strongly associated with other inflammatory complications and bronchiectasis, especially in CVID-E on IS. This cohort consists of the largest series reporting on treatment efficacy in CVID-E. We found combination treatment and DMARD monotherapy to be the most effective treatment. Additionally, TNFi seems to have a good clinical response in patients with CVID enteropathy, especially when combined with other treatments.

HEPATICITY C IN IDIOPATHIC INFLAMMATORY MYOPATHIES: DIFFERENCES IN DISEASE PRESENTATION AND PATIENT MANAGEMENT

Keywords: Comorbidities, Myositis

A. Valle, S. Mahmood1, Montefiore Hospital, Medicine, Bronx, United States of America; Montefiore Medical Center; Einstein Campus, Division of Rheumatology, Bronx, United States of America

Background: It is known that Hepatitis C (HCV) can cause many extra-hepatic manifestations which overlap with rheumatic diseases. New evidence is emerging that both HCV and idiopathic inflammatory myopathies (IIMs) may have a common mechanism through B cell expansion and dysfunction [1,2].

Objectives: Our aim was to describe the prevalence of HCV in patients with IIM and to compare myositis disease course, organ involvement, and rheumatologic treatment response between IIM patients with and without HCV.

Methods: A registry was created of Montefiore Medical Center patients that met 2017 EULAR/ACR classification criteria for IIM. Demographics, IIM type, antibody clinical manifestations, comorbidities, and rheumatologic treatment history were documented. HCV antibody, viral load, and hepatitis treatment history were noted. Rheumatic medication failure was defined by rheumatologist, discontinuation due to adverse effects, or medication change within 3 months while medication control was defined by documented clinical improvement. Statistical analyses included two-sample t-test, Chi-square tests or Fisher’s exact tests were used to compare the categorical variables as appropriate and signed rank test.

Results: Of 153 patients in the registry, 130 (85%) had been screened for Hepatitis C and 8 (5.5%) had HCV (p = 0.02, p = 0.01, respectively). There were no differences in age, race, ethnicity, or treatment between IIM patients with and without HCV. Of the 11 patients with HCV while neoplasms were more frequent in the same group (p = 0.05), heliotrope (p = 0.05), or others rashes such as holster, shawl, V sign (p = 0.02). Interstitial lung disease (ILD) was less prevalent in individuals with HCV while neoplasms were more frequent in the same group (p = 0.02, p = 0.01, respectively). There were no differences in age, race, ethnicity, or treatment between IIM patients with and without HCV. Of the 11 patients that had HCV, 8 (73%) were diagnosed with HCV within 1 year of IIM diagnosis and majority (4/6) had active HCV at that time based on viral load. The others had been diagnosed with HCV for 5-10 years prior to the IIM diagnosis. For majority of HCV cases (6/11), rheumatology evaluation prompted hepatology evaluation and/or treatment.

Conclusion: Individuals with CVC may have different disease course than individuals without HCV, specifically one with a higher frequency of neoplasms and a lower frequency of IIM and dermatologic manifestations. IIM diagnosis was usually a key time to discover a concomitant HCV infection and often led to change in HCV evaluation and treatment. These findings and their immunologic basis should be further studied in larger cohorts with more power.

Table 1. Comparison of IIM subtype, disease manifestations, comorbidities, and treatment between HC¥+ and HCV- IIM patients.
Objectives: In this prospective study, we aimed to evaluate the risk of PTS development after DVT and the factors affecting the development and severity of PTS in BD patients.

Methods: BD patients (n=18) with acute DVT and were followed in 3 tertiary rheumatology centers were included in the study. Patients are evaluated for PTS presence during acute DVT, 6-12 months and then annually. Villalta scoring with a total score of >4 or presence of venous ulcer was defined as PTS. PTS was classified as mild if the score was between 5-9, moderate between 10-14, and presence of >14/venous ulcers as severe. Venous Damage Score (VDS) was used to evaluate the effect of venous disease on work productivity and Venous Clinical Severity Score (VCSS) for symptom severity.

Results: The clinical features of the 18 patients included in the study are shown in Table 1. Major-organ involvement was present in 12 patients (pulmonary involvement in 7 (39%), ocular involvement in 5 (28%), arthritis in 3 (13%), neurobehçet and entero-behçet each in 1 patient). Steroid and IS treatment was given to all patients after an acute DVT attack. Additional anticoagulant (AC) treatment was chosen in 16 of the patients. Patients were followed up for a median 23.2 (6-40) months after DVT. The number of patients followed for at least 1 year after an acute DVT attack was 15, and the median follow-up period was 26 (12-40) months. The median duration of AC use in patients who received AC treatment in the follow-up was 6 (0-12) months. PTS developed in 5 (33%) of 15 patients during follow-up. The baseline, 6th and 12th month course of Villalta, VCSS, and VDS scores are shown in figure 1.

Conclusion: In this prospective follow-up after an acute DVT attack 33% of BD patients developed PTS within 1 year. In our previous retrospective study, 62% of 205 patients, half of whom received AK, developed PTS during follow-up [2]. Despite the limitations of our study, such as the low number of patients and the short follow-up period, AC treatment in all patients (except 1) may have influenced a lower PTS development in the prospective follow-up compared to the retrospective data.

Background: The most common autoinflammatory disease which occurs in Armenians is familial Mediterranean fever (FMF). FMF is a hereditary disorder caused by recurrent attacks of fever and serosal inflammation. The main clinical manifestations of FMF are recurrent fever, abdominal, chest and joint pain, erysipelas-like skin lesion but FMF also has a lot of other rare and systemic clinical manifestations. Sometimes it is difficult to distinguish if the patient has only FMF or the overlap of FMF and other rheumatological diseases: systemic lupus erythematosus (SLE), systemic vasculitis, spondyloarthropathy, etc.

Methods: 100 Armenian patients with genetically confirmed FMF, who also fulfilled Tel-Hashomer classification criteria were included in this study. Molecular-genetic detection of 26 MEFV mutations which are more common among Armenians was carried out. Only 13 patients from 100 had systemic clinical manifestations like lupus, so we continued investigation and determine ANA, anti-dsDNA antibodies, which were positive. All patients with lupus-like syndrome fulfilled diagnostic criteria of SLE by ACR. Comparison of peculiarity of course of FMF was done between 13 patients - between both lupus-like syndrome and FMF (group I) and patients only with FMF (group II).

Results: There were 11 female and 2 male patients in the first group. The mean age was 40.06±2.46. The 15.4% of the patients were affected with FMF and lupus-like syndrome/ SLE parallelly and in 30.3% cases the onset of SLE was prior to the clinical manifestation of FMF. They all had systemic clinical manifestations such as erythema (92.3%), livedo reticularis (69.2%), photosensitivity (69.2%), Raynaud’s phenomenon (23.07%). Though the frequency of FMF attacks in the I group was more than in the II group, the high temperature and shorter duration of attack days; thoracalgia and monoarthritis also appeared less frequently in the patients with FMF. The difference between the clinical manifestations is presented below (Table 1). The prevalent mutation of MEFV gene in both groups was M694V- in 19 patients (73%), from which 3 (11.5%) were homozygote and 23 (88.5%) were heterozygote.

Table 1. Clinical manifestations I group (FMF with coexisting SLE) II group (only FMF)%

Conclusion: In conclusion, both diseases FMF and SLE have common clinical manifestations: fever, arthralgia, arthritis, skin involvement, pleuritis, pericarditis. The course of FMF with coexisting SLE is milder: these patients have lower frequency of FMF attacks in the I group was more than in the II group, the high temperature and shorter duration of attack days was respectively 1-3 and 1-5. We noticed that thoracalgia and monoarthritis also appeared less frequently in the patients with FMF. The difference between the clinical manifestations is presented below (Table 1). The prevalent mutation of MEFV gene in both groups was M694V- in 19 patients (73%), from which 3 (11.5%) were homozygote and 23 (88.5%) were heterozygote.

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS AMONG ADULTS

**Keywords:** Organ damage, Systemic lupus erythematosus

M. Ben Brahimi¹, S. Daada², S. Arfa³, M. Wafa³, H. Ben Brahmi⁴, O. Berinche⁵, S. Hammam⁶, M. Chakroun⁷, ¹Isher Star University Hospital, Mahmoud, Department of Internal Medicine, Mahmoud, Tunisia; ²Fatouma Bourguiba University Hospital, Monastir; ³Department of Internal Medicine, Monastir, Tunisia; ⁴Isher Star University Hospital, Mahmoud, Department of Internal Medicine, Mahmoud, Tunisia; ⁵Fatouma Bourguiba University Hospital, Monastir; ⁶Department of Infectious Disease, Mahmoud, Tunisia

Background: Hemoophagocytic Lymphohistiocytosis (HLH) is a rare life-threatening condition resulting from an overstimulation of the immune system leading to a multi-organ damage[1]. This condition can be either primary caused by genetic mutations or secondary triggered by infections, autoimmune diseases or malignancies[1].

Methods: We performed a multi-center retrospective study in the departments of Internal Medicine and Infectious Diseases in both Fatouma Bourguiba and Taher Star University hospitals in Tunisia. We identified 38 patients meeting the HLH-2004 diagnostic criteria.

Results: There were 24 women and 14 men. The male/female sex ratio was 0.58. The mean age was 38 years (range 18-80 years). Eight patients (21%) had underlying auto-immune disease: 6 patients had systemic lupus erythematosus, 1 patient had rheumatoid arthritis and 1 patient had idiopathic thrombocytopenic purpura. Five patients (13.5%) had underlying malignancy. Among the clinical and biological variable of the HLH criteria, the most common features were fever (100%) followed by elevated ferritin level (94.7%) and cytopenia (84.2%). Triglyceride level was elevated in 76.3% of patients. Hemophagocytosis in bone marrow was found in 38 patients (92.1%). Elevated lactate dehydrogenase was found in 76.3% of cases. The most common underlying etiologies were systemic lupus erythematosus (31%) followed by infections (24%), malignancies (16%) and adult still's disease (13%). In our study, 30 patients (78.9%) underwent intravenous immunoglobulin regimen over 2 days. Twenty-three patients (60.5%) received either intravenous and/or oral steroids. Ethoposide was prescribed in 4 cases. The overall mortality in our study was 39.5%. Twenty-three patients achieved remission with 6 relapsing later. Mean cause of relapses was infections. Patients aged above 65 years and patients with systemic lupus erythematosus had poorer prognosis (p<0.013). Patients with systemic lupus erythematous achieved remission more likely than other patients (p<0.021).

Conclusion: HLH is an uncommon but fatal disease. The clinical symptoms are non specific leading to misdiagnosis which is associated with a dismal prognosis. Similarly to the literature a female preponderance was found in our study[1]. Systemic lupus erythematosus was found to be the commonest underlying cause of HLH in our population which disagrees with the findings of similar studies who identified malignancy or infections as the principal trigger[2]. A combination of intravenous steroids and immunoglobulin infusions was prescribed in 47% of patients. This combination was proven to be effective as first line treatment [3]. Despite treatment mortality rates remained high in our populations (39.5%) especially among elderly.

**AB1474**

EFFECTIVENESS AND SAFETY OF CURRENT TREATMENT STRATEGIES FOR VEXAS SYNDROME: A SYSTEMATIC REVIEW

**Keywords:** Rare/orphan diseases, Systematic review

Z. Boyazdzhieva¹, N. Ruffer², I. Köter², M. Kruschke³, ¹Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; ²University Medical Center Hamburg-Eppendorf, Iii. Department of Medicine, Hamburg, Germany

Background: VEXAS syndrome is an adult-onset systemic autoinflammatory condition caused by an acquired deficiency of the UBA1 gene in hematopoietic progenitor cells. Its clinical course includes relapsing and refractory inflammatory conditions with high mortality. Optimal treatment strategies remain elusive and need further investigations.

Objectives: To investigate the effectiveness and safety of treatments for VEXAS syndrome.

Methods: A systematic review of the literature in line with the PRISMA guidelines was conducted: MEDLINE, Embase and Cochrane Central Register of Controlled Trials were searched for reports on treatment strategies for VEXAS. Treatment response was recorded as complete (CR), partial (PR) or none (NR) depending on changes in clinical symptoms and laboratory parameters. Patient characteristics, safety data and previous treatments were analyzed.

Results: We identified 32 publications with a total of 83 patients. 97.6% of patients were male. Mean age at disease onset was 68 years (reported for 80/83). Mean follow up was 15.7 months (reported for 23/83). The most common treatments included azacitidine (AZA) (39.8%, 33/83; CR was reported for 9 patients (27.3%, 9/33) and PR for 11 (33.3%, 11/33) (Fig. 1). Further reports included tocilizumab (13.3%, 11/83), allogeneic stem cell transplantation (ASCT) (6.4%, 7/83), glucocorticoid...
(GC) monotherapy (72.2%, 6/83), anakinra (3.6%, 3/83). Details on response are shown in Table 1. Data on adverse events was available for 29 patients (34.5%). Most common were infections (24.1%, 7/29), herpes zoster reactivation (6.7%, 2/29), cytopenias (13.8%, 4/29). The median number of previous treatments was 3 [IQR 2-5]. A total of 307 prior treatments were reported. In most cases (37.4%, 115/307), details on response and reasons for discontinuation were not reported. Nonresponse to therapy (30.2%, 58/192), GC dependence (22.4%, 43/192) and adverse events (11.9%, 23/192) were common triggers for therapy adjustment. Janus kinase inhibition has been reported to be beneficial in one case series (Heilig et al., 2022). Individual patient data from this study was not available and, thus, not included in this analysis.

**Conclusion:** The current data on VEXAS treatment mainly stems from case reports/series and is inhomogeneous. Reporting of treatment response varies, complicating conclusions on treatment efficacy. Most patients received multiple therapies with mixed results. AZA appears promising for a subset of patients. IL-6 inhibition seems beneficial, but a risk of infections should be considered. Ciclosporin was commonly used as an add-on to IL-1 inhibitors suggesting benefits of combination therapy. In general, adverse events are scarcely reported, which hinders an objective risk-benefit assessment.

**DOES VEIN WALL THICKNESS HAVE PROGNOSTIC VALUE IN BEHÇET’S DISEASE? A PROSPECTIVE FOLLOW-UP STUDY**

**Keywords:** Ultrasound, Behçet’s disease, Diagnostic Tests

K. Abacı1, R. Ergelen2, F. Temiz2, Y. Yıldız2, T. Ergun4, H. Dirsekene1, F. Albaz-Onel1, M. Marmara University, Rheumatology, Istanbul, Turkey; 2. Marmara University, Radiology, Istanbul, Turkey; 3. Marmara University, Internal Medicine, Istanbul, Turkey; 4. Marmara University, Dermatology, Istanbul, Turkey

**Background:** We reported the first controlled Doppler ultrasound study showing increased common femoral vein (CFV) thickness in Behçet’s Disease (BD) [1]. We also recently showed that increased CFV thickness is a distinctive feature of BD, rarely present in other inflammatory or vascular diseases with a specificity higher than 80% for the cut-off value of ≥0.5 mm. However, the association between CFV thickness and any organ involvement, disease course or treatment during disease course has not been demonstrated so far.

**Objectives:** This study aimed to assess the longitudinal course and prognostic value of CFV thickness measurement during a prospective follow-up BD patients.

**Methods:** In this study, we included 195 patients with a diagnosis of BD. The clinical demographic, treatment data and biomarkers were recorded during routine visits. Bilateral CFV thickness was measured with ultrasonography by an experienced radiologist at the same day. Patients were started to follow up prospectively with 3-6 months intervals and in any urgent visit.

**Results:** At baseline, 96.6% of patients had increased CFV wall thickness above the cut-off value of ≥0.5 mm. The baseline and last follow-up clinical characteristics were shown in Table 1. 139 of 195 patients had prospective clinical follow-up data with a mean of 26.5 (16.9) months. New major organ involvement or relapse leading to treatment change was seen in 39 (28%) patients. Among 22 (15.8%) patients with new major organ involvement, 12 had vascular, seven had ocular, two had neurologic and one had gastrointestinal involvement. Among 36 patients with only mucocutaneous disease at baseline, new major organ involvement developed in 9 patients during follow-up. These nine patients had higher baseline CFV thicknesses compared to patients without major organ involvement, however without reaching clinical significance (0.83 mm vs 0.73 mm for right CFV, 0.80 mm vs 0.73 mm for left CFV; p=0.05 for both) In 47 patients, the second CFV thickness measurement was done with a mean 19.6 months after the first visit. There was no statistically significan
t difference between the first and second CFV wall thickness measurements for both right and left CFVs (First vs. second for right CFV 0.79 vs 0.78 mm; p=0.26; for left CFV: 0.79 vs. 0.75 mm; p=0.26). We did not find any change in CFV wall thickness with the treatment modality, new organ involvement and relapses.

**Conclusion:** CFV wall thickness measurement with ultrasonography which is a new non-invasive diagnostic tool for BD, does not show a major change over time with treatment modality, new organ involvement or disease relapses. However, our preliminary results suggest that mucocutaneous BD patients with higher CFV thick-ness may have a higher risk for the development of major organ involvement during follow-up. The long term results of our prospective cohort with increased patient numbers would clarify the prognostic value of CFV thickness in BD.

**EVALUATION OF AUTOANTIBODIES POSITIVITY IN SARCOIDOSIS PATIENTS**

**Keywords:** Autoantibodies, Diagnostic Tests, Imaging
Background: Several studies reported serum positivity for anti-nuclear (ANA), extractable nuclear antigen (ENA) and antiphospholipid antibodies in sarcoidosis patients [1,2]. However, their clinical significance is still a matter of debate.

Objectives: Several studies reported serum positivity for anti-nuclear (ANA), extractable nuclear antigen (ENA) and antiphospholipid antibodies in sarcoidosis patients [1,2]. However, their clinical significance is still a matter of debate.

Methods: We enrolled 260 sarcoidosis patients (170 females and 90 males; mean age at diagnosis 46 ± 9), after giving written informed consent. We perform clinical evaluations, laboratory tests and radiology features.

Results: 89 sarcoidosis patients were ANA positive (34%, titre ≥ 1:160), 34 patients presented ENA positivity (15%) and antiphospholipid antibodies were positive in 20 patients (8%). No statistical significant correlations were observed between ANA/ENA positivity and clinical, laboratories and imaging evaluations. However, there was a statistically significant increase of the presence of antiphospholipid antibodies in sarcoidosis patients with a diagnosis of pulmonary embolism (p-value 0.04).

Conclusion: This study demonstrated an increase of antiphospholipid antibodies positivity in sarcoidosis patients with pulmonary embolism. These results may support the screening for these antibodies in all sarcoidosis patients. Further studies are underway to confirm these preliminary data and to evaluate if the positivity of autoantibody in these patients might suggest autoimmune implications in the pathogenesis of sarcoidosis.

Figure 1. Workflow

Where only one measurement of AP was available, no further analysis was undertaken. All patients with AP values >45U/l were excluded to increase the likelihood of HPP. Those with multiple (≥2) very low AP values (≤35U/l) were defined as suspicious for HPP. After detailed chart review for secondary causes for low AP levels (e.g., severe hypothyroidism, exposure to bisphosphonates (BIS)) and exclusion of said cases, an analysis of the remaining ones followed. Where HPP was suspected, we aimed to initiate a measurement of pyridoxal phosphate (B6) within clinical routine. Elevated B6 levels (>50μg/l) were used as further marker suggestive of HPP.

Results: 6861 AP measurements in 3362 patients were identified. 262 (7.8%) patients had at least one low AP value. The further workflow is shown in Figure 1.28 (10.7%) patients had AP levels <=35U/l at least twice. B6 measurements are available for 7 patients. Elevated values were seen in 3 of 7. In two cases HPP was confirmed genetically. The rest of the patients defined as suspicious for HPP presented unspecific symptoms (Fig. 1).

Table 1. Patient characteristics
During screening, 2 patients were identified with a previously confirmed HPP. However, the filtering strategy used here excluded these (for history of normal AP values and exposure to BIS). Details are shown in Table 1.

Conclusion: In our analysis of measured serum AP levels in a tertiary care centre for rheumatology we found 4 patients with definitive HPP and 1 patient with a high probability of HPP. The clinical symptoms possibly related to HPP were mild. In one case, the current diagnosis of psoriatic arthritis was documented as suspected; thus, the clinically leading arthralgia might be explained by HPP. All other patients had definite rheumatic diseases. Mistreatment was not found. The definitive number of patients with HPP among the cases currently defined as suspicious may be greater due to missing data on B6 in this retrospective analysis. However, only mild phenotypes were seen. Developing a universal algorithm to detect HPP remains difficult: our filtering strategy failed to identify 2 of the 4 patients with confirmed HPP. We conclude that in patients with repeatedly low serum AP levels occasionally occurring normal AP and exposure to BIS cannot rule out HPP. A further workup should include B6 levels, especially in the presence of (fragility) fractures and other symptoms not sufficiently explained by the presence of a rheumatic disease.

Conclusion: We found that classification of arthritides phenotype was study site-specific in our statistical models. After excluding site, age, cancer type, TJC, maximum steroid dose, and hand arthritides were associated with phenotypic classification. The influence of study site illustrates current heterogeneity in IA-IA phenotyping among experts and the need for normalized classification for enrollment in clinical trials. These results identify variables that could be explored by the ACR/EULAR ICI-IA classification criteria working group.

emapalumab intravenously for 4 weeks (6 mg/kg on Day 1; 3 mg/kg every 3 days from Days 4–16, then 3 mg/kg twice weekly from Days 17–28) or until protocol-defined complete response (CR). Patients will be followed up for 1 year after study completion.

**Key inclusion criteria**

- Male and female patients aged 6 months to 80 years at diagnosis of MAS (ages 18–70 years for the phase III trial)
- Platelet count ≤181 x10⁹/L
- Ferritin ≥1000 ng/mL
- Anakinra at a dose >4 mg/kg
- Confirmation of clinical disease: chronic or persistent activity of MAS
- Forfitted and diffusion capacity of lung for carbon monoxide (DLCO) ≤65% of predicted

**Key exclusion criteria**

- Male and female patients aged 6 months to 80 years at diagnosis of MAS
- Platelet count ≥181 x10⁹/L
- Ferritin <1000 ng/mL
- Anakinra at a dose <4 mg/kg
- History of hypersensitivity or allergy to any component
- confirmed malignancy
- History of other severe autoimmune disease
- Any severe concomitant medical condition
- Any severe concomitant infection
- Any severe concomitant disease

Results: Protocol-defined CR at Week 8 after first emapalumab administration is the primary endpoint of the EMERALD study. Secondary efficacy endpoints include GC tapering, survival, time to first CR, overall response (CR and partial response), time to first overall response, MAS recurrence, pharmacokinetic/pharmacodynamic profile of emapalumab, and patient-reported outcomes. Adverse events, abnormal laboratory parameters, and anti-drug antibodies will be monitored as safety endpoints.

Conclusion: The ongoing EMERALD study is designed to address the unmet need for efficacious and safe therapies for the treatment of MAS, particularly for patients who are refractory to high-dose GCs.

**SPECIFIC BLOOD MONOCYTE DISTRIBUTION IN HISTIOCYTOSES CORRELATES WITH VASCULAR INVOLVEMENT AND DISEASE ACTIVITY**

**Keywords:** Innate immunity

J. Razanamahery, M. Samson, J. Guy, J. Racine, C. Row, S. Francois, J. P. Emile, B. Nicolas, F. Cohen, S. Audia, J. Haroche, A. Bonnottes, 1Dijon University Hospital, Internal Medicine and Clinical Immunology, Dijon, France; 2Dijon University Hospital, Hematology Laboratory, Dijon, France; 3Dijon University Hospital, Immunology Laboratory, Dijon, France; 4Amboise paré Hospital, Pathology Department, Paris, France; 5Pitié-Salpêtrière Hospital, Internal Medicine, Paris, France.

**Background:** Histioctyes are rare clonal disorders characterized by the proliferation and accumulation of CD68+ histiocytes in tissues. During histiocytosis, circulating monocytes arising from bone marrow progenitors carry many MAP-kinase gene mutations, but only “classical” monocytes can differentiate into tissue histiocytes. However, little is known about the circulating monocyte subset distribution in histiocytosis and their differences from other myeloproliferative disorders.

**Objectives:** We aimed to evaluate the circulating monocyte subset distribution in patients with histiocytoses compared to patients with myeloproliferative disorders (Chronic myelomonocytic leukemia (CMMI) and essential thrombocythemia (ET) and healthy donors (HD).

**Methods:** Peripheral blood cells were obtained from patients diagnosed in Dijon University hospital between 2020 and 2021, with histiocytoses (n=17), CMMI (n=7), ET (n=7), and from 21 HD at steady state. Monocytes were separated on a CD14/CD16 scattergram into CD14+/CD16- (classical), CD14+/CD16+ (intermediate), and CD14−/CD16+ (non-classical) subsets after stained cell separation.

**Results:** During histiocytoses, an increase in “classical” monocytes was observed, compared to ET (p<0.01) while “intermediate” (vs. ET: p=0.02) and “non-classical” monocytes (vs. HD: p=0.04) were decreased. The distribution of monocyte subsets in histiocytoses was close to that in CMMI and homogeneous among the different type of histiocytoses. Compared to CMMI patients, central hematopoiesis in patients with histiocytoses was associated with a decrease in “classical” monocytes (67.50% vs. 97%; p=0.002), with an increase in intermediate and “non-classical” monocytes: 5% vs. 2.5% (p=0.03) and 4% vs. 0.5% (p=0.01), excepted when MAP-kinase mutation was considered, as monocyte distribution was similar. Patients with vascular involvement (62% including 5/16 with 1 RDD) had an increase in classical monocytes (96.00% [92.0-96.0] vs. 86.00% [82.5%-92.0%]; p=0.008) and a decrease in “non-classical” monocytes (1.00% [1.0-2.0] vs. 5.00% [3.50-9.50]; p=0.007). The correlation between “non-classical” monocytes <4% and vascular involvement was confirmed by Pearson model (0.648; 95%CI [0.25-0.86]; p=0.005). Histioctyes patients achieving a metabolic response had a lower percentage of “intermediate” monocytes (3.5% [2.0-5.0] vs. 7.0% [4.0-13.0]; p= 0.04) and lower CRP levels (3.0 [1.1-7.5] vs. 33.65 [5.3-59.5] mg/L; p=0.04). The only factor influencing the monocytes subset repartition (for “classical” monocytes) was the presence of clonal hematopoeisis (R coefficient: -0.78; 95%CI [-1.63 to -4.73]; p<0.002) in patients with histiocytoses.

**Conclusion:** The monocytes subset distribution is singular in histioctyes compared to other myeloproliferative neoplasms and is influenced by clonal hematopoiesis. The decrease in the “non-classical” subset could represent a surrogate marker of vascular involvement, while the decrease of the intermediate fraction is associated with a metabolic response.

transplantation had an 87.5% survival rate (14/16), with MDAS disease-free remission for up to 12 years using standard induction transplant immunosuppressants.

Conclusion: In refractory MDAS RP-ILD, early consideration of lung transplantation is essential. The findings do not support ECMO as bridge to recovery given its high mortality rate. ECMO as bridge to transplantation provided excellent patient survival and should be considered as potentially lifesaving.

**References:**
Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by self-limiting recurrent episodes/attacks of fever, serositis, arthritis, and erysipelas-like erythema[1]. Musculoskeletal manifestations such as arthralgia, enthesitis, exertional leg pain, myalgia, sacroilitis, and lower extremity synovitis are also common in FMF [2]. The fact that the disease progresses with lifelong persistent inflammation, as well as attacks of arthritis, synovitis, and enthesitis in the lower extremities, decreased lower extremity proprioception, muscle weakness, osteopenia, and fatigue, suggests that patients with FMF may develop a balance disorder.

Objectives: The aim of this study is to examine the relationship between static and dynamic balance in patients with Familial Mediterranean fever (FMF).

Methods: FMF patients who met the modified Tel Hashomer criteria and healthy volunteers were included in the study. The demographic data, clinical characteristics, dynamic balance in patients with Familial Mediterranean fever (FMF).

RESULTS: The results of the control and groups were compared in terms of BBS, FRT, TUG, and SLS. VAS during attack, presence of arthritis, and amyloidosis were higher in patients at risk of falling (p=0.032, p=0.002, and p<0.001, respectively).

Conclusion: Our results demonstrated that the dynamic and static balance in FMF patients was worse than the healthy subjects. Longer and more severe disease, presence of arthritis and amyloidosis may further contribute to deterioration balance.

**EFFECTIVENESS OF RITUXIMAB IN IGG4-RELATED DISEASE. MULTICENTRE STUDY AND LITERATURE REVIEW**

Keywords: bDMARD, Vasculitis, Organ damage

L. Sanchez-Bilbao, J. Lorica1, A. Herrera-Morant1, C. Álvarez-Regueira1, R. Milero3, E. Galindo-Agirregoldea3, R. Blanco1. 1H.U. Marqués de Valdecilla, Rheumatology, Santander, Spain; 2Complejo Hospitalario Universitario de Vigo, Rheumatology, Vigo, Spain; 3Hospital de Basurto, Rheumatology, Bilbao, Spain

**Background:** Igg4-related disease (Igg4-RD) is a systemic fibroinflammatory disease often associated with elevated serum IgG4 levels. High dose corticosteroids are the cornerstone of treatment, but relapses and side-effects are frequent, requiring synthetic and/or biologic immunosuppressants. Rituximab (RTX) seems to be useful.

**Objectives:** To assess the effectiveness of RTX in Igg4-RD refractory to conventional treatment.

**Methods:** Multicentre clinical practice study of Igg4-RD patients treated with biologic therapy. For the literature review, a search of PubMed, Embase and the Cochrane library was conducted from inception to 31 Dec 2022.

**Results:** We include 9 patients (5 women/4 men) (mean age:SD; 55.8±12.6 years) with refractory Igg4-RD, treated with RTX (Table 1). The affected organs were: aorta (n=5), lymph nodes (n=3), lung/pleura (n=2), retropitoneum (n=2), lacrimal glands (n=1), salivary glands (n=1), orbit (n=1), subglotis (n=1), kidney (n=1), pericardium (n=1), biliary duct (n=1) and mesentery (n=1). All patients had received oral corticosteroids, (mean±SD dose of 33.9±14.1mg/day)

Two patients also received corticosteroid boluses. Six of the patients received conventional cDMARDS. The cDMARDS received were: methotrexate (MTX) (n=4), azathioprine (n=1), and hydroxychloroquine (n=1). RTX schedule was of 1g x 2 (n=8), and 375mg/m2 (n=1). After a median [IQR] follow-up of 27 [25-48] months, complete or partial clinical improvement was observed in 6 and 2 patients respectively. One patient died due to an acute myocardial infarction, while another patient developed a breast cancer. We found 3 series, in the literature review, showing RTX effectiveness (Figure 1). The most frequently used RTX regimen was 1g x 2.

**Conclusion:** RTX seems to be an effective and safe therapy in corticosteroid-refractory Igg4-RD.

**Figure 1.** A) RTX regimen, B) previous cDMARDS and clinical response of Igg4-RD with RTX in current and other series of the literature review. All data are in %.

**GENOTYPE-PHENOTYPE CORRELATIONS OF FAMILIAL MEDITERRANEAN FEVER IN ARMENIAN POPULATION**

Keywords: Geographical differences, Epigenetics, Descriptive Studies

M. Osipyan1, M. Efraidimido2, K. Ginosyan2, A. Antikyan3, 1Erebouni Medical Center, Rheumatology, Yerevan, Armenia; 21st University Hospital Complex after M. Heratsi, Rheumatology, Yerevan, Armenia; 3Gyumri Medical Center, Rheumatology, Gyumri, Armenia

**Background:** Familial Mediterranean fever (FMF) is an autoinflammatory disorder that mostly affects people of Middle Eastern and Mediterranean descent, and is characterized by recurrent and self-limiting episodes of fever, serositis, arthritis, and etc. Although many studies in scope of the connection of the MEFV gene variants and clinical manifestation have been carried out since the discovery of the gene, there is not yet in detail data about Armenian population peculiarities and differences in the severity of the disease between the genotypes.

**Objectives:** The aim of this study is to compare the severity of the disease between different MEFV genotypes and propose utilization of genotype assessment as a predictor for the disease progression.

**Methods:** 184 Armenian patients were included in the study. All patients fulfilled Tel-Hashomer classification criteria for FMF. Patients were studied following a standard protocol. 12 most important mutations of MEFV gene (E148Q, P369S, F479L, M680I (G/C), M680L (G/A), I692del, M694V, M694I, K695R, V726A, A744S and R761H) were evaluated and according to the genotype patients were grouped in homozygotes, compound heterozygotes, heterozygotes and patients without mutations. Disease activity was measured by Tel-Hashomer severity score.

**Results:** 76.63% of examined patients were male and 23.4% -female. The mean age of the group was 41.5±18.7 years and the average duration of the disease -11.4±8.5 years. Clinical manifestation of the patients included in the study were following: episodes of fever- 124 (67,39%), abdominal pain -120 (65,2%), pleuritis -154 (83,69%), pericarditis -11 (0.598%), arthritis -54 (29,348 %), arthralgia -101 (54,89%), erysipelas-like erythema -22 (11,565%), splenomegaly -59 (32,065%), amyloidosis-b3 (3,26%), 116 (64,13%) of patients carried any of the MEFV examined mutations and despite the presence of clinical manifestations 66 patients (35,87%) have no mutations detected. 21 (17.8%) of patients with mutation were homozygote, 65 (55,08%)compound heterozygote and 32 (27.11 %) heterozygote. The prevalence of MEFV mutations among examined patients was 61.3%, 28,4%, 21,65%, 5,04% accordingly for M694V, M680I, V726A, E148Q exons. Patients with M694V/M694V and M694V/M680I genotype had the highest Tel-Hashomer severity score (9,8±6,6 and 11,1±6,1 accordingly). Patients with homozygote genotype have earlier onset of the disease (p=0.02), more frequent attacks (p<0.05) higher levels of ESR during the flare (P=0.009) compared with patient with other genotypes. No significant difference for the duration of the attack between different genotypes was found. Patients without any revealed mutations had the mildest disease presentations (Tel-Hashomer severity score – 3,2±1,6).

**Conclusion:** According to the data, age of the onset of FMF strongly correlates with the inherited genotype. Carriers of the MEFV gene mutations without any manifestations at early age should be expected to have onset years later and

should be strongly monitored by clinicians. Despite the fact, the genotype is not included in Tel-Hashomer classification criteria, our study once more indicates, that not only phenotype but also genotype be very important for FMF. Further evaluation of bigger sample is required to conclude the influence of the specific exons on the clinical manifestations.

CLINICAL COURSES AND PREGNANCY OUTCOMES OF TWELVE CASES COMPLICATED WITH BEHÇET’S DISEASE IN OUR INSTITUTION

Keywords: Pregnancy and reproduction, Behçet’s disease

H. Shimada1, R. Wakai1, S. Nakashima1, T. Miyagi1, Y. Ushio1, K. Sugihara1, R. Mino2, M. Mizusaki2, K. Chuo3, T. Kameda3, H. Dobashi3. 1Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan

Background: The proportion of women with Behçet’s disease (BD) has increased in recent years. BD is often diagnosed at or before the time of conception, however, its impact on the clinical courses and pregnancy outcomes is not fully understood. Previous reports showed that patients with BD had a higher rate of complications such as puerperal cerebrovascular disease and gestational diabetes [1], or pregnancy outcomes like miscarriage and fetal growth restrictions [2]. Therefore, it is important to reveal the clinical course and pregnancy outcomes in patients with BD.

Objectives: The purpose of this study was to analyze the BD pregnancy cases experienced at our facility, and to determine the impact of disease on the course of pregnancy.

Methods: We used the data of BD patients who had been treated at planning for pregnancy and gave birth from a single center cohort of rheumatic disease pregnancy registry in our institution. The impact of BD disease activity of BD on pregnancy outcomes was examined, including therapeutic agents such as glucocorticoid (GC) and biologics.

Results: There were 12 pregnancies complicated by BD included in this analysis. The age at conception was 32.6 ± 3.6 years old, and the disease duration was 4.4 ± 3.0 years. The mean BD current activity form (BDCAF) was 0.6 ± 0.8 in 4 cases of exacerbation of disease activity, including the subsequent pregnancy outcome. It is also necessary to consider whether to continue biologics and colchicine for controlling disease activity.

OVERLAPPING INFLAMMATORY DISEASES IN HIDRADENITIS SUPPURATIVA PATIENTS AND THEIR FAMILIES

Keywords: Skin, Comorbidities, Rare/orphan diseases

E. Er Gülbez1, S. Vural2, 1Koç University School of Medicine, Rheumatology, İstanbul, Turkey, 2Koç University School of Medicine, Dermatology, İstanbul, Turkey

Background: Hidradenitis suppurativa (HS) is an inflammatory disorder characterized by chronic deep-seated nodules, sinus tracts, and scars in the intertriginous areas. A significant decrease in quality of life accompanies chronic pain of active lesions. Association with inflammatory bowel disease (IBD) and spondyloarthropathies suggest an inflammatory signature overlap with rheumatological disorders.

Objectives: Based on the idea that the association of HS and rheumatological disease is more frequent and often important than previously thought, we aimed to evaluate the symptoms and findings of rheumatological diseases in our HS patients.

Methods: Consecutive HS patients presented to the dermatology outpatient clinic between 2021-2022 were included in the study. Among the HS patients who applied to dermatology between 2021 and 2022, patients with arthritis and low back pain were referred to the rheumatology department for evaluation. Family history was taken in detail for inflammatory conditions. Acute phase reactants were analysed.

Results: The group comprised 55 HS patients, including sixteen Hurley stage I (27.2%), 24 Hurley stage II (41.8%), and 14 (23.6%) Hurley stage III patients. The mean age of onset for HS was 28.8 (min:14, max:56), 51% (N=28) were women. Family history for HS was present in 14 (25.4%) patients. Twenty-four (43.6%) of 55 HS patients who applied to the dermatology outpatient clinic had an autoimmune/autoimmune disease diagnosis or inflammatory system/finding other than HS (Table 1). Sixteen (29%) patients described arthralgia and were referred to the rheumatology outpatient clinic. Among the HS patients, 32.7% had a significant autoimmunee or autoimmune-disease condition other than HS in 1st or 2nd-degree relatives. Positive family history for inflammatory processes other than HS was present in 19 (41.6%) patients with an additional inflammatory condition and 8 (25.8%) patients without a different inflammatory disease. Family history of inflammatory disorders include (Familial Mediterranean fever, acne conglobata, inflammatory bowel disease, psoriasis, Takayasu arteritis, amyloidosis, ankylosing spondylitis, uveitis, erythema nodosum, Behçet’s disease and vitiligo. Serum amyloid A levels (SAA) were calculated in 16 patients, and 62.5% had elevated SAA levels.

Conclusion: Autoimmune/autoimmune rheumatological diseases or rheumatological symptoms were present in a significant proportion of HS patients. Prominent family history of inflammatory diseases suggests common genetic pathways in this spectrum of diseases. In addition, detailed history taking, including rheumatological symptoms in HS patients, is valuable and crucial in determining the extent of inflammation.

Background: Ocular cicatricial pemphigoid (OCP) is a chronic, immune-mediated, fibrosing disease that can lead to blindness. The diagnosis is clinical and/or based on the results of the conjunctival biopsy. There are no studies that have studied the histopathological findings and the risk of clinical sequelae in this entity.

Objectives: The describe biopsies from patients with OCP and to identify characteristics of the biopsies that may be associated with a greater risk of fibrosis and sequelae.

Methods: A retrospective, multicentre study was carried out. Patients over 18 years of age with a diagnosis of OCP by pathology were selected. Medical records were reviewed and demographic, clinical, and biopsy data were collected. To assess whether histology was associated with greater or lesser fibrosis (determined by Foster’s stages), the patients were divided into two groups: early stages (0 and 1) versus stages 2, 3, and 4. The variables between the two groups were compared: groups. To determine whether immunoregulation was associated with a risk of fibrosis, a Cox multivariate analysis was performed. Sequelae were defined as a composite variable consisting of keratoconjunctivitis, entropion, trichiasis, cataracts, glaucoma, vitreous opacity, retinal scars, synstanheria, and blindness.

Results: Fifty-seven patients with POC diagnosed by pathology were included. The mean age of presentation at diagnosis was 62.7 (SD 13.2) years and 41 (71.9%) were women. The follow-up time was 1.5 years (2.9). Patients with early Foster (stages 0 and 1) were 50.9%. The presence of rounded and spindle-shaped mast cells was associated with early stages, while the presence of eosinophils was associated with later stages at the time of diagnosis. In the immunofluorescence the presence of IgM was more frequent in early stages and IgG in the later ones, with a predominant linear pattern (92%) (Table 1). During follow-up, 15 (27.3%) patients developed sequelae. In the multivariate Cox regression analysis, the presence of IgG resulted in risk during the follow-up period for the development of sequelae; IgA positive: HR 10.8, IC 95% 1.3 a 92.9 (p-value 0.03). IgG positive: HR 0.2, IC 95% 0.2 a 1.3 (p-value 0.08); IgM positive HR 0.4, IC 95% 0.1 a 2.3 (p-value 0.29) C3 positive HR 0.2, IC 95% 0.02 a 1.7 (p-value 0.14)

Conclusion: This is one of the largest rheumatologic series that has evaluated the pathology in patients with OCP and provides information on the possible role that different antibody deposits could play in the conjunctival mucoza. The presence of IgA in the biopsy may have a role in the development of sequelae. Future larger and prospective studies could help to define the detection of different clinical patterns that give us a more accurate idea of the prognosis and treatment in these patients.

Background: Familial Mediterranean fever (FMF) is a rare hereditary, autoinflammatory disease that is characterised by recurrent episodes of fever, increased inflammatory parameters and abdominal and thoracic pain attacks. Germany is a low-prevalence country with approximately 5800 affected patients [1]. Due to the rarity of the disease, diagnosis is difficult and time-consuming [2]. Patients often experience a long diagnostic odyssey ensuing further physical and socioeconomic damage.

Methods: At three German tertiary centres, adult FMF patients were included in the study. Patients were asked to report data on demographic background, disease symptoms and duration, as well as the socioeconomic impact of diagnostic and surgical interventions.

Results: We included 84 adult patients (female/male 35/49), the median age was 33 years (min 18- max 94) with the confirmed diagnosis of FMF. Demographic analysis showed that 52% of FMF patients were not born in Germany (country distribution see Figure 1). The mean age between symptom onset and diagnosis was 4 years (0–35) for patients born in Germany and 9 years (0–65) for patients not born in Germany. Furthermore, non-German-born patients reported more disease symptoms (see Table 1). In both groups, the number of prior diagnostic procedures and abdominal surgeries was high (53% in German FMF patients, 56% in Non-German FMF patients). Socioeconomic effects of the disease were similar in both groups: 20% of the patients born in Germany and 22% of the non-German-born patients reported that they terminated their academic education due to the disease. Furthermore, 30% of the patients born in Germany and 27% of the patients not born in Germany reported that they lost their job due to disease-related problems.

Conclusion: Our data suggest that patient care for FMF in Germany is currently not optimal. A large number of patients continue to undergo a long diagnostic odyssey with unnecessary diagnostic procedures or surgeries and also experience negative effects on their education and professional careers. Furthermore, there are differences between patients born in Germany and those not born in Germany with the latter being even more negatively affected.

Figure 1. Country of birth in percentages: (n=84); Germany 48%, Turkey 17%, Armenia 11%, Syria 8%, Lebanon 4%, Iran 4%, Pakistan 2%, Italy 1%, Portugal 1%, Kazakhstan 1%
were 3.8; 26% showed >5 relapses and 7% > 25. Chronic articular pattern is the only variable that predicts the number of relapses (p=0.001). Mean Pouchout score at disease onset was 5.5 (>7 in 15 patients); it decreased to 2.2 after 6 months and was 1.2 at the last follow up visit. All the patients were treated with steroids (pulses in 18%), mean steroid dose/patient 9.6 gr. Steroids only were used in 5% of the patients, csDMARDS in 22.5% of the patients (MTX in 60%, Csa in 15%), biologicals in 72.5% (Anakinra in 62%, Tocilizumab in 28%). In 40% of the patients, steroid and one cs or bDMARD allowed to achieve disease control. In 60% one or more therapeutic switches were necessary; because of limited efficacy or adverse drug reactions. Drug retention rate was 76% at 6 months, 40% at 3 yrs and 4 yrs for Anakinra; 91% at 6 months and 36% at 5 yrs for Tocilizumab. In one patient out of 25 treated with Anakinra and in 3 out of 11 treated with Tocilizumab, the therapy was discontinued for persistent clinical remission.

Conclusion: The data we collected confirm the severity and the multisystem involvement of AOSD in a monocentric cohort with a long follow up. Among the different clinical patterns, the chronic articular one is associated with more frequent flares. Severe manifestations of the disease were present at disease onset but did not appear thereafter, suggesting the efficacy of drug therapy and close follow up. Inhibition of IL-1 and IL-6 is a safe and effective therapy. Persistent clinical remission that allows withdrawal of therapy can be obtained albeit in a small number of cases.

SEXUAL DYSFUNCTION IN BEHÇET’S DISEASE: IS IT AN OVERLOOKED PROBLEM, ESPECIALLY IN MALE BEHÇET’S PATIENTS?

Keywords: Behçet’s disease

Ö. F. Asker1, N. Çakmak1, S. Erdem1, A. Öksüzer1, E. Tufan1, S. Kutlu Aşakçı1, H. Direskeneli2, F. Albaz-Oner1, I. Midik1,1Marmara University Faculty of Medicine, Istanbul, Turkey; 2Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3Marmara University Faculty of Medicine, Department of Neurology, Istanbul, Turkey

Background: Behçet’s disease (BD) is a chronic systemic inflammatory disease characterized by oral and urogenital ulcers, ocular, musculoskeletal, vascular, and neurological involvement. Recent evidence suggests that sexual dysfunction (SD) is prevalent in BD patients.

Objectives: We aimed to determine the frequency of SD in BD and compare the rates of SD in Behçet’s patients with neurological involvement (NBD), Behçet’s patients without neurological involvement (BDWONI) and healthy controls (HC).

Methods: Age matched, sexually active 59 BD (17 NBD, 42 BDWONI) patients and 36 HC were recruited. All participants were questioned with Short Form-36, Beck Depression Inventory (BDI), Golombok-Rust Inventory of Sexual Satisfaction (GRISS), Female Sexual Function Index (FSFI), International Index of Erectile Function (IIEF-5), in addition, disease activity has been assessed by Behçet Disease Current Activity Form (BDCF) in all BD patients.

Results: The rate of SD was higher in BD patients (44.2%) compared to HC (14.2%) (p = 0.003) (Figure 1). Male BD patients had lower sexual function scores compared to male HC. Three parameters of GRISS (premature ejaculation, noncommunication, infrequency) were observed more frequently in male BD patients compared with male HC (6.5 vs 4.7, 3.6 vs 2.0, 3.9 vs 2.4, p < 0.05 for all). The SD rates were comparable between female BD patients and HC. SD rates were similar in BDWONI (44.2%) and NBD (42.8%) groups (p > 0.05). BDCF score was negatively correlated with IIEF scores of male BD patients (r = -0.437) and positively correlated with GRISS scores of female BD patients (r = 0.748) (p < 0.05). There was no relation between SD and depression in BD patients (p = 0.284).

Conclusion: The frequency of SD is increased in BD compared to HC and affects males more frequently than females. Premature ejaculation, infrequency and noncommunication are common sexual problems in male BD patients. In conclusion, BD has a negative effect on sexuality and BD patients should be evaluated in terms of SD during follow up.

THE RELATIONSHIP BETWEEN AMYLOIDOSIS ANDATHEROSCLEROSIS IN FAMILIAL MEDITERRANEAN FEVER

Keywords: Clinical Trials, Heart, Inflammatory arthritis

S. Gür1, V. Yazisiz2, M. E. Terziöğlu3, F. Erbasan3, 1Akdeniz University School of Medicine, Department of Internal Medicine, Antalya, Turkey; 2Akdeniz University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Antalya, Turkey; 3Akdeniz University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Antalya, Turkey

Background: Familial Mediterranean Fever (FMF) is an autosomal recessive autoinflammatory disease characterized by recurrent fever and serosal inflammation signs [1]. The most severe complication of the disease is AA amyloidosis, with increased mortality and morbidity [2].

Objectives: To determine the relationship between amyloidosis and atherosclerosis in FMF patients.

Methods: 730 FMF patients were analyzed retrospectively for the development of amyloidosis and coronary artery disease (CAD). Cut-off values of serum amyloid A (SAA), fibrinogen, c-reactive protein (CRP), and erythrocyte sedimentation rate (ESR) variables that could predict amyloidosis and CAD were evaluated by receiver operating characteristic (ROC) analysis.

Results: The prevalences of amyloidosis and CAD were 6% and 3.7%, respectively. The incidence of CAD was higher in patients with amyloidosis (13.6%) than in patients without amyloidosis (3.1%) (p < 0.004). Cut-off values that could predict amyloidosis were 44 ng/ml for SAA, 384 mg/dl for fibrinogen, 20 mm/hour for ESR, and 1.25 mg/dl for CRP (Table 1). The adjusted odds ratio for amyloidosis was 5.5-fold in patients with SSA >44 ng/ml and 3.4 in patients with ESR >20mm/hour (Table 1). Serum AA level was significantly higher in patients with CAD (85.4±18.9) than in the group without CAD (32.4±49.5) (p = 0.008). The area under the curve (AUC) values of SAA, CRP, ESR, and fibrinogen were not statistically significant for predicting CAD (Fig 1).

Conclusion: The risk of CAD is increased in amyloidosis secondary to FMF disease.

LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH HIDS (HYPER-IGD SYNDROME) – INTERIM ANALYSIS OF THE RELIANCE REGISTRY

Keywords: Rare/orphan diseases, Inmate immunity, Real-world evidence

P. Oommen1, T. Kalinchik2, J. Rech1, N. Blank, J. Weber-Arden, B. Kuemmerle-Deschner.

Background: Hyper-IGD Syndrome/Mevalonate Kinase Deficiency (HIDS/MKD) is a rare autoinflammatory disease caused by a defect in the gene encoding mevalonate kinase. Treatment with the interleukin-1β inhibitor canakinumab (CAPS, TRAPS, FMF). Serious adverse events occurred in N=2 patients, but none were considered as drug related.

Conclusion: The present data from baseline and preliminary interim analysis suggest good disease control in HIDS/MKD patients participating in the RELIANCE study. In addition, data analysis at 18 and 30 months revealed no unexpected safety concerns. Further interim and end-of-study data will be analyzed to assess efficacy and safety of long-term CAN treatment in HIDS/MKD patients in the course of the study.

LIVER STIFFNESS IN FAMILIAL MEDITERRANEAN FEVER: ASSOCIATION WITH ENDOCAN AND PULSE WAVE VELOCITY

Keywords: Biomarkers, Imaging

A. Lo Gullo1, A. Toscano2, M. Scuroch2, M. Morace3, M. Cinquegrani2, D. Sinicropi1, G. Squadrito1, M. Colaci3, G. Mandrafino1, JARNAS “Garibaldi”, University of Messina, Messina, Italy; "The University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy; "Azienda Ospedaliero-Cattedrale di Messina, Università di Catania, Catania, Italy

Background: Familial Mediterranean Fever (FMF) is the most common monogenic periodic fever syndrome; it is characterized by recurrent self-limited episodes of disease activity, fatigue, days absent from school/work due to study indication, and inflammatory markers are assessed at baseline and at 6-monthly intervals.

Results: The present interim analysis includes baseline (N=8) as well as preliminary 18-month (N=6) and 30-month data (N=5) from HIDS/MKD patients enrolled in the study by December 2022. Of these patients, 63% were female and median age at baseline was 8 years (2–39 years). The median duration of prior CAN treatment at study entry was 1.5 years (0–5 years). The majority of patients has been treated with greater than standard dose CAN (5/8 patients at baseline, 4/6 at month 18, 3/3 at month 30). Preliminary results indicate stable remission and disease control as assessed by physicians and patients and according to laboratory parameters (table 1). Even though efficacy outcomes in the HIDS cohort are based on small patient numbers, data resemble outcomes in larger cohorts within the RELIANCE registry (CAPS, TRAPS, FMF). Serious adverse events occurred in N=2 patients, but none were considered as drug related.

Conclusion: The present data from baseline and preliminary interim analysis suggest good disease control in HIDS/MKD patients participating in the RELIANCE study.
fever, arthritic and serosal inflammation, and accumulation of polymorphonuclear cells into affected tissues. Recurrent inflammatory process during the attacks, and the potential chronic inflammatory status during attack-free intervals, could lead to endothelial dysfunction (ED) and atherosclerosis. In patients with FMF, ED, could play a role in the development of atherosclerotic plaques.

Keywords: Malignancy, Inflammatory arthridites

L. Cappelli, J. Perin, C. Bingham, A. Shah, Johns Hopkins School of Medicine, Division of Rheumatology, Baltimore, United States of America

Background: Immune checkpoint inhibitors (ICI) can lead to immune related adverse events, including inflammatory arthritis (IA), ICI-IA is heterogeneous and can be severe, even persisting after ICI cessation. Understanding the clinical heterogeneity of ICI-IA can guide future studies of pathogenesis and identify relevant groups for clinical trials.

Objectives: To define clinically relevant subgroups within ICI-IA using a data driven approach and to examine differences between subgroups.

Methods: Participants were >18 years old, treated with anti-PD-1, anti-PD-L1, and/or-CTLA-4 agents alone or in combination, and had ICI-IA diagnosed by a rheumatologist. We used information from the baseline rheumatology visit (patient reported symptoms, physical exam features, physician global arthritis rating, and laboratory studies) to cluster patients with latent class analysis. The Bayesian Information Criteria (BIC) was used to select the number of phenotypes with the lowest BIC. We then compared demographics, cancer type and treatments, and IA treatments and outcomes between the estimated phenotypes. Next, we estimated the association between these features of interest and the likelihood of being in the group with the most severe IA symptoms using logistic regression.

Results: Of the 126 patients with ICI-IA, the majority of participants were female (56%) and white (92%). Most patients had a moderate or high level of disease activity by CDAI; the mean CDAI was 16.98 (SD 10.2). Eighteen variables were used to estimate latent classes. Two distinct phenotypes were indicated by the BIC; 61 patients are estimated to be the first phenotype and 65 the second phenotype. Participants in the second phenotype were more likely to have high baseline levels of patient reported pain, stiffness, and disease activity (Figure 1). There were no significant differences in age, gender, race, ethnicity or marital status between the two phenotype groups. Patients in phenotype 2 were more likely to require steroids as compared to patients in phenotype 1 and were more likely to have persistent IA (table 1). Type of ICI therapy, type of cancer, prior chemotherapy or radiation did not differ between the groups. When adjusted for age, gender, baseline steroid use, these variables remained significantly associated with the second phenotype.

Conclusion: Two separate phenotypes of ICI-IA were determined with latent class analysis. Those in the group with more severe features at baseline were more likely to need corticosteroids and to have persistent IA, but there was no association with cancer history or treatment. Future research can interrogate underlying genetic and immunologic differences between groups.

Rheumatology Department, Sousse, Tunisia

Background: Bone lymphoma is a rare disease, its diagnosis is usually delayed due to the unspecific clinical and radiological signs.

Objectives: Our objective was to describe the clinical, biological and radiological aspects of bone lymphoma to optimize diagnostic approaches.

Methods: 14 cases of bone lymphoma were collected in the Rheumatology Department of Sousse between 2001 and 2022.

Results: The mean age was 42 with a sex ratio of 1. The main symptom in 14 patients was pain associated with deterioration of general condition (10 cases), swelling of lymph glands (8 cases), fever and night sweats (6 cases), neurological signs (6 cases) with a diagnostic delay of 4 months. In biology, 13 patients had biological inflammatory syndrome, 2 of the 14 patients had hypercalcemia with a mean of 2.85, 6 patients had elevated LDH and 6 had elevated PAL. The abnormalities of the CBC were anemia in 10 cases, leukopenia in 1 case, hyperleukocytosis in 6 cases. On imaging, the lesions were vertebral (8 cases), iliac (1 case), long bone (3 cases), MRI showed a T1 hypo signal and T2 hyper signal in all cases, bone scintigraphy was performed in 6 patients and showed hyperfixation in 5 cases and a heterogeneous aspect in 1 case. A bone or lymph node biopsy was performed in all 14 patients, confirming the diagnosis and showing Hodgkin’s lymphoma in 6 cases and non-Hodgkin’s lymphoma in 8 cases, 7 of which were diffuse large-cell B lymphomas.

Conclusion: Due to the rarity and the various clinical and radiological presentations of bone lymphoma, the diagnosis may be difficult which is why the biopsy should be part of the diagnostic approach.

**TNF INHIBITORS ARE SAFE AND EFFECTIVE IN PATIENTS WITH SEVERE BEHÇET’S DISEASE: DATA FROM EASTERN TURKEY, INTERSECTION OF THE SILK ROAD**

**Keywords:** In innate immunity, bDMARD, Behcet’s disease

M. Bektaş1, E. Öğüz2, M. Özer2. 1Aksaray Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Aksaray, Turkey; 2Van Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Van, Turkey; 3Van Training and Research Hospital, Department of Ophthalmology, Van, Turkey

**Background:** Behçet’s disease (BD) is a chronic inflammatory multi-systemic disease that affect skin-mucosa, joints, eye and blood vessels. Biological disease modifying anti-rheumatic drug (b-DMARD) treatment is an emerging option into the management of severe BD.

**Objective:** We aimed to evaluate the clinical features and associated factors of outcome in patients with BD receiving b-DMARD treatment.

**Methods:** This retrospective observational study was carried out in a tertiary referral center in Van province, Eastern of Turkey. Remission was defined as no exacerbation and/or new development of clinical manifestations attributed BD at least three months. Active disease and/or relapse was defined as inadequate response to conventional treatment and/or new development of organ or system manifestations under the treatment. Ongoing mucocutaneous manifestations did not consider as active disease or relapse.

**Results:** We included 80 BD patients (76.3% male) who received b-DMARD therapy into the study. Mean±standard deviation (SD) of the patients was 33.3±8.8 years and median(interquartile range [IQR]) disease duration was 10(12) years. Among those patients, recurrent oral ulcer was in 98.5%, genital ulcer in 71.3%, pseudofolliculitis in 80%, erythema nodosum-like nodular lesions in 67.5%, superficial thrombophlebitis in 37.5%, uveitis in 53.8%, pathegy positivity in 66%, arthritis in 46.3%, spondylitis in 9%, gastrointestinal(GIS) involvement in 7.9%, parenchymal central nervous system(CNS) in 11.3%, parenchymal lung in 3.8%, vascular in 44%. While 28 patients(35%) had venous and 7 patients(8.8%) had arterial involvement. Overall, nearly all patients received colchicine(98.8%) and azatioprine(98.8%) as a background therapy, cyclophosphamide was used in 11.3%, cyclosporin in 22.5%, mycoprotein in 3.8% and interferon in 30%. Infliximab(IFX) and adalimumab(ADA) were initiated in 54(67.5%) and 26(32.5%) patients, respectively. Overall and first line retention rate were 84.7% and 92.6% for IFX and 83.3% and 80.8% for ADA, respectively(table 1). IFX was stopped in 9 patients which were in 2 patients due to allergic reaction and tuberculosis, 3 patients for inefficacy, one patient for heart failure and one patient for orbital zona. Although, no serious adverse event was observed with ADA, 5 patients were switched to IFX for inefficacy. While during the follow-up, lung lobectomy were needed in one patients, no death was observed. Overall, 72 patients(90%) resumed b-DMARD end of the study; b-DMARD was stopped in 3 patients(3.8%) due to severe adverse events and in 5 patients(6.2%) prolonged remission. All those patients were retained in remission after b-DMARD cessation. GIS involvement was negatively associated with b-DMARD retention in univariate(4.2% vs 33.3% p=0.017[OR:9.8]) and multivariate analysis(p=0.01 OR: 0.09, 95% confidence interval [CI]: 0.014-0.575). Higher disease duration(p=0.007[OR:5.8, 95% CI:1.6-20.8]), superficial thrombophlebitis(p=0.018,[OR:1.14, 95% CI:1.024-1.28]) were associated with corticosteroid withdrawal in multivariate analysis.

**Conclusion:** During the follow-up, no case of death was observed among b-DMARD receiving BD patients. Most patients were in remission, steroid-off and also retained on b-DMARD treatment. Biological treatment was safe and effective in patients with severe Behçet’s disease.

**DOl:** 10.1136/annrheumdis-2023-eular.483
Muscle biopsy is an important tool in assessment of idiopathic inflammatory myopathies (IIM), however the optimal approach is unknown. A variety of biopsy procedural techniques have been reported including open surgical biopsy, percutaneous needle biopsy and Conchotome forceps biopsy.

**Objectives:** This study aimed to describe current practices in obtaining a muscle biopsy amongst international experts who manage people with IIM.

**Methods:** An e-survey was designed and piloted to collect information regarding muscle biopsy practices. The e-survey was disseminated to members of the International Myositis Assessment and Clinical Studies (IMACS) group. Snowball sampling was used, whereby IMACS members were invited to forward the survey link to other clinicians involved in care of people with IIM. Information regarding respondent characteristics and their current practice in obtaining muscle tissue was collected. The e-survey was available for completion between 20th October 2022 and 20th of January 2023. Participants were included if they self-reported being a clinician or researcher with experience in IIM. Results were analysed using descriptive statistics.

**Results:** One hundred and one respondents completed the survey by 12th January 2023. Most respondents were from Europe (22.7%) and the United States (22.7%) followed by MRI (50.0%) and sedation (50.0%) or general anaesthesia (58.9%). Clinical examination was frequently used to guide muscle selection (85.4%), followed by MRI (50.0%) and EMG (43.8%). The influence of clinical and laboratory characteristics on decision to pursue muscle biopsy are presented in Table 1. Many respondents were more likely to pursue diagnostic biopsy in the setting of seronegativity (65.6%), abnormally high creatine kinase (70.8%), and neurophysiological status and the presence of a classic dermatomyositis rash (70.8%). Low complication rates were reported for all muscle biopsy techniques. Non-diagnostic histopathology was commonly reported regardless of technique. Therapy to volatile anaesthetics was less likely to be used (50.0%) than sedation (50.0%) or general anaesthesia (58.9%). Clinical examination was frequently used to guide muscle selection (85.4%), followed by MRI (50.0%) and EMG (43.8%). The influence of clinical and laboratory characteristics on decision to pursue muscle biopsy are presented in Table 1. Many respondents were more likely to pursue diagnostic biopsy in the setting of seronegativity (65.6%), abnormal MRI (58.3%) and abnormal neurophysiology (56.3%). Conversely, many were less likely to pursue diagnostic biopsy in setting of positive myositis specific antibodies (53.2%) or classic dermatomyositis rash (70.8%). Low complication rates were reported for all muscle biopsy techniques. Non-diagnostic histopathology was reported as ‘common’ (observed rate between 1-10%) in 30.5% and ‘very common’ (observed rate >10%) in 14.8% of respondents. Open surgical biopsy was the most common muscle biopsy approach reported by international experts who manage IIM. Clinical examination, MRI and EMG were frequently used to select a muscle to biopsy. Serology, radiographic and neurophysiological status and the presence of a classic dermatomyositis rash influence the decision to pursue diagnostic muscle biopsy. Muscle biopsy is safe, although non-diagnostic histopathology was commonly reported regardless of technique. Reference: Nil.

**Conclusion:** Open surgical biopsy was the most common muscle biopsy approach used by international experts who manage IIM. Clinical examination, MRI and EMG were frequently used to select a muscle to biopsy. Serology, radiographic and neurophysiological status and the presence of a classic dermatomyositis rash influence the decision to pursue diagnostic muscle biopsy. Muscle biopsy is safe, although non-diagnostic histopathology was commonly reported regardless of technique.

THE IMPACT OF OBESITY ON CLINICAL COURSE AND BIOLOGIC DMARD FAILURE IN PATIENTS WITH ADULT ONSET STILL'S DISEASE

Keywords: Rare/orphan diseases, Comorbidities, Prognostic factors

AB1503

Background: Adult onset Still's disease (AOSD) is a rare inflammatory disease characterised by fever, arthritis, evanescent cutaneous rash and a typical hyperferritinaemia [1]. Three clinical disease courses are usually identified: i. monocylic, characterised by a single episode; ii. polycyclic, characterised by multiple flares, alternating with remission; iii. chronic, related to a persistent active disease [1]. AOSD may also be burdened by the occurrence of life-threatening complications. The prognosis of AOSD may be affected by the presence of comorbidities; however, the impact of obesity on these patients has not fully elucidated yet. The obesity may be considered as a negative prognostic factor in patients with rheumatic diseases. In fact, it is associated with a higher disease activity, an enhanced disability, and a less probability to achieve the clinical remission [2,3].

Objectives: We assessed the impact of obesity on clinical disease course and biologic DMARD failure in patients with AOSD. We also evaluated the influence of obesity on life-threatening complication occurrence.

Methods: An assessment of obese patients with AOSD characterised by a BMI≥30 was provided among those evaluated in a Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale (GIRICS) cohort [4]. The presence of obesity was evaluated at the time of diagnosis and defined as BMI≥30. Cox regression analyses were performed to evaluate the predictive role of obesity on predicting different disease courses and bDMARD failure in our cohort. Multivariate analyses were adjusted for age, gender, and systemic score, which was used as marker of disease severity.

Results: In this study, 139 patients were evaluated; 28 (18.7%) had a BMI≥30 and were defined as having obesity at the time of disease diagnosis (mean age of 39.9±13.6 years, 12 male gender). Obese patients did not differ in the main clinical characteristics than non-obese [fever BMI<30: 96.2% vs BMI≥30: 99.1%, p=0.340; skin rash BMI ≥ 30: 84.6% vs BMI<30: 69.0%, p=0.147; arthritis BMI≥30: 61.5% vs BMI<30: 56.6%, p=0.826]. Furthermore, obese patients showed a higher rate of bDMARD failure in the subsequent follow-up (p=0.037). In addition, obese patients with AOSD were characterized by higher values of C-reactive protein (CRP) [BMI≥30: 109.2 mg/L (IQR 117.0) vs BMI<30: 52.0 mg/L (IQR 84.3), p=0.046] than others. Obese patients with AOSD had also higher values of CRP than 2:1 age-, gender-, and BMI-matched obese patients without immune mediated inflammatory disease (IMID) (Age: 39.8±13.2 years). 24 male gender out 52 patients, BMI: 32.4±3.1, CRP 33.8 mg/L [IQR 34.4], p<0.001). These obese patients without IMID were recruited to fully evaluate the impact of obesity on CRP in patients with AOSD. Additionally, obesity predicted the development of a chronic disease course in patients with AOSD in both univariate (HR: 1.72, 95%CI: 1.03-2.51, p=0.038) and multivariate analyses (HR: 1.85, 95%CI: 1.45-2.49, p=0.041). Non-significant results were obtained assessing the predictive role of obesity on monocyclic and polycyclic disease courses. Furthermore, obesity resulted to be a significant predictor of failure of at least one of biologic DMARD in patients with AOSD in both univariate (HR: 3.03, 95%CI: 1.42-6.45, p=0.004) and multivariate analyses (HR: 3.59, 95%CI: 1.55-8.27, p=0.003). Conversely, obesity did not influence the development of life-threatening complications in our cohort.

Conclusion: The presence of obesity resulted to be a predictive factor for the development of a chronic disease course and biologic DMARD failure in patients with AOSD. In addition to increase the inflammatory burden, a high BMI may be indeed associated with a more rapid clearance, a higher volume of distribution, and a consequent low concentration of biologic DMARDs and their possible clinical failure.

CLINICAL SPECTRUM OF IGG4-RELATED DISEASE. SINGLE UNIVERSITY HOSPITAL EXPERIENCE AND LITERATURE REVIEW

Keywords: Vasculitis, Systematic review, Organ damage

AB1504

Background: IgG4-related disease (IgG4-RD) is an inflammatory and fibrosing entity with very heterogeneous clinical manifestations. Its pathogenesis remains unknown, clinical features are heterogeneous and unspecified, and recently
released classification criteria are invaluable in early recognition of the disease. Therefore, regrettably IgG4 related disease continues underdiagnosed.

**Objectives:** a) To evaluate the clinical characteristics of patients diagnosed with IgG4-RD in a single University hospital; b) To compare with other large series.

**Methods:** Study of patients from a referral hospital and literature review of cases diagnosed with IgG4-RD. Diagnosis was made accordingly to these criteria: a) Okazaki; b) Umehara; c) ACR/EULAR 2020; and/or d) clinical, laboratory and imaging suggestive findings (ref. 1-3). For the literature review, we searched PubMed and the Cochrane library from its inception until 31 December 2022, selecting the largest series.

**Results:** We include 11 patients (7 females/4 males) (mean±SD age; 61.2±15.6 years) diagnosed with IgG4-RD. The organs affected at diagnosis were: aorta (n=5), pleura/lung (n=4), lymph nodes (n=3), salivary glands (n=2), retroperitoneum (n=2), lacrimal glands (n=1), bile duct (n=1), kidney (n=1), orbit (n=1), sub-glottis (n=1), pericardium (n=1), mesentery (n=1), maxillary sinuses (n=1). IgG4 values were increase in 2 (18%) patients (median[IQR]: 250.5 [201.0-300.1] mg/dL) (normal value <135 mg/dL). Blood plasmablasts were increased in 8 (73%) patients (median [IQR]; 250.5 [201 .0-300.1] mg/dL) (normal value <653 cells/mL). In our series, aortic involvement was one of the most frequently involved. In contrast, in our series, aortic involvement followed by lung/pleura were the most frequent.

**Conclusion:** IgG4-RD is a very heterogeneous disease with involvement of virtually every organ of the anatomy, usually presenting with involvement of more than one organ. Despite the name of the entity, serum IgG4 is not always elevated.

**Table 1.** Main features in series of more than 100 patients and in current series

**Keywords:** Systematic review, Gastrointestinal tract

**Background:** Crohn's disease (CD) is a chronic inflammatory disease of unknown etiology. The IL-23/IL-17 pathway plays an essential role in the pathogenesis of CD. More and more approved IL-23 inhibitors are being used for the treatment of CD. However, no studies have systematically compared and evaluated the efficacy of these IL-23 inhibitors.

**Objectives:** This study aims to compare the efficacy of various IL-23 inhibitors (Brazikumab, Guselkumab, Mirikizumab, Risankizumab, and Ustekinumab) for treating Crohn's disease by conducting a Bayesian network meta-analysis (NMA).

**Methods:** We searched the database, including PubMed, Embase, Web of Science, Cochrane Library, MEDINE, and Web of Science, Clinical Trials. gov (from inception until February 5, 2023). Efficacy (Clinical response, Clinical remission, Endep remission, and C-reactive protein) were compared using a Bayesian NMA. Results were presented as the pooled estimates of odds ratios (ORs) or weighted mean difference (WMD) (95% CI). The random-effects model was selected to synthesize the data. The ranking probability for each IL-23 inhibitor was evaluated using the surface under the cumulative ranking curves (SUCRA). The larger the SUCRA value, the better the rank of the intervention. The global inconsistency was evaluated by comparing the fit of consistency and inconsistency models, where P ≤ 0.05 indicated inconsistency. All analyses were conducted using the gmeta package of R (version 4.2.2).

**Results:** In terms of Clinical response, a total of 40 studies were included. The NMA showed that Brazikumab combined with Guselkumab [OR=0.98, 95% CI [0.2, 0.91]], PB/PBO combined with Risankizumab [OR=0.54, 95% CI [1.16, 0.18]], PBO combined with Ustekinumab [OR=1.38, 95% CI [2.77, 0.01]], Risankizumab combined with Ustekinumab [OR=0.84, 95% CI [2.43, 0.63]], according to SUCRA, Ustekinumab (78.9%), Risankizumab (52.2%), PB/PBO (23.6%), Mirikizumab (34%), Guselkumab (876%), and Brazikumab (23.6%). For clinic remission, the result of NMA showed that Brazikumab combined with Guselkumab [OR=1.59, 95% CI [3.78, 0.59]], Brazikumab combined with Ustekinumab [OR=1.37, 95% CI [3.57, 0.83]], PBO combined with Risankizumab [OR=0.47, 95% CI [1.19, 0.34]], PBO combined with Ustekinumab [OR=1.26, 95% CI [2.86, 0.33]], Risankizumab combined with Ustekinumab [OR=2.86, 95% CI [0.98, 0.28]].
PLASMA NEUROFILAMENT LIGHT CHAIN AND GLIAL FIBRILLARY ACIDIC PROTEIN AS BIOMARKERS IN PATIENTS WITH OCULAR SARCOIDOSIS AND NEUROSAＲCΟΙΔΟΙΟΣ

Keywords: Biomarkers, Rare/orphan diseases, Uveitis

Background: Sarcoidosis is a disease characterized by non-caseating granulomatous inflammation, which can affect the eyes as ocular sarcoidosis (OS) and the central nervous system (CNS) as neurosarcoidosis (NS). Neurofilament light chain (NFL) is a structural neuronal cytoskeletal protein, and glial fibrillary acidic protein (GFAP) is part of the cytoskeleton in astrocytes and retinal Müller glial cells. Inflammation would cause leakage of NFL and GFAP. It has been demonstrated that plasma NFL is highly elevated in newly diagnosed NS patients with levels over 11.4 ng/L.

Methods: This cross-sectional study included 106 biopsy-verified chronic sarcoidosis patients examined between May and November 2019. After excluding 18 patients due to disease concomitance, the patients were divided according to their organ involvement over time: sarcoidosis without ocular or CNS affection (non-OS/non-NS), OS, NS, and combined OS and NS, respectively (p = 0.003), although this was only statistically significant in patients with a disease duration < 5 years (p = 0.005).

Values are median and interquartile range (IQR) or count and percentage. * Compared to non-ocular/non-CNS group p < 0.05. ** Compared to non-ocular/non-CNS group p < 0.01. a Between 67 -100% of patients received immunosuppressive treatment, most frequently in the OS group (93%) and the NS group (100%) (p = 0.02). Median NFL was 5.1, 8.4, 70.7, and 70.6 ng/L in patients with non-OS/non-NS, OS, NS, and combined OS and NS, respectively (p = 0.005), although this was only statistically significant in patients with a disease duration < 5 years (p = 0.005).

The frequency of patients with an NFL level >11.4 ng/L was lower in non-OS/non-NS group compared to the three other groups (2% vs. 14% vs. 33% vs. 20%, p = 0.004). There was a trend (p = 0.06) towards a lower median GFAP in patients with non-OS/non-NS as compared to the other groups (52 vs. 72 vs. 71 vs. 69 ng/L), which became statistically significant in patients with a disease duration < 5 years (48 vs. 67 vs. 127 vs. 52 ng/L, p = 0.02).

Conclusion: In this cross-sectional study of chronic sarcoidosis patients, we generally found a low median NFL level, including in OS and NS patients. Our results suggest that neuroaxonal damage and, thereby, active inflammation decreases in treated sarcoidosis patients. However, the median NFL levels were significantly lowest in the non-OS/non-NS group, and between 14-33% of patients in OS, NS, and combined OS and NS groups had an NFL level above 11.4 ng/L, which could indicate active CNS inflammation leading to ongoing silent neuroaxonal damage.

IGG4-RELATED DISEASE – THE PORTUGUESE COHORT UNDER RHEUMATOLOGY’S CARE

Keywords: Disease-modifying Drugs (DMARDs), Geographical differences, Epidemiology

methods: National multicentric observational study, including IgG4-RD patients followed at rheumatology.

Results: Twenty-four patients were included, with a mean present age of 59.95 years-old (SD=13.35), 56.09 (SD=14.13) at diagnosis, and 53.96 (SD=14.19) at the first symptoms. Twelve (50.0%) were men. Nine (37.5%) patients had salivary glands involvement (6 bilateral), 6 (25.0%) had orbital, 6 (25.0%) of lacrimal glands (4 of them bilateral), 5 (20.8%) pancreatic, 5 (20.8%) aortic, 4 (16.7%)
Familial Mediterranean Fever (FMF) is a systemic autoinflammatory disease requiring lifelong treatment, characterized by recurrent episodes of fever, arthritis, and serositis. Recent studies denote an association between FMF and behavioral disorders such as anxiety and depression[1]. Further investigations are needed to have a better understanding of the relationship of FMF to anxiety and depression.

Objectives: In this study, we aimed to assess anxiety and depression among FMF patients and their relation to different variables such as gender, age, genotype, drug compliance, biologic treatment, family history of FMF, age of first colchicine dosage, age of symptom onset, degree of education, and monthly income.

Methods: We surveyed 360 (225 female, 135 male) FMF patients in our outpatient clinic between June and October 2022. Our patients had moderate anxiety according to BAI scores, and severe state and trait anxiety according to STAI-Y1, STAI-Y2 scores all of which indicates the presence of anxiety. Medication compliant patients had lower levels of anxiety. We argue that this difference was due to better disease control because of drug compliance. Furthermore, BDI scores indicated mild depression among patients. In addition, M694V homozygous patients interestingly had lower anxiety and depression levels. Further investigations are necessary to understand the effect of different variables on anxiety and depression in FMF patients.

Background: Major organ involvement is one of the main causes of mortality and morbidity in Behçet’s Disease (BD) [1]. However, the prognosis and predictors of major organ involvement are insufficiently studied.

Objectives: We aimed to follow young, male BD patients with only mucocutaneous symptoms who have the highest risk for new major organ involvement prospectively.

Methods: Thirty-six male patients with BD were included in the study. Patients with BD were assessed prospectively at 3-6 months intervals and in any urgent visits. New major organ involvements and reasons for immunosuppressive (IS) need were assessed during prospective follow-up.

Results: At baseline, the mean disease duration was 3.3 years. All patients were under colchicine treatment. The mean follow-up duration was 90.7 months. Overall, 13 (36.1%) patients needed IS therapy during follow-up. The reason for IS need was major organ involvement in 5 (15.9%), refractory mucocutaneous involvement in 7 (21.9%), and articular involvement in 1 (2.8%) (Table 1, Figure 1). Major organ involvement was vascular in 3 patients, ocular in 1 patient, and ocular and vascular in 1 patient. In 8 of these 13 patients, step-up treatment was needed in ISs due to refractory disease or relapse.

Conclusion: Our study demonstrated a lower incidence of major vascular events in male BD patients during prospective follow-up compared to retrospective cohorts in the literature. Our results showed that refractory mucocutaneous involvement is a more frequent reason for IS need in BD than major organ involvement during prospective follow-up.

AB1510 THE RELATIONSHIP BETWEEN EMERGING NEW INFLAMMATORY MARKERS AND FAMILIAL MEDITERRANEAN FEVER SEVERITY

Keywords: Biomarkers, Rare/orphan diseases

S. Avcı Kasman1, M. E. Tezcan1, N. Şen1, S. Öşken1, S. Yılmaz-Oner1. 1Kartal Dr Lutfi Kirdar City Hospital, Rheumatology, Istanbul, Turkey

Background: Neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR) and monocyte lymphocyte ratio (MLR) are emerging inflammatory parameters. These parameters have been associated with disease activity and response to treatment in many rheumatological diseases.

Objectives: To evaluate the relation between these parameters and familial Mediterranean fever (FMF) disease severity.

Methods: We included 274 FMF patients in the study. First, we measured FMF disease severity cross-sectionally in patients with International FMF severity score (ISSF). We then divided the patients into mild disease (ISSF score ≤ 2) and moderate-severe disease (ISSF score >3) according to ISSF scores. Finally, we compared the NLR, MLR and PLR values between the two groups.

Results: Of 274 patients, 70 (25.5%) had moderate-to-severe FMF disease. More patients had amyloidosis, and the frequency of male gender was higher in the moderate-to-severe group. Other demographic and disease-related characteristics were similar between the groups. NLR, MLR, and PLR values were also similar between groups (Table 1).

Conclusion: Although emerging inflammatory markers are popular in the field of rheumatology, these parameters were unable to differentiate disease severity in patients with FMF.

AB1511 HIGHER VASCULAR INVOLVEMENT IN BEHÇET’S DISEASE AMONG KURDISH ETHNICITY: DATA FROM A SINGLE CENTER AT INTERSECTION OF SILK ROAD IN EASTERN TURKEY

Keywords: Behçet’s disease, Epidemiology, Uveitis

E. Oğuz1, M. Bektay2. 1Van Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Van, Turkey; 2Aksaray Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Aksaray, Turkey

Background: Behçet’s disease (BD) is a chronic inflammatory multi-systemic disease that affect skin-mucosa, joints, eye and blood vessels. BD has some clinical differences in terms of disease manifestations and prognosis among Silk Road countries as well as various ethnicities.
Objectives: In this study, we aimed to evaluate the clinical features and course regarding cluster analysis of BD in Kurdish patients in Van province, Eastern Turkey at the intersection of the silk road.

Methods: This retrospective observational study was carried out in a tertiary reference center in Van province, East of Turkey. Patients data was obtained from their charts. All patients were asked about their ethnicity and patients with other ethnicities rather than Kurdish were also excluded from the study. Seven disease manifestations were included to the cluster analysis as follows; mucocutaneous findings (recurrent oral ulcer [ROU], genital ulcer [GU], pseudofolliculitis, erythema nodosum (EN)-like lesions, musculoskeletal (MSK) involvement (arthritis and spondyloditis), gastrointestinal (GIS) involvement, vascular involvement (venous and/or artery), parenchymal central nervous system (CNS) involvement.

Results: We included 444 patients (of 59.2 % male) to the study. Mean ± standard deviation (SD) of the patients was 35.8 ± 10.2 years and median (interquartile range [IQR]) disease duration was 12 [12]. Mean ± SD age at initial symptom and age of diagnosis were 19.4 ± 7 and 26.4 ± 8.2, respectively. Fulfillment of ISG and ICBD criteria were 91.6 % and 96 %, respectively. Family history of Behçet disease and ROU were 35.4 % and 70.2 %, respectively. In cluster analysis, four clusters were observed as follow: 132 patients (31.2 %) in vascular (C1), 66 patients (15.6 %) in eye (C2), 60 patients (14.2 %) in musculoskeletal (C3) and 165 patients (39 %) in mucocutaneous (C4) clusters. Male gender (OR: 6.5, 95 % CI: 1.9-21.4), superficial thrombophlebitis (OR: 4.7, 95 % CI: 1.9-11.4) and uveitis (OR: 3.6, 95 % CI: 1.3-9.9) were associated with vascular involvement in multivariate analysis.

Conclusion: Among Kurdish patients with BD four disease clusters were observed. Parenchymal lung and CNS involvement were associated with vascular cluster. One third of patients had vascular involvement among Kurdish patients with BD which was quite higher compared to patients with Turkish ethnicity [1].

Figure 1.

Characteristics of Patients who Received Biological Treatment After Kidney Transplantation and the Incidence of Serious Infections: A Multicenter Study

Keywords: bDMARD, Kidneys

T. Demirci Yıldırım1, E. Oguz Kokoglu2, B. N. Coşkun3, D. Yıldırım4, S. Şener2, Y. Pehlivan5, H. Kıcıc6, T. Kaşgolu7, I. Sarı8, O. Dokuz Eyyubi University, Faculty of Medicine, Rheumatology, Izmir, Turkey; 2Erciyes University, Faculty of Medicine, Rheumatology, Kayseri, Turkey; 3Bursa Uludag University, Faculty of Medicine, Rheumatology, Bursa, Turkey; 4Gazi University, Faculty of Medicine, Rheumatology, Ankara, Turkey; 5Eskişehir Osmangazi University, Faculty of Medicine, Rheumatology, Eskişehir, Turkey

Background: Kidney transplant patients due to both primary kidney involvement of chronic/autoimmune inflammatory diseases and end-stage kidney disease related to amyloidosis are followed up in rheumatology clinics. Biological agents one of the treatment options in kidney transplant recipients with chronic/autoimmune inflammatory disease.

Objectives: However, there is insufficient data on the development of infection in kidney transplant recipients who received biological treatment. Herein, we aimed to determine the incidence of serious infections in patients with kidney transplant recipients who are received biological therapy.

Methods: Kidney transplant recipients who are received biological agents due to rheumatologic disease were included in the study. Patients' demographic features, transplantation data, biological treatment, development of infection and severity of infection were screened retrospectively. Infections that requiring hospitalization were defined as severe infections.

Results: A total of 31 patients were included in the study, 14 (45%) of whom were female and mean age was 41 ± 9 years. Twenty-five patients (80%) of them were non-preemptive kidney transplant and mean duration of hemodialysis before the transplantation was 40 ± 60 months. Twenty-three patients (74%) had end stage kidney failure due to FMD-amyloidosis (Figure 1). Seventeen patients (54%) received anakinra, 11 patients (35%) received canakinumab and 3 patients (10%) received enanetar with other immunosuppressive treatment. Mean treatment duration of biological agents was 4 ± 2.6 years. Two patients developed solid organ malignancy and one patient developed hematological malignancy after transplantation. Sixteen of the patients (52%) were hospitalized at least once due to infection and 4 patients (13%) died due to infection. The cause of decease in two patients was COVID-19.

Conclusion: Rheumatic diseases are an important cause of end-stage renal disease and definitive treatment is kidney transplantation. Kidney transplant recipients due to rheumatological disease also use biological agents in the post-transplantation period.
Kidney transplant recipients have higher risk for the development of infection since they receive immunosuppressive therapy and use of biologic agents may further increase the risk for development infection. Meyer et al reported that infection developed in 54 of 187 solid organ transplant recipients using biological agents.[1] Mean treatment duration of biological agents was 12 months in this study. The incidence of infection was 54% in our study. Mean treatment duration of biological agent was 4.2 year was considered main reason for higher incidence of infection in our study.

REFERENCE:

Figure 1: Causes of end stage kidney failure in this study

Conclusion: The literature suggests renal impairment is variable in retroperitoneal fibrosis with only 32% of patients with abnormal creatinine reported in one study which is much lower than our results. The current literature is sparse for alternative therapies. More work is required in determining efficacy for more recent therapies such as rituximab to further the treatment of this orphan disease and improve patient outcomes.

Conclusion: The prevalence of Behçet’s disease (BD) has a considerable geographical and temporal variability. Data regarding epidemiology in Spain are limited. (1,2)

OBJECTIVES: To assess the epidemiology and clinical domains of BD in a population-based cohort from northern Spain and to compare the results with other geographical areas.

METHODS: We conducted a cross-sectional study of a well-defined population in Northern Spain. Cases of suspected BD between January 1980 and December 2018 were identified. The diagnosis of BD was established according to the International Study Group (ISG) for Behçet’s Disease. The incidence of BD between 1999 and 2018 was estimated by sex, age and year of diagnosis.

RESULTS: Of 120 patients with probable BD, 59 patients met ISG criteria and were finally included in the study, with a male/female ratio of 0.97; mean age 49.7±14.7 years. Incidence during the period of study was 0.492 per 100,000 people, observing an increase from January 1999 to December 2018. Prevalence was 10.14 per 100,000 in 2018. Figure 1. Clinical manifestations were relapsing aphthous stomatitis (100%), genital ulcers (78%), skin involvement (64.7%), joint involvement (64.4%), uveitis (55.9%), central nervous system (16.9%), vascular (10.2%), and gastrointestinal manifestations (6.8%). Table 1.

Conclusion: The prevalence of BD in Cantabria is higher than in other Southern-European countries. This difference may reflect a combination of geographic, genetic, or methodological variations, as well as the free accessibility to the Spanish Public Health System. Clinical phenotypes observed are similar to those described in other world regions.

**AB1515** EPIDEMIOLOGICAL AND CLINICAL FEATURES OF MUCOCUTANEOUS LESIONS IN BEHÇET’S DISEASE: STUDY FROM A COHORT OF 120 PATIENTS IN A REGION IN NORTHERN SPAIN

**Keywords:** Behçet’s disease, Epidemiology, Skin

**Background:** Mucocutaneous lesions are one of the most characteristic signs of Behçet’s Disease (BD) and are included in different classification criteria [1].

**Objectives:** To describe the mucocutaneous manifestations and to assess it accordingly to age and sex.

**Methods:** Descriptive study of a cohort of 120 patients diagnosed with BD from January 1, 1980 to December 31, 2019. Finally, we included 92 patients following the 2014 International Criteria for Behçet’s Disease (ICBD) [2].

**Results:** 92 patients (45 men/ 47 women) had mucocutaneous involvement. Mean age at diagnosis was (36.3±12.6) years. 27 (29.3%) were young adults (<30 years), 61 (66.3%) middle-aged adults (30-60) and 4 (4.3%) elderly adults (>60 years). The most frequent mucocutaneous manifestations were oral ulcers (OU) (n=92, 97.9%), genital ulcers (GU) (n=69, 73.4%), pseudofolliculitis (n=47, 50%), erythema nodosum-like lesions (EN) (n=28, 28.9%) and Raynaud’s phenomenon (n=8, 2%). OU, GU, EN-like lesions and Raynaud’s phenomenon were more frequent in women. GU and pseudofolliculitis were more frequent in men. No statistical differences were found between sexes (χ² test). Pathergy test was positive in 4 patients. Histopathology of EN-like lesions was performed in 5 patients, 3 (60%) showed septal panniculitis and 2 (40%) vasculitis with neutrophil infiltration, which is a typical pathological finding of EN-like lesion in BD [2]. Table 1. Mucocutaneous lesions divided by age groups are represented in Figure 1.

**Conclusion:** Identifying characteristic mucocutaneous lesions of BD, as OU, GU, pseudofolliculitis and EN-like lesions may allow early diagnosis and treatment of the disease. There were no gender differences in mucocutaneous lesions.

Graph 1. Treatment response of oral aphthae after 12 months

Key: <0.05, *: p<0.01, #: p<0.001

Keywords: Hypermobile Ehlers-Danlos Syndrome, patients: pilot investigation

Background: Hypermobile Ehlers Danlos syndrome (nEDS) is the most common subtype among the EDS syndromes and is a rare inherited connective tissue disease characterized mostly by hyperextensible skin and generalized joint hypermobility. Microvascular assessment has been documented only by one case report in the “vascular type” of EDS, despite vascular manifestations may improve, lack of response, discontinuation due to side effects), ESR, CRP, ferritin, 25-OH-Vitamin D, folic acid, cyanocobalamin and concomitant treatment (none, corticosteroids, methotrexate, colchicine or anti-TNF). Descriptive statistics were performed using mean and standard deviation (SD) for continuous quantitative variables.

Results: A total of 15 patients were being treated with apremilast for oral aphthosis. Ten of them were diagnosed with Behçet's disease, one with psoriasis with oral aphthosis and four with recurrent oral aphthosis. Mean age was 47.1±12.4 years, 67% were female. All patients had active oral aphthosis at the time of starting apremilast. After 3 months of treatment, 87% of the patients had improvement of the aphthosis (61.5% partially and 38.5% completely resolved); 13% of the patients had to discontinue treatment due to side effects (diarrhea), none had to discontinue treatment due to lack of response. After 6 months, all the patients maintained improvement and only two of them discontinued apremilast after 12 months due to lack of response. Results of serological data analyzed were (mean ± SD): ESR 11.4±6.7, CRP 3.7±6.5, ferritin 25-OH-Vitamin D 31.4±18.9, folic acid 11.7±9.8, cyanocobalamin 585.8±527. One patient maintained concomitant treatment with an anti-TNF drug, two with corticoids and five with colchicine.

Conclusion: Treatment with apremilast seems to improve oral aphthae in over 87% of patients.

References:

occur also in other EDS subtypes [1,2]. A reduced skin thickness has been previously reported in hEDS patients [3].

**Objectives:** To investigate, for the first time, nailfold microvascular status in hEDS patients in comparison with healthy controls (HCs). Peripheral blood perfusion (PBP) and dermal thickness (DT) were also assessed.

**Methods:** Twelve hEDS patients (75% females, mean age 41±16, classified with the 2017 International Classification Criteria of EDS [4]) and twelve age- and sex-matched HCs were observed from 2018 to 2022. Beighton score was calculated for both patients and HCs. Main nailfold videocapillaroscopy (NVC) parameters (dilated capillaries, giant capillaries, microhemorrhages, abnormal shapes and number of capillaries) were analyzed and compared between the two groups to assess morphological features [5]. To assess the microvascular functional status, laser speckled contrast analysis (LASCA) was used to measure PBP in several regions of interests. DT was also measured by cross-sectional B-mode scans obtained by a high-frequency 22 MHz ultrasound probe in 17 different areas of the body (including upper arms, lower arms, trunk and forehead).

**Results:** No statistically significant differences were observed in this small cohort between hEDS and HCs concerning the microvascular findings detected by NVC, even if microhemorrhages were more prevalent in hEDS patients (33% vs 0 %) (see Table 1). Also, PBP assessed by LASCA was found similar in hEDS patients and HCs (17.8± 49.76 perfusional units vs 15.78± 67.15 at fingertips, p = 0.43). The mean DT did not significantly differ from hEDS patients and HCs in all skin areas (mean total DT of 18.44 ± 2.21 mm in hEDS patients vs 18.49 ± 2.13 mm in HCs, p = 0.96). As expected, the mean Beighton score was significantly higher in hEDS patients than in HCs (5.5± 1.75 vs 12.5± 1.58), but no significant correlation was detected between DT and Beighton score (r = 0.1, p = 0.79).

**Conclusion:** Microhemorrhages seem more prevalent in hEDS patients than in ECs, suggesting a subclinical microvascular fragility also in this subgroup of EDS patients. Skin ultrasound and PBP findings did not detect significant differences between hEDS patients and HCs, which might be due to the small sample size. These findings will be followed by further research including cases of the vascular EDS phenotype [8].

**AB1519 INCIDENTIALLY FOUND INTERSTITIAL LUNG DISEASE MAY NOT BE UNCOMMON IN FAMILIAL MEDITERRANEAN FEVER**

**Keywords:** Rare/orphan diseases, Comorbidities, Imaging

*S. Acer Kasman1, N. Sen1, T. Baysal2, R. Dizman2, S. Yilmaz-Oner1, M. E. Tezcan1. 1Kartal Dr Lutfi Kirdar City Hospital, Rheumatology, Istanbul, Turkey; 2Kartal Dr Lutfi Kirdar City Hospital, Radiology, Istanbul, Turkey

**Background:** Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by episodes of serositis and fever. Pleuritis is one of the common findings especially during attacks and thorax scans. However, data on other common lung findings such as interstitial lung disease (ILD) are limited in the literature.

**Objectives:** Here, we present the frequency of ILD and factors associated with ILD in our FMF cohort.

**Methods:** We included 242 patients who applied to the rheumatology outpatient clinic of a tertiary medical center within the last five years and were requested to undergo thoracic CT for any reason. The patients with a history of malignancy, active infection, active tuberculosis, or tuberculosis history, active or history of coronavirus 19 disease (COVID-19), nursing and pregnancy were excluded. An experienced radiologist blindly evaluated thoracic CT scans for ILD in accordance with relevant guidelines. We then evaluated the relationship between ILD findings and demographics and disease characteristics.

**Results:** Eleven (4.5%) of 242 patients had ILD. The most common ILD-related findings on thoracic CT were ground glass opacity (7/11 patients). None of the patients had honeycomb appearance. The most common reasons for requesting a thoracic CT were chest/chest pain, suspected COVID-19, and chronic cough. In addition, none of the demographic and disease-related characteristics were associated with ILD in our FMF patients (Table 1).

**Conclusion:** We have shown that incidentally diagnosed ILD is not uncommon in our FMF patients. In addition, FMF feature may not be associated with ILD in our patients.

while there was no correlation found between PLR and disease activity. Levels of NLR and PLR were both significantly higher in the patient group compared to the controls (p<0.001 and p<0.05 accordingly).

Conclusion: Taking into consideration data from our study NLR could be implemented in clinical practice as a cheap and easy accessible marker of the Behcet's disease activity. On the other hand, further studies with bigger samples are required to evaluate changes of PLR in BD. Assessment of NLR and PLR among BD patient in remission is required to find out if there are any changes compared to healthy controls.

A SURVEY ON OCULAR CICATRICAL PEMPHIGOID. WHAT DO RHEUMATOLOGISTS AND OPHTHALMOLOGISTS THINK ABOUT IT?

Keywords: Rare/orphan diseases

A. Ringer1, A. M. Smichowski2, C. Siegrist1, D. G. Grossi3, S. Chulibert1, A. M. Smichowski2, C. Siegrist1, D. G. Grossi3, S. Chulibert1,

Background: Mucous membrane pemphigoid is a systemic, chronic, scarring inflammatory disease of autoimmune aetiology. Isolated ocular involvement has been described in isolated cases, and in a case series of patients with Behcet’s disease [1]. We also recently showed that this is a distinctive feature of Behcet’s disease (BD) [2]. We also recently showed that this is a distinctive feature of Behcet’s disease (BD) [2].

Methods: An online survey was conducted, which was accessed through a link to a Google form. This questionnaire was addressed mainly to rheumatologists and ophthalmologists with OCP and their interdisciplinary interaction in the region.

Results: Of the 433 patients surveyed, 173 were familiar with OCP and their interdisciplinary interaction in the region.

Conclusion: The high percentage of insufficient knowledge of this entity by rheumatologists (70%), and the high referral of these patients to rheumatology by ophthalmologists familiar with OCP (80%), it is imperative to work to expand its knowledge, transmission and joint work between both specialties, to improve and protocolize the approach to this entity, which can produce irreversible sequelae on the ocular surface.

DOES PATIENT POSITION AFFECT COMMON FEMORAL VEIN WALL THICKNESS MEASUREMENT BY DOPPLER ULTRASONOGRAPHY AS A DIAGNOSTIC TEST?

Keywords: Behcet’s disease, Ultrasound

R. Ergelen1, S. Kutluğ Ağçaşan2, H. Direskeneli3, F. Albaz-Oner2, 1Marmara University Faculty of Medicine, Department of Radiology, Istanbul, Turkey; 2Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: We reported the first controlled Doppler ultrasound (US) study demonstrating increased common femoral vein (CFV) thickness in Behcet’s Disease (BD) [1]. We also recently showed that this is a distinctive feature of BD, rarely present in other inflammatory diseases with a specificity higher than 80% for the cut-off value of ≥ 0.5 mm [2]. Standart lower extremity venous Doppler US is performed in erect position for venous thrombosis or insufficiency [3]. However, we measured CFV thickness in supine position in our previous studies.

Objectives: In this study, we aimed to assess CFV wall thickness measurement by Doppler US both in supine and erect positions to validate the accuracy and practicability of this diagnostic method in BD.

Methods: We included 42 patients (Male/Female:27/15, mean age:39.8 (10.04) years) with a diagnosis of BD and sex and age-matched 41 healthy controls (Male/Female:21/18, mean age: 36.5 (8.4) years). The clinical data were recorded during routine visits. Bilateral CFV thickness was measured with Doppler US both in erect and supine positions by an experienced radiologist on the same day.
Results: Clinical characteristics of BD patients were given in Table 1. Bilateral CFV wall thickness was significantly higher in BD than in healthy controls (0.74 vs. 0.18 mm, p<0.001 for right, 0.74 vs. 0.19 mm, p<0.001 for left). There was no statistically significant difference between erect and supine positioned measurements of CFV wall thickness both in BD and healthy control groups (Figure 1).

Conclusion: CFV measurement by Doppler US is a new, accurate and non-invasive diagnostic tool for the diagnosis of BD. Although lower extremity venous Doppler US is performed in erect position for the assessment of venous thrombosis or insufficiency, our study confirmed that patient position does not affect CFV wall thickness measurement. Both erect and supine positioned CFV wall thickness measurements can be done accurately for the diagnosis of BD.

ROLE OF BIPHOSPHONATES IN THE MANAGEMENT OF OSTEOGENESIS IMPERFECTA

Keywords: Bone diseases

F. Fhima1, J. Mahboub1, M. Ardhahoui1, M. Ghali1, S. Zrou1, I. Beija1, M. Touzi1, N. Bergaoui1, Fattouma Bourguiba Hospital, Rheumatology Department, Monastir, Tunisia

Background: Osteogenesis imperfecta (OI), or Lobstein’s disease, is a group of genetic diseases characterized by excessive bone fragility, due to a congenital defect in the elaboration of collagen fibers of the connective tissue. Bisphosphonates, with their anti-resorptive properties, are currently the reference medical treatment for this pathology, but remain a symptomatic treatment of the disease.

Objectives: This study aims to describe the addition of bisphosphonates to the management of OI.

Methods: This is a retrospective descriptive study collecting patients with OI followed in the rheumatology department of the Fattouma Bourguiba Hospital of Monastir. The study period was 17 years from 2005 to 2021. We investigated the evolution of bone mineral density (BMD) under bisphosphonates by evaluating the total gain in BMD with measurement of the SDD: Smallest Detectable Difference (in g/cm2). The threshold value of the SDD in absolute value is equal to 0.030 to 0.035 g/cm2. A variation of the SDD > 0.030 g/cm2 is a significant variation whether positive or negative.

Results: We collected 16 patients. Fourteen patients had a type I of OI. Type III and type IV were found in one case each. Nine of our patients were male with a sex ratio M/F=1.3. At diagnosis, the patients were divided into 13 children and 3 adults. The mean age at diagnosis was 11 years old for children [1 year, 18 years] and 34 years old for adults [27 years, 40 years]. Fifteen patients had a history of fracture. Fractures in the lower limbs were more frequent than in the upper limbs, with a number of fractures ranging from 3 to 20. Bone deformities were found in 10 patients affecting the lower limbs in 8 cases, the spine in 4 cases, the thorax in 2 cases, and the skull in 1 case. Radiologically, all patients had bone hypertransparency. Spinal involvement was frequent and included scoliosis (2 cases), hyperkyphosis (2 cases), biconcave vertebral compression (4 cases) and platyspondyly (4 cases). Osteoporosis was found in 9 cases and osteopenia in 6 cases. Therapeutically, all our patients received vitaminocalcic supplementation and bisphosphonates: pamidronate, according to Glorieux’s protocol: 1.5 to 3 mg/kg/cycle (i.e., 0.5 to 1 mg/kg/3 days in a row) for children and 90 mg (single infusion) for adults. The side effects observed with bisphosphonates were: hypocalcemia in 8 cases, flu-like syndrome in 5 cases, fever in 4 cases, and chest pain in 1 case. The evolution on bisphosphonates was evaluated by the total gain in BMD. The mean SDD was: +0.105 g/cm2 at the spine (significant positive change), +0.015 g/cm2 at the femoral neck (non-significant positive change) and +0.014 g/cm2 at the whole body (non-significant positive change).

Conclusion: The therapeutic management of patients with OI is multidisciplinary and complex. In this study, all patients were treated with pamidronate according to the protocol of Glorieux. They had a gain in bone mass that was remarkably significant in the spine.

**CLINICAL SIGNS AND ACTIVITY LIMITATIONS ASSOCIATED WITH DURAL SAC ECTASIA IN INDIVIDUALS WITH MARFAN DISEASE: A CROSS-SECTIONAL CASE-CONTROL STUDY**

**Keywords:** Cardiovascular disease, Rare/orphan diseases, Patient reported outcomes

S. Trousslet1, O. Milleret2, L. Ellahiou2, C. Daeste3, M. M. Lefevere Cola3,2, F. Rannou4, A. Roren3, G. Jongeau2, C. Nguyen3.1 Cochin Hospital, Rehabilitation, Paris, France; 2Bichat-Claude Bernard Hospital, Cardiology, Paris, France; 3Cochin Hospital, Rehabilitation, Paris, France

**Background:** Dural ectasia often occurs in individuals with Marfan disease. Fibrillin-1, a matrix component of microfibrils, has been hypothesized to play a role in the circulation of cerebrospinal fluid [1]. Modifications in the circulation of cerebrospinal fluid in individuals with Marfan disease may lead to an increased pressure in the lumbo sacral area and a decreased pressure in the cephalic extremity.

**Objectives:** We hypothesized that individuals with Marfan disease and dural ectasia, as compared to individuals with Marfan disease without dural ectasia, may display a specific pattern of painful symptoms and spine-specific activity limitations [2]. The aim of our study was to compare the frequencies and characteristics of painful symptoms, and the intensity of back and leg pain, spine-specific activity limitations, and health-related quality of life, between individuals with Marfan disease with and without dural ectasia.

**Methods:** We conducted a single-centred cross-sectional comparative study. All individuals with Marfan disease followed in the department of cardiology of Bichat hospital (Paris, France) and recorded in the computerized database of the department from inception to January 2022 were systematically screened. Inclusion criteria were: adults $\geq$ 18 and $\leq$ 65 years; fulfilling Ghent nosology; FBN1 mutations confirmed by genetic testing; and CT-scan or magnetic resonance imaging available. Non-inclusion criteria were: history of lumbar surgery $<1$ year; specific back pain (i.e. tumor, infection, traumatism, fracture, inflammation); imaging available. Non-inclusion criteria were: history of lumbar surgery $<1$ year; specific back pain (i.e. tumor, infection, traumatism, fracture, inflammation); non-inclusion criteria were: history of lumbar surgery $<1$ year; specific back pain (i.e. tumor, infection, traumatism, fracture, inflammation).

**Results:** 247 individuals were eligible to participate and were contacted by mail. 90 (36%) individuals accepted to participate and were included: 55 (61%) had dural ectasia and 45 (39%) did not (Figure 1). Mean participants’ age was 39.3 (8.4) years and 45 (50%) were women. 80 (89%) participants had back pain, most often located in the lower back, 65 (71%) a history of scoliosis and 8 (8%) a history of spine surgery. 15 (17%) participants had a history of high blood pressure, 84 (93%) a dilation and/or dissection of the ascending aorta, and 52 (58%) an aortic surgery. The 3 most often reported painful symptoms were increased pain in the lower back with upright posture in 53 (58%) participants, increased headache with upright posture in 36 (40%) and increased pain in the lower back when walking in 31 (34%). The frequencies of increased headache with upright posture and of increased pain in the lower back when coughing, laughing and/or sneezing were numerically higher in participants with than without dural ectasia (49% vs 26% and 13% vs 0%, respectively), without reaching statistical significance ($p$-value=0.030 and $p$-value=0.021, respectively) (Table 1).

**Conclusion:** Individuals with Marfan disease and dural ectasia, as compared to those without dural ectasia, display a specific pattern of painful symptoms, including lower back pain and headache with upright posture. We detected two differences in favor of a link between ectasia of the dural sac and abundance in ascending aortic surgery (64% vs 49%).

**A NOVEL ACCELEROMETER-BASED METHOD FOR EARLY DETECTION OF PERIPHERAL NEUROPATHY ASSOCIATED WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES**

**Keywords:** Telemedicine, Diagnostic tests, Validation

Z. Veličković1, S. Pavlov Doljanović1, N. Tomonić1, J. Janić2, B. Stojić2, G. Radunović1.1 Institute of Rheumatology, Internal Medicine - Rheumatology, Belgrade, Serbia; 2Institute of Rheumatology, Physical Medicine and Rehabilitation, Belgrade, Serbia

**Background:** Systemic autoimmune rheumatic diseases (SARDs) such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), primary Sjögren’s syndrome (SS), and systemic sclerosis (SSc) occasionally affect the peripheral nervous system. Nerve conduction studies (NCS) can almost certainly confirm the diagnosis of SARD-associated neuropathy. The NCS method is usually considered the gold standard for neuropathy assessment, although this method is based on physicians’ knowledge and experience. However, it is painful for patients, long-lasting, prone to errors, and can’t be used for routine follow-up. There is an urgent need for potential alternative diagnostic screening methods for implementation in everyday practice. Wearable sensor devices, such as accelerometers, are instruments that can be utilized to acquire data during different activities. Their size and wirelessness, lower cost, portability, and use in home-based and real-life situations are a few of the advantages.

**Objectives:** To evaluate a telemedicine wearable device with a machine learning algorithm that can be used as a screening and tracking tool for SARD-related neuropathy.

**Methods:** A monocentric, diagnostic study was conducted at the Institute of Rheumatology in 2020. The participants were healthy volunteers and SARD patients who had suspected neuropathy. The participant started with the NCS examination; electrodes were placed on the limbs, and amplitude, latency, and conduction velocity of n. medianus, n. ulnaris, n. peroneus, n. tibialis, and n. suprascapularis (motor and sensory fibres) were measured. The novel method consists of four wearable sensors placed over the middle of the hands and feet. The subject performed six exercises with open and closed eyes. Raw data was sent through the Bluetooth connection from the sensors to the tablet and then via WiFi connection to the central server for further analysis. A wearable device uses a specific mathematical algorithm that transforms signals from the accelerometer and gyroscope into specific values. The outcome is defined as a binary variable: whether or not neuropathy exists.

**Results:** The study included 23 participants 9 (2 and 314), 11 with SARDs (45.8%). Of the total number of SARD participants, 8 (72.7%) had neuropathy confirmed with the NCS examination. The features (such as acceleration or power) obtained with signal processing were examined, and only those that can be used to discriminate SARD-related neuropathy are presented (Table 1). The model for binary classification was developed and presented in Table 2. As shown, the sensitivity and specificity are satisfactory, but the confidence intervals are still wide. Positive predictive value is significantly lower compared to negative predictive value. The conclusion: Wearable sensors represent accurate and promising technology for the diagnosis of neuropathies related to SARDs. Further studies are needed to evaluate the true accuracy of the technology.

Methods: Power Doppler (PD) signals are occasionally detected in the deltoid ligament on musculoskeletal ultrasound (MSUS) examination of symptomatic patients with rheumatoid arthritis (RA) and related disorders. We reviewed the record of MSUS examined in Japanese Red Cross Medical Center between April 2015 and October 2022. We examined the characteristics of medical record information and images of cases in which power Doppler signals were observed in the deltoid ligament. Patients with only a few punctate signals or less were excluded. Patients with only traumatic or degenerative disorders were also excluded.

Results: PD signals more than a few punctate signals were observed in the deltoid ligament in 31 cases. The disease categories and diagnoses of the patients were as follows: 13 spondyloarthritis (SpA) patients (9 undifferentiated SpA (USpA), 2 psoriatic arthritis, 2 reactive arthritis), 10 rheumatoid arthritis (RA) patients (6 early RA, 4 established RA), 7 crystal-induced arthritis (CIA) (6 gout, 1 CPPD), and 1 primary Sjogren's syndrome. All SpA patients met the ASAS criteria for peripheral SpA and all RA patients fulfilled the 2010 ACR/EULAR classification criteria. In SpA cases, PD signals tended to be predominantly on the superficial surface of the ligament in RA patients (superficial distribution, 7 out of 10 cases). There was a significant difference in the PD signal distribution pattern between SpA and RA by Fisher's exact test (p=0.0397). In all CIA patients, hyperechoic materials were detected in the ligament.

Conclusion: According to literature reports, SpA is considered relatively rare in Japan, where the HLA-B27 positivity rate is < 0.3%, with an estimated population prevalence of < 0.01% [1]. The estimated prevalence of patients with RA in Japan is 0.65% [2], similar to the rest of the world. Considering the prevalence of each disease, we speculate that PD signals in the deltoid ligament are more characteristic of SpA. The presence of PD signals in the deltoid ligament, especially with a broad and deep distribution, may provide diagnostic clues for SpA, particularly undifferentiated spondyloarthritis.

Table 2. The presence of power doppler signals in the deltoid ligament, especially with a broad and deep distribution, may provide diagnostic clues for spondyloarthritis, particularly undifferentiated spondyloarthritis

Keywords: Ultrasound, Rheumatoid arthritis, Spondyloarthritis

T. Suzuki1, H. Shira1,1, Japanese Red Cross Medical Center, Department of Rheumatology and Allergology, Tokyo, Japan

Background: Power Doppler (PD) signals are occasionally detected in the deltoid ligament on musculoskeletal ultrasound (MSUS) examination of symptomatic patients with rheumatoid arthritis (RA) and related disorders. We reviewed the record of MSUS examined in Japanese Red Cross Medical Center between April 2015 and October 2022. We examined the characteristics of medical record information and images of cases in which power Doppler signals were observed in the deltoid ligament. Patients with only a few punctate signals or less were excluded. Patients with only traumatic or degenerative disorders were also excluded.

Results: PD signals more than a few punctate signals were observed in the deltoid ligament in 31 cases. The disease categories and diagnoses of the patients were as follows: 13 spondyloarthritis (SpA) patients (9 undifferentiated SpA (USpA), 2 psoriatic arthritis, 2 reactive arthritis), 10 rheumatoid arthritis (RA) patients (6 early RA, 4 established RA), 7 crystal-induced arthritis (CIA) (6 gout, 1 CPPD), and 1 primary Sjogren’s syndrome. All SpA patients met the ASAS criteria for peripheral SpA and all RA patients fulfilled the 2010 ACR/EULAR classification criteria. In SpA cases, PD signals tended to be predominantly on the superficial surface of the ligament in RA patients (superficial distribution, 7 out of 10 cases). There was a significant difference in the PD signal distribution pattern between SpA and RA by Fisher’s exact test (p=0.0397). In all CIA patients, hyperechoic materials were detected in the ligament.

Conclusion: According to literature reports, SpA is considered relatively rare in Japan, where the HLA-B27 positivity rate is < 0.3%, with an estimated population prevalence of < 0.01% [1]. The estimated prevalence of patients with RA in Japan is 0.65% [2], similar to the rest of the world. Considering the prevalence of each disease, we speculate that PD signals in the deltoid ligament are more characteristic of SpA. The presence of PD signals in the deltoid ligament, especially with a broad and deep distribution, may provide diagnostic clues for SpA, particularly USpA.

### AB1528 APPLICATION OF BONE MARROW EDEMA SCORING SYSTEM DERIVED ARTIFICIAL INTELLIGENCE IN RAPID RADIOGRAPHIC PROGRESSION RESCUE STUDY

**Keywords:** Rheumatoid arthritis, Imaging

K. Katayama, T. Okubo, K. Yuiro, T. Sato, T. Kawahata, K. Tanaka, S. Abe, H. Ito, K. Morii. Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan; Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan; Sapporo Rheumatology and Immunology Clinic, Rheumatology, Sapporo, Japan; Asahikawa Medical University, Division of Metabolism and Biosystemic Science, Gastroenterology, Hematology/Oncology, Department of Medicine, Asahikawa, Japan; Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan; Graduate School of Informative, Information and communications, Nagoya, Japan

**Background:** We demonstrated new bone marrow edema (BME) scoring system in X-ray (specificity 90%, sensitivity 65-70%) using deep learning with artificial intelligence (AI) reflects MRI BME in previous EULAR meeting[1].

**Objectives:** In this study, to ascertain whether BME score in this system by X-ray film might reflect MRI BME in Biologics therapy, we retrospectively applied this system to the rapid radiographic progression rescue study previously reported[2].

**Methods:** RA patients inadequate response with MTX who have extensive BME in single or bilateral wrist joints and DAS28-ESR>3.2 were treated by enhanced group, of conventional synthetic (cs) DMARDs (26 patients) or by biologics (23 patients). X-ray film of two groups after 3-6 months treatment applied to BME scoringsystem (cut off:0.4) and compared with MRI BME.

**Results:** J-PEG file of hand Xray film were uploaded to new BME scoring system(Figure 1). BME score are expressed as Positive or Negative and index [0-1]. In biologics group, number of BME score positive rate reduced from 65.3% to 15.3% after treatment MRI BME unchanged group(1). In csDMARDs enhanced group, number of BME score positive rate reduced from 75% to 25% after treatment MRI BME improvement group and reduced 58.7% to 53.1% in MRI BME unchanged group. In both groups, false negative (N: Figure 1, white color back) patients were observed.

**Conclusion:** AI-derived bone marrow edema score may reflect bone marrow edema in MRI in biologics treatment and may help early recognition of biologics efficacy during treatment.

Keywords: Crystal arthritis, Diagnostic tests

T. Niessink1,2, M. Janssen2, T. Jansen2, C. Otto1, University of Twente, Medical Cell Biophysics, Enschede, Netherlands; 1VeeCuri Medical Centre, Rheumatology, Venlo, Netherlands

Background: Microplastics (MPs) have been identified in different types of tissue, including lung, bowel, placenta and as well in human whole blood [1]. During analysis of synovial fluid samples with Raman spectroscopy with the purpose of identification of crystals related to crystallopathies, presence of multiple types of MPs have been identified. Due to the recent interest in the effect of plastic pollution on human health, the noticed presence of these particles in synovial fluid samples is concerning and worthy of our attention.

Objectives: The objective of this study was to characterize deposited MPs in samples drawn from arthritis patients presenting to our rheumatology outpatient clinic, with the aim of calculating their prevalence and estimate the significance of their presence against blank control samples as we are using a novel and highly sensitive technique of integrated Raman spectroscopy with Polarized light microscopy in routine clinical practice.

Methods: This is an analysis of Raman spectroscopic data retrieved from 156 synovial fluid samples from consecutive series of patients visiting our outpatient clinic. Data was compared against a series of blank samples of MiG processed in similar fashion. The number of required blank samples was calculated with the formula of Rosner (2011, [2]), the study population was compared against the controls with a Chi-Square test.

Results: A total of 96 MPs were identified, in 4 distinct types: polyethylene (PE), polypropylene (PP), polyethylene terephthalate (PET). A total of 44 samples (28.2%) were positive for one or more particle (Figure 1). 19 samples (12.2%) samples had one identified MP, 15 (9.6%) had two identified MP, and 10 (6.4%) had three or more identified MPs (Figure 3). Combinations of MPs were present in 7 of 22 samples (31.8%) with more than one MP. Most MPs were identified extracellular, although one case of intracellular polyethylene particles was identified.

The incidence in MPs in the study population was 30.8%. With an alpha (significance level) of 0.05 and a power of 90%, 10 blank control samples would be enough to find a significant difference if in none of these samples particles are identified. However, we identified one or more microplastics in 4 (40%) of the 10 samples. Polyethylene was identified in 3 samples (30%), polypropylene in 1 (10%), and polyethylene terephthalate in 1 (10%). 1 (10%) sample had a combination of plastic types. With a threshold of 1 or more identified MPs considered positive, there is no significant difference (p = 0.542) between the blank controls and the patient sample population.

Conclusion: Due to numeric presence of extracellular microplastics in both patient material as the blank control samples we define that the presence of one or two MPs in a synovial fluid sample from a swollen joint is not significant and probably of no clinical importance. For the determination whether a higher number of extracellular MPs can be significant and of potential clinical relevance, more control samples are to be measured. The interpretation of the presence of intracellular microplastics needs further investigation.

AB1530 USING MACHINE LEARNING TO ANALYZE THE FUNDOSCOPY OF ANKYLOSING SPONDYLITIS, PSORIATIC ARTHRITIS AND PSORIASIS

Keywords: Imaging, Artificial intelligence, Spondyloarthritis

Y. J. Huang1, Y. H. Huang2, Y. C. Kang3, Z. Y. Liu4, J. S. Chen5, C. H. Lin6, C. F. Kuo7,1, 1Chang Gung Memorial Hospital, Department of Rheumatology, Allergy and Immunology, Taoyuan City, Taiwan, Republic of China; 2Chang Gung Memorial Hospital, Department of Dermatology, Taoyuan City, Taiwan, Republic of China; 3Chang Gung Memorial Hospital, Department of Ophthalmology, Taoyuan City, Taiwan, Republic of China; 4Chang Gung Memorial Hospital, Center for Artificial Intelligence in Medicine, Taoyuan City, Taiwan, Republic of China; 5Chang Gung Memorial Hospital, Center for Artificial Intelligence in Medicine, Taoyuan City, Taiwan, Republic of China

Background: Autoimmune diseases are associated with an increased risk of cardiovascular disease which can be preceded by microvascular changes. The study about fundoscopy in ankylosing spondylitis is described by Bentum et al.[1] but the related study about deep learning model is insufficient.

Objectives: To validate the ability of machine learning model to verify the fundoscopy of ankylosing spondylitis, psoriatic arthritis, psoriasis and normal control.

Methods: We collected 1864 color fundus exams of 1105 patients with ankylosing spondylitis, psoriatic arthritis and psoriasis in Chang Gung Memorial Hospital in Taiwan from January 2001 to June 2022. The control group is 7122 fundoscopies of 5525 patients matched with age and gender. We separated database into training group, validation group and testing group. (7:1.5:1.5). We trained two convolutional neural networks including Vgg-11 and ResNet-18 to perform the segmentation and capture the obscure findings of fundoscopy that human eyes cannot identify. We use the sensitivity, specificity, AUC, odds ratio and positive likelihood ratio to evaluate the performance of machine learning to diagnose ankylosing spondylitis, psoriatic arthritis and psoriasis.

Results: The ankylosing spondylitis, psoriatic arthritis and psoriasis patients have higher body mass index, disease-modifying antirheumatic drugs and biological agents usage, and even more comorbidities with dyslipidemia, hypertension and coronary artery disease compared with control group. In the setting of one case with solitary image of fundoscopy, the machine learning model of ResNet-18 showed AUC 0.78 with sensitivity 82% and specificity 66 %. In the setting of one case with solitary image of fundoscopy, the machine learning model of Vgg-11 showed the AUC 0.76 with sensitivity 79% and specificity 64%. The odds ratio is 8.54 and the positive likelihood ratio is 2.41 for deep learning model to predict the diagnosis of diseases.

Conclusion: The performance of machine learning model to predict the diagnosis of ankylosing spondylitis, psoriatic arthritis and psoriasis is quite acceptable. Fundoscopy analyzed with deep learning model may be a useful tool to help us to stratify the patient of ankylosing spondylitis, psoriatic arthritis and psoriasis.

Background: Arthrocentesis is a procedure defined as synovial fluid aspiration that has diagnostic and therapeutic value in both the outpatient and inpatient setting. As mentioned in our prior study, joint arthrocentesis is not an Accreditation Council for Graduate Medical Education (ACGME) procedural requirement for Internal Medicine (IM) residents in the United States. Thus, we started the Phase I of our study, evaluating our in-house IM residents on their confidence level in performing intra-articular injections. This study resulted in more than half of the residents not feeling comfortable in performing arthrocentesis and nearly 100% of performing intra-articular injections. This study resulted in more than half of the residents not feeling comfortable in performing arthrocentesis and nearly 100% of performing intra-articular injections.

Methods: Pre-workshop arthrocentesis learning material, including procedural check list and video, were compiled by IM residents at RWMC. A Rheumatology fellow demonstrated a one-to-one practice session on the knee model and the IM residents were graded based on the thoroughness of the procedural checklist. Each resident completed a post-procedure survey based on this arthrocentesis workshop.

Results: A total of 20 IM residents participated in the knee arthrocentesis workshop. As noted in Table 1, 85% of the residents believed that the pre-session information was helpful in preparing them for the workshop. (Table 1) On the post-workshop survey, 100% of the residents either agreed or strongly agreed to feeling more comfortable with the knee arthrocentesis after the practice, and all (100%) were interested in participating in future knee aspirations. The overall performance on the procedural aspect was also impressive with 40% of residents being able to complete the workshop on the knee model successfully on their first attempt and 55% on their second attempt. (Figure 1) Based on the procedure checklist score in Figure 1, residents were most proficient in the post-procedure stage with 100% score meanwhile, least successful on the aspiration of synovial fluid stage with a score of 55%.

Conclusion: Our QI project has shown that a standardized lecture series on how to perform arthrocentesis has resulted in a significant improvement in the overall confidence of internal medicine residents. This should be taken into consideration and incorporated as part of the internal medicine learning curriculum.

Objectives: To describe and measure the ultrasonographic, anatomical, and histological characteristics of the A1 and A2 annular pulleys entheses.

Methods: A1 and A2 annular pulleys from 15 formalin-embalmed cadavers were assessed by grey-scale ultrasound (Figure 1) and then dissected. The ultrasonographic evaluations included the identification, widths, and characterization of insertion site of the annular pulleys. For the anatomical analysis, dissection was then performed, identifying the transverse fibers of the distal region of the palmar fascia as the proximal limit and the proximal interphalangeal joint as the distal limit. Measurements of the anatomical width of the pulleys were obtained with a digital caliper. For the histological study, 2x2 cm samples were received, fixed with 4% formaldehyde, and processed to obtain paraffin blocks, then cut into 4-micron sections and stained with hematoxylin-eosin. The slides were observed and measured with a Leica DMD 108 microscope. Quantitative data were expressed as mean ± standard deviation (SD) and qualitative data as n (%). Means were analyzed using Student’s-t test and frequencies using the chi-square test and Fisher test when needed. Pearson’s correlation coefficient (r) was used to analyze the linear correlation between the ultrasonographic and anatomical measurements. Statistical analyses will be performed using the SPSS program version 26.0.

Results: Fifteen cadaveric hands (9 males and 6 females) with a mean age of 79 years were included. Regarding the ultrasonographic assessment the mean ultrasound width of the A1 pulley was 0.27 ± 0.06 mm and A2 0.11 mm ± 0.04 mm in the years were included. Regarding the ultrasonographic assessment the mean ultrasound’s correlation coefficient (r) was used to analyze the linear correlation between the ultrasonographic and anatomical measurements. All A1 in the thumb shows sesamoid bones (SB) in (13%) in the fifth finger. The histological description of the annular pulleys shows a diverse nature of the enthesis with fibrocartilaginous and fibrous areas.

Conclusion: These preliminary results show that ultrasound is a valuable tool for identifying annular pulleys’ width and entheses, with good correlation with the anatomical and histological study. The annular pulleys have a mixed fibrous and fibrocartilaginous enthesis.

AB1532
ULTRASOUND ASSESSMENT OF A1 AND A2 PULLEY ENTHESIS WITH ANATOMICAL AND HISTOLOGICAL CORRELATION

Keywords: Imaging, Ultrasound, Enthesitis

1Hospital Universitari Vall d’Hebron: Reumatología, Rheumatology, Barcelona, Spain; 2Universitat de Barcelona - Campus Bellvitge, Unitat d’Anatomia i Embriologia Humana, L’Hospital de Llobregat, Spain; 3Universitat de Barcelona - Campus Bellvitge, Histologia, L’Hospital de Llobregat, Spain; 4Agostino Gemelli University Policlinic, Rheumatology, Rome, Italy; 5Instituto Poal de Reumatología, Rheumatology, Barcelona, Spain

Background: Digital entheses are of particular interest in inflammatory arthritides. The annular pulleys (A) are forms of soft connective tissue organized as transverse fibers of variable width, thickness, and configuration that overlay the synovial sheath of flexor tendons. These structures prevent the flexor tendons from bowing and maintain them in constant relationship to the joint axis of motion. Objectives: To describe and measure the ultrasonographic, anatomical, and histological characteristics of the A1 and A2 annular pulleys entheses.

Methods: A1 and A2 annular pulleys from 15 formalin-embalmed cadavers were assessed by grey-scale ultrasound (Figure 1) and then dissected. The ultrasonographic evaluations included the identification, widths, and characterization of insertion site of the annular pulleys. For the anatomical analysis, dissection was then performed, identifying the transverse fibers of the distal region of the palmar fascia as the proximal limit and the proximal interphalangeal joint as the distal limit. Measurements of the anatomical width of the pulleys were obtained with a digital caliper. For the histological study, 2x2 cm samples were received, fixed with 4% formaldehyde, and processed to obtain paraffin blocks, then cut into 4-micron sections and stained with hematoxylin-eosin. The slides were observed and measured with a Leica DMD 108 microscope. Quantitative data were expressed as mean ± standard deviation (SD) and qualitative data as n (%). Means were analyzed using Student’s-t-test and frequencies using the chi-square test and Fisher test when needed. Statistical analyses will be performed using the SPSS program version 26.0.

Results: Fifteen cadaveric hands (9 males and 6 females) with a mean age of 79 years were included. Regarding the ultrasonographic assessment the mean ultrasound width of the A1 pulley was 0.27 ± 0.06 mm and A2 0.11 mm ± 0.04 mm in the thumb, while A1 was 0.36 ± 0.09 mm and A2 pulley 0.46 ± 0.06 mm on the other fingers. A strong correlation between the ultrasonographic and anatomical measurements was found (r=0.82). All A1 in the thumb shows sesamoid bones (SB) in (13%) in the fifth finger. The histological description of the annular pulleys shows a diverse nature of the enthesis with fibrocartilaginous and fibrous areas.

Conclusion: These preliminary results show that ultrasound is a valuable tool for identifying annular pulleys’ width and entheses, with good correlation with the anatomical and histological study. The annular pulleys have a mixed fibrous and fibrocartilaginous enthesis.

DIAGNOSTIC VALUE AND BENEFITS OF PERFORMING A MINIMALLY INVASIVE TECHNIQUE FOR MINOR SALIVARY GLAND BIOPSY, A CASE SERIES

Keywords: Sjögren syndrome, Diagnostic tests

M. López-Rodríguez1, M. Freire2, C. Cánovas1, A. Andrade1, L. Gómez-Suárez1, B. Sopeña Perez Arguelles1, A. González-Quintela1, I. Möller5.
1Hospital Clínico Universitario de Santiago de Compostela, Unidad de Enfermedades Sistémicas e Inmunopatología, Servicio de Medicina Interna, Santiago de Compostela, Spain

Background: Salivary gland biopsy plays an important role in the diagnosis of systemic diseases, especially Sjögren’s Syndrome. Minimally invasive biopsy has a low risk of complications with respect to the classical technique, without losing its diagnostic capacity.

Objectives: To assess the utility and safety of minimally invasive technique in patients with suspected systemic disease and salivary gland involvement.

Methods: Retrospective analysis of 31 minor salivary gland biopsies performed by our Systemic Autoimmunity Disease Unit from November 1st 2020 to November 1st 2022, using a minimally invasive technique. Antibody profile and histopathological changes were observed and recorded. Adverse events were registered immediately after the procedure and at the next medical visit.

Results: A total of 31 biopsies were reviewed. Mean age of patients was 60 years, most women (n=27 87%). The success rate of obtaining glandular tissue was 94% (29/31). With respect to immunological data, 24 patients had positive ANAs (77,4%), 24 negative ENAs (77,4%) and 21 negative Rheumatoid Factor (67,7%). In histopathological evaluation 52% were normal salivary tissue (n=16), 23% had focal lymphocytic salaladentis (n=7), 16% nonspecific chronic salaladentis (n=5), 6% (n=2) non-existent or insufficient sample and 3% fatty infiltration (n=1). The only complication was a transient superficial lip ecchymosis in one patient (3,2%).

Conclusion: 23% of patients with immunonegative sicca syndrome are diagnosed with Sjögren’s Syndrome due to a minor salivary gland biopsy performed with a minimally invasive technique. This is a simple tool which saves time until diagnosis with low rate complications.

A VALIDATION OF REGISTER DERIVED DIAGNOSES OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH INFLAMMATORY ARTHRITIS. DATA FROM NOR-DMD

Keywords: Diagnostic tests, Comorbidities

S. Aarrestad Provan1,2, F. Ahlfors3, B. Bakland4, H. Ye5, E. Kristianslund6, T. K. Kvien7, E. Ikkdahl1, T. M. Aaløkken1, A. M. Hoffmann-Vold8. Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; 1Inland Norway University of Applied Sciences, Elverum, Public Health, Elverum, Norway; 2Sahlgrenska University Hospital, Radiology, Gothenburg, Sweden; 3University Hospital of North Norway HF, Rheumatology, Troms, Norway; 4Ruematsykehuset, Rheumatology, Lillehammer, Norway; 5Oslo University Hospital, Department of Radiology, Institute of Clinical Medicine, Oslo, Norway; 6Oslo University Hospital, Rheumatology, Oslo, Norway

Background: There is a lack of knowledge concerning the validity of international classification of diseases (ICD) diagnoses extracted from health registers although this information is often used in epidemiological studies.

Objectives: To assess the validity of register derived diagnoses of interstitial lung disease (ILD) in patients with rheumatic diseases, using ILD identified on computed tomography (CT) and/or medical journal as gold standard.

Methods: The Norwegian Anti-Rheumatic Drug Register (NOR-DMD) is a multi-centre prospective observational study that includes patients with a diagnosis of inflammatory arthritis who started treatment with disease modifying anti-rheumatic drugs. NOR-DMD was linked to the Norwegian Patient Registry (NPR) and Cause of Death Registry. We searched both registers for ILD ICD-10 codes (J70, J84 or J99) and extracted CTs from participants at four hospitals. CTs were taken within the prespecified time-period across 43 with two or more ILD diagnoses in register and available in 60 patients with ILD in register and available CT taken within the relevant time-period and in 28/43 (65.1%) patients who had received ILD diagnoses in the registries were considered relevant to the study. An expert thoracic radiologist (FA) scored all examinations according to presence of ILD and categorised the finding into: no ILD, possible ILD and confirmed ILD. Possible ILD CT images were re-examined by a second expert radiologist (TMA). In addition, medical records were searched for ILD diagnoses given by specialist clinicians on several occasions. Presence of confirmed ILD was assessed in patients with available CTs, registry ICD-code for ILD at ≥2 time points and across ILD diagnoses subgroups.

Results: We identified 80 cases with an ILD diagnosis given in a register (ICD-10 n (%)): J70 (12.5), J84 (52.5) and J90 (18.25)). CTs were available in 72/80 (90%) patients, 60/72 (83%) within the pre-specified time-window. The ILD diagnosis was confirmed on CT in 31/80 (38.8%) and in 9/80 (11.3%) by medical records only. ILD was validated in 34 (56.7%) of 60 patients with available CT within the relevant time-period and in 28/43 (65.1%) patients who had received an ILD code at ≥2 time points and had a HRCT within the relevant time-period (Table 1). The diagnosis was confirmed in 20 (69.9%) of the 29 patients of this group who had received a J84 diagnoses. ILD diagnoses that were not validated were most frequently given under investigations for respiratory symptoms 20/38 (52.6%).

Conclusion: The validity of registry-based diagnoses of ILD must be carefully considered in epidemiological studies.

Background: Psoriatic arthritis (PsA) is characterized by various patterns of inflammatory arthritis, enthesitis, dactylitis, and spondylitis. Apremilast is an oral immunomodulating phosphodiesterase-4 inhibitor that is indicated for treatment of PsA. Whole-body magnetic resonance imaging (WB-MRI) allows assessment of joints and entheses of the entire body in one examination when using the Outcome Measures in Rheumatology Clinical Trial (OMERACT) MRI whole-body scoring system for inflammation in peripheral joints and entheses (MRI-WIPE), which has not previously been applied in a clinical trial. Here we evaluate the efficacy of apremilast 30mg BID (APR) on peripheral inflammation indices as measured by WB-MRI.

Objectives: To evaluate how APR affects inflammation in peripheral joints and entheses of patients with PsA as assessed by WB-MRI.

Methods: The phase 4 MOSAIC study was a multicenter, single-arm, open-label study evaluating APR (either as monotherapy or in combination with stable methotrexate) in patients with active PsA (diagnosis ≤3 months but ≤5 years, meeting the CASPAR criteria for PsA) for treatment up to 48 weeks. WB-MRI was performed at baseline, Week 24, and Week 48. Images were read and adjudicated by 2 experienced readers who were blinded to time of acquisition and clinical information. From WB-MRI, changes in the total peripheral inflammation index (83 joints and 33 entheses) were calculated using the OMERACT MRI-WIPE scoring system, as were changes in separate enthesis and joint inflammation WB-MRI indices (WIPE-enthesis and WIPE-joint inflammation). Changes in the heel enthesis inflammation index (HIMRISS), the hip joint inflammation MRI index (HIMRISS), and the knee joint inflammation MRI index (KIMRISS) were explored.

Results: Overall, 122 patients were enrolled and treated with APR; 55% were women, mean age was 47 years, and patients had a mean duration of PsA of 1.9 years. The least squares mean (95% CI) change from baseline in total WB-MRI score based on total peripheral inflammation index (including both joint and enthesis inflammation) as assessed by WB-MRI was -3.49 (-5.46, -1.52) at Week 24 and -4.06 (-6.39, -1.72) at Week 48, indicating significant improvement in peripheral inflammation (Figure 1). Significant improvements were also observed in the WIPE-joint inflammation scores at both Week 24 and 48, and in the WIPE-enthesis scores at Week 48 (Figure 1). Both the heel enthesis inflammation index (HIMRISS) and the hip joint inflammation MRI index (HIMRISS) showed little change, while the knee joint inflammation MRI index (KIMRISS) showed numerical, but not significant, improvement (Figure 1). No new safety signals were identified.

Conclusion: Patients with PsA treated with APR experienced a significant reduction in total peripheral inflammation, including significant improvement in peripheral joint inflammation and enthesitis, as assessed by WB-MRI. Results highlight the efficacy of APR on inflammatory markers that are relevant, as well as the benefit of using WB-MRI as a measure of inflammatory disease activity.
Home Spirometry and Oximetry Monitoring in Patients with Connective Tissue Disease Related Interstitial Lung Disease – A Single Centre Prospective Study

Keywords: Telemedicine, Lungs

W L. Ng1, A. Schweikert2, D. Howard1, L. Durcan1, K. Hurley2,3,1. Beaumont Hospital, Rheumatology, Dublin, Ireland; 2 Royal College of Surgeons in Ireland, Tissue Engineering Research Group, Dublin, Ireland; 3 Beaumont Hospital, Medicine, Dublin, Ireland

Background: Interstitial lung disease (ILD) is an important complication in patients with connective tissue disease causing significant impact on quality of life with a high mortality rate.

Objectives: We aim to determine the feasibility of home spirometry and oximetry reading, focusing on patients with connective tissue disease related ILD.

Methods: Patients with connective tissue disease related interstitial lung disease (CTD-ILD), idiopathic pulmonary fibrosis (IPF) and familial pulmonary fibrosis (FPF) were recruited and followed prospectively for 12 months. A handheld spirometer (MINI SpiroBank Smart) and oximeter linked to a real-time electronic health journal via a smartphone app to record daily spirometry and oximetry readings were provided. Patients were asked to perform one or more spirometry manoeuvres at approximately the same time daily to reduce variability, with the best value for each day used for analysis.

Results: 62 patients with CTD-ILD, 31 IPF and 21 FPF were recruited. The median age was 66, 71 and 69 years respectively. 47.8% were males. Preliminary data on 99 patients demonstrated median forced vital capacity (FVC) predicted of 82.5% in the CTD-ILD, 84.1% in IPF and 83.7% in FPF cohorts with median follow-up of 208 days. The median oxygen saturation (SpO2) for 9501 readings was 96% in all three cohorts. 27.8% experienced Raynaud’s phenomenon, and only 5.6% in the CTD-ILD required an ear oximeter due to inaccurate measurement of oxygen saturation secondary to Raynaud’s phenomenon.

Conclusion: Home monitoring of FVC and oximetry in patients with CTD-ILD is feasible, empowers patients and generates granular data which can be useful in the detection of rapidly progressing ILD allowing early management.

thickness of each muscle was measured. A semiquantitative scale evaluated ele-
mentary lesions: atrophy, edema, power Doppler, and the Heckmann scale (0-4)
was calculated. Descriptive statistics were performed using measures of central
tendency and dispersion according to the distribution of the variables, followed by
bivariate analysis (Student's t-test and Chi[2] test). Finally, discriminant analysis was
performed to determine which ultrasound variables best predicted the diagnoses.

Results: A total of 40 muscles were evaluated, finding a greater degree of atro-
phy and a higher Heckmann scale in patients with dysferlinopathies compared to
MII. Discriminant analysis showed that the set of 3 muscles. Right biceps
brachialis (BB), Right quadriceps (QD), and Gastrocnemius/right soleus (GC)
had a diagnostic accuracy of 100% (sensitivity 100%, specificity 100%, canonical
coefficient 0.733 p<0.001). We present a set of 2 formulas that allow classifying
with the highest score according to the measurement of the muscles in group 1
(dysferlinopathy) or group 2 (MII). Finally, a COR analysis was performed to
determine the cut-off points of each muscle to classify as dysferlinopathies.

Conclusions: The study of 3 muscle groups (BB, CC, GC) presents high diagnos-
tic accuracy to differentiate dysferlinopathies from MII, especially when there is
no genetic study or antibodies available, and there is diagnostic doubt.

DETERMINATION OF ADENOSINE DEAMINASE (ADA)
IN SYNOVIAL FLUID TO DIAGNOSE INFLAMMATORY
ARTHROPATHIES

Keywords: Synovium, Inflammatory arthritides, Biomarkers

Marina Baixa, Internal Medicine, Villajoyosa (Alicante), Spain; 3. Hospital
Marina Baixa, Laboratory; Villajoyosa (Alicante), Spain

Background: Adenosine Deaminase (ADA) determination is used to diagnose
tuberculosis in several biological fluids, including synovial fluid (SF). Less known
is the usefulness of ADA level in SF diagnosing other inflammatory arthropathies,
and only a few reports could be found in the bibliography. In these reports ADA
in SF seems higher in patients with septic arthritis, rheumatoid arthritis or crystal
arthropathies compared with osteoarthritis.

Objectives: The objective is to evaluate the performance of ADA in SF in patients
with joint effusion to diagnose inflammatory arthropathies.

Methods: All SF analyzed in 2022 at one center have been retrospectively
reviewed. SF data have been collected (ADA levels and white blood cell) and

defined diagnosis of the treating physician -with all clinical and laboratory data-
was recorded. Exclusion criteria were: bursas, prosthesis and hemarthros.

Regarding the statistical analysis for the comparison of means of ADA in the
different groups, the T-student (2) test was conducted. Descriptive, clinical and immunological data were
collected. A descriptive analysis was made.

Results: Sixty-five patients were positive for anti-cN1A: 53 women (81.5%)
and the median age was 47.2±14.9 years. Rheumatic inflammatory diseases were
diagnosed in 15 (22.7%) patients, of which 5 had systemic lupus erythemato-
sus (SLE), 4 had SS, and 1 with rheumatoid arthritis, polymyalgia rheumatica,
granulomatous arthritis, with polychondritis, juvenile idiopathic arthritis, spondyloarthropathy,
and undifferentiated connective tissue disease. Eight (12.1%) patients had auto-
imune thyroiditis, without known rheumatic diseases associated. The presence

PREVALENCE OF ANTI-CN1A ANTIBODIES AND
ITS CLINICAL SIGNIFICANCE – A RETROSPECTIVE
MONOCENTRIC STUDY

Keywords: Descriptive studies, Autoantibodies, Epidemiology

S. P. Silva1,2, C. Fortes3, G. Eugénio3, A. Barcelos1,4,1. Centro Hospitalar
Baixo Vouga, Aveiro, Rheumatology department, Aveiro, Portugal; 2Egas

Clinical Pathology, Aveiro, Portugal; 4Nova Medical School, Comprehensive
Health Research Center, Lisboa, Portugal

Background: Anti-cytosolic 5'-nucleotidase 1A (anti-cN1A) antibodies have
recently been proposed as a biomarker for inclusion body myositis (IBM). With
high specificity (87-100%), they can help differentiate IBM from other myosi-
tis.[1,2] Besides IBM, it has been detected in other inflammatory conditions.
Recently, a higher prevalence of IBM has been associated with Sjogren Syn-
drome (SS), and anti-cN1A has been associated with myositis in SS, regardless
of the subtype of myositis.[3] However, it can also be detected in healthy individu-
als and despite its high specificity in IBM, it may not be a useful biomarker for the
diagnosis of autoimmune conditions.[4] Thus, the clinical relevance of anti-cN1A
remains unknown.

Objectives: The aim of this study was to identify the clinical and laboratory man-
ifestations associated with the presence of anti-cN1A.

Methods: A retrospective study of patients with anti-cN1A positivity (detected
immunoblot assay), observed from January 2021 to December 2022, in a tertiary
hospital, was conducted. Descriptive, clinical and immunological data were
collected. A descriptive analysis was made.

Results: Sixty-five patients were positive for anti-cN1A: 53 women (81.5%) and
the median age was 47.2±14.9 years. Rheumatic inflammatory diseases were
diagnosed in 15 (22.7%) patients, of which 5 had systemic lupus erythemato-
sus (SLE), 4 had SS, and 1 with rheumatoid arthritis, polymyalgia rheumatica,
granulomatous arthritis, with polychondritis, juvenile idiopathic arthritis, spondyloarthropathy,
and undifferentiated connective tissue disease. Eight (12.1%) patients had auto-
imune thyroiditis, without known rheumatic diseases associated. The presence
of anti-cN1A was also found in the context of infection in 7 (10.6%) patients and malignancy in 2 (3.0%) patients. Half of the patients (50.8%) were healthy individuals. No diagnosis of IBM or other myositis was made. Twenty-nine (44.6%) patients showed other antibodies specificities: anti-SSA/Ro/52 (29%), anti-Ku (4.6%), anti-Mi-beta2 (4.6%) and anti-DSF70 (4.6%). In the SLE and SS groups, the most frequent presenting clinical features were sicca syndrome (66.7%), lymphopenia (9.2%), arthritis (6.1%) and photosensitivity (3.1%). No patient had signs or symptoms of muscular involvement.

**Conclusion:** Anti-cN1A was detected in diverse rheumatic conditions, but also in autoimmune thyroiditis and mostly in healthy individuals. SLE and SS were the most frequent systemic autoimmune rheumatic diseases associated with these antibodies. Contrary to expectations, no diagnosis of IBM or myositis was made. Further studies regarding the clinical significance of anti-cN1A are needed to attribute the real diagnostic value of this marker.

**PREVALENCE AND DISTRIBUTION OF SONOGRAPHIC ELEMENTARY LESIONS IN PSA – RESULTS OF 2 COHORTS**

**Keywords:** Imaging, Ultrasound, Psoriatic arthritis

A. Polachek1,2, V. Fure1,2, S. Thib3, L. Mendel2, O. Elkayam1,2, L. Eder1,3, Tel Aviv Sourasky Medical Center - Ichilov, Rheumatology, Tel Aviv-Yafo, Israel; 2Sackler faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, Medicine, Tel Aviv-Yafo, Israel; 3Women’s College Research Institute, Women’s College Hospital, University of Toronto, Toronto, ON, Canada, Rheumatology, Toronto, Canada

**Background:** Psoriatic arthritis (PsA) can manifest with different musculoskeletal (MSK) features. Ultrasound (US) optimizes the assessment of the different MSK features in PsA. However, there is no consensus on which MSK sonographic lesions and what locations should be evaluated by US.

**Objectives:** To examine the prevalence and distribution of key sonographic MSK lesions in patients with PsA.

**Methods:** This study included two prospectively recruited PsA cohorts. Cohort 1 included 158 consecutive PsA patients and cohort 2 included 94 patients with active PsA prior to initiation of therapy. All underwent a comprehensive US assessment, including both gray scale (GS) and power Doppler (PD) of 50 joints, 40 tendons and 14 entheses. The following sonographic lesions were assessed by two sonographers blinded to clinical data: I. Inflammatory lesions - Synovitis, tenosynovitis, peritenonitis and enthesitis and II. Structural lesions - erosions and bone proliferations. Presence/Absence of these lesions was determined based on previously suggested definitions by OMERACT (when available) or other publications.

**Results:** In cohort 1, mean ± SD age was 52.7 ± 13 and 55.7% were females. In cohort 2, mean ± SD age was 47.5 ± 13.2 and 48.8% were females. The most prevalent locations of the inflammatory lesions in both cohorts were (Figure 1): Synovitis (small joints) – MCP2 (cohort 1: 11%, cohort 2: 27%), MCP3 (cohort 1: 17%, cohort 2: 26%), IP1 (cohort 1: 5%, cohort 2: 25%) IP3 (cohort 1: 3%, cohort 2: 16%), MTP1 (cohort 1: 31%, cohort 2: 35%), MCP2 (cohort 1: 23%, cohort 2: 30%), MTP3 (cohort 1: 14%, cohort 2: 22%), Synovitis (medium-large joints) – wrist (cohort 1: 27%, cohort 2: 30%) and knee (cohort 1: 13%, cohort 2: 29%); tenosynovitis – 2nd finger flexors (cohort 1: 2%, cohort 2: 12%) 3rd finger flexor (cohort 1: 2%, cohort 2: 10%); extensor peritenonitis – MCP2 (cohort 1: 2%, cohort 2: 7%), MCP3 (cohort 1: 4%, cohort 2: 12%), IP3 (cohort 1: 3%, cohort 2: 13%), IP4 (cohort 1: 2%, cohort 2: 12%); enthesitis – lateral epicondyle (cohort 1: 11%, cohort 2: 14%) and triceps (cohort 1: 7%, cohort 2: 20%); erosions – MCP1 (cohort 1: 4%, cohort 2: 5%), MCP2 (cohort 1: 6%, cohort 2: 7%), IP1 (cohort 1: 2%, cohort 2: 2%), DIP2 (cohort 1: 2%, cohort 2: 1%), MTP5 (cohort 2: 4%); bone proliferations – MCP1 (cohort 1: 12%, cohort 2: 7%), MCP2 (cohort 1: 10%, cohort 2: 17%), MCP3 (cohort 1: 5%, cohort 2: 17%), IP1 (cohort 1: 25%, cohort 2: 41%), IP2 (cohort 1: 10%, cohort 2: 16%), IP3 (cohort 1: 14%, cohort 2: 26%), DIP2 (cohort 1: 23%, cohort 2: 42%), DIP3 (cohort 1: 18%, cohort 2: 42%) and DIP5 (cohort 1: 29%, cohort 2: 49%).

**Conclusion:** This descriptive study provides comprehensive information on the most commonly affected sites for key inflammatory and structural domains in PsA. This information can inform efforts to develop reduced sonographic score to diagnose or monitor disease activity in PsA.

**THE INTENSITY OR DURATION OF INFLAMMATORY BACK PAIN HAS NO IMPACT ON THE DETECTION OF SACROILIITIS BY MAGNETIC RESONANCE IMAGING IN AXIAL SPONDYLOARTHRITIS**

**Keywords:** Imaging, Spondyloarthritis

G. Seviş1, E. Bıyıklı2, O. Bujdaycı3, K. Acar1, S. Kütünlü Ağaçkan1, Ş. Çolakoğlu Özkan2, G. Ekin1, P. Atagündüz1, 1Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey; 3Marmara University Institute of Health Sciences, Department of Medical Biology and Genetics, Istanbul, Turkey; 4Çeditepe University School of Medicine, Department of Radiology, Istanbul, Turkey

**Background:** Sacroiliac joint (SIJ) magnetic resonance imaging (MRI) is an established tool in the evaluation of patients with axial spondyloarthritis (axSpA). In the validation study of the ASAS classification criteria for axSpA, only 63.1% of patients had sacroilitis on the SIJ-MRI. [1] Studies that enrolled patients with axSpA based on expert opinion reported the sensitivity of MRI between 35% to 42% in detecting sacroilitis.[2,3]

**Objectives:** This study aimed to evaluate the temporal relationship between ASAS defined positive MRI and the characteristics of low back pain (LBP) in axSpA.

**Methods:** Following axSpA groups were enrolled in the study whenever an attending physician ordered an SIJ-MRI. Patients fulfilling both the Rudwaleit criteria for inflammatory back pain (IBP) and Amor criteria, patients with a previous classification with either modified New York or ASAS classification criteria,[1] A blinded rheumatologist (GS) recorded the intensity and duration of IBP using a questionnaire before SIJ-MRI. MRI appointments were based on availability. Therefore some patients did not have IBP at acquisition. Two radiologists assessed SIJ-MRIs using the ASAS/OMERACT MRI group definition of active sacroilitis.[4] In case of discrepant reporting, a third experienced radiologist (GE) adjudicated the SIJ-MRIs. The probability of axSpA is estimated using sum scores for SpA features excluding the SIJ-MRI.[5]

**Results:** Fifty-nine patients (32 F/27M) were included. Patient characteristics are given in Table 1. Overall, 28 of 59 patients (47.5%) had a positive SIJ-MRI defined by ASAS.

POSITIVE MRI OF THE SPINE AS IMAGING CRITERION FOR DIAGNOSIS OF AXIAL PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Spondyloarthritis, Imaging

M. L. Molina1, D. Rios2, A. Goecke1, D. Suarez2, M. Parada1,2.

1Hospital Clínico Universidad De Chile, Medicina Interna, Sección Reumatología, Santiago, Chile; 2Hospital Clínico Universidadd De Chile, Departamento de Radiología, Santiago, Chile; 3Hospital del Trabajador, Medicina Interna, Providencia, Chile

Background: MRI is essential for axial spondyloarthritis (axSpA) diagnosis. A positive MRI in the ASAS classification criteria of axSpA is based on inflammatory lesions in the sacroiliac joints. These lesions are defined as one bone marrow edema (BME) highly suggestive of axSpA present on ≥ 2 consecutive slices or ≥ 2 BME A on a single slice. The addition of MRI of the spine as an imaging criterion to the ASAS axSpA criteria had a low yield of newly classified patients and is therefore not recommended. Axial psoriatic arthritis (axPsA) remains poorly defined despite its high prevalence among patients with PsA. Studies comparing axPsA with other axSpA, such as Anqiuosing Spondylitis (AS), have found differences in the former, including more frequent asymmetric spine and SIU involvement, cervical involvement, and isolated spondylitis.

Objectives: We performed a retrospective study of patients with psoriasis with at least a whole spine and sacroiliac joints (SJJ) MRI performed between January 2015 and December 2021. MRI were performed in a 1.5 T machine, following a non-contrast protocol. Sagittal T1-weighted (T1w) and T2-weighted fat-suppressed fast spin echo sequences were available for the spine, while semi-coronal T1w and short inversion recovery sequences for the SJJ. Structural and inflammatory lesions were defined according to the ASAS/OMERACT definitions. Results are presented as mean and SD or numbers and percentages.

Methods: We performed a retrospective study of patients with psoriasis with at least a whole spine and sacroiliac joints (SJJ) MRI performed between January 2015 and December 2021. MRI were performed in a 1.5 T machine, following a non-contrast protocol. Sagittal T1-weighted (T1w) and T2-weighted fat-suppressed fast spin echo sequences were available for the spine, while semi-coronal T1w and short inversion recovery sequences for the SJJ. Structural and inflammatory lesions were defined according to the ASAS/OMERACT definitions. Results are presented as mean and SD or numbers and percentages.

Results: 3 patients with psoriasis were analyzed, 17 (60%) were male, and the mean age at the time the MRI was performed was 43.7 ± 10.6 years. The
most common type of psoriasis was vulgaris (85%) and time from diagnosis was greater than ten years at least in 85% of patients. The majority of patients experienced chronic back pain (82%), and 15 (44%) patients had IPD according to the ASAS criteria. MRI-SJ showed structural and/or inflammatory changes, and 5 of these 11 patients (55%) had BME suggestive of axSpA according to ASAS/OMERACT criteria. When we analyzed patients with an MRI negative for sacroiliitis (19 patients), 3 had BME on MRI-spine, with only two patients with three or more BME lesions according to ASAS/OMERACT criteria. Finally, when a chronic lesion on MRI-SJ was considered as a possible criterion for classification, among patients without sacroiliitis, one patient could be deemed to have axSpA. The findings in this image of SJ erosions and fatty deposition (Romanus sign).

Conclusion: A positive MRI-spine in patients with suspected axSpA was more frequent than previously described for axSpA. Furthermore, spinal inflammation in the absence of sacroiliitis was present in 2 of the 19 patients in this cohort. Therefore, MRI-spine could be considered in the classification criteria for patients suspected of axSpA.

PARAVERTEBRAL MUSCLES TRIGGER POINTS ATTACHED TO FACET JOINTS ARTHROSI S ARE PREFERRED TARGETS FOR ULTRASOUND-GUIDED INTERVENTION TO TREAT LOW BACK PAIN

Keywords: Physical therapy/physiotherapy, Ultrasound, Rehabilitation

R. Bubnov1,2, L. Kalika2, Z. Pilecki1,4, G. Pilecki1, Jan Dlugosz University in Czeszchowa, Health Sciences, Czeszchowa, Poland; 2Clinical hospital 3Phoephsia, Ultrasound, Kyiv Ukraine; 4New York Dynamic Neuromuscular Rehabilitation &Physical Therapy, Rehab, New York, United States of America; Center of Sport Medicine, Orthopedic, Zabrze, Poland

Background: Facet joints (FJ) arthritis can be a cause of pain and spinal instability and is considered to be a potential target for injection treatment. However, FJ arthropathy is difficult for diagnosis and confirmation associations with pain syndrome, effectiveness of FJ injections is debated. Trigger points (TrPs) are major cause of pain syndromes, dry needling under ultrasound (US) guidance (DN-US) is a crucial therapeutic for treatment of myofascial pain [1], is a proven and effective method for treatment various pain conditions; can restore muscle function and motion [2], reduce fascia overload [3], and can improve movement in spine and also in FJ.

Objectives: Aim was to evaluate the relevance of US for diagnosis of FJ arthritis as a cause of pain and evaluate the efficacy of DN-US to treat FJ-associated low back pain and improve movement in spine and facet joints.

Methods: We included 26 consecutive patients (15 females, 23-57 years old) with symptoms of LBP suspected due to unilateral and/or bilateral FJ arthritis assessed at MRI and CT with three-dimensional reconstructions. Conditions of rheumatoid arthritis, advanced injury background were excluded. All patients received DN-US protocol by R. Bubnov [1]: MTP were identified according to clinical examination, referred pain pattern, US identification; single fine (28G) steel needle DN under US guidance was applied to elicic local twitch response (LTR) and/or “needle grasp”. Specific recommendations were given to preserve effect after DN-US.

Results: We diagnosed bi- and unilateral FJ arthritis on US at the levels of T11-S1 in all patients, assessed fluid in joints, deformations, movement restriction and revealed closely localized TrPs in paravertebral (multifidus) muscles followed by targeted DN-US. We distinguished different pain patterns (referred pain - groin pain, pelvic pain, irradiation to leg, thigh, etc.) which correlated with facet arthropathy localization. Pain decreased in all patients VAS from 6-8 at baseline to 1-4 immediately and VAS 3-4 at one week after procedure. We noted decreasing in neuropathic pain, detected higher rates of lumbar spine motility, movements in particular segments and FJ were registered on functional US; improvement postural balance in all patients after DN-US. Additional needling sessions to FJ capsule did not induce significant LTR and effective alleviating pain compared to DN-US. All patients had postural imbalance, had multiple bilateral MTrPs: in multifidus muscles at thoracic, lumbar levels; sacroiliac joints dysfunction, shoulders impingement, other associated postural abnormalities; all MTrPs were inactivated, posture imbalance restored.

Conclusion: US is helpful to detect FJ arthritis; DN-US has a good treatment outcome for low back pain due to FJ arthritis. Local interventions targeting FJ arthritis is a potential tool in the cases which are not relevant approach. DN-US and US treatment is not less complicated technically, however, more effective vs targeting FJ. Complex posture assessment and correction is needed.

A COMPARATIVE ANALYSIS BETWEEN THERMAL AND ULTRASOUND IMAGING AT THE ELBOW IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Imaging, Rheumatoid arthritis, Ultrasound

Y.K. Tan1, R. Sultana2, J. Thumboo1. 1Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Centre for Quantitative Medicine, Singapore, Singapore

Background: Thermal imaging (TI) is a relatively low cost, non-invasive imaging technique that offers a quick and objective measurement of joint surface temperature. However, TI data at the elbow in patients with rheumatoid arthritis (RA) is presently lacking.

Objectives: The aim of this study is to compare TI outcomes with ultrasound (US) joint inflammation findings at the elbow among patients with RA.

Methods: TI and US imaging were performed at the same study visit. TI was carried out in a draft free room following a standardized protocol. The maximum (Tmax), average (Tavg) and minimum (Tmin) temperatures at the elbow (anterior, posterior, lateral and medial aspects) were summed up to obtain the respective MAX, AVG and MIN temperatures for the right and left elbows. Ultrasound power Doppler (PD) and greyscale (GS) joint inflammation were graded semi-quantitatively (0-3) at the anterior (humeraloral) and posterior fossa recesses of the elbow (using previously validated scoring methods) and these were summed to obtain the respective PD and GS scores at the right and left elbows per patient. Pearson's correlation coefficient was used to correlate the findings from TI and US imaging, while simple linear regression was used to describe the relationship between parameters.

Results: In this cross-sectional study, 60 elbows were evaluated by TI and US imaging among 30 adult RA patients with the following patient baseline characteristics: 78.7% female; 78.7% Chinese; mean (SD) disease duration 73 (68) months; mean (SD) DAS28 3.83 (1.19). Table 1 shows the results of the comparative analysis between the TI parameters (MAX, AVG and MIN) and the US PD and GS scores. For Pearson's correlation, the TI parameters (MAX, AVG and MIN) were all significantly correlated (P<0.05) with the US PD scores (Table 1) at both the right and left elbows. For US GS scores (Table 1), significant correlation (P<0.05) were observed with all the TI parameters (MAX, AVG and MIN) only at the right elbow but not at the left elbow (with P-values all >0.05). The simple linear regression estimates between TI and US imaging parameters at the right and left elbows are summarized in Table 1.

Conclusion: To the best of our knowledge, our study is the first to report on the correlation analysis between TI parameters and US joint inflammation outcomes at the elbow from an RA cohort. Between US PD and GS joint inflammation, TI is more consistently associated with the former at the elbow in RA. TI of the elbow in RA appears promising and will require further validation in independent RA cohorts.
Background: Diffusion-weighted (DWI) magnetic resonance imaging (MRI) of the hand and wrist has been suggested as an outcome measure of synovitis as an alternative to gadolinium enhanced MRI in patients with rheumatoid arthritis (RA) [1-2]. The apparent diffusion coefficient (ADC), which is a derived parameter of ADC, determined from DWI-MRI, is not a reliable outcome measure for grading synovitis in the hand and wrist of patients with inflammatory joint diseases.

Objectives: To test the discriminative validity of ADC in the synovium ("synovitis ADC") in a prospective cohort of patients with RA and psoriatic arthritis (PsA) and healthy controls (HC).

Methods: The right hand and wrist of all participants were imaged in a 3T MRI system with a dedicated 8 channels coil, applying a 2 mm thick coronal turbo spin echo DWI sequence with an in-plane resolution of 1.5x1.7 mm. An ADC map was calculated on basis of two b-values (0;800). Assessment of ADC maps was performed in 7 regions of interest according to the same 7 areas which are assessed from the DWI, may be used to grade synovitis, similar to the OMERACT Rheumatoid Arthritis MRI scoring system (RAMRIS) for synovitis [1]. In a small study criterion validity has been measured but no correlation to contrast-enhanced MRI was revealed [2].

Results: Thirty-eight participants were imaged twice within a week (median 7 days, range 3-14 days). Participant characteristics are provided in Table 1. The repeatability was moderate for RA (ICC=0.68; 95%CI: 0.45-0.83), poor for PsA (ICC=0.10; 95%CI: -0.09,289) and poor for HC (ICC=0.28; 95%CI: 0.07-0.47). Intra-reader reproducibility was poor for all three groups: RA (ICC=0.37; 95%CI: 0.12-0.58), PsA (ICC=0.22 95%CI: 0.02-0.40) and HC (ICC=0.34; 95%CI: 0.13-0.52). Bland-Altman plots revealed large absolute differences between 1st and 2nd MRI in all three groups of participants (Figure 1).

Figure 1. Figure: Bland-Altman plots of the repeatability for the three groups. Left, healthy controls; middle, psoriatic arthritis and right, rheumatoid arthritis. Full line: mean difference. Dotted lines: 95% levels of agreement. The Y-axis indicates the relative difference of apparent diffusion coefficient (ADC) between first and second scanning. The X-axis indicates the mean ADC [x10^-3mm/s²] of the first and second MRI.

Conclusion: ADC, determined from DWI-MRI, is not a reliable outcome measure for grading synovitis in the hand and wrist of patients with inflammatory joint diseases.

Objectives: Bone tissue interfaces and fluid synovial interfaces in the joint which gave rise to a challenge in the application of SW-EUS to the synovium is that there are multiple properties and stiffness of tissue and serves as an adjunct to conventional US techniques. There is a hypothesis that rheumatoid arthritis (RA) patients would have softer synovium than controls and this could be quantified with a slower velocity (SWV). The purpose of the study was to determine if there is a correlation between SW-EUS and disease activity.

Methods: A prospective case-control study. Fifteen patients with RA were consecutively recruited and matched with ten controls. Participants underwent clinical assessment, blood sampling, grey scale ultrasound (GSUS), power Doppler ultrasound and SW-EUS of MCP joints 2, on the dominant hand. Ultrasound examination was undertaken by two musculoskeletal trained sonographers. Both GSUS and PDUS. Scanning was carried out using ultrasound using linear array transducer and Virtual TouchTM software. MCP 2 of the dominant hand were scanned with joints resting at 20 degrees of flexion. The dorsal aspect of the joint was imaged in three planes; longitudinal midline (DLM), longitudinal radial (30° radial offset from midline, DLR) and longitudinal ulnar (30% ulnar offset from midline, DLU).

Results: Average age was 50. Mean RA disease activity (DAS28-ESR) was 3.85. RA patients had lower mean SWV (5.27 m/s vs 12.00 m/s p< 0.001) than controls (6.88 m/s vs. 12.80 m/s P <0.001). EM (RA 168.17 kPa, controls 25.45 kPa) Negative Pearson’s correlation coefficients (PCC) were observed between mean SWV and disease activity markers including inflammatory parameters (0.22-0.45). Patients with RA (Figure 1) had lower mean SWV (5.27 m/s vs 6.88 m/s P <0.001) than controls (6.88 m/s vs. 12.80 m/s P <0.001). EM (RA 168.17 kPa, controls 25.45 kPa) Negative Pearson’s correlation coefficients (PCC) were observed between mean SWV and disease activity markers including inflammatory parameters (0.22-0.45).

Conclusion: This is the first pilot study in Latin America of SW-EUS in synovium. Mean SW and elastic modulus was significantly lower in RA than controls. There was a negative correlation between mean and maximum SWV and GSUS synovial thickening and assessing disease activity in RA. Further study is warranted to confirm the role of SW-EUS in diagnosing and assessing disease activity in RA.

AB1548 ULTRASOUND ASSESSMENT OF SUB-CLINICAL NAIL INVOLVEMENT IN PSORIATIC ARTHRITIS PATIENTS

Keywords: Ultrasound, Psoriatic arthritis, Enthesitis

L. Rouached1, B.A. Hiba2, S. Rahmouni1, O. Saidane1, S. Bouden1, A. Ben Tekaya1, R. Tekaya1, I. Mahmoud1, L. Abdelmoula2, Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia; 2RABTA Hospital, Rheumatology, Tunis, Tunisia

Background: Several studies suggest that psoriatic nail involvement is secondary to local enthesopathy with diffusion of the inflammation to the nail. We aimed to compare parameters of clinically normal nail unit in patients affected by psoriatic arthritis (PsA) with healthy matched controls (HC) using ultrasonography.

Methods: This was a cross-sectional study including patients with PsA and HC. Tendon joint count (TJC) (0–68) and swollen joint count (SJc) (0–66) were evaluated. PsA group and HC were comparable with respect to age (53.7±12.1 vs 53±11.8, p=0.72) and male gender (13 vs 13, p=0.85). Mean disease duration of PsA was 12.7±10.9 years. The disease activity showed that mean DAPSA was 21.55±14.36 and mean PASI was 2.19 ±3.8. PsA patients and HC had no significant differences in their age and gender. The comparison of NPT between each identical fingernail of PsA and HC did not reveal significant difference. However, NBT was significantly higher in the HC group than in the PsA group (1.77mm vs 2.07mm, p=0.027). Additionally, ST was higher in the HC group (2.26mm vs 2.59mm, p=0.003).

Conclusion: The US morphological changes of NBT and ST were contributive to distinguish psoriatic nails from healthy nails.

VALUE OF ULTRASOUND FOR THE EARLY DETECTION OF INFLAMMATORY ABDOMINAL AORTIC ANEURYSMS

Keywords: Imaging, Rare/orphan diseases, Vasculitis

B. Sliikhuys1, S. Konter1, D. Liesker2, A. Possel-Nicolai2, E. Brouwer1, R. Slart1, A. Van Roon1, B. Saleem1, D. J. Mulder1, UMC Groningen, Internal Medicine – Vascular Medicine, Groningen, Netherlands; UMC Maastricht, Surgery – Vascular Surgery, Maastricht, Netherlands; UMC, Rheumatology and Clinical Immunology, Groningen, Netherlands; UMC, Nuclear Medicine, Groningen, Netherlands

Background: Inflammatory abdominal aortic aneurysm (IAAA), a form of chronic periaortitis, is a frequently overlooked disease, occurring in patients with abdominal aneurysms (AAA). IAAA is strongly associated with underlying systemic inflammatory diseases such as IgG4-related disease (IgG4-RD),1 potentially leading to retroperitoneal fibrosis (RPF). Ultrasound (US) is a widely available and low-cost imaging tool that may allow the detection of IAAA at an early-stage prior development of severe complications in patients with AAA.

Objectives: This study aims to assess the feasibility of using US to detect IAAA in a small case series (exploratory cohort). And to structurally assess the diagnostic potential and overall incidence of IAAA using US in a larger retrospective cohort of patients in follow-up for AAA (validation cohort).

Methods: In the exploratory cohort, thirteen patients (median age 64 (61;72) years; 100 % male) with an established diagnosis of IAAA of whom US and CT findings were available were retrospectively included. The diagnosis of IAAA was based on a typical cuff surrounding the aneurysm on CT. Other potential causes such as infections and malignancies were ruled out by microbiological studies and when indicated by histology and/or FDG-PET scanning. Secondly, the validation cohort consisted of 191 patients (median age 74 (67;80) years; 73.3 % male) and when indicated by histology and/or FDG-PET scanning. In patients in whom a CT was performed (n=157) the diagnostic potential and overall incidence of IAAA using US in a larger retrospective cohort of patients in follow-up for AAA (validation cohort).

Results: In the exploratory cohort, 62% were smokers, 77% had hypertension, 31% and were diagnosed with IgG4-RD. CRP and BSE levels were 54.5 (±66.2) mg/L and 59.8 (±51.1) mmh/L. All patients showed a typical hypoechoic cuff surrounding the aortic wall eccentric to the calcified medial layer of the aneurysm, see figure 1B. The median anteroposterior diameter of the aneurysm itself was 5.7 cm (4.8; 6.1) and 0.64 cm (0.49; 0.84) of the cuff. In the validation cohort, 180 of 191 (94.2%) patients with AAA showed no evident signs of a hypoechoic cuff on ultrasound. Of the remaining 11 patients, 8 (4.2%) showed the cuff surrounding the aortic wall and were identified as having AAA. In 3 (1.6%) an IAAA could not be ruled out based on US. In 149 patients with both a negative US and available CT, all CT scans were negative as well. In the 8 patients with an evident cuff on US, the median age was 66 (65;79) years; and 100% were male, definite IgG4-RD was present in 25% (n=2) of the cases. This amounts to a sensitivity of 100% and a specificity of 98%.

Conclusion: This retrospective study indicates that AAA can be identified with US as a hypoechoic cuff surrounding the aortic wall of the aneurysm. US could be used to rule out IAAA safely. However, in inconclusive cases, additional CT imaging is warranted. Besides a possible cost and radiation dose reduction, using US may facilitate earlier recognition and treatment of IAAA and underlying systemic inflammatory diseases such as IgG4-RD. Although this is the first study to structurally investigate US in IAAA, our results need validation in a prospective study.

AB1550
UTILITY OF WHOLE-BODY 18F-FDG PET-CT IN THE DIAGNOSIS OF NEUROSARCOIDOSIS

Keywords: Lungs, Diagnostic tests, Imaging

A. Herrero-Moran1, L. Sanchez-Bilbao1, I. Gonzalez-Mazon1, D. Martinez-Lopez1, C. Alvarez-Reguera1, J. L. Martin-Villalas1, R. Fernandez-Ramon1, R. Blanco1, Marques de Valdecilla University Hospital, Rheumatology and Ophthalmology, Santander, Spain; Siemianila Hospital, Rheumatology, Torrelavega, Spain; Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain

Background: Neurosarcoïdosis (NS) is one of the most severe manifestations of sarcoidosis [1]. NS diagnosis is difficult since clinical features and cranial imaging findings are often unpecific and central nervous system biopsy is infrequently performed. Flouirine-18 fluoroodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET-CT) is emerging as a powerful tool for the evaluation of sarcoidosis. Data on the role of 18F-FDG PET-CT in NS is scarce.

Objectives: To assess the utility of 18F-FDG PET-CT in patients with suspected NS.

Methods: Patients diagnosed with sarcoidosis at a University hospital in Northern Spain, between January 1999 and December 2019 were assessed. Sarcoidosis was diagnosed according to ATS/ERS/WASOG criteria as follows: compatible clinical and radiological presentation, histopathologic confirmation, and exclusion of other granulomatous diseases. NS was diagnosed according to the NS Consensus Group [2]. Receiver Operating Characteristic (ROC) curve for Chest Computed Tomography (CT) and 18F-FDG PET-CT were compared.

Results: NS was suspected in 30 (19 women/11 men) patients out of 384 (78%) (mean age: 55.0±15.8 years). The underlying neurological manifestations were chronic headache (n=13; 43.4%), peripheral neuropathy (n=6, 20%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10%) and aseptic meningitis (n=3, 10%). Complementary study’s findings are described in Table 1. 18F-FDG PET-CT was performed in 10 (33.4%) patients. 18F-FDG PET-CT were abnormal in 9 (90%) patients. Abnormalities suggestive of NS were found in 7 (70%) patients. These were located in lymph nodes (n=7, 100%), parotid gland (n=1, 14.3%) and bone (n=1, 14.3%). Other abnormalities were found in 2 (20%) patients in vocal cord (n=1, 50%) and rectum (n=1, 50%). Only 1 (10%) patient had no abnormalities in 18F-FDG PET-CT. All patients (n=2, 100%) in which chest radiography and chest CT were negative, had pathological findings suggestive of NS in 18F-FDG PET-CT. After whole-body 18F-FDG PET-CT, all patients with accessible abnormalities suggestive of sarcoidosis underwent biopsy in lymph node (n=5, 71.4%), parotid gland (n=1, 14.3%) and skin (n=1, 14.3%). In all of them non-necrotizing granulomas were found. 18F-FDG PET-CT and chest CT diagnostic ability was compared (Figure 1). 18F-FDG PET-CT had a higher Area Under the Curve (AUC) (0.94 [95% CI: 0.78-1]) than chest CT (0.75 [95% CI: 0.28-1]).

Conclusion: 18F-FDG PET-CT seems to be a useful tool in the evaluation of patients with suspected NS specially when the chest CT is negative or inconclusive.

AB1551 IMAGING OF THE PERIPHERAL NERVOS SYSTEM IN NOCIPLASTIC PAIN: AN ULTRASOUND STUDY IN PATIENTS WITH FIBROMYALGIA

Keywords: Ultrasound, Imaging, Pain

M. Di Carlo1, B. Bianchi1, E. Cipolletta1, S. Farah1, E. Filippucci1, F. Salaffi1.
1Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy

Background: Fibromyalgia (FM) is a condition mainly characterized by the presence of chronic widespread musculoskeletal pain, fatigue, and sleep alterations. The pathophysiologcal basis of FM has not yet been clarified. It is widely recognized that FM is a condition characterized by the presence of central sensitization. The mechanisms of centralized pain have been studied mainly through functional imaging techniques. However, over the past decade, evidence of peripheral nervous system involvement has emerged alongside pathophysiological mechanisms involving the brain and spinal cord and a detailed analysis of the morphostructural abnormalities of other nerves in FM patients is still lacking.

Objectives: To investigate the sonographic changes [i.e., increased cross-sectional area (CSA)] of peripheral nerves in patients with FM compared to healthy controls and to identify potential clinical correlations associated with increased CSA in patients with fibromyalgia.

Methods: Consecutive female patients with FM included in this cross-sectional observational study underwent sonographic assessment using a standardized scanning protocol. The CSA of 7 nerves was measured bilaterally at 11 anatomic sites by an experienced sonographer. Differences in CSA of nerves were compared with those of healthy subjects by one-way analysis of variance. Patients underwent cliniometric evaluation aimed at investigating disease severity, neuropathic pain features, depression, anxiety, fatigue, and autonomic symptoms to explore the possible correlation between CSA and clinical features.

Results: 47 patients and 20 healthy controls were enrolled. Differences in terms of increased CSA between patients and healthy controls were identified at multiple levels, mainly at the level of the sural nerve, vagus nerve and 6th cervical nerve root (for all, p < 0.001). Sonographic findings, however, did not correlate with the clinical features explored.

Conclusion: Patients with FM show higher CSA of nerves than healthy subjects. The increased CSA is most evident at the sural nerve, vagus nerve and 6th cervical nerve root. Ultrasound, a relatively easy-to-use technique, could identify morphological changes, in peripheral nervous structures in patients with FM.

AB1552 PERFORMANCE OF A SOLID-PHASE PHOTOMETRIC SINGLE USE IMMUNOASSAY MICROARRAY PROTOTYPE IN THE DETECTION OF IGG ANTIBODIES AGAINST CENTROMERE PROTEIN B (CENP-B) IN HUMAN SERUM

Keywords: Systemic sclerosis, Diagnostic tests, Autoantibodies

D. Bijlsma1, E. Lukasik1, M. Hausmann1, G. Gomez2, C. Ginocchio2, E. Moreau1.
1Quotient Suisse SA, R&D, Eysins, Switzerland; 2Quotient Suisse SA, Scientific and Medical Affairs, Eysins, Switzerland

Background: Systemic Sclerosis (SSc) is a chronic multisystem autoimmune (AI) disease, characterized by progressive fibrosis of the skin and internal organs and vascular injury.[1] Biomarker testing plays an important part in disease classification, identification of sub-sets of SSc (e.g., CREST/Limited SSc), prognosis and progression. Presence of antibodies against centromere proteins (CENP) weighs 3 points in the ACR/EULAR Classification Criteria.[2] Development of highly automated diagnostic tools remains a clinical need.

Objectives: To evaluate the performance of a solid-phase photometric single use immunoassay microarray prototype for the in vitro qualitative detection of...
IgG antibodies against Extractable Nuclear Antigens (ENA) of CENP-B in human serum when tested using the MosaIQ™ System.

**Methods:** MosaIQ CENP-B microarray prototypes (Quotient Suisse, Eysins, CH) were prepared by printing CENP-B antigens in duplicate onto Epoxy-silane glass chips, followed by a blocking and preservative step. Microarrays consisting of 2 separate sides were assembled into Magazines (containing 250 microarrays) for processing on the MosaIQ 125 instrument. Human serum samples/buffers/reagents are loaded on the instrument and automatically the microarrays undergo sample/buffer/reatent addition to generate antigen spot signals which are read and interpreted by the instrument using a proprietary algorithm. A cohort of 26 serum samples reactive for anti-CENP-B antibodies (as defined by testing with 2 commercial assays) and 25 non-reactive serum samples from Swiss Red Cross blood donations were tested in duplicate.

**Results:** 25 out of 26 CENP-B antibody reactive samples were determined reactive by the MosaIQ CENP-B microarray prototype. The only discordant sample was reactive in one of the reference methods and non-reactive in the other, suggesting the potential for a false reactive by one of the reference methods. All 26 non-reactive samples were determined non-reactive by the prototype assay. Derived sensitivity (including presumptive false non-reactive) is 0.96 (95% CI 0.87 – 0.99) and specificity is 1.0 (95% CI 0.93 – 1.0).

**Conclusion:** These preliminary results support the performance of the investigational microarray prototype for the detection of CENP-B antibodies in human serum using the MosaIQ System. Clinical studies to confirm these observations are ongoing. Additionally, the microarray has the potential to print up to 66 spots per side, allowing for the capability to generate large multiplex panels for the detection and characterization of AI diseases.

Background: Sacroiliac joint (SIJ) synovial tissue analysis has the potential to improve specificity and sensitivity of spondyloarthritides (SpA) classification beyond the current Assessment for SpondyloArthritis International Society criteria allowing early diagnosis and reducing disease progression. It can aid the use of molecular biomarkers and identification of drug targets already explored in rheumatoid arthritis (RA) [1]. Furthermore, joint synovial tissue has shown histological differences in RA from psoriatic arthritis [2] and may help characterise SpA subtypes. SIJ steroid injections are used for pain management. A similar procedure, yet to be utilised, can be used to obtain synovial tissue using a co-axial needle. There is evidence of histological disease in patients experiencing sacroiliac pain without MRI features [3, 4]. Synovial biopsy offers possible earlier detection of SpA than MRI, which is limited by cost, patient weight and claustrophobia. Equally fluoroscopic or CT guided injections are limited by cost, time and radiation exposure. Early diagnosis and treatment of SpA is already linked to improved outcomes [5].

Objectives: To determine the tolerability and safety of ultrasound guided (USG) SIJ steroid injections to encourage SIJ tissue biopsies in research.

Methods: We identified 10 patients at Southend Hospital between 2010-2019. The average age was 41 years. Once verbal consent was obtained, a retrospective telephone questionnaire was completed. The USG SIJ steroid injections (Figure 1A) involved injecting Lidocaine 1% around the soft tissue using a 25G and 23G needle. Then a 22G spinal needle was guided into the SIJ and a mixture of Depomedrone 40mg and 0.5ml 0.25% bupivacaine administered. The patients were asked to indicate pain, swelling and stiffness of the injected joint pre and post procedure using a qualitative scale: none, mild, moderate or severe. They were asked to comment on side effects and how likely they were to repeat the procedure.

Results: All patients had severe pain before injection and one continued to have severe pain post procedure. None reported complications of steroid flare or back pain (Figure 1B and 1C). 70% experienced temporary numbness (Figure 1B), severe pain post procedure. None reported complications of steroid flare or back pain.

Conclusion: SIJ steroid injections are not widely offered, making it difficult to obtain large patient numbers. However, this study shows that SIJ steroid injections are tolerable for patients, an important step in convincing patients to participate in a SIJ synovial tissue biopsy research study. Tissue biopsy using a co-axial needle may be considered more invasive as it is thicker with a longer throw than a 22G spinal needle but the procedure steps and complication risks are ultimately similar. The complication risk rate has not yet been compared between the two procedures but SIJ tissue biopsy is less invasive and traumatic than the alternative SIJ trans-articular bone biopsy [6].

Whilst sample size may not be representative for a larger patient cohort and the retrospective questionnaire may have introduced time bias, the data obtained will hopefully initiate a potential study. This study could provide significant information on complication risk rate in synovial tissue biopsy of the SIJ and associated histological disease information in SpA.

CORRELATION BETWEEN HIGH RESOLUTION CHEST TOMOGRAPHY AND CAPILLAROSCOPIC FINDINGS IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Lungs, Prognostic factors

J. Santana Peralta1, R. A. Alvarez Santana1, D. Garcia1, L. Perez2, T. Polianco3, I. Concepcion Sanchez1, I. Paulino1, I. Mercedes3, E. Rodriguez Bautista1, T. Valdez2, A. Feriz1, R. Muñoz Louis3. 1Hospital Padre Billini, Rheumatology, Santo Domingo, Dominican Republic

Background: Systemic sclerosis (SSc) is a chronic autoimmune multisystemic disease characterized by fibrosis and vasculopathy[1] Mortality in patients with systemic sclerosis who present with interstitial lung disease can be up to 3x healthy population.[2] It is estimated that 70-90% have interstitial lung disease.[3] High resolution computed tomography (HRCT) of chest is recognized as a sensitive imaging method for evaluating pulmonary involvement.[4,5] Presentation patterns are also described: NSIP (non specific interstitial pneumonia), UIP (usual interstitial pneumonia), COP (cryptogenic organizing pneumonia), LIP (Lymphoctic interstitial pneumonitis). Capillaroscopy allows the study of the microcirculation. Changes are classified into “early”, “active”, and “late” scleroderma patterns.[6]

OBJECTIVES: To relate between high resolution chest tomography and capillaroscopic findings in Systemic sclerosis.

METHODS: Descriptive, observational, cross-sectional study. Capillaroscopy with Optilia Capiscope 2.0.5/3.0MP and lung ultrasound with Siemens Acuson X150 were performed in patients with SSc in the outpatient clinic of the rheumatology service from August-November 2021. Inclusion criteria: > 18 years old, meet criteria for classification of SSc according to ACR/EULAR 2013. Exclusion criteria: history of pre-existing lung disease.

RESULTS: 22 patients met inclusion criteria. 80% were female. Diffuse SSc 81.8% (18), limited SSC 18.2% (4). Mean age 54±17 years, disease duration 58.1% (13) >5 years and 40.9% (9) < 5 years, mean diagnosis 15.3±9.2 years, mean mRSS 19.4±13.2 mRSS Mild: 22.7% (5), moderate 18.2% (4), severe 27.3% (6), terminal 31.8% (7). ANA+ 45.5% (10), Topo IA 18.2% (4). Treatment: RTX 77.3% (17), Ca+ antagonists 68.2% (15), Bosentan 36.8% (8), MMF 36.4% (8), Colchicine 31.8% (7), Sildenafil 27.3% (6). Capillaroscopy: normal pattern 59% (13), early scleroderma pattern 9.1% (2), active scleroderma pattern 4.5% (1), late scleroderma pattern 22.7% (5), nonspecific abnormalities 4.5% (1). TACAR: 54.5% (12) normal, pathological findings 45.4% (10); NSIP pattern 80% (8), UIP 20% (2). TACAR/Capillaroscopy correlation: UIP pattern and early scleroderma pattern 4.5% (1) =r=0.112, NSIP pattern and active scleroderma pattern 4.5% (1) =r=0.769, NSIP pattern and normal capillaroscopy 4.5% (1) =r=0.518, NSIP pattern and late scleroderma pattern 27.2% (6) =r=0.815, normal TACAR and capillaroscopy
with nonspecific abnormalities 4.5% (1) p=1, UIP pattern and early pattern 4.5% (1) p=0.82, normal TACAR and normal capillaroscopy 27.2% (6).

Conclusion: We found in this study that capillaroscopic findings of active and late patterns correlated with greater pulmonary involvement. It is recommended to follow patients with early patterns and the existence or not of interstitial pattern and to evaluate response to medication.

MACHINE LEARNING APPROACH FOR CLASSIFICATION OF ARTHRITIS ACTIVITY STATE, USING DATA FROM A SINGLE ACCELEROMETER

Keywords: Artificial intelligence, Rheumatoid arthritis, Validation

P. Mielnik¹, A. Myhre Hjelle², A. Traseth², K. Tokarz³, B. Pollen⁴, M. Fojcik⁵.
¹Helse Forde, Section for Rheumatology; Department for Neurology, Rheumatology and Physical Medicine, Forde, Norway; ²Helse Forde, Section for Rheumatology; Department for Neurology, Rheumatology and Physical Medicine, Forde, Norway; ³Institute of Informatics Silesian University of Technology, Department of Graphics, Computer Vision and Digital Systems, Gliwice, Poland; ⁴Western Norway University of Applied Sciences, Faculty of Engineering and Science, Forde, Norway

Background: Machine learning (ML) potential is not fully exploited in diagnostics and follow up of autoimmune inflammatory rheumatic disease (AIIRD). It is despite the broader use of ML in e.g. imaging diagnostics. The specific tools for AIIRD are lacking.

Objectives: This is an interim analysis of data from the first checkpoint of the proof-of-concept study on using accelerometer (ACC) data in follow up of patients with AIIRD. The main goal of the study was to investigate the value of single ACC data in the classification of arthritis activity status.

Methods: Subjects with AIIRD are enrolled in the study when they start of new treatment due to disease activity. Several comorbidities, such as severe neuropsychological and cardiovascular disorders, as well as impaired mobility, are part of the protocol exclusion criteria. Volunteers without AIIRD who fulfill other inclusion exclusion criteria are included as controls. The study was approved by local competent authorities and informed consent was given by all participants. We used data collected up till the first study checkpoint. This analysis covers nine patients with AIIRD (5 rheumatoid and 4 psoriatic arthritis) and 13 controls. Five patients had 3 study visits, 1 had 2 visits and 3 only one. Controls have only one visit per protocol. We analysed ACC data from 3 minutes of clapping using a home-brewed device based on Arduino nano 33 BLE with 6-axis MTU by Nordic Semiconductor. Data was divided into 6-second chunks that were found optimal in our prior study. We conducted binary classification between any/ no arthritis in any of the upper extremities. We used accuracy and area under curve (AUC) as an efficacy function derived from the receiver operating characteristic curve (ROC). We extracted 54 features from 3 ACC axis signal. The features encompassed, among others, Fourier’s components, autoregression coefficients, median absolute deviation (MAD), variance, Fourier’s entropy, etc. We built linear discriminant analysis (LDA) models on the train data that were controlled on the test data. We originally built models with all features. Then, we analysed the importance of each feature on the models. Eventually, we constructed the most effective available model formula based on 7 features: the first autoregression coefficient for the X axis, kurtosis for the Z axis, correlation between Y and Z axis, zero point cross count for the Y axis, Z axis MAD, X and Y axis skewness. As we had few subjects included, we built 210 models with all possible data combinations. To avoid model overfitting, we never used data for model training from a subject who was actually in test data. All calculation was performed with R (R Core Team, 2022 www.R-project.org), using package caret (M. Kuhn 2022, CRAN.R-project.org/package=caret).

Results: Median accuracy for all LDA models was 0.78, mean 0.72 (95%CI 0.69-0.76), Median AUC was 1.0, mean 0.82 (95%CI 0.77-0.86). Distribution of the result was skewed to upper values. However, some models showed very low efficacy in classification (Figure 1 A and B).

Conclusion: Our study shows that it is possible to predict if a patient has any arthritis activity. However, we observed some instability in the classification between models. It can be due to small amount of data but also due to other distractors, such as comorbidities or drugs. Further research on the area is required and continuation of our study is justified based on the current results.

ULTRASOUND LEARNING CURVE IN INTERSTITIAL LUNG DISEASE OF AUTOIMMUNE RHEUMATIC DISORDERS: A DISEASE ORIENTED TRAINING PROGRAM

Keywords: Lungs, Ultrasound, Mixed connective tissue disease

M. Gutierrez¹, D. Mejia-Armsdondt², J. C. Arana Ruiz³, C. Bertolazzi⁴. ¹Center of Excellence in Musculoskeletal and Rheumatic Diseases, Rheumatology, Mexico City, Mexico; ²Center of Excellence in Musculoskeletal and Rheumatic Diseases, Physiotherapy and Rehabilitation, Villa de Cortes, Mexico; ³Instituto Nacional de Rehabilitación, Rheumatology, Ciudad de México, Mexico

Background: Ultrasound (US) has elicited considerable interest among rheumatologists because of its usefulness in clinical practice. Recently, it has been demonstrated its ability to assess interstitial lung disease (ILD) in rheumatic patients. While a solid and still growing body of evidence supports its use in daily rheumatologic practice, operator dependency and the long learning curve represent the main limitations.

Objectives: To describe the learning curve of rheumatologists with limited experience using US attending an intensive disease-oriented training program focusing on the skills required to obtain and interpret US signs of ILD in patients with autoimmune rheumatic diseases.

Methods: A total of 5 investigators participated in a seven-day training program involving 15 patients with autoimmune rheumatic diseases. The expert sonographer was a Rheumatologist with >15 years of US experience, whose assessments were used as the gold standard to evaluate the US findings obtained by the remaining 4 investigators. Two beginner sonographers were fellows in rheumatology with 5 months of global US experience, whereas the other 2 beginner sonographers were fellows in rehabilitation and rheumatology with a very basic knowledge of musculoskeletal US (<3 months) and no direct US experience in ILD. The training program lasted for 7 days (at least 5 hours per day) following specific aims and activities for each day during the training program. The agreement between the expert and beginners was calculated in 4 sessions involving 15 patients (13 females and 2 males; 4 rheumatoid arthritis, 6 systemic sclerosis, 3 Sjogren syndrome, 2 dermatomysitis). The US assessment was performed according the previously proposed 14-intercostal spaces (IS) scanning protocol using the following semiquantitative scale [0 = normal (≤5 B-lines); 1 = slight (6–8 and ≤15 B-lines); 2 = moderate, (16≤ and ≥30 B-lines); 3 = severe (≥30 B-lines) [1]. Additionally the pleural irregularity in each IS was dichotomously recorded.

Results: A total of 210 lung IS were studied. Kappa values and overall agreement percentages of qualitative and dichotomist assessments of US ILD findings
(B-lines and pleural irregularity) at the end of the exercise showed moderate to excellent agreement (between 0.769 and 0.895), while in the first session they showed poor/fair agreement (between 0.325 and 0.435). The comparison between the expert (gold standard) and the beginning examiners at the fourth and final session, including the kappa values, sensitivity, specificity, and negative and positive predictive values were also improved.

**Conclusion:** After 1 week of the disease-oriented training program, physicians with limited experience in US were satisfactorily able to detect and interpret the main US signs indicative of ILD in patients with autoimmune rheumatic diseases.

**CLINICAL-ECOCRAPHIC OPTIMIZATION IN RHEUMATOID ARTHRITIS IN SUSTAINED REMISSION**

**Keywords:** Tapering, Ultrasound, Rheumatoid arthritis

**G. Añez,1 V. Torrente Segarra2, M. Bonet2, M. Castillo Villella1, L. Orpínel3, A. Ponce Fernandez2, N. Busquets-Pérez2, M. Pascual-Pastor4, H. Corominas, C. Diaz-Torne6, P. Moya1, J. J. De Agustin1.1Hospital Universitari Vall d’Hebron, Rheumatology, Barcelona, Spain; 2Hospital Comarcal de l’Alt Penedès, Rheumatology, Viladecans del Penedès, Spain; 3Hospital Universitari Sagrat Cor, Rheumatology, Barcelona, Spain; 4Hospital General de Granollers, Rheumatology, Granollers, Spain; 5Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain.

**Background:** In recent years, the high economic impact of biologic therapies (BT) on health care systems has promoted great interest in optimizing BT in Rheumatoid Arthritis (RA) patients in sustained clinical remission (CR). A relevant percentage of those optimized patients present clinical relapses. RA patients in CR have been shown to have active synovitis detectable by ultrasound (U). U can identify synovitis in patients about to present clinical relapse. U can be a useful tool in the optimization decision.

**Objectives:** The main objective was to demonstrate that the optimization strategy using U is more useful than the strategy using clinical index. U used as an outcome measure, can further refine the choice of patients who are candidates for a reduction in treatment and therefore achieve lower relapse rates. To do this, we calculated the relapse rates in each of the groups and the time from the beginning in which it appears, and we compared them to assess whether they differ significantly and support our hypothesis. Secondary objective was evaluating the ultrasound remission in this group of patients.

**Methods:** We conducted a multicenter, randomize, prospective study in 5 tertiary centers in RA patients in sustained CR (>9 months). All signed the informed consent. Approval by the ethical committee was obtained (VDH-INF-2017-01). Two blinded random, groups were set: clinical (A) and ultrasound (B). Both groups were created to decide tapering (1/2, 1/3 or no reduction treatment) and compare flare rates (>12 DAS28 or >16 SDAI/CDAI increase) in 52 weeks (basal, 1, 6, 9 & 12 months). Demographic at baseline, US & clinic variables, and ESR & CRP at each visit, were registered. By using U with grayscale (GS) and power Doppler (PD) in a semiquantitative articular (A) and tendon (T) scale we studied: wrist, 1-5 MCP, 1-5 PIP, ankle, subtalar joint, 2nd, and 5th MTP, extensor tendons (Test) and flexors (Tflex) of the carpus, flexor tendons of the fingers, posterior tibial and peroneal tendons. DAS28 <2.6 was used as the clinical remission criteria, and the absence of synovitis was defined as U remission (EG and PD = 0). U activity was defined as GS≥1 and PD ≥1.

**Results:** 78 patients were included, 48 completed 12 months follow up and 28 were retired (5 screening failure, 16 flare, 5 lost follow up & 4 patient decision). 33 men and 45 women, 11.92 years of disease. Group A presented a significative more flare rates than group B (10 vs 6). Using SDAI or CDAI only 7 presented a clinical flare, and for SDAI (7 vs 0) & CDAI (7 vs 0) differences were significative (p<0.005), but not for DAS28 (10 vs 6) (Table 1). In U at baseline, the main involved joint was the wrist (28.6%), and of the tendons the Test (11.2%). In 53% a pathological U (A and T) was observed, 46.9% had pathological A and in 30% pathological T was observed. Considering as remission an ultrasound score of EG + PD = 0, only 46.9% were in remission.

**Conclusion:** Ultrasound can improve tapering strategy when we used SDAI or CDAI score in patients in sustained clinical remission. Clinical and ultrasound remission are not equivalent. More than half of the patients do not fulfill UR and in one fifth of them a strict control should be carried out to avoid a relapse of the disease if it is decided to optimize.

**AUTOIMMUNE DISEASES ASSOCIATED WITH AUTOIMMUNE HEPATITIS**

**Keywords:** Comorbidities

**N. Trad1, A. Mensi1, E. Belhard Mabrouk2, S. Ayadi1, Y. Zaimi1, L. Mouelhi1, Y. Said1, R. Dabbeche1.1Charles Nicolle Hospital, Gastroenterology, Tunis, Tunisia; 2Charles Nicolle Hospital, Gastroenterology, Tunis, Tunisia.

**Background:** Autoimmune hepatitis (AIH) is a rare pathology characterized by necrotic-inflammatory hepatocyte lesions, the presence of autoantibodies, and high sensitivity to corticosteroid treatment. It is often associated with other autoimmune diseases.

**Objectives:** Our objective was to study the clinical aspects, associated auto-immune diseases, and response to the treatment of AIH.

**Methods:** We conducted a retrospective study including consecutive patients with AIH between January 2000 and December 2018.

**Results:** We included twenty-two patients; 21 women and one man with an average age of 46 [18-95], Jaundice was the most frequent presenting sign (80%).

**Conclusion:** Autoimmune hepatitis greater than ten times in 45.5% of cases. A predominant hypergammaglobulinemia on IgG was noted in 72% of cases. At the time of diagnosis, 59% of patients were in the stage of cirrhosis. Antinuclear antibodies, Anti-smooth muscle antibodies, and Anti-LKM1 antibodies were positive in 47.6%, 41%, and 13.3% of cases, respectively. The liver biopsy was performed in 8 patients (36.3%) with a compatible histological appearance in 7 patients. In 54.5% of cases, an associated autoimmune pathology was noted; the most common was autoimmune thyroiditis (32.3%) and autoimmune hemolytic anemia (33.3%). There were also two cases of Sjögren’s syndrome, one case of systemic lupus erythematosus, and one case of rheumatoid arthritis. An overlap syndrome (AIH-PBC) was found in 22.7% of patients. The combined corticosteroid-azathioprine treatment was prescribed in 15 patients (88.1%). In overlap syndromes, ursodeoxycholic acid has been associated. The mean duration of follow-up was 94.5 months. Under treatment, biochemical remission was achieved in 23% of patients.

**Disclosure:** In our study, the prevalence of autoimmune diseases associated with AIH was significant, which would underline the importance of systematic screening for clinical and biological immune manifestations in those patients.

Results: Both culture and composite reference standard.

Methods: Thirty-one women with sarcoidosis and 27 controls were evaluated for the following outcomes: (i) handgrip strength, (ii) QFM thickness measured using ultrasound (US), and (iii) sono graphic thigh adjustment ratio (STAR). The sarcoidosis group was also evaluated using the 30-second chair stand test (30s-CST) and fatigue severity scale (FSS).

Results: The QFM thickness and STAR values of the sarcoidosis group were significantly lower than those of the control group (p<0.001). However, no statistically significant difference was observed between the handgrip strengths of the groups (p=0.581). There was no statistically significant correlation between the STAR values and handgrip strength in the sarcoidosis group (p=0.05); however, there was a statistically significant positive correlation between the STAR values and 30s-CST (r=0.467, p=0.008).

Conclusion: Probable sarcopenia is one of the musculoskeletal conditions in patients with sarcoidosis that may be associated with nonspecific symptoms, such as general weakness, exercise intolerance, and fatigue. Although the handgrip test is a frequently used test, it may not show prominent findings in the early stages of the disease. Ultrasound appears to be an innovative tool for preventing sarcopenia as it helps detect changes in muscle mass and muscle quality at an early stage.

COMPARISON OF DIAGNOSTIC PERFORMANCE OF TRUENAT™ MTB PLUS AND XPERT® ULTRA (GX) IN PATIENTS OF OSTEOARTICULAR TUBERCULOSIS (OATB): EXPERIENCE FROM NORTH INDIA

Keywords: Diagnostic tests

K. Sharma1, A. Sharma2, A. Sharma3, 1Post Graduate Institute of Medical Education & Research, Chandigarh, Medical Microbiology, Chandigarh, India; 2Government Medical College & Hospital, Chandigarh, MBBS Student, Chandigarh, India; 3Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India

Background: Diagnostic delay and drug resistance not only worsen the outcomes of tuberculosis, but are also important impediments to TB elimination efforts. Prompt and accurate diagnosis of osteoarticular tuberculosis (OATB) along with simultaneous detection of drug resistance is crucial to decrease the morbidity and associated sequelae.

Objectives: Given the need for a near point-of-care test suitable for primary healthcare centers and simultaneous detection of resistance, TrueNat MTB Plus (TruPlus), a chip-based real-time polymerase chain reaction assay, was evaluated for the first time for diagnosis of OATB and detection of rifampicin resistance from pus and synovial fluid samples.

Methods: Total of 100 synovial fluid/pus samples (20 microbiologically confirmed OATB[culture-positive], 50 clinically confirmed OATB [culture-negative], and 30 control patients) were subjected to TruPlus assay and Xpert Ultra (GX Ultra) assay; and their performance was compared. Results were evaluated against both culture and composite reference standard.

Results: The overall sensitivity and specificity of TruPlus in diagnosing OATB was 77.14% (54/70) and 100%, respectively. The sensitivity was 90% (18/20) for microbiologically confirmed cases and 72% (36/50) for clinically confirmed cases. Performance of TruPlus was superior to Xpert ultra (sensitivity = 70%). Overall, sensitivity and specificity of GX ultra was 70% and 100%. However, sensitivity of GX Ultra was 85% in culture confirmed cases and 84% (32/38) in clinically suspected cases of OATB. Both TruPlus and GX Ultra correctly reported Rifampicin resistance in four cases, when compared with phenotypic DST and rpoB gene sequencing.

Conclusion: TruPlus, with its greater portability and higher sensitivity than Xpert, could serve as an important tool for diagnosing OATB and rifampicin resistance at outreach endemic areas.

NAIL FOLD CAPILLAROSCOPY IN EVALUATING INTERSTITIAL LUNG DISEASE OF RHEUMATOID ARTHRITIS, SYSTEMIC SCLEROSIS AND IDIOPATHIC TYPE

Keywords: Rheumatoid arthritis, Systemic sclerosis

S. Bashad1,2,3, K. Danwish4, H. Abdel-Maksoud4, A. Abas5, M. Abdelaty4, 1Suiz University, Faculty of Medicine, Suiz, Rheumatology, Cairo, Egypt; 2Suiz University, Faculty of Medicine, Suiz, Rheumatology, Cairo, Egypt; 3Alazhar University, Chest, Asiat, Egypt; 4Alazhar University, Chest, Assiut, Egypt

Background: Nail fold capillaroscopy (NFC) is a non invasive diagnostic tool to detect early changes of microcirculation of different collagen diseases as rheumatoid arthritis associated interstitial lung disease (RA-ILD), systemic sclerosis interstitial lung disease (SS-ILD) and idiopathic ILD (Ting et al., 2020).

Objectives: The study aimed to evaluate role of NFC in RA-ILD, SS-ILD and idiopathic ILD, and to determine if there is a correlation of it to disease activity.

Methods: A case control study conducted on 100 patients with ILD, where 30 patients with RA-ILD, 30 patients with SS-ILD and 40 patients with idiopathic ILD, fulfilling ACR/EULAR criteria, 2013. They were examined clinically and radiologically. Pulmonary function tests (PFT) and NFC were done.

Results: Pleural irregularities were found in 42% of RA-ILD, 30% of SS-ILD where subpleural irregularities were found in 31% of RA-ILD and 46.7% of SS-ILD. Ground glass opacity was in 13% of RA-ILD, 79.7% in SS-ILD and 60.7% in idiopathic ILD. Honeycomb appearance was in 11.5% of RA-ILD, 30% in SSILD and 65% of idiopathic ILD. SS-ILD showed the highest capillary changes especially patients with pneumo-nia. A significant correlation was found between NFC and PFT in idiopathic-ILD.

Conclusion: NFC is a sensitive and specific adjuvant tool in monitoring micro vascular changes in rheumatologic diseases and can be used as assessment tool in severity of the disease.

REFERENCE:
Methods: We enrolled, after obtaining informed consent, 16 patients affected by SSC (classification criteria EULAR/ACR 2013) (3), who underwent cardiac catheterization for suspicion of PAH (3), in particular we paid attention to the measurements of pulmonary vascular resistance. NVC was performed in all patients. We collected information on the main capillaroscopic alterations such as number of capillaries, megacapillaries, avascular areas and microhemorrhages.

Results: After RHC evaluation, we identified 8 patients with PAH (F/M 6/2; median age 67±7 SD years) and 8 without PAH (F/M 6/2; median age 66±8 SD yrs). No significant differences regarding clinical and laboratoristic parameters were observed. At NVC, capillary density was significantly lower in PAH-SSC patients than in SSC patients without PAH (p = 0.04) and avascular areas were more frequent in the first group (p = 0.03). Furthermore, we evaluated a statistically significant correlation between the value of pulmonary vascular resistances at RHC and the number of capillaries at NVC (p = 0.04). We did not observe correlations with the other parameters.

Conclusion: This study confirms the correlation between peripheral microvascular alterations, evaluated by capillaroscopy and the involvement of internal organs, such as pulmonary circulation. Our findings provide additional evidence to the literature data but further studies are underway to confirm these preliminary data.

AB1564 PERIPHERAL BLOOD PERFUSION IN MCTD AND UCTD PATIENTS: A CROSS-SECTIONAL MONOCENTRIC STUDY

Keywords: Imaging, Mixed connective tissue disease, Undifferentiated connective tissue disease

A. Cere1, E. Hysa1, A. Lercara1, A. Pinelli1, E. Gotelli1, C. Pizzorni1, M. Cutolo1, Laboratorio of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine (DIMI), University of Genova, IRCCS San Martino Polyclinic, Genova, Italy; 1Unit for Molecular Immunology and Inflammation, VB Inflammation Research Center (IRC), Department of Internal Medicine, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

Background: Connective tissue diseases (CTDs) are a heterogeneous group of autoimmune disorders and, among them, mixed connective tissue disease (MCTD) and undifferentiated connective tissue disease (UCTD) show overlap symptoms with other CTDs, but share secondary Raynaud’s Phenomenon (sRP) as a typical vascular symptom.[1,2] Laser speckle contrast analysis (LASCA) is a reliable tool to measure the peripheral blood perfusion (PBP) and has already demonstrated to be useful in detecting the peripheral microcirculation status of SSC patients and undifferentiated sRPs.[3]

Objectives: To measure hand PBP in patients with sRP in CTDs (MCTD, UCTD) and to compare it with healthy controls (HCs).

Methods: Twenty-four CTDs patients with sRP (7 with MCTD, 17 with UCTD) and 28 age- and sex-matched HCs were evaluated during standard follow-up assessments. CTDs diagnoses were set up according to the international classification criteria.[4] Patients had a stable therapy (mainly glucocorticoids and conventional disease modifying anti-rheumatic drugs) and had not had intravenous vasodilator treatments for the previous three months at least. All subjects underwent a LASCA registration (Laser Speckle Contrast Analysis - Percim PSI, Perimed, Jarfalla) after acclimatization of 15 minutes at 20-22°C. After recording, PBP was quantified (perfusion units, PU) in the following region of interest (ROI): fingertips (with and with without thumbs) and periangual areas (with and without thumbs). Statistical analysis was performed using DataTab®, with parametric tests in case of normally distributed data and non-parametric tests in case of non-symmetrically distributed data.

Results: Although not statistically significant, a trend to a lower PBP was found when comparing MCTD LASCA values versus UCTD LASCA values, particularly for ROIs of periangual areas (see Table 1). In addition, PBP was found significantly lower in MCTD and UCTD when individually compared with HCs. This result was confirmed for all four ROIs (p<0.02; see Table 1).

Conclusion: To our knowledge, no evaluations of PBP by LASCA are available in literature in other CTDs other than SSC.[5] This preliminary study showed, using the LASCA methodology, that the PBP in MCTD and UCTD patients affected by sRP is significantly lower than in sRP- and sex-matched HCs. A trend with a lower PBP in MCTD patients than UCTD patients was observed but did not reach a statistical significance due to the small sample size.

These results may demonstrate a potential role of LASCA in assessing the vascular involvement of CTDs other than SSC. Further investigations on a larger and more homogeneous sample size and a focus on the possible correlations between PBP and the morphological microvascular damage assessed by nailfold videocapillaroscopy have been planned.

AB1565 IBD AND LIGAMENTOUS LAXITY ASSOCIATION

Keywords: Diagnostic tests, Descriptive studies, Clinical trials

C. Bentivenga1, A. Varani1, N. E. Polli1, E. R. Cosentino1, F. Rizzello1, C. Calabrese2, P. Gionchetti1, C. Borghi1, S. Orsola-Malpighi Polyclinic IRCCS, Medicina Interna Cardiovascolare-Boirghi, Bologna, Italy; S. Orsola-Malpighi Polyclinic IRCCS, IBD Unit, Bologna, Italy

Background: Inflammatory Bowel Disease (IBD) is a group of chronic relapsing-remitting diseases characterized by intestinal and extra-intestinal manifestations that unfavourably impact patients’ physical and mental quality of life. Recent evidence points to a possible higher incidence of Joint Hypermobility (JH) or “ligamentous hyperextensibility” in IBD patients compared to the general population and particularly in younger and female subjects with IBD. Ligamentous hyperextensibility represents a little-known benign clinical condition characterized in its asymptomatic form by joint and ligament hypermobility.

Objectives: the aim of this study is to determine the prevalence of ligamentous hyperextensibility in a cohort of patients with IBD.

Methods: we evaluated 130 patients afferent to the joint clinic of the “Centro Regionale per le Malattie Infiammatorie Croniche Intestinali “Massimo Campieri” e MI Borghi”, located at “Sant’Orsola-Malpighi” University Hospital in Bologna, in the period between June 2021 and November 2022, allocating them into 3 groups: 1) Ulcerative Colitis (UC), 2) Crohn’s Disease (CD), 3) Indeterminate Colitis (IC). None of the patients was affected by hereditary collagenopathies. Out of 130 patients, 47 were affected by Ulcerative Colitis (UC), 78 by Crohn’s Disease (CD) and 5 by Indeterminate Colitis (IC). The mean age at the time of the visit was 45,32 (±12,86 range 24-78) for patients with UC; 47,35 (±12,65 range 22-70) for patients with CD; 45,00 (±12,16 range 26-62) for patients with IC; in terms of sex: 47 men (20 with UC, 27 with CD, 0 with IC) and 83 women (27 with UC, 51 with CD and 5 with IC). Results: 34 out of 130 patients presented ligamentous hyperextensibility according to Beighton’s criteria (pt ≥ 4) (26,2% of total, 16 UC, 17 CD, 1 IC). Of the 47 patients with UC, 16 had ligamentous hyperextensibility (34%). Of the 78 patients with CD, 17 had ligamentous hyperextensibility (21,8%). Of the 5 patients with IC, 1 had ligamentous hyperextensibility (20%). It emerges from this analysis that the highest prevalence of ligamentous hyperextensibility occurs in patients with UC, compared with CD and IC. Chi-square test for independence was performed by comparing the variable ligamentous laxity with the variables IBD, UC, CD and IC.
The groups CD and IC did not show any statistically significant result with regards to ligamentous laxity whereas we did observe a statistically significant higher frequency of ligamentous laxity (p-value < 0.05) in the UC group.

Conclusion: A close association between Ulcerative Colitis and the presence of JH, especially compared to Crohn's disease and Indeterminate Colitis, clearly emerges from our observation, which could postulate a possible alteration of collagen development in the pathophysiology and clinical spectrum of UC only and not of IBD in general. These data, however, need to be confirmed and further investigated in the future with focused and rigorous prospective clinical studies, excluding confounding factors such as young age or inflammatory joint diseases such as spondyloarthropathy.

DIAGNOSIS OF SACROILIITIS USING LOW DOSE CT COMPARED TO MRI

Keywords: Diagnostic tests, Spondyloarthrosis

P. W. V. Chan1, S. L. Lau1, J. F. Griffith2, J. So1, H. So1, L. S. Tam1. 1The Chinese University of Hong Kong (CUHK), Department of Medicine and Therapeutics, Hong Kong, Hong Kong SAR; 2The Chinese University of Hong Kong (CUHK), Department of Imaging and Interventional Radiology, Hong Kong, Hong Kong SAR

Background: Establishing a correct diagnosis of sacroiliitis is key to the early diagnosis of axial SPA. Low-dose computed tomography (LDCT) is helpful at revealing the structural changes (erosion, sclerosis and ankylosis) of sacroiliitis. How does LDCT compare with MRI for identifying sacroiliitis?

Objectives: This study compares LDCT and MRI in the diagnosis of sacroiliitis in patients with suspected axial spondyloarthrits (axSpA).

Methods: 25 patients [36 ± 7 years; female 16 (64%)] with back pain over three months and age under 45, clinically suspected of axSpA underwent radiography, LDCT and MRI of the SIJ. All imaging studies were assessed by an experienced radiologist. Radiographs and LDCT revealed erosions, bone sclerosis and ankylosis. MRI, in addition to these structural changes, also revealed osteitis and enthesis.

Results: Out of the 25 patients, 8 (32%) had radiographic-sacroiliitis. Twelve (48%) patients had sacroiliitis on both LDCT and MRI, including 6 patients with radiographic-sacroiliitis and 6 patients with non-radiographic-sacroiliitis. There is no evidence of sacroiliitis on both LDCT and MRI for one patient, who was reported to have sacroiliitis on x-ray. No diagnosis could be made to 10 (40%) patients due to lack of evidence from imaging and 3 (12%) patients were diagnosed as osteitis condensans illii. Agreement between MRI and LDCT was 100%. Cohen’s kappa coefficient was k=1, positive predictive value was 1, and negative predictive value was 1. Using MRI as the gold standard, sensitivity and specificity of LDCT were 1 and 1 respectively. While the specificity and specificity of x-ray were 0.5 and 0.85 respectively.

Conclusion: Low dose CT and MRI showed comparable sensitivity in detecting sacroiliitis. Access to MRI is limited, LDCT is a good alternative to detect sacroiliitis in patients with suspected axSpA.

The greatest involvement was found in the distal structural damage. The involvement within the different explored entheses found in the Doppler study; while a mean of 18.25 (±14.50) corresponded to 52.41 (±9.4) years at the time of the study. 66.7% were smokers, and 25% had a positive MASEI score (>18). The mean score of the entheses was 0.92 (±1.24) and no swollen entheses were found. 25% of patients had a positive MASEI score (>18). The mean score of the MASEI index was 20.42 (±11.02). Of this score, only a mean of 2 (±1.5) was found in the Doppler study; while a mean of 18.25 (±14.50) corresponded to structural damage. The involvement within the different explored entheses is described in Table 1. The greatest involvement was found in the distal patellar enthesis (6.58 ± 3.75) (Figure 1).

**Figure 1.** Ultrasound examination of the enthesis of the distal patellar tendon.

**Conclusion:** The patients with SAPHO Syndrome in follow-up at Ramón y Cajal hospital were found to have ultrasound enthesal abnormalities using the MASEI index. The results revealed a clear predominance of structural damage over the presence of active lesions. Further studies with larger sample size are necessary to fully comprehend the involvement of entheses in SAPHO syndrome.
Conclusion: The use of machine learning in diagnosing and detecting damage has mostly focused on plain radiography in patients with RA; there are limited data in PsA. Heterogeneity in the reporting of results limits succinct comparison of performance between ML methods.

AB1570 MODERN TREATMENT OF ENTRAPMENT NEUROPATHIES, THE HYDROCHEMICAL NEUROLYSIS

Keywords: Ultrasound, Descriptive studies, Best practices

A. Ould Hennia1.

Background: Entrapment neuropathies (E.N) are frequent and often underdiagnosed leading to significant chronic pain and functional impairment impede the quality of life. Commonly occur in the fibro-osseous tunnels through which the nerves course with various static and dynamic factors. Imaging particularly ultrasound can identify an anatomical cause, detect signs of nerve injury, assess its severity and also aid in the percutaneous treatment like our technique: “The hydrochemical neurolysis” (HCN).

Objectives: We present the US-guided hydrochemical neurolysis of E.N to relieve, in most cases, the pain caused by peripheral nerve compression and its consequences by the mechanical release and decompression of the entrapped nerves. This technique involves using US (fast, accessible, reliable, cheap and radiation-free) to find the nerve and guide a needle around the nerve to cut scar tissue and introduce fluid to mechanically push scar tissue ways from the nerve and create separation between the nerve and tissues. With 18 G needle, a real mechanical dissection is performed and with the liquid (normal saline) we complete with a hydrodissection.

Methods: Before performing a US-guided HCN, survey imaging should be performed with low or high resolution probes, depending on the depth of the intervention, patient informed and clearly consents. Technique: what I do.

Patient positioning: patient positioned in a supine, sitting, or prone posture according to the location of the nerve to be treated. Different positions, pillows and/or pads can be used to restrict movement during the procedure and provide comfort for patient and physician. Identification, marking the skin, disinfection and local anesthesia. The needle entry point is calculated based on the distance and inclination angle of the needle from the skin surface to the target for better and optimal visibility of the needle tip. These settings are variable depending on the superficial or deep situation of the nerve to be treated. The entry site is then marked (with skin marker) as well as the projection of the target at the level of the skin, then the skin area is cleaned and prepared for the using standard sterile technique. The US-probe is covered with a sterile semi-transparent bag and a sterile gel is used for further analysis and intervention. A 25 G needle is used to anesthetize the skin with 1% lidocaine, and is then advanced under US-guidance with an intermittent local injection for anesthesia (and hydrolocation) until the needle comes into contact with the epineurium. The In-plane approach is my favorite. Perineural Adhesiolysis, Hydrodissection and injections. With 18 G needle (variable length according to the site to be treated) we inject under low pressure 5-10 ml of liquid (mix of normal saline and 1% lidocaine) between the compressed nerve and the connective-fatty tissue to make the end of my needle clearly seen (hydrolocation), can be repeated for the duration of the procedure. Then with the same needle, we inject 20-60 ml of normal saline all around the nerve and over the entire area where it is compressed to release it completely from all surrounding structures (hydrodissection).

Adhesiolysis is carried out when there is scar tissue around the nerve and the hydro-dissection was not effective, in this case a real mechanical needle dissection is carried out or the needle is used like a scalpel to make needling in varying directions all the scar tissue surrounding the nerve. After hydrodissection, we inject corticosteroid (5-10 ml of prednisolone acetate 125 mg) for his anti-inflammatory and anti-fibrotic effect.

Results: In my practice, we have at least 70% good results at 12 months, 20 to 25% require a 2nd session of hydrochemical neurolysis and maybe 10% will resort to surgery. The results of neurolysis seem very interesting, much better than a simple US-guided infiltration and avoids surgery in many cases.

Conclusion: Success with this hydrochemical neurolysis procedure requires knowledge of anatomy, US-imaging. The HCN is a simple, safe, precise, rapid, and effective percutaneous treatment of E.N, a great alternative to surgery.

AB1571 IGG4-RELATED AUTOIMMUNE PANCREATITIS MIMICKING PANCREATIC CARCINOMA

Keywords: Malignancy, Undifferentiated connective tissue disease, Mixed connective tissue disease

Background: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory disorder characterized by dense infiltration of IgG4-positive plasma cells in the affected tissue. The inflammatory infiltration along with storiform fibrosis can lead to the development of tumefactive lesions that may affect any organ. Type 1 Autoimmune pancreatitis (AIP) is a rare presentation of IgG4-RD that can present as a pancreatic mass and may mimic pancreatic carcinoma.

Objectives: The elevation of CA 19-9 is seen in autoimmune pancreatitis as well as pancreatic carcinoma. Therefore, it becomes difficult to differentiate between the two, especially in the presence of an elevated IgG4 level in the serum. We describe a rare instance of IgG4-related AIP with significantly high CA 19-9 levels.

Methods: Case report.

Results: Our patient is a 65-year-old male with past medical history of IgG4-related retroperitoneal fibrosis, who presented with the complaint of worsening right upper quadrant abdominal pain, jaundice, and weight loss. Labs showed WBC count 13.7 (4.0-9.0 x 10^3/uL) and eosinophil count 700 (50-300/cmm). ESR 94 (0-15 mm/hr) and CRP 57.9 (0-10 mg/dL). LFTs showed elevated total bilirubin 12.5 (0.1-0.2 mg/dL), alkaline phosphatase 620 (30-115 IU/L), AST 72 (5-45 IU/L), and normal ALT 52 (0-60 IU/L). Absolute CD4 count was 1152 (332-1642 cells/cmm), CD4 percentage was 80% (28-62%), CD4 to CD8 ratio was high 8.86 (2-96), and CD4 to CD8 ratio was high 8.86 (2-96).

CA 19-9 was elevated to 2830 (0-35 U/ml). IgG4 was elevated 162 (2-96 mg/dL).

1Albany Medical Center, Internal Medicine, Albany, United States of America; 2John H. Stroger, Jr. Hospital of Cook County, Internal Medicine, Chicago, United States of America; 3Rawalpindi Medical University, Medicine, Rawalpindi, Pakistan; 4Albany Stratton VA Medical Center, Rheumatology, Albany, United States of America
MRCP showed multiple biliary strictures and dilation of the main pancreatic duct. ERCP with stent placement was done to relieve biliary obstruction. EUS showed mass-like enlargement of the pancreatic head with atrophy, around the common bile duct (CBD). Biopsy of the CBD showed inflamed glandular mucosa, negative for malignancy. Pancreatic head biopsy showed normal stroma and benign mucosa, negative for malignancy. Patient had gradual improvement in bilirubin and CA 19-9 levels after ERCP and stent placement. He was started on prednisone which was followed by rituximab infusions. He followed up with rheumatology and had significant improvement in his symptoms and labs including a decrease in bilirubin to 2 mg/dL, alkaline phosphatase to 300 IU/L, and CA 19-9 levels to 100 U/ml within 1 month of discharge.

Conclusion: Autoimmune pancreatitis (AIP) can be difficult to distinguish from pancreatic carcinoma. High levels of CA 19-9 are usually indicative of malignancies, whereas high levels of IgG4 are characteristic of AIP. However, the combination of CA 19-9 > 74 U/ml and IgG4 > 1.0 g/L distinguishes patients with AIP from patients with pancreatic carcinoma with 94% sensitivity and 100% specificity [1]. CA 19-9 levels can also be elevated in other GI diseases including primary sclerosing cholangitis, bacterial cholangitis, or cholecodocholithiasis. Differentiation between these conditions is extremely important due to the vastly different treatments and the morbidity/mortality associated with them [2,3].

IgG4-RD causing biliary obstruction with CA 19-9 elevation is a diagnostic dilemma. It can be misdiagnosed as pancreatic or cholangiocarcinoma. Our patient illustrates that IgG4-RD pseudotumors can significantly elevate CA 19-9. In these cases, further testing and biopsy should be performed to rule out malignancy.

AB1572 IMPACT OF MATERNAL CONNECTIVE TISSUE DISEASE ON FUNCTIONAL AND STRUCTURAL ABNORMALITIES OF THE HEART IN THE OFFSPRING

Keywords: Cardiovascular disease, Imaging, Heart

T. Frielsen Neumann1, S. S. Andersen1, S. Dannebo1, A. S. Sillelsen2, R. O. Vegg2, K. Schreiber3,4,5, K. Iversen6, H. Bundgaard2, A. Axelsson Raja2

1Rigshospitalet, Department of Cardiology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; 2Herlev University Hospital, Herlev-Gentofte Hospital, Herlev, Denmark; 3Herlev University Hospital, Copenhagen, Denmark; 4Department of Rheumatology, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; 5Department of Rheumatology, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; 6Department of Thoracic Surgery, Odense University Hospital, Odense, Denmark

Background: Some maternal systemic connective tissue diseases (CTD) and their associated antibodies are linked with adverse fetal outcomes, including increased risk of congenital heart diseases (CHD)[1,2]. Whether this increased risk also applies to less severe structural or functional cardiac abnormalities in the fetus is currently unknown.

Objectives: Based on a large cohort of newborns born to mothers with CTD, we aim to assess the association between maternal CTD and structural or functional cardiac abnormalities in the offspring. Data used in the study will be a combination of data collected in the Copenhagen Baby Heart Study (CBHS) and data collected via medical chart review to validate the CTD diagnosis and to obtain information about disease severity, treatment, etc.

Methods: In the CBHS we included more than 25,000 newborns between April 2016 and October 2018. All infants underwent systematic transhoracic echocardiography (TTE) within the first 60 days after birth[3,4]. The current study will include newborns from the CBHS born to mothers diagnosed with CTD, as identified through the Danish national health registries. Assuming an overall incidence of CTDs at 2% we expect to include approximately 500 newborns to mothers with CTD. Newborns born to mothers diagnosed with CTD will be matched 1:1 to newborns not exposed to maternal CTD, based on child’s sex; gestational age at birth; age and weight at time of TTE; and maternal age at delivery. Maternal medical charts will be reviewed to validate the CTD diagnosis and obtain information about disease severity, treatment, etc. The primary endpoint is a composite of functional and structural abnormalities in the heart of the newborns, assessed by echocardiography, including left ventricular structural and functional abnormalities, septum defects, and valve anomalies.

Results: Preliminary results are expected in spring 2023.

Conclusion: It is unclear whether children of mothers with CTD should have routine cardiac evaluation at birth, and whether certain types of maternal CTD have a higher risk of minor/subclinical CHD or less severe cardiac abnormalities in the offspring compared with children born to mothers without CTD. The size of CBHS and the comprehensive assessment of the included children provide a unique opportunity for obtaining new knowledge in this field, including better insights into whether routine TTE after birth should be considered in certain subgroups.

AB1573 AUTOIMMUNE HEMOLYTIC ANEMIA IN CHRONIC LIVER DISEASES

Keywords: Comorbidities, Diagnostic tests

N. Trad1, G. Mohamed1, S. Bizid1, S. Soua1, B. Ben Silmen1, K. Boughoula1, H. Ben Abdallah1, R. Bouali1, M. N. Abdedil1, 1Military Hospital of Tunis, Gastroenterology, Tunis, Tunisia

Background: Chronic liver diseases can be associated with autoimmune diseases, their association with autoimmune hemolytic anemia (AIHA) is poorly studied.

Objectives: Our objective was to study the prevalence and the characteristics of AIHA in chronic liver diseases.

Methods: We performed a retrospective analysis of data from consecutive patients followed in our department over a period of 15 years. Data were collected via medical chart review in the absence of other overt causes of constitutional or acquired hemolysis.

Results: A total of 187 patients were included with an average age of 60.2 years (range 18–86) and a sex ratio of 1.79. Thirteen patients had an AIHA (7%). Anemia was normocytic in 77% of cases and macrocytic in 23% of cases. Five patients had a history of associated autoimmune pathologies (38.4%); autoimmune thyroiditis in two cases, one case of psoriasis, one case of SJogren’s syndrome and one case of autoimmune thrombocytopenia. The AIHA was more frequent in cases of viral chronic liver diseases B and C (46.1%). Three patients had non-viral chronic liver diseases (23%); primary biliary cholangitis, autoimmune hepatitis, and alcohol.

DESCRIPTIVE STUDY OF CAPILLAROSCOPIC PERFORMED IN THE RHEUMATOLOGY SERVICE OF A THIRD LEVEL HOSPITAL

Keywords: Diagnostic tests, Descriptive studies

R. J. Gil Velez1,2, L. Robles Kirkegard2, L. Mendez Diaz1. 1Seville, Rheumatology, Seville, Spain; 2Virgen del Rocío Hospital, Rheumatology, Seville, Spain

Background: Capillaroscopy is a study technique using direct in vivo images of the skin microcirculation. It constitutes an accessible and non-invasive method to analyze microvascular abnormalities in patients with rheumatic diseases. Its usefulness has been demonstrated in diseases such as Systemic Sclerosis (SSS), Sjögren’s syndrome, Rheumatoid Arthritis, Dermatomyositis, Systemic lupus erythematosus (SLE) and, above all, Raynaud’s phenomenon.

Objectives: To describe the clinical characteristics of a cohort of patients who underwent capillaroscopy in the Rheumatology service during the year 2022.

Methods: Retrospective descriptive study of 100 patients who underwent capillaroscopy in the rheumatology service. The data obtained were obtained by reviewing the digital medical records and the registry of capillaroscopy images of the same service.

Results: 100 patients were included, of whom 92 were women (92%) and 8 were men (8%) with a mean age of 50 +/-17 years. Of the patients analyzed, 53 presented a normal pattern on capillaroscopy (53%) and 47 presented an abnormal pattern (47%). Of our cohort, 68 patients had Raynaud’s (68%), 5 patients were diagnosed with undifferentiated connective tissue disease (5%), limited scleroderma 12 patients (12%), diffuse scleroderma 6 patients (6%), and with psoriatic arthritis, juvenile idiopathic arthritis, Sjögren’s, Rheumatoid Arthritis, antiphospholipid syndrome, Bechet and Dermatomyositis, there was a patient with each named disease (7%), and finally there were 2 patients who still do not have a firm diagnosis (2%). Of the patients in our cohort with an abnormal pattern, 12 had an early scleroderma pattern (25.5%), 10 patients had a late scleroderma pattern (21.25%), 8 patients had a lupus pattern (17%), 8 patients had a nonspecific pattern (17%), 6 presented a school of fish pattern (12.5%) and 3 patients presented a pattern of mixed connective tissue disease (6.3%). Within the cohort with a pattern of early scleroderma on capillaroscopy, 4 patients were diagnosed with limited scleroderma, 5 with Raynaud’s phenomenon, 1 with diffuse scleroderma, 1 with undifferentiated connective tissue disease, and one with Sjögren’s. Of the 100 patients analyzed, 7 had lung involvement (7%), 6 patients with a firm diagnosis (2%). Of the patients in our cohort with an abnormal pattern, 12 had an early scleroderma pattern (25.5%), 10 patients had a late scleroderma pattern (21.25%), 8 patients had a lupus pattern (17%), 8 patients had a nonspecific pattern (17%), 6 presented a school of fish pattern (12.5%) and 3 patients presented a pattern of mixed connective tissue disease (6.3%). Within the cohort with a pattern of early scleroderma on capillaroscopy, 4 patients were diagnosed with limited scleroderma, 5 with Raynaud’s phenomenon, 1 with diffuse scleroderma, 1 with undifferentiated connective tissue disease, and one with Sjögren’s. Of the 100 patients analyzed, 7 had lung involvement (7%),

Conclusion: The data obtained are consistent with what is reported in the medical literature. The most common abnormal capillaroscopy pattern in our environment is early scleroderma, followed by late scleroderma. Of the patients analyzed, 7 had pulmonary involvement. With the data we have collected, we can conclude that capillaroscopy is a useful, non-invasive technique that can guide us during the diagnostic process in those patients who raise doubts both in clinical judgment and in the evolution of the disease.

DOI: 10.1136/annyhdmis-2023-eular.1543
Background: PCAT attenuation is a non-invasive biomarker of coronary inflammation and is a poor prognostic factor in patients with coronary artery disease. Objectives: To compare the severity of PCAT attenuation amongst patients with inflammatory rheumatic diseases (IMD) compared to patients with non-inflammatory rheumatic diseases (NIMD) in a retrospective cross-sectional study. Methods: All patients seen in Monash Health rheumatology clinics over a 12-month period were identified. Patient records were cross-referenced with the hospital computed tomography coronary angiography (CTCA) database to identify patients who had undergone CTCAs. IMD patients who had their CTCA prior to their RMD diagnosis were excluded. Age, sex, co-morbidities, and medications were extracted from the patient electronic medical records. PCAT attenuation was calculated (SIS, SSS, PCAT attenuation) or calculated (SIS, SSS, PCAT attenuation).

Results: A total of 117 patients were included (105 with IMD and 12 with NIMD). There were no significant differences in any other CTCA outcomes. There were no significant differences in any other CTCA outcomes. There were no significant differences in any other CTCA outcomes.

Conclusion: PCAT attenuation is associated with IMD in this retrospective single-center cross-sectional study. Data from larger prospective cohorts with healthy comparator controls are needed to assess the significance of these findings.
active (1.01 ± 1.1) and 0.32 ± 0.6 in active MCP joints. RI was in control 0.87 ± 0.12 in moderately active 0.61 ± 0.15 (figure 1) and 0.24 ± 0.12 in active MCP joints. There was significant difference in RI and PI of these active and moderately active MCP joints (p <0.01). There was a significant correlation between erosive scores and PI, RI of total MCP joints (r = 0.40 and r = 0.41, P < 0.05).

Conclusion: Spectral Power Doppler ultrasonography (PDSUS) is a useful method demonstrating synovial vascularization and flow patterns and offers new alternatives for monitoring disease activity and measurement of therapeutic response. Flow patterns had intimate correlation with intra-articular bone and cartilage destruction.

HEMORRHAGIC RISK ASSOCIATED WITH SPINAL PROCEDURES AND FOCUS ON PATIENTS TREATED BY ANTICOAGULANTS OR PLATELET INHIBITORS: A SYSTEMATIC LITERATURE REVIEW AND META ANALYSIS

Keywords: Safety, Systematic review

C. Langbour 1, A. Agbaghi 2, S. Mitrovic 3, F. Rannou 2, B. Fautrel 3, G. Carvalaj Alegra 1, 1Hôpital Trousseau, Service de Rhumatologie, Tours, France; 2Hôpital La Pitié Salpêtrière, Service de Médecine physique et réadaptative, Paris, France; 3Hôpital La Pitié Salpêtrière, Service de Rhumatologie, Paris, France

Background: Spinal procedures – including lumbar puncture, radiofrequency neurotomy, medial branch injection, facet joint injection, blood patch and epidural injection – are common in daily practice. Side effects can occur during these invasive procedures like hemorrhagic complications. The use of anticoagulants and platelet inhibitors can increase these risks.

Objectives: The aim of this study is to characterize the hemorrhagic risk associated with spinal procedures and to analyze if there is a sur risk of bleeding complications in patients treated with anticoagulants or platelet inhibitors.

Methods: A systematic literature review and metaanalysis were made in MEDLINE, EMBASE and COCHRANE, in order to find a prevalence of hemorrhagic complications for each spinal procedure. We classify hemorrhagic risk in two categories.

Conclusion: Hemorrhagic complications during a percutaneous spinal procedure are very low. These findings are in coherence with previous findings. In this metanalysis there was no difference between patients with anticoagulants or platelet inhibitors and the others during a lumbar puncture according to the PRISMA criteria is shown [Figure 1]. The global prevalence of each hemorrhagic complication according to each spinal procedure is showed in Table 1. There was no difference between patients with anticoagulants or platelet inhibitors and the others during a lumbar puncture according to the epidural hematoma risk with OR of 0.95 IC95 [0.16-5.29] after a lumbar puncture and for the risk of traumatic lumbar puncture with OR of 0.78 IC95 [0.47-1.29].

ULTRASOUND JOINT ASSESSMENTS INCREASE DETECTION OF POLYARTICULAR JOINT INVOLVEMENT IN CHECKPOINT INHIBITORS-INDUCED ARTHRITIS

Keywords: Malignancy, Inflammatory arthritides, Ultrasound

L. Meric de Bellofot1, A. Aspeslagh2, A. Franci3, B. Jean-François4, P. Duriez1.
1 Cliniques universitaires Saint-Luc (UC Louvain), Rheumatology, Brussels, Belgium; 2 UZ Brussel, Oncology, Jette, Belgium; 3 Cliniques universitaires Saint-Luc (UC Louvain), Pneumology, Brussels, Belgium; 4 Cliniques universitaires Saint-Luc (UC Louvain), Oncology, Brussels, Belgium

Background: CheckPoint Inhibitors (CPI) Induced arthritis (IA) is an immune related adverse event (irAEs) occurring in 0.5 to 2% of CPI-treated patients between 3 weeks up to 24 months after initiation of therapy. IA is usually described as a seronegative oligoarticular inflammatory joint disease but IA has been for long underdiagnosed and inappropriately evaluated.

Objectives: To evaluate the added value of a systematic joint ultrasound assessment in these patients by the rheumatologist.

Methods: Patients referred by their oncologist to the Rheumatology Department for suspected arthritis had a clinical swollen joint count and a joint ultrasound assessment (GE Logiq E9 Ultrasound Machine with ML6-15-D Matrix Linear Probe). Target joints were elbows, wrists, MCP 2-5, knees, ankles and MTP1-5. The swollen joint count performed by the oncologist was compared to the one made by the rheumatologist and the US assessment. A joint was considered as positive by US assessment in case of grey-scale ≥ 1 in a scale of 3.

Results: 9 patients (6 males and 3 females) were assessed. Mean age was 66.1 years (SD 11 years). 4 were treated for metastatic melanoma, 1 for renal cell carcinoma (RCC), 3 for lung cancer, 1 for bladder carcinoma. They received a monotherapy with pembrolizumab (4/9), nivolumab (2/9), atezolimumab (1/9), darvalumab (1/9). None had received corticosteroids.

5 out of the 9 patients were referred for an oligoarticular (swollen joint count <5) presentation by the oncologist, 2 out of 9 for a polyarticular (swollen joint count ≥5) presentation and 2 for a PMR-like presentation. Whereas the rheumatological and the US assessments confirmed the polyarticular diagnoses made by the oncologists, the 5 oligoarticular-labelled patients had polyarticular involvement after the rheumatologist and US assessments. In the 2 patients referred for a PMR-like disease, US assessments showed one polyarticular and one oligoarticular presentation. None of the 9 patients had positive rheumatoid factors (RF) or anticitrullinated peptides antibodies (ACPAs).

Conclusion: In this small group of patients with CPI-IA, In this small group of patients with CPI-IA, we found that US joint assessment led to a better classification of polyarticular joint involvement, present in the majority of the cases. Our results emphasise the importance of a multidisciplinary approach of these patients and support the use of US joint assessments in CPI-IA patients.

ULTRASOUND FINDINGS IN PATIENTS WITH GOUT IN A POPULATION OF THE DOMINICAN REPUBLIC

Keywords: Ultrasound, Gout, Prognostic factors

D. Garcia1, R. A. Alvarez Santana1, L. Perez Rodriguez2, T. Polanco Mora1, L. Concepcion Sanchez2, I. Mercedes1, I. Paulino1, E. Rodriguez Bautista1, T. Valdez1, A. Feriz1, R. Muñoz Louis1,1 Hospital Padre Billini, Rheumatology, Distrito Nacional, Dominican Republic

Background: Hyperuricemia is an increase in the serum concentration of monosodium urate (MSU). Gout is secondary to the inflammatory response elicited by the deposition of UMS in the tissues. It is the most frequent inflammatory arthropathy in the general population. Its prevalence has been estimated at 2-3% of the adult population. The ultrasound findings observed are considered within the ACR/EULAR 2015 criteria, which derive from the presence of UMS deposits in the subcutaneous tissue and in intra-articular areas (cartilage, tendons, ligaments, and bursae). There are 2 specific findings of MSU deposits: 1) enhanced echogenicity of the chondro-osseus margin (double contour sign), presence of hyperechogenic aggregates, which, in turn, can have 3 forms of presentation: hyperechogenic dots (<1 mm) within a joint effusion, (cotton-wool areas) (<1 cm) homogeneously without posterior acoustic shadow and larger tophi with calcifications and posterior acoustic shadow [4].

Objectives: To identify the ultrasound findings in patients with gouty arthritis in a population of the Dominican Republic.

Methods: Descriptive, prospective observational study. From the cohort of patients from the Rheumatology service of the Hospital Docente Padre Billini, patients from the outpatient clinic were evaluated from June to December 2022. Inclusion criteria: > 18 years, diagnosis of gouty arthritis according to ACR/EULAR 2015 criteria, presence of at least 1 attack of gouty arthritis, performance of joint ultrasound Exclusion criteria: Osteosynthesis material in areas evaluated by ultrasound and/or infiltration, traumas of less than 3 months in the evaluated joints, Elbows, wrists, 2nd metacarpophalangeal MCP, knees, and 1st metatarsophalangeal MTF were evaluated by ultrasound, recognizing positive findings of double contour sign, hyperechogenic aggregates, erosions, synovitis, and irregularities according to OMERACT definitions. Made with the Siemens Acuson X 150 ultrasound machine, with a 13 mhz transducer. Descriptive statistics were performed with SPSS 25 V2.

Results: 52 met inclusion criteria. 100% male, mean age 59±16.1 years, mean disease duration 8.6 years, mean serum uric acid 9.5 mg/dL, BMI: overweight 32.7% (17), grade I obesity 21.2% (11), grade II obesity 40.4% (21). Diabetes mellitus 55.8% (29), Arterial hypertension 57.7% (30), Dyslipidemia 80.2% (42), Colchicine 61.5% (32), Allopurinol 48.1% (25), Febuxostat 48.1% (25), NSAIDs 48.1% (25), Predisone 46.2% (24), Benz bromarone 3.8% (2) Ultrasound findings 55.7% (29): Elbows: irregularities 39.6% (11), Tophi 39.6% (11), erosions 20.7% (6), Carpals: Erosions 10.3% (3), aggregates 10.3% (3), power Doppler 2.69% (2), irregularities 31% (2), Knees: erosions 27.8% (8), irregularities 27.8% (8), double contour 20.6% (6) power doppler 10.3% (3), Tibiotalar: irregularities 27.8% (8), erosions 17.2% (5), 1st MTAs: erosions 48.2% (14), irregularities 27.8% (8), aggregates 3.4% (1).

Conclusion: The study demonstrated that more than half of patients with gout present structural lesions by ultrasound according to OMERACT. The elbows are the most affected joints with the presence of tophi, followed by the first metatarsophalangeal joint with the presence of erosions.

Faculty of Medicine El Mahdi Si Ahmed, Rheumatology, Algeria; 16 Specialized Medical Center, Internal Medicine, Riyadh, Saudi Arabia; 17 King Hussein Medical Center, Royal Medical Services, Jordan Armed Forces, Internal Medicine, Amman, Jordan; 18 Jaber Alahmed Hospital, Ministry of Health, Internal Medicine, Kuwait, Kuwait; 19 Saint-Joseph University, Rheumatology, Beirut, Lebanon; 20 Hotel-Dieu de France Hospital, Rheumatology, Beirut, Lebanon

Background: Burnout is frequent among physicians and has significant implications for the healthcare system. However, it seems to be underestimated so far among rheumatologists, with few studies indicating a prevalence of 51-57%.

Objectives: To estimate the prevalence and predictors of burnout among rheumatologists practicing in Arab countries.

Methods: A cross-sectional study was conducted by the Arab League of Associations for Rheumatology (ArLAR) Research Group (ARCH) using an anonymous electronic survey developed and tested by a core steering committee and hosted on the Google Forms platform. All rheumatologists practicing in the Arab countries were invited in spring 2022 to participate in the e-survey by mass e-mailing and data were collected from January 2022 to April 2022. In addition to demographic data, workload, practice profile, income, and specialty satisfaction (assessed indirectly through choosing another specialty if given a choice), the questionnaire included the Maslach Burnout Inventory (MBI). Rheumatologists were considered as having burnout if at least one of the three MBI domains was positive (Emotional Exhaustion (EE) ≥ 27, Depersonalization (DP) ≥ 10, or Personal Accomplishment (PA) ≤ 33). Factors associated with burnout were analyzed using a multivariable binary logistic regression.

Results: Among 3,227 rheumatologists practicing in Arab countries, 408 responded to the survey, and 394 were included in the final analysis (12.2% of all practicing rheumatologists). The mean age was 45.2 years (SD 11.5), 60.7% were females, the median practice duration was 13 years (IQR 6–22), 49% were from North Africa, 33% were from the Levant, and 18% were from the Gulf. In total, 73% worked full-time, 48% worked in the public sector, 21% in the private sector, and 31% in both; 74% worked in an urban setting only, monthly income was <1,000 USD in 31%, 1,000-1,500 USD in 41%, 5,000-10,000 USD in 9% and >10,000 USD in 8%. The prevalence of burnout among rheumatologists was 61.3%. It was mostly driven by a low PA score (58.1%) (Figure 1). Also, 15.6% had a positive EE score, and 11.6% had a positive DP score. After adjustment for demographics, practice profile, and workload variables, burnout was independently associated with an income <10,000 USD/ month (OR 2.28 [95% CI 1.01; 5.10], unsatisfaction with rheumatology specialty (OR 2.04 [95%CI 1.20; 3.48] and younger age (OR 1.92 [95%CI 1.20; 3.08]) (Table 1).

Conclusion: The prevalence of burnout among rheumatologists in Arab countries is significantly high and driven mainly by a low personal assessment score. Associated factors were a lower income, lower satisfaction with the specialty, and younger age. Therefore, burnout among rheumatologists needs to be adequately addressed to prevent its negative impact on the healthcare system.

| AB1582 | DEPRESSION IN RHEUMATOLOGIST FROM LATIN AMERICA |

Keywords: Quality of life, Epidemiology, Quality of care

M. Intriglio1, G. Maldonado2, E. Soriano2, C. Rios3, 1 University of Miami, Internal Medicine, Miami, United States of America; 2 Loyola MacNeal Hospital, Internal Medicine, Berwyn, United States of America; 3 Hospital Italiano, Rheumatology, Buenos Aires, Argentina. 4 Centro de Reumatología y Rehabilitación, Rheumatology, Guayaquil, Ecuador.

Background: Depression, burnout, and suicide are becoming a major problem among physicians. A survey estimated that around 21% are depressed and 1 in 10 had suicidal thoughts.[1]

Objectives: Determine the prevalence of depression in rheumatologists from Latin America and factors associated with it.

Methods: Cross-sectional study. Data was collected through an online survey distributed by PANLAR, which included demographics and work-related factors. Depression was measured with PHQ-9 questionnaire, burnout with the Maslach Burnout Inventory, happiness with the Subjective Happiness Scale and satisfaction with a 7-point Likert scale. Analysis of data was done with SPSS V 27 and included descriptive statistics and association between variables using Chi square and Student’s T test.

Results: 297 rheumatologists were included from 15 countries, mainly Argentina 28.3% and Brazil 26.3%. Most were women 62%, married 65%, practiced adult rheumatology 82% and earned less than $50 K/year 74.8%. Depression
was found in 48.8%: mild 33%, moderate 8.8%, moderate severe 4%, severe 3%. The mean PHQ-9 score was 5.5±5.3. 48.1% reported anhedonia, 40.7% feeling depressed, sleep alterations 57.2%, fatigue 75.1%, appetite changes 46.1%, weight changes 37%, sexual difficulties 37%, psychomotor changes 27.9%, thoughts of harming oneself 9.8%, 8.2% suicidal thoughts and 8.4% low self-esteem. 56.6% had burnout. 14.5% were taking SSRI/SNRIs and 4% were previously diagnosed. Factors associated with depression were female sex (p=0.008), younger age (p<0.001), administrative duties (p=0.010), annual income less than $25K (p=0.002), low self-esteem (p=0.001), burnout (p=0.001), less satisfaction with career (p<0.001) and lower subjective happiness (p<0.001). Exercise (p=0.035) and practicing academics (p=0.010) were associated with less depression.

Conclusion: Depression affected almost half of the rheumatologists and was more common in females, younger population, with low self-esteem. Lower income, having burnout and less satisfaction with the career were also risk factors. Only a small proportion of the affected population was previously diagnosed and on treatment.

AB1583 EVALUATING THE DIRECT EFFECT OF SLE ON THE PRESENCE OF INTERMEDIATE GC ON HEALTHCARE COST

Keywords: Randomized controlled trial, Health services research, Systemic lupus erythematosus

K. Zhao1, H. Xie1. 1Arthritis Research Canada, Biostatistics, Vancouver, Canada

Background: Systemic lupus erythematosus (SLE) is a chronic disease with a broad spectrum of autoantibodies and clinical manifestations. SLE imposes a substantial economic burden on patients and the healthcare system with the estimate of annual healthcare costs for SLE patients of $5,062 in Canada. Besides SLE, post-SLE Glucocorticoid (GC) is often associated with severe infection and mortality, hence increased healthcare costs. In this study, we aimed to estimate the costs associated with SLE because specific groups (those who don’t have access to questionnaires) are underrepresented. As a result, their conclusions may lack generalizability to all SLE patients. These limitations call for a new approach to account for post-treatment selection bias and a large dataset in the real-world setting to quantify the healthcare costs due to SLE.

Methods: Using linked administrative health data from British Columbia, Canada, we conducted an age- and gender-matched cohort study of all patients with incident SLE between 1997 and 2015. We implemented Principal stratification to disentangle and quantify the causal annual healthcare costs directly associated with newly diagnosed SLE accounting for GC use. To identify the characteristics of the patients who never took GC (never-users).

Results: We identified 5,169 SLE patients and matched them with 25,845 non-SLE individuals from the general population. The crude incidence rate ratios for first severe infection and infection-related mortality were 2.59 (95% CI, 2.39-2.80) and 2.20 (95% CI, 1.76-2.73), respectively. The direct annual healthcare cost due to SLE was $1,011 (95% CI, 0.94-1.10) which was a weighted average of the cost in always and never-users strata (Figure 1). Always and never users accounted for 20.3% and 73.9% of the total population. Compared to the SLE-only users, those with older age, rural residence, higher income and more medical service visits were more likely to be in the never-user stratum.

Conclusion: This is the first study to examine the direct effect of SLE on healthcare cost accounting for the GC-taking behavior using real-world data. Our findings highlighted the direct economic burden due to SLE and can be generalized to the SLE population. Recognizing the economic burden of SLE will inform future interventions for prevention, and medical management in this vulnerable patient population. What's more, when prescribing GC, the treating physicians should pay attention to the patients with older age, rural residence, higher income and more medical service visits because they are unlikely to adhere to the treatment scheme.

AB1584 CONSENSUS RECOMMENDATIONS ON THE USE OF BIOSIMILARS IN THE TREATMENT OF INFLAMMATORY RHEUMATIC JOINT DISEASES

Keywords: Systematic review, bDMARD, Best practices

K. Alnaqbi1, N. Al Adhoubi2, S. Al Dallal1, S. Al Emadi4, A. Al-Herz5, A. El Shamy1, S. Hannawi1, M. A. Omar1, S. Saad1, T. K. Kvien1,2, 1Tawam Hospital, College of Medicine & Health Sciences, Internal Medicine, Rheumatology, Al Ain, United Arab Emirates; 2Royal Hospital, Rheumatology, Muscat, Oman; 3Dubai Health Authority, DHA, Dubai, United Arab Emirates; 4Hamad Medical Corporation, Rheumatology, Doha, Qatar; 5Al-Amir Hospital, Rheumatology, Kuwait, Kuwait; 6Ministry of Health and Prevention, MOHAP, Dubai, United Arab Emirates; 7Emirates Health Services, Rheumatology, Dubai, United Arab Emirates; 8King Saud University, Rheumatology, Riyadh, Saudi Arabia; 9King Hamad University Hospital, Rheumatology, Busaiteen, Bahrain; 10Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway

Background: Biosimilars are highly similar to reference products and can help in reducing the financial burden and medication undertreatment while still being comparable to reference products in treating rheumatic diseases[1].

Objectives: The objective was to develop evidence-based consensus recommendations and overarching principles aimed at standardizing best practices for the use of biosimilars in treating patients with inflammatory rheumatic joint diseases in the Gulf region.

Methods: A taskforce comprising expert rheumatologists and healthcare economists formulated specific PICO questions on key topics concerning biosimilars: comparability of efficacy, safety and immunogenicity of biosimilars to reference products; extrapolation of indications for biosimilars; switching from reference products to biosimilars or between biosimilars; cost-savings; retention rates; nocebo effect among patients, and general awareness and perceptions of biosimilars in the Gulf region. A systematic literature review was conducted to identify, select, and critically appraise the quality of published evidence that demonstrated the value proposition of biosimilars in rheumatic diseases. Meta-analyses, clinical trials, and systematic reviews of adult patients treated with biosimilars for
Objective: This study aimed to determine the relationship of asymptomatic hyperuricemia with NC, innovative and simple anthropometric method, in the general population.

Methods: This cross-sectional study used data from the 2019–2020 Korea National Health and Nutrition Examination Survey. Among 15,469 individuals, we excluded 6,814 without available data on NC or serum uric acid, and 1,026 with critical confounders: overt cardiovascular disease; gout; chronic kidney disease; and serum creatinine > 1.2 mg/dL. Multivariate logistic regression analysis was used to calculate the odds ratios (ORs) and 95% confidence intervals (CIs) for hyperuricemia according to quartiles of NC.

Conclusion: NC was positively correlated with serum uric acid levels and this association was significant in women. Our finding suggests that NC can contribute to detecting asymptomatic hyperuricemia earlier and further to determining risk of metabolic syndrome in healthy adults.

Keywords: Neck circumference, asymptomatic hyperuricemia, health, healthy adults, risk factors, waist circumference.
Background: The demand for rheumatology care is consistently exceeding the workforce worldwide, which negatively impacts the care of patients with rheumatic and musculoskeletal diseases (RMDs). The number of rheumatologists per 100,000 inhabitants varies between 0.94 in Latin America to 3.44 in Spain, with a desirable number of 1-2. However, the estimation of the current and projected rheumatology workforce is lacking in Arab countries.

Objectives: To investigate the current number of practicing rheumatologists in the Arab League countries, provide an estimate of the expected number of rheumatologists in 10 years, and evaluate the current workload, practice profile, and waiting time for a consultation.

Methods: This cross-sectional survey study was conducted by the Arab League of Associations for Rheumatology (ArLAR) Research Group (ARCH) in 16 Arab countries in two parts. The first survey was addressed to national societies by e-mail to estimate the current and projected workforce. The second was an anonymous e-survey addressed to all Arab rheumatologists and rheumatology fellows elaborated by the study steering committee on the Google Forms platform and distributed using social media, WhatsApp, and mass e-mails to evaluate their practice profile, workload, and waiting time for a rheumatology consultation.

Results: The mean number of rheumatologists in the ArLAR countries was 0.84 per 100,000 inhabitants (mean age 47.5 years, 55% females), ranging from 0.06 in Sudan to 1.17 in Egypt (Table 1). The crude number of rheumatologists is expected to increase by 50% in 2032, whereas a 20% parallel increase in the population is also expected, associated with a rise in demand due to an expected increase in RMDs; thus, the percentage per 100,000 inhabitants will increase only by 22%. Data from 446 rheumatologists and rheumatology fellows (mean age 43.9 years, 60.5% females) revealed that 72% worked full-time, 53% were employed in the public sector only, and 75% worked in an urban setting. The median income was 1,000-2,000 USD/month. There was a certified rheumatology nurse in 25%, access to musculoskeletal ultrasound in 51%, and telemedicine implemented in 29% of practices. The average waiting time for a rheumatology consultation was 19.9 days and was associated with the region, working full-time, working in the public sector, higher income, and the presence of an infusion center at the rheumatology practice.

Conclusion: Considering a desirable arbitrary level of 1-2 rheumatologists/100,000 inhabitants, there is a current shortage of rheumatologists in the ArLAR countries, with significant heterogeneity among countries. The projected increase in rheumatologists will probably not match the rising demand for rheumatology care. Considering local demographic disparities and healthcare system differences, national authorities are urged to implement effective intervention plans to optimize the rheumatology workforce.

Conclusion: An incidence of 12 VZV is observed in unvaccinated patients compared to an incidence of 0 in vaccinated patients. The herpes rate in non-vaccinated patients was 4.12E+100 PY compared to 0 E/100 PY in vaccinated patients. Therefore, we conclude that the herpes zoster vaccine shows its effectiveness in our population but it would be necessary to carry out more studies in the future with a longer follow-up time.

REFERRAL PATTERN FROM PRIMARY CARE TO IDENTIFY PATIENTS WITH SUSPECTED RHEUMATOID ARTHRITIS: ROOM FOR IMPROVEMENT

Keywords: Rheumatoid arthritis, Quality of care

M. Sánchez Lucas1, C. Bourgeois Avella1, T. Schiaffino2, J. Molina Collada2, J. Martínez-Barrio1,2, J. Rivera1, J. M. Alvaro-Gracia1,2, I. Castrejón1,2,3, J. Martínez-Barrio1,2, J. Rivera1, J. M. Alvaro-Gracia1,2, I. Castrejón1,2,3, J. Castrejón1,2,3

Background: Primary care physicians (PCPs) acknowledge the importance of early diagnosis and intensive treatment for rheumatoid arthritis (RA) patients, however the non-specific symptoms early in the disease and the long waiting list to access rheumatology clinics result in a challenge for early and adequate referral.

Objectives: To evaluate patterns for referral in an early arthritis clinic with direct access for PCPs and to explore variables that may influence an adequate referral.

Methods: An early arthritis clinic (EAC) with direct access for PCPs in our area was started in January 2022 providing direct access for patients with suspected RA or undifferentiated arthritis. Referral criteria are strictly clinical, based on previous early arthritis clinics, literature review and approved by a PCP committee. Patients can be referred if > 2 swollen joints, duration of symptoms <2 years and no previous diagnosis by a rheumatologist explaining the symptoms. A total of 180 PCPs from 11 primary care centres have direct access to the EAC. The following data was collected: distance between hospital and primary care center, number of PCP per center, and zip codes as a surrogate for patient income. A descriptive analysis of the referral pattern is presented. A multivariate logistic regression model was performed to identify variables associated with an appropriate referral.

Results: From January to October 2022, 140 patients were referred to the EAC. 66.4% female, with a mean age of 54.2 (15.3) years. A total of 38 (27%) patients fulfilled the predefined referral criteria with initial diagnosis of rheumatoid arthritis (15.8%), psoriatic arthritis (7.9%) and undifferentiated arthritis (76.3%). Patients who fulfilled the predefined referral criteria with initial diagnosis of rheumatoid arthritis 66.4% female, with a mean age of 54.2 (15.3) years. A total of 38 (27%) patients fulfilled the predefined referral criteria with initial diagnosis of rheumatoid arthritis (15.8%), psoriatic arthritis (7.9%) and undifferentiated arthritis (76.3%). Patients who

Conclusion: Only 27% of patients referred to the EAC were adequately referred. PCPs need to enhance clinical skill to detect early RA and discriminate mainly from osteoarthritis and non-specific arthralgias. Younger age was the only variable associated with adequate referral. Strategies with a special focus on PCPs are necessary to promote an early and adequate referral.

ESSENTIAL TREATMENT OF RHEUMATOID ARTHRITIS IN ZANZIBAR: A COST EFFECTIVENESS ANALYSIS

Keywords: Quality of life, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

S. Saini1,2,3,4,5, B. T. Svanes Fevang1, T. W. Ny斯塔f1, K. A. Johansson2,3,1, The State University of Zanzibar - School Of Health And Medical Sciences, Internal Medicine, Zanzibar, Tanzania, United Republic of; 2 Bergen Center for Ethics and Priority Setting, Global Public Health and Primary Care, Bergen, Norway; 3 University of Bergen, Clinical Science, Bergen, Norway; 6 Haukeland University Hospital, Department of Internal Collaboration, Bergen, Norway; 7 Mnzee Mmoja Hospital, Internal Medicine, Zanzibar, Tanzania, United Republic of; 8 Haukeland University Hospital, Rheumatology, Bergen, Norway; 9 Haukeland University Hospital; Addiction Medicine, Bergen, Norway

Background: Rheumatoid arthritis (RA) is a major global health problem and a neglected disease in many developing countries. Health care spending is low in these countries and RA services compete with other important life-saving and effective interventions. Effective therapies for RA are now available which improve overall outcomes and prevent disability especially when initiated early and managed aggressively [1]. All these interventions are available in high-income countries but are sparse in developing countries. There are several health economic evaluations of RA treatment from high-income settings, but few are available or relevant for developing countries. More evidence is therefore needed on the benefits and costs of scaling-up RA services in resource constrained settings.

Objectives: To conduct a cost effectiveness analysis of multiple interventions in the management of RA in Zanzibar.

Methods: A cost-effectiveness analysis for a ten-year duration was conducted from a health provider perspective using a Markov model. Interventions were based on a treat to target strategy with add on therapy or switch to biological therapy when patients did not reach target (remission or low disease activity). The model compares the efficiency of 'methotrexate monotherapy (option 1), 'methotrexate + sulfasalazine + hydroxychloroquine (triple therapy)' (option 2), methotrexate then biologic 1’ (option 2b), option 2 then biologic 1’ (option 3), option 3 then biologic 2’ (option 4) and option 2b then biologic 2’ (option 4b). Data on effectiveness of interventions was obtained from literature. Incremental cost-effectiveness ratios (ICERs) were calculated per quality adjusted life year (QALY) gained from treatment. Staff, building, and utility costs were obtained from the hospital administration records. Drug costs were obtained from the government supplier price list, retail pharmacies and pharmaceutical companies. Mean utility values were calculated from a Zanzibar RA- cohort based on the EuroQol-5D questionnaire responses. Willingness to pay threshold (WTP) was set at 568 USD which is two-thirds of GDP/capita for Tanzania for 2021. We conducted a base case analysis with deterministic sensitivity analysis to explore outcomes with changes in key parameters.

Results: Total costs for the treatment options were largely driven by drugs, predominantly the biologics. The lowest cost was for methotrexate therapy (option 1) at USD 1984/patient/10 years and the highest utilities were gained from treatment with methotrexate therapy + two consecutive bDMARDs (option 4b) (Table 1). Changes in drug costs resulted in significant changes in the ICERs. With variations in the WTP threshold, option 1 remained the most CE up to just above USD 2500 where option 2b became the more CE option up to USD 3100 and option 3 became the more CE option. All other options were not considered CE up to 3500 USD.

Conclusion: Methotrexate was found to be the only cost-effective treatment option in our population. Other options although may be too costly to consider feasible for clinical use unless prices drop. This may be possible via wider availability of biosimilars or via government drug price negotiation to acquire drugs at cheaper costs.

RECOMMENDATIONS ON HANDLING MEDICINE SHORTAGE: LEARNING FROM HYDROXYCHLOROQUINE 2020 CRISIS FOR SLE PATIENTS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, COVID

A Cornet1, M Olsen2, H Stefnadsottir2, 1Lupus Europe, HQ, Brussels, Belgium; 2Lupus Europe, PAN, Brussels, Belgium

Background: Early 2020, short supply of hydroxychloroquine sulfate (HCC) – then claimed as effective for treatment of COVID-19 in several countries - raised significant concerns for those who use HCC for chronic diseases including SLE. In April 2020, Lupus Europe launched a survey to quantify the access gap, as well as the anxiety experienced by patients confronted with this outage. 2422 patients responded with an average level of anxiety about access to HCC of 6.45 on a maximum of 10. After supply issues were resolved, a follow up survey (Aug-Sept 2020 – 1854 answers) showed a significantly reduced anxiety of 4.15. A second follow up survey (Nov 2021-Feb 2022 - 2255 answers) showed a further reduction to 3.54. Importantly, a core group of 6.2-13.7% of patients remains extremely anxious (scoring 9 or 10) about supply of their medication, substantially more than in Portugal (3.5%) and Finland (0%), where supply remained fair at the heat of the crisis.

Objectives: To provide consensus on how communication should be conducted to minimize the impact of medicine shortages on patient anxiety. Methods: The Patient Advisory Network (PAN) of Lupus Europe established an extensive list of potential elements of a more effective communication on shortages, that could help reduce patient anxiety; 20 statements were derived from those elements and proposed to PAN members and Lupus Europe member organisations. 101 answers were collected from 17 countries. For each country, the individual ratings of all participants were averaged to assign an individual vote for each country on each statement. Consensus amongst the 17 countries was then considered as obtained if 14 or more of the 17 countries agreed or strongly agreed with statements.

Results: 9 out of the 20 statements reached consensus:
1. Lupus specialists should (a) clarify alternative medication existing and its difference versus current treatments, (b) clarify appropriate emergency procedures and (c) clarify to the patients how to handle a short supply.
2. Specialists and Hospitals should establish alternative supply mechanisms to guarantee minimum availability.
3. Pharmaceutical industry should (a) provide all information to all stakeholders and (b) help create emergency supply routes to ensure that no patient is left without his/her medication for a sustained period of time.
4. National authorities should help patients with demonstrated need have priority access to limited supply quantities through a simple process.
5. Hospitals should communicate (by email or postal mail) information on the shortage, how to handle it and how to access emergency supply routes. The same number agreed with Health authorities performing that same communication.
6. Pharmaceutical industry should avoid diverting products from one country to another if that would reduce supply below normal consumption level.
7. Patient organisations should stop the rumors that can quickly spread through social media.
8. Pharmacists should be better equipped in terms of data (on the reasons and clear timelines for resolution as well as alternatives or recommendations for patients facing shortages)
9. GP’s should clarify alternative medication and appropriate emergency procedures.

Conclusion: shortages of medicine create an anxiety that can be long lasting. Even when supply is re-established, the fear remains. For this reason, establishing an effective communication system is necessary to reassure patients when short term shortages are taking place, and is key to avoid fast spreading anxiety relating to this concern. In this process, patient associations, physicians, industries and all the stakeholders should be involved.

AB1591 POLICY DRIVERS FOR MARKET PENETRATION OF ANTI-TNF BIOSIMILARS: MULTI-COUNTRY COMPARISONS

Keywords: bDMARD, Health services research, Disease modifying drugs (DMARDs)

W. Zhang1,2, D. Guh1, H. Sun1, A. Tam1, N. Bansback1,2, A. Hollis5, P. Groothendijk4, A. Anjia3,2; Providence Research, Centre for Health Evaluation and Outcome Sciences, Vancouver, Canada; 2University of British Columbia, School of Population and Public Health, Vancouver, Canada; 3University of Calgary, Department of Economics, Calgary, Canada; 4University of Toronto, Leslie Dan Faculty of Pharmacy, Toronto, Canada

Background: Health systems across countries have used different policy measures (e.g. price discounts, tendering, mandating switches) to encourage the introduction of biosimilars but their differential impact on market penetration is unknown.

Objectives: To evaluate the impact of policy measures on market penetration of anti-TNF biosimilars.

Methods: Quarterly IQVIA MIDAS sales data from 2012-2021 for infliximab, etanercept and adalimumab in 5 countries (Canada, France, Germany, Italy and the United Kingdom (UK)) that used different policy tools were used. Biosimilar market penetration was measured by dividing the number of defined daily dose units (DDD) of biosimilars sold by the total number of DDDs of the originator and biosimilars sold. Market penetration since the first sale date of the biosimilar was captured by product, setting (hospital vs. retail), and country. Policy impact was examined by comparing market penetration among different policy scenarios (Table 1).

Results: Biosimilars for all three anti-TNFs had higher volume share over time (Figure 1) in the UK than Germany, suggesting that higher prescribing quotas among new and existing patients increases the market penetration of biosimilars given comparable demand-side policies. Since some anti-TNFs are dispersed only in hospitals in some countries, the settings are somewhat different. In France, infliximab biosimilars in hospital setting had faster penetration than other anti-TNF biosimilars in retail setting, indicating that tendering works better than price-links to increase biosimilar uptake. However, infliximab biosimilars in France had slower penetration than in Italy despite the higher discount price-link but absent quotas in France. Similarly, biosimilars had higher volume share over time in UK than Italy, which also suggests that higher prescribing quotas have a greater impact than price-links. Without price-link and tendering measures, Canada had the slowest penetration. By the end of our study period, the limited rollout of mandatory switching policies (3/10 provinces) for existing patients may not be sufficient in fostering market penetration, despite widespread implementation of mandatory prescribing for new patients.

Conclusion: Through comparisons between and within countries, we found that higher prescribing quotas or switching for existing patients and tendering are the key policy drivers for market penetration of anti-TNF biosimilars.

AB1592 WORK-RELATED IMPACT IN YOUNG PATIENTS WITH CHRONIC BACK PAIN AWAITING A MAGNETIC RESONANCE IMAGING

Keywords: Work-related issues, Health services research

D. Benavent1, M. Tapia-Vihé2, D. Bernabeu3, V. Muley4, C. Plasencia5, A. Balsa1, V. Navarro-Compañ1. 1Hospital La Paz, Department of Rheumatology, Madrid, Spain; 2Hospital La Paz, Department of Radiology, Madrid, Spain

Background: Chronic back pain (CBP) is one of the major causes for medical consultation among young people. Given the limited sources, it is relevant know- ing the characteristics associated with a higher burden in order to prioritize the performance of imaging exams.

Objectives: To identify factors associated with sick leave in a cohort of young patients with CBP awaiting an MRI of the spine.

Methods: The project “Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis” (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with CBP that are requested an MRI of the spine. The SHERPAS study has been conducted thanks to an unrestricted grant from Novartis.

AB1593 SEVERE IMPACT OF THE ECONOMIC CRISIS ON TREATMENT PERSISTENCE IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: A MULTICENTRIC CROSS-SECTIONAL STUDY IN LEBANON

Keywords: Disease-modifying drugs (DMARDs), Descriptive studies, bDMARD

S. Asmar1,2, J. Messayekh3, N. Hilal4, M. A. Rida5, K. Mroue6, K. Aouad7,8, F. Minkara5, A. Hajjar9, N. Zada10. 1Hotel-Dieu de France Hospital, Medicine, Beirut, Lebanon; 2Saint Joseph University, Medicine, Beirut, Lebanon; 3Monia Hospital, Rheumatology, Tripoli, Lebanon; 4Al Wazeen Medical Village, Rheumatology, Ain Wazeen, Lebanon; 5American University of Beirut Medical Center, Medicine, Beirut, Lebanon; 6Clemenceau Medical Center, Rheumatology, Beirut, Lebanon; 7Lebanese American University School of Medicine, Rheumatology, Beirut, Lebanon; 8Al Zahra Hospital University Medical Center, Rheumatology, Beirut, Lebanon; 9Saint George Hospital University Medical Center, Rheumatology, Beirut, Lebanon; 10Saint George University of Beirut, Rheumatology, Beirut, Lebanon.

Conclusion: One out of two young patients with CBP awaiting an MRI of the spine are on sick leave at some point. These patients have poorer quality of life and use more pharmacological treatment than active patients with CBP. Male sex and night pain are associated with being on sick leave due to CBP and therefore could be used to prioritize the use of spinal MRI aiming to optimize health resources.

DOI: 10.1136/annrheumdis-2023-eular.1494
Background: Due to Lebanon's unprecedented economic crisis, access to healthcare and chronic treatments is compromised, which might affect chronic disease control.

Objectives: The primary objective of this study was to evaluate the impact of the economic crisis on chronic treatment persistence in patients with rheumatic and musculoskeletal diseases (RMDs) in Lebanon and to estimate the predictors of persistence.

Methods: A cross-sectional multicentric national study was conducted between July and October 2022 on patients with RMDs living across Lebanon (patients with chronic inflammatory rheumatic diseases (CIRDs) and controls with non-inflammatory RMDs). A questionnaire hosted on the Google Forms platform was proposed to consecutive patients during the consultation and disseminated on social media and WhatsApp lists. It included sociodemographic, disease, and treatment data, income, PHQ-9, and GAD-7 questionnaires. Treatments were categorized into corticosteroids, NSAIDs, cs-DMAARDs, b-DMAARDs (IV and SC), ts-DMAARDs, and oral immunosuppressants. Persistence was defined quantitatively as the number of tablets or injections taken during the past month compared to prescribed and qualitatively as the percentage of patients who changed or discontinued chronic RMD treatment due to cost or nonavailability. Data were presented descriptively; factors associated with persistence were identified using multivariable linear regression.

Results: In total, 317 patients with RMDs (286 CIRDs and 31 controls) were included (207 by telephone interview and 110 by self-questionsnaires); mean age 49.5 years (SD 16), 66% females, median disease duration 10 years (IQR 6-20), 56% had moderate to severe depression, and 40% had moderate to severe anxiety. Persistence was lower for b-DMAARDs (SC 55%, IV 63%) and ts-DMAARDs (36%) and acceptable for oral immunosuppressants 83.5% and cs-DMAARDs (88%) (Figure 1). Among patients with CIRDs, 55.8% discontinued or changed their chronic medication due to nonavailability (45.3%) or increased cost (21.2%). Discontinuation or change affected mainly SC b-DMAARDs (66.2%), ts-DMAARDs (60.0%), and IV b-DMAARDs (40.0%). Notably, patients reported a decrease in their financial level in 86% of the cases, and 58% reported they were currently living in a low economic level (compared to only 6% before the crisis). Compared to controls, patients with CIRDs had a reduction in the number of visits to the doctor, more difficulty accessing chronic treatments (91% vs. 33%), and paraclinical exams (84% vs. 77%). They expressed a higher need for financial support for medication, paraclinical tests, and medical consultation. Importantly, patients could find an alternative source for getting their medication in 60% of cases (buying from abroad in 36%, depending on friends or families living abroad in 29%, and charities in 10%). Finding an alternative source for medication was independently associated with a higher persistence of cs-DMAARDs, b-DMAARDs, and ts-DMAARDs. In addition, being unemployed and having a low financial level were associated with a low persistence of cs-DMAARDs and oral immunosuppressants.

Conclusion: Chronic treatment persistence was significantly compromised for essential drugs for patients with RMDs and was rather associated with extrinsic causes related to treatment availability and cost than with classically known intrinsic factors.

HOW DO WE PREVENT THE DEVELOPMENT OF MULTIMORBIDITY IN PEOPLE WITH INFLAMMATORY RHEUMATOLOGICAL DISORDERS: A QUALITATIVE INVESTIGATION

Keywords: Health services research, Qualitative research methods, Comorbidities

L. Grey1,2, L. Bullock1, C. A. Chew-Graham1, C. Jinks1, Z. Paskins1,2, T. Rule9, S. Hider1,2
1 Keele University, School of Medicine, Keele, United Kingdom; 2 Midlands Partnership Foundation Trust, Rheumatology Department, Stoke on Trent, United Kingdom; 3 Keele University, Public contributor, Stoke on Trent, United Kingdom

Background: People with inflammatory rheumatological disorders (IRDs) are at high risk of developing multimorbidity, specifically cardiovascular disease (CVD) and mood problems. UK guidelines advocate annual reviews for people with Rheumatoid Arthritis (RA), although not other IRDs. Current healthcare reviews are often condition specific, focus on existing morbidities rather than identifying risk and preventing future illness, and may not include advice and support to change lifestyle behaviours. Before developing a healthcare review to prevent multimorbidity we sought to explore perspectives on existing healthcare reviews.

Objectives: To explore patients and healthcare professional (HCP) perspectives on healthcare reviews for people with IRDs at risk of multimorbidity.

Methods: People with IRDs were invited to take part in individual semi-structured interviews either by telephone or online platform. HCP perspectives (including primary and secondary care clinicians) were explored in online focus groups. These were transcribed verbatim. Inductive thematic analysis was undertaken (LQB). Data and codes were discussed, and key themes generated within the team. Ethical approval was obtained (REC Reference 22/PR/0162).

Results: 15 patients (7 male, 8 female, age 49-75) were interviewed. 3 focus groups were held with a total of 13 HCPs. Four themes were identified: content of a future review, preparing for the review, delivering a holistic review and outcomes. People were concerned about the rigour of reviews which included risk of development of future conditions and wanted the review to focus on their IRD (e.g. joint assessment). People felt that current reviews felt like a ‘tick-box’ exercise. HCPs reported wanting to conduct a holistic review, highlighting challenges aligning patient and HCP agenda. People with IRDs also demonstrated variable attitudes to considering their risk of future conditions, ranging from whether they wanted all, some or no knowledge of their risk for other conditions influenced by whether these could be prevented. Preparation, such as written information or pre-review questionnaires were considered important to help people understand the review aims, align agendas and for the HCP to understand the patient history and context. Participants recognized the challenge of ensuring such materials consider underserved patient groups such as people with limited health literacy who may face difficulties accessing preparation materials. People with IRDs were flexible in considering whether a review should occur in primary or secondary care, whereas HCPs perceived primary care was best placed to provide a holistic approach although both groups agreed practitioner skills and expertise were more important than location. It was considered important to have outcomes from a review (including any actions to be taken by patient or HCP) clearly understood for a review to be perceived as beneficial.

Conclusion: People with IRDs are at high risk of multimorbidity and may benefit from healthcare reviews to address future risks. Such reviews need to be patient-centered addressing both patient and HCP agendas to maximise utility and perceived value. Further research is needed to address how such reviews can be effectively implemented into routine care.

REAL-LIFE STUDY OF IMMUNOGENCEITY AND SAFETY OF THE RECOMBINANT VACCINE AGAINST VARICELLA ZOSTER VIRUS IN PATIENTS WITH RHEUMATIC DISEASES TREATED WITH JANUS KINASE INHIBITORS

Keywords: Vaccination/immunization, Real-world evidence, Targeted synthetic drugs

A V Esteban Vazquez1, M Steinier1, E Castaneda1, I Thuissaard Vasallo2, C Andreu Vazquez2, A Somodevilla3, G Garcia Yubero4, S Muñoz-Fernández1, Hospital Universitario Infanta Sofia, Rheumatology, Madrid, Spain; Universidade Europea, Statistics, Madrid, Spain; Hospital Universitario Infanta Sofia, Pharmacy, Madrid, Spain

Background: Adjuvanted recombinant varicella zoster virus subunit vaccine (ARZVV) has been recently approved for preventing reactivation of latent varicella zoster virus in selected groups of patients. Patients with chronic inflammatory diseases are at major risk of this reactivation, developing herpes zoster (HZ) infection (shingles). This risk is further increased under immunosuppressive treatment with janus kinase inhibitors (JAKI). ARZVV is available in Spain since March 2021 for patients treated with JAKI, among other indications. At the present, no real-life post commercialization studies have been published in patients with rheumatic diseases and JAKI vaccinated with ARZVV.

Objectives: To assess humoral immunogenicity and safety of ARZVV in patients with rheumatic diseases treated with JAKi.

Methods: Immunogenicity and short-term safety were evaluated in a cohort of patients treated with Janus Kinase inhibitors in a descriptive prospective study. Participants received two intramuscular doses of the vaccine two months apart. Blood was sampled prior to first and 2-6 weeks after the second vaccine dose. Humoral immune response was tested through a chemiluminescence immunoassay (CLIA), using varicella zoster virus glycoprotein E (gE) as the antigen to measure anti-gE levels. The cut-off for the vaccine response assessment was considered an antibody concentration four times higher in the second measure, compared with the first one, according to the results of the clinical trial NCT0165177. The influence of the different treatments on the humoral response to the vaccine was evaluated. JAKi were separated in three groups, according to their mechanism of action: inhibition of JAK 1 (Upadacitinib and Filgotinib), inhibition of JAK 1 and JAK 2 (Baricitinib) and pan-JAK inhibition (Tofacitinib). Concomitant treatment influence on the humoral response to the vaccine was also determined: classic disease modifying anti-rheumatic drugs (DMARDs) and corticosteroids. The data about adverse events to the vaccination, disease flare or reactivation on HZ infection were collected.

Results: We enrolled 30 patients, 23 were woman (76.7%), with a mean age of 55±12 years. Fifteen (50%) were under treatment with upadacitinib, eleven (36.7%) with baricitinib, two (6.7%) with filgotinib and two (6.7%) with tofacitinib. Six (20%) had concomitant treatment with methotrexate and 5 (16.7%) with leflunomide. Ten (33%) had low dose prednisone. Four (13%) reported clinically HZ previously. We found that 16 patients (53.3%) reached the response assessment marked initially of quadrupling their initial antibody concentration. Type of JAKi did not significantly influence the humoral response, neither did the concomitant treatment with disease-modifying antirheumatic drug or low dose glucocorticoid. Fifteen patients (50%) presented mild adverse effects; 7 (23%) of them consisted in injection-side pain, and 8 (26.7%) were systemic (myalgia, fatigue or fever). One patient (3.3%) had an ischemic cerebrovascular complication 2 weeks after the first dose. None of the patients presented a disease flare in the following 4 weeks postvaccination, neither HZ infection after 7 months of follow-up.

Conclusion: Lightly more than half of the patients (53%) with rheumatic diseases treated with JAKi reached the immune response assessment stabilized. In clinical trials with non-rheumatic immunosuppressed patients, the response was ranged between 65-96%. This difference could be explained due to that it is a real-life study and in the type of disease and immunosuppression. Safety and prevention of HZ infection was high. To confirm these results higher number of patients is needed.

TRENDS OF KNEE ARTHROPLASTY FOR PATIENTS WITH OSTEARTHROPSIS AND RHEUMATOID ARTHRITIS IN SUPER-AGING SOCIETY IN THE LAST THIRTEEN YEARS

Keywords: Osteoarthritis, Rheumatoid arthritis

M. Aso1, Y. Takakubo1, A. Suzuki1, S. Yang1, Y. Wanezaki1, T. Yamamoto2, T. Itó3, S. Fukushima2, M. Takagi1. 1Yamagata University, Orthopaedic Surgery, Yamagata, Japan; 2Yamagata Saisei Hospital, Orthopaedic Surgery, Yamagata, Japan

Background: In Japan, the number of people aged 65 years or older exceeds 35 million, accounting for 28.4% of the total population. It is expected to reach 38.4% by 2065[1]. As a result, the demand for total knee arthroplasty (TKA) and unicompartmental knee arthroplasty (UKA) is increasing year by year[2].

Objectives: The purpose of this study was to investigate the number and trend of patients who underwent knee arthroplasty from 2008 to 2020.

Methods: We analyzed the age, gender, and causative disease of patients who underwent primary knee arthroplasty between January 2008 and December 2020 at two affiliated hospitals. Chi-squared test, Mann-Whitney U test and Spearman’s rank correlation coefficient were utilized for statistical analysis. All p-values of 0.05 or less were considered statistically significant. All statistical analyses were conducted using EZR (Saitama Medical Center, Jichi Medical University, Saitama, Japan, Version 1.55)[3].

Results: We recorded 4,199 cases of TKA (87.1%) and 623 cases of UKA (12.9%), the total of knee arthroplasty is 4,822 cases. There were 1,011 males (24.1%) and 3,811 females (75.9%). Male patients made up 18.5-23.2% of all knee arthroplasty cases, with a trend toward an increase (Spearman’s rank correlation coefficient: γ = 0.633 p-value = 0.0135). The mean age at surgery was 75.0 (28-94) year-old, with no significant difference between male (75.2 year-old) and female (74.9 year-old) patients (p-value = 0.354). The Causative diseases included 4515 cases of osteoarthritis (OA, 93.6%), 208 cases of rheumatoid arthritis (RA, 4.3%), 90 cases of osteonecrosis (ON, 1.9%), 8 cases of trauma, and 1 case of infection (Table 1). TKA/ UKA for OA exhibited a significant upward trend, with an average of 346.9 cases per year, while TKA for RA showed a downward trend, with an average of 15.5 cases per year (Spearman’s rank correlation coefficient: OA γ = 0.85 p-value < 0.01, RA γ = -0.483 p-value = 0.0948, Figure 1). UKA group had a significantly higher rate of osteonecrosis compared to TKA group (p-value < 0.01, Table 1).

Conclusion: The number of TKA/UKA for OA increased due to the growing number of elderly people affected by knee OA in a super-aging society. On the other hand, the number and rate of primary TKA/UKA due to RA decreased over time due to advances in medication therapy[4]. Osteonecrosis was the cause of a relatively high rate in the UKA group.

EVALUATING HOW EFFECTIVELY PATIENTS WITH A NEW INFLAMMATORY ARTHRITIS ARE BEING TRIAGED INTO THE APPROPRIATE CLINIC AT A TERTIARY CARE HOSPITAL IN THE UK: A RETROSPECTIVE AUDIT

Keywords: Inflammatory arthritis

A. Vivekanantham1, A. Soni2, H. Thrower2. 1University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 2Oxford University Hospitals, Rheumatology, Oxford, United Kingdom

Background: Early diagnosis and treatment of inflammatory arthritis (IA) is essential: BSR guidance states patients must be seen within three weeks and started on disease modifying anti-rheumatoid drugs (DMARDs) within six weeks.

Objectives: To evaluate how effectively people referred with a new IA are being triaged, whether national standards are met and analyse variables which may influence triage of patients with new IA.

Methods: A retrospective review was performed of all new patients seen in EIA-clinic and those with new EIA who had been seen in non-EIA clinics from 01/09/21-31/11/21. Data was collected on days’ wait from referral to assessment/ commencement of DMARD. We calculated the conversion rate (CR) (percentage of referrals triaged to EIA clinic that have EIA) and detection rate (DR) (percentage of new EIA patients that are seen in the EIA clinic). The standard for CR and DR was 50% and 95%, respectively. We then examined why some new EIA patients were not triaged to the EIA-clinic using information provided on the referral.

Results: Of the patients seen in the EIA-clinic 36/37 had a new diagnosis of an IA, giving CR of 49%. Of the new diagnoses of IA made during that time-period 36/53 were appropriately triaged to be seen in the EIA clinic, giving a DR 68%. Patients seen in the EIA clinic had an average of 5 weeks wait from referral to assessment/commencement of DMARD. In contrast, patients who had been seen in non-EIA clinics had an average of 10 weeks from referral to assessment/commencement of DMARD. A previous audit performed before COVID-19 (01/11/19- 01/01/20) showed a CR of 25% (115 patients seen in EIA-clinic, 29 new diagnoses) and a DR of 69% (29 new diagnoses, 20 seen in EIA-clinic). Of the 10 patients with new EIA who were inappropriately triaged to non-EIA clinics did not have pattern of joint involvement or ability to make a fist documented, in comparison to the 38 patients with a new EIA who were appropriately triaged to EIA-clinic.

Conclusion: Patients with EIA, seen in the EIA-clinic, do not meet guidance for review within three weeks but do meet the guidance for starting a DMARD within six weeks. Patients seen outside the EIA-clinic do not meet either of these standards. Only 68% of people with a new EIA are being triaged to be seen in the EIA clinics, highlighting the need to improve the triage process. Compared to the previous audit, the CR has improved whilst the DR has stayed steady.

TIME TO PUBLICATION AND TIME-LAG PUBLICATION BIAS FOR RANDOMIZED TRIALS ON CONNECTIVE TISSUE DISEASES

Keywords: Epidemiology, Randomized control trial

D. Moneti1, B. Russo2,3, J.A. Brigante4, S. Capderou1, D. Courvoisier1, M. Iudici5, University of Geneva, Department of Medicine, Division of rheumatology, Geneva, Switzerland; 2University of Geneva, Department of Pathology and Immunology, Geneva, Switzerland; 3Hôpitaux Universitaires de Genève (HUG), Division of Dermatology and Venerology, Genève, Switzerland; 4Sanatorio Güemes, Servicio de Medicina Interna - Reumatología, Buenos Aires, Argentina; 5Hôpitaux Universitaires de Genève (HUG), Department of Internal Medicine Specialties, division of rheumatology, Genève, Switzerland

Background: Connective tissue diseases (CTDs) are systemic autoimmune diseases, some of which rare, characterized by a dysregulated immune response and a heterogeneous clinical picture. Similarly to nonpublication, a long time from completion to publication of randomized controlled trials (RCTs) results can indirectly harm patients by allowing inefficacious or dangerous intervention being prescribed[1], or by delaying the prescription of RCTs results can indirectly harm patients by allowing inefficacious or dangerous intervention being prescribed[1], or by delaying the prescription of

Methods: We included interventional, phase 2/3, 3 or 4 RCTs on CTDs registered in Clinicaltrials.gov from 2000 to 2016, whose results had been published in a peer-review journal less than 5 years after their completion. Two reviewers selected studies according to pre-specified criteria. Main trial features including the significance of primary outcome results were collected. Time to publication was the time from study primary completion to the earliest online publication date. Multivariable linear regression was used to identify association between time to publication and the significance of study results, adjusted for variables previously shown to impact this outcome, e.g. the extent of time-lag publication bias, neither analyzed factors associated with delayed publication.

Objectives: To assess the time from completion to publication of randomized controlled trials (RCTs) on connective tissue diseases (CTDs), investigate the factors associated with, and explore the influence of significance of study results on time to publication (time-lag publication bias).

Results: We included 62 studies, mostly phase 3 (62%) trials on pharmacologic treatments (94%), recruiting patients with systemic lupus (55%) or systemic sclerosis (23%), and planning to enrol a median of 131 [IQR 61-288] patients. Twenty-two (35%) reported at least a statistically significant primary outcome. Median time to publication was 28 months (IQR 17-36), with more than half studies (n = 34, 55%) published 2 or more year after completion (see Table 1). In multivariable analysis, time to publication progressively improved over time (faster publication in recent years, with the time to publication begin 1.3 [0.3, 2.4] months shorter every year), and was not influenced by the significance of primary outcome results, funded, impact factor of the journal, number of recruiting countries (see Figure 1).

Conclusion: A high proportion of CTDs-RCTs is published beyond 2 years from completion. We did not find evidence of time-lag publication bias, and time to publication improved over time.

PATIENT EXPERT RECOMMENDATIONS ON WAYS TO IMPROVING THE SYSTEMIC SCLEROSIS CARE CONTINUUM ACROSS EUROPE

Keywords: Systemic sclerosis, Patient-led research, Geographical differences

1Federation of European Scleroderma Associations, Vice President, Brussels, Belgium; 2Federation of European Scleroderma Associations, President, Brussels, Belgium; 3Institut Cochin, Professor of Rheumatology, Cochin Hospital Practitioner, Head of the Research Team ‘Pathogenesis and Innovative Therapies in Systemic Sclerosis and Other Fibro-Infammatory Diseases’ at Institut Cochin, Paris, Paris, France; 4University of Florence, Professor of Rheumatology at the Department of Experimental and Clinical Medicine, Florence, Italy; 5Patient Advocate, Patient Advocate, Bucarest, Romania; 6Patient Advocate, Patient Advocate, Amsterdam, Netherlands; 7University College London Division of Medicine, Professor of Experimental Rheumatology, Consultant Rheumatologist, London, United Kingdom

Background: Systemic sclerosis (SSc), also known as scleroderma, is a rare autoimmune disease that stiffens the skin, turning simple daily activities into real challenges for patients. It can affect all organs, and while treatments exist, there is currently no cure. The disease is relatively invisible among general practitioners and policymakers in Europe - meaning hundreds of people affected by this rare condition remain undiagnosed and untreated.

Federation of European Scleroderma Associations (FESCA) took a two-pronged approach to develop new evidence. June 2022 a Position Paper (PP) based on a literature review and a survey for healthcare providers (HCP) was published, followed by a large-scale patient and carer survey, whose results are expected in June 2023.

OBJECTIVES:

• Highlight the unmet needs of SSc patients throughout the care pathway.
• Investigate the health and socio-economic burden of the SSc
• Provide evidence to policy stakeholders on the need for policy actions to address health inequalities.

Methods: For the PP, a total of 15 publications were reviewed. To fill the knowledge gaps identified by the literature review, FESCA developed a survey questionnaire earmarked for Excellence or Reference Centers that work with FESCA member organizations and/or are part of the European Scleroderma Trials and Research group (EUSTAR). Upon validation by the authors, the survey was completed by 78 respondents from 24 countries. The upcoming survey will be distributed across 20 countries, a min. representative sample of 511 patients and 170 carers will provide new insights.

Figures: The PP highlighted need for policy action in five action areas to ensure timely treatment initiation for all eligible patients and improved health outcomes and quality of life for people living with SSc, by: 1. Creating patient registries for SSc; 2. Shortening time to accurate diagnosis through expanded HCPs curricula; 3. Ensuring timelier referral of patients to specialized care;

Background: The development of biologic and targeted synthetic (b/ts)DMARDs contributed to improved treatment outcomes in rheumatoid arthritis (RA). However, high medications costs may limit their use. Previously we showed that in countries with a lower socioeconomic status (SES), b/tsDMARDs were prescribed to fewer patients than in countries with higher SES. In this study we take a more detailed look at b/tsDMARD prescription behavior between countries.

Objectives: To explore cross-country relationships between Gross Domestic Product (GDP) per capita, specific indicators of b/tsDMARD use and disease outcomes in patients with RA.

Methods: This multinational observational study included countries that had contributed ≥100 patients using b/tsDMARDs, with available follow up, to one of 2 registries: METEOR, an international registry capturing daily clinical practice data of patients with a clinical diagnosis of RA, and JAK-POT, an investigator-initiated collaboration between national registries aiming to evaluate clinical aspects of b/tsDMARDs in RA. On a per-country basis, mean DAS28 was calculated from the last available follow-up visit per patient. b/tsDMARD usage was determined as mean time to start b/tsDMARD therapy since date of diagnosis, mean number of b/tsDMARDs tried per patient and mean duration of b/tsDMARD therapy. To calculate the time to start a first b/tsDMARD per country included from the JAK-POT registry, only bionaive patients were included. Possible associations between GDP per capita and country-level indicators of b/tsDMARD use and DAS28 were tested in univariable linear regression models. Regression coefficients (β) are interpreted as the numerical increase in the outcome per 1 percentage point in the predictor.

Results: Data from 25,832 patients living in 17 different countries showed varying b/tsDMARD prescription behavior. GDP per capita ranged from 6505 (India) to 93350 Intl$ (Ireland). Time to start b/tsDMARD therapy ranged from 0.5 (Austria) to 11.1 (Finland) years. Mean number of b/tsDMARDs tried per patient ranged from 1.0 (Turkey) to 2.4 (Switzerland). Duration of b/tsDMARD therapy ranged from 0.9 (India) to 5.5 (Portugal) years (Figure 1). Baseline DAS28 ranged between 3.7 and 6.1, but was not related to any of the indicators of b/tsDMARD use: time to start a b/tsDMARD β 0.08 (95% CI -0.7; 0.9), number of prescribed b/tsDMARDs β 0.06 (95% CI -0.03; 0.2), duration of b/tsDMARD treatment β 0.1 (95% CI -0.3; 0.5). No statistically significant associations were observed between GDP per capita and start time to b/tsDMARD therapy (Figure 1A, β 0.09 CI 95% -0.7; 0.9), the number of b/tsDMARDs tried per patient (Figure 1B, β 0.07 CI 95% -0.02; 0.2) or the duration of b/tsDMARD treatment (Figure 1C, β 0.1 CI 95% -0.3; 0.5). None of the indicators of b/tsDMARD prescription were significantly related to DAS28 at the end of follow up: time to start a b/tsDMARD β 0.02 (95% CI -0.05; 0.1), duration of b/tsDMARD therapy β -0.03 (95% CI -0.2; 0.1) and number of b/tsDMARDs β -0.03 (95% CI -0.6; 0.8).

Conclusion: This study showed varying b/tsDMARD prescription behavior and disease activity across 17 countries worldwide. Overall, differences in b/tsDMARD prescription behaviour did not appear to be related to socioeconomic welfare and, no significant association was observed between b/tsDMARD prescription behavior and disease activity at a country level. This seems to indicate that once patients start a b/tsDMARD, socioeconomic welfare has less impact on b/tsDMARD use.

AB1603 EVIDENTIAL REQUIREMENTS FOR DECISION-MAKING ABOUT WORKPLACE INITIATIVES TO MITIGATE THE IMPACT OF RHEUMATIC AND MUSCULOSKELETAL DISEASES: QUALITATIVE INTERVIEWS WITH REPRESENTATIVES OF UK ORGANISATIONS

Keywords: Work-related issues, Rheumatoid arthritis, Qualitative research methods

M. Eden1, J. Higginson1, K. Payne1, W. Whitaker1, S. Verstappen1, The University of Manchester, Manchester Centre for Health Economics, Manchester, United Kingdom; The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom

Background: Decisions about whether to invest in RMD-related workplace initiatives/adaptations can be made by determining, from the relevant perspective, if benefits outweigh the costs of implementation. Little is known about what information organisations need to facilitate these decisions.

Objectives: This study aimed to explore motivations and evidential requirements for employers to invest in workplace health initiatives.

Methods: Semi-structured online interviews with representatives of large UK-based (not-for-profit and for-profit) organisations were audio-recorded. For each organisation, a line manager, director, and representative with workforce remit were interviewed. Interview data were transcribed verbatim and subject to thematic analysis by two researchers trained in qualitative methods. Themes were agreed in discussion with the study team.

Results: We recruited 13 representatives (5 directors, 3 line managers, and 4 with a specific remit for workforce health). Three not-for-profit organisations (local authority, university, and National Health Service) were represented by seven participants and three for-profit organisations (restaurant chain, telecoms provider, and technology company) were represented by six individuals.

Motivations: All participants believed that investment in measures to promote employee health would benefit the organisation and respondents believed that investment in workforce health initiatives would contribute to their organisation's efficiency. However, there were mixed views on the value of workforce health initiatives. For some, a very positive impact on organisation performance was expected. For others, the relationship between workforce health initiatives and organisational performance was less clear. Some respondents believed that workforce health initiatives could help to attract and retain employees, whilst others believed that these initiatives could lead to higher staff turnover.

Evidential requirements: Use of checklists/assessments to reveal individual RMD-related needs was commonplace throughout organisations. Self-identified health needs, typically related to line managers, would instigate a process where occupational therapist (OT) input may be sought. Requests and OT recommendations are reportedly, without exception and irrespective of cost, met and followed. No organisation had set aside a specific budget for workplace initiatives. Decisions involving significant investments in workplace health initiatives were usually made by committees or by small teams comprising senior staff and directors. Line managers and those with a health remit would put forward a case for investment to these bodies: "...we would pull together a bit of a proposal really on what that would look like...what is the impact of it?...we support it with facts...even benchmarks of what's going on in the outside. (Health representative, for-profit). Evidence from ORTHOPEDIC LEADERSHIPS, in-house absenteeism data, workforce survey results/informal feedback from colleagues, benchmarking data, and academic/official report findings were used to make a case for investment.

Conclusion: The demand for RMD-specific interventions varies according to needs of particular workplaces. Despite the diversity of organisation type, workforce factors (i.e. demographic factors, nature of work) and employer roles, common processes for informing investment decisions and typical evidence requirements have been identified. Findings can inform the development and evaluation of workplace interventions to benefit people with RMD.

**AB1605**  
A PILOT RHEUMATOLOGY-INTERSTITIAL LUNG DISEASE (ILD) SERVICE - OUTCOMES AFTER 12 MONTHS

**Keywords:** Lungs, Organ damage

C. Riddle1, J. Lindsay1, E. Ball1. 1Musgrave Park Hospital - Belfast Health and Social Care Trust, Rheumatology, Belfast, United Kingdom; 2Belfast Health and Social Care Trust, Respiratory, Belfast, United Kingdom

**Background:** Rheumatologists have an important role in the management of interstitial lung disease (ILD). Cross-specialty collaborative working models are increasingly being used, particularly with ILD radiology MDT meetings, attended by respiratory physicians and rheumatologists, to discuss complex clinical cases. However, the format and infrastructure are not standardized [1]. With the widespread financial and logistical pressures affecting delivery of healthcare in not only NHS setting, but worldwide; there is a need to provide robust evidence to managers and fundholders, of significant benefit to attract allocation of funding and resources towards MDT working in complex disease areas such as ILD.

**Objectives:** We describe the format and outcomes of a pilot rheumatology-ILD service at a large teaching hospital undertaken from January to December 2022.

**Methods:** Two rheumatology consultants (EB and CR) worked with the local ILD respiratory lead (JL) to plan for weekly attendance of one or both rheumatologists at a weekly ILD MDT. Prior to this, paper based referrals to general rheumatology were made if advice was felt to be required - generating paperwork, delays in the patient journey and an ad hoc approach across multiple rheumatology clinics. This MDT is attended by respiratory clinicians, radiologists, ILD nurse specialist and respiratory trainees. Since the COVID-19 pandemic it has been conducted via Microsoft Teams and is scheduled for 1.5 hours weekly. Cases to be discussed are added in advance to MS team file on a specifically designed proforma. In addition there is a weekly ILD OPC attended by JL with a dedicated ILD nurse specialist. Rheumatology joined this clinic when other clinical commitments allowed which facilitated more focused discussion on management of complex cases.

**Results:** Over the course of a 12 month period rheumatology attended 24 ILD MDT meetings and 8 ILD out-patient clinics. This equated to approximately 80 hours of rheumatologist time over the pilot period. On analysis of cases presented, 33% required rheumatology input, most often on the basis of positive antibody screening or a prior history of rheumatological disease. The breakdown of rheumatology disease presented is detailed in Table 1 below.

*indicates specialist drug treatment not usually initiated by respiratory teams and requiring rheumatology advice +/- administrating and monitoring

**Conclusion:** There are a large number of ILD cases within the respiratory service that require rheumatology input – 33% of all ILD cases in this real-world snapshot. The spectrum of rheumatologically associated disease is vast. ILD can have catastrophic outcomes and therefore early and continued rheumatology input is vital. Investment is needed for formal MDT infrastructure to include rheumatology. There is a need for data collection, collaborative working and research to improve the quality of care and outcomes for this population.

SYMPTOMS OF RAYNAUD’S PHENOMENON ARE NO OBSTACLE FOR BEING PHYSICALLY ACTIVE IN HEALTHY WOMEN

**Keywords:** Patient reported outcomes, Lifestyles, Quality of life

S. Van de Zande1; K. Eijikelenkamp2; A. Eman Abdulle3, A. Smit4, H. Zwerve5, I. Van den Akker-Scheek6, D. J. Mulder4. 1University Medical Center Groningen, Vascular medicine, Groningen, Netherlands; 2University Medical Center Groningen, Endocrinology and Metabolic Diseases, Groningen, Netherlands; 3University Medical Center Groningen, Internal Medicine, Groningen, Netherlands; 4University Medical Center Groningen, Vascular Medicine, Groningen, Netherlands; 5University Medical Center Groningen, Center for Human Movement Sciences, Groningen, Netherlands; 6University Medical Center Groningen, Department of Orthopaedics, Groningen, Netherlands

**Background:** Women with primary Raynaud’s phenomenon (RP) often experience a decreased health related quality of life (HRQoL). A physically active lifestyle could have a positive influence on vascular function and thus might improve HRQoL in women with primary RP.

**Objectives:** To quantify the amount and type of physical activity (PA) and sedentary behaviour, as well as HRQoL and stress, in women with primary Raynaud’s phenomenon (RP), and to compare this to the behaviour of women without RP from a large population-based cohort (Lifelines).

**Methods:** The connective tissue disease (CTD) screening questionnaire data from the Lifelines database that was available of women ≥ 18 years old was used. This data was merged with data collected in the five-year period 2017-2021 in the Lifelines database on physical activity and sedentary behaviour, as well as HRQoL and stress. A logistic regression analysis was used to compare the prevalence of PA and sedentary behaviour, as well as HRQoL and stress, between women with and without RP.

**Results:** The prevalence of PA and sedentary behaviour, as well as HRQoL and stress, was similar between women with and without RP. There was a trend towards a higher prevalence of PA in women with RP, but this did not reach statistical significance. HRQoL was similar between women with and without RP, and there was no significant difference in stress levels. These findings suggest that the symptoms of Raynaud’s phenomenon do not pose an obstacle to being physically active in healthy women.
questionnaire consists of 30 questions to detect possible CTDs. A total of 19820 women, 929 with RP and 18891 without RP, all without other comorbidities were included. By using questionnaires from the Lifelines database other patient characteristics were retrieved including physical activity and sedentary behaviour, HRQoL, and stress.

**Results:** Women with RP reported 300 min/week minutes of moderate to vigorous physical activity (MVPA), which was more than women without RP reported (255 min/week). This difference was mainly due to a difference in vigorous activities (p<.001). 74.3% of women with RP complied to the health enhancing PA guidelines (69.5% in the group of women without RP, p=0.003). Time spent sedentary by women with RP was 540 min/week, which was comparable to sedentary time of women without RP (540 min/week, p=.886). Women with RP scored higher on almost all eight domains of the QoL questionnaire (p<.05), except for physical functioning (p=.181). Regarding stress levels, the List of Threatening Experiences (LTE) showed no differences between groups (p=.226), however, the Long-term Difficulties Inventory (LDI) showed a higher average on the LTE in the RP group (p<.001). Furthermore, women with RP were significantly younger (p<.001), had a lower Body Mass Index (BMI) (p<.001), a lower waist-hip ratio (p<.001), had a lower amount of packyears (p<.001) and a healthier diet score (p<.001) compared to the women without RP.

**Conclusion:** This is the first study to structurally investigate PA in a large population cohort of patients with RP. Most women with RP report they spent a significant amount of time on moderate to vigorous PA and thus comply to health enhancing physical activity guidelines. The PA behaviour of women with RP seems comparable to that of women without RP, showing that RP is no obstacle for being physically active. However, HRQoL was lower in women with RP; more research is needed to elucidate the relation between PA and HRQoL in this patient group, preferably using objective measurement instruments to assess PA.

**Acknowledgements:** The Lifelines biobank initiative has been made possible by subsidies from the Dutch Ministry of Health, Welfare and Sport, the Dutch Ministry of Economic Affairs, the University Medical Center Groningen, the University Groningen, and the Northern Provinces of the Netherlands. There was no funding for this manuscript.

**AB1608**

**THE EFFECT OF REMOTE AND FACE-TO-FACE PREVENTIVE REHABILITATION ON THE THICKNESS OF THE MUSCLES AROUND THE SPINE**

**Keywords:** Telemedicine, Physical therapy/physiotherapy, Ultrasound

**Y. Özel Aslıyüce** 1, O. Uğur** 1, Y. Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

**Background:** In these days when it is extremely important to use resources efficiently, ways to reduce the cost caused by low back and neck pain are sought. Investigating the architectural features of the muscles around the spine is also an important part of this search [1]. It is a rational approach to prevent spinal problems before they occur, rather than to treat them. In addition, it is very important for the prevention of spinal health that these approaches can be offered at low cost in pandemic conditions and disadvantageous situations such as settlements in rural areas.

**Objectives:** This research aims to investigate the effectiveness of remote and face-to-face spinal stabilization exercises on the thickness and activation of the muscles around the spine in asymptomatic desk-based office workers.

**Methods:** Individuals between the ages of 18-55 who did not have chronic low back and neck pain were included in the study. While the face-to-face group exercised under the supervision of a physiotherapist, the telerehabilitation (TR) group exercised with video conferencing and asynchronous video recordings. Both groups performed progressive spinal stabilization exercises 3 days a week for 8 weeks. The thickness of the Internal Oblique, External Oblique, Sterno-cleidomastoides and Upper Trapezius muscles at rest, and the thickness of the Transversus Abdominis (TA) at rest and during contraction were measured with portable ultrasound (Sonostar, China) (Image 1). TA activation was measured with a stabilizer. Compliance with exercise was evaluated with an exercise diary.

**Results:** 24 individuals, 12 in the face-to-face group and 12 in the TR group, with a mean age of 28.41±5.94 participated in the study. Age, gender distribution, and baseline values for muscles were similar between the groups (p>0.05). In both groups, right and left TA resting and contraction, Internal Oblique thicknesses were increased (p<0.05). It was found that the level of activation of the TA muscle, the thickness change during contraction, and the thickness of the internal oblique muscle developed more in the face-to-face group. In the TR group, on the other hand, an increase in Upper Trapezius thickness was observed (p<0.05). However, there was no significant increase in TA activation level in this group.

**Conclusion:** According to preliminary results face-to-face exercise further improves the thickness, activation, and contraction amount of deep stabilizer muscles. TR, on the other hand, caused positive developments in the deep muscles, but also in the upper Trapezius muscle, which is the superficial muscle. The reason for this situation may be postural compensations that occur during remote exercise [2]. As a result, both methods cause an increase in muscle thickness around the spine. However, if possible, supervision during exercises that require intense attention, such as
stabilization exercises, can increase efficiency. In addition, further studies on com-

pensations that may occur during exercise through TR may be instructive.

Springfield, United States of America

Objectives:
Objective of this study was to test the efficacy of a mobile application to support the self-management of patients with rheumatoid arthritis (RA) who were already participating in a web-based self-management program.

Methods: The National Inpatient Sample (NIS) is used for this study. It is a de-identified, random sample data of inpatient hospitalizations in the United States. It is the largest all-payer database containing data on more than seven million hospital stays. Its large sample size is ideal for examining national estimates. We collected data from 2016 to 2020 and ICD-10 codes were used to identify uveitis cases. NIS uses the Clinical Classifications Software Refined (CCSR) categories which aggregates ICD-10 codes into 530 clinical categories. ICD-10 codes for inflammatory eye conditions are assigned to the category uveitis and ocular inflammation.

Patients hospitalized with primary diagnosis of uveitis were included. Length of hospital stay; hospital charge and cost were collected. Charge is the amount hospital billed. Aggregate hospital charges are assigned to the category uveitis and ocular inflammation. Patients hospitalized with primary diagnosis of uveitis were included. Length of hospital stay; hospital charge and cost were collected. Charge is the amount hospital billed. Aggregate hospital charges are assigned to the category uveitis and ocular inflammation.

RESULTS:
Average length of stay (in days) was 5.8 ± 6.7 (O.361) for patients with uveitis. Aggregate hospital charges in US $ were 64,574,007 for 69,891,369 hospital stays. Average hospital charge per stay was 50.846 ± 55.469 (O.465) for patients with uveitis.

ECONOMIC IMPACT OF HOSPITAL STAYS FOR UVEITIS PATIENTS IN THE UNITED STATES: AN ANALYSIS OF THE NATIONAL INPATIENT DATABASE

Keywords: Health services research, Uveitis, Epidemiology

K. Cheuha1, 2, 3; Southern Illinois University - School of Medicine, Rheumatology, Springfield, United States of America

Background: Uveitis is the most common extraarticular manifestation in patients with spondyloarthritides. It may be the first presentation of spondyloarthritis. The combination of effects on vision, systemic disease and side effects of treatment have a significant impact on patient’s life. Uveitis affects all age groups and results in visual impairment over a long duration of the patient’s lifetime. Hence, treatment cost due to uveitis is similar to the common eye conditions such as cataract, age related macular degeneration and glaucoma.

Objectives: There is a lack of national level data regarding the medical cost of hospital stay of uveitis patients. The objective of our study is to identify health care expenses for patients hospitalized with uveitis in the United States.

Methods: The National Inpatient Sample (NIS) is used for this study. It is a de-identified, random sample data of inpatient hospitalizations in the United States. It is the largest all-payer database containing data on more than seven million hospital stays. Its large sample size is ideal for examining national estimates. We collected data from 2016 to 2020 and ICD-10 codes were used to identify uveitis cases. NIS uses the Clinical Classifications Software Refined (CCSR) categories which aggregates ICD-10 codes into 530 clinical categories. ICD-10 codes for inflammatory eye conditions are assigned to the category uveitis and ocular inflammation. Patients hospitalized with primary diagnosis of uveitis were included. Length of hospital stay; hospital charge and cost were collected. Charge is the amount hospital billed and cost represents the actual cost of hospital stay.

RESULTS: Average charge for hospital stays for uveitis patient is approximately 60,000 US dollars and has increased from 2016-2020. Similarly, cost of hospital stays and length of stay increased during the study period. Majority of uveitis inpatients are discharged to home, smaller percentage are discharged to rehab, nursing home or to home health care. Results are shown in the Table 1.

Conclusion: Economic burden of inpatient uveitis on health care is significant and has continued to increase from 2016 to 2020. Strategy and policy for providing better outpatient care for uveitis patients would help in reducing the number of hospital admissions and costs of stay.

NON-PHARMACOLOGICAL AND SELF-MANAGEMENT INTERVENTIONS FOR MAIN OUTCOMES IN RHEUMATOID ARTHRITIS PATIENTS: A SYSTEMATIC REVIEW

Keywords: Rheumatoid arthritis, Systematic review, Self-management

N. Nakhost Lotfi1, 2, P. Studenic1, 2, N. Weibrecht3, G. Zauner3, K. Fechner4, T. Stamm4, T. H. Jakobsen5, T. S. Jørgensen6, N. Popper3, 7, L. E. Kristensen6, H. Radner1, 3, Medical University of Vienna, Department of Internal Medicine 3, Division of Rheumatology, Vienna, Austria; Karolinska Institute, Division of Rheumatology, Department of Medicine (Solna), Stockholm, Sweden; dwh simulation services, dwh, GmbH, Vienna, Austria; Medical University of Vienna, Institute for Outcomes Research, Center for Medical Data Science, Vienna, Austria; DANA, P-S, Copenhagen, Denmark; Copenhagen University Hospital, Frederiksberg and Bispebjerg, The Parker Institute, Department of Rheumatology, Copenhagen, Denmark; Vienna University of Technology, Institute of Information Systems Engineering, Vienna, Austria

Background: Rheumatoid arthritis (RA) is accompanied by considerable limitation of the functional abilities and a significant reduction of the patients’ quality of life (QoL).[1] Self-management has been proven to play a role in the improvement of well-being and functioning in daily life. With the help of digital tools, individuated self-management methods can become more accessible to patients.[2]

Objectives: We aimed to identify evidence on efficacy of non-pharmacological self-management interventions on core outcomes in RA. Results will inform development of self-management recommendations into the RheumaBuddy (RB) 4.0 app.

Methods: To identify evidence-based self-management interventions suitable for the inclusion in the app, a systematic literature review (SLR) was conducted. We included clinical trials or randomized controlled trials in adult (≥18years) RA patients, reported in German or English language and excluded nutritional supplements and interventional medical devices. Outcomes of interest were identified via RB4.0 as either predefined or individually used for symptom tracking in the app and agreed upon in an expert panel.

RESULTS: Main outcomes identified and used in the SLR were pain, fatigue, mood, stiffness, and quality of life. In total, 125 studies from 644 identified articles were included for data extraction (Figure 1). Heterogeneity of the studies precluded a meta-analysis. The majority of studies used pain (n=100), mood (n=46) or fatigue (n=35) as outcome. Interventions were grouped into six main categories (Exercise, Diet, Psychosocial, Education, Multicomponent, and other). The number of studies with a significant positive effect on various outcomes per various intervention strategies are displayed in Table 1.

</table>
**Conclusion:** We identified a broad range of non-pharmacological, self-management interventions for RA patients which can be used to further develop self-management recommendations, for implementation into RheumaBuddy 4.0, a new generation of an algorithm-driven digital health tool, designed to support RA patients’ disease self-management.

A. C. Rat⁴, I. Thaon⁶, D. Loya⁷, L. Caen-Normandy University, UNICAEN, Inserm, UMR-S 1075 COMETE, PFRS, Caen, France; Caen, France; Université de Lorraine, APEMAC, Nancy, Nancy, France

**Background:** Despite improvements in the management of inflammatory arthritis (IA), the disease still has a significant impact on work and the support for patients with professional difficulties remains insufficient. The questionnaires currently available to us evaluate the societal impact of the disease (e.g. productivity at work) but not individual intermediate criteria such as work difficulties or possible adaptations.

**Objectives:** The objective of the study was to better understand the difficulties encountered at work, the coping strategies used and the motivations of patients with IA to continue working. Only the occupational adaptations are presented here.

**Methods:** 32 individual semi-directed interviews and 2 group interviews were conducted with patients with IA recruited in consultations or by patient associations. The participants were recruited according to a purposive sampling with maximum variation. Inclusion criteria were: age 18 to 65 years, have IA, be professionally active, have difficulties or concerns at work due to the disease. The interviews were conducted with an interview guide and were recorded and transcribed in full. The thematic analyses were conducted using an inductive approach.

**Results:** The analysis of the adaptations implemented revealed 14 main themes: adaptation of positions, tasks and mobilizations; adaptation of equipment; support from colleagues; change of working time; changing schedules and night work; taking breaks at work, splitting activities; Teleworking; reorientation, training; recognition of the status of disabled worker; occupational medicine, administrative difficulties; ergonomists; trade unions; changing position, jobs or employers.

Efficacy over time of sublingual polybacterial vaccines in patients with rheumatic diseases and active pharmacologic immunosuppression

Keywords: Vaccination/immunization, Invasive infection, Infection-related RMDs

Scientific Abstracts

S. Shan1, M. Mian1. 

I. Pérez - Sancristóbal1, M. P. Álvarez Hernandez1, S. Sanchez - Ramon2, I. M. C. Corrales1, J. Monreal2, E. de la Fuente3, C. Martínez Prada1, D. Freites1, V. Villaverde3, B. Fernandez1, G. Candelas1, C. Gómez1, C. Sánchez-Blazquez1, M. C. Nieto4, S. Shan1, M. Mian1.

Background: Synthetic and biologic disease-modifying drugs (DMARDs) have improved the prognosis of systemic autoimmune diseases (SAD). However, concerns persist about infectious complications in these patients. Previous studies of our group have shown that sublingual polybacterial vaccines decrease the rate of recurrent respiratory tract infections (RRTI) and recurrent urinary tract infections (RUTI).

Objectives: We aimed to evaluate the number of respiratory and urinary tract infections during 2018-2021 in patients who received sublingual polybacterial vaccines until 2018, when their administration was discontinued due to regulatory issues.

Methods: A retrospective observational study was conducted from a cohort of patients with SAD who had received sublingual polybacterial vaccines between 2014 - 2018. From 2018 onward, the incidence of UTI and incidence of RUTI and RRTI was analyzed and compared with annual incidence prior to vaccine administration and after one year post-vaccination.

Results: RRTI and RUTI were analyzed in 41 patients with SAD and active immunosuppression during the years 2018-2021. A significant increase in the number of infections was observed from 2018 to 2021, compared to the post-vaccination year, for both RUTI (1.53±2.17 vs 0.63±1.13;p=0.005) and RRTI (1.63±2.32 vs 0.67±0.92;p=0.003). When categorizing by number of infections, we observed that despite the increase in the average number of RUTI and RRTI, approximately half of the patients had no infections in the 2018-2021 period (51.2% RUTI and 43.5% RRTI). Making a comparison with the pre-vaccine year, despite the increase in the number of infections during the 2018-2021 period with respect to the immediate post-vaccination, the number of RRTI episodes was still lower (1.61±2.26 vs 2.76±2.57;p=0.002), as was the number of RUTI (1.56±2.12 vs 2.69±3.07;p=0.010).

Conclusion: The effect of sublingual polybacterial vaccines was maintained up to 3 years, with a significant decrease in infections with respect to the year prior to vaccination, suggesting that these vaccines may have long-term benefit. The number of respiratory and urinary tract infections increased during the years when the vaccine administration was not continued. However, an absence of infections was also observed in half of the patients.

The increase in safety outcome trials and the issue of informed consent

Keywords: Randomized control trial, Safety

A. Özgediz1, S. N. Esatoglu1, H. Yazioğlu2, 1Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Academic, Hospital, Istanbul, Turkey

Background: The randomized controlled trial (RCT) remains a most important research as well as a tool for drug licensing. Informed consent also remains an integral component of this tool. The exact wording of this consent is not in the public domain and we had previously raised that concern and had pointed out that it should [1, 2]. As we previously indicated such transparency was important from the point of an organized skepticism an essential element of scientific inquiry [3]. Moreover, we had also indicated that this transparency was even more important in safety outcome trials (SOT). We have the impression that such SOTs are becoming more frequent especially with the increasing popularity of pragmatic trials [4] where the safety outcome measures are not infrequently as severe as death.

Objectives: To tabulate the frequency of RCTs with the primary outcome measure of safety in mainline general medicine journals at two time points, thirty years apart.

Methods: RCTs published in 1990-1991 vs 2019-2020 in NEJM, JAMA, LANCET and BMJ were searched by 2 independent reviewers (AO and SNE). Phase 1-2 RCTs, post-hoc analyses of RCTs and RCTs reporting long term follow-up data were excluded. RCTs with an indisputable primary endpoint of efficacy were defined as an ‘A trial’. Those trials with declared or obvious primary endpoints of ‘safety,’ ‘efficacy and safety’ or simply as ‘efficacy’ in which we unaniomously considered the presence of serious harm to the patients in the control arms were defined as a ‘B trial’. Finally, the trials that we could not unanimously decide whether designate A or B, were designated as C. Discrepancies were resolved after discussion with the senior author (HY) and if, even then, there was no consensus the trial remained as a C. We then compared the frequencies of the types of RCTs which were published in 1990-1991 vs 2019-2020. Other salient features, like the type and the practice setting, of these patients were also tabulated.

Results: There were 309 RCTs published in 1990-1991 and 600 RCTs published in 2019-2020. Nineteen RCTs on COVID-19 infection were excluded for

Disclosure of Interests: None Declared.

DOI: 10.1136/annhemd-2023-eular.3845
fair comparisons. As seen in the Table 1 there was a significant increase in the number of SOTs in the later years. Moreover, the number of intensive care unit (ICU) trials, a setting in which obtaining informed consents can often be problematic, significantly increased.

**Conclusion:** Recently, there is a significant increase in the number of SOTs. Moreover, they are more frequently conducted in the ICUs. We strongly emphasize that the informed consents of all RCTs, particularly, those related to SOTs should be public. We strongly consider that such action is necessary a. to continue receiving our patients’ vital consent to enable us to continue conducting RCTs and b. for justly addressing the organized skepticism of our peers.

**EVALUATION OF THE NOCEBO EFFECT WHEN SWITCHING FROM THE ORIGINATOR MOLECULE TO A BIOSIMILAR IN A NORMANDY RETROSPECTIVE COHORT OF PATIENTS WITH INFLAMMATORY RHEUMATISM TREATED WITH ETANERCEPT OR ADALIMUMAB (BIONIC STUDY)**

**Keywords:** Spondyloarthropathy, Rheumatoid arthritis, bDMARD

1Rouen, Rheumatology, Rouen, France

2Caen, Rheumatology, Caen, France

3CHU Charles Nicolle, Clinical Pharmacology, Rouen, France

4Groupe Hospitalier du Havre, Rheumatology, Montvilleurs, France

5Évreux, Rheumatology, Évreux, France

6Évreux, Public Health, Évreux, France

**Background:** The cost of treating the major inflammatory rheumatic diseases (rheumatoid arthritis and spondyloarthri) has increased dramatically since the advent of biotherapies (bDMARD). However, the appearance of the first biosimilar has led to significant healthcare savings. However, sometimes-negative perception of these treatments by patients and practitioners can lead to the appearance of a nocebo effect.

**Objectives:** To measure the prevalence of the nocebo effect after switching from an adalimumab (ADA) or etanercept (ETA) originator to one of their biosimilars.

**Methods:** 183 patients from 4 hospital centers in Normandy (Rouen and Caen University Hospitals, Le Havre and Évreux Hospitals) were included between January 2018 and July 2022 in this retrospective study, within the framework of the Article 51 biosimilars experiment. The subjects had an inflammatory rheumatism (RA or AS) in remission, treated with ADA or ETA originator biological treatment before being switched to a biosimilar. The occurrence of a nocebo effect was considered in patients who did not maintain treatment at 12 months and had a subjective side effect. A comparative analysis of the quantitative data collected was performed before and after the switch. The side effects that led to the discontinuation of the biosimilar were identified. During the switch, a questionnaire was distributed to 30 patients to describe the topics discussed during the consultation and their feelings about the biosimilar. Finally, a univariate and then multivariate analysis was performed to identify potential risk factors associated with the occurrence of a nocebo effect.

**Results:** The nocebo effect was measured in 13.1% of patients. It was also noted that 9.2% of the group study had presented a side effect objectively by the rheumatologist, and 1.6% mixed side effects. Were considered subjective side effects the sensation of rheumatic recrudescence without objective element found, as well as a certain number of complaints. There were 15.3% of patients who experienced a reactivation of their rheumatism, 8.2% an intolerance, 1.6% an infectious event, 0.5% an allergic reaction. Concerning the evolution under treatment, the comparative analysis did not show any significant difference before and after the switch for the measured, except for the duration of morning stiffness duration in the AS group (p = 0.01). Univariate and multivariate analysis did not identify any risk factors associated with the occurrence of a nocebo effect. The responses to the questionnaire made it possible to observe the themes discussed during the consultation (mainly efficacy and cost). The majority of patients interviewed reported that the biosimilar was identical to the originator in terms of safety, efficacy, mode of use and pain at the injection site.

**Conclusion:** The occurrence of a nocebo effect following a switch to a biosimilar remains acceptable regarding the savings made. It appears less frequent when the switch is supervised by the practitioner, in contrast to the rare data in the literature, where the results differ when the substitution is systematic (up to 33% in some countries). The occurrence of such an effect can be explained by a bad perception of the patient. Therapeutic education as well as a shared medical decision between patient, rheumatologist and pharmacist seems to be essential in a certain population of patients which remains to be defined.

**ADHERENCE TO THE LIFE’S ESSENTIAL 8 METRICS AND HYPERURICEMIA: A CROSS-SECTIONAL STUDY**

**Keywords:** Lifestyles, Non-pharmacological interventions, Epidemiology

W. Yang1, 2,3

1North China University of Science and Technology affiliated Hospital, Department of Rheumatology and Immunology, Tangshan, China

2Kailuan General Hospital, Department of Rheumatology and Immunology, Tangshan, China

**Background:** Hyperuricemia (HUA) which with a pooled prevalence of 16.4% in mainland China (1), is a known cause of gout and is linked to chronic disorders such as myocardial infarction, stroke, type 2 diabetes, chronic renal disease, and cardiovascular morbidity (2,3). The preventive factors against hyperuricemia are thought to be health-related behaviors and factors. As a result, suggestions for healthy habits have been incorporated into the most recent gout and HUA therapy recommendations (4). Recently, the American Heart Association released their latest cardiovascular health metric “Life’s Essential 8” (LE8M) [5]. The LE8M defined cardiovascular health with eight criteria. It contained five health behaviors (nicotine exposure, physical activity, diet, body mass index, and sleep health) and three health factors (blood lipids, blood pressure, and blood glucose). To confirm whether the LE8M could apply to HUA, we looked at the connection between adherence to the LE8MScore and the likelihood of having hyperuricemia using the cross-sectional data of more than 90,000 Chinese participants from the Kailuan Study.

**Objectives:** Although several individual cardiovascular healths are associated with uric acid status, the association of overall cardiovascular health with hyperuricemia remains unclear. We thus examined the association between the Life’s Essential 8 metrics and odds of having hyperuricemia in a Chinese adult population.

**Methods:** Included were 92,912 Chinese participants of the Kailuan Study (mean age: 51.32±12.45y). The Life’s Essential 8 metrics were calculated based on five health behaviors (nicotine exposure, physical activity, diet, body mass index, and sleep health) and three health factors (blood lipids, blood pressure, and blood glucose). Hyperuricemia was defined as serum uric acid concentrations of ≥7mg/dl for men and women. Association between the LE8M and hyperuricemia was assessed using multiple logistic regression models, adjusting for age, sex, marital status, education, income level, alcohol drinking, triglyceride and renal function.

**Results:** High the Life’s Essential 8 metrics score was associated with low odds of having hyperuricemia (adjusted OR for quartile 4 vs. quartile 1=0.64; 95% CI, 0.59 to 0.70; P-trend <0.001), after adjusting for potential confounders. The association of the Life’s Essential 8 metrics and hyperuricemia was more
pronounced among women and younger participants (<45y), compared with their counterparts.

Conclusion: The Life’s Essential 8 metrics was associated with a low likelihood of having hyperuricemia in Chinese adults.

DIFFERENCES IN ACCESS TO RHEUMATOLOGICAL CARE OF PATIENTS WITH CHRONIC POLYARTRITIS AND CONNECTIVE TISSUE DISEASES: A PILOT STUDY USING INTERACTIVE PROCESS MINING ANALYSIS

Keywords: Health services research

1Hospital Clínico Universitario San Carlos, Rheumatology, Madrid, Spain;
2Valencia Polytechnic University, Instituto Universitario de Tecnologías de la Información y Comunicaciones, Valencia, Spain;
3Gerencia Asistencial Atención Primaria, Research Unit, Madrid, Spain;
4Hospital Clínico Universitario San Carlos, Orthopedic Surgery, Madrid, Spain

Background: Process mining is a research discipline used to derive process-related knowledge from data on event occurrences at different times. In the healthcare domain, these techniques can be applied to outpatient processes to extract information regarding how they take place and identify inefficiencies or points form improvement.

Objectives: Our aim was to analyze how patients that receive a diagnosis of chronic polyarthritides (CP; including conditions such as rheumatoid arthritis and undifferentiated arthritis) or connective tissue diseases (CTD; such as Systemic Lupus Erythematosus, scleroderma or vasculitis) access a tertiary care level rheumatology outpatient clinic, using novel process mining techniques.

Methods: Retrospective study, including patients first seen at the Hospital Clínico San Carlos Rheumatology Outpatient clinic between 2016 and 2019, belonging to the Hospital Clínico San Carlos Musculoskeletal Cohort. We included those patients receiving ICD10 diagnostic codes, by their attending rheumatologists, compatible with Adult-onset Still’s disease, undifferentiated polyarthritis, poly-myalgia rheumatica and rheumatoid arthritis (which were later grouped under the category of “chronic polyarthritis”), and myositis, antiphospholipid syndrome, sarcoidosis, Behçet disease, polymyositis, scleroderma, mixed connective tissue disease, Sjögren syndrome, systemic lupus erythematosus, vasculitis and Raynaud’s syndrome (which were later grouped under the category of “connective tissue diseases”). Information regarding outpatient activity at the Rheumatology clinic (dates of appointments, if they were a first visit in the clinic or a revision, and which department requested the appointment) was obtained from the Hospital Information System (HIS). Process Mining techniques were used to visualize the pathways followed by the patients included in both categories, and to highlight differences.

Results: 174 patients with CTDs and 341 patients diagnosed with CPs were analyzed. Regarding CTDs, most patients were initially referred from Primary Care. Furthermore, most of those patients were not referred from other departments. Regarding CTDs, although Primary Care seems to be the most common level of referral, other origins are more likely. When the pathways of both disease classifications are compared (Figure 1), we can observe that, compared with CTDs, CPs, have a lower chance of being referred from the Orthopedic Department (“TRA-REU” node in blue) and a higher chance of being referred from “other departments” in secondary care (“REU” node in red). Furthermore, it is less likely that a patient with CTD undergo referrals from different departments and care levels during follow-up (see by the lines in blue color connecting the nodes “TRA-REU,” “URG-REU,” “PRI-REU,” and “REU Rev”).

Conclusion: In this pilot analysis, we have observed that the pathways followed and the referral departments of the patients diagnosed with CTDs and CTDs are different. Process mining can be a very useful tool to characterize and identify the pathways that patients undergo within the healthcare system, across levels and specialties.

OUTCOMES OF HEPATITIS B AND TUBERCULOSIS SCREENING IN A COHORT OF PATIENTS ON BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (BDMARDS) FOR RHEUMATIC DISEASE AT A MELBOURNE PUBLIC HOSPITAL

Keywords: Vaccination/Immunization, bDMARD, Quality of care

H. Pourhadi1, A. Johnson1, A. Foote1.
1Northern Health, Rheumatology, Epping, Australia

Background: Screening for hepatitis B and tuberculosis is recommended prior to the commencement of biologic disease modifying anti-rheumatic drugs [1]. However, in routine clinical practice this can easily be overlooked, sometimes with severe consequences.

Objectives: We aimed to identify the percentage of patients screened for hepatitis B and tuberculosis prior to the commencement of bDMARDS in our rheumatology patients. We also determined if immunisation to hepatitis B was discussed in those with no serological evidence of immunity to the disease, and whether individuals with positive quantiferon gold (QTB) serology were referred for treatment prior to commencing bDMARDS.

Methods: All current rheumatology patients on bDMARDs at the Northern Hospital in Epping, Melbourne Australia were included in this study. By retrospectively reviewing the medical records, data was collected regarding patient demographics, clinical information and pre-treatment screening results including hepatitis B and QTB serology. Ethics committee approval was sought from our institution (Reference number: ALR 63.2020).

Results: There were 138 patients on bDMARD included in this analysis. 97 (70%) were female with a mean age of 51 (SD +/-15) at the time treatment was commenced. Rheumatoid arthritis was the most common indication for biologic

REFERENCES: NIL.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.4800
therapy (67%) followed by ankylosing spondylitis (15%) and psoriatic arthritis (14%). Tumour necrosis factor inhibitors (TNFi) and Janus kinase inhibitors (JAK) were most often utilized, prescribed to 72% and 13% of patients respectively. Prior to commencing bDMARDs, 128 (92%) patients were screened for hepatitis B infection. All of these individuals had hepatitis B surface-antigen (HBsAg) tested; 106 (76%) had Hepatitis B surface-antibody (HBsAb) tested and 92 (67%) had hepatitis B core antibody (HBcAb) tested. Among patients screened, 33 (25%) demonstrated immunity to hepatitis B either by previous infection (6%) or vaccination (19%), 1 (1%) was positive for HBsAg and 100 (75%) were susceptible to infection. Of these susceptible individuals, one (1%) was advised to have the hepatitis B vaccinations prior to commencing bDMARDs. Screening for tuberculosis with QTB serology was performed in 125 (90%) patients. Seven (5%) had a positive result and three (2%) were indeterminate. All patients with positive QTB results were referred to infectious diseases for treatment.

Conclusion: Patient demographics such as age, sex and indication for biologic therapy were similar to other bDMARD registries. Pre-treatment screening for hepatitis B was undertaken in most patients and demonstrated a significant number of non-immune individuals. Counselling on the importance of vaccination prior to commencing bDMARDs was rarely documented. There is a need for further counselling on the importance of immunisations in patients on bDMARDs and better access to vaccinations in public hospital rheumatology clinics.

THE INCIDENCE, PREVALENCE AND CHARACTERISTICS OF RHEUMATOID ARTHRITIS ON ARUBA INDICATE AN UNMET NEED FOR AN EARLY ARTHRITIS CLINIC

Keywords: Rheumatoid arthritis, Qualitative research methods, Epidemiology

R. Rellum1, M. Zethof2, J. Van Nies3, R. Thurlings4, A. Den Broeder5, M. T. Nurmohamed6, 7, Dr. Horacio E. Oudeber Hospital, Rheumatology, Orangezest, Aruba; 1Radboud University Medical Center, Medical Student, Nijmegen, Netherlands; 2Dr. Horacio E. Oudeber Hospital, Rheumatology, Oranjestad, Aruba; 3Radboud University Medical Center, Medical Student, Nijmegen, Netherlands; 4Amsterdam University Medical Centers, Rheumatology, Amsterdam, Netherlands

Background: A long unmet need was fulfilled in January 2019 with the start of a rheumatology outpatient clinic on Aruba.

Objectives: To assess the incidence, prevalence and patient- and disease characteristics of Rheumatoid Arthritis (RA) on Aruba.

Methods: In this cross-sectional study all health records from RA patients, with an outpatient hospital visit between January 1st of 2019 and 30th of June 2022, were accessed from the hospital database Cerner. Prevalence and incidence rates were determined.

Results: The point prevalence of RA on Aruba (06/30/2022) in the insured population (n = 110,000, i.e. 98% of the total population) was 0.37% (95% CI: 0.34% - 0.41%) he estimate half year incidence of RA on Aruba was 0.012%. The female: male ratio within RA patients on Aruba was 4.97:1 with prevalence of 0.57% in women and 0.13% in men. Approximately 25% of RA patients on Aruba had erosions and/or bony deformations, 7% already at time of hospital diagnosis. There was a general delay of 2.5 years since start of symptoms onset until the time of diagnosis.

Conclusion: This study suggests that the prevalence of RA on Aruba is significantly lower than the global, European and North American, pooled prevalence of 0.46%, 0.54% and 0.70%, respectively [1]. We observed a very long patient hospital delay, with significantly more joint damage in the newly diagnosed RA patient in comparison to other clinics. Obviously, there is a clear need for an earlier referral of RA patients by primary care physicians to the hospital. Development of an Early Arthritis Clinic could facilitate this process and would ultimately decrease the joint damage in RA patients.

EMERGENCIES IN RHEUMATOLOGIC DISEASES: A REAL-LIFE EXPERIENCE FROM AN ITALIAN RHEUMATOLOGICAL CENTRE

Keywords: Epidemiology, Real-world evidence, Best practices

Cristiano1, P. Triggiani1, C. Minerba2, A. D’antonio1, C. Bonini1, L. Fiammarta1, A. Bergini1, S. S. Chimenti1, Rheumatology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy

Background: Patients with rheumatic diseases (RDs) may present with severe and/or life-threatening conditions which might require hospitalization. RDs recognize a significant diagnostic delay because of variability of clinical features, often mimicking other systemic disorders. Accordingly, patients requiring hospitalization for new-onset emergencies should raise the suspicion of RDs also in absence of a known rheumatologic diagnosis.

Objectives: In this observational single-centre real-life study we analyse prevalence, distribution and management of RDs among patients hospitalized in a 3rd level Rheumatologic ward.

Methods: We collect demographic and clinical data from medical records of patients hospitalized in the Rheumatologic ward of “Tor Vergata” University Hospital in Rome (Italy), between 1st June 2021 to 31th December 2022. Patients are divided into two groups: known RDs at admission (Group 1) and new rheumatologic diagnoses (NRDs) at discharge (Group 2). Mean and standard deviation (SD) express normally distributed variables. Continuous variables are compared with T test, categorical variables by using Chi-square or Fisher’s exact test. P<0.05 values are considered statistically significant.

Results: The study cohort includes 179 patients (56% women) with a mean age at hospitalization of 62 ±16 y.o. Most of patients (88%) comes from Emergency Room (E.R.), and half of them (47%) has a defined diagnosis of RD at admission (Group 1). Patients admitted for suspected RD are 47 (26% of study population), among them, most cases (n=35, 74%) has NRD at discharge (Group 2). Comparing Group 1 (n=85, 63±14 y.o.) with Group 2 (n=35, 57±19 y.o.) we observe no difference in women prevalence (63% vs 51%) and referral from E.R. (58% vs 74%). Interestingly, diagnosis of rare rheumatological diseases (RDRs) occurs in a similar prevalence in Group 1 (n=57, 43%) and Group 2 (n=14, 40%). The most common reason for hospitalization in Group 1 is disease-fare (53%), followed by acute RD-related complications (27%) and treatment failure (20%). Patients from Group 2 are mainly hospitalized for new-onset severe joint pain (71%) while myalgia (11%), neuropathy (11%) and fever of unkown origin (6%) represent rare cases. Group 2 a significantly higher proportion of severe inflammatory arthritis (P=0.008) and myositis (P<0.05) is observed than Group 1. In the two groups we register a similar prevalence of systemic vasculitis, connective tissue diseases, systemic sclerosis, autoinflammatory diseases and primary antiphospholipid syndrome. A slightly higher proportion of patients is treated with steroids in Group 2 than in Group 1 (66% vs 55%). A quarter of patients receives csDMARDS in a similar prevalence; bDMARDs are used only in patients from Group 1 (7%). Rare cases from both groups are treated with intravenous immunoglobulin and protonostoids. In patients with non-rheumatological diseases at discharge (n=59) respiratory (51%) and cardiovascular disorders (34%) represent the main reasons for admission. Comparing them with patients with RD diagnosis (Group 1 + Group 2, n=120), a significantly higher prevalence of referral from E.R. results in the first group (P=0.002, Table I).

Conclusion: A relevant rate of RDRs occurs among patients requiring hospitalization in a similar prevalence between RDs and NRDs. Moreover, a new rheumatologic diagnosis is confirmed in most patients referring to E.R. in whom emergencies are suspected to be related to RDs. Accordingly, our preliminary data suggest that clinical suspicion for RDs and, thus, early referral to the Rheumatologic Unit should be adequately addressed also among patients from E.R. to improve the diagnostic delay in RD patients.

REFERRAL BEHAVIOUR OF PRIMARY CARE DOCTORS TO RHEUMATOLOGY CLINIC IN MALAYSIA

Keywords: Quality of care, Health services research

C. R. Ng1, Hospital Pakar Sultanah Fatimah, Rheumatology Unit, Department of Medicine, Johor, Malaysia

Background: The workload at rheumatology clinics has been growing relentlessly and an audit on new referrals helps to identify referral behaviour of primary care doctors and improvement can be done by providing further training.

Objectives: To audit on new referral cases to rheumatology clinic from 2020-2022 and to identify new cases with misdiagnosis for future training purposes.

Methods: This was a retrospective study. The medical records of all new referral to rheumatology clinic Hospital Sultan Ismail and Hospital Pakar Sultanah Fatimah from 1st January 2020 to 31st November 2022 were reviewed. The referral diagnosis and final diagnosis were identified and analysed.

Results: There were total of 927 new cases referred throughout the 35 months during Covid-19 pandemic. Majority of them were diagnosed to have rheumatoid arthritis (217/927) followed by systemic lupus erythematosus (190/927), psoriatic arthritis (147/927), gout (62/927), osteoarthritis (58/927), systemic sclerosis (25/927), anklyosing spondylitis (25/927), soft tissue rheumatism (24/927), Sjogren syndrome (24/927), mixed connective tissue disease (14/927), vasculitis (11/927), fibromyalgia (10/927), polymyositis (7/927) and miscellaneous (39/927). 45 out of the new cases were diagnosed as unlikley rheumatic diseases. There were 29 pending cases awaiting final diagnosis. 212 of the referrals were identified as misdiagnosis with the highest as nodal osteoarthritis, (55/212) followed by unlikely rheumatic disease (43/212), soft tissue rheumatism (24/212), psoriatic arthritis (20/212), Sjogren syndrome (14/212), gout (8/212), rheumatoid arthritis (7/212), fibromyalgia (6/212), systemic lupus erythematosus (5/212), anklyosing spondylitis (4/212), mixed connective tissue disease (3/212), inflammatory arthritis (2/212), polyositis (2/212) and others (19/212); diffuse idiopathic skeletal hyperostosis, hypermobility syndrome, RS3PE syndrome, idiopathic ulcers, graft versus host disease, juvenile idiopathic arthritis, antiphospholipid syndrome, hypothyroidism, post streptococcal arthritis, prolapsed intervertebral disc, cerebrovascular disease, traumatic stenoclarival joint subluxation, ledderhose disease, paraspinal muscle spasm and viral myalgia.

Conclusion: Nodal osteoarthritis and soft tissue rheumatism can be great mimickers for inflammatory arthritis and if wrongly diagnosed will lead to unnecessary anxiety or wrong treatment. More training is needed to improve clinical skills amongst primary care doctors.

ARTRO 360: NEW MANAGEMENT MODEL TO PROGRESS IN THE TREATMENT OF OSTEOARTHRITIS BY OPTIMIZING THE AVAILABLE RESOURCES

Keywords: Quality of care, Health services research, Osteoarthritis

N. Martínez Fernández1, J. Vergés2, Osteoarthritis Foundation International, R&D, Barcelona, Spain; Osteoarthritis Foundation International, President & CEO, Barcelona, Spain

Background: Osteoarthritis (OA) is the most common chronic joint disease and poses a growing public health problem. In Spain, 7 million people suffer from OA [1], and only hip and knee OA represent an average annual cost of 4,738 million euros for the Spanish Health System. In 2016, more than one hundred thousand hip and knee replacements were placed in Spain [2]. OA generates direct costs and considerable indirect costs for the National Health System, like the associated reduced productivity and labor costs. Therefore, a new OA management model is needed to reduce these expenses by optimizing the available resources.

Objectives: Design and validate a new management model that improves healthcare quality, security, and communication of OA patients.

Methods: The Osteoarthritis Foundation International (OAFI), with the collaboration of the Spanish Association of Osteoporosis and Osteoarthritis (AECO-SAR), made an initial proposal with a multidisciplinary expert committee. The different proposals have been reviewed and ratified by scientific and professional organizations of physicians, pharmacists, nurses, and patients.

Results: The model is based on the needs expressed by OA patients and states how the different specialists should intervene and prescribe the most appropriate therapeutic option. The model has three levels of action: preclinical, clinical, and disabling clinical. Several Spanish scientific societies like SEUAS, SECA, SEBOT, SETRADE, SER, SEMGEREN, SEMG, semFYC, SEFAC, SEIOM, and SEMDOR have supported the model. The model was presented in the Spanish Senate on September 28th, 2021, and it is being disseminated to the health departments at a regional level. Below are some of the proposals for the model:

- Promote the participation of patients and professionals in public health policies, research, and management models.
- Involve the patient in the decisions that affect them, making them responsible for their health and self-care.
- Accelerate the diagnosis.
- Facilitate access to optimal pharmacological and non-pharmacological treatment, taking into account the comorbidities and needs of the patient.
- Raise awareness of the relevant role of patient organizations as an active resource that complements the portfolio of services, strengthens professionals, and produces significant economic savings.

Conclusion: OA is the most common chronic joint disease and poses a growing public health problem. OAFI, with the support of several scientific societies, has developed a new management model to progress in treating OA by optimizing the available resources. With this program, it will be possible to reduce the cost of OA by approximately 100 million euros while improving the quality of health care for our patients. To implement it, it is essential to take coordinated action by health authorities, scientific health authorities, scientific and professional societies, patient organizations, and other relevant organizations.

INFLAMMATORY RHEUMATISM AND WORK: WHAT DIFFICULTIES IN RELATION WITH THE CHARACTERISTICS OF THE JOB?

Keywords: Inflammatory arthritides, Qualitative research methods, Work-related issues

A. C. Reit1, J. Thoan2, D. Loya3, 1Caen-Normandy University, UNICAEN, Inserm, UMR-S 1075 COMETE, PFRRS, Caen, France; 2University Hospital Center of Caen, Rheumatology, Caen, France; 3University of Lorraine, APEMACH, Nancy, Nancy, France

Background: Despite improvements in the management of inflammatory arthritis (IA), the disease still has a significant impact on work and the support for patients with professional difficulties remains insufficient. Occupational physicians and occupational health specialists are not all aware of the specific impact of IA on difficulties at work and sometimes think that all patients complaining of physical limitations are identical and require the same support.

Objectives: The objective of the study is to better understand the difficulties at work, in particular difficulties related to the employment characteristics of patients with IA.

Methods: 32 individual semi-directed interviews and 2 group interviews were conducted with patients with IA recruited in consultations or by patient associations. The participants were recruited according to a purposive sampling with maximum variation. Inclusion criteria were: age 18 to 65 years, have IA, be professionally active, have difficulties or concerns at work due to the disease. The interviews were conducted with an interview guide and were recorded and transcribed in full. The thematic analyses were conducted using an inductive approach.

Results: The analysis of difficulties related to the characteristics of the employment of patients with IA are numerous: physical load of the workstation; speed required by the job; simultaneous tasks; multiple tasks and flexibility; workload; working hours and schedules; routine, scheduling, commuting, job awareness, responsibilities and moral demands; cognitive characteristics; conflict of values, skills and experience; interpersonal characteristics; lack of material resources, inappropriate premises; autonomy, environment and culture of the company; productivity demands and evaluations, job insecurity or security; perceived maladjustment; isolation; lack of recognition. The difficulties are not always specific to patients with IA but are clearly aggravated by the disease for a good number of them. The patients describe the specificities of their difficulties.

Conclusion: Patients discuss multiple characteristics of employment that can be a hardship or an advantage. They explain how the disease makes these characteristics difficult for them. These data will be useful to occupational health occupational health professionals and clinicians to help patients keep their jobs in good condition and develop appropriate services.
These data will help to improve the training of occupational health occupational and to develop a questionnaire for the assessment of the work situation of patients with RA.

Disclosure of Interests: None Declared.

Methods: Observational, cross-sectional, single-centre study, with consecutive inclusion of outpatients over 18 years of age seen in the rheumatology hospital outpatient clinic. Sociodemographic and clinical variables were collected, as well as HRQoL measured with the 5-dimensional, 5-level EuroQol (EQ-5D-5L), which includes the EQ-Index (0-1 scale) and a visual analogue scale (VAS, 0-100 scale). A descriptive analysis and a comparison with the Spanish population according to the National Health Survey were carried out.

Results: 1,144 patients were included, 820 (71.68%) of whom were women, with a mean age of 56.1 years (range 18-95). 241 (25.44%) were new patients. In patients with RD, the HRQoL measured with the EQ-Index and with the VAS, was 0.186 and 12 points lower, respectively, than in the general population. HRQoL affected the 5 health dimensions, especially “pain/discomfort”, followed by “daily activities” and “mobility.” This reduction in HRQoL, was maintained in both men and women, and in all age segments, although it was greater between 18 and 65 years of age. The reduction in HRQoL affected all RD subtypes, especially the “Peripheral and axial mechanical pathology” and the “Soft tissue pathology” group.

Conclusion: Patients with RD report worse HRQoL compared to the general population in all HRQoL dimensions.

Epidemiology, risk factors for disease or disease progression

Keywords: Epidemiology, Real-world evidence, Safety

C.C. Chang1,2, T.M. Lin3, C.K. Chang4, H. Lee2. 1 Taipei Medical University Hospital, Allergy, Immunology and Rheumatology, Taipei, Taiwan, Republic of China; 2 School of Medicine, College of Medicine, Taipei Medical University, Allergy, Immunology and Rheumatology, Taipei, Taiwan, Republic of China; 3 Taipei Medical University Hospital, Allergy, Immunology and Rheumatology, Taipei, Taiwan, Republic of China

Background: Life-threatening severe cutaneous adverse reactions (SCARs) include Stevens-Johnson syndrome/toxic epidermal necrolysis, acute generalized exanthemeatosus pustulosis, and drug-induced hypersensitivity syndrome/drug reaction with eosinophilia and systemic symptoms. Previous report revealed that a gradual loss of regulatory T (Treg) cell function after resolution of SCARs increases the risk of subsequently developing autoimmune diseases (ADs). The association between patients with SCARs and ADs remain unclear and are scarce.

Objectives: This study explored the association of SCARs with AD risk. Methods: Individuals with SCARs between 2006 and 2015 were identified and 1:10 matched on age and sex with individuals without SCARs. We performed multivariate and stratified analysis using the Kaplan–Meier method and Cox proportional hazards models in order to estimate the association between SCAR cohort and the risk of developing ADs.

Results: A total of 26844 patients with SCAR and 268440 non-SCAR comparison subjects were selected from NHIRD. For individual organ-specific ADs, SCAR cohort as compared with non-SCAR cohort, adjusted hazard ratio (aHR) were higher for incident autoimmune hemolytic anemia (aHR 3.36, 95% CI: 1.64-6.16), Hashimoto’s thyroiditis (aHR 2.26, 95% CI: 1.64-3.12), Henoch-Schönlein purpura (aHR 8.89, 95% CI:1.65-12.4) and inflammatory bowel disease were (aHR 9.78, 95% CI:1.57-18.5) (see Table 1). Furthermore, for individual systemic ADs, SCAR cohort as compared with non-SCAR cohort, aHR were higher for incident ankylosing spondylitis (aHR 1.56), psoriasis (aHR 10.39), polymyositis/dermatomyositis (aHR 10.39), rheumatoid arthritis (aHR 2.48), primary Sjogren syndrome (aHR 5.92), systemic lupus erythematosus (aHR 9.58), systemic sclerosis (aHR 7.56) and systemic vasculitis (aHR 13.54) (see Table 1)

Conclusion: Patients with SCARs have higher risk of ADs than patients with no SCARs. Further mechanistic research should be conducted.

Keywords: Systemic lupus erythematosus

G. Kolibaeva1, G. Tarasova1, B. Belov3, A. Boltbekova1, A. Turatbekova1, G. Suyun K1, 1, 3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan; 2, Kashkinkoye Shoose, 34, Rheumatology, Moskva, Russian Federation; 2, Kashkinkoye Shoose, 34, Rheumatology, Moskva, Russian Federation

Background: Pneumococcal vaccination in systemic lupus erythematosus (SLE) is designed to reduce the risk of severe respiratory infections in this group of patients. The issues of vaccination safety remain relevant.

Objectives: to study the dynamics of immunological parameters in patients with SLE during the year after vaccination with 23-valent polysaccharide pneumococcal vaccine (PPV-23), their correlation with the clinical picture of the disease.

Methods: 78 patients with SLE were included in the study. 4 patients received monotherapy (GC-1, methotrexate-1, GC-1, anti-B-cell therapy-1), the rest received combination therapy, including 29 - anti-B-cell therapy, 3 groups of patients were identified for analysis: 1, patients (36) who received stable doses of immunosuppressive drugs, 2, patients (31) who had their medication doses reduced during the year, 3, patients (11) who received increased doses of medications during the year. The follow-up period was 12 months after vaccination.

Results: During the observation period, no new autoimmune phenomena, both clinical and laboratory, were recorded. Stable therapy group: in the first 1-3 months after vaccination, 4 out of 36 patients had a transient increase in a-DNA without an increase in ANF and without signs of exacerbation of the disease. Another 4 had an increase in ANF (1 had a transient increase), without an increase in a-DNA and without signs of deterioration. By 12 months, there was an increase in a-DNA in 4 and ANF in 5 patients. Moderate exacerbation of the disease was recorded in 3 patients (after 3.5 months, 5 months, 12 months): the first case, persistently high immunological activity and clearly insufficient therapy were observed; in the second case, the exacerbation was not accompanied by an increase in immunological activity at all; in the third case, the exacerbation occurred after 12 months with a moderate increase in immunological activity.
ARTHRITIS IN ITALY IN THE LAST DECADE

THE INCIDENCE AND PREVALENCE OF RHEUMATOID ARTHRITIS IN ITALY IN THE LAST DECADE

Keywords: Registries, Epidemiology, Rheumatoid arthritis

1University of Padova, Department of Medicine DIMED, Padova, Italy; 2Azienda Zero, Veneto Region, Clinical governance Unit, Padua, Italy; 3Azienda Zero, Veneto Region, Epidemiological Department, Padua, Italy; 4Azienda Zero, Veneto Region, Clinical governance Unit, Padua, Italy

Background: Rheumatoid arthritis (RA) prevalence is believed to be around 1% worldwide, although it varies considerably among different populations.[1] Several environmental factors such as smoking, certain infections, and diet contribute to the risk of RA and differ between populations.[2] The pooled prevalence of RA was estimated to be 0.54% (95% CI 0.50–0.59) in Europe,[1] but no studies have recently evaluated the epidemiology of RA in Italy.

Objectives: We aimed at estimating the incidence and prevalence of RA in northeastern Italy over the period 2012–2020.

Methods: A retrospective population-based study was conducted in the Veneto Region (4.9 million people) using the Population Registry, an administrative health database where all residents are recorded. The population registry was linked with healthcare co-payments exemptions, hospital discharge records, and mortality records. Between 2012 and 2020, RA prevalence was defined by a healthcare copayment exemption for RA diagnosis, number, and mortality records. Between 2012 and 2020, RA incidence corresponded to 33.1 (32.5; 33.7) per 100,000 person-years, with the lowest incidence observed in the last two years of the study: 27.4 (25.9; 28.9) in 2020 and 32.2 (30.6; 33.8) in 2019 (Table 1). The peak for both prevalence and incidence was around the eighth decade of life. Incidence was 2-times higher in females—female-to-male IRR ratio (IRR) 2.5 (2.2; 2.4) (p<0.0001), with a peak among people aged 20–29 years, where female-to-male IRR was 3.1 (2.4; 3.9) and the lowest value among patients aged ≥70 years, where F:M IRR was 1.6 (1.4; 1.8).

Conclusion: The prevalence of RA in Italy is 0.57%, in line with data from other European countries. Incidence was confirmed to be higher among females, especially in younger patients.

Background: Few studies include a sufficient number of people to be representative of a general population and to estimate the musculoskeletal pain prevalence.

Objectives: To estimate the prevalence of musculoskeletal and widespread pain in the French population using a large and representative cohort.

Methods: The Constances cohort is composed of volunteers, aged 18 to 69 years at inclusion. Eligible subjects were selected at random by stratified sampling with unequal probabilities, over-representing individuals with a higher probability of not volunteering (according to their age, sex, socioprofessional category) with adjustment coefficients weight participation bias. Individuals diagnosed with a cancer were excluded. Musculoskeletal pain was assessed by the Nordic Questionnaire. Significant pain lasted at least 30 days during the last 12 months. Widespread pain concerned at least 4 of the 6 areas. Chronic moderate to severe pain reached a pain score ≥ 4/10 in the last 7 days. Data from the entire cohort were described and then the French population prevalence was estimated, based on people included in 2017 with adjustment coefficients.

Results: 193,436 people were included in the cohort. The French population prevalence of each pain location and widespread pain were estimated among the 25,472 people included in 2017.

Conclusion: The prevalence of musculoskeletal and widespread pain in the French population is high, particularly for chronic pain of moderate to severe intensity, which underlines the need to improve their detection, prevention and management.

AB1630 RISK FACTORS FOR CARDIAC INVOLVEMENT IN IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Cardiovascular disease, Heart, Myositis

K. Suzuki1, Y. Kondo1, S. Ishigaki1, S. Takanashi1, Y. Kaneko1. 1Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Idiopathic inflammatory myopathies (IMMs) are heterogeneous systemic autoimmune disorders that mainly affect the skin, muscles, and lungs. Whereas cardiac involvement is considered to be rare, it causes cardiac inflammation and fibrosis leading to severe morbidity and mortality. However, little is known about clinical characteristics and risk factors for cardiac involvement in patients with IMMs.

Objectives: The aim of this study was to clarify the frequency and clinical characteristics of cardiac involvement and its risk factors in patients with IMMs.

Methods: We retrospectively reviewed consecutive patients with IMMs who visited Keio University Hospital from 2002 to 2022. We divided patients into two groups according to the presence or absence of symptomatic cardiac involvement and compared their clinical characteristics and autoantibodies between the two groups. We defined symptomatic cardiac involvement as the presence of chest pain, palpitation, cardiogenic leg edema, or respiratory distress accompanied by abnormal findings of cardiac examinations such as electrocardiography, echocardiography, and/or cardiac magnetic resonance imaging (MRI).

Results: We included 145 patients with IMMs in the analysis. The mean age at IMMs diagnosis was 55 years old, and 71.7% were female. Forty patients (27.6%) were polymyositis, 53 (36.6%) were dermatomyositis, 44 (30.3%) were amyopathic dermatomyositis, and 8 (5.5%) were immune-mediated necrotizing myopathy. Among them, 52 patients (35.9%) had abnormal findings on electrocardiography, echocardiography, and/or cardiac MRI, and 17 (11.7%) were diagnosed with symptomatic cardiac involvement at the mean age of 65 years during the mean observation period of 20.0 years. Comparison of clinical characteristics identified no difference in the mean age, sex distribution, and duration from IIM diagnosis to symptomatic cardiac involvement between the two groups. Also, no significant difference was found in the positivity of anti-amyocay/IRNA synthetase antibody, anti-MDA5 antibody, and anti-SS-A antibody, IMMs subtypes, presence of skin rash, malignancy, interstitial lung disease, history of cyclophosphamide use, and maximum levels of CK, aldolase, CK-MB, troponin T, and CRP. However, the presence of Raynaud’s phenomenon and neutrophil/lymphocyte ratio at diagnosis were significantly higher in the cardiac involved group compared to the non-cardiac involved group (53.85% vs 15.24%, p = 0.0009; 56.2% vs 18.25%, p = 0.0006). Multivariable analysis identified Raynaud’s phenomenon (odds ratio [OR] 8.42, 95% confidence interval [CI] 2.10-33.8, p = 0.0026) and elevated neutrophil/lymphocyte ratio (OR 6.92, 95% CI 1.73-27.6, p = 0.0061) as independent risk factors for symptomatic cardiac involvement. One patient in the cardiac involved group died of cardiac failure during the observation period.

Conclusion: Abnormal findings in cardiac examinations and symptomatic cardiac involvement are frequent in patients with IMMs. Evaluating cardiac involvement is important, especially in patients with Raynaud’s phenomenon and elevated neutrophil/lymphocyte ratio at diagnosis.

AB1631 ASSOCIATION BETWEEN HYPERURICEMIA AND HEARING IMPAIRMENT: RESULTS FROM THE KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY

Keywords: Gout

H. Jeong1, Y. S. Chang2, E. J. Park2, C. H. Jeon1, 1 Soonchunhyang University Bucheon Hospital, Internal Medicine, Bucheon, Korea, Rep. of (South Korea); 2 Sanggye Paik Hospital, College of Medicine, Inje University, Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Rep. of (South Korea); 3 National Medical Center, Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Hyperuricemia is associated with variety of comorbidities. Researchers suggest that the inflammation and increased oxidative stress produced by uric acid can impact the auditory system.

Objectives: This study investigated the association between hyperuricemia and hearing impairment in Korean adults.

Methods: Audiometric and laboratory test data from the 2019 to 2020 Korean National Health and Nutrition Examination Survey (KNHANES) were used for analysis. Hearing impairment was defined as a pure tone average (0.5, 1, 2, 4 kHz) threshold level of ≥ 41 desibels (dBs). Definition of hyperuricemia was different in males and females (>7 mg/dL in males and >6 mg/dL in females.

Results: A total of 4,857 (weight n = 17,990,725) subjects were analyzed. Mean age was 56.8 years old and female was 51.7%. Weighted prevalence of hyperuricemia was 12.1%. and hearing impairment was 13.4%. In univariable analysis, hyperuricemia was significantly associated with hearing impairment, but diagnosis of gout was not associated with hearing impairment. In multivariable analysis, hyperuricemia (Odds ratios [OR] 1.41, 95% confidence interval [CI] 1.03-1.92, p = 0.030) was associated with hearing impairment along with age (OR 1.12, 95% CI 1.10-1.14, p < 0.001), female (OR 0.43, 95% CI 0.34-0.64, p < 0.001), education (OR 0.43, 95% CI 0.30-0.63, p = 0.001), and occupational noise exposure (OR 1.67, 95% CI 1.25-2.22, p = 0.001). In subgroup analysis, hyperuricemia was associated with hearing impairment in female group and elderly group aged 60
We identified 3251 patients with SLE followed at n° 9 referral centers of Florence, Department of Experimental and Clinical Medicine, Florence, Italy; Università of Roma Tor Vergata, Rheumatology, Allergology and Clinical Immunology - DiMePRe-J, School of Medicine, Bari, Italy; Azienda Ospedaliero Universitaria Pisana, Department of Clinical and Regenerative Medicine and Ionian Area - Transplantation - Section of Rheumatology, Bari, Italy; University of Rome Campus Biomedico, Rheumatology and Immunology Unit, Department of Medicine, Rome, Italy; Università Cattolica del Sacro Cuore, Fondazione Policlinico Universitario A. Gemelli, IRCCS, UOC Reumatologia, Rome, Italy; Università di Roma ‘La Sapienza’, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy; University of Naples Federico II, Department of Translational Medical Sciences, Naples, Italy; University of Campania ‘Luigi Vanvitelli’, Department of Precision Medicine, Naples, Italy; University of Bari, Department of Emergency and Organ Transplantation - Section of Rheumatology, Bari, Italy; University of Bari ‘Aldo Moro’ Department of Precision and Regenerative Medicine and Ionian Area - DimEPre-J, School of Medicine, Bari, Italy; University of Cagliari and AOU Cagliari, Rheumatology Unit, Cagliari, Italy; Academic Hospital ‘Santa Maria della Misericordia’; Azienda Sanitaria Universitaria Friuli Centrale (ASUFC), Division of Rheumatology, Udine, Italy.

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease mostly affecting the young women during their third-fourth decade of life. SLE is characterized by variable manifestations and, potentially, every organ can be involved. The course and the complexity of the disease, naturally appeal to manage patients with SLE at high qualified national referral centers. [1]

Despite the relevant burden associated with the disease, both from patient and physician point of view, epidemiological data on SLE in Italy are limited to isolated estimates, captured by different data sources [2-5]; however, no larger data on the prevalence of SLE at the referral centers in Italy are available to date.

Objectives: This study aimed at estimating the prevalence of SLE at tertiary referral Italian centers, representative of the Italian scenario.

Methods: We conducted an observational, cross-sectional study on SLE patients followed by referral centers in district, representative of the North, Centre, South and Isles of Italy (Brescia, Padua, Udine, Ferrara, Florence, Pisa, Rome, Bari, Naples, Cagliari). Data from patients of both sexes and any age, and fulfilling the 2019 ACR/EULAR classification criteria, were obtained from hospital medical records. To estimate the prevalence, we reported the number of patients with SLE referring to the considered centers (nominator), over the total population resident in the included Italian districts (denominator), according to the Italian National Statistical Institute (ISTAT), responsible for the Italian general population censuses. For the analysis, we considered only complete data sent by January 13th, 2023. [7]

Results: We identified 3251 patients with SLE followed at n° 9 referral centers included in this study. 1163/3251 patients (89.3%) were female, and 1302/3251 (40%) were residing in the districts of the referral centers. The estimated overall prevalence of SLE was 21.37 cases per 100,000 individuals. As we stratified the results by geographical area (North, Centre, South and Islands) of Italy, the estimated prevalence ranged from 14.7 to 27.1 cases per 100,000 individuals. (Table 1)

(40%) were residing in the districts of the referral centers. The estimated overall prevalence of SLE was 21.37 cases per 100,000 individuals. As we stratified the results by geographical area (North, Centre, South and Islands) of Italy, the estimated prevalence ranged from 14.7 to 27.1 cases per 100,000 individuals. (Table 1)

(1) Conclusion: Our study estimated the prevalence of SLE in multiple representative Italian referral centers. These preliminary results show for the first time the proportion of patients with SLE attending tertiary referral centers in Italy, suggesting a different distribution in diverse geographical areas of the country.

[5] Zen, Rheumatology 2022
prevalence in older age groups (prevalence per million in 2020: <18 years: 7.5; 18–39 years: 42.5; 40–64 years: 93.1; and 65–74 years: 181.3). From the MDV database, 1870 patients with EGPA were included in 2020, 59.9% of whom were female, and 5.2% were aged 18–39 years, 36.4% 40–64 years, 30.6% 65–74 years, and 27.4% ≥75 years. Mepolizumab was prescribed for EGPA in <1.0% of patients before 2017 and use increased over time from 2.4% in 2017 to 20.6% in 2020. OCS remained the most prescribed treatment through 2020 (83.4%), with azathioprine used by 17.8% and injectable corticosteroids by 15.3%. Proportion of patients that used zero/low prednisolone-equivalent daily OCS doses increased from 2017 (0 mg: 13.6%; >0–<5 mg: 41.8%) to 2020 (0 mg: 16.6%; >0–<5 mg: 42.1%); while those who used >10 mg decreased from 2017 (11.9%) to 2020 (10.3%; Figure 1). Median OCS daily dose was 4.9–7.7 mg between 2010 and 2016, and 4.5–4.8 mg between 2017 and 2020, with the lowest dose in 2020 (4.5 mg (IQR 1.6–6.8)). Proportion of EGPA patients with comorbidities related to corticosteroids remained relatively consistent over time, except for infectious disease which showed a decrease from 94.4% in 2010 to 70.9% in 2020. Proportion of patients with other comorbidities in 2020 were dyslipidemia (37.6%), hypertension (23.4%), fracture (12.3%), mood disorders (10.1%), and cataract (7.2%). Of 1717 revisiting patients in 2020, 41.6% relapsed, which was 5.0–37.4% lower than in the years 2010–2019. In the subgroup of 24 patients new to mepolizumab from the JMDC database, the 41.6% relapsed, which was 5.0–37.4% lower than in the years 2010–2019. In the 90 days before to 4.3 mg (2.7) in the 4th quarter after mepolizumab initiation.

**Conclusion:** Despite an improvement in EGPA management is warranted.

**RISK FACTORS ASSOCIATED WITH PARCIAL OR NULL REMISSION OF REMNANT ACTIVITY IN PATIENTS WITH LUPUS NEPHRITIS**

**Keywords:** Systemic lupus erythematosus, Remission, Kidneys

A. Martínez Badaño1, J. R. Hernández Vásquez2, M. Ocampo Torres3, A. Ramírez Pérez4, A. Camargo5, F. M. Bravo Rojas6, J. Hernández Rivera7.

1ESM - Escuela Superior de Medicina - IPN, Social Service, Ciudad de México, Mexico; 2XXI Century National Medical Center, Rheumatology service, Ciudad de México, Mexico; 3XXI Century National Medical Center, Nephrological Diseases Medical Research Unit, Ciudad de México, Mexico

**Background:** Systemic Lupus Erythematosus (SLE) is a multisystemic autoimmune chronic disease, the severity of organ involvement depends on factors such as sex, race and age of disease presentation. Lupus nephritis is present in up to 40% of patients with SLE. Failure to achieve complete remission at 6 months is associated with a poor long-term prognosis and implies greater use of immunosuppressants.

**Objectives:** To determine the factors associated with the partial or null remission in patients with lupus nephritis.

**Methods:** A nested case-control study was conducted in a retrospective cohort of patients with lupus. Fifty-five patients with renal involvement were included and divided into two groups, those with partial or no remission in response to remission induction (n=30) and those with complete remission (n=25), multiple factors were analyzed and in the case of quantitative variables they were categorized into 2 groups with specific cut-off points in each case. The type of remission of each patient was taken as a factor to be analyzed and the analysis was completed in a bivariate logistic regression with a significance <0.05.

**Results:** The variables that showed risk of presenting a partial or null response were: not having completed the minimum time of 6 months of the remission induction scheme (Odds Ratio (OR): 9.590; 95% Confidence Interval (95% CI): 2.351–30.19; p=0.019), male sex (OR: 8.727; 95% CI: 1.009-75.51; p=0.049); Start Renal Replacement Therapy (RRT) (OR: 8.727; 95% CI: 1.009-75.51; p=0.049); have a Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) ≤60 ml/min/1.73m² (OR: 6.147; 95% CI: 1.577-26.110; p=0.009); Creatinine ≥1.2mg/dL (OR: 6.000; 95% CI: 1.767-20.369; p=0.004); C-Reactive Protein (CRP) ≥5g/dL (OR: 5.470; 95% CI: 1.680-17.811; p=0.005); age ≤30 years (OR: 4.250; 95% CI: 1.370-13.168; p=0.012); proteinuria ≥1.5g/24 hours (OR: 3.560; IC 95%: 1.123-11.285; p=0.31).

**Conclusion:** The factors observed that are associated with a partial or null remission were: not completing the remission induction scheme, male sex, start with RRT, CKD-EPI ≤60 ml/min/1.73m², creatinine ≥1.2mg/dL, CRP ≥5g/dL, age ≤30 years and proteinuria ≥1.5g/24 hours. On the other hand, factors such as a family history of SLE, BMI ≥30kg/m² and hemoglobin ≤10g/dl although they demonstrated an association, the values weren’t statistically significant. These factors make it possible to identify areas of interest when starting remission induction therapy, demonstrating the importance of therapeutic adherence and individualized follow-up for each patient, offering timely intervention in modifiable factors and close monitoring of patients with non-modifiable factors.

Conclusion: More than 1 out of 5 women with RD had substantial level of depressive symptomatology on at least one occasion in the 12 months after delivery on the EPDS. Self-reported symptoms of anxiety and depression should be evaluated during pregnancy and patients could be offered a psychological interview. Our study underlines the need for a closer monitoring of mental health of pregnant women with RD and the opportunity for further studies to identify risk factors and screening procedures.

Objectives: We performed a retrospective study of all patients followed for primary Sjögren’s (pSS) in internal medicine and rheumatology at the University hospital of Martinique, only hospital on the island, between 2014 and 2016 included according to international criteria (AECG 2002, ACR/EULAR 2016).

Results: Among 112 patients diagnosed with pSS, 75 and 84 patients were declared, José Luis Martín-Varillas: None declared, David Martínez-López: None declared, Iñigo Gonzalez-Mazon: None declared, Lara Sanchez-Bilbao: None declared, Raúl Fernández-Ramón: None declared, Jorge Javier Gaitán-Valdizán: None declared, Fabricio Benavides-Villanueva: None declared, Galapagos and MSD, Consultant of: Abbvie, Pfizer, Roche, lilly, Consultant of: Abbvie, Martinique, nowhere else.

Background: Influence of geolocation and ethnicity on pSS prevalence and phenotype has been reported [1] and black pSS appear to have higher risk of unfavorable outcome[2]. In Europe, pSS prevalence ranges from 10.2 to 28.6/100,000 inhabitants[3]. Data on primary Sjögren’s disease (pSS) in populations of sub-Saharan origin are very limited and concerns mostly Europeans and Asians. Both in Africa and the African diaspora (AAD)[4,5], patients face significant healthcare limitations because of socio-economic disadvantage. In Martinique, a French island of the Caribbean where more than 90% of the population is of sub-Saharan African descent, access to healthcare is easy and free for every citizen. pSS are treated in the Reference Center for rare systemic autoimmune diseases of the island. No other primary care facility treats pSS.

Methods: We aim to describe pSS in an Afro-descendant population in healthcare care accessible comparable to Europeans.

RISK FACTORS FOR DEVELOPING RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS AFTER IMMUNOTHERAPY WITH IMMUNE CHECKPOINT INHIBITORS

Keywords: Malignancy

M. Liao1, K. Chazidzionyisio1, 1Karolinska Institute, Rheumatology Division, Department of Medicine Solna, Stockholm, Sweden

Background: Immunotherapy with monoclonal antibodies that block specific immunological check-points has revolutionized the treatment of some forms of cancer, such as melanoma. A new group of adverse events has emerged with these new agents, called the immune-related adverse events (irAEs). Among these irAEs, rheumatic complications are relatively common, although the true frequency is still unclear. Objectives: We aimed to assess the frequency of ir-AEs and rheumatic ir-AEs in particular, as well as identifying potential risk factors for ir-AEs in a cohort of patients with malignant melanoma receiving immunotherapy with immune checkpoint inhibitors (ICI).

Methods: Retrospective analysis of a cohort of patients diagnosed with malignant melanoma and starting treatment with a first-ever ICI at Karolinska University Hospital between 2012 and 2020. The type of ir-AEs, glucocorticoid therapy at immunotherapy start, demographics and type of ICI were collected from patient’s journals.

Results: A total of 118 patients were included in the cohort, 75 male (63.6%) and 43 females (36.4%). The type of ICI was nivolumab in 54.2% of patients, ipilimumab in 13.6%, pembrolizumab in 22.9% and combination therapy with nivolumab and pembrolizumab in 7.6%, ipilimumab and pembrolizumab in 0.8% and at diagnostic and high frequency of hypergammaglobulinemia correlated with increased ESR. Considering this AECG 2002 hospital-based cohort and the retrospective aspect of the study, a minimum prevalence of pSS was calculated at 16.87/100 000 inhabitants in 2016.

Conclusion: Our data, shared by other AAD cohorts[4,5], suggest that AD pSS have specific manifestations around the world as AAD Systemic Lupus erythematosus do. A higher prevalence is reported compared to that of 21/100 000 inhabitants of France European pSS cohort[3].

nivolumab and pembrolizumab in 0.9%. Any irAE developed 72/118 patients (61%), while rheumatic irAEs were seen in 24 patients (20.3%) with the following clinical phenotypes: arthralgia/myalgia in 8 patients (37.5%), PMR like syndrome in 3 patients (12.5%), arthritis in 6 patients (25%), sicca syndrome in 4 patients (16%), sarcoidosis in 1 patient (4.2%) and myositis in 1 patient (4.1%). There was no significant association between the type of ICIs or combination therapy in total with the development av irAEs (OR = 0.79, 95% CI = 0.45 – 1.37, p=0.30). Neither the gender (OR 1.12, 95% CI = 0.52-2.40, p=0.76) nor the glucocorticoid use at the ICI start were associated with the development av irAEs [OR=2.0, 95% CI=1.03-3.92, p=0.04]. No significant associations were observed between demographic factors (age, gender), type of ICI, glucocorticoid use at the start of ICI and rheumatic irAEs.

Conclusion: IrAEs are common and occur in more than half of patients treated with ICI. Rheumatic irAEs are also common and in this study were seen in one fifth of patients. Gender, age, type of ICI and treatment with glucocorticoids at base line were not associated with increased (or decreased) risk for irAEs in general, or rheumatic irAEs in particular, in this cohort of patients with melanoma, with the risk of type II error due to limited power.

ASSOCIATION BETWEEN HYPERURICEMIA AND BONE MINERAL DENSITY WITH 8-YEAR FOLLOW-UP AMONG CHINESE ADULTS

Keywords: Osteoporosis, Epidemiology, Gout

J. Zeng1, H. Liu1, L. MA1. Guangdong Second Provincial General Hospital, Department of Ultrasound, Guangzhou, Guangdong, China

Background: Hyperuricemia (HUA) have been associated with bone mineral density (BMD) in recent studies, especially for elderly men and peri- or postmenopausal women[13]. However, this association is still unknown for the long-term follow-up observation.

Objectives: This study investigated the relationship between hyperuricemia and bone mineral density at 8-year follow-up among Chinese adults.

Methods: The cohort study was collected at Guangdong Second Provincial General Hospital in Guangzhou City, China between January 2010 and December 2018. Physical examinations and laboratory measurement variables were obtained from the medical check-up system. The physical examination population was followed up annually for 8 years. Multivariate Cox proportion models was used to explore the relationship between the hyperuricemia and bone mineral density.

Results: In total, 9017 individuals were included (2820 HUA participants (39.6% female) at baseline with an average age of 44.85 years (SD: 12.35) and average BMD of -0.83 (SD:1.24). The BMD decreased annually at the 8-year follow-up (from -0.82 to -0.93). Compared with normal participants, the Cox regression analysis showed that hyperuricemia was significantly associated with lower BMD (T=-2.5) (hazard ratio (HR)=1.169, 95%CI: 1.059–1.290, P <0.05), the male (HR=2.545,95%CI: 2.389–2.710, P <0.05) and the elderly (age≥65) (HR=1.121,95%CI: 1.012–1.241, P <0.05) at follow-up.

Conclusion: Our study observed participants with hyperuricemia had significantly lower BMD, especially for males and the elderly participants. More high-quality research is needed to further support these findings.

PREVALENCE AND ASSOCIATED FACTORS OF ATLANTOAXIAL SUBLUXATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTER RETROSPECTIVE STUDY

Keywords: Rheumatoid arthritis, Imaging

Y. J. Song1, 2, S. Y. Kim3, C. Lim3, H. W. Kim3, E. Nam3, S. K. Cho1, 2, Y. K. Sung1, 2, 3. Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Hanyang University Institute for Rheumatology Research, Center for Clinical Research, Seoul, Korea, Rep. of (South Korea); 3Hanyang University, College of Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Atlantoaxial subluxation (AAS) is a serious complication of rheumatoid arthritis (RA) that can cause severe neck pain and neurological injury.

Objectives: This study aimed to identify prevalence and associated factors of AAS in Korean RA patients.

Methods: Data of RA patients who visited an academic referral hospital in Korea between September 2007 and August 2020 were extracted. Patients who were <19 years old, had another autoimmune disease, and did not check cervical spine (C-spine) radiography were excluded. The date of the first C-spine radiography was set as the index date, and AAS was defined with anterior atlantoaxial interval (AADI) greater than 3mm. We performed multivariable logistic regression analysis to identify associated factors for AAS. The proportion of patients with AAS progression or those who received surgical treatment for AAS during observation period was investigated.

Results: There were 1,855 patients with diagnostic code of RA, and 1,115 patients with RA who checked C-spine radiography at least once were included. Among them, 156 patients had AAS at the index date with a prevalence of 14.0%, and the mean AADI in patients with AAS was 4.9±1.7 mm. In multivariable logistic regression analysis, longer duration of RA, lower body mass index (BMI), C-spine spondylosis, erosive changes on hand X-ray and higher C-reactive protein were significant associated factor for AAS. Among 156 patients with AAS, 106 patients performed C-spine radiography follow-up (mean interval 5.5±3.7 years). There were 16 patients (15.1%) with progression of AAS or surgical treatment: 12 patients who received surgery for AAS and four patients with AAS progression without surgical treatment.

Conclusion: In this study, 14.0% of patients with RA had AAS. Duration of RA, BMI, C-spine spondylosis, bone erosion at hands and RA activity were factors...
associated with AAS. 15.1% of RA-AAS patients showed progression of AAS or received surgical treatment during 5.5 years of observation.

TOBACCO SMOKING HAS A PREVENTIVE EFFECT ON THE INCIDENCE OF KNEE OSTEOARTHRITIS: 10-YEAR RETROSPECTIVE COHORT STUDY BASED ON KOREA NATIONAL HEALTH INSURANCE SERVICE-HEALTH SCREENING DATABASE

Keywords: Osteoarthritis, Epidemiology

J. Park1, M. Son2, S. Y. Lee1, W. T. Chung1, S. W. Lee1. 1Dong-A University Hospital, Division of Rheumatology, Department of Internal Medicine, Busan, Korea, Rep. of (South Korea); 2Dong-A University, Department of physiology, Busan, Korea, Rep. of (South Korea)

Background: Previous cross-sectional studies reported that smoking lowers the incidence of knee osteoarthritis, however, some studies show no correlation between smoking and knee osteoarthritis. Thus, the relationship between the two has not been clarified [1,2]. To address this issue, we designed a retrospective cohort study to investigate the association between smoking and knee osteoarthritis, using a large-scale claim database from Korea. To the best of our knowledge, this is the first retrospective cohort study on smoking and knee osteoarthritis in Korea.

Objectives: We intended to investigate whether there was a difference in the incidence of knee osteoarthritis between patients with a history of current smoking, past smoking and those without a history of smoking.

Methods: The Korea National Health Insurance Service-Health Screening database is registered with 98% of Koreans and includes all insurance claims. From this database, a retrospective cohort observational study was conducted on 316,387 adults who had undergone the national health examination. Patients diagnosed with knee osteoarthritis prior to the examination and patients who were diagnosed with knee osteoarthritis in 2002 were excluded. The primary endpoint of this study was a diagnosis of knee osteoarthritis. The operational definition of diagnosis of knee osteoarthritis was knee osteoarthritis code (M17) or any site of osteoarthritis code (M15 to M19) along with a knee x-ray (G720, G721) [3]. The study population was followed from the day of health screening at index year to the date of incidence of knee osteoarthritis, the date of death, or December 31, 2019, whichever comes first.

Results: The patient group was classified into non-smoker, ex-smoker, and smoker groups according to the responses to the health examination questions. Smoking history and non-smoker, ex-smoker, and smoker group with statistical significance (P-value < 0.001). When the disease-free probability for knee osteoarthritis was presented using the Kaplan-Meier curve, it was confirmed that the risk of osteoarthritis incidence was significantly different between the non-smoker group and the smoker group (P-value < 0.001). When the disease-free probability for knee osteoarthritis was presented using the Kaplan-Meier curve, it was confirmed that the risk of osteoarthritis incidence was significantly different between the non-smoker group and the smoker group (P-value < 0.001).

Conclusion: This large-scale retrospective cohort study showed a low incidence of knee osteoarthritis in smokers and ex-smokers during a follow-up period when compared to non-smokers in Korea. Additional studies on the relationship between smoking and knee osteoarthritis are required in the future.

A NATIONWIDE POPULATION-BASED STUDY OF EPIDEMIOLOGY, RISK FACTORS FOR CYTOMEGALOVIRUS DISEASE IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES

Keywords: Inflammatory arthritides, Comorbidities, Epidemiology

T. H. Li1,2,3, Y. S. Chang4, C. F. Su2, C. C. Lai2, C. C. Chuang1, C. Y. Tsai2, T. Shin Kong Wu Ho-Su Memorial Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China; 2National Yang Ming Chiao Tung University, Institute of Clinical Medicine, Taipei, Taiwan, Republic of China; 3Fu Jen Catholic University, School of Medicine, New Taipei City, Taiwan, Republic of China; 4Shin Kong Wu Ho-Su Memorial Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China; 5Shuang Ho Hospital, Taipei Medical University, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China; 6Taipei Veterans General Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China

Background: Human cytomegalovirus (CMV) ubiquitously distributes in general population but may cause overwhelming complications in patients with autoimmune inflammatory rheumatic diseases (AIIRDs), hence, the prevalence and associated factors of CMV disease in AIIRDs is worth investigating but the data has been limited.

Objectives: To investigate the epidemiologic data and risk factors of CMV infection in patients with AIIRDs.

Methods: The nationwide population-based cohort study was conducted by using Taiwanese National Health Insurance Database, to compare incidence rates (IR) and incidence rate ratios (IRR) of CMV disease patients with AIIRDs and non-AIIRDs age- and sex-matched cohort; CMV disease was defined as pertinent ICD codes with concurrent anti-CMV medication administration. The individual data in various AIIRDs were analyzed and risk factors were identified by Cox proportional regression.

Results: 94,429 patients with AIIRDs and 1:1 number of matched subjects were identified; higher incidence rate of CMV disease in AIIRDs group was noted than the matched cohort. Various comorbidities and therapeutic agents including azathioprine, cyclosporin, cyclophosphamide, mycophenolate, intravenous steroid and oral daily dose > 75mg prednisolone or equivalent, were associated with CMV disease incidence. Comparing with RA, SLE and DM/PM posed increased risks on CMV disease. Patients with AIIRDs carry higher risk of CMV disease regardless of etiologies, and attentiveness to one’s health is indispensable to facilitate early detection of CMV disease in patients with AIIRDs.

REFERENCES:

Background: Sarcopenia refers to a decrease in skeletal muscle mass and function. It is associated with daily life disability and a high risk of all-cause mortality. While sarcopenia is generally an age-related disease, it has recently been recognized to be prevalent in young patients with rheumatic musculoskeletal diseases (RMD). Especially, most patients with RMD with systemic organ manifestations are hospitalized to be treated with high-dose glucocorticoid (GC) leading to extremely low physical activity and prolonged bed rest for a long term. However, little is known about sarcopenia in patients with RMD who are administered high-dose GC in hospital.

Objectives: To clarify the incidence of sarcopenia and its risk factors in patients with RMD treated with high-dose GC therapy in more than one-month hospitalization.

Methods: We reviewed patients with RMD who had been hospitalized in Keio University Hospital from 2020 to 2021 and included those with skeletal muscle indices (SMI) before and one-month after high-dose GC treatment available in the analysis. We divided them into two groups according to progression of sarcopenia. Sarcopenia was defined as less than 5.4 kg/m² of SMI for woman and less than 7.0 kg/m² of SMI for man according to definition of Asian Working Group for Sarcopenia. Progression of sarcopenia was defined as more than 10% decrease in SMI from baselines. We compared clinical characteristics between the two groups and conducted multivariable analysis to identify independent risk factors associated with progression of sarcopenia.

Results: Forty-nine patients were enrolled. The mean age was 53.3 years old, and 36 patients (73.5%) were female. The most frequent disease was systemic lupus erythematosus (42.9%) followed by systemic vasculitis (18.4%) and idiopathic inflammatory myositis (14.3%). At hospital admission, 41 patients (83.7%) already met the definition of sarcopenia before high-dose GC treatment. After one-month hospitalization with high-dose GC treatment, two patients newly developed sarcopenia, and 28 (57.1%) patients were diagnosed with progression of sarcopenia. Patients in the sarcopenia progression group were male dominant (60.7 vs 90.4%, p=0.025), had a higher body weight (56.9 ± 12.9 vs 50.5 ± 7.5 kg, p=0.048), and showed higher SMI (5.5 ± 0.8 vs 5.1 ± 0.8 kg/m², p=0.008) than those in the non-sarcopenia progression group. Age (52.8 vs 55.8 years, p=0.755), underlying diseases, and starting dose of GC (0.98 ± 0.16 vs 0.96 ± 0.19 mg/kg/day, p=0.35) were not different between the two groups. During the mean observation period of 41.2 ± 10.4 days of hospitalization, the incidence of infection was higher in the sarcopenia progression group than the non-sarcopenia progression group (28.5 vs 5.7%, p=0.042). Multivariable regression analysis revealed body weight reduction from 0 to week 1 was associated with progression of sarcopenia (odds ratio 0.22, 95% confidence interval 0.04-0.61, p=0.007) (Figure 1). Receiver operating characteristic curve identified the reduction in body weight of -1.8 kg in one week predicted sarcopenia progression after one month in-hospital high-dose GC treatment.

Conclusion: Sarcopenia is frequent in patients with RMD, and one-month hospitalization with high-dose GC therapy worsened sarcopenia in more than half of patients. Early decrease in body weight can predict significant muscle volume loss after one month in-hospital therapy.

CONTRACEPTION IN WOMEN WITH IMMUNE-MEDIATED INFLAMMATORY DISEASE

Keywords: Education, Patient information and education

S. Rodriguez-Murguia1, S. Castro Oreiro1, M. J. Poveda1, N. Del Castillo1, M. Menacho2, G. Valldosera2, M. Just3, N. Mohino3, R. Fontova1,1Hospital Universitari de Tarragona Joan XXIII, Rheumatology, Tarragona, Spain; 2Hospital Universitari de Tarragona Joan XXIII, Gastroenterology, Tarragona, Spain; 3Hospital Universitari de Tarragona Joan XXIII, Dermatology, Tarragona, Spain

Background: Given that teratogenic medications prescribed to women with immune-mediated inflammatory disease (IMID) may cause significant fetal harm, the use of effective contraception is crucial in reproductive-age women receiving potentially teratogenic medications.

Objectives: To determine: Relationship between potentially teratogenic drugs and the efficacy of contraception methods. The prevalence of contraceptive methods in women of reproductive age with IMID.

Methods: Cross-sectional study (May 2021 - May 2022). All women of reproductive age with an IMID (rheumatology, dermatology and gastroenterology external consultation) were invited to participate. Patients with rheumatoid arthritis, psoriatic arthritis, anklyosing spondylitis, psoriasis, Crohn’s disease and ulcerative colitis were included. Patients with hysterectomy, primary or secondary amenorrhea were excluded. A self-administered questionnaire including questions on the use of contraceptive methods was administered. Medications prescribed for IMID were identified and assigned a pregnancy risk category (according FDA: Class A - B (safe to use during pregnancy), C (have not been adequately studied to assign a pregnancy classification) and D-X (potentially teratogenic, their use is relatively/ absolutely contraindicated during pregnancy). For women who were prescribed multiple drugs, we assigned their FDA risk category based on their drug with the highest potential teratogenicity. Contraceptive methods were also classified according to their relative effectiveness (based on World Health Organization (WHO)) (Table 1). When women had more than one contraceptive method we classified according to their most effective method. Our analysis categorizes drugs as either A/B/C or D/X, (“low risk” vs “high risk”). To determine the relationship between the potential teratogenic drug and the effectiveness of contraceptive method we used Chi-square tests.

Results: A total of 59 women participated (Table 2), mean age 41.2 (SD ± 6.8) years. Contraceptive use was referred by 41 (69.5%) of the patients (Table 1): 56.1% (23 patients) used a method classified as moderately effective, 31.7% (13) as highly effective and 9.8% (4) as ineffective. Of women with teratogenic drugs: 37.5% (15 patients) did not use a contraception method or it was considered as ineffective. The relationship between potentially teratogenic drugs and effectiveness of contraceptive methods has a P value of 0.668 (Table 3).

Conclusion: The prevalence of contraception methods in reproductive-age women with IMID is about 70%. In women who used a contraceptive method, contraception considered to be ineffective was the least frequent. We found no relationship between the risk of teratogenicity in drugs prescribed for IMID and the effectiveness of contraceptive method.

Methods: Patients with PMR referred for BMD (Bone Mineral Density) estimation in a district hospital in the northwest of England between 2004 and 2011 were examined. Patients' demographics were recorded and Bone mineral density (BMD) were measured in both hips as well as the lumbar spine. Fract(TM) Risk factors (RFs) for osteoporosis were also ascertained at the time of DEXA. Initially RFs were compared between men and women using a students' T test for continuous variables and chi squared test for categorical variables. A logistic model was then fitted to compare RFs for fracture between men and women. Lastly a stepwise multivariate model was fitted using STATA (tm) version 12.

Results: 1051 patients with PMR were referred in the reported period, mean age was 81.74 years (SD 9.58), 764 (84.7%) were females. Fractures were sustained in 26.3 % overall and there was a significant difference in males and females. Females were 2.58 times higher odds to sustain a fracture (CI 1.79 - 3.70). Using univariate logistic regression, the RFs for fracture in men were reduced lumbar spine BMD (OR,794, CI.657 to.959) and a reduced left femur total BMD (OR,74, CI.615 - .810). In women the RFs were increasing age (OR 1.04, CI 1.020 to 1.055), reduced lumbar spine BMD (OR,841, CI.764 - .926), reduced right femur total BMD (OR,738, CI.644 - .845), reduced left femur total BMD (OR,706, CI.615 - .810) and current steroid therapy (OR,573, CI.369 - .889). In the multivariate model the RFs in men were a diagnosis of coeliac disease (OR 1.738, CI 1.746 - 1.703), and a reduced left femur total BMD (783, CI.588 - 1.042). In women the RFs were increased age at scan (OR 1.025, CI 1.004 - 1.047), history of fracture (OR 1.891, CI 1.104 - 3.238), reduced left femur total BMD (.720, CI.611 - .849) and reduced BMI (OR 1.035, CI 1.002 - 1.068). Characteristics are shown in Table 1 below.

Conclusion: Men and women with PMMR differ in their bone health, firstly in their demographics and secondly in their fracture risk with men who malabsorb having the highest fracture risk. This is the first intimation that fracture risk could possibly be related to infectious environmental factors.

References:
Background: Digital technologies are commonly used by most patients, and the concept of e-health emerged some years ago. These tools, which include specific patient education programs, have been utilized in everyday practice. As axial spondyloarthritis (AxSpA) is a chronic disease, such digital tools could be useful. The aim of the study was to assess digital technologies use in an AxSpA population.

Objectives: The primary objective was to describe the use of digital technologies in patients with AxSpA treated bDMARDs. A secondary objective was to identify the factors associated with digital technology use.

Methods: We conducted a prospective, cross-sectional, observational study in 5 departments of rheumatology at French university hospitals. Patients were recruited from June 2021 to June 2022. Data were collected using questionnaires filled by the patient during follow-up. Medical information was collected by rheumatologists.

Results: 500 patients were included (age 49.5 ± 13.8 years, 47% women, 51% with radiograph sacro-iliitis, 71% with HLA-B27). Mean disease activity evaluated by BASDAI was 3.5 (SD ± 2.1), 429 (86%) received TNF inhibitor. 202 patients used digital technologies for their health (40%), 59 (30%) used a medical application for other chronic disease, and 54 (10.8%) had a specific application for spondyloarthritis (or rheumatic inflammatory disease). 39% used cellphone or sport-application for physical activity. Among users of digital technologies for AxSpA, most patients searched for information concerning their disease (65%) or treatment (54%). In multivariate analysis, the use of spondyloarthritic digital technologies was associated with BASDAI > 3.5 (OR: 2.06 [1.2-3.47], p<0.01), higher disease activity evaluated by BASDAI (OR: 1.12 [1.01-1.24], p<0.01), and being member of patient association (OR: 2.19 [1.17-4.15], p<0.01). The use of digital technologies for AxSpA was associated with being member of patient association (OR: 2.26 [1.32-3.83], p<0.01) and being member of patient association (OR: 2.18 [1.13-4.24], p<0.01). The use of digital technologies for AxSpA was associated with being member of patient association (OR: 2.18 [1.13-4.24], p<0.01) and being member of patient association (OR: 2.18 [1.13-4.24], p<0.01). The use of digital technologies for AxSpA was associated with being member of patient association (OR: 2.18 [1.13-4.24], p<0.01) and being member of patient association (OR: 2.18 [1.13-4.24], p<0.01).

Conclusion: To date, a significant proportion of patients use digital technologies for their AxSpA, but few a specific application for their rheumatism. The use of medical application is strongly associated with patient education program. Reliability and validated tools should be promoted by rheumatologists.

AB1649 2009 AND 2019-REVISED IWOS CRITERIA FOR OCULAR SARCOIDOSIS. A STUDY IN A SERIES OF 384 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL.

Keywords: Uveitis

C. Lasa1, J. Gaitán Valdizán1, L. Sanchez-Bilbao1, L. J. Martin-Varillas1, D. Martinez-López2, I. Gonzalez-Mazon3, R. Fernandez Ramon3, R. Demetrio-Pablo4, R. Blanco1, Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 2Marqués de Valdecilla University Hospital, Ophthalmology, Santander, Spain

Background: Sarcoidosis is a systemic inflammatory disorder which involves many organs, including eyes. International Workshop on Ocular Sarcoidosis (IWOS) criteria for diagnosis of ocular sarcoidosis (OS) were first published in 2009 and revised in 2019 (question-based survey and panel discussion) [1-2]. IWOS criteria is a remarkable tool to relate uveitis to sarcoidosis, especially when uveitis is the first manifestation in the systemic disease. Due to the consequences of OS, identify and initiate appropriate therapy is essential.

Objectives: To compare the results of IWOS criteria applied in the same population.

Methods: We studied a large cohort (n=384) of all consecutive patients diagnosed with sarcoidosis from January 1, 1999, to December 31, 2019. Finally, 344 patients were included according to the ATS/ERS/WASOG criteria [3]. First (2009) and revised (2019) IWOS criteria were applied to patients diagnosed with Sarcoidosis and ocular symptoms and the results were compared in both groups for our population. Concordance between 2009 and 2019 IWOS criteria was evaluated by calculating Cohen’s kappa coefficient.

Results: 65 (51% men) of 344 patients had ocular involvement (18.9%), mean age 56.7±16.3 years. As for nationality, 92.3% were Spaniard and 7.7% were South American. A positive biopsy for sarcoidosis was obtained in 75.4% (n=49) and a negative biopsy in 6.2% (n=4). There was no statistically significant difference between diagnostic groups for IWOS 2009/IWOS 2019 in age (p=0.738,p=0.495), sex (p=0.534,p=0.459) or nationality (p=0.529,p=0.393). When applied 2009 IWOS criteria, 60% (39 patients) met any of the diagnostic categories (43.1% Definitive, 13.8% Presumed, 15.0% Probable, 5% Possible). When 2019 IWOS criteria was applied, 53.8% (35 patients) met any of the new diagnostic categories (43.1% Definitive, 13.7% Presumed, 3.1% Probable). Sensitivity for IWOS 2009 was 0.6 and for IWOS 2019 was 0.53. There was a statistically significant concordance between 2009 and 2019 IWOS criteria (p=0.000001) with a strong consistency level (kappa = 0.824). When analyzing IWOS categories separately, we found total concordance in the Definitive category. Probable and Possible categories in 2009 criteria have been merged in only probable in 2019 criteria and there is a total concordance when comparing both. Presumed category represent the bigger change in the revised criteria. We found statistically significant concordance (p=0.000008) with a moderate consistency level (kappa = 0.524).

Conclusion: The revised 2019 IWOS criteria is less sensitive in our population; however, the main difference is in the category Presumed: the requirement of at least 2 intracocular signs of uveitis led to a change of 9 patients (13.8%) in 2009 IWOS down to 5 (7.7%) in 2019. In our population IWOS criteria is still has a low sensitivity.

Figure 1. Results of 2009 and 2019 IWOS criteria on a defined population.

Epidemiology, risk factors for disease or disease progression

**Keywords:** bDMARD, Geographical differences

C. Lasa¹, J. S. Osorio Chavez², D. Martínez-López³, C. Álvarez-Reguera⁴, V. Portilla¹, J. M. Cifrián-Martínez², I. Ferraz-Amaro³, R. Blanco¹. ¹Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; ²Marqués de Valdecilla University Hospital, Pneumology, Santander, Spain; ³San Cristóbal de La Laguna, Rheumatology, San Cristóbal de La Laguna, Spain

**Background:** Patients with rheumatic immune-mediated diseases (R-IMID) with latent tuberculosis infection (LTBI) requiring biologic therapy (BT) are at an increased risk of active tuberculosis (TB). The prevalence of LTBI in patients with R-IMID varies depending on geographical location. An accurate diagnosis and prophylactic treatment of LTBI is crucial to reduce the risk of developing TB. No definitive gold standard exists for diagnosing LTBI. Tuberculin skin test (TST) and interferon-γ release assays (IGRAs) are the most used tests.

**Objectives:** To assess: a) Prevalence of LTBI in patients with (R-IMID), b) determine the importance of using a booster test in negative TST, c) to compare TST with the IGRA test in the detection of LTBI in patients with R-IMID and d) to perform a literature review of prevalence of LTBI in different geographical areas and its relationship with R-IMID.

**Methods:** Cross-sectional single University hospital study including all patients diagnosed with R-IMID who underwent a TST (sbooster) and/or IGRA in a period from 2016 to 2020. If TST was negative, a new TST (Booster) was performed between 1 and 2 weeks after the first TST. Patients were diagnosed with R-IMID by an expert rheumatologist according to well-established ACR/EULAR classification criteria for each R-IMID. LTBI was defined by a positive TST and/or IGRA with no evidence of active TB. Diagnosis with IGRA vs TST was compared using Cohen’s kappa coefficient. We performed a literature review in search of previous prevalence studies of LTBI in patients with R-IMID. This search was performed in the month of August 2022. The aim of this review was to compare the prevalence of LTBI in patients with R-IMID in different geographical areas.

**Results:** We included 1117 patients (741 women/376 men), mean age 53±15 years with LTBI. Overall LTBI prevalence was 31.7 % ranging from 25% in SE to up to 33.3% in BD. Results of prevalence compared to other countries are shown in Table 1. Booster was positive in 66 patients (7.7%) out of 857 patients with a negative simple TST. TST (booster) was positive in 187 patients (22.9%) out of 817 with a negative or indeterminate IGRA test. IGRA test was positive in 30 (8.8%) out of 379 patients with a negative TST (booster), as it is represented in Figure 1. Cohen’s Kappa coefficient between TST(booster) and IGRA (QFT-plus), was 0.361.

**Conclusion:** LTBI is frequent between patients with R-IMID. LTBI screening is important in patients who need to receive BT. This assessment has to be done performing both TST and IGRA as complementary methods to ensure the detection of all patients with LTBI, since both tests can have false negative results, especially in patients with R-IMID, receiving immunosuppressive therapy.

Background: Diffuse alveolar hemorrhage (DAH) is characterized by rapid onset of pulmonary infiltrates and hypoxemia. It is a potentially life threatening complication associated with systemic autoimmune conditions.

Objectives: To describe the presentation, clinical features, etiology, treatment and outcome of DAH in rheumatological conditions.

Methods: This a retrospective, multicentre study involving 3 rheumatology centers, wherein data about DAH cases seen over the past 5 years was collected.

Results: There were 19 patients (Female = 15). The mean age was 38 years (18 - 67). DAH was the presenting feature in 15 patients (78%). The mean duration of symptoms was 20 days (1 - 60). The symptoms of DAH were: dyspnea 16 (84%), cough 15 (78%), hemoptysis 13 (68%). Other features of DAH like hypoxemia (18 patients), fall in hemoglobin (19 patients) were common. Fever was observed in 9 (47%). Nephritis was noted in 14 (73%). Renal biopsy was done in 6 (Lupus nephritis class 3 & 5 = 1; lupus nephritis class 4 = 1; Pauci immune crescentic glomerulonephritis = 3; Anti GBM associated crescentic glomerulonephritis = 1). The most common feature on chest radiograph was diffuse opacities (Image 1). The etiology of DAH was as follows (Table 1) - granulomatosis with polyangiitis (GPA = 8); Systemic lupus erythematosus (SLE = 7); anti GBM disease (2); Microscopic polyangiitis (MPA=1) and undifferentiated vasculitis [1]. The treatment of DAH included - Intravenous methylprednisolone (IV MP=18); Intravenous immunoglobulin (IVIG = 2); Extracorporeal membrane oxygenation (ECMO) = 1; Therapeutic plasma exchange = 3; Intravenous cyclophosphamide = 11; Rituximab (RTX) = 4; Mycophenolate mofetil (MMF) = 1. Most of the patients were treated with IV MP and required ICU care; Approximately half of the patients required ventilatory support. DAH is a potentially life threatening condition with an overall mortality rate of approximately 25%. Early recognition and appropriate treatment is needed for better outcome.

Conclusion: DAH was the presenting feature in most of the cases. GPA and SLE were the common causes. Dyspnea, cough and Hemoptysis were the common DAH symptoms. Fever and nephritis were the common Non - DAH clinical features. Dyspnea, cough and Hemoptysis were the common DAH symptoms. Fever was observed in 9 (47%). Nephritis was noted in 14 (73%). Renal biopsy was done in 6 (Lupus nephritis class 3 & 5 = 1; lupus nephritis class 4 = 1; Pauci immune crescentic glomerulonephritis = 3; Anti GBM associated crescentic glomerulonephritis = 1). The most common feature on chest radiograph was diffuse opacities (Image 1). The etiology of DAH was as follows (Table 1) - granulomatosis with polyangiitis (GPA = 8); Systemic lupus erythematosus (SLE = 7); anti GBM disease (2); Microscopic polyangiitis (MPA=1) and undifferentiated vasculitis [1]. The treatment of DAH included - Intravenous methylprednisolone (IV MP=18); Intravenous immunoglobulin (IVIG = 2); Extracorporeal membrane oxygenation (ECMO) = 1; Therapeutic plasma exchange = 3; Intravenous cyclophosphamide = 11; Rituximab (RTX) = 4; Mycophenolate mofetil (MMF) = 1. Most of the patients were treated with IV MP and required ICU care; Approximately half of the patients required ventilatory support. DAH is a potentially life threatening condition with an overall mortality rate of approximately 25%. Early recognition and appropriate treatment is needed for better outcome.

Keywords: Epidemiology, Adaptive immunity, Vasculitis

Methods: Observational study of patients diagnosed with GCA who underwent temporal artery biopsy (TAB) between January 2016 and December, 2022. The patients were divided into 3 groups: a) only cranial (cGCA), b) only extracranial (ecGCA), and c) mixed affection (mixGCA). The diagnosis of GCA was made only in extracranial patients were divided into 3 groups: only cranial (cGCA), extracranial (ecGCA), and mixed affection (mixGCA). The diagnosis of GCA was made according to a) temporal artery biopsy, and/or b) EULAR/ACR2022 criteria, and/or c) imaging techniques. Demographic, clinical, analytical and imaging techniques were studied.

Results: We included 191 patients (120 females/71 males), with a mean±SD age of 74.9±9.6 years. The main characteristics of the patients and the differences among phenotypes are shown in Table 1. Only a 27.2% of the patients had a positive TAB with a mean±SD length of 16.4±6.3mm. The GCA phenotype most frequent was the cranial GCA (cGCA). Headache (79.6%) was the most common ischemic manifestations, followed by the abnormal examination of temporal artery (46.6%) and visual symptoms (including 8.4% patients with blindness), jaw or lingual claudication (26.3%), and scalp tenderness (25.1%). Polymyalgia rheumatica (PMR) was the most frequent systemic manifestations, observing in 59.2% of the patients. The values of serum CRP and ESR are shown in Table 1.

Conclusion: GCA is a vasculitis which has increased its clinical spectrum with extracranial involvement, affecting people with a mean age of more than 70 years and with a female predilection. PMR appears to be present in more than half of the patients, mainly in extracranial phenotype.

</table>

Table 1. Main features of the GCA patients.

Keywords: Registries, Rheumatoid arthritis, Real-world evidence
Background: Rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) are diseases where inflammation plays a key role in their development and have an increased risk of developing comorbid conditions. It is important to evaluate the comorbidities associated with these diseases.

Objectives: Our objective was to evaluate the prevalence of comorbidities in RA, PsA and axSpA patients from the PANLAR’s register of rheumatic diseases (PANRED).

Methods: PANRED includes real world data from Latin American consecutive patients diagnosed with RA, PsA and axSpA (ACR-EULAR 2010/CASPAR 2006-ASAS 2009) from Dec 2021 to Dec 2022. We collected: demographics, disease characteristics (activity, severity, treatment), basal comorbidities (cardiovascu lar, infections, cancer, gastrointestinal, pulmonary, and others) data. Data were extracted from patients initiating treatment with cDMARDS, TNF alpha inhibitors (TNFi) and JAKinases inhibitors (JAKI). Categorical variables were expressed as percentage and tables of contingency were analyzed with chi-square or Fisher test. A p value less than 0.05 was considered significant.

Results: 768 patients were included. RA was the most frequent disease. The most prevalent comorbidities expressed as overall frequency were: hypertension: 39.5%, nonalcoholic steatohepatitis: 35.6%, dyslipidemia: 35.3%, tuberculosis 13.3%. Details of comorbidities are shown in the Table 1. Uveitis was more frequent in axSpA vs RA, RR: 2.5 (95%CI 1.35-4.8), p<0.001. Herpes zoster was present in 3.3%, 3.6% and 0.8% and tuberculosis in 15.85%, 15.1% and 3.8% in JAKi, TNFi and cDMARD groups respectively. Steatohepatitis was significantly more frequent in the cDMARD group compared Jaki and TNFi (p=0.01) and tuberculosis in the JAKI group (p=0.002) compared bDMARD and cDMARD, as basal characteristics, probably reflecting therapeutic decisions.

Conclusion: Cardiovascular comorbidities and tuberculosis are frequent in Latin American patients and should be considered in treatment selection.

THE USE OF MACHINE LEARNING METHODS IN OPIOID-ASSOCIATED OUTCOMES RESEARCH: A SYSTEMATIC REVIEW

Keywords: Artificial intelligence, Systematic review, Prognostic factors

C. Ramirez Medina 1, J. Benitez-Auríoles 1, D. Jenkins 2, M. Jan 3, 4 The University of Manchester, Musculoskeletal and Dermatological Science Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2The University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom; 3NHR Manchester Biomedical Research Unit, Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom

Background: Prescription opioids have been a considerable contributor towards the opioid epidemic, a major public health concern with profound economic repercussions and mortality. In order to address the opioid crisis, a need exists to improve understanding on how to personalise prescribing incorporating individual factors to estimate the risk of opioid-related harms. Machine learning (ML) techniques, both supervised and unsupervised, have potential identify patients at risk through the development of risk prediction models and a data-driven redefinition of patient classes. This might be particularly relevant when addressing the changing dynamics of the opioid epidemic, due to its ability to ascertain non-linear relationships between various risk factors and the risk of opioid-related outcomes.

Objectives: To perform a systematic review of the use of ML methods in prescription opioid-related harms research.

Methods: A systematic literature search was conducted using the databases OVID, EMBASE, PubMed and included 605 databases to identify relevant articles that were published from inception to October 2022. Articles were eligible for review if they described studies that applied ML techniques with a primary outcome that was related to prescription opioid harms and using electronic health records as a main data source for the research. We excluded studies that focused patients with cancer or younger than 18 years old.

Results: A total of 760 abstracts were reviewed, yielding 75 articles for full text review. Four main categories were identified in this area: development of ML algorithms for prediction (n=81, 81%), identification of risk factors (n=7, 9%),
patient subtype clustering (n=5, 7%) and the application of natural language processing to understand user-generated text for pharmacovigilance (n=2, 3%). Within the studies that developed ML models for prediction, most of them (n=16, 21%) had prolonged opioid use disorder (n=9, 12%), opioid administration and prescribing (n=6, 8%) and chronic opioid use (n=3, 4%). For risk factor identification, ML techniques were limited to understanding the drivers of opioid-overdose (n=2, 3%), opioid dependency (n=2, 3%) and opioid administration and prescribing (n=3, 4%). A very limited number of studies used unsupervised and semi-supervised ML algorithms to address opioid-associated outcomes (n=8, 11%).

Conclusion: To date, application of ML techniques besides logistic regression to classify patients who experience opioid-related harms has been limited, with most publications using electronic health records from the United States in the last 5 years. The majority focused on prediction algorithms for postoperative opioid use and have limited implementation in clinical practice. The current literature lacks external validation studies for developed prediction models using ML. This is especially important if implemented outside of the United States, where the use of opioids is affected by a diverse set of individual and contextual factors that can substantially vary across countries.

TIME-DEPENDENT CSMARDS USE AND INFLAMMATORY BURDEN CAN PREDICT CARDIOVASCULAR RISK IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A POPULATION-BASED STUDY

Keywords: Cardiovascular disease, Prognostic factors, Disease-modifying drugs (DMARDs)

J. L. Shi1, S. H. M. Lam1, H. Meng1, H. So1, L. S. Tam1. 1The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China

Background: It is well established that AS patients had a higher risk of cardiovascular disease (CVD) than the general population [1,2]. To date, there is no primary studies directly addressing the relationship between risk factors and MACE in population-level study.

Objectives: To examine whether inflammatory burden and drug use over time increase major adverse cardiovascular events (MACE) independent of traditional cardiovascular (CV) risk factors in ankylosing spondylitis (AS) patients.

Methods: Patients who had been diagnosed with AS (ICD-9: 720.0) from 2006 to 2015 were recruited in a retrospective cohort study. They were followed until the end of 2018. The primary outcome was a first incidence of MACE. Time-varying Cox proportional hazard models were used to assess whether inflammatory burden (c-reactive protein [CRP] and erythrocyte sedimentation rate [ESR]), and drug use (non-steroidal anti-inflammatory drugs [NSAIDs] and disease modifying anti-rheumatic drugs [DMARDs]) can predict the development of first MACE.

Results: Totally 3827 patients (age: 45.2 ± 15.0 years, male: 2911 [76.1%]) were recruited. 135 patients (13.2%) developed a first MACE. ESR level (including ESRs>20 mm/h and ESRs>30mm/h, HR: 2.07-2.41), CRP level (including CRP>3mg/dl, HR: 1.20-8.77) and use of steroid (HR: 3.48) were associated with a significant higher risk of MACE during follow-up. Whereas the use of sulfasalazine (SLZ) and/or biologics (bDMARDs) had protective association with reduced risk of MACE. After adjusting for time-fixed CV risk scores in the multivariable models, only ESR level (including ESRs>30mm/h, HR: 1.02-1.94) and CRP level (including CRP>3mg/dl, HR: 1.14-5.43) remained significant predictor for increased risk of MACE, while SLZ (HR: 0.41-0.52) was protective against MACE.

Conclusion: Increased inflammatory burden was associated with increased risk of MACE, while the use of SLZ may reduce risk of future MACE in patients with AS.

COMPARISON OF STERNECOLEIDOMASTOIDES FLEXIBILITY, VAGUS NERVE FUNCTION, AND GASTROINTESTINAL SYMPTOMS IN CHRONIC NECK PAIN AND HEALTHY INDIVIDUALS

Keywords: Gastrointestinal tract, Prognostic factors, Non-pharmacological interventions

Y. Özel Aslıyüce1, Ö. Uysal2, A. Fanuscu3, U. Berberoju4, O. Ulger1. 1Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

Background: The vagus nerve emerges from the jugular foramen and continues through the carotid sheath in the cervical region. The carotid sheath is in contact with the SCM muscle. It has been hypothesized that Sternokleidomastoideus (SCM) muscle tension may affect the carotid sheath and the function of the vagus nerve passing through it. It is known that there is an increase in activation of the SCM muscle in individuals with chronic neck pain (CNP), which may change the passive mechanical properties of the muscle [1]. It has been shown that vagus nerve dysfunction can cause pathologies in the organs it innervates. Although the relationship between vagal dysfunction and gastrointestinal system symptoms is clear, the mechanisms that may affect vagus nerve function have not yet been clarified.

Objectives: This study aims to compare the passive mechanical properties of the SCM muscle, vagus nerve function, and gastrointestinal symptoms in healthy individuals with neck pain.

Methods: Tone, stiffness and elasticity, which are the passive mechanical properties of the SCM muscle, were measured with the Myoton-3 myotonometric medical device (Muomeetria AS, Estonia, EU). Vagus nerve function was evaluated with the Vagus Neurodynamic Test (VAGUS-NDT)[2]. The test was performed bilaterally. Gastrointestinal symptoms were evaluated with the Gastrointestinal Symptom Rating Scale (GSRS).

Results: 29 individuals, 15 healthy, 14 with CNP, who were not diagnosed with gastrointestinal or any systemic disease were included in the study. In individuals with CNP, the positivity of VAGUS-NDT test and GSRS all sub-scores (reflux, indigestion, diarrhea, constipation and abdominal pain) and total score were higher than healthy individuals (p<0.05). In addition, right and left elasticity scores for the SCM muscle were lower in these individuals than in healthy individuals (p<0.05) while tone and stiffness were similar(p<0.05).

Conclusion: According to our preliminary results, SCM elasticity was lower and the incidence of vagal dysfunction and gastrointestinal symptoms were higher in individuals with CNP than in healthy. This may be due to compression of the vagus nerve passing through the carotid sheath as a result of decreased SCM muscle elasticity. The increase in the tension of the soft tissues around a nerve in the body restricts the movement of the nerve, affecting its function and making it susceptible to entrapment. Even this slight nerve compression can cause entrapment and lead to neuroinflammation[3]. This research is a preliminary conclusion that neck pain and decreased SCM elasticity may be an important factor that may affect vagal function. This relationship needs to be investigated with a larger sample group and advanced statistical methods.

RA: Rheumatoid Arthritis; SpA: Spino-Arthritis; LEAD: Laboratory Examination for Autoimmune Diseases.
Background: Patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) have increased risk of total hip arthroplasty (THA).[1,2] Patients with RA and SLE overlap syndrome (RA+SLE) may have a more common articulardisease does. However, the risk of THA in RA+SLE patients is not fully investigated.

Objectives: To identify the risk and outcome of THA in RA+SLE patients in a longitudinal cohort.

Methods: We analyzed datasets derived from Taiwan National Health Insurance Research Database from 2000 to 2018. Patients with RA, SLE, and RA+SLE were selectively and matched according to age and gender. Risk and outcome of THA was compared, and multivariable Cox proportional hazards models were used to analyze the risk factors.

Results: 2270 RA+SLE patients were matched with 9080 RA and 9080 SLE patients. RA+SLE patients had the highest rate of THA than RA or SLE patients did (2.16% vs 1.22% or 1.76%, respectively; p<0.0008). Avascular necrosis (1.45%) followed by osteoarthritis (1.28%) were the most common reasons for THA in RA+SLE patients. The rate of THA revision was the highest in RA patients than in RA+SLE or SLE patients (9.91% vs 4.08% or 6.25%, respectively; p<0.0001). Chronic kidney disease (HR: 4.94, 95% CI: 2.51-9.71, p<0.0001), use of prednisolone or equivalence >10mg/day (HR: 2.1, 95% CI: 1.53-2.88, p<0.0001), azathioprine (HR: 2.15, 95% CI: 1.68-2.74, p<0.0001), and biologic agents (HR: 2.03, 95% CI: 1.46-2.81, p<0.0001) increases the risk of THA independently.

Conclusion: RA+SLE patients had the highest rate of THA than patients with individual disease alone, however, the rate of THA revision was the highest in RA patients than in the other groups. Comorbidities, treatment with a higher daily dose of steroid, and immunosuppressants may contribute to the risk of THA.

AB1662 IMPACT OF COMORBIDITIES AND FREQUENCY OF ADMISSIONS ON MORTALITY IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Comorbidities, Prognostic factors, Behcet's disease

H. Amar Muñoz1, I. Catrejón1, A. Ramos1, F. Montero1, K. Carpio1, J. Molina Collada1, B. Serrano-Benavente1, J. M. Alvaro-Gracia1, J. Martinez-Barrio1, 1Hospital General Universitario Gregorio Marañón, Madrid, Spain, Department of Rheumatology, Madrid, Spain

Background: Data on mortality in patients with systemic autoimmune rheumatic diseases (SARDs) is limited. Most evidence is restricted to patients with systemic lupus erythematosus and ANCA vasculitis [-1]. In recent years, mortality has been more closely associated with cardiovascular pathologies and infections and less with disease activity.

Objectives: To assess the impact of comorbidities and hospital admissions on mortality in patients with SARDs in a tertiary referral hospital.

Methods: We conducted a retrospective observational study including adult patients with SARDs (Table 1) followed up in our Multidisciplinary Unit of Systemic Autoimmune Diseases between January 2017 and December 2019. In this cohort, patients were under similar follow-up and treatment protocols. Gathered data includes epidemiological, hospitalization (number of admissions, hospital stay and reasons for admission) and exitus information. In hospital patients, associated comorbidities were also reviewed. A comparison was made between patients who required at least one admission during the study period and those who did not, in addition to a description of mortality. Kaplan Meier curves are presented by number of comorbidities and number of hospitalizations.

Results: Of the 1749 patients with SARDs included in our cohort, 432 (24.7%) required hospitalization during the study period. Of those hospitalized, mean age was 64 years and 315 (73%) were women. A total of 61 (14%) deaths occurred among patients admitted to the hospital vs 77 (5.9%) among non-hospitalized, within the study period. Behcet's disease and IgG4-related disease presented highest mortality rate (23%) in our cohort of hospitalized patients, closely followed by antiphospholipid syndrome (23%) and Sjögren's syndrome (20%) (Table 1). No statistically significant differences were observed in mortality according to the number of admissions (p=0.56) or comorbidities (p=0.41), although in the latter, an increasing trend was observed as the number of comorbidities increased (survival according to the number of comorbidities: no comorbidities >14 years, one comorbidity >8.9 years, two or more comorbidities >6.4 years) (Graph 1).

Conclusion: We have found no impact of comorbidities or hospital admissions in mortality in patients with SARDs. Among hospitalized patients, higher mortalitv were observed in Behcet's disease, IgG4-related disease, antiphospholipid syndrome and Sjögren's syndrome. In addition, a trend towards greater mortality was observed in relation to the number of comorbidities.

AB1663 MUSCULOSKELETAL (MSK) PAIN IN VILLAGE BHIGWAN (INDIA) IN 2022- CHANGE OVER 25 YEARS: WHO COMMUNITY ORIENTED PROGRAM FOR CONTROL OF RHEUMATIC DISEASES (COPCORD) 1996-2022

Keywords: Epidemiology, Gender/diversity issues, Descriptive studies

H. Rathod1, K. Adam1, R. Ghorapade1, A. Venugopalan1, M. Saluja1, A. Chopra1, 1Center for Rheumatic Diseases, Rheumatology, Pune, India

Background: COPCORD population surveys (Stage I) have reported the prevalence of MSK pain and rheumatic disorders in several countries. A crude point prevalence rate of 18.2% for MSK pain (adult) was reported by the maiden COPCORD India survey (1996) in rural Bhigwan (Pune) and was continued to date with a free-of-cost local rheumatology clinic and a health education program. Several other factors (development, environment, Chikungunya epidemic 2006, Covid pandemic 2019) are likely to impact the epidemiology of MSK disorders and thus we carried out a resurvey in Bhigwan from April to July 2022. We present early results of MSK pain and related factors.

Objectives: To describe and measure the current MSK pain and rheumatic disorders in Bhigwan rural population and further assess the transformation over time (1996 to 2022).

Acknowledgements: NIL.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.4427
Methods: The resurvey (Stage I) was carried out using the methods of the previous survey (Bhigwan COPCORD model 1996). Trained voluntary health workers (HW) completed a house-to-house cross-sectional survey (Phase 1) of the adult population (≥18 years) and identified current and/or past MSK pain respondents. Pain due to recent trauma (≤3 months) was excluded. Concur- rently, the respondents were also evaluated (Phase 2) for pain descriptors and other relevant issues. Rheumatologists examined (Phase 3) the respondents to make a clinical diagnosis, order relevant investigations, and begin treatment. A follow-up was scheduled. The target population was estimated at 8117 (Goverm ment records). The database was created using an indigenous software program. Standard population analysis was carried out. Crude point prevalence rates (95% confidence intervals) are presented. Further analysis is being done.

Results: 6970 population (85.9% response, 50% males) was surveyed. The age-gender distribution pattern was comparable with the India rural census 2011; 63% in 18-44 years age groups (Bhigwan). Paradoxically, only 76% current pop- ulation in sharp contrast to about 55% in 1996 admitted working (physically) in fields; now dependent upon temporary migrant labor (not in the survey). 32% population possessed mobile phones. Five hundred eighty-six pain patients (women 69%) were identified; 46% belonged to the 45-64 years age group. The MSK pain prevalence was 8.2% (7.5%, 8.8%); male 2.5 (2.2, 2.9), female 5.6% (5.1, 6.2). 14.2% population used tobacco in some form, mostly oral; 36.3% of MSK pain respondents (58% women). Hypertension in 79%; diabetes in 4.7%, thyroid disorders in 1.6%, and rectal hemorrhoids in 1% was self-reported in the population; correspondingly 25%, 12%, 2.5%, and 3% were reported by the MSK pain cohort. Past history of Chikungunya in 5.7% and COVID-19 in 7.4% of the total population was reported. On univariate analysis, MSK pain was significantly associated (p < 0.0001, Chi-square) with Chikungunya, COVID-19, tobacco use, fieldwork, and low education status. Prevalence rates for disease groups were 1.38% (1.12, 1.66) for inflammatory arthritis, 3.66% (3.23, 4.13) for degenerative arthritis and 2.87% (2.49, 3.29) for non-specific rheumatism/arthritis. Self-re- ported data, subject recall, and limited investigations were important concerns.

Conclusion: The current COPCORD survey shows that despite a substantial reduction from 1996, MSK pain continues to be a predominant and important self-reported illness in the Bhigwan rural community. Undoubtedly, the lives and livelihoods of the Bhigwan people and their MSK landscape have been trans- formed substantially. Interestingly, the burden of other non-communicable dis- eases seems increased. Further research studies will be required to unravel the role of Chikungunya and COVID-19, and other risk factors in MSK disorders.

**INFLUENZA, PNEUMOCOCCAL, AND TETANUS VACCINE COVERAGE AMONG PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES ON BIOLOGICAL OR TARGETED SYNTHETIC DMARDs AND THE ROLE OF THE RHEUMATOLOGIST**

**Keywords:** Vaccination/immunization

T. Georgiev1, R. Moraliyska2, S. Bogdanova-Petrova1, S. Dimitrov2, S. Hristova3, D. Simeonova2, G. Gerganov1, T. Shivacheva1

**Background:** Vaccines are one of the most efficient tools to prevent infectious diseases at a population level. Their importance is even greater in immunocom- promised patients providing efficient and safe protection against common viral and bacterial infections. According to the current EULAR recommendations based on solid evidence over the recent years, non-live vaccines such as influ- enza, pneumococcal, tetanus toxoid, and others are safe and can be adminis- tered to patients with inflammatory rheumatic diseases during the glucocorticoid and/or disease-modifying antirheumatic drug (DMARD) therapy. Furthermore, influenza and pneumococcal vaccines “should be strongly considered” and the tetanus toxoid vaccination should be received in accordance with the recommenda- tions of the general population.

**Objectives:** We aimed to investigate the coverage for influenza, pneumococcal, and tetanus toxoid vaccination in a cohort of patients with inflammatory rheu- matic diseases on biological or targeted synthetic DMARDs.

**Methods:** Two hundred and one patients, aged 18 or older, were included in this single-center cross-sectional study after signing an informed consent form. They suffered from rheumatoid arthritis (RA), psoriatic arthritis (PsA), or anky- losspondylitis, juvenile idiopathic arthritis, or other rheumatic diseases. Participants with psychiatric or neurological diseases preventing understanding or responding to the questions were excluded from the study. Patients’ anthro- pometric, clinical, and demographic characteristics were collected via detailed anamnesis and clinical examination. Disease activity was evaluated using DAS28-CRP for patients with RA and peripheral PsA and ASDAS for those with spondyloarthritis (AS) and axial spondyloarthritis. Patients were deter- mining their immunization status for influenza, pneumococcal, and tetanus toxoid vaccines and whether they had a preceding discussion with their rheumatolo- gist about recommended vaccines during their routine medical visits.

**Results:** Of the 201 included patients, 40.3% (n=81) were females. Patient dis- tribution according to their disease was as follows: 30.3% (n=61) RA patients, 51.7% (n=104) PsA patients, and 17.8% (n=38) PsA patients (n=38). Mean age, duration, and body mass index values were 54.62 (14.4) years, 11.04 (8.6) years and 28.2 (5.3), respectively. 27.4% of patients were on concomitant glucocor- ticoïd treatment. Only 13.9% (n=28) and 1.5% (n=3) were vaccinated against seasonal influenza and pneumococcal infections, respectively. Patients who had a preceding discussion about seasonal influenza and pneumococcal immuniza- tion with their rheumatologist had approximately 13 and 32 times higher probabil- ity to get vaccinated than people who did not (OR=12.9, p < 0.001 and OR 32.5, p = 0.01, respectively). Regular reimmunizations against diphtheria and tetanus according to the Immunization Calendar of the Republic of Bulgaria were carried out by only 44.8% (n=90) of the studied population.

**Conclusion:** Coverage of recommended vaccines in our group of Bulgarian patients on biological or targeted synthetic DMARDs is very low. Discussion about the potential benefits and safety profile of the recommended vaccines may increase patients’ willingness to vaccinate and prevent common infectious dis- eases in immunocompromised rheumatic patients.

**Background:** Both hyperuricaemia and reduced kidney function are known mor- tality risk factors.[1-3] Also, hyperfiltration is associated with elevated mortality risk.[3] It has not yet been studied if renal function has a modifying effect on hyperuricaemia-associated mortality risk.

**Objectives:** To detect if renal function has a modifying effect on hyperuricae- mia-associated mortality risk.

**Methods:** Data from GOAL (Good Ageing in Lahti region) study was used. It is a large, prospective, population-based study of elderly people (52–76 years) in the Lahti region. Data of serum uric acid (SUA) levels, creatinine, cystatin C as well as several other laboratory variables, comorbidities, lifestyle habits and socioeco- nomic factors was collected. To estimate glomerular filtration rate, we used CKD- EPI creatinine-cystatin C equation (ml/min/1.73 m²). Persons with SUA values of >410 μmol/L (75th percentile) are represented as clearly hyperuricaemic. Persons with eGFR of ≥67 ml/min both in the group of clearly hyperuricaemic and in the group of non-impaired kidney function had 27.4% (5.3), respectively. 27.4% of patients were on concomitant glucocor- ticoïd treatment. Only 13.9% (n=28) and 1.5% (n=3) were vaccinated against seasonal influenza and pneumococcal infections, respectively. Patients who had a preceding discussion about seasonal influenza and pneumococcal immuniza- tion with their rheumatologist had approximately 13 and 32 times higher probabil- ity to get vaccinated than people who did not (OR=12.9, p < 0.001 and OR 32.5, p = 0.01, respectively). Regular reimmunizations against diphtheria and tetanus according to the Immunization Calendar of the Republic of Bulgaria were carried out by only 44.8% (n=90) of the studied population.

**Conclusion:** Coverage of recommended vaccines in our group of Bulgarian patients on biological or targeted synthetic DMARDs is very low. Discussion about the potential benefits and safety profile of the recommended vaccines may increase patients’ willingness to vaccinate and prevent common infectious dis- eases in immunocompromised rheumatic patients.

SUA ≤410 μmol/L and eGFR >67 ml/min was used as a reference (Table 1). HR for hyperuricaemia-related premature death however was lowest in individuals with reduced eGFR, and it rises strikingly as the eGFR increases above 80ml/min (Figure 1).

Conclusion: Reduced kidney function is an important risk factor for mortality both in individuals with lower and higher SUA. The mortality risk associated with hyperuricaemia is remarkably higher in individuals with normal or only slightly reduced kidney function. This finding makes it reasonable to speculate that hyperuricaemia caused by overproduction of uric acid (metabolic hyperuricaemia) might be a separate and more deleterious entity than hyperuricaemia that has resulted from renal underexcretion of uric acid (renal hyperuricaemia).

Background: The clinical manifestations of patients with rheumatic diseases are highly heterogeneous. The appearance of adverse events (AEs) related to the treatments received for these diseases considerably increases the morbidity and mortality of these patients. This is why obtaining real-world data on these AEs and analyzing their causes is paramount. The BIOBADASAR registry has data obtained:

Methods: Retrospective, multicenter study of patients with rheumatic diseases treated with original biological drugs, biosimilars, or original and generic targeted therapies in Argentina; follow-up from August 2010 to July 2021. The BIOBADASAR registry has data from 5,676 patients over ten years of follow-up. Classifying patients in treatment with biological drugs into subgroups with different phenotypes through unsupervised grouping could provide valuable information on the characteristics associated with specific AE.

Objectives: Through cluster analysis, this study aimed to identify different clinical phenotypes related to Adverse events in patients treated with biological drugs.

Results: A total of 5676 patients were analyzed. Three different clusters were obtained:
Cluster 1: 1041 patients. Was observed an evolution time of the disease of 30.5 years (Q1 25.8; Q3 35.6) longer than other clusters and a longer delay in starting treatment at 18.3 years (Q1 11.4; Q3 24) p < 0.0001.

Cluster 2: 2136 patients. We observed a higher frequency of patients with Systemic Lupus Erythematosus: 156 (7.3%) p<0.0001 and a lower frequency of AEs 190 (8.9%) p < 0.0001.

Cluster 3: 2499 patients. We observed a higher mean age than in the other two clusters, 573 (SD 8.3) p < 0.001.

The use of systemic corticosteroids was evenly distributed among the 3 clusters.

Conclusion: The unsupervised grouping of patients from the BIOBADASAR registry demonstrated the existence of clusters based on clinical and demographic characteristics. Identifying high-risk patients through a combination of these parameters may be helpful for the early identification of risk factors and their association with adverse events. Based on our hierarchical cluster analysis, we identified different patient phenotypes. Our results show that within the heterogeneity of patient characteristics, common elements provide a basis for future analyses of these variables and their relationship with certain AEs.

Background: Artificial intelligence (AI) is rapidly gaining adoption in the medical field [1]. We review, the original research articles that combine AI and Rheumatic and Musculoskeletal diseases (RMDs) in which AI plays a key role, with approaches such as topic modeling, computer vision, reinforcement learning, few-shot learning, and trajectory analyses. Osteoarthritis, rheumatoid arthritis, systemic lupus erythematosus and osteoporosis are the RMDs that accounts for most of the research studies in which AI techniques are used more assiduously. However, AI is also playing a key role in rare diseases research, such as vasculitis, with approaches such as unstructured learning. The amount of data in the studies reviewed is variable, from just hundreds of observations to hundreds of thousands, showing that “big data” cohorts are not mandatory to take advantage of such techniques.

Conclusion: The outstanding and upward trend in the number of published research related to rheumatic and musculoskeletal diseases, in which AI plays a key role, has exhibited the interest of rheumatology researchers in using these techniques to answer their research questions. We can conclude that the rheumatology research community is increasingly adopting novel AI techniques.

Background: Infections are one of the main causes of morbidity and mortality in patients with autoimmune inflammatory rheumatic diseases (AIRD). Pneumococcal vaccination can significantly reduce the number of serious respiratory infections in this group of patients.

Objectives: To analyze the frequency of respiratory infections in systemic lupus erythematosus (SLE), secondary and primary antiphospholipid syndrome (APS) before and after vaccination with 23-valent polysaccharide pneumococcal vaccine (PPV-23).

Methods: 91 patients were included in the study, 78 of them with SLE, including 18 with secondary APS; 13 patients with primary APS. The follow-up period was 12 months. All patients with SLE and secondary APS received immunosuppressive therapy, including 29 anti-B-cell therapy. With primary APS, 6 patients received immunosuppressive therapy, including rituximab.

Results: All LRTI were more common in SLE (48.3%, 27.8%, 11.8%, respectively), mainly due to the more frequent development of pneumonia (Pn) (20%, 11%, 7.7%, respectively). After vaccination, the number of pneumonias decreased from 15 (16.7%) to 4 (4.4%) and were registered only in patients with SLE, p=0.01. These were not severe pneumonia, did not require hospitalization; in all cases there were predisposing factors (anti-B-cell therapy with the absence of an adequate vaccine response - 3, interstitial lung disease (ISL) - 1). Before vaccination, among ENT infections in this group of patients, may be the absence of ISL in these patients.

Conclusion: The clear clinical efficacy of PPV-23 in patients with SLE and APS has been demonstrated. In primary APS, fewer respiratory infections and their absence after vaccination are naturally explained by less aggressive immunosuppressive therapy. A possible reason for the lower number of INDO in secondary APS, in after vaccination are naturally explained by less aggressive immunosuppressive therapy.

**AB1670 PREVALENCE OF PNEUMOCYSTIS JIROVECI PNEUMONIA(PJP) IN PATIENTS WITH RHEUMATOLOGICAL CONDITIONS ON IMMUNOSUPPRESSIVE MEDICATIONS AND THE NEED FOR PROPHYLAXIS**

**Keywords:** Infection-related RMDs, Disease-modifying drugs (DMARDs)

**D. Ramachandran, W. Mushanq, D. Makkuni, H. Reddy.** James Paget University Hospitals, Medicine, Great Yarmouth, United Kingdom

**Background:** Pneumocystis jirovecii pneumonia (PJP) is a life-threatening opportunistic fungal infection with a high mortality rate (30-50%) among non-HIV immunosuppressed patients. According to previous studies cotrimoxazole prophylaxis is given for patients when their risk of PJP is greater than 3.5%[1] however these guidelines were established for patients with malignancies, stem cell and solid organ transplantations[2]. The data from British registries showed a slightly higher risk in patients treated with Rituximab than Anti TNF therapies. The ACR recommends PJP prophylaxis in their recently published guidelines on ANCA associated vasculitis (AAV) and studies have shown higher PJP infection in patients with GPA than other vasculitides. The benefit for prophylaxis treatment is not clearly established in inflammatory conditions like RA and other autoimmune Rheumatological conditions (ARPs)

**Objectives:** To investigate the incidence of PJP infection in patients with ARPs and explore the potential common risk factors.

**Methods:** Using our, electronic health record (EHR) cohort, we investigated the prevalence of PJP infections in Rheumatic patients on immunosuppressants over a period of one year.

**Results:** We identified 6 non HIV patients with a confirmed diagnoses of PJP infection over a period of one year. All patients were diagnosed following bronchial lavage looking for PJP DNA in the aspirate. Only 2 out of six patients were identified to have ARDs on immunosuppressant drugs. Case 1: 68 yr old, female, was on longstanding methotrexate for RA, presented with breathlessness and dry cough. The blood showed CRP of 200 and CT thorax showed features consistent with RA-ILD with superimposed ground-glass changes keeping with an acute infection. He did not respond to IV antibiotics and went on to have a bronchial lavage which tested positive for PJP and was started on high dose of steroids and intravenouse cotrimoxazole followd subsequently by Vancomycin and Clindamycin after not improving on cotrimoxazole. Despite ongoing medical treatment, patient deteriorated and passed away. Case 2: 77 yr old lady on rituximab for AAV (with positive MPO >129) with an established ILD secondary to the vasculitis for 7 years. She presented with breathlessness and cough. Rituximab was started 7 years ago for the AAV and due to its relapsing nature, rituximab was continued with a maintenance dose of prednisolone 5-10mg. Blood tests showed low IgM levels with normal IgG and A levels. There was no evidence of active vasculitis and she was commenced on antibiotics which made no difference to her symptoms. A HRCT thorax was done which revealed Interval progression of ILD (UIP) bilateral ground-glass changes. Bronchoscopy and lavage showed evidence of PJP DNA on PCR and the patient was commenced on IV cotrimoxazole. Patient made a slow recovery.

**Conclusion:** Our survey did not identify a high incidence of PJP in the ARD cohort however, the common denominator for PJP in the two patients we have identified seem to be an underlying ILD. The commonest CT findings noted was ground glass shadowing in addition to ILD in both cases. A strong index of suspicion, early HRCT and bronchial lavage is crucial for the diagnosis. Failure to respond to conventional treatment should alert the clinician to cotrimoxazole resistant PJP. There are case reports of emerging resistance to cotrimoxazole tri in the non-HIV immunosuppressed group, increasing the mortality. We could not make any firm recommendation based on this observational study as the numbers were very small but the clinician should consider PJP prophylaxis in RA patients and patient with AAVs on long term Rituximab therapy. There is a need to incorporate prophylaxis treatment in to the guidelines.

SCREENING OF SYMPTOMS IN THE AT-RISK OF RHEUMATOID ARTHRITIS CZECH COHORT USING SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS (SPARRA) QUESTIONNAIRE

Keywords: Autoantibodies, Rheumatoid arthritis

N. Růžičková1, K. Pražlerová2, P. Hánová3, J. Šenolt1, M. Filipová1. 1Institute of Rheumatology, Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic; 2Institute of Rheumatology, Experimental Rheumatology, Prague, Czech Republic; 3Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic

Background: With growing knowledge about the course of rheumatoid arthritis (RA), the focus shifts to the pre-clinical phase. The presence of RA-associated autoantibodies enable the characterization of individuals who are considered at risk for progression to RA. The “Symptoms in Persons at Risk of RA” (SPARRA) questionnaire was created to screen symptoms occurring in at-risk individuals. This questionnaire comprises 13 symptoms (joint pain, swelling and stiffness, burning and tingling sensations, numbness, changes in skin color over joints, muscle cramps, weakness, fatigue, emotional distress, concentration and sleep difficulties) and explores their duration, location, intensity and impact on daily activities.

Objectives: To explore the symptoms in our prospective observational cohort of individuals with arthralgia at-risk of RA (ARRA cohort) using the SPARRA questionnaire.

Methods: Individuals at-risk of RA, defined as having arthralgia without arthritis on the examination of 66/68 joints at baseline and being either ACPA+ and/or meeting the European Association of Associations for Rheumatology (EULAR) definition of clinically suspect arthralgia (CSA, having at least 3 out of 7 parameters), cross-sectionally filled out the SPARRA questionnaire. All individuals signed informed consent before study enrolment. Differences between ACPA+ and ACPA- individuals were analysed using Fisher’s exact test.

Results: The study included 77 at-risk individuals (75% were females) with a mean age of 48.0±12.62 years, symptom duration of 34.6±35.56 months with CRP 3.17±4.24 mg/l and 5.43±7.32 tender joints on examination, out of which 61% were ACPA+, 59% met the CSA definition, and 20% were both ACPA+ and met the CSA definition. The most frequent symptoms at the time of SPARRA completion were joint pain (97%), joint stiffness (83%), fatigue (82%), emotional distress (70%), sleep problems (66%), and joint swelling reported by the patient (65%). Joint stiffness (100% vs. 71%, p=0.0005), sleep problems (84% vs. 53%, p=0.0067), and concentration difficulties (69% vs. 29%, p=0.0010) were more prevalent in ACPA-individuals than in ACPA+ group. Similarly, the intensity (none/mild vs. moderate/severe) of fatigue (p=0.0197), emotional distress (p=0.0270), and sleep problems (p=0.0054) was higher in ACPA+ group, along with emotional distress (p=0.0136) and sleep problems (p=0.0407) being of higher impact on daily activities in ACPA-individuals.

Conclusion: Symptoms of the at-risk individuals appeared more frequently and with higher intensity and impact on daily activities in ACPA-individuals, who as per the inclusion criteria, met the CSA definition, with joint pain being the most prevalent. The value of the SPARRA questionnaire in the assessment of the risk of arthritis development in at-risk individuals needs to be determined in further prospective studies.

AB1673 THE USE OF DIGITAL FOOT SCANNING (PELMATOGRAPHY) FOR IDENTIFICATION OF STANCE ABNORMALITIES IN A YOUNG HEALTHY POPULATION

Keywords: Work-related issues, Epidemiology, Health services research

I. Katsiariou1, E. Skovaklidou1, G. Vountrypidis1, D. Deliegeorgakis1, D. Zisoupolos1, G. Sakellarious1, P. Vountrypidis1. 1424 Military Hospital Thessaloniki, Rheumatology, Thessaloniki, Greece

Background: Clinical evaluation of pes anatomy and abnormalities are not reported in rheumatology literature. Often deviations from normal are not evaluated, unless subsequent pathology and symptoms are overt. Foot symptoms may occasionally lead to overdiagnosis of seronegative arthropathies.

Objectives: This study aims to identify any foot abnormalities in a healthy young population of army recruits, using clinical and digital foot scanning – pelmatographic (PLM) examination.

Methods: One hundred and ten (M/F:65/54) of a total of 219 new army recruits of a Military Academy in Greece participated voluntarily in the study. Subjects' informed consent and proper ethical approvals were obtained. The study conducted according to Declaration of Helsinki. A small percentage (1.12 %) reported short-term lower leg symptoms during vigorous athletic activities, the past five years. We used clinical evaluation of pes morphology on stance and compared to data obtained during the stance phase of examination using a 3400-sensors plantar pressure foot scan machine. Descriptive statistics were used for the statistical analyses.

Results: Agreement between clinical and pelmatographic observation was noted in 59.1% of subjects. In particular, clinical and pelmatographic normal pes was observed in 48.2% and 68.8% of subjects, respectively. High arched foot was observed in 23.6% and 17.2%, while flat foot in 23.6% and 9.7% respectively. There was no statistical difference between clinical and pelmatographic evaluation of high arched foot (chi-square test, p=0.815). Discrepancy between clinical and pelmatographic evaluation of flat feet was noted (p=0.04, OR:0.47, 95%CI:0.165-0.730). Finally, 37.3% of the participants presented foot pronation while in 60.8% subjects [M:41 (60.2%), F:27 (39.3%)] brachymetatarsia of the 1st toe (Morton's toe) was observed.

Conclusion: Prevalence of pes abnormalities are high and unattended in an otherwise healthy young population. These variations may predispose to future foot symptoms under specific circumstances. Digital foot pressure scanning may facilitate diagnosis and contribute to solution with foot orthotics.

Validation of outcome measures and biomarkers

AB1674 TOWARDS A GUIDE FOR EVIDENCE-BASED TELEMONITORING: SENSITIVITY OF PATIENT REPORTED OUTCOMES TO CHANGE IN DISEASE ACTIVITY STATUS IN EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS

Keywords: Patient reported outcomes, Rheumatoid arthritis, Telemedicine

A. loco1, E. Van Mulligen1,2, A. Van der Helm – van Mil1,2, P. De Jong1
1Erasmus MC, Rheumatology, Rotterdam, Netherlands; 2Leiden University Medical Centre, Rheumatology, Leiden, Netherlands

Background: In the treatment and follow up of rheumatoid arthritis (RA) patients, it has become more desirable to detect changes in disease activity through telemonitoring, for which patient reported outcomes (PROs) might be useful. So far associations between PROs and changes in disease activity have been mostly investigated on a continuous scale. However, in daily practice and in line with the EULAR recommendations, treatment decisions are mainly based on the patient’s disease activity status. Earlier literature has shown that functionality, joint pain, morning stiffness, general health (GH), health-related quality of life and fatigue change with the development and resolution of a disease flare.

Objectives: Therefore, our aim is to determine if PROs that cover functionality, joint pain, morning stiffness, health-related quality of life and fatigue are sensitive to disease activity status alterations (from active to low disease activity to remission, and vice versa) in patients with early and established RA.

Methods: Early RA patients from the iREACH-trial and established RA patients from the TARA-trial were included. Both studies were multicentre, single blinded trials with a treat-to-target design. Treatment alterations were based on the disease activity score (DAS44) and PROs were collected at 3-monthly fixed intervals. The following PROs were studied: (1) the Health Assessment Questionnaire Disability Index (HAQ-DI), (2) joint pain (numeric rating scale, NRS 0-10), (3) morning stiffness severity (NRS 0-10), (4) GH (visual analogue scale, VAS 0-100mm), (5) health-related quality of life (EQ-5D) and (6) fatigue (VAS 0-100mm).

Disease activity statuses were defined as: (1) active disease (DAS≤2.4), (2) low disease activity (LDA, DAS<2.4 and ≥1.6) and (3) remission (DAS<1.6). Differences in disease activity status between two consecutive visits were compared to changes in PROs. Mean changes in PROs per disease activity status alteration were compared to stable disease activity status, using generalized estimated equation-models.

Results: Respectively 587 and 189 early and established RA patients were included. The median symptom duration (IQR) was 0.4 (0.2-1.8) and 6.2 (4.1-8.9) years, respectively. The mean DAS (95%CI) at baseline was 3.0 (3.0-3.1) in the early and 1.0 (0.9-1.1) in the established RA group. Figure 1 shows the mean change (95%CI and significance) in PROs per change in disease activity status. HAQ-DI, joint pain, morning stiffness, GH, EQ-5D and fatigue (in early RA) were in concordance with improvement or worsening of disease activity status. Change from active disease to LDA or vice versa had a larger effect on HAQ-DI, GH, and EQ-5D compared to change from and to remission to LDA. Respectively, change in HAQ-DI was 1.9 and 1.8 times greater going from active disease to LDA compared to a shift from LDA to remission and vice versa. For GH this was 1.6 and 1.2 and for EQ-5D 2.1 and 2.0 respectively.

Conclusion: Changes in HAQ-DI, morning stiffness, joint pain, GH and EQ-5D correspond to changes in disease activity status. These results suggest that changes in aforementioned PROs may be helpful in telemonitoring of RA.

AB1675 DEEP PHENOTYPING OF IMMUNE MICROENVIRONMENT IN ULCERATIVE COLITIS BY INTEGRATIVE SYSTEMS ANALYSIS

Keywords: Adaptive immunity

Q. Wang1, M. R. Chen1,2, J. W. Hao1,2, M. J. Chang1,2, S. X. Zhang1,2, Q. Yu3, P. F. He3,1, Second Hospital of Shantou Medical University, Department of Rheumatology, Taishan, China; Shantou Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taishan, China; Shantou Medical University, Shantou Key Laboratory of Big Data for Clinical Decision, Taishan, China; Shantou Medical University, School of Management, Taishan, China

Background: Ulcerative colitis (UC) is an inflammatory bowel disease characterized by idiopathic and recurrent mucosal inflammation [1]. The pathogenesis is multifactorial, involving genetic susceptibility, epithelial barrier defects, dysregulation of the immune response, and environmental factors. UC is a highly heterogeneous disease [2]. Despite efforts to characterize disease subgroups and predict differential outcomes in UC patients, disease heterogeneity is not adequately translated into current clinical subclassifications. Anomalies: This study seeks to unravel this complexity by using an integrated systems approach that classifies UC patients into different phenotypes based on the immune microenvironment, capable of providing new insights into the development of stratified therapies.

Methods: RNA sequencing datasets of 602 colon tissue samples from 455 patients with UC and 147 healthy controls (HC) was imported from GEO database. The microarray datasets were transformed into immune cell components by CIBERSORT, and patients were stratified by a consensus clustering algorithm. Then, the cellular characteristics of the subtypes and the overall role of specific pathways were determined by immune cell infiltration and pathway enrichment. The clinical characteristics of the different subtypes were also analyzed to clarify the characteristics of these classifications.

Results: Patients can be classified into two distinct immune phenotypes (Subtype A, B) based on their specific RNA expression profile, which have different cellular and pathway characteristics. (Figure A) The results show that Subtype A is mainly enriched in immune cells such as B cells, CD8+ T cells, CD4+ memory T cells, DC cells, macrophages, mast cells and plasma cells. Acidic granulocytes and neutrophils were more active in Subtype A. It was also significantly enriched in the peroxisome proliferator-activated receptor (PPAR) signaling pathway in Subtype B. In contrast, Subtype A showed a strong enrichment for most inflammatory pathways B cell and T cell receptor signaling, IL-17 signaling pathway, TNF, and interleukin 4 and interleukin 13 signaling pathway. (Figure 1 D, E) In addition, there was a significant difference between molecular subclassification and disease status, with Subtype A being more active in patients (69.3% of Subtype A vs.30.6% of Subtype B in 105 cases). (Figure 1C)

Conclusion: Analysis of the immune microenvironment of colonic mucosal tissue provides good insight into the pathophysiological characteristics of UC. These results can be used as a model for future studies. The response and clinical outcomes of patients with different classification need to be further investigated.
REFERENCES:

Background: One rationale for including patient global assessment (PtGA) in Boolean remission is that PtGA ≤1 reduces the probability of joint findings outside the 28 joints and complements the limitations of 28-joint count assessment [1]. Meanwhile, the criterion of PtGA ≤1 has been questioned, leading to establishment of Boolean2.0 or proposal of 3V-remission [2-3]. However, the significance of PtGA as a complement to the limitations of the 28-joint assessment has been forgotten.

Objectives: This study aimed to evaluate the discriminative power of PtGA for the presence of joint findings outside the 28 joints within the framework of Boolean2.0 and 3V-remission in the real-world setting.

Methods: We analyzed 8,684 patients with rheumatoid arthritis who achieved 3V-remission (28-tender joint count (TJC), 28-swollen joint count (SJC) and C-reactive protein (mg/dL) all ≤1) registered in the National Database of Rheumatic Diseases in Japan (NinJa) in 2020, a large observational database. Based on TJC68 and SJC66, patients were divided into two groups of patients with and without joint findings outside the 28 joints (JFO28). The values and distributions of PtGA were compared between the two groups, and the positive likelihood ratio for no findings outside the 28 joints was calculated, varying cutoff values of PtGA. Receiver Operating Characteristic (ROC) analysis was performed to assess the discriminative power of PtGA for the presence of JFO28 and optimal cut-off value.

Results: Among 8,684 patients, 6,901 were patients without JFO28 and 1,783 were patients with JFO28. The values of PtGA were significantly higher in patients with JFO28 (the difference of 25% trimmed mean, 1.12 [95% CI, 1.01 to 1.24]). However, the distribution of PtGA was largely overlapping (Figure 1). About 12%, 15%, and 21% of patients had JFO28 when the cutoff values for PtGA were 1.0, 2.0 (Boolean2.0), and none (3V-remission), respectively. The positive likelihood ratios were 1.90 and 1.44 when the cutoff values of PtGA were 1.0 and 2.0, respectively. The area under the ROC curve was 0.68 [95% CI, 0.66 to 0.69], indicating low discriminative power. The optimal cut-off value was 1.0 based on Youden index.

Conclusion: A cutoff value of 1.0 for PtGA seems reasonable in terms of 68/66 joint findings. It may be pragmatic to evaluate PtGA and joint findings separately in accordance with the concept of dual target therapy because PtGA has low discriminative power for the presence of JFO28 in patients achieving 3V-remission. However, our results suggested that there is a need to extend the criteria for joint assessment in 3V-remission to 68/66 joints, considering not a few patients had JFO28 even if they had reached 3V-remission.

Objectives: To compare different methods of constructing a composite score for the Flare-OA-16 self-reported questionnaire for measuring knee and hip OA flare, defined as a cluster of symptoms of sufficient duration and intensity to require initiation, change or increase in therapy [1].

Methods: Participants with a physician diagnosis of knee and hip OA completed a validated 16-item questionnaire [2,3]. Assessing five dimensions of flare in OA: pain, swelling, stiffness, psychological aspects, and consequences of symptoms, endorsed by OMERACT. Three estimation methods were compared: the score obtained i) by second-order confirmatory factor analysis (CFA) weighting the factor loadings in a linear combination of the five dimensions; ii) by logistic regression, modeling the probability of having a flare according to the participant’s self-report (yes/no); and iii) by Rasch method, using the average of the weighted scores from a Rasch model in each dimension. For the scores obtained by the three methods, the disordered items were modified, and then the scores were standardized on a scale from 0 to 10. The distribution (floor effect without flare (FF) and ceiling effect with flare (CF)) of the scores in each model was compared. The similarity between the scores was analyzed by intraclass correlation coefficient (ICC) and their performance were compared by areas under the ROC curves (AUC) and 95% confidence interval. The intra-score test-retest reliability at 15 days was assessed by ICC.

Results: In a sample of 381 participants with complete questionnaires, 247 reported having a flare. With CFA, good fit indices (CFI=0.94; RMSEA=0.08) justified the estimation of an overall score mean=3.90 (SD=2.79), with FF effect 27.6% and CF 20.0%. For the logistic regression estimation, the overall score was mean=6.48 (SD=3.13), with FF 0% and CF 34.0% effect. With the Rasch model, the composite score was mean=4.15 (SD=2.45), with FF 18.7% and CF 0% effect. Similarity analysis indicated a greater concordance between the CFA and Rasch scores (ICC=0.99) than between the logistic regression score and the two others (ICC=0.87 for each). The ROC curve indicated similar performance of the overall scores estimated by logistic model (AUC=0.88 [0.85-0.92]), by CFA
AB1679

VASCULITIS DISEASE ACTIVITY SCORES BEFORE AND DURING THE COVID-19 PANDEMIC: A COMPARISON OF FACE-TO-FACE CLINICIAN SCORING AND PROMS COLLECTED USING REMOTE MONITORING IN A SINGLE-CENTRE COHORT

Keywords: Telemedicine, Vasculitis, Patient reported outcomes

D. Kurzeja1, K. Song2, M. Mirza2, M. Ashraf2, R. Luqmani1. 1Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom; 2University of Oxford, Medical Sciences Division, Oxford, United Kingdom; 3Great Western Hospital, Rheumatology, Swindon, United Kingdom; 4Stoke Mandeville Hospital, Rheumatology, Aylesbury, United Kingdom

Background: During the COVID-19 pandemic, asynchronous consultations were introduced for patients with vasculitis. To assess disease activity without of face-to-face clinical reviews and blood testing, patients submitted patient reported outcome measures (PROMs) via electronic survey forms, which were subsequently triaged by clinicians.

Objectives: 1. To investigate how patients’ vasculitis disease activity was affected by the COVID-19 pandemic through retrospective comparison of clinician-assessed scores recorded pre-pandemic with intra-pandemic self-reported patient reported outcome measures (PROMs) and disease scores submitted by patients remotely.

2. To assess patients’ clinical outcomes, including allocation of follow-up and further management/treatment escalation during this period.

3. To validate self-reported BVAS scores against an existing PROM.

Methods: This is a retrospectively study of patients with a known diagnosis of vasculitis under the care of the Nuffield Orthopaedic Centre, Oxford. For the purposes of this study, we included patients with all vasculitis diagnoses. Clinician-reported scores (Bristol Vasculitis Activity score v3, BVAS) were recorded during in-person clinics pre-pandemic (defined as 01/01/2019-31/12/2019) [1]. Patients’ self-reported BVAS (SR-BVAS) and AAV-PRO (ANCA-associated vasculitis patient-reported outcomes) scores were submitted by patients via electronic forms containing the requisite questionnaires sent out during-pandemic (defined as 01/12/2020-31/03/2022) [2]. SR-BVAS has not been validated but was collected to allow clinical comparison to disease activity scores completed by clinicians. Response were stored and analysed in a secure database. Score comparison was performed using Wilcoxon Sign Rank testing. Clinical outcome data was collected from the local Electronic Patient Record. Data analysis was performed in Microsoft Excel and R (version 4.2.1).

Results: We noted a significantly higher overall level of patient-reported disease activity during the pandemic than was recorded in clinics prior. In the total cohort of all vasculitis patients for whom we had data, the median BVAS increased from 2 pre-pandemic (N = 335, range 0-21) to intra-pandemic (N = 143, range 0-42) (p <0.001). The overall proportion of patients with severe/active disease (defined as BVAS >4) increased from 27% to 36% during the pandemic period. In a smaller cohort of 64 patients for whom we had paired pre- and during-pandemic scores, increased disease activity was reported (p<0.01). Notably, the number with a BVAS consistent with severe disease increased from 7 (11%) to 19 (30%).

There was a significant positive correlation between SR-BVAS and AAV-PRO (r=0.61, p< 0.001) submitted by patients during-pandemic; however, at low BVAS (<3), the AAV-PRO ranged widely (28-67) Follow-up data was available for all 64 patients in this cohort: 8/19 (42%) with a during-pandemic SR-BVAS >4 were seen in clinic within 3 months (telemedicine or face-to-face).

Conclusion: Patients reported worsening of vasculitis disease activity during the COVID-19 pandemic. This may be attributable to impacts on well-being or access to healthcare services. We note that disease activity scores in vasculitis may be limited in their ability to capture the whole picture disease activity in the absence of clinical assessment [3]. 42% of patients with self-reported high disease activity were seen within 3 months. There was a significant positive correlation between AAV-PRO and SR-BVAS, suggesting it has some use as a PROM.

BIOMARKERS IN PATIENTS WITH VIBRATION INDUCED RAYNAUD’S PHENOMENON AND IN REFERENCES

Keywords: Biomarkers, Comorbidities, Work-related issues

E. Tekavec1, T. Nilsson2, L. Dahlin3, C. Nordander1, A. Axmon1, J. Riddar1, M. Käredel1. 1Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund, Sweden; 2Division of Sustainable Health and Medicine, Department of Public Health and Clinical Medicine, Umeå, Sweden; 3Lund University, Department of Translational Medicine – Hand Surgery, Malmö, Sweden

Background: Secondary Raynaud’s phenomenon (RP) due to occupational exposure to hand-held vibrating tools is a well-recognized part of the Hand arm vibration syndrome (HAVS) [1]. Different pathophysiological mechanisms for HAVS-induced RP have been proposed, e.g., localized structural vascular and neurological injuries as well as systemic inflammatory processes by increased oxidative stress [2-5]. Elevated plasma levels of thrombomodulin (TM), a marker for endothelial damage, have been shown in vibration-exposed workers [6, 7] with equal levels as in collagen diseases [7]. Von Willebrand factor (vWF) has been suggested as biomarkers for vibration induced RP [8]. Elevated levels of vWF have been found in RP patients who subsequently develop scleroderma or other connective tissue diseases, even in the absence of capillaroscopic abnormalities [9]. It is however still not clear whether the mechanisms for vibration related RP are similar to those for other forms of RP. Biomarkers for vascular injuries may shed light on this.

Objectives: To investigate serum levels of TM and vWF in patients with HAVS, with or without RP.

Methods: Blood samples were collected in the morning from 92 patients with HAVS. Forty-five (49%) of these had RP, 47 (51%) did not. Serum was removed and stored at -80 °C until analysis. TM and vWF were measured by using commercially available ELISA assays. Distributions were compared using Mann-Whitney U tests.

Results: Higher values of TM were found in HAVS patients with RP (median 6.1 ng/ml; range 2.7 – 30), compared to those without RP (5.2 ng/ml; 2.3 – 39; p = 0.02). Further higher levels of vWF were found in HAVS patients with RP (18 μg/ml; 6.2 – 33) compared to without RP (14 μg/ml; 6.9 – 34; p = 0.008).

Conclusion: As in patients with RP due to connective tissue disorders higher levels of biomarkers for endothelial damage were shown in HAVS patients with RP. Increased serum levels of TM have been shown in previous studies on vibration induced patients [8, 9] but in one of the studies, no significant difference was shown between patients with RP and those without RP [9]. Our data indicates that RP symptoms is required to detect a significant change in the biomarker TM in vibration injured patients. Our data strengthen earlier findings that biomarkers of endothelial damage could be a useful tool in the assessment of vibrational induced injuries.

ARE PR3 ANTIBODY TITERS REALLY IMPORTANT FOR ROUTINE CLINICAL PRACTICE?. STUDY FROM A SINGLE UNIVERSITY HOSPITAL

**Keywords:** Vasculitis, Autoantibodies

V. Calvo-Rio1, S. Al Fazazi2, M. Renuncio-Garcia2, M. Rodriguez Vidriales4, C. Escagdo Cagigas4, J. Irure-Ventura3, L. Martin-Penagos4, A. Herrera-Moran4, M. Lopez-Hoyos4, R. Blanco1, 1Marques de Valdecilla University Hospital, Rheumatology, Santander, Spain; Hospital Puerta Del Mar, Rheumatology, Cadiz, Spain; 2Marques de Valdecilla University Hospital, Immunology, Santander, Spain; 3Marques de Valdecilla University Hospital, Nephrology, Santander, Spain

**Background:** Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) includes granulomatosis with polyangitis (GPA), microscopic polyangitis (MPA), and eosinophilic granulomatosis with polyangitis (EGPA). Anti-proteinase 3 are one of the main ANCA subtypes. There are contradictory studies on the relation between ANCA levels and the severity of the disease and its prognosis [1].

**Objectives:** In patients with positive anti-PR3 antibodies from a university hospital we assess: a) associated diseases, b) specificity in diagnosing AAV and, c) determine if there is a cut-off point that allows to correlate the levels of anti-PR3 antibodies with the severity and prognosis of AAV.

**Methods:** Observational study of patients with positive anti-PR3 from a University Hospital, from 2003 to 2022. ANCA was determined by chemiluminescence. The specificity of anti-PR3 for AAV diagnosis, predictive value of severity and prognosis were determined with Receiver Operating Characteristic (ROC) curves. At diagnosis, AAV with renal failure (hematuria and/or proteinuria) and lung involvement (hemoptysis, asthma and/or respiratory failure) were considered severe. During follow-up, the prognosis was considered worse if the patient needed dialysis, a transplant, or died.

**Results:** We study 54 patients with positive PR3. Most of them (81.5%) had an underlying AAV being the most frequent GPA (61.1%). The non vasculitic disease more frequent was Ulcerative colitis (11.1%). The non vasculitic disease more frequent was Ulcerative colitis (11.1%). The non vasculitic disease more frequent was Ulcerative colitis (11.1%).

**Conclusion:** The presence of anti-PR3 is mainly associated with AAV, although in up to a fifth of cases it can be associated with other diseases. Anti-PR3 antibodies levels, at the moment of AAV diagnosis, correlates with disease diagnosis (specificity) and with severity but not with disease outcome.

ARE CHANGES IN SELF-REPORTED NSAID DOSE ASSOCIATED WITH MEANINGFUL CHANGES IN PAIN OR OTHER HEALTH OUTCOMES IN RHEUMATIC DISEASES?

**Keywords:** Patient reported outcomes, Osteoarthritis, Pain

K. Michaud1,2, S. Pedro2, N. Goei1,4, 1University of Nebraska Medical Center, Medicine, Omaha, United States of America; 2Arthritis Research Center: National Data Bank for Rheumatic Diseases, Research, Wichita, United States of America; 3ThalSpark, Research and Development, New York, United States of America; 4Duke University - Main Campus, Medicine, Durham, United States of America

**Background:** Rheumatic disease primary treatment effectiveness research inconsistently addresses confounding effects of nonsteroidal anti-inflammatory drugs (NSAIDs) on pain and inflammation. Further, NSAID comedication use is often captured either as a simplified binary measure (eg. yes/no) or with a more burdensome high level of detail (eg. daily pill dose).

**Objectives:** Evaluate if moderate complexity items measuring changes in monthly NSAID dose are associated with changes in pain.

**Methods:** Patient-reported data from 1998-2021 were analyzed from the Forward Databank, a US-based longitudinal rheumatic disease registry, with questionnaires completed every 6 months. Eligible participants with RA or OA reported NSAID use on ≥1 questionnaire and had ≥1 follow-up (FU) questionnaire. NSAID use recorded type of drug, initiation, discontinuation, re-use, and dose.

**Disclosure of Interests:** Declared, Marcos Lopez-Hoyos: None declared, Ricardo Blanco Speakers bureau: Abbvie, Lilly, MSD, UCB Pharma, Grunenthal and Celgene. Alba Herrera-Moran: None declared, Maria Rodriguez Vidriales: None declared, Luis Martin-Penagos: None declared, Alba Herrera-Moran: None declared, Alba Herrera-Moran: None declared, Alba Herrera-Moran: None declared, Alba Herrera-Moran: None declared, Alba Herrera-Moran: None declared, Alba Herrera-Moran: None declared.
frequency by 0-10, 11-20, or >20 days a month. Primary exposure was change in NSAID dose from baseline (increase, no change, decrease). Increase was defined as initiation, increase in frequency, increase in dose, or any combination of the 3; decreases were similarly defined directionally. Primary outcome was change in the pain visual analog scale (VAS, 0-10). Gaussian generalized estimating equations (GEE) models with robust standard errors [SE] were used to assess the association between pain and NSAID change or type of change (increase, decrease). Models were adjusted for demographics, rheumatic disease comorbidity index (RDCI), total joint replacement, other treatments (eg, opioids, disease-modifying antirheumatic drugs), and NSAID type.

**Results:** A total of 22,445 RA and 5,278 OA patients initiated ≥1 NSAID. Median (IQR) FU time of NSAID exposure was 4.5 (2–9) years for RA and 2.5 (1–5) for OA. Patients with RA vs OA were younger (59 vs 64 years [y]), but similar on other characteristics (male 20% vs 15%, White 96% vs 94%, disease duration 14 vs 16y, and RDCI 1.5 ±1.5 vs 1.7±1.5). Overall, 24% of RA 6-month observations (~160700 observations) included an NSAID increase and 18% a decrease; in OA (~39800 observations), 30% increased and 18% decreased. 70% of RA patients (OA 77%) had an NSAID increase during FU and 69% (OA 67%) decrease. Starting or stopping an NSAID was the most common change (Figure 1). In RA, any NSAID increase was significantly associated with increased pain of 0.15 units (and for any NSAID decrease, decreased pain of 0.06) (Table 1), supported by the statistically significant directional changes in pain for any individual category of NSAID increase or decrease. In OA, any NSAID increase was significantly associated with increased pain of 0.06 units but were not significant for any decrease; only the individual categories of NSAID initiation and increased dose were significantly associated with increased pain and decreased NSAID dose associated with decreased pain.

**Conclusion:** We quantified the change in pain associated with change in NSAID dose generally, directionally, and by change type. All types were important for an increase in pain, but a decrease in NSAID frequency was more significant than other types for RA. Further work is needed to extend the definition of change by including other confounding treatments, eg, anaglesics and opioids, and to understand optimal collection of concomitant medications that may influence trial results, especially in OA.

**Keywords:** Psoriatic arthritis, Outcome measures

**Methods:** Patients diagnosed with PsA according to CASPAR criteria were enrolled. The demographic, clinical, and functional characteristics of patients were evaluated. Functional assessment was performed with DH, Hand Functional Index (HFI), Health Assessment Questionnaire (HAQ), and VAS-disability scale. C-reactive protein level, patients’ and physicians’ global VAS, swelling and tenderness of the hand joints, gross grip strength and thumb strength, and disease activity assessments were recorded as non-functional parameters related to active disease status. The reliability of DH was assessed by internal consistency (Cronbach’s alpha coefficient), Face, content, and construct validity (convergent and divergent) were evaluated. Face and content validities were assessed via cognitive debriefing interviews with the patients. The correlations of the DH with HAQ, HFI, and VAS disability were assessed for convergent validity. The correlations of the DH with BASDAI, MDA, PASAQoL, Jenkins index, PASI, and grip strength were evaluated for divergent validity.

**Results:** One hundred and forty-four patients (74.3% female) with a mean age of 45.33 (SD: 11.58) years were included in this study. Cognitive debriefing showed the DH to be clear, understandable, and relevant. It was easy to complete and calculate, with the 4 minutes and 30 seconds, respectively. The Cronbach’s alpha coefficient was 0.963, and for the test–retest reliability of the DH, the intraclass correlation coefficient was 0.904 (p<0.001). DH showed good correlations with the functional disability scales (HAQ, HFI, VAS-disability), indicating its convergent validity and moderate to non-significant correlations with the non-functional parameters supporting its divergent validity (Table 1).

**Conclusion:** The DH is a valid and reliable scale to evaluate the functional disability of hands in patients with PsA.

DIFFERENCES BETWEEN DISEASE ACTIVITY MEASURED BY ULTRASOUND VERSUS THE STANDARDIZED CLINICAL ACTIVITY INDEX (DAS28 AND DAPSA) FOR RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS BEFORE STARTING BIOLOGICAL THERAPY: A RETROSPECTIVE STUDY

**Keywords:** Psoriatic arthritis, Rheumatoid arthritis, Ultrasound

**Background:** Numerous studies have been written about the role of ultrasound as an objective tool for measuring damage and to predict subsequent progression of inflammatory joint diseases, as well as to detect low-grade synovitis, even in patients with low disease activity.[1] It has been suggested that some patients with subclinical inflammation may experience radiological progression and joint damage despite being in clinical remission.[2]

**Objectives:** The main objective of this study is to analyze the differences between the disease activity measured by ultrasound versus the standardized clinical activity index (DAS28 and DAPSA) for Rheumatoid Arthritis (RA) and Psoriatic Arthritis (APS) before the start date treatment with biological therapies.

**Methods:** A retrospective, non-interventional study was performed by reviewing the databases of RA and APS patients from the Hospital Universitari Víctor Macarena's Rheumatology department as well as an inferential study comparing the disease activity measure by ultrasound to the standardized clinical activity index.

**Results:** Sensitivity of ultrasound for detecting disease activity in both RA (N=54) and APS (N=31) has been included and correlated with the baseline ultrasound activity before the start date of treatment with biological therapies. The contrast of the baseline DAS28 and DAPSA means for the different ultrasound findings did not show significant differences (Table 1).

**Conclusion:** In our daily clinical practice, an adequate correlation is found between ultrasound findings and DAS28 and DAPSA activity. Several factors could be responsible for this, such as the sample size and variability of the population. Further studies are needed to make recommendations about the role of ultrasound (in conjunction with the standardized activity index) to ensure the proper therapeutic strategies in inflammatory joint diseases.

ANTI-DFS70: ARE THEY HELPFUL WHEN ASSESSING FOR SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES?

**Keywords:** Descriptive studies, Autoantibodies, Diagnostic tests

**Background:** Autoantibodies against DFS70 (dense fine speckles 70) antigen (anti-DFS70) are purported to rule out systemic autoimmune rheumatic diseases (SARD) when detected in the absence of other SARD-related antibodies. They are recognized using indirect immunofluorescence (IFF) and are a common finding among antinuclear antibodies (ANA)-positive healthy individuals. Data published so far highlight the negative association between anti-DFS70 and SARD.

**Objectives:** Describe the characteristics of a cohort of anti-DFS70+ patients and its relationship with the presence of SARD and analyze the existence of other variables that could be related to SARD and might be used as clinical prediction tools.

**Methods:** Retrospective study of anti-DFS70+ patients at Hospital del Mar (Bcn, Spain) in 2021 and 2022. Demographic, clinical and biological data were collected. Presence of anti-DFS70 was determined by immunoblot using EUROLINE®EUROMUN kit, which allows qualitative in vitro determination of human autoantibodies of IgG isotype. Simultaneously, presence of autoantibodies against double-stranded DNA (anti-dsDNA) and extractable nuclear antigen antibodies (ENA) was also tested to exclude other autoantibodies that could produce similar staining patterns (i.e., AC-1 or AC-1 with AC-4,5). A descriptive and correlatives statistical analysis was performed using SPSS®.

**Results:** Sera from 85 ANA+ patients with a DFS IIF pattern were tested for anti-DFS70. 52 patients tested positive and were included: 10 males and 42 females. Mean age to first anti-DFS70+ determination was 40.67 ± 16.99 years. Table 1 depicts data comparison between anti-DFS70+ patients with/without SARD. No SARD was found in 44 patients (84.6%). From 8 patients with SARD, 2 tested positive for other autoantibodies. A correlation was found between higher ANA titers and presence of SARD. No other significant correlation was found.

**Conclusion:** Our data suggest that in a population of ANA-positive patients being studied for SARD, the presence of anti-DFS70, even at moderate to high titer, may be considered a reassuring result regarding the negative association with SARD. In our cohort, the only characteristic that might act as a predictor of SARD was higher ANA titer, which could warrant stricter assessment in these patients. To state the possible protective role of anti-DFS70, we should not settle exclusively with the typical ANA staining pattern, but confirm the autoreactivity as being directed specifically against DFS70. Finally, it is plausible that the clinical use of this test may result in considerable cost-saving potential.

Background: Health-related quality of life (HRQoL) is the ultimate objective of treatment in axial spondyloarthritis (axSpA) [1]. However, current treatments are mainly focused on improving disease activity. Therefore, it is of interest to better understand the link between disease activity and HRQoL in axSpA. **Objectives:** To explore through a systematic literature review the link between disease activity and HRQoL in axSpA. **Methods:** Systematic literature review in December 2022 of articles reporting an association between disease activity and HRQoL in patients with axSpA. PubMed was searched using keywords related to disease activity scores and HRQoL, for articles published in English after 2010. Disease activity was assessed by ASDAS or BASDAI. For HRQoL, we analysed the ASAS Health Index (ASAS-HI) as key outcome. All statistical measures of a potential link between ASDAS and HRQoL were collected; correlations were prioritised for homogeneity. The strength of the association was qualified as nil (no statistical association), weak, moderate or strong with cutoffs of 0.50 and 0.70 for correlations. No meta-analysis was performed. **Results:** Of 122 papers, 23 were relevant, ie, 14375 patients: weighted mean age 42.5 years, weighted mean disease duration 14.3 years, 67.4% were men; when reported, 37% patients were receiving a targeted treatment (biologic or synthetic targeted treatment). The link between disease activity and HRQoL was nil in 3 cases, weak in 9 cases, moderate in 11 articles, and strong in 5 articles (Table 1). The 4 largest studies (with more than 1000 patients) showed a weak link (one paper), a moderate link (2 papers) and a strong link (one paper). We did not evidence an association between year of publication or gender balance, and the link between disease activity and HRQoL (data not shown). **Conclusion:** HRQoL is a complex concept which is not only linked to disease activity in axSpA. When aiming for improved HRQoL for our patients, the shared decision-making process should take these elements into account. **REFERENCE:** [1] Ramiro S, et al. Background: The Flare-OA questionnaire is an instrument with five domains (painful, swelling, stiffness, consequences of symptoms, and psychological aspects) that was recently developed to measure the occurrence and severity of flares in patients with knee or hip OA. The Flare-OA scale consists of 33 items and has been validated and translated into Turkish following an established forward-backward translation procedure. After an expert committee reviewed the Turkish version, the final version was checked for the translation's understandability, interpretability, and cultural relevance with ten patients. Patients who were ≥45 years of age with clinical and radiological OA of the knee or hip, according to American College of Rheumatology criteria and confirmed by the recruiting physician, were included in the study. The Flare-OA scale consists of 33 items and has been reduced to 19 items by factor analysis and content approach (RMSEA = 0.06; CFI = 0.96; TLI = 0.94) [1]. The reliability of Flare-OA was assessed by internal consistency (Cronbach’s alpha coefficient). Face, content, and construct validity (convergent) were evaluated. The correlations of the Flare-OA with the Hip Disability and Osteoarthritis Outcome score (HOOS), Knee Injury and Osteoarthritis Outcome Score (KOOS), and the Mini Osteoarthritis Knee and Hip Quality of Life Questionnaire (Mini-OAKHQOL) were assessed for convergent validity.

Results: A total of 185 (71.9% females) patients with knee or hip OA were included in the study. The Flare-OA scale consists of 33 items and has been reduced to 19 items by factor analysis and content approach (RMSEA = 0.06; CFI = 0.96; TLI = 0.94) [1]. The reliability of Flare-OA was assessed by internal consistency (Cronbach’s alpha coefficient). Face, content, and construct validity (convergent) were evaluated. The correlations of the Flare-OA with the Hip Disability and Osteoarthritis Outcome score (HOOS), Knee Injury and Osteoarthritis Outcome Score (KOOS), and the Mini Osteoarthritis Knee and Hip Quality of Life Questionnaire (Mini-OAKHQOL) were assessed for convergent validity.

AB1690 SERUM PEPTIDES AS CANDIDATE BIOMARKERS FOR RELAPSING POLYCHONDRIITIS

Keywords: Biomarkers

1St. Marianna University Graduate School of Medicine, Disease Biomarker Analysis and Molecular Regulation, Kawasaki, Japan; 2St. Marianna University Graduate School of Medicine, Clinical Proteomics and Molecular Medicine, Kawasaki, Japan; 3Kindai University, Department of Genetic Engineering, Faculty of Biology-Oriented Science and Technology, Kinokawa, Japan; 4St. Marianna University School of Medicine, Department of Otolaryngology, Kawasaki, Japan; 5St. Marianna University School of Medicine, Division of Rheumatology and Allergology, Department of Internal Medicine, Kawasaki, Japan; 6St. Marianna University School of Medicine, Division of Neurology, Department of Internal Medicine, Kawasaki, Japan; 7Institute of Medical Science, St. Marianna University School of Medicine, Department of Rare Diseases Research, Kawasaki, Japan

Background: For relapsing polychondritis (RP), no useful biomarkers have yet been identified.

Objectives: We analyzed serum peptide profiles to identify candidate biomarkers.

Methods: Patients with RP or rheumatoid arthritis (RA) and healthy control (HC) subjects were divided into training (RP, n=19; RA, n=21; HC, n=17) and testing (RP, n=24; RA, n=21; HC, n=18) sets. Seven patients demonstrating granulomatosis with polyangitis (GPA) were used for validation. The ion intensity of peptides was comprehensively measured by MALDI-TOF/MS.

Results: 160 serum peptides were detected. In the RP group of the training set, 24, 8, and 7 peptides showed a ≥1.2-fold difference in ion intensity in comparison to the HC, RA, and HC+RA (non-RP) groups, respectively (p<0.05). Based on a supervised multivariate analysis of the ion intensity of 160 peptides, we generated 3 models that completely discriminated the RP group from the HC, RA, and non-RP groups (AUROC, 1.000). By selecting 11, 9, and 14 peptides, the RP group was also completely discriminated from the 3 groups (RP/HC-11P, RP/RA-9P model, and RP/nonRP-14P model; AUROC, 1.000). We attempted to identify the peptides with a ≥1.2-fold difference in ion intensity between the RP group and one of the 3 groups and the peptides comprising the RP/HC+11P, RP/RA-9P or RP/nonRP-14P models. Nineteen peptides were identified. Most were fragments of proteins associated with coagulation. As biomarker models for RP which consists of a few peptides, we found that 4 models consisting of 4 peptides difference (36.2 and 36.6; 33 and 19 items, respectively) between patients with and without flare. Pearson’s correlation coefficients of the Flare-OA questionnaire with the other parameters for construct validity are represented in Table 1.

AB1691 BURDEN OF AFFECTED FACE IN PATIENTS WITH SYSTEMIC SCLEROSIS: A TRANSLATION AND VALIDATION STUDY IN TURKISH

Keywords: Quality of life, Validation, Patient reported outcomes

Research background: Facial involvement is crucial for patients’ quality of life in patients with systemic sclerosis (SSc). The face is one of the main aspects that can be affected in SSc patients. The Burden of Face Affected (BoFA) scale is a useful tool for assessing skin-related quality of life in SSc patients.

Objectives: The aim of this study was to evaluate the reliability and validity of an adapted Turkish version of the BoFA.

Methods: The translation and cross-cultural adaptation of the French version of the BoFA was conducted. All steps of the cross-cultural adaptation process were performed by the Beaton guidelines. The Turkish version of the BoFA, the Mouth Handicap in Systemic Sclerosis (MHiSS), the Rosenberg Self-Esteem Scale (RSE), and Perceived Stress Scale (PSS) were performed to the 49 patients with SSc patients. Reliability was assessed using the test-retest method; internal consistency was analyzed using Cronbach’s alpha. Construct validity was assessed by correlating the BoFA with the MHiSS, RSE, and PSS questionnaires.

Results: The BoFA showed excellent test/retest reliability with an intraclass correlation coefficient of 0.96 for total score. Internal consistency of the BoFA was found to be excellent (Cronbach’s alpha 0.96). The BoFA demonstrated good construct validity with the MHiSS (r = 0.55, p < 0.001), the RSE (r = 0.53, p < 0.001), and the PSS (r = 0.50, p < 0.001). Also, the factor analysis showed the BoFA has four-factor subgroup by score plot graph. There were no BFA founds to be related to the floor and ceiling effects.

Conclusion: The Turkish version of the BoFA to assess the skin-related quality of life in SSc patients was found to have good validity, excellent reliability, and high internal consistency. The BoFA could be used in research and clinical studies on Turkish SSc patients.

DOI: 10.1136/annrheumdis-2023-eular.5553
Results: The fusion protein was purified as a calprotectin dimer mimic. Calcium addition could successfully transform calprotectin dimer into a calprotectin tetramer. Affinities to monoclonal and polyclonal calprotectin antibodies were comparable to native calprotectin. Spiking of different concentrations of recombinant calprotectin showed linear correlations in ELISA and turbidimetric assays. A perfect correlation (slope=1.009; R²=0.999) was shown when measuring 23 human serum samples based on native and recombinant calprotectin calibrators with a turbidimetric assay.

Conclusion: The recombinant protein can be purified in large quantities in defined oligomeric forms and it shows immunological properties comparable to native calprotectin. Recombinant calprotectin presents as a promising tool to overcome the prevalent fecal calprotectin standardization problem and prevent future standardization discrepancies for serum calprotectin.

IN VIVO MEASUREMENT OF POTENT AND DURABLE HUMAN ADIPOSE 11β-HYDROXYSTEROID DEHYDROGENASE TYPE 1 INHIBITION BY SPI-62

Keywords: Clinical Trials, Vasculitis, Targeted synthetic drugs

D. Katz1, G. An2, G. Schmicker2, B. Engeli3, T. Magers4, R. Basu5, J. Gutierrez6,7.

1Sparrow Pharmaceuticals, n/a, Portland OR, United States of America; 2University of Iowa, College of Pharmacy, Iowa City, United States of America; 3Q2 Biosolutions MD, Project Management, Indianapolis IN, United States of America; 4Q2 Biosolutions MD, Method Development and Validation, Indianapolis IN, United States of America; 5ProSciiento, n/a, Chula Vista CA, United States of America; 6ProSciento, n/a, Chula Vista CA, United States of America; 7Scripps Clinic, Medicine, La Jolla CA, United States of America

Background: 11β-hydroxysteroid dehydrogenase type 1 (HSD-1), an intracellular enzyme that converts glucocorticoids (GC) from inactive (e.g., prednisone, cortisone) to active (e.g., prednisolone, cortisol) form is a main source of intracellular GC that can bind to intracellular GC, mineralocorticoid, and non-genomic receptors. Prior clinical and non-clinical results support the hypothesis that HSD-1 inhibitors have potential to mitigate GC toxicity without eliminating GC efficacy. Results from tissue-specific HSD-1 knockout mouse studies indicate that adipose is a key target tissue for GC cardiometabolic toxicity prevention or reversal. However, several HSD-1 inhibitors have shown tachyphylaxis on adipose inhibition in human within 14 days of dosing.

Objectives: Learn whether SPI-62 achieves full and durable adipose HSD-1 inhibition in human.

Methods: Participants with type 2 diabetes and BMI 30-45 kg/m² received SPI-62 daily for up to 14 days in an open label Phase 1 clinical trial. Microdialysis catheters (Type 63, µ dialysis, Stockholm Sweden) inserted in subcutaneous adipose were infused continuously with [2,2,4,6,6,9,12,12-2H8]cortisone. D8E results below the limit of quantification during Day 14. Data from all 12 participants was used to model dose-exposure-response relationships to refine dose selection for future clinical trials.

THE EFFECTS OF TELE-REHABILITATION-BASED STABILIZATION EXERCISES ON BALANCE, GAIT, FUNCTIONALITY, PAIN AND DEPRESSION IN INDIVIDUALS WITH CHRONIC IDIOPATHIC NECK PAIN

Keywords: Rehabilitation, Physical therapy/Physiotherapy, Non-pharmacological interventions

H. Ayar1,2, B. Kara2, R. Erbayraktar3, Izmir Katip Çelebi University Vocational School of Health Services, Department of Medical Services and Techniques, Izmir, Turkey; Dokuz Eylül University, Institute of Health Sciences, Izmir, Turkey; Dokuz Eylül University, Faculty of Physical Therapy and Rehabilitation, Izmir, Turkey; Dokuz Eylül University, Department of Neurosurgery, Faculty of Medicine, Izmir, Turkey

Background: Chronic neck pain is associated with balance and gait disturbances [1,2]. The effects of tele-rehabilitation-based stabilization training on balance and gait in chronic idiopathic neck pain (CINP) are still unknown.

Objectives: This study aimed to compare the effects of tele-rehabilitation-based scapular and core stabilization training on balance, gait, functionality, pain and depression in CINP.

Methods: Forty-one individuals with CINP (36 females, 5 males) were participated in the study. Participants were randomized into two groups as scapular (SS) group (n=21, 19 females, 2 males, age 20.00 [19.0-21.0] years, VAS score 4.00 [3.0-5.0]) and core stabilization (CS) group (n=20, 17 females, 3 males, age 20.00 [19.0-21.0] years, VAS score 4.00 [3.0-5.0]). Tele-rehabilitation-based exercise sessions were conducted with mutual videoconferencing synchronously in groups of 2-3 participants, 45-60 minutes duration, once a-week for 8 weeks. Postural stability (PS) and limits of stability (LOS) were measured by a computerized balance platform. Spatiotemporal gait parameters (speed (m/sec), cadence (steps/min), stride length (m), step length (% stride length)) and right and left side pelvic tilt (°), pelvic obliquity (°) and pelvic rotation (°) symmetry (%) were assessed with a wearable sensor device. The gait was assessed during two different walking conditions.
Firstly, the participants walked at usual (normal) walking speed on the 10-meter walking path. Secondly, they walked this distance at the maximum speed they could walk safely. Neck Disability Index (NDI) for functionality, VAS for pain intensity, Depression and Beck Depression Inventory (BDI) for depression, FDI for flexion deficit index, WRVAS and posture parameters at the beginning of the study. The comparison of the results of the WRVAS and PostureZone scores of the cases within and between groups, while the sub-parameters of WRVAS and PostureZone of the patients increased significantly in both groups within the post-treatment group, a significant improvement was observed in the sub-parameters of WRVAS and PostureZone in Group I.

Conclusion: At the end of this study, PSE and CT applied to children with rheumatism had a corrective effect on flexibility, ATR, Cobb, WRVAS, posture. PSE were more successful than CT in improving these parameters. The results of our study, which we planned to investigate the effectiveness of PSE, showed that this method has superior aspects in many parameters compared to CT in children with rheumatism, and it may be beneficial to be included in the treatment plan.

AB1697 COMPARISON OF DISEASE ACTIVITY, INFLAMMATORY BIOMARKER, FUNCTIONALITY, PARTICIPATION AND BIOPSychosocial status OF INDIVIDUALS WITH JIA ACCORDING TO THE PRESENCE OF UPPER EXTREMITY INVOLVEMENT

Keywords: Physical therapy/Physiotherapy, Pain, Inflammatory arthritides

B. Duran1, N. B. Karaca2, M. Ö. Tüfekçi2, E. N. Atabay Gerlegiz3, E. Aliyev4, Y. Bayındır5, V. Yıldız Kabak6, S. Atasavun Uysal7, Y. Bilginer8, E. Ünal9, S. Özen1, 1Hacettepe University Faculty of Physical Therapy and Rehabilitation, Department of Heart and Respiratory Physiotherapy and Rehabilitation, Ankara, Turkey; 2Hacettepe University Institute of Health Sciences, Department of Basic Physiotherapy and Rehabilitation, Ankara, Turkey; 3Hacettepe University Faculty of Physical Therapy and Rehabilitation, Department of Basic Physiotherapy and Rehabilitation, Ankara, Turkey; 4Hacettepe University Faculty of Medicine, Department of Child Health and Diseases, Ankara, Turkey

Background: Musculoskeletal involvements due to synovitis and tenosynovitis in the upper extremity joints of individuals with JIA negatively affect their daily living activities with the progression of the process [1-2].

Objectives: The aim of this study is to compare the disease activity, inflammatory biomarker, functionality, participation and biopsychosocial status of individuals with JIA according to the presence of upper extremity involvement.

Methods: Forty individuals (21 girls, 19 boys) who were followed up with the diagnosis of JIA between March and December 2022 were included in our study. Individuals whose demographic information was obtained were divided into two groups as those with isolated upper extremity involvement (JIA+UE, n=11) and those without active and/or sequela joint involvement in the upper or lower extremities (JIA-UE, n=29). Disease activity (JADAS-71 and BASDAI), inflammatory biomarker (ESR and CRP), functionality (Childhood Health Assessment Questionnaire (CHAQ)), participation (The Child and Adolescent Scale of Participation (CASPI)) and biopsychosocial status (Juvenile Arthritis Biopsychosocial and Clinical Questionnaire (JAB-Q)) were evaluated.

Results: While there was no difference between the two groups in terms of age, gender and BMI(p>0.05), in the JIA+UE+ group, JADAS-71 (p=0.012), CRP (p=0.041), CHAQ-Pain (p=0.048), CRP-Overall Impact (p=0.003), JADAS-71 and BASDAI, inflammatory biomarker (ESR and CRP), functionality (Childhood Health Assessment Questionnaire (CHAQ)), participation (The Child and Adolescent Scale of Participation (CASPI)) and biopsychosocial status (Juvenile Arthritis Biopsychosocial and Clinical Questionnaire (JAB-Q)) were significantly different.

Conclusion: Disease activity and inflammatory biomarker levels of JIA+UE+ individuals were higher than those of JIA-UE+ individuals in addition, pain, functionality, participation and biopsychosocial status of JIA+UE+ individuals were worse than those of JIA-UE+ individuals. Our results were consistent with the literature, which
revealed that functionality, school performance, and general quality of life were negatively affected in JIAUE+ individuals [6]. The data obtained from the study revealed that the upper extremity joint involvement of individuals with JIA showed more negative effects than those without involvement. With these results, the need for a rheumatologist-physiotherapist-occupational therapist interdisciplinary team understanding was emphasized in order to include individuals with JIA with upper extremity involvement in the exercise-physical activity and participation processes in daily life at the earliest stage, taking into account the disease activity.

HIGH-VELOCITY LOW-AMPLITUDE SPINAL MANIPULATIONS FOR THE MANAGEMENT OF LUMBAR RADICULAR SYNDROME: A SYSTEMATIC REVIEW WITH META-ANALYSIS

Keywords: Systematic review, Rehabilitation, Physical therapy/Physiotherapy
G. Bertoni1, R. Serio1, F. Andreolletti1, F. Masellif, M. Testa1, S. Battista1.
1University of Genova, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Savona, Italy

Background: Lumbosacral Radiculopathy (LSRS) is a condition characterised by pain radiating in one or more dermatomes (Radiculopathy) and/or the presence of neurological impairments (Radiculopathy) [1]. Physiotherapy plays a crucial role in LSRS management [2]. So far, different reviews have investigated the effect of HVLA (high-velocity low-amplitude) spinal manipulations in LSRS [3–7]. However, these studies included mixed population samples (LBP patients with or without LSRS) and treatments other than HVLA spinal manipulations (e.g., mobilisation, soft tissue treatment, etc.). Hence, the efficacy of HVLAT in LSRS is yet to be fully understood.

Objectives: This review investigated the effect and safety of HVLATs on pain, levels of disability, and health-related quality of life in LSRS, as well as with any possible adverse events.

Methods: A systematic review with meta-analysis. We searched Randomised Controlled Trials (RCT) published in English in the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE (PubMed), EMBASE, PEDro and Web of Science up to June 2022. We considered eligible RCTs on an adult population (18-65 years) with LSRS that compared HVLATs with other non-surgical treatments, sham spinal manipulation, or no intervention. Two authors selected the studies, extracted the data, and assessed the methodological quality through the ‘Risk of Bias (RoB) Tool 2.0’ and the certainty of the evidence through the ‘GRADE tool’. A meta-analysis was performed to quantify the effect of HVLA on pain levels.

Results: A total of 308 records were retrieved from the search strings. Only two studies met the inclusion criteria. Both studies were at high RoB. Two meta-analyses were performed for low back and leg pain levels. HVLA seemed to reduce the levels of low back (MD = -1.48; 95% CI = -2.45, -0.50) and lower limb (MD = -2.36; 95% CI = -3.28, -1.44) pain compared to other conservative treatments, at three months after treatment. However, high heterogeneity was found (I² = 0.0%, p = 0.735). Besides, their certainty of the evidence was 'very low'. No adverse events were reported.

Conclusion: In line with our results, we cannot conclude whether HVLA spinal manipulations can be helpful for the treatment of LSRS or not. Future high-quality RCTs are needed to establish the actual effect of HVLA manipulation in this disease with adequate sample size and LSRS definition.

**Education**

**AB1699**  COVID-19 IMPACT ON SECOND YEAR MEDICAL STUDENTS EXPERIENCE WITH INTERACTIVE PATIENT ENCOUNTERS AS A SUPPLEMENT TO TEACHING THE SKIN AND RHEUMATOLOGY COURSE

**Keywords:** Education, COVID

E. Littman1, S. Rea1. 1. UCF College of Medicine, Internal Medicine, Orlando, United States of America

**Background:** The use of interactive patient scenarios has long been a valuable component of medical school curricula, as this type of learning facilitates empathy, comprehensive understanding, and cultural sensitivity.[1] The COVID-19 pandemic, however, has precipitated a shift to more virtual strategies to keep students, faculty, and patients safe.[2]

**Objectives:** To evaluate second year medical students’ (MS2s) perceptions on the use of live patient encounters during the teaching of the skin and rheumatology course (BMS 6635) using different teaching formats due to changes from the COVID-19 pandemic.

**Methods:** Four to five patients with dermatologic, autoimmune, and musculoskeletal diseases volunteered to participate in an interactive teaching session with MS2s at the University of Central Florida College of Medicine. MS2s enrolled in BMS 6635 were asked to voluntarily complete a survey about their learning experiences using these patient cases. Students who did not respond to the survey were excluded. Data analysis using Chi Square testing was performed on survey responses obtained pre-pandemic as compared to those collected in academic years 2020-2021 and 2021-2022 during the COVID-19 pandemic.

**Results:** 700 surveys were obtained after patient cases given in different formats. When the interactive patient cases were given in person before COVID-19, 93% of students enjoyed the cases and 95% of students believed that the cases were an appropriate learning experience in their education. When these cases were delivered virtually beginning in the academic year 2020-2021, however, students’ enjoyment of these cases decreased to 86%, with 92% of students believing that the cases were an appropriate learning experience. This is a 7% and 9% decrease, respectively, from pre-pandemic years. During the academic year 2021-2022, use of a hybrid model, with students and faculty in-person and patients participating virtually, resulted in 81% of students enjoying the interactive patient cases and 83% of students believing that the cases were an appropriate learning experience. This was a 12% decrease from before the COVID-19 pandemic (p < .001) and a 5% and 9% decrease, respectively, from the previous year (p < .001) (Figure 1). 37% of students who had their cases in a completely virtual format preferred the interactive patient sessions to stay completely virtual, while 51% of students who participated in hybrid sessions during COVID-19 preferred the sessions to be completely virtual (p < .019) (Table 1).

**Table 1. Medical student survey responses comparing live patient encounters given in person, completely virtually, and a hybrid format**

**Conclusion:** The use of interactive patient cases in medical education has been met with positive feedback over the years and should continue to be used in medical education. This study showed that MS2s enjoyed the patient encounters more when delivered in-person vs a virtual or hybrid format. Careful consideration should be given to delivery format to optimize student learning and enjoyment.

**Figure 1. Medical students’ feedback on live patient cases given in different platforms before COVID-19 and during the COVID-19 pandemic.**

**AB1700**  RHEUMATOLOGIST’S ASSESSMENT OF ACUTE SARCOIDOSIS

**Keywords:** Systematic review

G. Koolibaeva1, O. Egorova2, A. Bolotbekova1, A. Turatbekova1, G. Synbai K1, Togulok Moldo St, Rheumatology, Bishkek, Kyrgyzstan; Kashirskoye Shosse, 34, Rheumatology, Moscow, Russian Federation; Togulok Moldo St, Rheumatology, Bishkek, Kyrgyzstan

**Background:** Lofgren syndrome (LS) is the acute form of sarcoidosis, characterized by erythema nodosum (EN), joint involvement, fever and intrathoracic lymphadenopathy. LS clinical polymorphism leads to diagnostic errors.

**Objectives:** To study the clinical, laboratory and radiological features of early stages of sarcoidosis in a cohort of patients referred to rheumatology center.

**Methods:** The study included 135 patients (107 females and 28 males, mean age 37 ± 9.4 y) with clinical and radiological features of LS. All patients were referred to rheumatology center with EN diagnosis. The median duration of disease was 1 [0.5–2.0] months. All patients were subjected to comprehensive clinical and laboratory-instrumental examination, including biochemical panel and immunological parameters, chest X-ray or CT, as well as (20 cases) histopathology examination of nodular biopsy specimens of the skin and subcutaneous fat.

**Results:** In 97 % pts EN involved the lower legs, mostly the anterior surface, in 35 % - the hips, in 25 % - the upper limbs and in 3% - the trunk. Symmetric lesions were documented in 50% of patients. Confluence of nodules forming conglomerates was registered in 48% pts. The involvement of more than 50 % of lower leg surface (68 %) was directly associated with the number of nodules (p = 0.002; r = 0.54) and C-reactive protein level (p = 0.005; r = 0.34). There was a direct correlation between the number of nodules and EN duration (p = 0.03; r = 0.20), and also the tendency to nodules confluence (p = 0.001; r = 0.37). Joint involvement was documented in 115 (85 %) patients, with predominantly ankle (67.4%) and knee (40%) joints affected. Asymmetry of joint involvement was documented in 9% pts. Articular manifestations preceded the emergence of EN in 51 (36 %) patients by mean 9 ± 4 days. There was a significant direct correlation between the duration of articular syndrome and appearance of nodules and their number (p = 0.01; r = 0.42). Joint involvement after EN manifestation – in an average 4 ± 3 days – was documented in 20% of cases. Male gender (odds ratio (OR) 6.5; confidence interval (CI) 1.2–35; p = 0.024) and presence of nodular conglomerates (OR 4.8; CI 1.4 – 16.1; p = 0.01) were the key predictors of ground glass opacity CT phenomenon. In 87 % of patients EN did not relapse, and articular syndrome almost completely regressed during 1 year follow-up.

**Conclusion:** Patients with an acute form of sarcoidosis require coordinated action of different medical specialties, including rheumatologists, to determine the scope of further examination and adequate therapeutic regimen.

**AB1701**  HOW TO MAKE A VIRTUAL PRESENTATION USING ARTIFICIAL INTELLIGENCE?

**Keywords:** Artificial Intelligence, Best practices, COVID

A. C. Genç1,2, F. Turkoğlu Genç1, Z. N. Kayaba, E. Gönlüboğ1. 1. Hacettepe University Graduate School of Education, Artificial Intelligence, Istanbul, Turkey; 2. Sakarya University Faculty of Medicine, Rheumatology, Sakarya, Turkey

**Abstract:** This study aims to provide guidance on how to create and deliver effective virtual presentations for medical students and professionals using artificial intelligence. The study highlights the importance of incorporating AI tools to enhance engagement, simplify content delivery, and facilitate better understanding. Methods: A literature review was conducted to identify best practices in creating engaging virtual presentations using AI. Results: The analysis revealed several strategies that can be applied to create visually appealing presentations, such as using interactive quizzes and games, virtual simulations, and chatbots for real-time engagement. Conclusion: AI can play a crucial role in improving the quality of virtual presentations. However, it is essential to use these tools thoughtfully to avoid overwhelming the audience. Future research should focus on developing AI-driven tools that can automatically analyze the audience's understanding and adapt the presentation content accordingly. **References:** [1] Greenfeld D, Gonen I, et al. Artificial Intelligence in Medical Education: A Systematic Review. J Med Educ Curric Dev. 2019; 6:8. [2] Patil J, Reddy S, et al. The Use of Artificial Intelligence in Medical Education: A Review of Current Literature. Background: Virtual presentations have become increasingly common due to the COVID-19 pandemic and advancements in technology. However, it is not yet clear how to effectively use artificial intelligence (AI) in virtual presentations to enhance their effectiveness.

Objectives: The aim of this study is to investigate the current state of AI in virtual presentations and to develop practical guidelines for using AI to enhance the effectiveness of virtual presentations.

Methods: ChatGPT is an artificial intelligence chatbot [1]. The final version contains information up to years of 2021. We wrote to ChatGPT: “I want to submit a study for the European League Against Rheumatism (EULAR) 2023. Title: “How to make a virtual presentation using artificial intelligence?” Prepare a summary consisting of background and objectives sections for me.” The texts generated by ChatGPT were transferred to another virtual platform to be converted to audio and video. The text in the background and objectives sections in this abstract was voiced by the speaking avatar [2].

Results: ChatGPT wrote the background and objectives part of this abstract. As the authors, we have not made any changes in order to be objective. Thanks to another artificial intelligence, the content in this text was voiced by an avatar and turned into a video (Figure 1).

Conclusion: In the near future, artificial intelligence will be used more effectively in the preparation and presentation of scientific articles. In this way, artificial intelligence will help scientists to use their time more efficiently. Developing technology also offers equal opportunities for scientists with social phobia and visual or speech disabilities.

AB1702 SECOND YEAR MEDICAL STUDENT FEEDBACK ON LIVE PATIENT ENCOUNTERS AS A SUPPLEMENT TO TEACHING THE SKIN AND RHEUMATOLOGY COURSE

Keywords: Education
E. Litman1, S. Beq2. "UCF College of Medicine, Internal Medicine, Orlando, United States of America; 2UCF College of Medicine, Internal Medicine, Orlando, United States of America

Background: Live, interactive patient cases have shown to be a valuable resource in medical education. Although a few studies have shown that using patients as teachers helps students develop clinical reasoning, motivates students to learn, and has important educational benefits, there is little research understanding medical student feedback during these interactive patient cases.[1,2]

Objectives: To evaluate second year medical students’ perceptions on interactive patient encounters during the teaching of the skin and rheumatology course (BMS 6635) based on surveys collected from 2016-2022.

Methods: Second year medical students completed a survey on their experience from four to five interactive patient cases at University of Central Florida College of Medicine. The interactive cases, involving patients with diagnoses of systemic lupus erythematosus, psoriatic arthritis, dermatomyositis, scleroderma, and pyoderma gangrenosum. Second year medical students enrolled in BMS 6635 from 2016-2022 were included. Students who did not respond to the survey questions were excluded. Chi Square test was performed on survey responses. Regression analysis was performed on significantly different survey responses.

Results: A total of 700 surveys were completed after the interactive patient encounters. 90% of participants answered that they enjoyed the interactive patient cases with 92% of students agreeing that the interactive patient cases were an appropriate learning experience for their education. 76% of students agreed that the patient encounters helped them retain knowledge of the disease processes. However, only 36% agreed that the number of patients in the interactive patient cases should be increased (Table 1). From 2016 to 2022 there has been a slight decrease in enjoyment in the interactive patient cases over time (97%, 88%, 93%, 94%, 86%, 81%, p<.001, respectively per year). From 2016 to 2022, there was a slight decrease in students agreeing that the interactive patient cases were an appropriate learning experience in their education (98%, 92%, 94%, 95%, 93%, 84%, p=.001, respectively per year) (Figure 1).

Figure 1. Agreement trend in medical student’s response to survey questions from 2016 to 2022.

Conclusion: Interactive patient cases are a valuable resource in medical education and should be integrated in medical curricula. Overall, students enjoyed the interactive patient cases, believed they were an appropriate learning addition to their medical education even with a minimal number of cases, and aided in retention of material. However, from 2016 to 2022 a slight decrease in positive feedback regarding this approach was noted, which could be attributed to technological advancements and the increasing use of third-party resources among students. The decrease, while minimal, is an important consideration for academic institutions.

AB1703 EVALUATION OF A TRAINING COURSE ON BREAKING BAD NEWS IN RHEUMATOLOGY

Keywords: Patient information and education, Education
G. Khaldi1, S. Miladi1, W. Abdelghaffar2, A. Fazaa3, H. Boussa3, M. Yasmine1, K. Ben Abdelghani1, R. Rafati2, M. A. Laatar3. 1Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia; 2Hôpital Mongi Slim, Psychiatry, Marsa, Tunisia

Background: Although communication skills towards breaking bad news are an important aspect of medical care [1], future Tunisian rheumatologists have no formal training in this area. The gaps in communication skills are significant to date in the field of rheumatology.

Objectives: The aim of this study was to evaluate the impact of a training workshop on the disclosure of bad news in rheumatology.

Methods: We conducted a prospective, multicenter, interventional study over a six-month period during the academic year 2021-2022. 31 residents were
recruited on a voluntary basis. Two groups were individualized: the training group A (N=16) and the control group B (N=15). The training session included interactive lectures, video-case studies, role-playing and peer-to-peer discussions. A self-administered survey was used to assess residents’ abilities to deliver bad news before and three months after the training.

Results: Following training (T3), group A residents showed a significant improvement in their ability to plan the announcement consultation (p=0.004), prepare the patient for the announcement of bad news (p=0.009), deliver the bad news itself (p=0.003), as well as in their self-assigned skill level (p=0.003). The post-training ratings were significantly better than those of control group B. However, the training group’s progress in handling patients’ emotions was not statistically significant (p=0.488), and there was no distinction between the two groups after the training. Although both groups of residents were quite adept at managing their stress, their reactions to the announcement were primarily negative (sorrow and sadness). The inclusion of this training in the rheumatology curriculum received “extremely important” or “important” ratings from all residents (100%), when looking at the determinants of a successful announcement, the year of residency was the only factor that showed a statistically significant association with enhanced theoretical knowledge (p = 0.049).

Conclusion: This study highlighted the improvement of the residents’ competencies as well as their self-assigned skill level related to the use of role-play in the acquisition of competencies related to a particular situation such as the announcement of bad news. The training seminar on breaking bad news was beneficial and had a positive impact on the residents’ performance. It enabled them to pick up several new abilities.

DOI: 10.1136/annrheumdis-2023-eular.3543
Results: A total of 88 patients were included, 54 women and 34 men. The mean age was 43.1 ± 10.1 years. Rheumatoid arthritis (RA) was found in 39%, Spondyloarthritis (SpA) in 19%, gonarthrosis in 20%, chronic mechanical low back pain in 9%, cervicobrachial neuralgia in 7%, gout in 3%, degenerative shoulder pathology in 5% and mechanical talalgia in 2%. The average duration of the disease was 6 ± 3 years. Self-medication was reported in 63% of patients. Concerning the type of self-medication, 88% of the patients used a treatment not prescribed in the initial prescription, 9% increased the doses of treatments already prescribed and 3% prolonged the duration. The most frequently used self-medication drugs were level 1 analgesics (66.7%), level 2 analgesics (8.1%), general non-steroidal anti-inflammatory drugs (NSAIDs) (39.4%), topical NSAIDs (30.3%), proton pump inhibitors (PPI) (12.1%) and corticosteroids (36%). Risk attitudes were detected in 32% of patients, of whom 6% exceeded 4 g per day of paracetamol, 15% combined 2 systemic NSAIDs, 2% took long-term NSAIDs, and 9% used PPIs for a long time without indication. The use of self-medication was not associated with sex (p = 0.5), level of education (p = 0.6) or professional activity (p = 0.58). Only one significant association was found with the duration of the disease (p = 0.025).

Conclusion: Self-medication is practiced by the majority of our patients, motivated by various reasons and concerns the various analgesics drugs. The objective would be to rationalize the easy access to medication, to include therapeutic education in our medical practice in order to avoid the potential risks incurred.

AB1707 FACTORS ASSOCIATED WITH SEDENTARY BEHAVIOR IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASE

Keywords: Non-pharmacological interventions, Education

S. Bahajil1,2, H. Rkain1, S. E. Zaat1, F. J. Ei Joumani1, F. Kronbl1, R. Honsali1, S. Farih1, I. Bensaghir1, C. Nouri1, T. Latifa1, H. H. Najia3, F. Allali1.

1Hospital Al Ayachi, Rheumatology B, Salé, Morocco; 2Faculty of Medicine and Pharmacy of Rabat, Laboratory of Physiology, Rabat, Morocco; 3International University of Rabat, Health Sciences College, Rabat, Morocco

Background: The sedentary behavior is a priority for women and people with reduced mobility.

Objectives: To determine factors related to sedentary behavior in patients with a chronic inflammatory rheumatic disease (CIRD).

Methods: We conducted a cross-sectional study of 140 patients (mean age of 47.1 years, 66% females) affected by CIRD (Rheumatoid arthritis 56.4%, ankylosing spondylarthritis 32.1%, psoriatic arthritis 8.6% and juvenile idiopathic arthritis 2.9%), information on patients and disease characteristics were collected. Physical activity was measured objectively using the short version of the IPAQ questionnaire (International Physical Activity Questionnaire) for 7 consecutive days. Activity levels were subdivided into low physical activity and moderate to vigorous physical activity. We analyzed factors associated with sedentary behaviors.

Results: IPAQ Average was 413 (0.760) MET-min/week. The sedentary behavior was noted in 75.2% of patients. Table 1 summarizes factors associated with sedentary behavior in patients with chronic inflammatory rheumatic disease.

Conclusion: Sedentary behavior is very prevalent among CIRD patients. Awareness-raising actions on the importance of physical activity in CIRDs should be a priority for women and people with reduced mobility.

AB1708 SOCIAL MEDIA AS A SOURCE OF INFORMATION AMONG MOROCCAN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

Keywords: Education, Inflammatory arthritides

N. El Mansouri1, F. Z. Taik1, R. Bensaid1, H. Fouzia1, N. Soba2, M. Fourtassi2, F. E. Abourazzak1,2, Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco; 2Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco.

Background: Little research has been conducted on the use of different type of social media as a source information by Moroccan patients with chronic inflammatory rheumatic diseases and on the evaluation of the quality of this information that give an impact on the quality of life which that still poorly known in our context.

Objectives: The objective of our study is to evaluate the use of different type of social media by our patients and to identify the factors that may be associated with them.

Methods: This is a cross-sectional study including all patients followed in our rheumatology department for chronic inflammatory rheumatic diseases. Sociodemographic data, comorbidities, chronic inflammatory rheumatic diseases related findings (type, pain assessment, disease activity and treatment) were collected. Patient’s beliefs and attitudes regarding the various social media were assessed by a questionnaire. A list of 7 type of social media was provided, for which patients were asked to indicate the type of social media used and their confidence in them, followed by their experience with the usefulness of the sources used. Catastrophizing, trust in physician, and concerns about medicines were assessed by the validated Moroccan versions of the pain catastrophizing scale (PCS), trust in physician scale (TPS), and beliefs about medicines questionnaire (BMQ specific concerns).

Results: We included 189 patients. The average age was 47.49 ± 12.7, 75.7% of patients were women, 52.4% had comorbidities, and 49.2% were illiterate. The median duration of the disease was 8 [3-16.75]. Mean pain VAS was 4.77 ± 2.76. 37.6% of patients were in remission. 56.1% of the patients declared to look for information related to their chronic inflammatory rheumatic diseases on social media as a source of information. The 3 main sources were: YouTube (30.7%), Google (25.9%) and Facebook (16.9%). 19% have already applied some of this information. Only 20.1% discussed the information they found with their treating physicians and 67.2% would like to have health professionals in their virtual spaces to answer their questions. In univariate and multivariate analysis (Table 1), age, level of education, level of concern, and belief about medication were statistically significantly associated with the use of social media.

needs and promote the research interests of aspiring young academics. A considerable number of young physician work or train in rheumatology in Turkey.

Objectives: To assess the awareness of the educational and research offerings of EULAR and EMEUNET among young rheumatologists working in Turkey.

Methods: We sent an e-mail to rheumatology trainees and consultant rheumatologists below the age of 40 years. We surveyed the general information about the offerings of the EULAR School of Rheumatology and EMEUNET. Data were analyzed descriptively.

Results: The response rate of 61% (116/190) was obtained. A slightly over half of the respondents were female (n=82, 53.5%). Most of the respondents (n=75, 65%) were rheumatology fellows in training, and the remaining respondents were consultant rheumatologists. EULAR School of Rheumatology courses and EULAR research webinar series were well known (74% and 59%, respectively) among the participants (Table 1). However, less than half of the respondents who were aware of these events attended to a course or a research webinar previously (37.5% and 43%, respectively). The major obstacles to participation in these events were lack of enough time due to the clinical duties (50%) and language barrier (35%). Only 14% and 25% of the respondents were aware of the EULAR research consultation service and the EULAR scientific grant. 76 (85%) participants were aware of EMEUNET while only 13 (17%) of them were attended an EMEUNET event previously.

Conclusion: Educational offerings of EULAR and EMEUNET were well known by the young rheumatologists in Turkey. However, participation rate was not satisfactory. Majority of the respondents were unaware of the EULAR research offerings. Conducting a survey across Europe could show the main obstacles in a larger scale, thereby it helps to disseminate further offerings among young rheumatologists.

AB1710 LEARNING TO CARE FOR OLDER ADULTS WITH RHEUMATIC DISEASES: A NATIONAL SURVEY TO ASSESS CANADIAN RHEUMATOLOGY RESIDENTS’ KNOWLEDGE AND INTEREST IN GERIATRIC-RHEUMATOLOGY

Keywords: Comorbidities, Education, Qualitative research methods

S. M. Cho1, H. Mcdonald-Blumer2,3, L. Romanovsky4,5, A. Bookman2,8, A. Omai2,8. 1University of Toronto, Medicine, Toronto, Canada; 2University of Toronto, Rheumatology, Toronto, Canada; 3Mount Sinai Hospital, Rheumatology, Toronto, Canada; 4University of Toronto, Geriatric Medicine, Toronto, Canada; 5Mount Sinai Hospital, Geriatric Medicine, Toronto, Canada; 6University Health Network, Rheumatology, Toronto, Canada

Background: As the global population ages, the number of older adults with musculoskeletal and rheumatologic disorders is expected to rise.[1] This presents a challenge for rheumatologists, as the evaluation and management of older adults often requires understanding the unique considerations of multi-morbidity, polypharmacy, and geriatric syndromes.[2] Despite this growing need, it is currently unknown if rheumatology trainees receive sufficient education in geriatric-rheumatology during their training.

Objectives: To understand the perspectives and needs of rheumatology residents regarding geriatric-rheumatology education during their training in Canada.

Methods: The study conducted a cross-sectional needs assessment of rheumatology trainees in Canada who were enrolled in a residency or advanced fellowship training program within rheumatology. The survey underwent a pilot phase to ensure user-friendliness prior to its distribution. The survey was distributed to program directors of rheumatology training programs across Canada from December 2022 to January 2023, which was then forwarded to the residents within the respective rheumatology programs. The survey included multiple choice and open-ended questions exploring the residents’ demographic data, exposure to geriatric-rheumatology education, knowledge gaps in managing older adults with rheumatic diseases and attitudes towards learning about geriatric-rheumatology. Data was analyzed using descriptive statistics.

Results: Fourteen rheumatology residents participated in the study, with an estimated response rate of 31.1%. Most residents (79%) had not received formal geriatric-rheumatology training during their rheumatology training. Residents (85%) were also unaware of any clinical tools or educational resources to help assess and manage older adults with rheumatic diseases. Most residents (71%) reported that geriatric-rheumatology training would be useful for their future practice and for taking care of older adults. Additionally, 65% of residents felt that formal rheumatology training curriculum should include geriatric-rheumatology contents. Areas where residents reported least confidence were applying the geriatric 5M framework, managing frailty, and providing end-of-life care to older adults with rheumatic diseases. They were most interested in learning how presentations and management of vasculitis, systemic lupus erythematosus and inflammatory arthritis differ in older adults and recognizing the indications of anticoagulants and pain medications associated with the use of DMARs and biologics in this age group.

Conclusion: Our research revealed that rheumatology residents do not receive sufficient training in geriatric-rheumatology, indicating the need for a specialized curriculum in this field. Additionally, we discovered specific areas of interest among residents that can inform the development of future training initiatives. Overall, our study emphasizes the significance of incorporating geriatric-rheumatology education into rheumatology training programs.

knowledge score and male gender (p=0.001). The compliance score was negatively correlated with age (0.01; rs -0.65) and number of prescription drugs (0.01 rs -0.65) (p 0.014; rs -0.57), and positively correlated with the duration of disease progression (p 0.001; rs 0.87). No relationship was found between knowledge and compliance (p = 0.15).

Conclusion: The utilization of a score could be a method to evaluate knowledge and to adapt the content of educational actions to increase adherence to treatments.

THE BELIEFS OF MOROCCAN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES REGARDING MEDICATION AND THEIR IMPACT ON THERAPEUTIC ADHERENCE

Keywords: Self-management, Education, Inflammatory arthritides

N. El Mansouri1, F.Z. Taik2, R. Bensaid1, F.Z. Ahrane1, N. Soba2, M. Fourtassi3, F.E. Abouarazzak1, 1Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco; 2Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco

Background: Adherence is one of the key elements of management in patients with chronic inflammatory rheumatic diseases, and it is likely to be influenced by beliefs about medications, which will influence the management and quality of life of patients.

Objectives: Objective is to assess chronic inflammatory rheumatic diseases patient’s beliefs about medications, the factors associated with them, and their impact on therapeutic adherence.

Methods: This was a cross-sectional study that included any patient followed for chronic inflammatory rheumatic diseases. Sociodemographic data, comorbidities, information on inflammatory rheumatism ds (type, pain and activity assessment and and treatments) were collected. Beliefs about medication were assessed by the validated Moroccan version of the Belief on Medicine Questionnaire (BMQ). Catastrophizing, trust in physician and adherence to therapy were assessed by the validated Arabic versions of the pain catastrophizing scale (PCS), trust in physician scale (TPS) and Compliance Questionnaire Rheumatology (CQR)

Results: 189 patients were included. The average age was 47.49 ±13.75. 75.7% of the patients were women, 52.4% had comorbidities, 49.2% were illiterate, 56.6% were followed for rheumatoid arthritis, 35.4% for spondyloarthritis and 79% for undifferentiated chronic inflammatory rheumatic. The median duration of evolution of chronic inflammatory rheumatic diseases was 8 [3-16.75]. 41.3% of patients were on synthetic DMARDs and 4.2% on biotherapy. The mean VAS pain was 4.77 ± 2.76. 37.6% of patients were in remission. The average CQR was 55.16±8.1 P

The mean BMQ specific necessity was 20.75±4.77. 67.4% of the patients strongly believed that medication is essential to maintain their health. The mean of the BMQ concerns was 23.77±4.9. 74.1% of the patients thought that not taking their medication carries a risk. In multivariate analysis (Table 1), there was a statistically significant association between education level, catastrophizing, trust in the physician, and the necessity-concern differential. There was also a significant correlation between the therapeutic compliance score and the BMQ necessity score and the BMQ differential necessity-concerns.

Conclusion: Moroccan patients followed for chronic inflammatory rheumatic diseases have a rather positive perception of their medication. This perception seems to influence their adherence to treatment.

EVALUATION OF A TRAINING COURSE ON EMOTIONAL MANAGEMENT WHEN BREAKING BAD NEWS IN RHEUMATOLOGY

Keywords: Education, Patient information and education

G. Khald1, S. Milali1, W. Abdelghaffar2, A. Fazaia1, H. Boussaa1, M. Yasmine2, K. Ben Abdelghani2, R. Rafariti2, M. A. Laatari2, 1Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia; 2Hôpital Mongi Slim, Psychiatry, Marsa, Tunisia

Background: In recent years, attitudes towards breaking bad news have changed dramatically to emphasize patient autonomy and avoid psychological harm [1]. As a result, learning how to deliver bad news efficiently became a fundamental clinical skill in professional practice. [2]. In the field of rheumatology, with learning focused on technical skills, gaps in communication skills are to date significant.

Objectives: The aim of this study was to evaluate the impact of a training workshop on the disclosure of bad news in rheumatology.

Methods: We conducted a prospective, multicenter, interventional study over a six-month period during the academic year 2021-2022. We recruited 31 residents on a voluntary basis. Two groups were individualized: The training group (N=16) and the control group (N=15). The training session included interactive lectures, video-case studies, role-playing and peer-to-peer discussions. A self-administered survey was used to assess residents’ abilities to deliver bad news before and three months after the training.

Results: The comparison of the patient emotion management scores between the two groups in the post-training period showed no significant difference (p=0.115). And although there was a slight improvement in the scores in post-training, no significance was found either in the training group (p=0.488) or in the control group (p=0.523).

In terms of managing residents’ emotions, most residents in both groups experienced neutral feelings during the periods of silence during the announcement consultation, and there was no discernible difference between the two groups at either time. The percentage of residents in group A who felt negatively during the times of silence significantly decreased by 38% after the training (T3) (p=0.013), while the percentage of residents who felt positively increased by 25% (p=0.033). In Group B, no significant difference was found between the two time periods in terms of feelings during quiet time. Although the basic skills of the residents in dealing with stressful moments were quite good as more than 50% of the residents in both groups were able to maintain their neutrality during these difficult moments, it was shown that the training had a positive impact on the residents’ feelings during stressful moments such as the silent moments. At the end of the announcement, most residents in both groups unanimously had negative feelings (desolation and sadness) with no significant difference between the two groups at either time.

Conclusion: Emotional skills training requires a lot of practice and review, which was not possible during our one-day training intervention. However, our training workshop, although short in duration, had partially improved residents’ ability to respond to emotional cues.

GOUT TREATMENT: ARE TUNISIAN INTERNS FOLLOWING INTERNATIONAL RECOMMENDATIONS?

Keywords: Gout

F. Ali1, O. Hamdi2, S. Milali1, W. Abdelghaffar2, A. Fazaia1, H. Boussaa1, M. Yasmine2, L. Soueibni1, K. Cueninche2, S. Chekiel2, S. Kassabi1, K. Ben Abdelghani2, A. Laatari2, 1Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia

Follow-up
Background: Gout is a common metabolic disease affecting at least 1% of the population. Its therapeutic management was recently redefined by the recommendations of the French society of rheumatology (SFR) 2020 [1,2].

Objectives: We aimed to determine the level of adherence of Tunisian rheumatology interns to these recommendations.

Methods: We conducted a 26-item online questionnaire via Google Drive Forms destined to rheumatology interns. The questionnaire intended to assess the degree of application of the French recommendations for the treatment of gout.

Results: The online questionnaire was sent to 50 rheumatology interns, 19 of whom (38%) responded. Thirty-one percent of participants were in first year, 15.7% in second year, 16% in third year and 31.5% in fourth year. The mean age was 28.3 ± 8.7 years [26-33]. All participants were female. The average number of rheumatology internships performed was 3.9 ± 0.2 [1-6]. All of the participants declared informing their patients of their pathology. The information given concerned the disease (94.7%), the aim of treatment (78.9%), the need for long-term adherence to treatment (94.7%), the risk of onset of gout symptoms at initiation of treatment (84.7%) and necessary adaptations to lifestyle (94.7%).

Eighteen interns (94.7%) advised their patients to avoid certain foods: soda (84.2%), beer (89.4%), wine (36.8%), red meat (84.2%), fish (63.1%), chicken (26.3%) and seafood (73.6%). Almost all physicians screened for comorbidities (94.7%): hypertension (73.6%), dyslipidemia (78.9%), obesity (63.1%) and renal failure (78.9%). The therapeutic means that can be used in gout flares according to the doctors questioned were the following: non-steroidal anti-inflammatory drugs (NSAIDs) (94.7%), colchicine (100%), corticosteroid therapy (94.7%) and anti- interleukin 1 (36.8%). Faced with a gout flare, 17 interns (89.4%) prescribed colchicine within 12 hours after the symptoms onset. Eleven interns (57.8%) followed the therapeutic regimen recommended by the SFR for flare treatment with colchicine. In the event of the onset of diarhoea under colchicine, 8 interns (42.1%) stopped the treatment. Regarding corticosteroid therapy, the recommended dose of 30 to 35 mg/day was prescribed in 42.1% of cases. In case of kidney failure, doctors avoided prescribing NSAIDs in 89.4% of cases and colchicine in 63.1% of cases. Eighteen physicians (94.7%) prescribed allopurinol from the first gout flare. Colchicine was prescribed simultaneously with allopurinol in 47.3% of cases. Sixteen interns prescribed colchicine for six months in combination with urate-lowering treatment. Interns were aiming for a therapeutic uricemia target of 50mg/L in 15.7% of cases and 60mg/L in 73.6% of cases. The urate-lowering treatment was maintained for life by 57.8% of the interns, while it was stopped as soon as the therapeutic target was reached in 26.3% with retreatment if recurrence in 21% of the cases. Faced with a decrease in renal clearance, no intern stopped allopurinol and 78.9% of doctors prescribed it with retreatment if recurrence in 21% of the cases. Faced with a decrease in renal clearance, no intern stopped allopurinol and 78.9% of doctors prescribed it with retreatment if recurrence in 21% of the cases. Faced with a decrease in renal clearance, no intern stopped allopurinol and 78.9% of doctors prescribed it with retreatment if recurrence in 21% of the cases.

Conclusion: Tunisian rheumatology interns do not fully follow the new French recommendations for the treatment of gout. Thus, medical training on the subject seems necessary in order to optimize the treatment of this pathology in Tunisian hospitals.

AB1716 TREATMENT MODALITIES IN ANTI-MDAS DERMATOMYOSITIS: A CASE SERIES FROM SOUTH INDIA

Keywords: Myositis

D. R. Puligari1, S. C. Veeravalli1, Krishna Institute of Medical Sciences, Rheumatology, Hyderabad, India

Background: Anti-MDA 5 antibody – associated DM presents with rapidly progressive intestinal lung disease (RP-ILD), and is known to have poor prognosis. Early detection of ILD, given the risk of rapid deterioration and best treatment guidelines are of extreme importance due to high disease burden and mortality. As we encountered different cases of DM in our OPD at a renowned tertiary care centre in Hyderabad, India, we too had tailor-made diverse treatment regime based on patients’ condition and their circumstances, and henceforth we present 10 of such cases wherein the customized treatment plan brought about significant relief in their condition.

Objectives: To study and report 10 cases of Anti-MDAS ILD and treatment outcomes.

Methods: Among 10 patients newly diagnosed with Anti-MDAS ILD at our hospital, 5 patients had RP-ILD, out of which 3 suffered with refractory ILD. Among the varied treatments given 2 patients required IVIG and Plasma Exchange was used as an adjunct to standard treatment in 1 refractory ILD patient as salvage therapy. All patients were followed at least for six months post management and 7 patients reported significant improvement with maximum reversal of HRCT findings.
RESULTS:

Conclusion:

Dermatomyositis is a rare, multi-system idiopathic inflammatory myopathy characterized by skin rash and muscle weakness that is often accompanied by pain and fatigue. Other manifestations include intestinal lung disease and calcinosis. Malignancy is also highly associated with DM. The profound negative clinical impacts of DM on patients’ quality of life (QoL) are not yet well-characterized in the literature.[1]

OBJECTIVES:

1. Capture patient perspectives on the impact of DM on QoL (physical function, mental health, personal relationships, and work productivity), most bothersome symptoms (MBS), and severity of symptom burden in adults.

METHODS:

A 60-question survey was developed via sponsor-conducted focus groups and adaptations from existing patient-reported outcome (PRO) tools (e.g., WPAI-GH, SLE-FAMILY, and PROMIS). After IRB approval, members of The Myositis Association (~4000 individuals with DM) were invited to complete the online survey (eligibility criteria: 18 – 75 years of age, self-reported DM diagnosis, and current DM symptoms persistent for ≥ 1 year). Responses were collected per the following Likert scales: DM severity rated from “mild” to “very severe” (4-point scale), overall health rated from “poor” to “excellent” (5-point scale), life impact questions rated from “never” to “always” or “not at all” to “a great deal” (5-point scales), and severity of symptoms rated from “never experienced” to “very severe” (8-point scale).

RESULTS:

Of 195 respondents (97% from US), the median age was 57 years, 88% female, and 82% White. 53% and 35% had experienced DM symptoms for 3 to 10 years or > 10 years, respectively. 92% were currently receiving medication(s) to manage DM symptoms. The 5 MBS reported were muscle weakness (44%, n = 86), fatigue (43%, n = 84), muscle pain (30%, n = 59), itchy skin (24%, n = 46), and skin rash (19%, n = 37). A majority of respondents indicated DM had at least a “moderate” negative impact on the following domains: ability “to do the things they enjoy” (83%, n = 162), ability to engage in social activities (75%, n = 146), sexual desire and ability to engage in physically intimate relationships (64%, n = 125), relationships outside of family (57%, n = 112), and relationships with family (51%, n = 100). A majority reported negative impacts on mental health (83%, n = 162), defined as having felt “anxious or nervous” or “down, depressed or hopeless” at least “sometimes” due to DM. Almost half reported being “usually” or “always” worried about symptoms flares (49%, n = 96) and about their ability to carry out daily activities (42%, n = 82). DM symptom severity was associated with negative impact on overall health. “Fair” or “poor” health was reported by 50% (n = 98) of those experiencing “moderate” DM symptoms, by 83% (n = 27) of those with “severe” symptoms, and by 100% (n = 7) of those with “very severe” symptoms. All with “very severe” DM responded “usually” or “always” to questions about DM limiting their ability to “do the things they enjoy,” concern about symptoms “getting worse,” and ability to “carry out daily activities.” DM symptoms hindered physical functioning, with 63% and 65% of respondents, overall, reporting that DM limited their ability to climb stairs and perform usual daily activities. DM also affected respondents’ ability to work; nearly half were unemployed (47%, n = 92) and had to change their work; nearly half were unemployed (47%, n = 92) and had to change their employment status due to DM (49%, n = 95), while 24% (n = 47) were receiving disability assistance. Of respondents who were working, 69% (n = 77) reported that DM negatively impacted their career/career choices.

Conclusion:

The survey results highlight the marked physical and psychosocial burden of DM in adults and the impact of disease severity on the ability to perform daily activities, mental health, interpersonal relationships, and work productivity. These results underscore the unmet need for new treatment options to ameliorate the progressive and debilitating consequences of DM and further inform PRO-focused research in DM.

Ravindran14, Tircolour Hospitals, Rheumatology, Variotaria, India; Care Pain & Arthritis Centre, Udaipur, India; Rheumatology, Udaipur, India; Apollo Hospitals, Rheumatology, Kolkata, India; Kauvery Hospital, Rheumatology, Chennai, India; Shifa Medical Centre, Rheumatology, Srinagar, India; Ojas Centre for Autoimmune Diseases, Rheumatology, Indore, India; Apollo Hospitals, Rheumatology, Indore, India; Pune Rheumatology Centre, Rheumatology, Pune, India; Fortis Hospital, Rheumatology, Navi, India; Max Hospitals, Rheumatology, New Delhi, India; Shri Gangaram Hospitals, Rheumatology, New Delhi, India; Arthritis clinic, Rheumatology, Saharanpur, India; Dua’s Rheumatology and Arthritis Care, Rheumatology, Bilaspur, India; Karan Hospital, Rheumatology, Palanpur, India; Subodhaya Rheumatology Hospital, Rheumatology, Tirupati, India; Centre for Rheumatology, Rheumatology, Calicut, India

Background: Psoriatic arthritis (PsA) is a disease with heterogeneous manifestations, which affects personal and professional aspects of patients’ lives. Perception of disease state in PsA affects patients significantly. However, studies examining PsA patients’ outlook about their disease are scarce and there are no studies from India examining PsA patients’ viewpoints about their disease.

Objectives: The main objective of this multi-centre multiple domain survey was to study the PsA patients’ perspectives.

Methods: A survey questionnaire with items on PsA patients’ demographics, knowledge, awareness and perception of disease, its treatment, physical therapy, quality of life and the care they received was designed. After internal and external validation, a pilot survey was conducted, and survey modified. The final survey was (with translations in local languages) administered by the participating 16 centres across India.

Results: There were 262 respondents with mean age of 45.14±12.89 years (56% male), Forty percent of the patients had first consultation more than a year after the onset of joint pain and in a majority their current diagnosis was made by a rheu- matologist. Most of the patients had psoriasis (92%) and arthralgia (76%) for more than one year, however, only 60% respondents took a doctor’s opinion for joint symptoms within one year. For two third of the patients, a rheumatologist made the diagnosis of PsA followed by a dermatologist (15%) and general physicians (8%). Over 83% of patients were consulting their rheumatologist once every three months or earlier and were fully compliant with the treatment. Busy schedules and cost of therapy were the most common reasons for non-attendance to ther- apy (Table 1). Eighty-eight patients (34%) were not fully satisfied with their current treatment. Twenty-one. % of the survey respondents were still unaware of the term PsA and 10% were unaware of their current diagnosis. Over two-third of patients had never seen a physiotherapist and listed lack of time, pain and lethargy as the main barriers to exercising. PsA had affected social and employment status of about half of the survey patients. Fatigue, busy work schedule, not able to lift weights, not able to travel without pain were elucidated by patients as main reasons for this effect. Most of the patients were satisfied with disease information provided by rheumatologist and dermatologists. Eighty five % patients in this survey reported not taking any form of complementary alternative medicine therapy. The unmet needs of patients identified in this survey were better provision of remote or online consultation, reduction in pill load, better patient education on disease and drugs and financial help for biological therapies.

Conclusion: This survey informs that although survey participants are satisfied with care given by rheumatologist and dermatologists, the disease is influencing their quality of life significantly by affecting socialization and occupation.

Arthritis research

AB1718-PARE002 MAPPING THE JOURNEY OF PEOPLE WITH RHEUMATIC DISEASES TO DIAGNOSIS IN GREECE

Keywords: Gout, Patient-led research, Real-world evidence

K. Scurgian1, K. Koutsogianni1, F. Asimakopoulou1, E. Repa1, I. Papadakis1, M. Chatziagorou1, P. Pratsidou-Geral1, A. Venkou1, M. Chatziioannou1, 1PanHellenic Federation REUMAEZIN, PanHellenic Federation ReuMAzein, Thessaloniki, Greece

Background: Rheumatic diseases (RD) are chronic mostly autoimmune diseases, multi-dimensionally affecting the musculoskeletal system and possibly other organs. Additionally, they impact the patient and family quality of life in respect to health, work, socialization and future perspectives. Previous data indicate that early diagnosis of inflammatory and other RDs is important in order to improve long-term outcome.

Objectives: To capture the journey of RD Greek patients from disease onset to diagnosis aiming to define gaps regarding the early management and uneventful outcome of these potentially debilitating chronic diseases.

Methods: An online questionnaire survey of patients with several types of RDs was uploaded by the Greek Federation REUMAEZIN, an acronym meaning co-living with an RD. 463 patients - all members of the Federation- responded to the call and were enrolled in the survey.

Results: The majority were females (81%), mostly under 60yrs old (73%) and were residents of urban/suburban areas (65%). In respect to education, they were mainly graduate or postgraduate degree holders (56%). The prevailing RDs were RA (178) 38%, SLE (105) 23%, AS (61) 13% and PsA (58) 13%, respectively. The total lag time (mo) was 10.3. In respect to RD kind, it ranged from 5.9 for JIA to 19.7 for AS, respectively. The delay from disease onset to diagnosis was mainly attributed to patient underassessment of symptoms (53%) or ignorance of the proper MD specialist (45%). Only a minority of participants (36%) reported that the diagnosis was made by the first specialty they had initially visited. The initial physician’s (MD) specialist for all but SLE patients, was an orthopedic surgeon (33-60%), whereas for SLE ones, an internist (32%). The initial MD failed to establish the diagnosis in 64% pts, principally in AS ones (82%). Alternatively, rheumatologists as the primer reached MD, established the diagnosis in 60% of patients. Lag time to first visit in non-Rheumatology specialists and the corresponding diagnosis was 26mo; for AS pts it reached 50.9mo, respectively. The average lag time from symptom appearance to the first MD visit was 21.3mo and from the 1st visit to final diagnosis 72.2 mo. All patients reported as the most important problem until the final diagnosis, the lag time to diagnosis (36%), followed by a misdiagnosis (33%). Interestingly, those who looked for a second assessment pre-diagnosis, reported higher percentage either of delay or misdiagnosis (49%, 44%, respectively). The degree of satisfaction regarding information received by the MD who established the final diagnosis was totally high (3.5/5) and was irrespective of the RD type. At final diagnosis, patients were highly satisfied regarding information received by the MD for their most important problem, too. In respect of satisfaction to final diagnosis by rheumatologists vs. non-rheumatologists, the rates did not significantly differ.

Conclusion: Findings of this study indicate that the initial patient visit with an RD to the proper MD specialty, is highly important. A visit to a trained Specialist for RD as a Rheumatologist, significantly reduces lag time to diagnosis and leads to an early management and optimal prognosis. Most of the patients expressed a high rate of satisfaction at the establishment of final diagnosis in respect to the MD and his/her skill in problem solving. Therefore, informing and educating the public regarding the early recognition of initial symptoms and early guiding to

### AB1720-PARE

**NEGATIVE ILLNESS BELIEF ASSOCIATED WITH MORE ACTIVE DISEASE ACTIVITY AND POORER FUNCTION IN THAI PATIENTS WITH ANKYLOSING Spondylitis and Psoriatic Arthritis**

**Keywords:** Spondyloarthritis, Patient reported outcomes, Mental health

P. Chiochwaniswajkit1, Faculty of Medicine, Siriraj Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand

**Background:** Regarding the common sense self-regulatory model[1], illness beliefs play an essential role in both physical and psychological adjustment to illness. There were few studies about the value of illness representations in the outcome of spondyloarthritis[2] and no study in Thailand.

**Objectives:** To explore the illness perception and their associated factors in AS and PsA patients.

**Methods:** This was a cross-sectional study. Spondyloarthritis patients visiting at Siriraj Hospital for treatment were recruited between 27 April 2021 and 31 October 2022. They were invited to fill out the Thai version of brief Illness Perception Questionnaire(BIQ) (total range 0 (no or best)-80(worst)), the medication taking behavior measure for Thai patients(MTB) [range 4(low adherence)–24 (high adherence)], demographic data, Ankylosing Spondylitis Disease Activity Score(ASDAS), and Bath Ankylosing Spondylitis Disease Activity Index(BASFI) were collected. The variables were associated with total BIQ were computed by linear regression.

**Results:** A total of 132 patients with 73(55%) male, mean(SD) age of 49(12) years, median(IQR) disease duration of 11(14) years, median ASDAS of 1.7(1.2), median BASFI of 0.9(2.2), median BIQ of 26(12), and mean MTB of 23.2(10) were recruited. The BIQ was significantly positively associated with ASDAS and BASFI in multivariate analysis. Consequences, timeline, identity, illness concern, and emotional representation were positively associated with ASDAS while identity and emotional representation were positively associated with BASFI (Table 1). Positive emotional representation in BIQ was associated with higher MTB (p<0.05).

**Conclusion:** The patients with positive illness perception were associated with better function, lower disease activity, and higher medication adherence. The goal of treatment should be inactive or low disease activity and normalized function as soon as possible may lead to positive illness belief and psychological strength, or vice versa. The positive illness belief may maintain the good health outcome. A longitudinal study is needed to support this association.

| Table 1. The association of the brief illness perception and disease activity, and function |
|-------------------|-----------------|-----------------|------------------|-----------------|------------------|
| Item              | Total ASDAS1    | Total BASFI2    | Unstandardized B coefficient |  |
| 1. Consequences   | 2(3)            | 2(3)            | 0.233*            | 0.126*           |
| 2. Timeline       | 8(5)            | 8(5)            | 0.071*            | 0.037*           |

**PATIENT REVIEWERS OF APPLICATIONS FOR RESEARCH FUNDING - A PILOT STUDY**

**Keywords:** Patient-led research

H. Thorseng1, C. Ziegler1, The Rheumatism Association, Politics and Knowledge, Gentofte, Denmark

**Background:** Each year the Danish Rheumatism Association supports research in the field of rheumatology with approx. 1.5-2 Million EUR to strengthen the basis for developing better prevention strategies and treatment and thus increase the quality of life for many people. Since 2014 it has been mandatory for researchers applying for funding from the research committee of The Danish Rheumatism Association to indicated whether and how they involve patient representatives in their research. Our annual measurements show that involvement of patient representatives by researchers receiving a grant from The Danish Rheumatism Association has increased from 14 % in 2015 up to 65 % in 2021. To strengthen the patient involvement in research further The Danish Rheumatism Association would like patients to have a say in the research funding decisions by reviewing applications for research funding to the research committee of the Danish Rheumatism Association.

**Objectives:** To carry out a pilot study with patients as reviewers of applications for research funding to The Danish Rheumatism Association.

**Methods:** Three patients, one man and two women, with different RMDs participated in the pilot study and were requested to try to represent all patients with RMDs. The study was carried out from August to December 2022. The Danish Rheumatism Association provided the patients with an online introduction to the work as patient reviewer, they were provided with information material and The Danish Rheumatism Association supported them throughout their time with us. The patients reviewed a summary of 6-26 research funding applications in plain language at home individually. The applications were scored from zero to five, where zero was the lowest score and five the highest. The research committee of The Danish Rheumatism Association was presented the patients mean score of the applications and comments from one or more patients before their meetings and oral on the meetings in September 2022 and December 2022 respectively.

**Results:** When the research committee met to decide which research should receive funding, they took the patients mean score and comments for each application reviewed into their decision as with other parameters like methodology, research outcome, involvement of patient representatives in the research etc.

**Conclusion:** The patients in the pilot study represented patients with RMDs. They reviewed the applications for the research committee of The Danish Rheumatism Association based on their experience of being a patient and had a say in research funding decisions. In spring 2023 the pilot study will be evaluated and it is expected that patients with RMDs will be involved in the future research funding decisions in The Danish Rheumatism Associations and maybe in a larger scale than in the pilot study.

DOI: 10.1136/annrheumdis-2023-eular.3621
Background: There is a lack of knowledge about the nature and frequency of the main limitations in activities and participation experienced by a subgroup of people with rheumatoid arthritis (RA) and severe limitations in physical functioning. More insight is essential to optimize treatment for this subgroup and can be obtained by linking the treatment goals perceived by the patient to the International Classification of Functioning, Disability and Health (ICF) as a frame of reference. Goal setting is widely recognized for tailoring and optimizing treatment, and for this purpose the Patient Specific Complaint (PSC) instrument is recommended in physiotherapy practices in the Netherlands [1].

Objectives: To describe the nature and frequency of limitations in activities and participation of people with RA and severe limitations. Limitations will be derived from the PSC [1] and linked to the ICF and the comprehensive and brief ICF Core Sets for RA.

Methods: Baseline data from a randomized controlled trial on the effect of long-term exercise therapy in people with RA and severe limitations in functioning were used. For each participant, the three most limited activities were identified and prioritized using the PSC. Two researchers independently identified meaningful concepts within each PSC activity and linked them to the most specific ICF category within the ‘Activities and Participation’ component, following standardized ICF linking rules [2]. In case of disagreement, this was discussed with a third researcher until consensus was reached. The frequencies of ICF categories were calculated overall and for PCS activities ranked 1, 2 and 3. Finally, the uniquely identified ICF categories were compared to the content of the comprehensive and brief RA ICF core sets for the component ‘Activities and Participation’.

Results: From 206 RA patients (90.8% female, 58.7 (12.9) years of age, 1.5 (0.5) HAQ-DI score), 618 PSC activities were recorded, including 911 meaningful concepts. These concepts were subsequently linked to 909 ICF categories, with 72 unique ICF codes. Overall, the most prevalent ICF categories were: 1) d4501 walking long distances (n=121; 59%); 2) d4502 walking on different surfaces (n=79; 38%); 3) d451 stair climbing (n=62; 30%); 4) d4103 changing body position from sitting (n=60; 29%) and 5) d4401 grasping (n=51, 25%). The categories for the ranked PSC activities differed slightly, and manipulating, d4502, often proved limited too (see Table 1). The uniquely identified ICF codes covered 21 of 32 items (66%) of the comprehensive and 4 of 6 items (67%) of the brief RA ICF core sets.

Conclusion: The most prevalent limited activities involved walking (long distances, on different surfaces and climbing stairs), changing body position from sitting and hand use (grasping and manipulating). To optimize treatment for this subgroup, clinicians should be aware that not all RA core set items are prevalent in practice and that some frequent problems are not included in the core sets.

- New medication (avacopan) | Back on prednisone
- New medication (avacopan) | New medication (avacopan)
Background: People living with musculoskeletal pain conditions prefer pain self-reporting for better pain management [1]. In a recent feasibility study, 104 people living with musculoskeletal pain conditions completed daily pain mankin reports, along with an optional free text pain diary using their own smartphone [2]. People shared their motivation to daily self-report their pain if that could improve their self-management [3]. There is a potential of electronic pain diaries to improve pain management [4], while it is unknown what people would describe in an optional pain diary to improve their pain management.

Objectives: The objective was to explore what people have described in their free text electronic pain diaries, which could be useful for improving their pain management.

Methods: In a recent study, we assessed the feasibility of daily pain self-reports for 30 days. A daily pain self-report included a single overall pain intensity question, a two-sided two-dimensional pain diagram, and a free text pain diary (see figure 1). For the latter, people could provide additional information in response to the question: Is there anything you would like to share about your pain diagram? We conducted a secondary thematic content analysis of the free text pain diary entries and identified key domains and ideas described by people. We presented themes descriptively.

Results: Out of 104 people, 94 completed 957 unique pain diary entries. We have presented key domains, ideas and illustrative quotes in the table 1. People described how medication and self-management practices (e.g., heat therapy, physical activity) helped them in managing their pain. They also described different aspects of their pain, including pain descriptors (e.g., pain location, quality, radiation), perceived causes (e.g., physical activity, cold weather) and consequences of pain (e.g., limited mobility, lack of sleep). People perceived some factors, such as medication, and level of physical activity, as both cause and consequence of their pain.

Conclusion: Electronic free text pain diaries provide useful information about people’s pain management practices. However, how best to track pain and self-management practices for effective pain management requires research.

AB1724-PARE

SEQUENCE PATIENT SURVEY: PERCEPTION OF THE USE OF ADVANCED THERAPIES FOR PSORIATIC ARTHRITIS IN THE UNITED KINGDOM

Keywords: Psoriatic arthritis, Patient-led research, bDMARD

C. Gollins1,2, A. Vivekanantham3, M. Brooke4, L. Coates4, W. Tillet1,2. 1Royal National Hospital For Rheumatic Diseases, Rheumatology, Bath, United Kingdom; 2University of Bath, Department of Life Sciences, Centre for Therapeutic Innovation, Bath, United Kingdom; 3University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 4Bath Institute For Rheumatic Diseases, British Psoriatic Arthritis Consortium, Bath, United Kingdom

Background: Due to the chronic nature of psoriatic arthritis (PsA) and the increase in therapeutic options, many people are receiving multiple sequential lines of biologic and targeted synthetic disease modifying anti-rheumatic drugs (b/tsDMARDs). There is limited data on treatment response to advanced lines of therapy and therefore in the rationed UK National Health Service, some regions are limited in the number of sequential b/tsDMARD per patient. Patients have higher levels of treatment satisfaction with biologics compared to conventional DMARDs[1] but little is known about patient satisfaction with access to b/ts-DMARDs in the UK.

Objectives: To assess the perceptions of people treated with b/tsDMARDS in the UK for PsA, focusing on the experience of access to advanced treatments.
Methods: The cross-sectional SEQUENCE patient survey was developed as an anonymous online questionnaire on the SurveyMonkey platform, available to be completed by people with self-reported PsA and current or previous b/tsDMARD treatment. The freely available online survey was promoted through PsA support groups via websites and social media. Descriptive analysis of the results was performed, with categorical variables summarised with frequencies and percentages.

Results: 67 people from England, Wales and Scotland responded (male 8, female 59), mean age 54.5 years, mean psoriasis duration 22 years (range 0-55) and PsA 14 years (range 1-50). The number of lines of previous b/tsDMARD treatment per respondent is outlined in Fig 1. The most common first line treatments were adalimumab (33/60) or etanercept (12/60) with secukinumab the most common second line drug (15/42). Switching treatments was most commonly due to primary or secondary failure. 46.7% (28/60) of people felt that a decision to switch treatment had been a joint decision between patient and physician. Only 9% (6/67) had been advised that there was a maximum number of biologics permitted in their region. 24% (16/66) had been advised that a particular b/tsDMARD had to be prescribed first line for PsA in their region, 76% (13/17) of whom reported this was a TNF inhibitor. One respondent had to move hospital or region to obtain access to further biologics. 32% (21/65) had been told that an individual funding request had been applied for to fund their next b/tsDMARD (likely due to limited funded treatment options), and this was successful for 90% (20/23). Qualitative responses highlighted the significant improvement that b/tsDMARDs make to people with PsA e.g. ‘They have given me my life back’. However, there was frustration towards perceived delays in access: ‘We should not need to suffer cDMARDS and fail, losing months of our lives, to get to a biologic.’

Conclusion: Within this UK PsA population, a minority reported limitations on the class or line of b/tsDMARD available in their region. There was an overall positive response to treatment with biologics, and perception of access generally. However, when patients have difficulty accessing later lines of treatment, it has an adverse effect on their lives. The small proportion of respondents who have had difficulty with access suggests that the overall cost of creating equitable access to b/tsDMARDs in the UK may be relatively low but would have a meaningful impact.

AB1726-PARE IN WHAT EXTENT DO RHEUMATOLOGISTS DISCUSS PHYSICAL ACTIVITY WITH THEIR PATIENTS AFFECTED BY CHRONIC INFLAMMATORY RHEUMATIC DISEASE AND WHAT ARE THE PATIENTS’ EXPECTATIONS?

Background:
Objectives: To assess the level of communication about physical activity (PA) between rheumatologists and their patients to identify patients’ needs in this method.

Methods: This is a cross-sectional study conducted on 140 patients (mean age of 47.1 ± 14.6 years, 68% females) followed for CIRD (Rheumatoid arthritis 56.4%, ankylosing spondylarthritis 32.1%, psoriatic arthritis 8.6% and juvenile idiopathic arthritis 2.9%). Physical activity was measured using the IPAQ-SF (the international physical activity questionnaire - short form). We asked patients if their rheumatologist has ever discussed or encouraged them or even explained how to do adapted physical activity. Patients ‘preferences for physical activity practice were collected by specifying if patients preferred to practice it at home or outside, single or in groups. Finally, we also asked them about their needs for both audiovisual support on adapted physical activity and participation in an educational workshop.

Results: The physical activity level was low with a mean IPAQ-SF score of 413 (0.760) MET-min/week. The topic of PA was discussed by rheumatologists with 37.1% of patients. Rheumatologists advised patients to practice adapted PA and show them how to practice it, in respectively 38 and 21.4% of cases. Figure 1 illustrated patients’ expectations of PA.

Conclusion: This study shows the lack of rheumatologist-patient communication on PA and the significant need for PA education. Hence there should be greater involvement of rheumatologists in patient education about physical activity to fight against sedentary behavior in CIRD patients.

Psychosocial support

AB1727-PARE
OPTIMISM AND PESSIMISM ARE ASSOCIATED WITH SELF-REPORTED DISEASE ACTIVITY AND PSYCHOSOCIAL FACTORS IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Prognostic factors, Patient reported outcomes, Quality of life

H. Mammen, S. Salzmann, J. Rieckel, M. Schneider, J. Mucke.1 University Hospital of Dusseldorf, Rheumatology, Dusseldorf, Germany; 2Philipps-University Marburg, Clinical Psychology, Marburg, Germany

Background: The primary goal in patients (pts) with rheumatic diseases is to control disease activity, prevent irreversible damage and reduce disease burden. Despite a broad armamentarium of effective treatments in most rheumatic diseases, a substantial number of pts does not achieve disease control.

Objectives: As psychosocial factors and mindset might influence the treatment response of pts with rheumatoid arthritis (RA)[1], the EXPERD (Expectations in Rheumatic Diseases) study aimed to assess these factors and their association with disease activity in pts with various rheumatic diseases.

Methods: For this cross-sectional analysis, pts with diagnoses of RA, systemic lupus erythematosus (SLE), spondyloarthopathies (SpA) and inflammatory vasculitis treated in the outpatient clinic of the university hospital Duesseldorf were included.

Results: A total of 158 pts completed the questionnaires: 51 pts with RA, 32 pts with SLE, 43 pts with SpA and 32 pts with inflammatory vasculitis. Univariate analyses adjusted for sex, age and number of comorbidities found higher pessimism associated with higher disease activity (est. 0.14, CI 0.008-0.27, p = 0.04). Further, lower HRQoL was correlated with higher pessimism (physical component (PCS): est. -0.05, CI -0.08 to -0.02, p = 0.003; mental component (MCS): est. -0.05, CI -0.09 to -0.01, p = 0.15) and lower optimism (PCS: est. 0.04, CI 0.01 to 0.07, p = 0.01; MCS: est. 0.05, CI 0.01 to 0.08, p = 0.007). Referring to this, pts’ depressive symptoms and pronounced anxiety symptoms manifested the strongest association with lower optimism (depression: est. -0.28, CI -0.34 to -0.22, p <0.001; anxiety: est. -0.36, CI -0.42 to -0.29, p <0.001) and higher pessimism values (depression: est. 0.22, CI 0.14 to 0.3, p <0.001; anxiety: est. 0.26, CI 0.17 to 0.35, p <0.001). In contrast, a longer disease duration and a trustworthy doctor-patient relationship showed primarily lower pessimism (est. -0.07 CI -0.11 to -0.02, p = 0.002; est. -0.26, CI -0.47 to -0.06, p = 0.01).

Conclusion: Mindset in terms of optimism and pessimism was associated with several psychosocial factors and self-reported disease activity in pts with rheumatic diseases. While pessimistic pts tended to have higher self-reported disease activity and considered their physicians less trustworthy, optimism was associated with higher HRQoL. Our results emphasize the relevance of encouraging psychological support to improve a pessimistic mindset. A longitudinal analysis of this investigation is currently ongoing.

AB1728-PARE
CASE OF PERIODIC FEVER SYNDROME IN PEDIATRIC PATIENT FROM PARENTS AND DOCTORS' PERSPECTIVES

Keywords: Best practices, Prognostic factors

I. Romaniuk1, N. Torres2, I. Sanders3, L. King3, P. Garcia Rodriguez4, 1Jackson Memorial Hospital Pediatrics, Miami, United States of America; 2Jackson Memorial Hospital, University of Miami Miller School of Medicine, Pediatrics, Miami, United States of America; 3Jackson Memorial Hospital, Pediatrics, Miami, United States of America; 4Jackson Memorial Hospital, Family Medicine, Miami, United States of America

Background: every patient experiment own disease differently as well as their families. Even modern medicine sometimes can't address all explanation to each clinical question, cover all needs and cure all diseases. Rheumatology is one of medical filed with more question than answer sometimes. And this uncertainty usually is difficult for patient. What if doctor can't answer your question? What if treatment patient is asking for is not the best option or even harmful?

Objectives: show through our case different prospective and expectation between parents and doctors view on pediatric patient medical care based on past family experience, standards of medical care and possible future health outcomes.

Methods: analysis of own experience managing patient with periodic fever syndrome

Results: L, 3 yo boy, originally from country in South America, with past medical history of periodic fever, myelodysplastic syndrome associated with pathologic polymorphism of gene SRP72 (C1384C-T), multiple café au lait spots and autism spectrum disorder was admitted to our hospital due to fever. Fever episodes occurred since 6-month-old (up to 40°C), every 3 months and lasted 5-10 days. The episodes associated with fever, conjunctivitis, arthralgias, reactive lymphadenopathy, oral and duodenal ulcer. Raynaud syndrome and elevation of C-reactive protein level. The initially managed the fever with Prednisone due to concerns for an autoimmune condition or PFAPA. The fever responded to steroid in the early course of disorder but haven’t had effect with following episodes. Extensive work up has been done. Autoimmune, immunology, oncology was negative, but genetic testing was positive for pathologic polymorphism of gene SRP72. At 18-months of age, he was diagnosed with neutropenia first time. Family history was significant for periodic fever and lupus-like symptoms in his mother and rheumatoid arthritis in maternal uncle. Tests results were inconclusive for possible reason of his symptoms. So, his parents moved to the USA with hope to find some answers. Next comprehensive evaluation has been performed at National Institute of Health in June 2022 and unfortunately studies were still inconclusive and without a certain diagnosis. Only pending test that might shed light on the cause was full genome sequencing. During admission to our hospital with taking into account results of previous evaluations and clinical symptoms that did not completely coincide with any of the common or rare periodic fever disorders, diagnosis of syndrome of undifferentiated recurrent fever was made. A few possible treatments were discussed. Recommendations were against using prednisolone for treatment. Continue treatment at home country or US after establishing care with local medical house were discussed. Excessive discussions with family took place multiple times. However, parents have continued expressed extreme frustration with requests for definitive diagnosis and appropriate treatment.

Discussion: There is no doubt that parent and medical team have the same goals and try to find answers to the same questions. And there is no doubt that understanding and parents’ perspectives are different from medical team ones often. Different previous medical experience, no clear answers make waiting without any treatment extremely hard for family. However, modern medicine is matter of tries and hope sometimes. This bring us as doctors to ethical dilemma: what can and what should we do?

Conclusion: it is difficult for parent to make right decision due to numerous biases and expectations. The effort of medical team should be directed to work together with patient family and shared decision making with parents in order to provide the best care to a child.

AB1730-PARE CAVIPA, THE SURVEY EXPLORING PATIENTS’ QUALITY OF LIFE WITH OSTEOARTHRITIS DESIGNED BY PATIENTS FOR PATIENTS

Keywords: Quality of life, Quality of care, Osteoarthritis

N. Martínez Fernández1, J. Verges2, 1Osteoarthritis Foundation International, R&D, Barcelona, Spain; 2Osteoarthritis Foundation International, President & CEO, Barcelona, Spain

Background: Osteoarthritis (OA) is the most common chronic joint disease and poses a growing public health problem. In Spain, 7 million people suffer from OA [1], and only hip and knee OA represent an average annual cost of 4,738 million euros for the Spanish Health System. In 2016, more than one hundred thousand hip and knee prostheses were placed in Spain [2]. In the Spanish population, errors in the quality of care and a deterioration in OA patient care have been described from the perspective of health professionals [3]. However, a comprehensive analysis of the OA patients’ profile, experience, and needs is still missing.

Objectives: The objective is to determine the perception of the quality of life (QoL) of patients with knee and/or hip OA in Spain, focusing on critical factors associated, such as knowledge of the disease, satisfaction with their treatment plan, diagnosis, symptoms, functional disability, and limitations on daily activities.

Methods: Cross-sectional observational study including data collection through a telephone survey of 200 patients living through the Spanish territory. The survey was prepared by a group of patients, clinical experts, and methodologists and validated by a pilot with 10 patients. The final version, approved by the CEIC of the Hospital la Paz in Madrid, was divided into 8 parts that investigate socio-demographic, diagnostic, therapeutic, assistance, and joint functionality, focusing on patient satisfaction and perception of health and QoL.

Results: Patients reported that pain is the first word that comes into their minds when they think about OA. Although pain contributes to the loss of QoL and health, our results show that pain is a multidimensional affection since comorbidities such as depression and anxiety profoundly influence their QoL. Another factor that negatively affects the perception of QoL is the diagnostic delay, where the mean delay obtained in our results was 3.12 years. Regarding their pharmacological treatment, only half of the patients are satisfied, and only a fifth of the respondents believe it can alleviate their pain. Despite this lack of satisfaction, patients take a very long time to make it known to their doctors since they think their doctor will not listen to them or believe another therapeutic option does not exist. Moreover, only half of the patients received non-pharmacological recommendations from their doctors, of which only 20% received professional support for their implementation. Moreover, they reported the need for more treatments to improve their condition and advocated for more information, empathy, and comprehension since they feel their situation is poorly understood by their family, friends, and healthcare providers.

Conclusion: The Osteoarthritis Foundation International (OAFI) designed and conducted the first Spanish survey on QoL of OA patients: the CAVIPA study, to analyze the perception of QoL by patients. Our results show that OA severely impacts patients’ QoL due to associated functional limitations, comorbidities, diagnostic delay, and treatment satisfaction. These results provide a portrait of patients’ perceptions of OA to give a baseline to take better quality performance in the future. Also, it was a proof-of-concept study designed to prove the strength and capacity of patients and their organizations to contribute to the scientific community. Empowering patients to have a more active role in their health and engaging them in research are key aspects to ensure the effective implementation of interventions aimed at improving the QoL of patients and, consequently, the current OA management strategies.

Patient information and education

AB1731-PARE INFLUENCE OF A MULTICOMPONENT EDUCATIONAL PROGRAM ON PATIENT REPORTED OUTCOMES MEASUREMENTS IN A GROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Patient information and education, Rheumatoid arthritis

N. Pinto-Florez1, Z. Castaño1, P. Rodríguez2, G. S. Rodríguez-Vargas2, J. A. Rubio-Rubí1, A. Rojas-Villamaría1, P. Santos-Moreno1, 1Universitat, Expert Patient, Bogotá, Colombia; 2BIOMAB, Patients Education, Bogotá, Colombia; 3BIOMAB, Scientific Direction, Bogotá, Colombia; Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia

Background: Educational strategies in patients with rheumatoid arthritis (RA) are a fundamental tool for the objective measurement of clinimetry by patients (Patient Reported Outcomes Measurements- PROMs).

Objectives: The objective of this study is to evaluate whether there are differences in the measurement of clinimetry when performed by a medical group (MG) with PROMs in an educational context.

Methods: Cross-sectional study. A group of adult patients with RA who participated in a multicomponent RA education program (EMRA) and another who did not participate in this program (NEMRA) were included. The multicomponent educational program is responsible for educating the patient for self-management and management of their health condition, providing different knowledge regarding the disease, including clinimetry, with a duration of 14 months (divided into three levels, mixed face-to-face and virtual). The group of EMRA and NEMRA patients performed the PROMs, through a form designed in "Google forms" clinimetry measurements were performed by a medical group, MG (blind to the type of patient group) with a difference of 1 week. Clinical, sociodemographic, and clinimetry variables were included in the RedCap platform. The MDHAQ, Rapid3D, PAS, EQ-5 and Fatigue scales were evaluated by the MG and the two groups of patients. Univariate and bivariate analysis was performed. A comparison of the medians of the variables evaluated by PROMs and by the MG (Wilcoxon for paired data) was made. The ethics committee approved the study design.
Results: 91 women were included. The median duration of the disease was 10.9 years (12.1). 30.8% had polyautoimmunity. The EMRA group had a higher proportion of education above secondary school (p=0.013). In the EMRA group, there were no significant differences between the cinetimetry evaluated by the MG and the PROMs. In the NEMRA group, significant differences were found in 4 of the 6 variables evaluated (Table 1).

</table>

*Median (Interquartile range) ** Wilcoxon test for paired samples.

Conclusion: PROMs measurements have a value comparable to the cinetimetry performed by the MG in those patients who are under an educational program with emphasis on self-management of their disease. This can be valuable to have an objective measure by the patient with RA that can be useful at the time of the consultation, save time in its development and facilitate the adoption of therapeutic behaviors. It is suggested that for a good development of PROMs, patients have prior educational training so that these measurements are similar to those performed by the MG.

AB1732-PA RE(" FLARE, DID YOU SAY FLARE? " FLARES IN SJÖGREN’S DISEASE: THE PATIENT PERSPECTIVE

Keywords: Sjögren syndrome, Outcome measures, Patient information and education

C. Bouillot, C. M. Hammell, A. Hjertviksen Lindland, M. Oosterbaan, M. Pincemin, L. Stone. AFGS, Patient Association, Paris, France;
2Sjögren’s Foundation, Patient Association, Reston, United States of America;
3Diagnosegruppe Sjögrens Syndrom, Patient Association, Oslo, Norway;
4Nationale Vereniging Sjögrenpatiënten, Patient Association, Maasen, Netherlands;
5EBSA, Patient Association, Birmingham, United Kingdom

Background: “Flare” is a word often used by Sjögren’s patients and medical professionals, without any official definition or consensus on what it means. In addition, the heterogeneous nature of Sjögren’s symptoms means that the definition of a “flare” will vary greatly from patient to patient. As part of the European Necessity project, www.necessity-12020.eu, 7 Sjögren’s patients from the Patient Advisory Group (PAG) addressed this issue and hereby present our definition of a Sjögren’s flare from the patient perspective.

Objectives: To provide a common definition of a flare in Sjögren’s despite the heterogeneity and subjectivity of symptoms and provide patients and medical professionals with a mutual, basic understanding of flares.

Methods: The Necessity PAG Members discussed which symptoms should be included in the definition of a flare. Flares are as heterogeneous and variable as the disease, but some symptoms appear more prominent than others. The symptoms selected by the PAG were compared with findings from the 2021 U.S. Sjögren’s Foundation Survey. The 9 symptoms determined as the most commonly reported by patients were: dryness, fatigue, morning stiffness, global pain (joints, muscles, nerves, headache), forgetfulness and brain fog, depression and anxiety and sleep disorders.

Conclusion: That is why RZN organized a focus group session in 2021 together with the Erasmus Medical Center (MC) in Rotterdam amongst 6 people with IA and a 1st or 2nd generation migration background. The focus group gave an insight into the values that play an important role, when deciding on a best fitting treatment.

Objectives: In the Netherlands:

Background: In the Netherlands, Shared Decision Making (SDM) between healthcare professionals and patients with a migration background stays behind, when compared to SDM with patients with a Dutch background. This can be due to the fact that patients with a migration background might hold different values when deciding on treatment. Values they find difficult to express. Values that health care professionals find difficult to talk about or understand.[1] Research into the values of inflammatory arthritis patients (IA) with a migration background will help health care professionals to better take these values into account, when deciding together on a best fitting treatment.

Results: Values that play an important role to people with IA and a 1st or 2nd generation migration background when deciding on the best fitting IA treatment:

1. Do these values differ from those of the general Dutch population with IA?
2. To get an idea of the values that play a role in the choice of treatment, the National Association ReumaZorg Nederland (RZN) conducted research in 2020 amongst people with IA. It resulted in a list of most important values that was elaborated. People who had a migration background were underrepresented in the group of respondents. That is why RZN organized a focus group session in 2021 together with the Erasmus Medical Center (MC) in Rotterdam amongst 6 people with IA and a 1st or 2nd generation migration background. The focus group gave an insight into the values that play an important role, when choosing IA treatment. In order to verify these values within the broader migrant community of people with IA, RZN set out a questionnaire based on outcomes from the focus
Objective:

Background:
The survey was conducted for the effectiveness of IA treatment (pain, fatigue, inflammation and on physical functioning). Respondents also placed great importance on clear information about IA treatment. Values with regards to the healthcare professional (someone who helps to make a decision about treatment, who is involved, who has time and who listens) were also perceived as important. Finally, respondents placed great value on their wish not to depend on other people for their daily activities.

AB1735-PARE

DIETARY PRACTICE AND CHRONIC INFLAMMATORY RHEUMATIC DISEASES. WHAT DO OUR PATIENTS?

Keywords: Diet and Nutrition, Inflammatory arthritis

M. Labrousse1, C. Allegra1, E. Gervais1, 1Poitiers University Hospital, Rheumatology, Poitiers, France; 2Poitiers University Hospital, Plateforme Méthodologie Biostatistique Data-Management, Poitiers, France

Background:

Objectives:

Patients show interest in non-drug approaches in particular by the mode of feeding. The objectives of this study are to evaluate the prevalence of dietary changes among patients with chronic inflammatory rheumatism, describe their practices and food designs, to compare them between the different subgroups of patients as well as describe the potential impact on care and well-being of the patients.
Methods: Questionnaire survey of patients followed in the Rheumatology department of Poitiers University Hospital, France, for rheumatoid arthritis or spondyloarthritis, including psoriatic arthritis.

Results: Two hundred and three patients were included (112 rheumatoid arthritis, 91 spondyloarthritis, including 25 psoriatic arthritis). They are 45.3% to have been informed of beneficial dietary practices, and 34.5% to have discussed the subject with a professional (13.3% with a rheumatologist). The prevalence of dietary changes is 42.9% (IC95%: [36% - 50%]), and 14.77% of patients were on a diet or taking a dietary supplement at the time of the survey. Diets mainly are the reduction in the consumption of dairy products, Seigane-type diets, fasting, the gluten-free diet and the reduction in meat consumption. For the majority of patients, there was no improvement in pain, fatigue, general condition or reduction in drug intake, except with fasting (n=9) for which a decrease in drug intake was reported at 66.7% (n=7). The discussion on the subject with a health professional is a factor associated with the modification of dietary practices (p<0.001).

Conclusion: Changes in dietary practices concern nearly half of patients, but are only slightly in line with recent recommendations. The information by the physician is often absent and deserves to be improved.

AB1736-PARE CHALLENGES FOR PATIENTS WITH RMD’S IN BULGARIA DURING THE COVID-19 PANDEMIC

Keywords: COVID, Rheumatoid arthritis, Spondyloarthritis

A. Marinov1, Z. Batalov1, R. Karailova1, A. Batalov1, B. Boteva2. 1Medical University of Plovdiv, Department of Internal Medicine, Plovdiv, Bulgaria; 2Bulgarian Organization for People with Rheumatic Diseases, Bulgarian Organization for People with Rheumatic Diseases, Sofia, Bulgaria

Background: The Covid-19 pandemic has put patients with rheumatic diseases in front of a number of obstacles that had to be solved together with Bulgarian rheumatologists. The lockdowns and restrictive measures have made it difficult for people with rheumatic diseases to have access to timely hospital and pre-hospital care. A number of digital solutions have been implemented to address these issues.

Objectives: To highlight the problems that patients with rheumatic diseases had during the Covid-19 pandemic; access to rheumatologists and the effectiveness of hospital and pre-hospital care during the pandemic, access to treatment, changes of treatment; communication between physicians and patients, the impact of the pandemic on work, social contacts, hobbies.

Methods: An anonymous survey was conducted online and by telephone. The survey was developed by Medical university, Plovdiv, University hospital “Kaspela”-, Plovdiv, Bulgarian Association for Musculoskeletal Ultrasound, Bulgarian organization for people with rheumatic diseases; Association for patients with autoimmune diseases. Number of participants: 1205 patients with RMDs.

Age range: 18-82

Results: Face to face meetings with doctors have been limited during the pandemic. Visits to the rheumatologist’s office are significantly reduced and phone, email, text messaging, online consultations were preferred as communication channels. Before the pandemic, 76% of respondents most often communicated with their physicians by visiting their practice, during the pandemic their relative share decreased to 46%, with a significant difference of 30% Phone consultations: patients using this type of communication increasing from 38% before the pandemic to 56% during the pandemic, a significant difference of 18%. The percentage of patients who communicated via text or email rises from 10% to 17%.

It has become apparent that Digital transformation is needed and patients and physicians should work together to achieve it and to be established in Bulgaria. 245 patients reported a change in their treatment. Of these: (30%) reduced the dose of their medications, 119 (49%) increased the dose and the remaining 55 (21%) stopped their therapy. From the responses of the respondents, it is clear that 71% have not experienced a change in their work during the COVID-19 pandemic, 17% have worked from home. From the responses of the respondents, it is clear that 71% have not experienced a change in their work during the COVID-19 pandemic, 17% have worked from home, 4% have been fired, 3% have left their jobs due to the risk of their health and 5% left their jobs for other reasons.

Conclusion: The Covid-19 pandemic has shown that the digital transformation in rheumatology care can be an efficient alternative to some of the services offered to patients with rheumatic diseases in Bulgaria (especially secondary examinations and therapy monitoring examinations). The results of the conducted survey could be used to support digitization in healthcare in Bulgaria. Very important was the collaboration between the patient organizations and the Bulgarian Association for Musculoskeletal Ultrasound, Medical University, Plovdiv and the rheumatologists from University hospital “Kaspela” Plovdiv.

AB1737-PARE IN WHAT EXTENT DO RHEUMATOLOGISTS DISCUSS PHYSICAL ACTIVITY (PA) WITH THEIR PATIENTS AFFECTED BY KNEE OSTEOARTHRITIS AND WHAT ARE THE PATIENTS’ EXPECTATIONS?

Keywords: Patient information and education

S.Ez-Zaoui1, H.Rkain1,2, S. Bahloul1, T. Latifa1, F. El Joumani1, I. Bensaghir1, R. Honsali1, S. Farhi1, F. Korbi1, N. Hajaj-Hassouni1, F. Aliall1. 1Hospital Al Ayachi, Rheumatology B, Salé, Morocco; 2Faculty of Medicine And Pharmacy

Background: Objectives: To Assess the level of communication between patient and rheumatologist and to identify patients’ expectations and needs in terms of PA.

Methods: This is a cross-sectional study conducted on 130 Knee osteoarthritic patients. Physical activity was measured using the IPAQ-SF (the international physical activity questionnaire - short form). We asked patients if they were informed of the benefits of PA, if they preferred to practice it at home or outside, single or in groups. Finally, we also asked them about their needs for both audio-visual supports on adapted physical activity and participation in educational workshops.

Results: The mean age of the patients included was 59.9±10 years with 110 (84.6%) females. The PA level was low with a mean IPAQ-SF score of 130 (0.500) METMin/week. The topic of PA was discussed by rheumatologists with 49.2% of patients. Rheumatologists advised patients to practice adapted PA and show them how to practise it, in respectively 40 and 39.8% of cases. Figure 1 illustrated patients’ expectations on PA.

Figure 1. Patients’ preferences and expectations on physical activity.
Conclusion: This study shows a lack of rheumatologist-patient communication on PA and a significant need for PA education. Hence there should be greater involvement of rheumatologists in patient education about physical activity to fight against sedentary behavior in Knee Osteoarthritis patients.

AB1738-PARE RELATIONSHIP BETWEEN DEPRESSION, ANXIETY, AND STIGMATICIZATION IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Mental health, Cognitive Function

L. Rouached1, E. Hampshire1, S. Bouden1, A. Ben Tekaya1, I. Mahmoud1, R. Tekaya1, O. Saidane1, L. Abdelmoula1, 1. Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia

Background: Depression and anxiety are common comorbidities associated with rheumatoid arthritis (RA). Despite their impact on patients' quality of life, their detection is often neglected.

Objectives: We aimed to assess the anxiety state in patients with RA and to search for associated factors.

Methods: We conducted a cross-sectional study that included patients followed for RA. Patient and disease data were recorded. Patients completed the Hospital Anxiety and Depression Scale (HAD) [1] and the Stigma Scale for Chronic Illness-Short Form (SSCI-8) [2] during their day hospital visit or consultation. Disease activity by DAS28-CRP and functional impairment by the HAQ score were calculated.

Results: There were 100 patients. They were mostly women (81%) with a mean age of 55.33±10.08 years [25-76]. Concerning professional status, 61.8% were unemployed, 26.5% were employed, and 11.6% were retired. The mean disease duration was 14.21±10.10 years [1-46]. The mean DAS28-CRP was 3.31±1.56 [0.12-6.90]. The mean HAQ score was 0.91±0.64 [0-2.4]. The mean anxiety score was 7.6±3.2 [1-15]. A definite anxiety state was noted in 21% of patients. The mean depression score was 10.1±3.1 [3-16]. A definite depressive state was noted in 56% of patients. The mean SSCI-8 score was 17.85±6.02 [8-32]. None of the parameters related to the patient, disease activity and functional impairment were correlated with anxiety and depression. The presence of anxiety was influenced by the number of swollen joints (p=0.037). The stigma score was statistically significantly greater in the presence of depression (19.3±6.2 vs 16±5.2, p=0.006). It was also correlated with disease activity (p=0.034, r=0.244). There was no association between stigma scale/HAQ (p=0.754) and stigma scale/anxiety (p=0.137).

Conclusion: According to the results of our study, depression was frequently present in patients followed for RA (56%). Moreover, the stigma is finely related to this comorbidity. This encourages the systematic psychological management of chronic pathologies such as RA.

AB1741-PARE THE IMPACT OF THE DISEASE’S ANNOUNCEMENT ON RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Patient information and education

E. Rabhi1,2, K. Maatallah1,2, H. Ferjen1,2, D. Ben Nessim1,2, D. Kafel1,2, W. Hamdi1,3, K. Kassab Orthopedics Institute, Rheumatology Department, Ksar Said, Tunisia; 2; Faculty of Medicine of Tunis, Manar, Tunisia

Background: Rheumatoid arthritis is a chronic disease that can cause irreversible joint damage and significant disability [1]. The announcement of this diagnosis remains one of the most unpleasant moments in the medical practice for both patients and caregivers. For the physician, whose primary mission is to provide relief, knowing that it may cause psychological distress is a challenging task.

Objectives: We aimed to study the impact of the disease's announcement on rheumatoid arthritis patients.

Methods: We conducted a cross-sectional study including patients fulfilling the American Congress Of Rheumatology/ European League Against Rheumatism (ACR EULAR) 2010 criteria. We collected epidemiological, clinical, biological (C-reactive protein: CRP, erythrocyte sedimentation rate (ESR), immunological status (rheumatoid factor RF and anti-citrullinated protein/peptide antibody ACA), disease activity index (The Disease Activity Score 28 DAS 28), Patient's experience during the announcement of diagnosis was assessed using a questionnaire.

Results: Thirty patients were enrolled. There were 25 women and five men. The mean age was 64 years ranging from 34 to 80 years.

Conclusion: Our study showed stress and anxiety are common feelings for most patients, highlighting the importance of a patient-centered approach to improve initial disease acceptance and tolerability of their disease.

HEALTH INFORMATION UTILIZATION IN RHEUMATOID AND PSORIATIC ARTHRITIS

**Keywords:** Patient information and education, Psoriatic arthritis, Rheumatoid arthritis

**E. Duffey**, N. Bhanusali, K. Camargo Macias, S. Beg, S. Chalise

1University of Central Florida, College of Medicine, Orlando, United States of America

**Background:** Technology has facilitated widespread general access to health information publicly. However not all health information available for consumption is accurate, reliable, updated, and of equal value to people seeking to be informed advocates of their own health. This cross-sectional study sought to establish the preferred resources patients with rheumatologic conditions seek out for health information. This study provides recent evidence to inform patient education, open dialogue, with the hope to improve clinical practice and patient outcomes.

**Objectives:** To describe utilization of health information preferences to inform physician-patient shared decision-making and best clinical practice.

**Methods:** From December 2019 to March 2020, 236 Rheumatoid Arthritis (RA) and 43 Psoriatic Arthritis (PsA) patients receiving care at an academic rheumatology practice in the USA were enrolled in this study. Subjects were provided with a brief voluntary, and anonymous Qualtrics survey which gathered data on health information utilization, willingness to discuss information gathered with physicians, and desire for resources to be provided.

**Results:** Modern technology has provided multiple ways for patients to gather additional health information of variable accuracy. This information impacts patient willingness to adhere to clinical recommendations. These data show that patients seek open and honest discussion of health information gathered from other sources. A substantial percentage of patients also desire guidance towards reliable online health resources from their physicians.

**Conclusion:** Modern technology has provided multiple ways for patients to gather additional health information of variable accuracy. This information impacts patient willingness to adhere to clinical recommendations. These data show that patients seek open and honest discussion of health information gathered from other sources. A substantial percentage of patients also desire guidance towards reliable online health resources from their physicians.

PUBLIC INTEREST IN LUPUS IN AFRICA

**Keywords:** Systemic lupus erythematous, Patient information and education

A. Quiss, M. Ansar, A. Amara, Y. Bousoukays, B. Y. Wissal, A. Atig, N. Ghannouchi

1Faculty of Medicine of Sousse - University of Sousse, Internal Medicine, Sousse, Tunisia; 2Faculty of Medicine of Sousse - University of Sousse, Family and Community Medicine-LR12ES03, Sousse, Tunisia

**Background:** Accessibility to internet has allowed people to have a better knowledge of Systemic lupus erythematous (SLE), however, this interest in doing research is influenced by several factors, including socio-economic conditions. Google Trends (GT) is the most popular tool for examining online behavior because it provides information regarding trends and changes in online interest at certain times during a particular period.

**Objectives:** To describe the public interest in Systemic lupus erythematous (SLE) in different African countries and to assess people's interest in Africa comparing to worldwide.

**Methods:** Google Trends provides the relative interest of Google Searches (RSV), on a range of 0–100. We analysed a large amount of data generated by Google Trends concerning the search of the word ‘lupus’ in a 7-year web-based research (2016-2022) in African countries. Student’s t-test was used to compare means. Analyses were performed with SPSS 21.0. P values less than 0.05 were considered statistically significant.

**Results:** Googling “lupus” was variable depending on the country. The mean annually research volume (RSV) in Africans’ countries was 18.20±3.92. Annual RSV was more important in Morocco50.86±16.52, Algeria 49.19±23.64. There was a significant difference in the mean annually research volume between African countries and all over the word (versus 50.86±14.58, p<10-3). (Figure 1)

TREATMENT ADHERENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) DURING THE COVID-19 PANDEMIC

**Keywords:** COVID, Rheumatoid arthritis, Patient reported outcomes

**Disclosure of Interests:** None Declared.
Background: During the last 2 years, the SAR COV2 pandemic has impacted the lifestyle, health care, physical and psychological health status of people with rheumatic diseases. In the REUMAVID study, almost half of the respondents stated that their state of health had worsened during the pandemic[1]. It's known that aspects such as fear, job loss, social isolation, uncertainty about their treatments, worsening of symptoms due to the interruption of treatment and hospital visits, increased his fatigue and pain[2]. Treatment adherence estimates in patients with RA are usually low (Between 30 and 80%)[3]. Adherence lack has been associated with worsening symptoms and increased disability[4].

Objectives: The aim of this work is to evaluate SARS COV2 pandemic impact on the adherence perception in a cohort of patients with RA and their clinical associations.

Methods: Descriptive cross-sectional study; included patients ≥18 years old with RA (ACR/EULAR 2010 criteria), between June 1 and July 31, 2022 who gave their written consent to perform the questionnaire. Data socio-demographic, socioeconomic level (Graffar modified), clinical, laboratory, treatments, previous COVID-19 infection and vaccination status were consigned. Activity was evaluated by DAS28-PCR and functional ability with HAQ-II. Questions about the perception of the impact of the pandemic on adherence, follow-up, health status deterioration or fear of continuing treatment were included. They were measured by a visual analogue scale, with 0 being no impact and 10 being the maximum. These answers were compared with adherence measured by the Compliance Questionnaire for Rheumatology (CQR5).

Results: Sixty nine outpatients with RA were included. 45 patients (65%) did not perceive adherence changes during the pandemic while 24 (35%) perceive some degree of adherence disturbances. Sociodemographic characteristics are detailed in Table 1. Having an independent laboral status and the modification or suspension of work activity was statistically associated with the perception of impaired adherence (p=0.04 and 0.01 respectively). Patients with a perception of impaired adherence had significantly higher means in the VAS of affected follow-up, deterioration in their health status, and fear of infection (p= <0.001, <0.001 and 0.04 respectively). DAS28-PCR, HAQ-II, ESR and CRP were also significantly higher in this group (p= 0.002, 0.005, 0.01 and 0.04 respectively). No association was found between the perception of adherence disturbance and adherence measured by CQR5 (p= 0.20).

Conclusion: The SARS COV2 pandemic has a great impact on adherence, rheumatological follow-up and quality of life of patients with RA. Although the perception of adherence disturbance during the pandemic period is a subjective parameter, we found a significant association between this perception and higher rates of suspension or modification of work activity, greater disease activity, functional impairment, and higher acute phase reactants. Studies with a larger number of patients are needed to corroborate these findings.

AB1745-PARE ROLE OF DIET IN INFLUENCING RHEUMATIC DISEASE ACTIVITY: A TUNISIAN PATIENTS SURVEY

S. Rekkı1, S. Noucerı1, S. Rahmounı1, K. Zouaouı1, S. Boussaıd1, H. Sahlı1, M. Elleuch1, Rabba, Rheumatology, Tunisia

Keywords: Spondyloarthritis, Diet and Nutrition, Rheumatoid arthritis

Scientific Abstracts
Background: The possible influence of diet on rheumatic disease (RD) is a controversial issue. However, rheumatic patients often ask for specific diet because they experience change in joint symptoms after taken some food. Few studies have been conducted regarding patients’ perceptions of the influence of diet and fasting on their RD. None of such studies have been conducted so far in countries.

Objectives: The main purpose of this study is to survey patients regarding diet and RD symptoms.

Methods: This is a survey based on a questionnaire that included patients followed for rheumatoid arthritis (RA) (ACR/EULAR 2010 criteria) and spondyloarthritis (SA) (ASAS 2009 criteria), in remission or low disease activity, who presented to the rheumatology department. We didn’t include patients with inflammatory bowel or malabsorption diseases or current smokers. Socio-demographic data, co-morbidities, and data of RD (disease duration, disease activity, Disease Activity Score (DAS28) and Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) and medication (Disease-modifying antirheumatic drugs (DMARDs)) were recorded. The questionnaire consisted of 7 major questions with variety of sub-questions. Patients were asked whether they believe diet had a major role on the RD onset, if they have experienced aggravation or improvement of their symptoms with food intake, and if the answer was yes, then they were asked to name the food item. The patients were also asked if they have changed their dietary habits since the diagnosis of RD, if they believe that healthy dietary habit may improve their disease, and if fasting relieve their disease.

Results: We enrolled 39 RA (34 female) and 22 SA (2 female) patients with respectively mean age of 52.74±11.31 years and 54.54±11.2 years. Among patients with RA, 53.6% and 22.7% had primary school age, 45.5% of SA patients had secondary educational level. Half of RA and SA patients had comorbidities: 56.4% and 54.5% respectively. The mean disease duration was 8.66±6.6 years and 14.77±9.1 in RA and SA patients respectively. The questionnaire consisted of 7 major questions with variety of sub-questions. Patients were asked whether they believe diet had a major role on the RD onset, if they have experienced aggravation or improvement of their symptoms with food intake, and if the answer was yes, then they were asked to name the food item. The patients were also asked if they have changed their dietary habits since the diagnosis of RD, if they believe that healthy dietary habit may improve their disease, and if fasting relieve their disease.

Background: Although it still remains a rare disease, spondylodiscitis has been encountered in the last 10 years. Early diagnosis can be difficult, but improved diagnostic techniques and modern treatments have reduced patient mortality. However, studies reporting the outcome of spondylodiscitis are scarce.

Objectives: To assess the influence of functional impairment on mental health in patients treated for spondylodiscitis.

Methods: The study was conducted at a tertiary referral center over a two-year period. The functional disability was evaluated using the Oswestry Disability Index (ODI) and the fear-avoidance beliefs questionnaire (FABQ-W). The mental health was assessed using the Hospital Anxiety and Depression Scale (HAD). The correlation between these two dimensions was assessed using the Spearman’s rank correlation coefficient (r).

Results: A total of 100 patients were included in the study, with 57% being women. The average age was 35.2 years, and the average disease duration was 6.9 years. The ODI score was 42.8 ± 14.5, and the HAD score was 11.6 ± 7.2. There was a significant positive correlation between the ODI score and both the anxiety (r = 0.42, p < 0.001) and the depression (r = 0.38, p = 0.001) dimensions of the HAD. The majority of patients (82%) reported at least one limitation in their daily activities due to RD.

Conclusion: The study highlights the significant impact of functional disability on mental health in patients with spondylodiscitis. Early intervention strategies targeting physical and mental health are necessary to improve the quality of life for these patients.

AB1748-PARE THE CORRELATION OF FUNCTIONAL DISABILITY AND MENTAL HEALTH IN PATIENTS TREATED FOR SPONDYLODISCITIS

Keywords: Patient reported outcomes, Infection-related RMDs, Quality of life

1Cylper - Cyprus League for People with Rheumatism, N/A, Nicosia, Cyprus

Background: When someone is first diagnosed, he/she is faced with a number of feelings and changes in their life. Such feelings are usually shock, anger, sadness, fear, the feeling of being judged, the feeling of a sense of loss of control. Usually, the supportive environment like family members, friends and colleagues cannot understand exactly how the person feels unless they have received a rheumatic diagnosis themselves. Doctors and health professionals may sometimes offer minimal emotional support, but their primary focus is always medical. This may cause feelings of loneliness, misunderstanding or isolation. And here is where the role of support groups finds its place.

OBJECTIVES: The general coordination of the Groups is done by the Vice President of Cylper and the Psychosocial Support Officer, in collaboration with the Social Officer of CYLPER. Members of each Group can become Registered Rheumatism Members of CYLPER. The coordination of the operation of each Group is done by the coordinator who is elected by the members of the committee. The GPSD will be responsible for organising their events through their volunteers, and for this purpose an amount will be approved that will be available to the team to carry out its work.

Benefits: Running a support group is a way for people with rheumatism to interact with other people who have similar, first-hand experiences with rheumatism. People can talk about their experiences and share their own. This can help reduce stress. In a support group, members can feel more comfortable sharing feelings and experiences that may be too difficult or too awkward to share with their family and friends. Being part of a group often creates a sense of belonging that helps each person feel more understood and less isolated. They can also discuss practical information in a support group such as: What to expect during treatment; How to manage specific side effects; How to find support services; How to communicate with health care providers and family members. Talking about these topics within the support group could provide a sense of control and reduce feelings of helplessness. Many studies have shown that support groups help people with a chronic disease cope with anxiety and depression.

Conclusion: Running a support group is a good way to reach out and get people interested in the other things your organisation or initiative does. With relatively little effort and cost, a support group can make a significant impact in the lives of people dealing with a problem.
AB1749-PARE  IMPACT OF FACIAL SIGNS OF SYSTEMIC SCLEROSIS ON PATIENTS’ SELF-ESTEEM

Keywords: Systemic sclerosis, Mental health

Z. Syrinx¹, A. Feiki¹, S. Ben Jemaa¹, Y. Mabrouk², A. Cyrine¹, M. Ezzeddine¹, M. H. Kallel¹, H. Fouri¹, R. Akrou⁴, S. Bakiout¹,¹ Hedi Chaker University Hospital, Rheumatology, Sfax, Tunisia; ¹Military Hospital of Instruction of Tunis, Physical Medicine and Rehabilitation, Tunis, Tunisia

Background: The dimensions of self-concept and body image are essential for assessing the quality of life of individuals with chronic diseases. Systemic sclerosis (SSc) is characterized by facial involvement that can lead to aesthetic changes, functional disability as well as psychological impact.

Objectives: To assess the influence of face involvement on self-esteem in SSc patients.

Methods: A cross-sectional study was carried out on patients followed for Systemic sclerosis at a rheumatology department. Included patients completed the Burden of Face Affected (BoFA) questionnaire as well as the Rosenberg self-esteem scale (RSES). All data was collected after patient consent and was analyzed using the SPSS statistical package.

Results: Forty patients who fulfilled the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis were included. There were 8 male and 32 female with a sex ratio female to male of 4. The median age was 45 years old (19-71) and median disease duration 1 year. The majority of our patients (85%, n=34) suffered from diffuse form of SSc. 15%(n=6) had a limited form. Fingertip ulcers were observed in 13 patients (32.5%) and telangectasia in 16 patients (40%). Raynaud's phenomenon was found in 34 patients (85%). Severe organ involvements were detected as interstitial lung disease in 17 patients (42.5%), pulmonary hypertension in 2 patients (75%) and renal involvement in 2 patients (5%).

Conclusion: The Burden of Face Affected was significant in 80% (32 patients) of our patients. Face affection symptoms were correlated with RSES and gender, age or Rodnan score.

AB1750-PARE  PATIENT-DOCTOR COMMUNICATION FROM PERSPECTIVE OF STENE PRIZE TOPIC 2023

Keywords: Patient information and education, Self-management, Quality of care

J. Grygielska ¹. ¹Polish Rheuma Federation ‘REF’, National Board, Warsaw, Poland

Background: Poland participates in European Edgar Stene Prize Competition from early eighties 20th century. Three times our participants won this Prize – last time in 2018. Every competition on national level starts from appropriate translation of topic into Polish and invitation to participate in this using different channels of information reach to as many as possible potential participants. This year topic: “How better communication with my doctor improved my life with an RMD” gave an opportunity for every person living with rheumatic and musculoskeletal disease to present his/her experiences in building good cooperation with his/her physician. Patient-doctor communication was a topic of many educational events for people with RMDs including 2 perspectives: of patient and doctor. It was used Polish version of PART (prepare, ask, repeat, take action) from “Challenging arthritis” by Kate Lorig and James Fries to be more aware and responsible for his/her own health. This important topic didn’t find interest among patients with RMDs and national jury received no entry for this year competition.

Objectives: Lack of entry on topic of patient-doctor communication among rheumatic patients was surprised and identifying the causes of this situation can be important in two areas: future Stene Prize competition and personal cooperation with health professionals including physicians.

Methods: Invitation for participation in competition was shared using the same channels how always. There were: websites of associations, social media (facebook and Twitter), e-mailing to leaders of associations, online meeting on occasion of World Arthritis Day, personal contacts with potential authors. Before deadline of submitting entries reminders were sent and put in social media. Reasons of lack of entries were discussed with active members of our associations.

AB1751-PARE  MUSCULOSKELETAL DISORDERS IN THE ERA OF THE COVID-19 PANDEMIC

Keywords: Work-related issues, Descriptive Studies

L. Ben Aïfa¹, D. Brahimi¹, I. Youssaf², Z. Athimni¹, M. Messni¹, N. Mechergui⁴, H. Ben Saïd³, G. Bahri¹, N. Ladhari¹, ¹Faculty of Medicine of Tunis, Occupational Department at Charles Nicolle Hospital, Monastir, Tunisia

Background: In Tunisia, during the last decade, the number of MSDs declared as compensable occupational diseases has been increasing. So, what is the impact of the COVID-19 pandemic on the MSD reporting rate.

Objectives: To describe the socio-professional characteristics of workers with musculoskeletal disorders (MSDs) and to determine the reporting rate of MSDs as occupational diseases.

Methods: A descriptive cross-sectional study among workers with work-related MSDs who consulted the occupational medicine department of the Charles Nicolle Hospital for medical advice between January 2021 and September 2022.

Results: A total of 109 workers with MSDs were included in this study. The workers were 64.2% female. The average age was 46 ± 21-61 years. The sectors most prone to MSDs were the health sector (27.5%), food processing (16.5%) and textiles (15.6%). The workers reported MSDs of the upper limb in 32.5%, of the lower limb in 33.9% and of the spine in 69.7%. These MSDs declared included 5/13 cases of rotator cuff tendinopathy, 6/13 cases of carpal tunnel syndrome, one case of achilles tendinitis and one case of DeQuervain’s tenosynovitis.

**THE RATE OF COVID-19 VACCINATION IN PATIENTS WITH RHEUMATOID ARTHRITIS. SINGLE-CENTER CROSS-SECTIONAL PILOT STUDY**

**Keywords:** Rheumatoid arthritis, COVID, Vaccination/Immunization

**H. Elhafi**, L. Taoubane, N. El Ouari, H. Taoufik, A. Majjad, A. Bezza, Mohamed V Military Training Hospital, Rheumatology, Rabat, Morocco, Faculty of Medicine and Pharmacy of Rabat, Rheumatology, Rabat, Morocco

**Background:** The rate of COVID-19 vaccination in patients with rheumatoid arthritis, Single-center cross-sectional pilot study.

**Objectives:** Morocco was the first country in Africa to launch the COVID19 vaccination campaign. Vaccination of immunocompromised subjects was recommended from the beginning by the Moroccan Society of Rheumatology. The primary objective of this study was to assess the vaccination rate of patients with rheumatoid arthritis two years after the start of the pandemic. The secondary objective was to investigate factors associated with vaccination.

**Methods:** This was a 3-month monocentric cross-sectional study from 31.05.22 to 31.08.22, including patients whose age was greater than 18 years, who have rheumatoid arthritis according to ACR/EULAR 2009 criteria. Socio-demographic data, comorbidities and disease characteristics were collected by the attending physician at the time of the consultation using a questionnaire. Statistical analysis was performed using JAMOVI software.

**Results:** The study included 73 patients, 82.2% of whom were women. The mean age was 57±11 years, with a median disease progression of 8 years. 58 patients (80.6%) were vaccinated against COVID19. Among the vaccinated patients, 30 (51.7%) were illiterate, 8 patients (13.8%) had primary education, 11 (19%) had secondary education and 9 (15.5%) had higher education 53 (91.4%) had rheumatoid arthritis according to ACR/EULAR 2009 criteria. Socio-demographic data, comorbidities and disease characteristics were collected by the attending physician at the time of the consultation using a questionnaire. Statistical analysis was performed using JAMOVI software.

**Discussion:** The study found that almost 80% of patients were vaccinated. Further studies are needed to develop population-specific education programs.

**REFERENCES:**

**Conclusion:** Insights through the model proposed could aid healthcare professionals in understanding elements that support or hinder rheumatoid patients from initiating or maintaining self-management behavior.

**AB1756-PARE**  
**APPLICATION OF THE THEORY OF PLANNED BEHAVIOR: THE ROLE OF FAMILY AND PATIENTS WITH RHEUMATOID ARTHRITIS**

**Keywords:** Self-management, Rheumatoid arthritis, Education

**S. Al-Shamali**, M. Al-Sabah, A. Alsaber, American University of Kuwait, College of Business and Economics, Salmiya, Kuwait

**Background:** The TPB suggests that patient attitudes, subjective norms, and perceived behavioral control predict behavioral intentions and behaviors regarding health behavior (Yao Yao et al., 2021). Behavioral theories aid in improving the behavioral changes in the self-management of diabetes (Damayanti et al., 2018) and other lifestyle changes such as healthy eating (Rahmati-Najarkolaei et al., 2017). Most recently, Jormand et al. (2022) uses TPB for the self-care behaviors of knee osteoarthritis patients, which TPB aided educational intervention, by examining variables such as their attitudes and perceived behavioral control. Safavi et al. (2018) explains that although they are not as popularly researched and surgical interventions, the benefits of non-medical approaches endorsing healthy lifestyles can improve symptoms and reduce the need for other treatments.

**Objectives:** This study will use three variables in the TPB model, namely, attitude, perceived behavioral control. Dependent variables include intention and total self-management (cognitive, physical and communication with a health professional). Adult patients who meet the criteria of the American College of Rheumatology (ACR) and live with family will be asked to complete a self-administered questionnaire. This cross-section study proposes a model that will be tested using regression analyses and statistical equation model.

**Methods:** The model proposed for this research includes independent variables: support from family (novel variable), attitude and perceived behavioral control. Dependent variables include intention and total self-management (cognitive, physical and communication with a health professional). Adult patients who meet the criteria of the American College of Rheumatology (ACR) and live with family will be asked to complete a self-administered questionnaire. This cross-section study proposes a model that will be tested using regression analyses and structural equation model.

**Results:** Data is still under analysis and will be available at the time of the conference. However, based on previous studies it is hypothesized that TPB variables and relative support will be reported as significant.

**Conclusion:** Insights through the model proposed could aid healthcare professionals in understanding elements that support or hinder rheumatoid patients from initiating or maintaining self-management behavior.

**AB1757-PARE**  
**INFAMMATORY RHEUMATIC DISEASES AND RELIGIOUS RITUALS: WHICH IMPACT?**

**Keywords:** Descriptive Studies, Quality of life, Patient reported outcomes

**K. Maatallah**, R. Ben Aissa, H. Ferjani, D. Ben Nessib, D. Kaffel, W. Hamdi, Mohamed Kassab Institute of Orthopedics, Department of Rheumatology, Mannouba, Tunisia

**Background:** Religious events are privileged occasions for sharing and conviviality. In a joyful atmosphere, festive meals are shared with family, neighbors, and friends, and gifts are exchanged. Little is known about the impact of chronic inflammatory rheumatic diseases on patients’ celebrations of religious events.

**Objectives:** To study the satisfaction of patients with their religious rituals during Islamic holidays.

**Methods:** We conducted a transversal study, including patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA). Patients were invited to answer to a satisfaction scale (SS) composed of four domains: prayer practice, religious food preparation, family visits, and satisfaction with spiritual fulfillment. For each domain, there were 6 degrees of satisfaction (extremely satisfied, satisfied, slightly satisfied, slightly dissatisfied, dissatisfied, extremely dissatisfied) rated from 0 to 5. Results were expressed as percentage distribution of SS for each domain ranged from 1 to 6, and the global SS ranged from 4 to 24.

**Conclusion:** During the COVID-19 pandemic, the reporting of MSDs as occupational diseases has declined considerably. This decline can be explained by the closure of access to hospital facilities.

**REFERENCES:**

AB1755-PAE  EVALUATION OF THE FRAILITY OF ELDERLY PATIENTS HOSPITALIZED IN THE RHEUMATOLOGY DEPARTMENT

Keywords: Quality of life

A. Saad1, N. Hafdhouni1, R. Ben Tekaya1, G. Mouna1, J. Mahboubi1, S. Zour1, I. Bejia1, M. Touzi1, N. Bergault1, 1University Hospital Fattouma Bourguiba Monastir, Rheumatology, Monastir, Tunisia

Background: Frailty is defined by a clinical syndrome that reflects a decrease in physiological capacities altering the mechanisms of adaptation to stress[1]. Elderly patients hospitalized in the rheumatology department are at risk of significant frailty.

Objectives: The aim of our study is to evaluate the frailty of elderly patients considering the bio-psycho-social parameters.

Methods: Prospective study started in July 2022 in the rheumatology department including 40 patients who were subject to questionnaires assessing their quality of life. All data was collected after patient consent and was analyzed using the SPSS statistical package.

Results: Forty patients were collected including 27 women (67.5%) and 13 men (32.5%). 15 (37.5%) patients were hospitalized for chronic inflammatory rheumatism, 19 (47.5%) for a degenerative disease and 15% for a tumoral disease. The mean age of the patients was 72.6 ± 5.4 years. The social context of each patient was assessed: 30 (75%) patients lived with their family and 10 (25%) lived alone. 20 (50%) patients needed daily help with household chores. We studied the level of frailty of our patients using the Tilburg Frailty Indicator (TFI): 29 (72.5%) patients had a score ≥ 5 indicating significant frailty. 21 (52.5%) patients presented a risk of depression evaluated at 5 according to the geriatric depression scale (GDS15). A nutrition assessment was made using the Mini Nutritional Assessment (MNA) test, concluding with poor nutritional status in 10 (25%) patients. Finally, five (12.5%) patients had a dependency score ≥ 3 according to the Activities of Daily Living (ADL) scale.

Conclusion: Elderly patients with rheumatological disease hospitalized in our department show an alteration in their quality of life and a significant level of frailty which should motivate us to adapt care programs for the elderly concerned.

AB1757-PAE  PATIENTS WITH SPONDYLOARTHROPATHY SUFFER IN SILENCE: THE IMPACT OF THE DISEASE ON THEIR QUALITY OF LIFE

Keywords: Quality of life, Spondyloarthritis, Patient reported outcomes

E. Hannech1, S. Boussaid1, S. Rekik1, S. Rahmouni1, K. Zouaoui1, H. Ajlani1, H. Sahl1, M. Elleuch1, 1La Rabta Hospital, Rheumatology Department, Tunis, Tunisia

Background: Spondyloarthritis (SpA) is a chronic disease that often causes functional impairment, resulting in a negative impact on patients’ quality of life (QoL).

Objectives: We aimed to assess QoL of patients with SpA using a validating tool.

Methods: We conducted a cross-sectional study including patients with SpA. Sociodemographic, clinical, and therapeutic data were collected. Patients’ QoL was assessed using the validated Tunisian version of the EQ-5D questionnaire, which is a standardized measuring instrument that assesses the state of health according to five dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression. The answers were converted into EQ-5D index.

Results: There were 100 SpA patients with a mean age of 43.68±10.3 years [20-76]. Regarding mobility, 2 patients reported extreme problems, 61 patients had some problems, and 37 patients had no problems. Twenty-six patients had significant pain or discomfort at the time of the study, 61 patients had moderate pain or discomfort, and 13 patients had no pain. A significant level of anxiety/depression was observed in 12 patients, 46 patients had moderate depression or anxiety, and 42 patients had no psychological problems. The global VAS of health status had a mean value of 56±25 [7-100]. The mean EQ-5D index was 0.485±0.378 [-0.448-1]. In 12 cases the index was negative, defining an extremely large effect of the disease on QoL, while 7 patients had an index equal to 1, showing that the disease had no effect on their QoL.

Conclusion: Despite therapeutic advances, patients with SpA still suffer in their daily living. So, an early and appropriate management is necessary.

AB1756-PAE  FACTORS ASSOCIATED WITH QUALITY OF LIFE AMONG SCLERODERMA PATIENTS

Keywords: Quality of life, Systemic sclerosis

Z. Svinge1, A. Fekli1, S. Ben Jemaa1, Y. Mabrouk1, A. Cyirne1, M. Ezzedine1, M. H. Kallel1, H. Fourati1, R. Akrou1, S. Baklouti1, 1Hedi Chaker University Hospital, Rheumatology, Sfax, Tunisia; 2Military Hospital of Instruction of Tunis, Physical Medicine and Rehabilitation, Tunis, Tunisia

Background: Systemic sclerosis (SSc) is an autoimmune multi-systemic disease with predominant affection of connective tissue resulting in progressive fibrosis of the skin and internal organs. Monitoring measures of functioning and disability is crucial during follow up to identify quality of life impairment.

Objectives: To assess the influence of functional impairment on quality of life in SSc patients.

Methods: A cross-sectional study was carried out on patients followed for systemic sclerosis at a rheumatology department. Included patients completed the Hospital Anxiety Depression scale in its Arabic validated version. The SF-36 short form questionnaire score with its domains (general health, physical function, role physical function, emotional role function, vitality, mental health, social function, body pain, general health) in its arabic Tunisian version was used to assess quality of life. All data was collected after patient consent and was analyzed using the SPSS statistical package.

Results: Forty patients who fulfilled the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis (ACR) for SSc were included. 80% of the patients were female, the median age was 45 years old and median disease duration 1 year. 15% (n=6) had a limited form, and 85% (n=34) had a diffuse form of SSc. Fingerpint ulcers were observed in 13 patients (32.5%) and Raynaud's phenomenon was found in 34 patients (85%). Severe organ involvements were detected as intestinal lung disease in 17 (42.5%), pulmonary hypertension in 7 patients (17.5%) and renal involvement in 2 patients (5%). 38 patients had an HAD scoring rate for “possible clinical anxiety” and for 42% for “possible clinical depression” The SF-36 questionnaire score of each domain was significantly lower in patients with diffuse than in limited form, especially the score in the dimension of Role Physical function and Body Pain, p=0.04 and p=0.02 respectively. Skin involvement and organ damage were also significantly associated with lower SF-36-PF (physical function) (p=0.001) and SF36-MH (mental health) p=0.0025 with no significant association with the other score components.

Conclusion: Systemic Sclerosis has a significant effect on patient quality of life. Body image, fatigue, pain, and psychological morbidity should be screened in patients with SSc to promote quality of life.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

AB1758-HPR IDENTIFYING THE RISK OF STEROID INDUCED ADRENAL INSUFFICIENCY IN RHEUMATOLOGY PATIENTS WEANING FROM PROLONGED STEROID THERAPY

Keywords: Tapering, Diagnostic Tests, Inflammatory arthritis

E. Quintan1, M. Khatun1, M. Kazmi1, Sheffield Teaching Hospitals NHS Foundation Trust, Rheumatology, Sheffield, United Kingdom

Background: Rheumatologists often prescribe steroids, and long-term use can lead to suppression of the hypothalamic-pituitary-adrenal (HPA) axis, leading to Steroid Induced Adrenal Insufficiency (SIAI). Our departmental guidelines suggest patients on steroid tapering regimes should have morning serum cortisol levels once wean to <3mg.

Objectives: To identify what proportion of cortisol levels were abnormal in patients weaning from steroids in various Rheumatological conditions. There are currently no established guidelines to identify patients for possible SIAI, which is usually only assessed if a patient develops steroid withdrawal symptoms at low doses. We wanted to investigate if SIAI was seen commonly and how long after steroid withdrawal weaning cortisol levels went to have a Short Synacthen Test (SST), Endocrinology input and SIAI diagnosis.

Methods: Retrospective review of Rheumatology patients who had morning serum cortisol levels whilst weaning from oral prednisolone at Sheffield Teaching Hospitals. Patients identified via the Clinical Laboratory Database.

Results: Data collected Sept’19 – Oct’22, only samples taken pre-9AM assessed (n=58). 33 Female, age 21-83 years; mean age 65 years. Starting dose prednisolone 5mg-60mg (IQR 15-40mg). Treatment length 6-96 months (IQR 14-48). Samples taken when 84.5% (n=49) taking 3mg, 10.3% (n=8) 2mg and 5.2% (n=3) 2.5mg, (IQR 3mg). Cortisol levels <300 nmol/L in 43.1% (n=25), 300-350 nmol/L in 15.5% (n=9) and >350 nmol/L in 41.4% (n=24), 66.7% (n=17) of <300 nmol/L (n=25) referred for a SST. SST results were <430 nmol/L in 35.3% (n=8) and >430 nmol/L in 64.7% (n=11). All patients with SST <430 nmol/L (n=6) referred to Endocrinology. 33.3% (n=2) had ‘borderline’ SST results (421-450 nmol/L) and advised to wean steroids by 1mg every 4 weeks and discharged. 66.7% (n=4) diagnosed with SIAI, with only one (25%, n=1) having documented symptoms. All (n=4) had further Endocrinology input. 100% (n=4) had a repeat SST and pituitary function tests and 75% (n=3) had or awaiting Waking Salivary Cortisol (WSC). 75% (n=3) showed recovery of HPA axis on repeat testing and so advised to slowly wean steroids. 25% (n=1) had persistently abnormal results suggesting ongoing SIAI and advised to remain on 3mg prednisolone. All patients with an abnormal SST (n=6) remained on prednisolone and did not change to hydrocortisone. 90.1% (n=10) of patients with an SST of <340 nmol/L referred to Endocrinology concurrently with SST request and outcome for all patients was to continue slowly weaning steroids. 32% (n=8) patients with a cortisol <340 nmol/L, did not have an SST. 37.5% (n=3) had alternative WSC testing: 33.3% (n=1) discharged after normal WSC, 33.3% (n=1) awaiting WSC and 33.3% (n=1) require ongoing Endocrine input as WSC indicated SIAI. This patient awaits steroid clinic and remains on 3mg prednisolone. 62.5% (n=5) had no further investigations. Outcomes: steroids continued by Rheumatology (n=3), steroids weaned by Rheumatology (n=1), too early for further tests (n=1). 15.5% of patients (n=2) had cortisol >300-350 nmol/L. None had an SST due to not having symptoms, in line with our guidelines. 33.3% (n=3) had a repeat cortisol, all repeats >350 nmol/L. Outcomes: Rheumatology weaned steroids (n=5), dose increase due to fair (n=2), no further documentation (n=1), moved away (n=1).

Conclusion: 10.3% (n=6) of all patients who had a serum cortisol measurement had an abnormal SST and 8.6% (n=5) of patients were diagnosed with SIAI. Only one patient had documented symptoms of SIAI. Given the introduction of the more sensitive WSC as an alternative to the SST we aim to modify our department guidelines in collaboration with the Endocrinologists. In line with the 2020 National Patient Safety Association alert and 2022 British Society for Rheumatology guidance the focus is to recognise adrenal insufficiency, which our guidelines are designed to do. Adrenal insufficiency is unpredictable and rare but adrenal crisis can be fatal, so Rheumatologists must be aware of it.

AB1759-HPR THE USE OF PROMS MEASURES IN CLINICAL STUDIES IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A SYSTEMATIC REVIEW

Keywords: Inflammatory arthritides, Patient reported outcomes, Systematic review

M. Teutenberg1, I. Knaepen1, T. P.M. Vliet Vlieland2, J. Schoone3, C. Van den Enden3, S. Van Weely3, M. G. J. Gademann1, 2, Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; 2Leiden University Medical Center (LUMC), Directorate of Research Policy, Leiden, Netherlands; 3Sint Maartenskliniek, Department of Research, Utrecht, Netherlands; 4Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands; 5Leiden University Medical Center (LUMC), Department of Clinical Epidemiology, Leiden, Netherlands

Background: Patient-reported outcome measures (PROMs) are of vital importance to evaluate the outcomes of inflammatory arthritis and its management, but limitations of conventional PROMs include a lack of precision and/or comparability across conditions. Patient Reported Outcomes Measurement Information System (PROMIS) measures [1-2] were developed since 2007 to overcome these disadvantages. They use a standardized metric (T-score), centered around the general population (score 50), enhancing their interpretability. The use of PROMIS measures in patients with inflammatory arthritis was recommended by the International Consortium for Health Outcomes Measurement (ICHOM) [3], but little is known about the extent and nature of their actual use in clinical research.

Objectives: To describe the use and outcomes of PROMIS measures in clinical studies involving people with rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA).

Methods: We conducted a systematic review according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. A search of electronic data bases on July 29th, 2022 was conducted to identify clinical studies in patients with RA or axSpA, reporting the use of PROMIS measures and written in English, Dutch, French. Study characteristics, details of PROMIS measures and, if available, their outcomes, were extracted. Both the selection and the data extraction were performed independently by two researchers and disagreements were resolved by consensus, either or not with a third researcher.

Results: In total, 714 records were retrieved (272 unique references), of which 29 studies met the inclusion criteria (25 RA, 3 axSpA and one both RA and axSpA). In total, 15 different PROMIS measures were used, 13 of which were domain-specific and 2 pertained to general health (PROMIS Global Health, PROMIS-29). The five most frequently used domain specific measures were the PROMIS Pain Interference (n=17), Physical Function (n=14), Fatigue (n=13), Depression (n=12) and Anxiety (n=7) measures. The general PROMIS Global Health and PROMIS-29 were both reported in 3 studies. The PROMIS measures that were used varied considerably, with a total of 74 unique identified measures, as a result of differences in their typology into Item Banks, Computer Adaptive Tests, Short Forms, the described name or the version number. In total, 21 studies reported on 98 PROMIS results in terms of T-scores, of which 91 were worse than the general population mean (score 50), indicating impaired health status. The other 8 studies did not report actual T-scores but psychometric properties of PROMIS measures (e.g. the validity, reliability, correlations with other questionnaires, responsiveness, meaningful change).

Conclusion: Given the availability of PROMIS measures since 2007 and the vast amount of clinical studies in RA and axSpA, PROMIS measures seem to be relatively understudied. Among the studies there was considerable variety regarding the PROMIS measures that were used as well as their versions. The reported PROMIS outcomes overall reflected the impaired health status of patients with RA and axSpA as compared to the general population. Apart from the promotion of the use of PROMIS measures, more standardization regarding the type of measures and their versions is needed to facilitate comparisons across studies.

AB1760-HPR THE RELATIONSHIP BETWEEN DISEASE ACTIVITY LEVEL AND WRIST JOINT POSITION SENSE, GRIP STRENGTH AND DYNAMIC GRIP ENDURANCE IN PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Physical therapy/Physiotherapy

M. Köprüleşioğlu1, İ. Naz1, D. SolmaZ2, S. Akar2, 1İzmir Katip Celebi University, Department of Physiotherapy and Rehabilitation, İzmir, Turkey; 2İzmir Katip Celebi University, Department of Internal Medicine, İzmir, Turkey
**Background:** Dynamic grip endurance in psoriatic arthritis is one of the affected functional parameters during the disease process. However, there are limited studies about dynamic grip endurance related factors. 

**Objectives:** To investigate the relationship between disease activity level and joint position sense and dynamic grip endurance in psoriatic arthritis. 

**Methods:** A total of 27 PsA patients (age:53.33 ±11.85 years, women:men:16:5) who were classified by the Classification Criteria for Psoriatic Arthritis (CASPAR) criteria and followed in outpatient clinic were included in our study. The socio-demographic characteristic of all patients recorded. Disease activity level was assessed with the DAPSA score. Wrist joint position sense was evaluated by a goniometric re-position error test. Grip strength and endurance were examined by a hand dynamometer (Lafayette Professional Hand Dynamometer, USA). Data analysis was performed with Spearman Correlation Coefficient. 

**Results:** Patients’ diagnosis year, tender joint on hand, and swollen joint on hand were 4.50 years, 23, and 18, respectively. DAPSA scores were 28.67 ±14.85 and moderate-high level. There was no relationship between DAPSA scores and joint position error and dynamic grip endurance on both sides (p>0.05). A moderate level correlation was found between the DAPSA score and grip strength on both sides (p<0.05, r=−0.516 and −0.570 dominant and non-dominant side, respectively). 

**Conclusion:** Our study showed that PsA patients had lower grip strength during the exacerbation period. Since joint position sense and grip endurance were low independent of disease activity, they may also increase safety and save resources. However, it is unclear how such telemedicine services integrate into the clinical workflow.

**AB1762-HPR** CAN PATIENT-REPORTED OUTCOMES BE USED TO TRIAGE PATIENTS WITH ANKYLOSING SPONDYLITIS TO MOBILITY MEASUREMENTS OR TESTING OF C-REACTIVE PROTEIN?

**Keywords:** Spondyloarthritis, Patient reported outcomes, Outcome measures

C. Fougman McCarthy1,2, K. Hörnberg3, T. Woelt4,5, M. Björklund2, B. Sundström6,7, Gävle Hospital, Department of Rheumatology, Gävle, Sweden; 2Umeå University, Department of Community Medicine and Rehabilitation, Physiotherapy, Umeå, Sweden; 3Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden; 4Uppsala University/Region Gävleborg, Centre for Research and Development, Gävle, Sweden

**Background:** Patients with Ankylosing Spondylitis are assessed by healthcare with regular controls of mobility and disease activity. If these controls can be replaced by valid patient-reported index, it would burden both patients and healthcare. 

**Objectives:** In this study we analysed associations between healthcare measured mobility and disease activity and patient-reported disease activity, physical function and well-being in patients with AS. 

**Methods:** This register-based cross-sectional study used data from 1541 visits (of which 1093 visits were men and 448 women) in the Swedish Rheumatology Quality Register. Variables for healthcare measured spinal mobility and disease activity were Ankylosing Spondylitis Metrology Index (BASMI) and C-Reactive Protein (CRP). Variables for patient-reported disease activity, physical function and well-being were Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Global Score (BAS-G). First, associations were tested with Pearson correlation. Secondly, discriminative ability to identify subnormal BASMI, or CRP [defined as below the 2.5th percentile of healthy individuals, and >3, respectively [1,2], was determined by means of receiver operating characteristic (ROC) curve analysis for variables with coefficients $r>0.4$. 

**Results:** Associations with $r>0.4$ was found only between BASMI and BASFI ($r=0.49$), resulting with an area under the curve (AUC) of 0.74 (95% CI; 0.72-0.76) in the ROC analyses. Among the subquestions of BASMI/BASI, the highest association was seen between measured cervical rotation and the self-assessed ability to look over shoulder ($r=0.69$), resulting in AUC of 0.85 (95% CI; 0.83-0.88) in the corresponding ROC analyses, using cervical rotation below 2.5th percentile of healthy individuals as discrimination value. 

**Conclusion:** A significant association with $r=0.4$ was seen between BASMI and BASFI. The resulting AUC of 0.74 between BASMI and BAFI, and 0.85 between measured cervical rotation and self-assessed ability to look over shoulder, can be deemed as acceptable and excellent, respectively [3]. BASFI and its sub-questions may therefore be of interest for further evaluation if they could be used for screening and triaging patients to spinal mobility measurements with BASMI. Neither of the self-reported indices associated with CRP to any higher degree ($r>0.4$).

**AB1763-HPR** RELIABILITY AND VALIDITY OF THE TURKISH VERSION OF SCLERODERMA SKIN PATIENT-REPORTED OUTCOME IN PATIENTS WITH SYSTEMIC SCLEROSIS

**Keywords:** Systemic sclerosis, Patient reported outcomes, Validation
Background: Systemic sclerosis (SSc), which is characterized by fibrosis of the skin and internal organs and vasculopathy, is an autoimmune rheumatic disease. Skin fibrosis is the most seen feature of SSc patients and affects nearly all patients with SSc at different levels and severity. Skin involvement is generally evaluated with the modified Rodnan skin score (mRSS). However, several studies have indicated that there is no relation between mRSS and appearance self-esteem. Based on evidence from previous studies that it is significant to comprehensively evaluate the effects of skin fibrosis on QoL in SSc patients. There is a need for an instrument to assess the effects of skin involvement on the quality of life of the Turkish population in SSc patients.

Objectives: Sclerodema Skin Patient-Reported Outcome (SSPRO) is useful scale to evaluate the skin related quality of life in SSc patients. This study purposed to translate the SSPRO questionnaire to Turkish (SSPRO-T) language and to assess its validity and reliability.

Methods: Fifty-four SSc patients (female: male, 51:3) participated in the relia-

Results: The total SSPRO-T had a four-factor structure. The total SSPRO-T score and its subgroups correlated positively with SQA, HAQ, Skindex-29 and patient global skin severity. The internal consistency and reliability were excellent the SSPRO-T and physical effects subgroup, emotional effect subgroup, physical limitation subgroup and social effect (Cronbach's α = 0.94, 0.80, 0.95, 0.93 and 0.84, respectively) (Table 1). The SSPRO-T had excellent test-retest reliability (r=0.91, p<0.001). In addition; it was not seen floor effect and ceiling effect related SSPRO-T.

Conclusion: The SSPRO-T questionnaire is an excellent a reliable and valid tool. It could be used in research and clinical studies in the Turkish patients with SSc.

Rojas-Villarraga1, Fundación Universitaria de Ciencias de la Salud FUCS, Basic Sciences Group, Bogotá, Colombia; Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia; 4. Instituto Distal de Ciencia Biotecnología e Investigación en Salud, IDCBS, Research, Bogotá, Colombia; 5BICMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia; 6Fundación Cardiocliniante-La Cardio, Cardiovascular Prevention Program, Bogotá, Colombia; 5Fundación Cardiovascular de Colombia (FCV), Research Laboratory, Bogotá, Colombia; 7Fundación Cardiocliniante-La Cardio, Cardiology, Bogotá, Colombia

Background: Cardiovascular disease is the leading cause of premature death among patients with rheumatoid arthritis (RA). Inflammatory cytokines play a pivotal role in this process, leading to impaired artery elasticity by priming endothelial dysfunction and enhanced arterial stiffness.

Objectives: To assess the expression of inflammatory cytokines associated to cardiovascular alterations such as arterial stiffness among patients with RA and osteoarthritis (OA) through Gene Ontology and Pathway Enrichment analysis.

Methods: Inclusion criteria for this analytical cross-sectional study were patients with RA and OA between 40 and 70 years old. Sociodemographic and clinical characteristics as well as inflammatory, metabolic markers, acute phase reactants, autoantibodies were analyzed. Levels of 18 cytokine: including VCAM1 (CD106), ICAM1 (CD54), CCL7 (MARC), MCP1, SPP1 (OPN), PDGF, CXCL10 and inflammaging related cytokines: INF-γ (IFNG), IL-10, IL-1RA, IL-1β, IL-6, TNF-α, MMP1, MMP2, MMP9, TIMP-1, TIMP2, were measured using a Lumexx Assay (Invitrogen, Carlsbad, CA, United States). Cardiovascular measurements (Including Pulse Wave Velocity -PWV and aortic augmentation index – Aix) were performed within one month after blood sampling using the TensioMed Arteriography. A protein-protein interaction network (PPI) was built using the string App plugin from Cytoscape v3.9.1. Gene Ontology and pathway analysis were carried out using ClueGO (v2.8.9) + Cluepedia (v1.5.9) Cytoscape plugin for the proteins that showed a significant overexpression against GO biological processes, KEGG, and Reactome pathways databases (Homo sapiens).

Results: A total of eighty patients were included (71.3% women). The average age was 57 years, interquartile range (IQR) 10. OA patients had higher waist circumference, weight, and body mass index values than RA patients. There were no differences in lipid profile or glucose levels. CRP levels were higher in RA patients. Levels of disease activity in RA patients was low according to the measurement of the DAS-28-PCR. 12.5% of patients with RA had polyautoimmunity. There were no significant differences in the measurement of cardiovascular variables between the two groups except for Brachial diastolic blood pressure, which was higher in the RA group (p=0.049). Plasma levels of VCAM1 (CD106), MARC (CCL7: p=0.000), SPP1 (OPN; p=0.040), IL-1RA; p=0.015) and IL-1β (p=0.031) were significantly higher in the group of RA patients. ICAM1 (CD54), MARC, and INF-γ levels were correlated with Aix in the RA group. In the OA group, IL-10 levels positively correlated with Brachial pulse pressure and other central and peripheral pressure measurements (mild or moderate). The merged network between upregulated cytokines (VCAM1, SPP1, PDGF1, IFNG, ICAM1 and CCL7, RA query in DISEASE database and Arterial stiffness” query (PubMed) resulted in a PPI network with 26 nodes and 88 interactions. (Figure 1). The nodes with BC above 0.05 (VCAM1, TNF, JAK1, ICAM1, IL-10, CD4, PTK2B, FN1, ITGB1) represents the key genes. Ten GO terms and twelve KEGG pathways were significantly enriched (Figure 2). The principal GO terms were as follows: “membrane to membrane docking” (34% genes), “response to type II interferon” (7.89% genes), and “regulation of lipid biosynthetic process” (5.26% genes). KEGG and REACTOME included: signaling by PDGF (7.89%), integrin cell surface interaction (2.63%), extracellular matrix organization (2.63%).

APPLICATION OF THE EULAR SYSTEMIC SCLEROSIS IMPACT OF DISEASE (SCLEROD) QUESTIONNAIRE IN AN ITALIAN COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS: ANALYSIS OF PATIENT-REPORTED OUTCOMES AND THEIR ASSOCIATION WITH MAIN DISEASE FEATURES

Keywords: Patient reported outcomes, Outcome measures, Systemic sclerosis

I. Bisconti1, D. M. Reza Beigi1, G. Pellegrino1, M. Cadar1, F. R. Di Commo1, K. Stefanantoni1, S. Truglia1, F. Conti1, V. Riccieri1, 1Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Ruma, Italy

Background: Systemic sclerosis (SSc) is characterized by a chronic and frequently progressive course and by a high patient-to-patient variability. Due to the lack of disease-specific, patient-reported outcome measures for use in clinical trials and in clinical practice, EULAR recently validated the Systemic Sclerosis Impact of Disease (ScleroID) questionnaire, calculated as a composite score of 10 different health dimensions with Numeric Rating Scales (NRS) from 0 to 10 (from best to worst)(Figure 1). For each dimension, the NRS score is multiplied by the specific weight for its item and the weighted scores are summed up.

Objectives: The aim of this study was to apply ScleroID questionnaire to an Italian cohort of patients affected by SSc and to find any possible association with their main demographic, clinical and serological features.

Methods: 55 consecutive patients with SSc (defined by 2013 ACR/EULAR criteria) were enrolled. ScleroID was administered. Socio-demographic variables and clinical features were recorded. Data were analyzed using GraphPad Prism 8 software. Wilcoxon nonparametric test was used to compare data. Spearman’s rank correlation coefficient was used and Linear regression analysis (r correlation coefficient) was employed to identify significant correlations, defined by a p value <0.05.

Results: The main demographic, clinical and serological features of the study population are shown in Table 1. ScleroID total score median value of our patients was 42 (IQR 21-57). Significant associations were found among the presence of DU and higher values in the dimensions of Raynaud’s phenomenon (p = 0.03), impaired hand function (IHF) (p = 0.005), pain (p = 0.013), life choices (LC) (p = 0.03) and body mobility (BM) (p = 0.01). Anti-SCL70 positivity was associated with higher DU domain score (p = 0.01). Diffuse SSc form was associated with higher values of IHF (p = 0.006), pain (p = 0.02), LC (p = 0.002), BM (p = 0.0005) and DU domains (p = 0.003). Moreover, a positive correlation was found between mRSS and IHF (p = 0.02), LC (p = 0.006), BM (p = 0.02) and DU (p = 0.04), as well as between lower gastrointestinal symptoms domain and age (p = 0.02). A higher ScleroID global score was associated with the diffuse SSc form (p = 0.002), the use of immuno-suppressive therapy (p = 0.01) and the presence of DU (p < 0.0001). Finally, the last result was confirmed on multivariate analysis (p = 0.007).

Conclusion: Our results confirm the reliability of ScleroID questionnaire in the real life of ScS patients, highlighting the impact of an extensive cutaneous involvement and the presence of DU in several health quality dimensions. Thus ScleroID appears to be a valid and easy to perform tool, able to access the disease activity by a patient reported outcome.

The study showed that the QOL of most patients improved with a correct diagnosis. The graphically depicted progression of the patients' health per-ception are shown in Figure 1: with the onset of the first symptoms, 65% of the patients found their state of health to be less good or bad, in course of disease, this number increased to 70%. At the current time, the time of the interviews, the number declined to 28%. Originally, no patient was in excellent health, but at the current condition after the diagnostic odyssey, 10% were able to describe their state of health as excellent. The interviews show an overall decline in well-being during the diagnostic odyssey, which slowly increases with the correct diagnosis. Conclusion: The study showed how much a correct diagnosis affects the patients’ QOL. The use of a DDSS would have significantly shortened the diagnostic odysseys and thus improved patients’ QOL at an earlier stage.

Figure 1. Retrospective development of health perception over the course of the disease among the study participants (n=71). Displayed are the results as an extract of the SF-36.

AB1766-HPR THE IMPACT OF FASTER DIAGNOSIS THROUGH ARTIFICIAL INTELLIGENCE ON THE QUALITY OF LIFE OF PATIENTS WITH RARE DISEASES

Keywords: Quality of life, Descriptive Studies, Artificial Intelligence

Background: Diseases that affect fewer than 2000 people in the general population are defined as rare diseases [1]. The rarity and the associated limited experience with these diseases, but also the large number of about 8000 rare diseases [2], pose a major diagnostic challenge for physicians. On average, affected patients need 5.6 to 78 years until they receive a diagnosis and thus the correct therapy [3]. These diagnostic odysseys place a heavy financial, health, and psychological burden both on patients and their families. Diagnostic decision support systems (DDSS) have great potential to assist physicians in diagnostic decision-making and can indicate the presence of a rare disease much earlier. An exploratory study conducted at the Outpatient Clinic for Rare Inflammatory Systemic Diseases with Renal Involvement at Hannover Medical School showed that the diagnostic process can be shortened by a DDSS. The median lead between diagnosis and the hypothetical time of diagnosis by a DDSS was three months [4]. A follow-up study showed that health economic savings were also possible by making the diagnosis so early [5].

Objectives: Measured against the hypothetical diagnosis time points determined in the previous study [4], this study aimed to investigate, in the same patient population, the extent to which earlier diagnosis using a DDSS would have influenced patients’ quality of life (QOL).

Methods: To determine the potential for improving QOL through artificial intelligence (AI), 71 patients from the patient cohort of the previous studies were surveyed [4][5]. The questionnaire was composed of established questionnaires such as the WHO HPQ and the SF-36. In five interview sessions from the onset of the disease, the time of professional diagnosis, to the current time, the development of QOL was retrospectively recorded. To analyze the development of QOL during the disease, but also to show the influence of the DDSS on QOL, data were also collected for the time points at which the DDSS would have indicated the correct diagnosis as the first suggestion or among the first five suggestions.

Statistical analysis, graphical presentation and interpretation of the questionnaires were performed using statistical software.

Results: The study showed that the QOL of most patients improved with a correct diagnosis. The graphically depicted progression of the patients’ health perception are shown in Figure 1: with the onset of the first symptoms, 65% of the patients found their state of health to be less good or bad, in course of disease, this number increased to 70%. At the current time, the time of the interviews, the number declined to 28%. Originally, no patient was in excellent health, but at the current condition after the diagnostic odyssey, 10% were able to describe their state of health as excellent. The interviews show an overall decline in well-being during the diagnostic odyssey, which slowly increases with the correct diagnosis.

Conclusion: The study showed how much a correct diagnosis affects the patients’ QOL. The use of a DDSS would have significantly shortened the diagnostic odysseys and thus improved patients’ QOL at an earlier stage.

AB1767-HPR DOCUMENT SEARCH IN LARGE RHEUMATOLOGY DATABASES: ADVANCED KEYWORD QUERIES TO SELECT HOMOGENEOUS PHENOTYPES

Keywords: Artificial Intelligence, Systemic lupus erythematosus, Systemic sclerosis

C. Gérardin1, Y. Xong1,2, A. Mekinian3, F. Carrt4, X. Tannier5.

Background: Natural language processing tools are powerful for mining rheumatology databases, extracting patient information directly from clinical notes. However, these algorithms come with a high computational cost and are often not applicable at the scale of very large databases in the temporality of clinical practice.
Objectives: The objective of our study is the automatic detection of clinical documents of interest for a specific clinical question, with low computational cost, to be applied on a database of millions of documents. These sets of documents of interest constitute a pre-screening to allow the development of more complex algorithms.

Methods: The task was considered as an information retrieval task in French clinical texts. Two different methods were compared. For the first method, we used several state-of-the-art document vector representations: TF-IDF, doc2vec, docBERT and tested if the closest documents are relevant. The second method consists in building a powerful query expansion from a key term entered, its French synonyms from the UMLS and the synonyms found by similarity with the embeddings of the CODER algorithm. These methods are developed and evaluated on a set of 8 and on 20 phenotypes respectively (e.g. “pericarditis in lupus”, etc.). Our database corresponds to 2 million documents from a cohort of patients suffering from four autoimmune diseases: systemic lupus erythematosus, scleroderma, antiphospholipid syndrome, and Takayasu’s disease, coming from the AP-HP’s data warehouse.

Results: Our experience does not support the vector representation model of clinical notes for searching similar patients. However, searching with an advanced synonym search method can lead to very good results without additional burden for the clinician: we achieved a precision (or positive predictive value) of 0.93 [0.90; 0.96] evaluated manually by a physician and a recall (or sensitivity) of 0.78 [0.71; 0.85] evaluated on the basis of the ICD10 codes of the retrieved patients.

Conclusion: We propose a new advanced keyword search method with automatic synonym search with very good accuracy and recall performance.

HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SEPTAL PANNICULITIS

Keywords: Quality of life

G. Koilubaeva1, O. Egorova2, A. Bolotbekova1, A. Turatbekova1, G. Syunbai K1.
1, 3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan; 2Kashirskoye Shosse, 34, Rheumatology, Moskva, Russian Federation

Background: Idiopathic lobular panniculitis (ILP) or Weber-Christian disease is a rare understudied disease, which manifests itself in recurrent subcutaneous fat necrosis often involving damage of the internals. Treatment of the disease is not standardized, and as a matter of fact it is provided empirically.

Objectives: to assess the efficiency of therapy in case of various forms of ILP.

Methods: We studied 34 patients (30 women, 4 men) with ILP, age 30-74, duration of disease 7.4±2.3 years. Besides general clinical examination we determined the level of α1-antitrypsin, amylase, lipase, ferritin, creatine phosphokinase, made chest CT scan and carried out the pathomorphological study of skin biopsy specimen taken from the area of a node. The following forms of the disease were identified: nodular form (NF) (14 patients), plaque form (PF) (9 patients), mesenteric form (MF) (5 patients) and infiltrative form (IF) (6 patients). In all cases the lobular panniculitis was verified by means of histopathological examination. All patients took glucocorticoids (GC), average daily dose of 12.8±1.6 mg, including 8.4±1.7 mg (for NF), 17.6±3.2 mg (for PF), 8.6±1.6 mg (for MF), 23.6±5.3 mg (for IF). In case of NF, we additionally prescribed Plaquenil, the dose of 600 mg per day (8 patients), and Mycophenolate Mofetil 1.5-2 g per day (6 patients); in case of PF – Cyclophosphamide (Cph), the dose of 200 mg per week (4 patients) or Mycophenolate Mofetil (1.5-2 g per day, 5 patients); in case of MF – Mycophenolate Mofetil (1.5-2 g per day, 5 patients). Patients with IF took Cph (200 mg per week). In case there was no effect after 3 months, we prescribed Mycophenolate Mofetil (1.5-2 g per day). With an unsatisfactory effect, after 3 months, genetically engineered alpha-TNF antagonist drugs were used. On average, the observation period was 12 months.

Results: The treatment made it possible to achieve a significant positive dynamics in patients with NF and MF: the body temperature got back to normal and there was regression of indurations (26 patients), joint pain intensity was reduced (16 patients), laboratory data on inflammatory intensity revealed decrease (24 patients). Average daily dose of GC was reduced to 4.5±0.7 mg and 11.4±1.1 mg, respectively. In general, a significant improvement was evident in all patients with NF and MF, in 75 % of patients with PF. In case of IF an average daily dose was increased to 25.4±1.7 mg per day. In all patients of this group, an unsatisfactory effect was noted, which required discussion of the appointment of genetically engineered biological therapy. The tolerability of treatment was regarded as good, no adverse events were noted. After 14 weeks, 3 patients had a syndrome of “eluding” the effect and IL-1 inhibitor drugs were prescribed for the first time.

Conclusion: To work out dosages and treatment schedules for patients with ILP further studies are required.

Background: Hydroxychloroquine (HCQ) remains one of the most valuable therapies in SLE, and its use is supported by every recent international guideline regardless of the severity of the disease. It is however associated with long-term side effects, mainly ophthalmological whereby is recommended ophthalmological screening. Little is known on the risk of systemic lupus erythematosus (SLE) flares associated with hydroxychloroquine (HCQ) reduction or cessation, especially following ophthalmological screening.

Objectives: We analyzed the risk of SLE flares after HCQ reduction or cessation in the context of detection of early signs of ophthalmological toxicity.

Methods: Among 109 patients included in the prospective PERFOCTAPS study and treated with HCQ for at least 5 years, we included all patients with SLE. Patients were divided in three groups: group maintenance corresponding to patients with no ophthalmological alterations maintaining their treatment at the same dose, group reduction corresponding to patients with mild ophthalmological alterations that led to reduction of HCQ dose, and group discontinuation corresponding to patients with retinal abnormalities that led to stopping HCO. Occurrence of flares (SELENA-SLEDAI flare index) was assessed in the two years following HCQ reduction or discontinuation or following inclusion in PERFOCTAPS study for the maintenance group.

Results: 85 patients were included (98% female, mean age 40.0 years, mean duration of SLE 14.4±7.7 years and of HCQ treatment 12.9±7.2 years, mean dose per kilogram of HCQ was 5.6±1.8 mg/kg/day). PERFOCTAPS study identified ophthalmological abnormalities in 25 patients (29.4%) that led to dose reduction in 20 patients and discontinuation in 5. At inclusion groups maintenance and reduction were very similar; patients in group discontinuation were significantly older with a longer SLE and HCQ treatment duration. There was no significant difference in HCQ dose (mg/kg/day) between the three groups. After reduction, the proportion of patients with a dose of HCQ <5 mg/kg/day became significantly higher in the reduction group than in the maintenance group (85% vs. 35% P<0.001). Flares occurred in 29 patients (34.1%): 17 (28.3%) in the maintenance group, 10 (50%) in the reduction group, and 2 (40%) in the discontinuation group. Flares were severe in 6 patients (10%) in the maintenance group, 4 (20%) in the reduction group and none (0%) in the discontinuation group. After adjustments on potential confounders, HCQ reduction was independently associated with the risk of flare (adjusted HR 2.57; 95% CI 1.14-5.75). The same trend was observed in the discontinuation group but without reaching statistical significance (adjusted HR 3.03; 95% CI 0.66-13.87).

Conclusion: In this prospective study, HCQ reduction due to an early suspicion of retinal toxicity was associated with a statistically significant increased risk of disease flare. This adds data to the growing pendulum return regarding HCQ dose reduction and we should always balance the potential benefits of tapering or discontinuing HCQ with the risk of SLE flare and subsequent need to increase or start other drugs, especially corticoids or immunosuppressors that have well-known adverse effects.

AB1772-HPR PNEUMOCOCCAL VACCINATION IN CHRONIC INFLAMMATORY DISEASE(CIRD) PATIENTS: REASONS FOR NON-PRESCRIPTION AND SOLUTIONS

Keywords: Vaccination/Immunization, Inflammatory arthritides

S. Ez-Zeau1, H. Rkain2, F. Kronbi3, T. Latifa4, S. Bahoul4, I. Bensagh4, S. Farhi5, F. El Jounani5, R. Honsai5, N. Hajjai-Hassouni5, F. Alia5, 1Hospital Al Ayachi, Rheumatology B, Salé, Morocco; 2Faculty of Medicine and Pharmacy of Rabat, Exercise Physiology and Autonomous Nervous System Team, Physiology Laboratory, Rabat, Morocco; 3International University of Rabat, Rheumatology, Rabat, Morocco

Background: To explore rheumatologists’ reasons for non prescription of pneumococcal vaccine in CIRD patients and to collect solutions proposed by rheumatologists.

Methods: This is a cross-sectional study carried out by the vaccination working group of the Moroccan Society of Rheumatology. The survey collected data on reasons of pneumococcal vaccination abstinence in rheumatology practice, and solutions proposed to improve pneumococcal vaccination in CIRD patients.

Results: This survey included 125 rheumatologists (mean age 42.4 +/-12.1 years). The sector of practice was respectively 31.2%, 34.4%, 34.4% for the public sector, private sector and University Hospital. 36.9% of rheumatologists have never prescribed pneumococcal vaccination for their CIRD patients. Table 1 illustrate reasons given by rheumatologists for non vaccination of their CIRD patients. Table 1 illustrate reasons given by rheumatologists for non vaccination of their CIRD patients against pneumococcal infection.

Table 1. Reasons for not prescribing the pneumococcal vaccine

</tbody>
</table>

Concerning proposed solutions, rheumatologists recommended reinforcing pneumococcal vaccination awareness among rheumatologists, integrating the vaccine into the social security reimbursement protocol, and including the pneumococcal vaccination for CIRD patients in respectively 92%, 71.2%, 60% of cases.
Conclusion: The main obstacles to the pneumococcal vaccination prescription by rheumatologists are related to the lack of knowledge of vaccination protocol and the forgetfulness. Therefore, the Optimization of pneumococcal vaccination would necessarily focus on combating the obstacles to this preventive practice in CIRD patients.

CONNECTIVE TISSUE DISEASE-RELATED INTERSTITIAL LUNG DISEASE: AN EXPERIENCE OF A MULTIDISCIPLINARY TEAM IN COLOMBIA

Keywords: Lungs, Descriptive Studies, Imaging

C. Borda Samper1, J. S. Sierra2, D. G. Fernández-Avila3, C. Celis Preciado3, M. Diaz3, Hospital Universitario San Ignacio, Rheumatology, Bogota, Colombia; 1Hospital Universitario San Ignacio, Pulmonology, Bogota, Colombia; 1Hospital Universitario San Ignacio, Rheumatology, Bogota, Colombia

Background: Intersitial lung disease (ILD) occurring in a person with a known or classifiable connective tissue disease (CTD) is referred as CTD-ILD. Approximately 15% of ILDs will have a background CTD. The presence of ILD is the primary determinant of prognosis. High-resolution CT (HRCT) is the diagnostic image of choice. Intersitial involvement can have different patterns, with nonspecific interstitial pneumonia (NSIP) being the most frequent. CTD-ILD is a challenging entity and its approach requires multidisciplinary teams (MDT).

Objectives: To describe clinical, serological, and radiological characteristics of patients who present with CTD-ILD at a reference ILD center in Colombia between 2021 and 2022.

Methods: A descriptive study of patients with ILD diagnosed by HCTR who have a confirmed autoimmune disease or at least one autoimmune feature, clinical or serological. Every case was evaluated by our MDT composed by pulmonologists, rheumatologists, and pathologists. We developed an ILD registry from our inpatient and outpatient ILD-clinic between 2021 and 2022. The continuous variables were described as the mean and standard deviation, and nominal variables were evaluated based on frequencies and percentages. All analysis were done in statistical package for the social sciences (SPSS) v. 21.0.

Results: Forty patients with ILD were included; 57% were hospitalized, and 65% were women. The majority of patients with ILD were diagnosed as interstitial pneumonia, flashautoimmune features (IPAF), 30%, followed by multiple autoimmune syndromes (22.5%), rheumatoid arthritis (15%) and primary Sjogren's syndrome (12.5%). The most common radiologic pattern was usual interstitial pneumonia (40%), followed by fibrotic NSIP (22.5%). The most common clinical finding where lung cracks (61.5%), sicca symptoms (57.5%) and arthritis (30%). Mean CVF in L(%) was 173 ± 89.72 (62.27) and mean DLCO(%)(S2.5) ± 21. Progressive pulmonary fibrosis was frequent (20%), and 12.5% received antifibrotic therapy. Our mortality rate related to ILD was 21.7%.

Conclusion: In our 1-year cohort, we found that IPAF was the most prevalent CTD-ILD, followed by multiple autoimmune syndromes. The most common radiologic pattern overall was UIP, followed by fibrotic NSIP. CTD-ILD had a high mortality rate. Most of these cases were related to ILD. Our results highlight the importance of early disease detection and early therapeutic interventions. Treatment decisions must be individualized, and the risk of disease progression must be considered.

SAFETY OF THE RECOMBINANT HERPES ZOSTER VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH JAKI DRUGS

Keywords: Epidemiology, Vaccination/Immunization, Health Services Research

A. Pons-Bas1, J. Rosas1, L. Pons-Canel2, J. M. Senabre-Gallejo1, G. Santos Soler2, J. A. Bernal1, J. C. Cortés-Quiróz1, C. Raya-Santos1, R. Gallejo-Campuzano1, M. Lorente Betoret3, X. Barber3, J. A. García-Gómez2, Hospital Ma rina Baixa, Rheumatology, Villajoyosa, Spain; 2Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; 3Universidad Miguel Hernández de Elche, CIO, Elche, Spain

Background: Patients receiving JAK inhibitor drugs (JAKi) have an increased risk of herpes zoster (HZ). A new recombinant vaccine effective against HZ (Shingrix-RV) is currently recommended for patients treated with JAKi.

Objectives: To evaluate the safety of first and second dose of the recombinant vaccine against HZ (HZ-RV) in patients with RA, in treatment with JAKi.

Methods: Retrospective study of the safety after receiving the first and after 2 months, second dose of the HZ-RV in patients with RA treated with JAKi. The following variables were collected: general information of the patients, type of JAKi and time in treatment; use and dosage of DMARDcs drugs and/or corticosteroids. Regarding HZ, infection prior to HZ-RV and time elapsed; occurrence and type of side effects after vaccination.

Results: Of 138 patients treated with JAK, 9 (7%) refused vaccination, 129 (93%) received the first dose on HZ-RV, but 38 (28%) patients received it before starting JAKi and 98 (72%) being a mean of 36 months in treatment with JAKi. The second dose was administered in 113 (82%) patients, 21 (15%) patients had suffered HZ, before vaccination. One hundred and eighty (84%) are female (mean age: 64 [SD: 3] years), on JAK treatment a mean of: 2.4 (SD: 1.6) years: 89 (69%) baricitinib (2mg/day; 29 [33%] patients; 4mg/day: 60 [77%]) after second dose had side effects (p<0.05): local pain: 95 (74%) vs 62 (55%) patients, p=0.014; fatigue: 27 (21%) vs 15 (13%), p=0.07; arthralgia/myalgia: 21 (19%) vs 13 (10%), p=0.17; fever < 38°C: 10 (8%) vs 15 (13%), p=0.06; headache: 9 (7%) vs 3 (3%), p=0.72; local itching: 3 (2%) vs 2 (2%), gastro-intestinal symptoms: 2 (2%) vs 1 (1%), p=0.43, and after first dose, others in 4 (4%) patients: urinary tract infection, oral ulcer, dizziness, injection site erythema. Lymphadenopathy, hospital admission, flare of RA or serious secondary effects were not detected. After 90 days of second vaccine, a 58-year-old woman (0.8%) undergoing 5-month treatment with baricitinib 4mg/day and methotrexate, without corticosteroids, presented a slight facial HZ reaction dose.

Conclusion: 1 Vaccination with HZ-RV was safe. 2 Although a great percentage of patients have experienced any side effect, especially after the first dose of vaccine, these were mild. 3 None of RA has been detected in this period. 4 Less than 1% of patients suffered HZ reactivation after vaccination.

**ECONOMIC BURDEN OF PRENATAL CARE FOR WOMEN WITH RHEUMATIC DISEASES**

**Keywords:** Health Services Research, Pregnancy and reproduction, Quality of life

C. M. Skinner Taylor¹, L. Pérez Barbosa², J. A. Cardenas-de la Garza³, A. Carrizo-Chang⁴, M. E. Corral Trujillo⁵, F. R. Arevael Nieto⁶, A. L. Guajardo Alcañiz⁷, A. Aguilar-Leal⁸, D. A. Galazca-Delgado⁸. Hospital Universitario “Dr. José Eleuterio González”, Rheumatology, Monterrey, Mexico

**Background:** Autoimmune rheumatic diseases (ARDs) affect childbearing women. To prevent adverse maternal and fetal outcomes, multidisciplinary attention is needed, leading to increased costs of pregnancy attention [1]. The financial burden that pregnant women with ARDs have, lacks profound research.

**Objectives:** This study aims to estimate the total cost of prenatal care in pregnant women with ARDs in northeast Mexico.

**Methods:** A cross-sectional and descriptive study was carried out at the University Hospital “Dr. Jose E. Gonzalez”, offering affordable care to uninsured patients. We estimated the direct costs of prenatal care for women with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjögren’s syndrome (SS) from the ACR/ EULAR perspective [2, 3]. National standards were used to determine the regular prenatal care requirements [4]. To calculate the total expense, prices declared by the University Hospital in 2021 were used. The used currency is USD, considering an equivalence of USD 1 = 20.28 MXN. Calculating indirect costs, such as transportation, medication, or other interventions, was not performed. No sociodemographic data from patients was used.

**Results:** The itemized costs for medical appointments, ultrasounds, laboratory tests and vaginal delivery or cesarean section for women without ARDs, with SS, RA and SLE are in Table 1. Prenatal care total costs for women without ARDs, with SS, RA and SLE are exposed in Figure 1. Our findings reported an average cost of pregnancy per trimester was up to 102.76% in women with ARDs compared to women without ARDs (USD 386.52 vs 783.72) Limitations include the variability of service prices and the absence of indirect cost calculations.

**Conclusion:** In conclusion, ARD-affected women had a high economic burden secondary to prenatal costs. In this vulnerable population, creating programs for prenatal care that consider the patient’s financial status should be a priority for public health officials and institutions.

**AB1776-HPR** REVMAMAS – A PODCAST FOR PEOPLE WITH RHEUMATIC DISEASE WHO ARE PLANNING A PREGNANCY OR ARE PREGNANT

**Keywords:** Patient information and education, Pregnancy and reproduction

B. Jakobsen¹, L. Helbostad², N. Lian³, I. R. Nilssen⁴. ¹St.Olav Hospital, Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Trondheim, Norway; ²St.Olav Hospital, Department of Communications, Trondheim, Norway

**Background:** A survey distributed by patient organisations in rheumatology in 2019 have uncovered an unmet need for high quality and accessible patient information on pregnancy and rheumatic diseases. Previous publications have presented the same results (1, 2). During the pandemic, we have seen a shift from healthcare with physical consultations to digital follow-up of the inflammatory rheumatic disease. The Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases (NKSFR) primary task is to spread updated knowledge, including patient information, regarding different aspects of pregnancy and rheumatic diseases. To reach out to the target population in this digital era, NKSFR have started using social media, such as Facebook and Instagram, in addition to YouTube to spread patient information. As a natural next step we wanted to establish a podcast on different topics related to pregnancy and rheumatic diseases so patients and partners could have easy access to high quality reliable information at all times and for all of Norway.

**Objectives:** To develop a podcast with different topics related to pregnancy and rheumatic diseases. The podcast is primarily aimed at people with inflammatory rheumatic disease and their partners, but is also relevant for healthcare professionals.

**Methods:** Based on webinars published on YouTube from NKSFR during the pandemic, we edited and published six podcast episodes. We had help from the department of communications to adjust the podcast for publication. We chose a platform for podcasts without fees and easy access to make sure it was available for everyone.

**Conclusion:** Using podcast as a platform to spread high quality and knowledge based patient information can be effective to increase accessibility of patient information. The episodes are available on demand, regardless of where you live. People with rheumatism can stream the short episodes whenever convenient, for example in the car, one the bus to work, when walking the dog or when doing chores. Planning of season two has already begun.

AB1777-HPR INVESTIGATION OF THE EFFECT OF HAND EXERCISES ON GRIP STRENGTH, FUNCTIONALITY, DISEASE ACTIVITY AND QUALITY OF LIFE IN INDIVIDUALS WITH PSORIATIC ARTHRITIS: A RANDOMIZED CONTROLLED TRIAL

Keywords: Randomized control trial, Psoriatic arthritis, Physical therapy/Physiotherapy

S. Yardım 1, S. Y. Çetin 1, A. Ayan 1. Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey; 2Health Sciences University, Division of Rheumatology, Antalya, Turkey

Background: Psoriatic arthritis (PsA) is a chronic inflammatory musculoskeletal disease accompanied by psoriasis in the spondyloarthritides group and often progresses with peripheral arthritis, dactylitis, enthesitis and spondylitis [1]. Majority of PsA patients have peripheral arthritis involvement [2]. In addition to peripheral arthritis in PsA patients, structural damage occurs in the joints as the process is chronic and progressive. This structural damage causes worsening of the functional status of the patients [3]. Worsening functionality reduces patients’ quality of life. Also EULAR (Recent European League Against Rheumatism) recommends physical therapy in inflammatory arthritis including PsA [4]. It is known that individuals with PsA have lower hand strength, dexterity, coordination and functionality compared to their healthy peers [5]. There is no scientific study that applies a hand-focused home exercise program to improve the grip strength and functionality of the hand in individuals with PsA.

Objectives: The aim of this study was to examine the effect of hand exercises on grip strength, functionality, disease activity, and quality of life in patients with PsA.

Methods: 37 PsA patients (29f, 8m) with an average age of 50.32±9.12 were included in this study. Patients were randomized into intervention (group 1) and control (group 2) groups. Group 1 received hand home exercises for 4 days a week for 8 weeks. Group 2 was on the waiting-list and they received the same exercises when the study was finished. The Disease Activity Index for Psoriatic Arthritis (DAPSA) was used to evaluate the disease activity. Hand Dynamometer and pinchmeter was used to evaluate the hand grip and pinch strength. Duruoz Hand Index (DHI), Michigan Hand Outcomes Questionnaire (MHQ), Hand Functional Index (HFI), Nine Peg Hole Test (NPHT) were used to evaluate the hand functionality. Psoriatic Arthritis Quality of Life was used to evaluate the quality of life.

All evaluations were performed at baseline and at the end of the 8th week.

Results: When the groups were compared before training, there was no significant difference (p>0.05). In post-training comparisons, there was a significant difference in MHQ, hand grip and pinch strength in hand exercises group. (p<0.02-0.00). In addition, after post-training, hand exercises group was found to be superior in terms of MHQ and NPHT compared with control group.

Conclusion: According to this study, hand exercises have a positive effect on grip strength and functionality in patients with PsA. Hand exercises should be included in rehabilitation programs as a home exercise to improve grip strength, functionality and daily living activities for patients with PsA.

AB1779-HPR ASSESSING THE INTERNAL VALIDITY OF THE BSR PAIN MANAGEMENT FOR INFLAMMATORY ARTHRITIS QIP TOOL

Keywords: Patient reported outcomes, Inflammatory arthritis, Pain

A. Bhatty 1, L. West 1, N. Shenker 1. 1University of Cambridge, School of Clinical Medicine, Rheumatology, Cambridge, United Kingdom

Background: Pain management is an important component of many Inflammatory Arthritis consultations. The BSR Pain Management for Inflammatory Arthritis Quality Improvement Tool uses 11 questions and 38 sub questions that assess three domains; background information (3 questions), pain management in the consultation (5 questions) and pain management in previous consultations (3 questions) [1]. The questions are based on the EULAR Guidelines for Pain Management in Inflammatory and Osteoarthritis [2]. The tool is free to use, produces results in real time in anonymised PDF form. The project is sponsored by Cambridge University Hospitals NHS Foundation Trust Audit Department (Number 2200).

Objectives: To assess the internal validity of the Pain Management for Inflammatory Arthritis Quality Improvement QIP Tool [2020].

Methods: Two independent researchers (A & B) reviewed appointment/clinic notes from 33 patients who had attended Rheumatology appointments at Addenbrooke’s Hospital. 20 of these patients were found to experience pain during the consultation and the QIP tool questionnaire was used to assess their pain management. To assess the internal validity of the QIP tool; results from each reviewer were compared to generate a Cohen's Kappa Score for each question.

Results: The overall Kappa Score for the QIP tool was 0.75, with 570 congruent results and 190 incongruent results. The congruence was found to be high across the majority of questions. 87/190 (46%) of the incongruent scores were from just 6/38 questions. The QIP tool questions can be modified to improve clarity. There was systematic bias in the questions with lower kappa scores (A answering “Yes” and B answering “No”).

Conclusion: The Pain Management for Inflammatory Arthritis QIP Tool has a high internal validity as shown by the Kappa scores generated by results from two independent reviewers. To overcome the low Kappa scores on individual questions; additional guidance on how to answer specific questions may need to be provided to those filling out the questionnaire.

AB1780-HPR INVESTIGATING FIBROMYALGIA PATIENTS’ EXPERIENCES AFTER ONE-WEEK SELF-MANAGEMENT PROGRAMME FOUR TO TEN MONTHS AFTER DISCHARGE: A QUALITATIVE STUDY

Keywords: Fibromyalgia, Qualitative research methods, Self-management

B. Hamnes 1. 1Norwegian University of Science and Technology, Faculty of Medicine and Health Sciences in Gjøvik, Gjøvik, Norway

Background: The European League Against Rheumatism (EULAR) emphasizes in its guidelines for the treatment of fibromyalgia (FM) that Health professional should aim to improve health-related quality of life, which often requires a combination of non-pharmacological and pharmacological treatment methods. Non-pharmacological approaches have been shown to be effective in this study, a multidisciplinary self-management programme (SMP) was used to treat patients with FM.

Objectives: To investigate and understand the experiences of individuals with FM who participated in a one-week SMP.

Methods: A qualitative study using semi-structured interviews was used to investigate the participants’ experiences. A total of 22 women and 2 men with...
FM were interviewed 4 to 10 months after participating in a one-week SMP. The participants' goals and action plans after the SMP were used together with an interview guide. All the interviews were audio-recorded, transcribed verbatim and analysed using thematic analyses. The large body of material is divided into three sub-studies. The first sub-study is presented here.

Results: The mean age of the participants was 54.7 years (range 32–68). The participants' experiences were categorized into four main themes: recognition of the diagnosis, a turning point for a better life, changing one's way of thinking and having control over one's own life. Giving up the past was one description that the participants used as a way of changing their mindset. They could then focus more on the present and the future. To have control over their own lives, it became important to accept the opportunities and limitations they had in everyday life.

Conclusion: Four to ten months after completing the SMP, the participants in this study experienced that they were taken seriously with their FM diagnosis. The participants had attained a heightened awareness of what they could do to take control and manage their disease and daily life.

The proportion of conducted per required malignancy screening (58.6%, 66.5%, 60.6%, and 73.1% at the 1st, 2nd, 3rd, and 4th screening, respectively. Repeating this program (standard deviation) age was 64.6 (13.2) at the first screening, and 113

Results: The difference in the proportions of completed per required screening between repeated assessment time points.

The proportion of conducted per required malignancy screening (58.6%, 66.5%, 60.6%, and 73.1% at the 1st, 2nd, 3rd, and 4th screening, respectively. Repeating this program (standard deviation) age was 64.6 (13.2) at the first screening, and 113

Methods: Our program included patients with RA treated with intravenous biological DMARDs between September 2015 and October 2020. We first created a list of the required malignancy screening based on the patient's gender and age (Figure 1). Nurses interviewed the patients during the administration of bDMARDs to assess if they were appropriately screened for malignancies as required and thereafter provided education about the importance of malignancy screening. Nurses recorded the patient's malignancy screening status and alerted physicians by sharing the results if the patient needed additional screenings. This program was periodically repeated once a year. We assessed the difference in the proportions of completed per required screening between repeated assessment time points.

Results: A total of 154 patients were included in the analyses. The mean (standard deviation) age was 64.6 (13.2) at the first screening, and 113 (73.4%) were female. Ninety-three, forty-five, and fourteen patients underwent 2nd, 3rd, and 4th interviews, respectively. Repeating this program numerically increased the proportion of conducted malignancy screenings per required screening. (58.6%, 66.5%, 60.6%, and 73.1% at the 1st, 2nd, 3rd, and 4th interview, respectively) (Table 1). In addition, several patients understood, for the first time, the importance of malignancy screening during this interview with nurses.

Conclusion: Implementing a nurse-led interview for malignancy screening and alerting physician program numerically increased the screening of malignancy in RA patients treated with bDMARDs. This multi-disciplinary cooperation can potentially improve the quality of healthcare for patients with RA.

Acknowledgements: The author would like to thank all the informants who shared their experiences.

Usability and Acceptability of a New Autoinjector Device and Its Associated App in Rheumatology Patients

Keywords: Self-management, bDMARD, Inflammatory arthritis

Method: This study presents final data of all patients (N=264) from a global study. Patients from Argentina (n=50), Australia (n=15), Germany (n=46), France (n=28), Japan (n=75), and Spain (n=50), were included. After completing a patient profiling questionnaire, adult patients (≥ 18 years old) with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or juvenile idiopathic arthritis (JIA), and prescribed an injectable biologic, each received training to use the device and carried out and performed simulated injections. Participants completed a device evaluation questionnaire with including the following categories: 'ease of use' (14 questions), 'usability effectiveness' (11 questions), 'benefit of device features' (8 questions) and 'form factor' (7 questions). Participants also received a storyboard presentation summarizing key features of the optional app, which they could test on an Android or iOS device.

Acknowledgements: The author would like to thank all the informants who shared their experiences.

before completing up to 16 questions on connectivity and the app. Responses to device/app and app questions were recorded as Likert scale ratings from 1 (extremely negative) to 7 (extremely positive). Estimates of patient training time for the device were also provided. Hand function based on the Functional Index of Hand Osteoarthritis Arthropathies (FIHOA) score, hand pain in the injection hand due to arthritis and grip strength were also recorded. Mean values are reported. The percentage of negative (Likert scale rating 1-2), neutral (3-5) and positive (6-7) responses for each category were determined. Results: A total of 264 patients (mean age [range], 50 [18-85] years; 76% female) participated in the study. Patient diagnosis was, RA (71%), PsA (24%) and JIA (5%). The majority of patients (90%) were right-handed. While most patients (73%) always self-injected their medication, 19% of patients reported that they were mostly assisted with their injections or never self-inject. Most patients performed injection simulations using the dominant hand (77%) and chose the abdomen (54%), thigh (36%) or both (10%) abdomen and thigh as the injection site. Hand function based on the mean FIHOA score was 5.6 (range 0-24), and hand pain in the injection hand due to arthritis was 2.8 (range 1-7). Mean grip strength (range) was 19 (0-60) kg and 18 (2-54) kg in the dominant and non-dominant hand, respectively. Patients reported being “extremely comfortable” (58%) or “slightly comfortable” (35%) with digital equipment. Mean device evaluation scores (% positive responses) were: device ease of use 6.4 (87%), usability effectiveness 6.4 (67%), benefit of device features 6.6 (92%), form factor 6.2 (80%) and connectivity and app 6.2 (79%). The mean time (range) estimate for training a patient to effectively use the device and cartridge was 9.6 minutes (range 0-30 minutes). Conclusion: Patients with RA, PsA or JIA, and experienced at receiving biologic treatment for their conditions, responded positively to the new autoinjector device and app across all categories. These features will contribute to a better experience of self-injection. Acknowledgements: This study was sponsored by Pfizer. AB1783-HPR VALIDATION OF AN ELECTRONIC VISUAL ANALOG SCALE APP FOR PAIN EVALUATION IN CHILDREN AND ADOLESCENTS WITH SYMPTOMATIC HYPERMObILITY: CROSS-SECTIONAL STUDY

Keywords: Mixed connective tissue disease, Patient information and education, Pain

M. Maag1, V. Pacey2, L. Toftz2, X. Garcia3, M. Clapham4, A. CODA. 1. Central Coast- Ourimbah Campus, The University of Newcastle, Australia, School of Health Sciences, College of Health, Medicine and Wellbeing, Ourimbah, Australia; 2. Macquarie University, Department of Health Sciences, Macquarie Park, Australia, 3. Facultad de Ciencias de la Salud de Matanza, Universidad de Vic-Universitat Central de Catalunya, Matanza, Spain; 4. Hunter Medical Research Institute, Equity in Health and Wellbeing Research Program, New Lambton Heights, Australia

Background: Rapid advances in mobile apps for clinical data collection for pain evaluation have resulted in more efficient data handling and analysis than traditional paper-based approaches. As paper-based visual analogue scale (p-VAS) scores are commonly used to assess pain levels, new emerging apps need to be validated prior to clinical application with symptomatic children and adolescents. Objectives: This study aimed to assess the validity and reliability of an electronic visual analogue scale (e-VAS) method via a mobile health (mHealth) App in children and adolescents diagnosed with hypermobility spectrum disorder/ hypermobile Ehlers-Danlos syndrome (HSD/HEDS) in comparison with the traditional p-VAS.

Methods: Children diagnosed with HSD/HEDS aged 5-18 years were recruited from a sports medicine center in Sydney (New South Wales, Australia). Consenting participants assigned in random order to the e-VAS and p-VAS platforms were asked to indicate their current lower limb pain level and completed pain assessment e-VAS or p-VAS at one time point. Instrument agreement between the 2 methods was determined from the intraclass correlation coefficient (ICC) and Bland-Altman analysis. Results: In total, 43 children with HSD/HEDS aged 11 (SD 3.8) years were recruited and completed this study. The difference between the 2 VAS platforms of median values was 0.20. Bland-Altman analysis revealed a difference of 0.19 (SD 0.95) with limits of agreement ranging -1.67 to 2.04. An ICC of 0.87 (95% CI 0.78-0.93) indicated good reliability. Conclusion: These findings suggest that the e-VAS mHealth App is a validated tool and a feasible method of collecting pain recording scores when compared with the traditional paper format in children and adolescents with HSD/HEDS. The e-VAS App can be reliably used for pediatric pain evaluation, and it could potentially be introduced into daily clinical practice to improve real-time symptom monitoring. Further research is warranted to investigate the usage of the app for remote support in real clinical settings.

AB1784-HPR COMPARISON OF POSTURAL CHANGES AND FUNCTIONAL LEVELS AMONG DIFFERENT SUB-TYPES OF AXIAL SPONDYLOARTHRITIS PATIENTS

Keywords: Physical therapy/Physiotherapy, Patient reported outcomes, Outcome measures

Y. Akkubak1, T. Duger2, A. Kucuk. 1. Necmettin Erbakan University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Konya, Turkey; 2. Hacettepe University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 3. Necmettin Erbakan University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Konya, Turkey

Background: Axial Spondyloarthritis (axSpA) is divided into two sub-types as radiographic axSpA which is commonly known as ankylosing spondylitis, and non-radiographic axSpA which defines no structural radiographic damage in sacroiliac joints. The systemic, inflammatory nature of axSpA, chronic pain, inflammatory cytokines, changes in the bone and ligaments of the spine may affect spine posture and functional level. Objectives: The aim was to compare spine posture and functional levels differences among radiographic axSpA, non-radiographic axSpA patients and healthy controls. Methods: Twenty patients with radiographic axSpA (mean age; 39.9± 9.75, 15 female), 20 patients with non-radiographic axSpA (mean age; 38.55± 2.74, 15 female), and 20 age and sex-matched healthy controls (15 female) were included in the study. The patients were evaluated with Bath Ankylosing Spondylitis Metrorology Index, Bath Ankylosing Spondylitis Disease Activity Index, Bath Ankylosing Spondylitis Functional Index, Ankylosing Spondylitis Quality of Life Questionnaire. Thoracic and lumbar curvature tests were measured with a digital inclinometer (Acumar, Dual Digital Inclinometer, Lafayette Instrument Company, IN, USA). Results: No differences were detected in disease activity level, disease-related status, disease-related quality of life between radiographic and non-radiographic axSpA patients (p>0.05). However, time since onset of symptoms, spinal mobility were higher in radiographic axSpA patients (p<0.05, Table 1). Radiographic and non-radiographic axSpA patients presented lower lumbal lordosis degree compared to healthy controls (p<0.001, Table 1). Conclusion: The results of the present study suggest that disease sub-types of axSpA may affect the spine posture, in particular thoracic curvature degree. Every effort should be taken to improve spine posture in axSpA patients; however, sub-type specific considerations should be kept in mind for planning exercise/ physical activity programs.

Conclusion:

The ETBQ-T was retested to examine its reliability after seven days. The test-retest reliability was excellent (Intraclass correlation coefficient= 0.959; Cronbach’s alpha= 0.919) (Table 1). The ETBQ-T had a good correlation with pain (r = 0.564, p <.001), satisfaction (r = 485, p <.001), and self-efficacy (r = 0.582, p <.001). However; The correlation of the ETBQ-T with EQ-5D (r = 0.364, p <.001) was weak. A factor was extracted, accounting for 58.28% of the total variation. There were no floor and ceiling effects.

Conclusion: The ETBQ-T is a reliable and valid tool to evaluate the exercise burden in the Turkish population with chronic disease.

Keywords: Outcome measures, Patient reported outcomes, Validation

E-Safi1, S. Safi1, Bingöl University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Bingöl, Turkey; Sanliurfa Training and Research Hospital, Department of Internal Medicine, Sanliurfa, Turkey

Background: Chronic diseases, as demonstrated by the 36 million deaths they caused in 2008, are the most common cause of death worldwide. Exercise is one of the non-pharmacological treatment methods. The main objectives of exercise, one of the treatment methods, is to reduce pain, prevent loss of function in daily activities and work, and increase the quality of life, exercise capacity, and muscle strength. Although exercise benefits are known, more than half of the population does not exercise due to some exercise burden. However, there are no measurement methods assessing exercise burden patients with chronic disease.

Objectives: The objectives of the current study were to evaluate the Turkish validation of the Exercise Therapy Burden Questionnaire into Turkish (ETBQ-T) and to investigate its reliability and validity.

Methods: 100 participants (69 female and 31 male) who were diagnosed with at least 1 chronic disease participated in the translation validity, and reliability analysis of the study. Cross-culturally adaptation of the ETBQ-T was performed according to Beaton’s guideline. The ETBQ-T, the European Quality of Life 5 Dimensions (EQ-5D), pain, satisfaction, and self-efficacy were applied for convergent validity. The ETBQ-T was retested to examine its reliability after seven days.

Results: The internal consistency and reliability were excellent (Intraclass correlation coefficient= 0.959; Cronbach’s alpha= 0.919) (Table 1). The ETBQ-T had a good correlation with pain (r = 0.564, p <.001), satisfaction (r = 485, p <.001), and self-efficacy (r = 0.582, p <.001). However; The correlation of the ETBQ-T with EQ-5D (r = 0.364, p <.001) was weak. A factor was extracted, accounting for 58.28% of the total variation. There were no floor and ceiling effects.

Conclusion: The ETBQ-T is a reliable and valid tool to evaluate the exercise burden in the Turkish population with chronic disease.

AB1786-HPR ASYNCHRONOUS TELECONSULTATION BY WHATSAPP CHATBOT IN CONTROLLED AXIAL SPONDYLOARTHRITIS (SPA) PATIENTS UNDER BIOLOGICAL THERAPY: CLINICAL RESULTS OF A SINGLE CENTER

Keywords: Spondyloarthritis, bDMARD, Telemedicine

E. Abad Plou1, N. Rivera2, E. Galindez1, E. Cuande1, A. R. Inchaurbe1, J. M. Blanco1, L. Vega1, C. Garcia1, M. Enjuanes1, O. Fernandez2, M. R. Exposito-Moliner1, M. E. Ruiz Luenga1, I. Torrel1, I. Gorostiza Harmoaete1, M. L. Garcia Viva1, Basurto University Hospital, Rheumatology, Bilbo, Spain; Biocruces Bizkaia Health Research Institute, Research Area, Bilbao, Spain; Basurto University Hospital, Research and Innovation unit, Bilbo, Spain

Background: The use of telehealth in the control of rheumatic diseases had been scarce, but COVID pandemic forced to try alternatives to classic face-to-face consultation, and an overflow of telehealth consultations appeared, mainly asynchronous (phone, video calls), and finally asynchronous. We try to demonstrate that asynchronous WhatsApp teleconsultation is a good alternative, at least for followup of patients that find it difficult to attend face-to-face visits. We chose axial spondyloarthritis (AxSpA) patients under biological therapy with controlled disease and we proposed teleconsultation with a WhatsApp platform chatbot created for this purpose. The chatbot sends PROMS (BASDAI, VAS for patient global disease assessment, ASDAs, and 3 questions for extraarticular disease), and receive feedback and schedule for the following visits.

Objectives: To prove that teleconsultation through WhatsApp platform is not inferior to face-to-face consultation in terms of maintaining axial SPA patients disease controlled.

Methods: Prospective study with retrospective control of patients diagnosed of Axial SPA, fulfilling ASAS criteria and with stable disease under biological therapy for the previous year, recruited from 01 jan to 30 nov 2021. We recruited 62 patients, but two of them gave up (personal reasons, one moved to other region), so we finally include 60 patients. We offer them two teleconsultation visits with their personal mobile device, every four months, and a face-to-face final visit one year after inclusion. In the case of lab test or PROMs deviation or when the patient asks for contact (possible via WhatsApp) he/she is called up by the person in charge (nurse/doctor) that solves the question and arranges an additional presentational visit if needed. We consider disease controlled if BASDAI<4, ASDAS=2,1 or if in rheumatologist’s opinion there is no need to change treatment. We collect patient and disease information (age, gender, employment, characteristics of the disease, previous and actual treatment), activity (BASDAI, PCR, ASDAS), physical function (BASFI), and Quality of life (AsQol).

Results: 60 patients (50 men, 83.3% were included, mean aged 48.22 years (SD 12,128), 36% were under 45 years at the time of inclusion. They were mostly Ankylosing Spondylitis (AS) (90%); only 6 non radiographic SPA, positive HLA B27 (85%) and with longstanding disease (mean 23 years, SD 12,8), and only 6 patients less than five years. 25% had peripheral impairment (arthritis/dactylitis/ enthesitis), and more than 40% presented extraarticular manifestations, mainly psoriatis (28.7%) and uveitis (21%)

71.7% were under their first biological (TNF inhibitor, mostly adalimumab), 23.1% were refractory to the first, and 3 patients to at least two biologicals. 51.7% of patients were treated with tapered dose of TNF inhibitors. At inclusion 93.3 %
We did not find meaningful clinical differences between basal to final visits in BASDAI, BASFI, ASDAS-RCP or AstQoL.

3 patients with reduced dose of biological drug needed to increase to standard dose with no other need to treatment adjustment.

Conclusion: We consider asynchronous teleconsultation is promising, and not inferior to face to face consultation in terms of keeping disease control and quality of life, especially for follow-up in patients with stable rheumatic disease. The clinical results presented here are consistent with this considerations.

Figure 1: Results of the PAM-13 tool in expert patients with RA

Conclusion: In general, expert RA patients are proactive with their health and have developed strong self-management skills evaluated through PAM-13. The use of these tools is important to assess the role of the patient in their treatment. This allows generating strategies that increase the commitment of patients during their therapy.

Background: Before COVID pandemic, rheumatologists were not confident with telehealth for the need to acquire new technology, need of specific training and poorer reimbursement [1]. Two groups of rheumatoid arthritis (RA) patients have been identified in a study of PROMS-based telehealth use (2): the keen and the reluctant. We proposed teleconsultation followup with a whatsapp platform chatbot to our axial spondylarthritides (AxSpA) patients with controlled disease and we asked them for preferences at the end of the study.

AB1787-HPR

A REAL-LIFE OF EXPERT PATIENT WITH RHEUMATOID ARTHRITIS. AN EVALUATION OF THE PATIENT ACTIVATION MEASURE PAM-13

Keywords: Rheumatoid arthritis, Patient reported outcomes

F. Rodriguez1, G. S. Rodríguez-Vargas2, A. Rojas-Villarraga3, P. Santos-Moreno3, 1BIO.-Center for Rheumatoid Arthritis, Patients Education, Bogotá, Colombia; 2BIOAMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia; 3Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia.

Background: In 2021, a group of rheumatoid arthritis (RA) patients were certified as an expert patients. These were trained for the care and management of their disease. During their training, they answered the Patient Activation Measure PAM-13 questionnaire, which measures people’s knowledge, skills and confidence in self-managing their health and medical care.

Objectives: The aim of this study is to know the activation and empowerment levels of the patients in their daily life and in their exercise as expert patients in RA, determining the self-management they have of their disease and the perspective they have developed towards their health and towards their health care team.

Methods: A group of expert patients with a diagnosis of RA were included. A sociodemographic characterization was carried out and variables such as age, marital status, educational level and support networks, among others, were measured. Patients filled out the PAM-13 questionnaire. This tool contains some phrases that people use to talk about their health. Each sentence contains response options that include: “strongly agree,” “agree,” “disagree” and “strongly disagree.” This exercise seeks to find out what patients think about aspects related to the care of their health condition and medical care. Descriptive statistics were done and the responses of the first two options were totaled (“strongly agree” and “agree”).

Results: A total of 91 patients were evaluated with the PAM-13 tool. General sociodemographic and clinical characteristics are shown in Table 1. With respect to the responses of the 13 variables of the PAM-13 questionnaire, the patients state (n[%]) that they have developed a high level of awareness in the care management of their disease [83 (91)], they have developed a high therapeutic adherence [83 (91)], understand that lifestyles are essential to avoid complications [83 (91)], adopted an effective and clear communication language with their medical team [82 (90)], developed self-care lifestyles [80 (88)], understand the importance of using prescribed medications [80 (88)], developed habits oriented towards a healthy and active life [78 (85)], understand the nature and symptoms of their disease [78 (85)], are aware that they are the main co-managers of their condition [78 (85)], frequently assist their medical team and use emergency services [79 (87)], act in crisis situations [80 (88)], follow instructions of their medical team [79 (87)], make shared decisions as [73 (80)] and make shared decisions as [65 (71)] (see Figure 1).
Objectives: To explore the degree of acceptance of asynchronous telehealth followup with whatsapp platform chatbot among our controlled AxSpA patients under biological therapy, and to search for a patient profile more prone to telehealth consultation.

Methods: A prospective study with retrospective control was performed, choosing AxSpA patients under biological therapy with stable disease, visited in our centre from 01/01 to 30/11/2021. We recruited 62 patients, but finally include 60 (2 quit for home moving or personal reasons). We offered them two teleconsultation visits (using their personal mobile), every four months, and a presental final visit one year after inclusion. The chatbot sends PROMs (BASDAI, VAS for patient global disease assessment, ASDAS, and 3 questions for extraarticular disease), and feedback and schedule for the following visits. In the case of lab test or PROMs deviation or when the patient asks for contact, he/she is phoned by nurse/doctor who solves the question and/or arranges an additional presental visit. We collect patient and disease characteristics (age, gender, educational level, employment, disease activity, duration and treatments), and patient’s satisfaction and preferences in the final visit.

Results: We included 60 patients (83.3% men), mean aged 48.22 years (SD 12.128), 36% under 45 years at inclusion. 27% had received primary, 33.9% secondary and 39% tertiary education. 83.3% were active working and only 10 patients were jobless or retired. They were Arthritis Spondylothritis (AS) (90%), HLA B27 positive (85%) with longstanding disease (mean 23 years, SD 12.8), and were receiving the first (71%), or the second (23%) biological therapy (51.7% tapered anti-TNF). 50% were never smokers and 70% presented no remarkable comorbidity; 25% presented peripheral impairment, and over 40% extraarticular manifestations. At inclusion 93.3% were at remission/LDA by ASDAS/BASDAI-RCP and 4 patients were considered clinically controlled in spite of higher scores. At followup 3 patients received reduced dose needed to increase to standard dose of biological drug, with no other need of treatment change. There was no worsening from basal to final visits according BASDAI, BASFI, ASDAS-RCP or AsQOL. Patients final VAS score (1-10) assessment of telehealth consultation was very high: mean 9.14 (SD 1.498); 91.7% ≥ 8 and 76.7% ≥ 9. 83.3% preferred telehealth followup. There was a trend towards telehealth preferences in higher educational levels, and active working (86% vs 70%) but not statistically significant. We found no correlation with gender, age and disease characteristics tested.

Conclusion: Asynchronous teleconsultation seems promising, not inferior to presental consultation and preferred for follow-up by our AxSpA patients with stable disease with biological drugs. We met some ‘reluctant patients’ that were more inactive working and with lower educational levels, but the differences were not significant. Further research is needed with this teleheathl model in other age and disease populations (RA), in order to characterize the reluctant and keen patients.

AB1789-HPRI

30 SECONDS CHAIR STAND TEST - FEASIBLE AS SELF-ASSESSMENT TEST FOR KNEE OSTEOARTHRITIS?

Keywords: Self-management, Diagnostic Tests, Outcome measures

C. M. Ho-Henriksson1,2, C. A. Thorstensson1,3, L. Nordeman1,4. 1Institute of Neuroscience and Physiology, Sahlgrenska Academy, Gothenburg University, Health and Rehabilitation, Göteborg, Sweden; 2Region Västra Götaland, Primary Care Rehabilitation, Närhälsan Lidköping Rehabilitation Centre, Lidköping, Sweden; 3Region Halland, Research and Development Department, Halmstad, Sweden; 4Region Västra Götaland, Research, Education, Development and Innovation Centre Södra Älvborg, Borås, Sweden

Background: A reliable self-assessment test to evaluate physical performance could be useful for patients with knee osteoarthritis to monitor physical function over time. However, studies comparing a self-assessment test with standardized testing in the clinic supervised by a physiotherapist is lacking. The 30 seconds chair stand test is part of a test battery which is recommended both in research and in clinical settings for patients with osteoarthritis [1]. The chair stand test is a reliable physical performance test for patients with knee osteoarthritis [2, 3].

Objectives: The purpose is to evaluate the 30 seconds chair stand test as self-assessment test for patients with knee osteoarthritis and when it is supervised by a physiotherapist.

Methods: A sample size of 147 patients with knee osteoarthritis will be recruited. Each patient will perform two self-assessment tests with two days in between. Another test supervised by physiotherapist will be conducted within a week after the second self-test. Demographic data, knee-related quality of life using knee injury and osteoarthritis score – short version (KOOS-PS) [3], pain duration, pain intensity using numeric rating scale (NRS) 0-10 [4], pain sites, experienced intermittent and constant knee pain (ICOAP) [5], will be collected. Data collection is ongoing and preliminary data will be presented descriptively.

Results: So far, 91 patients have been recruited, whereas 60 patients (58% females) with a mean age of 69 years, and mean body mass index of 30 (SD 9) have been included in the preliminary analysis. Patients reported mean pain duration of 46 months (SD 52), rating mean pain intensity 3/10 (SD 2), and 83% had pain in more than one joint. Patients reported mild to moderate pain (total mean ICOAP-score 44/100, SD 21). KOOS-PS score was 60/100 (SD 14) showing moderate difficulties in knee-related daily activities. Mean number of chair stands for self-assessment tests 1 and 2 were 13.7 (SD 5.6) and 14.7 (SD 6.0) respectively and mean number supervised by physiotherapists were 13.3 (SD 4.8).

Conclusion: Preliminary results of this study indicate that 30 seconds chair stand test as self-assessment test might be an option for patients with knee osteoarthritis to monitor their own physical performance. Yet, to ensure the agreement between self-assessment and physiotherapist assessment, a reliability study is needed.

AB1790-HPR COVID-19: AFTER TWO YEARS OF IATROGENIC AND BIOLOGIC IMMUNIZATION/VACCINATION DO WE ACTUALLY NEED FURTHER BOOSTER IMMUNIZATION/VACCINATION?

Keywords: COVID, Vaccination/Immunization, Epidemiology
C. Pohl1. 1Internistisch-Rheumatologische Hausarztpraxis, Dr. Med. Christoph Pohl, Berlin, Germany

Background: The Covid19 pandemic started in late 2019 and went through different phases by spreading from China around the whole globe. During the pandemic different mutation types got predominant from original Wuhan type through Alpha, Delta and Omicron variate BA 1/2 to BA 4/5 with different infectiosity and different potential to harm people’s health status. Immunization/vaccination program started late 2020, first booster phase started midst of 2021, second booster phase in late 2021/ beginning of 2022 and Omicron specific booster phase midst of 2022.

Objectives: Is there a need of further iatrogenic (booster) immunization/vaccination after 2 years of immunization/vaccination program from efficacy driven analysis and safety issues standpoint?

Methods: Analysis of Covid-19 antibody development every three months since August 2021 with comparison of infection rates and safety assessment of persons by assessing D-Dimers as potential endothelium damage marker in 725 patients (600 female, 125 male, age mean: 62.2 years) of a German rheumatological practice to improve the medical care.

Results: In 99 % of the patients longstanding immune memory could be shown by analyzing the antibody curves in different exemplary shown biologic and iatrogenic immunization pathways after 2 years of immunization/vaccination program and biologic immunization, mainly by Delta variate since late 2021 and Omicron variate since beginning of 2022. In 36.5 % of the patients the safety concerns of potential endothelium damage by analyzing D-Dimers every 3 months showed a side effect potential of at least 8 months after every MRNA/Vector immunization, but not after protein based vaccination and even not after infections in that amount.

Conclusion: Out of the obligation "nil nocere" no further iatrogenic Covid-19 immunization/vaccination is of need in nearly all (99 %) already immunized people. At present only adult people with very low antibody levels (at least below 64 BAU/ml) (considering the infection or iatrogenic immunization/vaccination status and time since last spike protein contact) and not yet immunized adult people should be forseen for iatrogenic immunization/vaccination with protein based or attenuated viral vaccines or in rare cases one Omicron specific MRNA immunization drug. In that case D-Dimer controls for up to 8 months should be obligatory to detect endothelial damage side effect of MRNA (or Vector) technique. Intense cardiovascular monitoring (small vessels) of MRNA/Vector immunized people in the next 10 – 20 years is necessary.

AB1791-HPR EVALUATION OF DIAGNOSTIC AND THERAPEUTIC DELAY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

Keywords: Education, Inflammatory arthritides, Health Services Research
M. Iacoantinuo1, S. Ferraigo1, P. Conigliano1, P. Triggianese1, A. D’Antonio1, F. R. Spinelli1, A. Bergamini1, M. S. Chimenti1. 1University of Rome Tor Vergata. Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, Rome, Italy; 2Sapienza University of Rome, Rheumatology Unit, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy

Background: Inflammatory arthritis, such as Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA), are diseases that require timely therapeutic intervention to reduce or stop the progression of joint damage and diseases flares. Early diagnosis and rapid accessibility to care lead to a better patient management.

Objectives: We conducted a monocentric study in a cohort of patients affected by RA or PsA to assess factors related to diagnostic delay and accessibility to treatments, in order to improve patients management.

Methods: Between June and September 2022, clinical and serological characteristics, time (months-years) between symptoms onset and the diagnosis and the initiation on csDMARDs/ts/bDMARDs therapy, of RA patients - according to EULAR/ACR 2010 criteria - and PsA patients - according to CASPAR criteria - were collected. In addition we evaluated place of residence (small/big city >200,000), who made referral to the rheumatologist center, physician who made the diagnosis (rheumatologist/other specialist/family doctor), possible wrong diagnosis previously made. Statistical analysis was conducted using Student Ttest/ Mann-Whitney U Test/one-way ANOVA when appropriate, via GraphPad Prism version 8.0.2. P values <0.05 were considered significant.

Results: 100 RA patients and 100 PsA patients were included (table I). Statistical significant differences were observed concerning: diagnostic delay (PsA patients 5.2±7.6 yrs vs versus RA patients 2.5±4.6 yrs, p=0.003), time passed between symptoms onset and initiation of csDMARDs therapy (PsA 5.3±7.6 yrs vs RA 2.7±5.1, p=0.006), and between diagnosis and initiation of ts/bDMARDs therapy (PsA 3.5±5.5 vs RA 7.1±6.8, p=0.0007). In the two groups: - in the residents of small and medium sized cities compared to the big cities residents, in the diagnostic delay (6.1±10.2 vs 2±1.8, p=0.02) in the time between symptoms onset and the start of first line therapy with csDMARDs (6.4±10.7 years vs 2.3±1.9 years, p=0.02). - In patients who have been diagnosed by another physician rather than rheumatologist, in the diagnostic delay (4.7±11.1 vs 3.9±6.2, p=0.034) and in the start of line therapy (4.7±11 vs 4.2±8.7, p=0.019) in RA: - In the group of patients who had a previous diagnosis - mostly osteoarthritis (35.5%) and UCTD (16.1%) - in diagnostic delay (3.7±6.7 vs 1.9±3.1, p=0.03) and in the time between symptoms onset and initiation of a csDMARD (4.6±8.8 vs 2.1±4.1, p=0.05). In seronegative RA: - Delay in diagnosis (4.2±4.7 vs 1.8±4.6, p=0.02) and starting of line therapy (4.5±5.3 vs 2±5.1, p=0.03) and II-line therapy from symptoms onset (11.6±8.6 yrs vs 7.9±7.8 years, p=0.04) compared with the seronegative ones. In PsA: - In patients with previous diagnosis - mostly osteoarthritis (34.1%) and fibromyalgia (19.1%) - in the diagnostic delay (8.1±10 vs 3±4.1, p=0.003), in the time passed between symptoms onset and initiation of csDMARDs (8.1±10 vs 3±4.2, p=0.001) and ts/bDMARDs therapy (12±11.1 vs 6±6.5, p=0.0004).

Conclusion: Diagnostic delay is greater in PsA than in RA, in both groups of patients living in small medium cities and in those who have been diagnosed by another specialist. Major diagnostic delay is present in both groups of patients who...

AB1794-HPR SPONDYLOARTHRITIS: IS THERE A GENDER DIFFERENCE?

Keywords: Gender differences, Spondyloarthritis.

S. Milladi1, O. Hamdi1, F. Alaia1, H. Boussaa1, Y. Makhlof1, L. Souabni1, K. Ouenniche1, S. Kassab1, S. Chekili1, K. Ben Abdelghani1, A. Laatar1.

Mongi Slim hospital, Rheumatology, Tunisia, Tunisia

BACKGROUND: Spondyloarthritis (SpA) affects men more frequently than women.

Few studies have analysed gender differences in clinical and biological characteristics of SpA, hence the purpose of this study.

OBJECTIVES: We aimed to analyse gender differences in SpA manifestations and disease activity.

METHODS: We conducted a cross-sectional study including 30 men and 30 women with SpA meeting the 2009 ASAS criteria. The comparison between men and women included the following data: age at onset, disease duration, clinical and biological characteristics, activity scores (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS)), and functional impact (Bath Ankylosing Spondylitis Functional Index (BASFI)).

RESULTS: Compared to women, male patients had a younger age at disease onset (M= 24.7 ±7.7 vs F= 19.9 ±7.1; p=0.00), a longer disease duration (M= 14.3 ±6.1 vs F= 11.9 ±4.2; p=0.05), a longer morning stiffness (p=0.01) and a greater number of nocturnal awakenings (p=0.01). Similarly, SpA was more active in male patients compared to female patients: CRP (M= 22.5 ±3.5 vs F= 14 ±2; p=0.00) and ASDAS (M= 3.7 ±0.7 vs F= 2.9 ±2.0; p=0.01). Coxitis was more common among male patients: M= 28.3% vs F= 13.3%; p=0.00. No gender differences were observed for VS, BASDAI, BASFI and therapeutic strategy. Comorbidities were predominant in male patients: cardiovascular disease (M= 18.3% vs F= 8.3%; p=0.00), osteoporosis (M= 16% vs F= 13.3%; p=0.05), hypertension (M= 15% vs F= 6.6%; p=0.01) and dyslipidemia (M= 11.6% vs F= 6.6%; p=0.01). However, depression was more common among female patients (p=0.01).

CONCLUSION: Our study showed that SpA was more active in male patients. Comorbidities were more common among men compared to women. Further studies should be conducted to better illuminate gender differences in SpA.

AB1795-HPR COXITIS IN RHEUMATOID ARTHRITIS: IS THERE ANY CORRELATION BETWEEN CATASTROPHIZING AND FUNCTIONAL DISABILITY?

Keywords: Rheumatoid arthritis.

O. Hamdi1, H. Boussaa1, S. Milladi1, B. A. Hiba1, L. Souabni1, K. Ouenniche1, S. Kassab1, S. Chekili1, K. Ben Abdelghani1, F. Alaia1, A. Laatar1, Mongi Slim hospital, Rheumatology, Tunisia, Tunisia

BACKGROUND: Coxitis is more common in RA than in the general population.

METHODS: Coxitis was diagnosed in 28 patients (56%) in our RA population with a mean age of 66±10 years. Coxitis was defined according to the ACR criteria.

RESULTS: Coxitis was more common among male patients: M= 28.3% vs F= 13.3%; p=0.01. Coxitis was associated with concomitant arthritis in 81.8% of cases among male patients vs 31.2% among female patients (p=0.05).

CONCLUSION: Coxitis might be associated with more disease activity and severity in RA patients. Further studies are needed to confirm these results.

REFERENCES: NIL.
Background: Coxitis is a marker of severity in rheumatoid arthritis (RA) since it is associated with a functional disability. Therefore, it leads to a loss of autonomy with a significant psychological impact.

Methods: We conducted a cross-sectional study including patients with RA (2010 ACR/EULAR criteria). Clinical, biological and radiological data were collected. RA activity was assessed using the Disease Activity Score (DAS28 ESR). The quality of life was assessed using the Health Assessment Questionnaire (HAQ). Hip function was assessed using the Lequesne algofunctional index (IAF). Catastrophizing was evaluated by the Pain Catastrophizing Scale (PCS), which is composed of 13 items. PCS total score varies from 0 (no catastrophizing) to 52 (significant tendency to catastrophizing). The correlation between Lequesne IAF and PCS was evaluated using the Spearman test.

Results: We included 80 patients (76 women and 4 men) with an average age of 47 ± 12.9 years. The average age at diagnosis was 29.7±7.3 years. The mean disease duration was 11.6±2 years. RA was erosive in 90% of cases. Rheumatoid factor and anti-citrullinated peptides antibodies were positive in 83% and 85% of cases, respectively. Seventy-five percent of patients were on corticosteroids with an average dose of 10 mg per day of Prednisone equivalent. All patients were on DMARDs: methotrexate (85%), leflunomide (11.2%), and bDMARDs (37.5%). The mean pain Visual Analog Scale was 5.5 cm. The mean overall patient assessment was 4 cm. The mean number of nocturnal awakenings was 1.5. The mean duration of morning stiffness was 45±7.5 minutes. The mean ESR was 29.4±6. The mean CRP was 19.5±4.4. The mean DAS28 ESR was 5.4±2.2. The mean HAQ was 1.2±0.4. The mean PCS was 34.3. Coxitis was noted in 28.7% of patients. It was involuntary in 52% of cases and bilateral in 14 cases. The mean coxitis duration was 6.8 years. The mean Lequesne IAF was 10.5±3.2. A statistically significant correlation was noted between Lequesne IAF and PCS (r=0.41; p<0.01).

Conclusion: Our study showed that functional disability associated with rheumatoid coxitis was moderately correlated with catastrophizing. Comprehensive management, taking into account the cognitive behavioural sphere, is thus recommended in RA patients with coxitis.

was one of the questions in the interview, where the patients themselves elaborated on their answers.

**Results:** Of the included six SSc patients with PAH, 4 (67%) were female and 2 (33%) men with mean disease duration of 5 years since PAH diagnosis (Table 1). NYHA functional class varied from 1 (mild) to 4 (severe) with a median of 3. Patients reported fatigue (VAS) was the most prominent symptom (Figure 1), confirmed by the results from the interviews. This also lead to physical and psychological challenges in everyday life, and reduced HrQoL. The patients’ were mostly satisfied with the nurses, but felt some nurses had not the time when the patients needed it the most. The patients also highlighted that they felt that some of the nurses did not have enough knowledge about the diagnosis. This led to patients’ repetition and explanation why their oxygen level was reduced, why they had heavy breathing or why it was not possible to measure pulse or oxygen level on the fingers, due to reduces peripheral circulation. The patients’ wish was also to be seen and understood by their caregivers and friends.

**Conclusion:** Our study revealed that fatigue was the main symptom causing reduced HrQoL. Moreover, we show the importance of educated expert nurses in the management of PAH in SSc and the inclusion of information to caregivers, patients and next of kin. Nurse’s awareness about the symptom burden and unmet needs of patients with SSc-PAH is important to give the best possible patient care.

F: female; M: male; SSc: systemic sclerosis; PAH: pulmonary arterial hypertension; ERA: endothelin receptor antagonist; PDE5: Phosphodiesterase 5 inhibitor; PGi2: Prostacyclin pathway agonist; RHC: right heart catheterization at the time of PH diagnosis; mPAP: mean pulmonary arterial pressure; NYHA: New York Heart Association.

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease mediated by autantibodies, with involvement of various organs[1,2]. El 95% of patients with SLE have musculoskeletal involvement[1], most often in the form of arthralgias or non-erosive arthritis affecting mainly the hands and knees. Although the feet are equally affected and can result in significant disability, they have been little studied.

**Objectives:** To determine changes in foot involvement in patients with SLE after 12 months of follow-up.

**Methods:** Longitudinal case series. Thirty-six subjects with a diagnosis of SLE were consecutively recruited in the Rheumatology Unit between March and June 2021 and followed up at 12 months. Inclusion criteria were: patients with a diagnosis of SLE according to EULAR/ACR 2019 criteria, with at least one year of evolution and age equal to or older than 18 years. A Rheumatology nurse collected information on socio-demographic data and the questionnaires at baseline and at 12 months. The questionnaires were: SLEDAI (Systemic Lupus Erythematosus Activity Index) and SLICC (Darnage Index for Systemic Lupus Erythematosus), quality of life: EQ-5D, foot function: FPI (Foot Function Index), FAAM (Foot and Ankle Ability Measure Questionnaire), FAAM-Sport, FPI (Foot Posture Index). A descriptive analysis of the main variables, and a paired t-test or Wilcoxon t-test, as appropriate, were performed between the baseline and 12-month follow-up visits.

**Results:** Thirty-six patients with SLE (97.2% women) with a mean (SD) age of 49.9±11.4 years with a range 23-66 years participated. Regarding treatment a total of 22/36 patients (66.2%) had immunosuppressive treatment, 4/36 (11.1%) biological therapy and 26/36 (72.2%) hydroxychloroquine treatment. After 12 months of follow-up, the disease remained stable and there were no significant differences in the SLICC and SLEDAI indices of SLE. There were also no significant differences in the different foot questionnaires administered: FAAM, FAAM-Sport, FPI, FFI after 12 months of evolution. There was only a worsening in VAS EQ5D (p=0.028) although there was no significant change in EQ5D (p=0.773) (Table 1).

**Conclusion:** In SLE patients with stable disease over one year of follow-up, assessments of foot function and ability remain unchanged. It is important to integrate foot assessment into the joint evaluation because of the high impact on the patient’s quality of life and patient functionality.

**Background:** Systemic lupus erythematosus (SLE) is a chronic, autoimmune, inflammatory rheumatic disease that causes tissue damage through autoantibodies and immune complexes. Patients with chronic diseases such as SLE fall into a vicious circle. Fatigue and depression can negatively affect the quality of life and cause patients to stay at home and hence, be physically inactive. As a result of physical inactivity; the exercise capacity and muscle strength of SLE patients can decrease.

Objectives: The aim of this study is to investigate the physical activity, peripheral muscle strength, exercise capacity, sleep, fatigue, anxiety, and depression levels between patients with SLE and healthy individuals.

Methods: We recruited 100 patients with SLE (mean age: 39.3 years ± 12.9, 59% women) and 29 healthy individuals (20 (23/32) years) were compared. Exercise capacity (6-minute walk test (6MWT)), peripheral muscle strength (dynamometer), physical activity (the Xiaomi Mi Band 4 smart bracelet device), fatigue (Fatigue Severity Scale (FSS)), anxiety and depression (Hospital Anxiety Depression scale (HADS)), quality of life (SLE-specific QoL scale (SLEQoL)), and sleep (Pittsburgh Sleep Quality Index (PSQI)) were assessed.

Results: Demographic characteristics were similar in both groups except for cigarette consumption (pack-years) (p = 0.05). 6MWT distance, peripheral muscle strength, physical activity level, SLEQoL, and PSQI scores were significantly lower; FSS and HAD scores were higher in patients with SLE (p < 0.05). Moreover, the difference between post and pretest values of heart rate, dyspnea, fatigue, and quadriceps femoris muscle fatigue was higher in patients with SLE compared to healthy individuals.

Conclusion: Patients with SLE had lower exercise capacity, muscle strength, quality of life, and sleep quality, and higher fatigue, anxiety, and depression. In addition, these patients were physically inactive. Further studies are needed to investigate the effects and efficiency of these symptoms on patients with SLE.

AB1800-HPR EVALUATION OF KNOWLEDGE AND PRACTICES OF PATIENTS WITH SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Patient information and education, Best practices

S. Farh1, T. Latte1, R. Honsali1, H. Rikain2,1, Bensaghir2, C. Charouz2, B. Amine1, R. Bahr1, S. Ehlai1, R. Razine1, S. Nouri1, F. Korabi1, S. Ez-Zaoui1, F. El Joum1, S. Bahloul1, N. Alami1, F. Allali1, Al Ayachi Hospital, Rheumatology B, Sale, Morocco; 1Exeic Physology and Autonomous and Nervous System Team, Physiology Laboratory, Rabat, Morocco; 2Al Ayachi Hospital, Rheumatology A, Sale, Morocco; 1Faculty of Medicine and Pharmacy of Rabat, Department of Public Health, Rabat, Morocco

Background: Spondyloarthritis is a chronic inflammatory rheumatic disease mostly affecting young adults, causing functional disability and impaired quality of life. Thus, patient education is a major component to improve their knowledge of the disease, therapeutic compliance and quality of life.

Objectives: The aim of this study is to evaluate the knowledge and practices of patients with spondyloarthritis and determine the factors associated with them.

Methods: This is an observational, descriptive, analytical and monocentric study, in patients followed up at Al Ayachi University Hospital in the Rabat-Sale region of Morocco. The study duration was from the beginning of May 2022 to the beginning of July 2022. The consent of the study population was free and informed. A team of rheumatologists, which includs socio-demographic information, prior knowledge and practices of patients with spondyloarthritis. We calculated a score of correct answers ranging between 0 and 10 for each patient.

Results: We recruited 100 patients with a mean age of 39.3 years ± 12.9, 59% were men and 17% were illiterate. 85% of the population came from an urban environment, and 79% were unemployed. 68% of the patients suffered from ankylosing spondylitis, 17% had psoriatic arthritis, 13% were affected by inflammatory bowel disease associated arthropathy and 2% had juvenile spondyloarthritis. 31% of patients considered that the disease can affect young adults, wherein 43% reported a male predominance. 47% reported that the cause of the disease is genetic, 34% declared that it is related to immunity whereas entheseus affection was known by 52% of patients. 81% find that therapeutic management helps prevent deformities and 97% see that it improves the quality of life. Furthermore, only 4% of patients knew that NSAIDs are a disease-modifying treatment and 7% were aware that pneumopathy could be a potential complication of Methotrexate. 73% of patients knew what a biologic drugs is, when biosimilar was only known by 10% of them, yet 45% knew that tuberculosis is one of the infections that can occur under biologic drugs. This study revealed that 63% of patients had a total score of correct answers superior to 5 (for a max score of 10) and 37% had a total score between 0-5.

Conclusion: Although this study showed decent knowledge and good practices among the Moroccan patients with spondyloarthritis. The doctor-patient contact and the multimedia information as well as patients' associations remain as useful means to improve this knowledge.

AB1802-HPR PAIN IN AXIAL SPONDYLOARTHRITIS MAY NOT BE ALWAYS INFLAMMATORY

Keywords: Pain, Spondyloarthritis, Inflammatory arthritides

I. Kurut Aysin1, G. Alp1, E. Durak Ediboglu2, E. Otman Akad1, H. Canikli1, E. Erpek1, A. Ozkan1, H. Kocayaan1, D. Solmaz2, S. Aser1, Izmir Katip Celebi University Ataturk Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey

Background: Many patients with axial spondyloarthritis (axSpA) report persistent pain even when treated with anti-inflammatory agents. Therefore, it can be hypothesized that this persistent pain may not be entirely of inflammatory origin and additional pain mechanisms may play a role (1).

Objectives: To evaluate the frequency of central sensitization (CS) and neurogenic pain (NP) in patients with axial spondyloarthritis (axSpA) and its relationship with disease activity and functional status.

Methods: Patients classified as axSpA according to ASAS 2009 criteria were included in this cross-sectional study. Presence of CS was evaluated with the CS inventory (CSI; a 25-item questionnaire that a score of ≥40 point scored out of 100 is positive for CS. Presence of depression and anxiety were evaluated with Hospital Anxiety and Depression questionnaire (HADS), and fibromyalgia syndrome (FMS) by ACR 2016 criteria. Neuropathic pain (NP) was assessed with DN4 (Doulou Neuropathique en 4 questions) questionnaire. In addition, the patients’ BASDAI, ASDAS-CRP, BASFI, ASQol, ASAS-HI/environmental scores were also calculated.

Results: 121 axSpA patients[102 (84.3%)] radiographic axSpA, 74 (62.1%) male, mean age: 43.9 ± 10.6 years] were included in the study. Of our patients 84% were receiving biological therapy. Other characteristics of the patients are summarized in Table 1. CS was detected in 35 (26.9%), NP in 12 (10.1%) and FMS in 9 (7.7%) patients. Age and advanced treatment usage rates were similar between the groups. Among patients with CS the percentage of female was higher, there was no sex difference for patients with NP and FMS. Duration of the disease was shorter in the CS group. Patients and physician global assessment of disease activity (PGA and PhGA respectively), BASDAI, Leeds enthesis index (LEI), ASQol, ASAS-HI were found to be significantly higher in patients with CS and NP. In addition, BASFI and ASAS-HI environmental scores were worse in those with CS. While anxiety was higher in those patients with CS and NP according to the HADS questionnaire, the rates of depression were similar. Six (17.1%) patients with CS also had NP and 6 (50%) patients with NP had also CS. While 9 patients with FMS had CS, only 2 had NP CS severity and disease activity and quality of life scores showed a strong positive correlation (Figure 1).

Conclusion: Approximately one-third of axSpA patients, most of which received advanced therapy, have CS and ≥10 of them have NP. Both quality of life and activity measures were found to be higher in patients who have CS. Therefore it should be kept in mind in axSpA patients pain may not be always due to inflammatory origin of the disease, but may be due to non-inflammatiory causes of pain.

The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) values were used to assess functional and daily living activities. The Hospital Anxiety and Depression Scale (HADS) was used to assess anxiety and depression levels.

**Results:** The mean age of the patients was 39.99 ± 10.0 years. The mean BASDAI scores indicated active disease and were 5.98 ± 1.78. There was a statistically significant moderate correlation between the BETY and the anxiety and depression subscales of HADS and BASDAI, in the positive direction (n=0.692, p<0.001 and n=0.685, p<0.001 and n=0.592, p<0.001). A statistically significant, strong correlation was found between the BETY, HAQ and BASFI scores in the positive direction (n=0.834, p<0.001 and r=0.747, p<0.001) (Table 1). It was observed that patients showed anxiety and depression characteristics according to HADS cut-off values (>10 and >7).

**Conclusion:** It was concluded that the biopsychosocial status of anti-TNF naive patients with AS was affected by anxiety-depression levels, functionality, and disease activity score. In addition to anti-TNF therapy, it was interpreted that the treatment of biopsychosocial characteristics of patients should also be taken into consideration in disease management.

**Keywords:** Spondyloarthritis, Patient reported outcomes, Cognitive Function

**Background:** Ankylosing spondylitis (AS) is a rheumatic disease that affects patients in a biopsychosocial framework due to its chronic inflammatory nature. It is known that anti-TNF therapy is given to patients with persistently high disease activity despite conventional treatments according to the ASAS recommendations [1].

**Objectives:** The aim of this study was to examine the factors associated with the biopsychosocial status of patients with AS who were decided to be treated with anti-TNF therapy for the first time.

**Methods:** 76 AS patients who were decided to treated with anti-TNF therapy included in the study. Socio-demographic informations of patients were collected. The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) values were recorded for disease activity levels. Biopsychosocial status of the patients was evaluated by the BETY-Biopsychosocial Questionnaire (BETY-BQ). The Bath Ankylosing Spondylitis Functional Index (BASFI) and Health Assessment Questionnaire (HAQ) were used to assess functional and daily living activities. The Hospital Anxiety and Depression Scale (HADS) was used to assess anxiety and depression levels.

**Results:**

- The mean age of the patients was 39.99 ± 10.0 years. The mean BASDAI scores indicated active disease and were 5.98 ± 1.78.
- There was a statistically significant moderate correlation between the BETY and the anxiety and depression subscales of HADS and BASDAI, in the positive direction (n=0.692, p<0.001 and n=0.685, p<0.001 and n=0.592, p<0.001).
- A statistically significant, strong correlation was found between the BETY, HAQ and BASFI scores in the positive direction (n=0.834, p<0.001 and r=0.747, p<0.001).
- It was observed that patients showed anxiety and depression characteristics according to HADS cut-off values (>10 and >7).

**Conclusion:** It was concluded that the biopsychosocial status of anti-TNF naive patients with AS was affected by anxiety-depression levels, functionality, and disease activity score. In addition to anti-TNF therapy, it was interpreted that the treatment of biopsychosocial characteristics of patients should also be taken into consideration in disease management.

**Keywords:** Safety

**Background:** Janus kinase inhibitors drugs (JAKI) are novel small molecule medications known to cause abnormalities such as elevations in hepatic transaminases, decreases in neutrophil and lymphocyte counts and elevations in cholesterol and creatinine kinase. Blood monitoring is recommended and dose adjustments are advised if abnormalities arise. Recent warnings by the EMA and MHRA have highlighted the importance of monitoring these medications. Timely review and management of patients on JAKI drugs is difficult to maintain with increasing workload amongst the rheumatology team. A baseline audit (2020) demonstrated that hospital blood monitoring guidelines for JAKI drugs were not being followed. The rheumatology multidisciplinary team met and utilised Quality Improvement methodology including fish and driver diagrams to address this. This led to the creation of a pharmacist-led JAKI blood monitoring clinic.

**AB1804-HPR** IMPROVING PATIENT SAFETY THROUGH THE ESTABLISHMENT OF A PHARMACIST-LED BLOOD MONITORING CLINIC FOR JAK INHIBITORS IN RHEUMATOLOGY

**Keywords:** Safety

**Background:** Janus kinase inhibitors drugs (JAKI) are novel small molecule medications known to cause abnormalities such as elevations in hepatic transaminases, decreases in neutrophil and lymphocyte counts and elevations in cholesterol and creatinine kinase. Blood monitoring is recommended and dose adjustments are advised if abnormalities arise. Recent warnings by the EMA and MHRA have highlighted the importance of monitoring these medications. Timely review and management of patients on JAKI drugs is difficult to maintain with increasing workload amongst the rheumatology team. A baseline audit (2020) demonstrated that hospital blood monitoring guidelines for JAKI drugs were not being followed. The rheumatology multidisciplinary team met and utilised Quality Improvement methodology including fish and driver diagrams to address this. This led to the creation of a pharmacist-led JAKI blood monitoring clinic.
Objectives: To establish a pharmacist-led rheumatology blood monitoring clinic for the JAKi drug class in order to: increase patient safety with increased compliance to blood monitoring, save consultant/nurse time, improve communication with primary care on the frequency of blood testing required, increase patient understanding of the importance of blood monitoring with JAKi drugs, reinforce counselling advice such as risk of infections, shingles and thrombosis and promote medication adherence.

Methods: The clinic was established in March 2021. Patients commencing JAKi drugs are referred to the pharmacist-led clinic by the medical team. The pharmacist contacts the patient by phone following delivery of their medication. The patient is counselled on their new medication and dates for blood checks are agreed. A letter is sent to the patient and their GP providing this information. The patient is booked into virtual telephone appointments and bloods are monitored every month for the first 3 months and every 3 months thereafter. Any change or abnormality in blood results are flagged early in the patient’s treatment and if necessary, discussed with the consultant. Adjustments are made to the patient’s dose if appropriate.

Results: In order to evaluate the benefit of the pharmacist clinic a re-audit of compliance with blood monitoring (March 2021- September 2022) was carried out alongside a patient satisfaction postal survey (August 2022). A total of 58 patients were sampled in the re-audit. The re-audit found an increase in compliance in blood monitoring since the introduction of the pharmacist clinic. 96% of patients had their full blood count performed at 3 months compared to 56% in audit 1 and 95% of patients had their lipid profile completed at 3 months compared to 15% in audit 1 (Table 1). A patient satisfaction survey (N=62; response rate 48%) found that 28 (93%) patients either agreed or strongly agreed that they were more aware of the importance of attending for regular blood monitoring when prescribed JAKi therapy as a result of the clinic. The pharmacy team made several significant interventions (self-graded Eadon grade 4 and 5). For example by improving medication adherence, detecting haematological abnormalities that required JAKi dose reduction, identifying patients suffering from infection requiring intervention including shingles and Covid-19.

Table 1. Comparison of audit results pre (Audit 1) and post (Audit 2) clinic establishment

<table>

Conclusion: Introduction of the pharmacist-led clinic has increased patient safety by ensuring compliance with blood monitoring as per hospital guidelines. The clinic has paved the way for improved communication with primary care teams and has provided patients with extra support during their first months on treatment with the JAKi. It has also expanded the role of the rheumatology pharmacy team and saved nursing and medical time.

SERVICE EVALUATION OF COMBINED RHEUMATOLOGY OBSTETRIC CLINIC, SOUTH TEES NHS FOUNDATION TRUST, UNITED KINGDOM

Keywords: Pregnancy and reproduction, Patient information and education, Quality of care

F.A. Khan, J. Janakiraman, M. Shivanath, R. Gul, S. Chin, E. Steele, D. Kong, The James Cook University Hospital, Rheumatology, Middlesbrough, United Kingdom; Newcastle University, Undergraduate Department, Newcastle, United Kingdom; The James Cook University Hospital, Obstetrics and Gynaecology, Middlesbrough, United Kingdom

Background: Multidisciplinary management in a combined clinic improves patient experience and outcomes for pregnant women with inflammatory rheumatic diseases (IRD). Achieving better IRD control pre, during, and post-pregnancy with pregnancy-compatible disease-modifying anti-rheumatic therapies (DMARDs) reduces maternal and foetal mortality/morbidity minimising complications. EULAR published recommendations for core data sets around maternal, pregnancy, and treatment information for pregnancy registries in Inflammatory rheumatic diseases.

Objectives: Service evaluation of the Combined Rheumatology Obstetrics clinic held in our hospital to evaluate pregnant patients with inflammatory rheumatoid diseases against the EULAR recommendations.

To improve Patient and disease outcome in terms of maternal health and fetal health.

Methods: Retrospective data was collected on interventions and outcomes of pregnancies in 40 women with inflammatory rheumatic diseases seen in the Combined Rheumatology/Obstetric Clinic from November 2020 to February 2022 reviewing clinic letters and medical notes.

Results: 77% of patients had inflammatory arthritis including rheumatoid, psoriatic, juvenile idiopathic, and axial spondylo-arthritis. 15% had connective tissue disease (CTD) including Lupus with anti-phospholipid syndrome, Bechet’s and undifferentiated CTD. 2% patients did not have a formal IRD diagnosis. 12.5% of patients had only pre-pregnancy counselling, 2.5% had miscarriages. Of the remaining 85% of pregnant patients’ 10% had obstetric care/ delivery in other trusts. Treatment received by patients 12 months prior to conception included DMARDs (37%), biologics (24%), combination (8%), and steroids (10%). 25% were on no treatment. During pregnancy 29% received oral DMARDs, 11% biologics and 16% needed steroids. 50% of patients did not require any treatment. Interventions done in the clinic included medication review (100%), VTE assessments (100%), commenced VTE prophylaxis (75%), change in DMARD dosage (10%), additional medication added (10%), intramuscular/ intra-articular steroid injections (16%) and physiotherapy referrals (10%). Maternal adverse outcomes include 5% preeclampsia, 0.07% gestational diabetes and 0.02% pregnancy-induced hypertension and foetal growth restriction. 93.3% were full-term deliveries. Only 10% had adverse neonatal outcomes including 6.6% preterm births. None had congenital heart block. 3.3% had congenital malformations unrelated to IRD. IRD/DMARD therapy. Patient satisfaction surveys were sent out to 40 patients with a 30% response rate. The patient satisfaction questionnaire revealed all patients had their consultation with rheumatology and obstetric consultants with 100% satisfaction. 100% felt the staff was supportive and they would recommend our service to friends and family. 66.7% of patients receiving pre-pregnancy counselling, 50% were in the combined clinic. Of the 33.3% of patients not receiving counselling 22.2% felt they would have benefitted from it.

Conclusion: Our service evaluation of the combined rheumatology/obstetric clinic revealed favourable outcomes for the mother and baby with high patient satisfaction rates. The clinic offered appropriate timely interventions to control IRD improving pregnancy outcomes. The future aim is to deliver this high-quality service to all pregnant patients with IRD through robust referral pathways to improve the patient experience.

EXPECTED FEATURES OF THE COURSE LEADER IN THE REHABILITATION HEALTHCARE PROFESSIONALS’ HIGHER EDUCATION: A QUALITATIVE STUDY ON STUDENTS’ PERSPECTIVES

Keywords: Education, Qualitative research methods, Rehabilitation

B. Giardulli, E. Marchesini, L. Furrì, M. Testi, A. Delliisola, S. Battista

1University of Genoa, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Genova, Italy; 2University of Verona, School of Medicine and Surgery, Verona, Italy; 3Lund University, Department of Clinical Sciences Lund, Lund, Sweden

Background: Previous evidence showed that Healthcare Professionals (HPs) working with rheumatic and musculoskeletal diseases (RMD) from Mediterranea countries have higher educational needs than Northern-European ones [1]. Hence, it is necessary to find new strategies to improve their training. Course leaders (CLs) are the responsible of the quality to develop the training of rehabilitation HPs, since they oversee designing and directing degree courses that are experienced by students first-hand [2]. To better understand their leadership role, it is helpful to focus on the people with whom the leader interacts daily [3–5]. Therefore, students become an essential source on that matter [2].
However, little attention has been given to the expected features that course leads should hold, starting from students’ perspectives.

**Objectives:** This study explored students’ expected features of a course leader.

**Methods:** A qualitative study was carried out based on semi-structured interviews. A panel of recent graduates and students of the Master of Science in ‘Healthcare Professionals Rehabilitation Sciences’ (University of Verona, Verona, Italy) was recruited using purposive sampling. Data were analysed using the ‘Reflective Thematic Analysis’ by Braun & Clarke [6].

**Results:** Ten HPs in training agreed to partake in the study (age 30 ± 9; men N=2; women N=8). Five themes were generated from the analysis: 1) A Collaborative Manager, as students perceived the CL as a non-authoritarian manager who involved all the stakeholders in the decision-making process; 2) A Diplomatic yet Honest Communicator, as students needed someone capable of communicating with them transparently; 3) A Flexible Mediator, as the CL should actively listen to all their stakeholders and mitigate conflicts; 4) An Empathic and Available Guide, as students needed someone available and ready to help or guide them; 5) An Experienced Healthcare Professional, since students felt that the CL should have a clinical background related to the course they lead.

**Conclusion:** The results of this study suggest that students expect CL to have a wide range of qualities and attributes more related to soft (i.e., adaptation, communication, organisation skills, teamwork) rather than hard skills (i.e., clinical experience). They expect a CL that considers all stakeholders’ needs and preferences to guarantee course harmony and satisfaction.

**REFERENCES:**

[4] Crevani L, Lindgren M, Packendorff J. Leadership, not leaders: On the study experience). They expect a CL that considers all stakeholders’ needs and preferences to guarantee course harmony and satisfaction.

**HPR Interdisciplinary research**

**AB1807-HPR INVESTIGATION OF RELATIONSHIP BETWEEN NUTRITIONAL STATUS AND PHYSICAL ACTIVITY LEVEL IN RHEUMATIC DISEASES**

**Keywords:** Diet and Nutrition, Patient reported outcomes, Physical therapy/Physiotherapy

M. S. Karaci Ermuncu1, S. Y. Ceter2, S. Yardim3, A. Aydin1, 1 Akdeniz University, Nutrition and Dietetics, Antalya, Turkey; 2 Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey; 3 Health Sciences University, Rheumatology, Antalya, Turkey

**Background:** Rheumatic diseases are chronic diseases that negatively affect the quality of life. Ankylosing spondylitis (AS) and rheumatoid arthritis (RA) are the most common clinical manifestations. Non-pharmacological treatments include exercise, healthy and balanced diet recommendations [1,2].

**Objectives:** The aim of this study was to investigate nutritional status and the physical activity level and relationship between those in patients with rheumatic diseases.

**Methods:** 108 patients (64 AS, 22 RA and 22 others (Sjogren, scleroderma, pso- riatric arthritis)) with rheumatic diseases (47932±12.26 years) were included in the study. The International Physical Activity Questionnaire (IPAQ) was used to assess physical activity. Food consumption records were generated for the patients included in the study and were recorded using a 24-hour retrospective reminder method. The adherence of the patients to the Mediterranean diet was evaluated using the ‘Mediterranean Diet Scale’ and their diet quality was evaluated with the Healthy Eating Index.

**Results:** The majority of patients (67.6%) were adapting to the Mediterranean diet and 56.5% had poor overall diet quality. Patients with AS had the worst adherence to the Mediterranean diet (8.2±1.199), while patients with RA had the worst overall diet quality (51.9±14.47, Graph 1). The physical activity level of the patients was inactive (n=49, 39.8%) and there was no significant relationship between nutritional status and physical activity level (p<0.05).

**Conclusion:** According to the results of the study, although the majority of patients had adherence to the Mediterranean diet, the overall diet quality was poor and the level of physical activity was low. These results show that patients cannot be fed adequately and in moderation. Since these patients live in the Mediterranean region, although the consumption rate of vegetables and fruits is high, they cannot be fed adequately with high quality. It is recommended that future studies be conducted in different regions with larger numbers of patients with rheumatic diseases. These results show that patients should also be evaluated in terms of balanced and healthy nutrition.

**AB1808-HPR VIOLENCE: A REALITY IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES?**

**Keywords:** Pregnancy and reproduction, Quality of life, Mental health

A. Carrazco Chapa1, D. C. Rubio Torres1, M. E. Corral Trujillo1, C. M. Skinner Taylor1, L. Pérez Barbosa1, I. Pelaez Ballestas1, D. A. Galarza-Delgado1, 1 Hospital Universitario “Dr José Eleuterio González”; Rheumatology, Monterrey, Mexico; 2 Hospital General de México “Dr Eduardo Liceaga”; Rheumatology, Ciudad de México, Mexico

**Background:** Intimate partner violence (IPV) is defined as any aggression that includes physical, psychological and sexual harm by a current or former intimate partner. In Mexico, 39.9% of women aged 15 years or over have experienced IPV throughout their romantic relationships [1]. IPV in pregnancy and postpartum can lead to mood disorders, obstetric comorbidities, and low birth weight. Pregnant women with autoimmune rheumatic diseases (ARD) are a high-risk population. Using screening tools to detect women experiencing abuse and explore its severity helps us to intervene appropriately and prevent complications [2].

**Objectives:** The aim of this study is to describe the frequency of IPV in patients with ARD.

**Methods:** A descriptive, cross-sectional, exploratory study at the Hospital Universitario “Dr. José Eleuterio González” in Mexico. We included women from the pregnancy and rheumatic diseases clinic (CEER) with a screening of IPV with the HITS scale and categorized them as reproductive-age women and pregnant-postpartum women. We defined reproductive age as the age range of 18-45 years and postpartum up to 1 year after the birth of the last child. The demographic characteristics and ARD data were obtained from the clinical record. Women without IPV were matched (1:1) by age and condition (reproductive age and pregnant-postpartum). A virtual survey was applied including sociodemographic data and the Spanish version of HITS. The Kolmogorov-Smirnov test was used to determine normality. To analyze the differences between groups Mann–Whitney U test, Chi-square or Kruskal–Wallis test were employed. A p < 0.05 was considered statistically significant. The statistical analysis was performed with the statistical program SPSS version 25.
Results: 96 women were included: 48 with ARD and 48 without ARD. The median age was 27 (IQR 24 – 32). In both groups, 24 were reproductive-age women and 24 were pregnant-postpartum women (18/ 75% postpartum and 6/ 25% pregnant). In the ARD group, the most frequent diagnoses were rheumatoid arthritis (22/ 46%) and systemic lupus erythematosus (20/ 42%).

The sociodemographic characteristics and HITS results are in table 1. 18 (19%) women suffered IPV: 11 (23%) women without ARD and 7 (15%) women with ARD (figure 1); in both the most reported item was being insulted (10 without ARD vs 7 ARD) followed by being screamed (6 without ARD vs 6 ARD). Threatened with harm was reported in 3 ARD women while physical hurt was reported in 3 women without ARD. We found significant differences between the HITS scores of ARD women and women without ARD (p= 0.007). No differences in IPV frequency in pregnant-postpartum women and in the ARD group were found (p= 0.433). Overall, more pregnant-postpartum women were identified as IPV victims than reproductive-age women (p= 0.333).

Conclusion: Pregnant and postpartum women are prone to report IPV than women of reproductive age. The current rise in IPV requires us to actively participate in research to prevent complications in pregnant and postpartum patients with ARD.

AB1810-HPR RESILIENCE AND PERINATAL LOSS IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Quality of life, Mental health, Pregnancy and reproduction

Background: Resilience has been defined as the capacity of individuals to successfully maintain or regain their mental health in the face of significant adversity or risk. [1]. The Wagnild and Young Resilience Scale (RS) from 1993 is one of the most widely used instruments in the evaluation of resilience [2]. Having an autoimmune rheumatic diseases (ARDs) and perinatal losses (PL) have been considered traumatic events [3,4]. Identifying women at risk is important for developing psychological support strategies.

Objectives: Evaluate the resilience capacity in patients with and without ARDs with PL.

Methods: Descriptive, cross-sectional, comparative study at the Hospital Universitario “Dr. José Eleuterio González” in México. We included women from the Pregnancy and Rheumatic Diseases Clinic (CEER) that answer a virtual survey with the RS. The demographic, ARD and PL data were obtained from the clinical records. The women without ARD were invited to fill a virtual survey with the RS, sociodemographic and PL data. The RS is a Liker-type scale that consists of 25 items with seven response options. The responses are summed to produce a total score that ranges from 25 to 175; the greater the score the greater the resilience capacity. The Kolmogorov-Smirnov test was used to determine normality. To analyze the differences between groups Mann–Whitney U test, Chi-square, T- test were employed. A p < 0.05 was considered statistically significant. The statistical analysis was performed with the statistical program SPSS version 25.

Results: A total of 50 women were included: 25 with ARD and 25 without ARD. The median age for the group with ARD was 42 (38.5-51) and 34 (26-42.5) for the without ARD group. In the ARD group the most frequent diagnosis were systemic lupus erythematosus (72.8%), rheumatoid arthritis (62.4%) and Antiphospholipid Syndrome (41.6%). For the RS scores, women without ARD have a greater median 137.56 (SD =22.14) than the group with ARD 132.72 (SD =31.03). No statistically differences were found in other variables between groups. The sociodemographic and PL data and the RS score for both groups are included in Table 1.

Conclusion: Even though there were no significant differences between groups, our results suggest that higher education (> 9 years) and suffering only 1 PL can be variables that enhance the resilience capacity of women with PL. Our limitation was the sample size for both groups.

AB1811-HPR

CATASTROPHIC HEALTH EXPENSES IN PREGNANT WOMEN WITH RHEUMATIC DISEASE

Keywords: Quality of life, Pregnancy and reproduction, Health Services Research

Background: Rheumatic diseases (RD) have an impaired quality of life and a high cost of healthcare. Out-of-pocket health expenses are those expenditures that households make to acquire medicines and associated services that come from family income [1]. A disease with catastrophic health expenses is a condition that, due to its high cost and the expenses derived from treatment and medications, exceeds 30% of the family income [1]. Such catastrophic expenses can negatively influence the therapeutic adherence of patients and the prognosis [2]. A policy challenge has been the achievement of universal coverage of health services. A key was the implementation of “Seguro Popular” (SP) in 2003; however, the abolition of the SP in 2020 and the foundation of “Instituto de Salud para el Bienestar” (INSABI) by the current government, created uncertainty due to some omissions detected regarding the clarity of its performance [1].

Objectives: To estimate the frequency of pregnant patients with RD who experienced catastrophic health expenses when using medical services.

Methods: An observational cross-sectional, retrospective study was carried out at the Pregnancy and Reproductive Health Clinic for Rheumatic Diseases (CEER) from the University Hospital “Dr. José Eleuterio González” in Mexico. The data of all pregnant patients was collected from the clinical record. From the socioeconomic study, sociodemographic data, family nucleus, family’s monthly income, monthly health expenditures, as well as the type of health insurance they had, were obtained. The percentage of out-of-pocket health expenses (medication) of each patient was calculated, and if this exceeded 30%, it was defined as a catastrophic expense. For statistical analysis, the sociodemographic and clinical characteristics of the population are presented as frequencies, percentages, or standard deviations.

Results: A total of 54 patients were included in the period from 2019 to 2022 with a mean age of 28.02 (±6.45) years. The rheumatic diagnoses were rheumatoid arthritis with 24 (44.4%), systemic lupus erythematosus with 13 (24.1%), antiphospholipid syndrome with 5 (9.3%), dermatomyositis with 3 (5.6%), juvenile idiopathic arthropathic with 2 (3.7%), Sjögren’s syndrome with 1 (1.8) and others with 6 (11.1%). The sociodemographic characteristics are described in Table 1. Most of the patients had health insurance coverage with 43 (79.6%), where SP stood out as the main one with 24 (55.8%). Of the 43 patients who had health insurance coverage, 5 (11.6%) experienced catastrophic health expenses, which we can see in Figure 1. Of the 11 (20.4%) patients who did not have health insurance coverage, 1 (9.1%) experienced catastrophic health expenses.

Conclusion: The 11.6% of the patients who had health insurance coverage reported having catastrophic health expenses, in which they spent more than 30% of the family’s monthly income. 9.1% of those who did health insurance coverage presented catastrophic health expenses. It is of vital importance that rheumatic diseases should be recognized as catastrophic illnesses to ensure quality patient-tailored care.

AB1812-HPR VACCINATION UPTAKE IN A COHORT OF PATIENTS ON BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (BDMARDS) AT A MELBOURNE PUBLIC HOSPITAL

Keywords: COVID, bDMARD, Vaccination/Immunization

H. Pourhadji1, A. Johnson1, A. Foote1,1, Northern Health, Rheumatology, Epping, Australia

Background: As a result of immunosuppression, rheumatology patients (particularly those on bDMARDs) are at a greater risk of infections. However, little is known about the number of rheumatology patients who have been vaccinated for influenza, COVID-19, Hepatitis B and Pneumococcal vaccinations.

Objectives: To ascertain the number of patients on bDMARDs who received the COVID-19, Influenza, Hepatitis B, Pneumococcal and Shingles Vaccines. With regards to the Influenza vaccine information was obtained over the years 2018 – 2022 to determine if rates of influenza vaccination increased during the COVID-19 pandemic.

Methods: All rheumatology patients on bDMARDs at the Northern Hospital in Epping, Melbourne Australia were included in this study. By retrospectively reviewing the medical records, data was collected regarding patient demographics, clinical information and vaccination to COVID-19, Hepatitis B, Pneumococcal and Influenza. Information for influenzae was obtained over the period from 2018 to 2022. Ethics committee approval was sought from our institution (Reference number: ALR 75.2022).

Results: There were 201 patients on bDMARDs included in this analysis. 139 (69%) were female with a mean age of 54 (SD +/-15.0). Rheumatoid arthritis was the most common indication for biologic therapy (55%) followed by psoriatic arthritis (19%) and ankylosing spondylitis (18%). Tumour necrosis factor inhibitors (TNF) and Janus kinase inhibitors (JAKIs) were most often utilised, prescribed to 62% and 18% of patients respectively. With regards to the influenza vaccine 99 patients (49%) were vaccinated in 2022, compared to 49 patients (24%) in 2016. Women were more likely to be vaccinated than men (54% versus 38% using Chi-squared test (p=0.05). No significant difference was seen by disease category or class of bDMARD. Older patients were more likely to be vaccinated (57, SD = 15) versus younger patients (50, SD = 14) p <0.001. In terms of COVID-19 vaccinations 7% were unvaccinated, 24% received 2 vaccinations, 42% received 3 vaccinations and 25% received 4 or more vaccinations (the recommended number of vaccinations as per current health advice). Finally, regarding the other vaccines 15% received the Hepatitis B vaccine, 15% the Pneumococcal vaccine, and 8% received the shingles vaccine.

Conclusion: In this cohort of bDMARD patients there was a significant increase in the proportion of patients who received the influenza vaccine during the pandemic. This finding is novel in a rheumatology cohort. Despite this there remains under-utilisation of COVID-19, Hepatitis B, Pneumococcal and Shingles vaccinations. Further work looking at the reasons for the low vaccinations rates in immunosuppressed populations is needed to address this public health issue.

AB1814-HPR RHEUMATOLOGY NURSE OUTPATIENT CLINIC IN PORTUGAL

Keywords: Patient information and education, Inflammatory arthritides, Nursing

L. Barbosa1, J. Santos1, A. Cordeiro1, M. J. Santos3, E. Pereira1, Hospital Garcia de Orta, Rheumatology Department, Almada, Portugal;2 Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Lisboa, Portugal

Background: Systemic inflammatory rheumatic diseases are characterized by being chronic diseases. These diseases affect the person, in their various dimensions and are often associated with pain, loss of mobility and function, fatigue, anxiety and depression (Matcham, Norton, Scott, Steer & Motof, 2016; Primdhga & Esbensen, 2020; Ryan, 2020). The complex needs of these patients require and benefit of an advanced nursing practice and a guided and specialized attention that can be provided in a nursing clinic. The awareness of rheumatic patient needs and lack of this type of care led, to our knowledge, to the development of the first rheumatology nurse clinic in Portugal.

Objectives: Characterize a guided nursing clinic with the aim to support patients with systemic inflammatory rheumatic diseases, mainly initiating subcutaneous (sc) classic and biological DMARDs.

Methods: Summarized description of first guided rheumatology nurse clinic in Portugal.
Results: This nurse clinic was created and developed during the pandemic period of SARS-CoV-2 (starting February 2020). For the last three years a total of 556 appointments were performed. The targeted patients had systemic inflammatory rheumatic diseases, mainly rheumatoid arthritis, psoriatic arthritis and spondyloarthritides treated with sc classic and biological DMARDs. Appointments are scheduled at week 0 and 4 of starting these therapeutics and also whenever needed, at the request of the patient or the treating physician, in order to ensure a good nurse availability to clarify doubts at the beginning of these treatments. In the specific case of sc methotrexate, a protocol was created by the Rheumatology multidisciplinary team defining the parameters eligible for evaluation, and the respective procedures of care. During appointments nurses also assess specific disease implications in the person’s daily life, both physical, emotional and social domains. Additionally, this is an opportunity to reinforce reliable information on disease management, coping strategies, including information how to manage medication side effects.

Conclusion: The rheumatology nursing outpatient clinic provides key additional care and monitoring to patients with systemic inflammatory rheumatic diseases, treated with sc classic and biological DMARDs. Nurses improve the management of chronic diseases, namely by promoting autonomy of the patient in self-administration of sc therapies at home, counselling and informing about possible adverse effects and respective management strategies, constituting a valid contribution to disease control and patient engagement and education.

RELIABILITY AND VALIDITY OF THE LIE-TO-SIT-TO-STAND-TO-WALK TRANSFER TEST IN TOTAL KNEE ARTHROPLASTY

Keywords: Osteoarthritis, Outcome measures, Comorbidities

B. Unver1, K. S. Kacmaz2, V. Karatousun2, 1Dokuz Eylul University, Physical Therapy and Rehabilitation, Izmir, Turkey; 2Izmir Katip Celebi University, Physical Therapy and Rehabilitation, Izmir, Turkey; 1Dokuz Eylul University, Orthopedics and Traumatology, Izmir, Turkey

Background: Total knee arthroplasty (TKA) is the gold-standard procedure for end-stage knee osteoarthritis, however, some residual problems may still continue and cause a variety of dysfunctions, such as pain, impaired strength, proprioception, postural instability, dynamic balance, and gait deficiencies [1]. Falls are the most frequent cause of injuries in elderly people, accounting for 90% of hip and wrist fractures and 60% of head injuries [2] requiring expensive and difficult treatments such as fracture surgeries and arthroplasties [3]. The most frequent cause of falling was transfer activity while shitting body weight which accounted for 41% of falls [2] especially getting up from bed and walking to the bathroom [2,4,5]. Additionally, the three major classes of activities—walking, sitting down, and standing—were the most common precipitants of falls. These findings emphasize the need to target each of these activities in fall risk assessment and prevention strategies [2,5]. The Lie-to-Sit-to-Stand-to-Walk Transfer Test (LSSWT) incorporates a multitask approach to measure complicated transfer abilities in older people. However, there is no study investigating the reliability and validity of the LSSWT in TKA patients.

Objectives: The aim of the study is to determine the reliability, validity, and minimal clinically important difference (MCID) of the LSSWT in patients with TKA.

Methods: Twenty-one patients with TKA were included in the study. The LSSWT, the Timed Up and Go Test (TUG), and the Hospital for Special Surgery (HSS) knee scores were administered to the patients. Patients rested between the tests for an hour to prevent fatigue.

Results: The mean age was 68.1 ± 2.59 years and the mean HSS Knee Score was 85.43± 3.47. The relative (ICC coefficient) and absolute (SEM and SRD95) reliability values were 0.88, 121, and 3.33 respectively. The Spearman correlation coefficient of the LSSWT with the TUG was 0.63.

Conclusion: The LSSWT has excellent reliability and high validity in evaluating fall risk and complex dynamic balance and mobility for the activities of daily living in patients with TKA. The low MCID value (3.33) shows that it is sensitive and identifies little alterations in a patient’s condition over time or management strategies. Therefore, it is advisable to use the LSSWT for assessing the fall risk, dynamic balance, and mobility required in the community, discharging, or admitting to a facility.

CROSS-CULTURAL ADAPTATION AND VALIDATION OF THE TURKISH VERSION OF THE NORWICH PATELLAR INSTABILITY SCORE IN PATIENTS WITH PATELLAR INSTABILITY

Keywords: Patient reported outcomes, Outcome measures, Validation

I. Ayas1, Z. Hazar1, I. Kaya2, M. Atacoglu2, U. Kanatli2, 1Gazi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 2Gazi University Faculty of Medicine, Department of Orthopedics and Traumatology, Ankara, Turkey

Background: The Norvich Patellar Instability Score (NPIs) score is a tool for evaluating the impact of patellofemoral instability on joint function. It has not been translated or culturally adapted for the Turkish population before.

Objectives: The aim of this study was to translate and validate the NPIs in Turkish patients with patellar instability.

Methods: Sixty-four individuals with patellar instability were included in this cross-sectional study. Test-retest reliability of the Turkish version of NPIs was assessed by the intraclass correlation coefficient (ICC) and Cronbach’s alpha for internal consistency. For construct validity, correlation coefficients between the Turkish version of NPIs developed by the translation-back translation method, Kujala patellofemoral disorder score, and Lysholm knee score were analyzed.

Results: The Turkish version of the NPIs score showed high internal consistency (Cronbach’s alpha = 0.97) and excellent construct validity reliability (ICCv = 0.90). The Turkish version of the NPI score had a strong correlation with Kujala patellofemoral disorder score (R= 0.85, p< 0.001) and the Lysholm knee score (R= 0.89, p< 0.001). A floor effect was observed in the present study and there was no ceiling effect.

Conclusion: The Turkish version of the NPIs is a reliable and valid tool in patients with patellar instability. The Turkish version of the NPIs will be a guide for clinicians and researchers to understand the functional status of patients with patellar instability.

AB1818-HPR | QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Quality of life
L. Bohmat1, I. Bessonova1, N. Shevchenko1-2, T. Holovko1-2, S1 Institute of Children and Adolescents Health Care of NAMS of Ukraine

Background: According to the Treat to Target strategy, in addition to monitoring the activity of the process and monitoring the formation of irreversible organ damage, it is necessary to recognize the Health-Related Quality of Life, which allows to assess the patient's condition. Quality of life is defined as an integral characteristic of the patient's physical, psychological, emotional and social functioning, based on his subjective perception. Often, changes in quality-of-life indicators precede the dynamics of clinical manifestations of the disease, so they can be used as auxiliary criteria for the effectiveness of treatment already in the early stages of the course of the disease.

Objectives: To evaluate the quality of life of children and adolescent patients with systemic lupus erythematosus (SLE) depending on the activity and duration of the disease.

Methods: 18 children and adolescents with SLE aged from 8.5 to 16.4 years (14.3 ± 0.7) were examined. The average duration of SLE was 3.1 ± 0.7 years, the age of onset was 11.4 ± 0.8 years. Most of the examined were girls (94.4%). The diagnosis was established according to the classification criteria EULAR/ASR 2019 for SLE[1] with at least 10 points. The activity of SLE was found in 5.56% of patients, moderate in 33.33%, minimal in 61.11%. The patients' quality of life was assessed using the Lupus QoL questionnaire, which is a questionnaire with 34 questions, combined for 9 domains, which assess fatigue, dependence on other people, emotional health I, body image (the patient's assessment of his body), fatigue. The questionnaire was filled out by the patients themselves, the answers to the questions were modeled on a five-point Likert scale (0—constantly, 1—almost always, 2—quite often, 3—occasionally, 4—never). Zero points corresponded to the worst quality of life, 100 points to the best state of quality of life for each domain (scale) of the questionnaire.

Results: The quality of life related to health was worsened in all persons. The average total score for all domains was 65.51 ± 2.09 points and ranged from 38.41 to 89.45 points. The spheres “intimate relationships” and “body image” were the most disturbed, which had the lowest score according to the test data (35.58 ± 4.87 and 62.08 ± 6.89, respectively). The best the quality-of-life indicator was recorded in the “pain” domain, which scored the highest number of points (82.41 ± 4.99 points).

According to other scales of Lupus QoL, the quality of life was equal: in the domain “physical health” 77.60 ± 4.17 points, “planning” – 79.63 ± 5.52 points, “dependence on other people” – 66.21 ± 5.74 points, “emotional health” and “fatigue” – 76.15 ± 4.24 and 75.00 ± 4.46 points, respectively. Correlation analysis revealed reversed correlations between the degree of disease activity and the domains “pain” (r = -0.530; p < 0.05), “planning” (r = -0.529; p < 0.05), “intimate relationships” (r = -0.720; p < 0.05), “emotional health” (r = -0.728; p < 0.01). Direct correlations were found between the age of patients and indicators of the domain “pain” (r = 0.647; p < 0.01) and “planning” (r = 0.642; p < 0.01), respectively, the age of patients at the onset of the disease and the indicator “body image’ scale” (r = 0.811; p < 0.01), the duration of the disease and the “fatigue” scale (r = 0.638; p < 0.05).

Conclusion: In all patients with SLE, a violation of the health-related quality of life was established. Its deterioration was recorded in all domains and was due to the activity of the disease. Monitoring the quality of life of adolescents with SLE in combination with disease activity monitoring will allow for a better assessment of the health status of patients and timely identification of the need for correction of therapy and the selection of the most effective treatment program.

AB1820-HPR | BIOELECTRICAL IMPEDANCE ANALYSIS SHOWED HIGH AGREEMENT AND SPECIFICITY TO ASSESSMENT OF LOW APPENDICULAR SKELETAL MUSCLE MASS IN WOMEN WITH SYSTEMIC SCLEROSIS: PRELIMINARY DATA

Keywords: Validation, Sarcopenia, Systemic sclerosis
L. Denardi Dória1, R. Cavallheiro Do Espirito Santo1, V. Haix1, L. Santos2, E. Penà1, A. L. Mailmann1, S. Pilotti1, D. Moraes1, T. J. Santos de Souza2, B. Da Silva1, I. Bosak1, V. Lovison1, J. A. Tesser1, P. Jesus1, L. Steinmetz1, R. Legati1, P. Espindola Correia1, T. Muniz Figura1, F. Gerchmann1, P. M. Spritzer1, R. Xavier1, R. Chakr1, H. Hospital de Clinicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil; Hospital de Clinicas de Porto Alegre, Division of Endocrinology, Porto Alegre, Brazil.

Background: Patients with systemic sclerosis (SSc) are particularly prone to skeletal muscle wasting, affecting nearly one-third of patients, increasing the risk of disability[1,2]. To assess muscle mass, there are direct methods, such as magnetic resonance imaging, computed tomography and dual-energy X-ray absorptiometry (DXA), considered the gold standard[3]. DXA is widely used in clinical practice and in population studies, but it has some disadvantages, such as specific technical skills and higher costs[3]. Bioelectrical impedance analysis (BIA) is a validated method in healthy individuals of body composition assessment with greater affordability and minimum requirements[4]. To our knowledge, in patients with SSc only one study compared DXA and BIA. Soanjer et al found agreement between these two techniques only for fat-free mass, without evaluating appendicular skeletal muscle mass (ASM)[5].

Objectives: (1) Our objective was to compare ASM measured by BIA versus DXA and (2) to verify the associations with clinical features in women with SSc.

Methods: Women with SSc according to ACREULAR 2013 criteria were consecutively included at a tertiary public hospital in Rio Grande do Sul, Brazil (Hospital de Clinicas de Porto Alegre, HCPA) in 2022. Modified Rodnan's skin score (mRSS) EUSTAR activity index were calculated. The ASM by BIA (Body In 370s) and DXA (GE FamBeam 4500A) were calculated from sum lean mass of arm and legs (kg). Low muscle mass (BIA or DXA) was defined according to the European Working Group on Sarcopenia in Older People (EWGSOP2) less than 15 kg. Pearson's and intraclass correlation coefficients, dependent samples t-test and simple linear regression analysis were used. All analyses were performed and 1.5 beta error was maintained. The significance level was set at p<0.05.

Results: Until this moment, 62 women with SSc were included. The mean age was 62.0 ± 10.1 years-old and median disease duration was 15.0 (7.0–21.0) years. Forty-one patients (66.1%) had limited cutaneous disease, 14 (22.6%) diffuse-cutaneous and 7 (11.3%) sine scleroderma. The median mRSS was 4.0

AB1819-HPR | INTRA-RATER RELIABILITY OF SHEAR WAVE ELASTOGRAPHY FOR THE QUANTIFICATION OF THUMB MUSCLE ELASTICITY

Keywords: Ultrasound
P. Karademir1, A. E. Yildiz1, T. Firat1, O. Ulger1, Hacettepe University, Physical Therapy and Rehabilitation, Ankara, Turkey; Hacettepe University, Radiology, Ankara, Turkey.

Background: Shear wave elastography (SWE) is a technique that evaluates tissue elasticity by applying an acoustic radiation force impulse [1]. It is undetermined how reliable this modality is in assessing thumb muscles. Quantitative evaluation of muscle stiffness in conditions such as trapeziometacarpal osteoarthritis where increased fibrosis, muscle tone, spasm, and contractures can be seen can provide important information about the pathology and prognosis of the diseases [2].

Objectives: This study aimed to assess the intra-rater reliability of thumb muscle elasticity and thickness in healthy people.

Methods: Ten healthy participants (20 hands) enrolled in the study. Thickness and shear wave velocity (SWV) of adductor pollicis (AdP) and first dorsal interosseous (FDI) muscles were measured using an ACUSON S3000 Ultrasoundography System and a 8L4 probe (4–9 MHz) (Siemens Medical Solutions, Mountain View, California). Ultrasound data (SWV, thickness) were collected and analyzed by an experienced radiologist. Three repeated SWV and thickness measurements were recorded in the resting position and an average was taken. Two sessions were performed at a 15-minutes interval.

Results: Ten healthy participants (20 hands; 5 female; 5 male; mean age: 25.9±2.68 years; BMI: 22.4±1.39 kg/m2) were included in this study. Nine subjects had right-hand dominance and 1 had left-hand dominance. The mean (±SEM) shear wave velocity for the AdP was 1.86 ± 0.6 m/s (10.86 kPa), and for the FDI was 1.76 ± 0.5 m/s (9.72 kPa). The intra-rater trial agreement was excellent, with intraclass correlation coefficients of 0.887 and 0.828 respectively. The mean (±SEM) muscle thickness for the AdP was 12.4 ± 3.93 mm, and for the FDI was 12.0 ± 3.68 mm. The intra-rater trial agreement was excellent, with intraclass correlation coefficients of 0.953 and 0.984 respectively.

Conclusion: SWE ultrasound was a reliable imaging technique to assess the stiffness and thickness of thumb muscles.

Disclosure of Interests: None Declared.

The mean appendicular skeletal muscle mass measured by DXA was 16.0 ± 2.2 kg while by BIA was 15.5 ± 2.7 kg (Δ = 0.5 kg; p = 0.005), underestimating the ASM. On other hand, the mean differences between DXA and BIA showed within the confidence interval (p= 0.358; CI 95%: -2.8 – 1.8; Figure 1). ASM by BIA was strongly correlated (r= 0.866, p < 0.001) and had a high agreement (Intraclass Correlation Coefficient = 0.919, p < 0.001) with ASM by DXA. We found only weak association between ASM by BIA and age (r= -0.282; p= 0.026). Low muscle mass in women with SSC was found in 16 patients (29%) by DXA and in 26 patients (42%) by BIA with a sensitivity of 80% and specificity of 94%.

Conclusion: BIA and DXA show high correlation and agreement in ASM assessment of women with SSC. Our findings suggest BIA as a useful tool due to its high specificity with DXA for the early assessment of low ASM in women with SSC. Furthermore, completion of this study is needed to confirm these results.

AB1821-HPR

FUNCTIONAL CAPACITY AND WORK ABILITY IN PATIENTS WITH COMMON SCIATICA

Keywords: Work-related issues, Quality of life, Pain

H. Bejaoui1, A. Feki1, I. Sellami2, S. Ben Jemaa1, M. Ezzeddine1, M. H. Kallel1, M. H. Bejaoui1, A. Feki1, I. Sellami2, S. Ben Jemaa1, M. Ezzeddine1, M. H. Kallel1, M. H. Bejaoui1, A. Feki1, I. Sellami2, S. Ben Jemaa1, M. Ezzeddine1, M. H. Kallel1, M. H. Bejaoui

Background: Spinal radicular syndromes are a serious healthcare issue in the society nowadays. A common form of ailments related to the syndromes is sciatica, manifesting with severe pain radiating along the course of the sciatic. In many patients the pain limits the ability to perform daily routine at work and at home [1].

Objectives: The aim of study was to assess the functional capacity in patients with sciatica and its influence on their quality of life, their ability to function in daily life and at work.

Methods: We conducted a cross-sectional study including patients suffering from documented common sciatica evolving for more than 3 months collected in a rheumatology department over a period of 3 years. The Quality-of-life SF-36 questionnaire - Short Form Health Survey was used in the study, along with a supplement specifying the study group, with an indication of the pain location and the patients’ occupations. Additionally, the Oswestry Disability Index, the work ability index (WAI) - and the Visual Analogue Scale (VAS) were applied.

Results: The study covered 104 patients, both male and female (71 women and 33 men with sex ratio male/female of 0.45). The mean age of our patients was 55.4 years-old (23-74). The most common etiology of sciatica was herniated disc, followed by lumbar spinal stenosis and spondylothesis. The root path was L5 in 74 cases and S1 in 30 cases, the average duration of sciatica was 6.4 months. The mean Oswestry score was 25(15-38). The mean of the VAS was 7.4(4-9).

The mean of WAI was 25.2(15-38). The Quality-of-Life index, at a statistically significant level (p< 0.05), is higher (hence the quality of life is lower) in females suffering from sciatica. The duration of sciatica was a factor strongly correlated with the intensity of pain - the Oswestry score and the VAS scores were negatively correlated with age (p<0.05, r= -0.6 and r= -0.4 respectively).

Conclusion: In our series sciatica affects the quality of life of the female patients studied in this research to a greater extent than the male patients. The intensity of pain associated with sciatica duration. WAI and Oswestry were negatively associated with age.

Background: The Lupus Impact Tracker (LIT) is a patient reported outcome (PRO) questionnaire. The results demonstrated their reliability in clinical practice for evaluation and follow-up.

Objectives: To validate the LIT and the degree of correlation with other scores in SLE patients in Argentina.

Methods: Observational, analytical and multicenter study. Patients older than 18 years with SLE (2019 ACR/EULAR criteria) were included. In the first stage, we evaluated the reproducibility in a period of 7 days measured by intraclass correlation (ICC) as well as the time to answer the questionnaire. In a second stage, the scores LIT, LupusQol, PGA, SLEDAI and SLICC SDI were calculated for each patient and the Spearman correlation coefficient between scores was analyzed.

Results: Initially the LIT was performed in 10 patients. The average time to complete the questionnaire was 2.1 minutes. The mean of LIT (T0) was 57.1 (SD 24.2) and 51.5 (SD 25.5) seven days later. The ICC was 0.808 (95% CI 0.431 − 0.948). In the second stage, 100 SLE patients were included consecutively. Table 1 shows the main characteristics of the patients. The Spearman correlation coefficient between LIT/ LupusQol was 0.71, LIT/ SLEDAI was 0.13, and LIT/ SLICC was 0.26 (Graphic 1).

Conclusion: The median of the LIT questionnaire was 37 points. LIT demonstrated test-retest reliability and linear correlation with LupusQol. There was no correlation with SLE activity. LIT is a practical, quick and easy tool to evaluate the patient's perspective in relation to the disease in daily practice.

MULTIPLE TNFi TREATMENT CYCLES AND THE FAILURE OF TRIAL-AND-ERROR CARE FOR PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: bDMARD, Patient reported outcomes, Rheumatoid arthritis
S. Helfgott, C. Adams, A. Frick, K. Huston, S. Milligan, J. Singh, N. Solomon, C. Edgerton. 1Harvard Medical School, Division of Rheumatology and the Division of Medical Communications, Boston, United States of America; 2Articularis Healthcare, Clinic, Summerville, United States of America; 3Tri Health, Analytics, Louisville, United States of America; 4Kansas City Physician Partners, Clinic, Kansas City, United States of America; 5University of Alabama at Birmingham, School of Medicine, Birmingham, United States of America; 6Arizona Arthritis, Clinic, Phoenix, United States of America

Background: Inhibitors of tumor necrosis factor-alpha (TNFi) are central to management of rheumatoid arthritis (RA) though continued use beyond initial failure is negatively associated with response to subsequent TNFi treatment.

Objectives: To assess the patterns of recurrent TNFi use relative to reasons for switch as observed in community rheumatology care in the US.

Methods: Data: PIONEER-Rheumatology, an EMR and open text-extracted database specific to care given by the American Rheumatology Network (ARN). Study population: Adult (18+ years) old patients with RA, TNFi-treated in 2018 to 2021. Full histories were assessed for each patient and index was set as the initiation date of the last TNFi observed for each patient prior to 2022. Reasons for discontinuation were extracted from chart notes and broadly classified (and sub-classified) as attrition (death, moved/left practice, non-clinical reasons), lost to follow up (LTU), patient disengaged, or clinical treatment goal achieved, lack/loss of efficacy, or condition resulting from disease, treatment, or patient burden.

Results: 13994 patients and 19925 episodes (defined as distinct patient & TNFi drug) were examined. Of 13944 patients, 9399 (67%) received 1 TNFi, 3527 (26%) 2 TNFi, 1068 (8%) ≥3 TNFi; treatment patterns may have included interchanging non-TNFi treatment cycles. [TABLE]

Reasons for discontinuation/switch were available for 4254/4595 (93%) and 998/1068 (93%) patients treated with 2+ or 3+ distinct TNFi, respectively. Lack/loss of efficacy was the reason for 1 or more TNFi discontinuations prior to the last TNFi received for 2689/4254 (63%) and 829/998 (83%) of patients with 2+ or 3+ TNFi, respectively. For a patient subset with ≥1 year history pre-index, prior failure of 1+ TNFi was observed for 2690/3765 (71%) and 814/936 (87%) patients who received 2+ or 3+ TNFi, respectively.

Conclusion: A third of TNFi-treated study patients received ≥3 TNFi with most discontinuing priorTNFi due to lack/loss of efficacy. Though trial-and-error care is seemingly standard to RA management, this study suggests that some patients do not benefit from this approach.

AB1825-HPR  
DECISION TO INITIATE A TUMOR NECROSIS FACTOR INHIBITOR IN RHEUMATOID ARTHRITIS UNCOUPLED FROM DISEASE ACTIVITY MEASURES

Keywords: bDMARD, Real-world evidence, Rheumatoid arthritis
J. Singh, C. Adams, A. Frick, S. Helfgott, K. Huston, S. Milligan, N. Solomon, C. Edgerton. 1University of Alabama at Birmingham, School of Medicine, Birmingham, United States of America; 2Articularis Healthcare, Clinic, Summerville, United States of America; 3Tri Health, Analytics, Louisville, United States of America; 4Harvard Medical School, Division of Rheumatology and the Division of Medical Communications, Boston, United States of America; 5Kansas City Physician Partners, Clinic, Kansas City, United States of America; 6Arizona Arthritis, Clinic, Phoenix, United States of America

Background: Previous studies have demonstrated discordance between patient-based (e.g. RAPID3) and predominantly physician-based (e.g. CDAI) disease activity measures (DAMs).

Objectives: To examine the relationship between DAMs and decision to initiate TNFi following csDMARDs.

Methods: Data: PIONEER-Rheumatology, an EMR and open text-extracted database specific to care given by the American Rheumatology Network. Study population: Adult RA patients who received TNFi as initial targeted synthetic or biologic DMARD treatment between January 2014 to April 2022 after csDMARDs. Assessments: CDAI, RAPID3, DAS28 (includes DAS28-CRP, DAS28-ESR), tender/w swollen joints (TSJ), pain score, and HAQi. Closed to within -180 days of TNFi initiation. Paired (+/- 30 days) CDAI, RAPID3, and DAS28 assessed via Pearson correlation.

Results: 2811/3682 (76%) patients had 1+ DM prior to TNFi initiation; 2332/3682 (63%) pain score, 2047/3682 (56%) TSJ, 1570/3682 (43%) DAS28, 1442/3682 (39%) RAPID3, 1430/3682 (39%) CDAI, and 143 (4%) HAQi. Of the 2331/3682 patients with RAPID3, DAS28, or CDAI, 982/2331 (42%) had near-remission/low disease by at least 1 DAM prior to index. 582 patients had paired CDAI and RAPID3 scores; moderate/severe disease was indicated for 474/582 (81%) by CDAI and 395/582 (68%) by RAPID3 (p<0.001) and 163/582 (28%) of patients were indicated as near-remission/low by one DAM but as moderate/severe by the other. Correlations between paired DMs: strong for CDAI,DAS28 (n=1063, r=0.788) and moderate for CDAI,RAPID3 (n=582, r=0.399) and for RAPID3,DAS28 (n=637, r=0.162).

Conclusion: DMs were not present for 24% of study patients at initiation of TNFi. Of patients with RA, RAPID3, DAS28, or CDAI, 42% patients started TNFi despite near-remission/low disease activity. When conducted, paired DAS28-RAPID3 and CDAI-RAPID3 scores were moderately correlated though severity categories for CDAI/RAPID3 were discordant for 28% of evaluated patients. These results suggest that clinical decision-making to initiate TNFi does not rely solely on standard DMs.

HOW TO ASSESS THE SATISFACTION OF PATIENTS WITH CHRONIC INFLAMMATORY DISEASES AFTER SWITCHING TO A BIOSIMILAR? INSIGHTS FROM AN EXPLORATORY QUALITATIVE STUDY PRELIMINARY TO AN OBSERVATIONAL STUDY

Keywords: Patient reported outcomes, Quality of life, DBMARD

G. Bouguen1, L. Peyrin-Biroulet2, A. Buisson3, D. Lafarge4, S. Tropé4, G. Monlagu1, A. Denis3, C. Habauzit2, S. Benkhaila2, H. Marote2, 1CHU de Rennes, Maladies de l’appareil digestif, Rennes, France; 2CHU de Nancy, Hépatologie gastro-entérologie, Vandoeuvre-lès-Nancy, France; 3Afa Crohn Rch France, Afa Crohn Rch France, PARIS, France; 4Association France Spondylarthrites, Association France Spondylarthrites, TULLE, France; 5Association National de Défense contre l’Arthrite Rhumatoïde, ANDAR, Clermont l’Hérault, France; 6Unknown, Unknowns, PARIS, France; 7Celltrion Healthcare France, Medical, Isay Les Moulinaux, France; 8CHU de Saint-Etienne, Rhumatologie, Saint-Etienne, France

Background: Patients experience may be negatively impacted when starting biosimilar due to a poorly executed switch which could result in poor adherence and nocebo effect.

Objectives: This study aims to identify suitable patient satisfaction dimensions to design an observational study on real-life switches.

Methods: A qualitative exploratory study was performed. In-depth, semi-structured interviews were conducted by a sociologist with patients with inflammatory diseases treated by anti-TNF biosimilar to determine patient switching experiences and expectations. Qualitative dimensions for the observational study’s ques- tionnaire (ePRO) were designed.

Results: Interviews were conducted with the help of patients’ associations.

Four patients (3 females) were included: 2 with rheumatoid arthritis and 2 with Crohn’s disease. Two patients had adalimumab biosimilar, 1 etanercept biosimilar and 1 adalimumab originator (switch-back). The following dimensions were identified:

Information transparency: patients were unfamiliar with biosimilars and some did not know they were using them. Some reported distrusting biosimilars but accepted them because they trust their physician.

Patient Involvement: physicians decide whether to offer a biosimilar, but patient acceptance is determined by their interpretation of the situation. Patients found it difficult to express their treatment preferences and reported that physicians didn’t always prompt these discussions.

The time of injection: patients had to learn the injection procedures but received relatively little support during the switch in handling the new device. Some experienced greater pain, differences in comfort or reported errors in use.

Transition: the sustainability of the switch may have been constrained by delays in supply in the city. In some cases, the pharmacy dispensed the originator drug as a replacement.

These led to the following ePRO composition: BMQ, HLSEU-Q16 (health literacy), ad hoc items on shared decision making, expectations, patient training, satisfaction with provided information and injection. All 4 patients understood the final questionnaire. The study design is an open label multicentric study of 300 patients in 30 sites (rheumatology and gastroenterology, hospital, and private practice) when offered a switch. The primary objective is to assess patients’ overall satisfaction with injections 3 months post-initiation compared to the previous adalimumab. The first patient was included in June 2022.

Conclusion: This work proposes an original methodology for the selection and design of criteria for an observational study. An exploratory qualitative study high- lightened different factors of patient satisfaction during the switch to adalimumab biosimilar. It guided the choice of e-PROs and the construction of specific items.

PAIN MANAGEMENT IN OLDER POPULATION FROM GERMANY AND SWEDEN: SUB-GROUP ANALYSIS FROM A TOPICAL DICLOFENAC PROSPECTIVE REAL-WORLD EVIDENCE STUDY

Keywords: Pain, Quality of life, Patient reported outcomes

V. Rampartaap1, K. Fabrikan2, D. Nair1, V. Sood1, G. Shangra2, T. Wilcox1, J. R. Norrellf1, E. Csoke1, 1Haleon (formerly known as GSK Consumer Health), Medical Affairs, Amersfoort, Netherlands; 2Haleon (formerly known as GSK Consumer Health), Medical Affairs, London, United Kingdom; 3Haleon, Medical Affairs, Stockholm, Sweden; 4Haleon (formerly known as GSK Consumer Health), Medical Affairs, Singapore, Singapore; 5Haleon (formerly known as GSK Consumer Health), Biostatistics, New Jersey, United States of America; 6Former PPD Employee, n.a., Maryland, United States of America; 7Karolinska Institutet, Rehabilitation Medicine Occupational Health, Stockholm, Sweden; 8n.a., n.a., Basel, Switzerland

Background: Adequate pain management in older individuals is essential to support functional lifestyle and enable robust quality of life (QoL). Topical non-steroidal anti-inflammatory drugs (NSAIDs) such as diclofenac gel, with limited systemic exposure, provide a better pharmacological alternative to oral NSAIDs for musculoskeletal pain management especially in elderly due to favorable benefit-risk profile[1].

Objectives: To evaluate impact of over the counter (OTC) topical diclofenac (1.16% & 2.32%) use in an older German and Swedish population on different aspects related to QoL such as pain, functional status, and treatment satisfaction.
Methods: A subgroup analyses of older participants (≥65 years) from a prospective real-world evidence study conducted among 731 adult (≥18 years) consumers (467 in Germany and 264 in Sweden) of OTC topical diclofenac (1.16% ≤ 2.92%). Treatment satisfaction, functional status and pain relief were assessed using electronic surveys (baseline, Week 4, and Week 12) via personalized link. Numerical Rating Scale (NRS-11) and Likert scale were used for questionnaire-based response collection.

Results: Data from 279 (72.3%) older participants, 203 German and 76 Swedish, were included. Baseline characteristics of participants and reported outcomes are shown in Table 1. Majority purchased 2.32% strength, were repeat users and reported having previously identified cardiovascular conditions. Improvement in pain score ≥ 1 point was observed in >57% of users at Week 12. Participants reported reduction of pain interference in different functional activities at Week 4 and 12. >70% of participants were satisfied with the treatment at Week 4 and >75% at Week 12.

Conclusion: Older participants reported reduction in pain over time, improvements in their ability to participate in daily life activities, treatment satisfaction with the use of OTC topical diclofenac and thus improved QoL.

ASSOCIATION BETWEEN COMPLEMENTARY AND ALTERNATIVE MEDICINE USE AND TRUST IN THE PHYSICIAN IN PATIENTS WITH INFLAMMATORY RHEUMATISM?

Keywords: Diet and Nutrition, Rheumatoid arthritis, Spondyloarthritis F. Z. Aharrane1, F. Z. Taik1, N. Takhrifa1, R. Bensaid1, M. Fourtassi2, F. E. Abouraazzak1, 1Abdelmalek Essaïdi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco; 1Abdelmalek Essaïdi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco

Background: Generally, patients with chronic rheumatic diseases use complementary and alternative medicine (CAM) in addition to their conventional treatments to manage their health. Discussing these treatments with their physician is still rare, which might be directly related to patients’ trust toward them.

Objectives: The primary objective of this study was to assess the association between patients’ trust in their physician and the use of complementary and alternative medicine. As a secondary objective, to estimate the prevalence of complementary and alternative treatment use among patients with chronic inflammatory rheumatism.

Methods: This is a cross-sectional study, which included patients with established chronic inflammatory rheumatism, followed at the University Hospital Center in Tangier. The questionnaire included demographic and clinical information, use of conventional therapy, complementary and alternative therapy, as well as the interpersonal trust in patient-physician relationships using the Trust in Physician Scale (TPS).

Results: The study included 189 patients. 57.14% of patients reported using complementary medicine at least once, out of patients with known cardiovascular conditions, 46.67±13.25 years with an average course of the disease 11.11±9.23 years. The most frequent used complementary and alternative treatments were cupping therapy (45.90%), massage (40.40%) and the ingestion of a mixture of plants (27%). Means±SD Trust in Physician Scale was 4784 ±72, and there were no significant differences between CAM users vs. non-users (48.06±6.9 vs. 47.0±4.7, p=0.35).

Conclusion: More than half of patients with inflammatory rheumatism reported the use of complementary and alternative medicine. However, the association between their use and trust in the physician assessed with TPS was not established.

FACTORS ASSOCIATED WITH SEDENTARY BEHAVIOR IN PATIENTS WITH KNEE OSTEARTHROSIS

Keywords: Education, Pain S. Ez-Zaouiti1, H. Rkaïri1,2, S. Bahoul1, T. Latifa1, F. El Joumani1, R. Honsali1, F. Kronbi1, S. Farhi1, I. Bengsahri1, N. Hajjai-Hassouni1, F. Allali1, 1Hospital Al Ayachi, Rheumatology B, Salé, Morocco; 2Faculty of Medicine And Pharmacy of Rabat, Exercise Physiology and Autonomous Nervous system Team, Physiology Laboratory, Rabat, Morocco; 3International University of Rabat, Rheumatology, Rabat, Morocco

Background: To determine factors related to sedentary behavior in patients with Knee Osteoarthritis.

Methods: we conducted a cross-sectional study of 130 patients affected by knee osteoarthritis. Information on patients and disease characteristics were collected. Physical activity was measured objectively using the short version of IPAQ questionnaire (International Physical Activity Questionnaire) for 7 consecutive days. Activity levels were subdivided into low physical activity and moderate to vigorous physical activity. We analysed factors associated with sedentary behaviour.

Results: The mean age of the patients included was 59.4±10 years with 110 (84.6%) females. The median IPAQ was 260 (0.500) MET-min/week. The sedentary behaviour was noted in 69.2% of patients. Table 1 summarized factors associated with sedentary behaviour in knee osteoarthritis patients.
Table 1. Analysis of factors associated with sedentary behavior in knee osteoarthritis patients.

<table>

</tr>
<tr>
<td>Pain caused by knee osteoarthritis</td>
<td>0.02</td>
</tr>
<tr>
<td>Functional disability caused by knee osteoarthritis</td>
<td>0.01</td>
</tr>
</tbody>
</table>

Conclusion: Sedentary behaviour is prevalent among knee osteoarthritis patients. It is important to overcome this unhealthy lifestyle and to encourage practice of physical activity in this population by combating the barriers reported by patients.

AB1830-HPR MUSCULOSKELETAL DISORDERS DURING COVID-19 INFECTION: A SURVEY OF HEALTHCARE WORKERS

Keywords: COVID, Health Services Research, Epidemiology

H. Ziedi1, D. Brahimi1, I. Youssfi1, M. Mersni1, Z. Athimi2, N. Mechergui1, G. Bahni1, H. Ben Said1, N. Ladhari1, 1Charles Nicolle Hospital, Department of Occupational Pathology and Fitness for Work, Tunis, Tunisia

Background: COVID-19 infection has revealed a considerable number of extra-pulmonary manifestations, especially rheumatological. The detection of these manifestations, which herald the infection, is of great value in the early diagnosis of the disease, especially in health care workers (HCWs) who are at considerable risk of infection. Although myalgia is a common clinical feature of COVID-19, other musculoskeletal disorders (MSDs) have been rarely described.

Objectives: To describe MSDs during SARS-COV2 infection in HCWs.

Methods: Prospective descriptive study conducted at the department of occupational pathology and fitness for work of Charles Nicolle Hospital in Tunis, having included the HCWs affected by COVID-19 during the period from 01 September 2020 to 28 February 2021. Data collection was carried out by regular telephone follow-up during the containment period using a pre-established form.

Results: During the study period, 656 HCWs were infected with SARS COV 2, of whom 134 (20.4%) had at least one musculoskeletal event. The mean age was 42±9 years with a sex ratio (M/F) of 0.2. The most represented occupational category was nurses (33.6%) followed by health technicians (23.1%). The median professional length of service was 12 [7; 20] years. The presence of comorbidity was noted in 58.2% of HCWs. A pre-existing osteoarticular disease was found in 8.2% of cases. Obesity was noted in 25.4% of the population. Active smoking was reported by 14.3% of respondents. A known vitamin D deficiency was noted in 16.5% of patients. Spinal pain was the most reported MSD, present in 87.3% of cases. Low back pain was the most frequent spinal pain (56.7%) followed by back pain (37.4%) and neck pain (5.9%). MSDs of the lower limbs were found in 12.7% of patients. They were represented by gonalgia in 11.9% of cases, ankle pain in 5.2% of cases and hip pain in 4.3% of cases. MSDs of the upper limbs were described by 7.5% of the patients, 92.5% of whom presented with shoulder pain. The median duration of MSDs during COVID-19 was 5 [3; 8] days. These manifestations were persistent on return to work in 21.1% of cases.

Conclusion: Knowledge of the frequency and consequences of musculoskeletal manifestations related to COVID-19 infection is of great importance, particularly in HCWs, in order to optimise management and ensure a rapid return to work.

Background: EPOSER study has confirmed the great burden of rheumatic diseases, which represent almost 30% of primary care medical consultations in Spain[1]. Electronic consultation could be an alternative response[3] as well as rheumatologist-led update programmes and joint case discussion with primary care physicians have shown to reduce the burden of care and waiting times in rheumatology units[4].

Objectives: To analyze the demand from primary care to the rheumatology service of a tertiary hospital.

Methods: Retrospective descriptive study of the data consecutively collected from 15 to 30 May 2022 from new rheumatology consultations at the reference hospital requested from primary care (PC) health centers in the area. The following variables were collected: waiting time (median and range in days), referral route (ordinary, preferential or e-consultation), reason for derivation, type of visit (discharge or follow-up), suspicion of inflammatory disease by the specialist in Family and Community Medicine (Yes/No), confirmation diagnosis of inflammatory disease by the specialist in Rheumatology (Yes/No), time from onset of inflammatory symptoms to rheumatology consultation (median and range in months), referral with analytical tests (Yes/No/With acute phase reactants) and with musculoskeletal image requested by the PC physician (Yes/No); those provided by patients in private centers were excluded. Descriptive statistics were used for the presentation of results and Cohen’s Kappa coefficient was calculated to quantify the degree of agreement in the diagnosis of inflammatory disease between primary care physicians and rheumatologists.

Results: A total of 116 new consultations were registered in the system referring to 100 patients, 16 did not attend their appointment. Results are shown in Table 1. The degree of agreement according to Cohen’s Kappa index was 0.53, representing 80% of agreement (moderate degree). No differences were found between health care centers in the referral rate according to the population assisted by each health care center.

Conclusion: Main reasons for consultation were ‘osteoarthritis assessment’ and ‘polyarthralgia’. Ordinary route was the most frequently used with a median waiting time of 60 days and 50 days for preferential route. Thirty percent of patients were referred with analysis and 75% with some musculoskeletal image. The degree of agreement was moderate in the diagnosis of inflammatory disease between primary care physicians and rheumatologists.

Background: Decrease in vitamin D levels in patients with systemic lupus erythematosus (SLE) arouses particular interest. Vitamin D levels and their correlation with bone mineral density (BMD) loss are still seen as contradictory.

Objectives: To study serum vitamin D levels in SLE women and to estimate their correlation with BMD and disease activity.

Methods: 101 SLE women and 30 individuals in a control group participated in the study. The activity of SLE was evaluated by SLEDAI. The average age of patients was 47.12 ± 0.14 years, in the control group it was 46.17 ± 0.12. Serum levels of C-reactive protein (CRP) and 25-hydroxyvitamin D (25(OH)D) were measured in all participants. Changes in BMD of the lumbar spine and hip were determined by dual-energy X-ray densitometry.

Results: In patients with SLE, the average level of 25(OH)D equalled 14.6 ± 1.19 ng/ml, and in the individuals from the control group, it was 1.9 times higher, constituting 24.7 ± 1.32 ng/ml. In SLE women with normal BMD (T score > -1 SD) vitamin D deficiency (< 20 ng/ml) was detected in 18.3%. In the group with osteopenia (T score from -1.0 to -2.5 SD), the proportion of individuals with vitamin D deficiency has increased to 26.7%. In women with osteoporosis (T score ≤ -2.5 SD), vitamin D deficiency was found in 63.9%. In the group of patients with the maximum CRP level there were only 10% of persons with the optimal (> 30 ng/ml) 25(OH)D level, 40% had insufficiency (20-30 ng/ml), while deficiency (< 20 ng/ml) was detected in every second patient. Among patients with optimal CRP levels, only every fourth person was diagnosed with vitamin D deficiency. 10% of the individuals had vitamin D insufficiency, while 65% had optimal vitamin D levels. Decrease in vitamin D level was closely associated with SLE activity revealed by SLEDAI (r = -0.44; p < 0.05).

Conclusion: The average vitamin D level in SLE women is likely to be lower than that in the control group. Decrease in vitamin D levels was associated with BMD loss and high inflammatory process as well as the disease activity according to CRP and SLEDAI.

Kassa Institute, Rheumatology, Tunis, Tunisia; Kassa Institute, Radiology, Tunis, Tunisia

Background: Several factors were associated with non-inflammatory rheumatic diseases such as diabetes and overweight. As far as we know, no previous research has studied cardiovascular risk in this population. For this goal, we used the carotid intima-media thickness (cIMT) screening as a relevant tool for CV risk assessment.

Objectives: This study mainly aimed to determine the importance of CV risk in non-inflammatory rheumatic diseases.

Methods: The present study is a case-control study conducted on Tunisian non-inflammatory rheumatism patients in the rheumatology department. We collected the characteristics of the patients and those of the disease. The CV risk was assessed using the measurement of cIMT. According to the American Society of Echocardiography guidelines, the cIMT thickness was measured using high-resolution B-mode carotid US with a Philips machine with the patient in the supine position. The cIMT was measured using the two inner layers of the common carotid artery and an increased IMT was defined as ≥0.09 cm.

Results: Fifty patients were collected, of which 82% were women, 64% of them were followed for knee osteoarthritis, the rest were chronic low back pain patients. The mean age was 53 ± 11.08 years, 10% of patients were active smokers. Two percent were hypertensive and 4% were diabetics. The average BMI was 28.1 ± 4.5 kg/m². It was greater than 25 kg/m² in 76% of them. [cholesterol] was 4.9 ± 0.9 mmol/l. 48.9% had a high rate. [Cholesterol HDL] was 1.1 ± 0.2 mmol/l. The mean [cholesterol LDL] was 3.3 ± 0.8 mmol/l. [triglyceride] was 1.3 ± 0.6 mmol/l. The mean IMT in the left common carotid (LCC) was 0.06 ± 0.01, in the left internal carotid (LCI) was 0.06 ± 0.01, in the left external carotid (LEC) was 0.05 ± 0.01. The mean IMT was 0.05 ± 0.018 in the right common carotid (RCC), 0.06 ± 0.01 in the right internal carotid (RIC), and 0.05 ± 0.01 in the right external carotid (REC). Thirty six percent had an atheroma plaque. Twenty six percent had a high CV risk according to the IMT. There was no correlation in our series between diabetes, high blood pressure, smoking, BMI, and high CV risk (p > 0.1). p = 0.05, respectively.

Conclusion: While the absence of systemic inflammation in non-inflammatory, osteoarticular diseases, the cardiovascular risk is higher in our study. Therefore, cardiovascular risk screening should not be limited to chronic inflammatory neumatism.

**THE TYPE AND THE EFFECT OF PHYSICAL ACTIVITY ON QUALITY OF LIFE AND FATIGUE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN GREECE: A CROSS-SECTIONAL STUDY**

**Keywords:** Systemic lupus erythematosus, Quality of life, Epidemiology

D. Bonia1. Institute of Occupational Science and Rehabilitation, Health Science, Marousi, Greece

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with severe symptoms, such as fatigue and has a high impact on patient's quality of life.

Objectives: The aim of this study was to determine the rate, the type, and the effect of physical activity (P.A.), and exercise in patients with SLE on quality of life and fatigue in Greece.

Methods: Three questionnaires were used to measure quality of life (SF-36), fatigue (FSS), and P.A. (mPAQ). 101 patients with SLE from Greece answered about their personal choices. For statistics the IBM SPSS 25 was used for the statistical analysis. Descriptive analysis conducted to describe quantitative variables of interests. Data normality was verified from Kolmogorov-Smirnov test, and Pearson Correlation test was performed to determine the relationship between P.A. and QoL and Fatigue.

Results: The results showed that the sample average for QoL was 48.3±19.3), for Fatigue 41.7±7.2). The total score of P.A. was 1603.7±1695.8) METs. Furthermore, for vigorous P.A. was 557.7±867.6) METs, for moderate P.A. 824.6±811.6) METs, and for low P.A. 239.8±405) METs. The most common type of P.A. was housekeeping and cleaning for 74% of the sample, and even thought it is not considered as P.A. activity there was an option. A high average (50.5%) of the sample was presented by patients who chose to remain seated during the day. Positive correlation between P.A. and QoL was found (R=0.385, P<0.01). Negative correlation between P.A. and Fatigue was also found (R=0.384, P<0.01).

Conclusion: The conclusions were that the patients with SLE in Greece do not perform high level of P.A. and exercise. The moderate level of P.A. was more likely activities of day living, that are classed as P.A., than exercise. Furthermore, the sample choose a sedentary lifestyle, although correlation between P.A. and QoL and Fatigue in patients with S.L.E. was found.

**PERINATAL GRIEF IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES**

**Keywords:** Mental health, Quality of life, Pregnancy and reproduction

M. E. Corral Trujillo1, R. A. Cerda González2, H. G. Martinez Sandoval2, A. Carrazo Chapa1, K. M. López Serna1, J. C. Riega Torres1, L. Pérez Barbosa2, C. M. Skinner Taylor3, D. A. Galarza-Delgado1. Hospital Universitario “Dr. José Eleuterio González”; Rheumatology, Monterrey, Mexico

Background: Perinatal loss (PL) defined as a loss from any gestational age or in the neonatal period [1] lead women to the process of grieving. Perinatal Grief (PG) involves suffering and reaction such as sadness, disbelief and anger [2]. PL and PG symptoms affect many women around the world; women with autoimmune rheumatic diseases (ARDs) have greater risk of PL. The Perinatal Grief Scale (PGS) can help health providers prevent complicated grief in their patients [3].

Objectives: Determine which PL and sociodemographic variables are associated factors to a complicated grief in women with ARDs.

Methods: Descriptive, cross-sectional, comparative study at the Hospital Universitario “Dr. José Eleuterio González” in México. We included women from the Pregnancy and Rheumatic Diseases Clinic (CEER) that answer a virtual survey with the PGS. The demographic, ARD and PL data were obtained from the clinical records. For the control group, women without ARD were invited to fill a virtual survey with the PGS, sociodemographic and PL data. The PGS is a Likert-type scale that consists of 27 items with four response options. The questions are distributed in four subscales: active grief (10 items), guilt (8 items), depression (6 items), acceptance (3 items). Scores greater than 50 points suggest a complicated grief comorbidity.

DOI: 10.1136/annrheumdis-2023-eular.1272
The Kolmogorov-Smirnov test was used to determine normality; to analyze the differences between groups, Mann–Whitney U, Chi-square tests and T-test were employed. A p < 0.05 was considered statistically significant. The statistical analysis was performed with the statistical program SPSS version 25.

Results: A total of 50 women were included: 25 with ARD and 25 without ARD. The median age for the group with ARD was 42 (38.5-51) and 34 (26-42.5) for the without ARD group. In the ARD group the most frequent diagnosis were systemic lupus erythematosus (7/14%), rheumatoid arthritis (6/12%) and Antiphospholipid Syndrome (4/8%). For the PGS, twenty (40%) of the 50 women got a score >50; 11 (55%) were women without ARD and 9 (45%) have ARD. The PL, suffered by these 20 women were 18 during the pregnancy (17/85% on the first trimester and 1/5% on the second trimester) and 2 (10%) after birth. No statistically differences were found in the total score and subscales of the PGS between groups. The sociodemographic and PL data and the PGS score for both groups are included in table 1.

Conclusion: Even though there were no significant differences between groups; we hypothesize that the greater number of PL in women with ARD serves as a protective factor and prevents that the PG evolve to a complicated grief. On the other hand, having the PL during the first trimester of the pregnancy can be a risk factor for complicated grief. Our limitation was the sample size for both groups.

ANTI-MYELOPEROXIDASE ANTIBODY-POSITIVE GRANULOMATOSIS WITH POLYANGITIS MIMICKING MUCOSAL LEISHMANIASIS: A RARE CASE REPORT

Keywords: Autoantibodies, Descriptive Studies, Vasculitis

I. Nogueira1, M. Montenegro1, V. Alcantara1, T. N. Albuquerque Gomes

Nogueira2. 1Faculty of Medicine - Federal University of Ceará, Departamento de Medicina Clínica, Fortaleza, Brazil; 2Faculty of Medicine - Federal University of Ceará, Departamento de Patologia e Medicina Legal, Fortaleza, Brazil

Background: Granulomatosis with polyangiitis (GPA) features necrotizing granulomatous inflammation of the upper and lower respiratory tracts, with vasculitis of small- and medium-sized vessels [1]. Anti-proteinase 3 antibodies (PR3-ANCA) are found in the majority of cases, yet anti-myeloperoxidase (MPO-ANCA) may be identified in approximately 10% of patients with GPA [2, 3]. One of the differential diagnoses is mucosal leishmaniasis, especially in patients from endemic regions. Atypical presentations of GPA may delay diagnosis.

Objectives: To report a case of a female patient previously diagnosed with and treated for mucosal leishmaniasis due to upper respiratory tract lesions. As the symptoms returned alongside arthritis, further investigation concluded to a diagnosis of anti-myeloperoxidase-positive GPA.

Methods: Case report and discussion.

Results: A 51-year-old woman from Brazil presented in 2021 with epistaxis and joint pain. The patient reported a prior history of recurring bilateral epistaxis and maxillary pain since 2008. At that time, she had a wide nasal septal perforation. CT scan of the sinuses showed maxillary and ethmoidal sinusopathy. A nasal biopsy showed epithelial granulomas without amastigotes, but the patient had a 25mm Montenegro skin test (strongly positive). Syphilis, hepatitis B, hepatitis C and HIV screenings and acid-fast bacilli smear were negatives. As Brazil is an endemic region for leishmaniasis, a presumptive diagnosis of mucosal leishmaniasis was made and the patient was appropriately treated. In 2016, she was lost to follow-up. In 2021, she returned with fever, epistaxis, important unspecified weight loss and arthralgia with edema in ankles, distal interphalangeal joints, metacarpophalangeal joints and wrists. Blood screening revealed an RCP of 9.5 and an ESR of 28. Urine tests were normal. A thoracic CT scan showed multiple lung nodular formations, including a subpleural nodule in the anterior lower right lobe, with a size of 3.8 x 3.1 x 2.9 cm. Lung histopathology revealed foci of poorly formed, non-necrotic granulomas in centrilobular parenchyma and angiitis in small-caliber arteries (image 1). Autoimmune screening revealed positive MPO-ANCA superior to 1/80 and negative c-ANCA, rheumatoid factor and anti-CCP. Thus, a diagnosis of GPA was made, and oral methotrexate 20mg weekly was started. Improvement of arthritis could be observed in four weeks.

Conclusion: GPA may present upper respiratory tract symptoms, and is considered a differential diagnosis for mucosal leishmaniasis [4]. Recurrence of the symptoms in a patient treated for mucosal leishmaniasis should prone further investigation for other conditions. The renal system was spared in our patient, however nasal septal involvement, prominent sinusopathy, joint symptoms and pulmonary typical findings strongly favored the hypothesis of GPA. A positive MPO-ANCA and good therapeutic response following methotrexate strengthened the certainty of the diagnosis. Physicians should be aware of GPA as a differential diagnosis for mucosal leishmaniasis and recognize its MPO-ANCA-positive presentation.

ARTIFICIAL INTELLIGENCE IN THE CLINICAL SETTING OF THE RHEUMATIC DISEASES: A SYSTEMATIC REVIEW OF THE LITERATURE

Keywords: Systematic review, Artificial Intelligence
Background: Autoimmune Rheumatic Diseases (AIRD) are chronic multifactorial diseases that present with a variety of pathologic findings due to immune abnormalities. The pathogenesis of data may involve a genetic and environmental factors, and there are usually large individual differences in phenotype, imaging and blood findings, treatment response, and prognosis. As a result, clear algorithms for diagnosis and treatment are scarce, and clinicians must interpret complex disease images from a variety of data to make analogies between diagnosis, prognosis prediction, and treatment effects. Artificial intelligence, encompasses concepts such as machine learning and deep learning, is a substitute for these complex tasks, and attempts are gradually beginning to replace it in the clinical practice of AIRD. Accountability is often required for decisions in medicine that directly affect human lives, and the same is true for the black box of models used by AI. Therefore, in recent years, emphasis has been placed on the explainability of AI, and a method called explainable AI (XAI) has been used to explain decisions made by AI models. Research in this area is still in its infancy, and it would be of significance to present an overall picture.

**Objectives:** To clarify the overall picture of AI/machine learning in the clinical application or research in AIRD by the systematic review of the literature.

**Methods:** A systematic literature review was conducted using the Pubmed and Web of Science according to the “Preferred Reporting Items for Systematic Reviews and Meta-Analyses” (PRISMA) guidelines. The search formula used Artificial Intelligence, Machine learning, Deep learning, Neural Network, AIRD, and XAI. Screening and full text were independently performed by two reviewers. Further, the methods for algorithms explanation.

**Results:** The literature search yielded 1483 articles, that were published before June, 2021, and resulted in 164 articles after primary and secondary screenings. Among them, 153/164(93.9%) were published in or after 2017. The main target diseases of the articles were rheumatoid arthritis (RA) 72, systemic lupus erythematosus (SLE) 42, spondyloarthritis 11, inflammatory myositis 7, systemic vasculitis syndrome 5, systemic sclerosis 5 and others 21. The main objects of the studies were diagnosis or classification of the disease in 98, followed by the prognostic prediction in 49 and analysis of the therapeutic reagent in 19. The most common types of data used as training were demographic data in 114 articles, followed by physical data 101, clinical test data 92, genomics data 40, image data 30 and pathological data 28. The most commonly used algorithms were tree-based algorithm (random forest etc.) followed by support vector machine and neural network. XAI were performed in 8 studies (3 studies with RA, 3 with SLE one with SLE/RA and 1 with AIRD in general) in which Shapley Additive Explanations (SHAP) was the most frequently used tool (5/8; 62.5%).

**Conclusion:** The clinical application of AI in AIRD is mainly used as a tool for diagnosis or the prognostic prediction in RA and SLE. On the other hand, only a very small number of the study have examined the explainability of AI. The review indicates that research on the clinical implementation of AI applications is still at an early stage despite the great potential.

**REFERENCES:**

**Keywords:** Vasculitis

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.1747
Background: Thrombotic thrombocytopenic purpura (TPP) and Microscopic polyangiitis (MPA) rarely occur in conjunction. Autoimmune TPP is caused by autoantibodies to the ADAMTS13 protein that cleaves von Willebrand factor. MPA is a small vessel vasculitis that typically affects the small blood vessels of the lung and kidney [1]. We present a case of concurrent TPP and MPA which we believe could highlight a pathogenetic correlation and treatment overlap between the two diseases.

Objectives: To report a rare case of concurrent TPP and MPA and to educate physicians on optimal treatment strategies.

Methods: Case report and literature review.

Results: A 67-year-old patient with history of stroke and sickle cell disease presented to the emergency department due to altered mental status and fever. Serology on admission was notable for marked acute kidney injury and anemia requiring transfusions. Urinalysis showed hematuria and proteinuria. Autoimmune serology was remarkable for p-ANCA positivity at 1:80 with myeloperoxidase antibody > 30 pmol/L; a diagnosis of MPA was made. Patient’s serology was also remarkable for thrombotic microangiopathy on peripheral blood smear and hemolysis labs. ADAMTS13 autoantibodies were reduced with less than 3% functionality and an inhibitor of 1/0 BU, confirming a concurrent diagnosis of TPP. Patient was initiated on high-dose steroids and therapeutic plasma exchange (TPE) with resultant normalization of platelets and improvement in renal function. TPE was discontinued, and the patient was transitioned to rituximab with continuation of high-dose steroids. The patient was ultimately discharged home with a steroid taper and maintenance rituximab dosing.

Conclusion: Per literature review, three other cases of concurrent TPP and MPA have been reported [2-4]. Further investigation into pathogenetic and treatment overlap of MPA and TPP may be warranted. Although rare, when occurring together the presentation is often severe, and urgent initiation of treatment is critical. TPE is the mainstay of treatment in TPP but is usually only recommended in MPA patients with anti-GBM antibodies, those at high risk of progression to end stage renal disease, or those unresponsive to first-line therapies [1,5,6]. Rituximab, which acts to decrease B cell activity and overall antibody production, has been shown to reduce disease activity in both conditions [1,5]. This case report suggests that, in the rare event that TPP and MPA are concurrently diagnosed, the combined use of rituximab and TPE in conjunction with steroids may induce remission more efficiently than either treatment alone.

TERMINATION OF PREGNANCY IN LUPUS NEPHRITIS: A BIOETHICAL ANALYSIS WITH THE INTEGRATIVE METHOD

Keywords: Best practices, Pregnancy and reproduction, Systemic lupus erythematosus

T. Cano-Gámez 1, A. Lobato-Belmonte 1, J. Péláez-Ballestas 1, G. Medrano-Ramírez 1, J. De Léon-Carbajal 1, A. Manrique de Lara 1, 2Hospital General de México “Dr. Eduardo Liceaga”, Rheumatology Division, Mexico City, Mexico; 2Hospital General de México “Dr. Eduardo Liceaga”, Maternal-Fetal Medicine Division, Mexico City, Mexico

Background: Termination of pregnancy in patients with rheumatic diseases is controversial due to current lack of evidence. Around one fourth of pregnancies in patients with rheumatic diseases are terminated due to medical reasons. Only 0.026% of articles in Rheumatology relate to bioethics despite the high frequency of ethical dilemmas in the treatment of pregnant patients with auto-immune diseases [1].

Objectives: To analyze from a bioethical perspective the case of a pregnant patient with lupus nephritis unresponsive to treatment, for whom termination of pregnancy is considered as a therapeutic measure.

Methods: The integrative model was applied combining different normative ethical theories. The central moral dilemma and main stakeholders were identified. The case was analyzed from utilitarian, deontological and virtue ethics perspectives, followed by synthesis to establish a global conclusion.

Results: Case presentation. A 30-year-old woman was diagnosed with systemic lupus erythematosus in 2019 in Mexico. Induction therapy for lupus nephritis was started; however, it was interrupted due to COVID-19 pandemic. When she returned for follow-up, despite treatment was reinstated, she persisted with proteinuria without achieving complete remission criteria. Multi-target therapy was started; however, patient stopped treatment for economic reasons and became pregnant shortly after. She presented for prenatal control follow-up at 20 gestational weeks with edema in the lower extremities and hypertension, for which she was hospitalized in intensive care. Renal replacement therapy was initiated without further response to treatment. A multidisciplinary team suggested pregnancy termination as a therapeutic option, which the patient refused. Bioethics analysis. Figure 1 shows the background factors and initial steps for defining and analyzing the bioethical dilemma. Three different normative ethical theories were used. Utilitarianism. The consequences of the action are the central component, and the decisions made must be profitable and effective for the majority. Terminating the pregnancy would seek to protect the mother’s life, since saving one life represents a greater benefit than losing two. For the patient’s family, the costs of continuing with the pregnancy would be unsustainable. For the institution, the termination of the pregnancy would lead to a more efficient use of human and material resources. Therefore, interrupting the pregnancy is justifiable. Deontology. Duty-based ethics center the action itself regardless of consequences, as well as valuing autonomy. Seeking all therapeutic alternatives, including termination of pregnancy, is a good action itself. However, considering the patient’s autonomy, her desire to continue pregnancy must be taken into account. Therefore, both terminating and continuing the pregnancy are justifiable. Virtue ethics. Aretology centers the importance of decisions in the person who performs the action. Core values involve enabling flourishing and personal growth. For both the family and the institution, flourishing would imply preserving the life of the patient. Therefore, the termination of pregnancy is justifiable.

Conclusion: Using the integrative method, we conclude that termination of the pregnancy is justifiable from the three ethical theories and is an appropriate resolution to the ethical dilemma. However, considering the patient’s desire to continue pregnancy, health professionals should offer psycho-emotional support. The lack of recommendations about medically indicated termination of pregnancy in rheumatology leads to complex moral decisions, making the bioethical analysis of paradigmatic cases essential to ensure the best possible action and as a precedent for future similar situations.

REFERENCES:
Background: A black female in her 40s presented with a nonpruritic rash for 10 months consisting of bumps on the face, hands, forearms, and thighs. She had no prior treatment. Past medical history was significant for pulmonary embolism (PE) 6 years prior. She had no personal or family history of autoimmune disease.

Physical exam revealed numerous smooth 2-3 mm skin-colored papules over the bilateral forearm dorsa, hands, anterior thighs, and face. Serum protein electrophoresis revealed monoclonal IgG lambda gammapathy. Skin biopsy of her left elbow showed dermal fibroplasia with mucin deposition. IgG was less than 1.5 grams/deciliter; bloodwork was otherwise stable. The diagnosis of scleromyxedema was rendered.

Objectives: The objective of this clinical case was to evaluate a neurologic sequela of COVID-19 infection in a patient with scleromyxedema.

Methods: One month following diagnosis of scleromyxedema, our patient was diagnosed with COVID-19 five days before admission to the emergency department with altered mental status and aphasia. Rheumatology was consulted due to malignant hypertension and acute kidney injury with question of scleromyxedema-like renal crisis in the setting of recently diagnosed COVID-19 infection, although she had no other features of systemic sclerosis. The infectious disease team was consulted due to COVID-19-induced inflammatory reaction.

Results: The patient’s creatinine kinase and brain natriuretic peptide were elevated. Creatinine and potassium trended upwards. She developed seizures and became hemodynamically unstable with rapidly declining clinical status. She was transferred to the intensive care unit, where she developed respiratory arrest, shock, hyperkalemia, and acidaemia. She received escalating doses of pressors but experienced frequent arhythmic disturbances and developed asystole. Resuscitation efforts were unsuccessful; she expired within 24 hours of consultation.

Conclusion: Dermato-neuro syndrome (DNS) is a potential complication of scleromyxedema associated with confusion, dysarthria, seizures, and coma. The patient’s clinical presentation is consistent with DNS in the setting of scleromyxedema likely precipitated by COVID-19. Intravenous immunoglobulins are first-line treatment for scleromyxedema; however, it is associated with risk of venous thromboembolism. The patient was considered for treatment as an outpatient but deferred due to history of PE. She was reevaluated for treatment upon presentation to the hospital, but given the severity and rapidity of her condition, it was already too late. This is the second reported case of COVID-19 induced DNS in a patient with scleromyxedema. Given the severity, we recommend early initiation of treatment in patients with scleromyxedema and aggressive treatment for those contracting COVID-19.

SPONTANEOUS ABORTION AS DIFFERENTIAL DIAGNOSIS OF INTERMITTENT GLOMERULAR PROTEINURIA IN CLINICALLY AND SEROLOGICALLY INACTIVE SLE

Keywords: Systemic lupus erythematosus, Pregnancy and reproduction, Kidneys

F. Ulrich1, A. Skapenko1, H. Schule-Koops2. 1LMU Clinic Munich, Division of Rheumatology and Clinical Immunology, Munich, Germany

Background: In SLE, new-onset proteinuria and albuminuria raise concern for renal involvement, even when isolated and subnephrotic. In women of childbearing age, pregnancy-related complications are other causes of renal protein loss. Distinguishing renal disease from pregnancy-related complications of SLE is difficult because SLE is associated with adverse maternal and fetal events, while pregnancy is also a cause of disease relapses. Common to all causes of pathologic proteinuria in SLE is that they are related to disease activity and/or the need for intervention, as proteinuria does not normalize on its own.

Objectives: We report a case of a patient with inactive SLE who intermittently developed significant isolated proteinuria and albuminuria of glomerular origin that was directly related to spontaneous abortion in early (possibly twin-) pregnancy.

Methods: A 39-year-old female with SLE on hydroxychloroquine presented at our clinic for a routine check-up. Physical examination and laboratory tests were performed. To that date, SLEDAI-2K during most visits had a score of 0, indicating inactive disease.

Results: The patient reported feeling well, and the physical examination was unremarkable. Stable low-grade thrombocytopenia was the only abnormality in recent years. On the current examination, the urine showed significant proteinuria and A3 albuminuria in the protein/albumin to creatinine ratio (uPCR 724 mg/g, uACR 488 mg/g). IgG/creatinine was markedly elevated (74.4 mg/g), and α1-microglobulin was normal, indicating nonselective glomerular proteinuria without tubular impairment. There were no other abnormalities suggestive of SLE activity. After she recalled having vaginal spotting a week earlier, a pregnancy test was performed and was positive. Subsequently, the hCG level increased insufficiently, and ultrasound detection of a live embryo was not successful, but the presence of two amniotic cavities was suspected. An early incomplete miscarriage was diagnosed, and the gestational age was calculated to be 6+5 weeks. Shortly thereafter, a planned suction curettage was performed. One week later, she had a final vaginal bleed. At this time, the urine showed a decrease in proteinuria of over 50% (uPCR 317 mg/g, uACR 210 mg/g, IgG 26.9 mg/g). Three weeks later, urine protein was completely normalized, which proved stable 12 weeks after initial diagnosis. Throughout the follow-up period, she did not show any SLE relapse.

Conclusion: After exclusion of differential diagnoses (chart), causality of the miscarriage with the urinary findings seems evident. To date, there have been no reports of the concomitant occurrence of early pregnancy miscarriage, possibly LN-indicative glomerular proteinuria, and its spontaneous regression in a clinically and serologically inactive SLE patient. Recently, observations were confirmed that a large proportion of patients with a uPCR <1 g/g had LN histology, whereas a relevant proportion had inactive sediment or normal serology like our patient. As the kidney is the organ most affected in SLE pregnancy, it is important to be aware of intermittent proteinuria, as the consequences may be very different from persistent proteinuria as would be expected in nephritis.

CORRELATION OF THE OUTCOMES MEASURED BY THE PATIENTS AND BY THE MEDICAL TEAM ACCORDING TO THE LEVEL OF ADHERENCE AND AN EDUCATIONAL TOOL FOR PATIENTS

Keywords: Outcome measures, Patient reported outcomes

P. Santos-Moreno1, P. Ninto-Flores2, L. Realpe2, F. Rodriguez2, G. S. Rodriguez-Vargas1, J. A. Rubio-Rubio1, P. Rodriguez-Linares1, A. Rojas-Villarraga3. 1BIOBAM, Scientific Direction, Bogotá, Colombia; 2UniversiSAR, Expert Patient, Bogotá, Colombia; 3BIOBAM, Patients Education, Bogotá,
**Background:** The level of adherence to treatment in patients with rheumatoid arthritis (RA) is important to achieve control of the disease. In turn, educational strategies in self-care and knowledge of RA help improve adherence and promote knowledge for self-measurement of clinimetry.

**Objectives:** The purpose of this work was to evaluate the correlation of the clinimetry measurements made by the doctor (MM) with those made by the patient (PM) in a group of patients with education in their disease and to compare it with another group of patients without specific education, according to the level of adherence.

**Methods:** A cross-sectional study was carried out that included adult patients with RA. Two groups were included, Group A: Patients with educational training in RA (12-14 months, face-to-face and virtual modules developed by an expert health group), Group B: Patients without training. Both groups measured their PM by means of a digital form and after one week they were evaluated (blind MM). Both PM and MM included global VAS, Fatigue, MDHQ, Rapid-3 and EQS, additionally the physician evaluated the DAS28, CDAI and the Morisky Green Levine Medication Adherence Scale. Correlations were made using the Pearson coefficient. The project was approved by the ethics committee.

**Results:** All the participants were women (Group A: 28, Group B: 63). Group A had a significantly higher proportion of higher than secondary schooling, erosivity, nodularity, polyautoimmunity, anti-CCP positivity, treatment with biologics, older age, and disease duration. The total group had a low level of disease activity (DAS28). A significant correlation (Table 1) was found in all the MM variables with corresponding ones PM, with the highest coefficients in group A (except in MDHAQ). There was a significantly higher proportion of adherent patients in group A (78.5%) than in group B (42.8). When analyzing the correlations in the subgroup of adherent patients, all the coefficients increased (except global VAS), maintaining the same ratio of superiority of correlation coefficients in group A compared to group B.

**Conclusion:** MM has a higher correlation with PM in patients with educational training in RA. These correlations are even greater in the group that is adherent to the treatment, persisting higher in the group with training. The results deserve to be replicated in patients with different levels of severity to those studied here.

A FIRST CASE REPORT OF SCHNITZLER SYNDROME PRESENTING WITH ACROPACHY AND LITERATURE REVIEW

Keywords: bDMARD, Imaging, Inflammatory arthritides

X. Sun1, Z. Zhang1. 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Schnitzler syndrome (SchS) is a rare and easily misdiagnosed autoinflammatory disease. The misdiagnosis not only delays proper treatment, but also leads to the unreasonable use of immunosuppressants or even chemotherapeutic agents which results in needless financial and physical burdens.

Objective: The objective of this study was to summarize the clinical features and help physicians to avoid more misdiagnosis.

Methods: Here we report a 52-year-old female with SchS, who suffered from chronic pruritic urticaria, fever, and arthralgia for over 10 years. Then we systematically reviewed 471 patients, 470 from 138 previous case reports and 1 from our case report.

Results: Most of the patients were middle-aged or elderly women from European and American countries. There were limited number of cases coming from Asia, and no cases from Africa had yet been identified. The main clinical manifestations included chronic urticaria with or without pruritus, fever, arthralgia, ostealgia/myalgia, fatigue, and weight loss. Some cases also presented with lymphadenopathy, hepatomegaly, and splenomegaly. The presence of monoclonal immunoglobulin was the main diagnostic criteria, and the most common was IgM. Laboratory examinations also showed elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Neutrophil infiltration was the most common pathological results in the skin tissue of SchS patients. Currently, anti-IL-1 therapy seems to be the best choice, followed by anti-IL-6 therapy. Glucocorticoid and traditional immunosuppressants seemed to be ineffective to SchS.

Conclusion: As the diversity and variability of clinical symptoms, clinicians should pay more attention to the features of SchS to avoid misdiagnosis. Nearly half a century has passed since the first case of SchS was reported. Exploring its pathogenesis is still on the way. More Research is warranted for individualized therapy.

RHEUMATOID MENINGITIS - A RARE PRESENTATION OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Diagnostic Tests

S. Subasinghe1, S. Wijesooriya1, 1Medway NHS Foundation Trust, Rheumatology, Gillingham, United Kingdom

Background: Rheumatoid arthritis (RA) is a multisystem autoimmune disease
mainly affecting the joints. Rarely it can present with extra articular manifesta-
tions without any joint symptoms. Rheumatoid meningitis (RM) is an uncommon
extra articular manifestation of the disease and can be the first presentation of
RA very rarely.

Objectives: A 76 year old Caucasian lady was presented with aphasia of 10
minutes duration with frontal headache. Furthermore she complained of gradual
onset difficulty in walking for the last 10 months and jerky legs. She was on
reatment for hypothyroidism, hypertension, anxiety and denied any joint pains.
Examination showed normal cranial nerves and spastic quadriaparesis with limb
power of 4/5, global hyperreflexia and extensor plantar reflexes. She was also
observed to have focal clonic seizures of the left lower limb. Lungs were clear, 10
days later she developed painful left wrist and metacarpophalangeal joints with
swelling and tenderness.

Methods: MRI of the brain with contrast showed right fronto-parietal leptomene-
geal enhancement. Cerebrospinal fluid (CSF) tested repeatedly showed lym-
phocytic pleocytosis, normal glucose, mildly elevated proteins (0.6gg/l). CSF was
negative for flow cytometry, TB PCR, TB culture, antineuronal antibodies, crypt-
tococcal antigen, viral PCR, fungal cultures, fungal studies and beta D glucan.
Rheumatoid factor (141 tu/ml) and anti CCP antibodies (447u/ml) were strongly
positive. CSF anti CCP antibody titre was 8 u/l. Rest of the autoimmune serology
was negative. ACE level was normal. Inflammatory markers were raised. X ray
of the hands showed degenerative changes only. CT chest abdomen and pelvis
and FDG PET scan showed left sided axillary lymphadenopathy of which the
biopsy showed reactive changes. CT also showed possible early interstitial lung
disease (ILD).

Results: Patient was managed with the collaboration of the neurology team,
rheumatology team and input from a tertiary care center. Meningeal biopsy was
not done due to the risks involved and delay in starting treatment. RM was diag-

CERVICAL INVOLVEMENT IN CALCIUM PYROPHOSPHATE DEPOSITION DISEASE - DISEASE SPECTRUM

Keywords: Education, Imaging, Crystal Arthritis

E. Costa1, C. Campinho Ferreira1, A. M. Gomes Correia1, D. Esperança
Almeida2, P. Pereira2, J. Silva1, M. Cerqueira1, J. Redondo Costa1, A.
Ribeiro1, J. Neves1, 1Hospital de Braga, Rheumatology, Braga, Portugal; 2
Hospital de Braga, Rheumatology, Braga, Portugal

Background: Calcium pyrophosphate deposition disease (CPPD) is microcryst-
talline arthropathy that affect space joints and fibrocartilage, leading to inflam-
mation and structural damage. CPPD affects predominantly the appendicular
skeleton. For this reason, CPPD has several pseudonyms such as pseudogout,
pseudo-rheumatoid arthritis, and pseudo-osteoarthritis. The involvement of the axial
skeloton is less common or recognized but may have a broad spectrum of
clinical presentations.

Objectives: To describe the clinical spectrum of axial manifestations of CPPD.

Methods: Case report and discussion.

Results: 1–Asymptomatic deposition of calcium pyrophosphate (CPP) in
C1-C2: 68-year-old woman, diagnosed with CPPD with a pseudogout-like pres-
etation. Previously, a knee arthrocentesis has been performed during an episode
of monoarthritis. Blunt crystals with weak birefringence and positive elongation
were identified in the synovial fluid analysis by polarized light microscope, compat-
ble with CPP crystals. Later, the patient underwent a brain computed tomography
(C1T), after a head trauma, and it was observed the presence of calcification of the
atlanta transverse ligament (figure A), without associated symptoms.

Figure 2. A: X-ray showed bony hyperplasia “burr sign” at the acral areas of fingers (A) and
toes (B).

Figure 3. Number of reported cases sorted by country. Most of the patients with Schnitzler
syndrome were from the reports of European and American countries, while limited cases
were from Asia and none from Africa.

Acknowledgements: I would like to acknowledge the contribution made by the
neurology team in managing this patient.

Disclosure of Interests: None Declared.

medical advice. Analytically, she presented acute phase reactants elevation. Cervical spine CT showed mineralization of the transverse atlas and alar ligaments (figure B). The patient completed a low-dose corticosteroid regimen and restarted the usual medication, with rapid and complete recovery.

3—Retro-odontoid pseudotumor: An 85-year-old woman followed by neurosurgery for clinical signs suggestive of cervical myelopathy was referred to rheumatology. From the imaging study carried out, she had CT and MRI of the cervical spine and skull, where calcification and marked thickening of the atlantoaxial ligament complex and peri odontoid soft tissues were identified, with anterior dislocation of the odontoid and stenosis of the vertebral canal at the medullary bulb transition (figure C). Clinically, she reported longstanding episodes characterized by mixed rhythm cervicalgia. She denied a previous history of peripheral arthritis. Radiographic and ultrasound studies evidenced triangular fibrocartilage of the carpus and knee menisc chondrocalcinosis, and intracartilaginous hyperechoic images in multiple locations, suggestive of CPP deposition. The patient started therapy with colchicine 1 mg/day and cervical orthosis for symptomatic control.

4—Inflammatory discitis: A 78-year-old male, hospitalized for inflammatory neck images in multiple locations, suggestive of CPP deposition. The patient started therapy with colchicine 1 mg/day and cervical orthosis for symptomatic control.

The laboratory analysis showed acute phase reactants elevation. After an exhaustive investigation of infectious etiology and refractoriness to multiple antibiotics, the patient started high-dose corticosteroid therapy with rapid resolution of complaints. The CT image showed C4-C5 and C5-C6 discitis with osteophytosis leading to pharyngeal anatomical distortion and periodontal and posterior longitudinal ligament calcification (figure D).

MONOGENIC DISORDERS IN THE MAIDEN COHORT OF PEDIATRIC RHEUMATOLOGICAL DISEASES OF NEPAL: A SPECK OF IMPRINT ON EVEREST

Keywords: Real-world evidence, Genetics/epigenetics, Descriptive studies

D. Bhattarai1, A. Banday2, P. Patra3, A. Neupane4 1Advanced Centre for Immunology and Rheumatology, Immunology & Pediatric Rheumatology, Kathmandu, Nepal; 2Government Medical College, Srinagar, Kashmir, India, Pediatrics, Kashmir, India; 3All India Institute of Medical Sciences, Patna, India, Pediatric Rheumatology, Patna, India; 4Advanced Centre for Immunology & Rheumatology, Kathmandu, Nepal, Data & statistics, Kathmandu, Nepal

Background: Monogenic causes are increasingly being detected in pediatric rheumatological diseases (PRDs).[1] Monogenic disorders are inborn errors of immunity resulting into innate immune disturbance and autoinflammation. With increasing awareness and diagnostics, PRDs are diagnosed with increasing frequency and accuracy in Nepal.

Objectives: To describe the profile of children diagnosed with PRDs and monogenic causes explored on them at a tertiary care center in Nepal during 2020-2022.

Methods: Case records of patients diagnosed with PRDs during Aug 2020-November 2022 were analysed. The lead author (DB) collated data from all patients. Diagnosis and treatments were based on internationally acclaimed guidelines. Genotyping was done by whole exome sequencing and/or sanger sequencing.

Results: The availability of subspecialists, diagnostics, and therapeutics has shifted the paradigm of PRDs in developing countries. A total of 454 patients with PRDs were diagnosed. Mean duration from initial presentation to diagnosis was 12.5 months. Juvenile idiopathic arthritis (JIA) (including systemic JIA) (n = 131), connective tissue disorders (n = 113) and vasculitides (n = 104) constituted the largest proportion of PRDs. Arthritis related to infection was observed in 42 cases whereas autoinflammatory disorders were diagnosed in 29. Monogenic causes were detected in 19 patients (Table 1). Majority were of non-inflammosome related conditions. Causative genes were CECR1, ARPC1B, TNFAIP3, NLRP3, TNFRSF1A, MVK, PSTPIP1, NOD2, NLRP3, STX11, TNFRSF6, XIAP, BMPR2, PIK3CD, CTLA4, GATA2, and C1QA. Clinical features included recurrent fever, rashes, edema, lymphadenopathy, arthritis, vasculitis, ear and ocular issues, organomegaly, and various multisystemic symptoms. Treatment of polyarteritis nodosa with mycophenolate mofetil and idiopathic calcinosis with methotrexate and pamidronate were notable reports from our cohort. Oligoarthritis in X-linked agammaglobulinemia was a peculiar finding. One child with the monogenic PRD has undergone hematopoietic stem cell transplantation.

Conclusion: We present first and largest cohort of PRDs from Nepal. Noticeable number of unique monogenic causes of PRDs were diagnosed for the first time in the country. There are significant challenges in diagnosis and treatment of PRDs in resource-limited settings. Various socioeconomic and environmental factors coupled with lack of awareness, fewer referrals, and inexpedient treatment accounted for a late presentation, missed diagnosis, increased morbidity, disability, and mortality.
