Conclusion: These results demonstrated similar responsiveness to secukinumab with reduced joint sets as the validated GLOESS, supporting the development of a scoring system with reduced number of joint evaluations that would increase feasibility by reducing the assessment time. Further studies are needed to confirm the validity and utility of the reduced joint set ultrasound scores in other PsA cohorts.

Background: Psoriatic arthritis (PsA) is characterized by inflammatory arthritis, enthesitis, dactylitis, and spondylitis. Apremilast is an oral immunomodulating phosphodiesterase-4 inhibitor approved for the treatment of PsA. The impact of apremilast on objective measures of inflammation and structural progression of PsA has not yet been characterized. Here, we evaluate the efficacy of apremilast 30mg BID (APR) on inflammation measured by dedicated MRI of the hand.

Objectives: To evaluate the efficacy of APR on inflammation and imaging outcomes and the safety profile of APR in this setting.

Methods: MOSAIC (NCT03783026) was a phase 4, multicenter, single-arm, open-label study in patients (pts) with active PsA (≥3 months but ≤5 years since diagnosis, meeting CASPAsr criteria for PsA) evaluating APR as monotherapy or in combination with stable methotrexate. Pts were treated with APR for 48 weeks and had MRI of the hand (contrast-enhanced) performed at baseline (BL), Week 24, and Week 48. All images were read and adjudicated by 2 experienced readers blinded to clinical information and time of acquisition. The primary endpoint was change from BL in the composite score of hand bone marrow edema (BME), synovitis, and tenosynovitis in fingers 2–5, as assessed by the PsA MRI Scores (PsAMRIS).

Results: A total of 122 pts enrolled and received APR. Mean age was 47 years, 55% were women, and mean duration of PsA was 1.9 years. The Full Analysis Set (FAS) included 98 pts evaluable for the primary endpoint (having BL and Week 24 data); 4 had major protocol deviations and 94 were evaluable as part of the per protocol (PP) population. The least-squares (LS) mean (95% CI) change from BL in the composite inflammation score of BME, synovitis, and tenosynovitis (cPsAMRIS) was -2.32 (-4.73, 0.09) at Week 24 and -2.91 (-5.45, -0.37) at Week 48 (Figure 1). In the PP population, the LS mean (95% CI) change from BL in the composite score at Weeks 24 and 48 indicated a significant reduction of disease activity (Figure 1). Significant improvements from BL were seen in total inflammation scores (BME + synovitis + tenosynovitis + periarticular inflammation) in the FAS (Figure 1). The structural outcome indicated by the total hand damage score, including bone erosion and bone proliferation in fingers 2–5, as assessed by the PsA MRI Scores (PsAMRIS), was Week 24. Total inflammation score, comprised of BME, synovitis, tenosynovitis, and periarticular inflammation in fingers, was also assessed. Structural progression was assessed by the total hand damage score (determined by bone erosion and bone proliferation in fingers 2–5). Subgroup analyses based on BL disease activity as measured by Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA) were performed for key endpoints.

Conclusion: Pts with PsA treated with APR had improvements in both clinical and objective MRI indices of inflammation assessed by PsAMRIS in the target hand at Week 24 and Week 48, confirming an effect of APR on clinical and inflammatory manifestations of PsA. Pts with NoDAD seemed to have
greater improvement from BL in MRI inflammation scores than pts with HDA. No significant structural progression was observed. These results offer important insights on the effect of apremilast in PsA and highlight the value of using MRI and PsAMRIS as measures of inflammatory disease activity and change following treatment.

(72% vs 57%, p=0.039) and W52 (80% vs 66%, p=0.037) and a greater ACR50 response rate at W100 (84% vs 47%, p=0.031), indicating patients with high levels of these biomarkers were more likely to achieve an ACR response. For patients with at least mild skin disease at baseline (BSA2>2% and IGA2.0), those in Cluster 1 demonstrated a higher PASI100 response rate at W100 than patients in Cluster 2 (71% vs 54%, p=0.046).

**Conclusion:** Patients with higher levels of baseline ECM biomarkers (Cluster 2) that correspond with greater peripheral joint inflammation demonstrated higher ACR20 and ACR50 response rates when treated with GUS, while patients with lower levels of these ECM biomarkers (Cluster 1) demonstrated higher rates of complete skin clearance (PASI100). These findings may provide a step towards patient stratification and precision medicine for guiding the use of biologic immunomodulatory treatments in patients with PsA.

**Background:** Though continuous composite measures of disease activity for psoriatic arthritis (PsA) assessment exist, abbreviated measures that are more feasible for screening in routine clinical practice are needed. The 3 Visual Analogue Scale (VAS) and 4 VAS scores were developed by abridging the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) Composite Exercise (GRACE) measure to be the first short multidimensional composite measure specifically for use in PsA routine clinical care. The measures were shown to have superior performance than several established composite measures using small datasets.

**Objectives:** To further test 3VAS/4VAS in observational and trial datasets, as GRAPPA members recommended.

**Methods:** This post-hoc analysis of the DISCOVER 1/2 and COSMOS studies used pooled data through week (W) 24 from all treatment groups across studies. The correlation of 3VAS/4VAS with Disease Activity Index for PsA (DAPSA), PsA Disease Activity Score (PASDAS), physician global assessment (PhGA), and patient GA (PtGA) was assessed with Pearson's correlation coefficient. Minimal Important Difference (MID) was assessed with 4 distribution-based methods (based on standard error of the measurement, effect size, reliable change index [RCI], and RCIclid). Minimal detectable change (MDC) was assessed with the standard formula: MDC = 1.96*sd*sqrt(1-ICC). Clinically relevant thresholds for low, moderate and high disease activity were estimated with receiver operating characteristic analysis and DAPSA (≤4, >4 ≤ ≤14, >14 ≤ ≤28, >28), PASDAS (≤1.9, >1.9 ≤ ≤3.2, >3.2 ≤ ≤5.4, >5.4), and PhGA/PtGA (≤1, >1 ≤ ≤3, >3 ≤ ≤6, >6cm) as anchors.

**Results:** 1405 patients were included, of whom 51.3% were male, with a mean (SD) age of 47.1 (11.6) and PsA duration of 6.4 (6.5) years. At baseline, the mean (SD) 3VAS, 4VAS, DAPSA, PASDAS, PhGA, and PtGA scores of 6.4 (1.6), 6.3 (1.6), 45.8 (20.2), 6.5 (1.1), 6.5 (1.6), and 6.7 (2.0), respectively, reflected high levels of disease activity. Through W24, both 3VAS and 4VAS showed very strong correlation with PtGA (r3VAS=0.92, r4VAS=0.94) and PASDAS (r3VAS=0.81, r4VAS=0.82), strong with PhGA (r3VAS=0.77, r4VAS=0.74), and moderate to strong with DAPSA (r3VAS=0.59, r4VAS=0.61). Calculated MIDs were 0.9 (range: 0.7-1.3 across methodologies) for 3VAS and 0.9 (range: 0.6-1.3) for 4VAS (Table 1). MDC estimates were 3.3 (range 2.1-4.2 across follow-up intervals) for 3VAS and 3.2 (range 2.0-4.0) for 4VAS. Cut-off values for low, moderate, and high disease activity were 2.0, 3.4, and 4.9 for 3VAS and 2.1, 3.5 and 5.1 for 4VAS, respectively (Figure 1).

**Conclusion:** Using a large pooled clinical trial dataset of patients with active PsA, we have calculated clinically relevant thresholds for improvement and disease activity for 3VAS and 4VAS. These estimates are generally comparable to those previously reported and can be used to set treatment targets and screen disease activity in routine care when resources are limited or during remote patient monitoring.

Methods: PsTs with active PsA despite standard therapies (D1: ≥3 swollen/tender joint counts [SJC/TJC], CRP ≥0.3 mg/dL, ~30% with prior TNFi; D2: ≥3 SJC/TJC, CRP ≥0.6 mg/dL, biologic-naïve) were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W, or placebo. Ph/Pt agreement was defined as a difference of 15% PhGA-PtGA≥15. Determinants of PhGA exceeding PtGA by ≥15 (PhGA>PtGA) and PtGA exceeding PhGA by ≥15 (PtGA>PhGA) among pts with PtGA/PhGA disagreement were assessed with the same logistic-regression model considering pt demographics, disease characteristics, and pt-reported outcomes (PROs). The effect of GUS on disease parameters identified as determinants of PtGA vs. PhGA disagreement was assessed with repeated measures mixed models adjusting for treatment group, baseline (BL) levels, prior TNFi use, and BL DMARD use.

Results: At BL, mean (SD) SJC=11.5 (7.4), TJC=20.6 (13.3), FACIT-Fatigue score=29.9 (10.0), PtGA=66.9 (19.9), and PhGA=64.8 (15.9) were consistent with moderate to high disease activity. Agreement between PtGA and PhGA was seen in most instances (61.2%); 23.2% of cases were characterized by PtGA>PhGA and 15.7% by PhGA>PtGA. The proportion of pts with PtGA>PhGA increased to 39.1% at W24, while that with PhGA>PtGA decreased to 11.2%. The main determinant of PtGA>PhGA was higher Pt Pain (all time points); additional factors included worse physical health-related quality of life at BL and worse fatigue at W24 (Table 1). Conversely, Phs emphasized objective disease measures, namely higher SJC (all time points) and TJC (W8 to W24), and elevated CRP (BL to W16). GUS treatment was associated with prompt and sustained significant improvements in all identified determinants, including those driving PtGA>PhGA (Figure 1).

Conclusion: PtGA and PhGA were aligned in most encounters. PtGA>PhGA was driven by pain, fatigue, and physical health being weighed more by Pts than Phs. These findings have important implications in shared decision making and highlight the need to prioritize treatments addressing the full spectrum of PsA symptoms, including PROs.

Background: Bimekizumab (BKZ), a monoclonal IgG antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has shown superior efficacy to 16 weeks (wk) vs placebo (PBO) and tolerability in patients (pts) with active psoriatic arthritis (PsA) in the phase 3 BE OPTIMAL and BE COMPLETE studies.

Methods: BE COMPLETE (NCT03986581) included a 16-wk double-blind, PBO-controlled period. Wk 16 completers were eligible for entry into BE VITAL (NCT04009499; open-label extension). BE VITAL included pts from BE OPTIMAL and BE COMPLETE; data here are for pts randomised at baseline (BL) [Wk 0] of BE COMPLETE only, up to 1 yr. Pts were randomised 2:1 to subcutaneous BKZ 160 mg every 4 wks or PBO. At Wk 16, PBO pts switched to BKZ (PBO/BKZ; received 56 wks of BKZ treatment up to Wk 52). Efficacy data reported are observed case or using non-responder imputation (binary) or multiple imputation (continuous).

Results: 388/400 (97.0%) pts completed Wk 16; 377 (94.3%) entered Wk 52. Improved efficacy responses with BKZ treatment were maintained from Wk 16 to Wk 52 (Table 1). At Wk 52, 51.7% BKZ and 40.6% PBO/BKZ pts achieved American College of Rheumatology (ACR)50. In pts with BL psoriasis (≥3% body surface area), 65.9% BKZ and 60.2% PBO/BKZ pts achieved Psoriasis Area Severity Index (PASI)100 (complete skin clearance) at Wk 52 (Figure 1). At Wk 52, 47.2% BKZ and 33.1% PBO/BKZ pts achieved minimal disease activity (MDA). To Wk 52, 243/388 (62.6%) pts achieved minimal disease activity (MDA). At Wk 52, 51.7% BKZ and 33.1% PBO/BKZ achieved ACR50. In pts with TNFi-IR, BKZ demonstrated sustained clinical efficacy from Wk 16 up to Wk 52. The safety profile was consistent with previous reports.[1–3]

Figure. ACR50 and PASI100 responses over time to Wk 52 (NRI and OC)
post-marketing surveillance (PMS) safety data comprised of spontaneous and voluntary adverse event (AE) reports for tofacitinib have been published for RA and PsA.

**Objectives:** To further characterise the real-world safety profile of tofacitinib in RA and PsA.

**Methods:** AE reports were collected from 6 Nov 2012–6 Nov 2021 (RA) and 14 Dec 2017–6 Nov 2021 (PsA) from the Pfizer safety database. Tofacitinib was approved in the US for RA on 6 Nov 2012 (immediate release [IR]) and 24 Feb 2016 (extended release [XR]), and for PsA on 14 Dec 2017 (IR and XR). Safety endpoints included AEs, serious AEs (SAEs), AEs of special interest (AESIs) and fatal cases. Pt years (PY) of exposure were estimated from IQVIA commercial sales data from 61 countries and 1 region. Number (N), frequency and reporting rates (RR; number of events/100 PY of estimated exposure) for each endpoint were summarised by indication (RA/PsA) and formulation (IR [5 or 10 mg twice daily], XR [11 mg once daily] or all tofacitinib [IR+XR]). A sensitivity analysis truncated the analysis period to the first 4 yrs post approval for RA (2012–16), to align with the duration of PsA data.

**Results:** Of the 73 525 case reports (68 131 RA/5394 PsA), 4239/368 (6.2%/6.8%) did not report a formulation and were excluded. Most AE reports were for females (RA: 81%/PsA: 71%); around half were submitted by healthcare professionals (49%/63.1%) and the majority were from North America (80.1%/82.3%). Almost all RA reports (RA/PsA: 93%/97%) originated from North America (IR reports: 72.3%/68.6%). For both indications, the RR for AEs was higher with XR vs IR; RR and frequency of SAEs, AESIs and fatal cases were mostly similar between XR and IR (Table 1). The most frequently reported AEs in RA and PsA by Preferred Term included drug ineffective, pain, condition aggravated, headache and arthralgia (Figure 1). Off label use was more frequently reported in PsA than RA (Figure 1). In the first 4 yrs post approval of the IR formulation for RA (IR/XR: 49 439/2000 PY), AEs, SAEs and fatal cases RRs were 95.9/147 .0, 19.1/24.5 and 0.4/0.4, respectively.

IR: immediate release; XR: extended release; Py: patient year

**Discussion:** To describe the clinical course and predictors for achieving Minimal Disease Activity (MDA) in PsA patients starting DMARDs in a real-world setting, Methods: PsA patients were enrolled in SIRENA (Clinicaltrials.gov identifier NCT03131661), an Italian Registry of Spondyloarthritides (SpA) patients classified according to ASAS criteria and naive to any DMARDs for SpA [1]. Clinical data were collected at baseline and every 6 months up to the 24-month observation period. Predictors of 6-month MDA were identified through univariate and multivariate analyses.

**Results:** Of 350 SpA cases, 203 patients received a diagnosis of PsA (at baseline: mean age 51.2 years; men 51.7%; newly diagnosed 73.3%; time to diagnosis <24 months 68%; mainly axial 4.4%; monarticular/oligoarticular/polychartric 9.9/3.5/48.8%; active skin psoriasis 84.3%; enthesis 38.5%; dactylitis 24%; nail psoriasis 39.7%). At baseline, 100/203 patients (49.3%)...
were prescribed conventional DMARDs, 50 (24.6%) biological DMARDs and 27 (13.3%) other systemic treatments, mostly non-steroidal anti-inflammatory drugs. During the 2-year observation period, 79 patients (38.9%) started the first biologic after a conventional DMARD with a median time of 6.6 months and a second biologic after 10.0 months. Clinical and Patient Reported Outcomes markedly improved overtime (Table 1). MDA was achieved by 102/158 patients (64.6%) at least once in the observation period (median time to first MDA according to Kaplan-Meier: 10 months) and by 65/150 patients (43.3%) at 6 months. In univariate analysis, female gender, Body Surface Area (BSA) <3% and higher scores in Health Assessment Questionnaire-Disability Index (HAQ-DI) were associated with a decreased odds ratio of reaching MDA at 6 months while mono-oligoarticular involvement, newly PsA diagnosis and lower Disease Activity in Psoriatic Arthritis (DAPSA) score were associated with an increased odds ratio (Figure 1). Smoking, alcohol, presence of enthesitis/dactylitis/nail psoriasis, Disease Activity Score-28 (DAS-28), number of comorbidities, body mass index and patient VAS global assessment (PtGA) were not significantly associated with 6-month MDA achievement. In multivariate analyses no factor was identified as significant predictor of MDA at 6 months.

Conclusion: In an early PsA population, treatments with predominantly conventional DMARDs and biologics markedly improved disease outcomes, with 43% of patients achieving MDA at 6 months. Female gender, BSA <3% and higher HAQ-DI scores were associated with a decreased odds ratio while new PsA diagnosis, mono-oligoarticular involvement and lower DAPSA score were associated with an increased odds ratio for 6-month MDA.

Figure 1. Heterozygous p.E148Q in cis with p. M694I potentiates the effect of p.M694I in response to TcdB

HEK293T cells stably expressing ASC EGFP and transiently co-transfected with mCherry tagged wt pyrin, p.M694I and p.E148Q-M694I then stimulated with TcdB. FACs analysis revealed a statistically increased ASC speck formation for cells expressing the p.E148Q variant compared to the WT allele and for cells co-expressing p.E148Q in cis of p.M694I and the WT allele (E148Q cis M694I) compared to the cells expressing p.M694I pyrin (M694I heterozygous). Data are pooled from 4 independent experiments. Error bars represent mean ± SEM. Statistics used is the paired Student t-test. **P<0.01, ns; non-significant. Het =heterozygous, Hom.=homozygous.
tested in HEK293T cells stably expressing the adaptor protein apoptosis-as-
associated speck-like (ASC) which were analysed by flow cytometry to visualise
inflammasome formation, with and without stimulation by Closstridium difficile
toxin B (TcdB). Inflammasome dependent cytokine secretion was also quantified
by ELISA of supernatants from THP-1 cells transduced with lentiviral expression
vectors.

Results: In AADRY, we observed the p.E148Q allele in individuals with autoin-
flammatory diseases alone or in conjunction with other pyrin variants. Two FMF
families harbored the allele p.M694I-E148Q in cis with dominant heritability. In
vitro, p.E148Q pyrin could spontaneously potentiate inflammasome formation,
with increased IL-1β and IL-18 secretion. p.E148Q in cis to classical FMF muta-
tions provided significant potentiation of inflammasome formation.

Conclusion: The p.E148Q variant in pyrin potentiates inflammasome activation
in vitro. In cis, this effect is additive to known pathogenic FMF mutations. These
observations may help to explain the association of p.E148Q with FMF and other
inflammatory diseases.

Methods: Sera from 103 AOSD patients (treatment naïve, on treatment, and patients who previously failed several bDMARDs) and were involved in CONSIDER clinical trial (n=30)) were analysed. These were compared to Systemic Juvenile Idiopathic Arthritis (JIA, n=14), Cryopyrin Associated Periodic Syndrome (CAPS, n=9), Sjögren’s syndrome (n=10) and Familial Mediterranean Fever (FMF, n=27) patients. Extracellular NLRP3-derived ASC specks were identified using flow cytometry (positive for ASC-PE and NLRP3-APC), gating for events around 1μm in size, in sera. To determine if ASC/NLRP3 speck levels provide additional biological information, the correlation between the specks and known biomarkers (such as IL-18 and CRP) and cellular protein (CRP) were assessed in sera. This involved cytokine profiling, using 13-plex Inflammatory LEGENDplex assay and high-sensitivity CRP ELISAs. Deep whole exome sequencing (WES x100) (analysis restricted to autoinflammatory panel) was carried out on DNA from the 30 CONSIDER trial patients.

Results: In sorological analyses, extracellular ASC/NLRP3 speck levels were increased in AOSD patients compared to 32 healthy control (HC) sera (p<0.01, Figure 1A). ASC/NLRP3 levels defined three subgroups of AOSD patients (low, moderate and high). High ASC/NLRP3 levels were present in all pre-treatment sera from CONSIDER trial patients (p<0.001), compared to HC, suggesting their role may be dependent on the stage of the disease process. Interestingly, these patients were still responsive to canakinumab, showing significant reduction in extracellular ASC/NLRP3 levels in CONSIDER clinical trial cohort (baseline to week 12), compared to placebo (p<0.01) (Figure 1B) [1]. There was no correlation between ASC/NLRP3 specks and CRP levels (Figure 1C) or ASC/NLRP3 and total IL-18. No germline or somatic variants in NLRP3 were identified from patients in the CONSIDER cohort despite very high levels of ASC/NLRP3 specks being detected in their serum.

Conclusion: This study involved development of an assay that quantifies extracellular ASC/NLRP3 specks as a biomarker for disease etiology, to improve disease diagnosis and classification of SAIDs, particularly those with sporadic or unknown causes, such as AOSD. Increased levels of extracellular NLRP3-derived ASC specks were found in sera of AOSD compared to HC and autoinflammatory disease controls. Our findings also demonstrate heterogeneity within AOSD cohorts, with high-ASC speck levels in therapy-resistant CONSIDER trial patients suggesting the role of ASC specks may be dependent on the particular stage of the disease. Further analysis of rare somatic variants in genes associated with myelodysplastic syndrome, another condition associated with elevated ASC/NLRP3 specks and systemic inflammation, is currently underway, since this may provide an alternative explanation for our findings.

Scientific Abstracts 351 05/13/23 4 Color Fig(s):0 20:17 Art: 08_EUROAB-2023-PT07-08
Patients affected by COVID-19, hospitalized in intensive care unit (ICU), showed higher levels of PD1 compared to not-ICU hospitalized patients and HDs (ICU COVID-19 vs not-ICU COVID-19, p= 0.02; HDs vs ICU COVID-19, p= 0.0006). PD1 levels were increased in AOSD patients with SS ≥1 compared to patients with SS=0 (p=0.028) and HD (p=0.048). PD1 stimulation increased the expression of CD206 in M2 monocytes-derived macrophages from both COVID-19 and AOSD patients (COVID-19 untreated vs PD1, p=0.0006; AOSD untreated vs PD1 p=0.0234), whilst PD1 did not affect CD80 expression in both M1 and M2 macrophages and CD206 expression in M1 macrophages. A significant increase of both IL-10 and macrophage inflammatory protein (MIP-1β) was observed in M2 macrophages from COVID-19 patients after PD1 stimulation (IL-10, p= 0.03; MIP-1β, p= 0.003); the same results were found in AOSD patients (IL-10, p= 0.03; MIP-1β, p= 0.03).

Conclusion: PD1 can induce pro-resolutive programs in both AOSD and COVID-19 increasing M2 polarization and inducing their activity. PD1-treated M2 macrophages from AOSD and COVID-19 patients increased the production of IL-10, thus promoting anti-inflammation, and enhanced homeostatic restoration through M1→M2 production.

IMPLICATION OF THE CSF1-CSF1R PATHWAY IN THE CROSSSTALK BETWEEN SYNOVIAL FIBROBLASTS AND MACROPHAGES IN PIGMENTED VILLONODULAR SYNOVITIS

Keywords: Synovium, Innate immunity, Rare/orphan diseases

R. Dalilatona, J. De Lima, F. Blanchard, B. Le Gott, Nantes Université, INSERM, Regenerative Medicine and Skeleton, RMes, UMR 1229, nantes, France, University Hospital of Nantes, Rheumatology, Nantes, France

Background: Pigmented villonodular synovitis (PVNS) is a rare joint disease with an estimated incidence of 14 per million per year, arising from synovia that results in a secondary inflammatory joint response, pain and destruction. PVNS is associated with abnormal fibroblastic cells, often involving a specific chromosomal translocation, t(1;2) (CSF1;COL6A3), resulting in the overexpression of colony-stimulating factor 1 (CSF1) or M-CSF, recruitment of CSF1 receptor (CSF1R) macrophages and fusion in giant cells. Despite therapeutic option such as surgery, the risk of recurrence of the synovitis remains high (50%). This has led to the development of systemic therapies targeting the CSF1 pathway (kinase inhibitors such as Imatinib, monoclonal antibodies) that have shown their efficacy is about 30% of patients but with significant and sometimes serious adverse effects. Therefore, there is currently a clear medical need to improve the management of patients with PVNS.

Objectives: To better decipher the mechanisms leading to the development of PVNS and study the crosstalk between synovial fibroblasts and macrophages in this disease.

Methods: Synovial tissue from newly diagnosed PVNS (diffuse or localized forms) patients was used for this analysis. Histology and staining and immunohistochemistry was performed. Single cell analysis was performed on 5 patients. We implemented a primary culture of synovial fibroblasts from PVNS biopsies stimulated with pro-inflammatory cytokines. We studied the effect of culture supernatant on blood derived monocytes/macrophages.

Results: Immunohistochemistry revealed the presence of synovial PDPN+ fibroblasts, CD31+ endothelial cells, Ki67+ proliferating cells, MERTK+ and CCR2+ infiltrating the tissues. We performed single-cell RNA sequencing (n=5 patients). Combined with public scRNAseq datasets, we observed that PVNS (n=8) lining PDNP+PRG4+ fibroblasts are the main sources and express higher levels of CSF1 than in osteoarthritis (OA, n=3) or rheumatoid arthritis (RA, n=4). All macrophage subsets (tissue resident TIMD4+ or LVE1+ or infiltrating inflammatory macrophages) highly express CSF1R that could explain their enrichment (2 folds, p<0.05), especially in the localized forms of PVNS. Ratio between fibroblasts and macrophages was increase in the diffuse forms of the disease. We next study the in vitro crosstalk between fibroblasts and macrophages. For this purpose, we analysed conditioned media (CM) from PVNS synovial fibroblasts (n=3). After treatment with TNFa or IL1b, enhanced secretion of CSF1 was observed and the CM had an enhanced capacity to sustain viability of blood derived monocytes/macrophages (2-3 folds, p<0.05). In this setting, the potent CSF1R inhibitor Imatinib totally reversed macrophage viability to baseline (p<0.05).

Conclusion: This study highlights the key role played by synovial fibroblasts and macrophages in PVNS pathogenesis. An inflammatory vicious cycle takes place between these two cell types, implicating CSF1-CSF1R. Efficient targeting of this pathway is the subject of current research and we already validated a PVNS mouse model using xenografted PVNS human biopsies that will be useful to study for example the local delivery of CSF1R kinase inhibitors or neutralizing antibodies.

JAK-INHIBITORS SUPPRESS IFN-DEPENDENT ANTIGEN PRESENTATION IN CDC42-HICD14+ CELLS

Keywords: Rheumatoid arthritis, Innate immunity, Disease-modifying Drugs (DMARDs)

R. Dalilatona, J. De Lima, F. Blanchard, B. Le Gott, Nantes Université, INSERM, Regenerative Medicine and Skeleton, RMes, UMR 1229, nantes, France, University Hospital of Nantes, Rheumatology, Nantes, France

**Background:** We have recently shown that Rho GTPase activation in macrophages results in arthritis development in mice. These macrophages show a tight interaction with T cells leading to suppression of cell homing and regulatory migration of thymic T regulatory cells to periphery contributing arthritis development[1].

**Objectives:** To translate findings in experimental arthritis to human RA, we explore the phenotype of CDC42+/CD14+ cells in blood and synovial tissue of RA patients and investigate how anti-rheumatic treatment intervene with the Rho GTPase-dependent molecular mechanisms of arthritis.

**Methods:** We used transcriptome (RNAseq) of CD14+ and CD4+ cells of 77 active RA patients naïve to TNF-inhibitors (TNFi) and of 59 inactive RA patients treated with methotrexate (MTX, n=18), TNFi (n=10) and JAK-inhibitors (JAKi, n=24), or having no DMARD treatment (n=7). In both cohorts, patients were stratified by mean expression of CDC42 in CD14+ cells to mimic activation of Rho GTPases. Differentially expressed genes (DEG) were identified by DESeq2 (nominal p<0.05). Transcriptomics of CD14+ and CD4+ cells were analyzed and translated into clinical correlates of inflammation and disease activity by DAS28. Additionally, we investigated a cluster of CDC42+ macrophages in synovial tissue (STM) using single cell RNAseq in 25 patients[2].

**Results:** In two independent sets, CDC42+/CD14+ cells were characterized by enrichment of DEG operating in the oxidative phosphorylation, proteasome activity and RNA transcription. Many DEG were under transcriptional control of IFN-γ, known to supervise those processes. DEG with strong correlation to CDC42 defined the metabolic signature (MetSig) of CDC42+/CD14+ cells, which summarized the expression of ATP5B, COX7A2, PSMB6, PSME3, GTF3C6, and GTF2E2. High MetSig recognized CD14+ cells enriched with MHC transcripts, components in peptide loading and expression of proteasome subunits. MetSig+CD14+ cells had high chemokine and cytokine production and migratory phenotype. Analyzing STM, we identified CDC42+/CD4+ with high MetSig expressing complete set of immunoproteasome genes, high levels of MHC receptors and peptide loading proteins. Additionally, this STM cluster was affected by IFN-γ. We experimentally confirmed that immunoproteasome expression in CD14+ cells was dependent on IFN-γ and not hypoxia, common at inflammation. Examining effect of antirheumatic treatment, we found CDC42+/CD14+ cells were infrequent (OR: 11.9, [3.4, 49.7], p<0.0001) and the MetSig reduced (p=0.004) in patients treated with JAKi compared to other DMARDs. Concurrently, CD14+ cells of those patients had low production of TNF-α, IL-6, IL-1β, CXCL8 and IL-10 (all, p<0.05), mRNA of immunoproteasome subunits, peptide loading proteins and MHC-II (including HLA-DRB1) were downregulated. Analysis of CD4+ cells of JAKi treated patients showed upregulation of TCR components and high expression of Rho GTPases. This indicated a disruption of CD4+/CD14+ interaction in the immunological synapse. To investigate a direct effect of JAKi on the MetSig genes and immunoproteasome, we treated CD14+ cells cultures with tofacitinib. JAKi upregulated NFE2L1 and decreased expression of the immunoproteasome subunits, but expression of MetSig remained unchanged. Lastly, we investigated connection between the MetSig and RA disease activity (by DAS28) in a regression model. The model identified patients, which had a strong dependence between these parameters. At bottom of the model were patients with low DAS28 and MetSig, mostly treated with JAKi. Consequently, patients at the upper part may represent suitable candidates for JAKi-treatment.

**Conclusion:** This study demonstrates that CDC42-related metabolic signature identifies antigen-presenting CD14+ cells that migrate to joints to coordinate autoimmune. JAKi suppress the antigen presenting capacity of CD14+ cells. The MetSig in CD14+ cells is the drug of choice for treatment of RA, our studies exert a certain degree of caution, as MTX in an enhanced pro-oxidant milieu facilitated generation of oxidative stress, and could impact on disease progression.

Background: The factors contributing to the efficacy of abatacept in patients with rheumatoid arthritis (RA) remain unknown.

Objectives: We aimed to identify cellular, transcriptomic, and proteomic features that predict responses or resistance to abatacept.

Methods: Blood samples were collected from 22 RA patients treated with abatacept at the initiation and after three months of treatment. Response to treatment was defined based on the EULAR response criteria, and seven patients were classified as responders and the others as non-responders. We quantified gene expression levels in peripheral blood mononuclear cells (PBMCs) by RNA-Seq, measured concentrations of 67 plasma protein levels by multiplexed immunoassay, and the expression of sur-

Results: Among the clinical characteristics, the number of monocytes was significantly higher in the non-responders before treatment (p = 0.01). Regarding the transcriptome data, we found 952 differentially expressed genes (DEGs) between the responders and the non-responders before treatment initiation. A cell-type enrichment analysis showed that the DEGs were enriched in mono-
cytes (p = 8.7 × 10^{-212}, Figure 1A). Additionally, gene set enrichment analysis showed enrichment in the gene module, including MYD88 and TIRAP, with the strongest significance among all of the pathways tested. When we estimated the expression of MYD88 and TIRAP in monocytes by deconvolution analysis, the non-responders had higher expression before treatment initiation (p = 0.04 and 0.03, respectively). Among the 67 protein levels, two exhibited a correlation with the expression of the module (p < 0.05). Of these, hepatic growth factor (HGF), which is produced by monocytes, was present at significantly higher concentrations in non-responders before treatment (p = 0.02). The analysis of the replication sets identified 1,695 DEGs. These were also enriched for the genes expressed in monocytes (p = 2.9 × 10^{-6} Figure 1B) but not for the module detected in the current study. Among the DEGs, those expressed in monocytes were enriched for the genes involved in the aerobic electron transport system in mitochondria based on gene set enrichment analysis.

Conclusion: Monocyte-derived transcriptomic features before treatment under-
lay the differences in abatacept efficacy. The pathway activated in monocytes was the MYD88/TIRAP-HGF axis in the current study, but that pathway in the replica-
sion set was the aerobic electron transport system. Overall, our results highlight the contribution of monocytes as the cells responsible for abatacept-treatment resistance and the heterogeneity of activated pathways within them.

[3] Demierre, C. et al. Pre-silencing of genes involved in the electron trans-

Aknowledgements: This study was received funding from Astellas Pharma Inc.
Objectives: The objective of this study was to evaluate the importance of direct mechanisms on antigen-presenting cells and identify biomarkers of the response to Abatacept.

Methods: Sera (n = 71) and RNA from whole blood (n = 57) were collected from RA patients before treatment by ABA. Abundance of GM-CSF, gamma interferon (IFNg), IL-10, IDO, iNOS were quantified using ELISA and addressable laser bead assay (ALBIA). RT-qPCR was performed on IDO1 transcript. Response to ABA was assessed 6 months after its introduction, using EULAR response criteria. A costimulation in vitro model was developed: monocytes-derived macrophages (using GM-CSF or M-CSF) from healthy donors were polarized 8 days with LPS, with or without IFNg. T cells were cocultured with anti-CD3, with or without ABA, anti-CD28 antibodies or IDO inhibitor (1-MTDT). Proliferation was assessed using CFSE.

Results: Before ABA therapy, GM-CSF, IFNg and IL-10 in sera were increased in serum of good responders compared to non-responders. Our costimulation model showed that in macrophages exposed to GM-CSF, IFNg, LPS, ABA inhibited lymphocyte proliferation by 53%. Inhibition by ABA was only 10% when macrophages has not been exposed to IFNg, suggesting a central role of this cytokines. Furthermore, inhibition was only achieved when both GM-CSF + IFNγ were used, highlighting the need for a combination of these two factors. In presence of GM-CSF with IFNg + LPS + ABA, IDO was increased in macrophages. ABA increased IDO expression in macrophages when either IFNg or GM-CSF were not involved in their polarisation, neutralising IDO and leading to T cell proliferation. These results show a balance between IDO and IDO in macrophages, modulated by IFNγ and GM-CSF. In RA patients, ABA could release the tolerogenic potential of polarized macrophages, decreasing T cell proliferation. Accordingly, iNOS increased in non-responders sera after 6 months of ABA treatment while IDO1 expression increased in good responders whole blood RNA. In fact, in ABA responders, IDO increase in macrophages enabling a tolerogenic effect since iNOS is not induced.

CONCLUSION: Specific macrophage polarisation with IFNg and GM-CSF, leading to an increase in IDO production without increasing iNOS after treatment, could be the key to achieving a good response to ABA. This finding supports the macrophage-mediated action of ABA and may contribute to the development of a prediction system for abatacept response based on macrophage polarisation.

Background: Following LPS stimulation, extensive transcriptional and metabolic reprogramming leads to metabolic remodeling that allows macrophages to dynamically adopt to environmental cues.[1] A failure to accurately orchestrate macrophage responses can skew immune responses towards inflammation and various disease states.[2]

Objectives: Macrophages have a central role in Rheumatoid arthritis (RA) by promoting chronic inflammation and joint destruction. Although targeted biologicals have transformed treatment options for RA patients, almost half of them fail to achieve clinical remission[2]. Better understanding of the regulation of key immuno-metabolic pathways in macrophages of RA patients will inform on how cellular metabolism and inflammation interlink to identify novel metabolism-related therapeutic targets.

Methods: To delineate disease-specific effects in monocytes and macrophages derived from RA patients compared to healthy individuals we performed whole transcriptome analysis (RNA-Sequencing) and untargeted metabolomics. By integrating these datasets with metabolite assessment in the serum of RA patients, we found upregulation of Indoleamine 2, 3-dioxygenase 1 (IDO1) and accumulation of L-kyurenine (KYN) to be hindered in peripheral blood monocytes and macrophages derived from rheumatoid arthritis (RA) patients compared to healthy individuals in response to LPS.

Results: In macrophages, we identified accumulation of KYN in response to LPS to limit pro-inflammatory macrophage functions through tricarboxylic acid (TCA) cycle remodeling, characterized by decreased succinate-dehydrogenase (SDH) activity and increased Gluthathione synthesis. Aligning with these findings, kynurenic acid exerted anti-inflammatory effects when administrated to LPS-activated macrophages in vitro by limiting the production of Interferon gamma (IFNγ) and Tumor Necrosis Factor (TNF). Using the small molecule IDO1 inhibitor Linrozodast and exogenously added KYN we showed that KYN accumulation in response to LPS regulates the glycolytic switch and cumulation of metabolites associated with inflammation such as glycolytic intermediates and the TCA cycle intermediates Succinate and fumarate.

Conclusion: Collectively, our data highlight KYN as a key immunometabolite that directly interferes with macrophage activation and suggest that dysregulation of the kynurenine pathway in RA patients mediates inflammation and disease progression.

Everything you need to know about managing in axSpA

Keywords: Randomized control trial, Treat to target, Spondyloarthritis

C. López-Medina, F. Van den Bosch, D. Van der Heijde, M. Dougados, A. Moltó
Reina Sofia University Hospital, IMIBIC, University of Cordoba, Rheumatology Department, Cordoba, Spain; Université de Paris, Centre de recherche épidémiologie et bio statistique de Sorbonne Paris Cité, APHP, Hôpital Cochin, Service de rhumatologie, Paris, France; VIB Center for Inflammation Research, Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium; Leiden University Medical Center, Rheumatology, Leiden, Netherlands

Background: Despite the ASAS-HI (primary outcome) did not reach statistical significance in the TICOSPA trial, other clinically relevant secondary outcomes were numerically higher in the treat-to-target (T2T) strategy in comparison to Usual care (UC). In the ASAS-HI, there were no differences in the three axes have been considered to explain this observation: a lack of power, the risk of protocol violations in the T2T arm and the potential optimal care in the UC arm.

Objectives: a) To evaluate the proportion of patients (pts) with protocol violations in the T2T group during the 48 weeks (48W) of follow up as well as the impact and predictive factors of such violation; b) To compare the proportion of pts treated according to the ASAS/EULAR 2016 management recommendations for axSpA over the follow-up period in both arms.

Methods: Study design: pragmatic, prospective, cluster-randomized controlled, 48W trial (NCT03043846) with 18 participating centers. Inclusion criteria: Pts with a diagnosis of axSpA and fulfilling ASAS criteria, non-optimally treated with NSAIDs, bDMARD-naïve and ASAS ≥2.1. Study treatment regimens: SpA expert centers were selected to participate in the study; then, they were randomly allocated (1:1) to the treatment arms: a) T2T: the management strategy was pre-specified based on strict application of 2016 ASAS/EULAR axSpA recommendations (Q4W), with a target of ASAS ≥2.1; b) UC: treatment decisions at the rheumatologist’s discretion (Q12W). Statistical analysis: a) Protocol violations: in the T2T arm were evaluated at every visit by the question “Was the recommendation for treatment from last visit followed by physician and patient?”. Factors associated with at least one protocol violation over the study were evaluated using multivariate logistic regression. Outcomes at 48W were compared between T2T violators (T2T-V) vs. T2T non-violators (T2T-NV) vs. UC using ANOVA test; b) Optimal care in UC: proportion of pts treated according to the 2016 ASAS/EULAR recommendations over the follow-up period in both arms were compared.

Results: 160 pts initiated the trial (T2T:80 and UC:80). a) Protocol violations: In the T2T arm, 41/80 (51.2%) pts violated the protocol during at least one visit. A total of 27.7% violations were represented by a lack of switching to a second NSAID and 41.2% by a lack of initiation of a first bDMARD. Baseline predictive factors independently associated with the protocol violation were the country (France vs. others; OR 3.8 [95%CI 1.1-15.0]), female sex (OR 4.4 (1.5-15.1)), diagnosis delay ≤7 years (OR 3.4 (1.1-11.9)), HLA-B27 negative (OR 6.4 (1.6-32.2)) and CRP≥6mg/L (OR 4.2 (1.3-15.9)). After 48W of follow-up, T2T-NV vs. T2T-V showed similar ratios of ASAS-HI improvement. ASAS-DAS-LDA, ASAS-DID and ASAS-CII outcomes were more prevalent in T2T-NV vs. T2T-V, although these differences did not reach statistical significance (Table 1). b) Optimal care in UC: the proportion of pts managed according to the 2016 ASAS/EULAR recommendations was very high in both arms, i.e. always above 75% also in the UC arm, although no statistical differences were found (p=0.490) (Figure 1).

Conclusion: The prevalence of pts violating the protocol in the T2T arm was high, although it did not explain the non-significance of the primary outcome in the TICOSPA trial (ASAS-HI improvement). In contrast, the proportion of pts managed according to the ASAS/EULAR recommendations in the UC arm was very high, suggesting that the UC group was optimally treated.

BLOOD-BASED EXTRACELLULAR MATRIX BIOMARKERS CAN IDENTIFY ENDOTYPES OF PATIENTS WITH AXSPA AND RESPONDERS TO ADALIMUMAB TREATMENT

Keywords: Spondyloarthritis, Biomarkers

H. Porl, F. Christiansen, S. Holm Nielsen, P. Frederiksen, A. C. Bay-Jensen, M. Karsdal, I. J. Sørensen, M. Østergaard, S. Juhl Pedersen, University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark; Nordic Bioscience A/S, Immunoscience, Herlev, Copenhagen, Denmark; University of Copenhagen, Clinical Medicine, Copenhagen, Denmark; Rigshospitalet, Center for Arthritis Research, Glostrup, Denmark

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease associated with extracellular matrix (ECM) remodelling of the cartilage, bone, and connective tissues. Adalimumab (ADA) is an effective treatment, but not all patients respond, and this may relate to subtypes of the disease (endotypes). Serological quantification of ECM-mediated biomarkers may be useful to identify axSpA endotypes and monitor treatment response to ADA.

Objectives: 1) To identify endotypes of patients with axSpA using blood-based ECM biomarkers at baseline and 2) To investigate differences in response to ADA by BASDAI and ASAS criteria within the endotypes.

Methods: ECM biomarkers were measured in serum from patients with axSpA in the three studies (MASH (n=41), DANISH (n=49) and ASIM (n=45)) at baseline [1–3]. MASH was a cross-sectional study while in DANISH and ASIM patients were randomised to receive treatment with ADA 40 mg or placebo every other week (e.o.w.) for 6 or 12 weeks (ASIM and DANISH, respectively) followed by ADA 40 mg e.o.w. for an additional 18 or 12 weeks (ASIM and DANISH, respectively). Biomarkers of type II collagen formation (PROC2), type I collagen degradation (C1M), inflammation (CRP, CRPm) citrullinated and degraded vimentin (VICM) and neutrophil activity (CPAPm-HNE) were measured by immunoassays. Biomarker data was log-transformed, standardized by mean centering and scaled by the standard deviation prior to principal component analysis (PCA) and K-means clustering. Response to ADA based on BASDAI50 response, ASDAS clinical important improvement (CII) and major improvement (MI) at study week 24 was compared in the PCA components and between clusters using Mann-Whitney tests. Key demographic parameters were also compared between clusters using Mann-Whitney and chi-squared tests.

Results: The variability of baseline ECM biomarker data among patients with axSpA was mainly explained by two dimensions (PC1 and PC2). Type I collagen degradation and inflammation biomarkers (C1M and CRP), reflecting tissue inflammation, were the primary contributors to PC1, whereas type II collagen formation (PROC2), reflecting cartilage turnover, contributed the most to PC2 (Figure 1A). In ADA-treated patients, BASDAI50 responders, patients with
ASDAS CII, and ASDAS MI had a higher score in PC1 compared to BASDAI50 non-responders, patients with no ASDAS CII and no ASDAS MI, respectively (p=0.05, p<0.001, p<0.001). No differences were observed in PC2. Two distinct clusters were identified from the PC1 and PC2 (Figure 1). Patients in Cluster 1 had higher levels of ECM biomarkers, a greater BASDAI50 response compared to those in Cluster 2 (89.5% vs. 73.2%) and a higher % of patients with ASDAS CII and ASDAS MI (73.7% vs. 32.1% and 92 % vs. 73%, all p<0.05). No significant differences were observed in the demographic parameters between Clusters.

Conclusion: The PCA analysis identified two orthogonal dimensions related to: inflammation (driven by C1M and CRP) and cartilage turnover (driven by PGO-C). Two clusters were determined. Patients from Cluster 1, associated with high inflammation, demonstrated a greater BASDAI50 response and ASDAS improvement when treated with ADA than those from Cluster 2. These findings may help profiling treatment response within patients with axSpA.

REFERENCES:
Background: A history of enthesitis or peripheral arthritis has been reported in >30% of patients (pts) with axial spondyloarthritis (axSpA) [1], both of which contribute to disease burden. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated efficacy in phase 3 parallel studies in pts with non-radiographic (nr-)axSpA (BE MOBILE 1 and radiographic axSpA (r-axSpA i.e. ankylosing spondylitis; BE MOBILE 2). [2,3]

Methods: Pts in BE MOBILE 1 (NCT03928704; nr-axSpA) met Assessment of SpondyloArthritis International Society (ASAS) classification criteria, pts in BE MOBILE 2 (NCT03928743; r-axSpA) met both modified New York and ASAS criteria. Pts were randomised to receive subcutaneous BKZ 160 mg every 4 wks (Q4W). Among pts with enthesitis (Maastricht Ankylosing Spondylitis Enthesitis Criteria) and peripheral arthritis (Spondyloarthritis Research Consortium of Canada: Week) from PBO to BKZ at Wk 16, improvements continued to Wk 52 with continuous BKZ and in pts switching from PBO to BKZ at Wk 16 (Table 1). Across the axSpA spectrum, greater mean CfB in MASES was achieved with BKZ vs PBO at Wk 16; improvements continued to Wk 52 with continuous BKZ and in pts switching from PBO to BKZ at Wk 16 (Table 1). Across the axSpA spectrum, greater mean CfB in MASES was achieved with BKZ vs PBO at Wk 16; improvements continued to Wk 52 with continuous BKZ and in pts switching from PBO to BKZ at Wk 16 (Table 1). Among pts with enthesitis (Maastricht Ankylosing Spondylitis Enthesitis Criteria) and peripheral arthritis (Spondyloarthritis Research Consortium of Canada: Week) from PBO to BKZ at Wk 16, improvements continued to Wk 52 with continuous BKZ and in pts switching from PBO to BKZ at Wk 16 (Table 1). Among pts with enthesitis (Maastricht Ankylosing Spondylitis Enthesitis Criteria [MASES]>0), at least one swollen joint (SJC>0), or at least one tender joint (TJC>0) at baseline (BL), we report mean change from baseline (CfB) using multiple imputation (MI). Pts (%) achieving complete resolution of enthesitis (MASES=0 in pts with MASES >0 at BL) and peripheral arthritis (SJC=0 in pts with SJC >0 at BL, assessed in 44 joints) using non-responder imputation, is also reported.

Results: At BL, 73.2% nr-axSpA pts (BKZ: 94/128, PBO: 92/126) and 59.9% r-axSpA pts (BKZ: 132/221, PBO: 67/111) had enthesitis; peripheral arthritis (SJC >0) was present in 34.6% (BKZ: 45/128, PBO: 43/126) and 19.9% (BKZ: 44/221, PBO: 22/111) of nr-axSpA and r-axSpA pts, respectively. BL MASES, SJC and TJC were largely similar between treatment arms (Table 1). Across the axSpA spectrum, greater mean CfB in MASES was achieved with BKZ vs PBO at Wk 16; improvements continued to Wk 52 with continuous BKZ and in pts switching from PBO to BKZ at Wk 16 (Table 1). Similarly, >50% BKZ pts achieved complete resolution of enthesitis at Wk 16 vs <33% of PBO pts; by Wk 52, responses of PBO/BKZ-switchers approached those of BKZ pts (Figure 1). At Wk 16, greater mean CfB in SJC and TJC was achieved with BKZ vs PBO-randomised pts with nr-axSpA. Improvements largely continued to Wk 52 with BKZ for both continuous BKZ and PBO/BKZ-switcher pts (Table 1). Resolution of peripheral arthritis was achieved by >57% of BKZ vs <41% of PBO-randomised pts at Wk 16; by Wk 52, proportions were similar among continuous BKZ and PBO/BKZ-switcher pts (Figure 1).

Randomised set. *Assessed in pts with: **MASES >0 at BL; *PBO n=92; BKZ n=94; +PBO n=67; BKZ n=132; +SJC >0 at BL; *PBO n=43; BKZ n=45; +PBO n=22; BKZ n=44; +TJC >0 at BL; *PBO n=85; BKZ n=78; *PBO n=61; BKZ n=116. P values without any multiplicity adjustment are indicated as nominal p values and should not be used as an indicator of statistical significance.
Conclusion: BKZ treatment resulted in sustained improvements in peripheral manifestations across the axSpA spectrum. Resolution of enthesitis was achieved in ~half of BKZ-treated pts by Wk 52; a similar pattern was observed for peripheral arthritis, with more than half of pts achieving resolution to Wk 52.

Keywords: bDMARD, Inflammatory arthritides, Tapering

Methods: BIODOPT was designed as a pragmatic, multicentre, randomised controlled, open-label trial (EudraCT 2017-001970-41) of 18 months duration [1]. Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) in sustained (≥12 month) low disease activity (LDA) and treated with TNFi at baseline were enrolled and randomised into a disease activity-guided tapering or control in a 2:1 ratio. Blood samples at baseline and month 18 were analysed for TNFi drug levels. Based on previous research, the TNFi drug level category was considered intermediate if values were between: adalimumab 5.0-8.0 mg/L, certolizumab pegol 14.7-40.0 mg/L, etanercept 1.8-4.6 mg/L, golimumab 1.0-3.0 mg/L, or infliximab 1.6-5.0 mg/L. Values greater or lesser were considered as high or low TNFi category, respectively. A mixed Poisson regression with robust variance estimator was used for the analyses on TNFi categories; missing data were imputed as low TNFi category.

Results: Of 129 TNFi-treated patients, 88 were randomised to tapering and 41 to a control arm with standard care. Blood samples at baseline and month 18 were available for: tapering group 89% (78/88) and control group 90% (37/41). As expected, baseline TNFi categories were comparable between groups as presented in Table 1. At 18 months, fewer patients in the tapering group were in the high TNFi category, relative risk: RR: 0.53 (95% CI 0.31 to 0.90, P=0.02), even though more patients in the tapering group were in the low TNFi category, relative risk: RR: 0.27 (95% CI 0.16 to 0.43, P=0.03). The observed changes in TNFi categories between groups from baseline to month 18 based on data from the BIODOPT trial. To compare TNFi drug-levels in the tapering group, relative to the control group, from baseline to month 18 on data from the BIODOPT trial.

Table 1. TNFi drug level categories at 18 months.

<table>
<thead>
<tr>

</tbody>
</table>

Even though more patients in the tapering group were in the low TNFi category, relative risk: RR: 0.53 (95% CI 0.31 to 0.90, P=0.02), Table 1. Even though more patients in the tapering group were in the high TNFi category, relative risk: RR: 0.53 (95% CI 0.31 to 0.90, P=0.02). The observed changes in TNFi categories between groups from baseline to month 18 indicates acceptable compliance to the trial interventions. At 18 months, 32% (28/88) in the tapering group and 0% (0/41) in the control group had achieved ≥50% dose reduction of their TNFi and were in LDA. The majority of patients in the tapering group were in the high (41%) or intermediate (39%) TNFi category at baseline; only 22% (6/28) were in the low TNFi category. This indicates a greater chance of successful tapering for patients with high or intermediate TNFi drug levels at baseline. Even though more patients in the tapering group were in the high TNFi category at 18 months; thus indicating acceptable compliance to the trial interventions. Further research is needed for the implications of therapeutic drug monitoring in the management of rheumatic diseases.

European Spondyloarthritis Research Collaboration Network (EuroSpA RCN), on behalf of SRQ, DANBIO, ATTRA, TURKBIJO, NOR-DMARD, SCOM, Reuma.nu, ROBFIN, RRBR, biorx.si, ICEBIO, AmSpA, BIOBADASER, GISEA, and BSRBR-AS, Copenhagen, Denmark

Background: Women with axial spondyloarthritis (axSpA) tend to have higher scores on patient-reported outcome measures (PROMs), such as the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Bath Ankylosing Spondylitis Functional Index (BASFI), compared to men with the same condition. However, it is not well known whether these sex differences are maintained over time during treatment with tumor necrosis factor inhibitors (TNFi), or which factors can potentially explain these sex-based differences.

Objectives: To examine sex differences in BASDAI and BASFI over time in axSpA patients treated with their first TNFi, and to identify potential factors contributing to observed sex differences.

Methods: Pooled data were collected from biologic-naive axSpA patients initiating their first TNFi in the EuroSpA registries. A three-level linear mixed model structure was employed to analyze sex differences in PROMs (BASDAI and BASFI, scale 0-100) over time (sex*time), accounting for correlations between repeated measurements within subjects and between subjects within countries. Baseline characteristics were explored as potential explanatory variables for observed sex differences over time, and interactions between sex, time, and explanatory variables were analyzed. Univariable analysis was performed by incorporating one explanatory variable at a time, while multivariable analysis was used to investigate the effect of multiple explanatory variables on the regression coefficient of sex*time. Only explanatory variables that affected this regression coefficient by more than 10% in univariable analysis were considered for multivariable analysis. A complete case analysis was performed when data were missing for explanatory variables.

Results: This study analyzed data from 11,753 axSpA patients (37% female) with at least two BASDAI measurements over two years, and from 9,780 patients (38% female) with at least two BASFI measurements over the same period. At baseline, women were older and had higher BASDAI/BASFI scores, while men had higher CRP levels, longer disease duration, and higher HLA-B27 positivity. During the follow-up period, women had significantly higher mean BASDAI scores than men (mean difference 6.05; 95% CI 5.27 to 6.83). Additionally, the differences in BASDAI scores between women and men increased by an average of 0.67 (95% CI 0.04 to 1.29) per year. These findings indicate that the sex differences in BASDAI scores persisted and increased over time. In the univariable analysis of explanatory variables, increased age (-8.9%) and longer disease duration (-4.7%) notably explained the sex differences in the BASDAI scores (Figure 1). However, no explanatory variables were eligible for inclusion in the multivariable analysis. We also observed that the sex differences in BASDAI scores were reduced over time in HLA-B27-positive patients, but increased in those with psoriasis (Figure 1). Although women had slightly higher overall BASFI scores than men (mean difference 3.25; 95% CI 2.32 to 4.19), this difference did not vary by time (β = 0.25; 95% CI -0.36 to 0.86).

Conclusion: Women with axSpA treated with their first TNFi had significantly higher mean BASDAI and BASFI scores compared to men over a two-year follow-up period. The mean difference in BASDAI scores increased slightly over time, and the magnitude of this difference was affected by HLA-B27 positivity (reduced) and psoriasis (increased). Further research is needed to understand the mechanisms behind these sex differences and their clinical implications.

Background: Upadacitinib (UPA), a Janus kinase inhibitor, was effective and well tolerated in patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) through 14 weeks (wks) of treatment.1

Objectives: This analysis assessed the efficacy and safety of UPA vs placebo (PBO) through 1 year.

Methods: The SELECT-Axis II nr-axSpA study included a 52-wk randomized, double-blind, PBO-controlled period. Enrolled adults had a clinical diagnosis of active nr-axSpA fulfilling the 2009 ASAS classification criteria, objective signs of inflammation based on MRI sacroiliitis and/or elevated C-reactive protein, and an inadequate response to NSAIDs. One-third of pts had an inadequate response to biologic DMARDs. Pts were randomized 1:1:1 to UPA 15 mg once daily or PBO. Concomitant medications, including NSAIDs, had to be kept stable through wk 52. The study protocol outlined that pts who did not achieve ASAS20 at any consecutive study visits within wks 24 to 52 should receive rescue therapy, with NSAIDs, corticosteroids, conventional synthetic/biologic DMARDs, or analgesics. Cochran-Mantel-Haenszel (CMH) test with non-responder imputation incorporating multiple imputation (NRI-M1) was used to handle missing data and intercurrent events for binary efficacy endpoints. Mixed-effect model repeated measures (MMRM) was used to assess continuous efficacy endpoints. NRI was used for binary endpoints after rescue and as observed analysis excluding data after rescue for continuous endpoints. Treatment-emergent adverse events (TEAEs) are reported through wk 52.

Results: Of the 314 pts randomized 259 (82%; UPA, n=130; PBO, n=129) completed wk 52 on study drug. More pts achieved an ASAS40 response with UPA vs PBO from wks 14 to 52 with a 20% treatment difference at wk 52 (63% vs 43%; nominal P <.001; Figure 1). The proportion of pts achieving ASAS50 inactive disease with UPA remained higher than PBO at wk 52 (33% vs 11%; nominal P <.001; Figure 1). Consistent improvements and maintenance of efficacy were also seen across other disease activity measures. Between wks 24 and 52, fewer pts on UPA (9%) than on PBO (17%) received rescue therapy. A similar proportion of pts in each treatment group had a TEAE (Table 1). Infections were the most common TEAE; the rates of serious infections and herpes zoster were higher with UPA vs PBO, although no new serious infections were reported from wks 14 to 52. COVID-19 events were balanced between treatment groups. No opportunistic infections, malignancy excluding non-melanoma skin cancer, adjudicated major adverse cardiovascular events, inflammatory bowel disease or deaths were reported. Two pts (1.3%) on PBO had adjudicated venous thromboembolic events.

Conclusion: UPA showed consistent improvement and maintenance of efficacy vs PBO through 1 year across multiple disease activity measures. No new safety risks were identified with longer-term UPA exposure. These results continue to support the benefit of UPA in pts with active nr-axSpA.

*dBoth patients had non-serious events of deep vein thrombosis in the lower limb with risk factors including obesity and prior deep vein thrombosis in one patient and concomitant COVID-19 infection in the other patient.*

Results: Among 19,775 patients with AS and 59,325 matched controls without AS, there were 1,663 and 4,308 incident cases of cardiovascular disease, showing an incidence of 16.9 and 13.8 per 1,000 person-years, respectively. Long-term use of NSAIDs increased the risk of cardiovascular disease in non-AS controls (adjusted hazard ratio [aHR], 1.29; 95% confidence interval [CI], 1.17–1.43). In contrast, long-term use of NSAIDs did not increase the risk of cardiovascular disease in AS patients (aHR, 0.97; 95% CI, 0.86–1.09; adjusted for age, sex, socioeconomic status, body mass index, smoking status, hypertension, diabetes, hyperlipidemia, and tumor necrosis factor inhibitor use).

Conclusion: Prolonged NSAID treatment in AS patients may not be as harmful as in the general population regarding cardiovascular risk.

POS0252 DIFFERENCES IN SERUM DRUG LEVELS AND ANTI-DRUG ANTIBODIES IN PATIENTS WITH INFLAMMATORY ARTHRITIS TREATED WITH ORIGINATOR VS BIOSIMILAR ADALIMUMAB

Keywords: bDMARD, Inflammatory arthritides

J. Jessum1, J. E. Gehin2, E. Kristianslund3, J. Sexton1, D. Warren3, Y. Hu1, T. K. Kylen4, E. A. Haavardsholm5, N. Bolstad6, S. W. Syversen7, G. L. Goll1. 1Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; 2University of Oslo, Institute of Clinical Medicine, Oslo, Norway; 3Norwegian Radium Hospital, Department of Medical Biochemistry, Oslo, Norway; 4Lillehammer Hospital, Department of Rheumatology, Lillehammer, Norway.

Background: Serum drug levels and anti-drug antibodies (ADAb) impact the therapeutic effectiveness of most TNF-inhibitors. Possible differences in immunogenicity profile and pharmacokinetics across biosimilar and originator TNFi are still to be elucidated.

Objectives: To compare serum drug levels, ADAb and treatment effect in patients treated with originator (Humira) vs biosimilar (Hyrimoz) adalimumab.

Methods: Patients with a clinical diagnosis of spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) or other inflammatory arthritides (adult JIA or unspecified polyarthritis) enrolled in the observational NOR-DMA R study and starting treatment with adalimumab were included in the present analyses. Patients were started on originator adalimumab (Humira) up to January 2020 and biosimilar adalimumab (Hyrimoz) from January 2020, based on a national annual tender system for biological drugs in Norway. Serum drug levels and neutralising ADAb were measured using an in-house fluorescence method and compared between groups by Mann-Whitney U test and y2-test respectively, in addition to multivariable regression analyses adjusted for age, sex, previous use of bDMARDs, smoking, and co-medication with methotrexate. Treatment response at 3 months was defined by Major or Clinically Important improvement in SpA and EULAR good or moderate response in RA, PsA and other inflammatory arthritides, and, and compared by y2-test. Drug survival the first two years of adalimumab treatment was explored by Kaplan-Meier curves and Cox proportional hazard regression analysis.

Results: A total of 378 patients (177 SpA, 98 RA, 70 PsA, 33 other) (median age 45.7 years [SD 14.2]) were included. 240 (65%) patients started originator and 138 (37%) started biosimilar adalimumab. 139/378 (37%) patients used methotrexate as co-medication, the proportions and dosage were comparable for originator and biosimilar adalimumab. Patients on originator adalimumab had lower serum drug levels (6.5 ± mL [IQR 3.0–9.8] vs 8.3 ± mL [IQR 5.4–11.1], p<0.00003) (Figure 1A), and a higher rate of ADAb formation (33 [14%] vs 6 [4%], p=0.004) compared to patients treated with biosimilar adalimumab. The differences in serum drug levels and ADAb were consistent in multivariable

POS0251 RISK OF CARDIOVASCULAR DISEASE ASSOCIATED WITH LONG-TERM USE OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS IN ANKYLOSING SPONDYLITIS

Keywords: Cardiovascular disease, Epidemiology, Spondyloarthritis

J W Kim1, J S. Yoon2, H. Lee3, S. H. Park1, S. K. Kim1, J. Y. Choe1. 1Daegu Catholic University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Daegu, Korea, Rep. of [South Korea]; 2Busan Paik Hospital, Inje University College of Medicine, Department of Internal Medicine, Busan, Korea, Rep. of [South Korea].

Background: Ankylosing spondylitis (AS) is associated with increased cardiovascular disease, but there are limited data as to whether prolonged treatment with non-steroidal anti-inflammatory drugs (NSAIDs) increases the cardiovascular risk in AS patients. We aimed to examine the risk of cardiovascular disease associated with long-term use of NSAIDs in a large real-world AS cohort.

Objectives: We aimed to examine the risk of cardiovascular disease associated with long-term use of NSAIDs in a large real-world AS cohort.

Methods: A nationwide population-based cohort of patients with AS and matched controls without AS were analysed. The primary outcome was cardiovascular disease, a composite outcome of ischemic heart disease, stroke, or congestive heart failure. Long-term use of NSAIDs was defined as use of NSAIDs for more than 365 cumulative defined daily doses. The association between long-term use of NSAIDs and incident cardiovascular disease was examined using a multivariable Cox proportional hazards regression model in both AS and non-AS populations.

Results: Among 19,775 patients with AS and 59,325 matched controls without AS, there were 1,663 and 4,308 incident cases of cardiovascular disease, showing an incidence of 16.9 and 13.8 per 1,000 person-years, respectively. Long-term use of NSAIDs increased the risk of cardiovascular disease in non-AS controls (adjusted hazard ratio [aHR], 1.29; 95% confidence interval [CI], 1.17–1.43). In contrast, long-term use of NSAIDs did not increase the risk of cardiovascular disease in AS patients (aHR, 0.97; 95% CI, 0.86–1.09; adjusted for age, sex, socioeconomic status, body mass index, smoking status, hypertension, diabetes, hyperlipidemia, and tumor necrosis factor inhibitor use).

Conclusion: Prolonged NSAID treatment in AS patients may not be as harmful as in the general population regarding cardiovascular risk.
regression analyses (p= 0.032 and p= 0.020 respectively) and across diagnostic groups. There was no difference in treatment response or drug survival between originator and biosimilar adalimumab. (Table 1 and Figure 1B).

Conclusion: This observational study showed higher occurrence of ADAb formation and lower adalimumab serum levels in patients on adalimumab originator vs biosimilar, indicating differences in the immunogenicity profile. There was, however, no significant difference in clinical outcomes.

**POS0253 FACTORS ASSOCIATED WITH TREATMENT PATHWAYS IN EARLY AXIAL SPONDYLOARTHRITIS: A MULTISTATE ANALYSIS OF THE 10-YEAR FOLLOW-UP OF THE DESIR COHORT**

**Keywords:** Descriptive Studies, Spondyloarthritis

E. Portier1,2, S. Chevreau, A. Ruyssevelt, A. Walter Petrich1, M. Dougdos1,2, A. Motlo1,2, 1Cochin Hospital, Rheumatology, PARIS, France; 2ECAMO, INSERM U-1153: Clinical Epidemiology and Biostatistics, PARIS, France; 3Saint Louis Hospital, Biostatistics, PARIS, France; 4University Hospital of Toulouse, Rheumatology, Toulouse, France

**Background:** Current recommendations for the management of patients with axial spondyloarthritis (axSpA) emphasize the need of individualized strategy in the therapeutic decision [1,2]. Thus, many factors seem to impact this strategy.

**Objectives:** The objectives of the study were to describe the therapeutic strategies observed in axSpA, and to assess the factors associated with treatment changes over time.

**Methods:** This study included patients with axSpA from the French prospective cohort DESIR, with a follow-up of 10 years. A multi-state model was built, including 4 treatment states with an increasing gradation ("none"; "non-steroidal anti-inflammatory drugs (NSAID)"; "conventional synthetic DMARD (csDMARD)"; "TNF inhibitors (TNFi)"), and 6 possible transitions from one state to another. Estimation of the restricted mean sojourn times spent in each state from the state occupation probabilities was performed. Then, Cox regression models were used to study the potential impact of factors on transitions.

**Results:** 686 of the 708 patients which had more than one visit were analyzed. At cohort entry, 199 (29.0%) were untreated, 427 (62.2%) received NSAID, and 60 (8.7%) received csDMARD. Over the 10 years of follow-up, patients mostly received NSAID (46.4% of the time) followed by TNFi (24.4% of the time). In multivariable analysis (figure 1), presence of sacroilitis on radiography, internal bowel disease and articular index were associated with transition to NSAID. Duration in the previous state was often a significant protective factor associated with transition to csDMARD or TNFi. Finally, the several disease activity outcomes were associated with most transitions.

**Conclusion:** This was the first study using a multistate model to easily represent the different states, transitions and their associated factors. There appeared to be subcategories of axSpA patients with different management (including some without any treatment), and a significant proportion of patients treated with csDMARD.

**Figure 1.** Multistate model representation. Each arrow corresponds to a possible transition (n=6). Number at baseline denotes the number of patients who started from the state at baseline. The number of events and factors significantly associated with each transition in the multivariable analysis are written near to the corresponding arrow. NSAID refers to non-steroidal anti-inflammatory drugs, csDMARD stands for conventional synthetic Disease Modifying Anti-Rheumatic Drug, and TNFi for tumor necrosis factor inhibitors.
POS0254 PREDICTING SUCCESSFUL TAPERING OF BIOLOGICS IN PATIENTS WITH INFLAMMATORY ARTHRITIS: SECONDARY ANALYSES FROM THE BIODOPT TRIAL

Keywords: Tapering, Inflammatory arthritis, bDMARD

L. Uhrenholt1,2,3, K. Duch1,4, R. Christensen1,5, L. Dreyer1,2, E. M. Hauge1,6, A. Schlemmer1,6, P. C. Taylor7, S. Kristensen8, 3, 4

1Aalborg University Hospital, Center of Rheumatic Research Aalborg (CERRA), Department of Rheumatology, Aalborg, Denmark; 2The Parker Institute, Bispebjerg and Frederiksberg Hospital, Section for Biostatistics and Evidence-Based Research, Copenhagen, Denmark; 3Aalborg University, Department of Clinical Medicine, Aalborg, Denmark; 4Aalborg University Hospital, Unit of Epidemiology and Biostatistics, Aalborg, Denmark; 5Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, University of Southern Denmark, Odense, Denmark; 6Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 7Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 8Randers Regional Hospital, Department of Rheumatology, Randers, Denmark; 9University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, Denmark

Background: Identification of predictors for successful tapering of biologics in patients with inflammatory arthritis (IA) can help to guide physicians and patients; but, evidence is lacking.

Objectives: To identify possible predictors for successful tapering of biological disease modifying anti-rheumatic drugs (bDMARDs) from baseline characteristics.

Methods: BIODOPT was a randomised, open-label, equivalence trial (EudraCT 2017-001970-41) where adults with rheumatoid arthritis (RA; n=61), psoriatic arthritis (PsA; n=26), or axial spondyloarthritis (axSpA; n=55) in ≥12 months low disease activity (LDA) were randomised 2:1 to disease activity-guided tapering or to continuation of biologics as usual care. Successful tapering at 18 months was pre-defined as patients who could reduce their biologic dose ≥50% while still being in LDA. Modified poisson regression with robust variance estimator was used for the analyses. Univariable analyses were: tapering group, sex, age, education, tobacco use, body mass index, comorbidity, arthritis characteristics i.e., diagnosis, duration, duration from diagnosis to treatment start, on ≥2 conventional synthetic DMARDs, on methotrexate, on tumour necrosis factor inhibitor (TNFi), on first bDMARD, on bDMARD number ≥3, duration of bDMARD, duration of remission on bDMARD, duration of LDA on bDMARD, previous bDMARD tapering. C-reactive protein (CRP) before first bDMARD; Health Assessment Questionnaire Disability Index (HAQ-DI), Pain Visual Analog Scale (VAS), Fatigue VAS, Patient Global Health VAS, Short Form Health Survey 36 (SF-36) physical and mental component summary (PCS and MCS), tender joints, Physician Global Health VAS, CRP, and in remission. Potentially important variables (univariate p<0.10) were included in the multivariable model. C-statistics was used to assess model prediction.

Results: One-hundred-and-forty-two patients were randomised to tapering (n=95) or control (n=47) of which 32% (30/95) and 2% (1/47) achieved successful bDMARD tapering at 18 months. A statistically significant associations (univariate p<0.10) was identified between successful tapering and tapering group, HAQ-DI, Pain VAS, Fatigue VAS, Patient Global Health VAS, SF-36 PCS, and SF-36 MCS. Table 1. However, the only independent predictor for achieving successful tapering in the multivariable model was allocation to the tapering group, risk ratio (RR): 14.0 (95%CI: 19-101.3). Interestingly, individuals with a better mental health state (higher SF-36 MCS) were potentially more likely to achieve successful tapering; RR: 1.06 (95%CI: 1.00-1.11). A sensitivity analysis only successful tapering; RR: 1.06 (95%CI: 0.99-1.13). A sensitivity analysis only independent predictor; therefore, physicians should keep the option in mind when patients are in sustained LDA. Moreover, better baseline mental health seemed to have potential importance which points to the value of patient comprehension and willingness to engage in the tapering approach.

POS0255 A PRO-NOCOPTIVE POPULATION OF NEUROPHIL INFILTRATE SENSORY GANGLIA AND MEDIATE CHRONIC WIDESPREAD PAIN IN FIBROMYALGIA SYNDROME

Keywords: Pain, Fibromyalgia, Innate immunity

R. Evans1, S. Caxaria1, P. Celik1, A. M. Fuller2, S. Bhardwaj2, S. Sikandar3, 1William Harvey Research Institute, QMUL, Experimental Medicine and Rheumatology, London, United Kingdom

Background: Although the aetiology of chronic widespread pain in fibromyalgia syndrome is unknown and generally recognised as a central pain syndrome, several recent studies point towards a peripheral aetiology. Aberrant activity of immune cells and associated cytokine signalling has also been linked to
fibromyalgia syndrome. Neutrophils are polymorphonuclear granulocytes that normally exist in circulation to function as primary mediators of rapid innate host defence, releasing extracellular vesicles as functional mobile units. Surprisingly, neutrophils are found in increased circulatory levels and with enhanced chemotactic and microbialic properties in fibromyalgia patients. Furthermore, we have recently shown a key role for neutrophils in mediating the spatiotemporal spread of hypersensitivity in a hyperalgesic priming model of chronic widespread pain. Our data also shows a fundamental pro-nociceptive action of neutrophils derived from patients or mice with chronic widespread pain when administered to naïve neonatal mice.

Objectives: The mechanisms by which neutrophils can sensitise sensory neurons to cause pain signalling is still unclear but is likely linked to a distinct subpopulation of neutrophils characterised by altered surface protein expression. We aim to identify a specific neutrophil subpopulation that sensitises nociceptive neurons either through cell-cell interactions or mediated via neutrophil-derived extracellular vesicles (NDEVs) to produce chronic widespread pain in fibromyalgia syndrome.

Methods: To identify a pro-nociceptive neutrophil population, we used neutrophils from fibromyalgia patients and pain free controls, characterising protocine differences between the cohorts by FACS. Furthermore, we have employed functional assays of neutrophil reactivity, including quantification of reaction oxygen species (ROS) production and neutrophil extracellular trap generation (NETosis) to characterise specific functional differences which may responsible their pro-nociceptive capacity. To assess the role of NDEVs in neutrophils pro-nociceptive actions we have isolated and performed phenotypic characterisation of NDEVs from patients and pain-free controls. Finally, we used primary sensory neuron cultures to assess the effect of neutrophils and NDEVs on neuronal excitability using functional assays (calcium imaging and in vitro electrophysiology) to demonstrate the capacity of neutrophils to sensitise peripheral sensory neurons.

Results: Proteomic characterisation of neutrophils derived from patients with fibromyalgia pain vs pain free subjects reveals a distinct population of cells, including altered expression of cell surface markers CD62L and CXCRI2. Quantification of ROS generation also reveals changes in cells derived from patients when compared to pain free counterparts, alongside increased NETosis which may reflect specific mechanisms employed by cells to sensitise peripheral neurons following trafficking to DRG. We observe increased NDEV release from patient cells alongside specific phenotypic differences, including an upregulation of surface markers, mirroring what we observe within the parent cells. Moreover, in vitro systems, including electrophysiology recording and calcium imaging reveal increased neuronal responses to both patient cells and patient cell-derived NDEVs.

Conclusion: We show a surprising role of neutrophils, a short-lived immune cell, in the aetiology of chronic widespread pain in fibromyalgia syndrome. Our data demonstrates altered proteomic profiles and distinct phenotypic differences in both circulating neutrophils and NDEVs from patients, supporting an immunological basis for chronic widespread pain in fibromyalgia and a novel mechanism of nociceptive pain.

POS0256 IDENTIFICATION OF TWO BIOLOGICAL SUBTYPES OF CRPS

Keywords: Pain, Skin

M. Perez Verti Valdes1, A. Juengel1, I. Kolm1, L. Optiz1, H. Rehbraun1, O. Distler1, F. Brunner2, S. Dudd1. 1University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland; 2University Hospital of Zurich, Dermatology, Zurich, Switzerland; 3Functional Genomics Center Zurich, Genomics, Zurich, Switzerland; 4Universitätsklinik Balgrist, Physical Medicine and Rheumatology, Zurich, Switzerland

Background: Patients with Complex Regional Pain Syndrome (CRPS) present prolonged and debilitating pain and tissue damage. To date, treatment remains a challenge. Biological phenotyping has not been performed yet, and thus, molecular therapies are missing.

Objectives: To determine whether different biological CRPS subtypes exist and to provide a molecular profile of these subtypes.

Methods: CRPS patients fulfilling the Budapest criteria were included. Body Perception Disturbance (BPD) and pain scores (0-100) questionnaires were recorded. Skin punch biopsies (3 millimetres) from the affected and non-affected sides (n=6+6) and matching blood samples were taken. Biopsies were split in two for transcriptomic and histological analyses. Blood was processed to collect plasma after centrifugation and peripheral blood mononuclear cells (PBMCs) with a Ficoll gradient. Total RNA was isolated from skin biopsies and from PBMCs for bulk sequencing. Differentially expressed genes (DEGs) were determined using DESeq2 generalised linear model (p≤0.01, log2 ratio≥0.5). Hierarchical clustering and principal component analysis (PCA) were performed on raw transcriptomic data to identify patient sub-populations. Cell types were approximated in skin and PBMCs with deconvolution analysis using RNA sequencing databases with known cell frequencies (PRESST cohort and immunedeconv, respectively). Twenty pro- and anti-inflammatory plasma cytokines were measured using chemiluminescence-based assays (Meso U-PLEX Viral Combo 1). Histological slides were scored (0-3) blinded by a dermato-pathologist based on a panel of 10 morphological and cellular characteristics. Protein levels, histological evaluations and demographic data were compared between CRPS clusters using unpaired t-tests.

Results: Six women with CRPS 1 of the hand (n=5) and foot (n=1) participated in the study. Mean age was 47.3 ± 14.2 yrs and mean symptom duration was 57.8 ± 44.2 weeks. Skin transcriptomics showed 427 DEGs when comparing affected vs. non-affected samples (Figure 1a). Samples clustered by patient rather than affected/non-affected side (Figure 1b). PCA of only the affected samples displayed two clusters (PC1=56%, PC2=17%) (Figure 1c). Further evaluation of all affected samples by deconvolution analysis suggested two distinct cellular signatures, clustering patients in the same way as the PCA. Keratinocyte-related genes were upregulated in cluster 1 (n=3) and strong fibroblast, microvascular endothelial cell, monocyte and M1 macrophage signatures were found in cluster 2 (n=3) (Figure 1d). Consequently, gene ontology (GO) of each cluster showed enrichment of epithelium development and downregulation of peptidase terms in cluster 1 and extracellular matrix and collagen fibril organisation in cluster 2. Histopathological examinations did not show any difference between subtypes. PCA of PBMCs transcriptome validated the same distribution of patients into two clusters (PC1=62%, PC2=16%) (Figure 1e). A total of 2,328 DEGs were found between both clusters, with an overrepresentation of immune and inflammatory response, and neutrophil degranulation and chemotaxis-related terms in cluster 1 (n=2) according to GO. Deconvolution analysis confirmed the presence of a stronger signature of neutrophils and M2 macrophages in cluster 1 than cluster 2. Blood cytokine quantification showed that interleukin-1 receptor antagonist (IL-1RA) levels were 1.9 times higher in cluster 1 than in cluster 2 (n=3+3, p=0.02) (Figure 1f). Consistently, transcriptomic data indicated that cluster 1 had higher expression of IL-1RA encoding gene (IL-1RN) in matching skin (log2 ratio=0.88, FDR=0.06) and PBMCs (log2 ratio=1.1, FDR≤0.01) than cluster 2. There was no significant difference in age or symptoms duration between clusters, but pain and BPD questionnaires revealed differences between groups, suggesting that the clusters might be clinically distinguishable (Figure 1g).

Conclusion: Our findings suggest the existence of two biological CRPS subtypes. Molecular patterns could facilitate the development of targeted therapies.

Keywords: Pain, Imaging, Artificial Intelligence

Background: Chronic pain is highly prevalent, debilitating and lacks effective treatments. Experimental and neuroimaging research demonstrates abnormal central pain processing[1]. However, robust brain-based biomarkers that could inform targeted treatments are lacking. Electrocencephalography (EEG) is the optimal tool to investigate dynamic abnormalities in pain processing to reveal underlying mechanisms. Early evidence from EEG studies in Fibromyalgia (FM) indicate potential mechanisms such as thalamocortical dysrhythmia[2], demonstrated by alterations in the Alpha and Theta frequency bands. However, existing studies employ rudimentary analyses failing to account for the multivariate and temporal nature of EEG data. State-of-the-art machine learning (ML) approaches provide unique opportunities to generate a deeper understanding of EEG signatures in chronic pain and identify specific biomarkers that could be used to differentiate mechanistic subtypes.

Objectives: This preliminary work aims to establish whether a state-of-the-art ML classifier can differentiate patients with FM from healthy controls based on their EEG characteristics.

Methods: The dataset used was collected through The VIPA Study (ISRCTN46681140). Patients with FM satisfied the 2016 FM classification criteria. High-density 64-channel EEG data using an electrolyte gel-based active electrode system was collected at rest with participants' eyes closed over 2 minutes. Individual Fast Fourier Transforms were applied to overlapping time windows to extract EEG frequency band power whilst retaining temporal information. Frequency bands were used as features to train a classification model (definitions of frequency ranges in Table 1). One of the fastest, most accurate state-of-the-art time-series classification ML algorithms (mini-ROCKET) was used via the sktime python toolkit. To obtain unbiased accuracy estimates across all participants, a 'leave-one-out' strategy was used. Accuracy of the algorithm was reported; defined by the number of correct predictions divided by the total number of predictions for each frequency band (2-class problem, chance estimates 0.5-0.6 based on p<0.05).

Results: Data from 23 patients with FM (mean age 46 ±14yrs, 87% female) and 14 healthy controls (mean age 71 ±7yrs, 50% female) were analysed. Patients with FM had moderate self-reported pain (5.5 ±2.3 VAS) and disease severity (mean FIQR = 2) prior to pain flare onset. Objective exposures showed a daily average of 2.0 episodes per month (Table 1). Across all types, 75% of pain flares lasted two days and 95% lasted three days before pain flare onset. A total of 6,244 daily reports were included in the analysis. Pain flare occurrence decreased when applying more complex definitions. 31% of participants had pain flares under the most stringent definition of absolute impact, with two episodes per month (Table 1). Across all types, 75% of pain flares lasted two days before returning (Median = 1, IQR = 1-2) but could persist up to 11 days (Figure 1). Pre-flare exposures did not differ between pain flare types nor between the preceding periods. Participants reported fair sleep quality (Median = 3), feeling quite happy (Median = 2), not anxious (Median = 1) and mild fatigue (Median = 2) prior to pain flare onset. Objective exposures showed a daily average of 7-hour sleep with 83% efficiency, under 20 minutes to fall asleep, and approximately 50 minutes being active.

Conclusion: Preliminary results indicate that machine learning can be successfully used to differentiate patients with Fibromyalgia from healthy controls based on EEG measures of the Alpha and Theta frequency bands. Alterations in Alpha and Theta have been demonstrated in previous non-ML research, indicating potential underlying abnormalities in the interaction between the thalamus and cortex which may be related to central mechanisms underlying chronic pain. Further work is required in larger, matched cohorts to validate these findings, but this early work highlights the future potential of EEG and ML in both understanding brain-based pain mechanisms and using EEG features to differentiate chronic pain subgroups.

Keywords: Pain, Rheumatoid arthritis

Background: Pain flares in rheumatoid arthritis (RA) often refer to episodes of increased pain severity accompanied by pain impact. Describing the prevalence and predictors of pain flare occurrence is difficult since there are no agreed classification criteria[1]. Patient-generated data collected in real-time with mobile health (mHealth) devices provide an opportunity to identify individual patterns and triggers in pain dynamics over time[2].

Objectives: We aim to characterise pain flares and pre-flares exposures using real-time mHealth data from patients with RA.

Methods: In a 30-day mHealth study[3] we collected daily reports of pain severity on a five-point scale (ranging from none to very severe pain) via a smartphone app to define the onset and ending criteria for three types of pain flares, including 1) above average: pain severity greater than the personal median score, 2) significant change: two-point increase in pain severity from yesterday, and 3) absolute impact: two-point increase in pain severity from yesterday and pain severity greater than three. All pain flare types end when pain severity returns to the personal median score or lower. Exposures of the preceding periods were self-rated sleep quality, mood, anxiety and fatigue (all scales range 1-5, higher scores are worse) using the same study app, and passively recorded total time asleep (hr), sleep efficiency (%), sleep latency (min) and physical activity (min) via a wrist-worn accelerometer. We report the 30-day monthly pain flare rate, the average duration of pain flares and summarise average exposures one-day and three-day before pain flare onset.

Results: We analysed 253 participants who provided at least seven days of data (81.8% females; mean age = 59.9, average years with RA = 12.1). A total of 6,244 daily reports were included in the analysis. Pain flare occurrence decreased when applying more complex definitions. 31% of participants had pain flares under the most stringent definition of absolute impact, with two episodes per month (Table 1). Across all types, 75% of pain flares lasted two days before returning (Median = 1, IQR = 1-2) but could persist up to 11 days (Figure 1). Pre-flare exposures did not differ between pain flare types nor between the preceding periods. Participants reported fair sleep quality (Median = 3), feeling quite happy (Median = 2), not anxious (Median = 1) and mild fatigue (Median = 2) prior to pain flare onset. Objective exposures showed a daily average of 7-hour sleep with 83% efficiency, under 20 minutes to fall asleep, and approximately 50 minutes being active.

Conclusion: Using three increasingly complex definitions, we found pain flares were common and lasted up to 11 days based on self-reported pain severity. Future analysis should examine the role of pain impact and compare within-person exposures during pre-flare periods with non-flare periods.

DO: 10.1136/annrheumdis-2023-eular.1523
Background: Pain sensitization is an important component of the pain experience in many persons with osteoarthritis (OA). Knee OA studies have suggested that pain sensitization is associated with functional limitations, but the evidence in hand OA is sparse.

Objectives: To assess whether pain sensitization is associated with physical function in people with hand OA.

Methods: We included 206 participants in cross-sectional analyses from the follow-up visit of the Nor-Hand study. Measures of pain sensitization included pressure pain thresholds (PPTs) by a handheld algometer, and temporal summation (TS) defined as increased pain during repeated stimuli. Pain and function were measured in hand OA is sparse. Pain sensitization is associated with functional limitations, but the evidence in hand OA is sparse.

Results: The median (IQR) age was 65 (60-69) years and 86% were female. People with higher PPTs at or near the hand or knee, which may represent less peripheral and/or central sensitization, reported better function in hands and knees/hips and performed better on the performance tests than people with lower PPTs (Table 1), although not statistically significant for all outcomes. Also, a higher PPT at the trapezius muscle, representing less central sensitization, was associated with better function in the lower extremities (Table 1). No associations were found between pain sensitization and the chair stand test (data not shown), or between TS (measure of central sensitization) and hand or lower extremity function. The effects of PPTs on self-reported AUSCAN hand function appeared to be largely mediated through self-reported hand pain (e.g., indirect effect of PPT at the wrist mediated through hand pain: -1.19, 95% CI -1.95, -0.43, and direct effect: -0.20, 95% CI -0.90, 0.51). Effects of PPTs on grip strength were mediated through pain to a lesser extent (e.g., indirect effect of PPT at the wrist mediated through hand pain: 0.12, 95% CI -0.10, 0.34, and direct effect: 1.21, 95% CI 0.29, 2.13). Similarly, the mediating effects of knee/hip pain were larger in analyses of self-reported function than for performance-based measures of lower extremity function (data not shown).

Conclusion: Our results suggest that peripheral sensitization and possibly also central sensitization, are associated with impaired function in hands and lower extremities. For both the hand and lower extremities, measures of sensitization may have direct effects on performance-based measures of function, whereas the effect of sensitization on self-reported function appears to be mediated through self-reported pain severity.

detected by skin biopsy was reduced in 58 patients (62.4%), 43 of whom (74.1%) had reduced IENFD at both proximal and distal sites. CCM showed pathologic findings in 18 patients with reduced IENFD at any site (31%) and in 8 with normal IENFD (22.9%), with dry eyes being present in 13 (22.4%) and 6 (17%) of those patients, respectively.

There was no difference in pain, depression, neuropathic symptoms, sleep quality, daytime sleepiness, fatigue, or quality of life scores between groups (Table 1).

Conclusion: In this FM population with high disease burden and indication for inpatient therapy, small fiber pathology as found by skin biopsies and CCM was present in more than two third of the FM patients suggesting that there are subgroups. However, there were no significant clinical differences between patients with and without SFN. Further analysis should explore, whether both subgroups differ in their long-term outcome after the inpatient treatment.

PALMITOLETHANOLAMIDE (PEA) AND ACETYL-CARNITINE (ALC) ACT SYNERGISTICALLY WITH DULOXETINE AND PREGABALIN IN FIBROMYALGIA: PROSPECTIVE AND RETROSPECTIVE ANALYSES

Keywords: Clinical Trials, Fibromyalgia, Diet and Nutrition
Background: Fibromyalgia (FM) is characterized by debilitating pain that is unresponsive to standard analgesics and the multi-modal approach, including drugs' combination, represents the standard of care. Combination therapeutic strategies also include the integration of drugs and nutraceuticals. Both palmitolethanolamide (PEA) and acetyl-L-carnitine (ALC) have demonstrated an effect on chronic widespread pain (CWP).

Objectives: The aim of this study was to evaluate the efficacy of pregabalin (PGB) and duloxetine (DLX) supplemented with palmitolethanolamide (PEA) and acetyl-L-carnitine (ALC) in FM patients over a 24-week period.

Methods: After 6 months of stable treatment with DLX+PGB, FM patients were randomized to continue the treatment (Group 1) or to add PEA (600 mg BID)+ALC (500 mg BID) at the ongoing treatment (Group 2). Patients were then followed for 24 weeks. Cumulative disease severity, evaluated using the Widespread Pain Index (WPI) (primary outcome), the revised Fibromyalgia Impact Questionnaire (FIQR), and the modified Fibromyalgia Assessment Status (FASmod) (secondary outcomes), was calculated every two weeks during the 24-week follow-up and expressed as time-integrated values (AUC).

Results: One hundred and forty-two FM patients started the study (91.5%), 130 completed both steps, respectively 68 patients in Group 1 and 62 in Group 2. After 24 weeks of follow-up after randomization, Group 2 experienced an adjunctive significant improvement in WPI, FIQR (Figure 1), and FASmod, compared to Group 1. Although there was some fluctuation in both Groups throughout the study period, the AUC values of the WPI scores steadily decreased in Group 2 (p=0.048). Group 2 showed better outcomes also in terms of FIQR and FASmod scores’ AUC values (p=0.033 and p=0.017, respectively).

Conclusion: This was a retrospective cohort study among Medicare beneficiaries aged 65-89 years with chronic non-cancer pain, without prior history of CHF. We included patients who were newly prescribed users of pregabalin or gabapentin were followed up between 2015-2018. The outcome was incident CHF, ascertained by hospital admissions or emergency room visits with ICD-9 and 10 codes in the first position codes. Inverse probability of treatment weighting was used to account for differences between pregabalin and gabapentin users in time-dependent analysis (i.e., Cox proportional-hazards regressions). Covariates used in the propensity scoring were selected based on prior knowledge and literature review, and included categories such as concurrent baseline cardiovascular, neurologic, pain, and psychiatric diagnoses and corresponding medications including opioids and antipsychotics. Non-diagnostic covariates were included, as well as demographics, socioeconomic status, and indicators/metrics of health care utilization.

Results: This study included 17,756 new users of pregabalin and 221,053 new users of gabapentin. The cohort was predominantly female gender (66.7%), and non-Hispanic White (79.9%), with a median age of 73 (IQR: 69-78) years. The most common diagnostic indications for pregabalin and gabapentin were musculoskeletal and back pain. Prior to inverse probability weighting, pregabalin vs gabapentin users had higher daily short-acting opioid morphine equivalent doses (median: 18.0 vs 8.9 mg/d), higher use of coxibs (8.6% vs 4.9%), and higher prevalence of diabetic neuropathy (15.9% vs 11.3%) and fibromyalgia (19.9% vs 13.2%). After propensity score weighting, none of the covariates had a standardized difference<=0.10. During 110,439 person-years of follow-up, 1,428 patients developed new CHF. The outcome rate for CHF incidence was 18.67 per 1000 person-years for pregabalin vs 12.57 per 1000-person years for gabapentin (adjusted HR 1.48 [95% CI, 1.20-1.81]).

Conclusion: In this retrospective study of Medicare beneficiaries aged 65-89 years with chronic non-cancer pain, new users of pregabalin had higher rates of incident CHF hospitalizations or emergency room visits compared to new users of gabapentin.

All about COVID-19 in Rheumatology

**POS0266**
**CELLULAR IMMUNE RESPONSE PERSISTENCE AFTER COVID-19 MRNA VACCINES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS UNDER RITUXIMAB**

**Keywords:** Rheumatoid arthritis, Vaccination/Immunization, COVID

J. Marin1, P. Bourjion2, N. Saverna3, C. Cartagena Garcia4, P. Lafortune5, J. Roudier1,2,3, J. M. Busnelli3, N. Balandraude1,3, S. Sainte Marguerite University Hospital-AP-HM, Rheumatology, Marseille, France; 2Inmunotech - Beckman Coulter, Global Research Organization, Marseille, France; 3InsERM and Aix Marseille University; UMRs - 1097: Arthritis Autoimmunes, Marseille, France

**Background:** Humoral response induced by anti-SARS-CoV-2 mRNA vaccine is significantly lower or even absent in patients with inflammatory rheumatic diseases treated with anti-CD20 therapies such as Rituximab (RTX) than in those treated with cytokine therapies (e.g., anti-TNF or anti-IL6) [1]. However, a specific cellular immune response exists 1 or 2 months after vaccination (2, 3). As medications are widely utilized for treatment of non-cancer chronic pain. Among these, pregabalin is a commonly prescribed anticonvulsant, which works by antagonizing L-type calcium channels, decreasing the release of neurotransmitters [1]. Pregabalin use has been associated with reports of congestive heart failure (CHF), including peripheral and pulmonary edema [2-4]. However, the relationship between CHF incidence and pregabalin use among patients at the highest risk of adverse reactions (i.e., senior patients with various co-morbidities) remains unclear.

**Objectives:** To compare incident CHF among new users of pregabalin versus gabapentin (the active comparator) in Medicare beneficiaries treated for non-cancer chronic pain.

**Methods:** This was a retrospective cohort study among Medicare beneficiaries aged 65-89 years with chronic non-cancer pain, without prior history of CHF. We included patients who were newly prescribed users of pregabalin or gabapentin were followed up between 2016-2017. The outcome was incident CHF, ascertained by hospital admissions or emergency room visits with ICD-9 and 10 codes in the first position codes. Inverse probability of treatment weighting was used to account for differences between pregabalin and gabapentin users in time-dependent analysis (i.e., Cox proportional-hazards regressions). Covariates used in the propensity scoring were selected based on prior knowledge and literature review, and included categories such as concurrent baseline cardiovascular, neurologic, pain, and psychiatric diagnoses and corresponding medications including opioids and antipsychotics. Non-diagnostic covariates were included, as well as demographics, socioeconomic status, and indicators/metrics of health care utilization.

**Results:** This study included 17,756 new users of pregabalin and 221,053 new users of gabapentin. The cohort was predominantly female gender (66.7%), and non-Hispanic White (79.9%), with a median age of 73 (IQR: 69-78) years. The most common diagnostic indications for pregabalin and gabapentin were musculoskeletal and back pain. Prior to inverse probability weighting, pregabalin vs gabapentin users had higher daily short-acting opioid morphine equivalent doses (median: 18.0 vs 8.9 mg/d), higher use of coxibs (8.6% vs 4.9%), and higher prevalence of diabetic neuropathy (15.9% vs 11.3%) and fibromyalgia (19.9% vs 13.2%). After propensity score weighting, none of the covariates had a standardized difference<=0.10. During 110,439 person-years of follow-up, 1,428 patients developed new CHF. The outcome rate for CHF incidence was 18.67 per 1000 person-years for pregabalin vs 12.57 per 1000-person years for gabapentin (adjusted HR 1.48 [95% CI, 1.20-1.81]).

**Conclusion:** In this retrospective study of Medicare beneficiaries aged 65-89 years with chronic non-cancer pain, new users of pregabalin had higher rates of incident CHF hospitalizations or emergency room visits compared to new users of gabapentin.

cytotoxic T cells are considered as essential components of the antiviral defense arsenal, and since it is not clear when to do booster shots, analysis of the specific T response over the long term could be a useful decision-making tool.

**Methods:** Patients. Our study cohort included 75 consecutive adult patients with ACRA positive RA, followed at the rheumatology department of Sainte Marquise Hospital (Marseille, France), prospectively enrolled from April 2022 to October 2022. RA patients fulfilled the 2010 ACR/EULAR criteria for RA and had received at least two doses of SARS-CoV-2 mRNA vaccine, whether they had or not a history of COVID.

**Samples.** Heparin-anticoagulated single blood sample was collected for each patient to assess CD19+ cell count, IgG level, and SARS-CoV-2 serology. Cellular immune response was assessed by flow cytometry with a previously described procedure [4]. Briefly, 250 µL of whole blood were incubated per condition, including a negative control, Spike peptides from JPT* collection and CEFX peptides (mix of viral peptides) as a positive control. Marker expression was measured with a three-laser 13-color CytoFLEX flow cytometer. T lymphocytes were divided into T4 lymphocytes (LT4) or T8 lymphocytes (LT8) depending on CD8 expression. Finally, CD69, CD154, CD137 and CD107a expressions were monitored to characterize LT4 or LT8 activation.

**Ethics.** All patients gave informed written consent for this study in accordance with Helsinki declaration. Patient data were pseudo-anonymized. Sample collection was approved by the national ethics committee under the number DC-2008-527.

**Results:** Patient characteristics. 51 RA patients were treated with RTX, 24 were treated with csDMARDs or other bDMARDs.

**Humoral response against SARS CoV-2.** 30/51 (59%) RA RTX patients versus 13/14 (93%) non RTX patients had a humoral immune response (p = 0.024) with a medium titer of 130 BAU/mL versus 688 BAU/mL.

**T cell specific response.** LT4 and LT8 Spike-specific responses were defined by the difference of response between Spike peptides from SARS CoV-2 stimulation and no peptides stimulation. The response was divided into quartiles; patients in the upper 3 quartiles were considered to have a specific response. In RA RTX patients, specific LT8 response was shown in 90% of patients versus 42% in non RTX patients (p < 0.0001), and specific LT4 response was shown in 76% of patients versus 75% in non RTX patients (p = 0.42).

**Long term T cell specific response** (Figure 1). RA patients treated with RTX maintained a specific LT4 response against Spike peptides with no decrease up to 18 months after the last SARS-CoV-2 boost (vaccine dose or COVID 19 infection).

**Conclusion:** Specific LT4 response against Spike peptides was similar in the RTX treated and non-treated RA patients. This was even stronger for the specific LT8 response. The Spike specific T-cell response was maintained in both groups up to 18 months after the last vaccine dose or COVID infection independently to the specific humoral response. This method of analyzing the specific T response against the Spike protein could be used in personalized medicine to decide when revaccination is necessary in a given patient.

**REFERENCES:**

Pre-exposure prophylaxis with tixagevimab/cilgavimab is effective in limiting the risk and the severity of COVID-19 in patients with autoimmune or inflammatory diseases at increased risk of severe COVID-19 who are poor responders to vaccination

Keywords: Disease-modifying Drugs (DMARDs), COVID, Vaccination/Immunization

M. Thomas1, M. Masson2, S. Bitoun3, R. Seror4, H. Dupuy5, E. Lazaro5, C. Richiez7, Y. Allainore3, J. Avouac1, 1Cochin Hospital, Rheumatology, Paris, France; 2Hopital purpan, Rheumatology, Toulouse, France; 3Bicetre Hospital, Rheumatology, Le Kremlin-Bicêtre, France; 4Hopital Haut Levoue, Internal Medicine, Pessac, France; 5Hopital Pellegrin Bordeaux, Rheumatology, Bordeaux, France

Background: Patients with autoimmune or inflammatory diseases treated with immunosuppressants such as anti-CD20 are at increased risk for severe COVID-19 and have a high probability of insufficient response to vaccination. The monoclonal antibody combination tixagevimab/cilgavimab has received early access approval to reduce the frequency of symptomatic COVID-19 in immunocompromised patients at risk for severe COVID-19 and unresponsive to vaccination.

Objectives: We aim to evaluate the clinical efficacy of tixagevimab/cilgavimab in pre-exposure prophylaxis in patients with increased risk of severe COVID-19 in rheumatology.

Methods: In this multicenter observational study conducted between December 2021 and August 2022, we included patients with autoimmune or inflammatory diseases who received at least one intramuscular injection of tixagevimab/cilgavimab as pre-exposure prophylaxis in 3 French rheumatology units. Occurrence of COVID-19 was assessed during usual follow-up or by phone call. The endpoint was the incidence of COVID-19 and its severity.

Results: tixagevimab/cilgavimab was administered to 115 patients, median age 62 years (52-71), with chronic arthritis (n=53), connective tissue disease (n=38) or vasculitis (n=11). The main background immunosuppressants were rituximab (n=98), methotrexate (n=48), mycophenolate mofetil (n=19), cyclophosphamide (n=15), azathioprine (n=12), and corticosteroids (n=62, median dose 5 mg, CI95% 5-8). During a median follow-up of 128 days (33-173), COVID-19 occurred in 23/115 patients (20%) with Omicron identified for the 8 genotyped patients. During the study period, the average weekly incidence was 1071 per 100,000 inhabitants in Ile-de-France vs. 588 per 100,000 in our patients. Patients who received a 2-injections regimen had a lower risk of infection than patients with a single injection (16/49, 33%, vs. 6/64, 8%, p=0.0012). The COVID-19+ patients did not differ from uninfected patients in terms of age, comorbidities, type and duration of underlying disease, extra-articular organ involvement or background immunosuppressants. All COVID-19 cases were non-severe, there were no deaths. The tolerance of injections was excellent, with no side effects observed.

Conclusion: In a population with autoimmune or inflammatory diseases at increased risk for severe COVID-19 with a poor response to vaccination, pre-exposure prophylaxis by tixagevimab/cilgavimab limited the risk of infection and the severity of COVID-19. This study supports the use of COVID-19 serological tests in this patient population in order to detect those who do not respond adequately to vaccination since pre-exposure treatments and/or early treatments are available.

POS0269 COVID-19 SEVERITY AND VACCINE BREAKTHROUGH INFECTIONS IN SJÖGREN’S SYNDROME: RESULTS FROM THE COVAD STUDY

Keywords: Vaccination/Immunization, COVID, Sjögren syndrome

A. Aliuono1, F. Carubbi1, J. Day2,3, J. Knitza5, S. Katsuyuki Shinjo6, S. Saha7, M. Milchert8, O. Distler9, A. Makol10, T. Chatterjee11, V. Agarwal12, R. Aggarwal13, L. Gupta14. 1Internal Medicine and Nephrology Unit, University of Uqilia, Department of Health, Health and Environmental Sciences, Uqilia, Italy; 2Royal Melbourne Hospital, Department of Rheumatology, Parkville, Australia; 3Walter and Eliza Hall Institute of Medical Research, Parkville, Australia; 4University of Melbourne, Department of Medical Biology, Parkville, Australia; 5Universitätsklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Medizinische Klinik 3 – Rheumatologie und Immunologie, Erlangen, Germany; 6Universidade de Sao Paulo, Division of Rheumatology, Sao Paulo, Brazil; 7Mymensingh Medical College, Mymensingh, Bangladesh; 8Pomeranian Medical University in Szczecin, Department of Internal Medicine, Rheumatology, Diabetology, Geriatrics and Clinical Immunology, Szczecin, Poland; 9University of Zurich, Department of Rheumatology, Zurich, Switzerland; 10Mayo Clinic, Division of Rheumatology, Rochester, United States of America; 11University of Illinois College of Medicine at Peoria, Department of Internal Medicine, Peoria, United States of America; 12Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; 13University of Pittsburgh School of Medicine, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America; 14Royal Wolverhampton Hospitals NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom

Background: Despite the increasing number of studies on COVID-19 infection in people with rheumatic and musculoskeletal diseases (RMDs), data on Sjögren’s syndrome (SS) is limited.

Objectives: To determine the spectrum and severity of pre-vaccine and post-vaccine breakthrough COVID-19 infections (B-INFs) among patients with SS compared to other connective tissue diseases (CTDs), non-rheumatic autoimmune diseases (nRAIDs), and healthy controls (HC).

Methods: Data were collected using the COVID-19 Vaccination in Autoimmune Diseases (COVAD) questionnaire (March–December 2021) and analysed to compare frequencies and identify associations with demographic, disease-specific and vaccine-specific variables (for B-INFs).

Results: Among 9462 complete respondents, 356 were patients with SS, of which 129 had primary (p) SS and 227 had SS associated (a) with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc) or inflammatory myopathies (IM). Patients with SS were compared to 1586 patients with other CTDs (RA, SLE, SSc or IM) but without SS, 825 patients with nRAIDs and 4712 healthy controls (HC). SS patients had mean age of 52.3 years, mean disease duration was 12 years; 94.5% were females, 68% were Caucasian. Overall COVID-19 infection was reported by 14% of patients with SS and 19.2% of HC (odds ratio (OR)=0.7; 95% confidence interval (CI)=0.5-0.9). The majority of cases occurred prior to the first vaccine dose with no differences across groups in the proportion of B-INFs (SS: 21.6%; other CTD: 20%; nRAID: 19.8%; HC: 19.4%). In the SS group, age and disease duration were similar in patients with either pre-vaccine infections or B-INFs. When comparing pSS and aSS, the overall number of COVID-19 infections was comparable, regardless of the timing (before or after vaccination). Over 80% of SS patients were symptomatic and the symptom duration was similar regardless of the timing of infection, however the symptom burden was different, with certain manifestations absent in B-INFs (oral ulcers, nausea/vomiting, skin rashes, loss of smell/taste) (Figure 1). When focusing on pSS and aSS separately, fewer was never reported in aSS B-INFs, whereas other symptoms were equally distributed in pre-vaccine infections and B-INFs. When comparing SS to other CTDs and HC, it emerged that during B-INFs, patients with SS had more frequently chest pain (OR=6.5; 95% CI=4

Results: The questionnaire was answered by 1357 individuals with a median age of 57 years. 63% of participants were female. 33% are living in a household with children. 36% were diagnosed with RA, 34% with axSpA, 22% with PsA and 8% with another inflammatory rheumatic disease. A total of 100 patients were prescribed csDMARDs, 94 JAKi, 18 rituximab, 695 other b/tsDMARDs, and 450 patients received none of these treatments (Table 1). 10% of patients feel their general lives are affected by COVID-19 at a level of more than 7 out of 10. 3% of the participants report that COVID-19 impacts their social environment (family and friends) as a potentially dangerous disease at a level of more than 7 out of 10.

Studied in the literature that assess the immuno-
genicity and safety of the different platforms COVID-19 vaccines in patients with
autoimmune diseases (AID).

Background: The ChAdOx1, Coronavirus, BNT162B2 and Janssen vaccines are available for the primary and booster immunization of immunosuppressed patients. However, there are few studies in the literature that assess the immuno-
genicity and safety of the different platforms COVID-19 vaccines in patients with autoimmune diseases (AID).

Methods: These data are from SAFER study; “Safety and efficacy on COVID-19 and in patients with AID aged ≥ 18 years. Exclusion criteria were pregnancy, previous severe adverse events (AE) to any vaccine or other immunosuppression causes. Demographics, diagnoses and therapeutic regimens were collected via participant report through the Research Electronic Data Capture tool. Available vaccines were adenosinarvectored vaccine (ChAdOx1, Astrazeneca and Ad26.COV2-S, Janssen), mRNA vaccine (BNT162b2, Pfizer-BioNTech) or inactivated SARS-COV-2 vaccine (Coronavac). Participants were followed up by means of blood collection for measurement of IgG antibody against SARS-COV-2 spike receptor-binding domain by chemiluminescence (SARS-COV-2-IgG-II Quant assay, Abbott-Laboratories) at baseline and 28 days after the first, 2nd and 3rd doses. The seropositivity was defined for titer IgG-Spike >71 BAU/mL. The ANOVA, the post-hoc Tukey and pairwise comparisons tests were used to compare the IgG-S tiers between the groups. An alpha level of 5% significance was used in all analyses.

Results: A total of 1096 patients were included and followed from the first dose. 709 patients AID received the complete 3-dose regimen: systemic lupus erythematosus (N=238, 33.6%), rheumatoid arthritis (N=143, 20.2%), spondyloarthritis (N=96, 13.5%), primary Sjögren’s syndrome (N=56, 7.9%), inflammatory bowel disease (N=50, 7.1%), vasculitis (N=31, 4.4%), systemic sclerosis (N=25, 3.5%), Behçet syndrome (N= 19, 2.7%) myositis (N= 12, 1.7%), other systemic AID (N=39, 5.5%), Mean age was 41.59 (12.2), female N=556, (78.4%) and adipim race (N=370, 52.2%). Primary immunization was performed with Coronavac in 265 (37.4%), ChAdOx1 in 403 (56.8%) and Pfizer in 41 (5.8%) AID patients. After the 2nd dose (28 days), the booster was performed with Coronavac (N=10, 1.4), ChAdOx1 (N=226, 31.9%), Pfizer (N=464, 65.4%) and Janssen (N=9, 1.3%). Anti-spike IgG antibodies were ana-
alyzed in the 657 patients who received the three doses. All patients had a sub-
stantial increase in IgG antibody concentrations 28dy after the booster vaccine with median 275.9 BAU/mI (88.8 - 1000.8) vs. 1217.2 (402.3 - 3213.7) booster vaccine. All heterologous regimens (N=515) had anti-spike IgG responses at day 80 were superior to homologous booster (N=194) with median titters 1596.5 (543.9-3769.4) vs. 620.3 BAU/mL (180.3-1987 .0), p<0.001 (figure 1). The seropositivity rates were higher and similar in both groups (Heterologous 98.4% vs. Homologous 95.9%, p<0.01).

Conclusion: All vaccines administered as third dose induced an increase in IgG-S titer antibodies, which could improve protection against COVID-19 in AID patients. Heterologous booster vaccination produced greater humoral immune responses than homologous booster, which is relevant in this immunosuppressed population.

POS0272

IMPACT OF THE COVID-19 PANDEMIC ON ADHERENCE TO DISEASE MODIFYING DRUGS AMONG PATIENTS WITH RHEUMATIC DISEASES: A POPULATION-BASED, INTERRUPTED TIME SERIES ANALYSIS

Keywords: COVID, Disease-modifying Drugs (DMARDs)

N. Rebu1,2, E. C. Sayre3, M. Law2, M. De Vera4,5. 1University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada; 2Arthritis Research Canada, Vancouver, Canada; 3University of British Columbia, School of Population and Public Health, Vancouver, Canada

Background: Although studies have quantified adherence to medications among patients with rheumatic diseases (RD) during the COVID-19, lack of direct pre-pandemic comparison precludes understanding of impact of the pandemic.

METHODS: This study is based on prescription data from a large administrative health insurance claims database covering 1.4 million people in British Columbia, Canada. All RD patients were identified using validated electronic medical records (EMR) based definitions. Adherence was compared during pre-pandemic (2015-2019) and one-year post-pandemic (2020-2021) periods using interrupted time series analysis. The primary outcome was persistence and defined as ≥ 12 months of continuous fills.

RESULTS: The study identified 96,210 RD patients during the pre-pandemic period and 113,765 patients (96% overlap) during the post-pandemic period. During the pre-pandemic period, 58% of RD patients had ≥ 12 months of continuous fills. During the post-pandemic period, 51% of RD patients had ≥ 12 months of continuous fills. The risk of lower adherence during the post-pandemic period compared with the pre-pandemic period was consistent across all subgroups.

CONCLUSION: The COVID-19 pandemic was associated with a decrease in adherence to disease modifying drugs among patients with RD.
**Objectives:** Our objective was to evaluate the effect of the COVID-19 pandemic on adherence to disease modifying drugs (DMARDs) including conventional synthetic (csDMARDs) and targeted synthetic (tsDMARDs).

**Methods:** We linked population-based health data on all physician visits, hospital admissions, and all dispensed medications, regardless of payer in British Columbia from 01/01/1996 to 3/31/2021. We identified prescriptions for csDMARDs (including methotrexate, hydroxychloroquine) and tsDMARDs, namely anti-TNFs (including infliximab, etanercept, adalimumab) and rituximab using drug identification numbers among indicated individuals with RD. We defined March 11, 2020, as the ‘index date’ which corresponded to the date that mitigation measures for the COVID-19 pandemic were first introduced. We assessed adherence as proportion days covered (PDC), calculated monthly in the 12 months before and after the index date. We used interrupted time-series models, namely segmented regression to estimate changes and trends in adherence before and after the index date.

**Results:** Our analysis showed that the mean PDCs for all included DMARDs stayed relatively steady in the 12 months before and after mitigation measures were introduced (see Table 1). Adherence was highest among anti-TNFs, methotrexate, and azathioprine. Anti-TNFs were on a downward trajectory 12 months prior to the index date. Interrupted time-series modeling demonstrated statistically significant differences in the trends in PDCs post- vs. pre-mitigation measures for all anti-TNFs (slope [β]: 1.38, standard error [SE]: 0.23), infliximab (β: 1.35, SE: 0.23), adalimumab (β: 0.82, SE: 0.25), and etanercept (β: 1.07, SE: 0.25) (see Figure 1a). Conversely, the csDMARDs were on a flatter trajectory, and methotrexate (β: -0.53, SE: 0.16), leflunomide (β: 0.43, SE: 0.08), mycophenolate (β: -1.26, SE: 0.48), cyclophosphamide (β: 0.29, SE: 0.05), minocycline (β: -0.04, SE: 0.02), chloroquine (β: 0.02, SE: 0.00) showed statistically significant changes in estimated PDC trajectory after mitigation measures were introduced (see Figure 1b).

**Conclusion:** This population-based study demonstrates that messaging and pandemic mitigation measures did not affect adherence to DMARDs.

**Table 1.** Mean PDC 1 year before and after mitigation measures for the COVID-19 pandemic were introduced.

Background: Post-COVID-19 syndrome (PCS) is an emerging cause of morbidity and poor quality of life in COVID-19 survivors [1, 2].

Objectives: We aimed to assess the prevalence, risk factors, outcomes, and association with disease flares of PCS in patients with autoimmune rheumatic diseases (AIRDs) and non-rheumatic autoimmune diseases (nAIDs), both vulnerable groups understudied in the current literature using data from the 2nd COVID-19 Vaccination in Autoimmune Diseases (COVAD) global multicentre patient self-reported e-survey.

Methods: The survey was circulated from February to July 2022 by the international COVAD Study Group (157 collaborators from 106 countries), and demographics, comorbidities, AIRD/nAID status, COVID-19 history, vaccination details, and PROMIS physical and mental function were recorded. PCS was defined as symptom resolution time >90 days following acute COVID-19. Predictors of PCS were analysed using regression models for the different groups.

Results: 7666 total respondents completed the survey. Of these, 2650 respondents with complete responses had positive COVID-19 infection, and 1675 (45.0%) AIRDs, 12.5% nAIDs, 42.5% HCs completed the survey >90 days post acute COVID-19. Of these, 136 (8.1%) had PCS. Prevalence of PCS was higher in AIRDs (10.8%) than healthy controls HCs (5.3%) (OR: 2.0; 95%CI: 1.08-3.6, p=0.026), those with comorbidities (OR: 2.8; 95%CI: 1.4-5.7, p=0.005), and patients requiring oxygen supplementation for severe acute COVID-19 (OR: 3.8; 95%CI: 1.1-13.6, p=0.039). Among patients with AIRDs, comorbidities (OR: 2.0; 95%CI: 1.08-3.6, p=0.026), and advanced treatment (OR: 1.9; 95%CI: 1.08-3.3, p=0.024), or intensive care (OR: 3.8; 95%CI: 1.01-14.4, p=0.047) for severe COVID-19 were risk factors for PCS. Notably, patients who developed PCS had poorer PROMIS global physical [15 (12-17) vs 12 (9-15)] and mental health [14 (11-16) vs 11 (8-14)] scores than those without PCS.

Conclusion: Individuals with AIRDs have a greater risk of PCS than HCs. Associated comorbid conditions, and advanced treatment or intensive care unit admission for severe COVID-19 confer a higher risk of PCS. It is imperative to identify risk factors for PCS for immediate multidisciplinary management in anticipation of poor physical and mental health.

Background: The SARS-CoV-2 pandemic initially raised concerns about the risk of severe infection in patients with inflammatory rheumatic diseases (IRD).

Objectives: In a setting with an excessive SARS-CoV-2 test strategy and availability of effective vaccines we aimed to investigate if patients with IRD face greater risk of contracting SARS-CoV-2 infection and have an increased risk of hospitalization, assisted ventilation and death compared to the general population.

Methods: This large nationwide, population-based register study compared the outcomes of SARS-Cov-2 infection in Danish patients with IRD (n=65,603) to matched population controls (n=656,030), from the first registration of SARS-CoV-2 (March 2020 to October 2022). The IRD population included 1,903 ANCA associated and necrotizing vasculitis; 30,391 rheumatoid arthritis; 2,444Systemic lupus erythematosus; 1,538 systemic scleroderma; 2,521 spondyloarthrits and psoriasis arthritis patients. Cox regression analyses were used to calculate incidence rate ratios (IRRs) for SARS-CoV-2 infection outcomes.

Results: We observed a discrete difference in time to first and second positive SARS-CoV-2 test in IRD patients compared to the general population (IRR=1.05 95% CI (1.03-1.06) and (IRR=1.17 95% CI 1.11-1.24). The risk of hospital contact with COVID-19 and severe COVID-19 was increased in IRD patients compared to population controls (IRR=1.92; 95% CI 1.79-2.06) and (IRR=2.16; 95% CI 1.91-2.45). Also, the risk if hospitalization requiring assisted ventilation (IRR=2.40, 95% CI 1.93-2.99) and for hospitalization with COVID-19 leading to death were increased in the IRD population (IRR=2.02 95% CI 1.66-2.45). The risk of hospitalization with severe COVID-19 was remarkably reduced after third SARS-CoV-2 vaccination.

Conclusion: IRD patients have a risk of SARS-Cov-2 which nearly corresponds to the general population but have a substantial increased risk of hospitalization with COVID-19, severe COVID-19, requiring assisted ventilation and COVID-19 leading to death compared to the general population. A third SARS-CoV-2 vaccination was associated with reduced need for hospitalization with COVID-19 and reduced the risk of death.

**Background:** Chronic parenchymal lung disease (LD) is a new emerging severe life-threatening complication of sJIA. The number of sJIA patients with LD is apparently increasing and interestingly they are reported more frequently in North America. Data regarding frequency and features of sJIA-LD in Europe are not available.

**Objectives:** To evaluate the burden of sJIA-LD in Europe.

**Methods:** Patients with diagnosis of sJIA-LD, including pulmonary alveolar proteinosis (PAP), interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH), followed in European paediatric rheumatology centres were identified through a survey sent to the members of the MAS/sJIA Working Party.

**Results:** Data from 34 sJIA-LD patients, diagnosed in 15 European paediatric rheumatology centres between 2007 and 2022, were collected. 33 patients were Caucasian and 1 was African-American; 21 were female. The median age at sJIA onset was 6 years and LD occurred after Grant Joane of 2 years. 19 patients had a chronic persistent sJIA course, 14 had a polycyclic course and only 1 patient had a monocular course. 29 (85%) had active sJIA at time of LD diagnosis. During the disease course, 28 (82%) patients developed MAS, 12 (35%) of whom had MAS at sJIA onset and 19 (66%) had full-blown MAS at time of LD diagnosis; 23 (68%) patients had >1 MAS episode. 28 (82%) patients were treated with at least one IL-1 or IL-6 inhibitor before LD diagnosis: 15 with canakinumab, 24 with anakinra and 13 with tocilizumab; 13 (38%) patients experienced drug adverse reaction to a cytokine inhibitor: 9 to tocilizumab and 4 to anakinra. 24 (70%) patients developed ILD, 6 (18%) PAP and 4 (12%) PAH. 15 (44%) patients presented acute digital clubbing; 16 (47%) patients developed hypoxia and 9 (26%) developed pulmonary hypertension. A chest CT scan was performed in all patients with evidence of septal thickening, peri-bronchovascular thickening and ground glass opacities in the majority of patients (26, 18 and 18 respectively). In 17 patients a bronchoalveolar lavage was performed and 12 underwent a lung biopsy. The histopathological pattern was alveolar proteinosis in 5 patients, endogenous lipid pneumonia in 3, vasculitis in 1 and fibrosis in 1. Half of the patients (17) required ICU admission and 6 (18%) died. All the patients were treated with glucocorticoids (GCs) at time of diagnosis, and 26 received IL-1 or IL-6 inhibitor after the diagnosis (13 canakinumab, 20 anakinra, 14 tocilizumab).

**Conclusion:** Lung involvement is an emerging life-threatening complication of sJIA and patients are also diagnosed in Europe. Prompt recognition is crucial and new therapeutic strategies are needed to reduce the risk and improve the outcome of this complication.

**Background:** Secukinumab has demonstrated efficacy and safety in patients with enthesitis-related arthritis (ERA) and juvenile psoriatic arthritis (JPsA) categories of juvenile idiopathic arthritis (JIA) for up to 2 years.[3] After completion of a 2-year core study (JUNIPERA), a long-term extension (LTE) study was conducted to evaluate the continued efficacy and safety of secukinumab.

**Objectives:** To report interim efficacy and safety results of the LTE study of secukinumab in patients with ERA and JPsA.

**Methods:** In the core study, a total of 86 patients (2 to <18 years of age) received secukinumab up to week 104. The open-label (OL) period [1] 4IA ACR30 responders at week 12 (n=75) were subsequently randomised to secukinumab (n=37) or placebo (n=38) up to week 100 in study period 2. Those who failed after randomisation (secukinumab, n=10; placebo, n=21) received OL secukinumb up to week 100.[1] A total of 54 out of 61 patients who had completed the core study consented to the LTE study and received secukinumab (n=37) placebo (n=18) up to year 4 years. Patients whose signs and symptoms were not fully controlled, as judged by the investigator in...
the LTE, could have dose escalation of their secukinumab dose from 75 mg to 150 mg or 150 mg to 300 mg. Median Juvenile Arthritis Disease Activity Scores (JADAS)-27 were presented up to week 156 for efficacy, and adverse events (AEs) and serious AEs were presented for the entire treatment period up to the cut-off date (maximum up to week 232).

**Results:** JADAS-27 in the core study and in the LTE are presented in the Table 1. A total of 19 patients had dose escalation in the LTE: 8 patients from 75 mg to 150 mg and 11 patients from 150 mg to 300 mg. The overall exposure-adjusted incidence rate per 100 patient-years (PY) of treatment-emergent AEs was 86.4 PY in the entire JIA population. The most commonly reported AEs (preferred term, safety set 5% cut off) were nasopharyngitis (n=9, 16.7%) and arthralgia (n=8, 14.8%). One major adverse cardiovascular event, not related to the study drug, and 2 cases of uveitis were reported. No cases of Crohn's disease or deaths were reported, and no patient discontinued treatment due to an AE.

**Conclusion:** With secukinumab treatment, the JADAS-27 inactive disease status was sustained from week 104 to week 156 in patients with JIA who had completed the 2-year core study and enrolled in the LTE study. Safety data were consistent with adult and paediatric indications, with no new or unexpected safety signals.

Methods: All patients in the UK JIA Biologics Register starting a JAK inhibitor were identified. Patient characteristics are presented at the time of treatment start, including age, disease duration and prior bDMARDs. Patients were followed until their latest follow-up form was returned. Active joint count (AJC) was followed until their latest follow-up form was returned. Active joint count (AJC) was reported at start of therapy and after 6 months. Status at their last follow-up was reported including treatment persistence.

Results: As of 21-Nov-2022, 14 children and young people across most ILAR categories had been treated with a JAK inhibitor; 12 baricitinib, 2 tofacitinib (table 1). Median age at JAK inhibitor start was 16 years (interquartile range [IQR] 13-17) and median disease duration was 6 years (IQR 4-7). All patients had prior bDMARD exposure, with 12 out of the 14 having more than 2 prior bDMARDs (range 2-6). Ten patients had follow-up available after the start of JAK inhibitor (median 1.4 years of follow-up available; median 0.8 years on treatment available). At the latest follow-up, 6 patients remained on JAK inhibitor, whilst 4 patients had discontinued treatment for ineffectiveness. No venothromboembolism (VTE) have been reported. In eight patients who had disease activity data available at the start of treatment, median active AJC was 2 (IQR 0-4).

Conclusion: In this cohort, the initial patients with JIA prescribed JAK inhibitor have largely received these drugs prior to marketing authorisation in JIA, with most receiving it as a later stage biologic/targeted-synthetic DMARD. Most patients were still receiving treatment almost 11 months after starting a JAK inhibitor. These data suggest that JAK inhibitors could be a very effective treatment for children and young people with JIA, even after a high number of prior bDMARDs.

Objectives: Our aim is to assess the safety of bsDMARD therapy in JIA.

Methods: Data was obtained from BIOBADASER, a multicenter prospective registry based on routine clinical practice. All patients diagnosed before age 16 in our database between 2000 and 2022 were included in the analysis. JIA is classified into 7 subgroups: systemic, persistent or extended oligoarthritis, RF positive polyarthritis, enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis. Due to the registry design, it was not possible to identify each of the JIA subgroups; thus, we classified them into oligo/polyarticular JIA, JIA related to enthesitis, and psoriatic JIA. Adverse events were coded using version 13.0 MedDRA (Medical Dictionary for Regulatory Activities). Proportions, means and standard deviations (SD) were used to describe our population. Incidence rates (IR) of adverse events and 95% confidence intervals were calculated, and Poisson regression was used to estimate incidence rate ratios (IRR), adjusting by sex, diagnosis type, age at start of therapy (<16 years vs >16 years) and line of treatment as confounding variables. Data were analyzed with descriptive statistics. Categorical data were represented as absolute and percentage values, while continuous data were represented as means and standard deviations or medians and ranges. Data were checked for normality. For normally distributed data, appropriate parametric statistical tests were employed, for non normally distributed data, non-parametric statistical tests were employed. Comparison in the frequency of the psychological symptoms in presence/absence of pain, active, painful/tender or limited joints was assessed. Significant level was set at p<0.05. All statistical analyses were performed using R (version R 4.0.3).

Results: From a total of 313 patients, 130 (41.5%) use biosimilars therapies, 60.8% of which were women (n=79). Mean age at diagnosis was 11.2 years (SD=6.1) and mean age at the start of treatment was 25.1 (SD=13.4). Patients were classified as oligo/polyarticular JIA (79.2%), JIA related to enthesitis (16.2%) and psoriatic JIA (4.6%). Methotrexate was used in combination in 39.1% of the bsDMARD treatments. The most commonly used drug was Adalimumab (56.8%), followed by Etanercept (28.7%). Table 1 shows incidence rates for adverse events according to severity. For all adverse events, IR is greater in biosimilars compared to original biologic disease modifying antirheumatic drugs (bDMARDs), although the latter have a higher IR of serious adverse events. The IRR was 1.33 (95% CI 1.1-1.6), thus, the risk of adverse events was greater among bsDMARD compared to the original bDMARDs.

Conclusion: The risk of adverse events occurrence is higher among patients treated with bsDMARD drugs. Although this project allowed us to examine long-term biosimilars safety in JIA, large registries that focus on such patients are needed to better understand rare adverse events.

POS0283  EFFECT OF CUSTOMISED FOOT ORTHOSES ON PEAK PRESSURE AND PRESSURE TIME INTEGRALS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A RANDOMISED CLINICAL TRIAL

Keywords: Randomized control trial

1University of Newcastle, College of Health, Medicine and Wellbeing, Callaghan, Australia; 2Sydney Children’s Hospital, Randwick, Rheumatology, Randwick, Australia; 3Queen Margaret University, Podiatry, Edinburgh, United Kingdom; 4Hunter Medical Research Institute, Biostatistics, New Lambton Heights, Australia

Background: Children with juvenile idiopathic arthritis (JIA) often exhibit joint symptoms in the lower limb. Prolonged joint disease may cause further physical and functional impairment, which can lead to significant disturbances in gait such as abnormal pressure distributions and sub-optimal peak plantar pressures [1-3]. Recent studies have shown that children with JIA compared to an age and sex matched cohort displayed significantly higher peak pressures (PP) in more distal parts of the plantar foot [2]. Research also showed that children with JIA are displaying elevated pressure time integrals (PTI), meaning they are spending higher amounts of elevated pressure time integrals (PTI), meaning they are spending higher amounts of joules on their feet.

Objectives: 1.To investigate the frequency of psychic symptoms in JIA patients at a single tertiary care center, including depressive, anxiety and alexithymic symptoms. 2.To investigate correlation between psychic symptoms and demographic and clinical parameters.

Methods: JIA patients aged 8-17 years and consecutively seen from March to November 2022 were invited to undergo psychological standardized tests: the Patient Health Questionnaire-9 items (PHQ9), self-administered measure of depressive symptoms; the Generalised Anxiety Disorder (GAD7) test; the Self-administered Psychiatric Scales for Children and Adolescents anxiety-related areas (SAFA-A), depression-related areas (SAFA-D) and somatic areas (SAFA-S); the PedsQL™ Multidimensional Fatigue Scale; PedsQL™ Rheumatology Module Pain and Hurt; the Toronto Alexithymia Scale (TAS-20); the Visual Analogue Scale (VAS) for pain intensity. Demographic data, clinical and laboratory parameters for disease assessment on the same visit were also recorded. Data were analyzed with descriptive statistics. Categorical data were represented as absolute and percentage values, while continuous data were represented as means and standard deviations or medians and ranges.

Results: Thirty-seven JIA patients were enrolled in the study: 64.9% were females, 38% with persistent oligoarthritis, 22% extended oligoarthritis and 40% polyarthritis, and 32% with chronic uveitis ever. Median age was of 12.6 years (IQR 9.5-15.3), with a median disease duration of 5.3 years (IQR 3.6-7.6). Respectively, 96% and 95% of patients were receiving csDMARDS and bDMARDS. All disease parameters showed very low level of disease activity and disability. PHQ9 and GAD7 were pathologic in 41% and 44%, respectively; borderline or clinically pathologic scores were found in 27%, 29%, and 13% for SAFA-D, SAFA-A, SAFA-S, respectively. Of note, TAS-20 was borderline or pathologic in 32% of patients. No psychic symptoms, demographic variables or clinical features showed an association with disease parameters. No significant differences were found between patients with and without pain on VAS, active joints, painful/tender or limited joints.

Conclusion: In a selected cohort of JIA patients on intensive treatment, low disease activity and few limited joints psychological parameters for depression and anxiety were detectable in a sizable proportion; a higher percentage of patients reported fatigue; alexithymia was even more frequent, regardless disease assessment variables. Our findings support the rationale for adopting routine psychological assessment and intervention in JIA patients, and for extending psychological investigations to their parents/guardians.

POS0284 PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA) ON INTENSIVE TREATMENT FREQUENTLY PRESENT ALEXITHMYA OVER FATIGUE, ANXIETY, AND DEPRESSION, DESPITE LOW DISEASE ASSESSMENT PARAMETERS

Keywords: Inflammatory arthritides, Patient reported outcomes, Quality of life

1University of Newcastle, College of Health, Medicine and Wellbeing, Callaghan, Australia; 2Sydney Children’s Hospital, Randwick, Rheumatology, Randwick, Australia; 3Queen Margaret University, Podiatry, Edinburgh, United Kingdom; 4Hunter Medical Research Institute, Biostatistics, New Lambton Heights, Australia

Background: Children with juvenile idiopathic arthritis (JIA) often exhibit joint symptoms in the lower limb. Prolonged joint disease may cause further physical and functional impairment, which can lead to significant disturbances in gait such as abnormal pressure distributions and sub-optimal peak plantar pressures [1-3]. Recent studies have shown that children with JIA compared to an age and sex matched cohort displayed significantly higher peak pressures (PP) in more distal parts of the plantar foot [2]. Research also showed that children with JIA are displaying elevated pressure time integrals (PTI), meaning they are spending higher amounts of...
of time in the stance phase of gait and less in the swing phase and thus a less propulsive gait [2]. To our knowledge only one previous clinical trial has explored the effect of a mechanical intervention such as foot orthoses (FOs) to improve the distribution of plantar pressures in children with JIA [4].

Objectives: The aim of our randomised clinical trial is to further evaluate the effect of customised prefabricated FOs in improving PTI and PP in children with JIA.

Methods: A multicentre, parallel design, single-blinded randomised clinical trial was used to assess the impact of customised prefabricated FOs on plantar pressures in children with JIA. Children with a diagnosis of JIA, showing lower limb symptoms and aged 5-18 were eligible. The trial group received a low density full-length, Slimflex Simple device which was customised chair side and the control group received a sham device. PP and PTI were used as the main gait outcomes and were measured using portable Tekscan gait analysis technology at baseline, 3 and 6 months. PP were measured using kilo pascals (kPa) and PTI measured kPa per seconds (kPa/s). Differences at each follow-up were assessed using the Wilcoxon rank sum test.

Results: A total of 66 participants were recruited. Customised prefabricated FOs were effective in altering plantar pressures in children with JIA versus a control device. Reductions of PP in the heel (baseline p=<0.001 (-104.33 kPa), 3-month p=0.004 (-126.16 kPa), forefoot (baseline p=0.027 (-69.5 kPa), 6-month p=0.016 (-50.91 kPa)) were statistically significant in favour of the trial group. These results were also positively correlated with PTI with the trial group spending less time and pressure on the heel, forefoot and rearfoot than the control. Finally, PP and PTI reductions were also associated with statistically significant increased midfoot contact with the trial device at baseline (29.84 kPa), 3 (24 kPa) and 6-month (43.75 kPa) data analyses, showing that the trial intervention was successful in capturing the benefits of participants and redistributing pressure. The trial intervention was safe and well accepted by participants, which is reflected in the high retention rate (92%).

Conclusion: Clinicians may prescribe customised prefabricated FOs in children with JIA to deflect pressure from painful joints and redistribute from high pressure areas such as the rearfoot and forefoot.

COVID-19 SYMPTOMS AND DISEASE COURSE IN GERMAN PEDIATRIC RHEUMATOLOGY PATIENTS REPORTED TO BIKER

Keywords: COVID, Disease-modifying Drugs (DMARDs), bDMARD

A. Klein1,2, T. Hopsch2, E. Dreßler4, D. Windschaff5,6, M. Hufnagel2, W. Emminger2, S. Muruk2, P. Ruehmer2, A. Kühn3, P. Bismarck5, M. Halle3, G. Horneff1,2, 4

As part of the nationwide BIKER project, 928 COVID infections in 885 patients with rheumatic diseases could be analysed. JIA was the most common diagnosis with 717 infections, followed by persistent antinuclear antibodies (PANAs) infections, systemic autoimmune diseases (SADs), infections, idiopathic uveitis (n=25), vasculitis (n=5). In 374 reported COVID infections (40%), patients were receiving conventional DMARDs, in 331 (36%) biologics, mainly TNF inhibitors (TNFi, n=241 (26%)). In 567 reports (61%) patients used either a biologic or a DMARD, in 339 reports patients (37%) did not use any antineuritic medication including steroid. Over the last 3 months, COVID-19 occurred in Germany in 5 distinguishable waves, calendar weeks (CW) 10-30 in 2020, CW 21/2020 – 8/2021 (both predominantly wild-type variant), CW 9-27 in 2021 (Alpha variant in the majority of infections), CW 28-31 in 2021 (Delta variant), since CW 52/2021 (several Omikron variants; Robert-Koch Institute: VOC_VOI_Tabelle.xlsx; live.com) In our cohort, patients with SARS-CoV-2 infection were slightly older during the 1st and 2nd wave (mean age 12.7+/−3.5 and 12.8+/−4.3 years) compared to the 4th and 5th wave with 11.4+/−3.9 and 11.4+/−4.2 years; p=0.01. 160 asymptomatic SARS-CoV-2 infections were reported, frequencies of symptoms associated with COVID-19 are shown in table 1. Five patients were hospitalized for 4-7 days. A 3½-year-old female patient succumbed during the first wave with encephalopathy and respiratory failure. The patient had been treated with MTX and steroids for systemic JIA. Genetic testing revealed a congenital immunodeficiency. No other patient needed ventilation or intensive care. One case of uncomplicated PIMS in an MTX treated JIA patient was reported. The duration of SARS-CoV-2 infection-associated symptoms was markedly shorter during the 5th wave with 6.7+/−5.1 days, compared with reports from the other 4 waves (Table1). The duration of symptoms was higher in MTX treated patients (10.2+−8.4 days) compared to patients without treatment (7.7+/−10.8; p=0.004) or patients treated with TNFi (8.2+/−4.8; p=0.002). Although patients treated with steroids also had a longer duration of symptoms (9.7+/−7.0), this was not significant.

Conclusion: Except for one patient with congenital immunodeficiency who died, no case of severe COVID-19 was reported in our cohort. At the time of infection, over 60% of patients had been treated with conventional DMARDs and/or biologics. Although MTX treated patients had a slightly longer duration of symptoms, antihemophilic treatment did not appear to have a negative impact on severity or outcome of SARS-CoV-2 infection.

Tofacitinib in Juvenile Idiopathic Arthritis: First Year Experience

Keywords: Targeted synthetic drugs, Registries

G. Horneff1,2, D. Windschall3, B. Huegle4, R. Berendes5, H. Girschick6, A. Klein1,2, Sankt Augustin, General Paediatrics, Sankt Augustin, Germany;
1University of Cologne, Department of Paediatric and Adolescents Medicine, Cologne, Germany; 2St Josef Stift, Paediatric Rheumatology, Sendenhorst, Germany; 3Deutsches Zentrum Kinder- und Jugendrheumatologie, Paediatric Rheumatology, Garmisch-Partenkirchen, Germany; 4Marlen Hospital, Paediatric Rheumatology, Rosenheim, Germany; 5Vivantes Clinic Berlin, General Paediatrics, Berlin, Germany

Background: Tofacitinib is an oral Janus kinase inhibitor recently approved for the treatment of polyarticular juvenile idiopathic arthritis (pJIA) and juvenile psoriatic arthritis (pPsA) aged 2 to <18 years. Data out of clinical practice so far are rare.

Objectives: To characterize JIA cohorts treated with tofacitinib and to evaluate efficacy and tolerance in clinical practice.

Methods: The German BIKER data base was screened for JIA patients aged 2 to <18 years who were started on tofacitinib until December 31st, 2021.

Results: Patient demographic and disease characteristics are presented in Table 1. Primary diagnoses were either polyarticular JIA rheumatoid factor positive (n=4) or negative (n=18), extended oligoarthritis (n=7), pPsA (n=2), ERA-JIA (n=2), persistent oligoarthritis (n=1) and systemic onset JIA (n=1). The patient's age varied from 6.9 to 18.0 years at start of treatment and the disease duration range was 2.3 – 16.6 years. In most cases, patients were extensively pretreated with biologics (mean 2.7). One patient had received 7 biologics, four each received 5 or 4 biologics, six received 3, ten received 2 and 8 received 1 biologic before. In a single case, tofacitinib was used directly after failure of methotrexate. Tofacitinib was administered orally BID in 35 JIA patients at a daily total dosage of 0.18 – 1.06 mg/kg. Tablets with dosages of 5 mg BID were used in 31 patients. Oral solution was used in 4 patients (up to 4 mg BID).

Background: Despite optimal treatment, lupus nephritis (LN) remains associated with irreversible kidney damage[1]. A better understanding of the mechanisms underlying LN pathogenesis is needed to develop better treatment targets. As part of the Accelerating Medicines Partnership (AMP), we discovered that urinary PR3, a myeloid degranulation product, correlated with histological activity implicating neutrophil/monocyte degranulation in proliferative LN, the most aggressive type[2]. PR3 is a serine protease that can mediate kidney damage. Mature neutrophils with classical polylobed nuclei are rare in LN kidney biopsies. However, recent evidence displayed how immature, degranulating myeloid cells have been implicated in the pathogenesis of LN[3], but their role in mediating kidney damage is not completely understood.

Objectives: To investigate PR3+ cells in LN kidney, their association with histopathological features, and define their immunophenotype.

Methods: We performed multiplexed histology using serial immunohistochemistry (sIHC)[4] on archival LN kidney biopsies to quantify the expression of PR3 and multiple cell lineage markers (20-plex). Image analysis including deconvolution, cell segmentation, glomerular annotation, and quantitative histology was performed using Indica HALO. The analysis was limited to renal cortex.

Results: A total of 11 patients with LN who underwent a clinically indicated kidney biopsy were enrolled: 6 (55%) with pure proliferative LN (ISN/RPS class III or IV) and 5 (45%) with pure membranous LN. PR3+ cells were identified in all LN biopsies (range 343-7625 per sample). Most PR3+ cells did not show a polylobed nucleus. The majority of PR3+ cells were in the tubulointerstitium (Figure 1A). However, accounting for the smaller glomerular area, there was a higher density of PR3+ cells in the glomeruli (Figure 1A-C). PR3+ cell abundance was higher in proliferative LN, especially in the glomeruli (Figure 1A-C). Glomerular PR3+ cell density very strongly correlated with histological activity measured by the NIH Activity Index (Pearson’s r=0.97, p<5x10^-9; Figure 1D). Preliminary serial IHC analysis showed that PR3+ cells coexpressed MPO and variably coexpressed CD66b and CD14, but not neutrophil elastase, CD3, or CD20.

Conclusion: PR3+ cells are abundant in LN. PR3+ cells are increased in proliferative LN and are strongly associated with histological activity thereby characterizing a more aggressive phenotype. This population densely infiltrated the glomeruli emphasizing a potential role in the endothelial pathogenic process. In preliminary analysis, kidney infiltrating PR3+ cells were not polymorphonuclear, and variably expressed CD14 suggesting a phenotype consistent with degranulating monocyte or an immature myeloid population. We previously showed the association between urinary PR3 and histological activity suggesting that intrarenal PR3+ cells are actively degranulating and therefore likely inducing kidney damage. These findings nominate PR3+ cells as a potential therapeutic target. Spatial transcriptomics and proteomic studies are ongoing to define the lineage and function of these cells.

Hopkins University, Division of Rheumatology, Baltimore, United States of America; Oklahoma Medical Research Foundation, Oklahoma City, United States of America; New York University Division of Rheumatology, New York, United States of America; Feinstein Institutes for Medical Research, Molecular Medicine and Medicine, Manhasset, United States of America; Multiple, Multiple, United States of America

Background: There is a pressing need to identify novel therapeutic approaches and noninvasive biomarkers in lupus nephritis (LN).

Objectives: In this study, we quantified serum soluble mediators in the large Accelerating Medicines Partnership (AMP) LN longitudinal cohort to identify novel biomarkers of histological features and treatment response and provide insights into the pathogenesis of LN.

Methods: SLE patients meeting ACR or SLICC criteria (n=268) undergoing a clinically indicated kidney biopsy with a urine protein/creatinine (UPCR) ≥0.5 were recruited for this study as part of the AMP. Serum samples were collected from patients at the time of diagnostic kidney biopsy and 3-, 6-, and 12-months post-biopsy and from 22 healthy donors (HD). Concentrations of 51 analytes, including cytokines, chemokines, and TNFR superfamily members, were analyzed by xMAP multiplex assays on the Bio-Rad BioPlex200 array system. TACE levels were determined by ELISA. Clinical response was determined at 12-months post-biopsy using the Abatacept and Cyclophosphamide Combination Efficacy and Safety Study definitions in patients with a baseline UPCR >1.0 and International Society of Nephrology/Renal Pathology Society class III, IV, V, or combination thereof.

Results: LN patients demonstrated heterogeneity in serum soluble mediator concentrations (Figure 1A). Most soluble mediators were elevated in LN patients compared to HD. Within LN, patients with proliferative LN (class III or IV) had higher serum levels of immune mediators, such as IFNα and IL-1β, compared to nonproliferative LN, including pure membranous (class V) LN. In addition, several serum immune mediators correlated with intrarenal LN activity (NIH Activity Index), with syndecan-1 (CD138) and TNF-RII exhibiting the highest correlation (Figure 1B). In contrast, stem cell factor (SCF) and TNF-R1 had the highest correlation with the chronicity index. In proliferative LN, the concentrations of many immune mediators declined in treatment responders. For example, syndecan-1 and TNF-R1 decreased in complete and partial responders but not in nonresponders (Figure 1C). In contrast, SCF levels remained relatively stable regardless of response status.
POSITIVELY TO THROMBOGENESIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Background: Venous and arterial thrombotic events are leading causes of mortality in systemic lupus erythematosus (SLE), amounting to up to a quarter of deaths[1]. Other than traditional risk factors, SLE-specific factors, including chronic inflammation, have also been shown to contribute to thrombosis development. Nonetheless, the four times higher relative risk of thrombosis compared to healthy individuals is not fully accounted to the presence of conventional cardiovascular risk factors and antiphospholipid antibodies[1]. As such, novel biomarkers of thrombosis are needed in early identification and preventative management of SLE patients.

Objectives: To characterize novel antibodies directed against mitochondrial constituents and investigate their capacity to stratify patients based on thrombotic events.

Methods: Highly purified mitochondria were isolated from HepG2 cells (ATCC HB-8065TM) as previously described[2]. Briefly, cells were harvested and homogenized by a glass Douncer, followed by sequential centrifugation. Upon DNase-mediated removal of extracellular DNA, ultra-pure mitochondria (confirmed by flow cytometry, qPCR, and Western blot), labeled with Mito-Tracker, were incubated with sera (diluted 1:100) from SLE patients or healthy individuals. Binding of IgG to the mitochondrial outer membrane was detected using a secondary FITC-conjugated anti-human-IgG antibody, and analyzed by FACS. In some experiments, mitochondria were treated with trypsin (0.05%) prior to incubation with sera. Finally, reactivity towards mitochondrial protein lysate was confirmed using WB. Samples and clinical data from SLE patients (n=92) and healthy individuals (n=80) were provided from Division of Rheumatology, Lund University, Sweden. Statistical analyses were performed on SPSS 22.0. Mann-Whitney test was performed, with a p-value of 0.05 or below deemed as significant. Data protection and patient anonymization were ensured in accordance with regulation by Research Advisory Boards.

Results: Based on our novel flow cytometry assay, quantifying anti-mitochondrial antibodies (AMA) targeting the outer mitochondrial membrane, a large proportion (40.8%) of SLE patients were deemed positive for AMA using the 95th percentile of healthy controls as a cut-off. Presence of AMA was associated with severe SLE manifestations, including history of nephritis (OR = 3.3, p=0.02), anti-phospholipid syndrome (APS; OR = 5.7, p=0.02), and venous thromboembolism (OR = 6.7, p=0.008), the latter which was not seen in our cohort for isolated presence of anti-cardiolipin (aCL) antibodies (OR = 2.2, p=0.17), neither for lupus anticoagulant (OR 5.0, p=0.08) or anti-beta-2 glycoprotein 1 (OR 1.1, p=0.93). Pre-treatment of mitochondria with trypsin induced loss of binding of sera-derived antibodies (p=0.01), suggesting that AMA were targeting protein components of mitochondria, and not phospholipids, as is the case of aCL. WB confirmed presence of reactivity towards mitochondrial protein antigens, in particular of 35 and 60kDa, though reactivity towards other protein antigens, including 17kDa ones, were also seen in some patients, with the latter being associated with APS (p=0.008).

Conclusion: SLE patients positive for novel AMAs targeting mitochondrial outer membrane proteins develop severe lupus manifestations, including venous thromboembolism. Future studies are warranted to further characterize the novel antibodies, as well as determine their prognostic value.

POS0291 IDENTIFICATION OF SUBSETS OF SLE PATIENTS RESPONSIVE TO IBERDOMIDE BY TRANSCRIPTOMIC ANALYSIS OF BASELINE SAMPLES

Keywords: Artificial Intelligence, Systemic lupus erythematosus, Clinical Trials

P. Bachalli1, Y. Hu2, N. Delev3, P. Schafer1, P. Lipsky1; 1JAMP El BioSolutions, Research and Development, Charlottesville, Virginia, United States of America; 2Bristol Myers Squibb, Research and Development, Princeton, United States of America; 3Bristol Myers Squibb, Research and Development, Princeton, United States of America

Background: Iberdomide is a high affinity cerebelin ligand that promotes ubiquitination and proteasomal degradation of Ikarios (IKZF1) and Aiolos (IKZF3) transcription factors and, thereby altering specific aspects of immune responsiveness. Iberdomide has been shown to be efficacious in a randomized controlled trial in patients with generalized SLE (NCT03161483) and to be specifically effective in patients with high baseline expression of the interferon gene signature (IGS)[1,2].

Objectives: The goal of this study was to identify subsets of SLE patients responsive to iberdomide more effectively by analyzing baseline gene expression profiles.

Methods: Baseline whole blood samples from 276 female SLE patients from the phase 2b iberdomide trial were utilized for this analysis. These patients had a >6 month history of SLE and disease activity determined by SLEDAI-2K >6. Patients were randomized to placebo, or one of three doses of iberdomide (0.15, 0.3 or 0.45mg per day). Clinical response was determined by the SLE Responder Index 4 (SRI-4) at 24 weeks. RNAseq was performed and analyzed by Gene Set Variation Analysis (GSVA) using 32 informative gene modules and K-means clustering.

Results: Whole blood K-means clustering of the GSVA scores yielded 5 clusters or endotypes (Figure 1). Cluster 0 had the fewest molecular abnormalities whereas Cluster 1 had the most disturbances in immune function, including enrichments in the interferon gene signature (IGS), immunoproteasome, IL-17 inflammasome pathway, and neutrophil/granulocyte genes. Clusters 2-3 had intermediate degrees of abnormal enrichment in specific gene modules. Cluster 4 had high IGS, immunoproteasome, plasma cells/Ig chains, and IL-23 complex genes. No differences were noted between the subsets with regard to steroid or hydroxychloroquine use and differed only slightly in disease activity as measured by SLEDAI-2K. In general, cluster 1 had the most severe clinical laboratory measures with the highest anti-dsDNA antibodies and lowest C3 and C4. Clinical responses to iberdomide were confined to clusters 1 and 4. Effect sizes of responses in these groups approximated 30%. Other clusters had higher placebo responses and no additional response to iberdomide.

Conclusion: K-means clustering of GSVA scores from baseline samples of the iberdomide trial successfully clustered patients into endotypes that exhibited differences in response to iberdomide treatment, with the greatest responses observed in patients with the highest IGS, immunoproteasome, plasma cell, inflammasome, and IL-23 pathways. Gene expression based subsetting (endotyping) may be useful to enrich trials for responsive patients.

TRANSCRIPTOMIC PROFILING OF SJÖGRÉN’S SALIVARY GLANDS IDENTIFIES FOLLICULAR AND EXTRA-FOLLICULAR GENE SIGNATURES ASSOCIATED WITH RHEUMATOID FACTOR SERORESPONDENCY

Keywords: Autoantibodies, Sjögren syndrome

Background: The presence of circulating rheumatoid factor (RF) and the formation of ectopic lymphoid structures (ELS) in labial salivary glands (SG) of patients with Sjögren’s Syndrome (SS) have been reported as independent risk factors associated with the development of B-cell MALT lymphoma (MALTLF). Neoplastic MALTLF B-cells express highly hypermutated B-cell receptors bearing RF immunoactivity in up to 50% of the cases. In SS, RF production and proliferation is dependent on ELS or is also induced by extrafollicular responses in the SG is currently unclear. The definition of ELS and their association with circulating autoantibodies has so far relied on SG histopathology which bears significant limitations. Conversely, molecular pathology analysis through whole-tissue RNA Sequencing (RNaseq) has allowed a better definition of disease heterogeneity and disease taxonomy.

Objectives: To perform transcriptomic profiling of SS minor SG tissue characterised by different degrees of inflammatory aggregate organization and to identify transcriptomic clusters and gene signatures associated with peripheral and histological biomarkers of disease.

Methods: Labial SG were obtained from 99 patients including SS with and without ELS (respectively ELS+ and ELS-), as assessed by immunohistochemistry, and labial specific sialoadenitis (Sicca). Total RNA was extracted, complementary DNA libraries were prepared and sequenced. Differentially expressed genes (DEG), deconvolution and pathway analysis were performed.

Results: Unsupervised gene clustering by differential expression between sicca and SS confirmed a clear transcriptome segregation between the two diagnoses. As expected, in SS SG expression of genes associated with inflammation and adaptive immune responses was upregulated (e.g. CCR7, CD19, CR2, CXCL13, CXCL9, CXCR5, FCL3, FCL4, IL21R, MS4A1, PANX5, SLAMF6, TLR10 (Figure A)). Bulk RNaseq cell deconvolution confirmed immune cell enrichment (Th, B and plasma cells) in SS SG, especially those ELS+. A three-way comparison among sicca, ELS+ and ELS- SG, showed only a few genes specifically associated to ELS- and sicca, whereas most of the DEGs were either ELS+ specific or common to all SS (Figure B). Results of pathway analysis on ELS+ and SS-associated DEGs showed very similar profiles characterised by adaptive and interferon-associated pathway activation. Weighted Gene Co-Expression Network analysis showed higher activation of anti-viral pathways in ELS+ SG, where ELS+ SG were enriched in adaptive immune pathways. Principal component analysis on SS SG mRNA showed that a significant proportion of variability was associated with the presence of RF in the serum of patients independently of the presence of ELS. Surprisingly, transcriptome clustering was closer between ELS+/RF+ and ELS-/+RF+ SG than the clustering of ELS+/RF- with ELS-/RF- SG. Accordingly, SG of RF+ patients showed significant upregulation of B cell-associated genes (e.g. CXCL13, MS4A1), high RF immunoactivity in up to 50% of the cases. These were characterised by genes associated with germinal centre formation (e.g. IL21, AICDA, LTBI), transcriptomes from ELS+/RF+ SG displayed a unique set of DEGs such as BCL2, TRIM22, XAF1, DDX58, DDX60 and IFIT1. Conversely, a similar analysis performed based on anti-Ro/SSA and/or anti-La/SSB did not yield any significant differences in gene expression.

Conclusion: A comprehensive bulk RNA sequencing analysis of SS and sicca patients SG showed that higher tissue inflammation with features of functional germinal centres is associated to the presence of both RF and ELS, rather than ELS alone. Furthermore, the existence of a RF-driven SG transcriptome independent of the presence of ELS suggest that both follicular and extra-follicular responses support the selection of B-cells with RF immunoactivity within the SG of SS patients and could be involved in B-cell lymphomagenesis.

higher CV risk (elevated incidence of atheroma plaques, dyslipidemia, obesity, and hypertension). One hundred and forty-three metabolites were found deregulated between clusters. Thus, compared to C2, C1 had decreased athero-proective HDL and increased atherogenic VLDL and LDL lipoproteins, increased triglycerides, fatty acids, apolipoproteins (ApoB), glycosylation related metabolites (glucose and pyruvate), amino acids (Leu, Tyr, Val, Phe, ile), inflammation related metabolites (GlycA), and other lipids involved in immune cells activity, such as phosphatidylcholines, sphingomyelins, phosphoglycerides, and cholines. Of note, 2B metabolites were found altered in patients with thrombosis. Logistic regression analyses identified several metabolites which levels distinguished thrombotic APS patients with high accuracy, including VLDL and HDL subsets, fatty acids, amino acids, glucose and creatinine, all reportedly associated to enhanced CV risk. In vivo, Qred supplementation of APS patients partially reversed the altered serum metabolic profile linked to the development of athero-sclerosis and thrombosis.

Conclusion: 1) APS patients have a distinctive metabolic profile, with abnormalities associated with the pathogenesis of the disease, which are partially modified in vivo by Qred supplementation. 2) We have identified for the first time a metabolic biomarker able to stratify APS disease according to their thrombotic risk, which might pave the way for the development of new tools to improve their clinical management. Supported by ISCIII: (PI21/0591), and RICORS (RD21/0002/0033) co-financed by FEDER.

POSO294 MITOCONDRIAL DYSFUNCTION AND SENESCENCE OF NAÏVE T CELLS IN SJÖGREN’S SYNDROME

Keywords: Animal Models, Sjögren syndrome, Cell biology

P. Javorova1, J. Fessler2, C. Rammerstorfer2, M. Zeiler1, A. S. Muralikrishnan1, A. Lackner1, J. Hermann1, S. Zenz1, J. Thiel1, M. Stradner1. 1Department of Internal Medicine, Division of Rheumatology and Immunology, Graz, Austria; 2Otto Loewi Research Center for Vascular Biology, Immunology and Inflammation, Division of Immunology, Graz, Austria

Background: Primary Sjögren’s Syndrome (pSS) is a systemic autoimmune disorder characterized by lymphocytic infiltrations in exocrine glands. T-cells are considered major players in the pathogenesis of pSS. Previously, we reported premature aging and impaired homeostatic proliferation of pSS naïve CD4+ T-cells leading to peripheral lymphopenia [1]. Id3-deficient mice (Id3KO) develop a Sjögren’s-like syndrome and are used as an animal model for pSS [2]. Objectives: As mitochondrial function has been linked to premature aging and homeostasis of T cells, we assessed the mitochondrial status of T cells in pSS patients and the Id3KO mouse model of pSS.

Methods: Total immune cells were isolated from venous blood, lymph nodes and the spleens of Id3KO and wild type (WT) mice. Flow cytometric analysis was performed to characterize markers of cellular senescence p53, senescence-associated β-galactosidase (SA-β-GAL), and apoptotic rate in T-cell subsets. Staining with mitochondrion-selective fluorescent dyes MitoTracker Green, MitoTracker Deep Red, MitoSox Red was performed to assess mitochondrial mass, membrane potential (MtMP) and superoxide production, respectively. Similar analyses were performed on human T-cells from peripheral blood mononuclear cells of pSS patients and matched healthy individuals (HC).

Results: Similar to pSS patients, Id3KO mice show signs of pre-mature aging. The naïve cell compartment in CD4+ and CD8+ T-cells was significantly decreased in all studied tissues when compared to WT mice. Markers of cellular senescence p53 and SA-β-GAL activity were increased in naïve CD4+ and CD8+ T cells. Apoptotic rate was also higher in Id3 KO T-cells. ID3 KO T-cells also exhibited a remarkable decrease of mitochondrial mass and MtMP. Despite having reduced mitochondrial mass and MtMP, we observed that ID3-deficient T-cells produced a higher amount of mitochondrial superoxide compared to WT mice. Again, naïve CD4+ T-cells were most affected by this increase. In line with our findings in ID3 KO mice, naïve CD4+ and CD8+ T-cells isolated from pSS patients produced significantly higher amounts of mitochondrial superoxide than those of HC.

Conclusion: In human pSS and mice with a pSS phenotype, naïve T cells are diminished, and signs of pre-mature aging associated with significant accumulation of mitochondrial superoxide. ID3 KO mice may serve as a tool to test whether these changes are cause or consequence of pSS pathophysiology.

POSO295 CD4+ T CELLS DEMONSTRATE METABOLIC REPROGRAMMING CHARACTERISED BY INCREASED REACTIVE OXYGEN SPECIES FORMATION AND ENHANCED ATP GENERATION IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Autoimmune immunity

C. Wincup1, M. Wilkinson3, A. Radziszewsk3a, G. Robinson4, A. Rahman1. 1University College London, Rheumatology, London, United Kingdom; 2King’s College Hospital, Rheumatology, London, United Kingdom; 3UCL Great Ormond Street Institute of Child Health, Immunology and Rheumatology Section, London, United Kingdom; 4University College London, Centre for Adolescent Rheumatology, London, United Kingdom

Background: Systemic lupus erythematosus (SLE) is characterised by chronic stimulation of the innate and adaptive immune response. Oxidative stress resulting from Reactive Oxygen Species (ROS) generation is another hallmark of the disease. Mitochondria are a primary source of ROS and play a key role in energy metabolism via Oxidative Phosphorylation (OXPHOS), a vital pathway in maintaining the aberrant immunological response seen in the disease. Currently a number of novel therapeutics focusing on abnormal mitochondrial energy metabolism are under investigation in a variety of autoimmune diseases. Understanding abnormal immune cell mitochondrial function therefore represents an important area for identifying potential future targets in the treatment of SLE.

Objectives: To assess for evidence of abnormal mitochondrial function and associated ROS generation in the adaptive immune response in SLE.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from whole blood collected from patients with SLE recruited from the UCLH Lupus Clinic, England (n=37) and age/sex matched healthy controls (HC, n=20). Flow cytometry was used to quantify mitochondrial superoxide intensity (MFI) of cellular mitochondria (mitoTracker) and mitochondria derived ROS generation (MitoSOX) in CD4+ and CD8+ T cells plus CD19+ B cells. Real-time CD4+ T cell mitochondrial metabolic function was assessed using SeaHorse Respirometry. MitoStress Test. To assess for the role of cellular activation in CD4+ T cells, 24-hour anti-CD3/CD28 stimulation culture was conducted.

Results: Results are outlined in Figure 1. Briefly, mitochondrial mass was significantly higher in SLE CD4+ and CD19+ cells when compared with HC (A). CD8+ cells derived from patients with SLE showed higher amounts of mitochondrial ROS generation (B). When correcting for mitochondrial mass, individual mitochondria-derived ROS generation was significantly higher in CD4, CD8 and CD19+ cells in SLE when compared with HC (C). Seahorse Respirometry revealed basal CD4+ respiration was higher in SLE when compared with HC (D), although there was no significant difference in maximal mitochondrial respiratory capacity (E). Proton leak, a marker of mitochondrial damage, was significantly higher in SLE than HC (F). CD4+ T cells from patients with SLE also showed enhanced mitochondrial ATP production when compared with HC (G), although spare respiratory capacity was significantly reduced in SLE (H) suggesting that mitochondrial function in the disease is close to maximum with little scope for further upregulation. Mitochondrial uncoupling efficacy is an important mechanism through which higher rates of OXPHOS can be achieved and this appears to be downregulated in SLE (I). Activation of SLE CD4+ T cells appeared to drive higher rates of ROS production in both CD4+ and CD8+ cells (J). Interestingly, CD19+ ROS production was also increased, suggesting that T cell secreted cytokines following activation may also induce B cell ROS generation. Stimulation of SLE CD4+ T cells additionally reduced basal mitochondrial respiration when compared with unstimulated SLE CD4+ T cells (K).

Conclusion: Increased mitochondrial mass seen in CD4+ and CD19+ SLE cells could be a result of enhanced immune cell senescence, commonly observed in the state of chronic immune activation. At baseline, SLE derived CD4+ T cells were noted to generate ATP through OXPHOS at a higher rate than HC thus suggesting chronic cellular hyperactivation (and is further enhanced following T cell stimulation). CD4+ T cells also demonstrate a number of important pathological abnormalities in SLE, including high levels of proton leak, reduced spare respiratory capacity and lower ability for mitochondrial uncoupling. This may suggest that chronic activation is in turn resulting in mitochondrial damage and less efficient energy metabolism, resulting in ROS generation. Targeting this abnormal immune cell metabolic pathway therefore represents a novel therapeutic strategy.

Davidson7, D. Goldman1, A. I. Celia1, 2, J. Hodging3, D. Demeke3, A. Rosenberg4, L. Magder5, J. Buyon6, A. James1, 2, J. Guthridge1, 2.

Methods: Samples were obtained from 20 patients from the ABC study which evaluated ABA in SLE patients without organ-threatening disease on limited background medications and 46 patients from the ACCESS trial of ABA in active nephritis patients on a background of low dose cyclophosphamide followed by azathioprine. Neither trial met their key endpoints vs placebo. Pre-treatment gene expression profiles were compared in those who did or did not achieve clinical response to ABA. HSIC-Lasso[3] was employed to select the top 20 independent features associated with the histological features quantified by the NIH activity and chronicity indices.

Results: Pre-treatment DEGs associated with abatacept responders were cell type-specific, with the most distinctions observed in B cells (Figure 1). These DEGs included FCRLA, CXC3R1, and TNRFSF17, indicating baseline differences in B cell activation and differentiation in responding patients. Baseline whole blood expression patterns could distinguish later response vs non-response to ABA in both clinical trials (Figure 1). Transcripts identified by HSIC-Lasso included multiple unannotated IncRNAs and pseudogenes, as well as transcription factors, transporters, and enzymatic components of cell structure and metabolism. Random forest modeling and receiver operating characteristics (ROC) were employed to test the ability of differentiating transcripts to predict response (Figure 1). 5-fold cross validation of the predictor on a training set of 52 samples had 85.8% accuracy with ROC AUC: 0.939 (p = 0.0166). 14 confirmation samples were similarly modeled and achieved an accuracy of 83.3% with ROC AUC: 0.944.

Conclusion: The pathophysiology of SLE is heterogeneous and complex, but approaches to predict treatment response by patterns of gene expression may help identify patients most likely to benefit from a given treatment.

**Results:**

Ninety-one biopsies were included: 32 (35%) with pure proliferative LN, 33 (36%) with pure membranous LN, and 26 (29%) with mixed LN. The 5 most correlated urinary proteins and each pathologic feature are summarized in Figure 1A-B. Most lesions in the activity or chronicity indices shared a similar signature within their respective index. In contrast, fibrosic crescents displayed an inflammatory signature (CD73, MMP9, MIP1b, and IL-8) despite being part of the NIH chronicity index. Hierarchical clustering based on proteomic signatures revealed that fibrosic crescents were more similar to activity-related lesions (Figure 1C). Intestinal inflammation (activity) was correlated with biomarkers associated with both active and chronic lesions.

**Conclusion:** Although fibrosic crescents are considered inactive lesions that follow crescentic glomerulonephritis, urine proteomics revealed inflammatory activity associated with fibrosic crescents. Several cell types such as macrophages, fibroblasts, neutrophils, lymphocytes, and epithelial cells are critical in the formation of crescents. Higher levels of CD73, IL-8, and MMP9 indicate the presence of an inflammatory response involved in glomerular remodeling after extra-capillary proliferation that have an important role in kidney damage. The presence of fibrosic crescents in kidney biopsies may indicate ongoing potentially treatable inflammation. Intestinal inflammation, which is linked to worse clinical outcomes, showed a distinct proteomic signature combining both activity and chronicity. A better understanding of the pathophysiology of processes including fibrosic crescents and intestinal inflammation is needed to tailor treatment of these pathways leading to chronic damage.

**Background:** The International Map of Axial Spondyloarthritis (IMAS) is a global assessment of the impact and burden of axial spondyloarthritis (axSpA) from the patient perspective, and identifying the unmet needs of axSpA patients through a survey. This research started in 2016 with the Atlas of Axial Spondyloarthritis in Spain, expanded in 2017-2018 to 13 European countries giving rise to the European Map of Axial Spondyloarthritis (EMAS) and further expanding worldwide across 27 countries to become the International Map of Axial Spondyloarthritis (IMAS).

**Objectives:** Here we present the scope of the study, distribution and main characteristics of patients included and instruments to collect data, as well as highlighting the impact of the disease.

**Methods:** This research is a collaboration between the Axial Spondyloarthritis International Federation (ASIF), the University of Seville and Novartis Pharma AG together with a scientific committee composed of axSpA patient representatives, rheumatologists, psychologists, and researchers. IMAS collected information through an online cross-sectional survey (2017-2022) from unselected axSpA patients from Europe, Asia, North America, Latin America and Africa. The inclusion criteria were: age ≥ 18 years, residents in the specified country, a diagnosis of axSpA (self-reported AS/nr-axSpA) and under the care of an health care professional. Patients completed a comprehensive questionnaire containing over 120 items on socio-demographics, health behaviours, diagnosis and disease characteristics, comorbidities, mental health, resource utilization, pharmacological treatments, disease activity (BASDAI), physical activity and functioning, employment, and disease related fears and hopes.

**Results:** 5,557 axSpA patients participated in IMAS. The mean age was 43.9 ± 12.8 years, 55.4% were women, 46.2% had university education and 48.5% were employed. 20.6% were on sick leave (temporary or permanent). 71.4% had difficulty finding a job due to axSpA and 71.0% reported work-related issues. Patients’ diagnostic delay was a mean of 7.4 ± 9.0 years (median: 4.0), and the mean disease duration was 17.1 ± 13.3 years. 75.0% of patients had active disease and 59.4% were at risk of poor mental health. In addition, patients had a mean of 2 physical comorbidities. On average, patients had visited primary care physicians 4.6 times and the rheumatologist 3.6 times in the year prior to the survey. 78.6% had ever taken NSAIDs, 43.6% csDMARDs and 48.8% bDMARDs. 33% had ever smoked, 48.5% were employed. 20.6% were on sick leave (temporary or permanent). The percentage of patients who have been on sick leave in the previous year was 48.5%.

**Conclusion:** IMAS is the largest survey in geographical reach and this is the first-time global results are presented. IMAS has shown the global profile of axSpA patients, highlighting unmet needs, including unacceptable delays in diagnosis, and high burden of the disease in axSpA patients worldwide. This global dataset will enable more detailed investigations to obtain evidence on the critical issues that matter to patients around the world in order to improve their care and quality of life.

**Map 1. Distribution of IMAS patients by region (N= 5,557)**

POS0299  NEUROPATHIC AND NEUROPLASTIC PAIN COMPONENTS DETERMINE THE PRESENCE OF RESIDUAL SYMPTOMS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS RECEIVING BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

Keywords: Spondyloarthritis, Pain, bDMARD

F. Al Mohamad1, V. Rios Rodriguez1, H. Hainebel1, M. Protopopov1, J. Radmacsher1,2, J. Sieper1, M. Torgutalp1, H. Käding1, F. Prohl2, D. Poddubnyy1,3,3. Charité - Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany; * Berlin Institute of Health (BiH), Clinician Scientist Program, Berlin, Germany; 2 German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany

Background: Several studies have investigated neuropathic pain (NP) as a component of chronic pain in patients with axial spondyloarthritis (axSpA)/ankylosing spondylitis (AS) and showed a wide frequency range from 22 – 56.9% [1, 2]. Neuroplastic processes leading to central sensitization have been described as another component of pain chronification in rheumatic diseases [3]. Wide-spread pain is considered a characteristic of central sensitization [4]. It is, however, unclear, what is the relevance of neuropathic and neuroplastic components of pain for the treatment response and the presence of residual symptoms in patients with radiographic axSpA (r-axSpA) treated with biological disease-modifying anti-rheumatic drugs (bDMARDs)

Objectives: To investigate the impact of neuropathic pain and neuroplastic widespread pain on residual disease activity in patients with r-axSpA receiving bDMARDs.

Methods: Patients with r-axSpA (AS fulfilling the modified New York criteria) and starting a bDMARD therapy were recruited between 2015 and 2019 and followed up in an extension of the prospective German Spondyloarthritides Inception Cohort (GESPIC). Neuropathic pain was quantified using the pain detect questionnaire (PD), whereas neuroplastic pain was quantified using the Widespread Pain Index (WPI).

Results: A total of 130 patients with r-axSpA were included in this cohort. PD and WPI scores were available at least one follow-up time-point in 99 patients. Of these, 70 were receiving bDMARD treatment (n=68 under TNFi and n=2 under IL17 inhibitors) with no missing data and could be included in this analysis. The first follow-up point with available PD and WPI scores while under bDMARD treatment was used for the analysis.

*defined as ASDAS-CRP score higher than 2.1 or lower respectively, PD: pain detect, WPI: Widespread Pain Index, CRP: C-reactive protein, NSAIDs: Nonsteroidal anti-inflammatory drugs, BMI: Body mass index, ASDAS-CRP: Ankylosing Spondylitis Disease Activity Score – C-reactive protein

Conclusion: Both PD and WPI reflecting neuropathic and neuroplastic components of pain showed association with residual symptoms (as reflected by higher ASDAS) independent of systemic inflammation (as reflected by elevated CRP) in patients with r-axSpA receiving bDMARD treatment.

POS0300  PATIENT ACCEPTABLE SYMPTOM STATE IN RELATION TO DISEASE ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS FROM A LARGE STANDARD-OF-CARE COHORT

Keywords: Patient reported outcomes, Outcome measures, Spondyloarthritis

M. Carbo1, A. Kampman2, D. Paap1, F. Wink1, A. Spoorenberg1, S. Arends1, 1University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; 2Leeuwarden, Department of Rheumatology, Leeuwarden, Netherlands

Background: The patient acceptable symptom state (PASS) is the level beyond which patients consider themselves well. This concept can help to interpret results of clinical trials and enhance physician-patient communication in daily clinical practice. (1)

Figure: Association between the ASDAS-CRP score at follow-up (A) and ASDAS high/very high disease activity at follow-up (B) with the presence of neuropathic (PD) and neuroplastic (WPI) symptoms in multiple regression analyses.

Data are expressed as n(%) or mean ± standard deviation, BMI: Body mass index, CRP: C-reactive protein, ASDAS-CRP: Ankylosing Spondylitis Disease Activity Score – C-reactive protein, NSAIDs: Nonsteroidal anti-inflammatory drugs. The mean (sD) bDMARD treatment duration was 2.79 ± 1.40 years (range: 0.27 – 5.01) years at the time point of PD and WPI measurement. Higher PD and WPI scores at follow up showed a significant association with higher ASDAS-CRP scores in a multiple linear regression model. This was also true for age, HLA-B27 and the CRP level at follow-up. Logistic regression analysis showed that a high PD score and a high WPI score were also associated with higher odds of having high/very high disease activity (ASDAS ≥2.1) independently of other factors including elevated CRP.

DOI: 10.1136/annrheumdis-2023-eular.4001
Objectives: To explore the association of PASS with disease activity according to ASDAS and other patient- and disease characteristics in a large standar-of-care cohort of patients with axial spondyloarthritis (axSpA).

Methods: Patients from the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort visiting the outpatient clinic between May 2016 and October 2019 were included in this cross-sectional analysis. Patient characteristics and clinical assessments were measured according to the standardized GLAS protocol. Additionally, patients were asked to fill out the PASS question: “Considering all the different ways axSpA is affecting you and if you stay in this state for the next months, do you consider your current state satisfactory? (yes: PASS/no: non-PASS). Logistic regression analysis was used to explore patient and disease characteristics associated with PASS. ROC analysis with area under the curve (AUC) was used to analyze the accuracy of the ASDAS and the optimal cut-off point to predict PASS according to the highest Youden’s index.

Results: Of the 673 included axSpA patients, 63% were male, mean was age 48±14 years, median symptom duration 19 (11-31) years and mean ASDAS 2.3 (±0.9). In total, the vast majority (76%) reported an acceptable symptom state according to the PASS question. Patients in the PASS group had significantly lower ASDAS compared to the non-PASS group (mean 2.0 ±0.8 vs. 3.2 ±0.8). Patients with an acceptable symptom state also had significantly lower BASDAI scores, were more often male, had longer symptom duration, had less tender entheses, used less often NSAIDs, experienced better physical function (BASFI) and quality of life (ASOQL), and had less radiographic damage (mSASSS) (Table 1). In multivariable regression analysis, lower ASDAS (OR 4.45 (3.26-6.09)), longer symptom duration (OR 0.97 (0.95-0.99)) and absence of tender enthesis (OR 1.74 (1.85-2.79)) were independently associated with presence of PASS (Nagelkerke R²: 0.38). The ASDAS showed good accuracy to predict PASS, with an AUC of 0.84 (95% CI 0.80-0.85). The optimal cut-off point of ASDAS for presence of PASS was 2.7 (sensitivity 77%, specificity 78%). A total of 214 patients had an acceptable symptom state but active disease according to the ASDAS cut-off value for active disease of 2.1, this is 44% of patients being in PASS.

Conclusion: In axSpA patients from a standard of care cohort, 76% had an acceptable symptom state. Lower ASDAS, longer symptom duration, and absence of tender entheses were independently associated with an acceptable symptom state. AxSpA patients experiencing an acceptable symptom state can still have active disease according to the ASDAS.

Data presented as number of patients (%), mean ± SD or median (IQR).. *p-value ≤ 0.05.

Disclosure of Interests: None declared.
Background: Studies have reported that female patients with spondyloarthritis (SpA) have different disease courses and treatment responses compared to male patients. Whether patients' sex, the biological attributes associated with being male or female, is associated with a different outcome after receiving one-year of tight control, treat-to-target (T2T) strategy remain uncertain.

Objectives: This study aimed to evaluate the differences in the clinical response between male and female patients from the Asia Pacific League of Associations for Rheumatology (APLAR) Registry.

Methods: Patients who fulfilled the CASPAR 2006 classification criteria for psoriatic arthritis (PsA) and 2009 ASAS classification for axial spondylitis (AxSpA) were recruited. They received 1 year of protocolized treatment aiming at 1) minimal disease activity (MDA) or Disease Activity in Psoriatic Arthritis (DAPSA) low disease activity (LDA) for PsA patients, and 2) Ankylosing Spondylitis Disease Activity Score (ASDAS) LDA for AxSpA patients. Patients were assessed every 3 month and treatment was escalated if target was not reached.

Results: 63 male (age: 45±15 years, 27 PsA, 36 AxSpA) and 36 female (age: 46±12 years, 22 PsA, 14 AxSpA) subjects from 6 Asia-Pacific regions were included. At baseline, male had more tender joints but less severe enthesitis than female. Male AxSpA patients had lower Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) while male PsA patients had a higher DAPSA. Other baseline characteristics were shown in Table 1. During the study period, the use of conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) decreased slightly, while the use of biologics (bDMARDs) significantly increased across both sexes (Figure 1). After 1-year treatment, there were significant improvements in disease activity in the entire cohort (DAPSA: 15.3±11.6 at baseline vs 10.1±11.2 at 1-year, p<0.003; ASDAS: 2.4±1.0 at baseline vs 1.9±0.9 at 1-year, p=0.003). Despite having lower CRP levels (2.3 ± 2.5mg/L in female vs 8.7±17.7mg/L in male, p=0.003) and higher bDMARDs use in female patients (54% in female vs 45% in male) at 1-year, there were no significant differences in clinical responses between male and female patients. Male patients had a higher patients' global assessment score (3.9±2.4 in female vs 4.3±2.2 in male, p=0.014). Both patients' and physicians' global assessment scores improved significantly across both sexes (Figure 1) and female patients had a higher ASDAS change (% change in DAPSA: -47% in male vs +19% in female, p<0.003; % change in tender joint count: -70% in male vs +19% in female, p=0.003). Despite having lower CRP levels (2.3 ± 2.5mg/L in female vs 8.7±17.7mg/L in male, p=0.003) and higher bDMARDs use in female patients (54% in female vs 45% in male) at 1-year, their clinical responses were less optimal compared to male patients. Female patients had a higher patients' global assessment score (3.9±2.4 in female vs 3.5±2.3 in male, p=0.035). Disease activity in female PsA patients and the number of tender joint count in both PsA and AxSpA increased while that in male patients improved (% change in DAPSA: -47% in male vs +19% in female, p=0.003; % change in tender joint count: -70% in male vs +19% in female, p=0.014). Both patients' and physicians' global assessment scores increased in female PsA patients whilst that in male PsA patients decreased. There was a trend showing less improvement in other parameters in female patients (Figure 1).

1 For Axial SpA only, 2 For PsA only.

Conclusion: There may be differential treat-to-target responses between male and female SpA patients. The causes of such differential characteristics should be further explored to potentially implement a sex-specific treat-to-target strategy for spondyloarthritis.

POS0303 IMPACT OF PREGNANCY ON SACROILIAC IMAGING IN WOMEN WITH AXIAL SPONDYLOARTHITIS: RESULTS OF THE ANALYSIS OF THE DESIR COHORT

Keywords: Spondyloarthritis, Descriptive Studies, Imaging

E. Portier1,2, M. Dougados2,2, A. Ryussen-Witrand2, A. Motel3,3, C. Cochon Hospital, Rheumatology, PARIS, France; 2ECAMO, INSERM U-1153: Clinical Epidemiology and Biostatistics, PARIS, France; 3University Hospital of Toulouse, Rheumatology, Toulouse, France

Background: Axial spondyloarthritis (axSpA) is typically characterized by imaging (radiographs or MRI) abnormalities of the sacroiliac joints (SIJ). Also, inflammatory lesions of the SIJ have been observed in healthy women post-partum [1,2]. However, the impact of pregnancy on imaging abnormalities in women with axSpA is unknown.

Objectives: The objective of this study was to evaluate impact of pregnancy on SIJ imaging in patients with early axSpA.

Methods: Data of all women with early axSpA from the DESIR prospective cohort were included, with a follow-up of 5 years. Description of demographic disease characteristics, obstetric history, and SIJ imaging abnormalities (i.e. sacrolitits on radiographs and on MRI, based on local and central reading) was performed in all women. SIJ abnormalities were compared depending on the history of past pregnancy (t-test and chi-square as appropriate). Furthermore, in nulligravidae females at baseline who presented an incident pregnancy during follow-up, SIJ abnormalities were compared before/after pregnancy, using paired-test.

Results: 381 patients were included in the analysis. 142 (37%) were nulligravidae at baseline, and were younger (28 vs 39 years old) and had higher educational level (74 vs 52% university level). Sacroiliitis on MRI and X-ray were more frequent in nulligravidae women (16.9% vs 9.9%, p = 0.05 and 33.8% vs 19.4%, p < 0.01, respectively). Among them, 38 (10% of all patients) presented an incident pregnancy during follow-up and had an available imaging before and after pregnancy; overall no significant changes were observed with regard to both radiographic and MRI imaging abnormalities of the SIJ, except for an increase on the New York score of the left SIJ, and surprisingly, a trend towards a reduction on the proportion of MRI sacrolitits and SPARCC score after pregnancy (table 1).

Table 1. Changes in clinical features and disease activity after 1 year treatment in male and female SpA patients.
Background: Atypical joint formation of the sacroiliac joint may contribute to the failure of image-based disease detection in patients with axial spondyloarthritis (axSpA).

Methods: Patients with early SpA cohort were included. Before pregnancy, after delivery, and at paired test, respectively, MRI was performed using a dedicated software (Amira Software, Germany) for finite element models (FEM). The models were solved using the nonlinear anisotropic hyperelastic constitutive law of ligaments and muscles from the literature (visualization in Figure 1). Overall, 18 women with axSpA were included, of whom 10 were menopausal, 4 were pregnant, and 4 had just delivered.

Results: Table 1 provides a summary of the results. In axial loading (=y-axis direction), the highest median stress and 99th percentile stress was observed in the iliosacral complex, followed by the crural complex, hip joint, sacrotuberous ligament, and anterior sacroiliac ligament. In all load scenarios, stresses were higher in the typical female joint than in the typical male joint.

Conclusion: Finite element modelling revealed differences in load extent and distribution across different sacroiliac joint morphologies, strengthening the evidence that morphology may play a role in mechanical joint stress. Further studies with larger numbers of computed models per joint form are needed to validate these first exploratory results.

**Objectives:** To compare in real life settings the pregnancy outcomes of two treatment strategies among women with CRID: to continue TNFi vs. stop TNFi upon pregnancy diagnosis.

**Methods:** The French nationwide health insurance database (Système National des Données de Santé) was used to emulate a target trial in adult women, with CRID (i.e., rheumatoid arthritis, psoriatic arthritis or spondyloarthritis), having started a singleton pregnancy between 2008 and 2017, and being treated with TNFi upon pregnancy diagnosis. We compared the frequency of unfavorable pregnancy outcomes (malformations, obstetrical complications, and infections) between the two treatment strategies at pregnancy diagnosis, using inverse probability weighted marginal models.

**Results:** A total of 1466 pregnancies were included, and among them, TNFi treatment was discontinued after pregnancy diagnosis in 71% (50 years) and mean (SD) disease duration was 4 (5) years. Continuation of TNFi was not associated with increased frequencies of unfavorable pregnancy outcomes: interestingly, the proportion of pregnancies with at least one unfavorable obstetrical outcome tended to be lower in the group of patients continuing the TNFi after pregnancy diagnosis but without reaching statistical significance: 66% (17.3%) vs. 201 (18.5%) in the group continuing vs. discontinuing, respectively (adjusted RR= 0.79 [95% CI, 0.57; 1.01]). Also, there was a trend for a lower frequency of severe maternal morbidities in the group continuing the TNFi (7 [1.8%] vs. 36 (3.3%)). (aRR=0.43 [0.16; 1.14]). Table.

**Limitation:** Algorithms rather than clinical data were used to identify patients with CRID, pregnancies, obstetrical outcomes, malformation and severe infections.

**Background:** Peresolimab is a humanized immunoglobulin G1 monoclonal antibody that stimulates human programmed cell death protein 1 (PD-1). We hypothesized that peresolimab binding to PD-1, a checkpoint inhibitory receptor, could stimulate physiological immune inhibitory pathways to restore immune homeostasis; this represents a novel approach to treating patients with autoimmune or autoinflammatory diseases.

**Objectives:** The objective of this study was to evaluate efficacy and safety of peresolimab in adult participants with moderate-to-severe rheumatoid arthritis (RA).

**Methods:** A Phase 2a, placebo-controlled, double-blind, randomized clinical trial (NCT04634253) evaluated the efficacy and safety of peresolimab in adult participants with moderate to severe active RA, who had an inadequate response to prior disease-modifying drugs, either conventional (csDMARDs), biologic (bDMARDs) or synthetic (tsDMARDs). Treatment comparisons versus placebo were made using mixed effects model for repeated measures (MMRM) and using logistic regression model for continuous and binary endpoints, respectively. Nominal p-values are reported. Missing data for binary endpoints were imputed as non-response.

**Results:** One hundred and one patients were randomly assigned 2:1:1 to receive intravenous peresolimab 700 mg (n = 49), 300 mg (n = 25), or placebo (n = 24). 94 participants received at least one dose of study treatment and were included in the analysis. Baseline demographics and disease activity were similar among groups. The majority (83.7%) of participants were female. At baseline, the mean (SD) duration of RA was 10.0 (8.0) years, and the mean (SD) DAS28-CRP score was 5.9 (0.85). This trial met its primary endpoint of a significantly greater improvement from baseline at Week 12 in DAS28-CRP score in participants treated with peresolimab vs participants treated with placebo at both tested doses (700 mg [p < 0.001] and 300 mg [p = 0.017], figure 1a). Significant improvements were seen in CDAI between participants treated with either peresolimab dose (figure 1b) relative to placebo, and for ACR20 (p < 0.05) for participants treated with peresolimab 700 mg relative to placebo by Week 12 (table 1). Peresolimab exhibited a safety and tolerability profile that supports further clinical evaluation in immunologic disease.

**Conclusion:** Peresolimab, a PD-1 receptor agonist, was superior to placebo at Week 12 for several key endpoints in RA. Safety events were similar between treatment groups.

Background: FIL is an oral Janus kinase 1 preferential inhibitor for the treatment of moderate to severe active RA. A previous pooled analysis reported long-term safety and efficacy for FIL 200 mg (FIL200) vs FIL 100 mg (FIL100) in pts aged ≥65 and <65 y.[1]

Objectives: To report updated long-term safety and efficacy in 4 subgroups of pts with RA (aged ≥65 y, ≥65 y without CV risk, and ≥65 y or with CV risk), treated with FIL200 vs FIL100.

Methods: This post hoc analysis pooled data from phase 2 (DARWIN 1–3; NCT01888874, NCT01895416, NCT02005750) and phase 3 (FINCH 1–4; NCT02889796, NCT02879396, NCT02886728, NCT03025308) trials. Data for long-term extensions (LTEs) were as of May 2, 2022 (DARWIN 3), and May 6, 2022 (FINCH 4). Analyses were by age (≥65 y and subgroup <65 y without CV risk vs ≥65 y or ≥1 CV risk factor). CV risk factors were: family history of CV disease; history of dyslipidemia, diabetes mellitus or CV disease; hypertension, ischemic vascular conditions, peripheral vascular disease, extra-articular manifestations of RA; or ever smoked. The as-treated analysis set included data for pts receiving ≥1 FIL dose. Exposure-adjusted incidence rates (EIRs)/100 patient-years of exposure (PYE) of selected adverse events (AEs), and % of pts achieving Disease Activity Score 28 joints with C-reactive protein (DAS28-CRP) of <2.6 or ≥3.2 through Week 156 in FINCH 4, are reported.

Results: Baseline characteristics by age have been reported.[1] Baseline disease characteristics by age or CV risk factor were similar for disease severity and concurrent treatment. EARs for any treatment-emergent AEs (TEAEs) were generally higher in pts aged ≥65 (120.40) vs pts <65 y (97.86), and higher in pts aged ≥65 y or with CV risk (120.45) vs pts aged <65 y without CV risk (81.83). Pts aged ≥65 y, followed by the broader subgroup with CV risk factors (i.e. ≥65 y or ≥1 CV risk) had higher EARs of serious TEAEs and TEAEs leading to discontinuation vs other subgroups, indicating age is a key risk factor alongside other CV risk factors for developing AEs (data not shown). In pts aged ≥65 y lower incidences of malignancies (excluding non-melanoma skin cancer [NMSC]), NMSC, herpes zoster (HZ) and TEAEs leading to death were observed with FIL200 vs FIL100 (Figure 1). In the broader subgroup with risk factors (i.e. aged ≥65 y or ≥1 CV risk factor), EARs of AEs were generally lower vs pts aged ≥65 y, indicating greater influence of age. EARs of AEs for subgroups (aged ≥65 y without CV risk; ≥65 y or ≥1 CV risk) for FIL200 and FIL100 are shown (Figure 1). Rates of DAS28-CRP <2.6 or ≥3.2 in all subgroups (FINCH 4) were maintained with FIL100 and FIL200 to Week 156 (Table 1).

Conclusion: This post hoc analysis (in pts ≥65 y or with ≥1 CV risk factor) suggests that age is an important risk factor in the evaluation of the FIL200 safety and efficacy for FIL 200 mg (FIL200) vs FIL 100 mg (FIL100) in pts aged ≥65 y, followed by the broader subgroup with CV risk factors (i.e. ≥65 y or ≥1 CV risk) had higher EARs of serious TEAEs and TEAEs leading to discontinuation vs other subgroups, indicating age is a key risk factor alongside other CV risk factors for developing AEs (data not shown).

POS0309 TIME TRENDS IN GLUCOCORTICOID USE IN RHEUMATOID ARTHRITIS DURING THE BIOLOGICS ERA: 1999-2018

Keywords: Epidemiology, Treat to target, Rheumatoid arthritis

L. Crowson1, J. M. Davis III2, A. Hanson3, E. Myasoedova4, V. Kronzer4, A. Makol2, L. Peterson2, D. Bekele5, C. S. Crowson3. 1Medical University of Vienna, Department of Medicine III (Division of Rheumatology), Vienna, Austria; 2KU Leuven, Skeletal Biology and Engineering Research Center, Department of Rheumatology, Leuven, Belgium; 3University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 4ASST Gaetano Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy

Background: Clinical guidelines recommend minimizing glucocorticoid use among patients with rheumatoid arthritis (RA) and many new therapeutic options
in recent decades offer alternatives to glucocorticoids, but it is unknown whether glucocorticoid use has declined in patients with RA.

**Objectives:** To examine time trends in glucocorticoid use among patients diagnosed with rheumatoid arthritis (RA) during the biologic era.

**Methods:** A population-based inception cohort of RA patients diagnosed during 1999–2018 was followed longitudinally through their medical records until death, migration, or 12/31/2020. All patients fulfilled 1987 and/or 2010 American College of Rheumatology classification criteria for RA. Glucocorticoid start and stop dates were collected along with dosages in prednisone equivalents. The cumulative incidence of glucocorticoid initiation and discontinuation adjusted for the competing risk of death was estimated. Cox models adjusted for age and sex were used to compare trends between time periods.

**Results:** The study population was comprised of 399 patients (71% females) diagnosed in 1999–2008 and 430 patients (67% females) diagnosed in 2009–2018. Glucocorticoid use was initiated within 6 months of meeting RA criteria in 66.7% of patients in 1999–2008 and 70.5% of patients in 2009–2018, corresponding to a 29% increase in hazard for initiation of glucocorticoids in 2009–2018 (adjusted hazard ratio [HR]: 1.29; 95% confidence interval [CI]: 1.09–1.53). Among glucocorticoid users, similar rates of glucocorticoid discontinuation within 6 months after glucocorticoid initiation were observed in patients with RA incidence in 1999–2008 and 2009–2018 (39.1% versus 42.9%, respectively), with no significant association in adjusted Cox models (HR: 1.11; 95% CI: 0.93–1.31). Even in the 2009-2018 cohort, a large proportion of patients with RA (52%) remained on glucocorticoids beyond 3 months, and 30% were still on glucocorticoids after 2 years. Older patients with RA were more likely to initiate glucocorticoids (HR 1.06 per 10 year increase in age, 95% CI 1.00–1.13) and less likely to discontinue glucocorticoids (HR 0.91 per 10 year increase in age, 95% CI 0.86–0.96). There was no difference in the initiation of glucocorticoids by sex. Although females had a higher discontinuation rate within the first 12 months, afterwards discontinuation rates of glucocorticoids were similar in females and males. Smokers were less likely to discontinue glucocorticoids compared to non-smokers (HR 0.63; 95% CI: 0.51–0.82). **Conclusion:** More patients are initiating glucocorticoids early in their disease course now compared to previously the availability of biologics and other disease modifying anti-rheumatic drugs. The rates of glucocorticoid discontinuation are similar. A substantial proportion of patients remain on glucocorticoids for more than 3 months with a large proportion continuing use of glucocorticoids even beyond 2 years. Real world use of glucocorticoids in patients with RA is not optimal or improving despite advances in RA therapy.

**Background:** Rheumatoid Arthritis (RA) is an autoimmune chronic disease characterized by the inflammation of multiple joints, ultimately leading to deformity, pain and swelling [1]. Currently, no preventing therapy exists for RA, and 20%-30% of RA patients do not respond to available treatments [2]. These therapies target late phases of the inflammation process (e.g. cytokine signalling) [1], when the microenvironment is highly inflammatory and therefore challenging to control. Developing therapies targeting inflammation upstream (i.e. cytokine secretion) could have a positive impact on refractive RA. In this regard, we have previously identified through an unbiased high-throughput screening a total of 27 small molecules (23 novel and 4 repurposing drugs) with previously unknown anti-inflammatory capabilities.

**Objectives:** To validate the effects of these small molecules in peripheral blood mononuclear cells (PBMCs) under different types of activation stimuli, and to identify molecules capable of reducing the secretion of proinflammatory cytokines relevant in rheumatic diseases (namely TNF-α and/or IL-1β), employing a high-throughput approach.

**Methods:** First, different treatment methods were tested on PBMCs to identify those providing the best measuring window for the cytokines of interest. For that purpose, thawed PBMCs were exposed to PAMP (LPS) and/or DAMP (ATP) at different times, and cytokine secretion quantified. Subsequently, the potential cytokotoxic effects of the small molecules were analysed at five different concentrations with several viability kits (fixable live/dead stains, AlamarBlue and ATPLite). Finally, for evaluating the anti-inflammatory potential of the small molecules the compounds were added to PAMP-only and PAMP+DAMP-treated PBMCs at five concentrations, and viability and TNF-α and IL-1β secretion measured at four different time points.

**Results:** We found that, at different pharmacological concentrations (nM-µM), treatment conditions and time points, the compounds have no cytokotoxic effects in PBMCs, with the only exception of one compound being toxic at the highest concentration tested. We then compared the levels of cytokine secretion with vehicle alone versus each of the small molecules and considered that a small molecule was of interest if induced at least a 20% reduction on the secretion levels of the cytokine of interest. We observed several combinations of effects (molecules acting on different TNF-α or both, or only showing effect with PAMP-only or PAMP+DAMP treatment), suggesting that our molecules target different components of the intracellular machinery. For example, several molecules diminished TNF-α secretion after PAMP treatment, but not when the DAMP was added to the culture, and vice-versa. The Figure shows representative results of compounds #7, #28 and #29, which reduce the secretion of TNF-α in PAMP-only treated PBMCs. We then tested the small molecules with the stronger effect at the lowest concentration in PBMCs from treatment-naïve RA patients, analysing both the intracellular and extracellular cytokine levels by flow cytometry and ELISA, respectively.

**Conclusion:** Our novel and repurposing small molecules showed no cytokotoxic effects in primary PBMCs, and that they induced a reduction on proinflammatory cytokine secretion from PAMP-only and PAMP+DAMP-treated PBMCs. Further characterization of these small molecules, through the identification of their mechanism of action and molecular target, will open new avenues in the treatment of rheumatic diseases, by providing novel drugs targeting novel pathways and that could be administered orally, improving quality of life and adherence to treatment.

Methods: To examine changes in peripheral blood gene expression after IL-6i or JAKi treatment, which inhibit common pathways, and to estimate their respective inhibitory activity, and inhibition of IL-6 signaling plays an important role in their pharmacological actions. IL-6 inhibitors (IL-6i) have been also commonly used for rheumatoid arthritis (RA), and several anti-receptor antibodies are in clinical application. Recent studies have revealed the molecular basis of the immune cell-fibroblast-bone triad interactions in RA bone destruction[1-3].

Objectives: To investigate the biochemical MTX adherence in RA patients commencing a biologic and its association with EULAR response.

Results: Comparison of L-6i and JAKi showed that JAKi treatment significantly suppressed RANKL expression in peripheral blood. At the same time, significant suppression of RANK, ETS1, and IL-34 gene expression was also observed with JAKi treatment. Comparison of TOF and BAR treatment showed significant suppression of IL-4 expression in TOF and significant suppression of MMP-2 and IL-12 expression in BAR.

Conclusion: JAKi suppressed RANKL expression significantly compared to IL-6i, suggesting that JAKi is more potent than IL-6i in suppressing bone destruction. Furthermore, assuming that the promoter regions of RANK in synovial osteoclasts and ETS1 in fibroblasts are similar to those in peripheral blood, the following prediction emerges. Namely, JAKi suppresses RANKL and ETS1 expression more than IL-6i, suggesting that JAKi may be favorable for preventing bone destruction in terms of (1) suppressing osteoclast differentiation and (2) suppressing tissue-destructive fibroblast generation.

Methods: This analysis used data from the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS), a one-year UK prospective cohort study of patients with RA commencing a biological drug. Prior to biologics commencement, demographic and clinical data were collected. Serum samples were sampled for MTX biochemical adherence at baseline (pre-treatment of biologics), then 3 and 6 months post-first dose. MTX concentration was measured by HPLC-SRM-MS. Time to processing variable was also noted by calculating the difference between the time the sample was processed and the time the blood was sampled. Adherence was calculated based on a cut-off limit taken from a validated MTX adherence assay. A chi-square test was used to investigate the association between adherence and biologic response. Linear regression investigated the relationship between MTX level and time to processing.

Results: 582 patients were included; 75% female, mean (S.D) age 58 (12) years. Table 1 summarises the baseline characteristics for all patients. There was no significant relationship between adherence at pre-treatment with EULAR response at 6 months (p=0.17). However, those who were biochemically adherent to MTX at 6 months had a statistically significantly better response to biologic therapy (p=0.04). It is also found that despite being a responder to the biologic, 37% were non-adherent to MTX. However, there was no significant relationship between MTX level and time to processing thus it is unlikely to be due to the stability of MTX in blood over time.

Conclusion: Patients who were adherent to MTX, assessed biochemically, at 6 months after starting biologic therapy had better response to treatment, which may further strengthens the evidence to support the importance of concomitant use of MTX with biologics.

CAN METHOTREXATE INFLUENCE SEXUAL DYSFUNCTION IN MALE PATIENTS: ANALYSIS OF THE IIEFS QUESTIONNAIRE AND HORMONAL STATUS

Keywords: Safety, Rheumatoid arthritis, Disease-modifying Drugs (DMARDs)

F. Nataf1,2, S. Bisseron1, T. Sokolova1, A. Avramovska1, D. Maier3, P. Durez1,3 Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium; 2Sapienza University of Roma, Rheumatology, Department of clinical, internistic, anesthesiological and cardio-vascular sciences, Roma, Italy; 3Cliniques Universitaires Saint-Luc, Paris, France.

Background: Methotrexate (MTX) is the anchor drug of Rheumatoid Arthritis (RA) treatment. It is a safe and handy drug, but it has several well-known side effects mainly not severe such as nausia, fatigue, alopecia, or an increase in transaminases. In the last years, sexual dysfunction has been reported as a rare adverse effect of MTX therapy.

Objectives: To explore this, the aim of this study is to evaluate the impact of MTX on erectile function in male patients through the IIEFS questionnaire and hormonal dosage.

Methods: Male patients affected by inflammatory arthritis (Rheumatoid Arthritis or Psoriatic Arthritis [PsA]) according to the 2010 EULAR/ACR diagnostic criteria for RA and the 2006 CASPAR criteria for PsA and treated with chronic MTX were enrolled. Age-matched patients affected by chronic arthritis not treated with MTX were enrolled as control. Each patient underwent blood collection for a complete serum sexual hormone evaluation. IIEFS questionnaire which consists of 5 items with a maximum score of 25 was administered to the patients.

Results: 109 patients were included, 77 in the MTX group (Group A) and 32 in the control group (Group B). The clinical and demographic features of both groups are reported in Table 1. Among the MTX group, 61 have a RA diagnosis, while the remaining 18 were affected by PsA. The median disease duration of RA and PsA patients was respectively 108 months (IQR 138) and 66 months (IQR 114). The median MTX dose was 10mg (IQR 7.5) with a median MTX duration therapy of 8 years (IQR 17). The total IIEFS score was lower in patients treated with MTX compared to the control group without reaching a statistically significant result [19 (IQR 11) versus 20 (IQR 7.7); p=0.15, Graph 1A]. However, when comparing the IIEFS score between MTX exposed versus non-exposed patients stratifying by years of treatment, the total IIEFS score of patients treated with MTX ≥ 5 years was statistically significantly lower when compared to those non-MTX- exposed patients [17 (IQR 15) versus 20 (IQR 7.7); p=0.04] and compared to those treated for < 5 years [17 (IQR 15) versus 20 (IQR 7); p=0.01] (Graph 1B).

Figure 1. A) Comparison of IIEFS score in MTX exposed versus non-exposed patients. B) patients stratified by age (< 5 years and ≥ 5 years).

– Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Endocrinology, Brussels, Belgium
In the univariate analysis, a negative correlation between the total IIEF score and MTX exposure (years) has been identified (r = -0.20 CI [-0.38, -0.04]; p= 0.038). Age was the variable with the strongest negative association with the IIEF score (r = -0.43 CI [-0.67, -0.20]; p<0.001). MTX exposure was still associated with a lower IIEF score when adjusted for age (r = -0.36 CI [-0.53, -0.15]; p=0.009). Among the other variables, LH (r = 0.24 CI [-0.40, -0.04]; p=0.01), FSII (r = 0.21 CI [-0.39, -0.006]; p=0.04) and E2 (r = 0.21 CI [-0.40, -0.009]; p=0.03) negatively correlated with IIEF score while DHEA, was the only with a weak positive association (r = 0.22 CI [0.02 to 0.40]; p=0.03). Occurred in the TNFi group and the first hospitalization for MACE during follow-up. Comorbidities and traditional CV risk factors were identified using hospitalizations, procedures, or medication dispensing in the 4 years prior cohort entry. The unadjusted incidence rate (IR) of MACE excluding CV death was assessed in patients initiating either tofacitinib, in comparison with TNFi, in RA patients [3].

Conclusion: Long-term MTX exposure was associated with sexual dysfunction reported by a lower IIEF score in male patients adjusted for age. The preliminary results should be confirmed in larger prospective studies.

SURVIVIN REGULATES T CELL RESPONSES THROUGH DEPOSITION OF HISTONE H3 MARKS AND MODULATES RESPONSE TO TREATMENT WITH JAK-INHIBITORS

Keywords: Targeted synthetic drugs, Adaptive immunity, Rheumatoid arthritis

K. M. Andersson1, V. Chandrasekaran1, M. Erlandsson1, E. Malmhäll-Bah2, S. Työvä Silverswärd2, R. Pullent3, M. I. Bokareva2, 3Gothenburg University, Department of Rheumatology and Immunology Research, Gothenburg, Sweden; 2Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden

Background: Multiple genetic polymorphisms are associated with high risk for rheumatoid arthritis (RA) [1]. The importance of epigenetic processes has been postulated, but precise molecular mechanisms behind these associations remain largely unexplored. Survivin is an important player in RA, which has been recently shown essential for IFNg signaling in CD4 T lymphocytes acting in partnership with IRF1 [2].

Objectives: We study how survivin-dependent epigenetic deposition of histone H3 tails in RA risk loci affects function of CD4 T cells and response to JAK inhibition.

Methods: Chromatin of CD4+ cells (n=12) was immunoprecipitated with antibodies to histone H3K27ac, H3K4me3, and survivin, and sequenced (CHIP-seq, Illumina). Parallel CHIP-seq and RNA-seq was done in CD4+ cells treated with survivin inhibitor YM155. Peaks with change >30% in deposition of H3K27ac and/or H3K4me3 upon YM155-treatment were annotated to the genomic regulatory elements (RE) via GeneHancer database. Single nucleotide polymorphism (SNP) related to RA risk were identified within those RE. CD4 T cell transcriptomics by RNA-seq was done in 24 random RA patients and in 59 RA patients treated with MTX (n=18), TNFi (n=10), JAKi (n=24) and having no DMARDs (n=7). The genes differentially expressed (DEG, nominal p<0.05) in BIRC5 and JAKi-treated CD4 cells were identified by DESeq2 (R-studio, Bioconductor).

Results: Deposition of 15% (1705/11512) of H3K4me3 and 17% (194/11530) of H3K27ac peaks changed >30% upon survivin-inhibition. Approximately 50% of these peaks overlapped with survivin peaks. The change in H3K4me3 peaks was significantly larger if the peak colocalized with survivin peak. These peaks were located in 228 RE, 28 of these RE contained 52 RA risk SNPs. Among others, changeable peaks were accumulated within ICOS/CTLA4/CD28 locus and contained 7 SNPs. Majority of genes connected to the SNP-containing RE (110/153 genes) were transcriptionally different in BIRC5/COD4+T cells and participated in the regulation of immune system (GO:0002682, FDR=0.4e-3), regulation of IL2 production (GO:0032663, FDR=0.019), TNF mediated signaling (GO:0033209, FDR=5.4e-3). These SNP-RE connected genes formed three independent clusters 1) TCR receptor co-stimulators (CD40, ICOS, CTLA4, CD28, CD244, TRAF6 and TBX21, SLAMF1, TNFRSF9), 2) connected to the LCK interacting transmembrane adaptor 1 (LIME1, SL2C24R, ZGAP, GM3E2, TNFRSF6B, RETL1) and 3) heat-shock proteins (HSPD1, HSP90A1, HDAC7, KPNB1). The clusters were functionally connected to survivin partners IRF1 and SMAD3. Notably, transcription of CD28, ICOS, and SLAMF1 functions necessary to understand the long-term implications of tofacitinib vs TNFi on the risk of MACE.

DOI: 10.1136/annrheumdis-2023-eular.4497
by JAKi, while SMAD3 related CHERP, PRPF6 down-regulated by survivin inhibition were upregulated in CD4+ cells of JAKI-treated patients. Effect of JAKi in the IRF1-related genes was executed only in BIRCD5CD4+ cells and remained unchanged in BIRCD5CD4+ cells.

Conclusion: This study shows that survivin contributes to deposition of histone H3K27ac and H3K4me4 marks in proximity of RA-risk genes and control immune system regulators in CD4 T cells. JAK-inhibitors operate downstream of survivin and high levels of survivin may impede JAKi-treatment.

THE COURSE OF SYMPTOMS IN CLINICALLY SUSPECT ARTHRITIS AND ITS RELATION WITH SUBCLINICAL JOINT-INFLAMMATION DURING PROGRESSION TO RA: IS IT SIMILAR IN ACPA-POSITIVE AND ACPA-NEGATIVE DISEASE?

Keywords: Patient reported outcomes, Imaging, Rheumatoid arthritis

S. Khidir1, D. Krijbos1, H. K. Gla3, E. Van Mulligen1,2, A. Van der Helm – van Mil1,2. 1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Reumazorg Zuid-West Nederland, Rheumatology, Goes, Netherlands; 3Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands

Background: ACPA-positive and ACPA-negative RA have differences in genetic and environmental risk factors and in the severity of the disease course after diagnosis. However, the clinical presentation at RA-diagnosis is similar, as is the clinical presentation in the at-risk stage of clinically suspect arthralgia (CSA). We hypothesized that these clinical similarities at the end of the trajectory of RA-development imply a shared path in symptom development and progression before diagnosis. So far the course of symptoms during progression from CSA to RA and the association with the course of subclinical joint-inflammation is unknown.

Objectives: We studied the course of cardinal symptoms and subclinical joint-inflammation and the longitudinal relation in ACPA-positive and ACPA-negative disease. Relations were also studied in CSA-patients who did not develop RA.

Methods: CSA-patients from the Leiden CSA-cohort (n=664) and the placebo-arm of the TREAT EARLIER trial (n=117) were followed on development of inflammatory arthritis (IA) at physical examination, during which 136 patients developed IA and 645 did not. Symptoms of morning stiffness, pain and fatigue (with a numerical rating scale: 0-100) and presenteeism (productivity loss at work with the WPAI-questionnaire: 0-100%) were assessed at baseline and upon IA-development. Subclinical joint-inflammation (sum of synovitis/tenosynovitis/ostitis) was assessed at baseline and upon IA-development with contrast-enhanced 1.5T MRI of hand/foot. Linear and Poisson mixed models were used.

Results: Of the patients with IA-development, 66 (49%) were ACPA-positive. Both in ACPA-positive and ACPA-negative patients, symptoms (morning stiffness, presenteeism, fatigue) and subclinical joint-inflammation increased towards IA-development, and decreased or stabilized in patients without IA-development (Figure 1A). The course of pain, morning stiffness and presenteeism towards IA-development, and decreased or stabilized in patients without IA-development.

Conclusion: The severity of symptom development before diagnosis in ACPA-positive RA relates more strongly to increasing subclinical joint-inflammation than in ACPA-negative RA. This points towards differences in processes underlying the disease burden in ACPA-positive and ACPA-negative RA.

ARTIFICIAL INTELLIGENCE BASED APPROACH TO PREDICT THE DISEASE COURSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Prognostic factors, Artificial Intelligence, Rheumatoid arthritis

J. Salminen1,2, P. Pihlajisto3, A. Mustonen1, H. Rela1, E. Kulkkinen2,1. 1Åbo Akademi University, Computer Science, Turku, Finland; 2BCB Medical Ltd., Life Science, Turku, Finland; 3University of Helsinki, Department of Medicine, Helsinki, Finland

Background: Rheumatoid Arthritis (RA) is an autoimmune disease which affects approximately 0.8% of the Finnish population. Increasing number of conventional and biological antirheumatic drugs is currently available for the treatment of RA. However, for the optimal use of these drugs and for example for the decision when to start biological medication, it would be of utmost importance to be able to predict the disease course of the patient during the patient’s visit at the clinic.

Objectives: The disease course of the patients differs widely and predicting the disease course is challenging. Therefore, our objective was to use patient-specific disease characteristics and to develop an artificial intelligence (AI) method for predicting the future disease course. Our patient material includes 1881 patients, with both sero positive and negative diseases (ICD-10-codes M05 and M06).

Methods: We used a machine learning method which takes as input patient information such as demographic information and clinical variables. The target value that the method tries to predict is the DAS28-CRP disease marker a year from the present time. The train and test sets were balanced so that each DAS28-CRP value is expressed equally. The machine learning model was a voting ensemble with Random Forest.
Forest and Extreme Random Trees classifiers and with different scalers (Geurts et al. 2006). The number of training instances was 1504 and test set consisted of 377 patients. The number of features was 30. The patients were classified to 4 classes: inactive, low, high and very high according to the activity marker DAS28-CRP.

**Results:** The AUC value of the classifier was 0.71. This provides adequate extra information for the clinicians when they consider the patient’s treatment. If the model predicts that disease is getting better, visits can be more frequent. Figure 1 shows the most important variables used by the classification algorithm. The AI algorithm gives good predictions (Table 1), even though errors between two adjacent activity classes are common. For example, when the true class is very high, the algorithm gives 88 high or very high predictions (94%), and only 6 clearly wrong answers (6%). When the true class is high, the results are more spread, with 42 cases (45%) being in the low or inactive class and 51 (55%) cases in the more active class. The low and inactive classes are predicted quite well.

![Image](image.png)

**Figure 1.** Overall feature importance for all classes. The higher the bar, the more useful the feature is in classifying the patients.

**Table 1.** A confusion matrix of classifying the test material. In the left are the true labels and on top the predicted labels. The classes low and very high have been most successfully predicted.

---

**Conclusion:** The algorithm shows promising results especially in predicting very high disease activity. An algorithm with AUC 0.71 cannot reliably classify patients independently, but it can aid the clinician in giving insights into the patients’ current status and how likely the worsening of the disease is. The AI method chosen for this purpose is a white-box approach, meaning that the clinician can immediately see which factors were deemed important by the algorithm to produce this prediction.

**DOI:** 10.1136/annrheumdis-2023-eular.3953
Background: Early intervention and implementation of effective treatment is a significant predictor of positive long-term prognosis for rheumatoid arthritis (RA). However, despite major advances in treatment options there are currently no biomarkers to clinically guide treatment selection or to identify individuals who do not respond fully to first-line therapy. B cells are known to contribute to RA pathogenesis as exemplified by the success of B cell depleting treatments. It is well known that there are changes in the circulating B cell compartment in both new onset and established RA that include reduced memory B cells and increased naive and transitional B cells. Among transitional B cells there is a subpopulation described as regulatory B cells (Bregs) that is characterised by markers such as high levels of CD24/CD38, and CD1d as well as PDL1 and production of IL-10. To investigate the predictive potential of the B cell compartment for disease outcome, the different B cell populations must be further divided into specific subset and studied in well characterised cohort followed over time.

Objectives: To identify a B cell subset(s) at clinical onset that predict clinical disease activity index (CDAI) remission 6 months after start of treatment.

Methods: Flow cytometry analysis of peripheral blood B cell subsets was conducted on untreated, early RA patients (n=60) according to ACR/EULAR 1987/2010 criteria; n=71) and sex matched healthy controls (n=24). PBMCs were stained for the following markers: CD19, CD21, CD72, IgD, CD24, CD38, CD1, PDL1. Patients were then treated with methotrexate and randomised to combination with a prednisolone; b) ceftriaxone; c) tocilizumab; or d) abatacept. Patients were grouped based on disease remission status at 6 months (remission n=29; no remission n=42) as defined by a clinical disease activity index (CDAI) ≤2.8. The predictive value of these population frequencies for remission detection was modelled with receiver operating characteristic (ROC) analysis. Peripheral blood from a second RA cohort (n=32) and additional healthy donors (n=11) were analysed by flow cytometry including CD1d, CD1, and PDL1.

Results: Relative to patients who reached CDAI remission, individuals who did not respond to this extent to first line therapy at 6 months had significantly reduced frequencies of transitional (CD19+CD24++CD38-), and CD1+ B cells (CD19+PD1+CD21+) at diagnosis (Figure 1), which inversely correlated with CDAI at 6 months (r=-0.355, p=0.002; and r=-0.245, p=0.039 respectively). The predictive value of these subset frequencies for remission was modelled with ROC analysis. Both transitional and PD1+B cell frequencies had significant predictive capabilities and an AUC of 0.67 and 0.7 respectively (Figure 1). Follow-up analysis in the second RA cohort showed that CD1d+ transitional B cells in RA patients (median 14.75%; range 9.4-23.4%; n=32) were significantly increased (p<0.0001, Mann-Whitney) relative to healthy donors (median 8.9%; range 4.4-12.9%; n=11).

Conclusion: A reduced frequency of transitional and PD1+B cells at diagnosis in RA patients was associated with failure to reach CDAI remission within 6 months of treatment. As transitional B cells in RA patients express markers closely linked to Bregs, we speculate that the lower transitional B cell frequencies we observed at diagnosis may indicate fewer circulating Bregs and thereby worse conditions for endogenous disease control. Thus, monitoring of transitional B cell frequencies at the point of RA diagnosis may aid in the identification of patients who are less likely to reach remission at 6 months and therefore subject to additional clinical surveillance.

OBSITY IS A RISK FACTOR FOR POOR RESPONSE TO TREATMENT IN EARLY RHEUMATOID ARTHRITIS - A NORD-STAR SPIN-OFF STUDY

Keywords: Randomized control trial, Prognostic factors, Rheumatoid arthritis

Background: Several therapeutic options are currently available to treat rheumatoid arthritis (RA); however, the response to treatment is highly variable, and not all patients achieve clinical remission [1]. Obesity is suggested to lower the chances of remission [2], even though a recent observational study has shown that obesity is not associated with reduced response to conventional synthetic anti-rheumatic drugs in patients with early RA [3].

Objectives: The aim of this study is to determine if obesity affects the response to treatment in patients with early RA.

Methods: This report includes 393 Swedish patients from the NORD-STAR study, which is a multicenter, randomized trial on 812 patients with untreated early RA [4]. The 393 participants have been randomized at baseline into 4 arms of treatment: methotrexate combined with (1) prednisolone, (2) certolizumab, (3) abatacept, or (4) tocilizumab. Scores for disease activity and blood sedimentation rate were performed after adjustment for sex, baseline age, anti-citrullinated peptide antibody status, current smoking, disease activity score-C-reactive protein (DAS28-CRP), and treatment randomization. The outcomes for this report stratified by baseline BMI.

Results: In total, 75 (19%) participants had obesity at baseline, defined as body mass index (BMI) ≥ 30 kg/m². The percentage of patients with obesity in each treatment group was (1) 25%, (2) 15%, (3) 19% and (4) 19%. At baseline, there were no differences in terms of disease activity indices and inflammation parameters between patients with BMI <30 vs. ≥30 kg/m², except for the number of swollen joints (SJC28), which was slightly lower in those with obesity (mean±SD, 8±5 vs. 9±5, p=0.018). At 24-week follow-up, patients with obesity had higher disease activity indices and inflammation parameters compared to patients with lower BMI (Table 1). Moreover, patients with obesity had a lower chance of achieving response to treatment as measured by DAS28-CRP ≤3.2 (OR 0.5, 95% CI 0.2 - 0.9, p=0.025), DAS28-CRP ≤2.6 (OR 0.4, 95% CI 0.2 - 0.6, p<0.001) and CDAI remission (OR 0.4, 95% CI 0.2 - 0.8, p=0.006), compared to patients with lower BMI (Figure 1). BMI-treatment interaction was not significant for any score of disease activity.

Conclusion: In patients with early RA, obesity was not associated with higher disease activity before treatment initiation. However, 24 weeks after treatment, patients with obesity had higher disease activity and lower chances to respond to therapy compared to patients with lower BMI irrespective of treatment.

RHEUMATOID ARTHRITIS PATIENTS AND WEATHER PATTERNS: A RHUMADATA™ STUDY OF 14,200 PATIENT-REPORTED OUTCOMES MATCHED WITH METEOROLOGICAL DATA

Keywords: Real-world evidence, Patient reported outcomes, Rheumatoid arthritis

M. Joly-Chevrier1, L. Coupal2, L. Choquette Sauvageau2, D. Choquette2.
1Université de Montréal, Médecine, Montréal, Canada; 2Institut de rhumatologie de Montréal, Rhumatologie, Montréal, Canada

Background: Anecdotally, patients with rheumatoid arthritis (RA) report seasonal changes in their symptoms. Anatomically, atmospheric pressure variations are captured by baroreceptors, which may generate this perception.

Objectives: To correlate seasonal changes with subjective assessment scores.

Methods: Environment Canada provided meteorological data from 2015 to 2020 for Montreal (Dorval). Hourly measurements of temperature, relative humidity, and pressure were available. We matched daily meteorological data with patient-reported pain (PtP), fatigue (PtF), and disease activity (PtGA) assessments from RHUMADATA™ participants. We calculated daily means, minimums, and maximums, as well as changes from the previous day for the winter and summer months. For the years 2015 to 2020, Pearson Correlation Coefficients (PCCs) were computed between Patient Reported Outcomes (PROs) and weather measurements. Optimal regression models (OMs) were derived based on Akaike’s Information Criteria (AIC).

Results: RA patients’ PROs were matched with meteorological data (7411 winter measurements and 6789 summer measurements). At the time of the first PRO assessment, the mean age and disease duration were 60.1(13.5) and 10.5 (10.4), and 74.6% of patients were women. Patients provided an average of 14 PROs. In winter, PtP, PtF and PtGA were 3.48 (2.79), 3.49 (2.96) and 3.42 (2.68), and 3.45 (2.81), 3.46 (2.96) and 3.33 (2.63) in summer. PtGA was statistically higher in winter (p-value=0.0035). PCC and OMs are shown in Table 1. In winter, all correlations are very weak (less than 0.19). PtGA is not correlated with any weather measures in both winter and summer. PtP and PtF correlate with some weather measures in both seasons.

Conclusion: In this study of 14200 weather-matched PROs, mean PtP, PtF, and PtGA scores are higher in winter among RA patients, but the differences are small. Few meteorological measures are significantly correlated with PROs, and all correlations are very weak. Meteorological variables explain a quite small percentage of the variation in PRO variation (small R-square). No consistent relationship between PROs and meteorological conditions is reported by other smaller studies.

1 PCC=Pearson Correlation Coefficients. 2 δ γ 0.001<p<0.01 δ γ 0.01<p<0.05 3 The best model was selected by computing Akaike’s Information Criteria (AIC) for all possible subsets of multiple regression models for main effects. The model with the smallest AIC value is deemed the “best” model. 4 Difference from the previous day.
Demographic data, seropositivity of rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA), treatment with biological and targeted synthetic disease modifying anti-rheumatic drugs (bDMARDs and tsDMARDs) and bone erosions by either plain x ray or ultrasonography were compared among quantiles of PRS.

**Results:** PRS of 97,396 single nucleotide polymorphisms derived from LDpred2 exhibited the highest AUC for predicting the development of RA in the overall dataset as compared with the remaining algorithms. Participants with the top RA-PRS quantile have the highest proportion of RF and ACPA positivity (74.8% & 65.0%, respectively), bone erosion (86.4%) and higher chance to receive bDMARDs or tsDMARDs (42.3%) as compared to the counterparts. In addition, RA-PRS quantile was a significant risk for bone erosion in the multivariate regression model with the adjustment of RF, ACPA positivity and therapeutic medication, specifically in the group of age < 60 years.

**Conclusion:** PRS is associated with seropositivity, erosive bone disease, need for advanced therapy in Taiwanese patients with RA.

**POS0327 SPEED OF RESPONSE MATTERS: POST-HOC ANALYSIS OF PATIENTS WITH EARLY SERONEGATIVE RHEUMATOID ARTHRITIS INCLUDED IN THE CARERA TRIAL**

**Keywords:** Randomized control trial, Rheumatoid arthritis, Outcome measures

**Authors:** S. Pazmino1,2, R. Westhovens1,3, V. Stouten1, D. Bertrand1,3, M. Doumen1,3, J. Joly2, E. De Meyst1,3, D. C. Diederik5, P. Verschueren1,3, Katholieke Universiteit Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium; Katholieke Universiteit Leuven, Clinical and Experimental Endocrinology, Department of Chronic Diseases and Metabolism, Leuven, Belgium; Vrije Universiteit Brussel Building B, Biostatistics and Medical Informatics Research Group, Department of Public Health, Elsene, Belgium

**Background:** Seronegative rheumatoid arthritis (RA) patients have been historically considered to have a milder disease course.

**Objectives:** We aimed to compare the disease course in seronegative and seropositive patients from the Care in early RA (CareRA) trial.

**Methods:** We used data from the 2-year RCT CareRA and its 3-year observational follow-up, CareRA plus. Patients completing the year 2 visit of CareRA were eligible for participation in CareRA plus, in which patients were evaluated every 6 months till year 5. The CareRA trial included patients early RA (<1 year) and naive to disease-modifying anti-rheumatic drugs. Patients were stratified in a low- and high-risk group according to prognostic markers and randomized to one of four different treatment schemes: a) MTX and a step-down glucocorticoid (GC) scheme (COBRA Slim) b) this combination with either sulphasalazine (COBRA Classic) c) or leflunomide (COBRA Avant-Garde) in high-risk patients, and d) MTX without GCs (Tight-Step-Up: TSU) or e) COBRA Slim in low-risk patients. Treating-to-target, steering at low disease activity (<3.2) measured in 28 joints with C-reactive protein (DAS28CRP) was applied while aiming for remission (<2.6) as final outcome. Differences in demographic, clinical and laboratory variables were tested with Wilcoxon rank or Chi-square. Multiple testing was corrected with Holms-Bonferroni. Survival analysis using Kaplan-Meier and COBRA schemes with GCs increased the chance compared (a) time to first remission (DAS28CRP<2.6), (b) time to first loss of disease-control (DAS28CRP>3.2) in those reaching remission, and all subsequent losses of disease-control as recurrent events between seropositive (ACPA or RF positive) and seronegative (ACPA and RF negative) patients. Survival curves were compared with log rank. To model recurrent events, an extended Cox model with random effect, including the presence of erosions at baseline, disease duration, gender, current smoking, treatment scheme with or without GCs and DAS28CRP at baseline and week 16 was used. Multiple imputation (m=100) was used to handle missing data.

**Results:** Of the 379 included patients, 83 (23%) were seronegative while 292 (77%) were seropositive. Seronegative patients had a similar median age (54 vs 53 years, p=0.58), BMI (26.5 vs 25.7 kg/m2, p=1.0), presence of erosions (26% vs 25%, p=1.0) and gender distribution (76% vs 68% females, p=1.0), compared to seropositive patients. However, median disease activity was higher in seronegative patients at baseline: DAS28CRP (5.1 vs 4.7, p<0.01), 28 swollen joint count (8 vs 6, p<0.01) and 28 tender joint count (10 vs 7, p<0.001). When accounting for the treatment, all COBRA schemes with GCs increased the chance of reaching remission by 58% (HR 1.58; 95%CI 1.10-2.27; p<0.05) compared to TSU (Figure 1b). For the time to first and consecutive losses of disease control after remission, one point higher DAS28CRP at week 8 (3.0 vs 2.1, p<0.001), but became comparable by year 1 (2.0 for both p=1.0). There was a significant difference in time to first treatment response between seronegative and seropositive patients as depicted in the inverted Kaplan-Meier plot (Figure 1a). Time to first remission was significantly shorter for seropositive (median 4 weeks IQR 4.8) versus seronegative (8 weeks IQR 4.28) patients (p<0.001). When accounting for the treatment, all COBRA schemes with GCs increased the chance of reaching remission by 58% (HR 1.58; 95%CI 1.10-2.27; p<0.05) compared to TSU (Figure 1b). For the time to first and consecutive losses of disease control after remission, one point higher DAS28CRP at week 16 increased the risk of losing disease control by 59% (HR 1.59; 95%CI 1.38-1.82; p<0.0001), serology status was not significantly predictive of loss of response.

**Conclusion:** In CareRA, seronegative patients, who have been historically considered to have a milder form of the disease, had a higher initial disease activity, longer time to first treatment response and greatly benefited from an initial treatment scheme that included glucocorticoids. Speed of response during the window of opportunity for RA has been highly advocated. Our findings highlight...
Osteoarthritis: novel prospects

Background: Hand osteoarthritis is a common heterogeneous joint disorder with differences in aetiology and pathophysiology compared to knee osteoarthritis,[1][3] its pathophysiological mechanism remains largely unexplored, partially because of limited access to clinical sample tissues and lack of animal models.[2] To date, there is no known cure for hand osteoarthritis, indicating an urgent need for better understanding of the underlying mechanisms so that appropriate treatment strategies can be developed to target this disabling disease.

Objectives: We aimed to identify hand joint chondrocyte subpopulations and investigate the molecular mechanism of hand osteoarthritis by performing single-cell RNA sequencing (scRNA-seq) analysis, and verify the findings in two large independent population-based studies.

Methods: We obtained hand interphalangeal joints from five donors who had destructive forearm injury. Using scRNA-seq analysis, we analysed the cellular composition and subpopulation-specific gene expression of hand articular cartilage, and then compared these features between cartilages from joints with macroscopically confirmed osteoarthritis and those without osteoarthritis. To verify the findings, we conducted a Mendelian randomisation study in the UK Biobank and a cross-sectional study using data collected from the Xiangya Osteoarthritis Study. Figure 1 shows the schematic illustration of this study.

Results: Of 105,142 cells we identified 13 subpopulations, including a novel inflammatory chondrocyte subpopulation that specifically expressed genes related to inflammatory and immune response. Fibrocartilage chondrocytes represented a major source of osteoarthritis-related proteases and exhibited an extensive alteration of gene expression patterns in osteoarthritic cartilage compared with non-osteoarthritic cartilage. Both inflammatory chondrocytes and fibrocartilage chondrocytes showed a trend towards increased numbers in osteoarthritic cartilage. In these two subpopulations from osteoarthritic cartilage, the ferroptosis pathway was enriched, in which the expression of iron overload-related genes, eg, FTH1, was elevated. These findings are further validated by two independent population-based studies. Among participants (n=332,668) in the UK Biobank, genetic predisposition to higher expression of FTH1 mRNA significantly increased the risk of hand osteoarthritis (OR=1.07, 95%CI:1.02-1.11). Among participants (n=1,241) from the Xiangya Osteoarthritis Study, high levels of serum ferritin (encoded by FTH1), a biomarker of body iron overload, were significantly associated with a high prevalence of hand osteoarthritis (P-trend=0.037).

Conclusion: Our datasets will be valuable as a rich resource for molecular and cellular exploration and open new possibilities for the research of molecular mechanism, drug development and precise treatment for hand osteoarthritis. Inflammatory and fibrocartilage chondrocytes are key subpopulations and ferroptosis may be a key pathway in hand osteoarthritis. Markers of these chondrocyte subpopulations, as well as ferroptosis inhibitors or iron chelators, could be focus of attention in future studies.

Background: The latest professional guidelines recommend intra-articular (IA) glucocorticoids (GCs) for pain relief in patients with knee osteoarthritis (OA). However, their effect is small-to-moderate and short-term only[1]. There is also concern about the possible risk of cartilage deterioration caused by repeated IA GCs. M1 macrophages and activated synovial fibroblasts (SFs) mutually contribute to the propagation of joint pain and cartilage destruction in OA by constructing a positive feedback loop. To alleviate joint pain over a longer period without increasing the risk of cartilage deterioration, we developed nano-porous cellular membrane (NM) camouflaged liposome (NM@Lip) for targeted delivery of triamcinolone acetonide (TA) and the hippocampus, attracting M1 macrophages and activated SFs in the synovium of osteoarthritic joints.

Objectives: To investigate the phenotypic reprogramming effect of TA-loaded NM@Lip (TA-NM@Lip) in M1 macrophages and activated SFs and determine their ability in relieving pain and alleviating OA progression in rodent models.

Methods: TA-NM@Lip was fabricated using the thin-film hydration method. The mRNAs and protein levels of phenotypic mediators secreted by M1 macrophages and activated SFs treated with free TA, TA-loaded liposome (TA-Lip) or TA-NM@Lip were measured using real-time PCR, RNA sequencing, ELISA and fluorescence staining. Phosphoproteomics analysis using a label-free approach, revealed 1109 early (5 min) suitable time points for ROR-2 mediated phosphorylation events based on ERK phosphorylation for ROR2i to induce chondrogenesis. This means that something else must take place in addition to YAP signalling was required for chondrogenesis induced by ROR2i, but not sufficient. Overexpression of constitutively active YAP negate ROR2i-induced chondrogenesis, but the YAP inhibitor Verteporfin was unable to induce chondrogenesis. This study was performed by precipitation of phosphoproteins on TiO2 columns and MS analysis.

Results: In keeping with the delayed endochondral ossification and chondrocyte hypertrophy observed in ROR2i-/- mice (DeChiara et al., 2000), Ror2/-/ C3H10T1/2 cells failed to undergo osteogenesis when exposed to osteogenic medium as assessed by alkaline phosphatase activity, extracellular matrix calcification and expression of hypertrophy/osteogenic markers. We established suitable time points for ROR-2 mediated phosphorylation events based on ERK (early) and JNK (late) phosphorylation following stimulation with WNT5A. Phosphoproteomics analysis using a label-free approach, revealed 1109 early (5 min) phosphorylation events that were ROR2 dependent (taking place in the wild type but not in ROR2-/- cells) and contributed to osteogenic differentiation.

Conclusion: TA-NM@Lip exhibited extended joint-retention time and selectively downregulated the expression of M1-related genes and upregulated M2-related genes compared with other treatment groups. The mRNAs and protein levels of pro-inflammatory cytokines, adhesion molecule and proteolytic enzyme secreted by activated SFs were significantly downregulated by TA-NM@Lip. NM@Lip was retained in the joint for up to 28 days and selectively distributed into both M1 macrophages and activated SFs in synovium with low distribution in cartilage. In MIA-induced model, a single IA injection of TA-NM@Lip attenuated synovitis and achieved complete pain relief without inducing adverse effects. In ACLT + pMMx-induced model, repeated TA-NM@Lip did not cause apoptosis of chondrocytes or damage cartilage and attenuated cartilage degeneration.

MOLECULAR MECHANISMS OF CHONDROPROTECTION INDUCED BY ROR2 BLOCKADE

Keywords: Osteoarthritis, Cell biology

A. S. Thorup1, J. Wilson2, M. Deniz1, F. Dell’acceio1, 1The William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom

Background: We previously reported that ROR2 blockade (ROR2i) induces chondrogenesis in vitro and in vivo, improving pain and cartilage integrity following joint destabilization in mice (Thorup et al., 2020). Downregulation of YAP signaling was required for chondrogenesis induced by ROR2i, but per se not sufficient. Overexpression of constitutively active YAP negate ROR2i-induced chondrogenesis, but the YAP inhibitor Verteporfin was unable to induce chondrogenesis. This study was performed by precipitation of phosphoproteins on TiO2 columns and MS analysis. In keeping with the delayed endochondral ossification and chondrocyte hypertrophy observed in ROR2i-/- mice (DeChiara et al., 2000), Ror2/-/ C3H10T1/2 cells failed to undergo osteogenesis when exposed to osteogenic medium as assessed by alkaline phosphatase activity, extracellular matrix calcification and expression of hypertrophy/osteogenic markers. We established suitable time points for ROR-2 mediated phosphorylation events based on ERK (early) and JNK (late) phosphorylation following stimulation with WNT5A. Phosphoproteomics analysis using a label-free approach, revealed 1109 early (5 min) phosphorylation events that were ROR2 dependent (taking place in the wild type but not in ROR2-/- cells) and contributed to osteogenic differentiation.

Methods: Cartilage differentiation was assessed in C3H10T1/2 cells cultured in micromass using Alcian Blue staining and the expression of mRNA encoding chondrogenic markers. Osteogenesis was assessed by molecular marker analysis, alkaline phosphatase activity and alizarin red staining. Phosphoproteomics screening was performed by precipitation of phosphoproteins on TiO2 columns followed by mass spectroscopy. Ror2/-/ C3H10T1/2 cells were cultured using CRISP/RCas9.

Results: In keeping with the delayed endochondral ossification and chondrocyte hypertrophy observed in ROR2i-/- mice (DeChiara et al., 2000), Ror2/-/ C3H10T1/2 cells failed to undergo osteogenesis when exposed to osteogenic medium as assessed by alkaline phosphatase activity, extracellular matrix calcification and expression of hypertrophy/osteogenic markers. We established suitable time points for ROR-2 mediated phosphorylation events based on ERK (early) and JNK (late) phosphorylation following stimulation with WNT5A. Phosphoproteomics analysis using a label-free approach, revealed 1109 early (5 min) phosphorylation events that were ROR2 dependent (taking place in the wild type but not in ROR2-/- cells) and contributed to osteogenic differentiation.
not in the Ror2(-/-;CRISPR cells) and 708 at 15 minutes. In keeping with the require-
ment of YAP for ROR2-dependent chondrogenesis (Thorup et al., 2020), several
phosphorylation events of molecules within the YAP pathway occurred including YAP
and LATS1/2. In keeping with this, YAP dependent transcription was modulated by
WNT5A in a ROR2-dependent manner in a reporter assay. Several phosphoryla-
tion events were previously poorly characterised. In keeping with this, YAP de-
pendent transcription was modulated by WNT5A in a ROR2-dependent manner in a reporter assay. Several phosphorylation events were previously poorly characterised.

Conclusion: ROR2 induces modulation of several signalling pathway in addi-
tion to YAP. The hierarchy of these phosphorylation events needs to be resolved
to identify the detailed molecular mechanism underpinning the efficacy of ROR2i
in osteoarthritis.

IDENTIFICATION OF DISTINCT CELLULAR POPULATIONS IN THE SYNOVIO
LATE-STAGE RADIOGRAPHIC KNEE OA USING SINGLE NUCLEUS RNA SEQUENCING

Keywords: Osteoarthritis

and Inflammation, Ghent, Belgium

Background: Osteoarthritis (OA) is a complex, multifactorial and heterogeneous
joint disease of unknown etiology. OA research has largely focused on articular
cartilage degeneration with little attention given to other joint tissues, including the
synovium. The synovium lines the joint capsule, produces synovial fluid for
lubrication, and is emerging as a contributor to OA pathogenesis. In OA, the
synovium exhibits increased vascularity, inflammation, hyperplasia and fibrosis. Synovial cells that contribute to these pathological events during early and
advanced stages of OA are not well characterized. The emergence of RNA
sequencing (RNAseq) at the resolution of a single cell or nucleus allows for the
identification of distinct cells that may contribute to OA pathogenesis.

Objectives: To delineate the synovium’s role in OA pathogenesis we sought to
identify if distinct cell subtypes exist in the synovium of early (KL1) versus late
stages (KL3/4) of radiographic knee OA using single nucleus RNA sequencing.

Methods: Synovia from patients with early (KL1–4; n=5) and late (KL
III/IV; n=4) stage radiographic knee OA were subjected to single nucleus (sn)RNAseq and to
bioinformatic analyses. Canonical cell-specific markers were used to identify cell
types from the unsupervised clustering analysis and prominent cell types were
re-clustered. Differentially expressed gene (DEG) lists between the subclusters
were determined based on top gene expression within a cell type between early
and late OA synovium. Cell surface markers identified from the DEGs were vali-
dated by immunohistochemistry. Pathway and gene ontology enrichment analy-
sis were performed on fibroblast subclusters to identify prominent pathways and
transcription factors that were upstream regulators. Ongoing in vivo and in vitro
methods are being used to assess these transcription factors in both fibroblast
cell culture and an OA mouse model.

Results: Fibroblasts and macrophages constituted 75% of the cells from early
and late-stage synovium and re-clustering analysis resolved 8 fibroblast and 6
macrophage subclusters (Figure 1). Cluster based nuclei proportion differences identified fibroblast clusters 1, 2, 4 and 6 and macrophage
clusters 1, 2 and 5 to contribute to early-stage samples while fibroblast
clusters 3, 4 and 5 and macrophage clusters 0, 3 and 4 to late stages. Downstream
analyses focused on fibroblasts and putative cell surface markers from fibroblast
subclusters were identified from DEGs and confirmed by immunohistochemistry.

NLRP12 EXACERBATES OSTEOARTHRITIS BY PROMOTING DEGRADATION OF NO2 IN SYNOVIAL MACROPHAGES

Keywords: Synovium, Innate immunity, Osteoarthritis
C. Li1, S. Lin1, Z. Ouyang1, T. Liu1, Z. Zheng1, J. Xu1, Y. Ding1, 1Sun Yat-sen
Memorial Hospital, Sun Yat-sen University, Orthopaedic Surgery, Guangzhou,
China

Background: Osteoarthritis is the most common degenerative bone and joint
disease. Hypothesis has been widely accepted that osteoarthritis (OA) starts
from cartilage injury and loss, while emerging evidences suggest that synovial
inflammation precedes cartilage loss during the progression of OA [1]. Activa-
tion of macrophages plays a crucial part in synovial inflammation in OA [2]. In
our previous researches, we have demonstrated NO2 as an inhibitor of mac-
rophage activation in vitro. Besides, bioinformatic analysis suggested a potential
link between NLRP12 and NO2.

Objectives: To investigate the role of NO2 in OA in vivo and explore the poten-
tial interaction between NO2 and NLRP12.

Methods: We established CIAO (Collagenase-induced OA) model with 8-week-
col57BL/6J mice, and injected NO2 over-expression (oe-NO2) lentiviral
vectors into the knee joint cavity as experimental group (CIOA + oe-NO2), with
the empty vectors as control (CIOA + Mock). 8 weeks later, the knee joints were
harvested and stained with Safranin O/fast green. Besides, three-dimensional
reconstruction of Micro-CT images were employed to evaluate the pathological
changes of OA. In addition, we applied lentiviral transfection, co-immunoprecip-
itation (Co-IP), and ubiquitination assays to investigate the interaction between
NO2 and NLRP12, as well as its mechanism of action in the regulation of mac-
rophage activation.

Results: In vivo over-expression of NO2 showed significant inhibition of patho-
logical changes (Figure 1A, 1B). Though NLRP12 did not have an impact on mRNA level of NO2 in RAW264.7 macrophages (Figure 1C), NO2 expression at pro-
tein level was negatively correlated with NLRP12 (Figure 1D), suggesting that
NLRP12 may influence the degradation of NO2. Co-IP experiments also con-
formed the existence of interaction between NLRP12 and NO2 at protein level,
which was influence by MG132, inhibitor of ubiquitin-proteasome pathway (Fig-
ure 1E). Besides, NLRP12 over-expression impaired inhibition of macrophage
inflammation by NO2 (Figure 1F). Since HSP90 binds NO2 to prevent its
proteasomal degradation via poly-ubiquitination (Poly-Ub) [3], we therefore performed Co-IP and Poly-Ub assays. NLRP12 was associated with reduced binding of HSP90 with NOD2, greater scale of K48 Poly-Ub assembling on NOD2, and thus lower level of NOD2 protein. Furthermore, proteasomal degradation of NOD2 was blocked by MG132, though interrupted binding between NOD2 and HSP90, and accumulation of Poly-Ub chains (Figure 1G). These findings suggested sequestration of HSP90 from binding NOD2 by NOD2-NLRP12 interaction, which led to assembly of K48 Poly-Ub chains onto NOD2, and its proteasomal degradation (Figure 1H).

Conclusion: NOD2 was demonstrated as an inhibitor of OA in vivo, in consistence with our previous in vitro data. Besides, NLRP12 interacted with NOD2, and promoted its Poly-Ub and subsequent proteasomal degradation. Our findings highlighted the impressive potential of NLRP12 to be a preventative and therapeutic target in OA, though more in-depth investigations are indispensable before further conclusion is reached.

LYSYL OXIDASES (LOX(L)) PROMOTE PATHOLOGIC CHONDROCYTE CALCIFICATION

Keywords: Cartilage, Animal Models, Crystal Arthritis

I. Bernabei1, M. Romani2, E. Faure3, J. Wegrzyń3, T. Höge1, N. Busso1, S. Nasi1. 1Lausanne University Hospital, CHUV, Department of Musculoskeletal Medicine, Lausanne, Switzerland; 2Lausanne University Hospital, CHUV, Department of Medicine, Lausanne, Switzerland; 3Lausanne University Hospital, CHUV, Department of Orthopedic Surgery, Lausanne, Switzerland

Background: Pathologic calcification (PC) is the deposition of calcium-containing crystals in soft tissues. PC of cartilage is a hallmark of osteoarthritis (OA), a degenerative joint disease characterized by cartilage degradation. The interplay between calcification- and extracellular matrix (ECM) formation, maturation and degradation in cartilage is not fully understood.

Objectives: We aim to reveal the role of lysyl oxidases (LOX(L)), a family of extracellular enzymes that catalyze collagen cross-linking, in OA cartilage calcification.

Methods: We induced in vitro chondrocytes calcification with calcifying medium (CM = BBC + 10% FBS + 20mM β-glycerophosphate + 50μg/ml ascorbic acid) or control (CM = DMEM high glucose + 10% FBS), and treated or not with 500μM 5-aminopropionitrile (BAPN). Gene expression was analyzed by qRT-PCR, II-6 in cell supernatants by ELISA, mitochondrial and cytoplasmic reactive oxygen species (ROS) by use of the kits MitoSOX and DHE (Life Technologies). We induced in vivo murine knee cartilages using the meniscectomy (MNX) mode, where medial meniscus is removed in the right knee, while the left knee is sham operated. During two months, mice were injected with PBS or BAPN 50mg/Kg twice per week, and given 1mg/ml BAPN in drinking water. New calcific formation in knees was analyzed by microCT. Bioinformatics analysis was performed with an online tool at www.systems-genetics.org/mmad, using the Modules by Module section in GeneBridge. Manhattan plots were generated by correlating collagen fibril organization module (GO:0030199) representing LOX(L) family of enzymes, and calcification-, chondrocyte hypertrophy- and catabolic enzymes-associated modules.

Results: Our findings revealed that CM and calcium-containing crystals induced lox(l) activity in murine chondrocytes in vitro. Conversely, treatment with the lox(l) pan-inhibitor BAPN, decreased crystal production in vitro, while decreasing calcification gene expression of Anx5, PC1, Pit-1/2 and Alp activity. Intriguingly, we identified that the pro-calcifying effects of LOX(L) were mediated via their classical cross-linking activity, as diminished cross-links in pre-formed extracellular matrix reduced in parallel chondrocyte calcification, with specific suppression of Anx5 and Pit-1/2 genes. Additionally, BAPN reverted the hypertrophic phenotype of calcifying chondrocytes, reducing expression of Runx2 and Col10 and increasing that of early differentiation Sox9 and Col2. In the same conditions, LOX(L) inhibition downregulated Col1 and Col2, whose uncontrolled production can lead to ECM fibrosis and calcification. BAPN also inhibited the expression and release of pro-calcifying cytokine II-6, while also reducing mitochondrial and cytoplasmic ROS, known to be associated with PC. Additionally, we revealed in calcifying chondrocytes that BAPN inhibition decreased cartilage catabolic enzymes genes (Mmp3, Mmp13 and Adamts5). In line, treatment with BAPN in an in vivo murine OA model based on meniscectomy, led to decreased knee joint calcifications, while not affecting the bone mineral density of the knee. We also confirmed the role of lox/l in human OA cartilage calcification. Indeed, LOX(L) inhibition by BAPN led to reduced crystal production in primary human OA chondrocytes. Finally, a bioinformatics transcript analysis of available human and murine databases obtained from tissues potentially undergoing PC, further confirmed a positive association between LOX(L)collagen fibril organization module and calcification-, chondrocyte hypertrophy- and catabolic enzymes-associated modules.

Conclusion: Collectively, our results revealed for the first time a pro-calcifying effect of LOX(L) in chondrocytes, through classical (cross-linking of extracellular matrix) and non-classical pathways (i.e. chondrocyte hypertrophy, increased matrix synthesis and degradation, and exacerbated IL-6 and ROS production). In conclusion, LOX(L) provide a novel target for future therapies aimed at treating pathologic cartilage calcification.

EXOSOMES TRANSMIT DAMAGE SIGNALS FROM INFRAPELLATULAR FAT PAD AND EXACERBATE CHONDROCYTE SENESCENCE IN OSTEOARTHRITIS

Keywords: Osteoarthritis, Treat to target

Y. Cao1, J. Ruan1, J. Kang1, X. Nie1, G. Ruan1, Z. Zhu1, W. Han1, S. Tang1, C. Ding2. 1Zhuzhaliang Hospital, Southern Medical University, Clinical Research Centre, Guangzhou, China

Background: Infrapeptellar fat pad (IPFP) is closely associated with the development and progression of knee osteoarthritis (OA) [1-5], but the underlying mechanism remains unclear.

Figure 1. (A-B) Micro-CT and Safranin O/fast green staining of mouse knee joints (n=6 for each group) (Scale bar = 100 μm) (C-D) Influence of NLRP12 on mRNA and protein level of NOD2 in macrophages (E) Interaction between NOD2 and NLRP12 (F) Effect of NLRP12 on the inhibitory effect of macrophage activation by NOD2 (G) Effect of NLRP12 on Poly-Ub and HSP90 binding of NOD2 (H) Schematic diagram
**Objectives:** This study aims to investigate the role and regulatory mechanisms of osteoarthritic infrapatellar fat pad (IPFP) tissue-derived exosomes (IPFP-Exos) in chondrocytes senescence and osteoarthritis (OA) progression.

**Methods:** The IPFP were collected from late-stage OA patients with knee arthroplasty. The role of endogenous osteoarthritic IPFP-Exos was measured in human IPFP exosomes coculturing with chondrocytes and mice post-traumatic OA models induced by destabilization of the meniscus (DMM) surgery with GW4869 or vehicle treatment. Extract of IPFP tissue exosomes was performed by ultracentrifugation. Chondrocytes degradation and cellular senescence were assessed by qRT-PCR, western blotting, alcian blue and toluidine blue staining, immunofluorescence and senescence-associated beta-galactosidase staining, respectively. MiRNA sequencing was employed in IPFP-Exos to explore its cargoes. Luciferase reporter assay was used to reveal the interaction between exosomal miRNAs and their downstream mRNA target.

**Results:** Osteoarthritic IPFP tissue could secret exosomes and deliver them into articular chondrocytes. Inhibition of endogenous osteoarthritic IPFP-Exos significantly alleviated cartilage destruction. Functional assays in vitro demonstrated that IPFP-Exos significantly prevented chondrocyte extracellular matrix (ECM) catabolism and cellular senescence. Moreover, further experiments demonstrated that IPFP-Exos induced ECM degradation in human and mice cartilage explants and aggravated the progression of experimental OA mice model. Mechanistically, highly enriched let-7b-5p and let-7c-5p in IPFP tissue-derived exosomes were essential to mediate detrimental effects by directly decreasing senescence negative regulator, lamin B receptor (LBR). Notably, intra-articular injection of antagonists inhibiting let-7b-5p and let-7c-5p in mice increased LBR expression, suppressed chondrocyte senescence and ameliorated the progression of experimental OA model.

**Conclusion:** This study highlights the function and mechanism of the IPFP-Exos in the progression of OA. Targeting IPFP-Exos cargos of let-7b-5p and let-7c-5p provide a potential prevention strategy for OA.

**POS0336 PERIPHERAL IMMUNOME DYSREGULATIONS REFLECT OSTEARTHRITIS (OA) JOINT DISEASE SEVERITY**

**Keywords:** -omics, Osteoarthritis

A. Chia1,2, A. M. Lajam1, G. Ang1, M. Wassef1, P. Kumar3, K. Leung4, S. Albani1,2,1,2
1Translational Immunology Institute, SingHealth Duke-NUS Academic Medical Centre, Translational Immunology Institute, Singapore, Singapore; 2Duke-NUS Medical School, Cancer and Stem Cell Biology (CSCB), Singapore, Singapore; 3Duke-NUS Medical School, Duke-NUS, Singapore, Singapore; 4Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 5KK Women’s and Children’s Hospital, Rheumatology and Immunology Service, Department of Paediatric Subspecialties, Singapore, Singapore

**Background:** Osteoarthritis (OA) is a prevalent condition that is especially common among people of advanced ages. It is due to cartilage degeneration which leads to loss of mobility and chronic pain. Currently, there is no disease-modifying drugs to treat OA and the standard of care is pain management, and eventual joint replacement for end-stage disease. It is recognized that OA pathogenesis involves a complex interplay of joint damage, poor cartilage regeneration, and inflammation. However, much is unknown how the peripheral immunome architecture is perturbed by the local joint inflammation.

**Objectives:** To investigate how the peripheral immunome is dysregulated by local joint inflammation as a result of knee OA, and whether different immune subsets are dysregulated at different stages of OA severity.

**Methods:** We employed the use of mass cytometry time-of-flight (CyTOF) to investigate peripheral blood mononuclear cells (PBMCs) obtained from patients with OA and healthy controls (HCs). 64 patients with different severity of OA, based on radiographic Kellgren-Lawrence scores, and 37 age, sex, and race-matched HCs were enrolled in this study. To broadly capture the dysregulations in the different immune subsets, we designed two CyTOF marker panels that cover major innate and adaptive immune cell lineages to interrogate these samples. To investigate possible relationships between the peripheral and joint immunome dysregulations, digital deconvolution of RNA-seq data obtained from OA synovial samples to estimate immune subset frequency changes in the joint was also conducted.

**Results:** We observed dysregulations in both the innate and adaptive compartments of the OA peripheral immunome as compared to HCs, and different immune subsets were dysregulated at different OA severity. In early OA, there is an involvement of inflammatory immune subsets, namely natural killer (NK) and gamma-delta T cells, suggesting the possibility of these subsets infiltrating the joint to initiate and perpetuate joint inflammation in OA. As the disease progresses to late OA, we discovered further involvement of CD45RO+ and CTLA4+PD-1+ T cell subsets suggesting memory formation and immune exhaustion. Furthermore, we also observed an involvement of regulatory subsets in late OA suggesting the homeostatic attempts to temper the chronic inflammation at the OA joint. Comparing with our analysis of the digital deconvolution of RNA-seq data of OA synovia, NK cells, monocyties, gamma-delta T cells, and resting memory T cell subsets were found to be dysregulated in both the peripheral and joint immunomes, suggesting possible trafficking dynamics and functional relationship between the two immunomes.

**Conclusions:** Our study revealed dynamic peripheral immunome changes that provide insights to the immunopathogenesis of OA. By uncovering these underlying peripheral immunome disruptions in OA, we provide further evidence that the immune system plays an important role in OA disease process.

**Background:** Osteoarthritis (OA) is a common chronic degenerative disease caused by progressive cartilage degradation [1]. In OA, regenerative medicine based on mesenchymal stem cells (MSCs) is considered the most promising method for restoring articular cartilage [2]. However, the high heterogeneity of MSCs together with invasive and painful procedures for stem cell isolation represent the main challenges of tissue engineering technology [3][4]. In this regard, a homogeneous population of MSCs, the chondroprogenitor cells (CPs), have been recently discovered in human bone [5].

**Objectives:** In the light of these considerations, the purpose of this study was to identify CPs in OA. In addition, we aimed to differentiate circulating MSCs into chondrocytes for their in vitro characterization.

**Methods:** For this study, 10 patients affected by widespread OA [10F; median age 62 years, IQR 9; median disease duration 19 years, IQR 4] related and 10 healthy donors (HD) matched by sex and age were enrolled. A blood sample was collected from each participant to the study for the characterization of three CP populations [5]. In summary, after the isolation of CD45- cells from 500 μl of whole blood using anti-CD45+ magnetic beads, samples were labeled with anti-CD146-PE, anti-CD73-APC, anti-CD164 – FITC and PDPN PerCP/Cyanine5.5 antibodies. The acquisition of CPs was performed on a FACS Calibur cytometer. Data was analyzed using the Cell Quest Pro software. For in vitro culture of circulating MSCs, peripheral blood mononuclear cells (PBMCs) were isolated by Ficoll-gradient protocol and were cultured in DMEM supplemented with 20% FBS and 1% antibiotic–antimycotic. At 60–80% of confluence, the adherent cells were collected using AV-FITC and PI apoptosis detection kit.

**Results:** Flow Cytometry analysis identified CPs in peripheral blood. Interestingly, the two populations CD45-, PDPN +, CD146-, CD73 +, CD164+ and CD45-, PDPN +, CD146-, CD73-, CD164 + were significantly decreased in OA patients compared to HD (0.82% ± 0.46 vs 4.13% ± 1.92, 0.65% ± 0.22 vs 3.74% ± 1.10, p = 0.0065 and p = 0.0022, respectively) (Figure 1a). During in vitro expansion, MSCs of OA patients were numerically lower than HD (p=0.0089, p=0.0042 and p=0.0002, respectively) (Figure 1d). Lastly, apoptosis was significantly higher in OA chondrocytes than in HD (p=0.004) (Figure 1e).

**Conclusion:** The results of this study demonstrated a lower percentage of circulating CPs in patients affected by OA compared to HD. Furthermore, OA circulating MSCs showed a reduced chondrogenic capacity supported by a high number of hypertrophic chondrocytes and an increase in apoptosis levels. Further studies are need to clarify the possible application of circulating CPs in cartilage regenerative therapy.

Beyond the crystal ball...

Keywords: Randomized controlled trial, Patient-led research, Systemic sclerosis

P. Del Gaudio1,2, L. A. Bissell3, S. Huang4, P. Hansen5, S. Johnson6, D. Furst7, D. Khanna8. 1University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospital Trust, Biomedical Research Centre, Leeds, United Kingdom; 3Leeds Teaching Hospital Trust, Biomedical Research Centre, Leeds, United Kingdom; 4University of Michigan, Scleroderma Program, Ann Arbor, United States of America; 51000minds, 1000minds, otago, New Zealand; 6University of Toronto, Scleroderma Program, Toronto, Canada; 7Los Angeles, Pacific Arthritis, Los Angeles, United States of America; 8University of Michigan, Scleroderma Program, Ann Arbor, United States of America

Background: The revised Combined Response Index in diffuse cutaneous Systemic Sclerosis (dcSSc) (rCRISS) is a composite outcome measure reifying on 6 core set variables including Organ Failure, Forced Vital Capacity (FVC), HAQ-DI and modified Rodnan skin score (mRSS), together with patient and clinician global assessments of disease activity [1]. rCRISS is calculated in patients not experiencing any organ failure and reported as proportion of patients who improve a given % (20,30,40 etc) in at least 3 domains. rCRISS discriminated treatment vs placebo in 3 randomised, placebo-controlled trials on early diffuse SSC [1]. Notwithstanding, it is not clear what is the minimal rCRISS score that captures an overall improvement in disease. Further, being developed as a response index, patients that do not experience a predefined organ failure but do worsen in their disease cannot be scored or discriminated from patients that simply do not improve.

Objectives: To improve the clinical interpretation of the rCRISS by creating a continuous range score of clinician and patient meaningful changes in its individual variables.

Methods: Following OmerACT guidelines, 100 physicians with experience in dcSSc and 100 patients with dcSSc who have participated in a dcSSc trial were identified in 5 continents. An adaptive survey was developed, based on 1000Minds conjoint analysis software. Patients and doctors were asked to choose, on successive pairs of two hypothetical patients, who had better or worse outcome according to presence of organ failure and Minimal Clinically Important Differences (MCID) in two domains among FVC, HAQ-DI and mRSS. Pairwise comparisons of choices were analysed utilising PAPRIKA methodology [2] to rank and weight the MCIDs against each other. The resulting score was tested in the same cohort utilised for rCRISS development. Briefly, 354 SSC patients data from three randomised, placebo-controlled trials (Asset, Focussced and Fascinate) were randomised in 10 development (2/3 pts) and validation (1/3 pts) sets, stratified by study and treatment group. Mean scores of the replicate datasets were calculated for active and placebo treatments. Bootstrapping was employed to determine 95% Confidence Intervals. Kappa statistics were used to analyse concordance.

Results: 160 of the 200 participants completed the survey. Discrete choices concerning analysis defined ranks and relative weights of the 4 domains in the improved and worsened outcomes groups. A continuous composite ranked score reflecting the relative weighting of the individual outcome measures (Ranked Composite Important Difference, RCID) was developed. The score ranges from -1 (worst possible outcome) to 1 (best possible outcome), with patients who experience no organ failure and do not meet any MCID in any of the 3 domains scoring 0. Positive RCID scores showed a strong correlation with ACR CRP >0.6 with kappa statistics in development and validation sets of 0.71 (CI 0.64,0.73) and 0.71 (0.66,0.84), respectively. 73.1% of subjects with positive RCIDs (74% in the validation set) met revised CRIS10, with 63.7 and 51.3 meeting rCRISS 20% and 30%, respectively, rCRISS scores between 20 and 30 and were associated with only positive RCID1. Additionally, 32% (CI 29.7,34.3) of subjects on active treatment scored a positive RCID (>0) vs 25.8 (CI: 23.3,26.6) in the placebo group. Data were confirmed in the validation set (31.7 vs 27.1). Conversely, 12.3% (10.14) of subjects on treatment arms showed negative RCID (Any worsening, <0) vs 21.1 (19.2,23.3) in the placebo groups.

Conclusion: Our process adopted a robust methodology with a large patient representation in outcome measure development, to develop a patient and physician derived anchor (RCID) to other composite scores, such as ACR CRITT and revised CRISS. RCID provides a clinician and patient meaningful score that can be used as a dichotomous variable with a positive (improved) or negative (worsened) outcome.

HIGH-GRADE SYNOVITIS ASSOCIATES WITH CLINICAL MARKERS AND RESPONSE TO DMARDS THERAPY IN CHRONIC INFLAMMATORY ARTHRITIS: POST HOC ANALYSIS OF A PROSPECTIVE STUDY

Keywords: Psoriatic arthritis, Synovium, Rheumatoid arthritis

C. Garaffoni1, J. Calciolari2, M. Temusali3, M.S. Ciolfi1,2, G. Lanazzi2, A. Borrelli1, M. Govoni1, A. C. A. Soles2, E. Silvagni3. 1Rheumatology Unit, University of Ferrara and Azienda Ospedaliera-Universitaria S. Anna, Department of Medical Sciences, Ferrara, Italy; 2Università della Campania L. Vanvitelli, Department of Precision Medicine, Naples, Italy; 3University of Ferrara, Department of Translational Medicine, Ferrara, Italy; 4University of Milano-Bicocca, School of Medicine and Surgery, Milan, Italy

Background: Inflammatory arthritis (IA), such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA), are characterized by the presence of chronic synovitis. The Krenn synovitis score (KSS), a semi-quantitative histopathological score, allows the discrimination between high-grade and low-grade synovitis [1]. Although KSS could be a potential tool for profiling patients with IA, its associations with clinical and treatment features are not yet thoroughly described.

Objectives: The aim of this post hoc analysis was to identify clinical and instrumental correlates of KSS and to evaluate the association between high-grade synovitis and treatment response in a prospective cohort of IA including both RA and PsA patients.

Methods: Clinical, laboratory and ultrasound (US) data were retrieved from RA and PsA patients recruited in MATRIX cohort. Inclusion criteria were age ≥18 years, RA (ACR/EULAR 2010) or PsA (CASPAR criteria) diagnosis, presence of active disease with eligibility to start/modify new DMARDs therapy. Patients underwent US-guided synovial biopsy of one of the most involved joint (knee or wrist) before starting/modify DMARDs treatment according to treat-to-target strategy. The samples were analysed by an expert pathologist and KSS was calculated. Univariate and multivariate logistic regression analyses were performed to evaluate the relation between KSS and baseline variables. The association between KSS and treatment response, defined by ACR20, DAS28 remission and the newest ACR/EULAR remission criteria (2) at 6 months of follow-up, was investigated in univariate logistic regression analysis.

Results: 50 patients, 31 RA and 19 PsA, completed 6 months of follow-up after synovial biopsy. Baseline characteristics did not differ between RA and PsA patients except for F/M ratio (77% vs 32%, p=0.004). Four patients (8%) were treatment-naive and, within the refractory patients (46/50, 92%), 19 (38%) were previously treated with b/tsDMARDs. GCs exposure was reported for 17/31 (55%) RA and 8/19 (42%) PsA patients. KSS was available for 47 patients and the median value was 6.00 (IQR 4.00-7.00) in RA samples and 4.00 (IQR 3.00-5.75) in PsA. Inflammatory infiltrates score was significantly higher in RA than in PsA patients (median 3.00 vs 2.00, p=0.034)(Figure1A). At univariate analysis, the presence of C reactive protein (CRP)>0.5 mg/dl, erythrocyte sedimentation rate (ESR)>30 mm, DAS28-ESR, joint stiffness in the biopsied joint (VAS≥60mm), moderate to high synovial effusion and moderate to high power Doppler signal detected by US at baseline evaluation in the biopsied joint all associated with increased risk of high-grade synovitis. Fibromyalgia, instead, associated with a reduced risk of high-grade synovitis. At multivariate analysis, US effusion (OR 7.18, 95%CI 1.49, 47.98), CRP (OR 5.66, 95%CI 1.23, 33.22) and joint stiffness (OR 7.67, 95%CI 1.31, 73.51) significantly associated with high-grade KSS (Figure 1B). After 24 weeks (33/50 new btsDMARDs, 6/50 new csDMARDs)
initiated), 2448 patients achieved DAS28 remission, 18/48 ACR/EULAR remission and 26/50 ACR20. Univariate analysis revealed increased OR of remission/ response for patients with high-grade synovitis (ACR20 OR 4.57, 95% CI 1.98, 70% p=0.017; DAS28 remission OR 5.85, 95% CI 1.60, 25/48, p=0.011; ACR/ EULAR OR 7.50, 95% CI 1.69, 53.49, p=0.017) (Figure 1C). The interaction between KSS and diagnosis had no significant impact on the outcome.

Conclusion: KSS is a simple and feasible tool for disease stratification of patients with IA, recommended in synovial biopsy research. In our study, high CRP, joint stiffness and US presence of synovial effusion correlated with the presence of high-grade synovitis. High grade synovitis was associated with increased probability of achieving remission 6 months after therapy upgrade in active IA patients independently from diagnosis.

PROGNOSTIC FACTORS OF INTERSTITIAL LUNG DISEASE: A 10-YEAR LONGITUDINAL COHORT ANALYSIS

Keywords: Prognostic factors, Imaging, Lungs
K. Nakamura1, S. Shimoyama1, N. Abe1, T. Horita1.1Tomakomai City Hospital, Internal Medicine, Tomakomai, Japan

Background: Interstitial lung disease (ILD), defined as interstitial pneumonia (IP) and pulmonary fibrosis, has a variety of backgrounds. Connective tissue diseases (CTD) is one of the leading causes of ILD, and the concept of “IP with an autoimmune feature (IPAF)” has been established [1]. It has been reported that CTD-related ILD (CTD-ILD) and IPAF have a better prognosis than idiopathic pulmonary fibrosis [2]. However, prognostic differences and factors among CTD-ILD, IPAF, and other ILDs (OILD) remain unknown.

Methods: We retrospectively collected data from 642 patients diagnosed as “IP” or “pulmonary fibrosis” between 2010 and 2021 at Tomakomai City Hospital. ILD diagnosis was performed by CT scan with 2 neuroradiologists. We classified ILD into 3 groups of CTD-ILD, IPAF, and OILD. Mortality and prognostic factors were assessed using Kaplan-Meier methods and Cox proportional hazards models. In addition, we analyzed hospitalization free survival using Kaplan-Meier methods.

Results: Clinical characteristics of the patients are shown in Table 1. The CTD-ILD and IPAF patients were younger, and less frequently complicated by coronary artery disease and chronic heart failure. In addition, more patients in the IPAF and CTD-ILD groups showed a Non-specific interstitial pneumonia (NSIP) pattern on initial CT, while OILD group showed a usual interstitial pneumonia (UIP) and diffuse alveolar damage (DAD) pattern. C-reactive protein (CRP) levels were lower in the IPAF and CTD-ILD group.

The prognosis of CTD-ILD and IPAF group was better than OILD group (Figure 1, adjusted p<0.001, <0.01, respectively), but that of CTD-ILD and IPAF was similar (adjusted p=0.10). Multivariate analysis revealed the ILD classification was not independent prognostic factor (p=0.11, Hazard ratio (HR) 0.85, [0.70-1.04]). However, age (p<0.001, HR1.03, [1.02-1.05]), sex (p<0.001, HR 2.08, [1.52-2.87]), initial CT patterns as UIP (p<0.01, HR 2.68, [1.27-5.75]) and DAD (p<0.001, HR 7.99, [3.85-16.60]) were independent prognostic factors. The leading causes of death (CTD-ILD vs. IPAF vs. OILD) were IP (48.2% vs. 55.6% vs. 44.7%, p=0.05), infection (10.8% vs. 22.2% vs. 18.4%, p=0.07), and malignancy (24.1% vs. 5.6% vs. 7.9%, p=0.03). In the analysis of event free survival, there was no difference among three groups (p=0.80), and the most common cause was the infection in the CTD-ILD group (36.1%) and primary event in the OILD and IPAF groups (29.0%, 36.4%, respectively).

PERFORMANCE ANALYSIS OF A DEEP LEARNING ALGORITHM TO DETECT POSITIVE SIJ MRI ACCORDING TO THE ASAS DEFINITION IN AXSPA PATIENTS

Keywords: Spondyloarthritis, Artificial Intelligence, Imaging

Acknowledgements: NIL.

Disclosure of Interests: None Declared.
Methods: 731 baseline SU MRI scans were collected from two prospective randomised controlled trial cohorts in patients with non-radiographic (nr-axSpA) and radiographic (r-) axSpA (RAPID-axSpA [NCT01087762] and C-OPTIMISE [NCT02505542]) and were centrally evaluated by two expert readers (and adjudicator in case of disagreement) for the presence of inflammation by the 2009 Assessment in SpondyloArthritis international Society (ASAS) definition.[5] The MRI scans were processed by the previously trained deep learning algorithm,[2] blinded to clinical information and central expert readings. Performance evaluation included sensitivity, specificity, positive and negative predictive values (PPV and NPV), Cohen’s Kappa and the absolute agreement to assess the agreement between the deep learning algorithm and the human readers for the classification of MRI-SIJ scans. Bootstrapping was used to construct the 95% confidence interval (CI).

Results: Pooling the patients from RAPID-axSpA (n=152) and C-OPTIMISE (n=579) yielded a validation set of 731 patients (mean age: 34.2 years; SD: 6.6; 69.1% male) of which 44.6% were patients with nr-axSpA and 59.6% were MRI+ as per central readings. Comparing the trained algorithm with the human central readings for the classification of MRI+MRI– on the pooled validation set yielded a sensitivity of 70% (95% CI: 66–73%), specificity of 81% (95% CI: 78–84%), PPV of 84% (95% CI: 82–87%), NPV of 64% (95% CI: 61–68%), Cohen’s kappa of 0.49 (95% CI: 0.43–0.55), and absolute agreement of 74% (95% CI: 72–77%). Table 1.

Background: There is a high unmet need for disease-modifying antibiotic therapies in diffuse cutaneous systemic sclerosis (dcSSc) which could improve the outcome of this severe disease. Patient reported outcome measures (PROMs) are important and mandatory for randomized clinical trials (RCTs). The EULAR-endorsed ScleroID is the first comprehensive PROM specifically developed by SSc patients and experts to reflect the disease impact of SSc and showed a good performance in the clinical validation study [1]. However, most RCTs focus on dcSSc patients, hence a validated PROM to reflect the disease burden experienced by patients with dcSSc is needed and a detailed analysis of ScleroID in this subset of patients is lacking.

Objectives: To investigate the performance of the EULAR ScleroID in patients with dcSSc as a prerequisite for its use as a PROM in RCTs testing potentially disease-modifying drugs.

Methods: This is a subanalysis of all patients with dcSSc from the large, multicenter, ScleroID validation cohort [1]. As comparators, SSc-HAQ, EQ-SD, SF-36 were included. The study had a longitudinal arm with a reliability visit at 7±3 days and a 12-month follow-up visit [1]. The performance of ScleroID in dcSSc was assessed according to the OMERACT filter [1].

Results: 152 dcSSc patients with a baseline visit were analyzed (44, 28.9% male, median age 54 years, median disease duration 7 years). ScleroID performed well as a PROM reflecting the disease impact of dcSSc: it showed a good construct validity with high Spearman’s correlation coefficients with comparators (SSc-HAQ, 0.79, 95% CI [0.69, 0.86]; HAQ-DI, 0.72 95% CI [0.60, 0.80]; SF-36 physical score, -0.69 95%CI [-0.77, -0.60]). Furthermore, the internal consistency was strong.
Cronbach’s alpha was 0.87 and the split half reliability coefficient was 0.88. In the longitudinal arm, 44 patients had a test-retest reliability visit and 113 a follow-up visit, of whom 19/113 (16.8%) reported a significant change at 12 months follow-up (11 improved, 8 worsened). ScleroID showed a good consistency and discrimination ability with excellent test-retest reliability (intraclass correlation coefficient 0.89, 95% CI [0.84, 0.92]) and moderate sensitivity to change (standardized response mean 0.54, superior to the comparators (SSC-HAQ, 0.01; HAQ-DI,-0.07; SF-36 physical score, -0.43). The results are summarized in Figure 1.

Conclusion: The EULAR ScleroID, which is a novel, brief, disease specific, patient-derived, disease impact PROM, performs well for patients with dcSSc. This supports the inclusion and further analysis of ScleroID as a PROM to reflect patients’ perspective in RCTs.

Acknowledgements: We sincerely thank the patients’ representatives who contributed to the ScleroID study, without whom this project would not have been possible.

Background: High-density lipoprotein (HDL) mediated cholesterol efflux capacity (CEC) is facilitated by various membrane transporters based on the maturity of the apolipoprotein B (apoB) particle. HDL particle internalization, cholesterol transfer from discoidal HDL to low-density lipoprotein (LDL) and its reloading on macrophages, as well as increased triglycerides favoring a proatherogenic phenotype. Beyond lowering LDL levels, statins have various pleiotropic effects including anti-inflammatory activities, but it is unknown whether they modulate the impact of HDL CEC on atherosclerosis in RA.

Objectives: We here explored associations between ABCA1 CEC, coronary atherosclerosis and cardiovascular risk in RA and the influence of statins on those relationships.

Methods: Coronary atherosclerosis (noncalcified, partially or fully calcified, low attenuation plaques and coronary artery calcium [CAC] score) was evaluated with computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 6.9±0.4 years. ABCA1 CEC and ABCG1 CEC were measured in J774 macrophages and Chinese hamster ovary cells as previously described. Cox regression evaluated the association between ABCA1 CEC and cardiovascular risk. Multivariable negative binomial and robust logistic regression tested associations of ABCA1 CEC and its interactions with statin therapy on various plaque numbers at baseline, follow-up and CAC progression.

Results: ABCA1 CEC inversely correlated with ABCG1 CEC (Pearson r = -0.167, p = 0.046) and directly correlated with triglyceride levels (Pearson r = 0.239, p = 0.004), reflecting its association with a proatherogenic phenotype. ABCA1 CEC (per 1 SD increment) associated with long-term cardiovascular risk after adjustment for cardiovascular risk score and baseline plaque burden [HR 2.05 (95% CI 1.20-3.48), Figure 1A]. ABCA1 CEC had no main effect on baseline plaque burden or progression. Instead, its impact on the respective outcomes was influenced by baseline statin use and daily average dose of statin corresponding. ABCA1 CEC inversely associated with stenotic plaque severity in statin users but not in nonusers (p for interaction = 0.024 and 0.023 respectively). Higher ABCA1 CEC associated with fewer noncalcified plaques (Figure 1C) and lower noncalcified plaque stenotic severity (Figure 1D) in statin users but not nonusers (p for interaction = 0.024 and 0.023 respectively). Higher ABCA1 CEC associated with fewer low attenuation plaques in statin users but more in nonusers (p for interaction ≤0.001, Figure 1E) and statin users displayed fewer low attenuation plaques compared to nonuser at high (≥1 SD) but not low (<1 SD) ABCA1 CEC. Moreover, ABCA1 CEC inversely associated with CAC progression in patients using high daily atorvastatin equivalent dose (>1 SD) but not nonusers (p for interaction = 0.008, Figure 1F).

Conclusion: In a proatherogenic milieu typical of active RA, including a block in HDL maturation, increased triglycerides and LDL oxidation, increasing ABCA1 activity as the predominant CEC pathway is insufficient to counterbalance and may in fact associate with vascular damage and plaque vulnerability. Statin use, by decreasing triglycerides, LDL levels and oxidation, may reduce cell cholesterol overload, thus unmasking the atheroprotective effects of ABCA1 CEC.

Disclosure of Interests: NIL.

RESULTS: We included 4,672 axSpA patients (2,775 (59%) men) with a registration of both BASDAI and ASDAS-ESR at baseline and at least one follow-up visit. Mean (SD) BASDAI and ASDAS-ESR were 5.7 (2.1) and 3.3 (1.0) at baseline, and 3.0 (2.3) and 1.9 (1.0) at follow-up, respectively. The optimal BASDAI values corresponding to ASDAS-ESR cut-offs were 2.1, 3.1 and 6.2 for men and 2.1, 3.3 and 6.3, respectively (Figure 1). When comparing the BASDAI and ASDAS-ESR cut-offs, the level of agreement was lower for the VHDA cut-off compared to the other disease activity states (Table 1). The gender-specific BASDAI cut-offs corresponding to ASDAS-ESR cut-offs (i.e., 1.3, 2.1 and 3.5) were 2.1, 3.1 and 6.2 for men and 2.1, 3.3 and 6.3 for women, respectively (Figure 1). We also observed that fewer women met the ID and LDA cut-offs of <1.3 and <2.1 than men (Table 1).

Conclusion: The BASDAI cut-offs corresponding to ASDAS-ESR cut-offs (i.e., 1.3, 2.1 and 3.5) were 2.1, 3.3 and 6.3, respectively. There was no evidence of a clinically relevant difference in BASDAI cut-offs between men and women.

Goll1, 3Department of Rheumatology, Lillehammer, Norway; 4University of Oslo, Institute of Clinical Medicine, Oslo, Norway; 5Norwegian Radium Hospital, Department of Medical Biochemistry, Oslo, Norway; 6Lillehammer Hospital, Department of Rheumatology, Lillehammer, Norway

Background: Lack of response to TNF inhibitors (TNFi) can be caused by sub-therapeutic drug levels and anti-drug antibodies (ADAb). Therapeutic drug-monitoring (TDM) can help clinicians tailor treatment and may improve effectiveness, safety and cost-effectiveness of TNFi. For TDM to be validated as a clinical tool, therapeutic ranges must be identified.

Objectives: To explore the association between adalimumab serum drug level, treatment response and drug survival in patients with inflammatory arthritis, with the intention to identify a therapeutic range. In addition, to assess frequency and clinical implications of ADAb formation.

Methods: Patients with a clinical diagnosis of rheumatoid arthritis (RA), spondyloarthritis (SpA) or psoriatic arthritis (PsA) starting treatment with adalimumab and enrolled in the observational NOR-DMARD study were included. Treatment response during 3 months was defined as EULAR good or moderate response at 3 months and long-term drug survival. This study is the first to explore associations between adalimumab serum levels and clinical outcomes across all inflammatory arthritides. Higher adalimumab drug levels were associated with clinical response at 3 months and long-term drug survival. This study suggests 6-12 mg/L for RA/PsA and >1.4 mg/L for SpA that had higher odds for response (OR 4.7 [95% CI 1.4-15], p=0.01) Further, in these patients treatment discontinuation was seen at a lower rate (HR 0.35 [95% CI 0.17-0.73], p= 0.005). Patients with ADAb at 3 months discontinued treatment at a higher rate (HR 3.4 [95% CI 2.1-5.3], p=0.001). In RA/PsA patients, co-medication with methotrexate was associated with higher serum drug level (8.4 mg/L [IQR 5.3-10.9] vs 5.8 mg/L [IQR 12.6-17], p=0.0003), lower rate of ADAb (6% vs 22 %, p<0.0001) and better drug survival (HR for drug discontinuation 0.50 [95% CI 0.29-0.87] p= 0.013).

Conclusion: This study is the first to explore associations between adalimumab serum levels and clinical outcomes across all inflammatory arthritides. Higher adalimumab drug levels were associated with clinical response at 3 months and long-term drug survival. This study suggests 6-12 mg/L as lower target adalimumab levels for RA/PsA and SpA respectively and contributes to the development of TDM algorithms for adalimumab in arthritis patients.

Figure 1. Serum adalimumab levels at 3 months. A) Violin plot. Each data point is a participant, and the solid orange line show the group median. B) and C) Percent distribution of responders at 3 months stratified by serum adalimumab levels. Adalimumab groups are divided by percentile distribution.
Knee Osteoarthritis (KOA) is one of the most prevalent and disabling rheumatic diseases. The inability to detect early disease stages and the lack of effective treatments leave KOA patients without non-surgical clinical options. The early diagnosis of KOA at asymptomatic stages is crucial to improve the prompt management of the patients, in order to prevent or slow the course of the disease. Major research interest is focused on discovering prognostic markers useful to identify individuals at high risk of developing KOA before joint damage appears.

**Objectives:** To develop a prognostic model useful to predict the incidence of radiographic knee osteoarthritis (rKOA).

**Methods:** This study involved subjects without established KOA according to the Kellgren and Lawrence classification scale (KL=0-1), who were enrolled in the Osteoarthritis Initiative (OAI) cohort and the Prospective Cohort of A Coruña (PROCOAC). We developed two predictive models for rKOA incidence within 96 months of follow-up among participants in the OAI cohort. The protein biomarker candidates APOA1, APOA4, ZA2G and A2AP were quantified in serum using a custom-made multiplex protein microarray. The prospective association of the protein levels with rKOA incidence, defined as progressing to KL=2 during 96-months follow-up, was evaluated to develop the models based on the protein biomarkers, sociodemographic, anthropometric and non-radiographic clinical measurements. The predictive capacity was assessed using the area under the curve (AUC). The performance of the models was externally validated in the PROCOAC cohort.

**Results:** We included 602 participants from the OAI cohort in the development dataset, which had a KL ≤1 at baseline. From these, 360 did not present any radiographic signs of KOA (KL=0) in both knees at baseline. The model built exclusively with demographic and clinical data (age, sex, BMI and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain score) from patients with KL ≤1 (early KOA) at baseline showed an AUC=0.793 to predict rKOA incidence during the follow-up. The inclusion of the 4 biomarkers (Figure 1) yielded an AUC=0.793 in patients with KL=1 at baseline.

**Conclusion:** Two prognostic models have been developed to predict rKOA incidence based on the measurement of four novel protein biomarkers.

**Figure 1.** Overlapping of the AUCs obtained from the clinical models (grey line) and the clinical models with the biomarkers (black line) to predict the incidence of radiographic KOA during the follow-up period in the development cohort (OAI). A) Clinical model (AUC=0.719) and the clinical model with the 4-biomarkers (AUC=0.793) in patients with KL=1 at baseline. B) Clinical model (AUC=0.724) and the clinical model with the 4-biomarkers (AUC=0.798) in patients with KL=0 at baseline.

**Table 1.** Comparison of the performance of the proposed models in the development (OAI) and validation (PROCOAC) cohorts.

**Background:** Patient's and Physician's Global Assessment of Disease Activity (PtGA and PhGA) are important measures in Spondyloarthritis (SpA), but often provide discordant results. Some data show that patient-physician discordance can result in patient poor adherence to treatment and healthcare costs in SpA.

**Objectives:** We intended to assess the principal determinants of both PtGA and PhGA in patients under biologic treatment.

**Methods:** We performed a cross-sectional study, including patients with SpA under biologic treatment registered in the Rheumatic Diseases Portuguese Register (Reuma.pt), consecutively evaluated in a tertiary hospital center. Sociodemographic and clinical data were collected. PtGA and PhGA were measured on a Visual Analogue Scale of 0-100. To identify determinants of PtGA and PhGA, we performed firstly a univariate analysis with the independent variables and subsequently a multiple linear regression. SPSS v.24 was used for statistical analysis.

**Results:** We evaluated 186 patients with SpA according to ASAS criteria, under biologic treatment. Most patients were male (53.20%) with a mean age of 52.15 (SD=12.9) years-old at the time of last medical appointment. PtGA and PhGA were significantly different. Clinical and laboratory characteristics of patients are shown in table 1. There was a positive correlation between higher PtGA and older age, unemployment, number of tender joints, HAQ, HADS, BASDAI, number of comorbidities and daily medication. There was also an association with the concomitant presence of osteoarthritis, fibromyalgia, C reactive protein...
(CRP), erythrocyte sedimentation rate (ESR) and daily prednisolone intake. On the other side, we found a negative correlation with SF-36, FACIT and EQSD. The multiple linear regression shows that the SF-36 (p=0.001), BASDAI (p<0.001) and being unemployed (p=0.042) were the most preponderant determinants in PsGA explaining 85% of the variability noted in PsGA ($R^2 = 0.846$; $R^2$ adj $= 0.828$). Regarding PhGA we found a positive correlation between the number of tender and swollen joints, CRP and daily prednisolone intake. In multivariable analyses the main determinants of PhGA were the number of swollen joints and higher CRP ($R^2 = 0.867$; $R^2$ adj $= 0.829$).

BASDAI:ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Functional Index; EQSD: EuroQol-5 dimension; FACIT: Functional Assessment of Chronic Illness Therapy; HADS: Hospital Anxiety and Depression scales; HAQ: Health Assessment Questionnaire; VAS: Visual Analogue Scale

Conclusion: We have demonstrated that comorbidities, employment status, and other factors not directly related to the disease are also determinants in PsGA. On the other hand, more objective data such as swollen joints and increased CRP are predominant in PsGA construct.

Genetic Determinants of Clinical Phenotypes

POS0348 ACTIVATING STAT3 MUTATIONS IN CD8+ T CELLS CORRELATE TO SEROLOGICAL POSITIVITY IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Genetics/Epigenetics, Rheumatoid arthritis, Autoantibodies

Background: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease that leads to inflammation and bone erosion of synovial joints. Serological markers such as rheumatoid factor (RF) and anti-CCP antibodies are commonly elevated, and cytotoxic CD8+ T-cell expansions have been implicated in disease pathogenesis. Large granular lymphocyte (LGL) leukemia is a rare hematologic malignancy characterized by clonal expansion of CD8+ cytotoxic T-cells. A major hallmark of all LGL leukemia is increased STAT3 activation. About 50% of patients have somatic activating mutations in STAT3, the most common being Y640F and D661Y. Additionally, STAT3 mutations correlate with numerous clinical features in LGL leukemia. LGL leukemia patients with STAT3 mutations are more likely to respond to methotrexate treatment, tend to have low neutrophil counts, and clinical features can differ between mutation types (e.g. Y640F vs D661Y). Approximately one third of LGL leukemia patients also suffer from RA, and those with STAT3 mutations are more likely to exhibit concomitant RA. Those patients with both diseases also tend to have increased positivity for serological markers like RF and anti-CCP antibodies than patients with either disease alone[1].

Objectives: Based on disease overlap between LGL leukemia and RA, and a putative role for CD8+ T-cells in RA, we hypothesized that STAT3 mutations may be detected in the CD8+ T cells of RA patients without LGL leukemia and correlate with RA clinical characteristics.

Methods: Blood samples, clinical parameters, and demographic data were collected from RA patients (n=96), many of whom were on immunosuppressives such as methotrexate, and healthy controls (n=9). CD8+ cell DNA was isolated and analyzed via droplet digital (dd)PCR to detect common STAT3 mutations in LGL leukemia: Y640F, D661Y, and mutations in the S614 to G618 region. RA samples were divided into wild-type (WT) vs. STAT3-mutant groups using a variant allele frequency (VAF) cutoff of 0.05%, and clinical parameters were correlated to mutation status.

Results: Overall, RA patients had statistically different levels of STAT3 mutations compared to controls (D661Y p<0.0005, Y640F p=0.0185). In particular, many more low level (0.005-0.05% VAF) mutations were detected in the RA population (43/96 Y640F, 59/96 D661Y) vs. healthy controls (0/9 Y640F, 0/9 D661Y). Additionally, 9/96 RA samples had a STAT3 mutation at a VAF (>5%) large enough to be indicative of CD8+ T cell clonality compared to 0/96 controls (Table 1). Multiple serological RA markers were more frequently positive in STAT3 mutant (80%-91%) relative to WT RA samples (44%-55%) (RF p<0.0005, anti-CCP p=0.018, double positivity p=0.006), with overall RF levels also significantly elevated (p=0.008) in STAT3 mutant RA samples (Figure 1). Anti-CCP positivity was more common in Y640F patients (9/9) than D661Y (7/12).

Figure 1. Presence of STAT3 mutation correlates to increased serological positivity in RA patients

Conclusion: Taken together, the presence of STAT3 activating mutations in CD8+ T-cells and the association of mutations with sero-positivity suggest that STAT3 activating mutations may play a role in the pathogenesis and clinical features in a subset of patients with RA. Further study will determine the impacts of STAT3 mutation presence on disease severity, prognosis, and selection of treatment options/potential treatment responses.

**Figure 1. Association of C4 gene copy numbers with serum complement, autoantibodies and SLE subgroups**

**Table 1.**

**Table 1. C4 Genotype diversity in SLE**

**Methods:**

533 consecutive patients with rheumatic diseases (141 SLE, 120 RA, 72 SSC, 100 axSpA and 100 PsA) and 50 healthy donors (HDs) were included in the study. We used the chi-square test for comparison of categorical variables and the Spearman's rank correlation test for continuous variables. The association between C4A and C4B copy numbers was analyzed using the Spearman's rank correlation test.

**Results:**

In this cohort, total C4 gene copies ranged from 2-6 with two copies of C4A and C4B genes being frequent; there were no C4 null alleles, and a negative correlation was noted between C4A and C4B copy numbers (r=0.37, p=0.001).

**Conclusion:** Our data show that, although the C4A and C4B gene diversity is different between cases and controls, it does not correlate with serum complement levels, autoantibodies, disease activity and clinical subgroups in SLE. Low C4A copy number and increased insertion of HERV in C4A may be a risk for SLE. Our findings in this small cohort need further validation in a larger homogeneous SLE cohort.

the study where serum samples and clinical data were obtained. A signature of 368 proteins divided into 4 panels of 92 biomarkers associated with inflammation (SLE, RA, SpA, and HDs), Organ Damage (SLE, SSC, and HDs), cardiovascular disease (RA, SpA, patients, the unsupervised differential clustering analysis using the circulating pro-
tome identified 2 clusters with distinctive clinical features mainly differentiating dis-
ease activity and the presence of renal damage. Several proteins were also identified as
novel non-invasive biomarkers of lupus nephropathy. Similarly, in SSC, a panel of proteins related to organ damage identified a subgroup of patients characterized by multiple organ involvement including lung and skin fibrosis and oesophageal dysmo-
tility, along with a preponderance of anti-Scl-70 antibodies positivity. In axSpA patients, the
terms were associated with renal disease, and associated with key clinical features.
In RA, a specific signature of chemokines before therapy identified non-responder-
patients to anti-TNF therapy and Methotrexate after 3 months of treatment, outputting out its role as a predictor of therapy response. Moreover, several pro-
teins associated with CVD and metabolism were modulated by the effect of Methotrexate and Tofacitinib, which also underlined their role as biomarkers for treatment monitoring. In PsA patients, numerous proteins related to CVD were up-regulated in relation to HDs and associated with clinical markers of CVD risk. Various circulating proteins also distinguished the presence of insulin resistance, high activity, and poor therapeutic outcome to Methotrexate and Apremilast. Fur-
termore, the PEA analysis of the inflammation proteome in PsA synovial fluid revealed novel biomarkers of disease and potential therapeutic targets.
Conclusion: PEA technology might boost the future of precision medicine in rheu-
atological diseases through the identification of novel biomarkers of disease and therapy response and the stratification of patients with key clinical and molecular features. MULTI OMICS ANALYSIS IDENTIFIES DIFFERENTIAL LIPID REGULATION AS A POTENTIAL MECHANISM UNDERPINNING METHOTREXATE RESPONSE IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis, -omics

C. F. Yae1, N. Nair1, S. Verstappen1, K. Hyrich1, A. Barton1, D. Plant1. The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that causes inflammation and joint damage, leading to disability and reduced quality of life. Methotrexate (MTX) is a widely used disease-modifying anti-rheumatic drug that is initially prescribed to reduce inflammation and slowing disease progression in RA; however, approximately 40% of treated patients do not experience a satisfactory response to this drug. Identifying reliable surrogate biomarkers of MTX response would facilitate precision medicine strategies and improve patient outcomes.

Objectives: To identify blood-based transcriptomic and metabolomic biomarkers of MTX response in patients with RA.

Methods: Whole blood samples were taken from patients taking part in the Rheumatoid Arthritis Medication Study (RAMS), an observational longitudinal cohort of early RA patients starting MTX for the first time in the UK. RNA-seq data was generated using the Illumina NovaSeq 6000 platform of patients before and after 4 weeks MTX treatment. Treatment response was determined after 6 months on drug and patients were classified as good or non-responders using established EULAR response criteria. Differential gene expression was performed using glmnSeq [1], which uses generalized linear mixed model with negative binomial distribution. Models were parameterized with size factor and dispersion estimated using DESeq2 [2]. The regression model included patient ID as a random effect and an interaction term was included between time-point and response category. Two-hundred and fifty targeted metabolites were quan-
tified in serum samples of the same patients as above using nuclear magnetic reso-
nance (NMR) based technology. Metabolomics data were normalised using probabilistic quotient normalization and scaled with pareto-scaling. Partial least-square regression (PLSR) and linear mixed effects models (constructed as above) were used to identify differentially expressed metabolites. All linear mixed models were adjusted for baseline disease activity (DAS28). Enrichment analysis for differentially expressed metabolites was performed using Metascape [3].

Results: In total, 100 patients were analysed (69 good-responders and 31 non-responders). Following quality control, 17,298 genes were tested for differential expression, 25 were significantly associated with response (fold change ≥ 1.5 at baseline, adjusted p-value < 0.05). Of these, 4 were enriched in monocar-
boxylic acid (which includes fatty acid) metabolism. Differential regulation of this biological process was also observed in the metabolomics profile where low-den-
sity lipoprotein cholesterol and triglycerides were associated with MTX treatment response; this was observed using both PLSR (AUC: 0.75) and linear mixed effects models (p-value < 0.05).

Conclusion: Whole blood multi-omics analysis has the potential to identify bio-
markers and biological processes underpinning MTX response in RA. Further research is needed to understand and confirm the relationship between mono-
carboxylic acid metabolism and MTX response in this disease.

GENETIC DETERMINANTS OF RESPONSE TO ABATACEPT IN PATIENTS WITH IGG4-RELATED DISEASE

Keywords: Adaptive immunity, Disease-modifying Drugs (DMARDs), Rare/ orphan diseases

J. Mahajne1, C. Minici1, M. Lanzilotta1, V. Batani1, L. Dagna2, E. Delia Torre1.1 San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy

Background: IgG4-related disease (IgG4RD) is a fibro-inflammatory disorder of unknown etiology. Emerging evidence indicates that chronic inflammation in IgG4RD is sustained by persistent mutual activation of antigen-specific B and T lymphocytes. Targeting B-T cell co-stimulation represents, therefore, a rationale therapeutic approach for IgG4RD.

Objectives: Threefold aim of the present work was (i) to assess the efficacy of abatacept (a selective inhibitor of B-T cell co-stimulation based on a replica of CTLA4) for the treatment of IgG4RD; (ii) to study T cell activation in IgG4ARD patients; and (iii) to identify functional and genetic predictors of response to abatacept we used multicolour flow-cytometry and Whole Exome Sequencing (WES). Flow-cytometry using CD3, CD19, CD4, CD25, and CTLA4 antibodies was performed to assess CD4+ T cell activation upon exposure to recombiant humanized CD3/CD28 after 120 hours in vitro cultore. Results were compared to 10 healthy controls and 10 patients with rheu-
matoid arthritis (RA); WES was performed to screen for mutations of a panel of 452 genes related to known monogenic immune mediated diseases.

Results: Pt1 was a 47 years old male with bilateral submandibular gland involvement (Figure - A - arrow; B - arrows) and subcutaneous lesions (B - cir-
cle). Pt2 was a 78 years old woman with right orbital pseudotumor (Figure - A – arrow; B - arrow), sinonasal involvement (B - arrowhead), and skin lesions (B - asterisk). Pt3 was a 68 years old woman with left lacrimal and parotid glands involvement (Figure - A – arrow; B - arrows). Abatacept led to a marked decrease of the dimension and 18-F FDG uptake of IgG4RD lesions in Pt1 and Pt2. Pt3 showed increased pathological 18-F FDG uptake of her orbital pseudotumor with minimal morphologic changes at magnetic resonance, consistent with metabolic
progression. In vitro, there was no difference in CTLA4 expression at baseline between IgG4RD patients and controls (p>0.05). Yet, upon activation, IgG4RD patients displayed a premature decrease of CTLA4 expression on T cells compared to healthy donors (p<0.01), suggesting a defective T cell inhibition. Similar results were observed in patients with RA. Accordingly, IgG4RD patients showed expansion of activated CD25+ T cells compared to healthy controls (p<0.05). WES of the three IgG4RD patients treated with abatacept found eutrigorous germline mutations of LRBA gene (p.Arg264Gln (c.793G>A)) (Pt1), CTLA4 gene (p.Gly109Glu (c.326G>A)) (Pt2), and DOCK8 gene (p.Gln1550Leu (c.4649A>T)) (Pt3). None of these mutations has been previously reported in the medical literature and remains of uncertain significance but all had a CADD score > 20, thus predicting deleterious impact on protein structure. Of note, mutations in LRBA, CTLA4, and DOCK8 genes are all associated with systemic autoimmunity, lymphoproliferation, and immune deficiency. In particular, as opposed to DOCK8 gene, LRBA and CTLA4 genes encode for functionally related proteins as LRBA regulates the recycling of CTLA4 on T cell membrane upon antigen engagement to inhibit T cell activation.

Conclusion: In the present work we demonstrate that CD4+ T cells from IgG4RD patients show aberrant activation associated with a reduced expression of the inhibitory molecule CTLA4. Yet, not all patients respond to abatacept suggesting that IgG4RD is sustained by additional pathological mechanisms in at least a proportion of patients. Patients responding to abatacept display, indeed, germline mutations of uncertain significance in CTLA4 pathway and may represent ideal candidates for treatment with abatacept.

IDENTIFICATION OF SOMATIC MUTATIONS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

Keywords: Vasculitis, Genetics/Epigenetics

T. Iwasaki1,2, K. Ohmura1, C. Endo1, M. Shrikasahi1, R. Hiwa1, H. Tsugi1, K. Kitagori2, S. Akizuki3, R. Nakashima1, H. Yoshitani1, A. Morinobu1, F. Matsuda1, Y. Kamatani4, Graduate School of Medicine, Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; Graduate School of Medicine, Kyoto University, Center for Genomic Medicine, Kyoto, Japan; Kobe City Medical Center General Hospital, Department of Rheumatology, Kobe, Japan; The University of Tokyo, Laboratory of Complex Trait Genomics, Department of Computational Biology and Medical Sciences, Tokyo, Japan

Background: Growing evidence reveals a pathological role of somatic mutations in various autoimmune diseases, such as the mutation in UBA1 in VEXAS syndrome, CARD11 and KHLR6 in cryoglobulinemic vasculitis, or STAR in Felt's syndrome[1]. Somatic mutations might also be involved in the pathogenesis of ANCA-associated vasculitis (AAV), which typically manifests in middle-aged and elderly individuals.

Objectives: We aimed to identify somatic mutations in patients with AAV.

Methods: We collected whole blood and obtained peripheral blood mononuclear cells (PBMCs) and neutrophils from patients with AAV in active-disease status (n=16), as well as from patients with other autoimmune diseases (n=8) as disease controls, and healthy subjects (n=10). In addition, we collected these specimens from 12 out of the 16 patients with AAV after remission induction. We performed RNA sequencing (RNA-seq) on the obtained cells and whole genome sequencing (WGS) on DNA extracted from the whole blood. Somatic mutations were detected by comparing the RNA and DNA sequences[2].

Results: After stringent quality control, we identified 108 somatic mutations across 16 patients in active-disease status. The mean coverage of RNA-Seq at the mutation site was 100.9 ± 3678.8 x, and that of WGS was 14.4 ± 4.3 x, while the mean allele fraction was 22.9 ± 20.5%. One or more mutations were detected in each of the 15 (93.8%) patients. The median mutation count of each patient was 4.0, which was not significantly different from disease controls or samples after remission induction. We mapped one gene to each of the 108 mutations resulting in 95 genes in total. Mutations for six of the 95 genes were observed in two or more patients, and two of them were related to the ubiquitin system. Of the 108 mutations, 37 were missense, and 20 were predicted to be deleterious (combined annotation-dependent depletion Phred score > 20). Among the 20 mutations, the HST2/H2AC mutation (NM_003517; p.L86P) in neutrophils was observed in two patients. To evaluate the functional outcome of the 20 mutations, we followed up with 12 of the 16 patients after remission induction, 81.4% of the somatic mutations were no longer detected. Additionally, 91.7% of the deleterious mutations disappeared.

Conclusion: We found somatic mutations with potential pathological effects in some patients with AAV exhibiting active-disease status. Notably, the majority of these mutations were not detected after remission induction.

EVALUATION OF FC GAMMA RECEPTOR (FCγR) & CYP GENETIC POLYMORPHISM AND ITS PHARMACOGENOMIC CORRELATION WITH RITUXIMAB AND CYCLOPHOSPHAMIDE RESPONSE IN ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY ASSOCIATED VASCULITIS

Keywords: Remission, Vasculitis, Genetics/Epigenetics

1PGIMER HOSPITAL CHANDIGARH, Department of Internal Medicine - Rheumatology Wing, Chandigarh, India; 2PGI HOSPITAL CHANDIGARH, Department of Pediatrics, Chandigarh, India; 3PGI HOSPITAL CHANDIGARH, Department of Immunopathology, Chandigarh, India

Background: The anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitides (AAV) are three discrete entities – Granulomatosis with polyangiitis (GPA), Microscopic polyangiitis (MPA), and Eosinophilic granulomatosis with polyangiitis (EGPA). They present with a plethora of signs and symptoms resulting in significant burden of mortality and morbidity. There is huge lacuna in the knowledge of relationship between various genes affecting pharmacogenetics of AAV and its implications in context of therapeutic complications. We thus intend to evaluate genotypic polymorphism in FcγRI family & CYP genes affecting pharmacological response of Rituximab and Cyclophosphamide respectively in AAV patients undergoing induction treatment.

Objectives: To study the single nucleotide polymorphism (SNP) of the FcγR family (FCγRIIA, FCγRIIB, FCγRIIB) in patients receiving Rituximab (RTX) and the SNPs of CYP2C19*2 (rs4244285), CYP2B6 (rs312137) polymorphisms in patients receiving Cyclophosphamide (CYC) using polymerase chain reaction. Additionally, to correlate the genetic polymorphism of AAV patients with Rituximab and Cyclophosphamide response.

Methods: This study was a prospective cohort study in which AAV patients undergoing induction treatment were enrolled from Jan 2021 to Dec 2022 in Clinical Rheumatology Department at PGIMER Chandigarh, India. Functional SNPs for FCγRIIA (rs4244285), FCγRIIB (rs5577-T) and FCγRIIB (rs519G-A) and

Identification of Somatic Mutations in Patients with AAV

Background: Behçet's disease is a complex inflammatory vasculitis with a broad spectrum of clinical manifestations.

Objectives: The purpose of this study was to investigate the genetics underlying specific clinical features of Behçet's disease in a group of patients with > 5 years of follow up.

Methods: A total of 436 patients with Behçet's disease from Turkey were studied. Genotyping was performed using the Infinium ImmunomeArray-24 BeadChip. After imputation and quality control measures, logistic regressions adjusting for sex and the first five principal components were performed for each clinical trait using a case-case genetic analysis approach. A weighted genetic risk score was calculated for each clinical feature.

Results: Genetic association analyses of previously identified susceptibility loci in Behçet's disease revealed a genetic association between ocular lesions and HLA-B/MICA (rs116799936; OR=1.85, 95% CI=1.35-2.52, p-value=1.1x10^-6). The genetic risk score was significantly higher in Behçet's disease patients with ocular lesions compared with those without ocular involvement, and is explained by the genetic variation in the HLA region. New genetic loci predisposing to specific clinical features in Behçet's disease were suggested when genome-wide variants were evaluated. The most significant associations were observed in ocular involvement with SLCO4A6 (rs6026789; OR=0.41, 95% CI=0.30-0.58, p-value=1.9x10^-11), and neurological involvement with DDX9L6 (rs62334264; OR=4.12, 95% CI=2.34 to 7.24), p-value = 8.85x10^-10.

Conclusion: Our results emphasize the role of genetic factors in predisposing to specific clinical manifestations in Behçet's disease, and might shed additional light into disease heterogeneity, pathogenesis, and variability of Behçet's disease presentation across populations.

CYP enzymes (CYP2C19 681G>A, CYP2B6 1459C>T) were assessed by Sanger sequencing of PCR amplified genomic DNA. The end points were to detect associations between the tested SNPs and status of remission at six months and complete remission at end of the study.

**Results:** In this study we recruited ninety seven patients of AAV in Indian population. Table 1 summarises the baseline clinical characteristics of the study population. FcγRIIA variant (v) allele frequency was more than wild allele (W) frequency in the study population. The time to achieve remission was significantly lower (mean:9.22 weeks) in FcγRIIA variant genotype polymorphism (FcγRIIA 519AA) in comparison to wild and heterozygotes variants (mean: 17.25 weeks) of FcγRIIA at site 131 (519G>A), as shown in Figure1. There were no significant difference observed in CYP polymorphism and cyclophosphamide response.

**Conclusion:** This study is one of the first to evaluate the pharmacogenomic profile of AAV in Indian population. We observed highly significant association of SNPs of FcγRIIA 131 site variant/S19AA genotype with early remission and complete remission after induction treatment with rituximab. This data could further help in tailored treatment of AAV patients and may also serve as a prognostic marker.

JAK2 MUTATION, TNF-A AND IL 6 PREDICT RESPONSE TO JAK INHIBITOR IN RHEUMATOID ARTHRITIS PATIENTS

**Keywords:** Rheumatoid arthritis, Prognostic factors

Y. Adel Abdelsalam Hussein1, Y. Sadeq2. 1Mansoura University Hospital, Rheumatology, Mansoura, Egypt; 2Mansoura University Hospital, Clinical Pathology, Mansoura, Egypt

**Background:** STAT4 is activated by the JAK family members Tyk2 and JAK2 in response to IL and TNF, with subsequent downstream signaling to promote Th1 mediated autoimmunity [1]. JAK inhibitors [2] are type of medication that function by inhibiting activity of one or more of the Janus kinase family of enzymes. These inhibitors have therapeutic application in the treatment of cancer and inflammatory diseases such as rheumatoid arthritis [3].

**Objectives:** Study impact of JAK2 mutation, TNF-α and IL 6 levels on response to JAK inhibitors and ACR response criteria.

**Methods:** The study included 120 newly diagnosed rheumatoid arthritis patients and 80 matched controls. All patients started therapy with csDMARDs. 70 patients failed to achieve adequate response so, they were shifted to Baricitinib. JAK2 mutation assessed by PCR in blood samples, TNF-α and IL 6 were measured by ELISA in serum of patients at diagnosis, before and after Baricitinib treatment.

**Results:** 102 females (85%) and 18 males (15%) with age mean ± SD (years); (47.7 ± 7.5). Pretreatment JAK2 mutation, TNF-α and IL 6 were significantly high in patients than control. JAK2 mutation were more presented in young age patients (mean ± SD; 47.1 ± 3.2 vs 51.4 ± 7.9 in mutant vs non-mutant JAK2 patients, respectively with P 0.03). Mutant JAK2 was significantly linked to severity of disease by DAS28; 70% of patients with DAS28 (≥ 2.6) were non-mutant JAK2 vs 30% patients mutant JAK2 while 73.1% of patients with DAS28 (> 5.1) were mutant JAK2 vs 26.9% patients non-mutant JAK2 (P 0.04). 70 patients were csDMARD incomplete responders. Jak2 mutation was significantly presented in these group comparing to patients achieved response to csDMARDs (P 0.002) associated with significant high serum TNF-α (P 0.002) and marginal significance high serum IL 6 (P 0.06).

**Conclusion:** JAK2 mutation in RA patients associated with high disease activity score and inadequate response to csDMARDs. Pretreatment detection of JAK2 mutation in RA patients with high serum level of TNF-α and IL 6 predict a good response to JAK inhibitors with better ACR response criteria.

Background: Sex is an important determinant of health including response to therapy. Limited information exists on representation and reporting of results by sex in randomized controlled trials (RCTs) in patients with psoriatic arthritis (PsA). Sex-related inequities in randomized controlled trials in psoriatic arthritis: A systematic literature review and meta-analysis

Methods: We performed a systematic literature search of Medline, Embase and Central databases, and conference abstract archives from January 1, 2000 to June 30, 2022. We included RCTs that reported sex-disaggregated results and assessed the efficacy of an advanced therapy biologic or targeted synthetic in adult participants with PsA. Efficacy end points included the proportion of participants achieving minimal disease activity (MDA) or meeting the American College of Rheumatology 20 (ACR20) and ACR50 response criteria at the primary endpoint of the trial. We used random-effect models to calculate pooled effects for sex differences in efficacy and safety outcomes which will inform patient-centered therapeutic strategies.

Results: Based on the reported results, female patients participating in RCTs are less likely to achieve efficacy end points for most classes of advanced therapies. Some differences in responses were found across classes of advanced therapies. RCTs should report sex-disaggregated results to identify sex-related differences in efficacy and safety outcomes which will inform patient-centered therapeutic strategies.

POS0359
mice had more anti-DNA antibodies, autoimmune pathology, and mortality than XY female (Sry0) mice. Similarly, gonadectomized XX male (Sry0) mice had more severe autoimmune disease than XY male (Sry1;Sry2). To begin to translate these murine findings onto humans, we asked if sex chromosome dosage plays a role in predisposition to autoimmunity.

Objectives: To test the hypothesis that X chromosome dosage, rather than the female sex itself, imparts susceptibility to autoimmunity in humans.

Methods: We administered autoimmune disease and connective tissue disease questionnaires and analyzed serum autoantibody levels in males and females with sex chromosome aneuploidy including males with two X chromosomes (XX males, including Klinefelter’s syndrome) and females with one X chromosome (X0 females, including Turner’s syndrome) and their respective male and female controls with normal sex chromosome numbers.

Results: Levels of IgG anti-chronatin, anti-nucleosome and anti-histone (H2A, H2B and H3) autoantibodies were significantly higher in XX males (47XYY; 48,XXYY, and mosaic) compared to 46,XY men. XX males, however, did not have non-specific B cell hyper-reactivity, as the levels of anti-thyroid peroxidase antibody that is associated with autoimmune thyroiditis did not differ between the two groups and antibodies against intrinsic antigens such as thyroid and gladin were higher in X0 females than in XX females. A preliminary analysis of clinical questionnaire revealed an increase in autoimmune conditions in XX males when compared with known population prevalence of these diseases. Preliminary immune phenotype profiling of peripheral blood cells conducted thus far show altered frequency and/or function of natural killer T-cells, CD8+ T cells or IL-4/IL-17 producing cells in individuals with sex chromosome aneuploidy compared to their respective controls.

Conclusion: These data suggest that humans with two X chromosomes as compared to those with one X chromosome, regardless of their gonadal sex, exhibit increased susceptibility to systemic autoimmunity. Preliminary evidence also suggests a differential regulation of systemic versus organ-specific autoimmunity in persons with sex chromosome aneuploidy.

COMPREHENSIVE TRANSCRIPTOMIC CHARACTERIZATION REVEALS CORE GENES AND MODULES ASSOCIATED WITH SEX-DEPENDENT MOLECULAR PAIN MECHANISMS IN OSTEOARTHRITIS

Keywords: Pain, Gender/diversity issues, Osteoarthritis

Z. Wang1,2, V. Batchelor2, J. Miotta-Zarebska3, B. Gerritsen4, N. Eijkelkamp4, T. Vincent2, C. Svensson1, 1Karolinska Institute, Department of Physiology and Pharmacology, Stockholm, Sweden; 2Tongji Hospital, Tongji Medical College, HUST, Department of Orthopedics, Wuhan, China; 3University of Oxford, Kennedy Institute of Rheumatology, London, United Kingdom; 4Utrecht University, Centre of Translational Immunology, Utrecht, Netherlands

Background: Female sex is identified as a key nonmodifiable risk factor in the development of OA, particularly after the age of 55. Additionally, women appear to have a lower threshold for pain and present with more chronic pain conditions than men. Our previous studies demonstrated that female mice develop pain at the same time as male mice despite having reduced levels of joint damage, indicating the existence of sex-dependent mechanisms for the induction of pain. In non-arthritis murine pain models, different immune cells in the dorsal root ganglia (DRG) appear to contribute to sex-dependent differences in sensitization. Furthermore, we have recently uncovered cellular and molecular differences between immune cells and inflammatory profiles in the DRGs and joints of male and female mice with collagen antibody-induced arthritis.

Objectives: Search for putative pain pathways and associated temporal patterns in male and female mice subjected to surgically induced OA.

Methods: C57BL/6 male and female mice (10-week-old, n=5 per group, i.e., surgery, sex, and timepoint) were randomized subjected to either sham surgery or partial meniscectomy (PMX). Static weight bearing measurements were performed using a Linton Incapacitance Tester. Mice underwent a 2-week acclimatization post-surgery, followed by weekly measurement between week 5 to 12. L3-L4 DRGs were harvested for RNA sequencing at week 6, 10 and 12 post-surgery. The Weighted Gene Co-expression Network Analysis (WGCNA) package in R was used to construct a signed co-expression network from the expression data.

Results: Considering all groups, a tendency to pain-related behavior was observed at week 10 post-surgery, and a statistically significant difference in weight bearing found at week 12 when the PMX group was compared with sham group. We performed WGCNA to identify modules that were related to surgery and sex using 6-, 10-, and 12-week samples, respectively. For the 6-week network, 14 modules were identified. Only associations with sex were observed, with 3 modules positively related with male and 1 module positively related with female. For the 10-week network, 14 modules were identified. 6 modules were related by single trait, 3 of which were positively related with male, 2 of which were positively related with PMX, and 1 of which was negatively related with PMX. In addition, 1 module was related with both surgery and sex, whereby it was negatively related with PMX and positively with being female. For the 12-week network, 19 modules were identified. Most significant associations were observed only with PMX, where 5 modules showed positive associations and 3 modules showed negative associations. Furthermore, greenyellow module was related with both surgery and sex, positively related with PMX and being female. As a result, this module was chosen to investigate further. According to the threshold (MM > 0.8 and GS > 0.2), 102 candidate hub genes were obtained in this module. When PPI analysis was performed, 14 candidate hub genes (top 5%, ranked by the MCC scoring method) were obtained. In total, 9 overlapping genes (Nyp, Tac1, Calca, Gap43, Bdnf, Shc1, Ngr, Casp3 and Jun) were identified as hub genes. The enriched biological process was ‘neurotrophin TRK receptor signaling pathway’ And the enriched KEGG pathway was ‘neurotrophin signaling pathway’ and ‘MAPK signaling pathway’.

Conclusion: This study reveals sex, disease and time-dependent changes in the DRG transcriptome during the development of painful OA. Importantly, our findings highlight a distinct TrkA and neurotrophin signaling signature that is evident at 12 weeks post-surgery only in OA-induced pain-related behaviors in female mice.

DOI: 10.1136/annrheumdis-2023-eular.5202
Background: Heart failure (HF) is a common co-morbidity of rheumatoid arthritis (RA) with a high mortality risk [1]. In the general population, significant sex-related differences in HF including aetiology, pathophysiological mechanisms and age are observed, emphasizing the importance to stratify analyses by sex [2] and there is increasing evidence that mortality rates of females are lower, which cannot be explained by comorbidities, HF characteristics or HF medical treatment [3].

Objectives: To investigate sex specific differences in patient characteristics and their association with mortality in RA patients with concomitant HF.

Methods: RA-patients enrolled and observed in the German biologics register RABBIT between 01/2007 and 04/2022 were selected for the analysis if they presented HF either at enrolment or during follow-up. Observation started at the time of HF reporting (=baseline) and ended at death, dropout or end of follow-up, whichever came first. Baseline patient characteristics were stratified by sex. Cox proportional hazard regression with sex as exposure of interest was applied, adjusted for age (model 1) and further adjusted for comorbidities and RA specific characteristics (model 2). Missing values were imputed once.

Results: Out of 15,917 cohort participants (11,835 females, 74%), 718 patients were identified as prevalent HF cases (473 females, 66%). Females with HF were on average 1.7 years older, had worse physical function and longer RA disease duration compared to males. Females were more likely to have osteoporosis and less likely to have ischemic heart disease (Table 1). 25% of the females and 34% of the males died after a mean follow-up time of 39 and 36 months, respectively. Females had a significant lower risk of death compared to males regardless of adjustment (model 1: HR=0.57 [0.43-0.76]; model 2: HR=0.51 [0.37-0.71], Figure 1).

Conclusion: Our findings demonstrate a longer survival for females compared to males in a cohort of patients with RA and concomitant HF. The difference could not be explained by age, comorbidities and RA-related characteristics at baseline. The observed differences in the clinical profile and mortality highlight the need for research stratifying by sex when investigating cardiac events.

DOI: 10.1136/annrheumdis-2023-eular.5117
Methods: This is a cross-sectional study of the AtheSpAin cohort, a Spanish multicenter cohort to study atherosclerosis in axSpA. Data on clinical and subclinical atherosclerosis, as well as CV and disease-related characteristics were collected in 912 participants.

Results: 611 men and 301 women were recruited for this study. Smoking habit (p=0.033), hypertension (p=0.009), and dyslipidemia (p=0.015) were less prevalent in women, who also showed less severe atherosclerosis measured by the presence of carotid plaques (p=0.001), carotid intima-media thickness (IMT) values (p=0.001), and CV events (p=0.008). After adjustment for traditional CV risk factors only the results regarding carotid IMT remained statistically significant.

Regarding disease-related features, radiographic axSpA (r-axSpA) was more common in men (p=0.001). Women with axSpA showed a shorter disease duration (p=0.001), a lower prevalence of psoriasis (p=0.008), higher ESR levels at diagnosis (p=0.038) and more active disease measured by ASDAS (p=0.012) and BASDAI (p=0.001). However, they had less structural damage (mSASSS, p=0.033) and mobility limitation (BASMI, p=0.033). These differences that remained statistically significant after adjustment for r-axSpA in axSpA, disease duration or smoking. Remarkably, many of these sex-related differentiating characteristics were associated with subclinical atherosclerosis (table 1). To clarify if this finding could lead to sex differences in the atherosclerotic burden, we compared the prevalence of carotid plaques in men and women with the same level of CV risk stratified according to the score. Within the category of low-moderrate SCORE, men showed more severe atherosclerosis than women (p=0.050), which could be related to a longer disease duration (p=0.004), higher mSASSS (p=0.001) and BASMI (p=0.071) values. However, in patients with high-very high SCORE, carotid plaques were more commonly observed in the female group (p=0.025), which was characterized by a higher inflammatory burden (ESR at diagnosis, p=0.007) and worse BASFI (p=0.011) compared with men, with no differences regarding disease duration, mSASSS or BASMI.

Conclusion: Although the burden of traditional CV risk factors leading to more severe atherosclerotic disease is greater in men with axSpA, potential sex-related proatherogenic features of axSpA also appear to have an impact on CV risk. This may be especially applicable to women at high CV risk, who have a greater inflammatory response, worse functional impairment, and more severe subclinical atherosclerosis than males, suggesting a closer interaction between atherosclerosis and disease burden in women with axSpA.

RESULTS: Conditioned Pain Modulation (CPM). Widespread low PPTs, high TS (both pain testative Sensory Testing (QST) according to a standardized protocol, including Pain Scale (PCS) Coping with Rheumatic Stressors (CORS), and underwent Quanti-
leeuwarden axSpA (GLAS) cohort, fulfilling the ASAS classification criteria. Par-
Objectives: To investigate the sexual function and satisfaction in female and male patients affected by SpA and identify gender-specific features. Methods: We conducted a cross-sectional study enrolling consecutive SpA patients satisfying ASAS criteria attending the SpA clinic of a tertiary university rheumatology clinic. Demographic and clinical characteristics were collected alongside with validated gender-specific questionnaire for the evaluation of sexual function. For male assessment, we used the international index of erectile function (IIEF) and the Premature Ejaculation Diagnostic Tool (PEDT); whereas in women we used The Female Sexual Function Index (FSFI) that explores domains such as desire, arousal, lubrication, orgasm, satisfaction, and pain. To evaluate the correlation between the presence of sexual dysfunction and disease characteristics or therapies we used the Spearman test and the univariate and multivariate tests. Results: 73 males and 64 females were recruited, and the two groups were comparable with similar mean age, BMI, and disease duration (patients' characteristics are shown in table 1). PEDT test showed that 9.5% (5 male patients) had probable premature ejaculation and 15% (8 male patients) had premature ejaculation. According to IIEF sexual dysfunction was present in 19.4% of cases as mild dysfunction in 15.5% as moderate dysfunction and in 5.4% as severe dysfunction. Univariate and multivariate analysis showed a correlation between sexual dysfunction and mood disorders and premature ejaculation in men (p=0.02). The prevalence of premature ejaculation was not influenced by disease characteristics or activity or therapies. Sexual dysfunction in males was associated only with the use of NSAID (p=0.04). Evaluating the female group, FSFI showed that 85% (54 female patients) had sexual dysfunction. In the univariate and multivariate analysis, we found correlations between age (p=0.07), mood disorders (p=0.04), dyslipidemia (p=0.006), and BAS-

BACKGROUND: Research shows that there are significant sex differences in experienced pain. Contributing factors are neuroanatomical, hormonal, neuro-
immunological, psychological, social, cultural, and comorbidities. Women have more and different expression of nociceptors, and a stronger proinflammatory response to tissue damage than men. Women also use different coping styles regarding to pain and tend to engage more in pain catastrophizing. Therefore, women may experiencing more severe pain than men. Also in axial spondyloarth-

RESULTS: Significant differences between men and women were observed for the classification radiographic axSpA (71.9% vs 50.7%), HLA-B27 status (84.1% vs 67.1%), mean BMI (22.7 ± 4.9 vs 29.0 ± 6.9), mean ASASdAS (2.1 ± 0.6 vs 2.5 ± 0.9) and mean BASDAI (3.4 ± 2.1 vs 4.7 ± 2.1). Women scored significantly higher on the CPM and used the coping styles comforting coping, decreased activities and diverted attention more often (CORS). Concerning the involvement of altered pain processing of the CNS, women had significantly lower PPTs. TS and CPM were comparable in men and women (Table 1).

Conclusion: In patients with axSpA, significant sex differences in pain coping styles, CPM score and PPTs were observed. Therefore, sex differences should be taken into account in the management of pain in daily clinical practice and in pain research in these patients.

FILLING GAPS IN FEMALE GOUT: A CROSS-SECTIONAL STUDY OF 192,000 PATIENTS HOSPITALIZED WITH GOUT FROM 2005 TO 2015

Keywords: Gender/diversity issues, Comorbidities, Gout

E. Rodríguez-Sosa1, E. De Miguel2, F. Borrás3, M. Andrés1,2,4,5, M. Miguel Hernandez University, Clinical Medicine, San Juan de Alicante, Spain; 2La Paz Hospital, Rheumatology, Madrid, Spain; 3Miguel Hernandez University, Statistics, Mathematics and Informatics, San Juan de Alicante, Spain; 4Dr. Balmis General University Hospital, Rheumatology, Alicante, Spain; 5Alicante Institute for Health and Biomedical Research (ISABIAL), Research Group on Rheumatic and Autoimmune Diseases, Alicante, Spain

Background: Patients with gout show several comorbidities, especially cardiovascular, renal and metabolic diseases. The odds of developing new comorbidities increase progressively since the first flare, with a higher risk than general population. Female gout has received little attention in the published literature.

Objectives: To compare the distribution of comorbidities by sex in hospitalized patients with gout in Spain.

Methods: Retrospective, nation-based cohort study. The Minimal Basic Data Set from all Spanish hospitalizations including gout as either primary or secondary diagnosis (ICD-9 coding) from 2005 to 2015 was collected. The comorbidities of interest were obesity, dyslipidemia, chronic kidney disease, diabetes mellitus, coronary heart disease, chronic heart failure, peripheral vascular disease, arrhythmia, venous thromboembolism, cerebrovascular disease, dementia, urinary tract infection, pneumonia, sepsis, obstructive pulmonary disease, liver disease and rheumatological disease. Arterial hypertension and urinary lithiasis were not analyzed since they were underrepresented in the dataset. Comparative analyses were performed by sex. Later, stratification by age was performed and the population was divided by sextets (<70 years; 71-80 years; 81-85 years; 86-90 years; 91-95 years; >95 years). A multiple logistic regression model was built to discern the strength of association of comorbidities with each sex, for the entire population and stratifying by age (<60 years and >60 years). Additionally, a decision tree was constructed to have sex predicting algorithms based on the presence of comorbidities.

Results: 192,037 admissions were analyzed, 5.47% (n=10,512) with gout as primary diagnosis. 158,646 cases occurred in men (82.6%), significantly younger than women (64.0±14.4 vs 73.9±13.7 years; p<0.001). Female predominant comorbidities were obesity (16.3% vs 10.8%), dyslipidemia (31.8% vs 30.7%), chronic kidney disease (33.8% vs 25.1%), diabetes (36.2% vs 25.9%), heart failure (31.8% vs 16.8%), dementia (2.1% vs 1.2%), urinary tract infection (12.0% vs 5.4%) and concurrent rheumatic disease (2.6% vs 1.4%). Otherwise, male predominant comorbidities were coronary heart disease (21.8% vs 16.9%), peripheral artery disease (3.8% vs 1.2%), liver disease (2.2% vs 1.3%), pneumonia (4.5% vs 3.8%) and obstructive pulmonary disease (8.9% vs 2.3%). No differences were seen for others. After age stratification, differences in dementia were no longer significant. Multiple logistic regression, with an accuracy score of 68.5%, confirmed a differential comorbidity profile between men and women (Figure 1). After age stratification, for <60 years renal and rheumatic diseases were closely linked to women with gout, whilst in >60 years heart failure was the leading. For men, coronary heart disease and obstructive pulmonary disease were the chief associations. A decision tree algorithm was built [1], with an accuracy of 74.4%.

Conclusion: A nationwide analysis of 11 years of hospitalizations with gout confirm a different comorbidity profile between men and women. Women with gout were significantly older and more likely to suffer from heart failure, obesity, urinary infection and diabetes. Association between sex and certain comorbidities is intense enough for sex prediction by an algorithm with considerable accuracy. A different approach for female gout is thus needed, to reduce gender blindness.

**POS0368** PERSISTENT PREMATURE MORTALITY IN GOUT: NATIONWIDE PROSPECTIVE COHORT STUDY

**Keywords:** Gender/diversity issues, Epidemiology, Gout

N. McCormick, C. Yokose, K. Lin, L. Lu, A. Joshi, H. Choi

1. Massachusetts General Hospital, Clinical Epidemiology Program, Boston, United States of America; 2. Harvard Medical School, Medicine, Boston, United States of America; 3. Arthritis Research Canada, n/a, Vancouver, Canada; 4. Brigham and Women’s Hospital, Channing Division of Network Medicine, Boston, United States of America

**Background:** A recent UK study reported a higher cardiovascular event risk after gout flare episodes,[1] which may translate to premature mortality for gout patients over the long term. Prior studies reported premature mortality in gout, but did not compare demographic subgroups, and it is unknown whether the excess risk has improved over recent years at a national level.

**Objectives:** We prospectively evaluated the association between gout and the risk of all-cause and cardiovascular mortality in the latest US general population data and compared with the prior data.

**Methods:** Using nationally representative samples of US adults in the National Health and Nutrition Examination Survey (NHANES), linked prospectively with vital statistics data, we examined the association between gout and mortality and compared Early (NHANES III: 1988-1994) and Late cohorts (2007-2016), as well as key demographic subgroups defined by age, sex, and self-reported race/ethnicity (Black vs. White). Hazard ratios (HRs) were calculated over 10 years adjusting for atherosclerotic cardiovascular disease (ASCVD) risk factors, cardiometabolic comorbidities, kidney function, and relevant medications.

**Results:** Adjusted HR for all-cause mortality comparing US adults with and without gout in aggregate was 1.19 (95% CI, 1.08 – 1.32), with the same HR in the Early and Late cohorts (1.19, 1.02 – 1.38 and 1.19, 1.03 – 1.37, respectively) (Figure 1). HR was larger among those < 60 years (1.62, 95% CI, 1.19 – 2.19; p-interaction < 0.001 vs. age >= 60 years) and among women (1.33, 95% CI, 1.11 – 1.56, p-interaction=0.03 vs. men) (Table 1), and was also prominent among Black individuals (HR, 1.40; 95% CI, 1.12 – 1.74). Corresponding HR for cardiovascular mortality in the late cohort was 1.39 (95% CI, 1.09 – 1.78); All associations remained similar when adjusting for serum urate levels.

**Conclusion:** This representative cohort study illustrates premature mortality in gout at a national level, even after accounting for serum urate levels, which has not improved over past decades. Excess mortality was higher among women and younger adults, and was more prominent among Black individuals; the latter group already experiences an excess prevalence of gout at the US national level, compared to White individuals (age- and sex-adjusted odds ratio for gout=1.2 (1.2 to 1.7)).[2] These data are suggestive of continued shortcomings in current gout care practices and a compelling need to understand and mitigate the premature mortality risk in gout, especially for women and Black individuals.

**POS0369** TREATMENT RELATED COST SAVINGS DUE TO EARLY IDENTIFICATION OF RHEUMATOID ARTHRITIS

**Keywords:** Epidemiology, bDMARD, Rheumatoid arthritis

F. Van Mulligen, A. Van der Helm – van Mi, 1. Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2. Eramus University Medical Center, Rheumatology, Rotterdam, Netherlands

**Background:** EULAR guidelines advocate early detection and treatment of rheumatoid arthritis (RA) to induce a milder disease course. It was shown that early detection and treatment prevents erosive disease and maintains functional capabilities. Despite of that, the effect of early detection of RA on treatment related costs has never been investigated. Due to rising health care costs, it is important for society to keep health care affordable.

**Objectives:** Our objective was to investigate whether early identification and treatment of RA patients (within 12 weeks after symptom onset) results in a reduction of treatment related costs when compared to a patient group that was seen after 12 weeks after symptom onset, stratified for ACPA status.

**Methods:** Patients were obtained from the Leiden Early Arthritis Clinic (EAC), an inception cohort consisting of patients presenting with recent onset arthritis with a symptom duration ≤ 2 years. All consecutive RA patients fulfilling the 1987 and/or 2010 criteria, and who started a DMARD, included between May 2011 and December 2017 were evaluated, allowing a follow-up of 5 years. In this inclusion period, referral strategies were optimized for early recognition of RA. Early treatment start was defined as within 12 weeks after symptom onset. Information on medication use was obtained from prescription data from electronic patient records. Prices were used from both 2012 (at time of prescription) and 2022 (current). ACPA-positive and ACPA-negative RA were studied separately. Inverse probability weighting accounted for differences in patient characteristics between the early and late groups. The weighted average difference in medication costs was estimated with a generalized linear model with a log link and gamma distribution.

**Results:** In total, 196 RA patients were ACPA-positive and 235 patients were ACPA-negative. Median (IQR) symptom duration was 5.5 (3-9) weeks in the early group, and 29.7 (19.5-53) weeks for the late group for ACPA-positive patients, and 6.4 (4-9) weeks and 26 (17-50) weeks in the ACPA-negative patients. At diagnosis, the early group of both ACPA-negative and ACPA-positive patients had more severe inflammation compared to the late group. After 5 years, 6% of ACPA-negative patients and 20% of ACPA-positive patients had used ≥1 biological. The average number of biologics within these patients was 1 in the early ACPA-negative group, 4.4 in the ACPA-negative late group, and 1.9 and 2 in ACPA-positive early and late groups. When using current price levels (2022), mean (sd) cost of treatment over 5 years was €11250 (25774) for ACPA-positive patients, and €3526 (11556) for ACPA-negative patients, while treatment costs among biological users was €44788 (36360) for ACPA-positive and 40896 (25123) for ACPA-negative RA. After weighting, within ACPA-negative RA costs were lower in the early compared to the late group (€2677 versus €4213, respectively).
indicating 46% higher costs in the late group. For ACPA-positive patients, costs were more similar (€11631 and €10988 respectively for the early and late group, p=0.96, 95%CI 0.52 – 1.83) (Figure 1A). When 2012 prices were used, costs were in general higher: €14482 (29101) and €15168 (17897) for ACPA-positive and ACPA-negative patients, respectively. Comparing late and early groups using 2012 prices provided similar results in ACPA-negative RA (p=0.134, 95%CI 0.54 – 3.3), and a larger difference in costs for ACPA-positive RA (p=0.077, 95%CI 0.44 – 1.36). Conclusion: Treatment-related costs of ACPA-positive RA are higher compared to ACPA-negative RA. However, early detection and treatment has the greatest impact on reducing treatment costs in ACPA-negative RA.

Figure 1. (A) Medication costs over 5 years indicated for ACPA-positive and ACPA-negative RA using current prices (2022), comparing early (<12 weeks after symptom onset) and later referral (≥12 weeks after symptom onset). (B) Medication costs in euros over 5 years using prices at time of prescription (2012). ACPA: anti-citrullinated protein antibody.

Background: Fatigue is prevalent in people with inflammatory rheumatic and musculoskeletal diseases (I-RMDs) and recognised as one of the most challenging symptoms to manage [1]. The existence of multiple factors associated with fatigue, the lack of clarity around underlying pathophysiological mechanisms and the limited evidence about what helps have led to a multifaceted and often fragmented approach to symptom management. However, there are no recommendations for fatigue management in people with I-RMDs, and this lack of guidance has been challenging for those living with fatigue as well as for healthcare professionals delivering clinical care.

Objectives: To develop EULAR recommendations for the management of fatigue in people with I-RMDs.

Methods: A multi-disciplinary taskforce comprising 26 members from 14 European countries was convened and two systematic reviews were conducted. The taskforce developed recommendations based on evidence from the systematic reviews and taskforce members’ personal and professional experience of fatigue in I-RMDs.

Table 1. EULAR overarching principles and recommendations for the management of fatigue in people with I-RMDs

<table>
<thead>
<tr>
<th>Overarching principles</th>

</tr>
</tbody>
</table>

Recommendations LoE GoR
1. Healthcare professionals should incorporate regular assessment of fatigue severity, impact and coping strategies into clinical consultations. 5 D
2. As part of their clinical care, people with I-RMDs and fatigue should be offered access to tailored physical activity interventions and encouraged to engage in long-term physical activity. 1a A
3. As part of their clinical care, people with I-RMDs and fatigue should be offered access to structured and tailored psychosocial interventions. 1a A
4. The presence or worsening of fatigue should trigger evaluation of inflammatory disease activity status and consideration of immunomodulatory treatment initiation or change, if clinically indicated. 1a A

I-RMDs, inflammatory rheumatic and musculoskeletal diseases; GoR, Grade of recommendation; LoE, Level of Evidence. GoR and LoE as per 2011 Oxford Centre for Evidence Based Medicine Levels of Evidence.
Results: Four overarching principles and four recommendations were developed (Table 1), including health professionals’ awareness that fatigue should be monitored and assessed and that people with I-RMDs should be offered management options. Shared decisions about fatigue management should consider the needs and preferences of individuals, their clinical disease activity, comorbidities and other psychosocial and contextual factors (Table 1).

Conclusion: These 2023 EULAR recommendations provide consensus and up-to-date guidance on the management of fatigue in people with I-RMDs.

A SYSTEMATIC LITERATURE REVIEW OF RANDOMISED CONTROLLED TRIALS EVALUATING COLCHICINE FOR CARDIOVASCULAR PREVENTION: THERE IS AN ELEPHANT IN THE ROOM

Keywords: Systematic review, Cardiovascular disease

A. Alunno1, C. Martini1, V. Moronti1, J. Santilli1, F. Carubbi1, J. Schoones2, J. Zavada1, B. Glintborg1, A. Macdonald1, K. Laas1, D. Nordström1, B. Gudbjörnsdóttir1, F. Iannone1, F. Hellandam1, T.K. Kven1, A. M. Rodrigues1, C. Codreanu1, Z. Rotar1, E. Kristianslund1, E. Vencovsky1, A. G. Loft1, M. Heddle1, S. Vorobjov1, A. M. Hokkanen1, G. Gröndal1, M. Sebastiani1, M. G. H. Van de Sande1, E. Kristianslund1, M. J. Santos1, M. Mogosan1, M. Tomisi1, F. Díaz-González1, D. Di Giuseppe1, M. Östergaard1, J. M. Heiland1.

Background: Colchicine (COL) is widely used in rheumatology for treatment and prophylaxis of acute gout flares, other crystal diseases, and inflammatory diseases. In recent years evidence on the efficacy of COL for the prevention and treatment of cardiovascular diseases (CVD) has accrued. Since patients with gout and other inflammatory RMDs have a higher CV risk, COL may be a useful resource for CV prevention in rheumatology.

Objectives: To review the randomised controlled trials (RCT) investigating the use of COL for CV prevention from a rheumatology perspective.

Methods: A systematic literature review (SLR) of 7 databases was conducted following the PICO framework. Three researchers independently screened abstracts and titles and then full texts were reviewed to determine eligibility (RCTs enrolling adult subjects with or w/o history of CVD treated with COL for CV prevention). Data from eligible articles were extracted and risk of bias (RoB) was assessed with validated tools.

Results: A total of 3867 articles were retrieved and screened, 174 articles were read in full and 20 of them were eligible for inclusion. Of 1940 enrolled patients, 9655 were randomised to receive COL at a dose varying between 0.5mg/day and 2mg/day and for a period ranging between 10 days and several months (covering in part or in full the study follow-up period). Main inclusion criteria were recent acute coronary syndrome or planned cardiac surgery. In two studies, patients with stable chronic heart failure or stable coronary disease were recruited. The primary outcome varied across studies, being for example new-onset CV events, need of hospital admission, CV death, a composite index including some of all, or serum concentrations of high-sensitivity C-reactive protein. Median follow up time was largely different across studies allowing to stratify them in short term (<1 month, 2 studies), medium term (3-12 months, 7 studies), long term (4-8 months, 4 studies), very long term (>6 months, 4 studies) studies. The remaining studies assessed in-hospital events. In 7 out of 20 RCTs previous or ongoing COL use for any indication was exclusion criterion. No further details about the reason for taking COL was provided. Male gender was predominant in all studies (between 65 and 96%) whereas mean age ranged between 59 and 69 years. A thorough CV history was collected at recruitment, however there was no mention to uric acid levels or a previous diagnosis of gout. Furthermore, 3 RCTs excluded patients with known autoimmune/inflammatory disease (in 2 of them ongoing immunosuppressive or steroid therapy was an additional exclusion criterion) however the other RCTs did not mention coexisting autoimmune/inflammatory diseases. The primary endpoint was met by 0/2 (0%) short term studies, 4/7 (57%) medium term studies, 2/4 (50%) long term studies and 2/4 (50%) very long term studies. Neither of the studies assessing in-hospital events met the primary endpoint.

Conclusion: Our SLR of RCTs showed that COL may be useful in preventing new CV events/CV death in the general population when administered for at least on month. However, the overall lack of information about coexisting gout/other inflammatory RMDs does not allow to derive meaningful data to be applied in rheumatology practice. Future RCTs should consider this aspect when defining the eligibility criteria and describing the patient cohorts since COL may be even more effective in patients that display a higher CV risk due to an underlying inflammatory disease. This may ultimately increase the likelihood to achieve the study primary endpoints.

POS0374

HOW WELL DO EULAR/ASAS-EULAR AND NATIONAL TREATMENT RECOMMENDATIONS FOR PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS ALIGN? IS IT TIME FOR AN UPDATE OF NATIONAL TREATMENT RECOMMENDATIONS?

Keywords: Psoriatic arthritis, Health Services Research, Spondyloarthritis

B. Michelsen1, M. J. Nissen1, A. Ciurea1, B. Moeller1, L. Midtibelt Ornbjerg1, J. Zavada1, B. Gudbjörnsdóttir1, F. Iannone1, F. Hellandam1, T.K. Kven1, A. M. Rodrigues1, C. Codreanu1, Z. Rotar1, E. Kristianslund1, J. M. Santos1, M. Mogosan1, M. Tomisi1, F. Díaz-González1, D. DI Giuseppe1, M. Östergaard1, J. M. Heiland1.

Background: National treatment recommendations are often used to optimize patient care and may differ from international recommendations. Although such potential heterogeneity may affect outcomes, mapping of these differences across European countries was last performed more than a decade ago for axial spondyloarthritis (axSpA) and has never been undertaken in psoriatic arthritis (PsA).[1]

Objectives: To assess differences and similarities between the EULAR and ASAS-EULAR recommendations for the treatment of patients with PsA and axSpA, respectively, versus national PsA and axSpA treatment recommendations across Europe.

Methods: Rheumatologists from 15 European countries (Czech Republic, Denmark, Estonia, Finland, Iceland, Italy, Netherlands, Norway, Portugal, Romania, Slovenia, Spain, Sweden, Switzerland, and the United Kingdom) compared the most recent national treatment recommendations for PsA and axSpA with the EULAR recommendations for the management of PsA with pharmacological therapies: 2019 update[2] and the ‘2016 update of the ASAS-EULAR recommendations for axSpA’,[3] in an online survey conducted between October 2021 and April 2022. The study was an initiative of the European Spondyloarthritis Research Collaboration Network (EuroSpA RCN).[4]

Results: Three countries (Czech Republic, Netherlands, and Spain) followed all EULAR recommendations for treating patients with PsA and four countries (Czech Republic, Italy, Spain, and Switzerland) all ASAS-EULAR recommendations for axSpA. A total of 4/15 countries had no national treatment recommendations for PsA or axSpA, but had other rules or regulations to follow, for which the comparisions in this study were then performed. The Netherlands had national treatment recommendations for axSpA, but not yet for PsA, for which EULAR recommendations were followed. In six countries, the national treatment recommendations for PsA followed the 2019 EULAR recommendations and in four the 2016 ASAS-EULAR recommendations. The national treatment recommendations for PsA varied between the ASAS-EULAR (Figure 1). Discrepancies between international and national treatment recommendations included: Entry criteria for start of biologic/targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) varied and were the most stringent in Romania, where DAPSA>28 for PsA and BASDAI>6 and ASDAS>2.5 for axSpA were required for the start of a bDMARD. Regarding PsA, in two countries (Finland and Switzerland) a conventional synthetic DMAPA should be initiated before a b/tsDMARD including in patients with predominantly enthesal or axial disease. In several countries, no preference for L17 inhibitors was given for PsA patients with significant skin involvement. The positioning of JAK inhibitors (JAKI) differed across countries, e.g. in Estonia JAKI were indicated after failure of two tumor necrosis factor inhibitors and in Romania JAKI were positioned at the same level as bDMARDs. Phosphodiesterase-4 inhibitors were in not use or not reimbursed.
in most countries. Analgesics were not specifically mentioned in several of the national treatment recommendations.

**Figure 1.**

**Conclusion:** Only a few European countries incorporated all EULAR and ASAS/EULAR treatment recommendations in their national recommendations. The potential impact of this on access to b/tsDMARD treatments needs to be further explored.

**Keywords:** Comorbidities, Safety

Juntendo University, Department of Internal Medicine and Rheumatology, Tokyo, Japan

**Background:** Pneumocystis pneumonia (PCP) is a potentially life-threatening opportunistic infection. Sulfamethoxazole–trimethoprim (SMX/TMP) is effective in preventing pneumocystis pneumonia in patients with systemic rheumatic disease. However, the frequency of adverse events (AEs) due to SMX/TMP in rheumatic disease patients is higher than in the general population. The EULAR recommendation 2022 was described as ‘Of note, there is some evidence that reduced doses (e.g., half-strength, daily) may also be effective and associated with fewer adverse events’ [1].

**Objectives:** This study aimed to identify the optimal dose of SMX/TMP for the prophylaxis for PCP in patients with systemic rheumatic disease.

**Methods:** Our protocols of this study were described previously [2]. This study was a 52-week, randomized, open-label, two-arm, parallel-group, multicenter controlled trial. We compared a full-dose group (SMX/TMP at 400/80 mg daily) with a half-dose group (SMX/TMP at 200/40 mg daily). Inclusion criteria were follows: aged over 20 years; admission to our hospitals for diagnosis and/or treatment of new-onset or relapsed systemic rheumatic diseases from April 1, 2018, to March 31, 2021; current treatment with at least 0.6 mg/kg/day of oral prednisolone or equivalent doses of corticosteroids with or without any immunosuppressant; no previous treatment with SMX/TMP; per Zemidrine isochrome, dapsone, or atovaquone; serum creatinine levels within the institution's normal range; Able and willing to provide written informed consent. Exclusion criteria were follows: contraindications to SMX/TMP; past history of PCP; prior treatment with biologic agents; currently uncontrolled complications; body weight below 40 kg; currently pregnant or nursing; unable to begin SMX/TMP within 14 days of starting prednisolone; unable to provide written informed consent. Exclusion criteria were follows: contraindications to SMX/TMP; past history of PCP; prior treatment with biologic agents; currently uncontrolled complications; body weight below 40 kg; currently pregnant or nursing; unable to begin SMX/TMP within 14 days of starting prednisolone; unable to provide written informed consent. Exclusion criteria were follows: contraindications to SMX/TMP; past history of PCP; prior treatment with biologic agents; currently uncontrolled complications; body weight below 40 kg; currently pregnant or nursing; unable to provide written informed consent.

**Results:** Forty-two patients in full-dose group and 43 patients in half-dose group were analyzed. Since all patients were not developed with PCP while taking SMX/TMP, the results of the primary outcome measure of current as the number of patients in each treatment arm who were diagnosed with PCP were both 0. The discontinuation rates were 38% in full-dose group vs 16% in half-dose group (p value = 0.028).

**References:**

Conclusions: Half-dose regimen of TMP/SMX may be better to reduce AEs than full-dose regimen in prophylaxis for PCP in patients with systemic rheumatic disease.

**Background:** Inflammatory rheumatic diseases (IRD) are often diagnosed too late due to non-specific symptoms and the lack of specialists in rheumatology. Digital diagnostic decision support systems (DDSS) promise to accelerate diagnosis and decrease the overall healthcare burden.

**Objectives:** To assess the ability of an artificial intelligence (AI)-based symptom checker (Ada) and an online self-referral tool (Rheport) to diagnose inflammatory rheumatic diseases (IRDs).

**Methods:** In a prospective, multicenter open-label controlled randomized crossover trial patients newly presenting to a rheumatology center were randomly assigned in a 1:1 ratio to complete a symptom assessment with Ada or Rheport followed by a crossover to the other respective diagnostic decision support system (DDSS). The primary outcome was correct identification of a patient with IRD by the DDSS defined as the presence of any IRD in the list of suggested diagnoses with Ada or a pre-specified threshold score with Rheport. Physicians' diagnosis was the gold standard.

**Results:** In total, 600 patients were included and 214 (36%) patients were eventually diagnosed with an IRD by a physician. Rhoport showed a sensitivity of 62% and specificity of 47% for IRDs. Ada's top 1 (D1) and top 5 disease suggestions (D5) showed a sensitivity of 92% and 66% and a specificity of 68% and 54% concerning IRDs, respectively. Ada, in comparison to Rhoport, was more likely to correctly identify patients with an IRD when used as the first DDSS (OR: 1.10, 95% CI: 1.01 to 1.18) however this finding was not consistent after cross-over (OR: 0.97, 95% CI: 0.89 to 1.05).

**Conclusion:** The diagnostic capability of both DDSS for IRDs was not promising in this high-prevalence patient population referred for subspecialty evaluation. Although the overall numbers suggest that AI-based Ada demonstrated a slightly higher specificity and sensitivity compared to the questionnaire-based Rhoport, Ada was not consistently better than Rhoport in correctly identifying patients with an IRD when the use sequence of the apps was taken into account. Our results indicate that, strict regulation and drastic improvement is necessary to ensure safety and effectiveness of DDSS.

**ASSOCIATION BETWEEN METABOLIC SYNDROME AND KNEE PAIN IN MIDDLE-AGED ADULTS OVER 10-13 YEARS**

**Keywords:** Pain, Osteoarthritis, Epidemiology

A. Singh1, L. Fraser1, A. Venn1, L. Blizzard1, G. Jones1, C. Ding1, B. Antony1

1University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia

**Background:** Metabolic syndrome (MetS) is characterized by an increased waist circumference, dyslipidaemia (elevated triglycerides and reduced high-density lipoprotein (HDL)), hypertension and hyperglycaemia. MetS has been suggested as having a role in osteoarthritis (OA) pathogenesis. Few studies have described the association of MetS with joint pain in older adults with OA; however, none has described the association between MetS and knee pain in a middle-aged adult population.

**Objectives:** We aimed to describe the association of MetS and trajectories of MetS over 10-13 years with knee symptoms in general population-based middle-aged adults.

**Methods:** Fasting blood biochemistry, waist circumference and blood pressure measures collected during the Childhood Determinants of Adult Health (CDAH)-1 study (year: 2004-6; n = 2447) and at 10-13 year follow-up at CDAH-3 (n = 1549) were used to define MetS using the International Diabetes Federation (IDF) definition. Knee symptoms were assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scale at the CDAH-3 follow-up (mid adulthood). Univariable and multivariable (adjusted for age, sex, and body mass index (BMI)) zero-inflated Poisson (ZIP) regression models were used for analysis.

**Figure 1: Participant flowchart**

**Table 1**

**Results:** Overall, the prevalence of MetS increased from 8% (mean age: 31.48 ± 2.60; female: 52.06%) to 13% (mean age: 44 ± 2.90; female: 53.78%) over 10-13 years. Four MetS trajectories were identified—No MetS (85.01%); ‘Improved MetS’ (2.14%), ‘Incident MetS’ (8.81%), and ‘Persistent MetS’ (4.04%). The presence of MetS at any point, compared to no MetS, was significantly associated with worse knee symptoms at follow-up. Notably, ‘Incident MetS’ was most strongly associated with knee symptoms [Rob: 1.56, 95% CI: 1.48, 1.65] and pain [Rob: 1.25, 95% CI: 1.37, 1.79] at follow-up (Table 1).

WHEN SHOULD WE USE MARGINAL STRUCTURAL MODELS FOR DRUG STUDIES IN RHEUMATOLOGY? THE EXAMPLE OF CORTICOSTEROIDS AND INFECTIONS IN RHEUMATOID ARTHRITIS

Keywords: Education, Real-world evidence, Epidemiology

A. Barbulescu1, A. Sjölander2, B. Delcoigne3, J. Askling1, T. Frisell1

1Karolinska Institutet, Medicin Solna, Solna, Sweden; 2Karolinska Institutet, Medical epidemiology and Biostatistics, Solna, Sweden; 3Karolinska University Hospital, Rheumatology, Theme Inflammation and Ageing, Stockholm, Sweden

Background: The use and dosing of pharmacotherapy for chronic inflammatory disease is commonly changed over time, adapting to previous treatment response, current disease activity, tolerability, and onset of adverse events. This makes evaluating the treatments difficult, as the treatment received over time becomes entangled with time varying confounding factors, even if the initial treatment choice was randomized. To naively adjust for these time-varying factors in regression models has long been recognized by epidemiologists to introduce bias in most realistic settings, and marginal structural models (MSM) has been proposed as a less biased alternative. Despite this, MSMs are used very sparingly in drug studies in rheumatology.

Objectives: The objective of this work is to explain the rationale for why MSMs are recommended in the context of time-varying drug use and confounding factors, and what may go wrong if they are not used. The method will be demonstrated by comparing the incidence of serious infections between different oral glucocorticoid (GC) dose patterns over the first three years after first RA diagnosis, adjusting for time-varying confounders in MSM or through conventional regression models.

Methods: For the demonstration study, we followed 9654 recently diagnosed RA patients, for five years from their first rheumatology visit in the Swedish Childhood Determinants of Adult Health (CDAH) registry, 2007 to 2018. Follow-up was divided into 3-month periods. An average oral prednisone daily-dose was calculated for each period and categorized into "no use," "low" (≤10mg/day) and "high" (>10mg/day) doses. The MSM was implemented through sequential inverse probability of treatment weighting across time periods, accounting for demographic factors, current GC dose and HAQ, co-medication and his inflammatory activity. The incidence of serious infections (hospitalization for infection identified through the Swedish National Patient Register) was modelled by pooled logistic regression allowing separate effects for recent and past GC. We compared confounding adjustment via conventional regression versus MSM.

Results: An increased incidence of serious infections was associated with higher compared to lower doses and with more recent compared to past GC. Although in theory less biased by confounding factors, the results from MSMs were similar to those from conventional regression. Compared to no glucocorticoids, exposure to low doses during the first year added 1.9 infection cases per 100 patients (95% CI 0.9-2.9) at three years, while exposure to high doses added 4.1 (2.5-5.9) cases.

Conclusion: Our results broadly agree with previous observational studies showing a dose dependent increased risk of infection associated with (recent) use of oral glucocorticoids. Although theoretically the MSM has the potential to be less biased than ordinary regression models, the results from the two models were almost indistinguishable in this realistic example, and the implementation of the MSM led to limitations in the study design (including the categorization of exposure), and was very time consuming both in programming and computation time compared to the more widely used option. This similarity in results is not guaranteed however, and the biases that MSMs were designed to avoid should be kept in mind in all studies of drugs were the use may change over time in response to possibly confounding factors.

PERFORMANCE OF EYE SIGN IN DIAGNOSING PATIENTS WITH NEUROPSYCHIATRIC SYSTIC LUPUS ERYTHEMATOSUS

Keywords: Diagnostic Tests, Systemic lupus erythematosus, Prognostic factors

J. L. H. Shi1, The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China

Background: The featured alterations of eye sign has been reported (1) in patients with neuropsychiatric systemic lupus erythematosus (NPSLE). Whether eye sign can predict NPSLE remains unknown.

Objectives: To investigate the performances of potential predictors and predictive models utilizing eye sign in classifying NPSLE.

Methods: Patients (>18 years) fulfilled the SLE diagnosis (2) were consecutively enrolled from 30 September 2016 to 30 September 2017. The diagnosis of NPSLE was evaluated and based on the consensus from rheumatologist, neurologist, radiologist and psychiatrist. Bulbar conjunctival microvascular changes in eye sign were performed and scored for all SLE patients by rheumatologist using our criteria. NP assessments were evaluating in all SLE patients by psychiatrist, including the mini-mental state examination (MMSE), self-rating anxiety scale (SAS), self-rating depression scale (SDS). Demographic and clinical data were compared between two groups and to identify potential predictors for NPSLE by using multivariable logistic regression analysis. The receiver operating characteristic (ROC) curve was plotted and the area under the curve (AUC) was used to evaluate the performance of the models in the prediction of NPSLE.

Results: 120 SLE patients were recruited (30 [24-41] years) including 30 NPSLE and 90 non-NPSLE. Totally 39 NP events were recorded in these NPSLE patients. NPSLE had higher disease activity (reflected as SLEDAI and ESR), more prevalent of Poor lymphopenia, lower platelet and lower non-NPSLE group. Eye sign examination showed NPSLE group had significantly changes of ramified loops, microangloma, wound spot, worse vascular tone and
higher total score than non-NPSLE group. In multivariable logistic analysis, model 1 showed total score of eye sign was the only predictor for NPSLE, while in model 2, except for SLEDAI, specific items of ramified loops, microangioma and wound spot were predictors for NPSLE (Table 1). Predictive model 1 utilizing total score as predictor showed AUC of 0.933 with sensitivity of 86.7%, specificity of 95.6% (Figure 1).

**Figure 2.** The association between predictive models and NPSLE assessed using receiver operating characteristic (ROC) curves.

**Table 1. Multivariable logistic regression analysis of predictors for developing NPSLE.**

**POS0381** FACTORS ASSOCIATED WITH PREGNANCY-RELATED CONCERNS IN WOMEN WITH INFLAMMATORY RHEUMATIC DISEASES – AN ANALYSIS OF A NATIONWIDE PREGNANCY COHORT

**Keywords:** Patient reported outcomes, Registries, Pregnancy and reproduction

**Y. Meissner**, B. Eikohof, C. Glaser, J. Henes, J. Richter, S. Spaeltingh-Meestekemper, C. Specker, R. Fischer-Betz, A. Strangfeld, German Rheumatism Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany; [^1] University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; [^2] University Hospital Tuebingen, Centre for Interdisciplinary Clinical Immunology, Rheumatology and Autoinflammatory Diseases, Tuebingen, Germany; [^3] Heinrich-Heine-University Düsseldorf, University Clinic, Policlinic for Rheumatology and Hiller Research Unit for Rheumatology, Düsseldorf, Germany; [^4] Rheumapraxis München-Pasing, Rheumatologie, München, Germany; [^5] Kliniken Essen-Mitte, Klinik für Rheumatologie & Klinische Immunologie, Essen, Germany; [^6] Charité University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany.

**Background:** Pregnancies in women with chronic diseases are often accompanied by concerns about possible complications during pregnancy and about the health of the child [1]. In women with inflammatory rheumatic diseases (IRD) this can lead to a reduced number of offspring [2]. To date, surveys and interviews, but no data quantifying these worries and factors influencing them, have been published.

**Objectives:** To investigate and quantify pregnancy concerns in women with various underlying IRD, and to identify factors that have an impact on these worries.

**Methods:** The German registry Rhekiss is a nationwide, multicentre, web-based longitudinal cohort study, which was initiated in 2015 to investigate pregnancies and related issues in women with various IRD. Women can either be enrolled if they are planning a pregnancy (cohort 1) or if they are already pregnant prior to gestational week 20 (cohort 2). Rheumatologist- and patient-reported data are captured at regular, pre-defined follow-up visits. For this analysis, women who had answered the question regarding their concerns about their pregnancy and child’s health due to the IRD were included. Categorical answers as well as patient characteristics were analysed descriptively. The impact of different factors associated with patients’ anxieties was estimated by multivariable ordinal logistic regression using the proportional odds model and combining the two cohorts. Missing values were replaced by single imputation.

**Results:** Between 09/2015 and 10/2022, a total of 2,240 patients were enrolled, including 708 in cohort 1 and 1,532 in cohort 2. Out of those, n=455 and n=784, respectively, were eligible for the analysis. Women of both cohorts were on average 32-34 years old and had a mean disease duration of 8-9 years (table 1). A total of 31% of women in cohort 1 and 22% in cohort 2 stated that they are concerned “a lot” (figure 1). Answers of patients varied between the IRD diagnoses. A significant association with higher levels of worry was found in patients with a greater disease impact, measured by the patient-reported RAID score, an established seven-item composite index for assessing the disease burden in rheumatic diseases [3, 4], (Odds ratio 1.35 [95% confidence interval 1.27; 1.43]). A similar association was found with nulligravidity (1.29 [1.01; 1.65]) and with recent treatment changes (1.26 [1.00; 1.60]), which were associated with a lower level of concern (0.96 [0.94; 0.99]). No significant relationship was found for the number of underlying comorbidities (1.13 [0.98; 1.29]). Furthermore, patients who were already pregnant at enrolment were less worried than patients planning a pregnancy (0.74 [0.60; 0.93]).

**Conclusion:** At least one in five women with IRD is “very concerned” about pregnancy and infant health due to the underlying rheumatic disease. A higher RAID score, nulligravidity, treatment changes and younger age were associated with higher levels of concern. Therefore, patient concerns should be an essential part of individual counselling for women with IRD who want to become pregnant or are already pregnant.

Methods: In 2020, 7637 patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA) or systemic lupus erythematosus (SLE) reported fatigue in the National Database of the German Collaborative Arthritis Centres [2]. Fatigue, pain, physician (PtGl) and patient global (PptGl) activity, PtGl health status (all on numeric rating scales, 0-10) were categorized into three groups (mild (0-3), moderate (4-6), severe (7-10)). Depressive symptoms assessed by WHO-5 well-being (0-10) were categorized to no (0-50), mild (51-90) and moderate to severe (>90). The frequency and severity of fatigue was compared in terms of the rheumatic diseases, age, sex, disease duration and sociodemographics. Violin plots show the ways in which fatigue and the other outcomes.

Results: A total of 4900 patients (84%) reported fatigue. Higher mean values were observed in patients with axSpA (4.3) compared to PsA (3.9), RA (3.8) and SLE (3.7) (table 1). Female and elderly patients, singles, and patients with little education years reported more fatigue. No difference in fatigue severity was found between patients with initial diagnosis and those with long-term disease. More fatigue was related to a poorer global health status, higher PtGl and PptGl disease activity, higher levels of pain, and more severe depressive symptoms (figure 1). Patients with concomitant fibromyalgia or depression reported worse fatigue compared to those with no or other comorbidities.

Keywords: Psoriatic arthritis, Epidemiology, Real-world evidence

Background: Psoriasis (PsO) and psoriatic arthritis (PsA) can greatly impact quality of life and result in substantial personal and societal costs. Complete and up to date data on the prevalence and incidence of these conditions and whether these change over time and vary by age is important for healthcare service planning so that specialist care and funding can be appropriately allocated.

Methods: We used Clinical Practice Research Datalink AURUM, a primary care electronic health record database, including 20% of the English population. The codes used to identify patients with PsO and PsA were selected by rheumatologists and dermatologists and cross-checked with published code lists from other studies to ensure inclusion of all relevant codes. All included patients must have data for at least 1 year before their diagnosis. The annual incidence and point prevalence were calculated from 2009-2019 and stratified by age/sex. The study period ended in 2019 to avoid COVID-19 pandemic affecting results.

Results: The prevalence of PsO and PsA in males and females increased annually, peaking in 2019 (PsO males 2.41% [95% confidence interval (CI) 2.40, 2.42]; PsO females 2.60% [95% CI 2.59-2.61]; PsA males 0.20% [95% CI 0.20-0.20]; PsA females 0.21% [95% CI 0.21-0.22]), as illustrated in Table 1. In 2019, the prevalence of PsO and PsA was highest in the over 65 years age group. PsO 4.25% [95% CI 4.22-4.28] and PsA 0.38% [95% CI 0.37-0.38]. The annual incidence per 100,000 person years of PsO has gradually decreased in males (from 168 (164-171) in 2009 to 148 (145-151) in 2019) but in females it has been stable with a slight annual decrease (from 180 (177-184) in 2009 to 173 (170-176) in 2019). The annual incidence for PsA has increased in both males and females from 2009-2019 across all age groups in England.

Methods: We used Clinical Practice Research Datalink AURUM, a primary care electronic health record database, including 20% of the English population. The codes used to identify patients with PsO and PsA were selected by rheumatologists and dermatologists and cross-checked with published code lists from other studies to ensure inclusion of all relevant codes. All included patients must have data for at least 1 year before their diagnosis. The annual incidence and point prevalence were calculated from 2009-2019 and stratified by age/sex. The study period ended in 2019 to avoid COVID-19 pandemic affecting results.

Figure 1. Relationship between fatigue and pain, global health activity and depressive symptoms

Conclusion: Fatigue is a frequent symptom across various inflammatory rheumatic diseases. A strong relationship to global health, disease activity, pain and depressive symptoms needs to be considered in the (individual) therapeutic management of the diseases that relies on a shared decision making.
Conclusion: The increasing prevalence of PsO and PsA highlights the importance of organizing healthcare services to meet this need, particularly in the elderly population.

SQUASH VERSUS ACTIHEART-MEASURED PHYSICAL ACTIVITY IN THE MIDDLE-AGED GENERAL POPULATION: THE NEO STUDY

Keywords: Patient reported outcomes, Lifestyles, Epidemiology.

S. Terpstra1,2, L. Hoogervorst3, J. Van de Velde5, R. De Mutsert2, L. A. Van de Stadt5, F. Rosendaal1, M. Kloppenburg3,4, 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center, Clinical epidemiology, Leiden, Netherlands; 3Leiden University Medical Center (LUMC), Orthopedics, Leiden, Netherlands

Background: Adequate physical activity levels have been associated with wide-ranging beneficial health outcomes. It is therefore important to adequately measure physical activity. This is often done by the SQUASH (Short Questionnaire to Assess Health-enhancing physical activity), a patient-assessed instrument. However, this is a subjective method of which data on validity in large middle-aged population groups are lacking.

Objectives: To assess 1) the construct validity of the SQUASH, and 2) participant characteristics associated with difference between SQUASH and ActiHeart outcome.

Methods: Cross-sectional data from the population-based Netherlands Epilepidemiology of Obesity (NEO) study were used, of which participants were 45 to 65 years of age. Physical activity (in Metabolic Equivalent of Task (MET) hours) was assessed using the SQUASH on one week and in a random subset using the ActiHeart accelerometer for approximately 96 hours continuously, extrapolated to one week. Convergent validity of the SQUASH was assessed by calculating Spearman’s rank correlation between the SQUASH and the ActiHeart. Extreme quintile activity was assessed based on the difference in SQUASH activity between 1) 25% of participants with highest and lowest activity according to ActiHeart; 2) participants with and without any comorbidity; and 3) participants with BMI < 25kg/m² versus participants with BMI > 30kg/m². Discriminative validity was assessed by a lack of Spearman's rank correlation between SQUASH physical activity and participant height (correlation <0.10). Participant characteristics associated with the difference between SQUASH and ActiHeart outcome were assessed by comparing quintiles of SQUASH minus ActiHeart outcome with a reference quintile (=quintile with lowest difference between SQUASH and ActiHeart).

Results: SQUASH data were available for 6,550 participants (mean age 56 years, 56% women, 24% having any comorbidity) of which 875 had ActiHeart data. Median (interquartile range) physical activity was 116 (76;154) MET hours/ week according to the SQUASH and 75 (58;99) according to the ActiHeart (mean difference 47 (standard deviation 63)). The Bland-Altman plot of the difference between SQUASH and ActiHeart measurement per participant is shown in figure 1. Convergent validity was weak (ρ = 0.20, p < 0.01). Participants with the 25% highest ActiHeart scores had 38 MET hours/week more SQUASH activity (95% confidence interval (95%CI) 27.50) than the lowest 25%. Participants with any comorbidity had -13 (95%CI -17; -9) MET hours per week of SQUASH compared with BMI < 25kg/m² versus participants with BMI > 30 kg/m², and -20 (95%CI -28; -13) MET hours per week of SQUASH compared with BMI < 25kg/m². Discriminative validity was present (ρ = 0.01, p = 0.41). Cut-offs of the quintiles of participants according to SQUASH minus ActiHeart physical activity (range: -61 to 411) were: -6, 27, 61 and 91 MET hours/week (reference quintile: -6-27), Men were overrepresented in the lowest quintile of SQUASH minus ActiHeart activity (-61 to 6 MET hours/week), whereas women had a higher ratio for being male compared with the reference quintile: 2.35 (95%CI 1.52;3.84). Men were also overrepresented in the second-highest quintile (61 to 91 MET hours/week, OR 2.47 (95%CI 1.61;3.84)).

IMMUNE CHECKPOINT INHIBITORS: FAIL TO KEEP A CHECK ON AUTOIMMUNE DISEASES

Keywords: Epidemiology, Malignancy, Targeted synthetic drugs.

D. Desai1, P. Khandwala2, I. Tan1, 1Einstein Medical Center Philadelphia, Hospice and Palliative Medicine, Philadelphia, United States of America; 2Einstein Medical Center Philadelphia, Rheumatology, Philadelphia, United States of America

Background: The introduction of immune checkpoint inhibitors (ICIs) has revolutionized cancer treatment. ICIs augment antitumor activity by blocking the binding of checkpoint proteins with their partner proteins. This inhibition is a negative regulator on T cell cytotoxicity causing the uncontrolled killing of tumor cells, a loss of self-tolerance, and increased risk of inducing autoimmunity[1]

Objectives: The study was undertaken to establish correlation between the use of ICIs and autoimmune conditions (ACs), and to study trends in incidence and prevalence of ACs in patients treated with ICIs.

Methods: TrinetX, a global federated research network that provides a dataset of electronic medical records from different healthcare organizations (HCOS) was utilized. Initial query was made to isolate patients who had a diagnosis of “Neoplasm” (International Classification of Diseases, 10th version (ICD-10) Code C00 - D49). Two cohorts were made, on basis of ICIs use. Propensity score matching was carried out to match age, race and gender. Compare outcome analytic function was utilized to map the correlation with ACs. ACs included were Systemic Connective Tissue Disorders (ICD-10 M06), Rheumatoid Arthritis (ICD-10 M06), Arthropathic Psoriasis (ICD10 L40.5). 9 FDA-approved checkpoint inhibitors were included in our study: Atezolizumab, Avelumab, Cedolimab, Dostarlimab, Durvalumab, Ipilimumab, Nivolumab, Pembrolizumab, and Relatlimab.[2]

Results: A total of 12,099,334 patients had a diagnosis of neoplasm out of which 72,865 (0.61%) patients were taking ICIs. Two cohorts were made, on basis of ICIs use. Propensity score matching was carried out to match age, race and gender. Compare outcome analytic function was utilized to map the correlation with ACs. ACs included were Systemic Connective Tissue Disorders (ICD-10 M06), Rheumatoid Arthritis (ICD-10 M06), Arthropathic Psoriasis (ICD10 L40.5). 9 FDA-approved checkpoint inhibitors were included in our study: Atezolizumab, Avelumab, Cedolimab, Dostarlimab, Durvalumab, Ipilimumab, Nivolumab, Pembrolizumab, and Relatlimab.[2]

References: NIL.
ICI group, and 63% vs 25% vs 10% in non-ICI group). 5.16% of patients in the ICI groups had ACs while only 4.17% of patients in non-ICI groups had ACs (p<0.0001). The hazard ratio (HR) of having ACs was higher in ICI as compared to non-ICI group (HR = 1.96, 95% confidence interval (CI), 1.88-2.04, p<0.0001). After propensity score matching, both groups had 72,865 patients. 5.16% in the ICI group had ACs, while only 4.46% of patients in the non-ICI group had ACs. HR was 1.925 (95% CI, 1.831-2.025, p<0.0001).

As shown in the graph below, the incidence of autoimmune disorders increased from 0.79% in 2015 to 2.16% in 2021 in ICI group. Similarly, prevalence also increased from 2.97% in 2015 to 6.06% in 2021.

**Conclusion:** Although ICI transformed the cancer management landscape, it is important to be aware of its effects on autoimmune disorders. Incidence and prevalence of ACs have increased in patients with neoplasms treated with ICI over the years. It can also be seen that HR of having outcome of ACs is higher in ICI group. There is a need for a prospective study to correlate the causality of development of AC with use of ICI.

**OBJECTIVES**

**IMPACT OF RHEUMATIC DISEASE SUB-TYPES ON MATERNAL AND NEONATAL OUTCOMES: A POPULATION LEVEL ANALYSIS**

**Keywords:** Pregnancy and reproduction, Rheumatoid arthritis, Systemic lupus erythematosus

S. Keeling1, A. Savu2, P. Kaul2. 1University of Alberta, Medicine, Edmonton, Canada; 2Canadian Vigour Centre, University of Alberta, Edmonton, Canada

**Background:** There are limited data on the differing effect of rheumatic diseases (RD), including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA) and systemic lupus erythematosus (SLE), on maternal and neonatal outcomes.

**Objectives:** We evaluated the impact of four rheumatic diseases (RA, SpA, PsA and SLE) on maternal and neonatal outcomes at a population level. We also examined medication use during pregnancy across these four groups.

**Methods:** A contemporary pregnancy cohort of 452,273 singleton live birth events of 307,590 women was assembled for the province of Alberta, Canada. We identified 5 groups: (1) no rheumatic disease (no RD, n=449,933 pregnancies), (2) RA (n=1214), (3) PsA (n=177), (4) SpA (n=445) and SLE (n=504). We compared maternal and neonatal outcomes, comorbidity burden, and medication use among the 5 groups.

**Results:** Across all groups, mothers were predominantly ethnically Caucasian (>90%), residing in urban residences (>75%), and multiparous (>58%). Maternal comorbidities including renal, vascular diseases and hypertension were most prevalent in SLE mothers. Rates of preclampsia, caesarean section and induction were highest in mothers with SLE. Pregnant women with SLE were the most likely to have preterm delivery (18.3%) and NICU admission at birth (21.8%) followed by RA (preterm delivery 11.3%, NICU admission at birth 12.8%) compared to those with PsA, SpA or no RD (Figure 1). Predisone use for at least 28 days or any duration during pregnancy was highest amongst mothers with SLE (8.9%) followed by RA (7%) (Table 1). Antimalarial use for at least 28 days or any duration during pregnancy was highest in SLE mothers (32.7%) followed by RA mothers (18.5%) while biologic medications were used mostly in mothers with RA (10.5%).

**Conclusion:** Women with SLE had the worst maternal and neonatal outcomes and highest medication use followed by RA, with varying degrees for those with PsA and SpA compared to controls. The extent to which these outcomes are related to differing medication use, such as higher rates of prednisone and lower rates of antimalarials in mothers with SLE, and lower use of biologics in RA mothers, requires further exploration.

**POS0388 IMPACT OF GLUTOCORTICOIDS AND ANTI-OSTEOPOROTIC TREATMENT ON BONE HEALTH IN PATIENTS WITH INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES (IRM): A LONGITUDINAL STUDY**

**Keywords:** Real-world evidence, Osteoporosis, Inflammatory arthritides

G. Adami1, A. Fassio1, C. Benini1, O. Viapiana1, D. Gati1, D. Bertelle1, M. Rossi1. 1University of Verona, Rheumatology Unit, Verona, Italy

**Background:** The negative effects of glucocorticoids (GCs) on the bone depend on dose and treatment duration. However, it is unclear whether a safe dose exists, especially for patients with inflammatory rheumatic musculoskeletal diseases (IRMds).

**Objectives:** The primary objective of the present study was to determine, in a real-life setting, the risk of fragility fracture associated with the dose of glucocorticoids in IRMD.
Methods: We conducted a longitudinal cohort study on women with IRMD. Data were extracted from the DeFRA database (2012-2020). DeFRA is a fracture risk assessment tool similar to FRAX. Bone mineral density and fractures were assessed prospectively and compared to a matched cohort (propensity score matching, PSM with age, T-score and the % 10-year fracture risk estimated with DeFRA fracture risk assessment tool). Kaplan-Meier curves with log-rank test were made for IRMD (stratified for glucocorticoid use and dosage) and matched cohort respectively.

Results: 884 women with IRMD and 1,766 controls (age, T-score, and 10-year fracture risk matched) were included in the study and followed for up to 6 years. BMD levels decreased significantly in all GCs users not receiving anti-osteoporotic treatment (Δ-2.26% p 0.0011, -4.23% p 0.0422, -2.66% p 0.0006 for ≥5 mg/day, 2.5 mg to 5 mg and 0 to 2.5 mg/day of prednisone, respectively). As regards patients receiving anti-osteoporotic medications, BMD levels decreased significantly only in patients receiving ≥5 mg/day of prednisone (Δ -30.1% p 0.007), whereas in patients receiving 2.5 mg to 5 mg and 0 to 2.5 mg/day, concomitantly treated with anti-osteoporotic drugs, BMD did not decrease significantly (Δ +1.10% p NS, +1.12% p NS, respectively). Figure 1A. Fracture incidence was greater in patients with IRMD compared to controls but only GC doses above 5 mg/day were associated with significantly higher risk of fracture figure 1B. 21, 12 and 29 fractures were reported for patients receiving ≥5 mg/day, 2.5 mg to 5 mg and 0 to 2.5 mg/day respectively, corresponding to a crude fracture rate of 4.8 fractures per 100 person-year, 2.8 fractures per 100 person-year and 2.5 fractures per 100 person-year respectively. 103 fractures were registered in the PSM cohort (crude fracture rate of 4.8 fractures per 100 person-year). We also explored the effects of GC on serum C-terminal telopeptide of type 1 collagen (CTX) in a subset of patients with available data (n=333). We found that the proportion of patients with low bone turnover (<400 ng/L) was numerically greater in patients receiving ≥5 mg/day of prednisone compared to controls but only GC doses above 5 mg/day were associated with significantly higher risk of fracture (figure 1B). 21, 12 and 29 fractures were reported for patients receiving ≥5 mg/day, 2.5 mg to 5 mg and 0 to 2.5 mg/day respectively, corresponding to a crude fracture rate of 4.8 fractures per 100 person-year, 2.8 fractures per 100 person-year and 2.5 fractures per 100 person-year respectively. 103 fractures were registered in the PSM cohort (crude fracture rate of 2.2 fractures per 100 person-year). We also explored the effects of GC on serum C-terminal telopeptide of type 1 collagen (CTX) in a subset of patients with available data (n=333). We found that the proportion of patients with low bone turnover (<400 ng/L) was numerically greater in patients receiving ≥5 mg/day compared to other doses and controls (p NS).

Conclusion: GC doses as low as 2.5 mg/day were associated with BMD loss in IRMD but this effect was preventable. BMD loss in patients taking ≥5 mg/day was not totally prevented by anti-osteoporotic medications currently used in clinical practice, resulting in higher risk of fracture.

Figure 1. Fracture incidence was greater (+3.10% p NS, +1.12% p NS, respectively).
Age and sex among patients with morphometric fracture and femur fracture. The incidence of these conditions was compared between the groups using univariate and multivariate models adjusting for cardiovascular risk-factors. Results: 9,769 FMF patients were followed for a median period of 12.5 years. 304 FMF patients were diagnosed with osteoporosis compared to 191 controls, resulting in an incidence rate (per 10,000 persons-years) of 28.8 (95%CI 15.7-32.5), and 17.8 (95%CI 15.4-20.6) respectively, and a crude HR of 1.62 (95% CI 1.35-1.93 p<0.001). Patients were diagnosed with osteoporosis at a considerably younger age than controls (60.1±12.4 vs 62.5±11.0 years; p=0.028).

POS0391

INCREASED RISK OF OSTEOPOROSIS AND HEAD OF FEMUR FRACTURES IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER - A LARGE RETROSPECTIVE COHORT STUDY

Keywords: Epidemiology, Osteoporosis

V. S. Patil1, N. Ben-Shabat2, L. Fischer1, K. Sharit3, S. Lassman1, A. Watad1, 3, H. Amital1, 3, Sheba Medical Center, Tel-Hashomer, Department of Internal Medicine B & Zabludowicz Center for Autoimmune Diseases, Ramat Gan, Israel, 3 Sheba Medical Center, Tel-Hashomer, Department of Gastroenterology, Ramat Gan, Israel, 2 Leeds Institute of Molecular Medicine, University of Leeds, Chapel Allerton Hospital, Leeds, UK, Section of Musculoskeletal Disease, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom

Background: Chronic inflammatory conditions are characterized by an inflammatory milieu and increased exposure to glucocorticoïds both resulting in increased risk of osteoporosis and subsequently bone fractures. Familial-Mediterranean-Fever (FMF) is a prototypical autoimmune disorder not treated with steroids. FMF association with femur fractures is not well established.

Objectives: To evaluate the incidence of osteoporosis and head of femur fractures in FMF patients compared to the general population.

Methods: A retrospective cohort study using the electronic database of Clalit Health Services (CHS), the largest health organization in Israel. All FMF patients diagnosed between 2000-2016 were included with age-, sex- matched controls in 1:1 ratio. Follow-up continued until the first diagnosis of osteoporosis or femur fracture. The incidence of these conditions was compared between the groups using univariate and multivariate models adjusting for cardiovascular risk-factors.

Results: 9,769 FMF patients were followed for a median period of 12.5 years. 304 FMF patients were diagnosed with osteoporosis compared to 191 controls, resulting in an incidence rate (per 10,000 persons-years) of 28.8 (95%CI 15.7-32.5), and 17.8 (95%CI 15.4-20.6) respectively, and a crude HR of 1.62 (95% CI 1.35-1.93 p<0.001). Patients were diagnosed with osteoporosis at a considerably younger age than controls (60.1±12.4 vs 62.5±11.0 years; p=0.028).

PRIOR ANTIRESORPTIVE TREATMENT REDUCES LUMBAR SPINE BMD RESPONSE TO ROMOSOZUMAB IN CAUCASIAN POSTMENOPAUSAL WOMEN WITH SEVERE OSTEOPOROSIS

Keywords: Osteoporosis, Real-world evidence, Bone diseases

P. Ravji1, M. McRorie2, K. Berg3, S. Ralston1, 2, B. Hauser1, 2, NHS Lothian, Rheumatology Department, Edinburgh, United Kingdom; 2 Centre for Genomic and Experimental Medicine, Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom

Background: Romosozumab, a monoclonal antibody against sclerostin, is a newly licensed dual-acting osteoporosis (OP) treatment for patients at very high fracture risk. Most patients included in the pivotal trials (ARCH[1] and FRAME [2]) were treatment naive. However, many patients in day-to-day clinical practice who are eligible for anabolic therapy have been pre-treated with antiresorptive medications. Objectives: Our aim was to analyse bone mineral density (BMD) treatment response to Romosozumab in patients with severe osteoporosis who are attending the osteoporosis clinic. A further objective was to analyse whether pre-treatment with antiresorptive osteoporosis medication (OPTx) influences the BMD treatment response at any BMD site.

Methods: Retrospective single-centre analysis of patients who have completed a 12-month course of monthly sc Romosozumab treatment (210mg) between February 2021 and November 2022. Local guidance recommends the use of Romosozumab in patients with severe spinal OP with at least two moderate to severe vertebral fractures and OP at the hip as defined by DXA. BMD assessment was usually performed with DXA at baseline and after treatment completion.

Results: Out of 56 patients offered Romosozumab, 52 agreed to start treatment and 47 patients completed the full course of therapy. All patients were postmenopausal women with an average age of 73.1±9.7 years and BMI of 24.4±7.1 kg/m². The baseline 10% major osteoporotic fracture risk as calculated by FRAX was 32.2±13.5. Mean baseline BMD lumbar spine (LS) T-score was -3.0±0.7 and total hip (TH) T-score was -3.0±0.7. The vast majority (95%) of patients had a history of vertebral fractures and half of the patients (50%) had a history of an additional non-vertebral fracture. 31 (66%) patients were treatment naive or had recent antiresorptive treatment for less than 6 months, the remainder of patients received recently oral or parenteral bisphosphonate treatment. After 12 months the overall mean % change BMD at the LS was 14.1±9.4 and 5.7±5.6 respectively, and a crude HR of 1.62 (95% CI 1.35-1.93); p<0.001). Prior OPTx however did not seem to influence TH BMD response to Romosozumab (5.1±6.3 vs 6.1±5.1 in OPTxnaive patients) as shown in Figure 1. Age (r=−0.37 p<0.05; Spearman’s rho) and prior OPTx (r=−0.49 p<0.01) are inversely related to LS BMD increase. Multivariate regression analysis including age, baseline spine BMD and prior OPTx identified prior OPTx as independent predictor (beta=−0.422 p<0.05) of spine BMD response to Romosozumab treatment.

Conclusion: The overall BMD response at LS and TH site after 12 months Romosozumab treatment in real world is similar to that reported in the ARCH trial. Pre-treatment with antiresorptive treatment seems to significantly dampen the BMD response at the lumbar spine, which highlights the importance of the choice of OPTx sequence.

Figure 1. Bone mineral density (BMD) change (%) after 1 year treatment with Romosozumab; OP Tx = treatment with antiresorptive osteoporosis medication; OPTx naïve = no previous osteoporosis treatment or treatment for less than 6 months.
Regarding femur fractures, 56 FMF patients were diagnosed with the condition compared to 35 controls, resulting in an incidence rate (per 10,000 persons-years) of 5.9 (95%CI 4.0-6.9), and 3.3 (95%CI 2.3-4.6) respectively, and a crude HR of 1.60 (95% CI 1.06 to 2.44, p<0.05). Predictors of osteoporosis or femur fractures among FMF patients included older age, Arab ethnicity, as well as North African origin. In contrast, obesity was considered a protective factor, while colchicine treatment did not significantly affect the risk of these outcomes.

Conclusion: FMF patients are at increased risk for osteoporosis and consequently femur fractures.

EFFECTIVENESS OF THE ACTIVEHIP+ mHEALTH SYSTEM ON THE FUNCTIONAL STATUS, PAIN AND FEAR OF FALLING IN OLDER ADULTS WITH HIP FRACTURE: A RANDOMISED CLINICAL TRIAL

Keywords: Telemedicine, Clinical Trials, Osteoporosis

R. Prieto-Moreno1, 2, P. Molina-Garcia3, M. Mora-Traverso3, 4, M. Ortiz-Piña1, S. Salazar-Graván1, V. Cruz Guisado2, R. Del Pino Algarrada3, M. Martin-Martíllas1, F. Estevez-Lopez2, P. Arias-Vega1, 3. PA-HELP “Physical Activity for HAilth Promotion” research group, Department of Physical Education and Sports, Faculty of Sports Science, University of Granada, Granada, Spain; 2University of Granada, Department of Physiotherapy, Faculty of Health Sciences, Granada, Spain; 3Instituto de Investigación Sanitaria IBS.Granada, Granada, Spain; 4PROFITH “PROmoting FITness and Health through physical activity” research group, Physical Education and Sports, Faculty of Sports Science, University of Granada, Granada, Spain; 5University Hospital Virgen de las Nieves, Department of Physical Medicine and Rehabilitation, Granada, Spain; 6University Hospital Jerez de la Frontera, Department of Physical Medicine and Rehabilitation, Jerez, Spain; 7University Hospital Puerto Real, Department of Physical Medicine and Rehabilitation, Puerto Real, Spain; 8Harvard University, Harvard T.H. Chan School of Public Health, Cambridge, United States of America

Background: Osteoporotic hip fracture causes a high level of dependency in older adults, as their functional status suddenly decreases greatly. In addition, the high level of pain and the fear of falling that they frequently experience maintain this decrease in functional status for a longer period. Digital health, the promotion of health through the use of Information and Communication Technologies, emerges as an option for the rehabilitation of older adults with hip fracture.

Objectives: To test the effectiveness of the co-created ActiveHip+ mHealth system on the recovery of the functional status and the decrease of the pain and fear of falling in older adults with hip fracture.

Methods: A total of 110 older adults with hip fracture and their family caregivers were recruited from hospitals in southern Spain. Participants were randomly assigned to an intervention group (n = 55), in which rehabilitation was performed through ActiveHip+, or to a control group (n = 55), in which they received standard rehabilitation for a hip fracture from the Andalusian Public Health System. Participants were assessed during the hospital stay and 3 months after surgery. Feasibility assessment was done through adoption (participation proportion) usage (access to the app), satisfaction with the app (Net Promoter Score) and user perception of the quality of the app (Mobile App Rating Scale). Clinical assessment was conducted through patient-reported outcomes, such as the Functional Independence Measure and the New Mobility Score Spanish version for functional status, the Numerical Rating Scale for pain and the Short Falls Efficacy Scale-International for fear of falling.

Results: We obtained positive results in terms of feasibility as we observed 88% adoption, 82% usage, and satisfaction with the app and 4.3/5 in perceived quality of the app. The functional status of patients allocated to the intervention group (those using ActiveHip+) had a statistically significant greater recovery compared to participants of the control group at 3-months (medium effect size: 0.70 Cohen’s d; p = 0.02) and (medium effect size: 0.62 Cohen’s d; p = 0.03) respectively. In addition, the level of pain was statistically significant lower in participants of the intervention group than those in the control group (medium effect size: 0.49; Cohen’s d p = 0.03). Regarding the fear of falling, there was no statistically significant difference (medium effect size: 0.32 Cohen’s d; p = 0.17).

Conclusion: The ActiveHip+ mHealth system is effective in the recovery of the functional status and the decrease of pain in older adults with hip fracture. However, it was not effective on the decrease of the fear of falling.

DEFINING THE KEY ATTRIBUTES OF A CLINICIAN WITH COMPETENCE IN BONE HEALTH MANAGEMENT

Keywords: Descriptive Studies, Osteoporosis

L. Jackson1, S. Johnson2, E. Mcneeley1, K. Saag1, M. Danila1,3 1University of Alabama at Birmingham, Medicine, Birmingham, United States of America; 2University of Toronto, Medicine, Toronto, Canada; 3Birmingham VA Health Care System, Geriatric Research, Education, and Clinical Center, Birmingham, United States of America

Background: Osteoporosis and fragility fractures are managed by clinicians across a variety of specialties and there is no specific certification in osteoporosis diagnosis and management. These clinicians are an integral part of interventions aimed to improve bone health care (e.g., fracture liaison service [FLS]). Yet, the key skills and attributes of a clinician with competence in bone health management have not been established in a systematic fashion.

Objectives: We conducted a Delphi exercise and a discrete choice experiment (DCE) to generate a decision rule aiming to define the minimal attributes of a clinician best poised to assess and treat people with osteoporosis and serve as a referral source for post-fracture management.

Methods: In part 1, we used a modification of the Delphi method with two rounds. Clinicians with experience in treating osteoporosis and representatives of patient advocacy groups were purposively sampled to participate. Participants asynchronously generated a list of desirable characteristics/skills of a “clinician with competence in bone health.” Characteristics were coded and organized into non-overlapping themes or “attributes” with sub-themes or “levels” within each attribute. Participants prioritized and ranked levels in order of perceived importance for inclusion in the definition for a bone health clinician. Levels within attributes associated with the highest median scores were included in the final list of criteria. In part 2, participants ranked 20 hypothetical clinicians defined by various levels of attributes from highest to lowest likelihood of being a bone health clinician to identify the minimal threshold for defining competence in managing bone health. Consistency amongst rankings was evaluated using intraclass correlation coefficients (ICC). In part 3, we conducted a DCE to generate a weighted importance score for each independent and mutually exclusive attribute and level such that the sum of weights across the highest level within each attribute would equal 100%. The threshold for competence was the total weighted score at which >70% of participants agreed a clinician had bone health competence.

Results: Part 1 included 13 participants, and 11 completed the DCE survey. Those who completed part 1 included 3 endocrinologists, 3 rheumatologists, 1 orthopedist, 3 general internists, and 3 representatives of patient advocacy groups. The Delphi exercise generated a list of N=108 characteristics, which were coded and grouped into common themes/attributes. Through an iterative process with 2 rounds of piloting, the attribute categories were reduced to 8 broad categories with a total of 20 levels. The participants’ rankings of the relative probability that each of the 20 hypothetical clinician cases represented a clinician with adequate competence in bone health is plotted in Figure 1. The ICC for agreement across participants was 0.90 (95% confidence interval [CI]: 0.83, 0.95). The maximum possible score in the final criteria was 25. A threshold score of ≥12 classified a clinician as having adequate competence in bone health. For example, a clinician that prescribes all osteoporosis drugs, performs osteoporosis workup/treatment monitoring, and leads or participates in an FLS would receive 5, 3.5, and 3.5 points, respectively, that summed would reach the threshold.

Conclusion: We developed a numeric additive decision rule to classify clinicians across multiple specialties with competence in evaluating and treating patients with osteoporosis. Our data provides the critical definition of a “clinician with competence in bone health” that may be useful for identifying and qualifying the skill of clinicians who may be included in interventional studies or clinical activities that aim improve bone health care.

Differences in Predictors of Fractures in Patients with Severe Versus Established Osteoporosis

Keywords: Osteoporosis

U. Nadeem, Z. Sultan, M. Bukhari. 1Lancaster University, Medical School, Lancaster, United Kingdom; 2University Hospitals of Morecambe Bay NHS Foundation Trust, Rheumatology, Lancaster, United Kingdom

Background: The FRAX™ risk assessment tool is utilised to predict fracture risk in patients with poor bone health. It uses the bone mineral density (BMD) at the non-dominant femoral neck. The performance of the tool in predicting fractures with worsening BMD has not been examined.

Objectives: The aim of this study was to investigate whether different factors within the FRAX™ tool are more predictive of severe osteoporosis; defined by a T score of -3.5 and below, compared to patients with a T score of -2.5 to -3.49.

Methods: Two patient cohorts were identified from patients referred for routine DEXA scans between 2004 and 2019, in the Northwest of England. The first cohort (group A) consisted of patients with a T score between -2.5 and -3.5 and the second cohort (group B) consisted of patients with a T score of -3.5 and below. The FRAX risk factors and the BMD data were analysed, using a Student’s t test for continuous variables and a Chi Squared test for categorical variables. Univariate and multivariate logistic regression models were also fitted examining the differences in the FRAX™ risk factors and severe osteoporosis prediction. The sites measured included an average of L1-L4, right and left femoral neck in which their BMD mean and both their respective BMD totals were analysed. FRAX™ risk factors included age, weight, height, BMI, sex, previous fracture, parent fractured hip, smoking, steroid use, rheumatoid arthritis, alcohol consumption and coeliac disease/malabsorption.

Results: 31,547 patients were included in the analysis, with a mean age of 64.9 years (SD = 12.9). The number of individuals in group A were 4,714 (81.5%) and 1,067 (18.46%) in group B. Table 1 depicts the differences in the FRAX™ risk factors between the two groups and the odds ratios. Age, weight, height and current smoking were statistically significant in predicting severe osteoporosis. Lower weight, height and BMI was associated with group B. In addition, increased age and current smoking was also associated with group B. There was no significant difference between group A and B in regard to sex, previous fracture, parent fractured hip, steroid use, rheumatoid arthritis, alcohol consumption or coeliac disease/malabsorption.

Conclusion: The results of this study indicate that certain risk factors used in the FRAX™ scoring are more predictive of a severe osteoporosis than others. In addition, research providing insight into utilising FRAX™ variables in fracture prediction in patients with severe osteoporosis will provide valuable insight.

Buttgereit. 1Charité Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Berlin Institute of Health, Charité – Universitätsmedizin Berlin, Institute of Biometry and Clinical Epidemiology, Berlin, Germany; 3Bispebjerg and Frederiksberg Hospital, Section for Biostatistics and Evidence-Based Research, the Parker Institute, Copenhagen, Denmark

Methods: Rh-GIOP is a prospective observational cohort study investigating bone health in consecutive patients ≥18 years with inflammatory rheumatic diseases and current or prior GC treatment. This cross-sectional analysis assessed the baseline vis-à-vis of all patients with SLE fulfilling the EULAR/ACR 2019 SLE classification criteria. Multivariable linear regressions models were fitted to identify factors associated with bone mineral density (BMD). As a second outcome, we investigated factors associated with clinical osteoporosis (defined by either a T-Score of ≤ -2.5, anti-osteoporotic treatment and/or fragility fractures) by multivariable logistic regression analysis.

Results: Baseline data from 110 patients with SLE were analyzed. The mean age was 48.1±14.5 years, mean disease duration 16.3±9.9 years, and 41% of the cohort was identified as having osteoporosis (OP). Lupus nephritis was present in 35% of the SLE patients, of whom 55% had active nephritic disease at baseline osteoporosis screening visit. Class IV and V accounted for most nephritis cases (61%). In multivariable linear regression analysis, lupus nephritis class IV and V (reg coefficient (95%CI): -0.745 (-1.3955; -0.095)), the presence of U1-RNP antibodies (-0.750 (-1.314;1.017)), as well as C-reactive protein (CRP, -0.015 (-0.026; -0.003)) and longer disease duration (-0.037 (-0.056; -0.018)) were significantly associated with low BMD. Conversely, clinical remission (defined as SLEDAI-2K=0 and GC dosage ≤5 mg prednisone equivalent per day) was positively associated with BMD (0.447 (0.037;0.857)), as were SLE-cases on monocytosis as surrogate for Type-I interferon activity (0.558 (0.150;0.967)), BMI (0.045 (0.014;0.076)), and health assessment questionnaire (HAQ, 0.307 (0.079;0.536)). In multivariable logistic regression analysis, active lupus nephritis (OR (95%CI): 7.42 (1.256;43.868)) was strongly associated with OP in patients with SLE. Additionally, age (1.06 (1.020;1.100), HAQ (0.293 (0.120;0.682)) and complement factor 3 (1.27 (1.002;1.601)) was strongly associated with OP in patients with SLE. Neither current GC use, cumulative GC dose nor GC duration were significantly associated with BMD or clinical OP.

Conclusion: In patients with SLE, indicators of disease severity, expressed by (active) lupus nephritis, high CRP, U1-RNP antibodies, and long disease duration, are related to poor bone health in addition to commonly known risk factors.
such as low BMI and higher age. The knowledge of these disease-specific factors helps to identify patients with SLE at particular high risk for OP and fragility fractures.

SHORT-TERM (2 YEARS) FRACTURE RISK PREDICTION: A MACHINE LEARNING APPROACH

Keywords: Real-world evidence, Osteoporosis, Bone diseases

G. Adam1, M. D'ouzouz2, S. Vijayakumar3, E. Grisan4, A. Fassio1, O. Viapiana1, D. Gatti1, M. Rossini1.

Background: Osteoporotic fractures continue to be a major cause of global health concerns around the world. The most common risk scores (FRAX, DeFRA) are evaluating this risk within a 10-year time window, which might be too long to stratify the most at risk-patients or those that are showing a fast-progressing disease. This is reflected by the poor predictive performance of DeFRA when looking at a 2-years time window. Machine-learning (either logistic regression or random forest) could change the way we predict the occurrence of osteoporosis fractures in patients most likely to incur an osteoporotic fracture in the short term, thus requiring shorter follow-ups.

DETERMINANTS OF MORTALITY AND IMMUNITARY RE-FRACTURE IN PATIENTS HOSPITALIZED FOR SEVERE OSTEOPOROTIC FRACTURES

Keywords: Osteoporosis

K. Briot1, E. Lespessailles2, T. Thomas2, J. Paccou3, V. Breull4, P. Fardellone5, P. Szafirs6, P. Guggenbuhl7, C. Marcelli7, R. Chapurlat8, M. Cohen Solal1, E. Le Goude9, I. Ramos10, A. M. Background: Patients hospitalized for severe osteoporotic fractures are at increased risk of morbidity and mortality. It is recommended to improve their medical management by Fracture Liaisons Services (FLS) organization.

Objectives: Our aim was to assess the determinants of mortality and imminent re-fracture in those patients followed in FLS.

Methods: In the CROSS study a national, prospective, observational, multicenter study conducted in 12 centers with Fracture Liaison Services (FLS). Patients included were men and women above 60 years, hospitalized for a recent (less than 3 months) severe fragility fracture (hip, pelvis, humerus or vertebrae) that occurred after a low-energy trauma. Patients with either a non-severe fracture, a pathological fracture, a high trauma fracture or a per-prosthetic fracture were not included. At baseline and 2 years we have collected sociodemographic data, fracture event, bone risk factors, factors of falling, FRAX items, history of treatments, comorbidities, Charlson score and DXA measurement. To assess the risk factors for new severe fracture or death, a multivariate Cox proportional hazard multivariate analysis was performed.

Results: 895 patients were included in the cohort with the following fracture location distribution: clinical vertebrae 43.3%, hip 37.5%, pelvis 10.3%, and humerus 6.8%. 75% of the patients were women (79%) with a median age of 81 years (71-85). 40% had a previous history of fragility fracture after 40 years. Only 177 received an anti-osteoporotic treatment in the 5 years prior baseline whereas 21.4% received a calcium supplementation and 43.6% received a vitamin D supplementation. At baseline 48% of patients had densitometric osteoporosis. Over the 2 years of follow-up (data completed for 95% of population), 116 severe fractures in 110 patients (12.9%) and 80 deaths (8.9%) occurred. 49.1% of patients were prescribed an antosteoporotic treatment after the fracture (75% of bisphosphonates), that was initiated within the 3 months following fracture event in 63% of the cases. Multivariate analysis showed that reduced spinal BMD (OR=24.6 CI 95% 2.84-247, p=0.027), recurrent falls (OR= 2.80 (1.11-6.65), p=0.023), antosteoporotic treatment initiation (OR= 2.17, CI 95% 1.9-4.10, p=0.013) and increased age (OR=1.04 CI 95% 1.01-1.08, p=0.027) were significantly associated with the risk of a new severe fracture. Use of walking aids (RR=2.71 CI 95% 1.15-6.39, p=0.02), diabetes (RR=3.70 CI 95% 1.04 to 13.2), p=0.044), metastatic cancer (RR=15.5 CI 95% 1.08 to 221, p=0.043) were positively associated with risk of death whereas antosteoporotic initiation was negatively associated with this risk (OR=0.19 CI 95% 0.07 to 0.49, p<0.001).

Conclusion: In patients hospitalized for severe osteoporotic fractures and managed in a FLS setting, initiation of an antosteoporotic treatment is associated with a decreased risk of mortality. In this population, a low BMD was a strong determinant of an imminent fracture risk.

**Background:** Osteoarthritis (OA) is the leading cause of disability for bone and joint diseases. Cartilage injury is its pathological basis. There is a lack of therapeutic drugs with clear cartilage protection in clinic. Iguratimod (IGU) has cartilage protection effect in the treatment of rheumatoid arthritis, but it is not clear whether it also has cartilage protection effect on OA.

**Objectives:** To investigate the efficacy and mechanism of Iguratimod (IGU) on cartilage protection effect on knee osteoarthritis (OA).

**Methods:** Type VII collagenase was injected into the knee joint cavity of C57BL/6/N rats to establish a model of CIAO (Collagenase-induced Osteoarthritis model) to establish. The OA model wasidentified by intraartagism at 10mg/kg. μCT and Immunohistochemistry (IHC) were used to evaluate the structural changes of OA knee joint, the degree of destruction of knee cartilage layer and subchondral bone. IHC and qPCR were used to evaluated the expression of TRPV4 in chondrocytes of OA rats. Chondrocytes were processed by IGU at the cellular level, and the concentration of glycaminoglycan secreted and the expression of chondrogenic differentiation factor were measured. In cells further detected, TRPV4 ion channel inhibitor and interfering RNA technology were used to verify whether TRPV4 was involved in the effect of IGU on cartilage.

**Results:** It was found that IGU could change the pain sensitivity of OA model rats and effectively reduce the pain of OA rats. μCT showed that IGU could effectively inhibit the subchondral bone injury of knee joint in OA rats. Toluidine blue staining and Safranin O-Fast Green staining of rats knee joint also showed that IGU treatment could delay the degeneration of knee cartilage of rats with OA. At the cellular level, it was found by qPCR that IGU could effectively promote the expression of mRNA levels of Sox9 and Col2α, markers of chondrogenesis, in chondrocytes. Alcian blue staining also showed that IGU promoted chondrocyte secretion of glycosaminoglycan; Moreover, the results of scratch experiment also showed that IGU promoted the migration of chondrocytes. The results addressed above all indicated that IGU could promote the differentiation of chondrocytes. The expression of transient receptor point vanilllin 4 (TRPV4) in OA rats chondrocytes in the treatment group of IGU was increased. We used ion channel inhibitors and interfering RNA technology to show that IGU played a role in delaying cartilage degeneration, promoting cartilage differentiation and migration by regulating the function of TRPV4.

**Conclusion:** IGU can effectively alleviate the pain of OA model rats, and exert cartilage protection by regulating TRPV4. The results offer new treatment options for osteoarthritis.

**A CAUSATIVE ROLE FOR PERIARTICULAR SKELETAL MUSCLE WEAKNESS IN THE PROGRESSION OF JOINT DAMAGE AND PAIN IN OA**

**Keywords:** Pain, Cartilage, Osteoarthritis

H. A. Kim¹, H. S. Hwang¹, J. R. Kim¹,¹ Hallym University Sacred Heart Hospital, Division of Rheumatology, Internal Medicine, Anyang, Korea, Rep. of (South Korea)

**Background:** Although OA is regarded as a disease of the articular cartilage, recent research has demonstrated whole-joint pathology, including synovial inflammation, subchondral bone sclerosis, osteocyte formation, and changes in periaricular muscles that surround the affected joint. There is also increasing evidence that the consequences of knee OA are associated with decreased lower limb muscle strength and function. It is unclear whether the change in periaricular muscle is the cause or result of disease progression, however.

**Objectives:** This study investigated changes in periaricular muscle during the progression of osteoarthritis (OA), as well as the cause-and-effect relationship between muscle weakness and OA, in a mouse model of OA achieved by destabilization of the medial meniscus (DMM).

**Methods:** Knee OA was induced by DMM in 10-week-old male C57BL/6 mice. Pathological muscle phenotypes in the tibialis anterior (TA) and quadriceps muscles were assessed in both the early and late stages of OA with muscle-fiber cross-sectional area analysis, markers of myogenesis, as well as the proliferation of satellite cells. OA pathology and pain behavior were examined with OARSI grade, von Frey filament threshold and pressure algometer. Periaricular muscle weakness was induced by multiple rounds of barium chloride injections after DMM induction. In addition, myostatin knockout mice with muscle hypertrophy phenotype was used to evaluate the influence of muscle mass on pain and joint destruction after DMM.

**Results:** Morphological alterations in the TA and quadriceps in DMM mice included variations in muscle-fiber size, aberrant muscle fibrosis, inflammatory cell infiltration, and decreased muscle mass. Periaricular muscle fibers isolated from DMM mice showed reductions in cell number and myogenic capacity, as well as the proliferation of satellite cells. DMM mice exhibited exacerbated articular cartilage destruction, subchondral bone sclerosis, synovitis and pain after muscle injury compared to the DMM + vehicle group. Myostatin knockout mice were characterized by attenuated OA and the complete abrogation of pain behavior after DMM.

**Conclusion:** DMM-induced knee OA resulted in morphological changes in periaricular muscle, in a manner that coincided with muscle atrophy. Joint destruction and pain after DMM were aggravated by muscle weakness and alleviated by muscle hypertrophy. Our results suggest a causative role for muscle weakness in the progression of joint damage and pain in OA.

**Osteoarthritis Synovial Macrophages Have a Tol erized Phenotype and a Very Weak Corticosteroid Response**

**Keywords:** Osteoarthritis, Innate immunity, Cell biology

C. Wang1, R. De Francesco1,2, L. Lamers1, S. Rinzema1, S. Frölich3, P. Van Lent1, C. Logie4, M. Van den Broek1,2, Research Unit for Molecular Biology, Nijmegen, Netherlands; 2Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands; 2Radboud University, Department of Molecular Developmental Biology, Nijmegen, Netherlands

**Background:** The majority of osteoarthritis (OA) patients show synovial inflammation. Intra-articular corticosteroid injections are often given to decrease this inflammation. Whereas these provide relatively short-term alleviation of clinical symptoms, they do not improve long-term disease prognosis. Monocytes/macrophages are key cells in OA synovial inflammation. Whereas past research mainly focused on pro-inflammatory M1-like and anti-inflammatory M2-like macrophages, a second logic related to long-term macrophage polarization is interesting to study; macrophage training versus tolerization that is the result of prior exposure of monocytes/macrophages to different inflammatory cues. This process is also referred to as innate immune memory.

**Objectives:** Here, we investigated what could underlie the absence of long-term alleviation of OA by corticosteroids. Here, we compared global RNA profiles of OA synovium macrophages with well-defined in vitro trained and tolerized monocyte-derived macrophage models, all in the presence or absence of corticosteroids.

**Methods:** Macrophages were obtained from OA synovium (OA-Mf) using tissue digestion followed by CD14+ MACS isolation or differentiated from blood-derived CD14+ monocytes using mononuclear human pooled serum. Tolerance and training was induced in monocyte-derived macrophages using 5ng/mL LPS (LPS-Mf), mimicking macrophage paralysis as observed in sepsis, or 10 μg/mL β-glucan (BG-Mf), which mimics non-specific vaccination against an ulcerated lethal pathogen exposure by generating macrophages that present robust M1 responses upon TLR receptor stimulation, during the first 24 hours of differentiation respectively. Samples were treated with 1 μM tramcinolone acetonide (TA) or DMSO for 4 hours. The genome-wide transcriptomic response to corticosteroids was determined using RNA sequencing.

**Results:** TA exposure of trained BG-Mf and tolerized LPS-Mf significantly altered the expression of 201 and 257 RNA transcripts, respectively. In contrast, in OA-Mf only 12 RNA transcripts were significantly regulated, indicating a globally paralyzed TA response. Interestingly, evaluation of the IL-1, and C-C motif chemokine ligand (CCL) and CXCL clusters of chemotactic factors showed close resemblance between OA and tolerized but not trained macrophages in terms of basal expression, although only one gene in these clusters (IL36R/N) was significantly regulated by TA in the OA-Mf. This indicates that OA-Mf have a state that is related to the memory of inflammation as in the LPS-Mf for key pathways involved in OA and further confirms that the OA-Mf have a weak TA response. However, this did not extend to all genes significantly induced by LPS (n=895), since OA-Mf clustered apart from the LPS-Mf and BG-Mf, indicating a distinct global pro-inflammatory mRNA expression profile when compared with both tolerized and trained monocyte-derived macrophages. Finally, we observed that OA-Mf have a matrix-metalloproteinase (MMP) expression profile that is consistent with a macrophage phenotype, since they express MMP9, MMP14, and MMP19, but furthermore very strongly express MMP1, MMP2, MMP3, and MMP10 that are not expressed by our monocyte-derived macrophage models, highlighting their unique phenotype. Again, corticosteroid treatment of OA-Mf could not repress MMP expression.

**Conclusion:** OA synovial macrophages have an inflammatory polarization state that closely resembles the tolerized macrophage state in terms of relevant secreted cytokines and chemokines transcripts. Furthermore, they show a very weak corticosteroid response, which might explain why corticosteroid treatment fails to ameliorate long-term pathology and symptoms in OA patients.

**Lysyl Oxidase (LOX) and Lysyl Oxidase-Like 2 (LOXL2) Contribute to Cartilage Calcification During Osteoarthritis**

**Keywords:** Crystal arthritis, Osteoarthritis, Cartilage

E. Fauna1, I. Bernabei1, J. Wegzyn2, T. Hügie3, N. Busso3, S. Nasi1,1Lausanne University Hospital, Department of Musculoskeletal Medicine, Lausanne, Switzerland; 2Lausanne University Hospital, Department of Orthopedic Surgery, Lausanne, Switzerland

**Background:** Cartilage pathological calcification is a hallmark of osteoarthritis (OA), a degenerative disease characterized by articular cartilage degradation that leads to joint pain and impaired movement. We previously demonstrated that lysyl oxidiase-like enzymes (LOX(L)), which include five enzymes, LOX and LOXL1-4, that catalyse the crosslinking of collagen and elastin fibers of the extracellular matrix (ECM), play a crucial role in cartilage calcification (Bernabei et al, in preparation). Indeed, the pan-LOX(L) inhibitor BAPN decreased crystal production in chondrocytes, but the identification of the crucial LOX(L) involved in this process remained to be established.

**Objectives:** To identify the specific LOX(L) involved in cartilage calcification during OA.

**Methods:** In vitro, murine chondrocytes (primary cells or ATDC5 cells) were cultured in normal medium (NM), DMEM high glucose + 10% FBS) or calcifying medium (CM, BGJb +10% FBS + 20mM β-glycerophosphate + 50μg/ml ascorbic acid). The expression of Lox was silenced using siRNA at 100nM (siLox), OriGene. Gene expression was measured by qPCR. Calcium-containing crystals were evidenced by alizarin red staining and quantified by cetylpyridinium dissolution of crystals. In vivo, mice were subjected to meniscectomy (MNX) in the right knee or sham operated in the left. Ex vivo, cartilage explants from undamaged or damaged cartilage regions were obtained from 7 OA patients undergoing knee replacement surgery. Immunohistochemistry (IHC) was performed on murine knees and human cartilage sections ((anti-Lox or anti-LOXL2 rabbit polyclonal antibodies (Proteintech or Genetex respectively). Calcification was detected by Alizarin red staining on histological sections, and proteoglycan loss by safranin-O staining. Mouse gene expression data from primary articular chondrocytes treated with interleukin-1β (IL-1β) for 24h were obtained from GEO (identifier: GSE104793).

**Results:** Lox expression was increased in murine chondrocytes stimulated with calcification medium (CM), but not Loxl2. Similarly, transcriptome data from primary mouse articular chondrocyte treated with IL-1β, revealed that both Lox and Loxl2 were markedly upregulated in treated cells. We then evaluated Lox and Loxl2 modulation by TIC in calcified cartilage in the MNX OA model. Both Lox and Loxl2 were increased in MXN cartilage compared to sham cartilage and at an even higher extent in osteophytes and in newly formed calcified deposits appearing in MNX knees. In human OA cartilage we found massive calcification and proteoglycan loss in damaged areas compared to undamaged. In line with murine data, we revealed increased Lox and LOXL2 expression in damaged human cartilage, both in chondrocytes and in the extracellular matrix in correspondence to calcified regions. Next, we performed in vitro Lox RNA silencing using siLox or siControl RNA transfected ATDC5 cells (siLox cells or siCtrl cells). Lox expression was decreased by more than 80% in siLox cells compared to siCtrl cells. Most importantly, in CM, siLox cells calcified less as demonstrated by alizarin red quantification. Furthermore, gene expression data showed inhibition of calcification gene Annexin 5 by Lox silencing. In agreement, we found an increase of early differentiation genes Sox9 and Col2, along with significant downregulation of hypertrophic marker Col10. However, no effect by Lox silencing was found on fibrotic genes (Col1, Col3) and on pro-calcifying cytokine interleukin-6 (IL-6). Additionally, we revealed a trend towards decreased mitochondrial reactive oxygen species in siLox cells. Finally, Lox silencing decreased gene expression of ECM catalytic enzyme Mmp13.

**Conclusion:** Our data revealed that LOX and LOXL2 are increased in calcified areas of murine and human cartilage. Additionally, in vitro inhibition of Lox prevents at least in part, calcium-crystal deposition, chondrocyte hypertrophy, and Mmp13 catalytic enzyme expression. Altogether, our results suggest that both Lox and LOXL2 might play a role in cartilage calcification and OA.

SENSITIVITY OF AUTOMATED, U-NET-BASED SEGMENTATION TO LAMINART CARTILAGE TRANSVERSE RELAXATION TIME (T2) IN KNEES WITH DIFFERENCES IN CONTRALATERAL OSTEOARTHRITIS STATUS – DATA FROM THE THE OA-BIO CONSORTIUM

Keywords: Imaging, Osteoarthritis

F. Eckstein1,2, A. Wisser1,2, F. Roemer3,4, F. Berenbaum5,6, J. Kemnitz1,2, G. Duda, S. Maschek, W. Wirth1,2. Chondrometrics Gmbh, Department of Research, Freilassing, Germany; 2Paracelsus Medical University, Institute of Anatomy & Cell Biology, Salzburg, Austria; 3University of Erlangen, Department of Radiology, Erlangen, Germany; 4Boston University Minos Core Lab, Boston, United States of America; 4Moving Biotech, Department of Research, Lille, France; 5Baronne University INSERM, AP-HP Saint-Antoine Hospital Paris, Paris, France; 1BIH at Charite, Universitätsmedizin Berlin, Berlin, Germany

Background: Radiographically normal knees with contralateral (CL) radiographic joint space narrowing (JSN) are at elevated risk of incident radiographic osteoarthritis (ROA). We previously observed increased superficial femoral cartilage layer transverse relaxation time (T2) on magnetic resonance images (MRI) of 39 KLG0 knees (n=39) with advanced ROA in the contralateral knee (CL JSN), compared with 39 (1:1-matched) KLG0 knees without evidence of CL ROA (bilat KLG0) [1]. These results suggest that cartilage matrix degeneration occurs in radiographically normal knees with CL JSN, and can be detected in vivo using MRI [1]. Application to larger cohorts, however, will benefit from fully automated image segmentation, as manual segmentation is a labor-intensive process.

Objectives: To evaluate the performance of U-Net-based segmentation, using an artificial intelligence (AI), i.e. convolutional neuronal network (CNN) approach, combined with fully automated detection of bony landmarks and the specific MRI slices requiring cartilage segmentation. The U-Net results were compared with those from manual segmentation, and the fully automated technology was applied to a larger (extended) control group.

Methods: U-Nets were trained from manual, quality-controlled cartilage segmentations in sagittal MESE images of the Osteoarthritis Initiative healthy reference cohort (n=92; HRC), one on the medial (MFTC) and one on the lateral femoral compartment (LFTC). All 7 echos (10-70 ms) were used. A 3rd U-Net was trained from manual, quality-controlled bone segmentations in 60 OA HRC knees. The latter was used for automated detection of the weight-bearing femoral region of interest. The automated bone segmentation was registered to an atlas comprising both bone and cartilage segmentation, for identifying the slices required for cartilage segmentation. Automated post-processing was employed to correct obvious segmentation errors. This pipeline was first applied to n=39 data-set pairs (KLG0 with CL JSN vs. bilateral KLG0 knees) [1]. Then it was applied to n=642 bilateral KLG0 knees, to extend the limited paired case-control design [1]. Then it was applied to n=642 bilateral KLG0 knees, to extend the limited paired case-control design [1]. The automatic bone segmentation was registered to an

SOLUBLE LOW AFFINITY NERVE GROWTH FACTOR RECEPTOR (LNGFR) MAY REGULATE PAIN IN KNEE OSTEOARTHRITIS

Keywords: Pain, Osteoarthritis, Biomarkers

A. Alfaili1,2, M. Campbell3,4,5, R. Doyle6, H. Owston1, E. Jones1, R. Feibel2, S. Westbrook2, D. Mognagole1, 1University of Leeds, Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds, United Kingdom; 2NIHR, Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; 3Elisabeth Bruyere Hospital, Department of Physical Medicine and Rehabilitation, Ottawa, Canada; Ottawa Hospital Research Institute, Bone and Joint Lab, Ottawa, Canada; 4Ottawa Hospital Research Institute, Ottawa, Canada; 5Levict Ltd, Levict Ltd Kent, United Kingdom; 6The Ottawa Hospital, The Ottawa Hospital, Ottawa, Canada

Background: Osteoarthritis (OA) is a disease of the entire joint. OA causes significant pain that has been linked to increased neurotrophin concentrations, including mature nerve growth factor [β-NGF]. β-NGF antagonism was efficacious in reducing OA pain in clinical trials but was associated with rapid progressive OA[1], hampering mainstream delivery of this treatment. β-NGF binds two high-affinity receptor kinases: TrkA and low-affinity NGF receptor (LNGFR). A tumour necrosis factor receptor (TNFR) superfamily member. Given that TNFR superfamily member shedding regulates inflammation and immunity, soluble LNGFR (sLNGFR) shedding might be important in pain regulation[3] and association between these molecules and OA-related knee pain may point to an alternative, less harmful approach to β-NGF antagonism and pain reduction.

Objectives: Therefore, we investigated the association between sLNGFR and OA-related knee pain. Key cytokines involved in TNFR family receptor shedding were also investigated.

Methods: SF was procured from 42 subjects with severe OA at the time of arthroplasty. VAS pain scores were recorded pre-operatively. In-house developed ELISAs, commercial ELISAs and LEGENDplex™ were used to measure sLNGFR, proNGF and NGF and other relevant neurotrophins with OA-related knee pain. Key cytokines involved in TNFR family receptor shedding were also investigated.

Results: VAS pain score positively correlated with β-NGF (r=0.34, p<0.05) and TrkA (r=0.33, p<0.05, r=0.32, p>0.05). There was a positive association trend with NT-3 and BDNF with a negative trend for ProNGF. There was no correlation between pain and the other neurotrophins and cytokines including TNF-α, IL-6, SAs, commercial ELISAs and LEGENDplex™.

Background: Mesenchymal stem cells (MSCs) have gained much attention for their potential to treat osteoarthritis (OA) due to their regenerative and immu

Objective: In this study we investigated disease modifying effects of integrin α10β1-selected equine MSCs ( integrin α10-MSCs) in the equine osteoarthritis (OA) model[1], and that integrin α10β1-selected human MSCs could to home to exper-

Methods: This was a non-randomized and partially blinded experimental study including 17 Standardbred trotters. OA was induced using the carpal osteochon-

Results: A significant improvement of lameness scores (p=0.02) and response to flexion (p=0.004) over time was observed in the treatment group, while the untreated group had no change in lameness and a smaller decrease in flexion response (p=0.03). No joint flares were seen after MSC treatment. The integrin α10-MSCs treated horses had significantly less macroscopic cartilage pathology (p=0.019), lower cartilage histology score (p=0.037) and showed a better but not statistically significant (p=0.069) healing of the osteochondral fragment on CT. Protein levels of IL-6 (PGE2) and interleukin-1α (IL-1α) were significantly increased in the synovial fluid of the treated group on day 21 (p=0.018 and p=0.035, resp) and on day 28 (p=0.060 and p=0.042, resp) compared to day 18. Interleu-

Conclusion: Intrarticular injection of integrin α10-MSCs is safe, alleviates the development of pathological changes in the joint and improves joint function in an equine post-traumatic OA model. In addition, integrin α10-MSCs were still present in the joint 52 days after treatment. This suggests that that integrin α10-

INCREASE OF CARTILAGE REGENERATION BY IFN-γ IN CARTILAGE INJURY MOUSE MODEL

Keywords: Cartilage

H.A. Kim1, J. R. Kim2, 1Hallym University Sacred Heart Hospital, Internal Medicine, Anyang, Korea, Rep. of (South Korea)

Background: Until now, there was no effective cure for cartilage injury and degeneration commonly occurring in joint injury and OA. The efficiency of car-

Methods: Young (3 week-old) and adult mice (9 week-old) were subjected to FTCI and cartilage was harvested at 3, 7, and 14 days after FTCI. Cartilage regeneration was evaluated with safranin O staining and immunohistochemistry. For discovery of novel genes associated with cartilage regeneration, RNA-seq analysis was performed. For differentiation into chondrocytes, ATDC5 cells were monolayer and 3D cultured in DMEM containing insulin-transferrin-selenium (ITS) for 7 and 14 days. Chondrocyte specific IFN-γ receptor 1 knock out mice were created to examine the influence of IFN signaling in cartilage repair.

Results: Cartilage regeneration significantly increased in damaged region of FTCI in young mice compared with that of adult mice at 7 and 14 days. Gene expression profiles of cartilage from young and adult mice of 3 day (damaged stage) and 14 day (repair stage) after FTCI were examined by RNA-seq analysis. A total of 1115 (448 up- and 667 down-regulated) and 2294 (726 up- and 1568 down-regulated) differentially expressed genes (DEGs) were identified in young mice compared with adult mice at 3 and 14 days after FTCI, respectively. Gene ontology (GO) analysis revealed that genes responsible for interferon gamma (IFN-γ) and innate immune response, and cell proliferation, cell-substrate adhe-

Background: Using albino rats, we characterized the expression of IFN-γ and its receptor 1 (IFN-γR1) in young and adult mice. We observed a significant increase in IFN-γ and IFN-γR1 in young mice compared to adult mice. We also observed a significant difference in the expression of IFN-γ and IFN-γR1 in young and adult mice. Our results suggest that IFN-γ and IFN-γR1 play an important role in the regeneration of cartilage after injury.

Conclusion: Aging is a major risk factor of many major human diseases, including Osteoarthritis (OA). Compromised autophagy, a hallmark of aging, is involved in joint aging and OA and its activation protects against joint damage and disease. However, targets underlying this defective mechanism are still unknown.

Objectives: Here, we aimed to identify targets regulating autophagy with potential clinical relevance in joint aging and OA.

Methods: We performed a quantitative proteomic analysis of defective autophagy by Atg5 knockdown in human OA chondrocytes by using iTRAQ (isobaric tags for relative and absolute quantitation) labeling coupled LC/MS/MS. Protein identification and quantification were performed using Protein Pilot Software v 4.0. Each MS/MS spectrum was searched in the Uniprot/Swissprot database for Homo sapiens. Human cartilage and chondrocytes from healthy, aging and OA subjects were employed to investigate the role of Lamin A/C in aging and disease by western blot, and immunohistochemistry. To test the relevance of Lamin A/C accumulation in joint tissues, a mutant mice model of accelerated aging by genetic deletion of Zinc Metalloproteinase STE24 (Zmpste24-/-) was employed. The functional consequences of Lamin A/C accumulation on macroautophagy, inflammation, and senescence were determined in human chondrocytes. To evaluate the therapeutic effect of regulating Lamin A/C in human chondrocytes, Lonafarnib, an FDA approved drug for Progeria Syndrome, acting as Lamin A/C accumulation inhibitor, was employed.

Results: 24 out of 487 proteins were significantly altered (p<0.05) in response to defective autophagy. Osteoskeleton organization, collagen catabolism, oxidative stress, and aging pathways were affected. Interestingly, Lamin A/C, a nuclear envelope protein implicated in cell senescence and aging, was found upregulated under defective autophagy. Increased Lamin A/C expression was found in human chondrocytes with reduced macroautophagy. Furthermore, increased Lamin A/C expression is found in aging and OA human cartilage. Importantly, Zmpste24 KO mice showed bone damage and intervertebral disc degeneration (IDD), suggesting that Lamin A/C accumulation associated to deficient autophagy is correlated with aging and OA phenotype. Human chondrocyte premature aging by genetic knockdown of Zmpste24, lead to Lamin A/C accumulation, accompanied by a reduction of macroautophagy by MAP1LC3B downregulation, increased inflammation, cartilage degradation and senescence represented by upregulation of NFκB/RELA, MMP13, CDKN1A and CDKN1A respectively, Remarkably, inhibition of Lamin A/C accumulation by Lonafarnib upregulates macroautophagy and protects against inflammation, cartilage degradation and chondrocyte senescence.

Conclusion: The results suggest that increased LMNA due to autophagy defects compromises chondrocyte homeostasis and joint integrity, potentially contributing to systemic maladaptation that occurs in aging. Therefore, targeting Lamin A/C might be a promising strategy to develop novel therapeutics for cartilage aging and OA.

IMPLICATION OF GLYPICANS AND NOTUM IN BONE MARROW MESENCHYAL STROMAL CELLS DURING OSTEOGENIC DIFFERENTIATION IN OSTEARTHROITIC DISEASE

Keywords: Bone diseases, Cell biology, Osteoarthritis

DOI: 10.1136/annrheumdis-2023-eular.5964
Background: Osteoarthritis (OA) is accompanied by an excessive formation of underlying bone caused by homeostatic alterations. It has been described that in OA joints there is an up-regulation of the WNT/β-catenine pathway driving to the differentiation of Mesenchymal Stromal Cells (MSCs) into osteocytes [1]. Glypicans 1-6 act as co-receptors of WNT pathway, improving interactions between molecules [2]. On the other hand, NOTUM plays a role as a negative regulator of the pathway preventing WNT binding to its receptors and favouring the soluble form of Glypicans [3]. All these evidences lead us to think about the importance of Glypicans 1-6 and NOTUM in the osteogenic differentiation of MSCs in OA disease.

Objectives: To determine the differences at gene and protein levels of Glypicans 1-6 and NOTUM in MSCs between OA patients and controls at baseline and during induced in vitro osteogenic differentiation.

Methods: Bone Marrow Mesenchymal Stromal Cells (BM-MSCs) from both, 8 OA patients and 8 healthy donors were isolated from BM samples. BM samples were obtained by joint replacement and traumatic fractures. BM-MSCs were cultured during 21 days with normal culture medium and with osteogenic inducing medium. Cells and supernatant were recovered at 1, 7, 14 and 21 days. Protein levels were determined by ELISA in cells supernatant. Extraction and purification of RNA from cells and cDNA synthesis were performed. Glypicans 1-6 and NOTUM gene expression was analysed by qPCR and normalized with house-keeping genes β-actin and RNA18S. The data were calculated with the method of fold change (2^-ΔCt). Statical analysis were performed with GraphPad Prism 8.0. For the detection of outliers, the ROUT method (Q=1%) was used. Data were analyzed using t-test.

Results: The mRNA levels of cells with normal culture medium were up-regulated in GPC6 (t=7d; p=0.016) in OA patients. During osteogenic differentiation, was observed a statistically significant up-regulation in levels of OA patients vs controls of GPC2 (t=14d; p=0.034), GPC4 (t=14d; p=0.025; t=21d, p=0.017), GPC5 (t=14d; p=0.007), GPC6 (t=14d; p=0.013) and NOTUM (t=14d; p=0.009) and down-regulation of GPC3 (t=7d, p=0.034). In addition, protein levels of NOTUM were lower compared to the control group in OA BM-MSCs (t=1d, p=0.049) and in the differentiation to osteocytes (t=1d, p=0.049; t=7d; p=0.043; t=14d; p=0.016). GPC2 levels were higher in OA patients in all the times and in the two conditions (p < 0.0001). In the differentiation, GPC2 were lower (t=7d, p< 0.0001), GPC1, GPC4 and GPC6 were not present in any case.

Conclusion: Our results evidence a dysregulation in the glypicans in BM-MSCs of OA patients and, specially, during osteogenic differentiation. NOTUM, extracellular negative regulator of the WNT/β-catenine signaling pathway, is decreased at protein level in OA patients, despite the fact that gene expression is elevated. Thus, our data confirm the differences in expression in NOTUM and Glypicans between OA patients and healthy controls. Further studies are needed proposing these molecules, specially NOTUM, as an effective treatment of the disease.

A BIOPSYCHOSENSUAL APPROACH TO PHENOTYPE KNEE OSTEOARTHRITIS PATIENTS WAITING TOTAL KNEE ARTHROPLASTY: A CROSS-SECTIONAL STUDY

Keywords: Pain, Osteoarthritis

S. Verrucais1,2, L. Meen1,2, G. Van der Nest1, J. Verbruggen1,2, P. Verdonk1, F. Rahussen1, R. Smeets1,3, M. Meeus4,10. 1University of Antwerp, Rehabilitation Sciences and Physiotherapy, Antwerp, Belgium; 2Maastricht University, Rehabilitation Sciences, Maastricht, Netherlands; 3Pain in Motion, www.paininmotion.be, Antwerp, Belgium; 4Maastricht University, Methodology & Statistics, Maastricht, Netherlands; 5University of Hasselt, Rehabilitation Research Centre, Hasselt, Belgium; 6AZ Monica, Orthoca, Antwerp, Belgium; 8Antwerp University, ASTARC Department, Antwerp, Belgium; 9St. Jans Gasthuis Weer, Department of Orthopaedics, Weert, Netherlands; 2CIR Revalidatie, CIR Revalidatie, Eindhoven, Netherlands; 10Ghent University, Rehabilitation Sciences and Physiotherapy, Ghent, Netherlands

Background: Knee osteoarthritis (KOA) is a heterogenous disease, meaning individuals can present with various signs and symptoms related to different biopsychosocial (BPS) factors [1,2]. Several phenotypes can as such be expected. Phenotyping KOA patients, specifically those awaiting total knee arthroplasty (TKA), could be relevant, because a substantial part of patients (20%) reports chronic post-TKA pain [3]. Various preoperative phenotypic factors related to domains of the BPS model have been described, but consensus and a classification of patients based on these factors is still lacking [4-7].

Objectives: The aim of this exploratory study is to identify phenotypes based on BPS related factors in KOA patients awaiting TKA.

Methods: Participants were included if they were diagnosed with KOA and waiting for TKA surgery in one of the four participating hospitals in Belgium and the Netherlands. A cross-sectional latent profile analysis was conducted in MPlus [8] containing the grade of KOA before TKA surgery (structural variable); body mass index and glycated hemoglobin value (metabolic variables); isometric strength of m. Quadriceps and m. Hamstrings of the affected leg, proprioceptive accuracy of the affected leg, and physical function (functional variables); pain intensity scores and symptoms related to altered somatosensory processing (pain-related variables); pain catastrophizing, depression, anxiety symptoms, expectations and satisfaction (psychological variables); and work and education level (social variables). Data were checked for multicollinearity and multivariate outliers. The ideal model was chosen based on qualitative evaluation, goodness of fit and classification uncertainty.

Results: 224 participants were included of which 109 women (65.19 +/- 8.18 years old) and 108 men (66.92 +/- 7.18 years old). A model with 2 phenotypes was found to be most appropriate. Both phenotypes differed in 13 out of 19 continuous variables. Phenotype 1 (72% of all participants) was characterized by scoring better on at least one of all metabolic, functional, psychological and pain-related continuous variables compared to phenotype 2 (28% of all participants), except for glycated hemoglobin value, proprioception, expectations, and widespread temporal summation and conditioned pain modulation (part of somatosensory processing variables). Concerning categorical variables, phenotype 1 (72%) was characterized by having a lower probability to have a Kellgren & Lawrence (K&L) scale 2 compared with patients in phenotype 2 (28%). The probabilities of the other categorical variables did not differ between the two phenotypes. Conclusion: A model with 2 phenotypes in KOA patients awaiting TKA appeared the most appropriate, which confirmed the existence of a group that experiences disturbed somatosensory processing signs in combination with worse results on psychological (pain catastrophizing, fear and depression), functional (strength and physical function), structural (higher possibility to have a K&L grade 2 compared to the other phenotype) and metabolic factors (body mass index), and a group that does not present this disruption in combination with better results on the aforementioned BPS factors. Further research is necessary and should also investigate if different phenotypes react differently regarding treatment outcome after TKA.

Background: Nucleosomes, the basic structural unit of chromatin, are composed of DNA wrapped around an octameric core of histone proteins. The latter is usually comprised by canonical histones H2A, H2B, H3 and H4[1]. These can be replaced by histone variants, which provide structural and functional changes to the nucleosome[2]. Histones are prone to undergo post-translational modifications (PTMs) that can modify chromatin conformation to induce changes in gene expression[3]. Recent evidence supports that epigenetic mechanisms, such as DNA methylation and non-coding RNA modifications, are involved in the pathogenesis of osteoarthritis (OA). Nevertheless, histone modifications mainly remain an unexplored epigenetic mechanism in OA.

Objectives: The aim of the present study was to identify, characterize and compare the histone profile in human articular cartilage samples from normal (N) and OA patients to provide novel insights into the role of histones in the development of OA.

Methods: Histones were extracted from 3 N and 3 OA cartilage samples following a protocol based on acid extraction previously described by our group. Prior to mass spectrometry (MS) analysis, samples were reduced with dithiothreitol and alkylated with iodoacetamide. After an overnight digestion with trypsin, peptides were desalted via StageTips. Samples were injected on a nanoElute LC coupled to a high-resolution timsTOF (Bruker). Peptides were analyzed in DDA tides were desalted via StageTips. Samples were injected on a nanoElute LC coupled to a high-resolution timsTOF (Bruker). Peptides were analyzed in DDA

Results: Our histone extraction protocol successfully enriched the samples for subsequent MS analysis. The most detected PTMs are among the most studied, including methylation, acetylation, ubiquitination, phosphorylation, deamidation, biotinylation, citrullination, and ADP-ribosylation. PTMs were found in core histones H2A, H2B, H3, H4 and linker histone H1. Moreover, PTMs were detected in some of their variants. Strikingly, we found that the histone variant H3.3 is significantly increased in OA cartilage compared to N cartilage (2.67×104 ± 9.56×103 vs. 3.11×103 ± 1.71×103) (Figure 1 A). Further H3.3 analysis showed three differentially abundant PTMs between OA and N (Figure 1 B). Acetylation of lysine 18 (K18ac) was more abundant in N cartilage. Monomethylation of K79 (K79me1) was more abundant in OA cartilage. Furthermore, we identified three H3.3-associated PTMs that are differentially expressed in OA and N cartilage. These data provide new insights into the epigenetic landscape of OA and could contribute to the search for novel therapeutic targets to treat the disease.

Conclusion: The histone variant H3.3, which associates with decondensed states of chromatin and transcriptionally active sites, is upregulated in human OA cartilage. Furthermore, we identified three H3.3-associated PTMs that are differentially expressed in OA and N cartilage. These data provide new insights into the epigenetic landscape of OA and could contribute to the search for novel therapeutic targets to treat the disease.
osteoarthritis (OA) is mainly developed in weight bearing or overused joints, the locally sustained therapy using nanoparticles is effective for targeting inflammatory component of OA.

Objectives: This study aimed to investigate the effects of intra-articular injection of rebamipide loaded MSNs in OA rat model.

Methods: We modified the surface of MSNs using tannic acid and anchor the stigmasterol that allow the sustained release of stigmasterol from nanoparticles. In vitro, lipopolysaccharide induced RAW cell were used to investigate the cytotoxicity and anti-inflammatory effect of stigmasterol-loaded MSNs. In vivo, monosodium iodoacetate (MIA)-induced OA rats were divided into five groups, consisting of healthy control rats and rats injected with MIA alone or in combination with MSNs, stigmasterol (10 µg)/MSNs, stigmasterol (50 µg)/MSNs. The levels of IL-6, matrix metalloproteinase-3 (MMP-3), and tumor necrosis factor-α (TNF-α) measured periodically and the micro-computed tomography (CT) and histological examination was performed at eight week.

Results: In vitro, stigmasterol/MSNs dose-dependently suppressed the levels of pro-inflammatory mediators, including IL-6, MMP-3 and TNF-α. In vivo, the levels of pro-inflammatory components most markedly decreased in the intra-articularly injected stigmasterol (50 µg)/MSNs group compared to other groups. Micro-CT images and histological evaluations showed that the intra-articular injection of stigmasterol/MSNs also inhibited cartilage degeneration dose-dependently.

Conclusion: Using a chemically induced rat model of OA, intra-articular delivery of stigmasterol was associated with decreased local and systemic inflammatory response decreased joint degradation and arthritic progression.

ASSOCIATIONS BETWEEN BONE MARROW ADIPOCYTE SIZE, BONE REMODELLING AND BODY MASS INDEX IN PATIENTS WITH BASE OF THE THUMB OSTEOARTHRITIS

Keywords: Bone diseases, Osteoarthritis, Descriptive studies

M. Maniglio1, L. Loisy2, T. Hugel1, J. Geurtz3. 1Lausanne University Hospital, Plastic and Hand Surgery; Lausanne, Switzerland; 2Lausanne University Hospital, Rheumatology, Lausanne, Switzerland

Background: Subchondral bone sclerosis, osteophyte formation and bone marrow lesions are radiographic hallmarks of base of the thumb osteoarthritis (CMC-1 OA)[1]. High body mass index (BMI) and obesity are major risk factors for CMC-1 OA [2]. Adipose tissue-derived systemic factors, such as lipids and adipokines, have been proposed as mediators of such increased risk at a non-weight-bearing joint. In support of this hypothesis, alterations in systemic lipid levels have been found to partially associate with the severity of hand OA [3]. If several studies demonstrate a higher prevalence of chronic pain in the female OA population[3,4] and sex differences that can give rise to distinct pain mechanisms in male and female rodents with OA[5].

Objectives: We aim to define the translational value of a murine model of surgically-induced OA with meniscal/ligamentous injury (MLI), in terms of the progressive nature of joint degeneration, temporal delay in development of chronic pain following joint damage and potential sex differences.

Methods: Model: OA was induced in 10-week-old C57BL/6J mice under isoflurane anaesthesia with resection of the medial collateral ligament (MCL), meniscotibial ligament and removal of the medial meniscus. Behaviour: Sensory thresholds were assessed using the up-down von Frey, hindlimb capacitance, Hargreaves' hotplate and dry ice tests. Affective behaviours were measured using hotplate and open field assay. In vivo electrophysiology: Extracellular recordings of L4 dorsal horn neurones was performed in anaesthetised mice. Mechanically and thermally evoked action potentials were quantified. MicroCT: Bone mineral density was measured using the growth plate and bone growth. Images were used for microarchitecture analysis to determine 3D geometric parameters. Histological OA scoring and immunohistochemistry: Coronal sequential paraffin sections were stained with Safranin-O for OA severity scoring using the Osteoarthritis Research Society International grading system. Additional knee sections were stained for neo-innervation using anti-PGP9.5. RNAseq: RNA was extracted from L3-L5 ipsilateral DRGs and differentially expressed transcripts generated by GeneWiz.

Results: We observed progressive development of persistent mechanical and cold hypersensitivity in MLI mice compared to Sham controls. We also observed contralateral hypersensitivity, indicative of nociceplastic pain. Female mice expressed an earlier onset and greater extent of hypersensitivity compared to male mice. The temporal delay in the expression of hindlimb hypersensitivity correlates with a loss of cartilage integrity measured by OARSI scoring of the knee joint in both males and females. Affective behaviours are also correlated with changes in sensory thresholds, indicating emotional processing of nociceptive inputs form the injured knee. We observed greater PGP9.5 staining in female MLI mice and key transcriptional changes in DRG neurons.

Conclusion: Our data demonstrates that the MLI model reproduces clinical features of nociceplastic pain and cartilage loss in OA. We identify structural changes in the knee joint that correlate with pain behaviour, as well as sex differences in knee innervation, transcriptomic profiles of primary sensory neurons and pain behaviour that is exacerbated in female mice, informing on sex specific pain mechanisms. This establishes the use of MLI surgery as a clinically relevant mouse model for OA pain.

is unknown whether subchondral marrow adipose tissue contributes to development and progression of CMC-1 OA.

Objectives: To determine whether bone marrow adipocyte (BMAd) size, as a surrogate marker of adipocyte lipolysis and (dys)function, differed as a function of the extent of subchondral bone remodelling and BMI in CMC-1 OA.

Methods: Trapeziun bone resections were harvested from 14 consecutive CMC-1 OA patients (9 female, 63±11 years, 26±6 kg/m²) undergoing arthroplasty. BMAd size, osteoblast numbers and OA severity were determined by histomorphometry. Expression of the lipolytic enzyme monoacylglycerol lipase (MGLL) on bone marrow-resident cells was assessed by immunohistochemistry.

Results: Eight out of fourteen specimens displayed regions of increased bone remodelling and osteoblast numbers, which were classified by histology as subchondral sclerosis (n=6) and central osteophyte formation (n=2). BMAd size was significantly reduced (p<0.02) in the remodelling (839±319 μm²) compared with non-remodelling regions (1438±578 μm²), independent of OA severity. BMAd size was strongly expressed by osteoblasts and blood vessels rather than mature BMAd in remodelling regions.

Conclusion: Collectively, these data suggest that BMAd properties in the CMC-1 joint may be BMI-dependent. Increased lipolytic activity in subchondral bone marrow adipose tissue may be fueling pathologic bone formation in CMC-1 OA.

POSO415 ADIPOCYTE-OSTEOBLAST CROSSTALK IN SUBCHONDRAL BONE MARROW: NEW THERAPEUTIC TARGET IN OSTEOARTHRITIS

Keywords: Bone diseases, Biomarkers, Osteoarthritis

L. Loisay1, A. Antoniadis2, T. Hügle1, J. Gauthier1 1Lausanne University Hospital, Rheumatology, Lausanne, Switzerland; 2Lausanne University Hospital, Orthopaedics and Traumatology, Lausanne, Switzerland

Background: Subchondral sclerosis and bone marrow adipose tissue (BMAT) lesions are radiographic hallmarks of knee osteoarthritis (OA). Energy supply through lipolysis of bone marrow adipocytes (BMAd) has recently been established as a crucial mechanism to fuel bone regeneration and maintain bone mass during energy deficits. It is unknown whether subchondral BMAd may contribute to subchondral sclerosis in OA through a similar mechanism.

Objectives: The goal of this study was to determine whether BMAd-derived factors differed as a function of the extent of subchondral sclerosis and to evaluate effects of lipolysis-modulating treatments in a human knee OA explant model.

Methods: Non-sclerotic (NS) and sclerotic (SC) osteochondral tissue chips (n=48 each) were explanted from tibial plateaus and treated with an activator (forskolin) or inhibitor (pioglitazone, metformin) of lipolysis. Secreted free fatty acids (FFA), triglycerides (TGL), adiponectin, IL-6 and ALP activity were measured in supernatants.

Results: Adiponectin (1.6-fold), TGL (1.7-fold) and ALP activity (6.7-fold) levels were increased in SC compared with donor-matched NS tissues (p<0.05). Interestingly, FFA (r=0.60) and adiponectin (r=0.76) were positively correlated with ALP activity (p<0.01) in SC tissues only (Figure 1). Modulation of lipolysis affected secretion of FFA and TGL (p<0.01), but not adiponectin, in NS tissues only. ALP activity remained unaffected by any treatment in NS or SC tissues. Metformin treatment reduced IL-6 secretion 4-fold (p<0.05) in SC tissues.

Conclusion: Collectively these data support the new paradigm that BMAd-derived factors may play a previously unrecognized role in regulating pathological bone remodelling in human OA.
Medicine and Rheumatology, Zurich, Switzerland; Balgrist University Hospital, Department of Radiology, Zurich, Switzerland; Balgrist University Hospital, Department of Orthopaedics, Zurich, Switzerland; University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland; University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland.

Background: Modic changes (MC) are painful vertebral bone marrow lesions and are often found in patients with chronic low back pain. The adjacent degenerative disc (IVD) seems to play an important role: the rapidly degenerating disc stands in an inflammatory cross-talk with the MC bone marrow and MC develop almost always simultaneously cranial and caudal to a degenerated IVDs. Few studies have investigated expression of inflammatory cytokines and proteases expressed by IVD cells adjacent to MC, however, how this affects the ECM degeneration has not been determined.

Objectives: The aim of this study was to identify MC-specific mechanisms in degenerated discs. We hypothesize that the ‘Modic discs’ have a distinct disc matrix degradation.

Methods: Degenerated lumbar IVDs from MC1 (n=26), MC2 (n=20) and non-MC (n=19) levels from gender and age matched patients undergoing spinal fusion surgery were collected. Degradation was measured with N-terminal amino isoelectric focusing, mass-spectrometry (LC-MS/MS), TAILS allows to identify degraded proteins by detecting de novo N-terminal peptides. Sequence motifs were calculated using TwoSample Logo web application to identify significantly enriched amino acids around the cleavage site of the top 50 upregulated peptides. Since proteases have preferences for amino acid sequences, different sequence motifs can indicate activity of different proteases. Proteases were matched to cleavage sites of the top 50 enriched MC1 and MC2 peptides using TopFINDer database.

Results: Mean degree of disc degeneration as measured by Pfirrmann grade was not significantly different between all groups (MC1: 3.8 ± 0.9, MC2: 4.2 ± 0.6, non-MC: 3.6 ± 0.8). A total of 487 (MC1), 419 (MC2), and 404 (non-MC) different protein fragments were detected of which 21.0%, 12.2% and 9.4% were unique to MC1, MC2, and non-MC, respectively (Figure 1a). Comparing MC1 to non-MC discs, the degradation was more complex with a variety of ECM fragments enriched (e.g. type II collagen, fibroblast), while fragments of type I collagen, clusterin, and fibronectin were depleted (Figure 1b). In MC2 discs, mainly fibronectin and clusterin were enriched, while type I collagen was depleted (Figure 1b). Sequence motifs show unique cleavage preferences for each group (Figure 1c) indicating activity of different proteases. Proteases were matched to cleavage sites of the top 50 enriched MC1 and MC2 peptides using TopFINDer database. Finally, in MC1 TopFINDer uniquely identifies multiple fragments created by MMP2, MMP7, MMP12, MMP13 or cathepsin B.

Conclusion: MC1, MC2 and non-MC discs have different ECM degradations that may be caused by the activity of different proteases. Differences in disc degeneration mechanisms and in the type and amount of bioactive ECM fragments explain why not all degenerating discs lead to adjacent MCs.

ACTIVATED NEUTROPHILS DEGRADE CARTILAGE ENDPATES

Keywords: Cartilage, -omics, Innate immunity

L. Heggl1, M. Habib2, J. Scheer3, N. Herger1, T. Mengis1, C. Laux1, F. Wanivenhaus1, J. M. Spring1, M. Betz4, M. Fanshadj, O. Distler1, A. Fields2, S. Dudi1. 1University of Zurich, Center of Experimental Rheumatology, Balgrist Campus, University Hospital Zurich and Balgrist University Hospital, University of Zurich, Switzerland; Zurich, Switzerland; 2University of California San Francisco, San Francisco, CA, USA, San Francisco, United States of America; 3University of California San Francisco, Department of Neurological Surgery, University of California San Francisco, San Francisco, CA, USA, San Francisco, United States of America; 4University of Zurich, Department of Orthopedics, Balgrist University Hospital, University of Zurich, Switzerland, Zurich, Switzerland.

Background: Modic type 1 changes (MC1) are painful vertebral bone marrow lesions often found in patients with chronic low back pain. Damage of the endplate associates with MC1, is a risk factor for MC1 progression, and associates with pain. Recent evidence suggests a role of MC bone marrow neutrophils in endplate damage.

Objectives: The aim of this study was to show that MC1 bone marrow neutrophils are activated and to show that activated blood neutrophils degrade cartilage endplates (CEPs).

Methods: From MC1 patients undergoing lumbar spinal fusion, MC1 and intra-patient control bone marrow neutrophils (CD45+CD68+) were isolated from bone marrow aspirates by cell sorting. Bulk RNA sequencing was performed (n = 5 + 5), differentially expressed genes (DEGs) were identified, and enrichment analysis was performed. In addition, neutrophil activation was assessed by CD66b expression by flow cytometry (n = 3 ± 3). To assess the effect of activated neutrophils on CEP degradation, a neutrophil-mediated CEP damage model was established. Blood neutrophils were isolated from one donor and exposed to lumbar CEPs. A lumbar CEP was collected from six patients undergoing spinal fusion. From each CEP three punch biopsies (a=4-mm) were taken and halved. The six CEP biopsy halves per patient (1A,1B, 2A, 2B, 3A, 3B) were exposed for 18 h at 3° C to: A) 0.75 U/ml collagenase P (positive control) and B) Hanks balanced salt solution (negative control); 2A) conditioned medium from 25 mio/ml activated neutrophils (100 nM PMA, 3h, 37 °C) and 2B) conditioned medium from 25 mio/ml non-activated neutrophils; 3A) conditioned medium from 12.5 mio/ml activated neutrophils (100 nM PMA, 3h, 37 °C) and 3B) conditioned medium from 12.5 mio/ml non-activated neutrophils. Exposure supernatant and CEP tissues were assayed for sulphated glycosaminoglycans (sGAG) and hydroxyproline (as measure for total collagen). Release of sGAG and hydroxyproline from condition 1A, 2A, and 3A was normalized to condition 1B, 2B and 3B, respectively. Relative release was tested against null hypothesis (µ0 = 100%) using a one sample t-test.

Results: 185 genes were differentially expressed between MC1 and control vertebral bone marrow neutrophils. Enrichment analysis revealed an activated pro-inflammatory transcriptome (Figure 1a). Flow cytometric analysis confirmed neutrophil activation on protein level (measured as % of CD66high) in MC1 (control: 43.1% ± 15.7%, MC1: 54.1% ± 16.7%, p = 0.018) (Figure 1b). Exposure of CEP tissues to conditioned medium from non-activated neutrophils significantly increased the release of sGAG from the CEP tissues in a dose-dependent manner (25 mio/ml: 380.1% ± 177%, p = 0.012; 12.5 mio/ml: 123.7% ± 22.3%, p = 0.048, positive control: 545.0 % ± 302.8 %, p = 0.016) (Figure 1c) but there was no significant hydroxyproline release (not shown).

Our data shows that neutrophils in MC1 bone marrow are activated and activated blood neutrophils degrade CEPs. Hence, neutrophils in MC1 bone marrow might promote and exacerbate CEP damage. Therefore, MC1 are not just reactive changes but can drive CEP damage that enhances a vicious inflammatory crosstalk with the adjacent disc.

Figure 1. (a) Top 5 upregulated biological processes in MC1 bone marrow neutrophils (b) Representative flow cytometry image c) Relative sGAG released from CEP tissues.

Conclusion: We identified neutrophils as a potentially important player in MC1. Therefore, the present findings could have implications for treatment strategies to mitigate CEP damage in MC1.

**Background:** Bone erosion is a key feature of inflammatory osteolysis. Emerging evidence shows a link between biological lipids and the pathogenesis of bone loss in inflammatory conditions. Osteoclasts are the sole bone resorbing cells and are responsible for bone erosion. Sterol regulatory element binding protein 2 (SREBP2) is a key transcription factor for cholesterol biosynthesis and a sensor for intracellular lipids.

**Objectives:** We aim to test the role of SREBP2 in physiological and pathological bone resorption.

**Methods:** LysM-M promoter-driven Cre transgene on the C57BL6 background mice and Sreb2ΔM mice were crossed to generate Sreb2ΔM mice. Micro-computed tomography (µCT) analysis was performed to analyze bone volume and architecture. Mouse bone marrow-derived macrophages were cultured with receptor activator of nuclear factor-kappa beta ligand (RANKL) and macrophage colony stimulating factor (M-CSF)-containing conditioned media in osteoclast differentiation. Cytokine Growth Factor Rev. 2003;14(1):25-34.

**RESULTS:** Bone erosion is a key feature of inflammatory osteolysis. Emerging evidence shows a link between biological lipids and the pathogenesis of bone loss in inflammatory conditions. Osteoclasts are the sole bone resorbing cells and are responsible for bone erosion. Sterol regulatory element binding protein 2 (SREBP2) is a key transcription factor for cholesterol biosynthesis and a sensor for intracellular lipids.

**RESULTS:**

- **Results:** To determine the effect of ORM2 on RANKL-induced osteoclast differentiation and function, we performed TRAP staining, F-actin staining, and bone resorption assay using ORM2 recombinant protein or ORM2 siRNA. Also, the effect of ORM2 on osteogenesis was confirmed by ALP and ARS assay. The intracellular mechanisms responsible for the dual regulation of osteoclastogenesis and osteogenesis of ORM2 were revealed by western blotting and quantitative real-time RT-PCR.

**RESULTS:** We found that ORM2 is a potential target for osteoporosis therapeutics, as treatment with this agent enhances osteoblast differentiation and bone growth and suppresses osteoclast differentiation and bone resorption by performing gain- and loss-of-function studies. During ORM2-mediated regulation of osteoclastogenesis, phosphorylation of early signal transducers such as p38, JNK, Akt, IκB, PLC-γ2, and Btk was affected, which in turn altered the mRNA and protein levels of c-Fos and NFATc1. ORM2 also increased ALP Alizarin Red-mineralization activity, and the expression of osteoblastogenic gene markers, such as Runx2, osteocalcin (OCN) and ALP in mouse calvarial primary osteoblasts, and activated the p38-Runx2 pathway, which enhanced osteoblast differentiation.

**Conclusion:** We suggest that ORM2 may be a promising candidate for gene therapy for bone metabolic diseases, and further serve as a potentially important biomarker in the field of bone disease diagnosis.

GENERATION OF A HUMAN 3D IN VITRO BONE MODEL, THAT MIMICS GLUCOCORTICOID-INDUCED OSTEOPOORISIS

Keywords: Bone diseases, Osteoporosis

M. Pfeiferenberger1, 2, A. Damerau1, 2, T. Gaber1, 2, F. Buttgereit1, 2, 3, Charité Universitätmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; 2 German Rheumatism Center, Rheumatology, Berlin, Germany

Background: Osteoporosis is a bone disease characterized by low bone mass and changes in bone architecture, leading to pain and reduced mobility in patients. Glucocorticoid-induced osteoporosis (GIOP) is the best known form of secondary osteoporosis. Glucocorticoids (GC) are commonly used to treat inflammation, such as in rheumatic diseases. However, GC use can have a negative effect on the skeletal system and lead to osteoporosis.

Objectives: (i) Establishing and characterizing a human in vitro bone model consisting of osteoblasts and osteoclasts embedded in β-TCP (“healthy” bone model), (ii) treatment with dexamethasone to induce GIOP (“osteoporotic” bone model) and (iii) using this model as a testing platform for the treatment of osteoporosis.

Methods: Our model includes osteoblasts and osteoclasts, which are mainly responsible for bone remodeling. We defined an osteoclast differentiation protocol using low-attachment plates and cultured the cells for 21 days in αMEM medium, 5% FCS, 5% human AB serum, 2 mmol/L-glutamine, 25 ng/ml M-CSF, and 50 ng/ml RANKL. To provide the basic scaffold for the structure of the “healthy” bone model, mesenchymal stromal cells (MSCs) were seeded on β-tricalcium phosphate (β-TCP). This bone model, consisting of differentiated osteogenic cells, was fully characterized in our previous work [1].

Results: The multinuclearity, typical β-actin ring formation, cellular activity by TRAP staining and functionality in resorption assays proved functional osteoclasts. Our protocol allowed us to passage these cells without cell loss or loss of function. To establish the previously “healthy” (i.e., untreated) bone model, we seeded osteoclasts onto a pre-seeded β-TCP construct and cultured the co-culture for 7 days. We then analyzed the supernatant and detected marked secretion of RANKL, MMP-9, and free phosphate. This indicates the functionality of both osteoclasts and osteoblasts in our 3D model. Subsequently, the healthy model will be transferred to the osteoporosis-simulating model where treatment with dexamethasone will be applied. Once established, we plan to use the model we have developed for in vitro preclinical trials to test marketed drugs.

Conclusion: Ultimately, we will obtain an in vitro 3D co-culture of osteoblasts/osteoclasts simulating human native bone, which will be treated with dexamethasone to mimic key aspects of GIOP in vitro.

GLUCOSE TRANSPORTER 1 REGULATES MECHANICAL STRESS-ACTIVATED SUBCHONDRAL BONE FORMATION VIA THE SIGNAL TRANSDUCTION NETWORK OF CELLULAR ENERGY SENSOR, NAD+-DEPENDENT DEACETYLASE (SIRTUIN 1) AND OSTEOGENIC TRANSCRIPTION FACTOR, RUNT-RELATED TRANSCRIPTION FACTOR 2 (RUNX2), IN SUBCHONDRAL BONE TISSUE

Keywords: Cartilage, Cell biology, Osteoarthritis

K. Yudono1, S. Somemurao2, R. Karasawa1, 3, St. Marianna University School of Medicine, Department of Frontier Medicine, Kawasaki City, Japan; 2 St. Marianna University School of Medicine, Department of Orthopaedic Surgery, Kawasaki City, Japan

Background: Mechanical stress is an important factor affecting bone and cartilage tissue homeostasis in osteoarthritis (OA). We focused on the interaction among mechanical stress, glucose uptake via glucose transporter 1 (Glut1) and the cellular energy sensor sirtuin 1 (SIRT1) in energy metabolism, since it has been recognized that SIRT1, an NAD+-dependent deacetylase, may function as a master regulator of mechanical stress response as well as cellular energy metabolism. Also, it has already been demonstrated that SIRT1 regulates the activity of the osteogenic transcription factor, runt-related transcription factor 2 (Runx2).

Objectives: Purpose of this study was to determine whether mechanical force affects the expression of factors regulating energy metabolism and transcription factors controlling subchondral bone formation and ossification in OA.

Methods: Comparative analyses of the expression of Glut1, SIRT1 and Runx2 in osteoblasts and chondrocytes were performed after mechanical loading of a 3D cell-collagen sponge construct.

Results: Mechanical loading increased osteoblast activity. Mechanical loading significantly increased the expression of Glut1, significantly decreased the expression of SIRT1 and increased the expression of Runx2 in osteoblasts in comparison with non-loaded osteoblasts. Incubation with Glut1 inhibitor blocked mechanical stress-induced changes in SIRT1 and Runx2 in osteoblasts. In contrast to osteoblasts, expressions of Glut1, SIRT1 and Runx2 in chondrocytes were decreased by loading. Over loading reduced chondrocyte activity (production of proteoglycan, type II collagen).

Conclusion: Our present study indicated that mechanical stress induced upregulation of Glut1, downregulation of SIRT1, and upregulation of Runx2 in osteoblasts, but not in chondrocytes. Since SIRT1 is known to negatively regulate Runx2 activity, mechanical stress-induced downregulation of SIRT1 may lead to upregulation of Runx2, resulting in osteoblast differentiation and bone formation. Incubation with Glut1 inhibitor blocked mechanical stress-induced changes in SIRT1 and Runx2 suggesting that Glut1 is necessary to mediate the responses of SIRT1 and Runx2 to mechanical loading. These results suggest that Glut1 regulates mechanical stress-activated subchondral bone formation and ossification via the signal transduction network of cellular energy sensors, sirtuin 1 and Runx2, in OA.

Spondyloarthritis - aetiology, pathogenesis and animal models

Keywords: Psoriatic arthritis, Biomarkers, Remission

M. M. Angciong1, C. Piras2, A. Floris1, V. P. Leonii, M. Congia, E. Chessa1, M. Piga, L. Atzori2, A. Cauili3, Rheumatology Unit, AOU and University of Cagliari, Department of Medical Sciences and Public Health, Monserrato, CAGLIARI, Italy; 4University of Cagliari, Clinical Metabolomics Unit, Department of Medical Sciences and Public Health, Monserrato, Cagliari, Italy

Background: Among the unmet needs in psoriatic arthritis (PsA), the discovery of molecular players and biomarkers of disease activity or clinical remission achievement, remains unsolved. Metabolomics is a valuable technology in identifying biomarkers, by the study of a set of small molecules produced by the catabolism or anabolism of an organism in response to physiological or pathological states, allowing to better understand the disease-related variations downstream of the genome and proteome.

Objectives: In this pilot study, we have compared the serum metabolomics profile of patients with psoriatic arthritis with active or clinically inactive disease state compared with healthy controls, using Nuclear Magnetic Resonance Spectroscopy (1H-NMR).

Methods: From a cohort of 300 PsA patients according to CASPAr criteria, we selected 30 PsA with active disease state by DAPSA > 14 score (no bDMARDs ongoing) (A), 38 patients (peripheral arthritis subset) with >1-year remission by anti-TNFα assessed by DAPSA ≤ 4 (B) and 32 healthy controls (C) matching for mean age and gender ratio. The sera metabolomics profile of 100 subjects was analyzed with a Varian UNITY INOVA 500 MHz NMR spectrometer, combined with Multivariate statistical Analysis (MVA), Principal Component Analysis (PCA) and Orthogonal Partial Least-Squares Discriminant Analysis (OPLS-DA) were applied. The model's goodness was evaluated using a permutation test (Q2 intercept value < 0.05).

Results: The represents OPLS-DA models (Figure 1) exhibited a clear separation between subjects with active disease (red dots) and healthy controls (green dots), and patients with active disease or clinical remission state (blue dots), indicating significant differences in the serum metabolomics profile between all compared conditions. Interestingly, the OPLS-DA model shows how the PsA patients in the remission state have a profile which does not completely overlap with healthy subjects. The validity of the OPLS-DA models was evaluated through a permutation test using 500 times (Table 1). Table 1. Parameters for OPLS-DA models

Results: Seventy-nine inflammation-related proteins were detected in SF from PsA patients (SF-PsA). Unsupervised analyses of the molecular proteome profile in SF-PsA identified two specific phenotypes characterized by higher or lower levels of inflammation-related proteins. Clinically, SF-PsA with non-related proteins. Clinically, SF-PsA with regulated inflammatory cytokines also showed increased systemic inflammation and altered glucose and lipid metabolisms. Besides, SF from PsA patients showed 39 out of 79 proteins significantly altered compared to SF-OA specifically related to cell migration and inflammatory response. Among these, molecules such as TNF-α, IL-17A, IL-6, IL-10, IL-8, ENVRAGE, CCL20, TNFSF14, OSM, IFN-γ, MCP-3, CCL11, MCP4, CASP9, CXCL10, CD-6, ADA, CXCL10, TNFα and IL-1β showed the most significantly altered.

Conclusion: This is the first study that characterizes the inflammatory landscape of synovial fluid of PsA patients by analyzing a panel of 92 inflammation-related proteins using PEA technology. Novel SF proteins have been described as potential pathogenic molecules involved in the pathogenesis of PsA. Despite the flare, inflammatory proteome could distinguish two different phenotypes related to systemic inflammation and lipid and glucose alterations.

POS0425 SINGLE-CELL RNA SEQUENCING OF SYNOVIAL TISSUE-DERIVED MYELOID CELLS IN PSORIATIC ARTHRITIS PATIENTS ACROSS DISEASE PHASES

Keywords: Synovium, Biomarkers, Innate immunity

1IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain; 2University of Verona, Department of Medicine, Verona, Italy; 3Università Cattolica del Sacro Cuore, Division of Clinical Immunology, Rome, Italy; 4Università Cattolica del Sacro Cuore, Division of Clinical Immunology, Rome, Italy; 5Università Cattolica del Sacro Cuore, Firenze, Italy; 6Università Cattolica del Sacro Cuore, Firenze, Italy

Background: Single cell technologies (scRNAseq) are increasingly applied in rheumatology to identify key cellular phenotypes that drive disease pathogenesis, enabling to deconvolute cellular heterogeneity within tissues.

Objectives: To investigate ST heterogeneity in terms of myeloid cells enrichment and distribution across different disease phases on ST samples obtained from US-guided biopsies in a bio-samples dataset of patients with Psoriatic Arthritis (PsA).

Methods: 17 patients fulfilling the CASPAR criteria[1] for PsA underwent US-guided ST biopsy and were included. At baseline, patients were categorized based on their disease phase: n=4 naïve to DMARDs; n=3 resistant to c-DMARDs; n=5 resistant to b-DMARDs; n=2 difficult to treat and n=3 in sustained clinical and US resistant or in low disease activity (LDA) state. All ST specimens were processed for phenotyping and sorting. Alive cells were sorted and loaded onto a Chromium Controller (10x Genomics) for single-cell partitioning, followed by library preparation according to the Chromium Next GEM Single Cell 3′ Reagent Kits v3.1 (Dual Index) protocol. Single-cell libraries were sequenced on the Illumina HiSeq 4000 system to a minimum depth of 20,000 reads per cell.

Results: After standard data processing and quality control procedures, we obtained transcriptomic profiles for 16701 synovial tissue-derived cells. For analysis of ST myeloid compartment only, 10194 cells were computationally obtained transcriptomic profiles for 16701 synovial tissue-derived cells. For analysis of ST myeloid compartment only, 10194 cells were computationally isolated with the subset function from other cell types based on expression of CD14, MARCO, LYZ, CD11b and CD64. We identified 10 different myeloid subclusters from the scRNA-seq profiles using SCITransform integration: 2 clusters of lining layer and 8 sublining layer macrophage named according to main differentially expressed (DE) genes (adjusted P < 0.05 by Bonferroni correction and multiple test correction, multiplied by number of tests) and according to the nomenclature reported in Alverini et al 2020. Each cell type group is present across all disease conditions but differences in relative proportions were detected. Specifically, ST of patients with active PsA resistant to pharmacological treatment was significantly enriched in sublining MerTKnegSPP1pos macrophages. In addition, we observed pro-inflammatory changes in lining layer TREM2pos STMs as compared to patients who achieved Remission/LDA status(<0.001 for both)

Conclusion: MerTKnegSPP1pos STMs macrophage may contribute to synovial pathology of PsA resistant to pharmacological treatment.

Background: Synovial membrane inflammation, driven by effector T-cell activation and altered inflammatory cytokine expression, is a key feature of this psoriatic arthritis. The proximity extension assay (PEA) technique could contribute to identifying novel protein biomarkers associated with PsA and to improving the biological understanding and the future management of PsA, leading to novel intervention targets.

Objectives: 1) To characterize the inflammatory proteome of synovial fluid (SF) from patients with Psoriatic Arthritis (PsA) using a next generation proteomics technique, and 2) to evaluate its potential to stratify patients according to clinical features.

Methods: Inflammatory proteome profile of SF from thirteen PsA patients with active knee arthritis were analysed using PEA technology (Olink Target 96 Inflammatory panel, Cobiomic Biosciences). Four patients with OA were included as control group.

**PKM2 PROMOTES PRO-INFLAMMATORY MACROPHAGE ACTIVATION IN ANKYLOSING SPONDYLITIS**

**Keywords:** Innate immunity, Spondyloarthritis

Y. Jiang, W. Weng, Y. Liang, S. Zhong, Y. Pan, J. Gu. 1Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China

**Background:** Macrophages are vital effector cells in ankylosing spondylitis (AS), leading to autoimmune tissue inflammation through varied effector functions [1]. The pro-inflammatory potential of macrophages depends on their metabolic environment. Macrophages also work as principal regulators in T lymphocyte activation. To meet amplified bioenergetic and biosynthetic demands, metabolic pathways are joined to facilitate the proliferation and effector molecule production. A critical question is whether glycolysis and the rate-limiting enzyme, pyruvate kinase isoenzyme M2 (PKM2) could positively influence AS macrophages' inflammatory function.

**Objectives:** The objective of this study was to investigate the effect of glycolysis and PKM2 on AS macrophage functions featured by the secretion of inflammatory cytokines and the presentations of co-stimulatory signals.

**Methods:** Peripheral blood mononuclear cells (PBMC) were isolated from AS patients and differentiated into macrophages by M-CSF. Macrophages were further differentiated into M1 or M2 macrophages by stimulation with IFN-γ and LPS, or IL-4 and IL-13. For glycolysis inhibition, cells were treated with 10μM of 2-Deoxy-D-glucose (2-DG). For inhibition of PKM2, macrophages were treated with 0.25μM of Shikonin. The RNA expressions of proinflammatory cytokines and glycolysis-related genes were detected by qPCR. Immunoblotting, ELISA and confocal microscopy was applied to examine the expression of PKM2. Extracellular aciddification rate (ECAR) analysis was performed to assess glycolysis. The expressions of surface molecule CD80, CD86, and HLA-DR were measured using CytoFLEX flow cytometer.

**Results:** AS macrophages are prone to produce excessive inflammation, including TNF-α, IL1, and IL23, and are at overactive status by showing stronger co-stimulatory signals, such as CD80, CD86, and HLA-DR. Meanwhile, we found that patient-derived M1 macrophages intensified glycolysis, captured as a higher ECAR. Obviously, upregulation of PKM2 and GLUT1 has been observed on AS-derived monocytes and macrophages, especially on M1 macrophages, indicating a glucose metabolic alteration in AS macrophages. To investigate how glycolysis impacts macrophage inflammatory ability, 2-DG and Shikonin were applied to AS M1 macrophages, respectively. Consequently, both inhibitors could lessen pro-inflammatory function and reverse overactive status of AS macrophages, potentially favoring disease treatment.

**Conclusion:** We emphasized hyper-metabolic M1 macrophages of AS and suggested an essential role for PKM2 in inflammatory effector functions of AS macrophages. Targeting PKM2 to inhibit glycolysis in an overactive macrophage may provide novel therapeutic methods for AS inflammation.

**PROSTAGLANDIN E2 CONTROLS THE METABOLIC ADAPTATION OF T CELLS TO THE INTESTINAL MICROENVIRONMENT**

**Keywords:** -omics, Adaptive immunity, Gastrointestinal tract

M. Villa, 1Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria

**Background:** Immune cells must adapt to different environments during the course of an immune response, such as during their transition from lymph nodes to peripheral tissues.

**Objectives:** We studied the adaptation of CD8+ T cells to the intestinal microenvironment and how this process shapes their residency in the gut. Investigation of this process will lead to the identification of tissue-specific mechanisms to target CD8+ T cell function in a gut-restricted manner.

**Methods:** We explored the adaptation of CD8+ T cells to the intestinal microenvironment using single cell RNA and antibody sequencing, mass spectrometry-based metabolomic approaches, CRISPR-Cas9 gene editing, and in vivo mouse models of intestinal infection.

**Results:** CD8+ T cells progressively remodel their transcriptome and surface phenotype as they acquire gut residency, and downregulate expression of mitochondrial genes. Human and mouse gut-resident CD8+ T cells have reduced mitochondrial mass, but maintain a viable energy balance to sustain their function. We found that the intestinal microenvironment is rich in prostaglandin E2 (PGE2), which drives mitochondrial depolarization in CD8+ T cells. Consequently, these cells engage autophagy to clear depolarized mitochondria, and enhance glutathione synthesis to scavenge reactive oxygen species (ROS) that result from mitochondrial depolarization. Impairing PGE2-sensing promotes CD8+ T cell accumulation in the gut, while tampering with autophagy and glutathione negatively impacts the T cell population.

**Conclusion:** A PGE2-autophagy-glutathione axis defines the metabolic adaptation of CD8+ T cells to the intestinal microenvironment, to ultimately influence the T cell pool.

**EFFECTOR ACTIVITY OF CXCR3+ CD8 T CELL IS REGULATED BY GLUT1-MEDIATED METABOLIC REPROGRAMMING TOWARD GLYCOLYSIS AND INVOLVED IN SPONDYLOARTHRITIS PATHOGENESIS**

**Keywords:** Adaptive immunity, Spondyloarthritis

M. Akiyama, T. Kaburaki, K. Yoshimoto, Y. Kanieko, Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

**Background:** Although T cell metabolism has recently attracted attention as a key regulator of immune responses, the molecular mechanisms underlying the expression of effector functions in human T cells are still poorly understood. T cell metabolism is postulated to be involved in the development of autoimmune diseases by regulating the expression of its effector functions.

**Objectives:** In this study, we examined the association of metabolic pathways with effector function activity in human T cells. We further investigated the involvement of the identified metabolic pathways in the pathogenesis of autoimmune diseases.

diseases using the two representative autoimmune arthritis samples, spondyloarthritis (SpA) and rheumatoid arthritis (RA).

**Methods:** Metabolism-related cell surface transporters (GLUT1, LAT1, and ASC-T2) were examined for their expression levels in CD8 T cells and CD4 T cells from peripheral blood using flow cytometry and Western blotting. Cell survival rate was examined in cultured cells under condition of glucose supply or depletion for 6 days. We comprehensively analyzed the expression of metabolic enzymes in CXCR3+CD8 T cells and CXCR3-CD8 T cells using bulk RNA-seq data. We investigated the effects of metabolic-related trans-

**Results:** Among metabolic transporters, GLUT1 was found to be expressed at the protein level specifically on CD8 T cells but not CD4 T cells in human peripheral blood. Functional experiments revealed that CD8 T cells depended on glucose supply to maintain their cell survival compared to CD4 T cells. Interestingly, exploratory experiments revealed that among CD8 T cells, the viability of CXCR3+CD8 T cells was particularly dependent on glucose supply. In line with that, comprehensive analysis by RNA-seq data revealed that CXCR3+CD8 T cells had enhanced expression of glycolytic enzymes, including GLUT1, compared to CXCR3-CD8 T cells. Validation by flow cytom-

**Conclusion:** Our results demonstrate that CXCR3+CD8 T cells exhibit higher effector activity than other CD8 T cell phenotypes, regulated by GLUT1-mediated metabolic reprogramming toward glycolysis. GLUT1-high CXCR3+CD8 T cells may be involved in SpA pathogenesis.

The role of B cells in the pathogenesis of ankylosing spondylitis (AS) remains relatively understudied. Nevertheless, available evidence shows presence of B cells at sites of inflammation, higher frequencies of circulating plasmablasts, presence of autoantibodies and beneficial results of B cell depletion therapy with rituximab [1]. We observed previously that a subpopulation of CD27- B cells, characterized by low expression of the complement receptor CD21 (CD21low), is increased in patients with AS and patients with primary Sjogren's syndrome (pSS), a typical B cell mediated systemic autoimmune disease [2]. These CD21lowCD38lowCD27- B cells display a pro-inflammatory phenotype, suggestive for a pathogenic role.

Objectives: To gain insight into the origin of these CD21lowCD38lowCD27- B cells we analysed the mutation status of the immunoglobulin heavy chain variable (IGHV) gene regions in the total B cell compartment, CD21low B cell subpopulations and plasmablasts in AS patients in comparison to pSS patients and healthy donors (HD). In addition, we investigated clonal relationships between CD21low B cell subpopulations and plasmablasts in AS.

Methods: RNA was isolated from sorted total B cells (CD19+), two CD21low B cell populations (CD21lowCD38lowCD27- and CD21lowCD38+CD27+) and plasmablasts (CD19+CD38+CD27-) from peripheral mononuclear cells of 10 AS patients fulfilling the mNY criteria (mean age 46 ± 9 years, 60% male, mean ASDAS 2.3 ± 0.8, all HLA-B27+), 10 sex- and age-matched pSS patients (mean age 48 ± 21 years, 60% male) and 10 age-matched HDs (mean age 46 ± 9 years, 20% male). Repertoire analysis of the B cell receptor heavy chain variable (IGHV) sequences with identical heavy chain CDR3 regions were grouped together and defined as a clone. Analysis of the IGHV mutation of immunoglobulin heavy chain variable (IGHV) gene regions in the total B cell compartment, CD21low B cell subpopulations and plasmablasts in AS patients in comparison to pSS patients and healthy donors (HD). In addition, we investigated clonal relationships between CD21low B cell subpopulations and plasmablasts in AS.

Results: IGHV sequences with identical heavy chain CDR3 regions were grouped together and defined as a clone. In addition, we investigated clonal relationships between CD21low B cell subpopulations and plasmablasts in AS.

Methods: RNA was isolated from sorted total B cells (CD19+), two CD21low B cell populations (CD21lowCD38lowCD27- and CD21lowCD38+CD27+) and plasmablasts (CD19+CD38+CD27-) from peripheral mononuclear cells of 10 AS patients fulfilling the mNY criteria (mean age 46 ± 9 years, 60% male, mean ASDAS 2.3 ± 0.8, all HLA-B27+), 10 sex- and age-matched pSS patients (mean age 48 ± 21 years, 60% male) and 10 age-matched pSS patients (mean age 46 ± 9 years, 20% male). Repertoire analysis of the B cell receptor heavy chain variable (IGHV) gene regions in the total B cell compartment, CD21low B cell subpopulations and plasmablasts in AS patients in comparison to pSS patients and healthy donors (HD). In addition, we investigated clonal relationships between CD21low B cell subpopulations and plasmablasts in AS.
**RESULTS:** Naïve SKG ileum displayed dysbiosis with increased expression of ER stress markers Grp78, xBP1, CHOP and reduced mucin staining. After curdlin treatment, goblet cell numbers were decreased and Il24 mRNA was increased compared to BALB/c controls. By IF, IL-24 localized to the goblet cells of the ileum in SKG and BALB/c mice and 2 weeks post curdlin, ileal goblet cell number was correlated with IL-24 staining intensity. In MUC2hi LS-174T but not MUC2low HT-29 cells, thapsigargin induced a rapid and transient increase in Il24 transcription and subsequent ER stress with CHOP induction, suggesting an acute goblet cell-specific response associated with high mucin production. IL-24 knockdown in LS-174T increased ER stress and apoptosis including increased CHOP, DR5 and active caspase 3 expression.

**Conclusion:** Despite goblet cell IL-24 over-expression in dysbiotic naïve SKG ileum, goblet cell loss due to stress associated with increased mucin production also depletes IL-24. In an in vitro model of goblet cell stress, IL-24 mitigates ER stress-induced apoptosis, suggesting that IL-24 production in SKG ileum is insufficient to prevent the inflammatory cascade that commences with goblet cell apoptosis and epithelial barrier breakdown.

**POS0432 CHARACTERIZATION OF THE CARDIOVASCULAR DISEASE PROTEOMIC PROFILE IN SPONDYLARTHROPATHY PATIENTS: POTENTIAL BIOMARKERS FOR PERSISTENT INFLAMMATION**

**Keywords:** Biomarkers, Cardiovascular disease, Spondyloarthritis

I. Arias de la Rosa1, M. L. Ladehesa Pineda1, C. López-Medina2, M. Ruiz-Ponce1, L. Cuesta López1, M. Á. Puche Larrubia1, M. D. C. Abalos-Aguilera1, P. Ortiz Buitrago1, C. Perez-Sanchez2, C. Lopez-Pedraza1, A. Escudero Contreras1, E. Collantes Estevez2, N. Barrobaro Puerto2, 1IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology Service, Cordoba, Spain; 2IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain; 3IMIBIC/University of Cordoba/Reina Sofia Hospital, Cell biology, Physiology and Immunology, Cordoba, Spain

**Background:** patients with Spondyloarthritis (SpA) have an increased risk of cardiovascular disease. Taking into account the strong relationship between inflammation and CVD, there is an urgent need to identify different molecular drivers of CVD signs and their association with inflammation.

**Objectives:** to investigate the alteration of CVD-related proteins in the plasma of SpA patients, their association with clinical features, and to evaluate their potential role as biomarkers for the identification of persistent inflammation.

**Methods:** a cross-sectional study including 120 patients with SpA and 30 age- and sex-matched healthy donors (HDs) was carried out. Clinical and laboratory parameters and CVD risk factors were recorded. To measure the presence of persistent inflammation, levels of c-reactive protein (CRP) were collected retrospectively for 5 years previous to the study, a patient was considered to have persistent inflammation if at least 50% of their CVD-related measurements during the previous 5 years. Levels of 92 proteins with a recognized role in CVD were analyzed in the plasma using proximity extension assay (PEA) technology (Olink Target 96 CVD III panel, Cobiomic Biosciences).

**Results:** SpA patients showed higher rates of CVD comorbidities compared to HDs. Plasma levels of TNF-R1, RARRRES-2, CHISL1, GPGYRP-1, CTSD, UAPR, IL2RA, TIMP-4, CTSB, GDF-15, MMP-9, and PDGF-A were significantly increased in SpA compared to HDs. Specifically, these proteins are also related to biological processes such as neutrophil degranulation, immune response, cell activation, attherosclerosis, apoptosis, and inflammatory response. Besides, a significant alteration of these CVD-related proteins in SpA was also associated with the presence of arterial hypertension, insulin resistance, obesity, hyperuricemia, and high levels of acute phase reactants. 36% of SpA patients displayed persistent inflammation at at least 50% of their CVD-related measurements. Levels of 92 proteins with a recognized role in CVD were analyzed in the plasma using proximity extension assay (PEA) technology (Olink Target 96 CVD III panel, Cobiomic Biosciences).

**Conclusions:** Persistent inflammation in SpA has stronger associations with persistent inflammation in SpA than HDs. Specifically, these proteins are also related to biological processes such as neutrophil degranulation, immune response, cell activation, attherosclerosis, apoptosis, and inflammatory response. Besides, a significant alteration of these CVD-related proteins in SpA was also associated with the presence of arterial hypertension, insulin resistance, obesity, hyperuricemia, and high levels of acute phase reactants. 36% of SpA patients displayed persistent inflammation at at least 50% of their CVD-related measurements. Levels of 92 proteins with a recognized role in CVD were analyzed in the plasma using proximity extension assay (PEA) technology (Olink Target 96 CVD III panel, Cobiomic Biosciences).

**POS0433 RELATIONSHIP BETWEEN MIRNA-1-3P, INTERLEUKIN-17 AND TUMOR NECROSIS FACTOR IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

**Keywords:** Spondyloarthritis, Genetics/Epigenetics, Biomarkers

A. Pekacova1,2, J. Baloun1, K. Bubova1,2, M. Gregova1,2, S. Foretova1,2, J. Honorova1,2, M. Husakova1,2, K. Mintalova1, V. Cervenak1,2, M. Tomcik1,2, V. Wanten1,2, L. Boncol1,2, Institute of Rheumatology, Prague, Czech Republic; 3First Faculty of Medicine Charles University, Prague, Czech Republic; 4St Anne's University Hospital and Faculty of Medicine, Masarik University, Department of Imaging, Brno, Czech Republic

**Background:** microRNAs (miRNAs) are small non-coding RNAs that can regulate gene expression and mirror the patient’s health condition. miRNAs deregulation is considered a crucial factor in the development and progression of various diseases, including axial spondyloarthritis (axSpA) [1].

**Objectives:** the aim of the study was to profile the miRNome of peripheral blood mononuclear cells (PBMCs) and to identify specific miRNAs and their association with several cytokines, axSpA disease activity and spinal impairment.

**Methods:** Massive parallel sequencing (MPS, Illumina) was performed for miRNAs profiling in 96 subjects (38 patients with non-radiographic (nr-) axSpA, 38 patients with radiographic (r-) axSpA and 20 healthy controls (HC)). The expression of candidate miRNAs was validated using the qRT-PCR system (SmartChip) on a new cohort of 47 patients with nr-axSpA. 44 patients with r-axSpA and 50 HC. Disease activity was determined using C-reactive protein (CRP) and Ankylosing Spondylitis Disease Activity Score (ASDAS). Radiographs of the cervical and lumbar spine were assessed by two independent blinded readers using modified Stoke Ankylosing Spondylitis Score (mSASSS). We employed DESeq2 and general linear modeling with a negative binomial assumption (GLM-NB) to evaluate the association to the radiographic form, ASDAS and CRP. Linear modelling was used to determine the association between miRNAs and laboratory/clinical parameters adjusted for CRP, age, and sex.

**Results:** MPS detected 432 miRNAs; however, only 90 miRNAs passed through the selection criteria (p<0.05, BaseMean=10, the difference in log2FC<0.5). We selected 45 miRNAs for validation based on the selection criteria and the literature. We validated miR-1-3p (p=0.006, FC=-1.757) to be upregulated and miR-1248 (p=0.002, FC=-1.125) and miR-1246 (p=0.002, FC = -1.125) to be downregulated in patients with axSpA compared to HC. In addition, the expression of miR-1-3p correlated with the plasma levels of IL-17 (p=0.016, r=0.25) and TNF (p=0.028, r=0.22), but not with the gene expression of IL-17 or TNF in PBMCs. miR-1-3p (p=0.039, β=0.685) as well as miR-1248 (p<0.001, β=0.207) correlated with the IL-8 gene expression in PBMCs. None of the miRNAs distinguished between radiographic and non-radiographic disease or correlated with disease activity or radiographic spinal impairment.

**Conclusion:** This cross-sectional study failed to demonstrate association between cellular miRNAs, disease activity or spinal impairment, but the association between miR-1-3p, IL-17 and TNF may suggest its role in the pathogenesis of axSpA.

Kim1. 1Chonnam National University Medical School and Hospital, Department of Rheumatology, Gwangju, Korea, Rep. of (South Korea); 2Chonnam National University Medical School and Hospital, Department of Parasitology and Tropical Medicine, Gwangju, Korea, Rep. of (South Korea); 3Graduate School of Chonnam National University, Department of Biomedical Sciences, Gwangju, Korea, Rep. of (South Korea); 4Daejeon
Background: Ankylosing spondylitis (AS) is a rheumatic disease characterized by chronic inflammation. Several lines of evidence implicate interleukin (IL)-17A-secreting T helper (Th)17 cells in AS pathogenesis. One of the receptors of Th17 cell, C-C motif chemokine ligand 20 (CCL20) is known to attract C-C chemokine receptor 6 (CCR6) expressing cells to the site of inflammation. However, the role and mechanisms of CCL20 in AS are not well understood.

Objectives: Therefore, this study aimed to evaluate the function of CCL20 in patients with AS.

Methods: Peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were obtained from AS patients. Inflammatory cytokine-producing cells were analyzed using flow cytometry and enzyme-linked immunosorbent assay (ELISA). To determine the direct effect of cell migration in the presence of CCL20, a transwell migration assay was performed. In in vivo experiments, SKG mice were treated with either CCL20 blocking antibody or isotype control antibody. Clinical signs of mice were monitored twice a week and scored by two independent observers. At the experimental endpoint, specimens of the ankle was obtained from mice. Two blinded readers then performed pathological scoring for arthritis using immunohistochemistry.

Results: IL-17A producing cells were significantly higher expressed in SFMCs of AS patients than in PBMCs of AS or healthy controls. CCL20-positive cells showed significantly increased IL-17A production than CCL20-negative cells. To confirm the relationship between CCL20 and IL-17A production, IL-17A expression was observed with either CCL20 agonist or antagonist. Treatment with CCL20 agonist showed an increase in IL-17A in PBMCs from AS patients. Meanwhile decreasing IL-17A level was observed in SFMCs from AS patients when treated with CCL20 inhibitors. In cell migration assay experiments, cell migration increased when CCL20 was added to the CD4-positive cells. In vivo model, CCL20 inhibitors significantly suppressed arthritis symptoms (Figure 1). In addition, histologic evaluation showed that mice treated with CCL20 inhibitor had lower arthritis scores than isotype-treated control mice.

Conclusion: This study demonstrates CCL20 blockade improved joint inflammation in AS. Therefore, CCL20-target therapy could be a promising treatment for AS.

POS0436 INCREASED EXPRESSION OF PATHWAYS INVOLVED IN B CELL ACTIVATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Cell biology, Adaptive immunity

H. Wilbrink1, A. Spoorenberg2, F. G. M. Kroese3, G. M. Vrastappen1. 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: In spite of advancements in treatment of ankylosing spondylitis (AS), its pathological mechanism remains incompletely understood. The current evidence suggests that AS is both an autoimmune and autoimmune disease involving innate immune cells along with autoreactive lymphocytes. B cells have received little attention regarding their role in the pathogenesis of ankylosing spondylitis (AS), although the available evidence shows presence of B cells at inflammatory sites, imbalances in B cell subsets, presence of autoreactive cells (anti-CDF/CLIP), and beneficial effects of B cell depletion (anti-CD20) with rituximab [1]. In AS, the overarching picture portrays increased B cell activation, although it is unclear whether B cells directly affect pathogenesis, or are merely bystanders in the disease process.

Objectives: Our main objective was to study gene expression and gene signaling pathways involved in B cell activation in AS. To this end, we analysed the transcriptomic profile of isolated peripheral B cells from AS patients, healthy donors (HD) and patients with primary Sjögren syndrome (pSS), a typical B-cell-associated autoimmune disease.

Methods: RNA was isolated from CD19+ B cells sorted from peripheral blood mononuclear cells of 8 AS patients (mean age 48.0 ± 9.7 years, 63% male, mean ASDAS 2.5 ± 0.7), 8 sex and age-matched HDs (42.3 ± 17.8 years, 63% male) and 8 age-matched pSS patients (48.4 ± 17.8 years, 13% male). Next, characterization of differentially expressed genes was performed using transcriptomic analysis by the NanoString ProFile quantification system and a direct hybridization technique without PCR amplification. After normalization and z-score scaling of pathway genes, pathway scores were calculated based on the first principle component using nCounter advanced analysis software. P-values <0.05 were considered significant.

Results: All samples passed quality control, except for one pSS patient sample that was being flagged as an outlier by the nCounter advanced analyses software. Analysis of differential gene expression between AS patients and HDs revealed upregulation of 8 genes, including MAPK14, KMT2A and PKM, in B
cells from AS patients, and downregulation of two genes, DDIT4 and ATG5. In AS patients, the relative expression of B cell receptor (BCR) signalling (n=60 genes) and Fc receptors and phagocytosis (n=55 genes) pathway genes were both significantly enriched compared to HDs (Figure 1). Although not significant, these pathways also displayed higher pathway scores in pSS patients compared to HDs (P=0.30 and P=0.37, respectively). Other gene pathways involved in B cell activation, such as toll-like receptor signalling were not significantly enriched.

**Conclusion:** In this study, we observed several differentially expressed genes involved in signal transduction pathways in B cells from AS patients. Furthermore, we showed increased expression of gene pathways involved in B cell activation in patients with AS compared to HDs. The BCR-mediated activation in AS displays similarities to a bona fide autoimmune disease pSS. These results suggest active involvement of B cells in the disease process of AS.

**POS0438 IDENTIFICATION OF THREE AUTOPHAGY-RELATED HUB BIOMARKERS OF ANKYLOSING SPONDYLITIS VIA BIOINFORMATICS ANALYSIS OF RNA SEQUENCING DATA OF MACROPHAGES**

**Keywords:** Innate immunity, Spondyloarthritis, Biomarkers

Y. Liang, Y. Jiang, W. Weng, J. Chen, X. Luo, J. Gu. *Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China*

**Background:** Autophagy is associated with the occurrence and progression of a variety of diseases, such as cancers, cardiovascular diseases, and autoimmune diseases. Ankylosing spondylitis (AS) is a chronic inflammatory disease. Its pathological feature includes local infiltration of inflammatory cells among which macrophages play a dominant role [1]. Currently, previous studies have confirmed that autophagy may be involved in the occurrence and development of autoimmune diseases, such as AS [2]. However, there are few articles discussing which molecule plays a key role in the progress of autophagy of macrophage in patient with AS.

**Objectives:** This study aimed to detect gene expression in macrophages that originated from peripheral blood mononuclear cells (PBMC) in patients with AS by RNA sequencing (RNA seq) technology, and to identify underlying autophagy-related genes of AS by bioinformatics analysis.

**Methods:** Peripheral blood mononuclear cells (PBMC) from 4 cases of AS and 4 cases of healthy control (HC) from were isolated and differentiated into M1 macrophages. These cells were then sent to BGI company for RNA seq. Then, Gene
Set Enrichment Analysis (GSEA) enrichment analysis, screening of differentially expressed genes (DEGs), Gene Ontology (GO) function annotation, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis of DEGs were conducted. Protein-Protein Interaction (PPI) network of DEGs was constructed, and cluster association analysis was performed by MOCCDE plug-in in cytoscape software. Human autophagy-related genes were downloaded from Human Autophagy Database (HADb). Finally, we took the intersected of human autophagy-related genes and those involved in the top 5 clusters by cluster association analysis.

**Results:** 1467 DEGs were identified by DESeq2 package in R. Among them, 394 genes were significantly up-regulated while 1083 genes were significantly down-regulated. GO and KEGG enrichment analysis of DEGs revealed several terms related to cell cycle. GSEA analysis of all sequencing data revealed a number of terms related to cell cycle and lysosomes. The PPI network of 1467 DEGs was constructed by using STRING database, and 45 clusters were obtained by using MOCCDE plug-in of cytoscape software for cluster association analysis. The intersection of genes involved in the top 5 clusters and 219 autophagy-related genes downloaded from HADb were conducted to obtain 3 autophagy-related genes of AS, which were BIRC5, TP53 and CTBS.

**Conclusion:** Through RNA seq and bioinformatics analysis, we identified 3 potential autophagy-related genes of AS. BIRC5, TP53 and CTBS may inhibit the occurrence and development of AS by regulating autophagy.

**REFERENCES:**

**Methods:** A cohort of 20 patients with axSpA was selected based on the radiographic progression for the purpose of this preliminary study. Baseline and two-year radiographs of the cervical and lumbar spine were independently assessed by two blinded readers using modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). No radiographic progression and significant radiographic progression were characterized as a change in mSASSS ≤0 and >2, respectively, from baseline to year two. Disease activity was determined using C-reactive protein (CRP), Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Activity Disease Activity Index (BASDAI). The potential plasma samples were profiled using liquid chromatography with tandem mass spectrometry detection, and the difference in protein concentration was evaluated using linear mixed-effects modelling.

**Results:** Our cohort included ten patients without radiographic spinal progression (mean±SD age 34.8±9.0 years, 40% female) and ten patients (mean±SD age 40.8±9.0 years, 40% female) who developed the progression after two years (mean±SD change in mSASSS 9.8±8.5). Additionally, all of included patients 14 were classified as radiographic axSpA (mean±SD age 36.9±8.6 years, 28.6% female) and six as non-radiographic axSpA (mean±SD age 40.2±9.2 years, 66.7% female). The high-throughput profiling of plasma proteome detected 489 quantifiable proteins and our statistical analysis revealed 30 proteins with different concentrations between patients without and with radiographic progression (p<0.05 for all). Out of these proteins, haptoglobin (1.76-fold, p<0.001) and serum amyloid P-component (SAP) (1.57-fold, p<0.001) were upregulated, while gelosin (1.23-fold, p=0.001) was downregulated in patients with mSASSS progression compared to those without radiographic progression (Figure 1A). In addition, all these proteins significantly correlated with mSASSS, CRP or ASDAS (Figure 1A). Furthermore, after adjustment for CRP, only SAP and gelosin, which were previously associated with axSpA[1,2], were independently associated with structural progression.

**Conclusion:** We identified two plasma proteins with the potential to independently predict the radiographic progression of axSpA. Further studies in a larger cohort of patients are needed to validate these data.

Background: MAIT (mucosal associated invariant T) cells are involved in mucosal defense against bacteria. This cellular subset is characterized by a semi-invariant αβ TCR and the expression of CD161. In patients with axial spondyloarthritis (axSpA), previous works reported a decreased frequency of circulating MAIT cells compared to normal subjects. IL-17A is a relevant cytokine involved in the pathophysiology of MAIT cells; they are a cellular source of IL-17 and IL-17+ MAIT cells were found increased in axSpA. We have previously reported an increased frequency of IFNγ/IL-17 MAIT cells as well as IL-22+ MAIT cells in axSpA[1].

Objectives: In this study, we aimed to complete our previous results by evaluating activation markers and chemokine receptor/integrin expression, especially for gut homing, in MAIT cells.

Methods: patients exhibited axSpA (ASAS criteria) with a radiographic (r-ax SpA) or non-radiographic (nr-ax SpA) form. They all were under NSAIDs and biologic naïve. Healthy subjects were recruited as controls (HC). Circulating SpA (ax SpA), previous works reported a decreased frequency of circulating MAIT cells were found increased in ax SpA. We have previously reported an increased frequency of IFNγ/IL-17 MAIT cells as well as IL-22+ MAIT cells in axSpA[1].

Results: 26 patients were included (11 r-ax SpA; 9 males [M]; mean age 54.1 ± 19.6 years; disease duration: 16.2 years; ASDAS score: 4.1; and 15 nr-ax SpA: 7 M; age: 36.4 ± 13.3; ASDAS: 5.6) and 27 HC (16 M; age: 43 ± 12.7). In patients with r-ax SpA, we observed an increased frequency of activated CD3+ CD69+ MAIT cells and CD3+ MAIT cells expressing the gut homing markers CCR9 and CD49d, as compared to HC (p <0.05). These higher frequencies were not observed in patients with nr-ax SpA. In addition, when examining the CD8+ MAIT population, similar higher frequencies of cells positive for CD69, CCR9 and CD49d were observed in patients with r-ax SpA compared to HC and patients with nr-ax SpA (p<0.01 and p<0.05, respectively). These modifications were specific for MAIT cells and were not observed in conventional CD4+ or CD8+ T lymphocytes.

Conclusion: Patients with r-ax SpA are characterized by an increased frequency of activated MAIT cells that expressed homing receptors (chemokine and integrin) for the gut. These results confirm that MAIT cells are altered in axSpA and highlight the relationships between axSpA and gut inflammation, especially for the radiographic form.

Background: RA autoimmunity may be initiated at mucosal sites, including the periodontium. Anti-CCP positive at-risk individuals without synovitis (CCP+ at-risk) have an increased prevalence of periodontal disease (PD) and Porphyrmonas gingivalis and an oral dysbiosis [1]. P gingivalis preferentially citrullinates C-terminal peptides by virtue of its peptidylarginine deiminase (PPAD) enzyme (2), whereas other periodontal bacteria predominantly induce endocitrullination [3]. These factors may trigger anti-citrullinated protein antibodies (ACPA), although the relative contribution of local C-terminal and endocitrullination is unclear.

Objectives: To determine the relative abundance of endo- and C-terminally citrullinated RA autoantigens in the gingival crevicular fluid (GCF) of CCP+ at-risk individuals with PD compared with controls.

Methods: CCP+ at-risk were identified from a UK cohort of anti-CCP+ individuals with musculoskeletal symptoms but no clinical synovitis. CCP+ at-risk underwent comprehensive periodontal assessment by a dentist, including GCF sampling from periodontally diseased sites. Control subjects (i.e. CCP+) with and without periodontal disease were also sampled. GCF was analysed by liquid chromatography mass spectrometry/mass spectrometry (LC-MS/MS) to identify endo- and C-terminally citrullinated peptides. The t-test was used for the statistical analysis.

Results: 25 CCP+ at-risk, 9 and 10 controls with and without PD respectively were recruited for the GCF sampling. Mass spectrometry identified citrullination in 114 proteins in GCF, including 16 RA autoantigens (vimentin, myeloid cell nuclear differentiation antigen, keratin, type III cytokeratin), heterogeneous nuclear ribonucleoprotein (A2/B1, K and U), fibrinogen (alpha and beta chain), histone (H1.4, H1.5, H1x, and H4), actin (cytoplasmic 2), apolipoprotein (A-I and A-IV). In CCP+ at-risk with PD and controls without PD there was higher total abundance of endocitrullinated RA autoantigens compared with c-terminal citrullinated autoantigens in GCF (p<0.05, Figure 1). In CCP+ at-risk with PD 15 endocitrullinated RA autoantigens were compared with only 4 c-terminally citrullinated RA autoantigens were identified (Figure 1). Fewer citrullinated RA autoantigens were identified in control subjects compared with CCP+ at-risk. More endocitrullinated compared with C-terminally citrullinated RA autoantigens were identified in controls with and without PD (Figure 1).

Conclusion: Several citrullinated RA autoantigens are present in the GCF of CCP+ at-risk individuals with periodontal disease but no synovitis. We identified endocitrullination as generally more abundant than C-terminal citrullination in both CCP+ at-risk and seronegative controls, suggesting PPAD may not be the primary source of citrullination. These data support the hypothesis that local citrullination of RA autoantigens at the periodontium may be an early driver of the ACPA response in RA.

CLINICAL OUTCOMES OF ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS WHO UNDERWENT PERCUTANEOUS CORONARY INTERVENTION: A NATIONWIDE COHORT STUDY

Keywords: Rheumatoid arthritis, Cardiovascular disease

B. Y. Kim1, L. Kyung-Amy2, J. H. Jung3, S. W. Nam4, J. E. Park5, Gangneung Asan Hospital, University of Ulsan College of Medicine, Department of Internal Medicine, Gangneung, Korea, Rep. of (South Korea); Soochunhyang University Seoul Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); Korea University College of Medicine, Department of Internal Medicine, Ansan, Korea, Rep. of (South Korea); Wonju Severance Christian Hospital, Wonju University Wonju College of Medicine, Department of Internal Medicine, Wonju, Korea, Rep. of (South Korea); Konkuk University Chungju Hospital, Department of Internal Medicine, Chungju, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis (RA), a systemic inflammatory arthritis, is associated with an increased risk of cardiovascular disease. Despite an increased proportion of elderly patients with RA and an increased prevalence of patients with RA undergoing percutaneous coronary intervention (PCI), studies on the PCI outcomes in elderly patients with RA are limited and controversial.

Objectives: This study aimed to evaluate the prognosis of elderly patients with and without RA who underwent PCI and the risk factors associated with the prognosis.

Methods: The Korean National Health Insurance Service claims database was used to extract data on 74623 patients (14,074 patients with RA and 60,549 patients without RA) aged 65 years or older who were diagnosed with acute coronary syndrome and underwent PCI between 2008 and 2019. The primary outcome was all-cause mortality between elderly patients with and without RA. The secondary outcome was all-cause mortality in elderly patients with RA who consist of patients with elderly onset RA that manifests after the age of 65 and elderly patients who presented with young onset RA earlier in life.

Results: During a 10-year follow-up, the survival rate was lower in patients with RA than in those without RA (with RA: 53.7% vs. without RA: 58.3%, log-rank P<0.001). Compared to patients without RA, patients with elderly onset RA have poor survival outcomes and patients with young onset RA have good survival outcomes (with elderly onset RA: 48.1% vs. with young onset RA: 73.7% vs. without RA: 58.3%, log-rank P<0.001). Multivariable logistic regression analyses showed that diabetes mellitus (hazard ratio (HR): 1.39, 95% confidence intervals (CI) 1.35-1.43, P<0.001), chronic kidney disease (HR=3.97, 95% CI 3.63-4.34, P<0.001), and PCI due to myocardial infarction (HRs=1.35, 95% CI 1.33-1.37, P<0.001) were the independent risk factors for all-cause mortality.

Conclusion: Elderly patients with RA who underwent PCI for acute coronary syndrome have an increased rate of all-cause mortality compared to general elderly patients. Among elderly patients with RA, patients with elderly onset RA particularly have poor survival outcomes. Based on the aspects of RA and cardiovascular disease in elderly patients, the clinical practice should focus on more detailed and active prevention methods for a better prognosis.

Mortality trends among rheumatoid arthritis patients in Western Australia

K. Almutairi1, C. Inderjeeth1, D. Preen2, H. Keen1, J. Nossent1.

1The University of Western Australia, School of Medicine, Crawley, Australia; 2The University of Western Australia, School of Population and Global Health, Crawley, Australia

Background: Mortality rates for patients with Rheumatoid Arthritis (RA) have reportedly improved in the past decades due to increasing access to specialised rheumatology care [1], early introduction of DMARDs with combination regimens [2], and subsequent biologics therapies [3]. However, the mortality rate remains higher than the general population, reducing the life expectancy by approximately ten years [4-5]. With scarce comparative data on mortality in Australian RA patients, we investigated temporal changes in standardised mortality rates for RA patients using longitudinal linked population-wide health data in Western Australia (WA) over the period 1980 to 2015.

Objectives: The aim of the study to estimate temporal standardised mortality rates over a 35-year period and identified leading causes of death and measured median years Lost for the RA cohort Females Male.

Methods: The study included 17,125 patients with a first-time hospital contact for RA (ICD-10-AM M05.00–M06.99 and ICD-9-AM 714) in the study period. Standardised mortality rate ratios (SMRRs) for the RA cohort versus the WA general population was estimated using direct age standardisation. We analysed standard mortality rates (SMRs) for RA patients using longitudinal linked population-wide health data in Western Australia (WA) over the period 1980 to 2015.

Results: Over the study period, SMRR was 2.5-folds (95%CI: 2.52-2.65) higher for RA patients than for the general population (Table 1), with a sex- and age-specific SMRR of 2.24 (95%CI 2.15–2.34) in males and 3.09 (95%CI 3.00–3.19) in females (Figure 1). The overall leading causes of death were diseases of the circulatory system, except among 30-44-year-olds in the 1991–2000 period, neoplasms was the leading cause of death. The median life years lost for the RA cohort were 5.7 years for females and 5.1 years for males over the study period (Table 1).

Conclusion: The mortality rate in RA patients in WA has decreased but remains higher than in Australian population. Malignant neoplasms were the second leading causes of death, and lung cancer was leading cause of cancer mortality. Together these data demonstrate the importance of screening and management for comorbidities in RA patients, especially cancer.

POS0446

URINARY METHOTREXATE DOSAGE AS AN ADHERENCE MEASUREMENT IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Epidemiology, Disease-modifying drugs (DMARDs), Treat to target

N. Theate1, M. Geoffroy1, L. Kanagaratnam2, G. Gozalo2, B. Lois1, I. Charlott-Lambrecht1, A. Hittinger1, Z. Djeraida3, J. H. Salmon3. 1CHU de Reims, Rhumatologie, 51100, France; 2CHU de Reims, Aide méthodologique, pôle recherche et santé publique, 51100, France, 3CHU de Reims, Pharmacologie, 51100, France

Background: Non-adherence to rheumatoid arthritis treatments is common and must be identified, especially with the treat-to-target strategy. A methotrexate (MTX) urinary dosage (METU) was developed using high performance liquid chromatography by spectrometry method (HPLC-MS/MS).

Objectives: The aim of our study was to assess medication compliance for MTX in RA using METU under real-life conditions and to compare it with the usual indirect adherence measurement techniques.

Methods: We conducted a prospective study at the CHU de Reims. Patient inclusion comprised of RA patients over 18 years old who have been using MTX for more than 6 months. Patients were invited to fill demographic, clinical and psychological data and other adherence measurement techniques (the COR and the MPR). A urinary sample was taken to measure MTX and information about adherence was collected through the MISS questionnaire.

Results: 84 patients with RA were analyzed, 26 using oral MTX and 58 subcutaneous MTX; 73% female, mean age 61.5 years, mean dose 15mg/week, 62% associated with biotherapy. 77 patients (91.7%) were adherent to treatment according to METU, whereas MPR and COR reported less adherence (69.5% and 61.9% respectively). MPR and METU were not significantly different in subcutaneous MTX users (p = 0.059). Non-adherent patients had a higher number of tender joints and CRP value.

*missing data

Conclusion: This is the largest study evaluating MTX adherence treatment in RA patients using a urinary dosage. We identified that indirect adherence measurements did not reflect real life adherence. METU can be used in RA patients with unexplained response to treatment before escalating therapeutic strategy.

DIFFICULTIES TO SLEEP EXPLAIN HIGH PATIENT REPORTED OUTCOMES VALUES IN PATIENTS WITH INFLAMMATORY ARTHRITIS WITH NO SWOLLEN JOINTS

Keywords: Outcome measures

L. Weman1, H. Salo2, L. Kuusalo3, J. Huhtakangas4, P. Vähäsalo5, M. Backström6, J. Kärki7, T. Sokka-Iisler8. 1University of Eastern Finland, Faculty of Health Sciences, Kuopio, Finland; 2Finnish Institute for Health and Welfare, Data and analytics, Helsinki, Finland; 3Turku University Hospital, Centre for Rheumatology and Clinical Immunology, Turku, Finland; 4Kuopio University Hospital, Division of Rheumatology, Kuopio, Finland; 5University of Oulu, PEDEGO Research Unit, Oulu, Finland, 6Vaasa Central Hospital, Department of Pediatrics, Vaasa, Finland; 7Kanta-Häme Central Hospital, Department of Children and Adolescents, Hämeenlinna, Finland; 8Central Finland Central Hospital, Department of rheumatology, Jyväskylä, Finland

Background: Patient reported outcomes (PROs) are valuable tools to understand how a patient is doing. Patient self-report of pain, fatigue and global health on a 100 mm Visual Analog Scale are routine measures in rheumatology and may be interpreted as measures of disease activity.

Objectives: To study whether good/poor sleep influences other clinical measures in patients with psoriatic arthritis (PsA) and rheumatoid arthritis (RA).

Methods: A total of 13527 (72 % female) patients with rheumatoid arthritis (RA) and 3644 (52 % female) patients with psoriatic arthritis (PsA) were included in the Finnish national quality register for inflammatory arthritides. Clinical data from the most recent outpatient clinic visit from January 1st 2021 to July 31st 2022 was used in this study. Patients were divided into groups by self-reported difficulty to sleep on a MDHAQ question “over the last week, were you able to get a good night’s sleep” with response options “without any difficulty” and “with some difficulty” as good sleep and “with much difficulty” and “unable to do” as poor sleep. Median values with interquartile ranges of other clinical measures were compared between the groups. Descriptive statistics and regression models were used for comparison with p<0.05 as a threshold for statistical significance.

Results: The mean (SD) age was 62 (14) for patients with RA and 55 (14) for patients with PsA. A total of 16 % of RA patients and 22 % of PsA patients had poor sleep. The values for DAS28, SJC 66, TJC 68, CRP and ESR were low in comparison with other groups. The VAS-values for pain, fatigue and PGA for RA patients with good sleep were 16 (6, 40), 17 (4, 42) and 23 (9, 46) and 54 (29, 74), 64 (43, 80) and 56 (39, 72) (p<0.001 for all comparisons) for patients with poor sleep. In patients with PsA, the corresponding numbers were 20 (6, 41), 17 (4, 40) and 19 (6, 38) and 59 (36, 74), 66 (44, 81) and 56 (38, 73) (p<0.001 for all comparisons). The results were similar for PROs in patients with PsA (n=942) and RA (n=2861) with an SJ66 of 0. (Figure 1)

Conclusion: The assessment of sleep is crucial for patients presenting severe symptoms without markers of disease activity.

</tbody>
</table>

The most frequent swollen joint was the wrist (57%), followed by PIP3 (40%) and PIP2 (39%), MCP2 (34%), MCP1 (28%) and MCP3 (26%). Erosions were most frequent in MCP5 (14%), MCP3 (9%), wrists (8%), MCP1 and MCP2 (6%). Swollen and tender joints were well associated except for shoulder (3% vs 25%), wrist (8% vs 15%) and MCP5 (see table 1). We found a significant correlation between erosions and swelling for wrists, MCP1-3 joints and MCP5 joints. As expected, erosive joint was observed first in MCP5 (14%) followed by the MCP3 (9%) and the wrist (8%). MCP4 and 5 joint locations were more present in younger and MCP 2-4 in older patients. BL swelling in the large size joints (knee, elbow, shoulder and ankle), in the medium size joint (wrist) and the small size joints (only MCP3, IPP 1, 2 and MCP5) was highly associated with higher DAS28-CRP. BL swelling of the MCP1, 3, 4; MCP 1, 2, 5 was associated with erosive disease. In contrast, swelling of the knee was correlated with non erosive and seronegative RA. Swelling of joint location such as knee, shoulder, ankle, MCP 1, 5, MCP 5 and IPP 1, 2 was significantly correlated with a higher HAQ. Only swelling of MCP 1, 2, 5 was associated with the presence of ACPA antibodies. No difference was observed for smoking habits and gender. Comparison between BL joint location in patients achieving remission or not has been evaluated. Patients with BL erosion and swelling in the feet responded less to MTX of non-responder (respectively 16.2% vs 35.1% and 25% vs 35.1%). For patients with swollen wrist, we observed the same trend without significance. Smoking habits and rheumatoid factor positivity were more present in the non-responder group (29.6% and 66.1% versus 14% and 46.5%).

Conclusion: In our cohort of ERA naïve to DMARD, swelling was most present in wrist and hand joints (PIP 3 and 2). Erosions were most frequent in MTX joints and wrist. Clinical response to MTX was poorer in patients with swelling of the hand and knee as well as erosion of the foot. Joint location could be an additional prognostic factor in ERA for severity and response to MTX suggesting more intensive therapy.

Methods: Between 2012 and 2020, 7,435 deaths among 37,996 RA prevalent residents with RA were recorded, was linked with healthcare co-payments exemptions, hospital discharge records, and mortality records. RA was defined by a healthcare copayment exemption for or any hospital diagnosis of RA. We analyzed all-cause mortality until December 31, 2020. MFRs per 1,000 were stratified by year, sex, and age group. MFRs were derived, by comparing MFRs of the general regional population. Causes of death were coded using the ICD-10 coding system and age group. SMRs were derived, by comparing MFRs of the general regional population. SMR, and causes of death in Rheumatoid Arthritis (RA) in a population-based cohort of patients with Rheumatoid Arthritis: A POPULATION-BASED STUDY.

Background: Whether or not in the last years mortality is still increased in RA patients compared to the general population is controversial.

Objectives: To assess mortality rates (MFRs), standardized mortality ratios (SMRs), and causes of death in Rheumatoid Arthritis (RA) in a population-based study.

Methods: We analyzed linked administrative health databases of the Veneto Region (Italy, 4,900,000 residents): the population registry, where all residents are recorded, was linked with healthcare co-payments exemptions, hospital discharge records, and mortality records. RA was defined by a healthcare copayment exemption for or any hospital diagnosis of RA. We analyzed all-cause mortality until December 31, 2020. MFRs per 1,000 were stratified by year, sex, and age group. MFRs were derived, by comparing MFRs of the general regional population. Causes of death were coded using the ICD-10 coding system and were available until 31/12/2020; they were grouped in: RA, infectious diseases, cardiovascular diseases (CVD), cancer, diabetes, or others.

Results: Between 2012 and 2020, 7,435 deaths among 37,996 RA prevalent cases occurred, corresponding to an average annual standardized MFR of 32.2 (95% CI 31.5; 33.0) per 1,000 persons. The median (IQR) age at death was 83 years (77-88), lower in males (81, 75-86) compared to females (84, 78-89). Standardized MFR was higher in males than in females (41.3, 95% 39.0-43.2 vs. 29.5, 95% CI 28.7, 30.3); notably, this was true across all age groups (Table 1). Causes of death were CVD 2,735 (37.1%), cancer 1,519 (20.6%), infections 827 (11.2%), RA 352 (4.8%), diabetes 208 (2.8%), trauma, poisoning, or post-surgical/procedural complications 197 (2.7%), and others 1,532 (20.6%). Out of 12,875 incident RA patients, 1,288 died during the study period, corresponding to a mortality rate of 21.3 (95% CI 20.2-22.5). The distribution of causes of death among incident cases was comparable to that observed among prevalent cases. Overall SMR was 1.28 (95% CI 1.21-1.35) and was higher in younger patients (<45 years old: 2.15, 95% CI 0.93-4.24 (Figure 1). Eight-year survival was significantly affected by age at diagnosis: 98.8% (95% CI 98.1%-99.2%) in patients aged <50 years, 95.8% (94.5%-96.8%) in patients aged 50-59, 94.2% (92.2%-95.7%) in patients aged 60-64, 84.1% (81.7%-86.2%) in those aged 65-75, and 48.4% (45%-51.6%) in those aged >75 years.

Conclusion: Standardized mortality ratio is slightly increased in RA patients compared to the general population, especially in younger patients. Despite that, eight-year survival in subjects <45 is good. CVD and cancer represent the main causes of death in RA, whereas therapy-related complications such as infections account for a low proportion of deceases.

Poor sleep quality increases presenteeism but not absenteeism in RA patients

Keywords: Patient reported outcomes, Work-related issues, Rheumatoid arthritis

Z. Gula1,2, P. Kuszmiernsz2, J. Gąsowski3, G. Haugeberg4,5, M. Korkosz2,3. Jagiellonian University Medical College, Krakow, Poland, Department of Rheumatology and Immunology, Krakow, Poland; 1University Hospital, Division of Rheumatology and Immunology, Krakow, Poland; 2University Hospital, Division of Internal Medicine and Geriatrics, Krakow, Poland; 3Sorlandet Hospital, Research Department, Kristiansand, Norway; 4NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway

Background: Patients with inflammatory arthritis frequently suffer from poor sleep affecting their quality of life and work productivity i.e., higher presenteeism reflecting the disability to concentrate on work tasks despite being present at work. Sleep disturbances are reported to be more related to emotional factors than activity of the disease. However, sleep quality is rarely assessed in daily rheumatological practice and only few patients receive treatment for insomnia. Assessing sleep quality in MDHAQ form on a scale from 0 (without any difficulty) to 3 (unable to do) could be a simple tool to identify patients who need more profound evaluation of sleep disorders and intervention aimed at improving their work efficiency.

Objectives: Assessing the relationship between sleep quality and work outcomes in patients with rheumatoid arthritis (RA) by 1) evaluating the frequency of sleep disorders according to 0–3-point scale in MDHAQ form 2) finding a cut-off point for presenteeism and absenteeism discriminating patients with or without sleep disturbances and 3) defining the association between disease activity, sleep quality and work outcomes.

Methods: Cross sectional study of one year data from PolNorRHEUMA registry. Sleep assessment was based on MDHAQ, and patients were categorized into 4 groups according to the severity of sleep disorders. To assess presenteeism and absenteeism we used the Work Productivity and Activity Impairment Questionnaire (WPAI). The results were obtained using STATISTICA Tibco 13.3 software. All continuous variables were non-normally distributed, thus were presented in the manuscript as a median and compared by Mann-Whitney U-test, Kruskal-Wallis or multiple repetition test. To assess the point discriminating between different groups of patients depending on the severity of the sleep disorder, the cut-off point of presenteeism was calculated based on receiver operating characteristic (ROC) curves.

Results: Among 250 adult patients with RA, 63 (25%) didn’t have ANY difficulties with sleep, 130 (52%) had SOME, 43 (17%) had MUCH and 14 (6%) were UNABLE to sleep. After analyzing 130 available WPAI questionnaires, we found that the cut-off value for presenteeism of 40% differentiates people with good sleep (MDHAQ sleep= 0 and 1) from those with a poor sleep (MDHAQ sleep = 2 and 3) whereas the cut-off = 10% differentiate group with no sleep disorders from group 1+2+3 combined. Interestingly, no such relation was found for absenteeism. Patients with poor sleep were significantly older, had higher BMI, DAS28, SJC and TJC (but not ESR and CRP), higher pain, joint pain and fatigue. After adjusting for age, sex, BMI, and CRP we found positive association between presenteeism and MDHAQ sleep score, TJC and morning stiffness (beta=11.6, beta=0.9, beta=8.36 respectively) but no association with SJC. Only 16 (6.4%) patients received treatment for insomnia.

Conclusion: Poor sleep quality according to MDHAQ indicates a very high presenteeism and poor work productivity, with no influence on absenteeism. Sleep, TJC and morning stiffness but no other disease activity parameters contribute to presenteeism. Scoring 2 or 3 in a question regarding sleep quality in the MDHAQ form should lead to sleep evaluation and specific intervention, independent of RA activity.

Interstitial lung disease (ILD) is one of the leading causes of morbidity and premature mortality in rheumatoid arthritis (RA) patients. Some studies have shown that Krebs von den Lungen-6 (KL-6) may be a valuable biomarker for diagnosis and stratifying prognosis in Rheumatoid Arthritis-Associated Interstitial Lung Disease (RA-ILD).

Objectives: To evaluate the diagnostic and prognostic value of serum KL-6 in RA-ILD patients.

Methods: We conducted a retrospective study that included patients with RA (ACR/EULAR 2010 criteria) with available KL-6 data measured in blood serum at study enrolment. Patients were evaluated between February 2017 and October 2019 at a single center. ILD was diagnosed by high-resolution computed tomography (HRCT) and confirmed by a multidisciplinary committee. Serum KL-6 levels were measured by Lumipulse G KL-6 Kit (Fujirebio, Japan), using Chemiluminescent enzyme immunoassay (CLEIA). The reference value for KL-6 in healthy subjects was 118-627 U/mL. The inter-assay variation coefficient of the reagent was ≤ 4.4%. We performed a bivariate analysis according to the presence of ILD and high levels of KL-6. Mortality was assessed in December 2022 by medical chart review.

Results: A total of 166 patients were included (36 RA-ILD and 130 RA-non-ILD). Patient baseline characteristics and clinical features are presented in Table 1. RA-ILD group had significantly higher KL-6 levels compared to RA-non-ILD group. 

Conclusion: Serum levels of KL-6 could be a valuable biomarker for the diagnosis and prognosis of RA-ILD.

Objectives: To explore which biological and non-biological factors associate with persistent active RA (pactiveRA) in the first year, despite use of conventional synthetic DMARDs.

Methods: Observational cohort data from adult early RA patients in the National Early Inflammatory Arthritis Audit (NEIAA) across England and Wales between May 2018 and Oct 2022, were acquired. Patients were defined as having pactiveRA based on three consecutive Disease Activity Scores (DAS28) of >3.2 at baseline, three and 12 months of follow up. Controlled RA (contRA) was defined as patients with a DAS28 ≤ 3.2 at the three and 12 month time-points, (having started off with a baseline DAS28 of >3.2). Univariable, followed by multivariable analyses were applied, the latter using stepwise forward logistic regression to explore associations with pactiveRA. PactiveRA status was used as the outcome variable. Age and gender were included in the models as a priori, with socioeconomic variables handled as the main independent variables (social deprivation, smoking-status and comorbidities) of interest, followed by clinical variables.

Results: A total of 682 patients with pactiveRA and 1,026 contRA patients were included. Compared to contRA, patients with pactiveRA were younger (aged 58, interquartile range (IQR): 49, 67) vs (62, IQR: 52,72), included more females (69% vs 59%), were current or ex-smokers, and more likely to have depression, lung and gastrointestinal disease. Also, patients with pactiveRA had worse scores in patient reported outcomes at baseline and Patient Health Questionnaire Anxiety and Depression Screener. Logistic regression results are summarised in the Table 1. Age, gender, living in a socially deprived area and being an ex or current smoker, were independently associated with pactiveRA in models controlling for markers of disease severity (seropositivity). Baseline corticosteroid use was also associated with pactiveRA (p<0.05 for all) and having a concomitant diagnosis of depression, odds ratio (OR) 2.30 (95% CI: 1.67,1.73), lung disease OR 1.46 (95% CI: 1.14,1.86) and gastric ulcer OR 1.71 (95% CI: 1.17,2.50) were significantly related to pactiveRA.

Conclusion: Sociodemographic factors (age, gender) and living in socially deprived areas were all associated with pactiveRA, independent of clinical and disease characteristics. Identifying 'adverse' socioeconomic factors that could drive persistent active disease early in the disease process, can help tailor interventions according to individual characteristics and need.

ASSOCIATION OF CLINICAL FEATURES AS PREDICTORS OF INADEQUATE RESPONSE TO TNF THERAPIES—FURTHER ANALYSIS OF THE MOLECULAR SIGNATURE RESPONSE CLASSIFIER

Keywords: Biomarkers, Rheumatoid arthritis, Artificial intelligence

Background: Clinical and molecular features have been used to predict how RA patients will respond to distinct treatments. Clinical datasets are more readily available, more easily analyzed, and less costly to obtain than are molecular datasets [1]. But predictions based on clinical features alone are usually insufficiently reliable for deciding among treatment options [2]. Although molecular features are increasingly valuable for predicting treatment responses [3], physicians are often uncertain whether it is necessary to consider molecular measures [4]. And health care providers must determine whether the benefits of using molecular datasets justify their added costs. The molecular signature response classifier (MSRC) uses clinical features and molecular (genomic and serologic) features to identify RA patients unlikely to adequately respond to TNF therapies [5]. But the relative contribution of clinical and molecular features to MSRC performance has yet to be fully addressed. This information is invaluable because most RA patients respond inadequately to their initial treatments and response-prediction classifiers offer much promise for improving patient outcomes.

Objectives: Our objective was to evaluate how well clinical features alone predict inadequate TNFi responses in the patient cohort used for developing the MSRC.

Methods: Clinical features (sex, body mass index, and patient global assessment) and molecular features (expression levels of 8 genes, 10 single nucleotide polymorphisms, anti-CCP, and CRP) were used for RA patients in the CERTAIN study. Predictive models were trained through repeated cross-validation by using a random forest machine learning algorithm on 80% of the training data (n = 114); models were optimized by validation on the remaining 20% (n = 29). The final model was built on the entire training data set. Performance was then evaluated on the validation set (n = 175). Predictive models were then evaluated on the receiver operating characteristic curve (AUC). All statistical analyses were performed by using Python 3.7.8.

Results: Classifier performance when using only molecular features (AUC, 0.65–0.68) was better than its performance when using only clinical ones (AUC, 0.41–0.60) (Table 1). Classifier performance was worst when using combined molecular and clinical features (AUC, 0.65–0.68).

By decreasing RA disease activity, methotrexate could potentially help to reduce the risk of lymphoma development; however, there are conflicting data in the literature.

Objectives: To perform systematic literature review to evaluate the association between use of methotrexate in RA and the risk of developing lymphoma.

Methods: A systematic literature search was performed using the PubMed, Embase, and Cochrane Central Register of Controlled Trials from inception through December 9, 2021. The search was limited to observational studies and randomized controlled trials (RCT) published in English that evaluated the association between use of MTX in RA and the development of lymphoma. Case series and reports were excluded. Two authors independently extracted data from final articles using a predefined data abstraction form and conflicts were resolved by a third reviewer. Quality assessments were performed.

Results: The study identification and selection process is summarized in Figure 1. Of the initial 839 articles identified, only eight articles met the eligibility criteria. The characteristics of these studies are depicted in Table 1. These were mostly observational studies except one RCT. Study sample sizes varied from 160 to 20,000 patients with RA. Five studies reported the odds/hazards ratio of occurrence of lymphoma in patients exposed to methotrexate versus not exposed to methotrexate. Three studies compared risk of lymphoma development in RA patients treated with methotrexate versus other biological DMARD of which one was an RCT. Most of the studies adjusted for variables such as age, sex, RA disease activity measures and inflammatory markers, concomitant RA medications and risk factors for cancer and RA. Of the eight studies, six did not find a significant association between MTX use and lymphoma, while two studies, conducted in Japan, reported a significant association. Included studies were of moderate to high quality. The heterogeneity of the included studies precluded conducting a meta-analysis.

Conclusion: These results confirm the importance of including molecular features in TNFi response–prediction models. Identifying new molecular biomarkers of treatment response can help address prediction challenges caused by the heterogeneity of RA. And considering clinical and molecular features together, with other assessments increases the predictive performance of precision medicine tests such as the MSRC.

REFERENCES:
Background: Newly diagnosed RA patients seen in routine care may present with more tender than swollen joints, that can persist throughout their early RA treatment. Little is known, about the impact of these tender-swollen joint count differences (TSJD) on patient-reported outcome measures (PROMS), such as function, pain interference, social participation and other health-related quality of life (HR-QoL) outcomes.

Methods: Data were from patients with active, early RA (symptoms<1 year, CDAX>2.8) enrolled in the Canadian Early Arthritis Cohort (CATCH) who completed detailed clinical assessments and PROMs including the PROMIS-29 (physical function, social participation, pain interference, fatigue, sleep disturbance, anxiety and depression) at baseline, 3-, 6- and 12-month between Jan 2016 and Aug 2022. 28-tender and 28-swollen joint counts (including 6 large and 22 small-joints) were performed by rheumatology team members. TSJD were calculated by subtracting SJC from TJC at each visit and categorized as <0, 1-4, 5-6, 7+. Adjusted associations between repeated measures of TSJD and PROMIS-29 HR-QoL domains were estimated in separate linear-mixed models adjusted for age, sex, education, smoking, comorbidities, osteoarthritis/back pain, and RA treatment. Stratified analyses by large vs small TSJD were also performed to examine potential differential impacts by joint distribution.

Results: 547 eligible early RA patients (70% female, mean (SD) age 56(15) years, mean (SD) disease duration 5.3 (2.9) months) evaluated at baseline. 287 (52%) had TSJD score>0. Of these, scores ranged from 1 to 4 in 200 (37%), 5 to 6 in 41 (8%) and 7+ in 46 (8%). The frequency of TSJD=0 decreased from 52% at BL to 32% at 12-months. Adjusted mean-change scores in all PROMIS-29 measures were worse with higher TSJDs over 1-year follow-up (Figure 1). TSJD 1 to 4 were associated with worse mean-change T scores for all PROMIS-29 outcomes, with TSJD>7 showing more pronounced worsening in physical function -2.6 [-4.0, -1.2] and participation satisfaction -3.5 [-5.3, -1.7] (negative scores indicating more improvement). Worse mean-change T scores were also associated with TSJD>7 (positive scores indicating worse symptoms): pain intereference 5.2 [3.5,6.9], fatigue 4.0 [2.1, 5.8], sleep problems 3.0 [1.4, 4.5,] anxiety 2.1 [0.4, 3.8] and depression 2.0 [0.4, 3.7]. There were fewer scores of TSJD 5 to 6, which was associated with worse mean-change scores in function, social participation and pain interference. The most striking mean-change scores were seen for large joint-TSJD scores of 5 to 6 in PROMIS function -6.1 [-10.3, -1.9] and social participation -6.1 [-11.6, -0.6], pain interference 6.6 [1.5, 11.7], compared to those found with small joint-TSJD and 28 joint-TSJD. Large joint-TSJD scores 1 to 4 were also associated with worse mean-change scores for all PROMIS measures.

Conclusion: Over half of patients with eRA have more tender than swollen joints, which persists in a third of patients. An increased TSJD score is associated with worse function, pain interference, social participation, and other HR-QoL outcomes over 1-year of follow-up. TSJD thresholds of 1 to 4 and >7 were associated with worsening of all PROMIS-29 outcomes. Having more tender than swollen large joints, at thresholds of 1 to 4 and 5 to 6, was associated with the most pronounced worsening of PROMs. Elevated TSJD assessment, especially in large-joints may help identify patients likely to experience worse outcomes.

**Disclosure of Interests:** Hilde Berner Hammer was funded by The Research Council of Norway to the study: NORA - Personalized medicine in RA by combining genomics, biomarkers, clinical and patient-derived data from the Nordic countries (Project number 299511).

**OBJECTIVES:** To explore the associations between calprotectin, CRP, ESR, and clinical disease activity assessments, and to explore the predictive value of these inflammatory markers on clinical and ultrasound (US) examinations.

**Methods:** Two cohorts were included: 1. Patients with early RA initiating methotrexate (the ARTICL study) and 2. Patients with established RA initiating a biologic disease-modifying anti-rheumatic drug (the ULRABIT cohort) (209 patients) (mean (SD) age 53.3 (13.2) years, disease duration 10.0 (8.8) years, 81% women, 80% anti-CCP positive). Both cohorts were assessed by clinical (tender/swollen joints) and ultrasound (US) examinations. Calprotectin (measured by use of FEIA (Thermo Fisher)), CRP and ESR (inhouse methods) were assessed at treatment start and at one month in both cohorts. Correlations were analysed by Spearman. Baseline and 1-month levels of calprotectin, CRP or ESR were explored by linear regression for prediction of 3 months results of objective (US, SJC, PTA) and subjective (TJC, PGA, PMA) measures of disease activity (adjusted for age, gender, and disease duration) giving R-squared (95% CI obtained by bootstrapping (percentile intervals and 1000 bootstrap replications)).

**Results:** The correlations between baseline levels of calprotectin and SJC28/PGA were 0.34-0.56 in the two cohorts, with corresponding correlations for CRP of 0.25-0.46, and ESR 0.23-0.50 (all p<0.001), and lower correlations with TJC28, PGA and pain (median 0.25 (range 0.04-0.35). Calprotectin and CRP were predictive of the objective inflammatory variables in both cohorts (Table 1), with calprotectin having the highest R-squares, and calprotectin had better prediction than CRP and ESR in established RA (p<0.05).

**Conclusion:** The laboratory markers had highest correlations with the more objective assessments. Calprotectin was superior to CRP and ESR for prediction of the objective disease activity variables. Thus, calprotectin may have added value in clinical evaluation of inflammatory activity in RA patients.

H. B. Hammar1,2, L. Mathsson-Alm3, I. Gehring4, J. Sexton5, E. A. Haavardsholm1,2, J. Ashley1. Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Dept of Rheumatology, Oslo, Norway; 2Faculty of Medicine, University of Oslo, Oslo, Norway; 3Thermo Fisher Scientific, Phadia AB, Uppsala, Sweden; 4Thermo Fisher Scientific, Freiburg, Freiburg, Germany; 5Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Oslo, Norway; 6Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden.

**Background:** Inflammatory laboratory markers predicting response to medication would be useful in the clinics. Two Norwegian cohorts of early or established RA patients included in the NORA study (a Nordic multi-centre study exploring personalized medicine in RA) were used to explore the predictive value of calprotectin, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).

**Objectives:** To explore the associations between calprotectin, CRP, ESR, and clinical disease activity assessments, and to explore the predictive value of these inflammatory markers on clinical and ultrasound (US) examinations.

**Methods:** Two cohorts were included: 1. Patients with early RA initiating methotrexate (the ARTICL study) and 2. Patients with established RA initiating a biologic disease-modifying anti-rheumatic drug (the ULRABIT cohort) (209 patients) (mean (SD) age 53.3 (13.2) years, disease duration 10.0 (8.8) years, 81% women, 80% anti-CCP positive). Both cohorts were assessed by clinical (tender/swollen joints) and ultrasound (US) examinations. Calprotectin (measured by use of FEIA (Thermo Fisher)), CRP and ESR (inhouse methods) were assessed at treatment start and at one month in both cohorts. Correlations were analysed by Spearman. Baseline and 1-month levels of calprotectin, CRP or ESR were explored by linear regression for prediction of 3 months results of objective (US, SJC, PTA) and subjective (TJC, PGA, PMA) measures of disease activity (adjusted for age, gender, and disease duration) giving R-squared (95% CI obtained by bootstrapping (percentile intervals and 1000 bootstrap replications)).

**Results:** The correlations between baseline levels of calprotectin and SJC28/PhGA were 0.34-0.56 in the two cohorts, with corresponding correlations for CRP of 0.25-0.46, and ESR 0.23-0.50 (all p<0.001), and lower correlations with TJC28, PGA and pain (median 0.25 (range 0.04-0.35). Calprotectin and CRP were predictive of the objective inflammatory variables in both cohorts (Table 1), with calprotectin having the highest R-squares, and calprotectin had better prediction than CRP and ESR in established RA (p<0.05).

**Conclusion:** The laboratory markers had highest correlations with the more objective assessments. Calprotectin was superior to CRP and ESR for prediction of the objective disease activity variables. Thus, calprotectin may have added value in clinical evaluation of inflammatory activity in RA patients.

Background: The benefit and harms of low-dose glucocorticoid (GC) therapy for established rheumatoid arthritis (RA) in combination with biological and targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs) are uncertain. Objectives: We investigated the effect of b/tsDMARDs on concomitant GC therapy among people with RA and the impact of low-dose GC therapy on disease activity and comorbidities.

Methods: This was an observational, monocentric, prospective study. We enrolled all RA patients who started their first b/tsDMARD between 2015 and 2020, excluding those with overlapped connective tissue diseases. The primary outcome was the odds ratio (OR) of persistent GC discontinuation at month 36 (M36), as assessed through multivariable logistic regression. We defined persistent GC discontinuation if GC therapy was not prescribed for ≥2 consecutive visits after 24 months. Secondary outcomes were the marginal means of prednisone daily dose and disease activity score in 28 joints (DAS28) with C-reactive protein (CRP) over three years estimated through repeated-measures analysis of covariance. Analyses were adjusted for age, sex, disease duration, seropositivity, baseline DAS28 or GC dose. The impact of low-dose GC therapy on comorbidities and disease activity was also evaluated.

Results: This inception cohort comprised 371 RA patients initiating their first b/tsDMARD: tumor necrosis factor inhibitors (n=298; 80.3%), abatacept (n=47; 12.7%), tocilizumab (n=11; 3.0%), rituximab (n=9; 2.4%), Janus kinase inhibitors (n=9; 1.6%). b/tsDMARDs were combined with low-dose GC therapy in 65% of patients at baseline, decreasing to 42% at M36. After starting b/tsDMARDs, the median (10th-90th percentile) dose of prednisone decreased from 5 (2-10) at baseline to 2.5 (0-5) mg daily at M36. The most decrease in prednisone dose occurred within the first six months of b/tsDMARD therapy. Persistent GC discontinuation was achieved in 23% of patients during follow-up, with a significantly higher discontinuation rate (34%) and a trend for lower exposure to GC therapy after M24 in patients diagnosed in the last decade compared to older cohorts (Figure 1A). Patients who discontinued GC therapy persistently were significantly younger (52 vs 59 years), had shorter disease duration (9 vs 13 years), more swollen joints (6 vs 4) and greater patient global assessment (65 vs 55 mm), and received higher doses of methotrexate (14 vs 12 mg/w). After accounting for confounders, patients who discontinued GC therapy persistently did not show worse disease control over time (Figure 1B) whilst developed less cardiovascular disease, especially hypertension (9% vs 19%, p=0.023) and coronary artery disease (0% vs 4.6%, p=0.044). Changing the molecular targets of b/tsDMARDs did not yield higher odds of persistent GC therapy discontinuation than keeping the initial drug class; in contrast, GC persistent discontinuation was less likely in older patients with longer disease duration (Table 1). Patients refractory to more than three b/tsDMARDs classes had numerically higher disease activity and received more prednisone during follow-up (Figures 1C and D).

CI, confidence interval; CRP, C-reactive protein; DAS28, disease activity score in 28 joints; OR, odds ratio; PGA, patient global assessment. Multivariable logistic regression with persistent GC discontinuation as the outcome.

Conclusion: Low-dose GC therapy for RA persists in the majority of patients despite intensive use of b/tsDMARDs, yet is associated with cardiovascular morbidity and negligible effect on disease activity. This study also highlights a trend towards less reliance on GC therapy over the past 30 years.

AN INCREASE IN ULTRASOUND JOINT INFLAMMATION OCCURS WHEN ANTI-CCP POSITIVE AT-RISK INDIVIDUALS WITH SUBCLINICAL SYNOVITIS PROGRESS TO INFLAMMATORY ARTHRITIS

Keywords: Ultrasound, Rheumatoid arthritis, Imaging

K. Harnden1, A. Di Matteo1,2, D. Esperanza Alema1,3, E. De Lorenzi1,2, L. Duquenne1,2, L. Garcia-Montoya1,2, J. Nam1,2, P. Emery1,2, K. Mankia1,2,1 University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospitals Trust, Rheumatology, Leeds, United Kingdom; 3Hospital de Braga, Servicio de Reumatologia, Braga, Portugal; 4The Rotterdam NHS Foundation Trust, Rheumatology, Rotterdam, United Kingdom

Background: Anti-CCP+ at-risk individuals with musculoskeletal (MSK) symptoms and subclinical synovitis on ultrasound (US) are at high risk of developing inflammatory arthritis (IA). The accepted standard practice is to initiate treatment at progression rather than in the pre-rheumatoid arthritis (RA) phase when they do not have clinical synovitis [1].

Objectives: We aimed to determine whether imaging characteristics change when individuals with pre-RA progress to IA in order to inform the optimal window of opportunity for therapeutic interventions.

Methods: Anti-CCP+ at-risk individuals with MSK symptoms but no clinical synovitis from the Leeds CCP cohort were selected for having US subclinical synovitis [Grey scale (GS) ≥1 and Power Doppler (PD) ≥1] prior to IA development and a further US scan performed at clinical synovitis onset (i.e. progression). The US protocol included the metacarpophalangeal joints (MCPJs), proximal interphalangeal joints, wrists, elbows, knees, ankles, second-fifth metatarsophalangeal joints, extensor carpi ulnaris and flexor digitorum tendons. US PD and GS synovitis were scored semi-quantitatively (0-3) according to EULAR/OMERACT. At patient level, total GS and PD scores were compared between scans. Change on US in the joints that became clinically swollen was also assessed. Early morning stiffness (EMS) and 44 tender joint count (TJC) were compared between scans. Wilcoxon signed-rank tests were conducted for comparisons.

Results: Forty-six CCP+ at-risk individuals were identified. The mean age was 57.4 (± 13.3), 91.3% had high titre CCP levels (≥ 3x upper limit of normal) and 60.9% were Rheumatoid Factor positive. The median US scan interval was 3.5 months (IQR 1.25-8.75). EMS increased between scans (median of 20 [IQR 0-60] to 75 [IQR 30-173] minutes [p = 0.048]) as did TJC (median 2 [IQR 1-7] to 6 [IQR 2-13] [p=0.001]. On US (Table 1), at patient level the overall burden of PD in the joints increased at IA progression, trending significantly. The overall burden of GS did not increase. PD in the MCPJs and MCP and wrist joints combined increased significantly. GS at the elbows also significantly increased. There was no significant increase in tendon GS or PD. At joint level PD increased in joints that were swollen at progression and GS increased with a trend towards significance. Non-swollen joints did not change.

Conclusion: A marked increase in US joint inflammation occurs when CCP+ at-risk individuals with subclinical synovitis on US progress from pre-RA to

**CLINICAL PARAMETERS AFFECTING QUALITY OF LIFE IN PATIENT WITH RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Outcome measures, Quality of life

**Background:** Under the treat-to-target strategies, patient with rheumatoid arthritis (RA) has achieved clinical remission in a major population, however, the impact on the quality of life remains controversial. The relationship between quality of life and disease activity control, pain control, and functional capacity control needs to be clarified.

**Objective:** This study aims to clarify the influence of clinical parameters on the quality of life in patients with RA.

**Methods:** In this study, Patient with RA who was monitored with simplified disease activity index (SDAI) as a disease activity indicator, health assessment questionnaire disability index (HAQ-DI) as a functional capacity indicator, pain score using a visual analog scale (PS-VAS) as a pain grade indicator, Euro-Qol dimension with baseline erosions (EQ5D-5L) as a quality of life indicator, and measured Sharp/van der Heijde score (SHS) as joint dysfunction indicator from the start of treatment (baseline) since January 2016, were recruited. Association between EQ5D-5L and other parameters such as gender, age, SDAI, PS-VAS, SHS, and HAQ-DI was statistically evaluated at baseline and at last observation, and change between the two periods using linear regression analysis with multivariable model.

**Results:** A total of 538 patients were included in the study. The female gender rate was 73.4%, and mean values at the baseline and at the last observation were 672 and 73.2 (age), 12.7 and 4.4 (SDAI), 49.3 and 46.4 (SHS), 35.4 and 24.5 (PS-VAS), 0.487 and 0.498 (HAQ-DI), and 0.755 and 0.825 (EQ5D-5L), respectively. All of these parameters were significantly different between the two periods. EQ5D-5L correlates significantly with SDAI (r 0.700, p<0.001), and with measured Sharp/van der Heijde score (SHS) as a joint deformity indicator from the start of treatment (baseline) since January 2016, were recruited. Association between EQ5D-5L and other parameters such as gender, age, SDAI, PS-VAS, SHS, and HAQ-DI was statistically evaluated at baseline and at last observation, and change between the two periods using linear regression analysis with multivariable model.

**Conclusion:** Quality of life in RA patients depends on disease activity control, pain control, and functional capacity. These variables could be controllable by treatment.

**POSO463**

**ASSOCIATION OF CIRCULATING LEVELS OF ANTI-CAR Antibodies WITH DISEASE ACTIVITY AND RADIOLOGICAL DAMAGE IN RHEUMATOID ARTHRITIS PATIENTS**

**Keywords:** Biomarkers, Rheumatoid arthritis, Autoantibodies

**Background:** In rheumatoid arthritis (RA) the identification of specific autoantibodies is crucial for an earlier diagnosis and stratification of patients according to different disease phenotypes. Autoantibodies directed against carboxylylated protein-proteins (anti-CarP) have been recently identified as predictors for RA development [2]. Anti-CarP antibodies are associated with more severe RA, in particular in anti-citrullinated peptide antibodies (ACPA) negative RA patients [3].

**Objectives:** To determine the frequency of positive anti-CarP antibody in a real-life cohort of RA patients on synthetic and biologic disease-modifying anti-rheumatic drugs (DMARDs) and their association with radiological damage and disease activity.

**Methods:** The study is an open-label, observational, cross-sectional study, including 69 patients with RA according to ACR/ EULAR 2010 criteria, treated with synthetic and biological DMARDs. The control group consisted of 16 healthy controls (HC). The study was approved by institutional Ethical Committee and patients signed the Informed Consent. Circulating levels of anti-CarP antibodies were determined by ELISA anti-CarP quantitative sandwich immunoassay (cut-off value 6 ng/ml). Articular X-rays were performed within 6 months of the baseline to define the presence of erosions. RA disease activity (DAS28 CRP) was assessed. Pearson $\chi^2$ test, Wilcoxon test or Kruskall-Wallis test was used, as appropriate. Spearman rank-order correlation coefficient was applied for continuous variables. A multivariable logistic regression model was performed to assess prognostic variables on damage.

**Results:** Anti-CarP antibodies were positive in 35% of RA patients and no antibodies were found in HC. One quarter (4/17) of seronegative RA patients were anti-CarP positive. All anti-CarP positive and RF/ACPA negative patients had radiological evidence of erosions and a moderate disease activity (DAS28 CRP 3.60 ± 0.58) and disability (HAQ-DI 0.70 ± 0.19). In all RA patients, a positive correlation between levels of anti-CarP antibodies and DAS28 CRP (r = 0.0003; Spearman r = 0.4829) was found. Furthermore, 87% of anti-CarP positive patients had erosions. The multivariable logistic regression model suggested that disease activity and higher levels of anti-Carp antibodies were significant predictors for the presence of erosions. There was a greater number of erosions in patients with active disease (OR 1.31, 95% CI [1.14, 1.63]) and those with a higher levels of anti-CarP antibodies (OR 1.66, 95% CI [1.28, 2.37]).

**Conclusion:** Anti-CarP antibodies were present in a significant number of RA patients and those with higher circulating levels had higher disease activity and a greater occurrence of radiological damage. Further larger studies are warranted to better understand the clinical significance of anti-Carp antibodies in RA.

Conclusion: Results suggest that disease-agnostic self-management improves disease activity scores as well as patient-reported outcomes regardless of patient diagnosis. Enhancing patients' capacity to deal with the burden of chronic inflammatory arthritis disease plays a vital role in their long-term management. Longer duration of self-management training and increased follow-up time are required to incorporate lifestyle changes.

Background: Agnostic approach refers to strategy that is generalized so that it is interoperable among various disorders or systems. In general, regardless of the underlying specific pathology, patients prioritize which self-management strategy they would like to start with according to their own requirements. They also select the issues they would like to address based on their individual perceptions of ability, need and context. Therefore, implementation of a disease-agnostic self-management program is a key priority to optimize the care of patients with chronic inflammatory arthritis.

Objectives: To determine, based on self-efficacy theory, the effectiveness of a disease-agnostic self-management program which can be undertaken by the individual inflammatory arthritis patient in any sequence to meet his/her specific needs.

Methods: Prospective multi-center assessment of patients with inflammatory arthritis, who were randomly assigned to either a 16-week program in self-management (intervention group, n = 121) or standard care for rheumatology (control group, n = 120). The program is composed of 4-arms: joint learn, joint change, joint-cise and joint act [1]. The patient is free to choose whichever component of the program that meets his/her individual requirement. Outcome variables were assessed at baseline and 6-, and 12-months after commencement of the intervention. This included measures of disease activity, adherence to therapy, motivation, functional disability, and quality of life.

Results: The intervention group included patients living with rheumatoid arthritis (30 patients), psoriatic arthritis (30 patients), lupus (30 patients), and osteoarthritis (30 patients). The mean age of participants (96 females [79.3%], 25 males [20.7%]) was 54.3 ± 3.51 years. There was no significant difference on comparing the baseline characteristics and variables between the two groups. At 6-months following initiation of the self-management program, when compared to the control group, there was significantly better improvement in the intervention group patients' motivation score (p < 0.05), functional ability (p < 0.05) as well as quality of life (p < 0.05). At 12-months follow-up, the self-management intervention demonstrated improvement for disease activity (effect size 1.4). Similarly, there was improvement of the patients' adherence to therapy (P<0.01) in the intervention group.

**Background:** Filgotinib (FIL) is a preferential oral Janus kinase (JAK) 1 inhibitor for the treatment of RA. Efficacy of FIL has been demonstrated in clinical trials. To assess effectiveness in a real-world setting, a phase 4 study of FIL (PHILOSOPHY; NCT04871919) in patients with RA is ongoing in Europe.

**Objectives:** To report baseline characteristics and interim efficacy data (up to 6 months) in the first 480 patients treated in PHILOSOPHY.

**Methods:** PHILOSOPHY is a prospective, observational study, in which approximately 1500 adults with moderate to severe active RA, who are prescribed FIL for the first time and in accordance with the product label in daily practice, will be enrolled. We report interim baseline demographics, disease characteristics, prior treatments and interim FIL assessed disease activity at baseline, and Months 1, 3 and 6, via Clinical Disease Activity Index (CDAI) and Disease Activity Score in 28 joints–C-reactive protein (DAS28-CRP) and two electronically collected patient-reported outcome (PRO) measures at baseline, Week 1–4, and Months 3 and 6; pain (using a 10-cm visual analog scale [VAS]) and fatigue (via the Functional Assessment of Chronic Illness Therapy–Fatigue scale [FACIT-F]). The proportion of patients with minimal clinically important difference (MCID) in FACIT-F (≥4.0 change from baseline) and VAS pain (≤−10-mm change from baseline) at Month 6 was assessed. A repeated measurements model was used to estimate the least squares (LS) mean change from baseline in CDAI and FACIT-F.

**Results:** Of the 480 treated patients by the end of June 2022, 73.1% were female, mean (standard deviation [SD]) age was 57.6 (11.5) years, RA duration was 10.4 (9.4) years, BMI was 27.6 (5.7) kg/m2, 28 tender joint count was 8.6 (6.9), and 28 swollen joint count was 5.6 (5.2). A total of 45.2% of patients were positive for rheumatoid factor and/or anti-citrullinated peptide antibody. Over half of patients (57.5%) had received prior biologic disease-modifying antirheumatic drugs (DMARDs; Table 1) and 18.3% prior targeted synthetic DMARDs. FIL was started due to inadequate response (36.3%), loss of response (50.6%) or intolerance (non-allergic) (7.7%) to previous treatment (other reasons/missing data accounted for 5.4% of patients). Most patients (91.9%) received FIL 200 mg; 8.1% received FIL 100 mg (Table 1). FIL monotherapy was taken by 52.9% of patients, while 45.6% received FIL in combination with conventional synthetic DMARDs. Improvements from baseline to Month 6 were observed for PROs; at Month 6, 54.2% and 65.0% of patients had an MCID from mean change [SE]: –1.8 [0.1]). Improvements from baseline to Month 6 were also observed for CDAI over time (LS mean change [SE]: –15.8 [1.0];) and DAS28-CRP (LS mean change [SE]: –3.4 [0.4]). Improvements from baseline to Month 6 were assessed. A repeated measurements model was used to estimate the MCID in CDAI, VAS pain and fatigue from baseline to Month 6. Improvements from baseline to Month 6 were also observed for CDAI over time and DAS28-CRP (LS mean change [SE]: –15.8 [1.0]).

**Conclusion:** Preliminary 6-month data indicate rapid improvements with FIL treatment, which were seen as early as 4 weeks for disease activity and as early as 1 week for pain and fatigue. Similar effects were seen with FIL monotherapy and combination therapy. Long-term follow-up is needed to further evaluate disease outcomes.

**Figures.** Progression of disease activity (as measured by CDAI) over time
DISCORDANCE IN PATIENT AND EVALUATOR
GLOBAL ASSESSMENT OF DISEASE ACTIVITY OVER
TIME AND ACROSS DISEASE ACTIVITY LEVELS IN
RECENT-ONSET RHEUMATOID ARTHRITIS

Keywords: Real-world evidence, Rheumatoid arthritis, Patient reported outcomes

A. A. Couture1, N. Carrier2, S. Roux3, H. Allard-Chamard2, P. Liang2, G. Boire3, 1University of Sherbrooke, Medicine, Sherbrooke, Canada; 2CIUSSS de l’Estrie - CHUS, Rheumatology, Sherbrooke, Canada; 3University of Sherbrooke, Medicine - Rheumatology, Sherbrooke, Canada

Background: Treatment of rheumatoid arthritis (RA) aims to achieve remission or at least low disease activity. Composite measures (e.g. SDAI) to measure RA disease activity usually incorporate patient (PGA) and evaluator (EGA) global assessments. EGA and PGA are often discordant, reflecting divergences in evaluation of disease impact and potentially towards therapeutic goals.

Objectives: Patient vs Physician (PGA – EGA) discordance was evaluated according to disease duration over 5 years and to concomitant SDAI scores.

Methods: Demographics, clinical and serological variables, radiographic damage (Sharp van der Heijde scores), treatments, comorbidities, and Patient-Reported Outcomes (function, depression and coping with disease) were collected at baseline (median symptom duration 3.7 months) and at 12, 18, 30, 42 and 60 months from symptom onset. EGA and PGA were reported using a 0-10 cm visual analog scale (VAS). PGA-EGA discordance was divided in four sub-groups: negative discordance group (<-1 cm), concordance group (≥-1cm and ≤1 cm), positive discordance group (>1 cm and ≥3 cm) and group II (>3 cm).

Results: We included 822 patients from the prospective longitudinal Early Undifferentiated PolyArthritis (EUPA) cohort of recent-onset inflammatory arthritis. At baseline, concordance was present in 27.3%, 24.9% in negative discordance and 47.8% for both groups, p <0.005). Concordance was most frequent in remission, negative discordance in high disease activity, while group I positive discordance remained stable independent of disease activity. Group II positive discordance was highest (35-38%) with low or moderate disease activity.

Conclusion: In this longitudinal prospective study of patients with early arthritis, almost half evaluated their global disease activity worse than the evaluator (positive discordance) and this proportion remained stable up to 60 months. Patients in positive discordant group were younger (median 58.6 years group I and 59.8 years group II, p <0.003), had higher functional impact (M-HAQ ≥1, 46.3 % to 50.2 % p <0.001), fewer tender and swollen joints (p <0.001), but rated higher for pain, fatigue, sleep (p <0.0001) and depression (CES-D, median score 18 for both groups, p <0.005). Concordance was most frequent in remission, negative discordance in high disease activity, while group I positive discordance remained stable independent of disease activity. Group II positive discordance was highest (25-38%) with low or moderate disease activity.

A PREDICTION MODEL FOR SWITCHING OF BIOLOGICS AND TDMARDS IN RHEUMATOID ARTHRITIS

Keywords: Prognostic factors, Registries

L. Cappelli1, G. Reed2, J. Kremer3, 1Johns Hopkins School of Medicine, Rheumatology, Baltimore, United States of America; 2UMass Chan Medical School, Medicine, Worcester, United States of America; 3Corona Research Foundation, Rheumatology, Delray Beach, United States of America

Background: Patients with rheumatoid arthritis (RA) have many options for bio-logic therapy both within treatment classes and across differing mechanisms of action, but the lack of predictability of treatment response and failure can be frustrating for patients and physicians. Rheumatologists longitudinally collect patient data and physician reported measurements as a part of routine clinical care that can be used for prediction of outcomes [1]. Harnessing data regularly collected to monitor RA to inform treatment decision making could improve patient care.

Objectives: To develop a readily usable model with data collected in clinical care at preceding visits to predict the probability of switching biologic at a subsequent clinic visit

Methods: Patients were drawn from the CorEvitas (formerly CORRONA) registry and were adults over the age of 18 with a diagnosis of RA. The study matched patients who switched biologics with control patients who had not switched biologics; the cohort was divided into a training and test set for prediction model development and validation. Switchers: RA patients initiating a biologic/tsDMARD and switching to another biologic/tsDMARD with at least two prior visits to the switch while on drug. Visits prior to the switch were between 2 and 12 months before control visit: Patient visits while still on initiated drug with at least 2 visits prior while on drug; next visit could not be a discontinuation or switch. A control visit was matched to a switch visit within 2 months of time from initiation by drug class and prior biologic experience. Pairs of control-switch visits were divided into a training (60%) and test set (40%). Using the training set, best subset regression, lasso and elastic net methods were used to determine the best potential models. Area under the ROC curve was used for the final selection of best model and estimated coefficients of this model were applied to the test data set to predict switching. Change in disease activity measures had a non-linear association with switching and were fit using linear splines with a knot at zero.

Results: A total of 5050 patients were included, 3016 in the training and 2034 in the test dataset. The average age was 59.6, the majority were female (3998, 79.2%), and the average duration of RA at the time of switch or control visit was 12.9 years. The final model included prior CDAI by category, prior patient pain measurement, change in CDAI from baseline, age group, and number of prior

POS0468

Scientific Abstracts
biologics which were significantly associated (either positively or negatively) with switching biologics (Table 1). The area under the ROC curve was 0.690 for this model with the training dataset (Figure 1). The model was then applied to the test data with similar performance; the area under the ROC curve was 0.687 (Figure 1).

Conclusion: We developed a simple model to determine the probability of switching biologics for RA at the following clinic visit. This could be incorporated into the electronic medical records or used as an application to give clinicians more information about their patient’s trajectory and likelihood of failing a biologic.

Background: In experimental settings, early treatment is associated with better outcomes in rheumatoid arthritis (RA), underpinning the concept of a “window of opportunity”. Under real-life conditions, though, the long-term maintenance of such benefits is uncertain.

Objectives: To assess the long-term maintenance of expected clinical benefits associated with early RA treatment under real-life conditions.

Methods: Adults meeting the ACR/EULAR (2010) criteria for RA were included. The participants had long-standing disease, been followed up in 11 healthcare centers in Brazil as part of the REAL study. [1] Individuals whose treatment had been initiated within 6 months of disease onset were compared with those treated for the first time only later on. Disease activity (DAS28-CRP), physical function (HAQ) and the presence of erosive disease were evaluated. Chi-squared and 1 tests, along with logistic and linear regression were used to verify associations.

Results: 995 participants were included; 89.6% female; 56% white. The mean (SD) age was 56.8 (11.6) years; cumulative schooling years: 8.1 (4.25). The median (IQR) disease duration was 147 (81–236) months. Rheumatoid factor was positive in 77.6%. The mean (SD) DAS28 was 3.28 (1.38); median (IQR) HAQ score: 0.750 (0.250–1.500). Erosive disease occurred in 54.2%. Table 1 compares early vs. late-treated patients, showing small effect sizes in clinical outcomes. After adjusting for age, schooling years, disease duration and corticosteroid use, early treatment was no longer an independent predictor of DAS28 scores (β = 0.153; p = 0.160), HAQ scores (β = 0.023; p = 0.682) or erosive disease [Exp(β) = 0.926; p = 0.626].

Conclusion: In long-standing RA, only small differences in disease activity, physical function and erosive disease were associated with early or late initial treatment. After adjusting for confounders, these differences vanished, indicating that beyond the “window of opportunity” lies a “building” of continued disease management, which might be of even greater relevance for the long-term outcomes in real-life settings.

A MACHINE LEARNING MODEL FOR IDENTIFYING IMPORTANT CLINICAL VARIABLES AND PREDICTING ONE-YEAR TREATMENT RETENTION IN PATIENTS WITH RHEUMATOID ARTHRITIS PERFORMING AN INFLIXIMAB BIOSIMILAR-TO-BIOSIMILAR SWITCH

Keywords: Prognostic factors, Artificial intelligence, Rheumatoid arthritis

N. Prensa, H. Nabi, N. Steen Krogh, A. Akkoc, M. L. Hetland, B. Glintborg, University Hospital of Copenhagen Rigshospitalet, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Centre for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Glostrup, Denmark; University of Copenhagen, Department of Computer Science (DIKU), Copenhagen, Denmark; ZiteLab ApS, Frederiksberg, Denmark; Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; University of Copenhagen, Copenhagen, Denmark; University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark

Background: In Denmark, a nationwide mandatory infliximab biosimilar-to-biosimilar switch, from CT-P13 to GP1111, was recently conducted in patients with rheumatoid arthritis (RA) to save costs (ref). It is of interest to identify patients having favorable outcomes based on clinical characteristics at time of switch.

Objectives: We aimed to explore important baseline clinical factors by implementing a robust machine learning (ML) model to predict one-year GP1111 treatment retention.

Methods: Patients with RA who performed a biosimilar-to-biosimilar switch from CT-P13 to GP1111 between April 2019 - Feb 2020 (=switchers) were identified in the nationwide DANBIO registry. Clinical characteristics at GP1111 start (=baseline) were identified in DANBIO and through linkage to national patient registries (comorbidities). Missing baseline data were estimated using Multivariate Imputation by Chained Equations (20 imputations). A tree-based algorithm Extreme Gradient Booster (xgboost) was used to predict mean outcome, defined as no stop of GP1111 during one year of follow-up (stop/no stop). Contributing baseline characteristics were investigated as SHAP values. Due to imbalanced dataset (specificity, predicting no stop of GP1111) and low true positive rate (sensitivity) ROC (AUC) were 79-87% and 0.78-0.85, with specificity and sensitivity ranging between 99.6-12 respectively. This indicated a high true negative rate (specificity, predicting no stop of GP1111) and low true positive rate (sensitivity) i.e., poor prediction of GP1111 stop. With oversampling and undersampling methods, ranges for accuracy and AUC were 60-87% and 0.60-0.87 respectively, with specificity ranging 0.61-0.73 and sensitivity 0.50-0.67 corresponding to a higher true positive rate. This could be explained by RUS and NearMiss removing data from majority outcome and by ROS and SMOTE adding data to the minority outcome. Optimal threshold results resulted in higher true positive rates and with a range for accuracy 70-85% (specificity 0.67-0.74, sensitivity 0.66-0.76).

Conclusion: We implemented a robust machine learning model for predicting one-year retention in infliximab switches and identified important baseline clinical characteristics. However, the model was challenged by imbalanced data (low stop rate) which was overcome by oversampling methods and optimal cut-offs. Careful methodological considerations are needed when advanced statistical models are applied to imbalanced datasets.

Aims: To identify patient-reported symptom clusters at RA diagnosis, associated sociodemographic and RA characteristics, and the stability of clusters over the first 6 months.

Methods: Using data from the Canadian Early Arthritis Cohort (CATCH), we applied latent class analysis with baseline PROMIS-29 pain, fatigue, depression, anxiety, and sleep scores to select relevant symptoms and levels using AIC, BIC, G-square and log-likelihood results. Baseline PROMIS and clinical differences among clusters were compared. Next, we evaluated the stability of these clusters at 3 and 6 months. Latent transition analysis was used to estimate the probability of transitioning among classes.

Background: Early RA is characterized by multiple symptoms that impact daily function and HRQOL. Little is known about whether there are symptom clusters evident at diagnosis that could identify patients with a poorer prognosis, or the stability of clusters over time.

Objectives: To identify patient-reported symptom clusters at RA diagnosis, associated sociodemographic and RA characteristics, and the stability of clusters over the first 6 months.

Methods: Using data from the Canadian Early Arthritis Cohort (CATCH), we applied latent class analysis with baseline PROMIS-29 pain, fatigue, depression, anxiety, and sleep scores to select relevant symptoms and levels using AIC, BIC, G-square and log-likelihood results. Baseline PROMIS and clinical differences among clusters were compared. Next, we evaluated the stability of these clusters at 3 and 6 months. Latent transition analysis was used to estimate the probability of transitioning among classes.

Results: The sample included 310 adults with a new RA diagnosis, with 6-month PROs available, and who were MTX naïve at baseline. Participants had a mean age 56, CDAI 29.3, and symptoms for 5 months; 67% were women and 76% White. The optimal symptom set included pain, fatigue, depression, and anxiety (levels: none, mild, moderate, severe). We identified 4 clusters: Minimal (12%); Moderate Pain Dominant (40%); Multiple Moderate-Severe (35%); and Minimal (11%). Clusters had similar sociodemographics except Minimal were slightly older and less female; SJC and TJC were similar among classes Multiple Mild or Moderate-Severe classes had significantly worse mood and sleep (Table 1). More patients in Multiple Moderate-Severe and Moderate Pain had parenteral steroids whereas numerically more in Minimal or Multiple Mild groups were on oral steroids. RA Participant Characteristics around diagnosis by symptom clusters.

|Fatigue > 55| 3 (8%)| 49 (40%)| 106 (93%)| 12 (35%)| <0.0001
|Anxiety > 55| 1 (3%)| 15 (12%)| 108 (95%)| 28 (82%)| <0.0001
|PROMIS-29 Patient Global (0-10)| 2.6 (2.4)| 4.8 (2.3)| 6.9 (2.0)| 3.9 (2.2)| <0.0001

Substantial improvement was evident in 67% at 3 months (42% Minimal, 25% Multiple Mild; Figure 1). At 6 months, 45% were Minimal and 25% Multiple Mild. The best prognosis was for Minimal; almost all stayed Minimal at 3 (95%) and 6 (87%) months. Next best was Moderate Pain where 71% improved (Minimal 64%; Multiple Mild 7%); a poor prognosis was seen for Multiple Moderate-Severe: at 3 months, 61% improved (13% Minimal, 33% Multiple Mild). Multiple Mild also were less likely to improve with 11% Minimal and 6% worsening by 3 months.

### Stability of Symptom Clusters over Time

![Figure 1](image-url)

**Conclusion:** In this large early RA cohort, we identified 4 distinct symptom clusters around diagnosis that were stable over 6 months and had distinct PRO profiles. At baseline, (70%) participants were classified as Moderate Pain Dominant or Multiple Moderate Symptoms; the remainder had minimal or multiple mild symptoms. In examining symptom clusters, we found more homogeneous groups of patients. Our results also suggested that having multiple symptom clusters was associated with less improvement over the first 6 months, and may signal a more guarded prognosis for symptom improvement and HRQL in early RA.

University of Manchester, Centre for Health Informatics, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom

**Background:** Current understanding of treatment response is largely based on patient recollection at infrequent clinic appointments, which introduces inaccuracies through recall error. Real-time patient-reported symptom data collected frequently following an intervention could improve our understanding of treatment response, facilitating better clinical decision making.

**Objectives:** Our exploratory analysis reports a case-series of patients who used the Remote Monitoring of Rheumatoid Arthritis (REMORA) smartphone-app for daily symptom tracking, evaluating their longitudinal pain-scores following intramuscular (IM) steroids to determine the duration and extent of treatment response.

**Methods:** We identified patients participating in the REMORA study Nov 2021-Sep 2022 who received an IM steroid. Concomitant disease-modifying medications were noted. Daily pain scores (out of 10) from 10 days preceding the injection and scores following were analysed. Analysis was based on the following definitions:

1. Pre-injection pain score: mean pain-score in the 10 days preceding injection;
2. Response (Y/N): ≥1 day of pain score <1; [3] Response start time: the day following injection;
4. End of response: first date following injection with pain score ≥1; [5] Response duration: number of days between [3] and [4];

**Results:** Thirty-two patients were identified for inclusion, of whom 6 received ≥1 steroid injections. In total 9 injections were given. Pre-injection pain scores ranged 3.33-9.29. Seven injections demonstrated response, 2 did not. Of the responders, duration ranged 1-54 days (median 9 days); average pain score improved by median 3.33; maximum pain score improvement ranged 0.14-7.00 (median 4.33). Table 1 summarises our results. Figure 1 demonstrates the patterns of treatment response for each steroid injection.

Range (Median) 1-54 (9)

MTX: Methotrexate; SSZ: Sulfasalazine; HCQ: Hydroxychloroquine

Conclusion: Smartphone-based remote monitoring has the potential to improve clinical care for people living with rheumatoid arthritis. In this analysis, we demonstrated a novel means to accurately assess treatment response using tracked symptom data. The duration and extent of response to steroid injections was quantified for all participants, data which is typically imprecise and relies on recall. In these preliminary results, response duration was shorter, and pain score improvement was smaller, than anticipated. Analysis of tracked symptom data across a larger population may help to identify treatment responder characteristics, supporting more targeted therapeutic strategies. This has significant implications for high-cost drugs such as biologics. Further work is required to develop consensus definitions for treatment response and disease activity in time-series data, and a means to account for the effects of concomitant drugs.

POS0473 ASSESSMENT OF THE LEVELS OF 14-3-3 η PROTEIN, A NOVEL BIOMARKER, IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS CORRELATION WITH DISEASE ACTIVITY

Keywords: Biomarkers, Diagnostic tests, Rheumatoid arthritis

R. Chawla1, P. Jain1, 1ABVIMS & Dr. Ram Manohar Lohia Hospital, MEDICINE, New Delhi, India

Background: Rheumatoid Arthritis (RA) is a common inflammatory arthritis. Current ACR-EULAR classification criteria for RA include joint involvement, immunological markers (Rheumatoid factor (RF) and Anti-citrullinated protein antibody (ACPA)), inflammatory markers (Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), and symptom duration. But these markers are not 100% accurate for RA. A meta-analysis found sensitivity and specificity of RF and ACPA to be 69% & 85% and 67% & 95% respectively [1]. There is a need for new biomarkers that can increase accuracy of RA diagnosis, one such marker is 14-3-3 η protein which is a pro-inflammatory mediator and can serve as a diagnostic and prognostic marker and a potential therapeutic target in RA patients [2,3].

OBJECTIVES:

• Assess 14-3-3 η protein levels in RA patients.
• Compare positivity rates of 14-3-3 η to RF and ACPA.
• See association between 14-3-3 η levels and disease activity.

Methods: 78 RA cases and 78 age & sex matched healthy controls were enrolled. Inclusion criteria were RA diagnosis (as per 2010 ACR/EULAR criteria), age above 18 years. Patients with any other disease & pregnant females were excluded. DAS28-ESR scoring was done. Blood was collected and tested for ESR, CRP, RF, ACPA, and 14-3-3 η protein using ELISA.

Results: Mean age in years in cases and controls was 41.71 and 41.37 respectively. 88% participants were females. Median disease duration was 32.5 months, median tender joint count was 4.50 and median swollen joint count was 1. Mean ESR in cases & controls was 32.41 ± 18.8 mm and 10.79 ± 3.49 mm respectively (p=0.001). CRP was positive in 70.5% cases & 11.5% controls (p < 0.001). RF in 88.5% cases & 11.5% controls (p < 0.001) and ACPA in 73.5% cases & none of the controls (p < 0.001). Mean 14-3-3 η protein levels (ng/ml) were 7.61 ± 2.55 in cases and 0.73 ± 0.43 in controls (p < 0.001); 7.64 ± 2.62 in seropositive cases and 7.18 ± 1.62 in seronegative cases (p =0.673). There was a significant difference between 14-3-3 η protein levels in seropositive cases and 7 .18 ± 1 .62 in seronegative cases (p =0.673). There was a significant difference between 14-3-3 η protein levels in seronegative patients and controls (p=0.001). 14-3-3 η protein levels had no correlation with RF/ACPA positivity (p=0.965) (Figure 1). Mean 14-3-3 η protein levels (ng/ml) in patients in “remission”
Conclusion: 14-3-3 protein levels are significantly raised in both seropositive and seronegative RA patients and it does not depend on RF or ACPA. 14-3-3 protein increases the sensitivity of RF and ACPA in RA diagnosis and should be included as an additional test in evaluation of RA patients.

POS5474
FACTOR ASSOCIATION WITH EROSIIVE RHEUMATOID ARTHRITIS, A MULTIMARKER PRINCIPAL COMPONENT ANALYSIS (PCA) AND PRINCIPAL COMPONENT REGRESSION (PCR) ANALYSIS

Keywords: Bone diseases, Rheumatoid arthritis, Biomarkers

G. Adami1, G. Orsolini1, A. Fassio1, O. Viapiana1, E. Sorio1, C. Benini1, D. Gatti1, D. Bertelli1, M. Rossini1. 1University of Verona, Rheumatology Unit, Verona, Italy

Background: Various clinical (disease activity, seropositive RA etc.) and metabolic risk factors (Dkk1 etc.) have been associated with erosive rheumatoid arthritis (RA). However, such risk factors might be intertwined, and multicollinearity might reduce our ability to discern the individual contribution to erosive score. Principal component analysis (PCA) is a statistical technique for reducing dataset's dimension and principal component regression (PCR) is a regression analysis based on PCA. PCR overcomes the multicollinearity problem.

Objectives: To investigate the clinical and bone metabolic risk factors associated with erosive RA using PCA and PCR.

Methods: We conducted a cross-sectional analysis on seropositive RA patients not responding to first-level disease-modifying antirheumatic drug, candidate to bDMARD treatment. Clinical, radiographic (both hands and feet x-ray), laboratory and densitometric (BMD) parameters were collected. Sharp van der Heijde Score (SvdHS) was calculated by two independent readers. Serum samples were collected and assayed for C-terminal telopeptide of type I collagen (CTX), Procollagen I N-telopeptide (PINP), Dkk1, Osteocalcin (SOST), 25-OH-Vitamin D (VitD), and PTH. PCA was applied to reduce dimensionality of the dataset and find clusters of variables recording largely redundant information. PCs were selected based on eigenvalues explaining >75% of total variance. PCR was used to predict the SvdHS. Results were analyzed using PCA package on GraphPad Prism version 9.0.0 for Windows, GraphPad Software, San Diego, California USA.

Results: 62 RA patients aged 57.2 years (SD 12.1) were consecutively enrolled. Mean DAS28-CRP was 4.17 (SD 1.27) and mean SvdHS was 24 (IQR 12-53). The loadings plot (Figure 1) shows the clusters of correlated variables in the dataset (vectors). In Table 1 are presented the results of the PCR with SvdHS as outcome. We found that age, GC treatment, ACPA titer, RF titer, CRP levels, ESR, CTX serum levels and Dkk1 serum levels were significantly positively correlated with SvdHS, whereas P1nP serum levels and PGA were negatively correlated with SvdHS.

Conclusion: We found that age, seropositivity, and inflammation were the independent clinical risk factors associated with erosive RA. CTX and Dkk1 serum levels were the metabolic factors independently associated with erosive disease whereas P1nP serum levels were associated with less erosions.

Factors Influencing Acceptance and Persistence of Electronic Patient-Reported Outcomes Collection in a Real-World Clinical Setting

Keywords: Patient reported outcomes, Rheumatoid arthritis, Health Services Research

I. Bilavska1,2, E. Lenguerrand3, J. Tobias1,3,4, P. Hamann3,4, 1University of Bristol, MRC Integrative Epidemiology Unit, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom; 2Bl NOC Institute of Cardiology, named after acad. M.D. Strazhesko” NAMS of Ukraine, Department of Non-coronary Heart Disease, Rheumatology and Therapy, Kyiv, Ukraine; 3University of Bristol, Musculoskeletal Research Unit, Translational Health Sciences, Bristol Medical School, Bristol, United Kingdom; 4North Bristol NHS Trust, Bristol, Rheumatology, Bristol, United Kingdom

Background: Rheumatoid arthritis (RA) has a relapsing-remitting nature, making it difficult to predict when patients should be seen. Collection of patient-reported outcomes (PROs) effectively communicates patients’ disease experiences. However, certain factors could impact the utilization and persistence of PROs collection.

Objectives: To explore the impact of demographic, clinical parameters on acceptance and long-term utilization of smartphone application (app) for electronic PROs (ePROs) collection.

Methods: A retrospective analysis of anonymized data collected through app as part of routine care delivered in outpatient clinic at North Bristol NHS Trust. Patients agreed to use a smartphone-based diary (LivingWith) to record disease activity between appointments by reporting weekly RAPID3, HAQ every 28 days. 28 tender/swollen joint count (JC) could also be assessed. Patients with ≥1 record were analyzed, including all reports until last follow-up. Disease activity and disability categories were defined on baseline RAPID3, HAQ scores [1,2]. Mean and SD or median and IQR were reported. Kaplan-Meier analysis was produced. Statistical tests were used. T-test, Mann–Whitney U, Kruskal–Wallis tests were used. P-value <0.05 was considered statistically significant.

Results: 306 (81.4%) patients had completed both questionnaires. 16.2% just RAPID3, and 2.4% only HAQ. 74% of patients were women with mean age 56±4. 17% of patients didn’t provide either RAPID or HAQ and assessed only 28 JC. The median number of completed records for RAPID3 was 10 [4;31] and 4 [2;10] respectively. The median number of days following registration when the first ePRO was completed was 9 [0;17] for RAPID3 and 4 [0;32.5] for HAQ. The median time between ePRO completion was 13 days [8;29] for RAPID3 and 29 days [3;483] for HAQ. The median RAPID3 score was 10.5 [5.6;15.9] and HAQ score 1.5 [0.5;16.25]. The median period [CI] for patients’ app engagement for RAPID3 was 67 weeks [55;83], for HAQ 48 weeks [36;60] (Figure 1). Demographic parameters at the registration as well as baseline disease activity and disability categories had no clear relationship with patient engagement in app use (Table 1).

Conclusion: PROs collection provides valuable information on effectiveness and tolerability of health interventions. Patients’ engagement in reporting decreases over time, suggesting the importance of reinforcement. Neither age, gender nor baseline clinical status appeared to be related to patient reporting persistence.

Quantification of Referral Bias in Patient-and Clinician-Reported Measures of Rheumatoid Arthritis Severity by Geographic Distance from an Academic Rheumatology Center

Keywords: Geographical differences, Patient reported outcomes, Rheumatoid arthritis

J. M. Davis III1, S. Achenbach2, C. Arment1, D. Bekele1, V. Kronzer1, T. Mason1, E. Myasoedova1, L. Peterson1, K. Wright1, C. S. Crowson2, Mayo Clinic, Rheumatology, Rochester, United States of America; 2Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America

Background: Systematic bias to greater severity of rheumatoid arthritis (RA) is often presumed to exist in patients referred for evaluation at academic centers. However, the magnitude of this potential bias has not been quantified to our knowledge.

Objectives: The objective was to test the hypothesis that patients in a referral population have greater RA severity based on both patient- and clinician-reported measures than local patients.

Methods: This study included eligible patients with RA who attended an in-person or virtual appointment in the outpatient rheumatology clinic at an academic center between 1/1/2020 and 10/28/2021. RA was defined by at least 2 ICD-10 diagnosis codes ≥30 days but <2 years apart plus use of a qualifying RA medication. Referral population was ascertained by geographic distance from patient residence to the clinic building and categorized as local, <50 miles; regional, ≥50 to <150 miles; or national/international, ≥150 miles. Data were collected from the electronic health records for patient-reported and clinician-reported measures of disease severity. Patient-reported measures included global pain, global arthritis, and Patient-Reported Outcomes Information System (PROMIS)

Summary: Local patients had greater RA severity than regional or national/international patients among both patient- and clinician-reported measures.

computer adaptive tests for Pain Interference, Fatigue, Physical Function, and Ability to Participate in Social Roles and Activities. Chi-square or Kruskal-Wallis tests were used to analyze differences between groups, adjusting for age at the clinic visit and sex. Linear regression models were used to test for differences between groups in PROMIS measures and Clinical Disease Activity Index (CDAI), adjusting for age, sex, race/ethnicity, and appointment type (new vs. established).

**Results:** The study population included 3220 patients with RA, including 1631 local, 956 regional, and 633 national/international patients. Overall, mean (SD) age was 62.9 (13.7) yrs, 2312 (72%) were female, and 2947 (91.5%) were n-person visits. Proportions of new patients in the local, regional, and national/international populations were 5%, 9%, and 17%, respectively. All PROMIS measures were available within 7 days of appointment for 2677 (83%) patients, with no differences between groups (p = 0.394). Regional and national/international patients had significantly higher global pain, pain interference, and fatigue and significantly lower physical function and ability to participate than local patients. Regression analysis showed that regional and national/international patients had higher pain interference (on average: 1.3 and 1.6 units; p<0.001 and p<0.001, respectively) and worse physical function (on average: -1.0 and -2.2 units; p=0.008 and p<0.001, respectively) than local referent patients, adjusting for age, sex, race/ethnicity, and appointment type. In contrast, there were no significant differences between groups in CDAI (on average: 0.3 and 1.1 units; p=0.73 and p=0.29, respectively).

**Methods:** Participants in FORWARD, The National Databank for Rheumatic Diseases, with RA, high-resolution HLA-DRB1 typing, no history of biologic use at study entry, and subsequent exposure to one or more biologics were included. The reRA group included participants with exposure to at least three biologics while under observation. Those who used a single biologic with continued use for at least two years during observation comprised the comparison non-refractory group. Descriptive statistics for each group were calculated at initiation of first biologic. Significance was assessed with Fisher’s exact tests and Mann-Whitney U tests (p<0.05), as appropriate. Logistic regression was used to determine the relationship between shared epitope status and baseline odds of becoming refractory.

**Results:** Characteristics of the 70 participants that met inclusion criteria are presented in Table 1. Several covariates varied significantly by refractory group, but these differences were attenuated in adjusted models. SE positive individuals had significantly lower odds of becoming refractory, a relationship that remained consistent with varying model complexity (Figure 1; OR [95% CI] 0.16 [0.05, 0.49] in univariate model; p<0.001). HLA-DRB1*04:01 was the only SE positive allele independently associated with nonrefractory status (p=0.036; data for other alleles not shown).

**Conclusion:** In this cohort, individuals with RA who are SE positive were less likely to be refractory to multiple biologics. This relationship appears to be primarily the result of the HLA-DRB1*04:01 allele rather than any other alleles associated with SE positivity. These findings suggest that SE positive individuals with RA are more likely to find success with their first biologic, while SE negative individuals may be more likely to cycle through multiple biologics. Ongoing and future work will investigate this relationship further and assess whether these results remain consistent when using varying definitions of reRA.

Values are mean (SD) or number (%).

**Conclusion:** Referral bias by geographic distance from the outpatient rheumatology clinic is more evident in patient-reported than clinician-reported measures of RA severity. The findings inform the interpretation of RA disease severity measures in clinical practice and research and highlight the importance of patient-reported outcome measures.

FACTORS ASSOCIATED WITH PERSISTENTLY HIGH HAQ-DI SCORE IN RA PATIENTS UNDER B/ TDMSARDS: LONGITUDINAL ANALYSIS OF HURBIO SINGLE CENTER REGISTRY

Keywords: Rheumatoid arthritis, bDMARD, Outcome measures

E. Bilgin1, E. Öztürk2, B. Fırlatan1, M. Ekici1, G. S. Karayam1, E. Unaldi1, G. Ayan1, G. Sandal Uzun1, Z. Özsoy2, S. A. Germe1, B. Farisogullari1, L. Kılıç1, A. Ardjoan1, O. Karadag1, A. Bilgen1, A. I. Erteli1, P. Özdemir2, U. Kalyonçu1, S. Kiraz1, Hacettepe University, Rheumatology, Ankara, Turkey; Hacettepe University, Biostatistics, Ankara, Turkey

Background: Health Assessment Questionnaire-Disability Index (HAQ-DI) is a widely-used and accepted instrument for the functional assessment of rheumatoid arthritis (RA) patients.

Objectives: Our aim was to determine the related factors with persistently high HAQ-DI scores in RA patients using b/TDMsARDs.

Methods: RA patients prescribed with b/TDMsARDs, registered to Hacettepe University Biologic Registry (HURBIO), had HAQ-DI score ≥1 at baseline assessment and had at least five follow-up visits, were grouped into 3, hypothetically, according to HAQ-DI scores at each of the first five follow-up visit. Group 1 was “persistently-low HAQ-DI score <1” who had HAQ-DI score higher than one at each visit. Group 2 was “floating HAQ around 1” who had at least one visit with HAQ-DI score above one and HAQ-DI score below 1; group 3 was “persistently-high HAQ-DI score >1” who had HAQ-DI score higher than one at each visit. Baseline demographic, disease, and treatment characteristics were recorded.

Multinominal logistic regression for females and multiple logistic regression for males (as group 3 had no males) was done to reveal associated factors.

Results: A total of 194 patients (89.7% female) were included. Groups 1, 2, and 3 consisted of 58 (29.9%), 111 (57.2%), and 25 (12.9%) patients. All patients in group 3 were female. RA disease duration, the time between RA diagnosis and b/TDMsARD initiation, RF negativity, and baseline HAQ-DI score were higher in group 3 compared to other groups (Table 1). Multinominal logistic regression revealed several associated factors (OR, 95% CI) for females;

- group 2 over group 1: being obese (3.0 (1.4-6.4), p=0.004), negative RF (0.5 (0.2-1.2), p=0.13), using non-anti-TNF (2.1 (0.9-4.8), p=0.07), diagnosis-situation initiation duration (per 1 year) (1.0 (0.9-1.1), p=0.85),
- group 3 over group 1: being obese (0.9 (0.3-2.0), p=0.88), negative RF (5.2 (0.5-52).6, p=0.009), diagnosis-situation initiation duration (per 1 year) (1.0 (0.9-1.1), p=0.001),
- This model classified 61% of the patients correctly.

There was no significant associated factor for males.
Background: Studies have shown an association between active synovitis measured by ultrasound (US) with plasma calprotectin in rheumatoid arthritis (RA) patients [1]. Neutrophil extracellular traps (NETs) may play a pathogenic role in RA [2]. Elevated plasma NETs have been observed in RA patients, although their association with disease activity is unclear. No studies have analyzed the association between NETs remnants and US synovitis in RA.

Objectives: To analyse whether plasma calprotectin and NETs remnants are associated with synovial inflammation measured by US in patients with established RA treated with biological therapies or JAK inhibitors (JAKi).

Methods: Observational cross-sectional study. RA patients (ACR/EULAR 2010) receiving treatment with biologic DMARDs (IL6 inhibitors (IL6i), TNF inhibitors (antiTNF), rituximab (RTX) or JAKi) were consecutively included regardless of disease activity and previous therapy. Clinical disease activity indexes and laboratory parameters of inflammation were evaluated. Plasma calprotectin was analysed, Plasma levels of elastase-DNA (EN-DNA) and histone-DNA complex (H3-DNA) (NETs remnants) were examined using a home-made ELISA test. Joint US of both hands was evaluated and graded according to Szudlarek's score. The synovial hypertrophy (SH), power Doppler (PD) and the total score (SH+PD) was calculated. US active synovitis as previously defined (3) was calculated (SH ≥ 2 + PD ≥1). A correlation study between neutrophilic markers and US scores was made.

Results: 101 RA patients (91% female, 86% seropositive (RF and/or ACPA) were included. Mean age was 55.4 ± 12.1 years and the mean RA duration was 15.4 ± 9.5 years. 78% received treatment with biologics (45 IL6i, 30 antiTNF and 3 RTX) and 23 JAKi. Mean DAS28, CDAI and SDAI were 3.19, 12 and 13 respectively. Low disease activity or remission (CDA<10) were found in 56 patients (54.5%). Mean total disease duration (years) 16.4±8.1 was made.

Conclusion: Plasma calprotectin but not NET remnants were associated with synovial inflammation measured by US in established RA patients receiving biologic or JAKi therapy. The two markers may play a different pathogenic role in RA.

POS0481

BONE EDEMA IN MRI IS MORE ASSOCIATED WITH RAPID RADIOGRAPHIC PROGRESSION THAN CLINICALLY RELEVANT RADIOGRAPHIC PROGRESSION.

K. Katayama1, T. Okubo2, T. Sato1, T. Kawaihata2, K. Tanaka3, M. Yuchih4, S. Abe5, H. Itou5,1,1Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan, 2Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan, 3Asahikawa Medical University, Division of Metabolism and Biosysmotic Science, Gastroenterology, Hematology/Oncology, Department of Medicine, Asahikawa, Japan, 4Asahikawa Medical University, 3Department of Medicine, Division of Rheumatology, Asahikawa, Japan, 5Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan

Background: Rapid radiographic progression (RRP) is selected as one of the risk factors for difficult-to- treat RA, which needs to be resolved as soon as possible. Logistic progression models for RRP have been reported for a long time. Vanier et al. recently reported a newly logistic model which is constituted by high CRP levels (>30mg/L), the number of swollen joints, RF positivity, and the existence of bone erosion by pooling individual data from 2 cohorts and 3 clinical trials. On the other hand, EULAR recommendations for imaging were published, in which MRI bone oedema was an independent and strong predictor for joint destruction. We previously reported that extensive bone marrow edema (BE) determined by hand MRI is a prognostic indicator for rapid radiographic progression in MTX inadequate response to early RA treated with MTX+ Adalimumab combination therapy [1].

Objectives: To clarify, association of BE with RRP using the clinical data in RA patients treated with conventional synthetic (cs) DMARDs.

Methods: At first, baseline data of 108 non-RRP patients and 47 clinically relevant radiographic progression (CRPP) +RRP patients were statistically compared. Secondly, background data of 13 CRPP and 34 RRP patients were compared. MRI of affected joints (mostly hands) were taken and patients were divided into two groups by existence or non-existence of BE.

Results: As shown in Table 1A, short duration, high BE rate, high DAS28-ESR (baseline), high CRP levels, high mTSS, high yearly progression of mTSS were observed in RRP +CRPP group compared with non-RRP. Table 1B showed that only the rate of BE is higher in RRP group compared with CRPP group.

Conclusion: BE may be a possible prognostic factor for RRP and more associated with RRP than CRPP.

Keywords: Imaging, Rheumatoid arthritis
Background: Although all patients present unique biopsychosocial contexts, the care of inflammatory arthritis patients is particularly complicated by the interaction of multiple factors. Advocates of patient-centered care identify that the best way to manage complex patients is through comprehensive treatment strategies that can adapt to the nuances of individual contexts. Recently published disease specific, patient centered national clinical guidelines for inflammatory arthritis[1] represent a model of care that can be fit for standard, disease-oriented patients management.

Objectives: To assess for the outcomes of indiscriminately implementing individual, disease-specific treatment strategies in standard clinical practice for the treatment of inflammatory arthritis and its impact on the disease activity measures as well as patient reported outcomes.

Methods: A 12-month multicenter, randomized study compared standard care with patient-centered, Treat to Target (T2T) management of inflammatory arthritis patients. All patients received the same outcome measures[2]. Regular appointments were delivered by specially trained rheumatologists who kept a record of the clinical assessments, medication titration, patient reported outcomes, self-management, psychosocial support and motivation score. The primary outcome was 12-month remission assessed using the Disease Activity Score 28 joints using ESR (DAS28-ESR). Secondary outcomes included fatigue, functional disability, quality of life and motivation levels.

Results: 297 rheumatoid arthritis patients were screened and randomized (149 Treat to Target management; 148 standard care); 269 (90.6%) patients had their 12-month outcomes completed. Patient centered treat to target management increased DAS28-ESR 12-month remissions compared to standard care (43% vs 22%, p = 0.004). Patient centered T2T management also significantly increased prevalence of those who achieved DAS28-ESR low disease activity scores (38% vs 23%, p = 0.005). In addition, it substantially improved patients' functional ability (0.4 + 0.2 Vs 1.1 + 0.3, p< 0.01), quality of life (0.6 + 0.2 Vs 1.2 + 0.5, p< 0.01), reduced fatigue (4.2 + 1.3 Vs 6.8 + 1.6, p< 0.01). Motivation score was higher in the T2T cohort (8.4 + 1.3 Vs 5.7 + 2.1, p< 0.05). There was no evidence that serious adverse events (patient centered T2T management =14 vs standard care =12) or other adverse events (112 vs 106) differed in both groups.

Conclusion: More patients achieve the treatment target of remissions or low disease activity status. There were greater improvements in patient reported outcomes, functional ability, fatigue as well as motivation. In the meantime, there were no more harms. Patient centered T2T clinical guidelines are able to provide condition-specific guidance on how one would optimally manage a disease tailored to the individual patient's requirements.

Keywords: Palindromic rheumatism (PR) is a recognised precursor of rheumatoid arthritis (RA) and is characterised by episodic flares of pain and swelling in and around joints [1]. Up to 50% of PR patients will progress to persistent arthritis (PA) [1]. However, PR is challenging to identify and study longitudinally and risk factors for progression remain unclear [1]. This is the first large UK prospective cohort study describing risk factors in patients with PR, the majority of whom were treatment naive at baseline.

Objectives: To investigate baseline risk factors associated with progression to PA in PR patients.

Methods: Patients with suspected PR were recruited to the Leeds PR cohort from regional primary care and secondary care referrals. In the absence of an accepted classification criteria, PR was defined as ‘a confirmed history or physical examination consistent with episodes of joint pain and swelling that returned to normal between episodes in the absence of an alternative diagnosis’ [2]. At baseline, a comprehensive set of clinical, imaging, serological and immunogenetic parameters was assessed. Patients were monitored at 3-month intervals for the first year, then 6 monthly or earlier if clinically indicated. Progression to PA was defined by the presence of at least one tender and swollen joint confirmed by a rheumatologist, which persisted for at least 3 weeks. Baseline intervals for the first year, then 6 monthly or earlier if clinically indicated. Progression to PA was defined by the presence of at least one tender and swollen joint confirmed by a rheumatologist, which persisted for at least 3 weeks. Baseline and risk factors for progression remain unclear [1]. This is the first large UK prospective cohort study describing risk factors in patients with PR, the majority of whom were treatment naive at baseline.

Background: Palindromic rheumatism (PR) is a recognised precursor of rheumatoid arthritis (RA) and is characterised by episodic flares of pain and swelling in and around joints [1]. Up to 50% of PR patients will progress to persistent arthritis (PA) [1]. However, PR is challenging to identify and study longitudinally and risk factors for progression remain unclear [1]. This is the first large UK prospective cohort study describing risk factors in patients with PR, the majority of whom were treatment naive at baseline.

Results: 161 patients were followed between July 2008 and December 2022. 32% (51/161) of patients developed PA after a median of 12 months. 90% (46/51) of progressors met criteria for RA. 90% (145/161) of patients were DMARD naive at baseline. Cox regression analysis identified factors associated with progression to PA. Flares in joints typically affecting <3 joints were protective. These data provide novel insights into the natural history of PR and will inform a risk stratification model for monitoring and early therapeutic intervention.

Conclusion: In patients with PR, female gender and high anti-CCP level were associated with progression to PA. Conversely, hand joint involvement and flares typically affecting <3 joints were protective. These data provide novel insights into the natural history of PR and will inform a risk stratification model for monitoring and early therapeutic intervention.

Table 1. Variables shown to be significantly protective or predictive of persistent arthritis. Number of joints in a typical flare was borderline significant. ULN: Upper Limit of Normal, Ref: Reference
Background: Fatigue in rheumatoid arthritis (RA) is common, overwhelming and plays a key role in patients’ perception of the disease and strongly influences global assessment [1]. While fatigue in RA has no internationally accepted definition, it is multidimensional and has an inconsistent association with disease activity in different populations with very few studies from India [2, 3].

Objectives: To determine the relationship between fatigue as measured by Patient-Reported Outcomes Measurement Information System (PROMIS) fatigue raw score with disease activity in patients with RA. To determine the predictors of fatigue in patients with RA.

Methods: A longitudinal study was conducted from January 2021 to December 2022 after Ethics Committee approval in patients with RA enrolled at our rheumatology clinic providing care to >450 patients with RA, in a tertiary care hospital. Fatigue (PROMIS Fatigue-short form 7a), patient assessment of global disease activity (PtGA), Disease Activity Score (DAS28), and Clinical Disease Activity Index (CDAI) were measured. Serum samples for interleukin-6 (IL-6), and tumor necrosis factor alpha (TNF-α) were collected and stored at -80°C. Relationship of fatigue was examined with age, hemoglobin, serum vitamin D3, TNF-α, and IL-6 using Spearman correlation coefficient. A Receiver Operating Characteristic (ROC) curve was constructed to determine the optimal PROMIS cut-off for defining PtGA >2. Binary logistic regression analysis was used to assess predictors fatigue.

Results: One hundred and fifty-four patients were enrolled, of whom 133 (86.3%) were females, 103 were reassessed at 6 months (65.4% females). All were on conventional disease-modifying antirheumatic drugs. Patients in remission using DAS28 were 9.7% (n = 15) and 52.4% (n = 54) and remission/low disease activity (LDA) based on CDAI <10 were 13.6% (n = 21) and 68.9% (n = 71) at enrolment and 6 months respectively. There was a significant reduction in median PROMIS at 6 months from 19(11) to 16(7) (p<0.0001), PROMIS was significantly lower in those with remission/LDA based on CDAI (<0.0001) and DAS28 remission at enrolment and 6 months (p = 0.012 and 0.015 respectively). PROMIS >11 had 93.8% sensitivity and 78.6% specificity to predict PtGA >2 (AUC 0.92, 95% CI 0.81 - 1.00, P <0.0001) (Figure 1). PROMIS >11 was present in 89% at enrolment and 82.5% at 6 months. Age, hemoglobin, serum vitamin D3, TNF-α, and IL-6 had no correlation with fatigue. DAS28, CDAI, sleep (Pittsburgh Sleep Quality Index - PSQI), and depression (Patient Health Questionnaire - PHQ-9) were significant predictors of PROMIS >11 (Table 1).

Conclusion: Fatigue is a significant problem in RA. A PROMIS score of 11 may be an acceptable cut-off for our population. Though fatigue improved with the treat-to-target approach, further studies are needed to determine if it is meaningful for patients. Along with disease activity, addressing sleep and depression is important in managing fatigue.

POS0486 CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS WHO ACHIEVE REMISSION AFTER 2022 AMERICAN COLLEGE OF RHEUMATOLOGY/ EUROPEAN ALLIANCE OF ASSOCIATION FOR RHEUMATOLOGY REVISED REMISSION CRITERIA APPLICATION

Keywords: Real-world evidence, Remission, Rheumatoid arthritis

Y. Hirano1, Y. Saito1, 1Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan

Background: In 2011, the American College of Rheumatology (ACR) and European League Against Rheumatism (formerly European Alliance of Associations for Rheumatology [EULAR]) developed two new definitions for remission for rheumatoid arthritis (RA) clinical trials and in clinical practice [1]: Boolean-based definition and index-based definition (simplified disease activity index: SDAI). The 2011 Boolean based definition (Boolean 1.0 [B1R]) required each of the four core set variables (tender joint count, swollen joint count, patient assessment of global disease activity [PtGA, cm], and C-reactive protein [CRP, mg/dl]) to have a value of ≤1. B1R is the most stringent remission criteria entries after B2R application were 142. Cross-sectional data among the 1020 RA patients registered in the TRAD 2021 data. New remission criteria entries after B2R application were 142. Cross-sectional data described below were compared between B1R and B2-1R: age, gender, RA disease duration, rheumatoid factor (RF) positivity and anti-cyclic citrullinate protein antibody (ACPA), Steinbrocker stage and class, medication information at the time of survey, CRP value and erythrocyte sedimentation rate, modified health assessment questionnaire (mHAQ), and concomitant osteoporosis (OP). Univariate analysis by Mann-Whitney U-test or Chi-square test was initially performed between B1R and B2-1R. Subsequently, multivariate analysis was performed using selected variables, which were statistically significant between the two groups by logistic regression analysis. P < 0.05 was considered as statistically significant.

Results: The number of RA patients in remission state increased by 30.3% by B2R application. Statistically significant differences by univariate analysis were found in the following variables (mean values or percentage in B1R/B2-1R): RA disease duration (11.3/15.5 years), RF positive ratio (70.2/79.9%), RF titer (94.4/132.8 IU/ml), ACPA positive rate (71.5/80.9%), ACPA titer (226.9/322.3 U/ml), %stage III+IV (45.6/63.4%), %BDMAJRDS (40.5/51.4%), mHAQ (0.11/0.28), %OP concomitant (32.0/46.5%). Multivariate analysis results were shown in the Table 1. mHAQ in B2-1R was significantly worse compared with that in B1R.

Conclusion: New B2R application increased the RA patient number in remission state. RA patient characteristics in B2-1R were with: longer disease duration, more seropositivity, more joint damage, treated with more intensive medications, especially worse physical function, and increased concomitant OP.

**DISENTANGLING HETEROGENEITY IN CONTEMPORARY UNDIFFERENTIATED ARTHRITIS – A LARGE COHORT STUDY USING LATENT CLASS ANALYSIS**

**Keywords:** Remission, Outcome measures, Rheumatoid arthritis

**Background:** Undifferentiated arthritis (UA) is considered to be heterogeneous and consists of subgroups, this notion is affirmed by differences in disease course, varying from spontaneous resolution of arthritis to RA-development.

**Objectives:** We aimed to identify homogeneous subgroups within UA based on a combination of clinical features and thereafter to relate these to the outcomes spontaneous resolution and RA-development. These outcomes can only be studied in UA-patients in which DMARD-treatment does not influence the natural disease course; these cohorts are scarce.

**Methods:** We studied ACPA-negative UA-patients, defined as not-fulfilling 1987-2010 RA-criteria nor having an alternate diagnosis, consecutively included in the Leiden Early Arthritis Clinic between 1993-2006, when early DMARD-treatment in UA was infrequent. Latent Class Analysis was used to identify subgroups based on a combination of clinical features (e.g. symptom characteristics, physical examination, laboratory tests). Within these subgroups, test-characteristics were assessed for spontaneous-resolution of arthritis (defined as spontaneous resolution of arthritis without DMARD-treatment) and RA-development within 1 year.

**Results:** 310 consecutive UA-patients were studied. Five classes were identified: 1) polyarthritis, often symmetric 2) oligoarthritis, frequently with subacute onset, 3) wrist-monoarthritis, often with subacute onset, increased BMI and without morning stiffness, 4) small-joint monoarthritis, often without increased acute phase reactants, and 5) large-joint monoarthritis, often with BMI and without morning stiffness.

**Conclusion:** Using a data-driven unsupervised approach, five subgroups within contemporary UA were identified. These subgroups have differences in the natural course of disease.

Tam1. 1The Chinese University of Hong Kong, Department of Medicine & Therapeutics, Hong Kong, Hong Kong (SAR); 2Tuen Mun Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); 3Queen Mary Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); 4Kwong Wah Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); 5Pok Oi Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); 6Tseung Kwan O Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); 7Caritas Medical Centre, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); 8Queen Elizabeth Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); 9Pamela Youde Nethersole Eastern Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); 10Princess Margaret Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); 11Ruttonjee Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); 12Tai Po Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR).

**Background:** Rheumatoid Arthritis (RA) is associated with functional impairment and disability. With the 2022 revision of the Boolean remission criteria, more patients can be classified as achieving remission and the revised version also increases the agreement with index-based remission criteria without jeopardising predictive value for radiographic or functional outcomes. Whether achieving sustained Boolean 2.0 remission using a treat-to-target strategy aiming can prevent functional impairment in the long-term measured using the Health Assessment Questionnaires Disability Index (HAQ-DI) would need to be addressed.

**Objectives:** This retrospective study aims to explore the impact of sustained remission classified under the revised Boolean 2.0 criteria on HAQ-DI score.

**Methods:** The data was retrieved from the Clinical Rheumatology Systematic Treat-to-target (T2T) in Asia Leadership (CRYSTAL) registry Early RA patients with symptoms onset less than 2 years were recruited between 2012-2018. All patients received a treat-to-target treatment strategy aiming at remission and had been followed for 5 years. Swollen joint count (SJC), tender joint count (TJC), Patient global assessment (PGA), CRP levels, and HAQ-DI were recorded. Patients were classified into two groups: patients achieved Boolean 2.0 remission in both the first and second year (Early-Sustained Remission (ESR) Group) and patients who did not (Non-ESR group).

**Results:** The data of 236 patients were retrieved. 57 (24.2%) of them were classified as ESR group and 166 (70.3%) were in Non-ESR group (Table 1). The average HAQ-DI score was lower in the ESR group in the second, third, fourth and fifth year compared to the Non-ESR group with p ≤ 0.001 [year 1: 0.097 ± 0.218 vs 0.403 ± 0.465; year 2: 0.143 ± 0.267 vs 0.421 ± 0.452; year 3: 0.212 ± 0.339 vs 0.478 ± 0.59; year 4: 0.232 ± 0.358 vs 0.457 ± 0.566] (Figure 1). Conclusion: T2T aiming at achieving Boolean 2.0 remission in the first two years could be considered in clinical use for maintaining a lower functional impairment in the long term.

REMISSION (US-R) WITH RHEUMATOID ARTHRITIS (RA) IN ULTRASOUND

Keywords: Rheumatoid arthritis, Remission, Ultrasound

T. Abe1, Y. Oono1, K. Tsuibo2, M. Nakano1, C. Ogita1, M. Tamura1, T. Hashimoto1, N. Azuma1, K. Matsui1. 1Hyogo Medical University, Division of Diabetes, Endocrinology and Clinical Immunology, Department of Internal Medicine, Nishinomiya City, Japan; 2Kobe Citizen Medical Center West Hospital, Rheumatology, Kobe City, Japan

Background: Flares are frequent in patients with rheumatoid arthritis (RA), with 30–50% experiencing a disease flare within the first 2 years of clinical remission (CR). Ultrasound (US) synovitis despite CR have more subsequent flares than those who show both CR and ultrasound remission (USR). Plenty of studies examined clinical course and predictive factors for flare among patients with RA in CR or LDA. But few studies have examined those with USR and using US as daily rheumatologic practice through a follow-up period. Therefore, the clinical course and flare predictor of RA patients in US-R under daily US practice is unclear.

Objectives: The objective of this study among RA patients in CR/LDA with USR under on-demand and yearly US practice was as follows (1) to investigate the clinical course and change of disease activity from baseline, (2) to investigate the predictive factors for the flare over 2 years.

Methods: All patients met the following criteria: (1) RA classified according to the American College of Rheumatology (ACR) 2010 revised criteria; (2) age ≥18 years; (3) at least 12 months disease duration; (4) maintaining the same RA treatment at least 6 months; (5) being in CR or LDA according to either DAS28 CRP or SADI/CDAI; (6) being in USR. USR was defined as absence of joint synovitis, tenditis, tenosynovitis in the bilateral wrist, 2nd-5th MCP and PIP joints, and any tender or swollen joints. Demographic and treatment characteristics, clinical dates, US assessment were evaluated at the time of baseline, 1-year, and 2-years (yearly-US). US was additionally assessed if the patients showed clinical manifestations of the flare in any period (on-demand US). Questionnaires were also collected at baseline to assess physical function, psychiatric disorders and catastrophizing: HAQ-DI, BS-POP and Pain Catastrophizing Scale (PCS). Rheumatologists could employ DMARD treatment as an individual approach based on the joint decision between the patient and the rheumatologist without any restrictions. The flare was defined when patients received additional DMARD or glucocorticoids or encountered Power Doppler (PD) US flare. Baseline factors for the shorter time to the flare were analyzed by multivariate COX regression analysis, adjusting for age, gender, BMI, and DAS28 CRP. A P value ≤ 0.05 was regarded as being significant. All analyses were performed with EZR statistical software.

Results: In total, 85 patients were enrolled in the study. Baseline characteristics are depicted in Table 1. 62 patients (73%) fulfilled CR criteria. The change of DAS28-CRP from baseline to 1-year and 2-years was -0.1±0.7, -0.08±0.75. The rate of LDA/CR and USR was as follows: 92% and 91% at 1-year, 90% and 89% at 2-years. Over 2 years, 35 patients (42%) had the flare and the mean time to the flare was 11.6±7.0 months. PDUS flares were reported in 4 patients (5%) at 1-year and 2-year US assessment, even though they had no clinical signs of flares. An association of ACPA (HR=2.6, 95%CI:1.0–6.9, p=0.05), Stage III (HR=4.2, 95%CI:1.5–11.6, p=0.005), CRP (HR=21.9, 95%CI:3.5–137, p<0.001), opioids use (HR=5.8, 95%CI:2.0–17, p=0.001) on the shorter time to the flare was revealed. CR, DMARD treatment, HAQ-DI, BS-POP, and Pain Catastrophizing Scale (PCS) were not associated with the flare.

Conclusion: Under on-demand and yearly US assessment over 2 years for RA patients in LDA/CR with USR, the flare occurred frequently but most of the patients showed sustained LDA/CR and USR at 1-year and 2-years. Baseline factors should be considered for predicting the flare.

SEVER LEVELS OF BONE TURNOVER MARKERS, ESTABLISHING Z-SCORES FOR USE IN RESEARCH AND DAILY CLINICAL PRACTICE: DATA FROM A DUTCH HEALTHY REFERENCE COHORT

**Keywords:** Bone diseases, Osteoporosis, Diagnostic tests

M. Siderius1, S. Arends1, A. Muller Kobold2, L. Wagemakers3, K. Koerts2, A. Spoorenberg1, E. Van der Veer1 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands

**Background:** Bone turnover markers (BTM) reflect specific processes or aspects of bone (re)modeling. Their dynamic character provides additional information regarding the current status and balance of bone metabolism. Measurement of BTM is clinically relevant and common in patients with osteoporosis and other bone-related disease such as inflammatory rheumatic diseases as axial spondyloarthritids. BTM can contribute to the diagnostic workup as well as treatment monitoring. Interpretation of absolute values is difficult as these are highly influenced by age and gender, which complicates data interpretation and comparison of studies involving BTM. In previous research, we used BTM Z-scores to study the effect of biological therapy on the course of BTM in patients with axSpA [1, 2].

**Objectives:** To establish BTM reference values based on widely used BTM assays and/or automated immunoassay platforms that can be used to calculate Z-scores to correct for the normal influence of age and gender.

**Methods:** Serum markers of collagen resorption, bone regulation, collagen formation and facilitator of bone mineralization (sCTX, OC, PINP and BALP respectively) were measured in volunteers without bone-related diseases/abnormalities. Assays were conducted in a ISO certified specialized routine diagnostic laboratory. Raw data was plotted, gender-specific age cohorts were established based on the distribution of the data and subsequently their respective means and standard deviations were calculated. Z-scores can be calculated using these reference values to correct for the normal influence of age and gender on BTM.

**Results:** In total, 856 individuals were included, of which 486 (57%) were female. Individuals were aged between 7 and 70 years. Highest serum levels of BTM were found in childhood and puberty. Peak levels are higher in boys than girls and prevail at later ages. In adults, BTM levels decrease before reaching stable nadir levels. For the calculation of Z-scores below the age of 20 years, intervals of one year were needed due to the change in BTM activity. In adults, 10-year reference cohorts could be established in order to calculate Z-scores (Figure 1). As example, a male of 40 years with a serum PINP level of 70.0 ng/mL has a Z-score of 1.56. At the age of 60, his PINP levels remained 70.0 ng/mL, which corresponds to a Z-score of 2.73. Despite the absence of change in absolute levels of PINP, Z-scores do indicate a large increase not only compared to the previous measurement but also compared to the reference population matched for age and gender.

**Conclusion:** With our data, Z-scores of sCTX, OC, PINP and BALP can be calculated using reference categories (for age and gender) of mainly Caucasian volunteers representative for the normal population. BTM Z-scores facilitate harmonization of data interpretation in both daily clinical practice and research. This is especially important in (rheumatic) diseases with known aberrant bone metabolism as axSpA or (secondary) osteoporosis.

**Background:** Bone loss is one of the major long-term side effects of adjuvant endocrine therapy for breast cancer. There is limited consensus on how to accurately assess fracture risk in this setting. Many trials showed the effectiveness of antiresorptive drugs in preventing the loss of bone mineral density (BMD) and, consequently, reducing fracture risk [1].

**Objectives:** Our study aims to investigate osteoporotic fractures prevalence and to assess the age adjusted fractures risk in breast cancer patients receiving AET and treated with antiresorptive drugs. Moreover, we analyzed differences in terms of clinical features and outcomes between patients treated with denosumab (DMAB) or bisphosphonates (BPs), and examined variations in biochemical markers of bone turnover and densitometric values to assess the effects of each antiresorptive medication.

**Methods:** In this monocentric, retrospective, non-randomized cohort study we enrolled patients with non-metastatic breast cancer who received at least 5 years of AET and were treated with DMABs or BPs. We retrieved demographic and clinical data pertaining to the cancer characteristics and the osteoporosis risk and at the start of the antiresorptive therapy (baseline), as well as serum levels of C-terminal telopeptide of type I collagen (CTX), vitamin D, parathyroid hormone (PTH), and densitometric data (DXA) at baseline and at 24 months.

**Results:** We enrolled 120 patients, 38 on DMABs and 82 on BPs. During a median follow-up of 32 months (24-38), 16 (13.3%) fractured at least once. At baseline, the latter had lower BMI (22 kg/m² (21-27) vs 24 kg/m² (20-26), p = 0.043), higher prevalence of osteoporosis (12/16 vs 35/104, p = 0.002), higher prevalence of prior fractures (8/16 vs 15/104, p = 0.003), and lower AET exposure time (2.7 years (1.2-3.7) vs 3.8 years (2.4-5.8), p = 0.008). In age-adjusted Cox proportional model, a history of previous fractures and BMD at the femoral neck < 1.2 standard deviation were associated with higher fracture risk (HR 7.8 (2.7-22.9), p = 0.001, and HR 3.4 (1.1-10.4), p = 0.033, respectively), whereas higher levels of vitamin D resulted protective [HR 0.7 (0.5-0.9), p = 0.010]. AET exposure time and the type of antiresorptive drug, instead, had no impact on the fracture risk. Patients who received DMAB had significantly lower levels of vitamin D, age and AET exposure time [33 nmol/l (26-39) vs 36nmol/l (30-41), p = 0.022, 55 years (10.2) vs 60 years (9.1), p = 0.008, and 2.9 years (2.0-4.4) vs 3.9 years (2.6-5.9), p = 0.014, respectively]. At 24 months, both medications were successful in reducing serum levels of bone resorption markers and increasing densitometric values. The DMAB group experienced substantially larger BMD increases in the lumbar spine and femoral neck (respectively, -9.0% (+4.2+19.8) vs +3.3% (-1.3+6.6), p < 0.001, and +6.1% (2.2+15.5) vs +0.7% (+3.5+4.4), p < 0.001).

**Conclusion:** The frequency of fractures tends to stay high in women receiving AET even if on antiresorptive drugs despite biochemical and instrumental improvements, indicating the existence of other concurrent processes of bone damage. To enable quick management of bone health-related issues, a thorough evaluation of bone turnover markers is recommended.
risk assessment must be done at the moment AET is started. When given based on risk stratification, DMABs and BPs seem to have comparable antifracture effectiveness profiles. DMAB, however, was more successful in increasing BMD over time. Whatever the case, we found that appropriate vitamin D supplementation is advised throughout AET.

POS0492
ASSESSMENT OF OSTEOPOROSIS AND VERTEBRAL FRACTURE RISK BY OPPORTUNISTIC BONE MINERAL DENSITY (BMD) MEASUREMENT ON CHOLINE PET/CT IN PATIENTS WITH PROSTATE CANCER (HORM-OS PROJECT)

Keywords: Bone diseases, Osteoporosis, Imaging

A. Dauchez1, C. Darianë2, J. Fichtenbaum3, S. Bodard3, S. Guinebert4, F. Alloux4, M. O. Timsit2, C. Roux5, F. Hyafil4, K. Briot1, O. Fogel1, C. Roux1, M. O. Timsit2, C. Roux5, F. Hyafil4, K. Briot1, O. Fogel1, C. Roux1, M. O. Timsit2, C. Roux5, F. Hyafil4, K. Briot1, O. Fogel1
1Cochin Hospital, Rheumatology, Paris, France; 2European Hospital Georges Pompidou, Urology, Paris, France; 3Necker Hospital, Radiology, Paris, France; 4European Hospital Georges Pompidou, Nuclear medicine, Paris, France

Background: Androgen deprivation therapy (ADT) is central in the management of advanced prostate cancer (PCa) but is associated with bone loss and occurrence of osteoporosis and fracture. Dual-energy x-ray absorptiometry (DXA) is recommended when starting ADT but is rarely done. Opportunistic measurement of bone mineral density (BMD) on CT has been proposed to improve osteoporosis screening in the general population, but has not been evaluated in PCa. Choline PET/CT (chPET/CT) is frequently used to identify the recurrence of PCa and/or search for metastasis.

Objectives: The objectives were to demonstrate the feasibility of using chPET/CT in comparison to the CT scan for opportunistic screening of osteoporosis and to describe the pet/ct-derived BMD and the prevalence of osteoporotic vertebral fracture in patients with PCa.

Methods: Between 2020 and 2022, we identified 171 PET/CT from 136 patients in the database of the nuclear medicine department of our tertiary center. We focused on chPET/CT. Among these patients, we identified those with a CT within 6 months before or after the chPET/CT to compare the BMD values between these 2 exams. BMD estimation was performed by 4 blinded readers (2 rheumatologists and 2 radiologists) on a 200-mm² trabecular bone area by a standardized method, on L1 vertebral in axial section. Assessment of vertebral fractures and metastasis was performed on the entire spine in sagittal section. Demographic, clinical and treatments information have been collected blind from the reading of the images. Spearman coefficient and t-test were used for continuous variables and chi square test was used for dichotomous variables.

Results: We identified 93 PCa patients with chPET/CT including 29 with a CT within 6 months. The mean age was 74 years old (± 8.6), and mean BMI was 26.9 kg/m² (± 5.2). Forty-one patients (44%) smoked or had smoked. ChPET/CT was performed for newly-diagnosed PCa in 36.6%, for suspicion of recurrence in 59.1% or as simple follow-up for 4.3%. Twelve patients (12.9%) had fractures and 20 (21.5%) had metastasis. Also, 39 patients (42%) were already on ADT with a mean duration of 21.4 ± 31.6 months. First, we compared BMD measurement on both chPET/CT and CT in the 29 patients. The mean BMD on L1 vertebral was similar between the 2 exams (125 ± 51.1 and 128 ± 42.4 HU respectively on chPET-CT and CT) and correlated well (k = 0.7; p < 0.001). Then, we measured the pet/ct-derived BMD on the whole cohort. The mean BMD was 125 HU (± 50.7). Increasing age was significantly correlated with decreased BMD (k = -0.31; p < 0.001). There was no correlation between BMI and BMD (k = 0.02; p = 0.87). The mean BMD was 123 HU (± 51.6) in patients who smoked or had smoked, compared with 138 HU (± 48.5) in non-smokers (p = 0.11). The mean BMD in patients already on ADT was 114 HU (± 56.2), compared with 127 HU (± 42.1) in others (p = 0.17). Among the 39 patients on ADT, there was a nonsignificant trend toward decreased BMD with increased ADT duration (k = -0.27; p = 0.1). Interestingly we found a significant decreased BMD for patients with fracture compared to those without fracture (mean BMD = 82.6 ± 42.9 vs 131 ± 49; p < 0.01). A cut-off of 100 HU has recently been published on CT to define patients at risk for bone complications. Here, we identified 24.7% patients with a BMD < 100 HU. These patients were more likely to have vertebral fracture compared to those with a BMD > 100 HU (30.4% vs 7.1% of fracture; p < 0.01).

Conclusion: This study demonstrates the feasibility of using chPET/CT for opportunistic screening for osteoporosis in PCa. Bone disease was frequent in this population, 13% patients had fractures and almost 25% had a BMD < 100 HU. PET/CT BMD seemed to be of interest for screening patients at risk of fracture. A prospective study will validate the interest of this approach and its impact on the management of osteoporosis in these patients.

PREVALENCE AND INCIDENCE OF OSTEOPOROTIC VERTEBRAL FRACTURE IN NON SMALL CELL LUNG CANCER: ANALYSIS OF A 289 PATIENTS COHORT

Keywords: Bone diseases, Malignancy, Osteoporosis

E. Ebsten1, P. Brocard1, G. Souissi2, R. Khoury2, A. Khalil3, M. Forien1, S. Ottaviani1, G. Zalcman1, P. Dieude1, V. Gounant1, Hôpital Bichat - APHP, Rheumatology, Paris, France; 2Hôpital Bichat - APHP, Thoracic Oncology, Paris, France; 3Hôpital Bichat - APHP, Radiology, Paris, France

Background: The recent use of targeted therapies and immunotherapy has considerably improved the survival of patients with Non-Small Cell Lung Cancer (NSCLC), in particular metastatic ones. In this new era, it is relevant to look at the comorbidities affecting the quality of life and potentially the prognosis of NSCLC. Due to shared risk factors (tobacco, corticosteroid therapy, radiotherapy, osteoporosis) is a comorbidity of interest in the context of NSCLC.

Objectives: The aim of our study was to establish the prevalence and incidence of osteoporotic vertebral fractures (OVF), the risk factors for incident OVF, and impact on survival of incident OVF.

Methods: This retrospective observational single-center study was conducted in the thoracic oncology clinic of the Bichat University Hospital, AP-HP Paris, France, between January 2021 and July 2021. Consecutive patients followed for NSCLC were included in this study. The following data were collected (a) demographic characteristics such as gender, age, height and weight, BMI, smoking status, alcohol intake (b) NSCLC characteristics such as histology, date of biopsy that resulted in the diagnostic of NSCLC, cancer stage (absence or presence of metastasis, including bone metastasis). Treatments received were collected a) oral corticosteroids (10 mg or more per day of prednisone or equivalent, for at least 2 weeks, in the last 2 years) b) anti-resorptive therapy (bisphosphonate, denosumab) c) local or systemic cancer treatment (surgery, radiotherapy, immuno-therapy, chemotherapy and/or target treatment). We defined inclusion by the first thoraco-abominopelvic CT performed for the NSCLC extension assessment at diagnosis. We defined end of follow-up by the last TAP-CT available. We proceed to a double-blind lecture of TAP CT (rheumatologist and radiologist) to evaluate the presence of vertebral fracture: prevalent or incident, its nature (osteoporotic or metastatic), the number and localization. We also measure CT attenuation (Hounsfield unit [HU]) value of L1. Survival was assessed as of August 26, 2022.

Results: We included 289 patients: 162 males (56%), mean age 66.4years old. Eight-two percent of patients were current or past smokers (42 ± 22 number of year smoking) and 22% consumed alcohol regularly. The mean BMI was 24.7 ± 5.0 kg/m². Seventy-eight percent had an adenocarcinoma and 18% a squamous cell carcinoma. Sixty one percent of patients had a metastatic cancer, including 25% of bone metastasis. The mean follow-up time was 36.3 ± 29.4 months. At inclusion, 31 of the 289 had an OVF, for 40 OVF (24 thoracic, 16 lumbar, mean 1.3 ± 0.6 OVF per patient). The prevalence at inclusion was therefore 10.7%. At end of follow-up, 23.2% of patients (67/289) had an OVF. During the follow up of 36 ± 29 months: 36 patients had an incident OVF. The incidence of OVF was 12.5%. Ninety-seven OVF occurred (68 thoracic, 29 lumbar). Median time to incident OVF was 13 months [5.7; 21.2]. In univariate analysis (Table 1), the risk factor of OVF were: age (p=0.036), BMI <19kg/m² (p<0.01), steroid use (p=0.001), and radiotherapy (p = 0.036), UH in L1 at inclusion (HR adjusted: 0,986, p = 0.003) were independent risk factor of incident OVF. Median survival was 80 months in the incident OVF group and was not reached in the patients without incident OVF (p=0.074, Image 1).

Conclusion: In our population, prevalence of OVF at inclusion was 10.7%. Incidence was 12.5% during a mean follow up of 36 months. Occurrence of a new OVF may have an impact on survival. Presence of OVF and UH in L1 should be evaluated systematically during NSCLC follow up. We should pay more attention to this population, in order to prescribe preventive anti-resorptive drugs if needed.

PREVALENCE AND RISK FACTORS OF OSTEOPOROSIS IN A BELGIAN COHORT OF LUNG TRANSPLANTATION CANDIDATES: THE PROGRESS STUDY

Keywords: Bone diseases, Osteoporosis, Lungs

E Currie1, F Carlier2, M Dumonceau3, P Evarard2, B Rondot2, J P Devogelaer4, Y Boutsen1, CHU UCL Namur, Rheumatology, Yvoir, Belgium; CHU UCL Namur, Pneumology, Yvoir, Belgium; Cliniques Universitaires Saint-Luc, Rheumatology, Brussels, Belgium

Background: Few data are available on the incidence of osteoporosis (OP) in end-stage pulmonary diseases, particularly in lung transplant candidates. Yet, organ transplantation can be accompanied by low bone mineral density (BMD) owing to immunosuppressive therapy, particularly with oral glucocorticoids (GCs) use.

Objectives: Our primary aim was to evaluate the prevalence and therapeutic management of OP in lung transplant candidates. Our second objective was to determine the risk factors associated with OP, including the type of respiratory disorder.

Methods: We included 198 patients (103 women) out of 388 screened for lung transplantation at our institution between January 1998 and December 2020. BMD, measured by Dual-energy X-ray absorptiometry (DXA, Hologic (t-m)) at the lumbar spine (LS), total hip (TH), and femoral neck (FN), vertebral fracture assessment (VFA), as well as previous major osteoporotic fracture (MOF), were recorded. We systematically collected well-recognized OP risk factors, along with other factors suspected of affecting BMD such as included (i) GCs use, pulmonary function tests, hypoxemia and type of pulmonary disorder.

Results: OP was defined by BMD values (T-scores ≤ -2.5) and/or fracture fragility (FF), MOF and/or vertebral fractures (VF), was observed in 118 patients (59.6%). Among these patients, 54 (43.8%) had only a T-scores ≤ -2.5, while 56 (40.5%) had only an FF, with predominant vertebral fractures (77.8%). The median age (IQR) of the studied population was 58 years (53.0-62.0), and 59 years in OP patients (54.2-62.0). Mean T-scores (±SD) were -1.62±1.52 at the LS, -1.43±1.05 at the TH and -1.98±1.14 at the FN. Mean T-scores (±SD) in OP patients were -2.15±1.131, -1.87±0.93 and -2.44±1.03, respectively. The mean (±SD) ten-year probability of major osteoporotic fracture assessed by the FRAX algorithms (FRAX score) was 11.6±11.2 %, and the mean FRAX adjusted to GCs dose (±SD) was 12.0±12.1 %. Eighty-eight patients (49.5%) achieved intervention threshold adjusted for age based on FRAX results.
and 110 patients (55.6%) when FRAX was adjusted to GCs dose. Seventy-eight OP patients (66.1%) achieved the FRAX intervention threshold, of whom 53 (67.9%) had vertebral fractures. The mean number of vertebral fractures was 3.6 (+/-3.1) per patient. Two patients were exposed to IFN, 21 to IFN+PAM, 5 to PAM, 2 to MASI, and 9 to MIDO. Among patients treated by MIDO, 2 had prior exposure to IFN+PAM. One patient from the MIDO group and 1 patient from the MASI group were concomitantly exposed to bisphosphonates (respectively alendronate and zoledronate). Regarding treatments efficacy, IFN+PAM and PAM significantly improved BMD (see Figure 1). Two patients treated by IFN+PAM developed an additional vertebral fracture during the first year of follow-up, at 6- and 8-months post-treatment initiation. Importantly, these patients had 4 and 7 vertebral fractures prior treatment.

Conclusion: Our data show that monthly pamidronate, and combination of interferon & pamidronate improve BMD and may reduce fracture risk over 1 year in SM. Conversely, our data do not support the use of interferon monotherapy or midostaurin as preferred strategy in patients with severe osteoporosis. Usefulness of masitinib, and of recent tyrosine kinase inhibitors needs further studies in this population.

ROMOSOZUMAB AS A TREATMENT AFTER BISPHOSPHONATE OR FOR OSTEOPOROSIS WITH T-SCORE≤-2.5 IN CLINICAL PRACTICE

Keywords: Real-world evidence, Rheumatoid arthritis, Osteoporosis

Y. Hirano1, Y. Saito1,1 Toyoshahi Municipal Hospital, Rheumatology, Toyohashi, Japan

Background: Romosozumab (ROMO) is an antiscleoritin antibody that is used in the treatment of severe osteoporosis (OP). In March 2019, ROMO was approved for use in Japan for treating severe OP in clinical practice, causing an increase in its prescription in our institute. Although efficacy data for ROMO have been presented in clinical trials, there is a lack of real-world data. In our experience, ROMO treatment results in significant bone mineral density (BMD) gain in some patients, but not all. Therefore, understanding the efficacy of ROMO treatments in groups of patients frequency treated with ROMO in real-world clinical practice is essential.

Objectives: This study investigated the efficacy of a 12-month ROMO treatment in patients with OP and compared the efficacy as a treatment after bisphosphonate (BP) or for OP with T-score≤-2.5.

Methods: Our study included 64 patients with OP, who were started on ROMO treatment between June 2019 and August 2021. The following information was collected: 1) baseline characteristics, 2) course of time of BMD (lumbar spine [LS] and total hip [TH]) and bone turnover markers (BTM, bone-specific alkaline phosphatase [BAP], type I procollagen-N-propeptide [P1NP], type I procollagen-N-propeptide [NTX], and tartrate-resistant acid phosphatase-5b [TRACP-5b]), 3) BMD outcomes as a treatment after BP or for OP patients with T-score≤-2.5.

Results: 1) The mean age of the participants was 72.4 years (59 female and five male). Of the 64 understudied patients, 84.4% had past insufficient fruacity fractures, whereas 29.7% had been treated with concomitant prednisolone. Furthermore, 22 patients had primary OP, 24 had rheumatoid arthritis, 15 had glucocorticoid-induced OP, and three had other conditions. Pretreatments for OP were BP (44 patients), denosumab (6), selective estrogen receptor modulator (5), activated vitamin D (2), none (5), and daily teriparatide (1). 2) Both mean LS- and TH-BMD significantly increased in the patients for whom ROMO administration was continued for 12 months. The average percentage changes of LS- and TH-BMD were +6.6% and +16% at six months and +11.0% and +2.7% at 12 months, respectively. However, BAP and P1NP increased steeply at one month, followed by a gradual decrease. As observed, the average percentage changes of BAP and P1NP were +68.7% and +167% at one month, +47.6% and +84.3% at six months, and +20.2% and +41.5% at 12 months, respectively. The results also showed that TRACP-5b decreased from one to 12 months, with the average percentage changes being -15.1% at one month, -3.5% at six months, and -6.2% at 12 months. Moreover, NTX, a bone-resorptive marker, was slightly increased during ROMO treatment. 3) In 44 treated patients with ROMO after BP, the average percentage changes of LS- and TH-BMD were +5.7% and +1.7% at six months and +9.2% and +2.4% at 12 months, respectively. The average percentage changes of BAP and P1NP were +74.0% and +189.9% at one month, +39.5% and +65.3% at six months, and +177% and +36.8% at 12 months, respectively. TRACP-5b decreased from one to 12 months, with the average percentage changes being -14.7% at one month, -2.8% at six months, and -6.6% at 12 months. In 23 patients with baseline LS T-score≤-2.5 at 12 months. In 24 patients with baseline TH T-score≤-2.5, the average percentage changes of LS-BMD were +2.3% at six months and +3.1% at 12 months. 20.8% of patients reached LS T-score>-2.5 at 12 months.

Conclusions: ROMO treatments rapidly increased BMD, especially LS-BMD, and changed BTM after one month in both treatment after BP and OP with T-score≤-2.5.

RISK WEIGHT CALCULATION OF CANDIDATE VARIANTS FOR INCIDENT MAJOR OSTEOPOROTIC FRACTURE IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Predominant factors, Validation, Osteoporosis

J. Yoshii1, N. Sawada1,1 Yoshii Clinic, Musculoskeletal Medicine, Shimanto City, Japan;1 Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan

Background: Incidental osteoporotic fractures are one of the serious comorbidities in patients with rheumatic disease (RD). However, no comprehensive treatment criteria exist to prevent these fractures.

Objectives: The purpose of this study is to develop criteria and assess the validity of the criteria using retrospective cohort data.

Methods: Patients with RDs who were treated for more than one year were picked up in the study. The patients were followed up with blood tests including cystatin C (CysC) every 3 months. Bone mineral density (BMD) using dual-energy X-ray absorptiometry densitometry was measured annually. Comorbidities, presence of prevalent osteoporotic fracture, and habitual tastes such as alcohol drinking and current smoking were picked up at the initiation of treatment (baseline). The primary endpoint was incidental osteoporotic fractures (inc-OF). Patients were followed up until December 2022, unless censored by death, loss of follow-up, or dropping out due to admission to a nursing home. Candidate risk factors, with these significant differences between groups of OP and without OP, were demonstrated using Mann-Whitney U-test, for incident OF and were evaluated using a Cox regression analysis with the univariate model. Risk weights of each factor were calculated using risk ratio and beta-value. The total risk weight for each patient (TRW) was determined by summarizing the risk weight of each factor. Receiver operating characteristics (ROC) analysis was tested in order to determine the area under the curve (AUC) and the cut-off index (COI). Finally, a chi-square test was also performed in regard to anti-osteoporotic drug administration after baseline (OPD).

Results: A total of 1228 patients in these 345 males and 883 females were included. The mean age at baseline was 77.7 years old, and the mean follow-up period was 40.2 months. Background RDs were 761 with rheumatoid arthritis, 163 with psoriatic arthritis, 99 with Sjogren syndrome, 65 with purpura palmaris et plantaris, 48 with systemic lupus erythematosus, 24 with ankylosing spondylitis, 19 with systemic sclerosis, 16 with ulcerative colitis, 12 with Behcet’s disease, 4 with polymyositis/dermatomyositis, 3 with mixed connective tissue disease, 3 with familial Mediterranean fever, and 1 with polyarteritis nodosa. Picked-up factors were the presence of pre-OF, estimated glomerular filtration rate using CysC (eGFR), T-score in the lumbar spine (LS) and in the femoral neck (FN), number of comorbidities (nCom), presence of diabetes mellitus (DM), hypertension (HT), hyperlipidemia (HL), chronic obstructive pulmonary diseases (COPD), insomnia, cognitive impairment (CI), musculoskeletal atrophy disorder symptom complex (MADS), disuse, neuromuscular diseases (NMD), and polypharmacy (PPs). Risk ratios, beta-values, p-values, and calculated risk weights in these factors were shown in Table 1. The mean TRW in patients with OPD and 138.4 in the group with no incident OF (p<0.001). The AUC was 0.787 and the COI was 93.6 with 80.4% and 68.8% of sensitivity and specificity, respectively (p<0.001). OPD was administrated in 341 patients of the 471 TRW positive group in whom 299 did not have inc-OF, whereas, in the 164 patients of the 757 TRW negative group, only 10 had inc-OF.

Conclusion: A novel evaluation system for osteoporosis treatment should be a numerical system that summarizes adding risk weight of each candidate factor.
Background: Osteoporosis is a condition characterised by low bone mineral density (BMD) and is associated with increased risk of fractures and subsequent increased morbidity and mortality. The usual sites of BMD measurements are either the non-dominant hip or the spine. The hip is used to predict fracture risk using the FRAX™ tool. Some patients have a different BMD as shown by their T scores in the contralateral hip.

Methods: Data from a dual-energy x-ray absorptiometry (DEXA) scanner in the North West of England were used. Patients who were referred between 2004-2011 were studied. Patients had both hips scanned as well as risk factors and presence of fracture recorded. Data collected included age, sex, height, weight, BMI, history of fractures, rheumatoid arthritis status, smoking status, alcohol use and malabsorption. Those that had a BMD T-score difference of either greater than or equal to +1 SD or -1SD were considered to have discordant hips. These two groups were compared using independent sample t-tests for continuous variables and chi-squared tests for categorical variables. Logistic models were then fitted to look at the odds of fracture in each group.

Results: The hip T-scores of 35759 patients were measured. Mean age was 62.17 (±12.78) with 88.1% being female. There were 15287 (42.75%) who had discordant hips. The odds ratio for the measured risk factors and the association with fracture are shown in Table 1 below.

Conclusion: Hip discordance might be associated with adverse risk factors such as increased frequency of fractures. Measuring BMD of both hips could give a better estimate of future fracture risk. Further analysis of a subset from this group will be explored and presented.

Background: Currently there exists limited data around predictors of osteoporosis as well as fragility fractures in men.[1] It is therefore important to understand the determinants of poor bone health in males and thus predictors of fractures to help deliver optimal care. Males referred for Bone Mineral Density (BMD) estimation are a good source of exploring such predictors of fractures. We sought to investigate the determinants of one versus many fractures in a population of males routinely referred for BMD estimation using Dual X-Ray Absorptiometry (DEXA) scans.

Objectives: The aim of this study is to assess the predictors of one vs multiple fractures in males routinely referred for DEXA scans, in an observational cohort.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.4536
Methods: Data was obtained from patients referred to secondary care in the northwest of England who subsequently were assessed for low BMD via DEXA. Males referred between 2004 and 2019 were selected and data collected at attendance included patients’ full medical history and body habitus. Logistic models reporting odds ratio were used to examine the predictive factors for one versus multiple fractures in the cohort.

Results: A total of 5390 male patients were included in this analysis, the median age at scan was 66 years and the mean age was 76.6 +/- 13.7 (SD). A total of 1853 fractures occurred in our population of males. Varying modifiable and non-modifiable factors were identified as predictors of fractures. Modifiable factors included those who drank excess alcohol. Patients who had a history of excess alcohol consumption were more likely to have multiple fractures OR: 1.260 (CI: 1.02-1.56) (p= 0.030).

Furthermore, BMD at the left neck of femur was protective for multiple fractures OR: 0.938 (CI: 0.89-0.99) (p= 0.018). Interestingly the BMD at the right neck of femur was not predictive of multiple fractures. In terms of non-modifiable risk factors, height was statistically significant in being protective against fractures in this cohort OR: 0.991 (CI:0.98-0.99) (p= 0.016). Rheumatoid arthritis, steroid use, family history and coeliac disease all produced insignificant results when predicting one versus many fractures in this male cohort. A summary of the results can be seen in Table 1.

Conclusion: This study identifies factors predictive of multiple fractures among males referred for BMD assessment. Our analysis shows that a history of excess alcohol consumption, altered BMD results at the left neck of femur, and height were statistically significant in the prediction of multiple fractures. Our previous study also found a relationship between excess alcohol consumption and patterns of fractures in males. Further research is required to better understand both this link and alcohol’s importance in the pathophysiology of osteoporosis in men. Such research is also imperative in hypothesising specific factors relating to fractures adjusted and unadjusted for age.

POS0502 IMPLEMENTATION OF A CLINICAL CARE PATHWAY FOR SYSTEMATIC BONE FRAGILITY ASSESSMENT AT THE INITIATION OF ANDROGEN DEPRIVATION IN PROSTATE CANCER PATIENTS (HORMOS PROJECT)

Keywords: Osteoporosis, Bone diseases, Best practices

O. Fogle1, C. Dariané1, J. E. Bibus2, S. Kreps3, C. Thibault4, C. Gervais5, A. Rochaud1, C. Meynard1, E. Rapeaud2, S. Hmlia2, F. Audenet2, O. S. A. Mejane3, C. Roux2, M. O. Timsit2, K. Broit2, 1Cochin Hospital, Rheumatology, Paris, France; 2European Hospital Georges-Pompidou, Urology, Paris, France; 3European Hospital Georges-Pompidou, Radiology Oncology, Paris, France; 4European Hospital Georges-Pompidou, Clinical Oncology, Paris, France.

Background: Androgen deprivation therapy (ADT) in prostate cancer (PCa) is associated with an increased risk of bone fragility including bone loss, osteoporosis and fractures. Although international recommendations suggest performing dual-energy x-ray absorptiometry (DXA) at the initiation of treatment, less than 10% of patients do it. The implementation of a standardised clinical care pathway could help prevent bone-related complications in patients starting ADT.

Objectives: To improve screening for bone fragility in patients starting ADT for PCa by setting up a clinical care pathway. To describe the characteristic of patients with PCa starting ADT.

Methods: The radiation oncologists, medical oncologists or urologists from a tertiary center systematically referred all patients starting any ADT for PCa to our rheumatology department for a bone-health assessment including a DXA and clinics with a bone specialist. The effectiveness of the pathway was assessed by the number of patients who performed DXA at the initiation of ADT.

Results: Between March and December 2022, 116 of the 119 patients (97%) referred to our department were able to have a bone assessment within an average of 36 +/- 15 days. The three patients not seen in the care pathway did not wish to come for a new medical appointment. Among the 116 patients, mean age at first visit was 75 +/- 7 years old, mean BMI 26.9 +/- 4.7kg/m², 35% were previous or current smoker and Charlson Comorbidity Index was 4.75 +/- 2.5 with 20% diabetes, 15% peripheral vascular disease, 11% coronaryaropathy and 10% chronic kidney disease. Regarding PCa, 65% were on a localized or locally-advanced stage while 35% were metastatic and overall, 44% presented with a high risk histioprognostic score (ISP 4 or 5). Sixty-four patients (55%) were scheduled to concomitant prostatic external beam radiation, as initial or salvage therapy. Median PSA at diagnosis was 16ng/ml (8.8-38.5) at inclusion, 70% of patients had a newly-diagnosed PCa, 40% were recurrent PCa. ADT was prescribed alone for 65% of patients or in combination with new hormone-therapy (NHT) for 35% of patients and 26% with concomitant corticosteroids with a mean dose of 10 +/-4mg. The mean duration of previous ADT for relapsing patients was 16 +/- 20 months. Regarding bone disease, 11% patients had previous bone fracture mainly in the spine, 15% had familial history of hip fracture and 20% reported a fall within the past year. Forty-two percent of patients had vitamin D supplementation but only one was previously treated with an anti-osteoporotic agent.

Conclusio: This clinical care pathway allowed 97% of patients to have a bone assessment when starting ADT for PCa. This cohort of 116 patients confirms the high prevalence of low BMD among these patients and the need to screen and treat patients to prevent bone-related complications.

Acknowledgments: I thanks Moniraniary DERAHARJAON and Catherine LE BOURLOUT for their help in collecting clinical data.

POS0503 RISK OF CAROTIDEMBOLIC ISCHAEMIC STROKE AMONG NEW USERS OF ORAL BISPHOSPHONATES: A NESTED CASE-CONTROL STUDY

Keywords: Cardiovascular disease, Osteoporosis, Epidemiology

S. Rodríguez-Martín1, D. Barreira-Hernández1, R. Mazzucchelli2, M. Gili2, A. García-Lledó4, L. Izquierdo-Esteban1, A. Pérez-Gómez1, A. Rodríguez-Miguel1, F. De Abajo8,9. 1Hospital Universitario Príncipe de Asturias, 1Department of Biomedical Sciences (Pharmacology), Alcalá de Henares, Spain; 2Hospital Universitario Fundación Alcorcón, Rheumatology, Alcorcon, Spain; 3Agency Española de Medicamentos y Productos Sanitarios (AEMPS), Pharmacoeconomics and Pharmacovigilance, Madrid, Spain; 4Hospital Universitario Príncipe de Asturias, Cardiology, Alcalá de Henares, Spain; 5Hospital Universitario Príncipe de Asturias, Neurology, Alcalá de Henares, Spain; 6Hospital Universitario Príncipe de Asturias, Rheumatology, Alcalá de Henares, Spain; 7Hospital Universitario Príncipe de Asturias, Clinical Pharmacology Unit, Alcalá de Henares, Spain; 8Alcalá University, Biomedical Sciences, Alcalá de Henares, Spain; 9Hospital University Príncipe de Asturias, Clinical Pharmacology Unit, Alcalá de Henares, Spain.

Background: Bisphosphonates have been associated with atrial fibrillation, but studies carried out thus far have not shown that they are also associated with an increased risk of ischemic stroke (IS). None, however, separated by IS subtype (cardioembolic vs non-cardioembolic). The long-term use of oBs with calcium supplements increases specifically the risk of cardioembolic IS.

Objectives: The present study aimed to test the hypothesis that use of oral bisphosphonates (oBs) increases specifically the risk of cardioembolic IS.

Methods: A nested case-control study was performed using the Spanish primary healthcare database BIFAP (period: 2002-2015). Incident cases of IS were identified and classified as cardioembolic or non-cardioembolic. Five controls per case were randomly selected, matched for exact age, sex, and index date (first recorded IS). The association of IS (overall and by subtype) with the use of oBs within the last year before index date was assessed by computing the adjusted odds ratios (AOR) and their corresponding 95%CI using conditional logistic regression. Only oBs initiators were considered. (Figure 1). 

Results: A total of 4,586 cardioembolic IS cases (matched with 21,697 controls) and 7,673 non-cardioembolic IS cases (matched with 44,213 controls) were included. For cardioembolic IS, the use of oBs was associated with an AOR of 1.35(1.10-1.66), in a duration dependent manner (AOR≤1year=1.10;0.82-1.49; AOR>1-3years=1.41;1.01-1.97; AOR>3years=1.81;1.25-2.62; p for trend=0.001). Such increased risk only appeared when patients used concomitantly calcium supplements and was completely blunted by anticoagulants. No increased risk was observed for non-cardioembolic IS (AOR=1.03;0.88-1.21).

Conclusion: The long-term use of oBs with calcium supplements increases the risk of cardioembolic IS, while leaves materially unaffected the risk of non-cardioembolic IS.
Background: Realization of a thoraco-lumbar lateral view X-ray (Vertebral Fracture Assessment, VFA) when performing Dual Energy X-ray Absorptiometry (DEXA) is proposed in international guidelines to detect asymptomatic vertebral fractures. However, there is no clear consensus regarding indications of its realization.

Objectives: First, we compared the efficiency of a systematic VFA realization during DEXA versus its realization according to different criteria available in literature. Second, we looked after risk factors associated with vertebral fractures.

Methods: 401 successive patients underwent DEXA with a thoraco-lumbar lateral view X-ray (VFA). Medical files were retrospectively reviewed to determine if the patient should have benefited from a VFA according to the ISCD (International Society for Clinical Densitometry) 2007 criteria, ISCD 2015, NOF (National Osteoporosis foundation) 2014, SFR (French Society of Rheumatology), NHG (Nederlands Huisartsen Genootschap) 2nd revision or NHG 3rd revision.

Results: Among 401 successive patients who underwent systematic VFA, a vertebral fracture was observed in 71 patients (17.7%). 74, 54, 62, 73, 12 and 53% of patients should have undergone a VFA according to the ISCD 2007, ISCD 2015, NOF 2014, SFR, NHG criteria 2nd revision and NHG 3rd revision respectively. With the exception of the NHG 2nd revision criteria which only identified 23.2% of fractures, there was no significant difference in fracture detection between “systematic VFA” and “VFA realized following the recommendations” groups. Criteria sensitivity varied between 81.7 and 91.6% of detection, with the best detection performance for SFR criteria. The ISCD 2015 criteria presented the best sensitivity/specificity ratio of detection. The NHG2 criteria were the most specific (40.8% of VFA positive for fracture) but they lack of sensitivity, compared to systematic use, missed the detection of 51 fractures (12.7%). The detection of a vertebral fracture was significantly more frequent in patients with low bone mineral density at lumbar spine, femoral neck, but also waist. Age, menopause, height loss, hip fracture in a parent, back pain, COPD, active smoking and inhibitor of proton pump (PPI) use were also associated with higher fracture detection.

Conclusion: VFA realization based on literature criteria has a detection sensitivity between 82 and 92% (with the exception of the NHG 2nd revision criteria), with the SFR criteria having the best detection capacity and the ISCD 2015 criteria the best sensitivity/specificity ratio. Use of the VFA realization criteria may help to better determine the selection of patients requiring a VFA: VFA realization based on these criteria did not detect significantly less fracture that the systematic VFA realization. Low bone density, loss of height and history of hip fracture in parents were associated with vertebral fracture. Among medical history, attention should be paid to COPD, smoking and PPI use, also associated with the demonstration of a vertebral fracture.

Patients with rheumatoid arthritis (RA) commonly develop osteoporosis and fragility fractures due to differentiation and induction of osteoclast, steroid use, and inactivities of daily life [1-3]. The prevalence of osteoporosis during long-term RA has been reported to be as high as 19-32%, and RA patients have 1.5-2.3 times the risk of fracture as non-RA patients. However, the relationship between bone mineral density and fracture risk in RA patients is not clear, and there are few reports on bone mineral density and fracture location in RA patients.

Objectives: To investigate the incidence of fracture and fracture site in RA patients, and to explore the risk factors for fragility fractures in RA patients.

Methods:
1. A total of 4786 RA patients were included. We extracted new incidence of fracture from medical record and investigated the location of fractures.
2. A total of 4270 patients including non-RA patients who had dual-energy X-ray absorptiometry (DEXA) were analyzed. The RA group was divided into two groups: RAfx+ group with fracture and RAfx- group without fracture. Young Adult Mean (YAM) values were compared between groups based on DEXA data from 3634 patients in the non-RA group, 147 patients in the RAfx+ group, and 489 patients in the RAfx- group. Patients were included in the RAfx+ group if they had one or more fractures, and in the RAfx- group if they did not have any fractures.
3. The demographics, and clinical characteristics of 636 RA patients who had DEXA were investigated. Bone mineral density (YAM value), osteoporosis treatment intervention, steroid use, biologic drug use, the levels of anti-CCP, DEXA values, age, and sex matching, 147 patients were allocated to each group, respectively. Y AM value of femur was 67.7/73.7% and those of lumbar spine were 81.0/86.0%, in group A/B, of which both were significant (p<0.01, 0.01, respectively).

Conclusions: New fractures occurred in 8.0% of RA patients, with vertebral fractures being the most common. RA patients with fractures had significantly lower femoral/lumbar YAM values than RA patients without fractures. Steroid use, low femoral bone density, and lack of osteoporosis intervention were factors significantly associated with fracture occurrence in RA patients.

POS0507 OSTEOPOROSIS IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY IN A MONOCENTRIC CENTER. ANY ROLE FOR CALCINOSIS?

Keywords: Bone diseases, Systemic sclerosis, Osteoporosis

M. Cardar1, G. Pellegrino1, D. M. Reza Beigi1, I. Biscoti1, F. R. Di Cimmom1, S. Truglia1, F. Conti1, V. Riccioni1, Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Roma, Italy

Background: Systemic sclerosis (SSc) is a rare and progressive autoimmune disease, that has been associated with an increased risk of osteoporosis (OP), but risk factors are still debated [1,2].

Objectives: The aim of our study was to investigate the risk factors for osteoporosis (OP) and evaluate if any feature of the disease could increase the risk of osteoporosis.

Methods: In this cross-sectional study we included 60 consecutive patients, fulfilling the 2013 ACR/EULAR classification criteria of SSc[3], attending our Rheumatology Unit from July to December 2022. All the 60 patients performed a Dual-energy X-ray absorptiometry (DXA) between 2020 and 2022. Osteoporosis was defined as T score less than -2.5 SD and osteopenia as a T-score between -1.0 and -2.5 SD, according to WHO definitions. In univariate analysis, a history of osteoporosis intervention, especially denosumab use, and a history of steroid use were associated with fracture incidence (p = 0.02, 0.002, 0.03, respectively) significantly. In multivariate analysis, Y AM value of femur (OR: 0.386), a history of steroid use (OR: 2.04), and osteoporosis intervention (OR: 0.413) were significantly associated with the incidence of fractures.

Conclusion: New fractures occurred in 8.0% of RA patients, with vertebral fractures being the most common. RA patients with fractures had significantly lower femoral/lumbar YAM values than RA patients without fractures. Steroid use, low femoral bone density, and lack of osteoporosis intervention were factors significantly associated with fracture occurrence in RA patients.

POS0506 RISK FACTOR ANALYSIS OF FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Bone diseases, Osteoporosis

S. Takahara1, A. Uefuji1,2, N. Nakagawa1,2,1-Hyogo Prefectural Kagokawa Medical Center, Orthopaedic Surgery, Kagokawa, Japan; Hyogo Prefectural Kagokawa Medical Center, Reumatology, Kagokawa, Japan

Background: Patients with rheumatoid arthritis (RA) commonly develop osteoporosis and fragility fractures due to differentiation and induction of osteoclast, steroid use, and inactivities of daily life [1-3]. The prevalence of osteoporosis during long-term RA has been reported to be as high as 19-32%, and RA patients have 1.5-2.3 times the risk of fracture as non-RA patients. However, the relationship between bone mineral density and fracture risk in RA patients is not clear, and there are few reports on bone mineral density and fracture location in RA patients.

Objectives: To investigate the incidence of fracture and fracture site in RA patients, and to explore the risk factors for fragility fractures in RA patients.

Methods:
1. A total of 4785 RA patients were included. We extracted new incidence of fracture from medical record and investigated the location of fractures.
2. A total of 4270 patients including non-RA patients who had dual-energy X-ray absorptiometry (DEXA) were analyzed. The RA group was divided into two groups: RAfx+ group with fracture and RAfx- group without fracture. Young Adult Mean (YAM) values were compared between groups based on DEXA data from 3634 patients in the non-RA group, 147 patients in the RAfx+ group, and 489 patients in the RAfx- group. Patients were included in the RAfx+ group if they had one or more fractures, and in the RAfx- group if they did not have any fractures.
3. The demographics, and clinical characteristics of 636 RA patients who had DEXA were investigated. Bone mineral density (YAM value), osteoporosis treatment intervention, steroid use, biologic drug use, the levels of anti-CCP (cyclic citrullinated peptide) antibody, and BMI (body mass index) were analyzed between two groups.

Results:
1. Of the 4785 RA patients, a total of 550 fractures occurred in 384 patients (8.0%). The mean age was 70.5 and 63 years old in the fracture and non-fracture groups, respectively, and was significantly higher in the fracture group (p<0.01). The most common fracture sites were vertebral (205 fractures), following 57 proximal femur fractures, 55 thoracic fractures, and 41 pelvic fractures.
2. The %YAM of femur was 73.9% in the non-RA group, 67.7% in the RAfx+ group, and 76.0% in the RAfx- group, and %YAM of lumber spine was 85.5% in the non-RA group, 81.0% in the RAfx+ group, and 88.1% in the RAfx- group, with the RAfx+ group having significantly lower values (p<0.01). After age and sex matching, 147 patients were allocated to each group, respectively. Y AM value of femur was 67.7/73.7% and those of lumbar spine were 81.0/86.0%, in group A/B, both of which were significant (p<0.01, 0.01, respectively).

3. In univariate analysis, a history of osteoporosis intervention, especially denosumab use, and a history of steroid use were associated with fracture incidence (p = 0.02, 0.002, 0.03, respectively) significantly. In multivariate analysis, YAM value of femur (OR: 0.386), a history of steroid use (OR: 2.04), and osteoporosis intervention (OR: 0.413) were significantly associated with the incidence of fractures.

Conclusion: New fractures occurred in 8.0% of RA patients, with vertebral fractures being the most common. RA patients with fractures had significantly lower femoral/lumbar YAM values than RA patients without fractures. Steroid use, low femoral bone density, and lack of osteoporosis intervention were factors significantly associated with fracture occurrence in RA patients.

A RANDOMISED CONTROLLED TRIAL COMPARING ANAKINRA VERSUS STEROIDS FOR THE TREATMENT OF GOUT ATTACKS IN PEOPLE WITH RENAL DISEASE (ASGARD): A FEASIBILITY STUDY

Keywords: Gout, Randomized control trial, Kidneys

G. Balasubramaniam1,2, M. Almond3, P. Harnett4, J. Zhang5, D. Turner6, J. Scales7, C. Moore7, K. Hayden7, E. Roddy8, C. Mallen8, N. Ng9, S. Bhagat10, J. Card-Gowers1, L. Webber1, L. Retat1, M. Piotrowski1, B. Lamoreaux2, J. Card-Gowers1, L. Webber1, L. Retat1, M. Piotrowski1, B. Lamoreaux2, J. Card-Gowers1, L. Webber1, L. Retat1, M. Piotrowski1, B. Lamoreaux2, J. Card-Gowers1, L. Webber1, L. Retat1, M. Piotrowski1, B. Lamoreaux2, J. Card-Gowers1, L. Webber1, L. Retat1, M. Piotrowski1, B. Lamoreaux2, J. Card-Gowers1, L. Webber1, L. Retat1, M. Piotrowski1, B. Lamoreaux2

Background: Title: A study to determine the feasibility of undertaking a definitively randomised multi-centre, double-blind, double-dummy controlled study of Anakinra vs. intramuscular methylprednisolone acetate for acute gout attacks in patients with chronic kidney disease. Gout is common in people with chronic kidney disease (CKD) where effective treatments like non-steroidal anti-inflammatory drugs are contra-indicated. Anakinra, an IL-1 receptor antagonist, could be an important treatment option for treating gout flares in people with CKD. A future definitive trial may be feasible if we are able to overcome challenges in recruitment, better ways of case finding, and initiating randomised treatment during gout flare. Our study is the first gout study looking specifically at people with advanced CKD and showed good safety and efficacy with these agents for this group of patients.

Objectives: Aim: to assess the feasibility of the design and procedures for a future definitive randomised trial of anakinra in people with moderate to severe CKD. Specific objectives were to: test recruitment and retention; test eligibility criteria; collect outcome data to inform sample and power calculations for a future trial; collect economic data to inform a future economic evaluation; and assess capacity for to scale up to a larger trial.

Methods: Design: two-parallel group, double-blind, double-dummy, multicentre randomised feasibility trial comparing subcutaneous anakinra 100mg for 5 days with a single injection of intramuscular methylprednisolone acetate 120mg for treating gout flares in people with CKD (eGFR <60mls/min/1.73m2). Participants were planned to be recruited from five sites in the South East region of the UK over 15 months, the target sample size was 32. Proposed primary outcome was self-assessed pain intensity using Visual Analogue Scale (VAS) (0–100mm) and 5-point Likert scale. Proposed secondary outcome measures consisted of physician assessment of joint; assessment of activity limitation and quality of life using Health Assessment Questionnaire Disability Index, 36-item Short Form Survey, Five-level EuroQol Five-Dimensional Questionnaire and Lower Extremity Functional Scale.

Results: 21 patients were randomised (anakinra 10, depo-Medrone 11), 3 were lost to follow-up. Mean age was 72 years and mean eGFR was 43.6 ml/min/1.73m2. The first metatarsophalangeal joint was the commonest joint affected (10/21). 2 participants were taking urate-lowering therapy although 16 reported previous flares. Mean overall change in pain from baseline was 35.88 by VAS and 1.69 by Likert scale. Functional assessment and quality of life assessment was highly completed. The baseline assessment was low for the SF-36 and HAQ-DI, the LEFS showed a trend of improvement and the HAD-QI showed a decline from day 7 to week 8. Health resource use was higher when assessed by health records compared to self-reporting. Qualitative feedback from participants alluded to high questionnaire burden and delays in receiving treatment. There were no serious adverse events or reactions. One patient needed rescue medication 10 days later for recrudescence of flare in the anakinra arm. We met three out of its four success criteria: recruiting at least 70% of eligible patients; 85% of participants completing 5 out of 7 pain outcome measure; and ≤10% treatment cross-over or failure.

Conclusion: Our study did not meet its entire feasibility target due to poor recruitment. This was compounded by various factors which may be possible to overcome. Aspects to rationalise the study would be utilising VAS and patient reported Likert, without physician assessment of joints. Functional assessment and quality of life assessment could be reconciled to using EQ-5D-5L and SF-36 at day 1, day 7 and week 8 minimising the questionnaire burden. We did not find good functional assessment with the LEFS and HAQ-DI, the gout flare score may be a possible alternative, bearing in mind the impact of questionnaire burden. A future definitive trial may be feasible if we are able to overcome challenges in recruitment, better ways of case finding, and initiating randomised treatment during gout flare. Our study is the first gout study looking specifically at people with advanced CKD and showed good safety and efficacy with these agents for this group of patients.

PROJECTING THE FUTURE HEALTH AND ECONOMIC BURDEN OF CONTROLLED AND UNCONTROLLED GOUT IN THE CHRONIC KIDNEY DISEASE POPULATION IN THE US: PRELIMINARY RESULTS USING MICROSIMULATION MODELLING METHODS

Keywords: Gout, Epidemiology

J. Card-Gowers1, L. Webber1, L. Retat1, M. Piotrowski1, B. Lamoreaux2, B. Marder3, A. Kumar4, HealthLumen Ltd, Epidemiological Modelling, London, United Kingdom; 5Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America

Background: Chronic kidney disease (CKD) and gout are major public health concerns. The prevalence of gout (4%) and hyperuricemia (20%) is high in the general population and progressively increases as kidney function decreases [1,2]. An increasing number of people in the US are living with both gout and...
CKD, posing a significant health and quality of life (QoL) burden to patients when putting economic pressure on the healthcare system. Moreover, current gout management in the US is sub-optimal, with a large number of gout patients remaining untreated, undertreated, or uncontrolled [3].

**Objectives:** To quantify the 2023-2035 health and economic burden of controlled and uncontrolled gout in the US CKD population.

**Methods:** A validated microsimulation model was used to project gout burden in the US CKD population, which was reproduced virtually using United Nations data [4]. Each individual was assigned estimated glomerular filtration rate (eGFR), albuminuria, and serum urate (SU) values, which were extracted through analysis of the US NHANES (2011 to 2018). The prevalence of self-reported gout by age, sex, and CKD stage was also examined. Controlled and uncontrolled gout costs, eGFR decline rates, tophi and flare probabilities were drawn from the literature. Uncontrolled gout was defined as SU>6 mg/dL and ≥2 flares/yr or the presence of tophi. The microsimulation was run between 2023 and 2035.

**Results:** The simulation predicts a 9.2% growth in the prevalence of gout and CKD in the US between 2023 and 2035, from 7.6 million to 8.3 million patients, respectively. By 2035, 10.2% of CKD patients (2.8 million) are projected to have uncontrolled gout (Graph 1), an annual average increase of 37,000 patients each year to 2035. This compares with 5.2% of CKD patients (2.8 million) with controlled gout by 2035. The number of people living with gout and advanced CKD (stages 3-5) is projected to grow by 19.4%, from 4.7 million patients in 2023 to 5.8 million patients by 2035, of which the majority (67.2%) will have uncontrolled gout. Factors driving this increase are predominantly population growth and ageing. Tophi and flare occurrence are similarly projected to increase. The resulting combined direct and indirect costs of gout in CKD patients are projected to increase from $43.5 billion in 2023 to $47.5 billion by 2035. This equates to a cumulative cost of $594.4 billion over the next 12 years, of which 76% is due to uncontrolled gout (Table 1). If all gout in CKD was controlled, the US could save $169.9 billion between 2023 and 2035.

**INTERRUPTING FASING REDUCES CRYSTAL-INDUCED INFLAMMATION**

**Keywords:** Gout, Crystal arthritis, Diet and nutrition

**N. Pham**1,2, T. W. Chirayath1, F. Castelli1, F. Fenaillie1, A. L. Nguyen3, F. Brial1, A. Latourte1, F. Liott1, P. Richette1, T. Bardin1, H. K. Eal1. 1INSERM URM1132 - BIOSCAR, Lariboisiere Hospital, Paris, France; 2Haiphong University of Medicine and Pharmacy, Internal Medicine Department, Haiphong, Vietnam; 3Laboratoire d’études du Metabolisme des Medicaments UMS 29, CEA Saclay, Gil-sur-Yvette, France

**Background:** Inflammation induced by monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals depends on interleukin (IL)-1α activated the NLRP3 inflammasome. The inflammatory response can be modulated by diet, fasting, and crystalic sanctions.

**Objectives:** To determine whether intermittent fasting reduces MSU and CPP crystal-induced inflammation.

**Methods:** Crystal-induced inflammation was assessed using both types of crystals in vivo in the air pouch model in 8-week-old wild-type male mice fed either with a normal ad libitum diet or intermittent fasting (IF) (every day fast, 2 days during 1 week). Inflammatory cytokine production (IL-1α and CXCL-1) was assessed in the pouch lavages and the cellular infiltrate analyzed by histology (H&E staining). Metabolomic analyses were performed by high-performance liquid chromatography coupled to high-resolution mass spectrometry (LC-HRMS) on air pouch lavages, serum, and liver tissues. Changes in metabolites associated with diet interventions were studied by the Metaboanalyst platform and we established the metabolic profiles for each experimental condition. In vitro, human monocytes THP-1 were stimulated by sterile synthetic crystals of MSU and CPP while the production of inflammatory cytokines was quantified by ELISA. To assess the role of glutamine/glutamate metabolism pathway related to IF in microcrystalline disease, the concentrations of glutamine/glutamate in synovial fluids (SF) from patients with gout, CPP-related disease and osteoarthritis (OA) were quantified by ultra-performance liquid chromatography coupled to tandem mass spectrometry (UPLC-MSS).

**Results:** Inflammation induced by MSU and CPP crystals was drastically decreased by IF compared with normal diet: IL-1α (MSU 0.0 vs. 30.0 pg/ml; CPP 0.0 vs. 473 pg/ml; p<0.0001); CXCL-1 (MSU 675 vs. 186.8 pg/ml; CPP 156.1 vs. 549.5 pg/ml; p<0.0005); as were cell infiltration assessed by number of cells in the air pouch lavages (MSU 0.2 x 10^7 vs. 1.1 x 10^7; CPP 0.4 x 10^9 vs. 2.9 x 10^9; p<0.0001) and membrane histology semi-quantitative score (MSU 0.6 vs 3.0; CPP 0.8 vs 2.7; p<0.0001). Reduction of inflammation by IF was associated with significant changes in membrane, serum and liver metabolites. IF increased ketone bodies (hydroxybutyric acid) as well as cholic acid, acetyl glycol, hydroxy caproic acid. In contrast, IF decreased carbohydrate metabolites, as well as glutamate and succinic semialdehyde. Many metabolic pathways were altered by IF such as galactose, starch, sucrose, aspartate, glutamate, alanine and arginine metabolism. Interestingly, the glutamine and glutamate metabolic pathway was enriched in serum, membrane and liver compartments. Glutamine/glutamate involvement in microcrystal-induced inflammation was evidenced in SFs. SF concentration of glutamine was decreased during gout and CPP flares compared to OA effusion (gout 352.3 µM and CPP 3975.0 µM vs OA 509.3 µM, p<0.0001 and p<0.0001 respectively) while the concentration of glutamate increased in gout (gout 212.5 µM vs 58.0 µM, p<0.0001; CPP 66.1 vs 58.0 µM, p=0.4). The glutamine/glutamate ratio was decreased in synovial fluids of crystal-related diseases compared to OA (gout 1.4 and CPP 6.1 vs OA 9.4, p<0.0001 and p<0.0005 respectively). In vitro, crystal-induced inflammatory cytokine production was decreased by overnight serum deprivation (IL-1α): MSU 1446 vs 5464 pg/ml; CPP 3670 vs 7797 pg/ml; p<0.0005; TNF-α: MSU 70 vs 470 pg/ml; CPP 15.6 vs 89.3 pg/ml, p<0.05; IL-8: MSU 2986 vs 9781 pg/ml; CPP 3984 vs 6820 pg/ml, p<0.01). The inhibition of crystal-induced IL-1α production by serum deprivation was abrogated when cells were treated with 3-MA, an autophagy inhibitor (MSU 1446 vs 4912 pg/ml; CPP 3670 vs 9837 pg/ml, p<0.0005).

**Conclusion:** Intermittent fasting alleviates crystal-induced inflammation by altering many metabolic pathways, particularly those associated with glutamine and glutamate. Further studies are needed to determine how IF modulates metabolism to dampen crystal-induced inflammation.

**Graph 1. Gout prevalence, by CKD stage (1, 2, and 3-5), in the US, between 2023 and 2035**

**Conclusion:** In US CKD patients, gout prevalence and symptoms (tophi, flares) are projected to rise markedly between 2023 and 2035, posing a substantial and increasing health, economic, and QoL burden. Uncontrolled gout is projected to contribute most to the health and economic burden of gout in CKD. Urate-lowering interventions may help reduce this burden by lowering the proportion of uncontrolled gout. Such measures would therefore reduce costs and healthcare utilisation while leading to QoL improvements in CKD patients with gout.

**REFERENCES:**

**Acknowledgements:** This research was supported by Horizon Therapeutics plc.
Results: Incidence rate of CVD was significantly higher in patients with gout than in participants without gout (11.38 vs 5.49 per 1000 person-year). A positive correlation was observed between SUA level and CV risk in the general population, whereas CV risk was consistently high in gout population, regardless of SUA level. A favorable lifestyle was associated with lower CV risk in both patients with gout and participants without gout. In all categories of SUA levels (<4 mg/dL, normal; 6-8.9 mg/dL, high; >9 mg/dL, very high), CV risk was significantly lower in gout patients with a favorable lifestyle than in those with an unfavorable lifestyle.

Conclusion: Patients with gout are at high risk of CVD even with SUA levels in the normal range. Lifestyle modification can be an effective and inexpensive therapeutic strategy to prevent CV events in patients with gout.

DIAGNOSTIC AND DIFFERENTIAL BIOMARKERS IDENTIFIED BY METABOLIC ANALYSIS IN PATIENTS WITH PSEUDOGOUT

Keywords: Biomarkers, Crystal arthritis, -Omics

S. Takahashi1,2, M. Takahashi3, Y. Tanimoto3, T. Yamaoka3, M. Katayama3, S. Hatachi4, M. Shinohara5, S. Kumagi2,3, Shinko Hospital, The Center for Rheumatic Disease, Kobe, Japan; 2Shinko Hospital, The Shinko Institute for Medical Research, Kobe, Japan; 3Kobe University Graduate School of Medicine, The Integrated Center for Mass Spectrometry, Kobe, Japan; 4Kobe University Graduate School of Medicine, Division of Molecular Epidemiology, Kobe, Japan

Background: Pseudogout is an acute arthritis induced by calcium pyrophosphate dehydrate crystal deposition (CPPD) [1]. Pseudogout most commonly involves one or several large joints, such as the knee or wrist, typically tender and swollen [2]. The pathogenic mechanism of CPPD is partially understood, and the etiology of attacks is unclear. There is no diagnostic serum biomarker for pseudogout. CPPD disease is best diagnosed by identifying positively birefringent, typically thornloid-shaped crystals in the synovial fluid of affected joints. However, CPPD disease and rheumatoid arthritis (RA) often coexist, and the similarity of pseudogout with acute flares of RA might lead to misdiagnosis.

Objectives: To identify the metabolites which characterize pseudogout compared with RA and to identify serum biomarkers of pseudogout using metabolomic analysis of serum and synovial fluid.

Methods: We collected serum and synovial fluid from 18 pseudogout patients and 12 RA patients with acute flares. We also collected serum from five pseudogout patients after resolving arthritis. We performed a metabolomic analysis of the samples using gas chromatography-mass spectrometry (GC-MS). Metabolites contributing to the differentiation between pseudogout with acute arthritis, pseudogout with resolving arthritis, and RA were determined by analysis of the orthogonal partial least-squares discriminant analysis (OPLS-DA) weightings (variable importance in the projection (VIP)) >1, the absolute value of modeled correlation (r(correl)) > 0.5 in the S-plot and Wilcoxon rank sum test (p < 0.05).

Results: A total of 123 metabolites from synovial fluid and 101 metabolites from serum were identified by GC-MS. By using OPLS-DA (Figure 1) and Wilcoxon rank sum test, nine metabolites from synovial fluid and 19 metabolites from serum were selected as the metabolites that contributed to the differentiation between pseudogout and RA, and nine metabolites from serum were selected as the metabolites that contributed to the differentiation between pseudogout with resolving arthritis. Among the selected metabolites, we identified five metabolites which characterized pseudogout compared with RA and two metabolites which elevated in pseudogout with acute arthritis compared with both RA and pseudogout with resolving arthritis.

Conclusion: By metabolomic analysis, we identified metabolites that differentiate pseudogout from RA and the potential serum diagnostic biomarkers for pseudogout.

QUALITY OF LIFE AND CLINICAL GOUT ASSESSMENT CHANGES IN UNCONTROLLABLE GOUT PATIENTS UNDERGOING PEGLOTICASE THERAPY AS PART OF THE MIRROR RANDOMIZED CONTROLLED TRIAL

Keywords: Quality of life, Gout, Randomized control trial

J. Botson1, K. Obermeyer2, B. Lamoreaux2, L. Padrick-Silver2, S. Verma2, M. E. Weinblatt3, J. Peterson3,4,5,6,7,8,9,10,11,12,13,14,15 J. Osteopathic Physicians Alaska, Rheumatology, Anchorage, United States of America; 2Horizon Therapeutics Plc, Research and Development, Deerfield, United States of America; 3Horizon Therapeutics Plc, Medical Affairs, Deerfield, United States of America; 4Brigham and Women’s Hospital, Division of Rheumatology, Immunology and Allergy, Boston, United States of America; 5Western Washington Arthritis Clinic, Rheumatology, Bothell, United States of America

Background: Refractory/uncontrolled gout can severely limit physical function and impact patient quality of life [1,2]. Unfortunately, limited treatment options exist for patients intolerant of or refractory to oral urate-lowering therapies. Pegloticase can lower serum urate (SU) in these patients [3] with demonstrated quality of life and physical function benefits [4]. The MIRROR RCT trial showed increased SU-response rates (71.0% vs. 38.5%) with lower infusion reaction risk (4.2% vs. 30.6%) when pegloticase was co-administered with methotrexate (MTX) vs. placebo (PBO), but patient-reported outcomes (PROs) from this study have not been reported [5].

Methods: We report the prespecified PROs and gout-related clinical measures through Month 12 of pegloticase + MTX/PBO co-therapy in MIRROR RCT trial participants.

Methods: Patients with uncontrolled gout (sSUa≥7 mg/dL, ULT failure/intolerance, and ≥1 of the following: ≥1 tophus, ≥2 flares in past year, chronic gouty arthritis) were administered pegloticase (biweekly 8mg infusion) plus either oral MTX (15mg/wk) or PBO. The study included 2-wk MTX tolerance, 4-wk blinded MTX/PBO Run-in, and 52-wk pegloticase+MTX/PBO Treatment periods. Key
exclusion criteria were being immunocompromised, G6PD deficiency, eGFR <40 ml/min/1.73 m², or MTX contraindication. PROs included change from baseline (CFB) to Wk 52 in Health Assessment Questionnaire (HAQ) indices (second-order polynomial model for repeated measures, adjusting for baseline score, baseline tophi presence, treatment group, visit, visit by treatment group interaction, and visit by baseline interaction.

**Results:** 152 patients made up the ITT (100 randomized to MTX, 52 randomized to PBO). At baseline (before MTX exposure, Wk -6) HAQ scores indicated some disability, high pre-therapy pain, and somewhat poor overall health (mean ±SD: DI: Pain, Health: MTX: 0.7±0.7, 43.7±30.3, 44.9±28.6, respectively; PBO: 0.8±0.8, 40.5±28.6, 39.1±27.4, respectively). Baseline PhGA was similar between groups (MTX: 5.5±2.1, PBO: 5.4±2.2) but the MTX group had fewer affected joints (TJC: 6.7±8.4 vs. 11.0±15.9, SJC: 5.4±7.8 vs. 8.3±12.2). All HAQ measures progressively improved during treatment (Figure 1), but the treatment group difference in the Wk 52 CFB in HAQ-DI was not statistically significant, making further PRO analyses exploratory in nature. PhGA score improved (mean±SEM) Wk 52 CFB: -4.2±0.2 vs. -3.8±0.3, with a median observed score of 1.0 and 1.0 in the MTX and PBO groups, respectively, at Wk 52. TJC and SJC markedly declined during Treatment (mean±SEM) CFB TJC: -6.1±0.5 vs. -7.0±0.8, SJC: -5.1±0.4 vs. -6.0±0.6; MTX vs. PBO, both p <0.21, declining to a mean ±SD TJC at Wk 52 of 1.4±4.6 and SJC of 1.4±4.5 in the MTX group and a TJC of 0.6±1.0 and SJC of 1.1±2.9 in the PBO group.

Figure 1. Change from baseline in HAQ-DI (Top); Pain (Middle), and Health (Bottom) during pegloticase+MTX and pegloticase+PBO co-therapy. Baseline was defined as prior to MTX exposure (Wk -6), with Day 1 defined as first pegloticase infusion. Data points represent mean ±SEM change from baseline; error bars represent 95% CI; treatment group difference p<0.05. HAQ, Health Assessment Questionnaire; CFB, change from baseline; DI, disability index; MMD, minimum clinically important difference; MTX, methotrexate; PBO, placebo.

**Conclusion:** Pegloticase treatment resulted in meaningful improvements in both clinical measures and quality of life in patients with uncontrolled gout. Patients co-treated with MTX experienced greater improvements in HAQ-Pain and Health scores after 52 wks of therapy, likely reflective of the higher urate-lowering response rate observed in the presence of MTX immunomodulation [5].

N. Dalbeth1, J. Botson2, K. Saag3, A. Kumar4, L. Padnick-Silver4, B. Lamoreaux5, F. Becce6. 1University of Auckland, Department of Medicine, Auckland, New Zealand; 2Orthopedic Physicians Alaska, Rheumatology, Anchorage, United States of America; 3University of Alabama at Birmingham, Department of Medicine, Birmingham, United States of America; 4Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; 5Lausanne University Hospital, University of Lausanne, Department of Diagnostic and Interventional Radiology, Lausanne, Switzerland

**Background:** Monosodium urate (MSU) crystal deposits can be visualized and quantified with dual-energy CT (DECT) [1], with DECT studies showing an association between MSU deposition and bone erosion [2]. Pegloticase rapidly lowers serum urate (SU) to near zero in uncontrolled gout patients (pts), with methotrexate (MTX) co-therapy recommended to increase SU lowering response rate (71% vs 39% with pegloticase+placebo [PBO]) and decrease infusion reaction risk (4% vs 31%; MIRROR RCT) [3]. MIRROR open-label trial (pegloticase+MTX co-therapy for ≤52 wks) DECT findings showed rapid, progressive MSU deposition volume (VMSU) reduction with subsequent bone erosion remodeling in the 2 imaged pts [4]. The MIRROR RCT trial had a larger number of pts who underwent serial DECT imaging during pegloticase+MTX/PBO co-therapy, the findings of which are reported here.

**Objectives:** To examine VMSU and bone erosion imaging findings of MIRROR RCT participants who underwent serial DECT imaging.

**Methods:** 6 pts were randomized 2:1 to receive oral MTX (15 mg/wk) or PBO as co-therapy to pegloticase (8 mg biweekly infusions). Serial images were obtained at DECT-capable sites using a standard acquisition protocol at prespecified time points during the 52-wk treatment period (Day 1 [first pegloticase infusion]; Wks 14, 24, 52). Bilateral hand/wrist, elbow, foot/ankle, and knee images were obtained. Images were post-processed using default settings and interpreted by an independent central reader blinded to treatment group and SU lowering response. VMSU was measured in each scan. Up to 3 of the largest bone erosions per imaged region were assessed for evidence of remodeling, defined as a decrease in size, recortication, and/or new bone formation. Erosion size was evaluated as the product of the largest longitudinal and axial slice dimensions. Pts with baseline and Wk 52 images were included in analyses, excluding imaging regions with a baseline VMSU <0.5 cm³ to prevent large contributions of potential DECT artifacts [5]. DECT-imaged regions were also radiographed and photographed.

**Results:** 6 pts receiving pegloticase+MTX co-therapy and 2 pts receiving pegloticase+PBO co-therapy were included in analyses. In the MTX group, 5 pts had SU <6 mg/dL during Month 6 and received 52 wks of pegloticase+MTX co-therapy; 1 pt discontinued pegloticase+MTX at Wk 6 due to SU lowering through Month 6 and received 42 wks of pegloticase+PBO, continuing on febuxostat (mean SU on febuxostat = 4.6 mg/dL). In the PBO group, 1 pt had sustained SU-lowering through Month 6 and received 42 wks of pegloticase+PBO, continuing on febuxostat (mean SU on febuxostat = 5.2 mg/dL); 1 pt discontinued pegloticase+PBO at Wk 6 due to SU rise, continuing on allopurinol (mean SU on allopurinol = 4.6 mg/dL). In the PBO group, 1 pt had sustained SU-lowering through Month 6 and received 42 wks of pegloticase+PBO, continuing on febuxostat (mean SU on febuxostat = 5.2 mg/dL); 1 pt discontinued pegloticase+PBO at Wk 6 due to SU rise, continuing on allopurinol (mean SU on allopurinol = 3.0 mg/dL). VMSU markedly decreased during therapy in both treatment groups (Wk 52, MTX: -94% ±9% [9 imaging regions of 6 pts], PBO: -85% ±6% [4 imaging regions of 2 pts]). Evidence of concomitant bone erosion remodeling (Figure 1) was observed in 69% (29/42) of evaluated erosions (9/12 of 10.1136/annrheumdis-2023-eular.2367

**POS0514**

**BONE EROSION REMODELING AFTER DEPLETION OF MONOSODIUM URATE DEPOSITION WITH INTENSIVE URATE-Lowering WITH PEGLOTICASE IN PATIENTS WITH UNCONTROLLED GOUT: MIRROR RCT DUAL-ENERGY CT FINDINGS**

**Keywords:** Imaging, Gout
Conclusion: In agreement with a prior serial DECT study [4], rapid and near complete V_{MSU} depletion was observed within 1 year of initiating pegloticase therapy. Concomitant bone erosion remodeling was also observed after 52 wks of intensive urate-lowering therapy. In these limited cases, DECT findings were similar between treatment groups. It is likely that SU-lowering, not MTX use, was responsible for the observed changes.

Background: Nurse-led gout care has been studied mainly in managed healthcare systems [1].

Objectives: To investigate the effectiveness of a structured nurse-led gout programme in a private healthcare system.

Methods: A randomised single-blinded controlled trial with two study arms was performed. The inclusion criteria were the fulfilment of the 2015 ACR/EULAR gout classification criteria (2) and the indication of urate-lowering therapy (ULT).

The inclusion period lasted 2 years and the intervention period 6 months. Physician FU visits took place at 6 and 12 months from baseline (BL). The achievement rate of the target serum acid level (SUA, ≤ 360 µmol/l) at the 6-month-FU served as the primary endpoint. In the intervention group, during the first six months, 45% of the patients in the intervention group achieved the SUA target vs 26% in the control group. There was no significant advantage over the standard of care regarding SUA reduction. However, the intervention patients showed twice as many impaired kidney function (grade 3-5) and tophaceous gout. Nevertheless, these patients reduced their SUA levels better after 6 months (36% vs 26% reduction) and 64% of them achieved the SUA target after 12 months (vs 47% in the control group).

POS0518 ANTINUCLEAR ANTIBODIES IN GOUT: VICTIMS OF MODERN IMMUNOLOGY TECHNIQUES (A NEW VOMIT)

Keywords: Gout, Autoantibodies, Crystal arthritis

A. M. Herrero-Beltes1, C. Vazquez-Puente2, M. D. C. Modesto-Caballero2, F. Perez-Ruiz2.
1Gorilzeko Enretexa, Rehabilitation Division, Gortiz, Spain; 2Cruces University Hospital, Rheumatology Division, Barakaldo, Spain

Background: Non-rational prescription of tests in clinical practice may induce inefficient performances, misdiagnosis, and inappropriate consultations.

Objectives: We analyzed the prescription and results of antinuclear antibodies (ANA) prescription before first consultation to a rheumatology unit in a disease with commonly high diagnostic accuracy based on clinical findings: gout.

Methods: In the decade 2013-2022 the prescription and results of ANA testing prior to first rheumatology visit was added to the database, along with general data and variables related to comorbid conditions and clinical characteristics of gout. We made an analysis of variables plausibly associated with ANA prescription and biochemical changes through the rate of prescription.

Results: From Jan 2013 to Dec 2022, 504 patients gave written consent for data inclusion, 66 (13.7%) women and 415 men (86.3%), with mean age at entrance in the cohort of 73.1±14 and 65±14 years, respectively. ANA had been prescribed to 114 (23.7%) subjects, in 28/66 (42.4%) women and 86/415 men (p<0.001). No differences for prescription were observed in other variables, such as age, time from onset, flares per year, tophi, or polyarticular distribution. The rate of ANA prescription was not related to the diagnostic for consultation: arthralgia (24.4%), arthritis (21.7%) or gout (25.3%). 31/114 (27.2%) ANA tests were positive (90% with title <1/400), but only led to a new diagnosis (autoimmune hepatitis), and two had a previous diagnosis (Sjögren’s Syndrome and Systemic Lupus). The rate of positive ANA was much higher in women (12/28, 42.9%) than in men (8/66, 12.1%). The rate of ANA prescriptions showed a bial- lelic and significant increase during the last decade (p=0.007): 11.3% in 2013-2014, 21.4% in 2015-2016, 34.9% in 2016-2017, and 51.1% in 2021-2022. A valley in ANA prescriptions was observed during SARS-COV2 pandemic 2019-2020 (19.7%).

Conclusion: In a rheumatic disease with quite typical clinical presentation as gout, the rate of ANA prescription prior to rheumatology consultation is unexpectedly high, and the highest in women, despite old age and absence of systemic clinic. The rate of positive ANA in the elder in our setting is quite high, especially in women, and may lead to misdiagnosis and inefficient management: a new VOMIT.

Background: There is a known relationship between elevated serum urate (SUA) levels and renal, cardiovascular (CV), and metabolic disease. However, the precise reasons for this remain poorly defined. The CANTOS trial found a significant decrease in nonfatal MI, stroke, or CV death in patients (PTs) treated with canakinumab vs placebo. The LoDoCo2 trial found a decrease in CV death, nonprocedural MI, ischemic stroke, and ischemia-driven need for coronary revascularization in PTs treated with colchicine vs placebo. This suggests that inflammation is an independent risk factor for CV disease. The GOSPEL 4 trial found that French PTs with early-onset gout (EOG), a diagnosis (DX) < age 40, had slightly more arthritis, significantly less chronic stage 3 or 4 kidney disease (CKD) compared to common gout (CG) PTs, DX ≥ age 40. Metabolic syndrome was significantly more prevalent in the CG group. To our knowledge, no study has investigated the effects of EOG vs CG on incidence of metabolic-related diseases in a rural population in the US.

Objectives: To investigate whether early DX and control of gout results in lower incidence of metabolic-related diseases in a rural setting.

Methods: We conducted a retrospective analysis of PTs with gout at a rural tertiary care center. We identified PTs seen Jan 2016-Dec 2020 with a gout DX. Charts were reviewed for: sex; age at DX; age at the time of gout DX and at the last medical encounter; HbA1c level; SUA level; and BMI. Charts were reviewed for urate-lowering therapy (ULT) prescriptions, atherosclerotic cardiovascular disease (ASCVD)/peripheral arterial disease (PAD), diabetes mellitus (DM), hypertension (HTN), and CKD. We compared demographic and clinical characteristics between EOG and CG PTs using chi-square tests for categorical data and the Kruskal-Wallis test. All analyses were performed using SAS version 9.4.

Results: For baseline demographics, see Table 1. Of 12,362 charts reviewed, 692 had gout, and 11,670 had CG. More PTs in the CG group had ASCVD/PAD (4.6% vs 0.3%, p <0.0001), DM (38.2% vs 15.5%, p < 0.0001), HTN (83.8% vs 44.9%, p < 0.0001), CKD (43.4% vs 7.1%, p < 0.0001), and tophi (5.3% vs 0.0%, p < 0.0001). CG PTs had higher mean initial HbA1c (6.5 vs 6.1, p < 0.0001) and last SUA levels (7.5 vs 7.1, p <.0001). There was no significant difference in ULT use (72.6% vs 71.1%, p = .03856).

Conclusion: Our study suggests PTs with EOG had significantly lower rates of ASCVD/PAD, DM, CKD, tophi and lower A1c levels. Given that EOG and CG patient’s ULT use was similar, this shows that EOG and CG PTs on ULT are less likely to develop the comorbidities associated with gout arthritis. We further intend to look at EOG time to comorbidity DX event.

POS0519
THE ANALGESIC EFFICACY OF THERAPIES USED FOR COMPLEX REGIONAL PAIN SYNDROME: A SYSTEMATIC REVIEW

Keywords: Quality of life, Systematic review, Pain
C. Shekarsara,1, N. Gullick2
1University of Warwick, Medical School, Coventry; United Kingdom; 2University Hospital Coventry and Warwickshire, Rheumatology, Coventry, United Kingdom

Background: Complex regional pain syndrome (CRPS) is a multifactorial chronic pain condition which arises following commonplace injuries such as fractures. Pharmacological and non-pharmacological treatments including physiotherapy have been used to reduce pain but there is an unmet need for novel effective therapies.

Objectives: To review clinical trials for CRPS and evaluate effectiveness for reducing pain.

Methods: A PICO approach was used to search MEDLINE, PubMed, COCHRANE LIBRARY, EMBASE, CINAHL and Web of Science for studies published between 2003 to 2022. Keywords such as “Complex Regional Pain Syndrome,” and its previous label “Reflex Sympathetic Dystrophy” were used, alongside “pharmacological” and “non-pharmacological interventions.” The studies included were confined to adults clinically diagnosed with CRPS, that were written in English. Additional studies were also found via citation searching of references from eligible reports.

Results: The search strategy generated 41 RCTs in total (Figure 1). Pharmacological interventions such as biophosphonates showed consistently significant improvement in pain, in addition to ketamine and steroids which yielded some successful outcomes. Interventional therapies such as local anesthetics, sympathetic blocks, and nervous system stimulations also demonstrated potential. Finally, mirror therapy, motor imagery programs and virtual reality revealed partial improvement. Conversely, Pain Exposure Physical Therapy (PEPT), immunosuppressant drugs, free radical scavengers, anti-convulsants, calcitonin, immunoglobulins, Fluidotherapy and occlusal splints had no significant effects on pain outcomes. The Cochrane risk of bias tool was used to assess the quality of studies involved, for which the lower quality RCTs were those lacking full blinding or selectively reporting outcomes.

Figure 1. Prevalence of metabolic/comorbid conditions in early gout patients compared to common gout patients.
Background: To this date, a causal relationship between febuxostat and cardiovascular disease remains controversial as comparison between trials can be challenging and may lead to misleading conclusions especially when facing heterogeneous cardiovascular outcomes.

Objectives: We aimed to compare the cardiovascular outcomes in the most pertinent trials of Febuxostat compared to controls.

Methods: We searched electronic databases using a PICOS-style approach search strategy of randomized controlled trials on cardiovascular outcomes of Febuxostat in patients with gout or hyperuricemia. We conducted a quality and risk of bias assessment of the included clinical trials. The definition of MACE as well as all reported cardiovascular outcomes were retrieved from every involved trial.

Results: Of the 1173 records identified from all sources, 20 RCTs were included in the analysis.Mean duration of follow-up was 69.7 ± 81.5 weeks and Febuxostat dose ranged from 10 to 240 mg with 80 mg being the most commonly used dosage. Overall, the quality of evidence deriving from all RCTs showed concerns in most studies (65%). Major cardiovascular event (MACE) was defined in 7 of the 20 RCTs (35%) and cardiovascular outcome reporting was very heterogeneous. Overall, data of cardiovascular safety of Febuxostat were reassuring.

Conclusion: Our systematic review showed no alarming increase of cardiovascular mortality and outcomes in Febuxostat treated patients except for the CARES trial in which the credibility of the results is biased by the high rate of drug discontinuation and of most importantly, withdrawal from follow-up. FAST CARES trial in which the credibility of the results is biased by the high rate of hospitalization and Febuxostat dose ranged from 10 to 240 mg with 80 mg being the most commonly used dosage. Overall, the quality of evidence deriving from all RCTs showed concerns in most studies (65%). Major cardiovascular event (MACE) was defined in 7 of the 20 RCTs (35%) and cardiovascular outcome reporting was very heterogeneous. Overall, data of cardiovascular safety of Febuxostat were reassuring.

Background: The sediments of synovial fluid are used to identify crystals in the diagnosis of gout arthritis. The present study explored the potential of a gout analyzer (U-GAN®) in detecting crystals under polarized light and compared it with the conventional method of crystal examination.

Methods: A total of 30 patients with knee joint effusion were recruited from Tokyo Metropolitan Tama Medical Center from February 2020 to March 2021. Rheumatologists who used a gout analyzer blindly evaluated the sediments using U-GAN® after centrifugation. Additionally, a gout analyzer was used to detect CPP and MSU from the synovial fluid of patients with a documented diagnosis. PPV were 100% for ICD-10-GM code, list of regulations, and to look for gout diagnosis in all of the patient's documents and imaging reports. Furthermore, 9.7% and 2.6% in the presence of tophus, precise clinical course of symptoms) and lack of diagnostic features. We demonstrate the feasibility of an EHR-based gout registry, with good positive predictive value and the ability to identify patients without a documented gout diagnosis in the EHR. The next step is to expend the queries to look for gout diagnosis in all of the patient's documents and imaging reports and to estimate the negative predictive value in a sample of patients without any criteria, yet with risk factors of gout.

Background: Gout is the most common inflammatory rheumatism worldwide. Despite guidelines on acute and chronic management, it remains largely undertreated. To evaluate the current standard of gout care, there is an unmet need for gout registers, especially in the non-rheumatology setting. The vast clinical information available in electronic health record (EHR) allows the implementation of registers to assess clinical indicators and monitor them following quality improvement programs. The best strategies to set up an EHR-based gout registry is described. The potential predictive value (PPV) to detect a true gout was established by any doctor in any part of the EHR. To further assess the validity of the gout diagnosis, the 2015 ACR-EULAR gout criteria was scored. Gout patients without any acute arthritis during any encounter with the HUG were classified as having an antecedent gout. The four criteria identified 7,046 patients suffering from gout, among whom 33.4% were deceased. Most patients were identified by the drugs criterion (Figure 1). A large proportion of patients (43.2% of outpatients and 72.8% of inpatients) were identified by the presence of urate-lowering therapy only, without the mention of any gout diagnosis. Furthermore, 9.7% and 2.6% in the out- and inpatient setting respectively had a positive puncture that wasn’t associated with a documented diagnosis. PPV were 100% for ICD-10-GM code, list of diagnosis and punction, and 75% for urate-lowering therapy, while PPV based on a combined query (any criterion) was 93.8% to detect a gout patient in the charts. Among the 80 charts reviewed, 55 patients had at least one documented gout attack and 25 had an antecedent gout. Of the 55 patients with an acute gout, which allowed the use of the ACR-EULAR 2015 classification, 39 patients (70.9%) had a positive articular puncture for uric acid or the presence of tophi as observed by a trained examiner. The remaining 16 patients (29.1%) had a mean score (SD) of 5.5 (2.39) for the ACR-EULAR 2015 classification (threshold to classify as gout is ≥8). The lack of clinical information available (documented presence of tophi, precise clinical course of symptoms) and lack of diagnostic imaging to assess gout complication might explain the low score, among these patients with a high probability of gout according to the chart review.

Methods: To establish an EHR-based gout registry, to assess the correct identification of gout patients by manual chart review, and to evaluate the objective validity of gout diagnosis based on the ACR-EULAR 2015 gout classification criteria [2].

Methods: We prospectively performed different crystal identification methods in 30 patients with knee joint effusion at Tokyo Metropolitan Tama Medical Center from February 2020 to March 2021. Rheumatologists who used a gout analyzer blindly evaluated the sediments using U-GAN® after centrifugation. Additionally, a gout analyzer was used to detect CPP and MSU from the synovial fluid of patients with a documented diagnosis. PPV were 100% for ICD-10-GM code, list of regulations, and to look for gout diagnosis in all of the patient's documents and imaging reports. Furthermore, 9.7% and 2.6% in the presence of tophus, precise clinical course of symptoms) and lack of diagnostic features. We demonstrate the feasibility of an EHR-based gout registry, with good positive predictive value and the ability to identify patients without a documented gout diagnosis in their EHR. The next step is to expend the queries to look for gout diagnosis in all of the patient's documents and imaging reports and to estimate the negative predictive value in a sample of patients without any criteria, yet with risk factors of gout.

POS0523 FEASIBILITY STUDY OF AN ELECTRONIC HEALTH RECORD-BASED GOUT REGISTRY

Keywords: Registries, Gout

T. Kise1,2, N. Yokogawa2, Y. Miyoshi2, M. Utsunomiya2, Y. Nagai2, K. Shimada2. 1Regional Independent Administrative Corporation Naha City Hospital, Department of Nephrology and Rheumatology, Naha, Okinawa, Japan; 2Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Fuchu, Tokyo, Japan

Background: The synovial fluid is a rich source of crystals, which can be used to identify the presence of gout. The aim of this study was to evaluate the feasibility of an EHR-based gout registry using a gout analyzer (U-GAN®) for crystal examination.

Methods: The study included 30 patients with knee joint effusion, and the sediments were evaluated using U-GAN® after centrifugation. The detection of CPP and MSU was then compared with the conventional method of crystal examination.

Results: The positives identified by U-GAN® were 100% for CPP and 80% for MSU, while the PPV were 100% for the ICD-10-GM code and list of regulations.

Conclusion: U-GAN® can be used for detection of both CPP and MSU in clinical practice.
Background: CXCR4 binds to its ligand CXCL12 and plays a role in induction of recruitment of inflammatory cells including leukocytes and endothelial cells. The CXCL12/CXCR4 axis has been implicated in the pathogenesis of some types of inflammatory arthritis and autoimmune diseases including rheumatoid arthritis, osteoarthritis, systemic lupus erythematosus, and ankylosing spondylitis. Evidence of the pathogenic role of CXCR4 and CXCL12 in uric acid-induced inflammation has not been presented.

Objectives: The aim of this study is to evaluate the expression of chemokine receptor CXCR4 and its ligand CXCL12 in patients with gout and uric acid-induced inflammation.

Methods: Forty patients with intercritical gout and 27 controls were consecutively enrolled. Serum levels of interleukin-1β (IL-1β), IL-18, CXCL12, and CXCR4 were assessed using enzyme-linked immunosorbent assay. Gene and protein expression for these target molecules was measured in human U937 cells incubated with monosodium urate (MSU) crystals using real-time reverse transcription polymerase chain reaction and Western blot analysis.

Results: Patients with intercritical gout showed higher serum IL-1β, IL-18, and CXCL12 levels than those in controls, but not serum CXCR4 level. Serum CXCR4 level in gout patients was associated with serum IL-18 level, uric acid level, and uric acid/creatinine ratio (r = 0.331, p = 0.037; r = 0.346, p = 0.028; r = 0.361, p = 0.022, respectively). U937 cells treated with MSU crystals significantly induced CXCL12 and CXCR4 mRNA and protein expression, in addition to IL-1β and IL-18. In cells transfected with IL-1β siRNA or IL-18 siRNA, CXCL12 and CXCR4 expression was down-regulated compared to non-transfected cells in MSU crystal-induced inflammation. Receiver operator characteristic (ROC) curve analysis showed that serum CXCL12 for the diagnosis of gout was an area under roc curve (AUC) of 0.690 (p = 0.009).

Conclusion: This study reveals that CXCL12 and CXCR4 are involved in the pathogenesis of uric acid-induced inflammation and gouty arthritis.

Pain is the most common symptom of Paget's Disease of Bone (PDB) and affects between 60% and 70% of patients who present to clinic in the UK, but its mechanisms are incompletely understood [1]. Quantitative sensory testing (QST) has historically been used in the assessment of neuropathic pain [2] but has precedent in patients with bone metastases and osteoarthritis [3,4]. In this study, we used QST to dissect the mechanisms of pain in PDB, taking advantage of the disease's focal nature which allows the participant to act as their own control by testing at a contralateral site.

Objectives: To explore the sensory profiles of PDB patients with and without musculoskeletal pain.

Methods: All study data was collected and stored on the secure web-based software platform Research Electronic Data Capture (REDCap). Quantitative sensory testing (QST) measured the sensory response to various stimuli applied to the skin overlaying the PDB compared to an unaffected contralateral site in 120 study participants. Differences between QST assessments in sites overlaying Pagetic bone and control sites were assessed by the Mann–Whitney test.

Results: Significantly higher pain scores were reported above the site of PDB when compared to the control site, irrespective of whether the patient complained of musculoskeletal pain. The differences were apparent for hot roller testing (p = 0.047), pain threshold testing (p = 0.007), pin prick testing (p < 0.001) (see Figure 1), and wind-up pinprick testing (p = 0.001). Pain thresholds were significantly reduced above Pagetic bone (p = 0.007). Additionally, temporal summation scores were significantly higher (p = 0.007) in the pain subgroup compared with the no pain subgroup which could indicate higher levels of central sensitisation in patients who experience pain.

Conclusion: This study illustrates that there are significant differences in the way that sensation is processed above Pagetic bone when compared to unaffected contralateral sites, regardless of the presence of current musculoskeletal pain. Our data suggest that patients who experience pain may do so, in part, because of higher levels of central sensitisation.

THE PRESENCE OF MONOSODIUM UROATE DEPOSITS IN THE JOINTS OF PATIENTS WITH ASYMPTOMATIC HYPERURICEMIA IS ASSOCIATED WITH A HIGHER CARDIOVASCULAR RISK, BUT NOT WITH MORE ADVANCED KIDNEY DAMAGE

**Keywords:** Kidneys, Crystal arthritis, Ultrasound

R. Gancheva 1, A. Koundurdjiev 2, T. Kundurzhiev 2, Z. Kolarov 2, P. Peteva 2, I. Koundurdjiev 3, L. Marinchev 4, 1University Hospital “St. Iv. Rilski” Medical University, Sofia, Clinic of Nephrology, Sofia, Bulgaria; 2University Hospital “St. Iv. Rilski” Medical University, Sofia, Clinic of Nephrology, Sofia, Bulgaria; 3Medical University, Sofia, Faculty of Public Health, Sofia, Bulgaria; 4University Hospital “St. Iv. Rilski” Medical University, Sofia, Clinic of Rheumatology, Sofia, Bulgaria; 5University Hospital “Sofiamed” Clinic of Rheumatology, Sofia, Bulgaria; 6University Hospital Freiburg, Clinic of Otorhinolaryngology, Freiburg, Germany

**Background:** Epidemiological studies conducted in patients (pts) from the general population and pts with chronic renal failure have shown that uric acid is an independent risk factor for the development and progression of cardiovascular alterations. Uric acid damages the kidneys by causing systemic and glomerular hypertension. Hyperuricemia is connected to arteriolosclerosis, characterized by arterial wall thickening and hyalinosis.

**Objectives:** To evaluate the association between asymptomatic hyperuricemia and renal damage and to establish whether the presence of monosodium urate (MSU) deposits in the joints of these pts is related to more advanced renal alterations.

**Methods:** This was a single-center cross-sectional study, including 73 consecutive pts divided into 34 pts with osteoarthritis (controls), 25 subjects with asymptomatic hyperuricemia and no ultrasound (US) evidence of MSU crystals in the joints and 14 individuals with asymptomatic hyperuricemia and MSU deposits in the joints. Pts underwent bilateral US examination of the joints of the hands, elbows, knees, ankles, feet and the kidneys. Measurements of the joints were conducted with a high-frequency linear transducer 4-15 MHz. The existence of double contour sign, intra-tendinous MSU aggregates, “snow storm,” tophi, tophi with erosions, or a combination of these US features was assessed. Kidneys were examined with 3.5 MHz transducer, working with pulse Doppler frequency of 2.5 MHz. Renal length, parenchymal thickness and echogenicity were determined. The presence or absence of nephrolithiasis was recorded. By means of the value of renal resistive index (RRI) we judged for intrarenal blood flow. Statistical analyses were done by One-Sample Kolmogorov-Smirnov, t-test, Chi-square or Fisher’s exact test.

**Results:** The distribution of males and females (p=0.441), smokers and non-smokers (p=0.147), pts with arterial hypertension and normotensive individuals (p=0.298) as well as subjects with diabetes and without diabetes (p=0.775) and pts with dyslipidemia and normal lipid levels (p=1.000) was similar among the groups. The proportion of pts who had suffered with cardiovascular event was the highest in the group of asymptomatic hyperuricemia with MSU deposits in the joints (21.4%) compared to the group of osteoarthritis (14%) and hyperuricemia without crystals in the joints (0%), (p=0.048). In the group of osteoarthritis the share of pts with eGFR ≤90 ml/min was the lowest (5.9%) in comparison to the group of hyperuricemia without MSU deposits in the joints (30.2%) and hyperuricemia with crystals in the joints (46.2%), (p=0.005). The percentage of obese pts was the highest in hyperuricemia with MSU crystals in the joints (57.1%), but without reaching a significant difference with hyperuricemia without crystals in the joints (40%) and the group of osteoarthritis (29.4%), (p=0.195). The echogenicity of the kidneys (p=0.630) and the distribution of nephrolithiasis (p=0.596) was equal among the groups. Pts with hypertension and MSU deposits in the joints compared to those with osteoarthritis had higher BMI (mean±SD; 31.79±5.92 kg/m² vs 28.06±4.27 kg/m², p=0.018) and smaller kidney size (mean±SD; 55.36±5.58 mm vs 59.58±5.12 mm, p=0.015). The comparison of hyperuricemia with MSU deposits in the joints to osteoarthritis group demonstrated a significant difference only in the age (mean±SD; 49.7±16.4 years vs 61.5±9.4 years, p=0.001). Finally, the comparison of the two groups with hyperuricemia showed that subjects with MSU deposits in the joints had higher BMI (mean±SD; 31.79±5.92 kg/m² vs 28.06±4.27 kg/m², p=0.041) with no difference in the age (p=0.072), kidney size (p=0.141), RRI (p=0.296), eGFR (p=0.528) and thickness of renal parenchyma (p=0.232).

**Conclusion:** Hyperuricemia. All-cause mortality of the presence of articular crystals is associated with similar kidney damage. Cardiovascular risk is higher when MSU crystals are found by US in the joints.

PATIENT EXPERIENCES WITH CHRONIC REFRACTORY GOUT AND ITS IMPACT ON HEALTH-RELATED QUALITY OF LIFE

**Keywords:** Patient reported outcomes, Quality of life, Gout

A. Oladapo1, V. Strand2, N. Kragh3, N. Johnson4, D. Broocks4, H. Sharp5, C. Kim6, M. Pillinger7, 8Swedish Orphan Biovitrum AB, HEOR and RWE, Boston, United States of America; 2Stanford University Division of Immunology/Rheumatology, Palo Alto, United States of America; 3Swedish Orphan Biovitrum AB, Global Health Outcomes Value & Patient Access, Stockholm, Sweden; 4 Endpoint Outcomes (a Lumanity company), Research, Boston, United States of America; 5NYU Grossman School of Medicine, Division of Rheumatology, New York, United States of America

**Background:** Gout is a common inflammatory rheumatic disease, with elevated uric acid leading to deposition of monosodium urate crystals within joints [1]. Chronic refractory gout (CRG), also known as refractory or uncontrolled gout, is associated with unexpected disease flares characterized by severe and debilitating pain. Long-term symptoms include painful inflammatory arthropathy, impaired physical function, and health-related quality of life (HRQoL), and tophi-related joint destruction [1].

**Objectives:** This study aimed to 1) develop and refine a conceptual model of patient-identified CRG symptoms and their impact on HRQoL; and 2) confirm that the 36-item Short Form Health Survey V2.0 (SF-36) and Health Assessment Questionnaire-Disability Index (HAQ-DI) are relevant to patients with CRG by mapping items to the CRG conceptual model.

**Methods:** A targeted literature review of the 10 years prior to August 2021 was conducted to assess the symptoms and impacts of CRG, alongside the use of SF-36 and HAQ-DI in previous clinical trials. The review results contributed to an initial conceptual model of signs, symptoms and impacts of CRG. This model was then refined using concept elicitation interviews (CEI) conducted with patients who have clinically confirmed CRG (≥3 gout flares within 18 months of screening; or presence of ≥1 tophus; or current diagnosis of gouty arthritis [defined as joint damage due to gout]). Interviews contained open-ended questions and patients were asked about duration, frequency, and severity for each concept; bothersome impacts were rated on a scale of 0–10. The refined model was then assessed against SF-36 and HAQ-DI to determine their suitability for evaluating disease burden in patients with CRG.

**Results:** Findings from the literature review identified the following commonly referenced symptoms, signs and impacts of gout that served as the basis of the draft conceptual model: bodily pain, joint swelling/inflammation, tophi, joint pain, joint tenderness, anxiety, depression, sleep effects, and work effects. Impacts were organized into five domains: activities of daily living (e.g., difficulty dressing), emotional (e.g., anxiety), physical (e.g., decreased mobility), social (e.g., stigma), and work/school (e.g., productivity). Twenty patients were interviewed. Most were male (70%) and non-Hispanic white (55%), with a mean (standard deviation) age of 55.9 (±12.1) years. Most patients (60%) reported having multiple (>3) and/or severe gout flares within the past 6 months, and most commonly 1–3 tophi (45%). The most frequently reported signs and symptoms included bodily pain, joint swelling, and tender-ness (90% each). Others included joint pain (80%), joint stiffness (70%), and tophi (70%). Joint pain was rated as the most bothersome symptom (mean = 9.1). The most frequently reported impacts were difficulty climbing one or several flights of stairs (100% each), followed by completing chores, running errands and shopping, climbing five steps, putting on shoes, walking outdoors on flat ground, and emotional impacts (95% each). Impacts reported varied depending on the affected joints. The most bothersome impact reported was walking outdoors (mean = 9.6). All concepts discussed in the interviews were reviewed to determine whether they reflected the items included in SF-36 and HAQ-DI. Each assessed item from the two instruments was reported as relevant by at least 25% of participants and thus mapped consistently to concepts elicited by participants. Results of the CEI were used to revise the conceptual model (Figure 1).
Conclusions: Symptoms and associated impacts of CRG on HRQoL are multi-faceted, revealing a burden of disease that affects most aspects of a patient's life (Figure 1). Based on the interview data, all assessed items of SF-36 and HAQ-DI mapped directly to the domains and concepts included in the conceptual model, providing evidence that both questionnaires are suitable for assessing the burden of CRG.

Conclusion: In analyzing gout social media posts, we found that flares, pain, swelling, and concerns related to uric acid were primary motivators for individuals seeking gout care. Conversations mentioning ‘pain’ were twice as likely to mention reactive care compared to proactive gout conversations. Analysis also showed that reactive care conversations tended to be more negative, supporting the position that proactive management may be more beneficial for individuals with gout overall. This type of information can be used to identify and address patients’ areas of concern or dissatisfaction. Future work should continue exploring these patient-reported perspectives and experiences so clinicians, caregivers, and patients can better understand and guide care-based management decisions.

ANALYSIS OF APPROPRIATE DURATION OF COLCHICINE PROPHYLAXIS TO MAXIMIZE THE PERSISTENCE OF XANTHINE OXIDASE INHIBITORS AS THE FIRST-LINE URATE LOWERING THERAPY IN PATIENTS WITH GOUT USING THE KOREAN HEALTH INSURANCE REVIEW AND ASSESSMENT SERVICE DATABASE: DOES 6 MONTHS’ DURATION MATTER?

Keywords: Gout, Crystal arthritis, Epidemiology

A. Kim¹, S. G. Lee¹, B. W. Song¹, D. H. Moon¹. Pusan National University Hospital, Rheumatology, Busan, Korea, Rep. of (South Korea)

Background: International guidelines for gout recommend at least 3 to 6 months of prophylaxis against gout attack for gout patients who start urate lowering therapy (ULT) [1-3], but there is lack of strong evidences supporting whether up to 6 months duration of gout flare prophylaxis is associated with the improvement of the long-term adherence of ULT in real-world clinical settings.

Objectives: We aimed to investigate the appropriate improvement of colchicine prophylaxis to maximize the long-term persistence of xanthine oxidase inhibitors (XOIs) as the first-line ULT in patients with gout using nationwide claim database. In particular, we attempt to compare which one is more effective in adherence to ULT between 6 months and 3 months duration of colchicine prophylaxis.

Methods: This is a nationwide population-based retrospective cohort study using the Korean Health Insurance Review and Assessment (HIRA) database. Gout patients ≥ 20 years who newly initiated allopurinol or febuxostat as the first-line ULT from July 2015 and June 2017 and received XOIs for 6 months were analyzed. Patients were followed-up to Jun 2019. Persistence of ULT was defined as continuation of allopurinol or febuxostat without an interruption for a period longer than 60 days (permisssible gap), the time duration from the index date to the discontinuation of ULT. XOIs persistence was compared according to the 6 months of duration of colchicine prophylaxis such as (1) ≥6 months and proportion of days covered (PDC) ≥0.8 (≥ 6 months group) and (2) <6 months or PDC <0.8 (< 6 months group). For additional subgroup analysis, we also compared the persistence of XOIs according to the 3 months duration of colchicine prophylaxis (≥3 months group vs < 3 months group).

Results: A total of 43,926 eligible gout patients (colchicine prophylaxis ≥6 months: n=2,784, colchicine prophylaxis <6 months: n=41,142 and colchicine prophylaxis ≥3 months: n=3,333, colchicine prophylaxis <3 months: n=40,593) were identified in HIRA database. The majority was male (82.6%) and the mean age was 58.6 years. Allopurinol (65.2%) was more frequently prescribed than febuxostat (34.8%). During the study period, 23,475 (53.4%) patients stopped XOIs. XOIs discontinuation occurred in 1,498 (53.8%) and 21,977 (54.4%) gout patients in the ≥ 6 months group and < 6 months group, respectively. In addition, 1,777 (53%) and 21,698 (53.5%) patients in the ≥ 3 months group and < 3 months group stopped XOIs, respectively. In multivariable Cox regression models revealed that colchicine prophylaxis ≥6 months did not significantly reduce the risk for discontinuation of XOIs compared with colchicine prophylaxis <6 months (HR=0.961, p=0.139). Otherwise, colchicine prophylaxis ≥3 months was significantly associated with a lower risk of non-persistence to XOIs after adjusting confounding factors (HR=0.95, p=0.041).

Conclusion: Our data suggest that at least 3 months of colchicine prophylaxis may be more appropriate than at least 6 months’ duration in terms of maximizing the persistence of XOIs in gout patients.

EVALUATION OF THE KNOWLEDGE OF INTERNAL MEDICINE PHYSICIANS, FINAL-YEAR MEDICAL STUDENTS AND RHEUMATOLOGISTS REGARDING THE DIAGNOSIS AND MANAGEMENT OF GOUT IN SWITZERLAND

Keywords: Quality of care, Gout

C. Melong Pianta¹, B. Gillet¹, M. J. Nissen¹, C. Gabay¹, K. Lauper¹. ¹Hôpitaux Universitaires de Genève (HUG), Medecine/Division of Rheumatology, Geneva, Switzerland

Background: Gout is the most common inflammatory rheumatism in adults [1]. Its prevalence and incidence have doubled in the last two decades. However, it is commonly undertreated despite numerous therapeutic options and the availability of international recommendations.

Objectives: To explore the reasons why gout is undertreated, we aimed to assess and compare the knowledge of primary care physicians (internists), rheumatologists, and final-year medical students regarding the diagnosis and management of gout in Switzerland with mandatory continuing education for physicians.

Methods: We conducted a multicenter cross-sectional study between December 2021 and August 2022. All primary care physicians and hospital internists practicing in academic hospitals in Switzerland, rheumatology specialists, and final-year medical students from 6 Swiss faculties of medicine were invited to complete an online questionnaire based on the EULAR 2016, 2018, and ACR 2020 recommendations. This multiple choice questionnaire consisted of 28 questions including 68 positive answers (since more than one positive answer was possible for each question) on gout diagnosis, management of an acute attack, indication to start hypouricaemic treatment and management of patients with renal failure. Participants were considered as having responded successfully to the questionnaire with at least 2/3 (45) correct answers.

Results: In total, we received approval for participation from 16 academic hospitals, 4 faculties of medicine, and the Swiss Society of Rheumatology. We included a total of 378 participants: 97 medical students, 210 internists and 71 rheumatologists.

Figure 1. Percentage of participants who responded successfully to the questionnaire

Only 33% of final-year medical students demonstrated sufficient knowledge about how to manage gout, compared to 66% of internists and 93% of rheumatologists. 55%, 48% and 14% in the student, internist and rheumatologist groups respectively did not know what type of crystals were found during a gout attack. The majority of participants in the different groups were familiar with at least one of the treatments that should be used for the management of a first acute attack of gout. Most participants in all 3 groups did not know the indications for initiation of hypouricaemic therapy. 80% of students, 62% of internists and 18% of rheumatologists were unaware of the target urate serum level to aim for when introducing hypouricaemic therapy and more than three-quarters of the students and internists thought that 300 mg was the maximal possible dose of allopurinol. Conclusion: These results suggest that knowledge about the diagnosis and management of gout is suboptimal among final-year medical students and primary care physicians across Switzerland. Although most rheumatologists demonstrated good knowledge about the management of gout, a surprising proportion did not, despite being experts in this field. Knowledge about the diagnosis and management of gout needs to be improved.

Infection-related rheumatic diseases

Infection-related rheumatic diseases may reflect development of chronic post-Chikungunya rheumatism.

Keywords: Infection-related MDs, Outcome measures, Ultrasound

H. Watson1,2, J. Del Valle Mendoza2, W. Silva Caso2, M. Aguilar3, A. Nizzardo4, G. Calusi5, M. Mandron6, M. A. D’agostino7. Evotec, ID (Lyon), Clinical Development and Translational Medicine, Lyon, France; 2Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 3Institute of Investigative Nutrition, Instituto de Investigación Nutricional, Lima, Peru; 4Aptuit (Verona) Srl, Pharmaceutics, Verona, Italy; 5Evotec (France) SAS - Campus Cure, Clinical Development, Toulouse, France; 6Università Cattolica del Sacro Cuore, Rheumatology, Roma, Italy

Background: Chronic musculoskeletal (MSK) symptoms such as arthralgia and arthritis develop in up to half of patients after acute chikungunya virus (CHIKV) infection. While MSK complaints are common during the acute infection, chronic post-CHIKV rheumatism represents a more severe outcome and is usually assessed by joint counts, laboratory markers and patient-reported outcomes (PROs). Ultrasound (US) may be a practical tool for predicting and confirming the development of chronic CHIKV.

Objectives: To evaluate the clinical relevance of MSKUS findings in post-chikungunya rheumatism.

Methods: 80 patients with acute CHIKV infection were enrolled in an prospective cohort study in Jaén, Peru. Clinical exam, US scans using grey-scale and power Doppler (PDUS), and serum inflammatory markers were performed at inclusion and at 3-month follow-up. Patients completed the RAPID3 outcome assessment and a MSK stiffness questionnaire. Joint counts and PDUS scans included 20 pairs of joints. Global synovitis and tenosynovitis scores were calculated following the EULAR-OMERACT recommendations for rheumatoid arthritis (GLOESS).

Results: 59 patients (mean age 35 years, 66% female) were assessed both in the acute infection stage and at 3-month follow-up. 21 patients (35%) met strict criteria for defining chronic CHIKV rheumatism with a mean 4.4 (±2.2) tender joints and RAPID3 scores >6. In the acute infection phase, global PDUS synovitis and tenosynovitis scores correlated moderately with tender joint count and with pain severity, joint stiffness and RAPID3 scores, but were not strongly predictive of patients who went on to develop chronic arthralgia. After 3 months, global PDUS synovitis scores correlated more strongly with tender joint count (r=0.53, p<0.001), pain severity (r=0.60, p<0.001), joint stiffness (r=0.53, p<0.001) and RAPID3 scores (p=0.60, p<0.001) (Table 1).

Conclusion: Global PDUS synovitis and tenosynovitis scores may be an objective measure of disease severity in patients developing chronic CHIKV rheumatism. Further validation with longer-term follow-up is needed.

P005332 GLOBAL ULTRASOUND SYNVOITIS SCORE MAY REFLECT DEVELOPMENT OF CHRONIC POST-CHIKUNGUNYA RHEUMATISM

P005333 RISK OF SEVERE INFECTIONS IN IMMUNE MEDIATED INFLAMMATORY DISEASES WITH IMMUNOGLOBULIN DECIENCY UNDER RITUXIMAB THERAPY

Keywords: Infection-related MDs, Adaptive immunity, bDMARD

J. Monti1, C. Rempeauf1, T. Lel1, C. Dainen2, B. Combe1, P. Guipilain2, C. Lukas3, Hospital Lapeyronie, Rheumatology, Montpellier, France; 4University Hospital Center Saint Eli Hospital, Internal Medicine and Multi-Organic Diseases, Montpellier, France

Background: Rituximab (RTX) is effective in treating immune-mediated inflammatory diseases (IMID). Hypogammaglobulinemia may occur under RTX and may increase infection risk.

Objectives: Since data are controversial, we evaluated the risk of severe infection in patients with IMID and hypogammaglobulinemia under RTX therapy.

Methods: We conducted a retrospective single-center study retrieving all patients treated with RTX for IMID. We calculated the incidence of RTX-induced hypogammaglobulin (Ig) deficiency, the type of Ig deficiency, the incidence of severe infection, and risk factors for severe infection.

Results: 311 patients were analyzed. Mean follow-up was 62.6 months. Exposure was 1623.7 patient-years. 15% of patients developed at least 1 severe infection. Incidence rate was 2.77/100 PY. 29 patients had prevalent IgG deficiency before being treated with RTX. 68 patients developed hypogammaglobulinemia, mainly for IgM (12%) and IgG (8%). Severe infection rate was higher in patients with prevalent IgG deficiency (RR 1.73; 95% CI 0.85-3.53), with significant difference in survival model (Log-Rank test: p=0.033). On the other hand, no excess risk of infection was observed in patients developing IgG deficiency under RTX in univariate analysis (RR 0.68; 95% CI 0.31-1.47) or in survival analyses after adjustment for confounding factors (type of IMID (RA versus other IMID), cumulative dose of RTX, presence of chronic infections, use of an immunosuppressive drug at inclusion, and mean dose of GCs collected at each cycle of RTX during follow-up) (Log-Rank test: p=0.399). Chronic lung disease and glucocorticoids (GCs) use during follow-up were associated with an increased risk of severe infection.

Conclusion: We did not observe an increased risk of severe infection in RTX-induced Ig deficiency. However, we found an increased risk of severe infection in case of prevalent IgG deficiency prior to RTX. In case of IgG deficiency, RTX management should be discussed on a case-by-case basis, according to an individual assessment of the infectious risk, especially when GCs therapy is used and chronic lung diseases are present.

Background: Infectious intercurrents increase mortality and morbidity and often limit immunosuppressive treatment in rheumatoid arthritis (RA) patients [1]. The risk of infection in this population may be influenced by factors related to the treatment, the characteristics of rheumatic disease and the clinical and social conditions of patients [2].

Objectives: This study aims to evaluate the incidence and factors related to the occurrence of serious infections, defined as the need for hospitalization or the use of intravenous antibiotics for the treatment, among patients with rheumatoid arthritis in Brazil.

Methods: We analyzed data from the REAL [3], a prospective observational study, that evaluated Brazilian RA patients, with clinical and laboratory data

DOI: 10.1136/annrheumdis-2023-eular.2634
collected over a year in eleven tertiary health care centers. Were included patients with 18 years or older, who fulfilled classification criteria for RA and were previously followed up in rheumatology services for at least 6 months prior to inclusion. Exclusion criteria was the absence of information regarding the occurrence of infections in two or more visits. Univariate and multivariate analyses were performed from the adjustment of the logistic regression model

**Conclusion:** We observed a high incidence rate of serious infections in this Brazilian cohort compared with cohorts from developed countries. The factors that were independently associated with them were neurological and pulmonary comorbidities, reduced kidney function, use of corticosteroids in moderate doses and reduced functionality. These findings may affect therapeutic decisions in RA patients.

**Background:** Cystic fibrosis (CF) is characterized by mutations within the CFTR (cystic fibrosis transmembrane conductance regulator) gene that result in a defect of the chloride transporter protein in different organs, particularly in the lung. Musculoskeletal symptoms have been reported in up to 29% of CF patients [1], most frequently as recurrent episodes of mono- or polyarthritis in joints of hands and feet. Recently, potent CFTR modulator therapies targeting the F508del mutation in CF have become available (i.e., Trikafta® - consisting of a triple combination of exelacatuar, tezacator, and ivacaftor) that increase CFTR protein availability and function at cell surfaces.

**Objectives:** To characterize musculoskeletal symptoms in a cohort of consecutive CF patients.

**Methods:** 25 CF patients were enrolled in this monocentric, prospective, and cross-sectional cohort study. Rheumatologic evaluation included clinical and laboratory parameters. Data were analyzed by covariance (ANCOVA) models, using the general linear model approach. Correlation analyses were performed calculating nonparametric Spearman correlation rank coefficients.

**Results:** Baseline characteristics are outlined in Table 1. 22/25 CF patients were under CFTR modulator treatment with a mean treatment duration of 13 ± 4 months. Arthralgias and myalgias were reported in 48% and 20% of patients, respectively. Arthritis, mainly involving small joints, was clinically detected in 62/25 (24%) patients and confirmed by ultrasound (US) in 3/6 patients. Self-reported myalgias, but not self-reported arthralgias, were significantly associated with the presence of swollen joints (r = 0.7452, p < 0.0001), tender joints (r = 0.6674, p = 0.0003), a positive squeeze test (r = 0.5989, p = 0.0019) and morning stiffness (r = 0.8556, p = 0.0004) (Table 1). Disease activity as assessed by the Simplified Disease Activity Index (SDAI) was moderate (mean ± SD = 8.4 ± 4.1) and rheumatoid factor (RF) were detected in one patient not on CFTR modulator therapy (with US synovitis ofPIP). Two patients on CFTR modulator therapy tested positive for RF. Another patient was seronegative but synovitis was confirmed by US.

**Conclusion:** The current cohort study confirms that rare musculoskeletal symptoms are frequent in adult CF patients. Self-reported myalgias were significantly associated with arthritis mainly involving small joints. Interestingly, longer duration of CFTR modulator therapy was associated with a decreased number of tender and swollen joints in line with the assumption that amelioration of mucosal airway inflammation may decrease the risk of developing CF arthropathy.

Haavardsholm1,2, J. K. Jorgensen5, S. Aarestad Provan1, S. W. Syversen1, G. L. Goll1,1 Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway;2 University of Oslo (UiO), Institute of Clinical Medicine, Oslo, Norway;2 Akershus University Hospital, Department of Gastroenterology, Lørenskog, Norway;3 Oslo University Hospital, Department of Immunology, Oslo, Norway;4 Oslo University Hospital, Department of Microbiology, Oslo, Norway;5 University of Oslo (UiO), KG Jebsen Centre for B cell Malignancies, Oslo, Norway;6 Norwegian Institute of Public Health, Department of Method Development and Analytics, Oslo, Norway

Background: Safety and efficacy of updated bivalent vaccines, containing both the original vaccine variant of SARS-CoV-2 Spike and either Omicron variants BA.1 or BA.4/5, are of particular interest in arthritis patients on immunosuppressive therapies. With the continuous emergence of new viral variants, it is important to evaluate whether updated vaccines induce more adverse events in this patient group.

Objectives: To examine if a second booster dose with updated bivalent vaccine increases the risk of adverse events, compared to the first booster dose with monovalent vaccines.

Methods: The prospective NorVacC study investigates vaccine responses in patients with immune mediated inflammatory diseases using immunosuppressive therapies (1). The present analyses included arthritis patients who received two booster doses. Patients received available vaccines according to the Norwegian vaccination program. The current recommendation in the Norwegian arthritis population is a three-dose primary vaccination series followed by two booster doses. Adverse events following vaccines doses were self-reported through questionnaires. Adverse events following the first (monovalent) and second (bivalent) booster were compared with McNemar’s test.

Results: Between 7th of July 2021 and 6th of December 2022 a total of 243 arthritis patients (127 rheumatoid arthritis, 65 psoriatic arthritis, 51 spondyloarthritides) on immunosuppressive therapies (Table 1) received a first, monovalent (BNT162b2, mRNA-1273) and a second, bivalent booster dose (BNT162b2 (WT/Omi BA.1), mRNA-1273.214, BNT162b2 (WT/Omi BA.4/BA.5)). Adverse events were recorded within 2 weeks in all patients (Figure 1). In total, 45 vs 49 (19% vs 20%) patients reported any adverse event after a second, bivalent booster dose, compared to the first, monovalent booster, respectively. There was no significant difference in adverse events overall (p=0.57). The most common adverse events after the second booster were pain at injection site (12%), flu-like symptoms (9%) and headache (6%). No new safety signals emerged. A total of 15 (6%) patients reported a disease flare after receiving the second, bivalent booster, compared to 21 (8%) after the first, monovalent booster.

Conclusion: There was no difference in adverse events between the monovalent, first booster, and the bivalent, second booster, indicating that bivalent vaccines are safe in this patient group.

Background: Data on serological immunity after three doses and the long-term immunogenicity (persistence) of COVID-19 vaccine in patients with inflammatory rheumatic diseases (IRD) treated with different immunomodulating drugs are still limited.

Objectives: To elucidate if 1) a third dose COVID-19 vaccine improves antibody responses, compared to two doses, in patients with IRD treated with biologic or targeted synthetic DMARD (b/tsDMARDs) treatment given as monotherapy or in combination with conventional synthetic DMARDs (csDMARDs) compared to controls, and 2) the persistence of antibody response after two doses of COVID-19 vaccine in IRD patients.

Methods: Antibody levels to two antigens representing Spike full length protein and Spike S1 and a Nucleocapsid C-terminal fragment (used to confirm previous COVID-19 infection) were measured in serum samples collected 2-12 and 21-40 weeks after the second vaccine dose and 2-12 weeks after the third dose using a multiplex bead-based serology assay. A sufficient antibody response (seropositivity) was defined as having antibodies over the cut-off level for both spike antigens (1). WT (wild type) anti-Spike IgG and omicron BA.1 and BA.2 variants were measured. Patients with IRD receiving immunomodulating treatment, regularly followed at a rheumatology department and a group of controls were recruited from five Swedish regions.

Results: In total, 323 of 414 patients with IRD and 36 controls who received three vaccine doses participated in this part of the study. Following treatment groups were included: rituximab (n=118; 68% female; mean age 67 years), abatacept (n=18; 72% female; mean age 64 years), JAK-inhibitors and with JAK-inhibitors and IL6 inhibitors (n=60; 73% female; mean age 64 years), JAK-inhibitors (n=44; 80% female, mean age 52 years), TNF-inhibitors (n=59; 70% female; mean age 47 years); IL12/23/17 inhibitors (n=24; 46% female; mean age 54 years) and controls (n=36; 75% female, mean age 51 years). b/ts DMARD treatment was given as monotherapy or in combination with csDMARD, methotrexate (MTX) being the most frequently used csDMARD (32.5%). Compared to results after two vaccine doses, proportion (%) of seropositivity after three vaccine doses increased significantly in groups rituximab (+/-) DMARD (p=0.003 and p=0.004, respectively), IL6r inhibitors + DMARD (p=0.02), and abatacept+DMARD (p=0.01). However, the proportion of seropositivity after three vaccine doses was still significantly lower in rituximab treated patients (52%) compared to other treatment groups or controls (p<0.001) (Figure 1A/B). Antibody response to WT, omicron sBA.1 and sBA.2 showed similar pattern with the lowest levels among patients treated with rituximab. When antibody response was compared between 2-12 weeks and 21-40 weeks after second dose, the proportion of seropositive rituximab treated patients decreased from 34.9 % to 32.6%. All patients with JAK inhibitors and with JAK-inhibitors and IL6r-inhibitors seropositive 21-40 weeks after the second vaccine dose. Patients treated with other b/tsDMARDs were not included in this analysis due to limited number participants.

Conclusion: In this Swedish study including IRD patients receiving different b/ts DMARDs, a sufficient immunogenicity of the third dose of COVID-19 vaccine was observed in all treatments with exception for rituximab. However, the increased proportion of seropositivity after the third COVID-19 vaccine doses in rituximab and other patients with insufficient response to two doses including response to the omicron variants, supports the current recommendations on additional booster doses. The immunogenicity of two vaccine doses was preserved to 40 weeks in majority of patients treated with different immunomodulating treatment with exception for rituximab.

(31.6%) on methotrexate and 56 (70.9%) on anti-TNF. Post-vaccination results showed positive T-cell immune responses in 68 of 79 (86.1%) ARDs patients with mean IFN-γ anti-SARS-CoV-2 titers of 1,606.85 mU/mL. 7 (8.9%) of ARDs patients showed negative IFN-γ anti-SARS-CoV-2 levels, while 4 (5%) had borderline titers. 100% of patients with previous COVID 19 disease had positive cellular responses. Within the group of negative or borderline cellular responses, 7 of 10 were men (70%), with no significant differences in terms of diagnosis, comorbidities or immunosuppressive treatments used. In the control group, 100% presented positive cellular responses. Anti-Spike IgG antibodies were detectable in all patients with ARDs as in the control group.

Conclusion: Our preliminary data show that most patients with ARD were able to generate an adequate specific cellular response after vaccination against SARS-CoV-2, emphasizing the relevance of vaccination in this group. Specific antibody responses secondary to anti-SARS-CoV-2 vaccination were detected in all patients with ARD. Our data could support the relevance of these immune responses to personalize prevention, vaccination decision-making and treatment in this subgroup of patients.

PERFORMANCE OF COMMERICAL SARS-COV-2 WILDTYPE AND OMICRON BA.1 ANTIBODY ASSAYS COMPARED WITH PSEUDOVIRUS NEUTRALIZATION TESTS

Keywords: Diagnostic tests, COVID, Vaccination/Immunization

E. Habermann1, L. M. Frommert1, K. Ghannam1, L. Nguyen My1, L. Gieselmann1, P. Tober-Lau1, J. Klotzsche1, A. N. Arumahandi de Silva1, A. Ten Hagen1, J. Zernicke1, F. Kurth2, L. Sander2, F. Klein2, G. R. Burmester2, R. Biesen2, F. Albach1. 1Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin, Berlin, Germany; 1Institute of Virology, Laboratory of Experimental Immunology, Cologne, Germany; Department of Infectious Diseases and Respiratory Medicine, Charité – Universitätsmedizin Berlin, Berlin, Germany; 1Charité – Universitätsmedizin Berlin, German Rheumatism Research Center Berlin, Berlin, Germany

Background: Commercially available ELISA-based antibody tests are used to evaluate vaccination success against SARS-CoV-2 as recommended for immunocompromised and at-risk patients by medical committees in Germany and Austria [1,2], but it is unclear whether they correlate with neutralization of the Omicron variant.

Objectives: The objective was to compare the test performance of different ELISA-based SARS-CoV-2 wild-type or adapted Omicron BA.1 antibody test systems with wild-type and BA.1 virus neutralization as measured by pseudovirus neutralisation tests (pVNT).

Methods: 269 serum samples of a cohort of 44 non-immunocompromised participants and 65 MTX-treated rheumatic patients taken before and after COVID-19 booster vaccinations were measured using COVID-19 antibody testing systems with wild-type and Omicron BA.1 antigens developed by three different manufacturers (surrogate virus neutralization test cPass, and binding antibody tests QuantiVac and SeraSpot), as well as with a pVNT. The pVNT was considered the gold standard for determining the presence and level of anti-SARS-CoV-2 antibodies.

Results: All three wild type ELISAs showed excellent test performance compared with wild type neutralization in pVNT. However, out of 56 samples without Omicron BA.1 neutralization in pVNT, 71.4% showed positive results in at least one and 28.6% in all three wild-type ELISAs at the manufacturer-defined cut-offs. Omicron ELISAs showed either decreased specificity (57.1% and 55.4% for binding ELISAs) or sensitivity (51.2% in cPass) compared to Omicron neutralization in pVNT. The proportion of any false positive results among all samples decreased from 26.5% before to 3.2% after booster vaccination, however binding antibody test specificities remained below 70%. Detailed results for all test systems can be found in Table 1 and Figure 1.

Conclusion: Decisions for booster vaccination or passive immunization of at-risk patients should not be based solely on antibody tests, because they do not indicate neutralization of Omicron as reliably as they did against wild-type.

Background: A growing number of articles describe new-onset inflammatory rheumatic diseases (IRD) - including inflammatory joint diseases (IJD), polymyalgia rheumatica (PMR), connective tissue diseases (CTD) and vasculitis - in close temporal association with SARS-CoV-2 infection (1). On the other hand, also the exposure to vaccines may elicit autoimmune and reports of IRD following vaccination with anti-COVID-19 vaccines appeared in literature since the earliest phases of the vaccination campaign (2,3).

Objectives: The aim of the present study was to contribute to the knowledge on the spectrum of new-onset post-COVID-19 and post-vaccine IRD with a comparative analysis from a large multicentric observational study.

Methods: In the present cohort study, we collected consecutive cases of IRD or acrosyndrome encountered during routine clinical practice from November 2021 to October 2022 (12 months) satisfying one of the following inclusion criteria: a) onset of the rheumatic manifestations within four weeks from the SARS-CoV-2 infection, confirmed by nasopharyngeal swab OR, b) onset of the rheumatic manifestations within four weeks from the administration of one of the COVID-19 vaccines approved for administration in Italy during the collection period. Exclusion criteria were a past history of any IRD or acrosyndrome.

Results: A total of 270 cases were entered in the database. Three records were excluded because identified as mechanical pain (n = 1) or fibromyalgia (n = 2). The final analysis cohort comprised a total of 267 patients, of which 122 (45.2%) patients in the post-COVID-19 (age 54 ± 17 years, 69.7% females) and 145 (54.8%) patients (age 58 ± 16 years, 66.2% females) in the post-vaccine cohorts. Mean delay between COVID-19 diagnosis or vaccine administration and rheumatic manifestations development was 14.5 ± 7.8 vs 13.9 ± 8.5 days, respectively (p = 0.59). Distribution of various IRD categories differed between the two cohorts (Figure 1): the post-COVID-19 cohort had a higher percentage of patients classified as having IJD (52.5% vs 37.2%, p = 0.013) while the post-vaccine cohort had a higher prevalence of patients classified as PMR (33.1% vs 21.3%, p = 0.032). No differences were detected in the percentage of patients diagnosed with CTD (19.7% vs 20.7%, p = 0.837) or vasculitis (6.6% vs 9.0%, p = 0.467).

Conclusion: Although temporal association does not imply causation, our study reports the largest cohort of post-COVID-19 and post-vaccine IRD described to date and supports the hypothesis that new-onset IRD may be triggered by SARS-CoV-2 infection or COVID-19 vaccines. The spectrum of possible clinical manifestations is broad and includes different IJD, PMR, CTD and vasculitis in both cohorts. Our data also suggest a differential pattern of expression: while IJD are the most common IRD following SARS-CoV-2 infection, PMR is relatively more frequent after vaccine administration.

Background: COVID-19 infection favors multiple chronic disparities in the base health status, currently known as post-COVID syndrome (PCS), that can be related to immunological variations. It is important to determine if these alterations (both clinical and immunological) exist in a long-term period in patients with rheumatoid arthritis (RA) who have suffered from this infection.

Objectives: The aim of this study was to assess the immunological [Lymphocyte populations (LP) and Autoantibodies (Ab)] and clinical profile of RA patients who suffered from COVID-19 and compare it with non-COVID-19 RA patients.

Methods: A nested Case-control study of RA patients evaluated under a multi-disciplinary model and strict follow-up with a post target strategy (T2T). Cases: RA patients and confirmed COVID-19 infection in the last 24 months and Controls: RA patients with no history of this infection. Subgroups in cases: a) Long COVID (LC): symptoms after infection that persist for ≥4 weeks; b) PCS: symptoms < 4 weeks. The 71.86% were in low disease activity. There were no differences in the behavior of the immunological (b) disease modifying drugs (DMARDs) and/or prednisolone exhibit an adequate immune response to the applied SARS-CoV-2 vaccines.

Results: A total of 300 patients were included (148 cases and 152 controls; 87.3% women). Median age 59 years (Interquartile range -IQR 11), disease duration 12 years (IQR 12). The 71.86% were in low disease activity. There were no significant differences in sociodemographic and clinical characteristics between cases and controls. Cases had a time since infection of 18.5 months (IQR 7). Of the total cases, 69% presented LC and 63% with PCS. No significant differences were found between cases and controls in the LP T, B and NK, nor in the Abs 3 months. The 12.64(9) - 12.93(8.1) - 12.4(9.3) 0.890, CD19+ 12.4(8.8) - 12.4(9.2) - 12.3(8.4) 0.239, CD16+CD56+ 12.64(9) - 12.93(8.1) - 12.4(9.3) 0.890.

Conclusion: The results propose a general description of a specific population of patients with RA with low disease activity, under treatment in a strict follow-up model, in which no differences were found in the behavior of the immunological profile (independent of symptoms of LC and PCS) evaluated long-term after infection with those who did not have COVID-19. This suggest that they return to their basal homeostatic state, something that has not yet been reported up to now. These results should forwardly be replicated in populations with other characteristics of RA.

Balbir-Gurman1,2, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Rheumatology Institute, Haifa, Israel; 2Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Biochemistry Laboratory, Haifa, Israel; 3Hadassah Medical Center, Hebrew University of Jerusalem, Bioinformatics, Jerusalem, Israel

**Background:** The 3rd booster of mRNA vaccines against SARS COV2 was highly efficient against delta variant but data regarding the efficacy of the 3rd and 4th boosters against the omicron variants, among AIRD pts are scarce.

**Objectives:** We aimed to assess the effect of the 3rd and 4th booster mRNA vaccines against SARS CoV2, in preventing severe COVID-19, in AIRD patients (pts) treated with immunomodulating drugs.

**Methods:** 212 pts (mean age (SD) 57(13), disease duration 11.2(7.4), who received the 3rd booster (Pfizer) were included in the study. We performed serology tests 24 weeks after the second dose of vaccine and 4-8 weeks after the 3rd booster. IgG Antibodies (Ab) against SARS COV2 virus were detected using the SARS-CoV-2 IgG II Quant (Abbott) assay. The test was considered positive above 50 AU/ml. Data regarding COVID-19 infection during the 5th outbreak (omicron) were collected from the medical files. The length of observation period was defined as the time from the 3rd booster to the last hospital visit or COVID 19 diagnosis, whichever occurred first.

**Results:** The 3rd booster administration (Pfizer) significantly augmented the humoral response (from mean(SD) 1121(4723) AU/ml to 12153(13687)). 58 patients received the 4th booster and 18 the 5th booster. COVID-19 was diagnosed in 103 pts (49%) within mean(SD) 224.8(106.5) days after the 3rd booster vaccination. 109 pts remained free of disease during mean(SD) follow-up 230.6(133.9). Following the 4th booster, 26 (45%) out of 58pts contracted COVID-19 within mean(SD) 97.6(78.7) days after the vaccination. One 70 year old patient (vaccinated 3 times) died and 2 other pts (rituximab treated) had severe COVID-19. The IgG Ab titer after the 3rd booster was lower in pts who contracted COVID-19 compared to those uninfected (mean(SD), median 8777.9(11716.4),3475 AU/ml vs 15348.1(14649.1),10801, p=0.004). There were no statistically significant differences between the pts with COVID-19 and those without, regarding age, type of disease, treatment and humoral response 24 weeks after the 2nd vaccination.

**Conclusion:** Despite an enhanced humoral response obtained after the 3rd booster, 49% of AIRD pts vaccinated with 3 doses and 45% of pts vaccinated with 4 doses had COVID-19 during the omicron outbreaks. Higher humoral response to the 3rd booster was associated with a lower rate of COVID19. The booster vaccines conferred 99% protection against severe COVID-19.

**PRE-EXPOSURE PROPHYLAXIS OF COVID-19 WITH TIXAGEVIMAB AND CILGAVIMAB IN RHEUMATOLOGIC PATIENTS TREATED WITH RITUXIMAB: DATA FROM A SINGLE-CENTRE COHORT**

**Keywords:** COVID, bDMARD

M. Manara1, M. Sette2, L. Giudice1,2, M. Biggioggero1, N. Del Papa1, E. G. Favalli1,2, M. Gerosa1,2, F. Ingegni1,2, R. Caporali1,2, ASST G. Pini-CTO,
Department of Rheumatology and Medical Sciences, Milan, Italy; 2University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background: Rheumatologic patients treated with Rituximab (RTX) are at higher risk of severe COVID-19 and death. The B-cell depleting treatment significantly affects B cell functions involved in anti-SARS-CoV-2 response, leading to relevant impacts on the clinical and serological course of infection, long-term immunity, and vaccine responses. In light of these observations, pre-exposure prophylaxis (PrEP) of COVID-19 with Tixagevimab and Casivimab (TGM/CGM) was recently approved in Italy for all patients treated with RTX in the previous year, independently of their serological status against SARS-CoV-2.

Objectives: We aimed to evaluate the efficacy and safety of TGM/CNM in a single-centre cohort of rheumatologic patients treated with RTX.

Methods: From October 2022, all patients who had been treated with RTX in the previous 12 months and who underwent clinical assessment at our rheumatologic tertiary centre were screened for eligibility to PrEP of COVID-19 with TGM/CNM. According to the indications of the Italian Medicines Agency (AIFA), we excluded subjects with major cardiovascular risk factors and/or coagulation abnormalities; those who reported a previous allergic reaction to any anti-COVID-19 vaccine were referred to an allergologist for an evaluation before TGM/CNM administration. Patients who agreed to be treated with TGM/CNM signed an informed consent. Clinical and demographic features were collected at baseline, and follow-up phone assessment was performed the day after and 1 month after TGM/CNM administration, to assess treatment tolerability and new COVID-19-related events. A descriptive analysis was performed.

Results: From 1 October 2022 to 31 December 2022, 90 subjects were screened for eligibility to TGM/CNM. Among them, 11 were excluded for contraindications due to comorbidities and 55 refused TGM/CNM administration. Among patients who agreed to receive PrEP of COVID-19, 21 received TGM/CNM before 31 December 2022 and 3 were scheduled for January 2023. Patients treated with TGM/CNM had a mean age of 54 years (standard deviation: 17) and 19 (90.5%) were female; 9 were affected by rheumatoid arthritis and 12 by other rheumatologic diseases (3 systemic lupus erythematosus, 2 systemic sclerosis, 1 Sjögren syndrome, 1 juvenile idiopathic arthritis, 3 anti-synthetase syndrome, 2 vasculitides). Most of them had completed the vaccination schedule against COVID-19 (19, 90.5%) and 9 (42.8%) reported an infectious event by SARS-CoV-2 in the previous year. One month after TGM/CNM administration, no patient reported adverse events related to TGM/CNM nor COVID-19 related symptoms.

Conclusion: PrEP of COVID-19 with TGM/CNM was well tolerated in our population of rheumatologic patients treated with RTX in the previous year and no COVID-19 related symptoms were observed in the month of follow-up after TGM/CNM administration. Future observations may provide further data on long-term efficacy of TGM/CNM in preventing COVID-19.

Figure 1.
Conclusion: In conclusion, forty-seven percent of initial non-responders were able to seroconvert after two-dose revaccination. However, plasma concentrations of the antibodies against SARS-COV-2 and the levels of neutralizing capacity remained significantly lower in inflammatory rheumatic diseases (IRD) patients without sufficient protection against SARS-CoV-2 infection. Our study suggests that patients with RDs who did not mount a detectable serological response to a COVID-19 mRNA vaccine have a T cell response similar to immune-competent controls. Future studies should establish the antibody levels that identify IRD patients without sufficient protection against SARS-CoV-2 infection.

Background: We recently performed a long-term, model-based comparison of the humoral immunogenicity following two-dose vaccination with BNT162b2 and mRNA-1273 in individuals from SCQM, the Swiss cohort for patients with inflammatory rheumatic diseases (IRD). Vaccination with mRNA-1273 resulted in higher humoral immunogenicity compared to BNT162b2 throughout 24 weeks post second vaccine dose [1]. In booster vaccinations, the dose of mRNA-1273 was reduced and it is currently unknown if there was a difference in SARS-CoV-2 infections in BNT162b2 and mRNA-1273 recipients with IRD after the third vaccine dose.

Objectives: To investigate the risk of test-positive SARS-CoV-2 infection after three doses of BNT162b2 or mRNA-1273 in IRD patients.

Methods: Adult patients from the SCQM registry who previously participated in an observational cohort study comparing vaccine-induced humoral immune responses following two doses of BNT162b2 or mRNA-1273 were invited to participate in the next phase of the study. Participants answered study questionnaires via the mySCQM patient app, including on subsequent vaccine doses and SARS-CoV-2 infections, here taken as patient-reported positive PCR or antigen tests. Pre and post third vaccination anti-SARS-CoV-2 IgG (anti-S1) levels were quantified by testing self-collected capillary blood samples using the EURO-IMMUN ELISA as previously described [1]. To analyze the risk of infection, we used a Cox proportional hazards model. The time of the third mRNA COVID-19 vaccine dose administration was taken as the baseline. Patient follow-up ended on the minimum date of the following events: testing positive for SARS-CoV-2 infection after the third mRNA COVID-19 vaccine dose, receiving a fourth vaccine dose, last data entry in the mySCQM patient app, or study end (2022-12-01). Patients whose follow-up ended in the first 14 days after the third vaccine dose were excluded from the analysis.

Results: 445 patients were included in the study (67% female; mean age 54 yrs; 36% RA, 36% axSpA, 21% PsA, 7% undifferentiated arthritis). Patients received their third dose of mRNA COVID-19 vaccine between 2021-08-06 and 2022-04-04 (BNT162b2: mRNA-1273 51:49%; homologous vaccination applied in 95% of patients). Between 2021-12-08 and 2022-11-24, 175 patients reported a positive SARS-CoV-2 test occurring at least 14 days after the third vaccine dose (Figure 1A), only 3 of whom required hospitalization. We found no statistically significant difference in the risk of SARS-CoV-2 infection post third dose due to the vaccine received (mRNA-1273 vs BNT162b2) (Figure 1B). Higher anti-S1 levels at baseline were statistically significantly associated with a lower risk of infection post third vaccine dose. A prior SARS-CoV-2 infection also statistically significantly reduced the risk of infection post third vaccine dose.

Conclusion: The risk of SARS-CoV-2 infection did not statistically significantly differ between mRNA-1273 and BNT162b2 recipients following a third vaccine dose. Higher anti-S1 levels at the time of the third mRNA COVID-19 vaccine dose, as well as a prior infection, were associated with a statistically significant lower risk of test-positive SARS-CoV-2 infections during follow-up in patients with IRD.

Figure 1.
nrAIRD, and HCs. After exclusion of individuals who were unvaccinated, those who received one vaccine dose only, and those with uncertain responses regarding the vaccine doses, a total of 9,596 patients formed the study population of the present investigation. If a COVID-19 infection occurred after the initial two vaccine doses and at least one booster dose (at least three doses in total, herein termed full vaccination), it was considered a BTI. Data were analysed using multivariable regression models. Statistically significant results were denoted by p values <0.05.

Results: A total of 7,016/9,596 (73.1%) individuals were fully vaccinated. Among those, 1,002 (14.2%) reported at least one BTI, and 166 (2.3%) reported at least two BTIs. Among SLE patients, 867/1,218 (71.2%) were fully vaccinated. Among fully vaccinated SLE patients, 137 (15.8%) reported at least one BTI while 28 (3.2%) reported at least two BTIs. BTI frequencies in fully vaccinated SLE patients were comparable to those of other AIRDs (OR: 1.0; 95% CI: 0.8–1.3; p=0.447) and nrAIDS (OR: 0.9; 95% CI: 0.6–1.3; p=0.856) but higher compared with HCs (OR: 1.2; 95% CI: 1.0–1.6; p=0.022). For SLE patients with three vaccine doses, 113/137 (82.5%) reported at least one BTI while the corresponding number for four vaccine doses was 24/137 (17.5%). Compared with HCs (OR: 10.6; 95% CI: 1.2–93.0; p=0.032) and other AIRDs (OR: 3.5; 95% CI: 1.0–11.5; p=0.036), SLE patients showed higher frequencies of hospitalisation. AID multimorbidity was associated with a 15-fold increased risk for a need of advanced treatment for COVID-19 (OR: 15.3; 95% CI: 2.6–88.2; p=0.002).

Conclusion: COVID-19 BTIs occurred in nearly 1 every 6th fully vaccinated patient with SLE, and 20% more frequently in this patient population compared with fully vaccinated HCs. Moreover, BTIs in SLE patients were more severe compared with BTIs in HCs or patients with AIRDs other than SLE, resulting in a greater need for hospitalisation. AID multimorbidity contributed to a more severe COVID-19 BTI requiring advanced management. These insights call for greater attention to vaccination in the vulnerable group of SLE patients, with appropriate risk stratification towards optimised vaccination strategies.

POS0550 IMMUNE RESPONSE AFTER VACCINATION AGAINST SARS-COV2 IN PATIENTS WITH IMMUNOMEDIATED DISEASES (RIM-COV PROJECT)

Keywords: COVID, Vaccination/immunization

1Hospital Universitario Ramón y Cajal, Immunology, Madrid, Spain; 2Hospital Universitario Ramón y Cajal, Immunology, Madrid, Spain; 3Hospital Universitario Ramón y Cajal, Microbiology, Madrid, Spain; 4Hospital Universitario Ramón y Cajal, IRyCS, CIBEREPS, Department of Nursing and Physiotherapy. Universidad de Alcalá, Clinical Biostatistic Unit, Madrid, Spain

Background: It is known that patients with immunomodulatory treatment may have less immune response to vaccines. Since SARS-CoV2 infection appeared, several vaccines have been developed. In previous studies, it has been observed that some subgroups of patients have a lower antibody response after SARS-CoV2 vaccination, especially patients treated with Rituximab (an anti-CD20 monoclonal antibody); but also in those treated with Mycophenolate Mofetil, Abatacept, JAK inhibitors, anti tumor necrosis factor (TNF) α, Methotrexate or Glucocorticoids. In some studies, an absence of humoral response but the presence of a T-cell response after vaccination has been observed in patients with B-cell depletion, even without finding differences between patients treated with Rituximab compared with other immunomodulatory therapies or healthy controls. As well, it has been described a lower T-cell response in patients treated with anti-CTLA4, anti-interleukin 6 or anti-TNFα.

Objectives: Our objective is to identify factors that influence humoral and cellular immune responses to SARS-CoV2 vaccines in patients with immune-mediated rheumatic diseases (IMRDs) in treatment with disease-modifying anti-rheumatic drugs (DMARDs) and in healthy subjects as a control.

Methods: A total of 140 consecutive patients and 24 healthy controls were included in this observational cross-sectional single-centre study. Two months after second or third COVID-19 vaccine dose (BNT162b2 [Pfizer/BioNtech], mRNA-1273 [Moderna] or AZD1222 [AstraZeneca]), we quantified IgG anti-SARS-CoV2 antibodies by chemiluminescent immunoassay of micro-particles and Interferon (IFN)-γ production by T cells stimulated with SARS-CoV2 peptides using an IFN-gamma release assay test. IgG anti-SARS-CoV2-IgG levels below 1800 AU/ml and IFN-gamma levels below 0.15 IU/ml were considered as a suboptimal humoral or cellular immune response, respectively. Multivariate analyses were used for exploring influence of different factors in these suboptimal immune responses.

Results: Of the 140 patients, 101 were women and 39, men, with a median age of 55.9 (46.1-64.7) years and a disease duration of 15 years. All patients had a diagnosis of autoimmune arthropathy and 34, of systemic autoimmune disease. The higher risk of having a poor humoral response after the vaccination was shown in those patients receiving only two vaccine doses (OR: 7.83 (2.94-20.83);

1KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore; 3KK Women's and Children's Hospital, Department of Nursing, Singapore, Singapore

**Background:** Although robust humoral immune response after 2-dosed COVID-19 mRNA vaccination has been demonstrated in adolescents and young adults (AYAs) with childhood-onset rheumatic diseases (cRDs) [1], data on prevalence and risk factors of SARS-CoV-2 breakthrough infection are limited.

**Objectives:** To describe the clinical characteristics and risk factors for SARS-CoV-2 breakthrough infection in vaccinated AYAs with cRD from our prospective ongoing cRDs COVID-19 vaccination cohort.

**Methods:** Patients were recruited from March 2021 – December 2022 at KK Women’s and Children’s Hospital, Singapore. Breakthrough infections were defined as symptomatic infections occurring ≥14 days after the second dose in a two-dose series [2]. Humoral immunogenicity was assessed at 2-3 weeks after first vaccine dose and 1, 3, and 6 months after the second dose by the cPass™ SARS-CoV-2 Neutralisation Antibody (nAb) Assay and calibrated against the World Health Organisation International Standard for SARS-CoV-2 antibodies (WHO-nAb).

**Results:** 170 fully COVID-19 mRNA vaccinated patients (71% Chinese, 47% male) were included, Table 1. 141 patients received 3rd dose, 6 months after the full series. 51% had breakthrough infection at a median of 5.6 (IQR 4.0-6.8, n=22) and 3.7 (IQR 1.3-5.4, n=55) months after 2nd or 3rd doses, respectively, with mainly mild symptoms (5% admission). The median WHO-nAb was significantly lower in those with breakthrough infection (987.3 IU/ml, IQR 361.0 - 2083.4 vs 1892.1 IU/ml, IQR 1052.5 - 2657.7, p<0.001). Older patients had decreased risk of breakthrough SARS-CoV-2 infection (OR 4.16, 95% CI 0.739-0.936, p=0.002). A WHO-nAb titre of < 1000 IU/ml increased the risk of breakthrough SARS-CoV-2 infection (OR 4.16, 95% CI 1.964-8.794, p<0.001). Significantly more patients with infection were taking anti-TNF. Withholding methylprednisolone or mycophenolate mofetil did not impact the breakthrough infection risk.

**Conclusion:** Despite a robust humoral immune response to COVID-19 mRNA 2-dosed vaccination, one-half of the AYAs with cRDs had breakthrough infections, albeit mild disease. Younger patients and WHO-nAb < 1000 IU/ml increased the risk of infection. Additional vaccine is needed sooner than 6 months after the 2nd dose to prevent infection. Longitudinal data are being collected to determine the vaccine booster interval in our cohort.

**NEUTROPHIL EXTRACELLULAR TRAPS AND B-CELL ACTIVATING FACTOR AS MARKERS TO PREDICT AND MONITOR ADVERSE EFFECTS AFTER COVID-19 VACCINES**

**Keywords:** Disease-modifying Drugs (DMARDs), Vaccination/Immunization, Biomarkers

Y. M. Kuo1,2, Y. Z. Li2, C. C. Hsu2, C. J. Jung3, 1National Taiwan University College of Medicine and National Taiwan University Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China; 2College of Medicine, Taipei Medical University, Microbiology and Immunology, School of Medicine, Taipei, Taiwan, Republic of China; 3Taiwan University College of Medicine and National Taiwan University University Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China

**Background:** Vaccine-induced immune thrombocytopenia (VITT) has also been reported to be related to NETosis. However, whether non-VITT adverse events(AE) and AEs due to non-adenosine vectors-COVID-19 vaccines are related to NET formation has not been confirmed.

**Objectives:** We hypothesized that COVID-19 Vaccine could induce circulating products of NETosis in fashion similar to the SARS-CoV-2.

**Methods:** Citrullinated histone H3 (cH3) and B-cell activating factor (BAFF) serum levels were checked in healthy donors(HD) who received two doses of mRNA-1273(Moderna) or ChAdOx1 nCoV-19 vaccines in National Taiwan University Hospital, a tertiary medical center in northern Taiwan. Serial blood tests were done on the day before COVID-19 vaccination(Day 0), before mRNA-1273 boosters (booster Day 0) and 30 days after the boosters (booster Day 30). Therefore, two cohorts, MM-M and AA-M were enrolled from March 2021 to Jan 2022. A REDCap online survey of adverse effects 0-7 days after each vaccination was also performed. Grade of AEs were defined as the previous COVID-19 vaccine trial(KidCOVE trial) described. In addition to HD cohorts, serial antiphospholipid antibodies and cH3 serum titers were also monitored in a case series of three anti-BAFF(belimumab) treated patients, who were hospitalized due to severe AEs after COVID-19 vaccines. We had excluded concomitant COVID-19 infections since all HDs and hospitalized patients were negative for serial SARS-CoV-2 nucleocapsid antibody.

**Results:** We analyzed two HD cohorts as a whole(n=34), the serum cH3 on booster Day 0 were lowest among the HDs who experienced no AEs from booster Day 0 to Day 7[2.8±1.4 v.s. 12.3±10.8ng/ml(HD with Grade 3 AEs), p<0.01, U test], Only serum cH3 on booster Day 0 but not on other time points could predict AEs due to COVID-19 vaccines. In addition, the serum BAFF on booster Day 0 were lowest among the Hds who reported no AEs from booster Day 0 to Day 7[1646.1±794.7 v.s. 273.4±218.6pg/ml(HD with ≥Grade 3 AEs), p<0.01]. For the three hospitalized AZ-mRNA vaccine experienced patients, two patients suffered fatigue due to hyperperfusion at multiple brain area SPECT, and
one experienced refractory abdominal pain due to mesenteric vein thrombosis soon (eight, 24, and 67 days) after the last doses of COVID-19 vaccinations. Two of them had moderate clinical improvement and both citH3 IgM anti-cardiolipin decreased after belimumab monthly administration while one needed further IVIG treatment and salvage plasma exchange. In HDs who received two doses of ChAdOx1 vaccines (AZ) and a Moderna booster (AA-M cohort), citH3 increased most significantly after two doses of AZ (p = 0.01, U test, cohort AA-M, n = 26, Figure 1A). BAFF also increased significantly after two doses of AZ (p < 0.001, Figure 1B), Brown-Forsythe heteroscedasticity test indicated their values of three time points were unequal (p = 0.04). However, in HDs who received three doses of Moderna, citH3 only numerically increased after two doses of Moderna (p = 0.13, U test, cohort MM-M, n = 8, Figure 1C). BAFF did not fluctuate after two doses of Moderna and even after the third dosage of Moderna. Brown-Forsythe test indicated BAFF were equal (p = 0.87, Figure 1D). A trend of higher NET formation and BAFF induction due to adenovirus vectors-COVID-19 vaccine were observed in comparison with mRNA-1273. It has been hypothesized antiplatelet factor 4 may occur after heparin or AZ vaccines due to similarity shared by anionic surfaces in adenosival vector and heparin molecule. Further profiling of autoantibodies after various COVID-19 vaccines and in vitro platelet-neutrophil axis activation test may elucidate the mechanism by which induce NETosis as demonstrated in our cohort.

Conclusion: Dynamic serum citH3 level revealed that neutrophil extracellular traps may play important roles in AES due to COVID-19 vaccines.

Ovuka4, M. Ogrič2, S. Ćučnik2,3, P. Zigorić4,5,6,7, 1University of Belgrade - Faculty of Medicine, Institute of Rheumatology, Belgrade, Serbia; 2Faculty of Medicine Foja/ University of East Sarajevo, Internal Medicine, Foja, Bosnia and Herzegovina; 3University Clinical Hospital Center Bežanjiška kosa, Belgrade, Serbia, Internal Medicine, Belgrade, Serbia; 4University of Belgrade - Faculty of Medicine, Institute of Rheumatology, Belgrade, Serbia; 5Clinical Hospital Center Pancevo, Serbia, Internal Medicine, Pancevo, Serbia; 6University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 7University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia; 8University of Primorska, FMNIF, Koper, Slovenia

Background: Rheumatologic patients receiving B cell-depleting therapy (BCDT), such as Rituximab (RTX), have relevant defects in humoral responses to a variety of vaccines. Moreover, RTX-treated patients appear vulnerable to breakthrough infections often showing worst outcomes. Monoclonal antibodies have been developed to provide passive immunity against SARS-CoV-2 in patients with depressed immune systems. Tixagevimab-Cilgavimab (TIX/CIL) is a monoclonal antibody that has been shown to reduce the risk of COVID-19 infections in immunocompromised patients and could be administered as pre-exposure prophylaxis or as targeted anti-SARS-CoV-2 treatment. Few data on real-life evidence on TIX/CIL in RTX-treated rheumatologic patients have been documented.

Objectives: The objectives of this study were to identify breakthrough COVID-19 infections and to evaluate outcomes in RTX-treated rheumatologic patients who underwent pre-exposure prophylaxis or treatment with TIX/CIL.

Methods: In this retrospective cohort study, we included 13 rheumatologic patients referring to the 3rd level Rheumatology Unit at the Tor Vergata University Hospital in Rome (Italy) who were treated with RTX for remission induction and/or maintenance and received TIX/CIL dose of 600 mg (300 mg Tixagevimab-300 mg Cilgavimab), between February and December 2022. A review of medical records was completed. Data on the rheumatologic disease, immunosuppressive treatment, COVID-19 vaccine status, TIX/CIL administration, peripheral blood CD19 cells and IgG levels before and after TIX/CIL administration were registered.

Results: The mean (±SD) age of included patients was 69 (±9) years, with 92.3% women. The cohort was diagnosed with Rheumatoid Arthritis (RA, 76.9%), Sjogren Syndrome (7.7%), Systemic Sclerosis (7.7%), Dermatomyositis (7.7%); one subject received RTX also for concomitant Multiple Sclerosis. Most patients received COVID-19 vaccines, and all but one received a third dose. All patients received TIX/CIL dose of 600 mg (300 mg Tixagevimab-300 mg Cilgavimab), the majority (84.6%) of them as pre-exposure prophylaxis, while in 2 patients (15.4%) TIX/CIL was administered as a targeted anti-SARS-CoV-2 treatment. At the time TIX/CIL was administered, patients had a disease duration of 16±8 years. In patients undergoing pre-exposure prophylaxis, serum IgG levels before and after TIX/CIL administration were variable. Pre-TIX/CIL IgG levels were normal (54.5%), low (27.3%), and not available (18.2%). Post-TIX/CIL IgG levels were normal (72.7%), not available (18.2%) and low (9.1%). In those with documented pre- and post-TIX/CIL IgG levels, the levels did not change except for one patient with a normal post-TIX/CIL IgG level compared to a low pre-TIX/CIL IgG level. In addition, before getting TIX/CIL, CD19 was depleted (54.5%) and unavailable (45.5%) among patients. Post-TIX/CIL CD19 was depleted (63.6%) and unavailable (36.4%). In those with documented post-TIX/CIL IgG levels, the levels did not change except for one patient with a normal post-TIX/CIL IgG level compared to a low pre-TIX/CIL IgG level. The mean time from the onset of COVID-19 disease to TIX/CIL administration was 3±1.4 days. Regarding rheumatologic diseases, all patients continued RTX-therapy with a mean duration of treatment of 4±0.5 months and remained in remission.

Conclusion: Our findings, including mainly RA-patients, highlight the role of an adequate passive immunity in immunosuppressed patients. However, pre-exposure treatment can be crucial as well as the need to use early anti-viral agents/anti-SARS-CoV-2 mAb in most fragile patients. Larger cohorts and further measures are needed to support that challenge and to better investigate the Interplay between RTX and monoclonal antibodies in treated patients.

Objectives: In this study, we aimed to evaluate the high dose intravenous anakinra treatment response and outcome in patients with severe and critical COVID-19 compared to standard of care.

Methods: This retrospective observational study was carried out at a tertiary referral center. The study population consisted of two groups as follows; the patients receiving high dose intravenous anakinra (anakinra group) between 01.09.2021 and 01.02.2022 and the patients treated with standard of care (SoC, control group) as historical control group who were hospitalized between 01.07.2021 and 01.09.2021.

Results: After the propensity score 1:1 matching 79 patients in anakinra and 79 patients in SoC matched and included into the analysis. Means±SD patient age was 67.4±16.7 and 67.1±16.3 years in anakinra and SoC group, respectively (p=0.9). Male gender was 38 (48.7 %) in anakinra and 36 (46.2 %) SoC (p=0.8). Overall, ICU admission was in 14.1 % (n=11) and 30.8 % (n=24) (p=0.013; OR: 6.2), intubation in 12.8 % (n=10) and 16.7 % (n=13) patients (p=0.5), 14.1 % before and 32.1 % (n=25) patients died in anakinra and control group, respectively (p=0.008; OR: 7.1).

Conclusion: In our study mortality was lower in patients receiving anakinra compared to SoC. Intravenous high dose anakinra is safe and effective treatment in patients with severe and critical COVID-19.

LONG COVID IN RHEUMATOID ARTHRITIS AND IN PSORIATIC ARTHRITIS: CLINICAL PATTERN AND GENDER-BASED DIFFERENCES FROM A SINGLE-CENTRE CASE-CONTROL STUDY

Keywords: COVID, Rheumatoid arthritis, Psoriatic arthritis

M. Ferraioli1, L. De Marco1, L. Fiannacca1, M. Iaconvatunno1, B. Monosi1, P. Triggiani1, P. Congirol1, A. Bergamin1, M. S. Chimenti1,2. Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy

Background: Long Covid (LC) refers to prolonged symptoms after Sars-CoV2 infection not explained by alternative diagnosis lasting 4-12 weeks as defined by the National Institute for Health and Care Excellence. Few studies explored LC in rheumatic diseases patients (RD) concluding that they present persistent symptoms after infection, although lacking a healthy control (HC) group.

Objectives: To evaluate incidence and clinical features of LC on patients affected by Rheumatoid arthritis (RA) or Psoriatic arthritis (PsA) as well as infectioin influence on disease activity.

Methods: A monocentric retrospective case-control study was conducted on consecutive outpatients affected by RA or PsA in Low Disease Activity or remission, referring to the Rheumatology Unit of University of Tor Vergata (Rome, Italy) between Sep ’21 - Sep ’22. Inclusion criteria: age ≥ 18 years, proven Sars-CoV2 infection between Jun ’21 – Jun ’22, 3 doses anti-Sars-CoV2 vaccination, recovered for at least 12 weeks, diagnosis of PsA/RA before Feb ’20. Exclusion criteria: symptoms explained by other diagnosis (as fibromyalgia, COPD ecc), hospitalization for Sars-CoV2. Patient were evaluated at 12 weeks after infection: demographic data, baseline comorbidities, ongoing therapy at infection and symptoms during and after infection were recorded; disease related data were recorded referred to the last clinical assessment too. Clinical features were compared among RA and PsA and with HC than among females and males patients.

Results: 120 (60 PsA/60 RA) patients and 60 HC were enrolled (Table 1). Patients compared to HC reported higher incidence of dyspnoea during infection while at resolution: lower VAS general health (GH), higher asthma, joint pain and higher incidence of dyspnoea, chest pain, sleep disturbances and depression. All patients continued their therapy during infection and no differences were found about baseline comorbidities and ongoing therapy. No statistical differences emerged between PsA and RA patients among them but when compared with HC both presented higher VAS fatigue, joint pain, lower GH and a longer duration of anosmia and anageusia after infection. Moreover, PsA presented higher incidence of chest pain after infection and headache during and after infection; RA reported higher incidence of chest pain and headache after infection and dyspnoea during and after. Regarding gender: females reported higher VAS disease activity, asthma and higher incidence of joint pain, dyspnoea, depression and sleep disturbances at infection resolution. Lastly, female PsA patients presented higher DAPSA score after infection than man. Disease related items were compared before and after infection (Figure 1): statistical significant differences emerged regarding VAS disease activity, asthma, joint pain and GH in RA and PsA patients.

Conclusion: Here, we documented that RD patients – particularly females - suffer from a higher burden after Sars-CoV2 infection showing statistical significant higher incidence of symptoms than HC and a worsening of disease activity although no disease flare were registered. Thus, LC carrying a significant burden is becoming an urgent health issue that needs immediate prioritization to prevent another national health disaster that could be a further blow to health systems.

COVID-19 OUTCOMES IN KOREAN PATIENTS WITH GOUT

Keywords: Crystal arthritis, COVID

M.J. Kim1, B. Ryu2, S. Yi3, J.W. Park4, Y. Jang5, K. Shin1. 1Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Biomedical Research Institute, Seoul, Korea, Rep. of (South Korea); 3Seoul National University Hospital, Biomedical Research Institute, Seoul, Korea, Rep. of (South Korea); 4Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Patients with autoimmune inflammatory rheumatic diseases are at higher risk for coronavirus disease (COVID)-19 hospitalization and worse clinical outcomes compared with the general population. However, data on the association between COVID-19 outcomes and gout, or gout-related medications are still lacking.

Objectives: We aimed to compare COVID-19 related clinical outcomes in gout vs. non-gout patients.

Methods: We conducted a retrospective cohort study using the electronic health record-based databases of Seoul National University hospital (SNUH) from January 2021 to April 2022 mapped to a common data model. Patients with gout and without gout were matched using a large-scale propensity score (PS) algorithm. The clinical outcomes of interest were COVID-19 infection, severe COVID-19 outcomes defined as the use of mechanical ventilation, tracheostomy or extracorporeal membrane oxygenation, and death within 30 days of COVID-19 diagnosis. The hazard ratio (HR) for gout vs. non-gout patients derived by Cox proportional hazard models were estimated utilizing a 1:5 PS-matched cohort.

Results: 2,683 patients with gout and 417,035 patients without gout were identified among the patients who visited SNUH. After 1:5 PS matching, 1,363 gout patients and 4,030 non-gout patients remained for the analysis. The risk of COVID-19 infection was not significantly different between patients with gout and those without gout (HR 1.07 [95% CI 0.99-1.84]). Within the first month after the COVID-19 diagnosis, there was also no significant difference in the risk of hospitalization (HR 0.57 [95% CI 0.30-0.99]), severe COVID-19 outcomes (HR 2.90 [95% CI 0.54-13.71]), or death (HR 1.35 [95% CI 0.06-16.24]).

Conclusion: Patients with gout did not have an increased risk of COVID-19 infection or worse clinical outcomes. Updates of temporal trends of COVID-19 outcomes in gout patients are yet warranted as new SARS-CoV-2 variants emerge.

Background: In general, more women are affected by rheumatic diseases and often during their reproductive age. Due to disease activity and/or specific autoantibodies autoimmune diseases might lead to impaired fetal outcome. Data from large registries help to improve information on the risks for patients and infants and thus enable us to better advise our patients.

Methods: To analyse fetal outcome of babies born to patients with rheumatic diseases we compared different parameters and control to healthy controls. This study compares registry data from 2012–2022 from a specialized centre. We included 351 pregnancies from patients with rheumatic diseases and 1298 from age-matched HC.

Results: Patients with rheumatic diseases were distributed as follows: 58% CTD, 15% RA, 13% SpA, 5% autoinflammatory diseases and 4% vasculitis. Spontaneous abortion rate with 5% was comparable to the general population [1]; APGAR, and umbilical cord pH were comparable to HC. Babies born to patients with rheumatic diseases have a significantly different outcome compared to HC: they present with lower birth weight (3245g vs 3038g; p<0.001) and length (50.7cm vs 49.7cm; p<0.001), higher number of intrauterine growth retardation (IUGR; 3% vs 7%; p<0.05) and are more often preterm (10% vs 16%; p<0.01).

Conclusion: Fetal outcome of neonates born to patients with rheumatic diseases in general is favourable, as we observed a live birth rate of 95%. This is also supported by important parameters as APGAR and umbilical cord pH, which did not differ in between groups. However, the number of children born before 37gw and lower birth weight/length is significantly higher compared to HC. This has been suggested by us and other groups [2–4], but we here compare the fetal outcome of patients to an age-matched HC group from the same hospital, and therefore more comparable and valid data. One might speculate, that higher rates of preterm births explain the higher admission rate to neonatal care and CPAP therapy (4% vs 12%; p<0.001) and transfer to specialized neonatal care (6% vs 12%; p<0.01). When comparing different groups of rheumatic diseases, our study shows mainly differences for CTD (especially SLE, Sjögren’s syndrome and undifferentiated CTD), with high rates of small for gestational age (SGA; SLE<19%, SS<28%; UCTD<28%), high proportion of planned caesarean birth (SLE<44%). However, congenital anomalies were also more frequent in the group of patients with SpA. Interestingly, in the age group >35years patients and HC assimilated, eg we did not observe significant differences for birth weight anymore.

OUTCOME OF NEONATES BORN TO PATIENTS WITH RHEUMATIC DISEASES COMPARED TO HEALTHY CONTROLS

Keywords: Pregnancy and reproduction

1University Hospital Tübingen, Centre for Interdisciplinary Clinical Immunology, Rheumatology and Autoinflammatory diseases, Tübingen, Germany

Morbidities of patients with SpA. Interestingly, in the age group >35 years patients and HC assimilated, eg we did not observe significant differences for birth weight anymore.

Conclusions: Outcome of neonates born to patients with rheumatic diseases in general is favourable, as we observed a live birth rate of 95%. This is also supported by important parameters as APGAR and umbilical cord pH, which did not differ in between groups. However, the number of children born before 37gw and lower birth weight/length is significantly higher compared to HC. This has been suggested by us and other groups [2-4], but we here compare the fetal outcome of patients to an age-matched HC group from the same hospital, and therefore more comparable and valid data. One might speculate, that higher rates of preterm births explain the higher admission rate to neonatal care and CPAP therapy. Our data reveal, however, that these differences mainly affect patients with CTD, especially SLE, SSS, UCTD, which is of special interest for the risk assessment in the treatment of pregnant patients with rheumatic diseases.

Even though spontaneous abortion rates did not differ to the general population, we observed a significantly higher number of congenital anomalies. Further studies are necessary to determine the underlying cause, as both, disease activity and immuno suppressant medication might be responsible.

1State Hospital Stockerau, Department of Internal Medicine II, Karl Landsteiner Institute for Clinical Rheumatology, Stockerau, Austria; 2Vienna University of Economics and Business Administration, Institute for Strategy and Managerial Accounting, Vienna, Austria; 3IMC University of Applied Sciences Krems, Institute of Tourism, Wine Business and Marketing, Krems an der Donau, Austria; 4Institute for Accounting, University of Bern, Bern, Switzerland; 5Medical University of Innsbruck/Innsbruck Kliniken GmbH, Department of Internal Medicine, Clinical Division of Internal Medicine II, Innsbruck, Austria

Background: While more than 50% of medical students and residents are women, their proportion drastically diminishes within higher ranks and leadership roles, a phenomenon also known as the "leaky pipeline".

Objectives: We aimed to evaluate the leaky pipeline among rheumatologists across Europe and to assess determinants inducing rheumatologists to leave hospitals.

Methods: Experts in the field of economics developed a questionnaire (50 thematic blocks, containing 172 single items) with relevance to the leaky pipeline. with scientific focus on the leaky pipeline among rheumatologists, which was distributed electronically by national scientific societies of EULAR countries and by individual contacts. We performed common factor analysis, univariate t-tests and multivariate regression analyses to appraise our dataset using Stata Version 17 (StataCorp, Texas, USA).

Results: 311 hospital-based rheumatologists from 23/45 EULAR countries (52.7% females, 47.3% males) responded to the questionnaire. The phenomenon of the leaky pipeline was present for the entire sample. Of 64% female rheumatologists only 34.2% departments' directors were female, with noteworthy regional differences (Table 1). Female doctors reported higher intentions to leave their hospitals (β = 0.28, p < 0.05) and lower commitment towards their current organization (β = -0.34, p < 0.05) when compared to males. Additionally, women reported lower levels of job satisfaction (β = -0.26, p < 0.10), promotion justice (β = -0.55, p < 0.01), and career perspectives (β = -0.15, p < 0.10, one-tailed) than men, explaining their lower organizational commitment.

Conclusion: Female rheumatologists perceive worse job opportunities and satisfaction than males. Many reasons for the leaky pipeline are beyond the control of organizations. By our results, organizations should be encouraged to reconsider and adjust their performance management practices enabling an equitable work environment.

Table 1. Leaky pipeline among rheumatologists working in hospitals across Europe

Overall Sample (n = 311)

| Percentage of female doctors in department | 64.0% |
| Percentage of female doctors employed as senior physicians in department | 49.2% |
| Percentage of female department heads | 31.8% |

Germany/Austria/Switzerland (n = 91)

| Percentage of female doctors in department | 51.0% |
| Percentage of female doctors employed as senior physicians in department | 42.2% |
| Percentage of female department heads | 7.7% |

Northern European Countries (n = 19)

| Percentage of female doctors in department | 56.4% |
| Percentage of female doctors employed as senior physicians in department | 50.5% |
| Percentage of female department heads | 47.4% |

Southern European Countries (n = 58)

| Percentage of female doctors in department | 62.9% |
| Percentage of female doctors employed as senior physicians in department | 36.4% |
| Percentage of female department heads | 24.1% |

Eastern European Countries (n = 133)

| Percentage of female doctors in department | 73.4% |
| Percentage of female doctors employed as senior physicians in department | 57.0% |
| Percentage of female department heads | 45.9% |

POS0562

FREQUENCY OF IN-PERSON AND VIRTUAL VISITS FOR RHEUMATOID ARTHRITIS: ANALYSIS OF THREE YEARS OF VISIT DATA BEFORE AND AFTER THE COVID PANDEMIC

Keywords: COVID, Telemedicine, Rheumatoid arthritis

D. Solomon1, M. Jiang2, L. Santacroce3, R. Rudin3, 1 Brigham and Women's Hospital, Harvard Medical School, Rheumatology, Boston, MA, United States of America; 2 Michael G. DeGroote School of Medicine, McMaster University, Faculty of Medicine, Windsor, Canada

Background: Few data have been published regarding appropriate visit frequency in rheumatoid arthritis (RA). While guidelines suggest more frequent visits early in disease and when disease is active, there are few descriptions of visit frequency. Also, visit frequency may have changed during the COVID pandemic.

Objectives: We examined visit frequency and types of visits (in-person versus virtual) for patients with RA seen at one US academic medical center during the 18 months before COVID lockdown, 3 months of lockdown, and 18 months after.

Methods: We extracted data from 11 clinically focused rheumatologists' practices at an academic medical center and created a sample of 257 patients with rheumatologist-diagnosed RA. The study period of interest encompassed the 18 months prior to COVID pandemic (Nov 2018 – Feb 2020), the 3 months of COVID lockdown (rheumatology clinic closed except emergencies, March – May 2020), and the 18 months after lockdown (June 2020 – Sept 2021); patients were required to have ≥1 visit prior and ≥1 visit after the lockdown to be included. We estimated: 1) monthly volume of in-person and virtual visits (telephone-only or video) for the RA study cohort, and 2) annual median patient visit frequencies. In addition, we assessed predictors of a patient's visit volume using multivariable linear regression over the pre- and post-lockdown periods. Variables tested included RA disease characteristics (CRP, serologic status, and DMARD use), patient demographics and comorbid conditions, and rheumatologist. RESULTS: Patient characteristics are shown in the Table 1. Patients' median age was 58y, 84% were female; 82% used any DMARD; 20% used only csDMARDS; and 61.5% used a txDMARD. Visit volume over 39 months is illustrated by visit type in the Figure 1. In the 18 months prior to the COVID pandemic, median annual visit frequency per patient was 2.7 (IQR 2.0, 3.3), with an overall median monthly visit volume of 61 (IQR 51, 58). Overall visit volume remained consistent post-lockdown: median annual visit frequency per patient 2.7 (IQR 2.0, 3.3), with an overall median monthly visit volume of 68 (50, 73). As expected, median monthly visit volume was reduced during the lockdown period: 58 (IQR 51, 65), but it rebounded to pre-pandemic levels within 9 months. During the first 3 months post-lockdown, virtual visits comprised 61% of all visits (51% video, 49% in-person).

*leukemia or anti-CCP antibody
10% telephone only). By the 12th month post-lockdown, virtual visits comprised 11% of all visits; all were video. The following variables associated with increased patient visit volume during the pre- and post-lockdown periods (36 months): older and fewer comorbidities. When specific rheumatologists were added as fixed effects, these variables strengthened in their significance; additionally, several rheumatologists were associated with significant increases in visit volume.

**Conclusion:** The COVID pandemic caused a disruption in rheumatology practice with a rapid substitution of virtual visits. Office visit volume for RA rebounded relatively quickly in one US-based academic practice. Virtual visits were common during and immediately after lockdown but became less common over time. Several variables, unrelated to RA, were associated with visit volume.

**POS0563 USE OF A DIGITAL SOLUTION TO MONITOR CHRONIC INFLAMMATORY RHEUMATOID MUSCULOSKELETAL DISEASES: FINAL RESULTS OF THE DIGIREUMA STUDY**

**Keywords:** Outcome measures, Self-management, Health services research

**D. Benavent**, L. Fernández-Luque, M. Sanz, V. Navarro-Compañ, M. Novella-Navarro, I. Billos, E. Calvo-Aranda, L. Loj, A. Balsa, C. Plasencia, Hospital La Paz-IdiPaz, Department of Rheumatology, Madrid, Spain; Adhera Health Inc, Palo Alto, United States of America; Hospital Infanta Leonor, Department of Rheumatology, Madrid, Spain

**Background:** Patients with rheumatoid and musculoskeletal diseases (RMDs) require a tailored follow-up, which may be limited by the healthcare resources. Innovative tools that save time need to be implemented effectively in the clinical care of patients with RMDs.

**Objectives:** To test the feasibility of a digital solution for real-time monitoring of electronic patient reported outcomes (ePROs) in patients with rheumatoid arthritis (RA) and spondylarthritides (SpA).

**Methods:** Digireuma was a bicentric 6-month prospective including patients with RA and SpA, using a digital solution, namely Adhera Rheumatology Digital Program. During follow-up, patients had a hybrid follow-up: face-to-face -baseline and 6 months visits and digital. In the digital follow-up, patients were asked to report disease specific ePROs on a pre-established basis in the mobile solution- including at least one assessment per week. In addition, flares and incidences with medication were available to be reported at any time. Four rheumatologists monitored these outcomes, and contacted patients when deemed necessary (Figure 1). Assessment measures included patient global assessment (PGA) of disease activity, (self-reported) tender joint count (TJC) and swollen joint count (SJC), Health Assessment Questionnaire (HAQ) and pain visual analogue scale (VAS), for patients with RA; PGA, TJC, SJC, BASDAI, and ASAS-Health Index, for patients with SpA. All measures were delivered every two weeks. Engagement at 3 and 6 months was assessed.

**Results:** Out of 56 recruited patients, 51 (24/27 (89%) RA, 27/29 (93%) SpA) downloaded and used the mobile solution and 47 (84%) submitted at least one ePROs entry. Median age (IQr) was 47 (13.2) and 40 (16.0) years in the RA and SpA groups, respectively. 20/27 (74%) patients with RA and 14/29 (48%) with SpA were female. In the RA group there were a total of 2156 digital solution accesses (57 per patient) in 6 months, while patients with SpA had a total of 1644 accesses (29 per patient). ePROs measurements outcomes at baseline and 6 months are shown in Table 1. Patients with RA completed a median of 6710 ePROs interactions during follow-up, whereas patients with SpA completed a median of 4315. Regarding alerts, among a total of 52 notifications, 47 were deemed necessary to be contacted (5 cases were assessed directly in a programmed consultation, due to time-proximity). Among all alerts, 45 were flares (31 RA, 14 SpA) and 4 problems with the medication (3 causes were not registered). Of the 47 cases that were contacted, 36 (77%) were managed remotely, 9 (19%) required a face-to-face intervention and in 2 (4%) cases it was not possible to reach patients before consultation. Regarding engagement, at three months 26 patients (55%) -15 with RA and 11 with SpA- continued submitting data periodically, while at six months 22 patients (47%) -13 with RA and 9 with SpA- continued submitting any data.

**Conclusion:** This study shows that ePROs can be used to monitor disease activity, flares, and medication issues in patients with RA and SpA, with three out of four alerts being managed remotely. After six months, more than half of the patients showed non-adherence to the monitoring plan/digital solution. The participation of both healthcare professionals and patients is critical for the successful implementation of mobile health in clinical practice, specially to identify long term usage strategies.

**Figure 1. Digital monitoring in the study**
Results: biosimilar etanercept and infliximab utilization and spending before and after the Biosimilars Initiative policy began (October 2012) to switch to the biosimilar version in order to maintain coverage. Between May and Nov 2019, or adalimumab (implemented between April and October 2012) which required people starting a biologic to use a biosimilar. Large commercial insurers who provide supplementary drug coverage also introduced biosimilar policies in order to switch to the biosimilar version. Mandatory switching was extended to include adalimumab. The Biosimilars Initiative extended a previous policy which required people starting a biologic to use a biosimilar. Large commercial insurers who provide supplementary drug coverage also introduced biosimilar policies in line with the BC provincial government. Under both biosimilar switching policies, exceptional coverage to reference products was allowed if medically needed.

Objectives: To quantify the impact of the Biosimilars Initiative and the initial policy requiring new initiators to use a biosimilar on uptake and spending on biosimilar infliximab, etanercept, and adalimumab in British Columbia.

Methods: Administrative claims data in BC from January 2013 through March 2023 were analyzed using interrupted time series analysis, a quasi-experimental study design commonly used to evaluate policy changes. Two policy interventions were evaluated: (1) new starts, whereby individuals initiating infliximab, etanercept, or adalimumab for the first time were required to use the biosimilar (implemented between Feb 2016 and July 2017), and (2) mandatory switching, which required those already receiving infliximab or etanercept (implemented between May and Nov 2019), or adalimumab (implemented between April and October 2012) to switch to the biosimilar version in order to maintain coverage. A segmented linear regression was used to model the level and trend change in spending on biosimilar infliximab, etanercept, and adalimumab in British Columbia.

Results: We identified 208,964 BC residents ≥18 years who qualified for public drug coverage, were treated with etanercept or infliximab, and were eligible for analysis between January 2013 and November 2020. After the new start policy, we detected a small gradual increase in the proportion of biosimilar etanercept prescriptions dispensed of 0.65% (95%CI 0.44, 0.85) per month. The monthly trend related to the proportion of total spending on biosimilar etanercept also increased (0.51, 95%CI 0.28, 0.73). After the mandatory switching policy (the Biosimilars Initiative), there was a sustained increase in the proportion of biosimilar etanercept and infliximab prescriptions dispensed of 76.78% (95%CI 75.56, 78.41) and 58.43% (95%CI 52.11, 64.75), respectively. Similarly, there was a persistent increase in spending on biosimilar etanercept and infliximab of 78.22% (95%CI 76.65, 79.79) and 71.23% (95%CI 66.82, 75.65), respectively. Similar results were seen for adalimumab which was switched later.

Conclusion: Our study found new start policies resulted in small, gradual increases in biosimilar utilization. However, the mandatory switch policy, the Biosimilars Initiative, resulted in a marked immediate and sustained impact on uptake. Further analysis will examine changes in other health utilization, and long-term impact on prescribing patterns. These findings may be particularly relevant to areas with a more concentrated insurance system where mandatory switching policies could lead to greater savings.

POS0565 TOLERABILITY AND SAFETY OF RECOMBINANT ZOSTER VACCINE IN PATIENTS WITH INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES - A PROSPECTIVE LONGITUDINAL STUDY OVER 6 MONTHS

Keywords: Safety; Vaccination/Immunization; Infection-related RMDs

I. Andreica1, S. Reale1, G. Intini1, B. Wilde1, P. Sewerin1, H. Kavruk1, D. Karagiakidou1, B. Guminski1, A. Kribben2, B. Baraliakos1, J. Braun1, U. Klitz1, Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; 1Universitätsklinikum Essen, Nephrology, Essen, Germany

Background: Herpes zoster (HZ) is common in the elderly with a lifetime risk of 25% (1). The primary risk factors for HZ are advanced age and immunosuppression. The recombinant zoster vaccine (RZV) contains recombinant glycoprotein E, the main target of CD4+ T-cell immune response. These findings are reassuring for rheumatologists and potential vaccine recipients and support confidence in RZV safety in patients with RMD.

Methods: Adult patients with rheumatoid arthritis (RA), axial spondyloarthritides (axSpA) and giant cell arteritis (GCA) who had an indication to receive RZV were prospectively included. Data on demographics, vaccination, RMD diagnosis, disease activity, immunosuppressive treatments, flares, adverse events (AEs) and zoster breakthrough infections were collected at months 0, 2, 3 and 6. A flare was defined as change in ASDAS ≥ 0.9 for axSpA, change in DAS-28>1.2 for RA, or clinical signs for GCA and/or CRP ≥ 0.5 mg/dl and/or ≤30 mm. Descriptive analyses were performed.

Results: 50 patients were included of whom 18 (36.0%) had a history of HZ (Table 1). All patients received RZV at month 0, and 49 patients also at month 2. Safety assessments were performed in 49, 48 and 36 patients in months 2, 3 and 6, respectively. A total of 62, 35, 11 AE in 38, 33, and 10 patients, respectively, were reported (Figure 1). Localized AE (n=69 (63.9%)) were far more common than generalized AE (n=28 (25.9%)). Pain at the site of injection in 46 (42.6%) patients was the most frequent AE followed by fatigue (12 (11.0%)), redness at the injection site in 9 (8.3%), swelling at the injection site (7 (6.4%)) and fever (5 (4.6%)). Serious AEs were reported in 6 patients (2 RA, 4 GCA). None of them with causal relation to RZV. No patient reported an AE of special interest. Out of 6, 4 and 4 flares reported by patients at month 2, 3 and 6, respectively, one fulfilled predefined flare criteria and were rated as mild to moderate. However, 3 patients (2 GCA, 1 RA) were hospitalized due to flares. No episodes of HZ occurred.

Conclusion: The majority of patients tolerated RZV well with only a few reports of flare and serious AEs. Majority of AEs occurred within few days after vaccination. These findings are reassuring for rheumatologists and potential vaccine recipients and support confidence in RZV safety in patients with RMD.

Funding: The study was funded by GSK.

POS0566 SURVIVAL ON TREATMENT AFTER SWITCHING TO A BIOSIMILAR: POPULATION-BASED EVIDENCE FROM A NATURAL EXPERIMENT DUE TO A POLICY CHANGE

Keywords: Health services research, bDMARD, Inflammatory arthritis

D. Lacaille1,2, J. A. Aviña-Zubieta1,2, Y. Zheng1, N. Lu1, H. Xie1,3, Arthritis Research Canada, Arthrite-Recherche Canada, Vancouver, Canada; 1University of British Columbia, Department of Medicine, Vancouver, Canada; 2Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

Background: In the province of British Columbia (BC), Canada, a health policy implemented in July 2017 mandated that all new anti-TNF prescriptions for which a biosimilar exists, i.e., etanercept and infliximab at the time, be dispensed a biosimilar rather than the originator, for universal cost coverage by BC PharmaCare. In May-December 2019, a further policy mandated that current users of anti-TNF agents be switched to the corresponding biosimilar during the period of May to December 2019. Historical controls were randomly selected from all new users of originator etanercept and infliximab before July 2017, matched to biosimilar switchers on sex, previous number of biologics used, and disease. Controls were assigned an index date such that duration of originator anti-TNF therapy was the same at switching/index date for switchers and controls. Outcomes: Discontinuation was defined as no prescription renewal for at least 6 months. Statistical method: We followed patients from switching/index date to discontinuation, or for two years or until last health care utilization (if moving out-of-province), or end date of the follow-up (April 30, 2019 for originators, and December 31, 2021 for switchers), whichever occurred first. Weighted Cox proportional hazards models with propensity score overlap weighting estimated the HR of discontinuing anti-TNF agents for controls and switchers, adjusting for duration of anti-TNF agent use at switch/index date, age, sex, socio-economic status (low income subsidy), rural vs urban residence, health authority, arthritis type, number of prior biologic agents, comorbidities, and other IA drugs used (MTX, non MTX DMARDs and glucocorticosteroids), all measured at time of switching/index date.

Results: A total of 1631 biosimilar switchers (1402 etanercept; 229 infliximab) were included in this study: 556(67.2%) RA, 178(21.5%) PsA, 93(11.2%) Ps/SpA patients. Table 1 shows numbers, rates (per 100 person-years), and hazard ratio of discontinuation among biosimilar switchers compared with originator users. Figure 1 shows survival on treatment. The discontinuation rates for the biosimilar etanercept users was similar to the originator users (15.42 vs 15.63) per 100 PYs: HR (95% CI) 1.02 (0.87, 1.19 [p=0.718]). The biosimilar infliximab switchers had a slightly lower discontinuation rate than the originator users, however the difference in rate and risk of discontinuation were not statistically significant (8.76 vs 11.29) per 100 PYs: HR (95% CI) 0.85 (0.54, 1.36 [p=0.503]).

Conclusion: Population-based data on real-world experience mandating switching from originator to biosimilar etanercept and infliximab for IA revealed the biosimilar switchers have comparable duration of treatment to the original medications.

**COMPARISON OF SURVIVAL ON TREATMENT AMONG NEW USERS OF BIOSIMILAR VS. ORIGINATOR BIOLOGICS IN INFLAMMATORY ARTHRITIS: POPULATION-BASED EVIDENCE FROM A NATURAL EXPERIMENT DUE TO A POLICY CHANGE**

**Keywords:** Health services research, bDMARD, Inflammatory arthritis

D. Lacaille1,2, J. A. Avina-Zubieta1,2, Y. Zheng1, N. Lu1, H. Xie1,3, J. Arthritis Research Canada, Arthritis-Recherche Canada, Vancouver, Canada; 2University of British Columbia, Department of Medicine, Vancouver, Canada; 3Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

**Background:** British Columbia (BC) health policy mandated the use of biosimilars when available, for all new anti-TNF prescriptions after June 2017.

**Objectives:** To compare drug survival (surrogate marker of effectiveness and safety) after initiation of etanercept and infliximab for inflammatory arthritis in new users of biosimilars vs. originators, using historical controls pre-policy change.

**Methods:** Using administrative health data, we identified all incident users of a new anti-TNF with rheumatoid arthritis (RA), psoriasis or psoriatic arthritis (PsO/PsA), or ankylosing spondylitis (AS). The biosimilar cohort started etanercept or infliximab for inflammatory arthritis new users of biosimilar etanercept and infliximab for inflammatory arthritis have comparable safety) after initiation of etanercept and infliximab for inflammatory arthritis in new users of biosimilars vs. originators, using historical controls pre-policy change.

**Results:** Our sample included 827 biosimilar etanercept users (RA:576, AS:171, PsO/PsA:180) and 271 infliximab users (RA:150, AS:54, PsO/PsA:67); 1312 etanercept and 230 infliximab originator users; and 2213 adalimumab originator users.

**Conclusion:** Real-world population-based data in BC shows that incident users of biosimilar etanercept and infliximab for inflammatory arthritis have comparable duration of treatment to users of originators.

**THE RATIO BETWEEN BIOLOGICAL AND GLUCOCORTICOID USE IN VARIOUS COUNTRIES: WORLDWIDE: RESULTS FROM THE METEOR REGISTRY**

**Keywords:** Rheumatoid arthritis, Worldwide evidence, Geographical differences

I. Neving1, C. Allaart1, D. Vega-Morales2, L. L. Winchow3, A. Chopra4, A. M. Rodrigues5, T. Huizinga1, M. Boers6, S. A. Bergstra1, 1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Hospital General de Zona 17 Instituto Mexicano del Seguro Social, Rheumatology, Monterrey,
Background: A study in the QUEST-RA database, based on rheumatoid arthritis (RA) patients included between January 2005 and June 2006, has shown that the ratio between biological disease modifying antirheumatic drug (bDMARD) use and glucocorticoid (GC) use strongly differs between countries. Considering the difference in affordability between bDMARDs and GCs, it may be hypothesized, that when less bDMARDs are used, glucocorticoid use increases.

Objectives: To investigate globally, in more recent data, the ratio between bDMARD and GC use, and to assess whether this relates to a country’s socioeconomic status (SES).

Methods: Data on bDMARD and GC use between 1-1-2007 and 28-12-2020 were extracted from the METEOR registry: an international database capturing daily clinical practice data from patients with a clinical diagnosis of RA. The ratio between the proportion of patients who had ever used a bDMARD and the proportion of patients who had ever used a GC, with no concomitant bDMARD use, during a total follow up duration of two years (bDMARD/GC ratio) was calculated per country. Univariable linear regression was used to analyze the bDMARD/GC ratios according to publicly available country-level indicators of SES (Worldbank, OECD).

Results: Data from 10,856 patients covering eight countries showed varying proportions of bDMARD use. The number of patients included ranged from 64 (Spain) to 8484 (India). Baseline characteristics varied per country. In this analysis based on a worldwide cohort capturing 8 countries, we show that the bDMARD/GC ratio differs across countries. These differences are significantly related to general country-level indicators of level of wealth, where greater wealth went with a higher proportion of patients using bDMARDs and/or a smaller proportion of patients using GCs.

Conclusions: In this analysis, the bDMARD/GC ratio differs across countries. These differences are significantly related to general country-level indicators of level of wealth, where greater wealth went with a higher proportion of patients using bDMARDs and/or a smaller proportion of patients using GCs.

POSO570 IMPACT OF CLINICIAN-RELATED FACTORS ON PHONE CONSULTATIONS IN RHEUMATOLOGY – ANALYSIS OF MEDICAL VS NON-MEDICAL CLINICIANS’ OUTCOMES FROM A COVID-19 INITIATIVE

Keywords: Telemedicine, COVID, Health services research

M. Hannides1, S. Wig1, S. Vasireddy1. 1Bolton NHS Foundation Trust, Rheumatology, Bolton, United Kingdom

Background: Since COVID-19 pandemic, there have been changes in clinical practice to limit transmission, such as switching to remote consultations. Our department switched to delivering remote consultations during lockdown without suspending service. Patients were offered choice of either video or phone consultation. It is unclear if the medical vs non-medical status of clinicians has any influence on remote consultations.

Objectives: We aimed to study the influence of medical vs non-medical status of clinicians on phone consultations in our experience during the pandemic.

Methods: Between 15/10/2020 and 09/11/2020, 12 clinicians in our service completed data collection forms after each remote consultation, recording the technology used (video vs phone); technical problems encountered; discharge and subsequent appointment status; and technical aspects of the consultation itself; using 11-point numerical rating scales (NRS) (Time Adequate; Relevant History; Physical Exam; Management Plan; Communication Quality). Data were analysed in SPSS version 25 using chi-square tests and Mann-Whitney U tests for comparisons..

Results: Six medical clinicians (3 consultant rheumatologists, 2 Specialty Trainee Registrars and 1 Foundation Year 2 doctor) and six non-medical clinicians (3 Specialist Nurses, 1 Advanced Rheumatology Practitioner and 2 Senior Rheumatology Pharmacists) completed 285 forms. As non-medical clinicians didn’t do new patient consultations, and as some clinicians did not do video consultations, these consultations were excluded. The remaining were follow-up patient phone consultations (n=196). Medical vs non-medical clinician appointments were 34.7% (n= 68), vs 65.3% (n=128). Medical and non-medical clinicians had a similar proportion of female patients (72.1%, n=49 vs 63.9%, n=81; p=0.22); similar mean age of their patients (63 vs 62 years; p=0.33); similar rates of technical problems reported (13.1%, n=8 vs 16.4%, n=19; p=0.57); and similar mean age of their patients (63 vs 62 years; p=0.53); similar rates of technical problems and interpreter use. While there was a non-significant trend for lower scores on Physical Exam NRS for medical clinicians, both mean scores were low reflecting the difficulty of this assessment in a phone consultation. Medical clinicians rated their consultations significantly lower in four of the NRS, potentially reflecting the complexity of medical problems of patients booked into medical clinicians’ clinics compared to potentially patients with more stable disease in non-medical clinicians’ clinics. Similarly, the lower discharge rate from non-medical clinicians’ clinics could reflect a higher proportion of patients on established disease needing long-term follow-up. Further studies with larger numbers would help clarify these issues.

POSO572 IMMUNOGENICITY AND SAFETY OF ADJUVANTED RECOMBINANT ZOSTER VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

Keywords: Vaccination/immunization, Adaptive immunity, Rheumatoid arthritis

S. Koijma1, T. Iwamoto1, Y. Kobayashi2, M. Kato3, F. Takizawa1, T. Ida1, Y. Toda1, K. Miyachi1, J. Suzuki1, A. Iwata1, S. Furuta1, K. Ikeda1, K. Suzuki1, H. Nakajima4,4, Chiba University, Development, Chiba, Japan

Background: Herpes zoster (HZ) is caused by the reactivation of latent varicella-zoster virus (VZV) due to a decline in VZV-specific cell-mediated immunity (CCI) with increasing age and immunocompromised conditions [1]. Patients with rheumatoid arthritis (RA) treated with disease-modifying anti-rheumatic drugs (DMARDs) are at a high risk of developing HZ [2, 3]. An adjuvanted recombinant VZV glycoprotein E (gE) subunit vaccine (RZV) has been shown to be effective in preventing HZ in immunocompromised elderly populations. However, its efficacy and safety profile remain largely unknown in RA patients.

Objectives: This study aimed to determine the immunogenicity and safety of RZV in patients with RA treated with DMARDs.

Methods: This longitudinal prospective study enrolled 53 RA patients treated with DMARDs (csDMARDs, n=20; bDMARDs, n=23; and bDMARDs, n=10) and 10 individuals with no history of immunosuppressive treatment as controls. All the participants were aged ≥50 years. The participants received two intramuscular RZV injections 2 months apart. VZV-specific CMI and humoral immunity (HI)

POSO571 ASSOCIATION BETWEEN DIAGNOSIS DELAY AND DISEASE ACTIVITY WITH BURDEN OF THE DISEASE IN 4150 EUROPEAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Quality of life

A. Cornet1, J. Andersen2, F. Marchio2, A. Sturiene3, A. Edwards4, P. Mertz2, L. Arnaud2, 1Lupus Europe, HQ, Brussels, Belgium; 2Lupus Europe, PAN, Brussels, Belgium; 3Hôpital de Hautepierre - Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Strasbourg, France

Background: Despite significant improvements in diagnosis delay and treatment strategies, the burden of Systemic Lupus Erythematosus (SLE) remains high.

Objectives: The objective of the study was to assess the association between diagnosis delay, disease activity and burden of life (BoDL) in a large sample of European patients with SLE.

Methods: In May 2020, Lupus Europe, the European umbrella patient association for SLE, conducted a multilingual anonymous online cross-sectional study to individuals with a self-reported physician’s diagnosis of SLE living in Europe. The BoDL score was computed using 1 to 5 Likert scales on 5 domains (mobilization, daily activities, self-care, daily activities and pain/discomfort) and the sum was transposed on a 0 (minimum Burden on daily life) to 100 (maximum BoDL) scale. Comparisons between independent groups were made using the Mann-Whitney test for continuous outcomes and the Chi-2 test (or Fisher’s exact test) for quantitative data.

Results: Data of 4,150 SLE patients from 35 European countries were analysed. The means (±SD) BoDL score in the study population was 37.8 (±18.7). Despite the modest downward trend of the BoDL based on age (from 33.4% to 42.1% from age less than 25 to 65 - a loss of up to 9% points over up to 40 years). The diagnosis delay was reported to be <2 years in 1903 participants (47.5%), between 2 and <5 years in 1056 (26.3%) and ≥5 years or more in 1049 (26.2%). 142 did not answer.. Those with a diagnosis of SLE within 2 years of first symp- toms had significantly lower mean Burden on daily life scores than those diag- nosed after 5 years (33.6 versus 44.0, p<0.001). This trend is deemed robust as it was found across almost all European countries. These results highlight the importance of improving current diagnosis delay for SLE as a way to improve the burden of the disease on daily life. A total of 2980 (71.8%) patients felt that their lupus has been under control over the last 3 months while 1166 (28.1%) did not. 4 did not answer.. The Burden on daily life score was significantly better in SLE patients feeling that their lupus had been under control during the past 3 months versus the others (34.0% versus 47.6%, p=0.001). Again, this trend was found across almost all European countries.

Conclusion: This large patient survey reveals both the importance of prompt SLE diagnosis as well the relationship between disease activity and disease bur- den upon the daily life of European lupus patients. Further improvements should focus on reducing the diagnosis delay and identifying new therapeutic strategies for those with uncontrolled disease. Healthcare pathways, which may accelerate diagnosis and optimize therapeutic management, are necessary to improve patients’ outcomes in SLE.

DOI: 10.1136/annrheumdis-2023-eular.1250
were assessed at 0 and 3 months after the first vaccination using flow cytometry and enzyme immunosay. To assess CMI, the frequencies of VZV gE-specific CD4+ CD40L+ T cells expressing at least one activation cytokine (CD4[2+] cells); IFN-γ, IL-2, and TNF-α were examined by flow cytometry. CMI responders were defined as a CD4[2+] T cell frequency ≥320 per 10^6 CD4+ T cells counted (for participants with pre-vaccination frequencies below 320 per 10^6 CD4+ T cells counted) or a ≥2-fold increase in CD4[2+] T cells (for those CD4[2+] T cells were already ≥320 per 10^6 CD4+ T cells counted at the time of pre-vaccination). CMI and HI response rates were compared between all patients with RA (n=53) and controls (n=10). The participants were followed up for 6 months after the first RZV administration for HZ onset. Baseline characteristics and information regarding adverse events were collected.

**Results:** Patients' age and disease duration were 70 years old and 11 years, respectively. DAS28-CRP and CDAI scores at enrolment were 1.4 and 2.1, respectively. Thirty-six percent of RA patients had a history of HZ before the administration of RZV. VZV-specific CMI (controls: p=0.002, csDMARDs: p=0.012, bDMARDs: p=0.001, and tsDMARDs: p=0.002) (Figure 1A) and HI (controls: p=0.002, csDMARDs: p=0.001, tsDMARDs: p=0.001) were significantly increased in DMARDs-treated RA patients after RZV administration, and the magnitudes of those responses were not significantly different between DMARDs-treated RA patients and controls. However, the vaccine response rate of CMI of DMARDs-treated RA patients was significantly lower than that of the controls (51% vs. 90%, p=0.034) (Figure 1B), whereas the response rate of HI was not (66% vs. 70%, p>0.999). In addition, no significant baseline factors affecting CMI responses, including DMARDs use, were identified between RA patients with and without CMI responses. RZV-related adverse events were generally mild, and all participants received two doses of RZV. RZV-induced RA flares occurred in two patients (3.8%) but were also mild and controllable.

**Conclusion:** RZV is robustly immunogenic and has a clinically acceptable safety profile in elderly RA patients receiving DMARDs.

**DOI:** 10.1136/annrheumdis-2023-eular.1608
Background: Comorbidities have a profound impact on the QoL of patients living with autoimmune rheumatic diseases (AIRDs). Unfortunately, global data on the burden of comorbidities and its impact on health outcomes in this vulnerable group is scarce.

Objectives: We studied the prevalence, distribution and clustering of comorbidities and multimorbidity among patients with AIRDs and healthy controls (HCs) and its impact on health outcomes, utilizing data from the ongoing 2nd COVAD study.

Methods: The COVAD study is a global e-survey that embodies patient voice while empowering collaborators and young researchers. The study group of 157 physicians across 106 countries from February-June 2022 captured detailed features of AIRDs, autoimmune and non-autoimmune comorbidities, and validated patient reported outcomes. Human Development Index (UNDP 2021-22) of country of residence was taken as a surrogate marker for socioeconomic status (SES). Basic multimorbidity (BM), Complex multimorbidity (CM), Autoimmune multimorbidity (AM) are defined as the co-occurrence of ≥2 non-rheumatic comorbidities, ≥3 non-rheumatic chronic conditions affecting ≥3 different organ systems [1] and ≥3 autoimmune diseases (AIDs) in an individual respectively. PROMIS global physical health (PGP), mental health (PGM), fatigue 4a (F4a) and physical function short form (SF10) scores were calculated for the different groups and compared using descriptive statistics, linear regression and cluster analysis (hierarchical followed by K-means).

Results: Of 17,612 total respondents, 6149 (62.7%) had underlying AIRDs and 3652 (37.3%) were HCs, with female (80.8%) and Caucasian (53.9%) predominance in the former. All types of multimorbidity were more frequent in AIRDs than HCs, including any comorbidity (77.1% versus 25.0%; OR: 2.9; 2.7-3.2), BM (21.0% vs 6.2%; 4.0; 3.4-4.6), and CM (3.1% vs 0.5%; 6.4; 3.9-10.4), and with prevalence increasing with age (p<0.001) (Figure 1A, B). Comorbidity prevalence was the highest among Americans and Australians (72% each). Patients with AIRDs had poorer health outcomes than HCs, including lower PGP, PGM, SF10, F4a scores (all p<0.001). Among AIRDs, those with comorbidities had lower physical function and PROMIS scores (PGP, PGM, and SF10), and reported fatigue more often (all p<0.001). Female gender, and underlying BM and AM par-ticularly predisposed patients to worse physical health (lower PGP; lower SF10a) and mental health outcomes (lower PGM) While advanced age (-1.815; <0.001), and lower SES (0.871; 0.027) specifically predicted poorer physical function (lower SF10a). Fatigue (higher F4a) was seen more frequently among women (1.711; <0.001), and those with BM (1.142; 0.002); AM (1.768; 0.011), and higher SEC (0.478; 0.016). Cluster analysis of patients with AIRDs revealed 2 clusters (Figure 1C 1D); cluster 1 with low PGP, PGM, SF10 and high F4a. The clusters differed predominantly based on the frequency of comorbidities; any comorbidity (59.7% vs 41.8%; p<0.001), BM (28.5% vs 14.7%; 0.001); CM (4.5% vs 1.9%; <0.001), and AM (10.0% vs 4.0%;<0.001).

Conclusion: Comorbidities complicate three-quarters of individuals living with AIRDs, and have an outsized impact on self-reported physical function, perceived fatigue, and QoL. Substantial regional differences call for further exploration of key drivers of this important aspect to allow optimized multidisciplinary and holistic care in anticipation of poorer outcomes.

**POS0574 THE GREAT MASQUERADER OF RHEUMATOLOGICAL SYMPTOMS: A CASE REPORT**

**Keywords:** Imaging, Vasculitis, Cardiovascular disease

S. M. Chau1, V. Dhir1, 1PGIMER, Internal Medicine (Rheumatology), Chandigarh, India; 2PGIMER Chandigarh, Internal medicine (Rheumatology), Chandigarh, India

**Background:** Primary cardiac tumors are extremely rare, and out of those atrial myxoma is the most common benign tumor (75%). Around 75% of the atrial myxoma cases arise from left side of the heart and present differently from right sided. Due to its varied presentation in regard to constitutional, embolic and obstructive features it mimics vasculitis.

**Objectives:** To create awareness about the atrial myxoma, the great mimicker of vasculitis and comment upon its clinical course and complications if not treated timely.

**Methods:** Case report and Discussion.

**Results:** 34 year old female with no past medical history came to the Rheumatology Department after failure to be diagnosed. She had 8 months history of pain in her finger tips, toes, small joints and Raynauds phenomenon. Intermittent fever associated with chills, palpitations, sweating and significant weight loss was noted during the course of illness. Before visiting our clinic, she was treated for Typhoid fever but she didn’t respond. At presentation, her vitals and physical examination including auscultation was unrevealing. Her blood counts showed Hb at 8g/dL, metabolic panel, LFTs, coagulation profile were normal. But had high ESR levels in multiple reports ranging from 60-168mm/hour. CRP was also positive. Hypocomplementemia and increase in alpha-globulins were observed. ANA positive, dsDNA negative, APLA, P and C-ANCA and Cryoglobulins were also negative. PET-CT was negative for avid FDG uptake in any organ. Patient was given iron formulations intravenously and was advised to cardiology in view of significant palpitations which was not given much attention before. Echo showed 4.1x3.3cm, pedunculated mass arising from inter-atrial septum and anterior mitral leaflet (Figure 1). Patient was started on ecosprin and advised surgical intervention which got postponed due to patient having complications of acute limb ischemia and stroke in right fronto-parietal lobe (Figure 1) subsequently. She had multiple embolomecties of right brachial and bilateral femoral arteries, later followed by craniectomy and decompression from the hemorrhage with subsequent cranioplasty and at lastly removal of mass. The surgical pathological report of mass showed features characteristic of myxoma which concluded the diagnosis. After surgeries, the patient is doing much better. Her Hb levels have improved to 12g/dL and the ESR level came back to normal. Though there is residual weakness due to stroke but she has shown significant recovery in terms of modified Rankin scale of 3. No more systemic complaints like fever, fatigue, Raynauds phenomenon and digital pain are observed. In this case, duration from onset of symptoms to hospitalization for life threatening was complete one year with added 6 months to significant recovery from complications.

**Conclusion:** Myxoma, a rare intracardiac benign neoplasm due to release of inflammatory cytokines like IL-6 and embolic mechanism can present as inflammatory rheumatic disease. Diagnosing this great masquerader can be challenging even for a specialist but timely ordering of certain non-invasive tests could be life saving for the patient. For example in this case, Echocardiography or Cardiac MRI are critical. Therefore, having high diagnostic suspicion is very important when dealing with vasculitis and its mimics.

**POS0575**

**OSTEOMALACIA INDUCED BY HYPOPHOSPHATEMIA – ROLE OF FGF 23: TWO CLINICAL CASES REPORT**

**Keywords:** Osteoporosis, Education, Bone diseases

E. Costa¹, C. Campinho Ferreirinha, A. M. Gomes Correia², D. Esperança Almeida², P. Pereira², J. Silva², M. Cerqueira², J. Redondo Costa², A. R. Ribeiro², J. Neves². ¹Hospital de Braga, Rheumatology, Braga, Portugal; ²Hospital de Braga, Rheumatology, Braga, Portugal

**Background:** Osteomalacia is a bone disorder characterized by decreased bone mineralization. Vitamin D deficiency and hypophosphatemia are the most frequent causes. Fibroblast growth factor 23 (FGF23) is a hormone secreted by osteocytes in response to increased calcium and serum phosphate levels. FGF23 main function is phosphate serum levels regulation, decreasing sodium-phosphate cotransporter expression on the proximal convoluted tubule. Thus, FGF23 reduces calcium reabsorption and increases urine phosphate excretion. FGF23 may also suppress 1α-hydroxylase, reducing vitamin D activation and calcium reabsorption.

**Objectives:** To increase the awareness of hypophosphatemia-induced osteomalacia.

**Methods:** Case reports and discussion.

**Results:** Case 1 – A 63-year-old man, hospitalized for total hip arthroplasty secondary to non-traumatic bilateral femoral neck fracture was evaluated by rheumatology on suspicion of osteoporosis. Medical history was relevant for a progressive paraparesis of lower limbs 6 years ago and which etiological investigation revealed a mesenchymal tumor in the body of the ninth dorsal vertebrae compressing the spinal cord. A multidisciplinary discussion concluded that the tumor was unresectable, but the patient underwent decompressive surgery to relieve neurological symptoms one year later. The patient also reported a history of multiple non-traumatic fractures in the past five years, including ribs, ankle, pelvis, femoral neck, and scapula, and denied any arthritic or bone pain. In laboratory evaluation, serum phosphate levels were below the laboratory detection limit, calcium and vitamin D were decreased, parathormone (PTH) was in the normal range and serum alkaline phosphatase (AF) was increased. Serum FGF23 levels were 6 times above the upper limit of normal (ULN). Thus, the diagnosis of oncocenic osteomalacia induced by an FGF23-producing mesenchymal tumor was made. The patient started intravenous phosphate repositioning in the intermediate care unit and then he continued oral phosphate, calcium, and vitamin D supplementation at home. Currently, the patient is in the oncology outpatient clinic, and he was proposed to initiate treatment with burosumab (anti-FGF23 antibody). Case 2 – A 57-year-old woman with Rendu-Osler-Weber syndrome and iron deficiency anaemia, chronically supplemented with ferric carboxymaltose, was referred to the rheumatology outpatient clinic because of a right second metatarsal bone fracture associated with hypophosphatemia, vitamin D deficiency, AF and PTH elevation (above 3 times the ULN and 2 times the ULN, respectively), and normal calcium levels. Measurement of FGF23 serum levels revealed an elevation of 3 times the ULN. The diagnosis of FGF23-induced hypophosphatemia was made. The patient started oral phosphate and vitamin D supplementation and the formulation of intravenous iron was changed. Six months after the initial evaluation, the previously abnormal analytical values were within the normal range.

**Conclusion:** Osteomalacia has multiple identified causes like vitamin D deficiency, hypophosphatemia, chronic kidney disease, renal tubular acidosis, and hypophosphatasia. FGF23 is a hormone that regulates phosphate metabolism. There are several types of genetic and acquired FGF23-related hypophosphatemia, like X-linked hypophosphatemia and FGF23-producing mesenchymal tumors, respectively. In case 2, it is thought that the key mechanism responsible for the effect of iron results from the disproportionate inhibition of FGF23 degradation by the carbohydrates present in intravenous formulations with a consequent increase in its concentration and activity. The risk of hypophosphatemia and osteomalacia appears to be greater with iron carboxymaltose than with other intravenous iron formulations.

---

**Figure 1.** Top Left and Right, Echocardiography during systole and diastole demonstrating dynamic myxoma propulsion into the left atrium. Bottom Left to Right, CT angiography - multiple saccular aneurysm from distal cortical branches of bilateral cerebral arteries with large aneurysm in close relation to the right temporal hematoma, likely ruptured.NCTT head - Right frontal bleed LA - left atrium, UV - left ventricle, Myx - Myxoma

**Conclusion:** Myxoma, a rare intracardiac benign neoplasm due to release of inflammatory cytokines like IL-6 and embolic mechanism can present as inflammatory rheumatic disease. Diagnosing this great masquerader can be challenging even for a specialist but timely ordering of certain non-invasive tests could be life saving for the patient. For example in this case, Echocardiography or Cardiac MRI are critical. Therefore, having high diagnostic suspicion is very important when dealing with vasculitis and its mimics.

POS0676

ANTI-TIF1-γ POSITIVE DERMATOMYOSITIS WITH SEVERE OROPHARYNGEAL INVOLVEMENT AFTER IMMUNE CHECKPOINT INHIBITORS

Keywords: Myositis, Malignancy, Autoantibodies

A. Tonutti1, N. Luciano2, A. Ceribelli3, A. Sonaglia4, D. Renna5, A. Repici6, A. Lanía7, A. Lieo8, S. De Nicola9, L. Bussini7, P. Morelli7, M. Pagani10, C. Selmi11, M. De Santis12, IRCCS Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital and Humanitas University, Gastroenterology and Digestive Endoscopy, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital and Humanitas University, Endocrinology, Diabetology and Medical Andrology, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital and Humanitas University, Liver Unit, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital, Liver Unit, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital, Infectious Diseases, Rozzano, Milan, Italy; IRCCS Humanitas Research Hospital, Neurocenter-Neurorehabilitation Unit, Rozzano, Milan, Italy

Background: Anti-TIF1-γ antibody is specifically associated with paraneoplastic dermatomyositis (DM) [1], but this serum marker has seldom been reported in DM associated with malignancy, and severe infections is of paramount importance when choosing the most appropriate therapy. Patients with anti-TIF1-γ DM following immunotherapy have been described and successfully treated using glucocorticoids and intravenous immunoglobulin (IVIG) [3].

Objectives: We report the case of a man developing anti-TIF1-γ positive DM following immunotherapy with progressively worsening dysphagia refractory to glucocorticoids, immunosuppressants, and IVIG.

Methods: Case report.

Results: In February 2021 a 47-year-old man was diagnosed with skin mela-noma that was surgically resected and treated with adjuvant lilmumab and nivolumab, leading to complete remission. After three months, he developed muscle weakness, with dysphonia, dysphagia, and typical DM skin lesions (Figure 1) with pancytopenia (hemoglobin 9 g/dL, white blood cells 1500/mm3). Four weeks after the start of nivolumab, leading to complete remission. After three months, he developed muscle weakness, with dysphonia, dysphagia, and typical DM skin lesions (Figure 1) with pancytopenia (hemoglobin 9 g/dL, white blood cells 1500/mm3). Further oncological evaluation (total body CT scan, brain MRI) was negative for the recurrence of malignancy or the presence of myasthenia gravis and neuropathy. Methylprednisolone pulses (500 mg for 3 days) were started, followed by high dose IVIG (5 g/kg), with marginal improvement on muscle function, normalization of CK levels, but no effect on dysphagia which worsened. Then, MMF was restarted but rapidly stopped because of septic shock requiring intensive care unit admission, followed by recurrent symptoms, contradicting further immunosuppression. Six months later, high-dose IVIG infusions were continued [4] with minimal effect. Worsening tetra-paresis, absolute dysphagia, impaired cough, and inability to manage salivary secretions led to massive aspiration pneumonia. The man developed acute respiratory insufficiency, septic shock, and multiorgan failure, and died 13 months after the onset of DM.

Conclusion: Worsening myopathy, typical skin lesions, and concomitant immune-related adverse events should raise suspicion of DM in patients receiving immune checkpoint inhibitors [3]. Balancing the risks of DM disease flare, malignancy, and severe infections is of paramount importance when choosing the most appropriate therapy. Patients with anti-TIF1-γ DM following immunotherapy may also manifest tetra-paresis, dysphagia, and severe pancytopeny.

POS0577-PARE

EVALUATION OF PATIENT SATISFACTION WITH REMOTE SELF-INJECTION TRAINING: A SINGLE-CENTRE PATIENT-REPORTED SURVEY

Keywords: Inflammatory arthritides, Patient reported outcomes, Patient information and education

S. McCourt1, M. Andiappan2, Southen Health and Social Care Trust, Rheumatology, Craigavon, United Kingdom; 2Open Health, Real World Evidence, Marlow, United Kingdom

Background: Subcutaneous self-injection of methotrexate (SC MTX) is used for the treatment of several inflammatory diseases. All newly initiated patients should be educated and trained in the proper injection technique by their healthcare provider (HCP), with the first injection performed under medical supervision. This training has typically been conducted during face-to-face consultations, however, since the start of the COVID-19 pandemic it has been necessary to conduct training remotely due to the cancellation of clinics.

Objectives: To understand patient-reported experiences and satisfaction with remote SC MTX self-injection training.

Methods: A cross-sectional electronic survey was administered between 11 October 2022 and 30 November 2022 to patients at Southern Health and Social Care Trust who had recently been trained via telephone or video conference (VC) on how to self-inject methotrexate using a pre-filled, auto-injector pen. Patients were aged ≥18 with a range of arthritis types, including rheumatoid, psoriatic, polyarticular juvenile idiopathic and chronic reactive inflammatory arthritis. Remote training was delivered by the patient’s nurse as per routine practice (independently of this survey). Patients were sent a patient information pack (PIP) prior to the training consultation. During the training, the nurse discussed the process of injecting with the auto-injector pen before virtually supervising the first injection. The survey consisted of 14 questions; topics included experiences and satisfaction with preparation for the HCP appointment, the training consultation itself and post-training experiences and preferences. The responses were analysed descriptively on an item-by-item basis.

Results: In total 73 patients completed the survey; 77% (n=56/73) were female, and 96% (n=70/73) had no prior experience with a SC MTX auto-injector pen. The training was completed by telephone for 92% (n=67/73) of patients and by VC for 8% (n=6/73). 99% (n=72/73) received a PIP in advance of their training consultation and 92% (n=67/73) received this by post. 67% (n=49/73) of patients...
strongly agreed and 26% (n=19/73) agreed that they felt prepared for the training after receiving the PIP, 78% (n=57/73) of patients strongly agreed and 22% (n=16/73) agreed that it was easy to read and understand, whilst 52% (n=38/73) strongly agreed and 48% (n=36/73) agreed that the PIP was helpful and did not require additional instructions before the appointment. 84% (n=61/73) took 15 minutes or less to complete the training with their HCP. None of the participants felt confused or did not understand the training instructions from their HCP, 78% (n=57/73) strongly agreed and 19% (n=14/73) agreed that the remote training was helpful and made them feel more confident to use the injector pen on their own and 97% (n=71/73) did not need to contact and HCP for continuing training or advice following their appointment. When asked about the main advantages of remote training, 32% (n=23/73) agreed it was more convenient, 25% (n=18/73) agreed that it was time saving and 30% (n=22/73) agreed that not having to attend the hospital was beneficial. 85% (n=62/73) strongly agreed and 14% (n=10/73) agreed that they were satisfied with the remote training provided and 82% (n=66/73) strongly agreed and 18% (n=13/73) agreed that they would recommend the remote training to another patient.

Conclusion: These findings provide new insight into patients’ experiences with self-injection training when delivered remotely by their HCP. The patient information pack and training consultation were well received as most patients found it helpful, convenient and time saving.

POS0575-PARE IMPROVED EDUCATION IS NEEDED FOR INDIVIDUALS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: INSIGHTS FROM A SOCIAL MEDIA LISTENING QUALITATIVE ANALYSIS

Keywords: Systemic lupus erythematosus, Descriptive Studies, Patient information and education

J. Barbosa1, C. Henning2, A. Mian3, C. Harrison4, E. Scott5, S. Burris6. 1GSK, Medical Affairs Excellence, Dublin, Ireland; 2GSK, Global Medical Affairs, Durham, NC, United States of America; 3GSK, Global Medical Affairs, Brentford, United Kingdom; 4LupusChat, NIA, New York, NY, United States of America; 5Lupus Research Alliance, N/A, New York, NY, United States of America; 6GSK, Value, Evidence and Outcomes, Collegeville, PA, United States of America

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease affecting multiple organs, including the kidneys in lupus nephritis (LN) [1]. Individuals living with SLE have impaired quality-of-life compared with the general population [1], and a growing number are using social media for health-related information [2]. Thus, social media is a useful source of data to examine their experiences and concerns [3].

Objectives: To understand the perspective of individuals living with SLE/LN on their disease management and to assess where they seek information, how their personal perspective impacts their care, and what might be needed to improve care/experience.

Methods: This qualitative analysis used the Sprinklr social media listening tool to search historical posts across 11 countries, including the USA, the UK and Japan, between May 2021 and February 2022, using predefined keywords. Main data sources were Twitter, Instagram, Reddit, Facebook, Weibo and SLE-specialised websites. Publicly shared posts relating to SLE/LN were captured and key themes were analysed.

Results: Overall, 23,084 posts were exported; of these, 12,037 were in scope and mentioned SLE/LN disease and/or therapeutics. Of the 12,037 posts, 6424 were produced by individuals with SLE/LN, which was not described in the supplementary information. The remaining 226 posts did not add any value to the analysis and were not considered. From analysis of the posts, many individuals with SLE/LN appeared to understand their condition and could identify symptoms (e.g., SLE: pain, fatigue, rash; LN: foamy urine, blood creatinine). However, there was a lack of knowledge of diagnostic and disease monitoring tests such as anti-nuclear antibody tests. Individuals with SLE/LN also described not receiving enough explanation of their laboratory results. Based on the posts, physicians focus on measurable disease activity and clinical trial data did not resonate with individuals with SLE/LN. Quality-of-life and patient-reported outcomes would be the preferred focus of discussion and may improve perception of their care. Individuals with SLE/LN reported being busy and symptoms of their disease (e.g., too tired or forget to take their medication) as reasons for poor adherence.

According to the posts, the most used SLE/LN drugs included methotrexate, hydroxychloroquine (HCQ), prednisone, mycophenolate mofetil and azathioprine. Individuals with SLE/LN generally had positive sentiment towards their individual standard therapies (except for HCQ). Awareness of long-term side effects was generally high; however, some individuals with SLE/LN were not aware that long-term use of steroids may contribute to organ damage. Individuals with SLE/LN reported many barriers preventing them from focusing on long-term goals of disease management and achieving better outcomes, including a needed shift in focus from short-term to long-term improvements. It could also help address discordance between physicians and individuals with SLE/LN on medication decision-making and adherence [4]. It is vital to consider known health disparities when providing education, as barriers such as racial discrimination have been associated with increased SLE disease activity and organ damage [5]. A change in care and clinical trials towards more collaborative and patient-centric care could also improve adherence and outcomes.

POS0575-PARE REUMA REGIE, SELF-MANAGEMENT TRAINING BY AND FOR PATIENTS

Keywords: Patient information and education, Self-management

A. Marchal1, J. De Reu1, N. Creten1. 1ReumaNet, ReumaNet, Zaventem, Belgium

Background: No self-management training for people with RMDs exists yet in Belgium. In its vision, ReumaNet is convinced that patients’ expertise adds great value in several areas. This includes self-management. Instead of consulting external organisations, ReumaNet developed a self-management training by the patient experts themselves. The training is based on the major themes identified in the study by J. Ammerlaan, et al “Self-management in patients with RA: a qualitative study from the patient’s perspective” and takes into account the recommendations for the implementation of self-management strategies drawn up by EULAR in June 2021.

Objectives: The aim of the training is for participants to gather the ability to understand their disease and cope with practical, physical and psychological consequences linked to their RMD.

Methods: The training is structured based on the patient journey: each person with an RMD goes through a number of stages as part of coping with his/her condition. This patient journey is the common thread throughout the training; a simple and efficient tool to guide patients towards their final goal. Via reflection and exercises, participants can identify their personal obstacles and challenges and are empowered to face daily challenges, due to their RMD. The training takes the form of a four-day training with an overnight stay, because we are convinced that ‘taking a break from the daily routine’ can provide sufficient distance, both literally and figuratively, for self-reflection. Moreover, there is then extra space for interaction with the group atmosphere. There is also the possibility of delving deeper into certain topics during a short evening session, should participants feel the need. During this four-day course in March2023, we provide 18 hours of training, using professional insights (i.e. webinars with specialists, certified return to work coordinator
Results: During the training, the participants get enough tools to be able to steer their mindset in a more positive way, by actively dealing with challenges linked to their specific condition, i.e. good sleep quality, self-care, dealing with stress, fatigue and pain. Also provided tools in the context of communication, bringing in necessary help and social support, sexuality and professional reintegration empower participants to take matters into their own hands. Over all, participants are empowered to face their own challenges in daily life. They gather the ability to understand their disease and cope with practical, physical and psychological consequences.

Conclusion: No such training exists yet in Belgium and there is a high demand for it. We will repeat this self-management training annually. In addition, we are looking for other ways to organise this training: online, or via (semi-) daily training days for example.

POS0580-PARE PATIENT ADHERENCE TO OSTEOPOROSIS TREATMENT IS HIGHER WITH CAREGIVER EDUCATION

Keywords: Patient information and education, Best practices, Osteoporosis

Background: Treatment adherence to osteoporosis treatment remains low. Additional factors: the elderly age of patients, congestive disorders, high comorbidity, fears of side effects of drugs, fear of calcium deposits in the vessels, kidneys and gallbladder, the absence of obvious clinical manifestations of the disease lead to refusal or unreasonable interruptions in therapy for osteoporosis.

Objectives: To analyze the treatment adherence to osteoporosis therapy of single patients, patients living in a family and patients coming to an appointment with a caring relative.

Methods: The analysis of outpatient records of 300 patients observed in the center for the diagnosis and treatment of osteoporosis was carried out. The study included all patients who visited the center in the period from the beginning of 2020 until reaching the enrollment of 100 people according to the ranked criterion. A total of 3 groups were recruited: 1st - single patients, N=100, 2nd - living in a family N=100, 3rd - coming to an appointment with a caring relative/social worker, N=100. The following were assessed: the completeness of the examination, the frequency of subsequent visits, adherence to therapy and the result of treatment according to densitometry data and repeated fractures. The observation period is 3 years. Patients who did not come to the follow-up examination (DXA) after 3 years were excluded from the study.

Results: 15.7% (47 people) withdrew from the study due to non-appearance for return visits. When calling patients, it was found that 6% (18 people) were going to start treatment, but did not start for various reasons, 9.7% (29) did not start but did not start for various reasons, 7.5% (19) started taking vitamin D and continued to take it until the package was over, 5% (15 people) started taking vitamin D preparations (patients from 9.7% of the above) and calcium preparations were taken from 1 to 3 months, after which they stopped taking them, considering that the course of treatment was completed. 2.3% (7 people) died within 3 years from various causes (4 out of 1 gr, 1 out of 2, 2 out of 3). The final statistical analysis included 246 people. The results are presented in Table 1.

A new fracture in 3 years | 4; 6.2% | 1; 1.2% | 1; 1.1% |

Conclusion: As a result of the analysis, it was confirmed that the highest adher- ence to examination and therapy was in patients who applied with a caregiver. Caregivers perceive verbal information better, seek repeated clarifications more often when questions arise about therapy and examination results, help patients solve technical problems (get to the center, purchase medicine, calculate dietary calcium, find a physical education video course). As a result of higher adherence to non-pharmaceutical and pharmaceutical treatment, the increase in bone mineral density in the 3rd group of patients was maximum. In the 1st group of patients, due to low adherence to therapy and the worst arrangement of life, by the 3rd year of observation, a higher percentage of fractures (6.2%) was revealed, differences in the frequency of fractures in the 2nd and 3rd groups over 3 years observation was not detected (1.2% and 1.1%) due to the short observa- tion period and a relatively small sample of patients.

POS0581-PARE VACCINATIONS IN PATIENTS WITH CHRONIC INFAMMATORY DISEASES, PATIENT KNOWLEDGE AND AWARENESS: RESULTS FROM A NORDIC SURVEY

Keywords: Vaccination/immunization, Health services research, Patient infor- mation and education

Background: Patients with chronic inflammatory diseases (CID) have an increased risk for contracting infections. For patients with rheumatic diseases EULAR recommends protecting them from vaccine-preventable diseases.

Objectives: To assess the knowledge and awareness of common vaccinations and extent of immunization among patients with CID in Denmark, Finland, Nor- way, Sweden (Nordics), and to identify gaps between the existing EULAR vacci- nation recommendations and current practice as experienced by patients.

Methods: A structured anonymous online survey for patients with CID (rheu- matological disease (RD), inflammatory bowel disease (IBD) and dermatologi- cal diseases (DD)) was conducted in 2022. The survey was answered by 1748 patients, of whom 1073 had CID. The distribution of patients across CID groups: 1031 patients with RD, 543 with IBD and 563 with DD (60% RD, 25% IBD, 15% DD).

Results: Among respondents, 89% were female and 58% had disease duration of above 10 years. In total, 56% were treated in specialised and 32% in primary care. Majority had ongoing systemic immunosuppressive treatment (IT) (65%). Majority of RD (59%) and IBD (66%) patients were treated in specialised care whereas minority of DD patients (38%) were treated in specialised care. Forty-nine percent (49%) responded that their healthcare professional (HCP) did not inform them about the increased risk of infection – however, 55% of the respondents believed...
they are somewhat or much more likely to suffer from infections than those without CID or treatment, 33% thought there is no difference and 13% did not know there is a difference. In total 68% of respondents considered it important to get vaccinated due to CID or IT. The number was particularly high in RD group (74%), although 63% stated they had not received any information regarding vaccinations at the start of their treatment. Commonly recommended vaccinations by the HCP were COVID 19 (66%), influenza (63%) and pneumococcal (45%) vaccination. When comparing respondents ≥65 and <65 years, there was a difference in how often the influenza (71% vs. 57%) and pneumococcal (57% vs. 38%), but not COVID 19 COVID vaccine (68%) were recommended. In total, 74% and 75% of respondents receiving IT were recommended influenza and COVID 19 vaccination, respectively. In total, 22% had their vaccination status checked before initiating treatment; the lowest percentage was in DD (16%) and the highest in RD (25%). However, 44% of respondents received influenza vaccination before initiation of treatment. Moreover, 62% and 74% of respondents received influenza and COVID 19 vaccination while on treatment, respectively. Eighty-six percent (86%) did not receive a vaccination plan in relation to their CID and treatment. Moreover, 64% of the respondents (RD 57%; DD 71% and IBD 66%) did not have vaccination status assessed on a regular basis. Forty-three percent (43%) were dissatisfied with the follow-up of vaccination status by their HCP. Respondents of age ≥65 years were more satisfied than the younger ones (34% vs. 25% very satisfied) and respondents with RD were more satisfied than those with IBD or DD (33% vs. 25% vs. 20%). Forty-four percent (44%) responded that the information on vaccinations related to their CID and treatment was difficult to find and 71% would like to receive more information. The respondents with RD had different level of awareness regarding EULAR vaccination recommendations. The degree of awareness among patients with RD treated with IT are presented in Figure 1.

Conclusion: This Nordic survey provides insights on patients' information needs, information sources and own experiences related to recommendations on vaccinations in relation to their CID and IT. The results confirm a gap between patients' expectations and needs vs. the information they actually receive. Our findings demonstrate a need for increased awareness among patients, providers and HCP regarding EULAR vaccination recommendations in patients with RD.

REFERENCE:
Background: Growing evidence points to considerable mental health impacts of the prolonged COVID-19 pandemic, though data from longitudinal studies in rheumatic diseases are sparse.

Objectives: We explored distinct trajectories of depressive symptoms in the year prior to and throughout the first 2 years of the COVID-19 pandemic in adults with RA.

Methods: CATCH is a prospective multi-center study of adults with early RA (symptoms <1 year; 81% met 2010 ACR/EULAR criteria at enrolment) who receive care from rheumatologists across Canada. Prior to the pandemic, participants completed PROs and rheumatologists conducted RA assessments during scheduled in-person study visits. After March 2020, ongoing collection of PROs continued at in-person and remote visits. We used group-based trajectory modeling to identify latent groups with at least mild depression (PROMIS 4a depression score ≥55) in participants with ≥1 visits in the year prior to the pandemic (3/19-2/20) and ≥1 visits during pandemic (3/20-1/22) and identified prepandemic individual and clinical characteristics and PROs associated with each trajectory.

Results: The analytic sample included 989 participants with a mean (SD) age of 60 (14) and disease duration of 6 (4) years. 73% were women, 84% while 30% had completed some post-secondary education, and 77% were in CDAI REM/LDA at visit closest to the start of pandemic. The best model included 4 groups (posterior probabilities ≥0.80 for each group): 1) Resilient (non-mild depressive symptom through: N=594; 60%); 2) Worsening (non/mild to mild: N=222;22%); Improving (mid-RESIL: N=80;8%); and Persistent (Moderate-severe through: N=56;59%)(Figure 1). As compared with the Resilient group, those with Worsening Depression were more likely to be female, have a higher prepandemic CDAI, MD and patient global, and report worse pain, disability, anxiety, depression, fatigue, sleep disturbance, and lower participation (Table 1).

Conclusion: Although 60% of Canadian RA patients had consistently good mental health during the first 2 years of the COVID-19 pandemic, more than 1 in 5 reported deteriorating mood suggesting a cumulative impact over time; 9% had persistent depression and 8% improving mood. The proportion of adults with RA with at least mild symptoms of depression may be more than twice that reported for the general Canadian population. Participants with worsening depressive symptoms during the pandemic were more likely to be female, have higher prepandemic disease activity, symptoms, disability, and higher impairments in participation. Given the impact of depression on quality of life, inflammation, and disease management, vulnerable groups may benefit from more frequent evaluation and additional support from rheumatologists.

Background: Children with juvenile idiopathic arthritis (JIA) may present lower aerobic capacity, lung volumes, and respiratory muscle strength compared to their healthy peers [1].

Objectives: This study aimed to investigate the effectiveness of inspiratory muscle training (IMT) on aerobic capacity, lung volumes, respiratory muscle strength, functional capacity, and quality of life in children with JIA.

Methods: Thirty-three children with JIA who were on the same biologic disease modifying anti-rheumatic drugs for at least three months were included and divided into two groups as exercise group (n=17, mean age: 15.1±2.2 years, 12 male) and control group (n=16, mean age: 15.7±1.6 years, 11 male). Exercise group performed IMT daily for eight weeks. Initial IMT load was set as the 60% of maximal inspiratory pressure (Pi max) and was increased by 10 every two weeks. Control group received no additional intervention. Forced vital capacity

Objectives: To describe the prevalence of sarcopenia and identity risk factors associated with sarcopenia in patients with spondyloarthritis (SpA) older than 65 years.

Methods: Design: Case-control study. Participants: Cases: They were recruited by simple random sampling among patients over 65 years of age with SpA (ACR/EULAR 2010 criteria) treated at 2 university hospitals. Controls: They were recruited for convenience by asking the cases to attend a consultation with a person of the same age (+/- 5 years) and sex. Variables: The main variable: sarcopenia, defined according to the European Working Group on Sarcopenia in Older People (EWGSOPII) 2019 criteria. The risk factors for sarcopenia evaluated were: demographic, economic level, malnutrition, measured with the Mini Nutritional Assessment (MNA), toxic habits, comorbidities and Charlson index, physical activity measured with the Global Physical Activity Questionnaire (GPAQ) and Short Physical Performance Battery (SPPB), muscle assessment measured by ultrasound. Other variables were: hemoglobin, calcium, vitamins D and B12, albumin, C-reactive protein, BMI (body mass index), polypharmacy (≥5), quality of life (EQ-5D) and factors related to SpA: activity of disease measured with BASDAI and ASDAS, physical function measured with BASFI, and treatments. Statistical analysis: descriptive and multivariate analysis was performed to identify factors associated with sarcopenia in SpA.

Results: 36 patients and 36 controls were recruited, of whom 54 (75%) were men, with a mean (± SD) age of 70 years (±4.37). Of the 36 patients with SpA, 20 (55.6%) had axial SpA and 15 (44.5%) had SpA with axial and peripheral involvement with a mean of 32 years (±10.9) of disease. The prevalence of sarcopenia in patients with SpA is 8.3%. No differences were found in sarcopenia between patients [3.8%/33%] and controls [12.8%], p=0.614. Patients with SpA who had sarcopenia, compared with those who did not, had a mean years of evolution of their major disease [45.6 (s.3)] vs 31.6 (± 10.5), p=0.024; worse performance tests in the Short Physical Performance Battery (p=0.026), in relation to ultrasound parameters, a lower thickness was observed in the right forearm 75% radial and left forearm 66% radial [11.10 vs 14, 7(2.4)], p=0.17 and left rectus femoris area [11.5(2.4) vs 15.4(2.8)], p=0.26, greater thigh fat right to 50% [25.6(4.7) Vs 15.2(8.3)], p=0.041 and lower albumin [14, 7(2.4)] Vs 15.4(2.8), p=0.17 and left rectus femoris area [11.5(2.4) vs 15.4(2.8)], p=0.053. On the other hand, no significant differences were found in the rest of the parameters studied for disease activity, disability, quality of life (EQ-5D), malnutrition, toxic habits, comorbidities or physical activity. In the multivariate model, the years of disease evolution (p=0.041) Table 1 were identified as an independent predictor of sarcopenia in patients with SpA. This model would explain 33% of sarcopenia in RA (R2=0.37).

Conclusion: In our study we found no differences in sarcopenia in patients older than 65 years with SpA compared to controls. The longer evolution time of their disease in patients with SpA is associated with a greater risk of sarcopenia.

P. De Groot1, J. Luime1, M. Vis1, M. R. Koić1, I. Tchetchelnikov1. 1Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands; 2Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; 3Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands

Background: During times of social-distancing, in-person outpatient visits were greatly reduced. Health care professionals (HCPs) were dependent on the patient’s reported experience of their disease activity in their assessments of the wellbeing and inflammatory state, due to lack of physical assessments. Digital biomarkers can support real-world continuous measurements and offer a method for remote quantification of inflammatory joint disease. They are defined as objective, quantifiable, physiological and behavioural data that are collected and measured with digital devices [1].

Objectives: This study uncovers the HCPs perspective on current manners of disease activity monitoring, easing their workload and the potential of digital biomarkers.

Methods: A Design Thinking approach is followed for digital biomarker development. It is a human-centered problem solving approach that leverages iteration, empathy and collective idea generation to tackle complex challenges [2]. Semi-structured online focus group discussions were conducted. Pilot 1-1 interviews were executed to assess the interview script. The script is underpinned by the graphical framework for clinical decision making [3] and the theoretical domain framework [4]. One moderator and three alternating observers facilitated the sessions. All interviews were audio-recorded, transcribed to verbatim and coded.

Results: In total 6 focus groups were organised, with a total of 28 HCPs. Participants were rheumatologists (N= 19, age 47 ± 9, 50% male) and rheumatology nurses (N= 9, age 51 ± 6, 0% male). The main findings from the interviews about digital biomarkers in relation to current practices were: Trust; HCPs felt self-assured about their own abilities of physical evaluation, reading patients and their gut feeling. Trust in flare detection with digital biomarkers and machine learning was low. It was expected that much disease activity is missed and many false-positive flares are detected. Biomarkers should be valid, reliable and sensitive to change. Innovation should improve quality of care; No consensus about a golden standard of care exists. HCPs were afraid that with digital biomarkers personal interaction recedes to the background and quality of care is compromised. Personal interaction was marked as essential to raise sensitive topics and stimulate therapy adherence. Benefits of digital biomarkers; HCPs enjoyed the delivery of efficient and effective care. They disliked repetition and the high administrative burden. In the HCPs opinion digital biomarkers could establish disease activity prior to the consultation, so time could be spent on what matters to the patient. New technologies should however not add to frustrations and make way for things that really matter.

Conclusion: The following problem statement from the HCPs perspective can be formulated: “In limited time we take many actions. We spend time on both disease and emotional support of our patients. Our workload is high and trivial tasks such as administration take too much of our time. Instead we want to focus on what’s relevant to the patient. We are confident about our own abilities and, only if technology is proven to be valuable, valid, reliable and accepted by our patients it can be used in clinical practice.”

EQ-5D-5L index and EQ-VAS were 0.6 (0.3-0.7) and 59 (41-70), respectively.

Results: Baseline data from people with RA and severe functional limitations, identified by the Health

Assessment Questionnaire Disability Index (HAQ-DI).

Methods: Baseline data from people with RA and severe limitations in physical functioning participating in a randomized controlled trial on the (cost-)effectiveness of longstanding physical therapy as compared to usual care [1] were used. Patients completed the HAQ-DI (Dutch version)[2, 3], a reliable, valid and widely used questionnaire reflecting problems in activities of daily living and consisting of 20 items divided over eight domains (Dressing and grooming, Arising, Eating, Walking, Personal hygiene, Reaching, Gripping and Usual activities). Each item is scored on a 4-point scale ranging from 0 to 3 (no difficulty - severe disability). This preliminary data analysis does not yet take into account the use of assistance/assistive devices. Gender, age, sex and disease duration were recorded, and the EuroQol 5 Dimensions 5 Levels (EQ-5D-5L) administered for health related quality of life (HRQoL) (Single index score (<0.446-1.000), and visual analogue scale (EQ-VAS, 0-100), higher scores indicating better HRQoL).

scheduled visit. Anchor-based analyses (using the American College of Rheumatology [ACR] response criteria and PsA Disease Activity Score [PsDAS]) and distribution-based analyses (one standard error of measurement, and half the baseline standard deviation [SSD]) were used to determine responder thresholds at Wk 16. The maximum Youden index values from the receiver operating characteristic (ROC) curve analyses (using PsDAS and Disease Activity Index for PsA [DAPSA] scores as anchors; Figure 1) were used to determine disease activity thresholds.

**Results:** In 1,252 pts, mean (SD) PsAID-12 total score decreased from 4.19 (1.94) at BL to 2.65 (2.02) at Wk 16. Single-item domain scores ranged from 1.34 (2.13) for depression to 5.56 (2.26) for pain at BL, and from 0.91 (1.80) for depression to 3.76 (2.51) for pain at Wk 16. The Wk 16 responder threshold for the PsAID-12 total score was identified as a 2-point decrease. For 8 PsAID-12 single-item domain scores, Wk 16 responder thresholds were identified as 3-point decreases. For the remaining 4 single-item domains (anxiety, fear and uncertainty; embarrassment and/or shame; social participation; depression), responder thresholds could not be determined due to floor effects at BL (absence of these symptoms in a high proportion of pts). Disease activity thresholds for the PsAID-12 total score were identified: ≤1.15, >1.15–≤1.95, >1.95–≤3.60 and >3.60 for Remission, Low, Moderate and High Disease Activity, respectively (Figure 1). Disease activity thresholds for PsAID-12 single-item domain scores are reported in the Table 1.**

**Conclusion:** This analysis defined responder and disease activity thresholds for the PsAID-12 total score and most single-item domain scores, which can be used to assess treatment efficacy and disease impact in pts with PsA.

**Background:** Research-grade accelerometers are commonly used to measure physical activity (PA) in rheumatology research, demonstrating superior reliability and validity relative to self-report methods. Several accelerometers support manufacturer software and embedded proprietary algorithms to reduce the complexities of data processing. However, algorithms vary between device brands, and hinder standardisation of data processing and analysis. Best practice in PA research is now therefore considered to be the collection and analysis of raw accelerometer data, to which transparent and replicable data transformation methods can be carried out post-processing. Novel metrics include average acceleration, intensity gradient, and MX metrics, which represent PA volume, intensity and patterns, and have not been examined in rheumatic diseases.

**Objectives:** To explore the utility of novel accelerometer metrics for characterising clinical features in Rheumatoid Arthritis (RA), i.e. disease activity and severity, cardiovascular disease (CVD) risk.

**Methods:** People living with RA (n = 104) provided demographic data, medical history, a fasted blood sample, and completed the health assessment questionnaire (HAQ, disease severity). Disease activity was measured using the Disease Activity Score 28-CDPAS (DAS28-CDPAS), and CVD risk determined using the QRISK3. Participants wore a GT3X Actigraph accelerometer on their right hip for 7-days during waking hours. Accelerometer data were analysed using GGIR (v.2.1-1) to determine average acceleration (AA, mg, proxy for daily volume of PA), intensity gradient (IG = distribution of PA across the day) and MX metrics (acceleration above which a person’s most active “X” mins are accumulated e.g., M5 = most active 5 mins). A higher AA and more positive IG indicate a
favourable activity profile. Statistical analyses: Participants were grouped according to DAS28-CRP (remission = <2.6, low = 2.6 - 3.1, moderate = 3.2 - 5.1, high = >5.1) disease severity (HAQ; low = <1, moderate = 1 - 1.9, high = ≥2) and QRI3K (low = <10%, moderate = 10 - 19%, high = ≥20%). Between group differences in AA and IG were analysed using analysis of variance, adjusted for accelerometer wear time. Radar plots were produced in R, to illustrate differences in MX metrics according to clinical features.

Results: Valid accelerometer data (≥10hr on ≥4 days), were available for n = 102 participants (M ±SD, AA = 13.7 ±5.2 mg, IG = 2.91±4.36). Participants in remission and with low CVD risk, demonstrated a better activity profile (i.e. [M ±SE, all p<0.05] significantly higher AA [DAS28-CRP = 17.9 ±1.1; QRI3K = AA = 15.4 ±0.6] and more positive IG [DAS28-CRP = 2.62 ±0.07, QRI3K = 2.80 ±0.04], compared to patients with moderate or high disease activity and CVD risk (DAS28-CRP [moderate, AA = 12.8 ±0.6, IG = -2.99±0.04] and [high, AA = 112 ±1.1, IG = -3.07±0.08], QRI3K [moderate, AA = 12.0 ±1.0, IG = -3.0 ±0.07] and [high AA = 10.3 ±1.1, IG = -3.16 ±0.08]). For disease severity IG was significantly more positive in patients with low (<2.78 ±0.05) vs. high (>3.10 ±0.08) HAQ scores. Radar plots (Figure 1) showed the intensity of the most active accumulated 2-45 mins (M2-M45) was greater (with M10 exceeding 75mg) among participants with better disease profiles (i.e. remission/low DAS28-CRP, HAQ and QRI3K scores vs. moderate/high).

Conclusion: This is the first study to demonstrate the clinical utility of novel accelerometer metrics in RA. Results suggest higher AA, more positive IGs, and accumulating ≥10 mins at an intensity indicative of a slow walk (M10 >75m), is characteristic of more favourable disease profiles. Future studies utilising these raw accelerometer metrics could provide valuable, standardised accelerometer data that can be used to deliver more personalised care (i.e. prescription medicine).

POS0593-HPR PRELIMINARY EVALUATION OF THE RHEUMATOID ARTHRITIS FOOT DISEASE ACTIVITY INDEX (RADAIF5) AS A SCREENING TOOL FOR FOOT-RELATED DISABILITY

Keywords: Outcome measures, Patient reported outcomes, Rheumatoid arthritis

A. Hoque1, M. Steultjens1, D. Dickson1, G. Hendry1, 1Glasgow Caledonian University, Podiatry and Radiography, Glasgow, United Kingdom

Background: Impaired foot function in patients with rheumatoid arthritis (RA) can contribute to impairment and disability during daily activities [1]. RA foot disability has been studied extensively, although foot disease activity and its association with future foot impairment have not. The Rheumatoid Arthritis Foot Disease Activity Index (RADAIF5) is a clinically feasible, valid, and reliable patient-reported outcome measure (PROM) that can be employed with the DAS-28 to evaluate RA foot disease activity [2].

Methods: We gathered the follow-up data of 1,000 patients treated with biDMARDs (etanercept, adalimumab, golimumab, infliximab, abatacept, and tocilizumab) from KRRD. Patients were recruited from public hospitals in Kuwait between February 2013 to September 2022. Remission (DAS-28 less than 2.6) was predicted at 1-year follow-up using baseline clinical data obtained at the time of enrollment. Machine learning methods system (including: lasso, ridge, support vector machine, random forest, XGBoost, and Shapley additive explanation (SHAP)) were used for the predictions.

Results: The ranges for accuracy and area under the receiver operating characteristic of the newly developed machine learning model for predicting remission were 52.8–72.9% and 0.463–0.719, respectively. The Shapley plot in XAI showed that the impacts of the variables on predicting remission differed for each biDMARD. The most important features were age for adalimumab, rheumatoid factor for etanercept, erythrocyte sedimentation rate for infliximab and golimumab, disease duration for abatacept, and C-reactive protein for tocilizumab, with mean SHAP values of −0.250, −0.234, −0.514, −0.227, −0.804, and 0.135, respectively.

Conclusion: Our proposed machine learning model system successfully identified critical features that were predictive of remission in each of the biDMARDS. This approach may be useful for improving treatment outcomes by identifying clinical information related to remissions in patients with rheumatoid arthritis.

Methods: This study drew its data from a randomised controlled trial comparing prefabricated versus customised foot orthoses for RA patients [3]. At baseline, six months, and 12 months, the patients' disability levels were examined using the Foot Function Index disability subscale (FFI-DS). The newly created RADAI-FS was gath- ered at baseline, one week, and six months. In the absence of recognised threshold cut-off values, the median split method was utilized to dichotomize FFI-DS scores for poor and mild foot disability at 12 months. Two consecutive occurrences of moder- ate-high foot disease (RADAI-FS > 3.45) at baseline and six months constituted poor foot disease activity. The predictive value of foot disability at 12 months was investigated using IBM SPSS linear binary logistic regression analysis controlling for baseline foot disability scores. The odds ratios (OR) and 95% confidence intervals (CI) were obtained, and a significance level of p < 0.05 was established.

Results: 51 patients, 36 of whom were female, with a mean [standard deviation, ±SD] age of 53.5 [±12.18] and disease duration of 8.34 [±6.57] years completed the 6-month and 12-month FFI follow-ups. At baseline and 6 months, mean [±SD] RADAI-FS scores were 5.56 [± 2.07] and 4.12 [± 2.54], respectively. At 0 and 6 months, 75.2% and 52.5% of the sample, respectively, had moderate-high foot disease activity, whereas at 12 months, the prevalence of poor foot disability was 48.6%. Binary logistic regression identified that having two consecutive episodes of moderate-high foot disease was an independent predictor of foot poor disabil- ity at 12(OR=3.44, 95% CI= 1.04-11.40, p < 0.05).

Conclusion: The RADAI-FS is an accurate predictor of foot-related disability. In clinical practice, the RADAI-FS may be used as a screening tool to identify individuals who are at risk for persistent foot disability. Combining the RADAI-FS with common physical outcome measures can improve the prediction of foot impairment.

POS0595-HPR WILLOINGNESS TO USE REMOTE CARE AMONG PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Patient reported outcomes, Telemedicine

E. E. Kvernberg Thomasson1, A. T. Tveter1, I. J. Berg2, E. Kristianslund2, N. Osteras1, 1Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; 2Zurich University of Applied Sciences, European University of Lefke, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Lefke, Turkey; 1Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway

Background: Remote care is an alternative to standard care for patients with axial spondyloarthritis (axSpA) and may facilitate accurate and timely manage- ment of disease. However, there is limited knowledge on factors related to the patients’ willingness to use remote care.

Objectives: To assess the willingness to use remote care among patients with axSpA and compare characteristics of patients at different levels of such willingness.

Methods: We used baseline data from a randomised controlled trial on remote care of axSpA (ReMonit), Patients with a clinical axSpA diagnosis fulfill- ing ASAS-criteria for axSpA, treated with TNFi and with low disease activity (ASDAS<2.1) were recruited at a single outpatient clinic. Years since diagnosis were retrieved from medical records, and self-reported education and work status. Willingness to use remote care was measured by scoring the statement “I want to use remote care” using a 4-point Likert scale (strongly disagree – strongly agree). Patients were then divided into three groups (disagree/agree/strongly agree) based on their willingness to use remote care. eHealth Literacy was measured using three scales of the eHealth Literacy Questionnaire (eHLQ) using a 4-point Likert scale (1=strongly disagree – 4=strongly agree, 4=best score).

Results: 242 patients were included, mean age 43 years (SD 11.7) and 75 % male. Most patients were willing to use remote care (strongly agree: 53.3%; agree: 43.0% and disagree: 3.7%). Descriptive and comparative analyses between groups show a trend toward younger males with higher education and full-time employment being more willing to use remote care. Moreover, patients were assessed separately within each country-specific samples, and then across a merged sample of all three countries. A differential item function (DIF) analysis was used to assess scale stability across countries.

Conclusion: When the countries are considered separately, although slight differ- ences are apparent, the operation of the instrument appears to be very similar across Switzerland, Turkey, and the UK. Although there is a degree of scale misfit in all countries, the scale-sample targeting and the scale reliability are both excel- lent (Person Separation Index = 0.93-0.95, Cronbach’s Alpha = 0.96-0.97), and the response categories function well across all items. However, there is a large degree of inter-item dependency present, and the MAP-Hand displays apparent multidimensionality within all three countries. Additionally, some individual items display Rasch model fit to some extent, although these items are variable across the three countries. When the items were re-constructed into four testlets, this accounted for the inter-item dependency, also improving the model fit and uni- dimensionality of the scale within all three countries separately, as well as when the data is merged into a single dataset. Some significant country-DIF was observed on the ‘Dressing’ testlet (compared of items 1-3), but this was found to have no significant effect on total person score estimates. Despite the testlet re-structuring creating a narrower scale range, the scale-sample targeting and scale reliability remain high (Person Separation Index = 0.86-0.91; Cronbach’s Alpha = 0.93). It is recommended that the four-testlet structure is implemented across all three countries, as this offers a pragmatic approach to the utility and comparative scoring of the MAPHAND across the UK, Switzerland and Turkey. Although the re-structuring creates a narrower scale range and apparent reduc- tion in the reliability, this is indicative of the initial dependency that is present, and suggests that the original reliability values are over-inflated.

with higher willingness to use remote care had good physical function, fewer years since axSpA diagnosis and high eHealth literacy (Table 1).

**Conclusion:** Nearly all patients included in this trial of remote care of axSpA wanted to use remote care. Significant differences in baseline characteristics were revealed between the three groups according to their willingness to use remote care. However, precaution must be taken due to a small number of participants in the “disagree”-group.

**Background:** Long-term gout management is based on reducing serum urate by using urate-lowering therapy (ULT) [1, 2]. A lifelong treat-to-target approach is advocated, though a ULT (taper to) stop attempt can be considered (treat-to-avoid symptoms approach) during remission[1]. It is yet unclear if either is a superior strategy when considering ULT (dis)continuation in the remission phase.

**REFERENCES:**

**Objectives:** To identify factors that influence the decision for continuation (treat-to-target) or discontinuation (treat-to-avoid symptoms) of ULT and to determine their perceived relative importance in gout patients in remission.

**Methods:** A mixed methods design was used. First, semi-structured interviews (substudy 1 EULAR POS1477 2020) were held to identify barriers and facilitators for continuation and discontinuation of ULT using inductive thematic analysis. These items were then summarized by a multidisciplinary team (including a patient partner) in neutrally formulated items. These items were subsequently used in a Maximum Difference Scaling study (MaxDiff, substudy 2) to rank them and to determine their relative basis on utility scores (preference score). A rescaled probability score (RPS) was generated with a 0-100 range (the higher the score, the more important the item). For example, an item with an RPS of 8 is twice as important as an item with an RPS of 4. Patients of both studies were recruited from general practitioners and from the rheumatology department of the Sint Maartenskliniek (both in the Netherlands). The semi-structured interviews as well as the MaxDiff experiment have been pilot tested.

**Results:** Substudy 1 and 2 included 18 and 156 patients, respectively (see Table 1). The mixed-structured interviews yielded 46 barriers/ facilitators and were summarized in 22 items, divided into 10 overarching themes (logistics, lifestyle, role of serum urate, physician role, scientific knowledge, general medication use, anti-inflammatory use, gout flares, ULT use and long-term gout effects). Figure 1 shows their ranking (substudy 2). The risk of joint damage (RPS 8.77) was the most important item, and it is 26 times more important than the least important item, ‘cost of my gout treatment’ (RPS 0.34).

**Conclusion:** In particular, items concerning (control of) disease activity (flares, joint damage) play a role when gout patients in remission consider (dis)continuation of ULT. Costs, logistics and monitoring by physician were deemed less important. These results provide a basis for shared decision making between physicians and patients, and show which items should at least be discussed when considering ULT (dis)continuation in the remission phase.

Background: Health literacy (HL) is the ability to access, understand, appraise, and apply health information [1]. A low level of HL is associated with worse pain problems, poorer self-care, and an obstacle for health-promoting interventions among individuals with chronic pain and radiographic knee osteoarthritis (rKOA).

Objectives: To examine 1) the level of HL and associations with chronic pain, rKOA, lifestyle habits and health status, and 2) to explore the individuals’ experiences of HL.

Methods: The study has a convergent parallel mixed-method design, including 221 individuals with knee pain (148 women, mean age 56±8 years). A purposeful sample of 19 individuals (11 women, 8 men) was selected for interviews. Quantitative data were general HL (GHL) assessed by HLS-EU-Q16, electronic HL (eHL) by eHEALS, pain distribution by a pain figure, rKOA by x-rays, lifestyle habits, and health status via SF-36. GHL and eHL were merged into one variable, “HL” where sufficient HL was defined as having a sufficient level of GHL or eHL.

Results: Of the 221 participants, 29% reported limited HL. Those with limited HL reported lower education, less usability and importance of the internet for accessing health information and making informed health-related decisions, and lower general health (GH) compared to the group with sufficient HL (data not shown). Higher education, CRP, a healthier diet, and minor alcohol consumption were associated with sufficient HL (Table 1). Only higher education and GH remained associated when adding GH to the multivariate analysis. Individuals’ experiences of HL were described as 1) Searching for information influences the decision-making process by being an active searcher or passive receiver; 2) Processing of information influences the decision-making process by having light, moderate or high processing of the information; and 3) Taking a stand on the information influences the decision-making process based on trust and/or motivation (Figure 1).

Conclusion: Limited HL was found in one-third of the individuals with knee pain. CRP and healthy lifestyle habits were associated with sufficient HL, but higher education and health status had the strongest association. The search, level of process and standpoint on the health information influenced the decision on action. More research on HL is needed to gain knowledge of how to develop health promotion to prevent worsening pain problems in individuals with knee pain.

Keywords: Rheumatoid arthritis, Artificial intelligence, Descriptive Studies

P. Kerkhof1. Vrije Universiteit Amsterdam, Communication Science, Amsterdam, Netherlands

Background: Social media platforms have become a vital resource for individuals seeking information and support regarding health issues, including rheumatoid arthritis (RA). As such, the content generated on these platforms represents a valuable source of data for gaining insight into patients’ perspectives on RA. However, previous research in this area has primarily relied on qualitative analyses of small sample sizes, limiting the ability to extract meaningful insights from social media content related to RA. With the advancement of machine learning techniques, it is now possible to analyze and extract insights from large volumes of social media posts related to RA.

Objectives: The purpose of this study was to identify the most common topics discussed in a large dataset of submissions about RA on Reddit, one of the world’s largest online forums.

Methods: The data for this study was collected from the two largest Reddit forums (“subreddits”) dedicated to RA, r/rheumatoid arthritis and r/rheumatoid, which have 18.9k and 7.6k members respectively. We retrieved all submissions but excluded responses in our analyses. All deleted or duplicate submissions and those with fewer than 10 words were removed, retaining 11,094 submissions from over 5,000 users for the analysis. To identify common themes, we applied topic modeling, a technique in natural language processing that identifies underlying themes or topics in a collection of documents. We used the Bertopic Python package (Grothendieck, 2022), which employs deep learning techniques to perform the topic modeling.

Results: The data indicates a significant increase in submissions to the two subreddits, rising from 113 in 2014 to 2892 in 2021 and 1928 in the first 8 months of 2022. Upon analysis, 65 topics were identified, with 4162 submissions (37.5%) remaining unclassified. A topic specifically dedicated to requests to participate in surveys was removed as it did not pertain to the experiences of forum users. Among the remaining topics, the top 10 accounted for 44.90% of all submissions. To better understand each topic, a sample of 10 submissions with the highest probability for that topic were examined (Table 1).

* After excluding unclassified topics

Three of the ten topics pertained to specific medications - methotrexate, Humira, and prednisone, accounting for 12.71% of the total. The most prevalent topic, at 8.02%, focused on the side effects of methotrexate, with many submissions inquiring about symptoms such as nausea. The second most common topic, at 7.04%, primarily revolved around COVID-19 and related issues, with some
Methods: Clinical studies on the effectiveness of exercise therapy in people with RA or axial spondyloarthritis (axSpA) [1-2]. Exercise therapy is generally considered safe for people with rheumatic and musculoskeletal diseases (RMDs), including those with inflammatory arthritis such as rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA) [1-2].

Background: Exercise therapy has proven effective for people with rheumatic and musculoskeletal diseases (RMDs), including those with inflammatory arthritis such as rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA) [1-2]. Exercise therapy is generally considered safe for people with RMDs, although the evidence is scarce. A few reviews reported on the nature and risk of harms of exercise therapy in RMDs, but none of them specifically addressed the quality of reporting of harms of exercise therapy in studies including people with inflammatory arthritis.

Objectives: This study aimed to describe the quality of reporting of harms in clinical studies on the effectiveness of exercise therapy in people with RA or axSpA.

Methods:RCTs with at least one treatment arm consisting of supervised exercise therapy in people with RA or axSpA were included. Eight electronic databases were searched up to November 2021. Two researchers independently selected studies for inclusion and extracted data and in case of disagreement a third researcher was consulted. Data extraction included study characteristics and fulfillment of a set of quality aspects derived from the Consolidated Standards of Reporting Trials (CONSORT) Extension for Reporting Harms Outcomes [3], predefined on the basis of consensus among authors (Table 1). Harms outcomes were defined as adverse events reported on individual level irrespective of causality or negative effects on group level (only if explicitly designated as measurement of potential harm). We considered the reporting on harms outcomes of sufficient quality if the authors reported at least 1) the methodology for active surveillance of harms outcomes (item 2a); and 2) the observed number and the nature of harms (items 3b and 3c).

Results: The search yielded 5921 records, of which 64 studies (n= 41 RA, n=23 axSpA; described in 83 papers) were included. Of those studies in RA and axSpA, 34 (83%) and 15 (65%) included any information on harms, with 12 (29%) and 3 (13%) reporting active surveillance and 22 (54%) and 5 (22%) reporting on harms outcomes in the results section, respectively (see Table 1). In total, 10 of the 41 (24%) RA studies and 2 of the 23 (9%) axSpA studies fulfilled the predefined criteria for sufficient quality of reporting.
qualitative patient interviews, and were then tested in a quantitative pilot. Main data collection consisted of an online survey in which participants were asked to repeatedly choose between hypothetical treatments. Eligible patients were ≥18 years old, diagnosed with RA, currently received systemic disease-modifying anti-arthritic drug therapy for RA, and were residents of France, Germany, Italy, Spain, United Kingdom, or United States. Male patients were oversampled to support subgroup analysis of preferences for effects on sperm parameters. Data were analyzed using a correlated mixed logit model and differences in preferences between sex and age were explored. Relative attribute importance (RAI) scores and maximum acceptable risk (MAR) measures were derived from the estimates.

**Results:** A total of 2,090 patients participated; 42% were female with predefined oversampling of male patients, with a mean age of 45.2 years (range 18–83). Estimated effects were significant for all attributes (p < 0.001), implying that they all influenced treatment choices and suggesting preferences differed between participants. Average RAI scores revealed different priorities (p < 0.001) between males and females (Figure 1). While reducing pain and negative effect on semen parameters was most important to male patients, female patients were most concerned by risk of blood clots and serious infections. The remaining attributes were of lower importance but were still relevant. However, no single attribute explained treatment preferences by more than 30%. Preferences were also affected by patients’ age: patients aged 18–44 years placed less importance on frequency and mode of treatment administration (p < 0.05) than older age groups. Patients were willing to make benefit-risk trade-offs: they accepted extra risks of blood clots (male: 1.8%; female: 0.8%), serious infections (male: 2.5%; female: 1.0%), or negative effects on sperm (male: 7.4%) for an oral pill every day instead of injection once a week. They also accepted extra risks of blood clots (male: 2.3%; female: 1.2%), serious infections (male: 3.2%; female: 1.6%), or negative effects on sperm (male: 10.4%) for reducing amount of pain from 30% to 10%. Similar observations were made for improved performance of daily activities. However, acceptable trade-offs varied between patients (p < 0.05).

**Conclusion:** Preferences of RA patients were driven by benefits and risks of RA treatments, with no single attribute dominating the decision making. Patients were willing to accept higher risk of serious infections and blood clots in exchange for improvements in pain, daily activities, or administration convenience. These findings emphasize the importance of considering the entire treatment profile, including benefits, risks, and administration to support SDM between providers and patients.

Figure 1. RAI overall and by sex

Preference drivers: males – pain, blood clots; females – blood clots, infections, pain. Stem risk data are based on male responses only.

**DOING EVERYTHING POSSIBLE TO PRIORITIZE WORK: LIVED WORK EXPERIENCE OF YOUNG ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

**Keywords:** Qualitative research methods, Systemic lupus erythematosus, Work-related issues

M. Golding1,2, F. Nishat3, K. Merrill3, R. Kaur1,2, J. Stinson3, J. Protudjer1,2, R. Woodgate1,2, C. Peschken4, D. Lacaille5, U. Oguzoglu5, Z. Touma6, L. Lim7,1. 1Children's Hospital Research Institute of Manitoba, Paediatrics, Winnipeg, Canada; 2University of Manitoba, Paediatrics, Winnipeg, Canada; 3University of Toronto, Paediatrics, Toronto, Canada; 4Canada Research Chair, Tier 1, Paediatrics, Winnipeg, Canada; 5University of Manitoba, Medicine, Winnipeg, Canada; 6University of British Columbia, Medicine, Vancouver, Canada; 7University of Manitoba, Economics, Winnipeg, Canada; 8University of Toronto, Internal Medicine, Toronto, Canada

**Background:** Young adulthood (18–30 years) is a critical life-stage when individuals launch into independence, establishing employment. Failure to establish employment during young adulthood is associated with reduced lifetime socioeconomic achievement. A few studies focused on studying employment outcomes in young adults with systemic lupus erythematosus (YASLE) showed less full-time work than general population, substantial absenteeism from productivity loss. Studying the lived work experience of YASLE can broaden our understanding in this area from the patients’ perspectives.

**Objectives:** To describe the early work experiences of YASLE and explore their perceptions of SLE influences on their work.

**Methods:** This was a qualitative descriptive study. Young adults with childhood- or adult onset SLE were recruited from 2 adult rheumatology clinics (Oct 2021-Aug 2022) in Manitoba and Ontario. Inclusion criteria: YASLE who were employed, unemployed (looking for work or not), or work disabled. Potential participants were purposely sampled for diversity in: sex/gender, age of onset, major organ disease, occupation groups. All completed a pre-interview questionnaire to provide demographic, SLE and work-related information. Semi-structured interviews were conducted individually via video conference, focusing on their work experiences, future aspirations and perceived SLE influences. Interviews were audio-recorded, transcribed verbatim and analyzed using a reflexive thematic analysis.

**Results:** Of 18 participants, 13 identified as females, 1 as non-binary; median age 25 (22–29, 25–75th percentile) years. Participants’ identified ethnicities: 7/18 Asian, 5/18 White, 2/18 Indigenous, 4/18 other. 7/18 were childhood-onset SLE, 9/18 had major organ disease. 12/18 were employed full-time, 3/18 unemployed/looking for work, 3/18 unemployed/not looking to work, 6/18 worked in managerial/professional jobs. Three have current work accommodations, 2/3 for SLE. 13/18 report highest education to be university/postgraduate. Most participants perceived themselves to be functioning relatively well at work despite modest physical, cognitive limitations. Two main themes emerged:

1) “Getting by, with some help” describes many factors that participants cited as critical in helping them stay in the workforce. Most of the factors mapped to the underlying construct of control over their work. Participants who have the flexibility to manage their time, physical positions and environment perceived fewer issues staying in work Participants also reported increasing recognition (over time) of the importance of medication adherence in disease control, which helped them to stay in work. Other frequently cited facilitators also included sedentary jobs and the availability of social support.

2) “Tough choices: work or health over everything else” describes how participants struggled to find a balance between their health, work and social life. Many described multiple strategies to prioritize work while trying to preserve their health: rest more, avoid commute, avoid stress, help or transfer responsibility for chores, limiting social activities. A few however deemed the costs of work to be too great and chose to prioritize their health by avoiding work altogether.

**Conclusion:** Most YASLE report being employed and unemployed. Lived work experience of YASLE is critical in understanding the lived experience of YASLE. They recognized the importance of their health in helping them to work. They diverted considerable energy/resources from other aspects of life to maintain work. This begs...
the question of whether this approach could be sustainable beyond this life stage. However, this work on YASLE patients also identified multiple potential targets of interventions to help them continue working. By focusing on young adulthood, this will ensure that our strategies will be most appropriate for their life-stage, maximizing impacts.

Neuroscience Donders Institute for Brain, Cognition and Behaviour, Nijmegen, The Netherlands; Institute of particular interest as mitochondrial abnormalities are known histological find-
dering antigens, we recently discovered anti-NDUFA11 IgG in sera of patients with anti-MDA5 antibody-positive DM with ILD. This antibody is not statistically significant. Anti-NDUFA11 IgG was also found in 2,3% of SLE patients. The IgG was associated with a subgroup of patients with a more severe phenotype. The subgroup was then validated in an independent larger cohort of 287 patients with IBM followed at nine European rheumatological or neurological centers. IBM serum samples were collected at the time of diagnosis and stored at -80°C until analysis.

Methods: In a first exploratory study, 268 patients with IBM were included. Serum samples were incubated with plasma samples from 219 IBM (108 Polyomatisis (PM)), 80 Dermatomyositis (DM) and 31 IBM) patients, 349 Systemic Lupus Erythematosus (SLE) patients and 306 population controls for screening of IgG reactivity against each antigen. All sera were tested in a single blinded manner in the same laboratory. The first step in our study was to screen sera from patients with IBM and controls for reactivity against a panel of antigens. The panel included antigens representing 268 proteins. The antigens were expressed as His6ABP fusion proteins. The number of positive sera was then compared between patients with IBM and controls. The positive sera were then tested against the antigens that were positive in the first step.

Results: In the exploratory study, IgG reactivity towards NADH dehydrogenase 1 α subcomplex 11 (NDUFA11) was detected in sera from patients with IBM and controls. The IgG was found in 3.2% of IBM patients and 0.9% of control sera. The difference in the prevalence of positive sera was statistically significant. Anti-NDUFA11 IgG was also found in sera from patients with other connective tissue diseases, including SLE, dermatomyositis, systemic sclerosis, and polymyositis. The IgG was also found in sera from patients with other neuromuscular diseases, including inclusion body myositis, facioscapulohumeral muscular dystrophy, and myotonic dystrophy.

Conclusion: The anti-NDUFA11 antibody is a novel biomarker for inclusion body myositis. The antibody is associated with a more severe phenotype and is a potential target for future immunotherapies.

**REFERENCES:**

compare them to those of patients with anti-ARS antibody-positive polymyositis (PM) and DM with ILD, and investigate their association with clinical features.

**Methods:** Serum samples were collected from clinically active adult patients with anti-MDA5 antibody-positive DM (MDAS, n = 22), and anti-ARS antibody-positive PM and DM (ARS, n = 21) as well as healthy controls (HCs, n = 32). PM/DMS were classified according to the 2017 EULAR/ACR classification criteria for IIMs. Only patients with ILD diagnosed on high-resolution computed tomography findings and HCs were included. Patients complicated by infection or malignancy were excluded. The reporter cell lines (purchased from InvivoGen) which secrete embryonic alkaline phosphatase (SEAP) in response to IFN-α and SEAP in response to activation of IFNs and nuclear factor kappa B (NF-κB), respectively, were incubated with 20% (v/v) serum samples. The levels of SEAP and luciferase in supernatants were measured using a multi-mode microplate reader and their association with clinical features was statistically analyzed. IFNAR2-knockout reporter cells were also used.

**Results:** The sera of MDA5 patients demonstrated significantly higher IFN-α/β and IFN activities than those of ARS patients and HCs (p < 0.001 in all the comparisons), whereas no significant difference was detected in the NF-κB activities (Figure 1). The assays using IFNAR2-knockout reporter cells showed no significant difference in IRF or NF-κB activities. The serum ferritin levels in MDA5 patients were significantly higher than those in ARS patients (mean 679.7 ng/mL vs. 321.3 ng/mL, p = 0.03). The IFN-α/β and IRF activities induced by the MDA5 sera patients were correlated with the serum ferritin levels (r = 0.53 and 0.54, respectively), whereas they did not significantly correlate with the serum KL-6 levels, percent-predicted forced vital capacity (%FVC), or percent-predicted diffuse capacity of the lung for carbon monoxide (%DLCO).

**Conclusion:** IFN-α/β and IRF activities and their association with ferritin were demonstrated in sera of anti-MDA5 antibody-positive DM patients with ILD but not in those of anti-ARS-positive PM/DM patients with ILD. The present study suggests that activation of type I interferon pathway may be involved in the pathomechanisms of anti-MDA5 DM with ILD.

**Background:** Idiopathic inflammatory myopathies (IIM) or myositis are a group of chronic autoimmune disorders represented by lesions in muscle, skin, joints and lung. One of the most common autoantibodies with a prevalence of 25-35% is anti-Jo1, targeting histidyl-transfer RNA synthetase (HisRS). Importance of T-cells in disease is established by their presence at sites of inflammation such as the muscle. We have shown that upon stimulation of PBMCs with HisRS, CD4+ T-cells are activated and produce inflammatory cytokines. Genetic association of HLA-DRB1*03:01 further implicate the recognition of autoantigens by CD4+ T-cells. However, the presence of antigen-specific CD4+ T-cells has not yet been shown in patients with IIM.

**Objectives:** The aim of this project is to identify HisRS CD4+ T-cells using HLA Class-II tetramers (Tmr) and single T cell receptor (TCR) sequencing.

**Methods:** HLA-DRB1*03:01 monomers with selected HisRS- and tetanus peptides as controls were produced in E.coli. The peptides were covalently linked to the HLA b-chain via a flexible peptide linker. HLA-tetramers were assembled using a commercial APC or PE labeled streptavidin. The efficacy of Tmrs was validated upon stimulation of PBMCs from HLA-matched healthy controls with tetanus peptide. In parallel, upregulation of T cell activation markers such as PD-1, CD69, CD137 was also investigated. Next, we stimulated PBMCs from anti-Jo1 positive patients with IIM that were HLA-DRB1*03 (n=10) with both tetanus and HisRS peptides and cultured the cells for 6 days followed by tetramer staining. Fluorescence was performed for the detection of IFNγ and IL2 secretion and cultured cells and culture supernatants were collected for cytokine analysis using cytokine bead arrays. Summary of the workflow is presented in Figure 1.

**Results:** We detected HisRS+CD4+ T-cells from 5 out of 10 patients using tetramers upon stimulation with HisRS peptide. We detected increased IFNγ levels in the supernatants where Tmr+ cells were detected further supporting the activation of T-cells. HisRS+CD4+ T-cells from patients (n=5) were single cell sorted and TCR αβ chains were sequenced (n=58). A bioinformatics pipeline for the alignment and assembly of the TCR sequences, was developed and the clonality analysis revealed presence of expanded T cell clones in 4 out of 5 patients. Expanded T cells had high mean fluorescent intensity values (MFI) for HisRS tetramers, suggesting the responsiveness of autoreactive T-cells to HisRS.

**Conclusion:** IM are rare, chronic autoimmune disorders with no available cure. Previous studies indicate the importance of T cells in this disease. However, the phenotype and role of these cells in the disease pathogenesis has not been fully established. Our results indicate the presence of HisRS+CD4+ T-cells in IIM which will introduce the possibility of new targeted treatment approaches.

**Keywords:** Myositis, Targeted synthetic drugs, Cytokines and chemokines

**J. Venkovsky2, J. Feldman7, L. Mcconnachie2, B. Johnson2, Institute of Rheumatology, Rheumatology, Prague, Czech Republic; 2Virologists, Early Development, Durham, United States of America

**Background:** Dermatomyositis (DM), an idiopathic inflammatory myopathy, is a chronic and often debilitating condition characterized by a hallmark skin rash (e.g., Gottron’s sign and heliotrope rash) with perifascicular atrophy and subsequent muscle weakness [1]. The pathogenesis of DM involves dysregulation of Type I interferon (IFN-I) signalling and other cytokines (IFN-γ, IL-12, and IL-23). The kinases, TYK2 and JAK1, are essential for the signalling pathway of these cytokines. Brexpicitin, a selective and potent dual TYK2/JAK1 inhibitor is in development for the treatment of DM and is expected to reduce signalling of these cytokines, particularly IFN-I, and ameliorate the symptoms of disease.

**Objectives:** To evaluate the efficacy of brexpicitin in preventing IFN-I induced pathological changes characteristic of DM in human skeletal muscle and microvascular endothelial cells in vitro.

**Methods:** Human skeletal muscle myoblasts were cultured and differentiated into myotubes then treated with vehicle control or IFN-I (recombinant Human IFN
alpha A and Human IFN alpha D) to induce cellular damage. Myotubes were also preincubated for 1 hour with brepocitinib (1 μM or 130 nM, the latter is equivalent to the average free plasma concentration after administration of 30 mg once-daily) prior to IFN-I treatment. Immunofluorescence staining followed by image analysis to determine myosin 4 surface area were conducted after 48 hours of IFN-I treatment. Human dermal microvascular endothelial cells (HMEC-1) were cultured and, once vascular networks were established, cells were treated with IFN-I or vehicle control. Cells were also preincubated for 1 hour with brepocitinib as described above. Under light microscopy 9 hours after treatment, the number of nodes, master segment length, and total mesh area were analyzed. To determine statistical significance, one-way ANOVA followed by Tukey’s multiple comparison post-hoc analyses were performed.

Results: Myosin surface area was reduced by ~40%, relative to vehicle treated control, in myotubes exposed to IFN-I (p<0.0001). This cytokine induced damage was almost completely prevented by brepocitinib preincubation (both 130 nM and 1 μM) with mean myosin surface areas of 96% and 100% of the vehicle control, respectively. The differences between IFN-I treatment alone and brepocitinib were significant (p<0.0001 [1 μM] and P<0.001 [130 nM]). Similarly, HMEC-1 exposure to IFN-I significantly reduced the mean number of nodes, mean master segment length, and mean total mesh area by 47 to 50% relative to vehicle control (p<0.0001 nodes and segments, p<0.001 mesh area). With brepocitinib preincubation, this damage was prevented with the mean number of nodes, master segment lengths, and total mesh area ranging from 89 to 111% of vehicle control. These differences were statistically different from the IFN-I treatment at both brepocitinib concentrations and all endpoints (p<0.001 for all conditions).

Conclusion: One of the most debilitating aspects of DM is muscle weakness resulting from perifascicular atrophy leading to significant impacts on quality of life for these patients[2]. We report here the ability of brepocitinib to prevent IFN-I-induced damage in both myocytes and microvascularity in culture at clinically relevant concentrations, providing further pharmacologic rationale for brepocitinib in the treatment of DM.

REFERENCES:
leukemia. GSEA analysis also confirmed a downregulation of cell apoptosis processes in hyperexpanded clonotypes, a feature of T-FLG leukemia clones. **Conclusion:** Significant clonal expansion of CD68+ T cells in the blood was found in our IBM cohort compared to our age-matched healthy controls. Additionally, these hyperexpanded clonotypes have various T-LGL leukemia gene markers, in addition to elevated cytotoxic and T cell activation genes in comparison to their minimally expanded counterparts. These results highlight how the blood compartment of IBM, a progressive muscle disease, is important in IBM and how future studies and therapies should be targeting these aberrant blood CD68+ T cells.

**Background:** Ku-antibodies are one of the myositis-associated antibodies linked with muscle involvement in many connective tissue diseases. The histopathological pattern of Ku+ myositis is described diversely with inflammatory and necrotic aspects, however, a detailed morphological characterization of Ku+ myositis is still missing.

**Objectives:** The aim of the study was to analyze histopathological and transcriptional aspects of patients with Ku+ myositis to gain new insights in possible pathophysiological mechanisms.

**Methods:** 23 biopsy samples from patients with clinical and morphological signs of positive Ku-antibodies were studied by histopathology, immunohistochemistry, and quantitative polymerase chain reaction (qPCR) and compared with biopsies derived from non-disease controls (NDC) and immune-mediated necrotizing myositis (IMNM) at the Department of Neuropathology of Charité university hospital Berlin.

**Results:** Mean patient’s age was 55 years, 91% were women and the most common rheumatological diagnosis was overlap with systemic sclerosis (30%), followed by isolated myositis (26%) and overlap with primary Sjögren’s syndrome or rheumatoid arthritis (13% respectively). Creatine kinase elevation was present in 91% of the patients. Histopathologically, we noticed a broad phenotype spectrum with mild to severe myositis with predominantly MHC class I overexpression and milder MHC class II overexpression. 87% of the biopsies showed nuclear staining combined with inflammatory aspects of variable degree. Infiltrates were mainly CD68+ cells (average of 213 cells per 10 high power fields (HPF)), followed by CD3+ cells (76 cells/10 HPF), whereas CD20+ or CD138+ cells were rare (8 respectively 14 cells/10 HPF). Furthermore, we detected small vacuoles in 59% and large areas of p62+ aggregates in 62% of the biopsies. Similarly, aggregates of LC3 and myotilin were found in 60% and 76% respectively. Immunofluorescence staining showed co-localization of p62 and myotilin indicating protein aggregates and induction of autophagy pathways. P62 gene expression was neither elevated in Ku+ patients nor in IMNM patients compared to NDC (Figure 1A). SIGLEC1 gene expression was significantly elevated in Ku+ patients compared to IMNM patients and NDC (Figure 1B).

**Conclusion:** In this study, we defined a histopathological pattern of Ku+ myositis with predominant MHC class I expression, necrosis, small vacuoles and inflammation as well as peculiar p62+ and LC3+ aggregation in severely inflammatory biopsy samples. Whilst there definitely is a broad spectrum of presentation, MHC class I expression, necrosis and p62/LC3+ aggregates seem to be the defining aspects of the histopathological presentation.

**Figure 1.** Transcriptional analysis of LC3, P62 and SIGLEC1 Quantitative polymerase chain reaction was used to analyze the gene expression of LC3, P62 and SIGLEC1. Violin plots display fold-change versus non disease controls (NDC), calculated by [2^-(-ΔΔCT Ku+ patients/ΔΔCT NDC)].

**A** LC3 gene levels are elevated in Ku+ patients compared to IMNM (p<0.0015), whilst P62 levels do not differ from NDC.

**B** SIGLEC1 gene expression is significantly elevated in Ku+ patients compared to IMNM patients (p=0.0006) and NDC (p<0.0001).

**NEW INSIGHTS IN HISTOPATHOLOGICAL CHARACTERIZATION AND PATHOPHYSIOLOGICAL MECHANISMS OF KU-POSITIVE MYOSITIS**

**Keywords:** Systemic lupus erythematosus, Cytokines and chemokines, Myositis

S. Nakamura¹, Y. Okamoto¹, Y. Katsumata¹, M. Harigai², ¹Tokyo Women’s Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

**Background:** Type I interferon (IFN) plays a pivotal role in the pathogenesis of systemic lupus erythematosus (SLE) and dermatomyositis (DM)/polymyositis (PM) as typically evidenced by upregulation of type I IFN-stimulated genes (ISGs) in peripheral immune cells [1]. In addition, a distinct monocyte cytokine signature, which was induced by plasma from pediatric SLE patients and abrogated by Janus kinase (JAK) inhibition, was reported [2]. However, contribution of serum factors to expression of ISGs was not fully elucidated.

**Objectives:** To investigate the cytokine induction profile in multiple myeloid lineages by serum from patients with SLE or DM/PM using the whole blood stimulation system and identify the signaling pathway relevant to the monocyte cytokine signature.

**Methods:** Serum was collected from newly diagnosed, untreated, and clinically active adult patients with SLE (SLE group), anti-MDA5 antibody-positive DM (MDA5 group), and anti-aminocyt-3RNA synthetase (ARS)
antibody-positive DM/PM (ARS group), and healthy controls (HCs) (n = 10 for each group). Heparinized whole blood from healthy donors was incubated with control serum (10 v/v%), patient serum (10 v/v%), or IFN-γ in the presence of protein transport inhibitor cocktail for 6 hours. Red blood cells were lysed, and then leukocytes were fixed at a single step. Intracellular staining was performed and expression of 11 cytokines in CD14+ monocytes, CD1c+ dendritic cells (DCs), and CD123+ DCs were analyzed using flow cytometry. A cut-off level was determined by 2% positivity of each cytokine in unstimulated condition. For transcriptomic analyses, sorted CD14+ monocytes from healthy donors were incubated with serum (SLE, MDAS, ARS, or HCs), or IFN-γ (n = 3 for each group) for 4 hours, and bulk RNA-sequencing was performed using the Illumina NextSeq 500 platform. RNA-seq raw sequence reads analysis and pathway analysis were performed using the Strand NGS software. To evaluate significance of JAK-signal transducer and activator of transcription (STAT) pathway, whole blood from healthy donors was pre-incubated with upadacitinib, a JAK1 inhibitor, stimulated with patient serum for 6 hours, and analyzed for cytokine expression as described above.

Results: Serum from SLE and MDAS groups induced significantly higher monocyte chemotactic protein-1 (MCP1) and interleukin-1 receptor antagonist (IL-1RA) expression in CD14+ monocytes than serum from HCs (Figure 1). These monocyte cytokine signatures were closely resembled that induced by IFN-γ stimulation. Serum from ARS group did not induce any significant cytokine expression in CD14+ monocytes. No significant cytokine expression was observed in CD1c+ DCs or CD123+ DCs. RNA-seq demonstrated that 612 and 578 genes were upregulated (fold change >2 relative to control) following stimulation with serum from SLE and MDAS groups, respectively. In these upregulated genes, 383 genes were commonly upregulated across SLE and MDAS groups and IFN-γ. Pathway analysis revealed similar transcriptional profiles in SLE and MDAS groups; upregulated genes were most frequently involved in IFN-β and IFN-γ. Pathway analysis revealed similar transcriptional profiles in SLE and MDAS groups. Upadacitinib significantly abrogated the monocyte cytokine signature, and MCP1 and IL-1RA expression induced by serum from SLE and MDAS groups in a dose-dependent manner (p < 0.001 in all analyses).

Conclusion: These results suggest that serum factors in patients with active SLE and anti-MDAS antibody-positive DM can induce shared monocyte cytokine signature through type 1 IFN pathway. CD14+ monocytes ‘primed’ by serum might contribute to the pathogenesis of these diseases.

GENE ANALYSIS REVEALED THE USEFULNESS OF TRIPLE THERAPY WITH BARICITINIB, RITUXIMAB AND TACROLIMS FOR ANTI-MDAS ANTIBODY POSITIVE DERMATOMYOSITIS (MDAS-DM)

Keywords: Myositis

M. Sakamoto1, Y. Nakai1, Y. Sato1, Y. Koyama1. Japanese Red Cross Okayama Hospital, Division of Rheumatology, Center for Autoimmune Diseases, Okayama, Japan; *DNA Chip Research Inc, Medical Laboratory, Tokyo, Japan

Background: Anti-MDAS antibody positive dermatomyositis (MDAS-DM) is characterized by high mortality due to rapid progressive IILD. MDAS is a cytosolic protein and a family of RIG-I like receptor, which functions as a virus RNA sensor and induces the production of such as pro-inflammatory cytokines. It is unknown about the pathogenesis of MDAS-DM, it is notable that the similarities were reported between COVID-19 infection and MDAS-DM. It may suggest that there is a common underlying autoimmune inflammatory mechanism. We reported that in MDAS-DM, (1) RIG-I-like receptor signaling is enhanced and (2) antiviral responses such as type 1 IFN signaling are also enhanced as compared with anti-ARS similarity positive DM. (3) CREB binding protein is suppression of RIG-I-like and IFN signaling (EULAR2022, POS0390). We also found that a significant role for uncontrolled macrophage in the pathogenesis of IILD by our autopsy case. Recently, it has been reported that tacrolimus (TAC) and cyclophosphamide (CY) combination therapy (TC-Tx) has improved the prognosis of cases with early onset of the disease, but there are cases that cannot be saved. Therefore, we devised BRT therapy (BRT-Tx). The Tx combines baricitinib (BAR), which inhibits GM-CSF and IFN-mediating signaling and effectively suppresses uncontrolled macrophages, with rituximab (RTX) and TAC, which rapidly inhibits B and T cell interaction and ultimately prevents anti-MDAS antibody production.

Objectives: To determine the differences in gene expression between BRT and TC-Tx for MDAS-DM in peripheral blood

Methods: Total of 6 MDAS-DM (TC: 3, BRT: 3) were included and all of them had multiple poor prognostic factors. Peripheral whole blood was collected at just before and 2-3 months after the treatment. RNA was extracted, and quantified using a next-generation sequencer. Differentially Expressed Genes (DEGs) were identified by pre vs. post treatment. Gene Ontology (GO), clustering and Gene Set Variation Analysis (GSVA) were performed to DEGs. As one BRT case was added since our last year’s report, we also reanalyzed the surviving vs. fatal cases. The IFN signature was scored separately for Types 1, 2, and 3, and the changes between pre- and post-treatment were investigated.

Results: Two of three cases with TC died during treatment, while all three cases on BRT recovered. The cluster analysis of the DEGs separated deaths from survivors, not by type of treatment. Comparing surviving and dead cases, GO analysis revealed that the immune system via immunoglobulins and B cells was significantly suppressed in surviving cases. GO analysis of DEGs in each therapeutic group showed that expression of B cell-related genes such as lymphocyte proliferation and B cell receptor signaling pathway were significantly suppressed in BRT-Tx. On the other hand, TC-Tx significantly suppressed such pathways as cell proliferation and cell surface receptor signaling, and was less specific for the target cells than BRT-Tx. The changes in IFN signature score after treatment showed an increase in type 2 and 3 IFN scores in all fatal cases and an increase in type 1 IFN score in one fatal case.

Conclusion: BRT-Tx significantly suppressed gene expression associated with B cells, while TC-Tx was characterized by low specificity of therapeutic targets and suppression of total cell proliferation. Comparison of surviving and dead cases revealed that the combination of RTX contributed to the success of treatment, as suppression of the immune system mediated by immunoglobulins and B cells is the key for survival. Analysis of the IFN signature revealed an increase in IFN score after treatment in fatal cases, indicating that the combination of BAR is beneficial. The superiority of BRT-Tx seems clear from the fact that all patients survived with BRT-Tx while only three patients survived with TC-Tx.

Background: Gastrointestinal tract (GIT) is affected in approximately 90% of systemic sclerosis (SSc) patients from the earliest disease stages. Microbiota has recently emerged as an important environmental factor in SSc pathogenesis. 

Objectives: to test differences in the taxa composition of the fecal microbiota of very early SSc (VEDOSS) and established SSc patients.

Methods: Twenty-nine SSc patients classified according to the ACR/EULAR 2013 criteria (27 female, mean ± SD disease duration 13.1 ± 9.2 years) and 21 VEDOSS patients (19 female, mean ± SD disease duration 6.4 ± 5.2 years) were consecutively enrolled. For each patient, demographic, clinical and laboratoristic data were recorded and stool samples were collected. GI involvement and quality of life were investigated with UCLA-Gastrointestinal Tract Questionnaire (GIT)2.0 and Short Form Health Survey-36 (SF36).

Microbiota was assessed through 16S rRNA Next Generation Gene-Sequencing analysis.

Results: We found a different fecal microbiota profile between SSc and VEDOSS. In particular, classes of Bacilli and Choriobacteria, orders of Desulfovibrionales and Lactobacillales, the family of Eggerthellaceae, the genera Uncultured-Rhodospirillales, Lactobacillus, Streptococcus, Sutterella and Uncultured-Rhodospirillales were statistically significant increased in SSc, while the class of Clostridia, the family of Oscillospiraceae and the order UCG-002 were statistically significant increased in VEDOSS (Figure 1).

In SSc patients, we observed a significant positive association between the genus Lactobacillus and disease duration. In VEDOSS patients, we observed a significant positive correlation between the genera Bacilli and Lactobacillus genus and GIT.

Conclusion: Our data show, for the first time, a different microbiota composition in SSc and VEDOSS patients. In particular, we observed an increased abundance of genus Lactobacillus in SSc patients. However, no significant differences in the UCLA GIT score between the two groups were observed, confirming that GI symptoms also affect VEDOSS patients. Both these findings could suggest that the increased Lactobacillus values in SSc patients should raise the suspicion of more severe GIT involvement. This may account for the poor result of a lactobacillus-based probiotic treatment, usually observed in literature. It is necessary to confirm this data on larger groups of patients in the two phases of the disease.

Biomarker concentrations given in ng/ml; significant differences of concentrations between SSc and HC without or after stimulation (with TGF-β or IL-17, respectively) with * p-value < 0.05 or ** p-value < 0.01

Conclusion: Skin fibroblasts in SSc patients showed significantly stronger pro-inflammatory and pro-fibrotic properties compared with healthy controls as an indication of the fibro-inflammatory character of the disease. Furthermore, the significant increase of the expression of IL-6, MCP-1, procollagen and the decrease of the anti-fibrotic efficient protein MMP-1 after IL-17 stimulation suggest SSc-IL-17 as a well promising target in SSc.

Background: Systemic Sclerosis (SSc) is an autoimmune disease characterized by excessive fibrosis, inflammation and vasculopathy of the skin and internal organs. Interstitial lung disease (ILD) is the most important cause of mortality. Multiple autoantibodies (Abs) against nuclear proteins are present in >95% of patients. Anti-Topoisomerase-I (ATA), anti-CENP-B (ACA) and anti-RNA-polymerase-III (RNAP3) Abs are included in the 2013 SSc ACR/EULAR classification criteria. The detection of additional Abs is of interest to identify seronegative cases or specific clinical phenotypes. The particle-based-multi-analyte technology (PMAT) is a multiplexed system based on antigen covered paramagnetic particles with unique signatures. It allows to simultaneously obtain different autoantibody results.

Objectives: To evaluate the clinical performance of PMAT-Apta in a cohort of SSc patients from Hospital Clinic de Barcelona.

Methods: Study cohort includes serum samples of patients with SSc (n=138), disease controls with other autoimmune diseases (n=205) and healthy blood donors (n=25). Demographic characteristics and clinical manifestations of patients were collected. SSc specific (ATA, ACA or RNAP3) or SSc associated (Ro52, U1-RNP, Ku, Th/To (Rpp25 and Rpp38), Fibrillarin, Pm/Scl, BICD2, MIT3, Mup44, PUF60 (isoforms 1, 2 and 6), RNPC3r, RNPC3 (peptide 1, 2, 3, 4 and 5), RuvBL1/2, SMN1 and TERF1) Abs were tested on Aptiva by PMAT technology (Werfen, San Diego, USA). The prevalence of Abs was measured based on the manufacturer’s recommended cut-offs. CTD-Essential has calibrated units (FLU) whereas other novel biomarkers were RUO (MFI). Associations between categorical variables were determined with Fisher’s exact test. The relative measure of an effect was expressed by the odds ratio and the 95% CI when considering Ab positivity as the exposure. Results with p values <0.05 were considered statistically significant.

Results: From SSc patients, 109/138 (79.0%) were positive for ACA (n=71; 51.4%), ATA (n=29; 21.0%), RNAP3 (n=7; 5.1%) or double positive ACA-ATA (n=2; 1.4%) Abs, while the remaining 29/138 (21.0%) were negative for these three Abs. Nineteen of the 29 (65.5%) negative patients were also negative for all tested novel biomarkers. In 10/29 (34.6%) either single or multi-positivity was observed for anti-Pm/Scl, U1-RNP, Th/To (Rpp25 and Rpp38), TERF1 and Ro52 Abs. Specificity for all SSc related biomarkers was over 93.0%, MT3 and Ro52 were the most prevalent non SSc criteria Abs (17.4% and 16.6%, respectively). As expected, ACA, ATA and RNAP3 previously known associations with specific cutaneous phenotype and ATA and RNAP3 with the presence of ILD were confirmed (Table 1). Interestingly, Rpp38 and RubBL1 were more frequently found in patients with ILD. Additionally, PUF60 isoform 6 was associated with the presence of diffuse cutaneous phenotype whereas TERF1 was more prevalent in patients with d:toplastic dyskinesia. We did not find any association between any of the Abs studied and neoplasia, cardiac arrhythmias or conduction disturbances, pericarditis or myocardial damage, myositis, pulmonary hypertension or esophageal motility disorders.

Conclusion: In our SSc cohort, PMAT-Apta showed a proper specificity and represents a suitable option for patients’ evaluation. Confirmation of promising clinical associations for novel markers PUF60 (isoform 1 and 6), FHL1, RubBL1 and TERF1 in larger SSc cohorts is warranted.
Background: Connective tissue disease-associated interstitial lung disease (CTD-ILD) is a severe complication of rheumatic and musculoskeletal diseases, e.g. rheumatoid arthritis (RA), dermatomyositis (DM), systemic sclerosis (SSc) and so on. CTD-ILD is a heterogeneous syndrome driven by different diseases and cell types. This complexity provides a challenging field for elucidating the mechanism of the disease. Although some patients with CTD-ILD develop progressive fibrosing interstitial lung disease (PF-ILD) like as other I LD despite immunosuppressive treatment, it is difficult to predict which patients develop PF-ILD before treatment.

Objectives: The objective of this study is to find characteristics of immune cells and predictive biomarkers of PF-ILD in CTD-ILD patients.

Methods: We collected BALF and blood from 30 CTD-ILD and 12 idiopathic interstitial pneumonia (IIP) patients before treatment. Twelve out of 42 patients fulfilled PF-ILD criteria[1] in 1 year period. PF-ILD patients included 3 RA, 2 DM, 2 Sjögren syndrome, 1 ANCA-associated vasculitis, and 4 IIP patients. We applied Seq-Well, a portable platform of single-cell RNA sequencing[2], to analyze gene expressions in immune cells in BALF and blood. We compared the distribution of immune cells and differential gene expressions in BALF and blood between PF-ILD patients and patients without PF-ILD in CTD-ILD and IIP patients.

Results: We found that alveolar macrophages are the most abundant cell types in BALF of PF-ILD patients. We further classified alveolar macrophages and neutrophils into more detailed subsets based on their gene expression patterns and compared them between PF-ILD and patients without PF-ILD. In PF-ILD patients, we found increased Cxcl10, Cxcl8 alveolar macrophages and complement activation associated genes were upregulated in BALF. Moreover, we found increased interferon-induced proteins with tetracopeptide repeats (Ifit1), Mmp-9 and immature neutrophils, which were reported to be associated with severe COVID-19 pneumonia[3], in the blood of PF-ILD patients. Differentially expressed gene analysis revealed high levels of high mobility group box (HMBG)-2, IL-1β, and complement activation associated genes in alveolar macrophages in PF-ILD patients.

Conclusion: Alveolar macrophage phenotypes were changed in BALF while neutrophil phenotypes were changed in the blood of PF-ILD in CTD-ILD and IIP patients, which are consistent with the characteristics of severe COVID-19 pneumonia patients, suggesting common pathological pathways of lung fibrosis. We propose the hypothesis that alveolar macrophage phenotypic changes lead to complement and cytokine/chemokine mediated neutrophil activation and progression of PF-ILD (Figure 1). These cell subpopulations and up-regulated genes would be potential biomarkers or therapeutic target of PF-ILD in CTD-ILD patients.

Accordingly, BMPs expression and BMPs-pathway activation were exacerbated in CSE KO tenocytes compared to WT tenocytes. The protective role of CSE-H$_2$S was confirmed in vivo. Indeed, in aged mice, micro computer tomography revealed exacerbated Achilles' tendon calcification in CSE KO mice compared to WT. Interestingly, CSE deficiency led to reduced biomechanical strength, as the dynamic Young's modulus was significantly decreased upon increased tendon displacement. Furthermore, using a tenotomy model of CT, we found an inverse correlation between CSE expression and calcification in tendons. This was confirmed in human tendons from CT patients, which exhibited decreased CSE expression where calcification was present. In parallel experiments, we found that calcification in tenocytes was significantly reduced by addition of BAPN, a pan-inhibitor of lysyl oxidases (LOX(L)) enzymes. LOX(L) family includes 5 enzymes LOX and LOX1-4, catalysing elastin and collagen cross-links. We identified a pan-inhibitor of lysyl oxidases (LOX(L)) enzymes. LOX(L) family includes 5 enzymes LOX and LOX1-4, catalysing elastin and collagen cross-links. We then investigated if the anti-calcifying effect of H$_2$S in CT could be mediated by inhibition of LOX(L). Indeed, in CM-stimulated tenocytes we found that H$_2$S impacts both LOX/LOX2 expression (as CSE deficiency increased LOX/LOX2 gene expression) and LOX(L) activity (as CSE deficiency increased LOX(L) activity and conversely H$_2$S dose-dependently inhibited LOX(L) activity in WT tenocytes. Finally, in vivo we discovered that, CSE was inversely correlated with calcification and LOX and LOXL2 expression in mouse and human tendons.

Conclusion: Altogether, our results suggest that increasing H$_2$S levels in tenocytes could represent a future strategy to prevent or decrease calcification in CT, likely via down-modulation of LOX(L) expression and activity.

Background: Anti-fibrotic drugs aim at slowing disease progression in patients with fibrosing interstitial lung disease (ILD). Currently, only repeated pulmonary function tests and/or serial chest high resolution computed tomography (HRCT) scans spanning long periods can identify treatment responders. Imaging omics data (‘radiomics’) from HRCT scans, which integrate pathological physiologic information of the whole lung, may provide a powerful tool not only for prediction of disease progression as shown previously, but also for timely stratification of treatment response on an individual base.[1].

Objectives: To explore the potential of HRCT-based radiomics for stratification of treatment response to an established anti-fibrotic drug in a preclinical model of fibrosing ILD.

Methods: Fibrosing ILD was induced in mice by intratracheal instillation of 2 U/kg bleomycin on day 0. Treatment with (a) the (non)receptor tyrosine kinase inhibitor nintedanib at 60 mg/kg q.d. (n=10) or (b) vehicle-only (n=13) q.d. was administered by gavage from day 7 to 21. Lung pre- and post-treatment MicroCT scans were acquired at 35 μm resolution from each mouse. Lung tissue was collected post-mortem on day 21. Radiomic features (n=1386) were calculated from semi-automatically defined 3D lung volumes using the in-house developed software Z-Rad. Calculation of our composite quantitative radiomic risk score (qRISSc), developed for risk stratification of systemic sclerosis patients with ILD, was performed as previously described.[1]. Changes between pre- and post-treatment conditions (a.k.a. qRISSc) were used to stratify treatment response. Algorithmic scoring was used to evaluate severity of fibrosis. Markers of fibrosis and inflammation, as well as drug-associated targets, were assessed by gene expression profiling and immunostainings. Lung probe profiles were acquired by mass spectrometry in data-independent acquisition mode using a nanoLC-MS/MS workflow. Analysis of differentially expressed proteins and pathway enrichment were performed using R packages ‘limma’ and ‘clusterProfiler’, respectively.

Results: Post-treatment, non-omics readouts showed that response to treatment was heterogeneous with varied inter-individual responses. Yet, time-resolved radiomics analysis, capturing the individual pre- and post-treatment disease status, reliably allowed the detection of treatment response. A delta qRISSc threshold was established to distinguish responders from non-responders. Immunostainings of corresponding tissue revealed reduced infiltrates of αSMA+ myofibroblasts and F4/80+ macrophages in responders. In addition, transcriptional levels of fibrotic (Col1α1, Col3α1, Ftn1), inflammatory (Ccl2, Il6), and nintedanib-associated (Tgfβ1, Timp1, Cxcl1) targets were lower in these samples. Differential protein expression analysis demonstrated that protein expression downregulated in responders were enriched in pathways related to fibrosing ILD pathophysiology (Figure 1A). To identify a molecular basis of delta qRISSc, we performed correlation analysis to the proteome profiles of all samples, including controls. Thereby, qRISSc increase (्वon-response) strongly correlated with activation of pathways related to fibrosis and nintedanib mode of action (Figure 1B). These results indicate that radiomic signature changes reflect drug response on a molecular level.

Figure 1. Reactome pathway enrichment analysis. (A) Differentially expressed proteins down-regulated in treatment responders (log$_{2}$FC<-0.3, p<0.05). (B) Proteins correlated with delta qRISSc (Spearman’s $p<$0.5, $p<$0.05).

Conclusion: Upon clinical validation, HRCT-based radiomics may provide a powerful tool for early distinction of patients benefiting from anti-fibrotic therapy and thus serve as a foundation for a more individualized and improved patient management.

5University Medical Center Groningen, Pulmonary Diseases and Tuberculosis, Groningen, Netherlands

Background: Systemic sclerosis-interstitial lung disease (SSc-ILD) is a severe complication that affects most SSc patients causing one-third of SSc-related
There is an unmet need for predictive biomarkers of ILD to identify patients at risk, prior to clinical manifestation. Activated IFN-induced chemokines and proteins are implicated in the early inflammatory phase of SSC-ILD [2]. CXCL10 is an IFN-induced chemokine that is important in the chemotraction of inflammatory cells in SSc-affected tissue [3,4].

**Objectives:** We investigated CXCL10 serum levels in SSc, SSc-ILD, and healthy controls (HCs) to understand whether CXCL10 levels differ between groups and potentially play a role in ILD pathogenesis. We also sought whether CXCL10 levels in serum mirror those in the lungs to investigate whether systemic levels reflect those of the affected organ locally. The transcriptomic study investigated CXCL10 expression in inflammatory SSc-ILD lung sections compared to fibrotic sections to show whether CXCL10 is more prominent in early disease. We also assessed whether CXCL10 could serve as a predictive biomarker for the new onset of SSc-ILD. Finally, to better comprehend the clinical observations, in vitro studies aimed to reveal the inflammatory/fibrotic effects of local and systemic fluids of SSc-ILD patients compared to SSc without ILD and controls.

**Methods:** One-hundred sixty-five SSc patients (SSc-ILD = 41) and 13 age- and sex-matched HCs were retrospectively followed from 2013 to 2020. Furthermore, 15 SSc patients (SSc-ILD = 7) were prospectively recruited for bronchoalveolar lavage (BAL) procedure. CXCL10 mRNA and protein levels were measured on various levels (serum, BAL, and SSc-ILD lung tissues) by ELISA and nanoString transcriptic assay, Spearman’s correlations were performed between CXCL10 levels in serum and lungs. Kaplan-Meier analyses were performed to evaluate predictability of SSc-ILD using CXCL10 levels at baseline. Human primary lung fibroblasts were treated with BAL fluid or serum from SSc without ILD or SSc-ILD patients. After stimulation, inflammatory (IL-6 and CXCL10) and fibrotic (α-SMA and TGF-β) genes were assessed using qPCR.

**Results:** At baseline, serum CXCL10 was significantly higher in SSc-ILD patients compared to SSc without ILD (Median (IQR): 126 (66-282) vs 79 (50-122), p = 0.004) and HCs [Median (IQR): vs. 4 (4-9), p < 0.0001]. BAL fluid CXCL10 levels in SSc-ILD patients were not significantly higher than those in SSc without ILD [Median (IQR): 457 (42-725) vs 134 (72-333), p = 0.2]. However, BAL CXCL10 levels significantly correlated with serum levels (r = 0.7, p = 0.007). The nanoString showed that CXCL10 gene expression is significantly higher in inflammatory lung tissue compared to fibrotic tissue (fold change = 2.3, p = 0.029). Kaplan-Meier survival analysis (Figure 1) revealed that CXCL10 levels >3rd quartile at baseline in SSc patients significantly predicted new onset of ILD (p = 0.023). The in vitro studies showed that CXCL10 and IL-6 were significantly overexpressed in lung fibroblasts treated with SSc-ILD BAL fluid or serum compared to SSc without ILD [CXCL10: p = 0.0043; p = 0.0087); (IL-6: p = 0.0022; p = 0.0043), respectively] and controls (all: p = 0.0022). On the contrary, TGF-β and α-SMA expression did not change after treatment in all groups.

**Conclusion:** CXCL10 is a potential predictive biomarker for new onset of ILD in SSc patients. Further longitudinal studies with larger sample sizes are needed to verify the capability of CXCL10 to predict ILD. Additionally, our nanoString and in vitro data suggest that CXCL10 may play a significant role in the early development of SSc-ILD which might be amenable to therapeutic interventions.

**POS0620 BI 685509: A POTENT ACTIVATOR OF SOLUBLE GUANYLATE CYCLASE (sGC) AS A NOVEL TREATMENT OF VASCULOPATHY AND FIBROSIS IN SYSTEMIC SCLEROSIS (SSC)**

**Keywords:** Systemic sclerosis, Animal models, Cell biology

**Objectives:** To evaluate the efficacy of the potent sGC activator BI 685509 in cellular and in vivo models of SSc pathobiology.

**Methods:** Human dermal microvascular endothelial cells (HDMVEC) were cultured in normoxic or 1% O2 conditions in the presence of BI 685509 ranging in doses from 0.04 to 10 µM. After 48 hrs, culture supernatant was collected and the level of CXCL4 was measured. For the bleomycin induced skin and lung fibrosis studies, adult female C57Bl/6 mice were used. Mice received intradermal injections of bleomycin every other day for six weeks or a single intratracheal injection. Mice were treated with BI 685509, Riociguat or Nintedanib daily beginning at day 21 (dermal) or 14 (lung) after initiation of bleomycin injection. At 6 (dermal) or 4 (lung) weeks post treatment initiation skin or lung samples were analyzed via histologic analysis for various cellular and biochemical markers of tissue fibrosis.

**Results:** In HDMVEC, hypoxia induced production of the tissue remodeling factor TGFβ was determined. Human platelet rich plasma (PRP) was isolated and activated for 5 minutes with ADP in the presence of BI 685509 or Riociguat at doses of 0.1, 10 or 100 µM. Following activation, supernatants were collected and the level of CXCL4 was measured. For the bleomycin induced skin and lung fibrosis studies, adult female C57Bl/6 mice were used. Mice received intradermal injections of bleomycin every other day for six weeks or a single intratracheal injection. Mice were treated with BI 685509, Riociguat or Nintedanib daily beginning at day 21 (dermal) or 14 (lung) after initiation of bleomycin injection. At 6 (dermal) or 4 (lung) weeks post treatment initiation skin or lung samples were analyzed via histologic analysis for various cellular and biochemical markers of tissue fibrosis.

**Conclusion:** To evaluate the efficacy of the potent sGC activator BI 685509 in cellular and in vivo models of SSc pathobiology.

**Disclosure of Interests:** None declared, Johanna Westra: None declared, Douwe J Mulder Grant/ research support from: Dr DJ Mulder as an employee of the UMC received research grants from Sanofi which were paid to the UMCG.

**DOI:** 10.1136/annrhemud-2023-eular.1535
CXCL4 was effectively inhibited in activated PRP treated with the sGC activator BI 685509 whereas minimal inhibition was observed in samples treated with the sGC stimulator Ricoglut. Inhibition of CXCL4 production in activated human platelet rich plasma treated with the sGC activator BI 685509.

Figure 1.

Conclusion: Collectively, these results point to the use of the sGC activator BI 685509 as a novel treatment for SSC and suggests potential superior effects vs. sGC stimulators like Ricoglut in this autoimmune disease.

EFFECTS OF B CELL DEPLETION BY CD19-TARGETED CAR-T CELLS IN A MURINE MODEL OF SYSTEMIC SCLEROSIS

Keywords: Animal models, Systemic sclerosis

1Cochin Hospital, Rheumatology, Paris, France; 2Institut Cochin, INSERM U1016, Paris, France; 3Institut Pasteur, INSERM U1223, Paris, France

Background: Chimeric antigen receptor (CAR) T-cells represent a potentially curative strategy for B cell malignancies. A first successful clinical experience has been reported in systemic lupus erythematosus, suggesting that CD19-targeted CAR-T cell transfer was feasible and tolerable [1].

Objectives: Since systemic sclerosis (SSc) and SLE are both severe diseases sharing B cell implication in their pathogenesis, we aimed at assessing the efficacy and tolerance of two B cell depletion strategies, including one with CD19-targeted CAR-T cells, in a preclinical model mimicking the severe lung damages observed in SSc.

Methods: B cell depletion strategies were evaluated in the Fra-2 transgenic (Tg) mouse model. We considered a first group of 16 untreated mice, a second group of 15 mice receiving a single intravenous (IV) dose (50 µg) of anti-CD20 monoclonal antibody (mAb) at day 1 and a third group of 8 mice receiving 50 µg anti-CD20 mAb IV at day 1 followed by the IV injection of 2×10^6 CD19-targeted CAR-T cells at day 3. After 6 weeks, different validated markers of inflammation, lung fibrosis and pulmonary vascular remodeling were assessed.

Results: Following treatment with anti-CD20 mAb, CD19 expression was significantly decreased in peripheral blood and lesional lungs of Fra-2 Tg mice by 59% (p<0.001) and 40% (p=0.019), respectively, compared to control Fra-2. B cell depletion was even more pronounced in mice treated with CD19-targeted CAR-T cells: CD19 expression was decreased in peripheral blood and lungs of Fra-2 Tg mice by 92% (p<0.001) and 85% (p<0.001), respectively, compared to control Fra-2. CAR-T cell infiltration increased mortality in Fra-2 Tg mice (Figure 1A). In line with the above findings, mice receiving CD19-targeted CAR-T cells displayed a significant increase in lung density (mean difference of 55±28 Hounsfield Units, p=0.038) (Figure 1B-C) and a marked reduction of functional residual capacity (mean difference of 11.93±4.44 µg/mL, p=0.020) (Figure 1D). Histological fibrosis score (mean difference of 1.74±0.48, p=0.002) (Figure 1E-F) and right ventricular systolic pressure mean difference 8.52±2.70 mmHg, p=0.013) (Figure 1G). CAR-T cells accumulated in lesional lungs and promoted T infiltration and activation: a significant increase of CD4+ effector memory T cells was observed in CD19-targeted CAR-T cell-treated Fra-2 Tg mice compared to Fc control Fra-2 Tg mice (mean difference of 52±9%, p=0.019). Moreover, the fraction of CD69 and PD1-expressing cells was significantly increased within the CD4+ and CD8+ subsets in the lung of CD19-targeted CAR-T cell-treated Fra-2 Tg mice. Treatment with anti-CD20 mAb in monotherapy had no impact on lung inflammation-driven fibrosis and pulmonary hypertension.

Conclusion: B-cell therapies failed to show efficacy in the Fra2 transgenic mice. The exacerbated Fra-2 lung inflammatory burden stimulated accumulation and expansion of activated CD19-targeted CAR-T cells, secondarily inducing T-cell activation and systemic inflammation, finally leading to disease worsening.

BIFIDOBACTERIUM LONGUM RAPO AMELIORATES DERMAL AND PULMONARY FIBROSIS THROUGH THE MODULATION OF GUT MICROBIOTA AND IMMUNE RESPONSE IN BLEOMYCIN-INDUCED SYSTEMIC SCLEROSIS IN MICE

Keywords: Systemic sclerosis, -Omics, Lungs

1Cochin Hospital, Rheumatology, Paris, France; 2Institut Cochin, INSERM U1016, Paris, France; 3Institut Pasteur, INSERM U1223, Paris, France

Background: Bifidobacterium longum RaPo (B. longum RaPo) protects from bleomycin-induced dermal and pulmonary fibrosis in a murine model through the modulation of gut microbiota and immune response.

Objectives: To investigate the impact of B. longum RaPo on bleomycin-induced systemic sclerosis (SSc).

Methods: Female C57BL/6 mice were treated with bleomycin (BLM) to induce SSc-like pathology. Mice were divided into 3 groups: control (n=8), B. longum RaPo treated (n=8), and B. longumRaPo+Supplemented (n=8). The effects on pulmonary function, lung structure, and immune response were assessed.

Results: B. longum RaPo treatment significantly improved pulmonary function, reduced lung fibrosis, and moderated the immune response compared to the control group. The combination of B. longum RaPo with probiotics further enhanced these protective effects.

Conclusion: B. longum RaPo ameliorates bleomycin-induced SSc-like pathology through the modulation of gut microbiota and immune response.
Methods: We performed an immunoglobulin (Ig) M antibody microarray against 384 microbial species in the serum from SSc patients and healthy control (HC). Then, the antifibrotic effect of candidate microbial species was investigated using a bleomycin (BLM)-induced fibrosis model in mice.

Results: Bifidobacterium (B.) longum RAPO, which was less abundant in the serum of patients with SSc than HC, alleviated BLM-induced skin and lung fibrosis in mice. The administration of B. longum RAPO normalized fecal microbial diversity with an increase in short-chain fatty acid-producing bacteria. Moreover, infiltrated inflammatory monocytes or macrophages in the spleen, the skin, and bronchoalveolar lavage of BLM-injected mice were significantly reduced by treating B. longum RAPO. In vitro, B. longum RAPO downregulated LPS-induced inflammatory cytokines gene expression in mouse macrophage cell Raw 264.7.

Conclusion: B. longum RAPO could have an antifibrotic effect on skin and lung fibrosis through gut microbial restoration and macrophage regulation in BLM-induced fibrosis mice. Microbial intervention would be a potential option for SSc treatment.

[1]. In addition, a strong correlation between bag3 gene expression and patients’ survival was found in several types of fibrotic tumors [1].

**Objectives:** Our aim was to evaluate the presence of BAG3 in the serum of patients with SSC and to investigate whether circulating levels of BAG3 could have any relationship with different SSC subsets and disease features.

**Methods:** We enrolled SSC patients, all classified according to the ACR-EULAR criteria. Videocapillaroscopy (NVC) was performed at the time of serum collection. Lung involvement was assessed by spirometry and high-resolution chest CT. Patients were classified into 3 subgroups (no ILD, limited ILD, and extensive ILD). According to the diagram described by Goh et al. [2], SSC disease activity was assessed according to the activity indices defined by the EUSTAR score [3]. Evaluation of BAG3 protein in serum samples was performed by a sandwich ELISA assay.

**Results:** The study cohort included 106 SSC patients (47 were classified with lcSSc and 59 with dcSSc) and 100 sex and age matched healthy controls (HC). Serum levels of BAG3 were significantly higher in SSC patients (mean value 85.3 pg/mL, 95% confidence interval CI 47.2-123.4) when compared with HC (0.68 pg/mL, 95%CI 0.13-1.23) (p=0.001). When analyzed according to disease subset, dcSSc patients showed values (143.3 pg/mL, 95%CI 78-208.5) significantly higher and lcSSc patients (8.7 pg/mL, 95%CI 1.8-15.9) (p<0.001). No correlation was found between BAG3 levels and digital ulcers, mRSS and disease activity. Conversely, BAG3 values positively correlated with the extent of lung damage (237.8 pg/mL, 95%CI 131.2-344 in the extensive lung disease vs 16.3%CI 7.5-25.3 in the limited). Finally, BAG3 values were significantly higher in patients with late NVC pattern in comparison with NVC pattern early/active (p=0.0008).

**Conclusion:** Recent studies have highlighted a central role of extracellular BAG3 in maintaining the tumour microenvironment, as well as in the development of fibrosis in neoplastic tissues. To our knowledge, the presence of BAG3 in the serum of patients with SSC has never been described in the literature. Serum levels of BAG3 were found to be significantly higher in the dcSSc, mostly in those with lung involvement. This is not surprising since the diffuse form of disease has more extensive fibrosis, both in the skin and lung, than lcSSc. Accordingly, BAG3 values correlated with the late pattern at NVC, the one most frequently associated with the more advanced and fibrotic stages of the disease. Conversely, serum BAG3 values did not correlate with disease activity, since these scores reflect the evolution and progression of disease rather than the extent of fibrosis. Indeed, the close correlation between BAG3 levels and the more fibrotic features of the disease, suggests that BAG3 might be a new promising marker of fibrosis.

**EFFECTS OF DIFFERENTIATION STAGES OF HEALTHY AND SSC MACROPHAGES ON THE 3D CARDIAC MICROTISSUE (MT) CONTRACTILITY.**

**Keywords:** Cardiovascular disease, Heart, Systemic sclerosis

**L. Provenzale**, A. Hukara1, I. Kocherova1, E. Pacher1, A. Laimbacher1, O. Distler1, P. Blyszczuk1, G. Kania1, Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, University of Zurich, Schlieren, Switzerland

**Background:** Activated cardiac fibroblasts, key regulators of cardiac fibrosis, control contraction of human fibrotic cardiac microtissues (MT)[1]. Macrophages regulate fibrotic process by interfering with the extracellular matrix (ECM) turnover. The heart is one of the primary organs affected in systemic sclerosis (SSc).

**Objectives:** To study the role of healthy donor- and SSC patient-derived macrophages in the functions of 3 dimensional (D) human cardiac MT fibrosis model.

**Methods:** CD14+ blood-derived monocytes from healthy controls (HC) and SSC patients were isolated and differentiated into human monocyte-derived macrophages (hMDM) using human monocyte colony-stimulating factor (h-M-CSF). A timeline of macrophage differentiation stages was performed by incubation of the CD14+ cells for 1,3,5 and 7 days (d) with h-M-CSF. One MT was generated by 4’000 human induced pluripotent stem cell-derived cardiomyocytes (iCM), 1’000 human cardiac fibroblasts (HCF) and 1’000 HC or SSc HMDM, mixed in a ratio 4:1 (HC-HMDM/iCM:HC-FMT or SSC-hMDM/iCM:H-CF-MT), and formed by self-assembling in plates with ultra-low-attachment surfaces. Control MTs were composed with iCM/HCF in a ratio 4:1:2 (iCM:H-CF-MT). Two days after MT assembly, the fibrotic condition was induced with transforming growth factor (TGF-β1) for 10d. Contraction of each MT was assessed by recording videos, applying MUSCLEMOTION[2] and subsequent evaluation by relaxation time (ms), contraction amplitude (a.u.), contraction duration (ms), time-to-peak (ms) and beating rate (bpm). The level of fibrosis was analyzed by several levels: mRNA by qPCR, ELISA to measure secreted pro-collagen-Ix1, immunohistochemistry (IHC) using Sirius Red to visualize collagen depositions and degree of fibrosis. Apoptosis was assessed using Caspase-3/7 assay.

**Results:** Control-iCM:HCF-MTs (n=23-49), following TGF-β1 stimulation, revealed a shorter contraction duration (p<0.01) and a lower contraction amplitude (p<0.001) but not altered contraction duration (p=0.509) and contraction amplitude (p=0.7298) compared to untreated-iCM:HCF-MTs. Interestingly, untreated-SSc-hMDM/iCM:HCF-MTs showed a shorter time-to-peak (p<0.0001), lower beating rate (p<0.01) and higher contraction amplitude (p<0.01) compared to untreated-HC-HMDM/iCM:HCF-MTs (n=41-81, both conditions 3d). Next, TGF-β1-stimulated SSc-hMDM/iCM:HCF-MTs exhibited a lower contraction duration (p<0.01) and contraction amplitude (p<0.0001), shorter relaxation time (p<0.0001), and higher beating rate (p<0.0001) compared to TGF-β1-stimulated HC-HMDM/iCM:HCF-MTs (n=33-42, both conditions 1d). Upon TGF-β1-stimulation, control-iCM:HCF-MTs showed significantly increased profibrotic genes: ACTA2 (p<0.001) and COL1A1 (p<0.01) (n=4-5), secreted human pro-collagen-Ix1 (n=9-10, p<0.0001), and formed visible collagen-rich fibrotic ring. Remarkably, under fibrotic conditions, addition of HC or SSc HMDM into iCM:HCF-MTs resulted in lower mRNA expression of ACTA2 (n=4-5, p<0.05, both conditions 7d) and COL1A1 (n=4-5, p<0.05, both conditions 7d), lower excretion of human pro-collagen-Ix1 protein (n=9-10, p<0.0001, both conditions 7d) and lack of collagen-rich fibrotic ring compared to control-iCM:HCF-MTs. Importantly, independently of culture duration of HC or SSc HMDM, before MT assembly, a similar reduction in profibrotic gene and protein expression was observed. Lastly, the level of apoptosis was similar in all three undifferentiated or TGF-β1-stimulated MTs types.

**Conclusion:** For the first time, the combination of iCM, HCF and HMDM in a 3D cardiac fibrotic MT model has been established and investigated. Under fibrotic conditions, addition of HC- but not SSc-hMDM into iCM:HCF-MTs influenced MT contractility. Importantly, both HC- and SSc-hMDM reduced TGF-β1-induced fibrotic responses.

PERTURBED LIPID METABOLISM IS A CENTRAL METABOLIC REPROGRAMMING HUB IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, -omics, Skin

B. Burja1,2, H. Rehrauer3, D. Paul4, M. Whitfield5, M. Tomsic6, Z. Rotar6, M. Robinson5, O. Distler1, K. Lakota7, M. Frank Bertonecz7, 1Center of Experimental Rheumatology, University of Zurich, Zurich, Switzerland; 2University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 3Functional Genomics Center Zurich, ETH Zurich and University of Zurich, Zurich, Switzerland; 4Faculty of Science, Department of Molecular Life Sciences, University of Zurich, Zurich, Switzerland; 5Geisel School of Medicine, Biomedical Data Science, Hanover, United States of America; 6BioMed X, Institute, Heidelberg, Germany

Background: Perturbed cellular metabolism has been increasingly associated with fibroblast activation in fibrosis. A deeper understanding of metabolic rewiring might help to unravel the interplay between the metabolic and fibrotic pathways in systemic sclerosis (SSc).

Objectives: We aimed to identify transcriptomic alterations in metabolic pathway-related genes in fibrotic SSc skin and unravel whether fibroblasts could contribute to the perturbed skin metabolic networks in SSc.

Methods: We integrated transcriptomic microarray data from skin (clinically affected forearm and non-affected back skin) of 76 SSc patients and 26 healthy controls (HC, forearm skin) from three distinct cohorts (GSE:45485, 59785, 9285/32413). Differentially expressed (DE) genes (FDR<0.05) between healthy and SSc skin were identified using the limma package. The supervised gene set enrichment analysis (GSEA) was based on DE genes using the clusterProfiler package, focusing on metabolic pathways. Transcriptional changes in primary skin fibroblasts were linked to the TGFβ-induced changes in transcriptomes of primary human skin fibroblasts, measured by RNA-seq and scRNA-seq. For these experiments, cultured healthy skin fibroblasts were treated or not with TGFβ for 24h.

Results: Pathway enrichment analysis of DE gene in skin transcriptomes identified multiple alterations of metabolic pathways in SSc skin (Figure 1A) compared to healthy skin, pointing to enhanced pyrimidine/folate metabolism and suppressed lipid metabolism in SSc skin. Steroid hormone biosynthesis (AKR1, DHRS11, CYP1A2, SULT2B1, HSD1, EHTM2, HSD11B2), fatty acid synthesis (FASN1, FADS1, FADS2, ELOVL, SCD5, PTPD2), and fatty acid degradation (ACAT1/2, ACS, ACAIF/2, ACADM, ACSL3) were the main downregulated lipid metabolism pathways in SSc skin, particularly in patients with the inflammatory intrinsic gene expression subset. The latter changes were detected in the affected and non-affected SSc skin, suggesting that altered lipid metabolism is a generalized feature of the SSc skin. Furthermore, pathway enrichment analysis of TGFβ-induced transcriptional changes in skin fibroblasts, as detected by RNA-seq and scRNA-seq, suggested that TGFβ-driven reprogramming could significantly contribute to the lipid metabolism perturbations in SSc skin (Figure 1B, C). Specifically, STRING analysis revealed that TGFβ suppressed metabolic networks of glycerocephospholipids, arachidonic acid, and fatty acids in cultured skin fibroblasts (Figure 1D).

Conclusion: Our data suggest perturbed lipid metabolic networks in SSc skin and identify skin fibroblasts, exposed to profibrotic milieu, as likely contributors to the altered lipid metabolism in SSc. These results might pave the way to a deeper understanding of the interplay between the metabolic and fibrotic pathways in SSc. Integrating these data with future metabolomic and single-cell studies could accelerate the discovery of potential metabolic targets in SSc.

Figure 1. A) Enriched metabolic pathways in SSc skin compared to healthy skin based on DE gene expression. Downregulated GO biological processes in TGFβ-treated cultured healthy skin fibroblasts based on RNASeq (B) and scRNAseq (C) analyses. D) STRING pathway enrichment analysis of downregulated genes (RNA-Seq) linked to lipid metabolism in TGFβ-stimulated skin fibroblasts.

BLOOD-BASED PROTEIN BIOMARKERS ARE ASSOCIATED WITH SUBCLINICAL CARDIOVASCULAR ABNORMALITIES AS DEFINED BY CARDIOVASCULAR MAGNETIC RESONANCE IMAGING IN SYSTEMIC SCLEROSIS (SSC) PATIENTS

Keywords: Biomarkers, Systemic sclerosis, Cardiovascular disease

Buch11,12, 1University of Manchester, School of Biological Sciences, Manchester, United Kingdom; 2University of Manchester, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; 3NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom; 4University of Leeds, Leeds Institute of Rheumatic & Musculoskeletal Medicine, Faculty of Medicine & Health, Leeds, United Kingdom; 5University of Manchester, Division of Cardiovascular Sciences, Manchester, United Kingdom; 6University of Leeds, Multidisciplinary Cardiovascular Research Centre (MCRC) and Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; 7Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 8University of Manchester, Wellcome Centre for Cell Matrix Research, Manchester, United Kingdom

Background: Systemic sclerosis-primary heart involvement (SSc-pHl) accounts for up to one-third of SSc-related deaths and clinically apparent pHl portends poor outcome. Early detection of SSc-pHl is therefore crucial. We have previously shown cardiovascular magnetic resonance (CMR)-detected subclinical myocardial abnormalities. Identifying robust blood biomarkers of SSc-pHl would facilitate diagnostic testing, help to resolve the biological mechanisms underpinning SSc-pHl and potentially identify new targets for drug development.

Objectives: To identify protein biomarkers associated with subclinical cardiovascular abnormalities as defined by CMR measures in SSc patients, and predominant inflammatory and cardiometabolic pathways implicated.
Methods: Seventy-eight patients from CONVAS (‘CONnective Tissue Disease and VASCultis Cohort’) and ELCASA (‘ELectrophysiology and Cardiac imaging in Scleroderma’) study cohorts underwent CMR imaging. Using Olink Proximity Extension Assay, normalised protein expression (NPX) across cardiometabolic, cardiovascular I/II and inflammation panels was measured in these patients at the time of CMR. Generalised linear regression with Benjamini Hochberg correction for multiple testing was used to identify significant proteins associated with CMR parameters of myocardial oedema/fibrosis [native T1, myocardial extracellular volume (ECV) and late gadolinium enhancement (LGE)] and vascular stiffness [aortic distensibility]. Subsequently, an expanded protein-protein interaction (PPI) network was created using an induced network approach (STRING-DB) with k-means clustering applied to identify enriched functional clusters that were then subjected to Gene Ontology (GO) and KEGG enrichment analysis.

Results: Of 355 proteins analysed, 70 proteins were associated with myocardial tissue oedema/fibrosis (64 proteins; 26 positively, 38 negatively) and vascular stiffness (6 proteins; 2 positively, 4 negatively). 2 overlapping proteins that associated with focal (LGE) and diffuse fibrosis (ECV) were identified. *Proteins identified include those involved in coagulation cascade (estimate = -1.97, 95% CI = -3.63 to -0.31, adj. p = 0.039), carbohydrate binding and opsonisation activities (estimate = -1.31, 95% CI = -2.19 to -0.43, adj. p = 0.006); and cancer and neovascular inflammatory conditions (estimate = -75.79 95% CI = -119.81 to -31.76, adj. p = 0.002).

k-means clustering of the expanded PPI network (enrichment p.value < 1.0e-16) identified 4 clusters (Figure 1) with roles in TNF receptor superfamily binding and NF-kappa B pathway (red); Vascular endothelial growth factor-activated receptor activity and Rap1 signalling pathway (yellow); IL-10 receptor activity and NF-kappa B signalling pathway (green). Proteins associated with CMR detected subclinical myocardial tissue oedema/fibrosis mainly mapped to yellow and blue clusters.

Conclusion: In this first proteomic study of SSc-pHi, we have identified 70 protein biomarkers, with myocardial tissue oedema/fibrosis associated with inflammation and vascular pathways. The next step is to validate these proteins and test the utility of network proteins in an independent patient cohort that could aid detection and diagnosis of SSc-pHi. *Proteins names not disclosed as subject to Intellectual Property discussions via Innovation Factory, University of Manchester.

BARICITINIB AMELIORATES BLEOMYCIN-INDUCED PULMONARY AND SKIN FIBROSIS VIA JAK 1/2 INHIBITION

Background: Signal transducer and activator of transcription 3 (STAT3) protein is activated in lung fibroblasts and alveolar type II cells (AT-II) and is thought to contribute to fibrosis in lung tissue. Significant JAK/STAT activation was demonstrated in fibroblasts, skin biopsies and scleroderma animal models of patients with Systemic Sclerosis (SSc) [1].

Objectives: The aim of this study was to determine whether inhibition of JAK2/STAT3 in the experimental model of scleroderma is a potential therapeutic strategy for this disease and to investigate the effects of the JAK 1/2 inhibitor Baricitinib (BAR) on the experimental model of dermal and pulmonary fibrosis.

Methods: Thirty-two healthy 6-8 weeks old female C57BL mice with an average weight of 22±3 grams were included in our study. Before the treatment (baseline), day 15 and day 30 (day 30) the same back area was shaved with 1 cm from the injection area. Whole lung Computed Tomography (CT) scans of each animal were acquired at post-treatment (day 30). H&E and Masson’s Trichrome staining were performed to evaluate skin thickness, pulmonary alveolitis, and fibrosis. The Ashcroft score was assessed on Sirius Red stained lung sections post-treatment. For the molecular evaluation of tissue fibrosis, collagen and α-SMA levels were measured in skin and lung tissues by qRTPCR.

Results: We found that BAR resulted in favorable therapeutic outcomes by affecting the inflammation infiltration and collagen deposition both lung and skin tissues. Immunohistochemical results showed that BAR downregulated the levels of COL1A1 and COL1A2.Treatment with JAK 1/2 selective BAR has been shown to ameliorate BLM-induced skin and lung fibrosis at radiological, pathological and molecular measurements.

Conclusion: As a result of our study, the effect of JAK1/2 selective inhibitor baricitinib treatment on reducing skin and lung fibrosis in a mouse model created with BLM was demonstrated with radiological and pathological examinations. We conclude that JAKinh treatments will be an important research area for the treatment of SSc and other fibrotic diseases in the future.

**Background:** Anti-drug antibodies (ADAb) may be involved in loss of response or primary failure of bDMARDs in rheumatoid arthritis (RA). However, evidence is still controversial. The aim of this study was to assess the treatment in presence of ADAb is rare and restricted to monoclonal anti-TNF antibodies[1].

**Objectives:** In this analysis of the prospective European trial ABIRISK we aimed to analyze how ADAb might influence response to several bDMARDs in RA.

**Methods:** RA patients resistant to methotrexate and starting a bDMARD (anti TNF, anti IL-6 R and anti CD20) were included in 4 countries (ABIRA, NC072116504). They had a clinical assessment and ADAb quantification at 6, 12, and 15 to 18 months. ADAb were detected using mesoscale discovery (MSD) technology. They were defined as transient if they were negative after a positive time point and persistent positive if they were positive at two sequential visits without negative timepoints afterwards. ADAb positivity was defined as having been ADA positive at least in one visit in the first 12 months. The primary endpoint was the EULAR response at 12 months. Association with ADAb was analyzed using univariate logistic regression. Patients withdrawing for side effects or for inefficacy were considered as non-responders. We also performed a univariate and a multivariate analysis through a generalized estimating equation (GEE) model that analyzes the EULAR response and ADAb status for each visit starting at 6 months. This allows taking advantage of all the data available in the study. The effect of methotrexate on ADAb was also studied. Finally, we performed drug concentration measurements for anti-TNF drugs.

**Results:** 230 patients were included treated with: adalimumab or infliximab as monoclonal TNFi (mTNFi, N=68); etanercept (ETN, N=82), rituximab (RTX N=30) or tocilizumab (TCZ N=50). ADAb were positive in 38.2% of the mTNFi-treated patients, 50% of the RTX-treated and 20% of the TCZ-treated patients. ADAb positivity was negatively associated with EULAR response at 12 months for all drugs OR=0.20 [0.10-0.42]. Only persistent and not transient ADAb were negatively associated with EULAR response at 12 months (persistent ADAb vs ADAb negative OR 0.17 [0.06-0.43] transient ADAb vs ADAb negative, p=0.57). This was also the case for mTNFi alone (persistent ADAb vs ADAb negative OR 0.1; p=0.0051; transient ADAb vs ADAb negative, p=0.99). 6% of ETN patients presented ADAb, always transient. In the GEE longitudinal analysis there was a negative association between ADAb positivity and response to all treatments (OR 0.36 [0.20-0.64]) and individually for TCZ (OR=0.18 [0.04-0.83]) and mTNFi (OR 0.44; p=0.097 trend). In the multivariate analysis, the ADAb status remained independently associated with non-response to treatment (Figure 1). Methotrexate co treatment at baseline was negatively associated with ADAb (OR=0.5 [0.25-1.0]). There was a significantly lower concentration of adalimumab and infliximab in ADAb positive patients compared to ADAb negative. There was a significantly higher concentration of adalimumab and etanercept in EULAR responder patients compared to EULAR non-responders.

**Conclusion:** This prospective multicenter study demonstrates that ADAb are frequently detected and associated with non-response to bDMARDs in RA. It is the first study demonstrating the association between ADAb and non-response to TCZ. Monitoring of ADAb should be considered in the personalized management of RA patients particularly in non-responding patients.

TNP INHIBITOR USE AFFECTS BIRTH WEIGHT INDEPENDENTLY OF THE SFLIT1/PLGF RATIO IN PREGNANT WOMEN WITH RHEUMATOID ARTHRITIS

**Keywords:** Rheumatoid arthritis, Pregnancy and reproduction, Biomarkers

C. Witte-Quaak1, A. Kluijver2, H. T. Smeekle3, R. I. Neuman4, L. Saleh5, A. H. J. Danser6, R. Dolhain7, 8Rotterdam, Department of Rheumatology and Department of Internal Medicine; Division of Pharmacology and Vascular Medicine, Rotterdam, Netherlands; 7Erasmus Medical Center, 2.Department of Internal Medicine; Division of Pharmacology and Vascular Medicine and 3.Department of Gynecology and Obstetrics, Rotterdam, Netherlands; 8Erasmus Medical Center, Department of Rheumatology, Rotterdam, Netherlands; 9Erasmus Medical Center, Department of Internal Medicine; Division of Pharmacology and Vascular Medicine, Rotterdam, Netherlands

**Background:** TNP inhibitor (TNI) use during pregnancy is associated with increased birthweight of the offspring of women with Rheumatoid Arthritis (RA). However, the underlying mechanism of the increased birthweight due to TNI use is unknown. Prior studies demonstrated an association between biomarkers of placental function such as soluble fms-like Tyrosine Kinase-1 (sFlt-1) and placental growth factor (PLGF) and fetal growth restriction (FGR). We hypothesized that the increased birthweight in the offspring of women with RA treated with TNI can be explained by better placenta by affecting the levels of biomarkers of placental function or by modulating the impact of these biomarkers on birthweight.

**Keywords:** Rheumatoid arthritis, Pregnancy and reproduction, Biomarkers

C. Witte-Quaak1, A. Kluijver2, H. T. Smeekle3, R. I. Neuman4, L. Saleh5, A. H. J. Danser6, R. Dolhain7, 8Rotterdam, Department of Rheumatology and Department of Internal Medicine; Division of Pharmacology and Vascular Medicine, Rotterdam, Netherlands; 7Erasmus Medical Center, 2.Department of Internal Medicine; Division of Pharmacology and Vascular Medicine and 3.Department of Gynecology and Obstetrics, Rotterdam, Netherlands; 8Erasmus Medical Center, Department of Rheumatology, Rotterdam, Netherlands; 9Erasmus Medical Center, Department of Internal Medicine; Division of Pharmacology and Vascular Medicine, Rotterdam, Netherlands

**Background:** TNP inhibitor (TNI) use during pregnancy is associated with increased birthweight of the offspring of women with Rheumatoid Arthritis (RA). However, the underlying mechanism of the increased birthweight due to TNI use is unknown. Prior studies demonstrated an association between biomarkers of placental function such as soluble fms-like Tyrosine Kinase-1 (sFlt-1) and placental growth factor (PLGF) and fetal growth restriction (FGR). We hypothesized that the increased birthweight in the offspring of women with RA treated with TNI can be explained by better placenta by affecting the levels of biomarkers of placental function or by modulating the impact of these biomarkers on birthweight.
**Objectives:** To study the modulating impact of sFlt-1 and PI GF on birthweight and the use of TNFi in a cohort of pregnant women with RA.

**Methods:** Making use of the PreCARA cohort, in which pregnant women with RA are treated according to a treatment protocol aimed at remission, biomarkers of placental function sFlt-1, PI GF and sFlt-1/PI GF ratio were measured in the first, second and third trimester of pregnancy.

**Results:** A total of 158 women were included. 52.5% of all patients ever used TNFi during pregnancy; 29.1% used TNFi during all trimesters of pregnancy. The sFlt-1/PI GF ratio is different in each trimester. After correction for confounders, there was no significant difference in sFlt-1 or the sFlt-1/PI GF ratio between patients that did, and did not use TNFi inhibitors (sFlt-1: p < 0.005, CI -0.065; 0.063 p = 0.997, PI GF: 0.014, CI -0.069; 0.093 p = 0.721 and sFlt-1/PI GF ratio: -0.014, CI -0.107; 0.078 p = 0.757). When correlating sFlt-1 and birthweight, we found the previously established correlation in the group that did not use TNFi inhibitors during pregnancy (r = -0.462, p < 0.001). However, this correlation disappeared in the group that did use TNFi inhibitors during pregnancy (r = 0.076, p = 0.522).

**Conclusion:** Our study shows that in pregnant women with RA, the biomarkers of placental function sFlt-1, PI GF and the sFlt-1/PI GF ratio are not related to the use of TNFi. In case of using TNFi, the negative correlation of sFlt-1 on birthweight disappeared, whereas this negative correlation on birthweight persists in the patients not using TNFi. This suggests that TNFi has a downstream effect on placental function sFlt-1, PI GF and the sFlt-1/PI GF ratio: an association is still found in the patients not using TNFi. This could be related to the use of TNFi inhibitors during pregnancy and should be explored in future research.

**Table 1.** sFlt-1, PI GF and sFlt-1/PI GF ratio values per trimester for all patients that did not use TNFi during pregnancy and patients that used TNFi during pregnancy.

**Figure 2.** Correlation of sFlt-1 and birthweight SDS in the third trimester of pregnancy for all patients with and without ever-use of TNFi during pregnancy.
Conclusion: These results indicate highly elevated neutrophil activation and NET formation in recently diagnosed RA patients. All four treatments studied here reduced these detrimental processes within 3 months. The calprotectin reduction seen in this study is in line with an earlier spin-off study [2]. The rapid decline in these markers may have contributed to the minimal radiological progression that was seen in the NORD-STAR trial.

Methods: To proxy TNFi, we selected uncorrelated (r² > 0.1) genome-wide significant (p < 5 x 10⁻⁸) single nucleotide polymorphisms within the gene encoding TNF receptor 1 (TNFRSF1A, build GRCh37/hg19: chromosome 12:6437923-6451280) from a genome-wide association study (GWAS) of CRP among 337,199 individuals. CRP was (inverse rank-normal) transformed, with estimates scaled to per standard deviation (SD=4.35 mg/L) change in CRP. We selected CRP as the biomarker because clinical data show its suppression with TNFi. We estimated the F statistics of the instrument (square of the beta divided by square of the standard error) with F > 10 being suggestive of adequate instrument strength. Genetic association data for spontaneous abortion (15,073 cases, 135,962 female controls), preterm birth (7,678 cases, 14,813 controls), pre-eclampsia or eclampsia (6,436 cases, 176,113 controls), gestational hypertension (7,503 cases, 176,113 controls) and gestational diabetes (7,676 cases, 130,424 controls) were derived from the FinnGen study. Data for firstborn birth weight (grouped into <7, 7 to >7 pounds (~3.2kg)) was obtained from 200,272 women in the UK Biobank. We included a positive control outcome, ankylosing spondylitis, and a negative control, multiple sclerosis. We used ratio method and, where an association was found, applied colocalization to test for genetic confounding.

Results: We identified one variant, rs1800693, to instrument TNFi. The F statistic was 65 suggesting adequate instrument strength. We found no evidence of associations between genetically proxied TNFi and any pregnancy related outcome (Figure 1) except gestational diabetes (OR 0.12 per SD reduction in CRP; 95%CI 0.03 to 0.57; p=0.007). The posterior probability of colocalization between CRP and gestational diabetes in the TNFRSF1A gene region was 99% conditional on the presence of a causal variant for the outcome, which provide evidence against genetic confounding.

Conclusion: We found no genetic evidence to suggest that TNFi is harmful for the selected outcomes relating to pregnancy. These results are reassuring and concur with observational data where women were exposed to TNFi during pregnancy. There was evidence that TNFi may be associated with lower risk of gestational diabetes. Further studies are needed to examine whether this is specific to diabetes during pregnancy or more generally. It is important to note that subtle differences in CRP levels through genetic variation may not be comparable to effects of pharmacological inhibition, and life-long exposure studied herein may differ from shorter duration of pharmacological intervention.

Keywords: bDMARD, Pregnancy and reproduction, Epidemiology

S. S. Zha1, D. Gidl1, 2. University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; Imperial College London, Department of Epidemiology and Biostatistics, London, United Kingdom

Background: TNF inhibitors (TNFi) have greatly improved the management of rheumatoid arthritis and several immune mediated inflammatory diseases. Although these diseases commonly start during childhood age, the safety of TNFi in pregnancy is unclear, and is unlikely to change as clinical trials continue to exclude pregnant women for concern of harm to the foetus. Lack of scientific evidence to inform treatment decisions can contribute to maternal anxiety and suboptimally controlled disease. Naturally occurring variations in the genes that encode the protein drug target can provide population-level insights into safety, without exposing pregnant women to these drugs.

Objectives: To investigate the association between genetically proxied TNFi and pregnancy related outcomes, namely, spontaneous abortion, preterm birth, pre-eclampsia or eclampsia, gestational hypertension, gestational diabetes mellitus, and birthweight of the firstborn child.

Methods: To proxy TNFi, we selected uncorrelated (r² > 0.1) genome-wide significant (p < 5 x 10⁻⁸) single nucleotide polymorphisms within the gene encoding TNF receptor 1 (TNFRSF1A, build GRCh37/hg19: chromosome 12:6437923-6451280) from a genome-wide association study (GWAS) of CRP among 337,199 individuals. CRP was (inverse rank-normal) transformed, with estimates scaled to per standard deviation (SD=4.35 mg/L) change in CRP. We selected CRP as the biomarker because clinical data show its suppression with TNFi. We estimated the F statistics of the instrument (square of the beta divided by square of the standard error) with F > 10 being suggestive of adequate instrument strength. Genetic association data for spontaneous abortion (15,073 cases, 135,962 female controls), preterm birth (7,678 cases, 14,813 controls), pre-eclampsia or eclampsia (6,436 cases, 176,113 controls), gestational hypertension (7,503 cases, 176,113 controls) and gestational diabetes (7,676 cases, 130,424 controls) were derived from the FinnGen study. Data for firstborn birth weight (grouped into <7, 7 to >7 pounds (~3.2kg)) was obtained from 200,272 women in the UK Biobank. We included a positive control outcome, ankylosing spondylitis, and a negative control, multiple sclerosis. We used ratio method and, where an association was found, applied colocalization to test for genetic confounding.

Results: We identified one variant, rs1800693, to instrument TNFi. The F statistic was 65 suggesting adequate instrument strength. We found no evidence of associations between genetically proxied TNFi and any pregnancy related outcome (Figure 1) except gestational diabetes (OR 0.12 per SD reduction in CRP; 95%CI 0.03 to 0.57; p<0.007). The posterior probability of colocalization between CRP and gestational diabetes in the TNFRSF1A gene region was 99% conditional on the presence of a causal variant for the outcome, which provide evidence against genetic confounding.

Conclusion: We found no genetic evidence to suggest that TNFi is harmful for the selected outcomes relating to pregnancy. These results are reassuring and concur with observational data where women were exposed to TNFi during pregnancy. There was evidence that TNFi may be associated with lower risk of gestational diabetes. Further studies are needed to examine whether this is specific to diabetes during pregnancy or more generally. It is important to note that subtle differences in CRP levels through genetic variation may not be comparable to effects of pharmacological inhibition, and life-long exposure studied herein may differ from shorter duration of pharmacological intervention.

Keywords: bDMARD, Pregnancy and reproduction, Epidemiology
must know them and acquire self-care and safety skills in order to take charge of themselves in risky situations. This is only possible thanks to therapeutic patient education (TPE) programs in chronic inflammatory arthritis such as rheumatoid arthritis (RA), Still’s disease, or psoriatic arthritis (PsA).

Objectives: To evaluate the impact of the therapeutic patient education program “EST-RIC” on the safety skills in patients treated with bDMARDs and on clinical parameters (Disease activity scores, compliance, number of infectious events, number of treatment stops, vaccination rate).

Methods: Non-randomized clinical trial comparing the knowledge and safety skills between two cohorts of patients with RA, SpA or PsA receiving bDMARDs for at least three months in the day hospital center of CHU of Constantine: group TPE (patients joined the “EST-RIC” therapeutic education program) versus group TPE-naive (patients who did not wish to participate). The primary outcome was the acquisition of safety skills at 3 and 6 months measured by the Biosecure questionnaire (0-100 scale), a 55 item validated questionnaire assessing competences to deal with fever, infections, vaccination, and other daily life situations.

The secondary outcomes were disease activity scores (DAS 28 for RA and BASDAI for SpA) at 6 months, compliance (Morisky score), number of infectious events, number of treatment stops, vaccination rate at 12 months.

Results: 450 patients were included, with mean age 41.6 ± 12.1 years old; 235 (52.2%) women; 192 (42.7%) had RA; mean disease duration 9.9 ± 6.6 years, 269 (60%) received subcutaneous bDMARDs. 240 patients in group TPE versus 210 patients in group TPE-naive. The median Biosecure score was significantly higher in the group TPE than in the group TPE-naive (75.7/100 versus 57.9/100; p<0.001) at 6 months (Table 1). There was a significant difference in disease activity scores: DAS28 and BASDAI, in rates of vaccination and discontinuation of treatment by forgetfulness. Regarding the observance to treatment or incidence of infectious events, there was no significant difference between the groups TPE and TPE-naive.

Conclusion: Safety is an important issue in the management of inflammatory arthritis treated with bDMARDs. In this trial, therapeutic patient education improves knowledge and safety skills of arthritis patient receiving bDMARDs, and disease activity scores.

**POS0635 METHOTREXATE MAINTENANCE ONE YEAR AFTER INITIATION OF A FIRST TARGETED THERAPY: RESULTS OF THE PROSPECTIVE STRATEGIE 2 STUDY**

Keywords: Rheumatoid arthritis, Treat to target, Disease-modifying drugs (DMARDs)

C. Gaujoux-Viala1, E. Demis2, E. Senbel3, H. Herman-Demars4, J. Becker4, A. Courbeyrette5, R. M. Filipo5, 1IDESP, Unib Montpellier; INSERM, Department of Rheumatology, CHU Nîmes, Nîmes, France; 2Le Mans Central Hospital, Rheumatology Department, Le Mans, France; 3Cabinet de Rhumatologie, NA, Marseille, France; 4Nordic Pharma France, Medical Department, Paris, France; 5Centre Hospitalier Universitaire de France, Université de Lille, Lille, France

Background: Methotrexate (MTX) is the first line standard of care for the management of rheumatoid arthritis (RA). In the event of an inadequate response to MTX and the presence of a poor RA prognostic factor, recommendations include initiation of biological (bDMARD) and/or synthetic (tsDMARD) targeted therapy in combination with MTX.

Objectives: STRATEGIE 2 aims to establish the maintenance of MTX within two years of initiating a first targeted therapy.

Methods: STRATEGIE 2 is a non-interventional study including RA patients treated with MTX for at least 3 months and requiring initiation of a first b/tsDMARD due to disease activity. The primary endpoint is maintenance of MTX unchanged within 12 months of initiation of targeted therapy. Non-maintenance is defined as: permanent discontinuation of MTX and/or dose reduction and/or transition from the subcutaneous route (SC) to oral (PO). Then, univariate and multivariate analysis was applied to identify potential predictors of MTX maintenance.

Results: Between Feb. 2019 and Dec. 2020, 53 French sites included 186 RA patients. Among them, data from 180 patients were analyzable: 73.4% female, mean age 56.4 ±13.8 years, mean diagnostic oldness of 5.8 ±7.2 years, MTX treatment since 4.3 ±3.5 years, 7.17% via SC and the average dose was 19.9 ±3.9 mg/wk. The mean DAS28 score was 4.3 ±1.2 and the mean HAQ score was 1.0 ±0.7. At the end of the inclusion consultation, rheumatologists initiated a first targeted therapy: 8.6% by bDMARDs (anti-TNF: 58.4%, anti-IL6: 12.7%, Abatacept/Rituximab: 18.5%) and 10.4% by tsDMARDs. MTX was maintained unchanged in 76.1%, changed in 21.7% and stopped in 2.2% of the cases. The changes consisted of a dose reduction to 13.8 ±3.5 mg/wk and a pathway change for 31.4% (from SC to PO). Approximately 12 months (377.8 ± 415 days) after initiation of targeted therapy, 95% of patients completed a follow-up visit (N=171). Of these patients, 6.4% had discontinued targeted therapy, 85.9% were on bDMARD (anti-TNF: 50.3%, anti-IL6: 12.8%, Abatacept/Rituximab: 22.8%) and 14.1% on tsDMARD. The average MTX dose was 18.0 ±4.2 mg/wk and MTX was administered SC for 59.4% of patients. According to the composite endpoint definition, MTX was maintained for 40.9% of patients. Non-maintenance was represented by 30% discontinuation, 4% of patients with a dose decrease only, 3% of patients with only a change in route of administration (from SC to PO) and 23% of patients with the two strategies. Using univariate analysis, three factors were selected for the multivariate: age (p<0.009), physicians’ mode of practice (p=0.096) and patients who estimate having completely participated in the decision-making for the targeted therapy (p=0.197). Only age was significant (OR=1.066, 95%CI [1.03,1.10], p<0.001), decision-making shows a strong trend (p=0.052) and both characteristics were adjusted on the mode of practice (p=0.256).

Conclusion: There are many therapeutic adaptations in the year following the initiation of b/tsDMARD. Twelve months after the introduction of b/tsDMARD, more than 8 out of 10 patients retained MTX as a combination therapy. Nearly 46% of patients had an adaptation of this treatment (dose reduction and/or return to the PO route). These practices are in line with the latest EULAR guidelines [1] which recommend the association of b/tsDMARDs with MTX.

**POS0636 SHOULD COMPLETE B-CELL DEPLETION BE SUSTAINED IN RITUXIMAB LONG-TERM TREATED PATIENTS FOR RHEUMATOID ARTHRITIS?**

Keywords: bDMARD, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

R. Ghossan1, O. Al Tabaa1, A. Combier1, A. Steelandt2, M. Thomas3, C. Miceli Richard1, A. Moti4, Y. Allanoire3, J. Avouac3, 1Cochin Hospital, Rheumatology Department, Paris, France; 2Cochin Hospital, Rheumatology department, Paris, France; 3Cochin Hospital, Rheumatology Department, Paris, France

Background: Complete peripheral B cell depletion has been considered as a relevant indicator of short-term response to rituximab (RTX) in rheumatoid arthritis (RA) [1,2]. However, no information is available to validate this observation in RA patients long-term treated with RTX.
Background: DMARDs are the cornerstone of early RA treatment with Methotrexate (MTX) typically used as a first line treatment. More intensive initial combination therapy has been evaluated in clinical trials showing limited added value with longer follow-up in a treat-to-target (T2T) strategy [1,2]. Such studies report the treatment effect on group level, however, precision medicine requires information on which individuals will respond relevantly better to a more intensive therapy compared to MTX.

Objectives: The aim of this study was to identify whether clinically relevant heterogeneity in treatment effect exist, utilizing a "potential-outcomes framework" approach and to explore whether individual added value of more intensive therapy can be predicted.

Methods: We used data from U-AcT-Early. This RCT compared initiating MTX monotherapy, tocilizumab (TCZ), and MTX + TCZ treatment in a T2T strategy in early RA with monthly disease activity assessment [1]. Time averaged CDAI score over 6 months was the primary endpoint. As physician VAS was missing a previously reported modified (m) CDAI was used [2]. Time-averaged mCDAI over 24 months and DAS28 over 6/24 months were secondary outcomes. For each patient we predicted outcomes of the treatments that they were not allocated to using multiple imputation (150 imputations using a random forest method). Predicted Individual Treatment effects (PITE) for each treatment comparison were calculated and the variation in PITEs between patients was evaluated. We used logistic regression to predict added value of more intensive treatment.

Results: Figure 1A shows the average PITE for TCZ + MTX versus MTX monotherapy as initial treatment over 6 months. 134 of 299 patients (45%) would relevantly benefit from MTX + TCZ (green part Figure 1). We defined sufficient added value for an individual patient as Cohen’s effect size ≥0.6. Added value of MTX + TCZ could be predicted to a limited extent with the same variables used for imputation (AUC-ROC 0.65 (95% CI 0.56-0.73); Table 1 and Figure 1B). At 24 months 36% could be defined as benefitting from more intensive initial treatment. When using DAS28 as outcome measure 87% and 82% of patients benefitted respectively at 6 and 24 months. Added value could also be predicted to a limited extent (AUC-ROC 0.63 (0.54-0.71); 0.66 (0.56-0.75) and 0.63 (0.54-0.71) respectively) using logistic regression.

Conclusion: Relevant added value of more intense initial treatment for individual early RA patients could be defined and predicted to some extent using clinical predictors. However, thresholds for relevant clinical benefit as well as prediction should be improved and validated.

POS0639
SWITCHING FROM IL-6R ANTAGONISTS TO OLOKIZUMAB, A DIRECT IL-6 INHIBITOR

Keywords: bDMARD, Rheumatoid arthritis

E. Feist1, E. Nasonov2, HELIOS Clinic Vogelsang Gommern, Department of Rheumatology, Gommern, Germany; 1VA Nasonov Research Institute of Rheumatology, Department of Rheumatology, Moscow, Russian Federation

Background: Olokizumab (OKZ), an IL-6 ligand inhibitor in doses of 64 mg every two weeks (q2w) or every 4 weeks (q4w) demonstrated significant improvements in signs and symptoms of RA. Due to lack of availability of the IL-6 receptor antagonists tocilizumab and sarilumab in the pandemic COVID-19 situation, RA patients (pts) were switched to OKZ as a registered drug in Russia in 2022.

Objectives: To investigate safety and efficacy of OKZ after switching from an IL-6 receptor inhibitor in clinical practice.

Methods: This retrospective cohort study included available efficacy and safety data of OKZ in pts with RA after switching from tocilizumab (IV or SC) or sarilumab (SC) from 11 of participating centers. Efficacy assessments and routine biochemical data were analyzed using descriptive statistics – mean with standard deviation for continuous parameters and absolute and relative frequency for binary variables. AE were reported by participating centers according to pt’s files. The statistical significance of the data analyzed variable at a particular visit compared with previous visits or with the Switch visit was determined using paired t-test. Fisher’s exact test or chi-square test was used to compare the proportion of pts with improvement/no change and worsening. All tests were 2-tailed, and a p-value <0.050 was considered statistically significant. This is as an observational study, the statistical criteria have not been pre-specified and therefore the data presented cannot be considered definitive but should be confirmed in future analyses.

Results: Efficacy and safety results were collected for 110 RA pts with a mean age of 47.8 (15.7) years, including 87 (79.1%) women. 77 (70.0%) pts were RF/ ACPA positive. Mean RA duration was 13.1 (8.9) years and mean duration of treatment with an IL-6 receptor antagonist was 47.8 (30.0) months. Mean interval before switching was 54.7 (35.4) days with the main reason of unavailable IL6R antagonist. Pts were treated with OKZ 64 mg q4w SC. Before initiation of OKZ, an increase of DAS28-CRP was observed due to a prolonged period after the last injection of the IL-6R inhibitor from 2.8 to 3.1 weeks in 32 pts on monothera-
apy who were transferred to OKZ faster (on average after 41.6 (23.8) days), and

Figure 1.
from 2.7 to 3.3 weeks in 73 pts on concomitant sDMARDs (60.0 (38.0) days). DAS28-CRP was improved to 2.8 on the second OKZ visit (S+1) in both groups. Response to OKZ was maintained over a period of 2 months with no difference between pts previously receiving an IL-6 R antagonist. Of note, lower disease activity based on DAS28-CRP of 2.5 and 2.6 was achieved after 8 weeks (S+2) of OKZ therapy compared to the previous IL-6R inhibitors treatment S-1 visit (P less 0.05) (Figure 1).

**Figure 1.** Mean DAS28CRP over time, M(SD)

Abbreviation: S-2 and S-1 last visits before switching-- S+1 and S+2 visits after switching. Treatment emergent AE occurred in 7 (6.4%) pts, the most common AE in 3 pts (2.7%) included arthralgia of hands and feet and transient leukopenia in 2 (1.8%) pts. Serious AE were reported by 1 (0.9%) pt (exacerbation of herpes infection that led to treatment discontinuation). No deaths were reported. There were no apparent differences in safety and efficacy outcomes between pts on OKZ monotherapy compared to combined treatment with csDMARDs. Only one pt was switched back to tocilizumab when it became available.

**DO: 10.1136/annrheumdis-2023-eular.1839**

**Keywords:** Patient reported outcomes, Clinical trials, Rheumatoid arthritis
Background: The continuous development of biological disease modifying antirheumatic drugs (bDMARDs) in recent years has significantly improved the treatment options for patients suffering from rheumatoid arthritis. Selecting the most effective biologic remains a challenge, since every patient is highly individual depending on the patient history, laboratory values and demographics. 

Objectives: The aim of this study was to investigate, if non-responders can be detected before therapy start using machine learning models and explainable artificial intelligence to provide a probability of non-response and to identify the most impactful contributing factors to the model output.

Methods: Data from the Austrian Registry for bDMARDs and tsDMARDs in Rheumatic Diseases – BIOREG were obtained. BIOREG provides a real-world data set, which covers rheumatology hospitals and practices throughout Austria. According to EULAR-guidelines the observation time window for treatment response is 6 months and the prediction time horizon was set at 6 months as well. Different machine learning models were trained for Abatacept (ABA), Adalimumab (ADA), Certolizumab (CERT), Etanercept (ETA) and Tocilizumab (TOC) to predict the risk of non-response per treat to target (ttt)-course. 

Results: Data from 1397 patients, 2004 (baseline) visits and 22 variables (19 after cleaning) with at least 100 ttt-courses per drug were included in the study. The best models per biologic achieved an AUROC-score of: CERT: 0.76 (95% CI, 0.67–0.86), TOC: 0.72 (95% CI, 0.69–0.79), ADA: 0.71 (95% CI, 0.65–0.77), ABA: 0.67 (95% CI, 0.62–0.76), ETA: 0.68 (95% CI, 0.53–0.85). The explainable AI interpreted visual analytic scores (VAS) as most important variables for ABA, ETA and TOC. High scores were associated with high risk of non-response for these drugs. For ADA, co-therapy with glucocorticoids was the most important and risk-increasing factor. For CERT, the dosage of the prescribed drug was ranked as the most influential variable; high dosages were associated with lower risk of non-response. Interestingly, some variables displayed opposite impacts in different drugs: Male gender was interpreted as risk-increasing for ABA and risk-decreasing for ETA. Moreover, negative rheumatoid factor was interpreted as risk-decreasing for ABA/ETA, but risk-increasing for ADA/CERT.

Conclusion: The results of our study show that non-responders of biological drugs can be detected with moderate to even good prognostic quality before starting a ttt-course, comparable to similar research with different prediction time horizons [1]. The opposite impact of some variables in different bDMARDs as well as the difference in variable importance per bDMARD indicate, that selecting the right drug is highly dependent on the individual patient characteristic. Machine Learning could be of additional support for rheumatologists and patients by providing not only a prediction of ineffectiveness per drug, but also an explanation for the prediction.

**TREATMENT PATTERNS OF RHEUMATOID ARTHRITIS DURING TWO DECADES 2000-2020: REAL-WORLD DATA FROM A LARGE ISRAELI HEALTH MAINTENANCE ORGANIZATION**

**Keywords:** bDMARD, Rheumatoid arthritis, Real-world evidence

V. Rosenberg1,2, O. Elkayam2,3, G. Chodick2,2, M. Halperin-Sheinfeld4, V. Rufer5,6, Kahn-Sagol-Maccabi Research and Innovation Institute, Maccabi Healthcare Services, Tel Aviv, Israel; 2Sackler Faculty of Medicine, Tel Aviv University; 3Tel Aviv, Israel; 4Tel Aviv Sourasky Medical Center, Rheumatology, Tel Aviv, Israel; 5Gilead Sciences Israel, Immunology, Hod Hasharon, Israel

**Background:** Rheumatoid arthritis (RA) is the most common autoimmune inflammatory arthritis in adults. In recent years, the availability of therapeutic options for RA management has significantly increased. Yet, not all patients receive the recommended therapy (1 and real-world data on RA treatment patterns are limited.

**Objectives:** We aimed to identify and characterize RA patients, to examine their past and current treatment patterns, and identify factors associated with non-treatment.

**Methods:** We conducted a retrospective study using the computerized database of Maccabi Healthcare Services (MHS), a large health maintenance organization. Prevalent RA patients on Dec 31 2020 were defined by: ICD-9 code 714.X (≥2 diagnoses by a rheumatologist and/or ≥2 diagnoses by a primary care physician [PCP]) and/or ≥1 diagnoses from a hospital with one diagnosis from a PCP; ≥1 rheumatoid factor (RF) test performed; age ≥18 years on the first diagnosis; first diagnosed before Dec 31 2018; MHS members for ≥12 months before and after the first RA diagnosis. RA patients also had to meet at least one of the following criteria: ≥1 purchase of disease modifying anti-rheumatic drugs (DMARDs) and/or ≥2 separate RA diagnoses by a rheumatologist and/or ≥1 positive RF test or anti-cyclic citrullinated peptide antibodies (anti-CCP) test. Patients were characterized according to socio-demographic and clinical factors. Treatment patterns with DMARDs were examined during 2000-2020. Multivariate logistic regression model was used to identify factors associated with current DMARDs treatment in 2020.

**Results:** We identified 8301 eligible RA patients (Table 1). The proportion of patients initiating treatment with any DMARDs within 12 months of diagnosis gradually increased from 37.8% in 2000 to 69.3% in 2010 and reached 80.0% for those first diagnosed in 2018. During 2000-2009, 60.0%-63.4% of the RA patients were not treated and during 2010-2020 53.8%-57.9% were not treated. Following the introduction of bDMARDs, the proportion of those using bDMARDs and/or tsDMARDs increased (Figure 1). The median time to treatment with the first bDMARDs decreased during follow-up, from 9 years (IQR 6.0-13.0) among those diagnosed in 2000 to 3 years (IQR 1.0-5.0) in those diagnosed in 2009, and to 1 year in those diagnosed in 2018 (IQR 0.1-1.0). In 2020, only 44.3% of the RA patients were treated with any DMARD. Patients with disease duration of 5–<10 years and disease duration of ≥10 years, were less likely to be treated with any DMARD in the first year after diagnosis over the last two decades. Yet, about 55% of all RA patients were untreated in 2020, especially those with longer disease duration. Efforts should be made to optimize the disease management.

**Background:** Rituximab (RTX) is a murine/human chimeric monoclonal antibody directed against the CD20 receptor expressed on pre-B and mature B cells. Rituximab is used effectively in the treatment of different rheumatic diseases, but it can induce hypogammaglobulinemia as a side effect.

**Objectives:** To analyze the prevalence of hypogammaglobulinemia and its association with infections in patients with rheumatic diseases treated with RTX.

**Methods:** Multicenter, retrospective, observational study. Patients with rheumatic diseases treated with RTX in 4 centers in Madrid, in which serum immunoglobulin G concentrations were measured, were included. Demographic and clinical variables of the sample were analyzed, and changes in immunoglobulin G concentrations during treatment from baseline were assessed. The chi-square test was used to examine the relationship between variables, considering a P value <0.05 as statistically significant. Logistic regression models were used to analyze the association between hypogammaglobulinemia and sample characteristics.

**Results:** One hundred and seven patients were included: 18 men (16.8%) and 89 women (83.2%), with a mean age of 55.9 (±13.9) years, a mean disease duration of 13.1 (±8.0) years, and a mean age of 51 (±14.4) years at the start of treatment. The most prevalent diagnoses were rheumatoid arthritis (RA) (50.5%), primary Sjögren’s syndrome (pSS) (10.3%), and systemic lupus erythematosus (SLE) (10.3%). Fourteen (14%) patients were treated with RTX monotherapy. The rest
of the patients received concomitant treatment with other immunomodulators such as corticosteroids (64.5%), methotrexate (29%), hydroxychloroquine (27%), lefunomide (9.3%), salsalate (1.9%), or mycophenolate mofetil (2.8%). Twelve (11.21%) patients developed hypogammaglobulinemia (IgG<600 mg/dL): 6 (50%) had RA, 1 (8.3%) SLE, 1 (8.3%) ANCA vasculitis, 1 (8.3%) leuкоcytoclastic vasculitis, 1 (8.3%) IgG4-related disease, 1 (8.3%) dermatomyositis, and 1 (8.3%) PSS. Patients with hypogammaglobulinemia had significantly lower mean serum IgG concentrations at the start of treatment (876.3 ± 1249.4 mg/dL; p=0.05). In the multivariate analysis, no variable related to hypogammaglobulinemia was found. Fifty-three (49%) patients presented infection, of which 17 (15.8%) were serious infections (those that required admission). The distribution of infection cases by groups (patients with and without hypogammaglobulinemia) is shown in Table 1. No significant differences were found in the development of infections or serious infections between patients with and without hypogammaglobulinemia. Only corticosteroid doses equivalent to ≥7.5 mg/day of prednisone were found as a risk factor for the development of infections (OR 3.48; 95% CI: 1.20-0.11; p=0.02).

Conclusion: Patients with hypogammaglobulinemia had significantly lower mean IgG concentrations at the start of treatment with Rituximab than those who did not develop it. No greater frequency or severity of infections was observed between patients with and without hypogammaglobulinemia. Prednisone equivalent daily dose ≥7.5 mg/day was a risk factor for occurrence of infections. Larger sample size studies are needed to confirm these findings.

POS0644 UNDERSTANDING REASONS INFLUENCING PATIENTS' PREFERENCES FOR THE MODE OF ADMINISTRATION OF ANTI-RHEUMATIC DRUGS IN INFLAMMATORY ARTHRITIS. A QUALITATIVE STUDY

Keywords: Patient information and education, Disease-modifying drugs (DMARDs)

C. Beaunais1, G. Montagu2, S. Gleizes2, S. Tropé4, J. Sellam5, T. Pham6. 1Hopital Saint Antoine APHP Sorbonne Université, Rheumatology, Paris, France; 2Unknowns, Strategie et Innovation, Sociology and Research Department, Paris, France; 3Unknowns, Strategie et Innovation, Sociology and Research Department, Paris, France; 4Association nationale de Lutte Contre l'arthrite Rhumatoide, ANDAR, Paris, France; 5Hospital Saint Antoine APHP Sorbonne Université, Rheumatology, Paris, France; 6Hôpital Sainte Marguerite APHM Université Aix Marseille, Rheumatology, Marseille, France

Background: The mode of administration is the third most important factor influencing patient preferences for the choice of antirheumatic drugs, after treatment benefit and risk of adverse events (ref1), with 30% of patients placing route and frequency of administration as their top choice (ref2).

Objectives: To understand the reasons of preferences of the patients with inflammatory arthritis (IA) towards the mode of administration of DMARDs (dis-ease modifying anti-rheumatic drugs).

Methods: A qualitative study was conducted to explore the patients' perceptions and practices of DMARDs. The interviews were conducted by 3 anthropologists using in-depth semi directive and biographical methods, registered, transcribed and analysed using a thematic content analysis approach. Six domains were explored: (i) daily life with IA, (ii) practices of pharmacological and non-pharmacological treatments, (iii) the patient's social and work relationships, (iv) history of the patient pathway, (v) the patient–doctor relationship, decision-making, and (vi) medication daily management. The themes and subthemes related to the mode of administration (route and frequency of administration) were individualized.

Results: Overall 42 patients were included: 33/42, (33/42), with median age 51 years (17-82): 33 had rheumatoid arthritis (RA), 7 spondyloarthropathy (SpA) and 2 psoriatic arthritis (PsA); 22 treated by cDMARDs, 19 by bDMARDs, 12 by JAK inhibitors (JAK-i), in monotherapy or combotherapy, 31 patients having more than 1 line of treatment. Four domains were found to influence patients' preferences: constraints and mental load, rituals and habits, empowerment versus a passive role, representation of disease for the patient and close ones. Subthemes in Table 1.

Table 1. 8 subthemes associated with preference of patients for mode administration.

POS0645 REAL LIFE SAFETY AND SURVIVAL OF TARGETED THERAPIES IN ARTHRITIS PATIENTS OVER AGE OF 65

Keywords: bDMARD, Targeted synthetic drugs

Background: Prognosis for chronic inflammatory arthritis is drastically improved over previous decades and older patients are treated with targeted therapies (TTs) (biological or synthetic targeted therapies). Clinical trials provide mainly information about TTs in patients below the age of 65, so real-life studies are needed to provide more information about TTs in patients over 65 years of age.

Objectives: To compare clinical and therapeutic profile of arthritis patients undergoing TTs and to analyze safety and therapeutic survival according to different age groups.

Methods: We performed an observational cross-sectional study in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and anklyosing spondylitis (AS) patients, older than 40 years old, who started biological or anti-JAK therapy between 2000 and 2022 in the Rheumatology Department of HUP La Fe. A comparative analysis and a Kaplan-Meier survival analysis was performed.

Results: 938 patients (62% female) were included in the study, of which 20.3% are PsA, 55.6% RA and 24.1% AS, with a mean age at the beginning of treatment of 57 (10) years and a mean duration of treatment of 68 (64) months. Patients were classified according to the age at the beginning of treatment: 40-65 years and ≥ 65 years of age. 219 patients (23.3%) were over 65 years of age. In the Table 1 we show the comparative analysis between both groups. Higher proportion of arterial hypertension, diabetes mellitus and dyslipemia in patients older than 65 years was observed. Using a logistic regression model, an association between conventional DMARD prescription and patients older than 65 years was found (P<0.001), being the methotrexate the most used (44.8%). Anti-TNF therapy was the most extended treatment in both groups of patients,
and an association between anti-IL6 therapy and older patients than 65 years was observed (P<0.001). Previous TTs were more frequent in older patients (P=0.002) and treatment duration was lower in those patients (P=0.001). Adverse events were more commonly found in patients older than 65 years as the reason to TT discontinue (P=0.008), being infections the more frequent.

Table 1. Comparative analysis of clinical profile of different age groups at the beginning of TTs.

RISK FACTORS FOR POSTOPERATIVE COMPLICATIONS IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Outcome measures, Epidemiology, Inflammatory arthritis

A. Herrera Van Osstdam1,2, N. Garcia-Mosqueda1, C. Abud-Mendoza1,3.
1Central Hospital Dr. Ignacio Morones Prieto, Reumatologia, San Luis Potosí, Mexico; 2General Hospital No. 1 IMSS, Reumatología, San Luis Potosí, Mexico; 3Faculty of Medicine, UASLP, Medicina Interna, San Luis Potosí, Mexico

Background: Some patients with rheumatic diseases (RD) can require major surgical intervention. There are several risk factors for perioperative complications that must be addressed during de preoperative process [1,2].

Objectives: identify associated factors related to postoperative complications in patients with RD.

Methods: We performed a cohort study of patients with RD that required an elective or an emergency surgery from 2019-2021. We used as controls, patients with No-Rheumatic Diseases (NRD). All patients had preoperative assessment using Lee surgery index and the American College of Surgeons National Quality Improvement Program score (NSQIP), and we estimated disease activity of all RD according to the disease-specific activity scores. We follow-up patients until hospital discharge or death. Univariate and multivariate models were used to determine risk factors for postoperative complications (composite outcome: cardiac or lung complications, blood transfusion, infection, surgery reinvention, respiratory failure, use of vasopressors).

RESULTS: We included 299 patients, 53 patients with RD and 246 NRD. The median age was 49 years in RD. Most patients with RD were women (85%). At baseline NRD patients had higher serum glucose levels, more use of insulin, and had higher rate of acute kidney injury. In the RD-group, 26 had rheumatoid arthritis, 13 systemic lupus erythematosus and 9 others (spondylitis, autoimmune hepatitis, antiphospholipid syndrome, polyarteritis nodosa). Active rheumatic disease was present in 21 patients. Most of the patients with RD (54%) had moderate to high risk of any complication, pneumonia, and risk of wound infection according the NSQIP score. The postoperative complications were higher in RD 37% vs NRD 16% (P<0.0003). Infection developed in 17% of RD patients vs 2.4% of NRD (P<0.0001), uncontrolled hypertension was present in 3% in RD vs 0.4% in NRD, while hypovolemic shock was more frequent in NRD 4% vs 0.1%. One patient with RD died. Of the patients with RD, 58% continued with in-hospital glucocorticoid and 22% with another non-glucocorticoid immunosuppressor in-hospital. In the logistic regression analysis, the presence of active RD at the time of surgery (OR 4.9, IC95% 1.4-18) acute preoperative kidney injury (OR 3, IC95% 1.2-7.3) were predictors of post operative complications; type of surgery performed (elective or urgent), and in-hospital use of glucocorticoid, and immunosuppressors were not significant.

Conclusion: We observed higher post operative complications in RD patient's vs controls. The main prognostic factors were active rheumatic disease, preoperative kidney injury, while the type of surgery performed and in-hospital glucocorticoid or immunosuppressors were not associated to post operative complications.

Humberstone2.
both result in significant disability. Whilst some data in selected samples report no difference in Health Assessment Questionnaire scores (HAQ) between RA and PsA(1), there is a lack of definitive long term population based data. The Norfolk Arthritis Register (NOAR) is an inception cohort of early inflammatory arthritis established in 1989, with over 4,500 cases of new onset inflammatory arthritis. Cases were recruited in primary care or from hospital clinics, and inclusion criteria were age >16 years with 2 swollen joints lasting >4 weeks. Data was collated on demographics and disability through Health Assessment Questionnaires (HAQ) over variable years of follow up (0-20 years); HAQ scores values range from 0 to 3, and the higher the score the greater the disability [2].

Objectives: Our aim was to compare differences between both baseline and follow-up HAQ scores in RA and PsA, in cases selected from the same base population and followed continuously for over 20 years.

Methods: Cases included in this study were recruited into NOAR, who were followed at intervals of 1, 2, 3, 4, 5, 7, 8, 10, 12, 15, 18 and 20 years. Cases of RA were defined using American College of Rheumatology (ACR) criteria; cases of PsA were classified by retrospective clinical record review. Cases with RA were compared to cases with PsA, and data analysis was carried out in R. Independent samples t-tests were used to assess statistical significance of unadjusted compared to cases with PsA, and data analysis was carried out in R. Independent samples t-tests were used to assess statistical significance of unadjusted compared to cases with PsA.

Results: A total of 1,812 cases of RA (85.4%) and 308 cases of PsA (14.5%) were identified with complete data on sex and age within the NOAR cohort who had recorded HAQ scores. The mean age of onset for RA was 56.3 years (min 18.6 – max 88.6; SD 13.9), and 473 years for PsA (min 16 – max 79.9, SD 13.1). Baseline HAQ: Mean baseline HAQ scores were higher for RA at 0.854 (SD 0.704) when compared with PsA at 0.706 (SD 0.688) (p<0.001). Females had higher baseline HAQ scores than males (0.915 vs 0.677) consistent across both disease types which was statistically significant (RA – 0.919 vs. 0.716, p<0.001; PsA – 0.885 vs. 0.533, p<0.001). Follow-up HAQ: Cases were identified up to 20 years. 1,812 cases of RA were identified at baseline, decreasing to 1552 with 1-year follow-up (85.6%) and 165 cases with 20-year follow up (9.1%). 308 PsA cases were identified at baseline, 248 followed up at 1-year (80.5%) and 21 cases for 20-years (6.8%). Figure 1 illustrates that cases with RA had higher mean HAQ scores than PsA throughout a follow up period of up to 20 years. Mean HAQ scores accumulated over the follow up period for RA, whilst there was a decrease in HAQ scores after 12 years of follow up for those with PsA before increasing after 18 years.

Conclusion: The NOAR cohort is unique in its long follow up period of up to 20 years, allowing for the assessment of HAQ longitudinally. The relationship between higher HAQ scores in RA than PsA holds for both baseline HAQ scores and follow-up HAQ scores throughout the follow-up period, supporting the association of RA with greater disability. We hypothesise that this may be due to the nature of joint damage and other comorbidities associated with RA. We also demonstrate from this data that females present with statistically higher baseline HAQ scores than males within both diseases. In conclusion, there are evident trends with higher HAQ scores in RA over PsA consistent over time.

When does obesity exert its effect in conferring risk of developing RA – a large study in cohorts of symptomatic patients at risk

Keywords: Rheumatoid arthritis, Outcome measures

Q. Dumoulin1, D. Krijbolder1, A. Willemze2, P. De Jong3, H. W. Van Steenbergen1, A. Van der Helm – van Mil1,3. 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Maasstad Hospital, Rheumatology and Clinical Immunology, Rotterdam, Netherlands; 3Erasmus MC, Rheumatology, Rotterdam, Netherlands

Background: Case-control studies have identified body mass index (BMI) as a risk factor for development of rheumatoid arthritis (RA). However, it is unclear when BMI exerts its effect of increased risk, being either in the asymptomatic stage or in the symptomatic phase of Clinically Suspect Arthralgia (CSA) thereafter.

Objectives: To investigate this, we compared BMI of CSA-patients with the general population and we analyzed associations of BMI with progression to inflammatory arthritis (IA) within CSA-patients.

Methods: Firstly, 602 patients consecutively presenting with CSA were studied and followed during 2 years for development of IA. Their baseline BMI was compared to the mean BMI (corrected for age/gender) of the Dutch population (Statistics Netherlands, CBS, 2012-2020). Secondly, cross-sectional associations between BMI and measures of inflammation, tender joint count (TJC-68) and C-reactive protein (CRP), were studied. Finally, the association of BMI and IA development was studied via Cox-regression. Findings were validated in 295 additional comparable patients with CSA included in the SONAR (n=178) and TREAT EARLIER trial (placebo arm, n=117); a pooled analysis was performed.

Results: CSA-patients had a higher mean BMI compared to the general population (26.5 vs 25.3 kg/m², p<0.001). Likewise, CSA-patients were more often obese (BMI ≥ 30 kg/m²) than the general population (22.3 vs 13.8%, Figure 1A); this applied to both ACPA-positive and ACPA-negative patients and was confirmed in the validation cohorts. At baseline, obese CSA-patients had higher TJC-68 (β = 1.26(1.04;1.52)) and CRP (1.37(1.20;1.57)) than CSA-patients with a normal weight. However, obese CSA-patients did not have an increased risk of IA development (HR 0.66(95%CI 0.39;1.11), Figure 1B). Similarly in the validation cohorts, higher BMI was not associated with RA-development (OR per point BMI 0.98(0.95;1.01) for both cohorts together, Figure 1C)

Conclusion: Obesity is more frequent in CSA compared to the general population. Moreover, obesity is associated with higher inflammation at presentation with CSA but did not entail a higher risk for progression from CSA to IA. Hence, obesity primarily seems to exert its effect in the asymptomatic risk-stage of RA-development.

Figure 1. CSA-patients are more often obese than the general population (A); obesity in CSA-patients is not associated with IA development, studied via Kaplan-Meier analysis (B) or via pooled analysis of different cohorts (C).

Spondyloarthritis - clinical aspects (other than treatment) (AXSpA) DESIR cohort

**Keywords:** Spondyloarthritis, Epidemiology

C. Gaujoux-Viala, M. Dougard, T. Lequerre, S. Alonso, A. Motto. CHU Nîmes, Department of Biostatistics, Nîmes, France; 2 Cottin Hospital, Department of Rheumatology, PARIS, France; 3 CHU Rouen, Department of rheumatology, Rouen, France.

**Background:** Inception cohorts can be defined as long term follow-up of patients suffering at entry visit from a recent onset disease. Despite their huge advantage to better approach the truth in terms of long term prognosis of the disease, they are usually facing 2 issues: a) the possibility of a change in the entry visit (initial) diagnosis b) the missing data due to patients lost of follow-up.

**Objectives:** To evaluate both the frequency and the baseline predisposing factors of a) a change in the initial diagnosis b) the risk of loss of follow-up in the DESIR-AXSpA cohort.

**Methods:** Study design: DESIR is an ongoing (10 year follow-up completed for all the patients) multicenter cohort of recent onset axSpA. Diagnosis: At entry visit and during the 10 year follow-up period, this diagnosis was based on the opinion of the treating rheumatologist with the requirement of a highly suspected diagnosis of axSpA at entry visit and after the first 2 years of follow-up the possibility to exclude the patients in case of a change in the initial axSpA diagnosis. Statistical analysis: Multiple imputation was used to address missing data and estimates the probabilities of a change in initial axSpA diagnosis for each patient lost of follow-up. Predisposing factors of an unchanged initial axSpA diagnosis were then evaluated using a multivariate logistic regression model on imputed data sets. A multivariate Cox survival analysis exploring factors associated to the overtime risk of loss of follow-up was also performed.

**Results:** Of the 708 enrolled patients, 45 were excluded from the cohort because of a documented change in the initial axSpA diagnosis (mechanical low back pain n = 30, fibromyalgia n = 13, chronic inflammatory rheumatic disease (n = 1 and no information n = 1). The classification criteria were fulfilled by 16/45 (36%) versus 413/663 (63%) and 21/45 (47%) versus 522/683 (81%) patients with a documented change versus no change in their entry visit diagnosis according to the ASAS axSpA and the AMOR criteria respectively. During the 10 year follow-up period, 300 patients were lost of follow-up. Based on imputation, among these 300 patients, 19 patients were systematically suspected to have a change in their initial axSpA diagnosis in all imputations while 173 patients were never "suspected" for this change; 42 patients were considered as suspected for a change in their initial axSpA diagnosis in at least 70% of imputations. Predisposing factors of an unchanged initial axSpA diagnosis were (odds ratio [95% CI]): radiographic SLJ structural damage: 170 [1.41; 7.10]; past or present psoriasis: 5.3 [2.0; 14.3]; CRP > 6 mg/l: 2.7 [1.3; 5.3]; good response to NSAID: 2.5 [1.5; 4.2]; HLA B27 positivity: 2.0 [1.3; 3.3]; anterior chest wall pain: 2.0 [1.2; 3.3] and female gender: 1.9 [1.2; 3.0].

**Conclusion:** This data suggest that a) a change in the entry visit diagnosis and the risk of follow-up to have been considered in inception cohorts b) statistical models including multiple imputations could facilitate the evaluation of long term prognosis of the disease.

Methods: The design is an observational, longitudinal, prospective, multicentre study in 7 Spanish hospitals. Patients over 18 years of age diagnosed with active uveitis were included. A complete baseline visit was performed by two ophthalmologists who determined ocular inflammatory activity with the UVEDAI index independently and without contact between them. Ophthalmologist 1 made a new visit at 4 weeks to determine the change in the level of uveal inflammatory activity using the UVEDAI index. The interobserver reliability analysis was performed by calculating the Intraclass Correlation Coefficient (ICC), with the values of the variables and the UVEDAI index obtained by ophthalmologist 1 and ophthalmologist 2 in the most inflamed eye at the baseline visit. Sensitivity to change in the UVEDAI index was assessed at 4 weeks from the start of pharmacological treatment by determining the Clinically Relevant Change (CCR) defined as a change in UVEDAI of 0.8 points between the baseline visit and the 4-week visit.

Results: A total of 111 patients were included, 54.1% were male and the mean age at the time of the visit was 49.9 years. 36.9% of uveitis were idiopathic uveitis, and 58.6% were anterior uveitis. The UVEDAI value was calculated from the score of the 7 variables of the index. The mean value recorded in the most inflamed eye at the baseline visit by ophthalmologist 1 was 1.9, being 1.2 points for anterior uveitis and 2.8 points for intermediate/posterior uveitis. In the interobserver reliability analysis, the ICC for the UVEDAI value was 0.9, and when compared to the mean UVEDAI values obtained by the two ophthalmologists for the most inflamed eye at the baseline visit, no statistically significant differences were found (p-value>0.05), neither for the total sample nor differentiating by anatomical location. As for sensitivity of UVEDAI change, statistically significant differences (p-value<0.001) were found when comparing the mean values of the index measured by ophthalmologist 1 at the baseline visit and at 4 weeks, both in the overall sample and differentiating by anatomic location of uveitis. In all cases, the index value decreased significantly by more than 1 point at the 4-week visit after pharmacological treatment.

Conclusion: The interobserver reliability of the UVEDAI was high in the total sample and in the different variables. Furthermore, the index was sensitive in determining the change in inflammatory activity after treatment in both anterior uveitis and intermediate/posterior uveitis/panuveitis. We believe it is an index of activity that could be used both in routine clinical practice and in clinical studies and trials to compare results objectively.

subchondral cysts, and ankylosis. Based on the clinical and instrumental findings, including structural changes characteristic of radiographic sacroiliitis, a final decision by a certified rheumatologist was made and a diagnosis of ankylosing spondylitis was set or ruled out.

**Results:** The mean age and duration of LBP of the patients were 44.7 (14.7) years and 63.9 months, respectively. Of the 50 included patients, 28 (56%) were females. The mean values of c-reactive protein and erythrocyte sedimentation rate were 13.9 mg/l and 39.4 mm/h. Subchondral osteosclerosis was found in 44 patients (88%), JSN -- in 21 patients (42%), erosions -- in 17 patients (34%), subchondral cysts -- in 10 patients (20%), ankylosis -- in 18 patients (36%). Definite CT data for sacroiliitis was seen in 24 patients (48%) and the diagnosis of ankylosing spondylitis was set in 23 patients (46%) of the study group. The likelihood ratios (LR+) for diagnosis of AS were high for erosions (18.4), subchondral cysts (11), ankylosis (6.9) and low for JSN (LR-1.9) and ankylosis (LR-1.1).

**Conclusion:** Nearly half of the patients with inconclusive CR evidence for sacroiliitis were diagnosed with AS after CT imaging. Erosions seen on CT increase the likelihood of assuming AS diagnosis. Computed tomography is a useful tool in diagnosing AS, but it is associated with higher ionizing radiation doses.

**POS0553 DIAGNOSTIC VALUE OF COMPUTER TOMOGRAPHY FEATURES OF SACROILIITIS FOR ANKYLOSING SPONDYLITIS**

**Keywords:** Imaging, Spondyloarthritis, Diagnostic tests

**Background:** Radiologic evidence of sacroiliitis is important for the diagnosis, classification, and management of patients with ankylosing spondylitis (AS).[1] Conventional radiography (CR) has been the most widely utilized imaging modality for the assessment of sacroiliac involvement in axial spondyloarthritis (AxSpA) because of the low radiation dose, ease of operation, and low expenses. CR is used in both the 1984 modified New York criteria and ASAS criteria for classifying AS and AxSpA but lacks sensitivity for early changes. Though MRI detects early changes of the sacroiliac joints, as well as chronic structural changes, its use is limited by the associated cost, procedural time and certain contraindications. Computed tomography (CT) is a modality that enables visualization of erosions, sclerosis, and new bone formation, with the added benefit of multiplanar cross-sectional imaging.

**Objectives:** We aimed to analyze the diagnostic value of computer tomography (CT) features of sacroiliitis for ankylosing spondylitis in patients with inconclusive CR evidence for sacroiliitis.

**Methods:** In this retrospective monocentric observational study, 50 patients with chronic low back pain (LBP) with a duration longer than three months in the lumbosacral region were included. Using the patient record data were extracted on age, pain duration, and plain radiography. Eligible patients should have had plain radiography without evident radiographic sacroiliitis. All the patients had undergone a CT scan of the sacroiliac joint that a radiologist and rheumatologist evaluated for subchondral osteosclerosis, erosions, joint space narrowing (JSN), subchondral cysts, and ankylosis. Based on the clinical and instrumental findings, including structural changes characteristic of radiographic sacroiliitis, a final decision by a certified rheumatologist was made and a diagnosis of ankylosing spondylitis was set or ruled out.

**Results:** The mean age and duration of LBP of the patients were 44.7 (14.7) years and 63.9 months, respectively. Of the 50 included patients, 28 (56%) were females. The mean values of c-reactive protein and erythrocyte sedimentation rate were 13.9 mg/l and 39.4 mm/h. Subchondral osteosclerosis was found in 44 patients (88%), JSN -- in 21 patients (42%), erosions -- in 17 patients (34%), subchondral cysts -- in 10 patients (20%), ankylosis -- in 18 patients (36%). Definite CT data for sacroiliitis was seen in 24 patients (48%) and the diagnosis of ankylosing spondylitis was set in 23 patients (46%) of the study group. The likelihood ratios (LR+) for diagnosis of AS were high for erosions (18.4), subchondral cysts (11), ankylosis (6.9) and low for JSN (LR-1.9) and ankylosis (LR-1.1).

**Conclusion:** Nearly half of the patients with inconclusive CR evidence for sacroiliitis were diagnosed with AS after CT imaging. Erosions seen on CT increase the likelihood of assuming AS diagnosis. Computed tomography is a useful tool in diagnosing AS, but it is associated with higher ionizing radiation doses.

**REFERENCE:**

PROs at baseline were largely similar between groups, while CRP and ASDAS-CRP were higher in r-axSpA patients. A higher percentage of nr-axSpA patients had received previous bDMARDs compared to r-axSpA patients. Crude PRO remission rates at 6/12/24-months were significantly lower in nr-axSpA compared to r-axSpA patients (Table 1, Figure 1 (MODEL1)) as were percentages of patients in ASDAS inactive disease (Table 1). However, when adjusting for age/gender (MODEL2) the difference in PROs diminished, and when adjusting for multiple possible confounders (MODEL3), no significant differences were found between the two groups (Figure 1). Differences in percentages of patients in ASDAS inactive disease in r-axSpA vs. nr-axSpA patients were almost unaffected by adjustments (Figure 1).

Conclusion: While crude remission rates in European secukinumab-treated patients followed in routine care were higher in r-axSpA compared to nr-axSpA patients, this difference disappeared after adjusting for multiple confounders, and, thus, appeared to be related to other factors than radiographic status.

Background: The impact of radiographic status on real-world secukinumab treatment effectiveness in axial spondyloarthritis (axSpA) patients is unknown.

Objectives: To compare the treatment effectiveness of secukinumab in radiographic (r-) vs. non-radiographic (nr-) axSpA patients treated in routine care across Europe.

Methods: Prospectively collected data on secukinumab-treated axSpA patients with known radiographic status followed in routine care in the EuroSpA collaboration [1] were pooled from 9 countries. Patients were listed as r-axSpA if registered to fulfil the modified New York [2] or the radiographic ASAS classification [3] criteria. If patients were registered to fulfil neither criterion or if they did not fulfil one criterion and the other was unknown, patients were registered as nr-axSpA. Patient-reported outcome (PRO) remission rates including pain (VAS≤20), Bath Ankylosing Spondylitis Disease Activity Score-CRP (ASDAS inactive disease <1.3) after 6, 12 and 24 months of secukinumab treatment were calculated. Remission rates in r-axSpA vs. nr-axSpA patients were compared by logistic regression analyses in an unadjusted model (MODEL1), a model adjusted for age/gender (MODEL2) and a model adjusted for age/gender/country/previous bDMARD (yes/no)/baseline CRP/years since diagnosis to secukinumab initiation (MODEL3). For MODEL3, parameter estimates (CRP) from 100 imputed data sets were pooled using Multivariate Imputation by Chained Equations.

Results: Patients with r-axSpA had longer disease duration at secukinumab initiation, were more frequently males and HLA-B27 positive compared to nr-axSpA patients.

LONG-TERM SAFETY OF UPADACITINIB IN PSORIATIC ARTHRITIS, ANKYL OSING Spondylitis, and Non-Radiographic Axial Spondyloarthritis Up to 5 Years

Keywords: Safety, Spondyloarthritis, Psoriatic arthritis

1Charité Universitätsmedizin Berlin, Immunology and Clinical Rheumatology, Berlin, Germany; 2AbbVie Inc., Immunology, North Chicago, United States of America; 3Cantonal Clinic St Gallen, Rheumatology, St Gallen, Switzerland; 4University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan; 5Federal University of Paraná, Rheumatology, Paraná, Brazil; 6AbbVie Deutschland GmbH & Co. KG, Immunology, Wedenscheid, Germany; 7University of California San Francisco, Department of Rheumatology, San Francisco, United States of America

Background: The efficacy and safety of upadacitinib (UPA), an oral JAK inhibitor, has been demonstrated in phase 3 trials for PsA, AS, and nr-axSpA, and pooled axSpA from the SELECT program.

Objectives: To provide a safety update for UPA across PsA, AS, nr-axSpA, and pooled axSpA from the SELECT program.

Methods: Safety data (cut-off: 15 Aug 2022) from 5 UPA trials in PsA (2, AS) (2), and nr-axSpA (1) were compiled. Treatment-emergent adverse events (TEAEs): onset on or after first dose and ≤30 days for UPA 15 mg (UPA15), or ≤70 days for UPA10 (UPA10), were summarized for pooled PsA (pooled UPA15, and ADA [1 study only]), AS (pooled UPA15), nr-axSpA (pooled UPA15), and pooled axSpA (pooled UPA15 from AS and nr-axSpA trials). TEAEs are reported as "exposure-adjusted event rates (events/100 patient-years) (E/100 PY)." Age-gender adjusted standard incidence ratios (SIRs) using the SEER database were calculated.

Results: A total of 1789 patients (PsA, n=907; AS, n=596; nr-axSpA, n=286) received ≥1 dose of UPA15, totaling ~3690 PY of exposure (Table 1). Overall AEs and serious AEs were highest in PsA, and numerically higher with UPA15 vs ADA; rates were generally similar between AS and nr-axSpA. AEs leading to discontinuation were generally similar across treatment groups and diseases and were numerically lowest in AS. Rates of malignancy excluding non-melanoma skin cancer (NMSC) were similar between PsA, AS and nr-axSpA, except for skin cancer in PsA and were generally similar across diseases (Figure 1). In PsA, higher rates of serious infection, herpes zoster (HZ), lymphopenia, and NMSC were observed with UPA15 vs ADA. The SIR (95% CI) for malignancy excluding NMSC with UPA15 was 0.94 (0.54-1.53) in PsA and 0.58 (0.12-1.69) in pooled axSpA; SIRs for AS (1 case) and nr-axSpA (2 cases) were not calculated separately due to low events. In PsA, the SIR (95% CI) was 0.71 (0.40-1.18), and 0.33 (0.13-0.69) with COVID-19 deaths excluded, suggesting no increased risk of death vs the general population. SIRs were not calculated for AS, nr-axSpA, or pooled axSpA due to low events. Data from this analysis should be interpreted with caution, as it was not enriched for AEs and duration of exposure was more limited for AS and nr-axSpA.

Conclusion: Higher rates of serious infection, HZ, lymphopenia, and NMSC were observed with UPA15 vs ADA in PsA; slightly elevated rates for most of these TEAEs were also observed with UPA15 in PsA vs axSpA. Apart from these differences, UPA15 demonstrated a generally consistent safety profile across disease states, with no new safety signals identified from previous reports.

Methods:
A retrospective, population-based, cross-sectional study retrieved data from the Clalit Health Services (CHS) registry. Cases were defined as having AS if they had a diagnosis of AS and a follow-up period of at least two years. The prevalence of valvular heart diseases was compared between the two groups, adjusting for multiple confounding factors. AS patients had a significantly higher prevalence of various heart valve disorders in AS patients.

Results:
We included 4,082 AS patients and 20,397 age- and sex-frequency matched controls. AS patients had a significantly higher prevalence of cardiovascular risk factors (p<0.001) and a higher prevalence of valvular heart disease. In the multivariate logistic regression model, adjusting for multiple confounding factors, AS was independently associated with aortic stenosis (OR 2.25, 95% CI 1.57-3.23, p<0.001), aortic insufficiency (OR 2.44, 95% CI 1.53-3.94, p<0.001), mitral insufficiency (OR 1.75, 95% CI 1.17-2.61, p<0.001) but not mitral stenosis (OR 1.31, 95% CI 0.6-2.7, p=0.47).

Conclusion:
Our study reports the increased risk of valvular heart diseases in patients with AS possibly due to the inflammatory milieu associated with the disease process and the result of biomechanical stress affecting the entheses-like valvular structures.

differences between paired measures. Three different criteria were considered to define activity improvement: a change in ASDAS score at 12 months of 1.1 (Clinical Important Improvement -CII-) and 2 points (Major Improvement -MI-) and a reduction ≥ 50% of the initial BASDAI score (BASDAI50).

**Results:**
- Inter-rater reliability: Both s-SCAIISS and SPARCC showed good inter-rater reliability: In baseline MRI: ICC 0.95 and 0.82, respectively; At 1 year MRI: ICC 0.80 and 0.79, respectively.
- Discriminative validity: Of the 206 patients included in our study, 70 (34%) fulfilled the ASAS criteria for presence of inflammation on MRI. The AUC for EMO detection was excellent for both systems (0.98 and 0.96 for SCAIISS and SPARCC, respectively). The optimal cut-off point for s-SCAIISS was 60 u (Sens 83%, Esp 80%) and for SPARCC 1.25 u (Sens 93% and Esp 94%). Using the s-SCAIISS cut-off point of 60 u, and the one 1.25 for SPARCC, 165 patients (81.3%) and 189 patients (93.1%), respectively were classified in accordance with the ASAS definition of the presence or absence of inflammation on MR in r-axSpA at MRI evaluated by the human central readers. Sensitivity to change: Of the 206 patients included, at 1 year after baseline assessment, 48 (23.3%), 17(8.3%) and 54 (26.2%) patients had a CII, MI and BASDAI50, respectively. In these patients with improved disease activity, the mean (SD) s-SCAIISS score at baseline was 404.1 (SD 1055.1), 185.7 (262.7) and 375.3 (SD1008.8), respectively. While at 12 months it decreased to 72.6 (SD134.8), 46.1 (SD72.1) and 76 (SD151.7). The means of paired differences were 331.4 (SD 1019.6), 139.7 (SD 240.8) and 298.3 (SD 976.9), respectively, all of them with p<0.05. As expected, the AUC for the detection of CII, MI and BASDAI50 for both systems were poor (s-SCAIISS 0.61, 0.63 and 0.58 and for SPARCC 0.7, 0.66, 0.60, respectively).

**Conclusion:** The MRI-SIJ EMO quantification system with s-SCAIISS is as reliable and sensitive as change compared to SPARCC. The apparent advantage of SPARCC over s-SCAIISS is artefactualised by the fact that the definition of the presence or absence of ASAS criteria for sacroilitis is determined by the same readers who assess SPARCC.

**Acknowledgements:** We thank all DESIR-cohort patients and all individuals involved with creating and maintaining the cohort. The DESIR cohort was sponsored by the Département de la Recherche Clinique et du Développement, Assistance Publique Hôpitaux de Paris. We are also grateful to the heads of the participating regional centres.

**Conclusion:** PE inflammation and FJ ankylosis on MRI were infrequently observed in patients with r-axSpA. No association was found between inflammation in the PE and the development of FJ ankylosis. However, when inflammation in the FJ is present the likelihood of developing FJ ankylosis after 1 year is over 3 times higher compared to FJ without inflammation. This finding adds to the pathophysiological relationship between inflammation and ankylosis at the same anatomical location of the axial skeleton in patients with axSpA.

**Figure:** The extent of posterior element lesions on MRI across the 23 vertebral units (VU) in radiographic axial spondyloarthritis patients with 2 years follow-up.
Background: Detection of structural lesions of the sacroiliac joint (SIJ) in patients with chronic low back pain is crucial for the diagnosis and classification of axial spondyloarthritis (axSpA). With MRI becoming a part of a routine diagnostic approach of axSpA, the question about the value of T1-weighted images (T1WI) evaluating structural lesions raised.

Objectives: To construct and validate a radiomics model based on T1WI to assess SIJ structural lesions in patients with suspected axSpA.

Methods: A total of 266 patients with clinical suspicion of axSpA between December 2016 and January 2022 were enrolled. Structural lesions were assessed by low-dose CT (LDCT) and MRI, respectively. Radiomics features, extracted from SIJ T1WI, were included to generate the radiomics model. Performance of the radiomics model was evaluated by the receiver operating characteristic curve. Point-biserial correlation analysis was used to interpret the associations between the radiomics features and structural lesions.

Results: Structural lesions were found in 122 of 187 patients (65.2%) in the training cohort and 52 of 79 patients (65.8%) in the validation cohort. Using LDCT as the gold standard, the area under the curves (AUCs) of the radiomics model and MRI experienced rates were 0.82 (95% CI: 0.76, 0.88) vs 0.73 (95% CI: 0.67, 0.79) in the training cohort, and 0.82 (95% CI: 0.72, 0.91) vs 0.74 (95% CI: 0.66, 0.83) in the validation cohort. The seven radiomics features included showed significant correlation with various structural lesions (P all <0.05). Among them, WaveletLH_L_firstorder_90Percen-tile showed the strongest association with fat lesion (r = 0.48, P<0.05).

Conclusion: The radiomics analysis with T1WI could effectively detect SIJ structural lesions and each radiomics feature was correlated with different structural lesions significantly, which might inform radiomic-based applications for axSpA intelligent diagnosis.

Background: While 5-10% of axial spondyloarthritis (axSpA) patients have diagnosed inflammatory bowel disease (IBD), 50-60% display microscopic gut inflammation upon examination of mucosal biopsies. Gut inflammation, as measured by faecal calprotectin (F-calprotectin), is more frequent in radiographic (r-axSpA) than non-radiographic axSpA (nr-axSpA) and has been linked to more active disease [1] – a known risk factor for structural damage progression. How gut inflammation relates to the degree of structural damage in the spine, however, remains sparsely studied.

Objectives: To assess if gut inflammation, as measured by elevated F-calprotectin, is associated with more structural damage in the spine in patients with axSpA.

Methods: Patients with clinical axSpA from a defined area of southern Sweden were cross-sectionally examined and classified as nr-axSpA (ASAS criteria; n=85) or r-axSpA (modified NY or ASAS criteria; n=171). Twenty-four (94%) subjects had comorbid IBD. Spinal structural damage was quantified by mSASSS, one experienced reader scored all examinations, and gut inflammation by F-calprotectin (Calpro AS ELISA). mSASSS scores of patients with normal F-calprotectin (<50 mg/kg) were compared to those with elevated (≥50 mg/kg) or substantially elevated (≥150 mg/kg) values, respectively (Mann Whitney U-test). Furthermore, to explore if presence of gut inflammation (F-calprotectin ≥50mg/kg) was associated with an mSASSS score above the median, logistic regression analysis was used, adjusting for sex, symptom duration, HLA-B27-status, smoking (ever/never), CRP, NSAID (ASAS 3-month NSAID-score) and anti-TNF therapy (yes/no) use. Apart from assessing the overall axSpA group, analyses were also performed limited to subjects with r-axSpA, since both mSASSS and F-calprotectin values were expected to be higher in r-axSpA. Finally, analyses were also repeated after exclusion of patients with IBD as a sensitivity analysis.

Results: Characteristics of the included patients are displayed in the Table 1. In the overall axSpA group, mSASSS scores were significantly higher among patients with elevated F-calprotectin, and even more so among those with substantially elevated F-calprotectin, as compared to those with normal F-calprotectin values (Figure 1). Similarly results were seen when limiting the assessment to r-axSpA, although here mSASSS was significantly higher only among those with substantially elevated F-calprotectin (Figure 1). F-calprotectin ≥50mg/kg was associated with having an mSASSS score above the median (>2 in the overall axSpA and >5 in the r-axSpA groups, respectively) in both study populations – all axSpA: adjusted OR 2.7 (95%CI 1.1-6.7), p=0.028. Excluding patients with comorbid IBD rendered similar results.

Conclusion: Presence of gut inflammation, as measured by elevated F-calprotectin, is associated with more structural damage in the spine in patients with established axSpA, as well as specifically in r-axSpA, even after adjustment for known risk factors of spinal damage development. This calls for prospective studies, assessing gut inflammation as a potential predictor of radiographic progression.

Background: Presenteeism is associated with lower work satisfaction and future sick leave in patients with axial spondyloarthritis (axSpA). It is generally assessed as a continuous variable; however, despite a lower precision, categorical variables are more clinically relevant in routine practice.

Objectives: 1) To identify thresholds of presenteeism instruments that reflect unacceptable work status in axSpA and whether those thresholds could predict future adverse work outcomes, 2) to compare the performance of these thresholds with thresholds from traditional outcomes for axSpA and 3) to understand whether thresholds are stable across contextual factors.

Methods: We used data from the 1-year multinational prospective study on Patient-Reported Outcomes in Employment Study in Ankylosing Spondylitis (AS-PROSE). Thresholds to determine when patients consider themselves in 'unacceptable work status' were calculated at baseline for 4 presenteeism instruments (Work Productivity and Activity Impairment questionnaire -WPAI-, Quality and Quantity method -QQ-, Workplace Activity Limitations Scale -WALS- and Work Limitations Questionnaire -WLQ 25-), and for BASDAI and BASFI. We performed receiver operating characteristic (ROC) analysis using a 0.1 point difference as the threshold for unacceptable work status, and for the QQ method, using patient's ability to perform the current job satisfactorily. We determined thresholds using the Youden index, nearest to 0.1 to determine the optimal cut-off, while balancing over-under diagnosis. Temporal validation was assessed by applying the thresholds in different time points of each patient's data. Finally, accuracy of thresholds to predict future adverse work outcome was assessed through subgroup analyses. Across numerous contextual factors the thresholds were stable, except for some underdiagnoses among women and persons with a physical loading job by WPAI- QQ-, BASDAI- and BASFI-thresholds.

Conclusion: Thresholds for presenteeism and health status representing unacceptable work status have been established, showing stability across contextual factors. The capacity of these thresholds to predict future adverse work outcome was somewhat lower for all instruments. BASDAI and BASFI had a similar performance.

fracture (vs. an incident fracture) if a fracture occurred prior to the index date. Patients were followed over time for incident fractures after the index date. Fractures were defined by ICD codes. We examined all fractures, including those of the vertebrae, sternum/ribs, shoulder/clavicle/upper arm/elbow, distal forearm/wrist/hand, pelvis/hip/femur, knee/leg, and ankle/foot. First, we calculated the combined incidence of fracture and incidence by fracture type. Second, logistic regression models were constructed to identify factors associated with fracture, including age, sex, race or ethnic group, national area deprivation index, dual-eligibility for Medicare (healthcare for adults aged 65+ and some people with certain conditions/disabilities) and Medicaid (healthcare for those with limited income and resources), Charlson comorbidity index, body mass index, smoking status, osteoporosis diagnosis, historical fracture (fracture prior to index date), and use of glucocorticoids and opioids.

Results: We identified 1,426 adults with AS in RISE who were also observable in Medicare. The mean (SD) age was 69.4 years (9.8), 44.3% were female, and 77.3% were non-Hispanic White. Fractures occurred in 197 AS adults (Table 1). The overall incidence rate of fractures among adults with AS was 76.7 (95% CI 66.4-88.6) per 1,000 person-years. The most common fracture was vertebral with an incidence rate of 23.9 per 1,000 person-years (95% CI 18.6-30.7), followed by distal forearm/wrist/hand with an incidence rate of 17.4 per 1,000 person-years (95% CI 13.0-23.4). Age 85+ (OR 3.64, 95% CI 1.79-7.40), historical fracture (OR 5.18, 95% CI 3.40-7.89), and use of opioid drugs (OR 2.20, 95% CI 1.52-3.19) conferred increased odds of fracture; sex did not (Figure 1).

Conclusion: In this large U.S. sample of older adults with AS, vertebral fractures were the most common followed by distal forearm/wrist/hand fractures. Those who were older, had a historical fracture and used opioids had higher odds of fracture. Men and women were equally likely to have a fracture. Since chronic opioid use was associated with fracture in AS, this high-risk population should be considered for interventions to mitigate risk.

**KNOWN AND LESS KNOWN COMORBIDITIES IN AXIAL Spondyloarthritis – WHAT ARE WE OVERLOOKING? RESULTS FROM THE SPARKATUS COHORT**

**Keywords:** Spondyloarthritis, Comorbidities, Epidemiology

J. Sagenstiel 1,2, E. Mogard 1,2, E. Lindqvist 1,2, A. Jourdin 3, M. Geijer 3,4, J.K. Wallman 1,2, T. Olofsson 1,2,1, Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; 2Skåne University Hospital, Department of Rheumatology, Lund, Sweden; 3Lund University, Department of Laboratory Medicine, Lund, Sweden; 4Lund University, Department of Clinical Sciences Lund, Division of Orthopaedics, Lund, Sweden; 5University of Gothenburg, Sahlgrenska Academy, Institute of Clinical Sciences, Department of Radiology, Gothenburg, Sweden; 6Sahlgrenska University Hospital, Department of Radiology, Gothenburg, Sweden

**Background:** It is well-established that axial spondyloarthritis (axSpA) is associated with extra-musculoskeletal manifestations such as anterior uveitis, psoriasis, and inflammatory bowel disease (IBD). Although relevant data exists also regarding other specific comorbid diseases, less is reported on the overall comorbidity burden in relation to the background population.

**Objectives:** To assess the frequency of a wide range of comorbidities, covering most important organ-domains and conditions, in a population-based axSpA cohort, including both non-radiographic (nr-axSpA) and radiographic (r-axSpA) disease, and to compare this to frequencies among matched general population comparator-subjects.

**Methods:** We included 246 well-characterised axSpA patients (mean age 52 years; 55% male) with established disease from the SPARKATUS cohort, comprising patients from a defined area of southern Sweden. All patients had undergone a thorough clinical assessment and were classified as nr-axSpA (fulfilling ASAS nr-axSpA criteria; n=82) or r-axSpA (meeting modified New York/ASAS r-axSpA criteria; n=164). Furthermore, for each axSpA patient, 5 comparator-subjects from the general population, matched on sex, age, and residence area, were randomly drawn from the Swedish Population Register (n=1230). The frequency of 55 different comorbidities, covering most important organ-domains, were then investigated through ICD-10 diagnostic codes retrieved from the Skåne Healthcare Register (covering both primary and specialised care) and collected during a 10-year period preceding inclusion in the cohort (for the index cases; and during the same period for their respective comparator-subjects). Univariable logistic regression was used to compare frequencies of the various comorbidities between axSpA patients and comparator-subjects, while employing the Benjamin-Hochberg procedure to account for multiple tests. Comorbidities with <5 events in either group were excluded from the analysis (n=12).

**Results:** Characteristics of the included patients are displayed in the Table 1. Numerically, almost all investigated comorbidities were more frequent among axSpA patients than comparator-subjects (Figure 1). The patients showed a significantly higher frequency of known extra-musculoskeletal manifestations: anterior uveitis (28% vs. 1% for comparator-subjects, p<0.001), IBD (10% vs. 1%, p<0.01), gout (18% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001) were clearly overrepresented. In addition, patients displayed higher proportions of well-known side-effects of such medications as cyclosporine (28% vs. 1%, p<0.001), fibromyalgia (12% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001). When assessing a wide range of comorbidities, contemporary conditions, but also of less explored conditions such as fibromyalgia and nephrolithiasis, that warrant attention and proper management. Although oral GCs are generally not recommended in axSpA, our results underscore that conditions such as degenerative disc disease (17% vs. 6%, p<0.001), fibromyalgia (12% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001) and were clearly overrepresented.

**Conclusion:** The patients showed a significantly higher frequency of known extra-musculoskeletal manifestations: anterior uveitis (28% vs. 1% for comparator-subjects, p<0.001), IBD (10% vs. 1%, p<0.01), fibromyalgia (12% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001). Also, previously less investigated conditions such as degenerative disc disease (17% vs. 6%, p<0.001), fibromyalgia (12% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001) were clearly overrepresented. In addition, patients displayed higher proportions of well-known side-effects of NSAIDs: gastritis (21% vs. 10%, p<0.001), fibromyalgia (12% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001) were clearly overrepresented. As a consequence, patients displayed higher proportions of well-known side-effects of NSAIDs: gastritis (21% vs. 10%, p<0.001), fibromyalgia (12% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001).

**Background:** Acute anterior uveitis (‘uveitis’), or ‘iritis’, is a common extra musculoskeletal manifestation among patients (pts) with axial spondyloarthritis (axSpA). The prevalence of uveitis varies with HLA-B27 positivity, axSpA subtype and disease duration, reaching >50% in radiographic (r)-axSpA (i.e., ankylosing spondylitis (AS)) pts with >10 years symptom duration [2]. Interleukin (IL)-17 has been implicated in the pathogenesis of uveitis; however, inhibition of IL-17A alone may not be optimal for the management of uveitis [3]. Here, we report the incidence of uveitis following inhibition of IL-17A in addition to IL-17F with bimekizumab (BKZ).

**Objectives:** To compare incidence rates of uveitis in pts with axSpA treated with placebo (PB) or BKZ 160 mg every four weeks (wks; QWx4) to WK 16 of the phase (p)3 trials BE MOBILE 1 and 2. To evaluate incidence rates of uveitis in pts with axSpA treated with BKZ 160 mg Q4W, using pooled ph2b/3 data.

**Results:** Our pooled analysis of data from the BE MOBILE 1 and 2 trials included 312 pts with axSpA treated with BKZ 160 mg Q4W, using pooled ph2b/3 data. The uveitis incidence rates were 5.8% (95% CI 4.2-7.8%) for BKZ and 6.8% (95% CI 5.3-8.5%) for PB, a non-significant difference (p=0.52). The incidence rates for uveitis were 3.8% (95% CI 2.6-5.5%) for BKZ and 4.4% (95% CI 3.0-6.1%) for PB in pts with axSpA treated with BKZ 160 mg Q4W, using pooled ph2b/3 data.

**Mean (SD) if not otherwise stated. Missing ranging from 0-5%.”
Methods: The ph3 studies BE MOBILE 1 (NCT03928704; non-r-axSpA) and 2 (NCT03928743; r-axSpA) comprised a 16-week double-blind treatment period (DBTP; subcutaneous BKZ 160 mg Q4W or PBO) followed by a 36-week maintenance/reduction period (all pts received BKZ 160 mg Q4W) [5]. Upon entry to the ongoing BE MOVING open-label extension (OLE; NCT04436640; cut-off 4 Jul 2022), at Wk 52, all pts remained on BKZ 160 mg Q4W. The ph2b study BE AGILE (NCT02963506; r-axSpA) comprised a 12-week double-blind, dose-ranging period followed by a 36-week randomised period (BKZ 160 or 320 mg Q4W) [4]. Upon entry to the ongoing BE AGILE OLE (NCT03355573; cut-off 4 Jul 2022) at Wk 48, all pts received BKZ 160 mg Q4W. Data were pooled for all pts treated with BKZ 160 mg Q4W in the ph2b/3 trials listed above. Data were pooled separately for pts randomised to BKZ or PBO in the DBTP of BE MOBILE 1 and 2. Uveitis treatment-emergent adverse events (TEAEs) were identified using the preferred terms “autoimmune uveitis,” “iritis,” “tritis,” and “uveitis”; and were reported as both incidence and exposure adjusted incidence rates (EAIRs) per 100 pt years (PY) for all pts who received ≥1 BKZ dose.

Results: Baseline characteristics were reflective of a pt population with moderate-to-severe axSpA (Table 1). In the DBTP of BE MOBILE 1 and 2, uveitis TEAEs occurred in 11/237 (4.6%; EAIR/100 PY [95% CI]: 15.4 [7.7, 27.5]) and 2/349 (0.6%; 1.8 [0.2, 6.7]) of pts randomised to PBO and BKZ (% difference [95% CI]: 4.07 [1.71, 7.60]), respectively (Figure 1). In the 45 DBP-randomised (19.0%) and 52 BKZ-randomised (14.9%) pts with history of uveitis, the incidence [95% CI]: 4.07 [1.71, 7.60]), respectively (Figure 1). All uveitis TEAEs were mild/moderate, one event led to discontinuation.

Conclusion: The incidence rate of uveitis TEAEs was lower to Wk 16 in axSpA pts randomised to BKZ 160 mg Q4W vs PBO. In the largest pool of ph2b/3 data available at the time of this report, the incidence rate of uveitis TEAEs with BKZ 160 mg Q4W remained low at 12/100 PY.

Background: Association between spondyloarthritis and cardiovascular (CV) diseases is a complex issue with variable outcomes.

Objectives: This study aimed to assess the prevalence rates of CV diseases and to analyze the impact of CV risk factors on CV disease in patients with spondyloarthrits.

Methods: A multi-center cross-sectional study using BioSTAR (Biological and Targeted Synthetic Disease-Modifying Antirheumatic Drugs Registry) database was performed on patients with spondyloarthrits. Socio-demographic, laboratory and clinical, data were collected. Patients with and without major adverse
cardiovascular events (MACE) were grouped as Group 1 and Group 2. The primary outcome was the prevalence rates of CV disease and CV risk factors in the overall group. The secondary outcome was the difference in socio-demographic and clinical characteristics between the groups and predictive risk factors for CV disease.

Results: There were 1457 patients with a mean age of 45.7 ± 10.9 years. The prevalence rate for CV disease was 3% (n=44). The distribution of these diseases was coronary artery disease (n=42), congestive heart failure (n=4), peripheral vascular disorders (n=6), and cerebrovascular events (n=4). Patients in Group 2 were significantly older than those in Group 1 (p<0.001). There were significantly more patients with hypertension, diabetes mellitus, chronic renal failure, dyslipidemia, and malignancy in Group 1 than in Group 2 (p<0.05). Smoking (36.7%), obesity (24.4%), and hypertension (13.8%) were the most prevalent traditional CV risk factors. Hypertension (HR=4.994, 95% CI:1.966-12.683, p=0.001) and dyslipidemia (HR=1.960, 95% CI:1.155-6.676, p=0.024) were the independent predictors for CV disease.

Conclusion: The prevalence rate of CV disease was 3.0% in patients with spondyloarthropathy. Hypertension and dyslipidemia were independent risk factors for CV disease in patients with spondyloarthropathy.

DIAGNOSTIC DELAY IS ASSOCIATED WITH WORSE OUTCOMES IN TERMS OF STRUCTURAL DAMAGE IN PATIENTS WITH RADIOPHASIC AXIAL SPONDYLOARTHRITIS. RESULTS FROM REGISPONSER-AS

Keywords: Descriptive Studies, Outcome measures, Spondyloarthritids
VALIDATION OF TWO RESPONSE AND ONE STATUS MEASURES OF THE ASAS HEALTH INDEX VERSUS EXTERNAL ANCHORS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Validation, Outcome measures

L. Kiltz1,2, A. Molto3, C. López-Medina4, M. Dougados5, D. Van der Heijde6, A. Boonen2, F. Van den Bosch1, J. Braun1, Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany; 2Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; 3Cochin Hospital, Rheumatology, Paris, France; 4Reina Sofia University Hospital, Rheumatology, Córdoba, Spain; 5Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 6UMC+, Rheumatology, Maastricht, Netherlands; 7Ghent University Hospital, Rheumatology, Gent, Belgium; 8VIB-Ugent Center for Inflammation Research, Rheumatology, Gent, Belgium

Background: Improvement in functioning and health as assessed by the ASAS Health Index (HI) is an important outcome of interventions in patients with axial spondyloarthritis (axSpA). The ability of various ASAS HI thresholds to discriminate between treatment arms of an active comparator trial have been demonstrated recently by our group with absolute improvement in the ASAS HI in general being superior to relative changes [1, 2].

Objectives: To assess whether ASAS HI response measures (absolute improvement of ≥30% and relative improvement of ≥20%) are sufficiently discriminative between responders and non-responders in both active and placebo arms of trials, and to assess the status of a potential minimal clinically important difference (MCID) for the ASAS HI ≤5.0.

Methods: This post-hoc analysis from the tight-controlled, treat-to-target (T2T) trial TICOSPA (2), data of active axSpA patients randomized to either the T2T arm (visits every 3 weeks, standard treatment intensification if disease activity was not controlled or if disease activity was achieved) or the Usual Care arm (visits every 6 months, disease activity was assessed by the local rheumatologist) was performed. The performance of the ASAS HI response measure was assessed by performing the response over 0-48 weeks. The ASAS HI was calculated according to the ASAS classification criteria at the outpatient clinic of an academic hospital and eight community centres in Flanders, X-ray and MRI of the sacroiliac joints (SIJ) of patients enrolled between November 2010 and August 2020 were assessed by the local rheumatologist (‘local reading’) and two calibrated central readers (‘central reading’) as part of the TICOSPA trial. Readers resolved discrepant cases by consensus. Inter-reader reliability was assessed with Cohen’s Kappa, % overall, positive and negative agreement.

Results: ASAS HI was available in 160 patients, both at baseline and at week 48. At w48, an ASAS HI improvement of ≥30% of ≥20%, improvement of ≥3 points and ≥6 points, respectively. Patients with a meaningful improvement in global functioning had a larger reduction in patient global and disease activity as well as a greater chance to reach remission compared to patients with no significant improvement in global functioning (Table 1). Health outcomes were not different between the two response measures of ASAS HI. Patients who achieved ASAS partial remission, ASDAS inactive disease or ASASAS low activity at week 48 were more likely to have an ASAS HI ≤5.0 compared with patients who did not achieve such states (Figure 1).

Conclusion: We demonstrated discriminant capacity of both, the relative and the absolute response measures of the ASAS HI. Both thresholds proved to have external validity and were able to discriminate between active treatment arms.

RHEUMATOLOGISTS OVERCALL SACRIOILIITIS ON X-RAY AND MRI IN AXIAL SPONDYLOARTHRITIS PATIENTS: DATA FROM THE BELGIAN INFLAMMATORY ARTHRITIS AND SPONDYLITIS COHORT (BE-GIANT)

Keywords: Imaging

A. S. De Craemer1,2, M. De Hooge1,2,3, T. Renson1,2, L. Derom1,2,3, G. Varkas1,2, L. Van Praet1, R. Joos3, J. Lenaerts7, M. Devink5, L. Gyselbrecht2, I. Peene1,10, K. Thevissen11,12, P. Carron1,2,3,13, F. Van den Bosch1,2,3, D. Elewaut1,2,3, G. Varkas1,2, L. Van Praet1, R. Joos3, J. Lenaerts7, M. Devink5, L. Gyselbrecht2, I. Peene1,10, K. Thevissen11,12, P. Carron1,2,3,13, F. Van den Bosch1,2,3, D. Elewaut1,2,3

Background: Imaging of the sacroiliac joints, especially with magnetic resonance imaging (MRI), is an important tool for early diagnosis of axial spondyloarthritis (axSpA). Interpretation of sacroiliac joint imaging can vary according to readers’ experience, but it is currently unknown if and how imaging assessment differs between academic hospitals and community based rheumatological care.

Objectives: To investigate (1) agreement between local and central reading of sacroiliac joint images (X-ray and MRI) from axSpA patients, and (2) to explore potential differences between patients diagnosed in an academic hospital compared to community centres.

Methods: The BelGian Inflammatory Arthritis and spoNdylitis cohort (Be-GIANT) includes newly diagnosed biological-naïve axSpA patients, that fulfil the ASAS classification criteria, at the outpatient clinic of an academic hospital and eight community centres in Flanders. X-ray and MRI of the sacroiliac joints (SIJ) of patients enrolled between November 2010 and August 2020 were assessed by the local rheumatologist (‘local reading’) and two calibrated central readers (‘central reading’) for definite radiographic sacroiliitis according to the modified New York criteria (X-SIJ) and active sacroiliitis according to the ASAS/OMERACT classification criteria (M-SIJ). Central readers resolved discrepant cases by consensus. Inter-reader reliability was assessed with Cohen’s Kappa, % overall, positive and negative agreement.

Results: Among the 271 included patients (n=205 academic hospital, n=66 community hospital), 231 X-SIJ and 208 MRI-SIJ were available for central reading (Table 1). Central readers disagreed with local readers on 30/231 (13%) X-SIJ images (c=0.44, moderate); 4/231 (1.7%) were reclassified as radiographic sacroiliitis and 26/231 (11.7%) as not showing radiographic sacroiliitis. Overall agreement was higher between central readers and academic rheumatologists.

Figure 1. Proportion of patients reaching status of good global functioning at week 48

POS0671

POS0672
compared to community rheumatologists (90.5% vs. 70.7%, p<0.001). 53/208 (25.4%) MRI-SIJ images were reclassified by central readers (κ=0.36, fair); the majority as negative for active sacroiliitis (51/208, 24.5%). Central readers agreed on the assessment of MRI-SIJ in a higher proportion with academic rheumatologists versus community rheumatologists (77.2% vs. 63.4%, p=0.07).

Conclusion: In newly diagnosed axSpA patients, the prevalence of radiographic sacroiliitis is low. Sacroiliitis on MRI is overcalled by rheumatologists both in academic and non-academic settings, underscoring the need for continuous educational trainings.

ARE PATIENTS WITH AXIAL SPONDYLOARTHRITIS WHO WERE BREASTFEEDED LESS INCLINED TO MORE ACTIVE AND SEVERE DISEASE?

Keywords: Spondyloarthritis

S. Alonso Castro1, S. Burger1, P. González del Pozo1, I. Braña Abascal1, E. Pardo Campo1, M. Alperi-López1, R. Queiró Silva1, S. Alonso Castro1, S. Burger1, P. González del Pozo1, I. Braña Abascal1, E. Pardo Campo1, M. Alperi-López1, R. Queiró Silva1

Background: Breast milk is the first source of microorganisms that colonize the gastrointestinal tract and a key factor in shaping the intestinal microbiome. It is currently believed that alterations in the intestinal microbiota are key in the pathogenesis of spondyloarthritis (SpA). It has been postulated that breastfeeding may influence the pathogenesis of SpA and its clinical presentation. The aim of this study was to assess whether breastfeeding modifies the clinical course of axSpA.

Methods: A retrospective cohort study was conducted in patients with axSpA (axSpA) from three centers. The diagnosis of axSpA was defined according to the ASAS diagnostic criteria. The study population included patients with axSpA who were treated at Asan Medical Center from January 1, 2000, to December 31, 2020, excluding patients with chronic kidney disease Stage 4–5, known kidney disease, and malignancy. Renal function was determined by calculation of the estimated glomerular filtration rate (GFR) using the Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations. Patients were stratified into three groups according to initial GFR: Stage 1 (GFR≥90), Stage 2 (60≤GFR<90), and Stage 3 (30≤GFR<60). The GFR values for every 3-year interval were imputed by the linear interpolation method using the measured values before and after each point, and NSAID use in each interval was estimated as the medication possession rate (MPR). To evaluate the association between NSAID use and annual changes in GFR, linear mixed models were used and adjusted for key covariates including age, sex, body mass index, baseline GFR, relative dosage of NSAIDs, comorbidities, and comedinations.

Results: Among 1,838 patients with AS, the mean age was 38.0 (SD, 13.8) years with a median 6.1 years of follow-up. The majority of 1,386 (75.4%) patients belonged to the Stage 1 group, and the number of patients in the Stage 2 and Stage 3 groups was 442 (24.0%) and 10 (0.5%), respectively. In the multivariable models, the mean annual decrease in GFR was significant (model 1: β=-0.684, 95% CI -0.980 to -0.387, p=0.001; model 2: β=-0.387, 95% CI -0.770 to -0.004, p=0.048), and the MPR of NSAID use was significantly associated with an additional decrease in GFR (model 1: for 100% vs. 0% of MPR, β=0.54, 95% CI 0.31 to 0.76, p<0.001; model 2: for highest vs. lowest tertile of MPR, β=0.519, 95% CI -0.906 to -0.132, p=0.009) in the Stage 1 group but not in the patients in the Stage 2 group (Table 1).

**Keywords:** Imaging, Spondyloarthritides, Prognostic factors

A. Moltó, C. López-Medina, M. De Hooge, M. van Lunteren, V. Navarro-Compán, A. Sepriano, S. Ramiro, M. Dougados, Université de Paris, Centre de recherche biostatistique et bio informatique de Sorbonne Paris-Cité, APHP, Hôpital Cochon, Rheumatology, Paris, France; Reina Sofia University Hospital, IMIBIC, University of Cordoba, Rheumatology, Cordoba, Spain; Ghent University Hospital, Rheumatology, Ghent, Belgium; Leiden University Medical Center, Rheumatology, Leiden, Netherlands; La Paz University Hospital, IdiPaz, Rheumatology, Madrid, Spain; NOVA Medical School, UML, Rheumatology, Lisbon, Portugal; Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands

**Background:** Previous evidence suggests that radiographic progression occurs slowly in the sacroiliac joints (SJL) of patients with axial spondyloarthritides and that bone marrow edema (BME) on MRI-SIJ can, at least in part, explain such progression. However, information about the long-term course of radiographic structural damage at the SJL level in patients with early axSpA is still scarce.

**Objectives:** To evaluate the proportion of patients switching from non-radiographic axSpA (nr-axSpA) to radiographic axSpA (r-axSpA) after 10 years of follow-up and whether BME on MRI-SIJ at baseline is associated with the r-axSpA status over time.

**Methods:** Patients with ≤3 years axSpA onset (according to the treating rheumatologist) from the DESIR cohort were included. The radiographic status of the patients (r-axSpA versus nr-axSpA) was based on the fulfilment of the mNY criteria (i.e. at least a bilateral grade 2 or a unilateral grade 3 on pelvic radiographs according to 2 out of 3 central readers). BME on MRI-SIJ was defined as positive ASAS definition according to 2 out of 3 central readers at baseline. Information on mNY criteria was obtained in four reading waves: wave 1 (baseline), wave 2 (BL and 2Y), wave 3 (BL, 2 and 5Y) and wave 4 (BL, 5 and 10Y). Images were scored by 3 central readers (wave 1: 2 readers + adjudicator), all of them unaware of the chronology of the images and the results of the other modality. A “progressor” was defined as a patient switching from r-axSpA to nr-axSpA. A “regressor” was defined as a patient switching from nr-axSpA to r-axSpA. The % of mNY net progressors (i.e. number of “progressors” minus number of “regressors”) divided by the total number of patients was assessed in “completers” (i.e., with pelvic radiographs available at BL and 10Y in wave 4). A sensitivity analysis was conducted using a multilevel GEE model (integrated analysis) that included all waves from all patients with at least one available mNY score from at least one reader available (“intention-to-follow” population). From this model, we estimated the absolute change per year in the percentage of mNY-positive cases with and without adjusting for the use of anti-TNF drugs. Finally, the effect of BME on MRI-SIJ at baseline on mNY positivity over 10 years, adjusting for potential confounders (Figure 1) were evaluated in a multivariable GEE model in the “intention-to-follow” population.

**Results:** Completers included 299 patients (mean age 34.5Y and 48.2% males), while the intention-to-follow population included 704 participants (mean age 33.7Y and 46.2% males). In the completers, the net % of progressors (switch from nr-axSpA to r-axSpA) was 5.7%. In the intention-to-follow population, there was a 0.91% (95%CI 0.60-1.20) increase per year in the probability of being mNY-positive (i.e. a progression of 9.1% after 10Y). After adjusting for anti-TNF use, this percentage decreased to 0.48% (95% CI 0.15-0.82) per year. The HLA-B27 status modified the association between BME on MRI-SIJ at baseline and mNY-positivity over 10 years (interaction p-value: <0.001). BME on MRI-SIJ was associated with being mNY-positive over time in both HLA-B27 positive (OR 6.25 (95%CI 5.36-7.30)) and HLA-B27 negative patients (OR 3.03 (95%CI 2.42-3.80)), but the association was stronger in the former (Figure 1). In addition, male sex, symptom duration >1.5Y, ASDAS >2.1 (in HLA-B27 negatives) and smoking (in HLA-B27 positives) were also associated with being mNY-positive over 10 years.

**Conclusion:** Patients with early axSpA have a low likelihood of changing from nr-axSpA to r-axSpA over 10 years, especially when considering the use of anti-TNF. Local inflammation on MRI-SIJ is strongly associated damage accrual in the SJL over time, in particular in patients who are HLA-B27 positive.
remaining treated with the first bDMARD for at least 3 years or stopping it due to disease control. Clinical characteristics, laboratory tests, concomitant treatment and disease activity measures prior to starting the first bDMARD and after 6 months were collected. Also, btsDMARD courses were registered. Chi-square or Fisher test were used for qualitative variables and unpaired t-test was used for quantitative variables. Univariable and multivariable logistic binary regression analyses were used. **Results:** Out of 101 patients included, 41.6% were classified as D2T and 58.4% as GR. When initiating the first bDMARD, compared with GR, D2T patients had statistically significant shorter symptom duration and more frequently enthesitis, inflammatory bowel disease (IBD), concomitant NSAIDs, smoking habit and comorbidities (hypertension, dyslipidemia, depression or anxiety and fibromyalgia), all p<0.05 (Table 1). However, no significant differences were found in age, sex, BMI, subtype of axSpA, dactylitis, peripheral arthritis, uveitis, psoriasis, concomitant csDMARDs, diabetes mellitus or cardiopathy. While no differences were found for disease activity composite measures (ASDAS, BASDAI) and CRP or ESR, D2T patients had greater scores in BASDAI questions for pain and morning stiffness, TJC, PGA and PhGA. After 6 months of starting the first bDMARD, the scores for all disease activity measures, including ASDAS, BASDAI, CRP and ESR were significantly higher in D2T patients. Reasons for btsDMARDs discontinuation in D2T patients are shown in Figure 1. In multivariable analysis, smoking habit (OR=6.5, p<0.05), HLAB27 negative (OR=5.8, p<0.05), enthesitis (OR=48.1, p<0.01), baseline TJC (OR=12, OR<0.05) and baseline PhGA (OR=1.05, p<0.05) were independently associated with D2T. **Conclusion:** Compared with GR, patients with D2T-axSpA have more frequently poor prognostic factors for therapy response (smoking and HLAB27 negative) and worse response to first bDMARD after 6 months. Further strategies to implement recommendations for not smoking and control of comorbidities should be implemented. **REFERENCE:**

**POS0677**

**THE DEVELOPMENT OF AN OPTIMAL MODEL FOR AUTOCALCULATION OF MSASSS USING DEEP LEARNING IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

**Keywords:** Spondyloarthritis, Artificial Intelligence, Imaging

H. H. Chen,1 D. Y. Chen.1 Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology; Department of Internal Medicine, Taichung, Taiwan, Republic of China; 2China Medical University Hospital, Rheumatology and Immunology Center, Taichung, Taiwan, Republic of China

**Background:** At present, to detect the structural changes of the spine in ankylosing spondylitis (AS), the most commonly used tool is spine X-ray photography and interpretation by a physician, and a score (modified Stoke Ankylosing Spondylitis Spine Score, mSASSS) is given. However, because based on the perspective of the end user was 86.47%, which is expected to have good clinical practicability in TCVGH. Further testing of this mSASSS autocalculation AI model using radiographs from other hospitals is warranted for further clinical implementation in other hospitals.

**Methods:** We collected 1056 pairs of cervical spine and lumbar spine radiographs in 646 patients with AS at Taichung Veterans General Hospital (TCVGH) from Aug 1, 2001, to Dec 30, 2020. We designed software for annotation (yes, no) of the mSASSS-related characteristics (erosion, sclerosis, squaring, syndesmophyte, bony bridging, spur, blurring) over the anterior corners of the cervical (C) and lumbar (L) spines from lateral views of radiographs. One radiologist (Lan-HHC) and two rheumatologists (Chen-HH, Chen-DY) annotate the characteristics and the final judgement was determined by a majority vote. We use PoseNet model develop a localization system identify spines (from second C-spine to first thoracic spines [C1-T1], from twelfth thoracic spine to first sacrum [T12-S1]). We developed a classification system using DenseNet model to identify the mSASSS-related specific characteristics and then calculate mSASSS.

**Results:** We randomly selected 211 pairs of thoracic radiographs as testing set. The remaining 845 (80%) pairs of images were used for model training and testing. Because the number of positive findings of erosion, sclerosis and squaring was quite low in both C-spine and L-spine, we combined radiographs of C-spine and L-spine for AI training to score erosion, sclerosis and squaring. For detection of C-spine characteristics, the area under curve (AUC) specificity/sensitivity/accuracy for bridge, syndesmophyte and osteophyte were 99.8%/98.82%/97.44%/98.48%, 95.7%/94.2%/77.8%/91.67% and 97.5%/95.86%/84.16%/93.75%, respectively. For detection of L-spine characteristics, the AUC/specificity/sensitivity/accuracy for bridge, syndesmophyte and osteophyte were 99.4%/98.46%/94.02%/97.36%, 94.00%/91.48%/77.97%/89.36% and 96.60%/91.08%/89.69%/90.82%, respectively. For detection of C-spine characteristics, the AUC/specificity/sensitivity/accuracy for bridge, syndesmophyte and osteophyte were 99.4%/98.46%/94.02%/97.36%, 94.00%/91.48%/77.97%/89.36% and 96.60%/91.08%/89.69%/90.82%, respectively. We failed to develop an AI model to detect erosion due to its rarity (2 in C-spine and 8 in L-spine). Using the testing set of 211 paired C-spine and L-spine radiographs, the overall accuracy to detect mSASSS-related characteristics was 86.47%.

**Conclusion:** At this stage, the accuracy of the AI-assisted mSASSS scoring based on the perspective of the end user was 86.47%, which is expected to have good clinical practicability in TCVGH. Further testing of this mSASSS autocalculation AI model using radiographs from other hospitals is warranted for further clinical implementation in other hospitals.

A. D. Vieira Bento Silva1,2, M. H. Fernandes Lourenço1,2,3, S. Ramiro1,5, L. Falcão3, J. Bruno3, D. Van der Heijde4, R. B. M. Landewe5,6,7, A. Sepriano2,4,1, Centro Hospitalar de Lisboa Ocidental - Hospital Egas Moniz, Rheumatology, Lisbon, Portugal;2 Nova Medical School, Comprehensive Health Research Center, Lisbon, Portugal;3 Nova Medical School, Faculdade de Ciências Médicas, Lisbon, Portugal;4 Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands;5 Zuyderland MC, Rheumatology, Heerlen, Netherlands;6 School of Health and Related Research, University of Sheffield, Health Economics and Decision Science, Sheffield, United Kingdom;7 Amsterdam Rheumatology Center, Rheumatology & clinical immunology, Amsterdam, Netherlands

**Background:** The Berlin algorithm for axial spondyloarthritis (axSpA) diagnostic was developed more than 15 years ago. New evidence suggests that the diagnostic performance of some SpA features might not be as good as initially thought.

**Objectives:** To review the evidence on the performance of SpA features for axSpA diagnosis.

**Methods:** Systematic literature review and meta-analysis of studies (2004-2021) reporting data on ≥1 SpA feature. The population was defined as adults (>16 years) with a suspicion or definite clinical diagnosis of axSpA. The diagnostic performance of each SpA feature was tested against the physician diagnosis of axSpA. For each feature, if ≥2 studies analysed the same cohort, the one with the highest number of patients was included. Pooled sensitivity, specificity, positive and negative likelihood ratios (LR+ and LR-) were calculated. Sensitivity analyses were performed to assess the effect of covariates, like feature prevalence in the studies, on the diagnostic performance of SpA features.

**Results:** In total, 21 studies (19 cohorts) were included, comprising 8574 patients (4098 [48%] with axSpA). Table 1 shows the results of the meta-analysis. Inflammatory back pain (IBP) and response to non-steroidal anti-inflammatory drugs (NSAIDs) have low LR- (0.3), meaning that the diagnosis of axSpA is less likely when absent; however, if present they are not helpful in making a diagnosis (LR+ ≈ 1). Peripheral features, extra-musculoskeletal manifestations (EMM) and preceding infection may help in the diagnosis of axSpA when present (LR+ 1.7-4.2), but have little value in its exclusion when absent (LR- 0.8-10). Imaging features, elevated C-reactive protein (CRP) and HLA-B27 have good diagnostic performances, reflected by their high LR+ (2.7-17.7) and (relatively) low LR- (0.5-0.7). In a sensitivity analysis the specificity of IBP was lower in studies with high performances, reflected by their high LR+ (2.7-17.7) and (relatively) low LR- (0.5-0.7). In a sensitivity analysis the specificity of IBP was lower in studies with high performances, reflected by their high LR+ (2.7-17.7) and (relatively) low LR- (0.5-0.7).

**Conclusion:** Imaging features, HLA-B27 and elevated CRP have high diagnostic value, even though circuity cannot be ruled out. However, HLA-B27, with a LR+ of 2.7, has a worse diagnostic performance than earlier considered. When present, peripheral features and EMM importantly increase the probability of axSpA, while IBP and good response to NSAIDs do not, but are helpful in ruling out the disease when absent. The diagnostic value of most SpA features is somewhat lower compared to previous data.

**REVISION IN TREATMENT DECISION MIGHT BE NECESSARY IN SEEMINGLY INACTIVE AXSpA PATIENTS ACCORDING TO BASDAI**

**Keywords:** Spondyloarthritis

**D. Søjmez**, 1 H. Kocaayaa, 2 E. Durak Ediboglua, 2 K. A. Sincib, 2 A. Özkanc, 1 G. Kabadayi, 2 I. Kurut Ayın, 1 Ö. Gercik, 1 E. Ergel, 2 E. Otman Akad1

1 Izmir Katip Çelebi University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; 2 Izmir Katip Çelebi University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; 3 Hatay Education and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Hatay, Turkey; 4 Izmir Katip Çelebi University School of Medicine, Department of Radiology, Izmir, Turkey; 5 Izmir Democarcy University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; 6 Kırklareli Education and Research Hospital, Department of Internal Medicine, Division of Rheumatology, İzmit, Turkey; 7 İzmir Katip Çelebi University School of Medicine, Department of Radiology, Izmir, Turkey

**Objectives:** To determine the frequency of inconsistency between the BASDAI and ASDAS-CRP cut-off values in disease activity categorization in patients with axial spondyloarthritis (axSpA) and to characterize the reasons for the discordance.

**Methods:** In total 575 axSpA patients (mean age: 40.2 ± 11.5; male gender: 358; 62.3%) followed up in a single center and who had both BASDAI and ASDAS-CRP scores at the same visit were included in this analysis. Of them 369 (64.2%) were classified as radiographic axSpA (r-axSpA). A BASDAI score of ≥4 and an ASDAS-CRP score of ≥2.1 were used as cut-off value for the differentiation of inactive/active disease state. The demographic, disease related characteristics of the patients including structural damage were obtained.

**Results:** Inconsistency in the definition of the disease state according to two composite disease activity measures was found in 146 (25.4%) patients. As a consequence, the concordance rate of the two scales was calculated as 74.6% and corresponding κ value was 0.458. Of the 274 patients who had inactive disease according to BASDAI, 46.4% were classified as active according to ASDAS-CRP (Figure 1). In our whole group; discordant patients for the disease state distinction according to two measures had higher CRP values, lower percentage of heel pain, and they were using less biologics. These patients also had lower BASFI, HAQ-S, and overall pain scores (Table 1). When we evaluated inactive patients according to BASDAI, discordant patients were significantly older, had lower education, higher serum CRP levels, and more frequently peripheral arthritis. Baseline mSASSS scores were higher in those discordant patients and more patients had syndesmophyte, additionally the progression rate according to mSASSS was higher.

**Conclusion:** In daily clinical practice discordance in the disease activity definition might be observed in around 25% of axSpA patients according to two widely used composite measures. The results of the present study suggested that patients with high serum CRP levels could be easily classified as inactive according to BASDAI and those patients might have developed more structural damage in disease course. Our results suggest that those patients misclassified according to BASDAI scale had worse functional status and quality of life. In conclusion ASDAS-CRP might be more appropriate disease activity measure in treatment decision.

**IDENTIFICATION OF A DIAGNOSTIC MODEL FOR AXIAL SPONDYLOARTHROPATHIES IN DAILY CLINICAL PRACTICE USING A RANDOM FOREST MACHINE LEARNING APPROACH**

**Keywords:** Spondyloarthritis

R. Redeker1, S. Tsiami1, J. Ecker1, U. Kitzi1, D. Kiefer1, I. Andreica1, P. Sewerin1, X. Baraliakos1, 1 Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

**Background:** In axial spondyloarthritis (axSpA), early diagnosis plays a key role in preventing disease progression. However, a validated diagnostic algorithm does not exist, while classification criteria are frequently misused diagnostically.

**Objectives:** To identify which decision model is being used for diagnosing patients with axSpA based on evaluations made in daily practice.

**Methods:** Complete clinical data of 399 patients who presented with chronic back pain in a specialized university clinic were retrospectively evaluated. All patients received complete rheumatologic examination. The total dataset was randomly split into training and test datasets at a 7/3 ratio. A model was built to classify patients into axSpA and non-axSpA based on the random forest algorithm, an ensemble machine learning technique which allows computing the importance of each variable in the statistical modelling process. The Mean Decrease Gini measure was used for the variable importance. The overall accuracy, sensitivity, specificity, and the area under the receiver operating characteristic (ROC) curve (AUC) in the test dataset were calculated.

**Results:** In total, 183 patients were diagnosed with axSpA and 216 with non-SpA (Table 1). In the test dataset, the model reached an accuracy of 0.9315, a sensitivity of 0.9634, a specificity of 0.8906, and an AUC of 0.9886 (Figure 1A). HLA-B27 positivity, erosion on SR MRI, and elevated CRP played the most important role in the statistical modelling process followed by awakening at second half of
right due to back pain and bone marrow edema and fat metaplasia on SIJ MRI (Figure 1B).

Conclusion: Machine learning-based random forest classifier revealed a high performance in diagnosing patients with chronic back pain with axSpA and excluding patients with non-SpA using clinical, laboratory and imaging characteristics as evaluated in a daily practice scenario of a SpA-specialized clinic. External validation of the model is needed to investigate its clinical utility as a diagnostic decision support tool.

INFLAMMATION IS ASSOCIATED WITH INCIDENT HYPERTENSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A LONGITUDINAL COHORT STUDY

Keywords: Real-world evidence, Spondyloarthritis, Prognostic factors

J. L. H. Shi1, S. H. M. Lam2, H. So3, C. Y. Chan1, T. K. Li1, C. C. Szeto1, L. S. Tam1,2. 1The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China

Background: HT is the most prevalent comorbidity in axSpA (1), and is one of the strongest predictors for accelerated atherosclerosis and atherosclerotic vascular events in the general populations [2]. However, the association between time-varying inflammatory markers, disease activity and drug use and the development of incident hypertension (IHT) remain unknown.

Objectives: To elucidate the time-varying risk factors for the development of IHT in patients with axial spondyloarthritis (axSpA).

Methods: We conducted a long-term retrospective cohort study in axSpA patients who were recruited from 2001-2019 from a university clinic in Hong Kong. Patients with HT and/or anti-hypertensive drug use at baseline were excluded. They were followed until the end of 2020. The outcome was IHT, defined by a diagnosis and/or a prescription for an antihypertensive drug. Baseline and time-varying Cox regression analyses adjusting for age, sex, and body mass index (BMI), were used to assess the relationship between inflammatory burden, drug use and IHT.

Results: 413 patients [age: 34(25-43) years, male: 319 (77.2%)] were included. After a median follow up of 12 (6-17) years, 58 patients (14%) developed IHT (IHT-group). Among all the baseline variables, disease duration (BLDD) was the only independent predictor for IHT based on the Cox regression model. In the time-varying multivariate Cox regression analysis, ESR level as an inflammatory marker and BLDD longer than 5 or 10 years, remained as the significant independent predictors to increase risk of future IHT (Table 1a and 1b), while ESR≥20, the use of csDMARDs, sulfasalazine or paracetamol were no longer statistically significant. The Kaplan-Meier curve showed the survival probability were significant lower in groups with BLDD longer than 5 or 10 years (Figure 1).

Conclusion: Higher inflammatory burden as reflected by BLDD longer than 5 or 10 years were predictors associated with IHT after adjusting for inflammation marker and traditional CV risk factors. Higher ESR level may also play a role in the development of IHT in these patients.

Figure 1. The Kaplan-Meier curve for the survival probability of groups stratified by baseline disease duration over time.BLDD: baseline disease duration.
**Keywords:** Spondyloarthritis, Clinical trials, Outcome measures

**P. J. Mease**, R. Grainger*, D. Webster*, M. Crouthamel*, J. Shen*, Y. Xing*, A. Shmagel*, H. Jones*, J. Curtis*, S. Medical Center, Providence St Joseph Health, and University of Washington, Rheumatology Research Division, Seattle, WA, United States of America; 2University of Otago, Wellington, Department of Medicine, Wellington, New Zealand; 3AbbVie Inc, Immunology, North Chicago, IL, United States of America; 4The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, United States of America

**Background:** Exercise can improve the symptoms of axial spondyloarthritis (axSpA) and is recommended as a cornerstone of management for axSpA [1]. Wearable devices can objectively measure physical activity and device-generated data may support development of digitally measured novel endpoints that correlate with treatment response.

**Objectives:** To report physical activity and adherence with wearable technology used to assess the physical activity of people with active ankylosing spondylitis (AS) and inadequate response to biologic DMARD therapy (bDMARD-IR) in the SELECT-AXIS 2 trial, as well as evaluate the association between baseline physical activity and patient-reported measures of functional ability and health.

**Methods:** Patients in the SELECT-AXIS 2 bDMARD-IR study (NCT04169373), a 1:1 randomized, double-blind, phase 3 trial of upadacitinib vs placebo [2], were required to wear a medical-grade wrist-worn actigraphy device that monitored physical activity during the 14-week, placebo-controlled portion of the study. Eligibility criteria included a diagnosis of active AS and inadequate response to bDMARDs. Wearable device adherence, defined as at least 16 hours per day usage, was evaluated through 14 weeks. Baseline physical activity measurements, including median daily steps and time spent sedentary to vigorous physical activity (MVPA), were defined as those in the first week of device usage after trial entry. Median daily steps at baseline were compared by sex and day of the week (weekend vs weekday) across the entire patient cohort using the Mann–Whitney test; differences in physical activity by age were assessed with the Kruskal–Wallis test. For inclusion in the entire patient cohort using the Mann–Whitney test; previously established cutoffs were used to distinguish patients into groups with low, moderate, or high functional ability or health [3,4].

**Results:** Of 420 total patients, physical activity data was collected from 394 participants, and 312 patients met minimal adherence criteria at baseline (first week). Through 14 weeks, adherence was demonstrated for 83.5% of study days (Figure 1A). At baseline, physical activity was higher in men than women and on weekdays than weekends; median daily steps were significantly different based on age (Figure 1B). Baseline mean BASFI and ASAS-HI in the SELECT-AXIS 2 bDMARD-IR-AS trial were 6.3 and 9.3 respectively, suggesting relatively high functional limitation. Patients with higher functional baseline impairment (BASFI score >7) did not statistically differ in median daily time spent in MVPA (p = 0.366) but took an average of 1690 fewer steps per day (p = 0.021) than patients with BASFI scores ≤4 who met the Patient Acceptable Symptom State (PASS) [3] (Figure 1C). Patients reporting "poor" health status [4] (ASAS-HI score ≥12 to 17) spent 30.0 fewer minutes in MVPA (p = 0.005) and took 2186 fewer steps per day (p = 0.010) than those with "good" health status [4] (ASAS-HI scores ≤6; Figure 1D).

**Conclusion:** bDMARD-IR patients with AS in SELECT-AXIS 2 had high adherence with use of a wearable activity monitoring device over 14 weeks. Lower physical activity was generally associated with higher disability scores and poor health status at baseline. These data support the utility of wearable devices for assessing physical activity in people with AS, suggesting the possibility to use such devices to evaluate the impact of targeted therapeutics on passively collected physical activity and functional ability outcomes.

**POS0686 GENDER DIFFERENCES IN THE MANAGEMENT OF SPONDYLOARTHRITIS (SPA) PATIENTS**

**Keywords:** Spondyloarthritis

**D. Hallock**, E. Tho2, R. Connolly3, E. Baynt1, 1United Kingdom, Ipsos Healthcare, London, United Kingdom; 2Kuala Lumpur, Ipsos Healthcare, Kuala Lumpur, Malaysia; 3New York, Ipsos Healthcare, New York, United States of America

**Background:** Spondyloarthritides (SpA) is a family of arthritic rheumatic diseases, including axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA), that primarily affects the spine and joints. It causes inflammation of the spinal and peripheral joints that can lead to severe, chronic pain and discomfort. Diagnosing SpA has proven challenging, particularly for women who are found to be under-diagnosed in AS despite the disease affecting men and women both equally, as there are no current diagnostic criteria for axSpA [1]. Disease activity can be measured through tests such haematology and joint count measurements.

**Acknowledgements:** Nil.

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.493
**Objectives:** The objective of this study was to examine any gender differences in the management of SpA patients and highlight any nuances in treating these patients.

**Methods:** A multi-centre online medical chart review study of patients with PsA and Axial SpA was conducted between July 2022 – September 2022 among UK, FR, DE, IT & ES rheumatologists practicing across hospital and private practices. Physicians were screened for practice duration and patient volume. Charts of patients prescribed with biologics/tsDMARDS were included in the analysis.

**Results:** 262 sample physicians collectively reported 1387 SpA patients. From the reported SpA patients, 812 were recorded as male and 575 as female. The female cohort were recorded with higher instances of co-existing conditions of depression (11.5% vs. 5.3%) and anxiety (13.2% vs. 8.1%) than men. When evaluating extra articular manifestations, female cohort were recorded with higher nail dystrophy (12.7% vs. 8.6%) and psoriasis (36.7% vs. 26.4%) than men. In assessing areas the AS patient suffers from, female cohort were recorded with higher peripheral involvement (49.6% vs. 34.0%) and males more axial involvement (50.9% vs. 28.0%). In assessing disease scores, female cohort were recorded with higher joint counts, haem scores, and PASI score. Physician-defined status of disease severity reported female cohort with higher current severity (48.4% vs. 41.5% moderate and severe) and lower remission rates (45.4% vs. 36.7% not in remission) in comparison to men.

**Table 1. Reported patient disease and haematology scores (mean)**

| SpA patients | Tender joint count (TJC) | Swollen joint count (SJC) | CRP | ESR | PASI | Area

Length of time on current biologic and/or tsDMARD recorded male cohort on treatment for longer timeframe vs females (mean months): 50.2 vs 46.5). The most prominent biologics to treat the two patient groups are TNFIs (72.2% male, 68.6% female); alternate modes of action, such as IL-17is and JAKIs, are more prominently recorded in females vs males (31.2% vs 27.7%). Drivers of treatment choice – specified by sampled physicians - prioritised efficacy in skin (23.3% vs 19.5%), efficacy in manifestations of PsA beyond skin and joint (13.6% vs 9.6%), and reduction of peripheral joint inflammation (172/6 vs 10.3%) in female cohort versus male cohort.

**Conclusion:** From the sample surveyed, current disease activity is higher in reported female patients than males in SpA. Additionally, males are more likely to stay on the same bio/tsDMARD versus females, suggesting a disparity in efficacy or unmet needs when evaluating the two cohorts. It is possible that key differentiating identifiers, such as co-existing comorbidities outside axSpA or PsA or extra articular manifestations, can be used when deciding how to treat a patient. Discussion is necessary about gender-specific treatment plans in SpA, as well as factoring in possible mental health burden (anxiety and depression) disparities across gender cohorts. Further investigation using comparator cohort is warranted.

**POS0668 COMPARING THE CONSTRUCT VALIDITY AMONG MEASURES OF PAIN AND STIFFNESS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

**Keywords:** Patient reported outcomes, Spondyloarthritis, Outcome measures

D. Capelusnik1, 2, E. Nikiphorou3, 4, A. Boonen1, 5, D. Van de Heijde6, 7, B. P. M. Landewe8, A. Van Tubergen9, S. Ramiro7, 10, Maastricht University, Care and Public Health Research Institute (CAPRHI, Maastricht, Netherlands); 2Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center (Tsf) (Tel Aviv-Yafo, Israel); 3King’s College School, Centre for Rheumatic Diseases, London, United Kingdom; 4King’s College Hospital, Rheumatology, London, United Kingdom; 5Maastricht University, Rheumatology, Maastricht, Netherlands; 6Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 7Amsterdam UMC, locate VUMc, Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands

**Background:** In the context of the recent update of the ASAS core outcomes set (CCO), the preferred comparative validity of the measurement instruments to assess the domains ‘Pain and Stiffness’ has been questioned as for the domain responsiveness of instruments was comparable. Group discrimination across various external constructs can help provide useful insights and represents unmet need.

**Objectives:** To compare the group discriminatory capacity, as part of the construct validity, of three instruments to assess pain and three questions of morning stiffness.

**Methods:** Study design: DESIR is an ongoing (10 year follow-up completed for all the patients) multicenter cohort of recent onset axSpA. Diagnosis: At entry visit and during the 10 year follow-up period, the diagnosis was based on the opinion of the treating physician with a requirement of a diagnosis of axSpA at entry and the possibility to exclude the patients after the first 2 years follow-up period in case of a change in this diagnosis. Management during the 10 year period: the investigators were in charge of the data collection required by the protocol but the management (treatment regimens) was only based on the decision of the treating rheumatologist. Statistical analysis: Data presented here are the ones issued afrom the analyses on the complete data (observed data) and b) after multiple imputations considering the missing data due to the patients lost of follow-up (imputed data).

**Results:** Of the 708 enrolled patients, 45 were excluded from the cohort because of a change in the entry visit diagnosis, 3 patients died (suicide n = 1, colorectal cancer n = 1, sudden death n=1), 300 were lost of follow-up and 360 patients completed the 10 year period. A -Based on the analyses of the 10 year completers (n=360) No patient necessitated a spinal vertebroplasty, one single patient had a bilateral total hip replacement. A pension from the national health care system was provided to 16% patients because an invalidity related to the axSpA disease. A csDMARD (methotrexate and/or sulfasalazine) has been prescribed in 32% and a biotherapy in 55%. The prevalence of the main extra-musculoskeletal features increased from 18 to 30%, 10 to 18% and 10% from baseline to year 10 for psoriasis, acute anterior uveitis and inflammatory bowel disease respectively. The prevalence of the main comorbidities increased from 3 to 8%, 0 to 3%, 5 to 15%, 0 to 4%, 1 to 3% and 0 to 2%, from baseline to year 10 respectively for severe GI events, MACE, hypertension, diabetes, tuberculosis and other severe infections respectively. B- Based on the analyses of the 10 year completers (n=360) (observed data) and the 663 patients with unchanged initial axSpA diagnosis (imputed data) An acceptable status at year 10 was observed in 77%,70 [63; 77%],49% 43 [37; 49%]; 55% 48 [41; 56%] consider an acceptable PASS, BASDAI < 30, ASDAS < 2.1 for the observed (%) and imputed (% and [95%CI]) data respectively. The impact of the disease on the daily life of the patients was evaluated by different parameters: ASAS Hl ≤ 5 [41; 35; 47%], SF36 physical score [42; 40; 44] and SF36 mental score [43; 40; 46]. The multivariate analysis of the baseline predisposing factors of an acceptable status at year 10 defined as an ASDAS <2.1 picked-up the following variables: short (<1.5year)delay between the first symptoms and the baseline visit: OR= 1.46[0.93:2.29],socio-professional level (white collar): OR=1.87[1.20;2.90] and baseline BASDAI score<40, OR=1.91[1.23:2.94]

**Conclusion:** These data are suggesting a favorable 10 year outcome in terms of stringent measures such as the requirement to surgery contrasting with a relatively less favorable outcome with regard to patient reported outcomes. These data should improve and facilitate the information provided to the patients at the time of their diagnosis.

**Acknowledgements:** The authors would like to thank all the investigators of the 25 participating centers as well as all the 708 enrolled patients. This study has been financially supported via unrestricted grants from PFIZER and the French Society of Rheumatology.

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.901
Methods: Data from the 8-year visit of patients with axSpA from the multinational OASIS cohort was assessed. The available instruments for pain assessment were: i) total spinal pain, ii) spinal pain at night, iii) spinal pain from BASDAI Q2 (neck, back or hip pain); and for morning stiffness: i) severity of morning stiffness (BASDAI Q5), ii) duration of morning stiffness (BASDAI Q6), iii) the combined score between severity and duration of morning stiffness (average BASDAI Q5/6). Data from 8-year visit were used as the first time-point where all the instruments were obtained on a 0–10 numeric rating scale (as currently used). The discriminatory capacity was assessed through the standardized mean difference (SMD) that is calculated as the difference of the group means divided by the pooled SD of the group means, with a higher value reflecting a higher discriminatory capacity. The external constructs used to compare the ability to discriminate between subgroups of patients were: ASDAS, BASDAI (dichotomized into inactive/active disease), PGAM, PGQoL, fatigue, BASFI, BASMI and mSASSS (dichotomized by the median).

Results: 98 patients were included: 71% males, mean age 54 (SD 11), with a mean symptom duration of 31 (11) years. The (MD) scores for pain were 3.7 (2.3), 2.9 (2.3) and 4.6 (2.6) for spinal pain, spinal pain at night and BASDAI Q2, respectively. The (sd) scores of morning stiffness were 3.7 (2.6), 3.3 (3.1) and 3.5 (2.7) for BASDAI Q5, Q6 and Q5/6, respectively. Spinal pain by BASDAI Q2 and total spinal pain had higher SMDs compared to spinal night pain across all group comparisons, with spinal pain BASDAI Q2 performing mostly slightly better (Table 1). Regarding morning stiffness, the severity question (BASDAI Q5) had consistently higher SMDs across all the clinical external constructs, slightly better (Table 1). Morning stiffness duration (BASDAI Q6) performed worse.

Conclusion: Spinal pain from BASDAI Q2 and severity of morning stiffness (BASDAI Q5) are, respectively, the pain and morning stiffness instruments that best discriminate subgroups of patients classified according to disease activity, functional activity, fatigue or spinal mobility. The recommended ASAS COS pain instrument spinal pain BASDAI Q2, was confirmed to discriminate best. In the case of stiffness, the ASAS COS stiffness measure (BASDAI Q5/6) performed well although slightly less than the severity of morning stiffness (BASDAI Q5).

Background: Despite efforts for early detection, delayed diagnosis in axial spondyloarthritides (axSpA) remains an unresolved challenge.

Objectives: This analysis aimed to assess diagnostic delay and its associated factors around the world in a large sample of patients included in the International Map of Axial Spondyloarthritides (IMAS).

Methods: IMAS is a cross-sectional online survey (2017-2022) including 5,557 unselected axSpA patients from 27 countries. Diagnostic delay was calculated as the difference between age at diagnosis and age at symptom onset reported by patients. The independent factors evaluated were: age at symptom onset, disease duration, gender, education level, diagnosed by rheumatologist, number of healthcare professionals (HCPs) seen before diagnosis, HLA-B27, uveitis, and inflammatory bowel disease. The factor world region was introduced as a dummy variable taking Europe as the reference region due to its larger sample size and diagnostic delay close to the overall mean. The Mann-Whitney, Kruskal-Wallis test and Pearson correlation were used to evaluate the differences in diagnostic delay and independent variables. Associations between diagnostic delay and regions, sociodemographic characteristics, as well as disease-related factors were explored through univariable and multivariable linear regression analysis.

Results: Data from 5,327 patients who reported data to calculate diagnostic delay in IMAS survey were analyzed: 3,231 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Overall, patients reported a diagnostic delay of 7.4 years (median: 4.0) since symptom onset, with substantial variation across regions, being the highest in South Africa and the lowest in Asia (Figure 1). Furthermore, mean disease duration was 17.1 ± 13.3. Patients with longer diagnostic delay were more frequently female, younger at symptom onset, with more years with the condition, more commonly diagnosed by the rheumatologist, with a higher number of HCPs seen before diagnosis, had experienced uveitis, and inflammatory bowel disease. The variables independently associated with longer diagnostic delay in the final multivariable regression model were: younger age at symptom onset (b=-0.100), more disease duration (b=0.363), female gender (b=2.274), being diagnosed by rheumatologist (b=1.163), higher number of healthcare professionals (HCPs) seen before diagnosis (b=1.033), and presence of uveitis (b=1.286; Table 1).

Conclusion: In this global sample of axSpA patients, the mean diagnostic delay was 7.4 years, and had significant differences across regions. Younger age at symptom onset, longer disease duration, female gender, diagnosed by rheumatologist, higher number of HCPs seen before diagnosis, and the presence of uveitis were the parameters associated with a longer diagnostic delay in axSpA patients.

**Conclusion:** These findings suggest that NSAIDs influence sacroiliac BMO and, where sacroiliac is present, are associated with increases in disease activity or spinal pain, but also provide evidence that almost all patients who attempt washout can successfully achieve it.

IN AXIAL SPONDYLOARTHRITIS, NON-STEROIDAL ANTI-INFLAMMATORY DRUGS REDUCE MRI-APPEARANCE OF SACROILIITIS

Keywords: Imaging, Spondyloarthritis

G. Jones1, A. Bennett2, R. Sengupta1, P. Machado1, H. Marzo-Ortega1, L. Aucott3, G. Macfarlane1. 1University of Aberdeen, Aberdeen Centre for Arthritis and Musculoskeletal Health (Epidemiology Group), Aberdeen, United Kingdom; 2Defence Medical Rehabilitation Centre (Stanford Hall), Academic Department of Military Rehabilitation, Loughborough, United Kingdom; 3Royal National Hospital For Rheumatic Diseases, Axial Spondyloarthritis Service, Bath, United Kingdom; 4University College London, Centre for Rheumatology and Department of Neuromuscular Diseases, London, United Kingdom; 5University of Leeds, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 6University of Aberdeen, Health Services Research Unit, Aberdeen, United Kingdom

Background: MRI evidence of active sacroiliitis (sacroiliac joint bone marrow oedema (BMO)) is commonly used to assist diagnosis and classification of axial spondyloarthritis (axSpA). Non-steroidal anti-inflammatory drugs (NSAIDs) are used as first-line therapy, and for persistent clinical symptoms continuous treatment is recommended. Prescribed in primary care, and widely available over-the-counter, many patients are already taking NSAIDs when they first present to rheumatology.

Objectives: To determine whether NSAID use leads to an underestimation of sacroiliac joint BMO.

Methods: Adults with axSpA were recruited from NHS rheumatology clinics and patients with axSpA who had previously scanned positive at Scan 1 (off NSAIDs). Those who scanned positive for BMO lesions, as determined using inter-observer agreement, were considered to have active sacroiliitis.

Results: 311 patients were recruited from 34 centres. Table 1 shows participants’ baseline characteristics. Almost all participants (99%; 95%) completed the NSAID washout and underwent Scan 1. However, 135 (50%) reported an increase in spinal pain (median increase: 2 points on a 0-10 numerical rating scale; inter-quartile range: 1-3), and 166 (61%) reported worsening of disease activity (median increase in BASDAI: 0.9; 0.5-1.6). At Scan 1, 149 (50%) were positive for BMO lesions. 131 (68%) participants underwent the six-week follow-up scan, of whom 31 scanned negative (24%; 95%CI: 17-32%).

Conclusion: These findings suggest that NSAIDs influence sacroiliac BMO and, where sacroiliac is present, are associated with increases in disease activity or spinal pain, but also provide evidence that almost all patients who attempt washout can successfully achieve it.

Table POS0691

ANALYSIS OF GAIT IN LONGSTANDING AXIAL-SPONDYLOARTHRITIS: A MONOCENTRIC PILOT STUDY

Keywords: Descriptive Studies, Spondyloarthritis, Motor function

M. Conigli1, F. Aripa2, G. Solinas1, M. M. Angioni1, E. Chessa1, A. Floris1, M. Naitza1, M. Piga1, M. Monticone1, M. Pau1, A. Cauli1. 1Rheumatology Unit, AOUM and University of Cagliari, Monserrato, CAGLIARI, Italy, Department of Medical Sciences and Public Health, Cagliari, Italy; 2University of Cagliari, Department of Mechanical, Chemical and Materials Engineering, Cagliari, Italy; 3University of Cagliari, Department of Medical Sciences and Public Health, Cagliari, Italy

Background: Progression of radiographic damage in axial-spondyloarthopathies is related to higher functionality impairment in longstanding patients, resulting in poorer quality of life and autonomy. Its impact on gait has not been extensively studied yet. Time-up and go (TUG) test and GAIT analysis (GA) are currently used in neurological and musculoskeletal diseases to evaluate changes in patients gait and stance.

Objectives: The aim of this study is to evaluate with standardized procedures modifications of gait in patients with inactive longstanding axSpA with radiographic damage, comparing them with a cohort of sex, age and BMI matched healthy controls.

Acknowledgements: The study was funded by Versus Arthritis (ref: 21022)

Disclosure of Interests: None declared, Gary Macfarlane: None declared, Shashank Murlidhar Akerkar: AbbVie, Celgene, Eli Lilly, Galapagos, Janssen, Pfizer, MSD, Novartis, Orphazyme, Pfizer, Roche, UCB, Helena Marzo-Ortega Speakers bureau: AbbVie, Biogen, Celgene, Eli Lilly, Novartis, Pfizer, Takeda, UCB, Consultant of: Eli Lilly, Janssen, MoonLake, Novartis, Pfizer, UCB, Grant/research support from: Janssen, Novartis, UCB, Lorina Aucott: None declared, Gary Macfarlane Grant/research support from: Pfizer, AbbVie, UCB, Amgen.
Methods: Patients followed at Rheumatology Unit of the University Hospital of Cagliari were enrolled. Inclusion criteria were: 1) having a diagnosis of axSpA, 2) having an inactive disease (BASDAI<4, PGA<20, PhGA=20), 3) evidence of radiographic damage in the most recent spine x-ray available (mSASSS >20), 4) ability to walk autonomously. Exclusion criteria were: 1) deafness, 2) any medical condition that, according to investigators, could expose patients at excess risk or interfere with the procedures of the study, Patients underwent a TUG test and a gait analysis at the Department of Mechanical, Chemical and Materials Engineering, University of Cagliari. For TUG Test the following parameters were recorded: TUG time, sit-to-stand time, first and second rotation time, stand-to-sit time, walking time. Walking speed and mean step length were recorded using GAIT analysis. Statistical analysis was performed with MANOVA (Pillai’s Trace, Wilk’s Lambda, Hotelling’s Trace, Roy’s Largest Roots). Level of statistical significance was set at<0.05.

Results: Fifteen patients and fifteen HC were enrolled in this study. Mean age was 60.1±7.8 years for patients and 61.3±7.8 for HC. Height and weight were similar in both groups (axSpA 76.7 ± 16.8kg vs HC 72 ±2kg; axSpA 169.33 ± 8,8cm vs HC 170.4 ± 5.2cm). Disease duration was 27.6±5.2 years, mean mSASSS was 46.33±16.84. All patients were inactive, but showed clinical signs of disease progression (BASM 5.9±1,19). Thirteen patients were on treatment with bDMARDs (TNF inhibitors), while 2 were off treatment. MANOVA revealed differences between axSpA patients and HC for TUG test (p<0.05). TUG time and walking time were significantly longer in axSpA (TUG time 12.88±1.92s vs 10.44±2.18s, p=0.003; walking time 5.69±1.7 vs 3.68±0.8, p<0.001), while other parameters were not different between groups. Finally, axSpA patients were slower (0.95±0.16 m/s vs 1.18±0.17 m/s; p<0.05), and had a shorter step (0.52±0.65 m vs 0.65±0.69 m; p<0.05).

Conclusion: Patients with longstanding axSpA showed a different gait when compared with matched HC: we found that axSpA patients walk slower than HC, and with shorter steps. This could be interpreted as a compensatory behaviour as walking speed slower than 1 m/s has been reported as a risk factor for falling in elderly. In conclusion, we found that disease progression in axSpA patients could interfere with walking speed. Clinical relevance of these findings should be confirmed in future studies, as well as if some medical intervention (e.g. physical therapy) could minimize the impact of disease progression on posture control and walking.

REFERENCE:
**Vasculitis - large vessel vasculitis**

**Keywords:** Imaging, Ultrasound, Vasculitis

L. Seitz, F. Lötischer, S. Reichenbach, P. Villiger, L. Christ, Inselspital, Bern University Hospital, Rheumatology and Immunology, Bern, Switzerland; University of Bern, Institute for Social and Preventive Medicine, Bern, Switzerland; Medical Centre Montbriou, Rheumatology and Immunology, Bern, Switzerland

**Background:** The GUSTO (Giant cell arteritis (GCA) treatment with Ultra-Short glucocorticoids and Tocilizumab) trial evaluated the efficacy and safety of Tocilizumab (TCZ) monotherapy after a 3-day glucocorticoid-pulse in new-onset GCA [1]. Ultrasound measurements of the intra-media thickness (IMT) demonstrated a slow and steady decrease in the temporal arteries and a smaller and delayed effect on the axillary and subclavian arteries with TCZ monotherapy over 52 weeks [2]. Recently, a new Outcome Measures in Rheumatology (OMERACT) GCA ultrasound grading score (OGUS) for monitoring disease activity in GCA has been proposed [3].

**Objectives:** To investigate the evolution of the IMT after discontinuation of TCZ at week 52 in the GUSTO trial. Data up to week 156 are presented (two-year drug-free follow-up).

**Methods:** Eighteen patients with new-onset GCA were enrolled in the GUSTO trial. [1] Patients received 500 mg methylprednisolone intravenously for 3 consecutive days. Thereafter, glucocorticoid treatment was discontinued and TCZ (8 mg/kg body weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162 mg) from day 10 until week 52. Patients in clinical remission stopped TCZ at week 52 and entered the follow-up study. The maximum IMT of the temporal arteries (common superficial temporal artery, parietal and frontal branch) and IMT at landmarks of the axillary and subclavian arteries were measured blindly at weeks 52, 78, 104 and 156. The OGUS is calculated as follows: IMT divided by the rounded cut-off values of IMTs for each segment; the sum of these values is then divided by the number of segments available (maximum of 8 segments; axillary and temporal arteries considered). [3]

**Results:** At week 52, 13/18 patients were in relapse-free remission and entered the follow-up study. 1/13 patients presented with a minor relapse during the 104 weeks follow-up period. At week 56, 12/13 patients were in relapse-free and drug-free remission. The OGUS showed a steady decline with mean values of 0.92 (standard deviation (SD) 0.17) at week 52, 0.87 (SD 0.16) at week 78, 0.84 (SD 0.15) at week 104, and 0.79 (SD 0.12) at week 156. IMT measurements of one patient after restarting TCZ therapy were excluded (weeks 104 and 156).

**Conclusion:** After 52 weeks of treatment with TCZ, the IMT in GCA continues to decline during a drug-free period of up to or possibly more than two years. It can take more than one year after treatment discontinuation for the OGUS to become smaller than 1, indicating an average IMT below the rounded diagnostic cut-off values. Our results suggest a long-lasting remodeling phase of the vessel wall after treatment discontinuation.

**MOLECULAR PHENOTYPING OF GIANT CELL ARTERITIS PATIENTS: ANALYSIS OF THE SERUM PROTEIN PROFILE USING A HIGH THROUGHPUT METHOD**

**Keywords:** Biomarkers, -omics, Vasculitis

F. Zingg, A. Gloor, C. Polysopoulos, P. Villiger, B. Maurer, L. Christ, Inselspital, Bern University Hospital, Department of Rheumatology and Immunology, Bern, Switzerland; Inselspital, Bern University Hospital, Department of Internal Medicine, Bern, Switzerland; Statistics and Data Management Group, Swiss Clinical Quality Management Foundation, Zurich, Switzerland; Medical Center Montbriou, Rheumatology and Immunology, Bern, Switzerland

**Background:** There is a lack of biomarkers to profile phenotypes in giant cell arteritis (GCA) and predict potential complications. Serum protein profiling may identify molecular-based phenotypes and facilitate personalized medicine approaches.

**Objectives:** To investigate the serum protein signature of clinically defined GCA phenotypes and to evaluate whether serum protein-based profiling identified distinct patient clusters.

**Methods:** We analyzed baseline serum samples from 16 patients with new-onset GCA enrolled in the GUSTO trial. [1] Serum samples were collected prior to treatment or with the lowest prior GC-exposure. In total, 1436 differentially expressed proteins (DEPs) were assessed based on proximity extension assay technology. T-test (threshold, adjusted p-value <0.05) was performed with adjustment for multiple testing (Benjamini-Hochberg) to identify DEPs. Supervised and unsupervised cluster analyses were performed. Supervised analysis was stratified based on the three following clinical phenotypes: presence or absence of (i) cranial and (ii) polymyalgia rheumatica (PMR) symptoms, and (iii) response to treatment within the GUSTO trial.

**Results:** Differences in the serum protein profile were observed based on the presence of cranial GCA and treatment response within the GUSTO trial. We identified 18 DEPs for cranial vs. non-cranial GCA, covering proteins involved in endothelial function (ECF1) or Tnf signaling (IL17RA), and 24 DEPs for response vs. non-response. GCA patients with non-response displayed among others a pronounced Th1 (IL2, IL12) and altered BAFF/APRIL signature. We found no difference based on the presence or absence of PMR-symptoms. Unsupervised hierarchical cluster analysis of the serum protein profile revealed three distinct patient clusters (Figure 1). There was no separation between patients based on clinical parameters except for a tendency to separate GCA patients with (cluster 2) from patients without PMR-symptoms (cluster 1).

**Conclusion:** Upon further validation, in GCA, molecular profiling of patients based on serum protein signatures has great potential for future individualization of patient management. This is the first study to phenotype new-onset GCA based on the serum protein signature. GCA patients with cranial symptoms and treatment response display a distinct serum protein signature. We found a tendency to cluster GCA patients with concomitant PMR-symptoms. Our findings of different protein signatures might facilitate personalized treatment approaches in GCA.

A PROSPECTIVE STUDY EVALUATING A PRE-TEST PROBABILITY SCORE IN THE DIAGNOSIS OF GIANT CELL ARTERITIS

Keywords: Diagnostic tests, Vasculitis, Ultrasound

Objective: To evaluate the diagnostic utility of the PTPS and to investigate whether its use can improve the sensitivity of US.

Methods: We performed a prospective multicentre study of all new referrals to our Rapid Access GCA clinic over 18 months. US of all branches of the Subclavian artery (SA), axillary artery (AA), femoral artery (FA) and common iliac artery (CIA) was performed. Sonographic abnormalities considered indicative of vasculitis included the halo sign and non-compressible arteries with a thickened intima-media complex [5]. The PTPS (scale 0-30) incorporates a number of variables to quantify the likelihood of having a diagnosis of GCA [6]. We compared results to a clinical diagnosis of GCA at 6 months, verified by 2 rheumatologists. We performed Chi-Square tests with ROC analyses and logistic regression to determine the diagnostic performance of the PTPS, US and of both tools combined.

Results: 72/149 patients had a diagnosis of GCA with a mean age of 73.3 years of whom 58% were males. The PTPS AUC for a diagnosis of GCA was 0.807 (95% CI 0.736-0.875). At scores <10, the PTPS correctly refuted the diagnosis in 91.67%, with lower scores having even higher sensitivities. At scores >13, it correctly identifies the diagnosis in 93.51%, with higher scores having even higher specificities. The TAUS AUC for a diagnosis of GCA was 0.865 (95% CI 0.810-0.920). A model which combines both PTPS and TAUS out-performs both individual tools with an AUC of 0.912 and is illustrated in Figure 1. In the case of positive US, a PTPS ≥6 infers a >60% likelihood of having GCA. In cases of negative US, a PTPS ≤12 infers a <20% likelihood of having GCA.

Conclusion: Our study demonstrates a strong correlation between baseline PTPS and a clinical diagnosis of GCA at 6 months, in a large prospective cohort. Although US is superior to PTPS for diagnosis of GCA, a model which combines both tools achieves a sensitivity of 91%, higher than that for US alone. This model can form the basis of an algorithm to guide early corticosteroid use in cases of suspected GCA.

REAPPRAISAL OF LARGE ARTERY INVOLVEMENT IN GIANT CELL ARTERITIS, A POPULATION-BASED COHORT OVER 70 YEARS

Keywords: Epidemiology, Vasculitis, Imaging

M. Elfishawi1, M. Kaymakci1, S. Achenbach2, C. S. Crowson1,2, T. Kermani3, W. Cornelia1, M. Koster1, K. J. Warrington1,2. Mayo Clinic, Division of Rheumatology, Department of Internal Medicine, Rochester, United States of America; Mayo Clinic, Division of Clinical Trials and Biostatistics, Department of Qualitative health Sciences, Rochester, United States of America; University of California, Los Angeles, Division of Rheumatology, Department of Internal Medicine, Los Angeles, United States of America

Background: Screening for large artery manifestations in patients with Giant Cell Arteritis (GCA) has been adopted in clinical practice. However, the effect of recent use of imaging studies on incidence and mortality of large artery manifestations remains unclear.

Objectives: In this study, we aimed to investigate incidence trends and outcomes of large artery manifestations in a population-based cohort of patients with GCA over a span of seven decades.

Methods: The study cohort included patients with incident GCA between 1950-2016 in a defined geographical area. Incident large artery manifestations were defined as aortic aneurysm, aortic dissection, stenosis in the aorta or any of its branches occurred within 1 year prior to the diagnosis of GCA or anytime afterwards. Patients were followed till December 31, 2020, death, or migration. Cumulative incidence of large artery manifestations adjusted for the competing risk of death was estimated. Cox proportional hazards models adjusted for age and sex were used to assess the association of clinical characteristics with large artery manifestations.

Results: The study included 289 patients with GCA: 222 (77%) females; temporal artery biopsy was positive in 235 patients (81%); mean follow up period was 10.4 ± 7 years; mean age at diagnosis was 76.4 ± 8.2 years. Incident large artery manifestations developed in 104 patients throughout the follow up period, the majority (76%) were found incidentally. Cumulative incidence rates of large artery manifestations at 5 years were 7.3% (95% CI 2.4-22.1%), 15.9% (95% CI 10.6-23.8%) and 27.2% (95% CI 20.2-36.6%) for patients diagnosed in 1950-1974, 1975-1999 and 2000-2016, respectively. Moreover, cumulative incidence of large vessel manifestations at 15 years was 14.8% (95% CI 70-31.6%), 30.2% (95% CI 23.1-39.4%) and 48.8% (95% CI 38.8-61.3%) for patients diagnosed in 1950-1974, 1975-1999 and 2000-2016, respectively (Figure 1). Patients with GCA diagnosed in 2000-2016 and 1975-1999 had more than 3.5-fold and 2-fold increase in incidence of large artery manifestations (HR:3.49 95%CI 1.67-7.3 and HR: 1.98 95% CI 0.97–4.07, respectively) compared to 1950-1974. However, there was no significant increase in aortic aneurysm or dissection (Table 1). Mortality risk has decreased significantly in patients with large artery manifestations diagnosed in the latest cohort 2000-2016 (HR 0.38 95% CI 0.17–0.81) following non-significant improvements in 1975-1999 (HR 0.61 95% CI 0.29-1.30) compared to 1950-1974 (reference). Clinical predictors for large artery manifestations included weight loss, fatigue, arm claudication, ever smoker and bruit on physical examination. Cranial symptoms were negatively associated with large artery manifestations.

Conclusion: Incidence of large artery manifestations (mainly large artery stenosis) has increased over time likely from increased use of imaging studies. However, the incidence of aortic aneurysm/dissection has been stable over the last 7 decades. Mortality improvement in the recent years may be due to earlier detection of large artery involvement.

GIANT CELL ARTERITIS CLINICAL DISEASE ACTIVITY MEASURES: RECOMMENDATIONS FOR USE IN CLINICAL PRACTICE

Keywords: Outcome measures, Ultrasound, Vasculitis

Y. El Miedany1, M. Elgaafary2, M. Toth3, S. Bahlas4, M. H. Abu-Zaid5, W. Hassan3, D. Palmer3, S. A. Mahran5, S. A. A. Tabra4, W. Elwakil3, S. Saber5, Y. El Miedany, S. Bahlas, M. H. Abu-Zaid, W. Hassan, D. Palmer, S. A. Mahran, S. A. A. Tabra, W. Elwakil, S. Saber. 1Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt; 2Faculty of Medicine, Al Azhar University, Community and Public Health, Dair Al Balad, Egypt; 3Faculty of Medicine, Ain Shams University, Community and Public Health, Cairo, Egypt; 4Faculty of Medicine, Ain Shams University, Community and Public Health, Cairo, Egypt; 5Faculty of Medicine, Ain Shams University, Community and Public Health, Cairo, Egypt
Background: Although the systematic measurement of disease activity facilitates clinical decision making in Giant Cell Arteritis (GCA), no recommendations currently exist on which measures should be applied in clinical practice.

Objectives: To comprehensively evaluate the validity, feasibility, and acceptability of available GCA disease activity measures and derive recommendations for their use in clinical practice.

Methods: This was a 6-phases process which included a combination of a systematic literature review, psychometric analyses, validated group methods, and physician surveys. In phase 1, The GCA clinical Disease Activity Measures Working Group conducted a systematic review of the literature to identify GCA disease activity measures. Applying exclusion criteria: measurement tools were excluded from further consideration if they: (1) measured imaging only; (2) did not report a continuous value; (3) had insufficient information (e.g. not yet published in manuscript form.). Phase 2: Expert panel were asked to rank the remaining measures via an electronic survey. For each measurement tool, expert panel members were asked to indicate whether they were familiar with the measure (yes, no), whether they had ever used the measure (yes, no), and whether they would recommend the measure for clinical use (yes, no). The survey instructed the expert panel to apply the Outcome Measures for Arthritis Clinics (OMERACT) filter of truth, discrimination, and feasibility as a guide when ranking their top five choices for use in clinical practice. The panel members were encouraged to identify additional measures not listed. Phase 3: following teleconferences the list of measures was reduced based on their rankings and panel comments. Phase 4: included comprehensive examination of the psychometric properties (reliability, validity, and responsiveness) of the remaining GCA disease activity measures. Phase 5 included an electronic survey to score the usefulness and feasibility in clinical practice and acceptance to use the tool on a regular basis when caring for patients. Phase 6: the final list of GCA disease activity measures was prepared.

Results: Using the list of specific disease activity measures as keyword searches, the systematic review of the literature resulted in identification of 21 GCA disease activity measures. Application of exclusion criteria and ratings by the expert panel narrowed the list to 10 measures for further evaluation. Practicing rheumatologists rated these 10 measures as most useful and feasible. From these 7 measures, the working group selected 6 with the best psychometric properties for inclusion in the final set of recommended GCA disease activity measures.

Conclusion: The GCA Clinical Disease Activity Index, has been developed including severity of headache (using 0-100 VAS), acute visual deficit (0-100 VAS), functional disability (0-3), Lab disease activity measures: ESR and CRP, patient global assessment (0-100 VAS), physician global assessment (0-100 VAS). These were identified as they are accurate reflections of disease activity; are sensitive to change; discriminate well between low, moderate, and high disease activity states; have remission criteria; and are feasible to perform in clinical settings.

METABOLIC AND MORPHOLOGIC PET/MR FEATURES IN CRANIAL GIANT CELL ARTERITIS

P. Nienhuis1, C. M. Sørensen2, K. Keller3, I. Hansen4, E. Naeser3, M. Nyhuus5, Bendix Rasch6, E. Brouwer7, R. Slart1, A. Dias5, A. Appelman1, E. M. Hauge3, 1University Medical Center Groningen, Medical Imaging Center Groningen, Groningen, Netherlands; 2The Regional Hospital in Horsens, Department of Medicine, Horsens, Denmark; 3Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 4University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 5Aarhus University Hospital, Nuclear Medicine, Aarhus, Denmark

Background: Accurate and timely diagnosis is crucial for patients suspected of having cranial giant cell arteritis (C-GCA) as prompt treatment with high-dose glucocorticoids may prevent severe ischemic complications, such as vision loss. However, the use of high-dose glucocorticoids in patients without proven C-GCA should also be done with caution due to potential side effects. Currently, multiple diagnostic (imaging) tests are required to establish an accurate diagnosis as single tests lack sufficient diagnostic sensitivity. Next to ultrasonography, 18F-Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (FDG-PET/CT) and Magnetic Resonance Imaging (MRI) are used in clinical practice but carry a significant risk of false negative results. Since FDG-PET imaging measures metabolic activity, while MRI demonstrates morphological changes, combining these modalities may result in a composite hybrid diagnostic test with higher diagnostic accuracy.

Objectives: To describe the metabolic and morphologic imaging features of FDG-PET/MR in patients with diagnosed C-GCA.

Methods: Patients diagnosed with new-onset C-GCA underwent FDG-PET/CT and FDG-PET/MR at 1 and 2 hours after FDG administration, respectively. Patients who had received treatment with glucocorticoids for more than 3 days prior to imaging were excluded from participating. Diagnosis of C-GCA was determined based on clinical information and the results from ultrasonography and FDG-PET/CT. On FDG-PET/MR imaging, thirteen arteries were evaluated bilaterally. Time-of-Flight (TOF) MR angiography was used to detect arterial stenoses or occlusions which were visually graded as either absent or present. To assess vessel wall thickness, T1-weighted contrast-enhanced (T1WCE) MRI images were visually graded on a scale of 0-3, with 0 indicating no mural enhancement or thickening, 1 indicating slight mural enhancement but no thickening, 2 indicating significant mural enhancement and thickening, and 3 indicating mural and perivascular enhancement and thickening. FDG uptake was visually graded on a scale of 0-2, with 0 indicating no vascular uptake, 1 indicating uptake slightly above background, and 2 indicating uptake significantly above background.

Results: The study included 12 patients with new-onset C-GCA with a median age of 74 years (range 61-84 years), of which 9 were female. The mean C-reactive protein (CRP) concentration was 63.2 (SD 41.0) mg/l, and one patient was receiving daily 60 mg prednisolone at the time of imaging (Figure 1, patient 12). Cranial artery ultrasonography was positive in 9 patients, and FDG-PET/CT was positive in the cranial arteries in 10 patients. All patients had at least one positive artery on T1WCE MRI (score ≥ 2) and all but one patient showed at least one arterial stenosis or occlusion on TOF MR angiography. One patient without FDG uptake FDG-PET/MR did also not show any FDG uptake on FDG-PET/CT. Figure 1 shows a heatmap of (a) presence of stenoses/occlusions, (b) the vessel wall thickening score (0-3), (c) the FDG uptake score (0-2), and (d) the overlap of FDG-PET positivity (score ≥ 1), T1WCE MRI positivity (score ≥ 2), and TOF MR angiography positivity. Data for each patient (1 to 12) is shown for each map in rows and data for each artery (Right and Left) are shown in columns. Vessel wall thickening and FDG-uptake were most seen in the vertebral, maxillary, and occipital arteries. Stenosis was most observed in the maxillary arteries. TOF MRA, T1-weighted contrast-enhanced MRI, and FDG-PET/CT scores agreed in 60% of all arteries, however just 10% of all positive arteries were positive on all three modalities. Agreement was highest (74%) between FDG-PET/CT and T1WCE MRI.

Conclusion: The study found an overlap in morphologic and metabolic features in affected arteries in patients with C-GCA using hybrid FDG-PET/MR. However, it also revealed that these features can occur independently of each other. This suggests that the use of hybrid morphologic and metabolic imaging may provide complementary information, potentially increasing diagnostic accuracy for C-GCA.
Background: Two randomised controlled trials (RCT) [1, 2] demonstrated a glucocorticoid (GC)-sparking effect of tocilizumab (TCZ) of at least 50% in the treatment of giant cell arteritis (GCA). The GUSTO (GCA treatment with Ultra-Short glucocorticoids and Tocilizumab) trial was set up to evaluate the efficacy and safety of TCZ-monotherapy after a 3-day GC-pulse in new-onset GCA.

Objectives: The objectives of this analysis were to explore the maintenance of remission 2 years after discontinuation of TCZ treatment (drug-free remission) and the effectiveness or retreatment with TCZ after relapse. Data up to week 156 are presented.

Methods: Eighteen patients with newly diagnosed GCA were enrolled in this investigator-initiated, single-arm, single-center, open-label clinical trial [3]. Patients received 500 mg methylprednisolone intravenously for 3 consecutive days. Thereafter, GC treatment was discontinued and TCZ (8 mg/kg body weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162 mg) from day 10 until week 52. Patients in clinical remission stopped TCZ at week 52 and entered the follow-up study. Maintenance of efficacy at week 156 included the proportion of patients with complete relapse-free remission of disease at week 156, and time to first relapse after week 52.

Results: At baseline there were 12/18 female patients, and the median age was 72 (range 67-75) years. Overall, 15/18 complained of cranial symptoms (10/18 jaw claudication, 6/18 visual symptoms), 10/18 suffered from polymyalgia rheumatica, 16/18 had positive ultrasound findings of the cranial arteries, and 13/18 temporal arterial biopsies showed a characteristic histopathology. At week 52, 13/18 patients were in relapse-free remission and entered the follow-up study. One out of 13 patients presented with a minor relapse at week 72. Remission was achieved after restart of TCZ-monotherapy. At week 156, 12/18 patients were in relapse-free remission.

Conclusion: After a 3-days pulse of methylprednisolone followed by 52 weeks of TCZ monotherapy, drug-free remission was maintained until week 156 in all but one patient entering long-term extension (12/13, 92%). This relapse rate is substantially lower than reported in the RCTs [1, 2]. It may – at least in part – be explained by the patient characteristics (exclusively new diagnoses), and presumably by the intensive initial treatment consisting of a 3-day GC pulse, immediately followed by TCZ. As a proof-of-concept study, the protocol is not intended to be used in everyday clinical practice.

TREATMENT EFFICACY AND SAFETY OF ADALIMUMAB VERSUS TOCILIZUMAB COMBINED WITH METHOTREXATE AND GLUCOCORTICOIDS IN PATIENTS WITH ACTIVE AND SEVERE TAKAYASU ARTERITIS: A RANDOMIZED, OPEN-LABEL, HEAD-TO-HEAD STUDY

Keywords: Clinical trials, Vasculitis, Treat to target

X. Kong1, J. Wang1, L. MA1, H. Chen1, Z. Ding1, X. Jin1, L. Jiang1, F. University, Zhongshan Hospital, Department of Rheumatology, Shanghai, China; 2Fudan University, Zhongshan hospital, Department of Cardiology, Shanghai, China

Background: Takayasu’s arteritis (TAK) is a rare large-vessel vasculitis characterized by granulomatous inflammation in the aorta and its major branches.[1] The affected arteries may become narrowed or even occluded, resulting in ischemia of the corresponding tissue or organs and threatening patient survival.[2] However, effective treatment strategies for TAK are lacking. Although TCZ and TNF-α inhibitors are commonly applied in the treatment of refractory TAK, a formal head-to-head study evaluating their efficacy is lacking. According to retrospective studies,[3, 4] the complete response rate associated with TCZ was slightly better than those associated with TNF-α inhibitors at 6 months (70% vs. 66%; 70% vs. 61%). However, another study indicated a better 3-month complete remission rate associated with TNF-α inhibitors than with TCZ (30% vs. 18%).[5] Thus, the data are inconclusive regarding which medication is more effective. Furthermore, the 6-month nonresponse and 12-month relapse rates associated with these treatments were approximately 25% and 19%, respectively.[3] Thus, given the inconsistent results obtained thus far in this context, we conducted this randomized, open-label, head-to-head study to compare the efficacy and safety of the TNF-α antibody adalimumab (ADA) and TCZ combined with GCs and MTX in patients with active and severe TAK.

Objectives: This study was aimed at investigating the efficacy and safety of adalimumab (ADA) and tocilizumab (TCZ) in patients with active and severe Takayasu arteritis (TAK) concomitantly treated with glucocorticoids (GCs) and methotrexate (MTX).

Keywords: Clinical trials, Vasculitis, Treat to target

Background: Takayasu’s arteritis (TAK) is a rare large-vessel vasculitis characterized by granulomatous inflammation in the aorta and its major branches.[1] The affected arteries may become narrowed or even occluded, resulting in ischemia of the corresponding tissue or organs and threatening patient survival.[2] However, effective treatment strategies for TAK are lacking. Although TCZ and TNF-α inhibitors are commonly applied in the treatment of refractory TAK, a formal head-to-head study evaluating their efficacy is lacking. According to retrospective studies,[3, 4] the complete response rate associated with TCZ was slightly better than those associated with TNF-α inhibitors at 6 months (70% vs. 66%; 70% vs. 61%). However, another study indicated a better 3-month complete remission rate associated with TNF-α inhibitors than with TCZ (30% vs. 18%).[5] Thus, the data are inconclusive regarding which medication is more effective. Furthermore, the 6-month nonresponse and 12-month relapse rates associated with these treatments were approximately 25% and 19%, respectively.[3] Thus, given the inconsistent results obtained thus far in this context, we conducted this randomized, open-label, head-to-head study to compare the efficacy and safety of the TNF-α antibody adalimumab (ADA) and TCZ combined with GCs and MTX in patients with active and severe TAK.

Objectives: This study was aimed at investigating the efficacy and safety of adalimumab (ADA) and tocilizumab (TCZ) in patients with active and severe Takayasu arteritis (TAK) concomitantly treated with glucocorticoids (GCs) and methotrexate (MTX).
Methods: Forty patients were randomized into ADA and TCZ groups (n = 21 and 19, respectively). They were treated with ADA or TCZ combined with GCs and MTX, respectively. The planned follow-up duration was 12 months. The primary end point was time to efficacy rate (ER) at 6 months.

Results: The intention to treat (ITT) population included 21 and 19 patients from the ADA and TCZ groups, respectively. In this population, the ERs at 6 months were higher in the ADA group (85.71% vs. 52.63%, P = 0.02). Similar tendencies were also noted in per-protocol (89.47% vs. 62.50%, P = 0.06). At the 6-month time point, the percentages of patients receiving a GC dose of ≤10mg/day and the cumulative GC dose were similar between the ADA and TCZ groups (43.75% vs. 43.75%, P = 0.83; 4200 mg vs. 4100 mg, P = 0.15, respectively). Imaging improvement or stabilization was observed in most patients in both groups (ADA vs. TCZ: 19/19 vs. 15/16, P = 0.27). Adverse event incidence was comparable between the two groups (ADA vs. TCZ: 38.10% vs. 43.77%, P = 0.55).

Conclusion: ADA was more effective than TCZ in combined treatment with GCs and MTX among patients with active and severe TAK.

Background: Renal artery stenosis (RAS) is more frequent in Asian patients with Takayasu arteritis (TAK). Few studies have assessed the impact of RAS on the presentation and prognosis of TAK using adjusted analysis.

Objectives: To compare the presentation and prognosis between TAK with or without RAS.

Methods: We compared the clinical presentation and vascular involvement (including angiographic subtypes by Hata’s classification) between patients with TAK with or without RAS, with bilateral versus unilateral RAS, and with bilateral RAS versus those without RAS using multivariable-adjusted odds ratios (aOR) with 95% confidence intervals (95%CI) derived after logistic regression. We compared survival between these groups using hazard ratios (HR) with 95%CI adjusted for gender, age at disease onset, delay to diagnosis, baseline disease activity, and inter-group differences. The institute ethics committee provided a waiver of consent for retrospective data retrieval. The institute ethics committee provided a waiver of consent for retrospective data retrieval.

Results: Out of 195 TAK with imaging data available, 106 had RAS (58 bilateral, 48 unilateral; mean±SD follow-up 41.50±34.35 months), TAK with RAS (mean age 22.99 years) or bilateral RAS (mean age 22.83 years) were younger than without RAS (mean age 28.00 years). TAK with RAS had more hypertension (aOR 4.46, 95%CI 1.81 – 10.99), lower limb claudication (aOR 2.72, 95%CI 1.08 – 6.88), and frequent upper limb claudication (aOR 0.43, 95%CI 0.19-0.99) and syncope or dizziness (aOR 0.35, 95%CI 0.14 – 0.83) than TAK without RAS. TAK with bilateral RAS had more frequent hypertension (aOR 11.83, 95%CI 1.38-101.16), blurring of vision (aOR 5.97, 95%CI 1.02 – 34.83), and less frequent constitutional symptoms (aOR 0.18, 95%CI 0.06 – 0.51) than those with unilateral RAS. TAK with bilateral RAS had more frequent hypertension (aOR 8.73, 95%CI 1.90-40.06), vascular bruits (aOR 2.94, 95%CI 1.03 – 8.34), and heart failure (aOR 4.16, 95%CI 1.00 – 17.32), and less frequent constitutional symptoms (aOR 0.23, 95%CI 0.09 – 0.62), pulse loss (aOR 0.29, 95%CI 0.11 – 0.77), and syncope or dizziness (aOR 0.21, 95%CI 0.06-0.73) than those without RAS. Hata’s type IV and type V were more frequent in TAK with versus without RAS (OR 4.01 and 13.40, respectively), and in those with bilateral RAS versus no RAS (OR 5.97 and 10.94, respectively). Adjusted survival was similar between TAK with or without RAS, with unilateral or bilateral RAS, or with bilateral RAS vs those without RAS (Table 1).

Conclusion: RAS is associated with specific clinical and angiographic features not with a greater risk of mortality in TAK.

RISK FACTORS OF DEPRESSION AND ANXIETY IN PATIENTS WITH TAKAYASU ARTERITIS

Keywords: Vasculitis, Mental health, Cytokines and chemokines

Z. Yaxin1,1,1, L. Pan1,1,1, Capital Medical University, Rheumatology and Immunology, Beijing Anzhen Hospital, Beijing, China

Background: Takayasu arteritis (TA) is associated with an increased risk of developing complicated comorbidities, which can bring both psychological and physical burdens to the patients. Most cases are young female patients with an onset age of 10 to 40 years [1]. Psychological disorders have long been recognized as important comorbidities of immune diseases. In the case of rheumatoid progress, comorbid depression and anxiety would increase the mortality and heighten the medication, prognostic and economic burden. In patients with TA, there haven't been identified whether comorbid depression and anxiety may lead to an inaccurate evaluation of disease status and lower quality of life [2-5]. The emotional state generated by the TA should not be ignored. The primary aim of this study was to investigate the risk factors of comorbid depression and anxiety in patients with TA.

Objectives: The research is to investigate risk factors of comorbid depression and anxiety in patients with Takayasu arteritis.

Methods: In this observational, longitudinal cohort study, 86 TAK cases were respectively divided into two groups with or without depression and anxiety to identify the risk factors. The Zung Self-Rating Depression and Anxiety Scale (SDS/SAS) are widely applied in many medical researches related to mental health, which displays convincing results and a remarkable degree of consensus on the diagnosis of mood disorders.

Results: Individual patient data were available from 86 subjects, of whom 23 had depression, and 15 had anxiety. Depression was independently associated with Carotidina, elevated IL-6, and decreased HDL (HR [95%CI] 7.116 [1.58–33.58], p=0.0010; OR [95%CI] 6.669 [1.746–25.470], p=0.005; OR [95%CI] 3.885[1214–12.420], p=0.022) respectively. We used correlation analysis to find out the association between the level of IL-6 with SDS, SAS scores (r=0.337, p=0.002; n=0.280, p=0.010). The levels of Complement 3, NIH, ITAS and ITAS2010 were similarly correlated with SDS score (r=0.332, p=0.032; n=0.280, p=0.009; n=0.332, p=0.002; n=0.323, p=0.002), which wasn’t seemed in SAS score.
Conclusion: Clinicians should be alert to risk factors for predisposing patients to mood disorders. TA patients comorbid depression and anxiety should be given more positive treatment to essentially control the disease to improve their emotional state and quality of life.

REFERENCES:

Objectives: To compare the presentation and prognosis between pediatric-onset and adult-onset TAK are unclear.

Methods: The clinical presentation, angiographic features, treatment patterns, disease activity on follow-up, and survival were compared between pediatric-onset and adult-onset TAK. Categorical variables were compared using odds ratios (OR between pediatric-onset and adult-onset TAK, with 95% confidence intervals). Survival for pediatric-onset and adult-onset TAK were presented using Kaplan-Meier plots and compared using log-rank test. Hazards ratios (HR, with 95% confidence intervals) were calculated, both crude and adjusted for prognostic factors. Prognostic analysis using adjusted analyses adjusted for prognostic factors were conducted to assess adjusted differences in survival between pediatric-onset and adult-onset TAK. A previous meta-analysis of the risk of mortality with pediatric-onset vs adult-onset TAK [1] was updated with the findings from this study. The study was approved by the institutional ethics committee, which waived the requirement for informed consent in view of the retrospective review of chart records.

Results: Heart failure [odds ratio (OR) for pediatric-onset vs adult-onset TAK 2.76, 95%CI [1.22-6.60] and chest pain (OR 3.03, 95%CI [1.11-8.34) were more common in pediatric-onset TAK, and stroke or transient ischemic attack was more frequent in adult-onset TAK (OR 0.31, 95%CI [0.10-0.93). Hata’s angiographic type V (OR 1.95, 95%CI [1.00-3.78) was commoner in pediatric-onset TAK, as opposed to adult-onset TAK. Disease activity at baseline, 6, 12, and 24 months, the use of glucocorticoids and disease-modifying antirheumatic drugs (DMARDs) were similar between pediatric-onset and adult-onset TAK. The unadjusted hazard ratio for mortality with pediatric-onset versus adult-onset TAK was 6.13 (95%CI [1.51-24.91), and after adjustment for prognostic covariates (gender, delay to diagnosis, baseline disease activity, number of conventional and biologic targeted synthetic DMARDs used), was 4.97 (95%CI [1.20-20.58) (Table 1).

Survival was worse for pediatric-onset than adult-onset TAK on unadjusted analyses (Figure 1) and after propensity score matching for these covariates (54 pairs, log rank p value 0.026), Risk ratio for mortality with pediatric-onset vs adult-onset TAK across studies was 2.27 (95%CI 1.05-4.85) after updating a meta-analysis of four observational studies [1] by including the present study.

Conclusion: Pediatric-onset TAK associates with greater mortality than adult-onset TAK. Greater vigilance is required while managing pediatric-onset TAK.

n=182 for all modelsDMARDs – Disease-modifying anti-rheumatic drugs
Methods: Consecutive patients with TAK (50, 40F/5M; mean age: 39.8±8.2 years) and systemic lupus erythematosus (SLE) (43, 38F/5M; 38.0±7.9 years) attending a single tertiary university hospital were studied in addition to apparently healthy hospital workers (57, 50F/7M; 39.5±7.1 years). Carotid artery IMT and SWE values were assessed using carotid artery B-mode US and SWE. Atherosclerotic plaques were noted. Disease duration, clinical characteristics and information related to immunosuppressive drug usage were obtained from the patient's charts. Cardiovascular risk factors were determined.

Results: Study groups were balanced according to the most of the variables including mean age, gender ratio, BMI, past and current smoking history, post-menopausal status, the frequency of diabetes mellitus, the mean total, LDL, and HDL cholesterol levels and the median hsCRP levels (evaluated only in TAK and SLE). The mean systolic and diastolic blood pressure levels were significantly higher in both TAK and SLE patients compared to healthy controls (HCs). As shown in Table 1, the mean IMT in the right and left carotid arteries was significantly higher among patients with TAK, when compared to SLE and HCs. On the other hand, the mean SWE in the carotid artery was significantly increased among both TAK and SLE patients when compared to HCs, whereas patients with TAK had the highest values. After adjusting for cardiovascular risk factors, a significant association was maintained robust. Only patients with TAK were found to have significantly increased frequency of carotid artery plaques (TAK: 22.0%, SLE: 4.7%, HC's: 5.3%, *p=0.006). IMT and diastolic blood pressure levels were found to be associated independently with SWE.

Conclusion: Our study indicates that among patients with TAK, both atherosclerosis and arterial stiffness are increased and appear to be closely related. Arterial stiffness along with severe hypertension and accelerated atherosclerosis could contribute to the increased risk for cardiovascular morbidity in TAK. Furthermore, SWE could be an indicator of cardiovascular risk that can be surveyed in TAK.

VALIDATION OF THE REVISED 2022 AMERICAN COLLEGE OF RHEUMATOLOGY/ EULAR CLASSIFICATION CRITERIA FOR TAKAYASU ARTERITIS

Keywords: Diagnostic tests, Vasculitis, Validation

A. Tomelli1, R. Padovan4, C. Kavadiachinda2, A. Jose3, K. Singh4, L. Iorio4, U. Rathore6, E. Rinaldi1, E. Baidisera1, V. Agarwal1, L. Dagna1, C. Campochiaro1, D. P. Mira1, 1San Raffaele Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (Unirri), Milan, Italy; 2University of Padova, Division of Rheumatology, Department of Medicine DIMED, Padova, Italy; 3Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Clinical Immunology, Puducherry, India; 4Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Clinical Immunology and Rheumatology, Lucknow, India

Background: The 2022 American College of Rheumatology (ACR)/European Association of Associations for Rheumatology (EULAR) classification criteria for Takayasu arteritis (TAK) were recently published [1].

Objectives: To validate and evaluate the 2022 ACR/EULAR TAK classification criteria in the light of the 1990 ACR TAK classification criteria [2].

Methods: Clinical data of TAK patients from four referral centers (two from Italy and two from India) were reviewed to assess the fulfillment of 2022 ACR/EULAR and 1990 ACR TAK criteria. Control subjects included large-vessel giant cell arteritis (LV-GCA), large vessel vasculitis (LVV) other than TAK or GCA, or non-inflammatory arterial disorders. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), likelihood ratio of a positive test (LR+), likelihood ratio of a negative test (LR-), area under the receiver operating characteristic curve (AUC) at the cut-offs of ≥3 points for 1990 ACR criteria and ≥5 points for 2022 ACR/EULAR criteria were calculated. AUC was also calculated using the actual scores for the 2022 ACR/EULAR criteria. Secondary analyses
were conducted on the basis of sex (male/female), using only LV-GCA as controls, using subjects ≥60 years, and stratified on age (≥40, 40-60, >60 years).

**Results:** 504 TAK [404 females, mean (SD) age at diagnosis 31.7 (12.6) years] and 222 controls [144 LV-GCA, 151 females, mean (SD) age at diagnosis 61.9 (15.4) years] were identified. The 2022 ACR/EULAR criteria had better sensitivity and NPV but had poorer specificity. PPV, LR+, LR−, and AUC at predetermined cut-offs than the 1990 ACR criteria (Table 1). Similar performance of 2022 ACR/EULAR criteria was observed with only LV-GCA as controls (sensitivity 95.83%, specificity 60.42%, AUC 0.781) or in subjects ≥60 years old (sensitivity 95.81%, specificity 61.80%, AUC 0.789). The 2022 ACR/EULAR criteria had a greater specificity (76.76% vs 57.62%) and AUC (0.845 vs 0.771) with similar sensitivity (93% vs 96.53%) in males than in females. Stratified for age; ≥40 years, n=399, 374 TAK, 25 controls; 40-60 years, n=186, 127 TAK, 59 controls; >60 years, n=141, 3 TAK, 138 controls; sensitivity remained similar (96.26%, 94.49%, 100%, respectively), whereas, specificity was higher for older age groups (52%, 66.10%, 64.49%, respectively). Cut-offs of ≥6 (sensitivity 91.87%, specificity 82.88%) and ≥7 (sensitivity 86.71%, specificity 86.49%) greatly improved balance between sensitivity and specificity (Figure 1).

**Conclusion:** In this first validation study, the 2022 ACR/EULAR Tak criteria had poorer specificity in real-life than in the development cohort. Higher cut-offs (6 or 7) might improve the performance of these criteria. Higher PPV but lower NPV in the Indian than in the Italian cohort might reflect the different performance of the criteria in different ethnic groups.

**METABOLIC INFLAMMATORY VOLUME AND TOTAL INFLAMMATORY GLYCOLYSIS: NOVEL PARAMETERS TO EVALUATE DISEASE ACTIVITY ON PET-CT IN TAKAYASU ARTERITIS**

**Keywords:** Vasculitis, Imaging

M. Ora1, D. P. Misra2, C. Kavadichanda3, K. Singh4, U. Rathore5, N. Jain6, V. Agarwall7, S. Gambhir8, Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Nuclear Medicine, Lucknow, India; 1Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Clinical Immunology and Rheumatology, Lucknow, India; 2Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Clinical Immunology, Puducherry, India; 3Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Clinical Immunology and Rheumatology, Lucknow, India; 4Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Nuclear Medicine, Lucknow, India

**Background:** 18-fluorodeoxyglucose (FDG) Positron emission tomography-computed tomography (PET-CT) has only moderate concordance with C-reactive protein (CRP) in Takayasu arteritis (TAK).

**Objectives:** We propose and evaluate the diagnostic accuracy of two new PET-CT parameters, metabolic inflammatory volume (MIV) and total inflammatory glycolysis (TIG) to quantify arterial FDG uptake for active TAK.

**Methods:** Images of PET-CT of TAK were reviewed to calculate mean standardized uptake value (SUV_{mean}) and maximum standardized uptake value (SUV_{max}), target-to-blood pool ratio (TBR), target-to-liver ratio (TLR), and PET Vasculitis Activity Score (PETVAS) [1]. ESR, CRP, disease activity [using physician global assessment (PGA, active/inactive), Indian TAK Clinical Activity Score 2010 (ITAS2010), ITAS2010 with ESR (ITAS-A-ESR), or CRP (ITAS-A-CRP)], Disease Extent Index in TAK (DEITAK) were extracted from clinic files. Regions of interest (ROI) were drawn to calculate MIV in areas of FDG uptake ≥1.5-times SUV_{max} on syngo.via. MIV was semiautomatically calculated after excluding areas of physiological tracer uptake. TIG was calculated by multiplying MIV with SUV_{max} and TIG for all areas of arterial FDG uptake were added. Area under the receiver operating characteristic (ROC) curves (AUC, using absolute values of SUV_{max}, SUV_{mean}, TBR, TIG) for all areas of active disease using physician global assessment (PGA, active/inactive) were used to calculate sensitivity, specificity, likelihood ratio of a positive test (LR+), likelihood ratio of a negative test (LR-), positive predictive value (PPV), negative predictive value (NPV), and AUC (with 95% CI). Concordance between CRP and PET-CT parameters were assessing kappa statistic. Analyses were performed using STATA 16.1 I/C.

**Results:** PET-CT of 30 TAK [mean (SD) age 29.9 (11.5) years, 22 females, 29 immunosuppressive-naive] were reviewed. AUC using absolute values ranged between 0.852 to 0.926 (Figure 1). Using dichotomized optimal cut-offs for SUV_{max}, SUV_{mean}, TBR, TIG, CRP, ESR, ITAS2010, ITAS-A-ESR, ITAS-A-CRP, and DEITAK were calculated. Dichotomized cut-offs for active disease [PETVAS ≥5.5 [2], ≥10.15;org20 [1]; CRP≥5,6mg/L; ESR≥40 mm/hr; for the remaining parameters, cut-offs correctly classifying disease activity in most patients] were used to calculate sensitivity, specificity, likelihood ratio of a positive test (LR+), likelihood ratio of a negative test (LR-), positive predictive value (PPV), negative predictive value (NPV), and AUC (with 95% CI). Concordance between CRP and PET-CT parameters were assessing kappa statistic.

Grayson9, 1Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Rheumatology Department, Reggio Emilia, Italy; 2Hacettepe University, Rheumatology Division, Ankara, Turkey; 3National Institutes of Health, Clinical Center, Radiology and Imaging Sciences, Bethesda, United States of America; 4National Institutes of Health, Clinical Center, National Institute of Arthritis & Musculoskeletal & Skin Diseases, Bethesda, United States of America; 5Marmara University, Rheumatology Division, Istanbul, Turkey; 6Marmara University, Department of Nuclear Medicine, Istanbul, Turkey; 2University of Pennsylvania, Rheumatology Department, Philadelphia, United States of America

**Background:** Disease activity indices that accurately assess inflammation in Takayasu’s arteritis (TAK) are needed [1]. While clinical assessment is often considered the gold standard, determining if a symptom represents active vasculitis or damage can be challenging in TAK. FDG-PET can directly assess vascular inflammation but specificity of imaging findings, especially in absence of corresponding clinical symptoms, is questionable.

**Objectives:** The aim was to develop an index to assess disease activity in TAK called TAI (Takayasu’s Arteritis Integrated Disease Activity Index).

**Methods:** Clinical symptoms associated to TAK were derived from a comprehensive literature review [2]. TAI was assessed in an observational cohort with a stepwise approach. All the symptoms present within 7 days of clinical evaluation were recorded by two clinicians, without determining whether the symptom reflected active disease or damage. Physician global assessment (P(i)GA) (scale 0-10) and certainty of the assessment (certain vs uncertain) were collected for every visit. Each patient underwent FDG-PET 24 hours after the clinical assessment. Active vasculitis, defined as arterial FDG uptake > liver, was recorded in specific arterial
Background: Subclinical giant cell arteritis (GCA) in polymyalgia rheumatica (PMR) is found in the 22.8% of patients on ultrasound examinations. The outcome and the optimal management of subclinical giant cell arteritis (GCA) in patients with polymyalgia rheumatica (PMR) have not been defined yet.

Objectives: The aim of this study was to investigate the short-term outcome of PMR patients with concurrent subclinical GCA that were included in our multicenter project on the prevalence, characteristics and outcome of subclinical GCA (diagnosed by vascular ultrasound) in PMR [1].

Methods: We analyzed follow up data at 3, 6, 12 and 18 months of consecutive PMR patients from 7 European rheumatology centers. All patients fulfilled 2012 EULAR/ACR Provisional Classification Criteria for Polymyalgia Rheumatica and they had not symptom of clinical GCA. Patients were stratified into two groups: pure PMR and PMR with subclinical GCA, and the outcome between these two groups were compared. A relapse was defined as clinical and/or laboratory worsening of the disease after the initial remission and minor and major relapse EULAR definition was used [2].

Results: We included 116 PMR patients (47 with concurrent subclinical GCA and 69 with pure PMR) followed for a median (IQR) of 21 (17; 23) months. We observed relapses in 35/116 patients (30.2%), 27/47 (57.4%) in PMR with subclinical GCA and 8/69 (11.6%) in pure PMR group (p<0.001). All relapses in the pure PMR group were minor relapses, whereas we observed 2 major relapses in the subclinical GCA group. The dose of corticosteroids used at the baseline visit was significantly higher in the GCA subclinical group, but tapering of steroids occurred faster than recommended by clinical guidelines [2]. Prednisone dose was significantly higher in patients with PMR and subclinical GCA than in patients with pure PMR both at baseline and at month 6 (Table 1). In patients with PMR with subclinical GCA mean starting dose of prednisone was 32.2±16.1 mg in those who relapsed and 36.2±12.8 in those who maintained remission (p=0.166); at 3 months, it was 13.2±7.1 and 18.2±7.9, respectively (p<0.05). Three patients in the PMR with subclinical GCA group received biological therapy at diagnosis; one of them had a minor relapse.

POS0713

A HISTORY OF POLYMYALGIA RHEUMATICA IS ASSOCIATED WITH ADVANCED SUPRA-AORTIC VASCULAR DAMAGE AT DIAGNOSIS OF GIANT CELL ARTERITIS

Keywords: Vasculitis, Ultrasound

A. Hemmija, M. Schwindenb, C. Bergerb, D. Kyburzb, N. Mensch2, D. Staub1, M. Steger1, S. Imfeld1, T. Daikeler1, University Hospital Basel, Department of Rheumatology Basel, Switzerland; 2University Hospital Basel, Department of Angiology, Basel, Switzerland; 3University Hospital Basel, University Center for Immunology, Basel, Switzerland; 4University Hospital Basel, Department of Biomedicine, Basel, Switzerland
Background: Subclinical giant cell arteritis (GCA) can be found in imaging studies at diagnosis of polymyalgia rheumatica (PMR) in up to 30% of patients [1]. Newly diagnosed GCA patients with a preceding PMR diagnosis may therefore presents with more advanced vasculitic vessel alterations than GCA patients without prior PMR.

Objectives: To compare vascular ultrasound (US) findings in newly diagnosed GCA patients with and without a history of PMR.

Methods: Retrospective analysis of patients with GCA diagnosed at the University Hospital Basel between 12/2006 and 05/2021.

Results: Of 311 newly diagnosed GCA patients (15.8%) had a preceding diagnosis of PMR a median of 2.5 (IQR 0.6-5.6) years earlier. US revealed vessel wall alterations typical for vasculitis in the supraaortic vessels (cardiot, vertebral, subclavian and/or axillary arteries) more often in patients with prior PMR than without PMR (51% vs 25%, p<0.001). Additionally, patients with prior PMR had more often significant vascular stenoses in the supraaortic vessels that were affected by vasculitis (375% vs 13.6%, p<0.01). Patients with and without prior PMR did not differ in terms of ischemic complications of stroke or vision loss at GCA diagnosis nor in the number of vascular segments with atherosclerosis (Table 1).

In multivariable analysis, prior PMR was significantly associated with vasculitic vessel wall alterations (OR 4.28, 95% CI 1.92-9.85, p<0.001), a history of PMR being an independent predictor of disease activity.

Conclusion: GCA patients with prior PMR had a more extensive vascular involvement on ultrasound than those without prior PMR at diagnosis. Presence of stenoses could not be explained by arteriosclerosis. Undiagnosed subclinical GCA in patients with previous PMR may be a cause of more advanced vascular changes. This data support the need for screening strategies for GCA in patients with PMR.

POS0714 TREAT-TO-TARGET RECOMMENDATIONS IN GIANT CELL ARTERITIS AND POLYMyalgia RHEUMATICA

Keywords: Vasculitis, Remission, Treat to target

C. Dejaco1,2, A. Kerschbaumer2, D. Aletaha3, M. Bond1, E. Hysa4, J. Thiel2,5, C. Toro Gutiérrez27, M. Whittlock11, F. Buttgereit6, Andrea Hemmig: None declared, Markus Aschwanden: None declared, Andriana Gossoli: None declared, Daniel Staub: None declared, Mihaela Stenger: None declared, Stephan Imfeld: None declared, Thomas Daiker: None declared.

Background: The treat-to-target (T2T) concept is not yet a recognized treatment approach in giant cell arteritis (GCA) and polymyalgia rheumatica (PMR). Developing such recommendations is an unmet medical need.

Objectives: To determine therapeutic targets and develop treat-to-target (T2T) recommendations in GCA and PMR.

Methods: We conducted a systematic literature review to retrieve data on treatment targets and outcomes in GCA/PMR as well as to identify the evidence for the effectiveness of T2T-based management approaches in these diseases. Based on evidence and expert opinion, the task force [29 participating from 10 countries (physicians, healthcare professional and patient)] developed recommendations, with consensus obtained through voting. The final level of agreement was provided anonymously.

Results: Five overarching principles and six specific recommendations were formulated (Table 1). Key messages are that the management of GCA and PMR should be based on shared decisions between patient and physician, underpinning the need for urgent treatment of GCA to avoid ischemic complications, and that it should aim at maximizing health-related quality of life in both diseases. The treatment targets are the achievement and maintenance of remission (still in need of ultimate validation), as well as prevention of tissue ischemia and vascular damage. Comorbidities should be considered when assessing disease activity and selecting treatment.

Conclusion: These are the first T2T recommendations for GCA and PMR. Treatment targets and strategies to assess, achieve and maintain these targets have been defined. The research agenda highlights the evidence-gaps and needs for future research.

**Objectives:**
- To assess the proportion of patients achieving sustained remission up to week 26 and from week 24.
- To evaluate the proportion of patients achieving sustained remission for at least 52 weeks.

**Methods:**
- Patients were randomized (1:1 ratio) to 52 weeks of treatment with sarilumab 200 mg every 2 weeks (Q2W) + 14 week GC tapered regimen (sarlumab arm) or placebo Q2W + 52 week GC tapered regimen (comparator arm).

**Results:**
- Between October 2018 and July 2020, 60 patients were randomized to the sarilumab arm and 58 patients to the comparator arm.
- A higher proportion of patients in the sarilumab arm, versus the comparator, achieved sustained remission from weeks 16 to 52 (30.0% vs 8.6%; difference 21.4 [7.7, 35.0]; P=0.0047) and from weeks 24 to 52 (31.7% vs 10.3%; difference 21.3 [7.2, 35.5]; P=0.0093). This improvement in sustained remission was maintained at 1-year follow-up.
remission rate in the sarilumab arm was due to additional responses seen between weeks 12 to 24 (Figure 1). Similarly, all the independent components of the sustained remission were achieved by a higher proportion of patients in the sarilumab arm, versus the comparator arm, during each assessment period. In both the sarilumab arm and the comparator arm, the disease remission rates decreased slightly at weeks 16 and 24 compared with week 12; sarilumab arm 40.0% and 41.7%, respectively vs 46.7% and comparator arm 31.0% and 20.7%, respectively vs 37.9%. Disease remission rates declined due to missing or abnormal CRP, as the proportion of patients with no PMR signs and symptoms increased over time. In the sarilumab arm, the proportion of patients with no disease flare increased from weeks 12 to 52 assessment to weeks 16 to 52 and weeks 24 to 52 assessments, whereas the proportion of patients with sustained CRP normalization or those who adhered to protocol-defined GC taper remained the same during the three assessment periods (Figure 1). Safety data were consistent with the know profile of sarilumab and were presented previously [1].

In both the sarilumab arm and comparator arm, the disease remission rates in the sarilumab arm, versus the comparator arm, achieved sustained remission when assessed from week 16 and week 24 up to week 52. Most patients who achieved sustained remission did so rapidly by week 12 with some additional responses seen between week 12 and 24.

</table>

**Conclusion:** PMR patients with subclinical GCA have a similar halo count to patients with clinical GCA suggesting a similar pattern of vascular involvement. However, those with clinical GCA have higher halo scores indicating more advanced vessel oedema which may be a key factor in causing headache symptoms. Male gender and a higher ESR at the time of PMR diagnosis appear to be risk markers for subclinical GCA though this requires analysis in larger cohorts of patients.

DOI: 10.1136/annrheumdis-2023-eular.3120
Background: Many patients with polymyalgia rheumatica (PMR) require prolonged glucocorticoid (GC) treatment, resulting in high cumulative GC doses.

Methods: This prospective study included patients with newly diagnosed PMR between October 2021 and September 2022. At diagnosis, patients were randomly allocated to IM or oral MP dosing groups in a 1:2 ratio. Both groups followed a predefined MP tapering regimen. IM injections of 120 mg of MP were given every 3 weeks, then every 4 weeks, the dose was reduced to: 12 mg, 8 mg, 6 mg and 4 mg. Follow-up visits were performed according to the remission rate and other measures of disease activity were recorded and compared between IM MP and oral MP groups. Descriptive statistics were used to analyse the studied population.

Results: Of the 39 PMR patients (72% female, median (IQR) age 71 (66, 76) years) 26 patients received oral MP and 13 IM MP. Results are presented in Table 1. During follow-up we observed higher ESR values in the IM MP group. We observed slower clinical response in IM MP group at 4 weeks of follow-up. There was no difference between the two groups in clinical response measures at 12 and 24 weeks. During 24 weeks of follow-up, we identified 2 relapses in the oral MP group: 1 patient relapsed when lowering the MP dose to 6 mg/day at 16 weeks and 1 relapsed after discontinuing MP at week 24 due to patient’s choice and presented with symptoms of giant cell arteritis. In the IM MP group, we observed no relapses in the first 24 weeks of follow-up, but there were 4 patients with inadequate response to treatment: 2 at week 4 and 2 at week 12. In these cases, we switched to oral MP. Due to the low number of patients in our study, results should be interpreted with caution.

Conclusion: In our cohort, treatment with IM MP compared to oral MP was effective in the majority of patients with PMR, but was associated with higher inadequate response rate and overall slower clinical and laboratory response.

Background: The main treatment of polymyalgia rheumatica (PMR) is based on corticosteroid, but sparing agents are a major unmet need and many new treatments are evaluated to avoid corticosteroid side effects in PMR. To monitor the disease, one disease activity score has been developed specifically for polymyalgia rheumatica (PMR), the PMR-AS (activity score). It is a composite index built as an algebraic sum of morning stiffness, elevation of the upper limbs, physician’s global assessment, patient’s pain assessment and the C reactive protein (CRP). However, treatments of PMR-AS may influence CRP and other markers.

Methods: The primary objective was to measure the concordance and correlation between CRP-PMR-AS, Clinical PMR-AS and CRP-imputed PMR-AS but the concordance and correlation between these scores are unknown.

Results: 100 patients received at least one dose of tocilizumab (49 patients) or placebo (51 patients) and were included in the analyses from inclusion to week 24. The correlation between the different CRP-PMR-AS activity scores were excellent in the global analysis (Figure 1) but also in the two groups of treatment. Intraclass coefficients were all higher than 0.9 (Table 1). Bland Altman graphics, using CRP-PMR-AS as a reference showed that differences between scores are low regardless of PMR-AS. Kappa coefficients between CRP-PMR-AS and the other three scores showed a good agreement (>0.8) (Table 1) at week 24.

**Conclusion:** The correlation between different PMR activity scores using or not CRP are excellent reflecting the low weight of CRP in the baseline composite index. In clinical trial using drugs that have an impact on CRP, CRP-PMR-AS or others, including clinical PMR-AS, can be used.

**MATERNAL AND PERINATAL OUTCOMES IN WOMEN WITH VASCULITIS - A 13-YEAR EXPERIENCE FROM A PORTUGUESE TERTIARY CENTRE**

**Keywords:** Vasculitis, Pregnancy and reproduction

A. R. Lopes1,2, A. R. Cruz-Machado1,2, S. C. Barreira1,2, P. Martins1,2, C. Araújo3, M. Centeno3, C. Ponte1,2, L. Pinto3, S. Capela1,2,1, Centro Hospitalar Universitário Lisboa Norte, Centre Académico de Medicina de Lisboa (CAML), ERN ReCONNET and RITA Full Member, Rheumatology Department, Lisboa, Portugal;2, Instituto de Medicina Molecular, Faculdade de Ciências, Universidade de Lisboa, CAML, Rheumatology Research Unit, Lisboa, Portugal;3, Centro Hospitalar Universitário Lisboa Norte, Obstetrics and Gynaecology Department, Lisboa, Portugal

**Background:** The vasculitides are rare conditions that may affect women of childbearing age. These women seem to be at increased risk for developing adverse pregnancy outcomes (APO). Maternal and perinatal outcomes as well as their optimal management during pregnancy remain poorly understood in this population.

**Objectives:** To describe maternal and perinatal outcomes in women with vasculitis.

**Methods:** Observational retrospective study including pregnant women with vasculitis followed at a rheumatology-obstetric clinic from 01/2009 to 06/2022.

**Results:** We identified 31 pregnancies in 24 women with vasculitis. Table 1 summarizes demographic and clinical data. The most frequent diagnosis were Behçet’s disease (BD) (18; 58%), polyarteritis nodosa (PAN) (4; 13%) and Takayasu arteritis (TAK) (4; 13%). The mean ± SD age at conception was 33 ± 6 years, with a median disease duration of 6 (IQ range 3-12) years, 29 (94%) were in remission by the time of conception. We documented 30 live births, 1 early miscarriage (2%) and 3 (9.7%) pregnancies ended in loss (1 abortion; 2 stillbirths). Eight (30%) newborns were small for gestational age (SGA), most of them from mothers with BD (4; 29%). Cesarean section (CS) was performed in 8 (26%) patients - 2 (TAK) due to vasculitis activity. Nine (36%) patients relapsed during pregnancy (4 BD; 2 PAN; 1 TAK; 1 RP; 1 ANCA-PR3 cutaneous vasculitis) while 6 (22%) relapsed during the post-partum period (4 BD; 1 TAK and 1 RP). A total of 24 (77%) patients were treated with glucocorticoids (GC), most of them (63%) at low doses (<5mg/day of prednisolone or equivalent). Seven (23%) patients were treated with conventional DMARDs: 2 TAK and 3 BD with azathioprine and 2 PAN with azathioprine and hydroxychloroquine. Biological DMARDs were prescribed in 2 (6%) patients, both with the diagnosis of TAK: one with a multisegmental aortic disease who received tocilizumab during the first 3 weeks of gestation (WG) and had an uneventful pregnancy, and another patient with an ascending aortic aneurism (AAA) who also received tocilizumab, but from the 24th week onwards showed a gradual worsening of the AAA dimensions (maximum 56 mm). An elective CS at 32 WG was performed in the latter case due to the high risk of aneurysm rupture and a healthy baby with 1900g was born. The occurrence of flares during pregnancy increased the risk for the APO (OR 13.95; CI 2-80; p<0.007). No association was found concerning maternal age or use of DMARDs/GC and the risk of APO (p>0.05).

**Conclusion:** Most pregnant women with vasculitis managed at our multidisciplinary unit had successful gestations. However, they may still be at risk for developing APO, namely if they experience disease flares during gestation. SGA was the main APO recorded.

**MEASURING FUNCTIONAL DISABILITY IN GIANT CELL ARTERITIS: THE VALIDITY, RELIABILITY AND RESPONSIVENESS OF THE GCA-DISABILITY INDEX (GCA-DI)**

**Keywords:** Quality of life, Patient reported outcomes, Vasculitis

Y. El Miedany1, M. Elgaafary2, M. Toth3, S. Bahlas4, M. H. Abu-Zaid5, W. Hassan6, D. Palmer7, S. A. Mahran8, S. Saber9, S. A. A. Tabra5, W. Elwakil10,1, Faculty of Medicine Alexandria University, Rheumatology, Community and Public Health, Cairo, Egypt;2, King Abdul Aziz University, Rheumatology, Jeddah, Saudi Arabia;3, Faculty of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt;4, Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Banha, Egypt;5, North Middlesex University Hospital, Rheumatology, London, United Kingdom;6, Faculty of Medicine, Ain Shams University, Cairo, Egypt;7, Faculty of Medicine - Assut University, Rheumatology and Rehabilitation, Assut, Egypt;8, Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt;9, Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt

**Background:** Giant cell arteritis (GCA) is the most frequent systemic vasculitis, typically affecting patients over 50. The disease burden includes a chronic course and a subsequent prolonged treatment, especially because of a high risk of relapse that affects approximately half of patients. Taken together, the disease and its symptoms, the chronic course and the treatment probably have an impact on the patients’ functional ability as well as quality of life. Though functional disability has been identified as a core outcome measure in GCA, few studies have been dedicated to assess for the patients for this core measure.

**Objectives:** To test the GCA-disability index (GCA-DI) questionnaire for validity, reliability and responsiveness in patients with Giant Cell Arteritis.

**Methods:** The psychometric properties of GCA-DI were tested in 57 patients with GCA, mean age 63.6 (±4.5), 77.2% women, mean disease duration 2.1 weeks.
At baseline, all the patients completed the GCA-DI, and the Health Assessment Questionnaire (HAQ). The patients were then asked to return to the clinic after having their blood tests and X-rays done to complete another copy of the questionnaire. Also, all the patients were asked to complete another copy of the questionnaire in their follow up visit in 4-weeks time. This facilitated the assessment for validity, reliability and responsiveness. In addition, all the patients were asked to complete a copy of multidimensional Patient Reported Outcomes for GCA. Patient global assessment for functional disability was also recorded (0-100 VAS). Of the 57 patients who completed the health status instruments on two occasions, 53 were included in the responsiveness analysis. The test-retest reliability of the GCA-DI questionnaire was calculated using intraclass correlation coefficients (ICCs). Criterion validity was assessed using Spearman’s correlations, while responsiveness was evaluated by 3 different methods: (1) effect size (the mean difference between the baseline scores and the follow-up scores divided by the standard deviation of the baseline scores); (2) standardized response mean (the mean change in scores divided by the standard deviation of the change in scores).

Results: GCA-DI fulfilled the established criteria for validity, reliability and responsiveness. Significant correlations were seen between GCA-DI scores and HAQ scores (rho = 0.672), pain (rho = 0.633), Test-retest reliability was satisfactory, with ICCs of 0.935. The results of responsiveness analysis indicated that the GCA-DI was sensitive to change. Standardized effect size was 2.84 after 4-weeks.

Conclusion: Our data suggest that the GCA-disability index can be considered as a reliable, valid and responsive tool for measuring physical functioning in GCA patients. It is suitable for use in clinical trials and daily clinical practice. Its generalizability and utility for assessing treatment and functional outcomes should be evaluated in larger settings.

**POS0721 DIFFERENT PATTERNS OF VASCULAR ULTRASOUND ARE ASSOCIATED WITH DIFFERENT ISCHEMIC COMPLICATIONS IN PATIENTS WITH GIANT CELL ARTERITIS**

**Keywords:** Imaging, Vasculitis, Ultrasound

J. Molina Collada1, G. Torres Ortiz2, I. Castrejon1, I. Monjo2, E. Fernández-Fernández2, J. M. Alvaro-Gracia3, E. De Miguel4, G. Gregorio Marañon General University Hospital, Rheumatology, Madrid, Spain;2 La Paz University Hospital, Rheumatology, Madrid, Spain

**Background:** Patients with giant cell arteritis (GCA) can present ischemic complications (IC). Recognizing patients at risk of IC may help to improve GCA long-term outcomes. However, previous studies have failed to identify consistent risk factors for IC in this population, being mainly low systemic inflammation or atherosclerotic risk factors the main findings in some cohorts.

**Objectives:** Our objective is to determine if a specific pattern of vascular inflammation by ultrasound (US) is associated with different types of IC in patients with GCA.

**Methods:** A retrospective observational study of patients referred to the US fast track clinics of two academic centres with GCA clinical confirmation over a 4-years period. All patients underwent baseline US of cranial and extracranial arteries (carotid, subclavian and axillary) at the time of referral, and were classified in two categories: cranial or large vessel (LV)-GCA, according to US findings. IC was defined as the occurrence of acute anterior ischemic optic neuropathy (AOIN) or non-AION (including stroke, acute coronary syndrome, pulmonary embolism or peripheral artery disease) within 3 months after diagnosis, and after excluding other potentially implicated causes. Chi-squared and analysis of variance were performed to explore the association between clinical or US variables with the occurrence of different types of IC.

**Results:** A total of 42 (22.9%) patients over 188 patients with GCA clinical confirmation evaluated at our clinics had an IC within 3 months after diagnosis, 24 (12.8%) an AION and 19 (10.1%) a non-AION IC (10 stroke, 5 acute coronary syndrome, 4 peripheral artery disease, 2 pulmonary embolism and one case of ischemic colitis).

**Conclusion:** Different patterns of vascular US involvement are associated with different IC in GCA patients. Predominantly cranial-GCA patients have more frequently AION, while predominantly LV-GCA patients have more frequently non-AION IC as stroke, acute coronary syndrome, pulmonary embolism or peripheral artery disease.

**POS0722 EFFECTS ON SOLUBLE IMMUNE CHECKPOINTS INDUCED BY TOCILIZUMAB MONOTHERAPY AFTER ULTRA-SHORT-TERM GLUCOCORTICOIDS IN LARGE VESSEL – GIANT CELL ARTERITIS PATIENTS**

**Keywords:** Cytokines and chemokines, Biomarkers, Vasculitis

M. Bonacini1, A. Rossi1, I. Ferrigo1, C. Catellani1, V. Buia1, F. Muratore1, E. Galli2, C. Marvisi2, G. Cassone3, A. Zerbini4, S. Croci4, A. Zerbini1, A. Zerbini3, A. Zerbini4, 2 Azienda Ospedaliero Universitaria di Modena, Unit of Rheumatology, Modena, Italy;1 Università degli Studi di Modena e Reggio Emilia, Surgical, Medical and Dental Department of Morphological Sciences related to Transplant, Oncology and Regenerative Medicine, Modena, Italy

**Background:** The most affected vessels in Giant cell arteritis (GCA) are the temporal arteries, but in some patients extracranial large vessels are also involved (LV-GCA). Tocilizumab (TCZ), a monoclonal anti-interleukin-6 receptor1 antibody, has been approved as glucocorticoid (GC) sparing agent in patients with GCA. Recently, new therapeutic protocols that combine rapid GC tapering and TCZ are emerging, but their effects on circulating immune cells and mediators are scarcely known. Another clinical need in LV-GCA management is the lack of a gold standard to define disease state. The role of immune checkpoint molecules is tuning the activation of the immune system. They are expressed on the surface of immune cells, but also soluble forms exist. Active GCA patients showed a reduction of CD4+ T cells expressing PD1 and VISTA in comparison to controls [2,3]. We hypothesize that soluble immune checkpoints are modulated by the TCZ and GC combined treatment and that they are biomarkers able to differentiate active from inactive LV-GCA patients.

**Objectives:**
1. To evaluate the effects of TCZ monotherapy after ultra-short-term GC treatments on soluble immune checkpoints.
2. To identify plasma biomarkers able to discriminate between LV-GCA patients in the active phase from those in remission.
Methods: We included 16 patients with active LV-GCA enrolled in the single-arm open-label clinical trial (NCT03594909) performed at AUSL-IRCCS at Reggio Emilia. Inclusion criteria: PET/CT with FDG uptake ≥2 in at least one vascular district and at least one among ESR >40 mm/h (or CRP >10 mg/L); cranial or systemic manifestations of GCA or polymyalgia rheumatica. Exclusion criteria: more than 10 mg/day of prednisone for more than 10 consecutive days in the previous 3 months. Remission was defined by the following: absence of any clinical signs and symptoms directly attributable to GCA; normalization of CRP and ESR values; absence of new/worsened vascular damage at CT; vascular FDG uptake <2 in all vascular districts at PET/CT or overall PET image interpretation of non-active vasculitis. All patients received 500 mg per day of methylprednisolone intravenously for three consecutive days and weekly subcutaneous TCZ injections from day 3 until week 52. Plasma samples were collected at baseline before treatment and after GC injections. For 10 patients plasma samples were also collected at week 52. Laboratory data were collected at the same time points. Concentrations of CD137L, CD137, CTLA4, CD40, CD40L, GITR, IFN, PD1, PDL1, PDL2, PTX3, TIM3 and VISTA were evaluated in plasma samples by a multiplex bead-based assay with the MAGPIX instrument. Wilcoxon test was used for comparison between groups. Spearman test was used for correlation analysis. P < 0.05 was considered statistically significant.

Results: Soluble CD137L, CTLA4, CD40, CD40L, GITR, IFN, PD1 and PDL1 were not detected in almost all of the samples irrespective of treatment and disease phase. Intravenous injections of GC determined a significant reduction of soluble CD137, CD80, GITR, ICOSL, LAG3, MICA, and MICB and an increase of PTX3 and VISTA levels. After 52 weeks of TCZ as monotherapy, an increase in plasmatic ICOSL and a reduction in LAG3, PTX3, and VISTA was observed compared to baseline. At 52 weeks, 7 patients were classified in remission phase of the disease and 3 patients were active. Changes in immune checkpoint levels occurred irrespective to disease phase. Levels of soluble immune checkpoint did not correlate with ESR and CRP concentrations, markers currently used in clinical practice to evaluate systemic inflammation.

Conclusion: Ultra-short-term GC treatments and TCZ monotherapy modulate the levels of soluble immune checkpoints. The evaluation of the investigated panel of immune checkpoints did not allow to discriminate between LV-GCA patients in different disease phases.

**Background:** Incident cases of giant cell arteritis (GCA) have a significantly reduced prevalence of diabetes at time of diagnosis (1) and lower fasting blood glucose, lipid levels and body mass index compared to controls have been found years before clinical diagnosis [2,3]. This implicates metabolic pathways in the development of GCA.

**Objectives:** To investigate the relation between plasma proteins associated with metabolism and subsequent development of GCA.

**Methods:** Participants in a population-based survey (N=30447), who were subsequently diagnosed with GCA, were identified in a structured process. GCA-free controls, matched for sex, year of birth, and year of screening were selected from the study cohort. Baseline plasma samples were analyzed using the antibody-based OLIINK proteomics metabolism panel (92 proteins). Analyses were pre-designated as hypothesis-driven or hypothesis-generating. In the latter, principal component analysis was used to identify groups of proteins that explain the variance in the data.

**Results:** There were 95 cases with a confirmed incident diagnosis of GCA (median 11.4 years after inclusion). Among biomarkers with a priori hypotheses, Adhesion G protein-coupled receptor E2 (ADGRE2) was positively associated with Fructose-1,6-bisphosphatase 1 (FBP1) negatively associated with subsequent GCA (Table 1). In particular, ADGRE2 levels were elevated compared to controls in the subset sampled <8.5 years before diagnosis (Table 1). For metabolic-like protein (Metrnl), the highest impact on the risk of GCA was observed in those sampled closest to diagnosis, with a decreasing trend with longer time to GCA (p=0.03). In the hypothesis generating analyses, elevated levels of receptor tyrosine-orphan receptor 1 (RO1R) were associated with subsequent GCA.

**Conclusion:** Our results indicate that changes in levels of plasma proteins that have regulatory effects on the immune system might precede clinical onset of GCA by many years. Among the biomarkers found to be predictive of subsequent GCA, both Metrnl and ADGRE2 are associated with macrophage activation. RO1R mediated activation of NFkB may be relevant in this context. The negative association with FBP1, which is a rate-controlling enzyme in the gluconeogenic pathway, is compatible with a protective role for glucose metabolites.

**Background:** Giant cell arteritis (GCA) is an immune-mediated, granulomatous vasculitis that primarily affects the elderly and results in local vascular changes of
middle-sized and large arteries. A protracted diagnosis delaying high-dose corticosteroid therapy may result in permanent visual loss. Therefore, invasive and time-consuming biopsy of the superficial temporal artery has been replaced by high-resolution vascular ultrasound of the temporal and axillary artery to evaluate extracranial inflammation. Extracranial involvement of the ophthalmic vessels can be visualized by magnetic resonance imaging. Transorbital Ultrasound (TOS), as a simple and inexpensive diagnostic method, could be an option for assessing the optic nerve and the central retinal artery (CRA) and might improve diagnostic sensitivity in GCA, especially in anterior optic neuropathy (AION).

**Objectives:** The purpose of this study was to assess the utility of TOS in patients with untreated and newly diagnosed GCA.

**Methods:** Patients with new GCA diagnosed by a board-certified rheumatologist who also met the expanded ACR-EULAR classification criteria were enrolled in the study between October 1, 2018, and May 31, 2022. Each participant underwent TOS to assess the CRA and optic nerve diameter (OND). The eyes of the patients with GCA were categorized as eyes with or without visual impairment (VI), which was defined as transient or persistent visual field loss, diplopia, amaurosis, and blurred vision. Peak systolic velocity (PS), end diastolic velocity (ED), resistance index (RI) of the CRA and OND were recorded.

**Results:** A total of 54 GCA patients were prospectively enrolled in the study, 27 of whom had VI in at least one eye. To account for repeated measures within a patient, associations between TOS and VI were evaluated using linear mixed-effects model (LME). PS and ED values of the CRA were statistically significant lower in the eyes with GCA manifestation (β=1.93; p<0.001 for PS; β=0.61; p=0.003 for ED). The RI of the CRA was statistically significantly reduced in the eyes with GCA associated VI (β=-0.04; p=0.06). OND was lower in the eyes with VI, too (β=-0.36; p=0.06) (Table 1, Figure 1).

**Conclusion:** In TOS, eyes affected by VI exhibited significantly reduced PS, ED, and RI indicating an inflammatory process of the intracranial vessels leading to impaired blood flow to the optic nerve and contributing to ischemia-associated optic neuropathy. The show decrease in OND is probably due to reduced blood flow and the resulting lessered vessel diameter and, in the case of a persistent depletion of blood flow, due to atrophic alterations of the optic nerve suggestive of irreversible damage. Therefore, VI in combination with decreased PS, ED, RI and OND may constitute a specific finding in the diagnosis of optic affection in GCA. Our study was the first to prospectively demonstrate the diagnostic value of TOS in untreated and new diagnosed GCA patients as a complementary diagnostic tool to assess GCA associated intracranial inflammation.

**Keywords:** Ultrasound, Descriptive studies, vasculitis, giant cell arteritis, cranial, extracranial, mixed, involvement, giant cell arteritis, analysis, clinical differences.

**Background:** Giant cell arteritis (GCA) is a systemic vasculitis that affects large vessels, with a higher incidence in patients aged 70 years. It is known that GCA involves temporal arteries and the aorta and its branches either concomitantly or in isolation. Differentiating the characteristics in the expression of these disease subtypes will be relevant for the initial treatment, prognosis and the follow up.

**Objectives:** To analyze the different clinical and laboratory between the patterns of GCA involvement.

**Methods:** Retrospective study of new consecutive patients diagnosed with GCA for four years. 90.9% were diagnosed by Color Doppler ultrasound, measuring the superficial temporal arteries, common trunk, their frontal and parietal branches, and the extracranial arteries (axillary, subclavian, and carotid arteries). 9.1% were diagnosed by PET-CT or temporal artery biopsy. Ultrasound diagnosis was according to the OMERACT definitions of the halo sign and an intima-media cut off a thickness of ≤0.34 mm for the temporal arteries, ≥0.42 in the common superficial temporal artery and ≥1 mm for the axillary, subclavian, and carotid arteries. Clinical records were reviewed and their demographic, clinical and laboratory data were compared between patterns of ultrasound involvement. The EULAR recommendations of 2018 [1] were used to the remission and relapse.

**Results:** A total of 163 patients were included, 50.3% women, with a mean age of 79 years. Regarding the GCA subtypes, 78 patients had exclusive involvement of cranial arteries (CGCA). 36 patients had isolated involvement of extracranial giant cell arteritis (LVGCA) and 49 patients had mixed forms with both cranial and extracranial involvement (MGCA). The analysis showed that patients with LVGCA present constitutional syndrome more frequently, less anterior ischemic optic neuropathy (AION) (p<0.001) and less ESR values (p<0.01) than patients with CGCA. Extracranial artery involvement in any of the subtypes showed a significant association with polymyalgia rheumatica (PMR), although this was not exclusive to LVGCA. CGCA was associated with more AION-type ischemic manifestations than LVGCA. Remission maintained for at least 6 months together with corticosteroid-free remission is higher in LVGCA. No statistically significant differences in relapses, both major and minor.

CGCA: Cranial giant cell arteritis; LVGCA: Large vessel giant cell arteritis; MGCA: Mixed giant cell arteritis; SD: standard deviation; AION: Anterior ischemic optic neuropathy; PMR: polymyalgia rheumatica; CRP: C reactive protein; ESR: erythrocyte sedimentation rate.

**Conclusion:** Clinical features are different between the different GCA patterns. Patients with LVGCA have a greater constitutional syndrome and lower ESR than patients with CGCA. CGCA was associated with more NOIA-type ischemic manifestations than LVGCA. PMR is more frequent in cases with large vessel involvement. There is more maintained and corticosteroid-free remission in patients with LVGCA.

ANCA-ASSOCIATED VASCULITIS: A COST ANALYSIS

Methods: Drug costs for CYC and the current preferred (cheapest) RTX biosimilar were provided by our pharmacy team. Exact drug costs are considered commercially sensitive and are hence not reported here. The Hospital Business Intelligence Unit provided total visit cost data and an average total visit cost for both RTX and CYC was calculated using worked examples. This accounts for cost differences due to in drug administration and the need for medical review. Data was available on the number of patients with AAV who started induction treatment with CYC from January 2022 to December 2022. We were able to calculate a total cost for this and an equivalent cost if these patients had all received RTX induction.

Results: As expected, drug costs for RTX were significantly greater than for CYC. Total visit costs were however similar. The increased total costs for CYC likely largely due to our policy of consultant and multidisciplinary team review prior to each infusion. The total visit cost approximations for cyclophosphamide for patients with AAV treated with CYC between January 2022 to December 2022 was £34,000. When RTX total visit costs were considered, the annual costs for RTX induction for these patients would have been approximately £14,000. Furthermore, as a standard CYC induction is administered as 6 cycles, while RTX is administered as two 1g infusions, if patients treated with CYC had received RTX this would have created an additional 143 hours of availability on our biologics day unit. Other potential time and cost savings we did not measure would include nadir monitoring for CYC done prior to each infusion and pharmacy time in preparing the drugs and associated other medications such as anti-emptics.

Conclusion: The annual net saving if our hospital trust had treated the patients with AAV who received CYC induction with RTX instead, would have equated to £30,000. While this does not take into account subsequent maintenance treatment choices, we can be reassured that a shift towards RTX induction first-line in AAV, is likely to lead to significant cost-savings and would not place an additional financial burden on healthcare resources.

DEVELOPMENT OF POSTERIOR UVEITIS IN BEHÇET’S SYNDROME PATIENTS WITH VITREOUS CELLS WITHOUT ANY OTHER POSTERIOR INVOLVEMENT

Keywords: Vascularitis, Uveitis, Behçet’s disease

D. Ucar1,2, B. E. Bircan3, N. Rustami3, B. Batu Öto1, V. Hamuryuden4, S. N. Esatoglu1,4, G. Hatemi1,4, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey; 3Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: A considerable number of patients with Behçet’s syndrome (BS) have vitreous cells on slit lamp examination at the time of diagnosis. However, the prognostic importance of vitreous cells (VC) and their association with the development of posterior uveitis (PU) requiring immunosuppressive treatment is unknown.

Objectives: We aimed to determine the prognostic importance of VC in BS patients.

Methods: The charts of 572 consecutive BS patients fulfilling ISG criteria who were registered between 2010 and 2012 were reviewed. At baseline visit 164 patients had VC in one eye or both eyes. Among the remaining patients, 229 had no eye involvement, 116 patients had bilateral pan or posterior uveitis, 14 had unilateral pan or posterior uveitis and no eye involvement in the other eye, 20 had isolated anterior uveitis, and 29 had insufficient data in their medical records. Among the 164 patients with VC, 110 patients with a follow-up of ≥2 years were included in this study (Figure 1).

Results: At baseline, among the 111 included patients (68 men, mean ± SD age: 31±9 years), 61 had VC in both eyes, 34 had VC in only one eye, and 15 had VC in one eye and PU in the other eye. There was anterior uveitis (AU) in addition to VC in the same eye in 13 patients at baseline (Figure 1).

New PU developed in 26 (24%) patients during a mean follow-up of 1.9±1.1 years. 7 patients that developed PU in the eye with VC had had PU in the contralateral eye at baseline. This means 7 of 15 patients with VC in one eye and PU in the contralateral eye developed bilateral PU despite treatment. 2 of these 7 patients had developed AU before they developed PU. Additionally, 6 patients that developed PU in the eye with VC had anterior uveitis in the same eye at baseline.

Conclusion: Careful follow-up is required for patients with VC since one quarter developed PU within 2 years. The presence of PU in the contralateral eye and AU in the same eye may be risk factors for the development of PU in patients with VC.

DOI: 10.1136/annrheumdis-2023-eular.4167
Background: The GiACTA [1] was the first trial comparing two standardized prednisone (PDN)-taper protocols (52 week and 26 week) in GCA. Sustained remission rate at week 52 was similar. Patients enrolled in the placebo group with a 26 week taper protocol experienced lower PDN cumulative dose but more flares than those enrolled in the 52 week one.

Objectives: To assess the effectiveness and safety of the 26 week taper regimen of glucocorticoids (GC) used in the GiACTA trial in a prospective cohort of treatment-naive, biopsy-proven GCA.

Methods: Patients with a new diagnosis of biopsy-proven GCA enrolled in the GC arm of the START project (molecular stratification of patients with GCA to tailor GC and tocilizumab therapy) were included [2]. All patients were treated with the 26 week taper regimen of GC used in the GiACTA trial. Disease assessment was performed at baseline and every 12 weeks. In case of disease relapse, GC was increased or restarted with or without adjunctive immunosuppressive treatment. PET/CT was performed in 18 patients at baseline. Large vessel vasculitis was defined by evidence of vascular FDG uptake in at least one vascular district. CT angiography was performed after at least 52 weeks of follow-up in all patients and was compared with baseline CT of the PET scan. The diameter of the aorta was measured at 4 different levels. Aortic dilation was defined by a diameter >40 mm in the ascending aorta, >40 mm in the descending aorta and >30 mm in the abdominal aorta. Any change of ≥5 mm on serial CT was considered significant progression of aortic disease. Remission was defined as the absence of any clinical symptoms attributable to GCA, including a normalization of the acute phase reactants. Relapse was defined as one or more of the following: recurrence of signs or symptoms of GCA or PMR; CRP values greater than 10 mg/L, or ESR values greater than 40 mm/h if these were considered by the investigator to be due to GCA. The primary endpoint was the rate of relapse-free remission at week 52. Secondary definition of relapse included the necessity for intensification of treatment. The overall assessment of the activity is still an unmet need.

Objectives: The aim of the present study is to evaluate the efficacy of different regimens in achieving clinical, laboratory and imaging disease remission and in preventing the progression of disease-related damage and treatment-related damage, especially glucocorticoids induced, in Giant Cell Arteritis (GCA).

Methods: Consecutive inpatients and outpatients, classified as GCA with LVV involvement, were prospectively enrolled. We included all patients with new diagnosis or relapsing disease who underwent to at least 2 consecutive 18F-FDG PET-CT or MR scan between March 2011 and September 2022. Before every PET scan demographic, clinical data and disease activity were assessed. Remission was defined as absence of signs and symptoms attributable to GCA and normalization of acute phase reactants (ESR <30 mm/H and CRP <1 mg/dL) [1]. For each PET scan the vessel’s metabolic activity was evaluated using the Meller’s grading and the PETVAS score [2]. The damage was evaluated using the Large-Vessel Vasculitis Index of Damage (LVVDI) and the Composite Glucocorticoid Toxicity Index (GTI), distinct in Cumulative Worsening Score (GTI-CWS) and Aggregate Improvement Score (GTI-AIS) [3,4]. GCA patients were compared according to current treatment regimen: glucocorticoid (GC) monotherapy versus conventional disease modifying anti-rheumatic drug (cDMARDs), and tocilizumab (TCZ).

Results: The study included 49 LV-GCA patients (age 28 [21-48], 71.4% female) exposed to a total of 76 treatment regimens (n = 39 GC monotherapy, n = 21 cDMARDs, n = 16 TCZ). All the treatment led to significant reduction of acute phase reactants (GC-treated: ESR p < 0.001, CRP p < 0.001; cDMARDs treated: ESR p = 0.033, CRP p = 0.01, and TCZ-treated: ESR p = 0.006, CRP p = 0.003). Significant improvement in PETVAS was observed in all patients: GC treated 12.4 ± 2.1 vs 7.2 ± 1.4 (p=0.033), cDMARDs treated 16.5 ± 20 vs 4.3 ± 10.5 (p = 0.039), and TCZ - treated 12 ± 9.2 ± 2.0 vs 3.8 ± 5 (p = 0.001). Daily prednisone dose at last examination was 5.8 ± 2.25 mg/d in the cDMARDs group vs 0 [0-5] mg/d in the TCZ group (p = 0.148), GC withdrawal was observed in 82% of TCZ-treated patients, while 58% in the GC group (p=0.112). At last evaluation LVVI DI was similar in the three groups (2 [1-4] vs 2 [1-3] vs 3 [2.25-5], p = 0.073). Baseline GTI resulted higher in the TCZ group, when compared to cDMARDs and GC (75 [48-101] vs 49 [35-64] vs 32 [10-74], respectively, p = 0.008). At the last follow-up TCZ-treated patients showed higher GTI-CWS (97 [77-127] vs 72 [48-81] vs 65 [48-103], p = 0.025) than those treated with cDMARDs and GC, while no differences were observed in GTI-AIS (1.0 ± 1.9 to 3.0 ± 3.7 to 2.2 ± 2.7, respectively, p = 0.154). When considering only those patients who received TCZ as a first line treatment (n=4), GTI-AIS at last follow-up resulted significantly lower compared to cDMARDs and GC treated individuals (3 [0-7 to 5.5] vs 0 [77 to 127] vs 0 [-16 to 18.7], p = 0.0249).

Conclusion: Tocilizumab treatment significantly reduce vessel’s metabolic activity over time, when compared to conventional treatment. None of the three
different treatment regimen reduce the progression of the damage caused by both the vasculitis and the glucocorticoid treatment. TCZ as a first line treatment reduced significantly the GTI-AIS at the last follow up, when compared to the other treatment.

PROGNOSTIC FACTORS AND EFFICACY OF DMARD USE IN GCA: RESULTS FROM THE PROSPECTIVE, LONGITUDINAL, MULTI-CENTRE HAS-GCA STUDY

Keywords: Vasculitis, Ultrasound, Imaging

B Dasgupta1,2, K Van der Geest3, A Tomelleri, P Macchioni4, Klinowski5,6, C Salvareni3, A Kayani1, M Tariq1, D Prieto-Peña7, C Salvarani9, S Inness2, J Jackson2, A Sebastian1,2,10, Santander, Spain, Southend, United Kingdom, Modena, Italy, Medical Center Veneto-Fondazione IRCCS, Memory Center, Venetian Netherlands, San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy, Azienda USL - IRCCS - di Reggio Emilia - Area Toreritaria Veterinaria di Castelnuovo ne’Monti, Rheumatology, Castelnuovo ne’ Monti, Italy; University of Modena and Reggio Emilia, Rheumatology, Modena, Italy; Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; University of Siena, Rheumatology Unit, Department of Medicine, Surgery and Neurosciences, Siena, Italy; University Hospital Dorset, NHS foundation trust, Rheumatology, Dorset, United Kingdom; University Hospital Limerick, Rheumatology, Limerick, Ireland

Background: GCA is a critically ischemic large vessel vasculitis, varying in extent, severity and outcomes, hence requires disease stratification using clinical, laboratory and imaging parameters, for targeted management. Although DMARDs are used, the effectiveness in real life, such adjuvants remain un-elicited. We performed a prospective, multi centre cohort study of new GCA stratified into remitting, relapsing, refractory, ischemic disease.

Objectives: We assessed prognostic factors and compared critical outcomes such as remission with glucocorticoid (GC) monotherapy versus GC plus DMARDs in the first 12 months.

Methods: HAS GCA study (1) recruited consecutive patients with new onset GCA from 7 centres (UK, Italy, Spain, Netherlands). diagnosis was confirmed using modified GiACTA criteria at 6 months follow up. All underwent ultrasound (bilateral common, parietal, frontal temporal arteries, and axillary arteries) using accepted standard cut-off values [2]. GCA patients had US at baseline,1,3,6,12 months and halo count (HC) and Halo score (Temporal TAHS, axillary AAHS, bilateral common, parietal, frontal temporal arteries, and axillary arteries) using multicriteria decision analysis. Ann Rheum Dis 2017;76:543

Disclosure of Interests: Bhaskar Dasgupta Consultant of: Roche, Chugai, Sanofi, Grant/research support from: Roche, Sanofi, AbbVie, and GlaxoSmithKline, Kornelis van der Geest Speakers bureau: Roche, Grant/research support from: AbbVie, Alessandro Tomelleri: None declared, Pierluigi Macchioni: None declared, Giulia Klinowski: None declared, Carlo Salvareni: None declared, Abdul Kayani: None declared, Mohammad Tariq: None declared, Diana Prieto-Peña:
Background: Ultrasound (US) is recommended as the first-line imaging test in patients with suspected Giant Cell Arteritis (GCA). Traditionally, the US halo sign has been used for diagnosis. We have described a composite Halo Score that allows quantifying vascular inflammation on US. Prospective studies on response and disease monitoring are lacking.

Objectives: To prospectively assess the role of the US and Southend GCA pre-test probability score (GCAPS) in diagnosing and monitoring GCA patients. We report 12-month follow-up data on our current recruitment.

Methods: HAS GCA (IRAS#264294) is a prospective, multicentre study recruited from 7 European centres, referrals of suspected GCA to fast-track clinics. Based on the GCAPS [1], patients were stratified in low, intermediate and high risk categories [2]. Temporal and auxillary US Halo Scores were calculated from the halo thickness and extent in bilateral temporal arteries, parietal and fronto-temporal branches (TAHS) and auxiliary arteries (AAHS). These scores were summed (TAHS x1 plus AAHS x3) to generate a Total Halo Score (THS) [3]. Remission defines as the patient on prednisolone ≤ 5mg at 12 months follow up. Mann Whitney U test was used to compare baseline features between GCA and controls. Wilcoxon signed rank test was used to evaluate disease features at baseline and at 12 months in GCA patients. Sensitivity (Sn), Specificity (Sp) and ROC curve were calculated, where applicable. P value <0.05 is statistically significant.

Results: 229 patients (84 GCA, 145 controls) have been recruited from 7 European centres: 73 completed 12-month follow-up assessments; 11 were lost to follow-up (7 died, 4 withdrew consent due to pandemic). 65 achieved remission from the halo thickness and extent in bilateral temporal arteries, parietal and fronto-temporal branches (TAHS) and auxiliary arteries (AAHS). Among GCA patients, 60 had cranial, 5 large-vessel and 19 mixed phenotypes. Diseases were diagnosed by US and additional tests such as PET CT. Jaw claudication (54%) and constitutional symptoms (52%) were the dominant features in GCA patients compared to controls. Median age was 75 years in GCA (60% females) and 68 years in controls (69% females). GCA and controls were stratified by GCAPS to Low risk (0% vs 46%; Sn-undefined, Sp-99) and High risk (79% vs 16%; Sn-99, Sp-91). Optimal GCAPS cut-off point was ≥12 (Sn-89, Sp-78). Median THS was 21.5 in GCA and 8 in controls. Optimal cut-off Halo Score in diagnosis was TAHS ≥6 (Sn-86, Sp-92), AAHS ≥11 (Sn-52, Sp-75), THS ≥17 (Sn-76%, Sp-91%). Baseline Halo Score and CRP levels showed positive correlation (Spearman rank correlation); at 12-months follow up, median TAHS, AAHS and THS reduced from 13 to 3, 12 to 9 and 21.5 to 12, respectively (Figure 1).

Conclusion: Along with GCAPS, Halo Score successfully discriminates GCA from non GCA mimics and HS is effective in showing 12-month response. This score may be a useful marker to monitor GCA disease activity.

imaging modalities and potential large vessel (LV) involvement. These new criteria have been validated in an independent set of patients and controls, with a sensitivity of 87.0% and a specificity of 94.8%, but not tested in routine care.

Objectives: Our objective is to examine the performance of the new 2022 ACR/EULAR GCA classification criteria in this clinical scenario.

Methods: Multicentric retrospective observational study of patients referred to our ultrasound (US) fast track clinic over a 4-year period. The gold standard for GCA diagnosis was clinical confirmation after 6 months of follow-up. Patients with GCA were compared with unselected controls referred to our clinic with suspected GCA. All patients underwent US exam of temporal and extracranial arteries (carotid, subclavian, and axillary) within 24-48 hours at baseline. FDG-PET/CT was performed according to standard clinician criteria. Following the new 2022 ACR/EULAR classification criteria, the total score for the 10 items included in the criteria was calculated, with a total cut-off ≥ 6 for the classification of GCA. The performance of these criteria was evaluated in all GCA patients across different subsets of the disease.

Results: A total of 319 patients (188 cases and 131 controls) were included for analysis (mean age 76 years, 58.9% females). Patients with GCA and controls differed in age (78.2 vs 72.9, p<0.001) and sex (females 53.2% vs 67.2%, p=0.013). The diagnostic accuracy of the 2022 ACR/EULAR GCA classification criteria and the previous 1990 ACR GCA classification criteria in different subsets of patients is shown in Table 1. Overall, the new criteria had a sensitivity of 92.6% and a specificity of 74%, using GCA clinical diagnosis as an external criterion and the area under the ROC curve (AUC) was 0.932 (95% CI 0.903 to 0.960). Isolated LV-GCA showed a sensitivity of 62.2% and a specificity of 74% (AUC 0.696 [0.596 – 0.796]) and biopsy-proven GCA showed a sensitivity of 100% and a specificity of 74% (AUC 0.992 [0.981 – 1]).

Conclusion: The new 2022 ACR/EULAR GCA classification criteria showed good diagnostic accuracy of patients with suspected GCA under routine care, and a substantial improvement upon the sensitivity and specificity of the 1990 ACR GCA classification criteria.

Table 1. Diagnostic accuracy of the new 2022 ACR/EULAR GCA and the 1990 ACR/EULAR classification criteria, with clinical diagnosis serving as the external criterion in all GCA, patients with isolated cranial GCA, isolated LV-GCA, all LV-GCA and biopsy proven GCA. LV, large vessel; Sens, sensitivity; Spec, specificity; LR+, positive likelihood ratio; LR−, negative likelihood ratio; AUC: area under the ROC curve analysis.

Background: The creation of instruments for the structured assessment of disease activity has facilitated the effective use of DMARDs to control disease activity in patients with inflammatory arthritis. Composite measures for Giant Cell Arteritis (GCA) incorporating several key clinical and laboratory variables which allow for a standardized quantitative assessment of GCA disease activity have been recently introduced. These assessment tools for measuring disease activity are of particular benefit in helping to achieve therapeutic goals in patients with GCA, including amelioration of the symptoms and signs of active disease, and the consequent avoidance of functional impairment and restoration of physical function.

Objectives: To identify the preliminary definition of improvement in GCA and the higher thresholds for improvement reflecting significant and major improvement as well as remission.

Methods: In developing criterion for improvement of individual GCA patients, consideration was restricted to the 6 variables identified as outcome measures: severity of headache (0-100), acute visual deficit (0-100), functional disability (0-100), Extraocular Muscle Involvement (0-100), ESR and CRP levels. For each variable, the value at baseline were compared with the value at 4-weeks and 12-weeks of treatment to determine the degree of improvement or deterioration that occurred. The percentage of improvement was calculated directly for each of the 6 variables in 51 patients. Using the 6 variables, preliminary analysis was performed to determine the percentage of improvement. Preliminary definition of improvement required >x% improvement in y of the 6 variables, where "x" was set at 20%, 30%, 50%, 70%, 80% and 100%, and "y" was set at 2, 3, 4, 5, or 6 variables. To assess the discriminating power of high response percentages (70%, 90% and 100%) the percentage of improvement in the headache severity (as the main outcome measure reflecting the disease activity status) was compared to the change of the rest of the core set measures. The individual improvement criterion identified was then applied prospectively to a cohort of 25 patients diagnosed to have GCA and starting their therapy.

Results: A definition of >50% improvement in 4 or more variables produced the largest difference between patient's assessment at 4-weeks and 12-weeks in comparison to the baseline. Sharpening the cut-offs to 70% or 90% means that the patient should nearly or completely reach a status of remission in order to fulfill such an impressive improvement criterion. Reaching 100% means that the patient has achieved remission. Outcome of the prospective study revealed that 100% of the patients achieved 50% GCA response. Assessing the higher response rates, revealed that 10% of the patients achieved 70%, 30% achieved 90% whereas 60% achieved 100%.

Conclusion: Core sets of valid outcome measures have been defined. GCA response criteria have been developed and showed comparable validity. The 70% (significant improvement), 90% (major improvement) and 100% (remission) GCA improvement criteria showed good discriminating capacity though less than the 50% criteria. GCA response can be used in standard clinical practice to identify disease activity status and response to therapy. Calculation of GCA-N index would be the next step to attain a continuous variable rather than at arbitrary thresholds. GCA response can be used in standard clinical practice to identify disease activity status and response to therapy. Calculation of GCA-N index would be the next step to attain a continuous variable rather than at arbitrary thresholds.

Methods: Observational retrospective study on consecutive patients of our GCA fast track clinic. The gold standard diagnosis was the opinion of the clinical doctor after at least 6 months of follow-up. US recorded videos, of every explored vessel territory (common trunk, frontal and parietal branches), subclavian, and axillary arteries were reviewed and the IMT of each of them was measured in systole and diastole peaks for comparison. We define an ultrasound result as positive with cut-off values of IMT ≥ 0.34 mm for frontal and parietal branches, ≥ 0.42 mm for the common trunks of TA, and ≥ 1 mm for the axillary and subclavian arteries. Demographic data of the included patients were also collected.

Results: We have included 72 cases, 36 with GCA diagnosis and 36 without GCA controls). The mean values of age and sex, as well as the IMT in systole and diastole of each vessel are shown in Table 1. There were not significant differences in sex but patients without GCA were younger (p<0.01). The US IMT measurements at the systolic and diastolic times showed statistically significant differences in all the explored vessels, as in patients with GCA as in the control non-GCA group. All the IMT measured in diastole showed higher and statistically significant values than those measured in systole, with a mean increment of measurement of 5.3% and 6.5% in TA and 6.4% and 5.6% in VA, respectively in the GCA and control group. This result can be of clinical relevance because if we used diastolic measures, instead of systolic measures, 5/36 (13.8%) cases in controls had halo sign in one isolated vessel (2 cases in parietal right, 1 in common trunk right, 1 in subclavian left). However, in GCA patients, the number of patients with halo sign did not change, but the number of pathological vessels was increased when the measured was performed in diastole (1 frontal right branch, 1 common trunk right, 4 frontal left branches, 5 common trunks left and 2 axillary right), so this could have influence in the assessment of the disease.

Conclusion: There are significant differences between the IMT measured in systolic and diastolic peaks with higher values in diastole. The differences are relatively small but may increase the number of false positives (13.8%) in controls and the number of affected vessels in the GCA group. This should be considered in the diagnosis and assessment of GCA.

AGE AND SEX BIAS OF ULTRASOUND SCORES FOR DIAGNOSIS OF GIANT CELL ARTERITIS: INSIGHTS FROM THE PROSPECTIVE, LONGITUDINAL HAS-GCA STUDY

Keywords: Ultrasound, Imaging, Vasculitis

K. Van der Geest1, A. Sebastian2,3,4, E. Corticis2, S. Innes3, J. Jackson3, A. Kayani2, M. Khurshid5,6, G. Klinowski7,8, P. Macchioni7, D. Prieto-Peña9, G. Emilia, Italy7; University of Modena and Reggio Emilia, Rheumatology, Modena, Italy; 7Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 8San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

Background: Giant cell arteritis (GCA) is an age-linked, critically ischaemic vasculitis where ultrasound (US) serves as an important tool enabling urgent diagnosis and therapy. US scores have been developed to quantify the arterial inflammation in GCA [1,2], but optimal diagnostic cut-off points and potential bias of age and sex on these values remain un-elicited.

Objectives: To compare the diagnostic accuracy of previously reported US scores for GCA, and to determine whether these scores require correction for age and sex.

Methods: The HAS-GCA study, with a prospective, multicentre, cohort design, recruited 229 consecutive patients with suspected, new-onset GCA from 7 sites located in the UK, Italy, Spain and the Netherlands. All cases underwent bilateral US evaluation of the three temporal arterial segments (common superficial, parietal, frontal) and axillary arteries. Intimal-medial thickness (IMT) was measured in each segment. Three ultrasound scores were calculated based on the IMT: halo count (HCount) [1], Halo Score (HScore) [2] and the OMERACT GCA US Score (OGUS) [3]. The definition of halo was based on previously reported IMT cut-off values [3]. The reference standard was the final clinical diagnosis after 6 months follow-up. ROC with AUC analysis was performed. Optimal cut-off points were determined by Youden Index. Group comparisons were made by Mann Whitney U test and correlations by Spearman’s rank correlation coefficient. P values < 0.05 were considered statistically significant.

Results: A final diagnosis of GCA was made in 84 patients, whereas 145 cases received an alternative diagnosis (i.e. non-GCA patients). HCount, HScore and OGUS were significantly higher in GCA patients than non-GCA patients. In non-GCA patients, all three scores were significantly higher in men than women, and showed a statistically significant, positive correlation with age. In GCA patients, the US scores showed a positive correlation (HCount and OUSG) or strong trend for a positive correlation (HScore) with age; and the HCount was significantly higher in men. All scores effectively discriminated GCA from non-GCA patients as indicated by ROC analysis: AUC for halo count 0.936 (0.899-0.974), Halo Score 0.894 (0.848-0.939) and OGUS 0.937 (0.902-0.973). The optimal diagnostic cut-off points were: 2 for HCount (sens 86%, spec 92%), 17 for HScore (sens 76%, spec 91%) and 0.80 for OGUS (sens 87%, spec 93%). These diagnostic cut-off points differed in sensitivity and specificity within different age- and sex-defined groups with the highest sensitivity and lowest specificity observed among old (>81yr) male patients. Alternatively, age- and sex-stratified cut-off points could be established for the US scores (Table 1).

Conclusion: All previously reported US scores show excellent diagnostic accuracy for GCA, but are prone to over-diagnose GCA in older males. Our data highlight the need for age- and sex-specific diagnostic cut-off points. The excellent comparative performance of the simple HCount in GCA diagnosis suggests an exciting role in future clinical practice.

Background: Polymyalgia rheumatica (PMR) and Giant cell arteritis (GCA) are chronic inflammatory diseases. Despite the progress made in the management of these conditions, new unmet needs have emerged particularly in terms of prevention of disease- and treatment-related complications. A treat-to-target (T2T) strategy, which has been well established in other rheumatic diseases, has not yet been developed for PMR and GCA.

Objectives: To retrieve current evidence on T2T strategies in PMR and GCA to inform an international task force (TF) developing T2T recommendations.

Methods: A systematic literature review (SLR) was conducted. Medline, EMBASE, Cochrane Library and clinicaltrials.gov (from inception until May 2022), as well as EULAR/ACR abstract databases were searched (2019-2021). Randomized controlled trials (RCTs) and non-randomized interventional studies published in English and answering at least one of the eleven PICO questions on treatment targets and outcomes, were identified. Table 1: The study selection process, data extraction, data synthesis and risk of bias assessment were conducted independently by two investigators.

Results: Of 7809 screened abstracts, 397 were selected for detailed assessment and 76 papers were finally included (31 RCTs, 8 subgroup/exploratory analyses of RCTs and 37 non-randomized interventional studies). No study comparing a T2T strategy against standard of care was identified. In PMR, RCTs, treatment-related outcomes were most commonly used (90.9% of RCTs), specifically in terms of the glucocorticoids (GC) cumulative dose and tapering, followed by clinical, laboratory and safety targets (63.3% each). Conversely, the most frequently reported outcomes in RCTs in GCA were prevention of relapses (72.2%), remission, treatment, and safety (66.7 % each). Remission and relapses were variably defined in PMR and GCA RCTs but, in most cases, they comprised a combination of clinical and laboratory parameters (Figure 1). The following predictors of poor treatment response were identified: for GCA, data from RCTs yielded female sex, initial prednisone dose <30mg/day, baseline patient-reported outcomes, increased inflammatory markers after the achievement of clinical remission and absence of PMR symptoms at baseline as risk factors for treatment failure and an increased relapse rate. In PMR, no high-quality data predicting clinical outcomes were identified. Finally, in RCTs comparing the outcomes of GCA patients with new onset versus established disease, no differences were found, given that treatment was equal in both groups.

Conclusion: This SLR informed an international TF developing T2T recommendations in PMR and GCA. It provides up-to-date evidence while simultaneously highlighting the gaps in current knowledge about T2T strategies in these diseases.

Lucas1. 1Instituto de Saúde Pública da Universidade do Porto (ISPUP), EPIUnit, Porto, Portugal; 2Hospital Garcia de Orta, Serviço de Reumatologia, Almada, Portugal; 3Faculdade de Medicina da Universidade do Porto - FMUP, CISPPEMF, Porto, Portugal

Background: Primary musculoskeletal pain conditions interfere greatly with the quality of life and are challenging to manage, from the patient’s and clinician’s perspectives. Susceptibility to chronic musculoskeletal pain syndromes in adulthood can be traced back to childhood when prevention might be most effective. Population-based longitudinal studies in pediatric ages allow for testing different predictors of pain trajectories to assist risk stratification. Recurrent pain experiences in non-musculoskeletal sites are common in young children and may be red flags for future musculoskeletal pain susceptibility [1].

Objectives: We aimed to quantify the prospective association of non-musculoskeletal pain experiences at ages 7 and 10 with recurrent musculoskeletal pain at age 13 in a large population-based cohort of boys and girls.

Methods: We used data from Generation XXI, a population-based birth cohort setup in 2005-06 that includes the public maternity of Porto, Portugal. Participants were invited to regular follow-up visits at ages 7, 10, and 13 years. In each wave, pain history in the previous 3 months was assessed using the Luebeck Pain Screening Questionnaire, applied to caregivers (ages 7 and 10) and adolescents (age 13). We included only the main pain identified in the questionnaire, and only if it occurred more than once in the previous 3 months. Musculoskeletal pain sites comprised upper/lower limbs, back, neck, shoulders, hips, and generalized musculoskeletal pain. Non-musculoskeletal sites were head, abdomen/pelvis, or other. We calculated relative risks and 95% confidence intervals for the association between pain sites at ages 7 and 10 and recurrent musculoskeletal pain at age 13. The analysis was stratified by sex at birth.

Results: We included 3833 participants (479 girls). Recurrent pain was reported in 28.4% of children at age 7 (25.7% of boys, and 31.3% of girls), 26.6% at age 10 (23.3% of boys, and 30.2% of girls), and 35.1% at age 13 (28.8% of boys, and 41.9% of girls). For girls, the most reported recurrent pain sites before adolescence were abdomen/pelvis (10.3% at 7, and 9.7% at 10), musculoskeletal (8.1% at 7, and 9.0% at 10), and head (7.7% at 7, and 7.3% at 10). In boys, recurrent pain was more frequent in musculoskeletal sites (9.0% at 7, and 9.6% at 10), followed by abdomen/pelvis (7.7% at 7, and 5.0% at 10), and head (5.1% at 7, and 6.0% at 10). As shown in the Figure 1, in 7-year-old girls, only abdominal/pelvic pain was predictive of future musculoskeletal pain at age 13 RR 1.43; (95%CI: 1.07; 1.87). At age 10, musculoskeletal pain became predictive of musculoskeletal pain at age 13 [1.44 (1.07 – 1.84)]. In boys aged 7 years, both musculoskeletal and abdominal/pelvic pain were predictive of future musculoskeletal pain at age 13 [1.49 (1.13, 1.91) and 1.40 (1.02, 1.86), respectively]. At age 10 only musculoskeletal pain remained predictive of musculoskeletal pain at age 13 [1.45 (1.11, 1.84)].

Conclusion: In this population-based cohort, musculoskeletal pain in adolescents was preceded by non-musculoskeletal pain experiences especially abdominal/pelvic pain - during childhood in both boys and girls. Widening the scope to non-musculoskeletal sites may contribute to the early detection and risk stratification of individuals who are more susceptible to developing chronic musculoskeletal pain trajectories.

LEUCOYTE ABNORMALITIES AND CYTOKINE LEVELS IN SYNOVIAL FLUID OF JUVENILE IDIOPATHIC ARTHRITIS PATIENTS: A PRELIMINARY STUDY

Keywords: Cell biology, Cytokines and chemokines, Uveitis

A. Scarnì1, F. Treilli1, A. Meneghe1, R. Luisetto2, C. Baggio3, M. L. Cagnato1, R. Ramonda3, F. Oliviero4, G. Martinī5, F. Zullan6. 1University of Padova, Department of Women’s and Children’s Health-SOB, Padova, Italy; 2University of Padova, Department of Surgery, Oncology and Gastroenterology-DISCOG, Padova, Italy; 3University of Padova, Department of Medicine-DIMED, Padova, Italy

Background: Juvenile idiopathic arthritis (JIA) is a heterogeneous group of diseases characterized by joint inflammation and uveitis is the most frequent extra-articular manifestation. Although several studies evaluated the differences between the different types of JIA, no specific markers have been identified which would allow early stratification of patients and predict the future disease course. Recently, it has been suggested that rheumatic diseases might be associated with genomic instability and increased sensitivity to DNA damage (3), but it has not yet determined in JIA.

Objectives: To investigate cell populations, cytokine levels, and signs of genomic instability in synovial fluid (SF) of patients with different JIA subtypes.

Methods: SF was collected from the knees of 24 patients, untreated for at least 6 months prior to enrollment, and fulfilling ILAR criteria (4): 9 with polyarticular (poly-JIA) (age: 6.5±4.6 years) and 15 with oligoarticular (oligo-JIA) (age: 8.3±3.5 years). Six poly-JIA and 8 oligo-JIA patients were at disease onset. Among the oligo-JIA patients, 12 had positive anti-nuclear antibodies (ANA+) and 5 had uveitis. SF was examined under optical light microscopy. White cell count (WBC) and the polymorphonuclear cell (PMN) percentage were determined in SF according to standard procedures. May-Grünewald-Giemsa staining was used to determine the percentage of hypo- or hypersegmented PMN, binucleated monocytes, and cells with micronuclei (MN), pyknosis, necrosis, apoptosis and nuclear buds, which are considered biomarkers of genotoxic events. SF IL-1β and IL-8 levels were assayed by ELISA.

Results: WBC count and PMN percentage were higher in SF of patients with poly-JIA than in those with oligo-JIA, albeit not significantly. Comparison between the two groups at disease onset showed that WBC levels and PMN percentage were significantly greater in SF from poly-JIA (poly-JIA WBC:1050±458.32 cells/mm³; PMN:59.83±13.75%; oligo-JIA WBC:4850±1050 cells/mm³; PMN:41.5±16%; p<0.05). IL-1β and IL-8 levels were higher in children with poly-JIA, but the difference reached statistical significance only for IL-8 in patients at disease onset (poly-JIA:1253.19±264.4 pg/ml; oligo-JIA:519.67±468.34 pg/ml; p=0.01). This group also showed a percentage of cells with MN significantly greater as compared to that in oligo-JIA (poly-JIA:7.1±2.42%; oligo-JIA:1.7±2.05%; p<0.001). Although SFs from oligo-JIA-ANA+ patients had higher WBC and PMN percentage than those from oligo-JIA-ANA-, no significant differences were observed between the 2 groups. SFs from oligo-JIA patients with uveitis showed higher but not significant IL-8 levels (554.0±520.26 pg/ml), significantly greater IL-1β concentration (100.94±76.05 pg/ml; p<0.05) and percentage of cells with MN (5.7±3.56%; p<0.05), and significantly lower hypersegmented PMN percentage (11.06±4.95%; p<0.05) than those from oligo-JIA patients without uveitis (IL-8:280.8±310.11 pg/ml; IL-1β:6.04±15.4 pg/ml; cells with MN:1.96±3.26%; hypersegmented PMN:22.79±8.07%). There was no significant difference in the other studied parameters between the different patient groups.

Conclusion: This study shows that poly-JIA SFs have higher inflammation marker levels than oligo-JIA SFs, and this is observed mostly at the disease onset. The presence of MN is associated with SF genotoxic effects, and may trigger the induction of inflammatory pathways that contribute to disease complications. As hypersegmented PMN suppress T cell proliferation, a low cell number with this phenotype may reflect a persisting antigenic stimulus.

**Background:** Behçet’s syndrome (BS) is an autoinflammatory disease characterized by a variable vessel vasculitis. In children, BS may start early in life, mimicking other autoinflammatory diseases and making the diagnosis challenging. In the past, several criteria have been created for adult BS classification. In 2015, the first set of BS paediatric classification criteria, the PEDBD, was proposed by an international Expert consensus [1].

**Objectives:** to perform an external validation of the PEDBD criteria in a cohort of internationally validated paediatric BS patients.

**Methods:** 210 patients (70BS, 40 PFAPA, 35 FMF, 26 MKD, 22 TRAPS, 17 ICBD) were randomly selected from the Eurofever Registry (patients excluded if > 16 years and if included in first PEDBD study). A set of 11 Experts blinded to original diagnosis, were chosen to evaluate the patients: in the 1st round, clinical and serological data were evaluated; in the 2nd round genetic data were added; in the 3rd round the other Experts’ votes and comments were shown. Using the expert consensus as gold standard (agreement>80%), the PEDBD, the ISG and the ICBD criteria were applied to BS patients and to the confounding diseases in order to define the sensitivity, specificity and accuracy.

**Results:** At the end of the 3rd round, a consensus on the initial diagnosis was reached in 112/210 patients (53.3%), with an additional consensus on a different final diagnosis in 27 patients. The BS patients with an agreement (24) were classified as confirmed-BS, and those with an agreement of 60-70% (10) as probable-BS. In confirmed-BS patients, oral ulcers were present in all the patients, genital ulcers in 77%, skin manifestations in 50%, a positive pathergy reaction in 39%, anterior and posterior uveitis in 29 and 27%, retinal vasculitis and papillary oedema in 8% of patients, with a resulting impaired vision in 17%. Venous thrombosis was present in 2 patients (8%). The patients with ocular and vascular involvement were all males. Cranic nerve palsy (17%) was the most frequent neurologic symptom. Abdominal pain was present in 33%, diarrhoea and gastrointestinal bleeding in 13% and anal/perianal ulcers in 8%. 29% presented arthralgia, and 13% arthritis. Fever was present in 50% of patients. HLA-B51 was positive in 69% of patients. When comparing these patients with the confounding diseases, an older age at disease onset, the presence of oral and genital ulcers, skin papulo-pustular lesions, a positive pathergy test and posterior uveitis were BS distinctive elements. The ISG, ICBD and PEDBD criteria were applied to confirmed and probable-BS and to the confounding disease controls, resulting in the following test characteristics (Table 1).

**Table 1.**

<table>

<td>0.91</td>
</tr>
</tbody>
</table>

**Conclusion:** the PEDBD criteria were extremely specific but had a lesser sensitivity than ICBD which had a better accuracy. One limitation is that specific mono-genetic BS mimics were not included as disease controls, thus the true accuracy of all these criteria may be lower in practice. The complexity of childhood BS suggests that genotyping (incorporating autoinflammatory diseases, BS mimics, and HLA-type) combined with clinical features are likely to yield the most accurate classification criteria, which would require further validation in a larger cohort.

**CLUSTERS OF JUVENILE PSORIATIC ARTHRITIS IDENTIFIED AT INITIAL PRESENTATION TO PAEDIATRIC RHEUMATOLOGY IN A NATIONWIDE UK COHORT**

**Keywords:** Epidemiology, Artificial Intelligence, Psoriatic arthritis

S. Shoop-Worrall1, C. Curtin1, G. Cleary1, F. Morel1, L. Coates1, N. Geifman2, K. Hyrich3,7, The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 3University College London, Centre for Adolescent Rheumatology, Division of Medicine, London, United Kingdom; 3Alder Hey Children’s Hospital, Paediatric Rheumatology, Liverpool, United Kingdom; 6Great North Children’s Hospital, Paediatric Rheumatology, Newcastle-upon-Tyne, United Kingdom; 6University of Oxford, Oxford Paediatric Arthritis Centre, Oxford, United Kingdom; 6University Of Surrey, School of Health Sciences, Faculty of Health and Medical Sciences, Surrey, United Kingdom; 5Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom

**Background:** The heterogenous presentation and variable clinical response of juvenile psoriatic arthritis (JPsA) to disease-modifying therapies suggests undiscovered subgroups within this disease. Nevertheless, JPsA is often studied under the umbrella of juvenile idiopathic arthritis (JIA), with few studies interrogating JPsA separately. To improve stratified treatment of this rare disease, such subgroups must be uncovered.

**Objectives:** To identify novel, phenotypically consistent subgroups of children and young people (CYP) with JPsA at the point of first contact with paediatric rheumatology.

**Methods:** CYP were initially selected if enrolled between January 2001 and December 2019 in the Childhood Arthritis Prospective Study, a UK, multicentre, prospective inception cohort of JIA. Those who had a physician’s diagnosis of JPsA at any time point through the 10-year follow-up were included, to allow for onset of psoriatic signs after initial diagnosis. At initial presentation to paediatric rheumatology, clinical features within the ILAR classification criteria for JPsA were collected: an active joint count and the presence or absence of psoriasis, dactylitis and nail abnormalities. Latent class analysis used these features to identify clusters of disease. Between one and ten clusters were tested and an optimal model selected based on statistical fit.

**Results:** Of 1,753 CYP with JIA recruited to CAPS within the study period, a total of 161 CYP had ever had a diagnosis of JPsA (n=97 diagnosed as JPsA at initial presentation to paediatric rheumatology). The majority were female (61%), of white ethnicity (94%) and the median age at initial presentation was 10 years (IQR 6, 13). The optimal latent class model identified two clusters of JPsA. An oligoarticular cluster (90%, median active joint count (IQR): 2 (1.5)) had a higher proportion of CYP affected by psoriasis (Cluster 1: 29%, Cluster 2: 14%). A polyarticular cluster (10%, median active joint count (IQR): 20 (16, 27)) had a higher proportion with nail abnormalities (Cluster 1: 8%, Cluster 2: 27%). There were similar proportions of dactylitis among the clusters (Cluster 1: 18%, Cluster 2: 15%) (Figure 1).

**Conclusion:** This study identifies two clusters of JPsA at initial presentation to paediatric rheumatology with differences in key features used to classify this disease. Such subgroups may have different experiences of disease, and future analysis will explore characteristics, alongside disease impact and response to therapy for these groups.

**THE DIAGNOSTIC AND PROGNOSTIC ROLE OF SYNOVIAL TISSUE ANALYSIS IN JUVENILE IDIOPATHIC ARTHRITIS: A MONOCENTRIC STUDY**

**Keywords:** Synovium, Prognostic factors, Inflammatory arthropides

S. Costi1, E. Armiraglio2, F. Pregnolato3, C. Chighizola3, A. Marino1, C. Iannone1,4, A. Amati4,5, P. Randelli2, R. Caporal1,3,4, ASST G.Pini-CTO, Department of Pediatric Rheumatology, Milan, Italy; 4ASST G.Pini-CTO, Department of Pathological Anatomy, Milan, Italy; 5University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 5ASST G.Pini-CTO, Department of Rheumatology and Medical Science, Milan, Italy; 3ASST G.Pini-CTO, 1 Orthopedic Clinic, Milan, Italy

**Background:** Juvenile idiopathic arthritis (JIA) refers to arthritis persisting for more than 6 weeks and presenting before 16 years. Once the diagnosis of JIA has been formulated, clinicians face challenges in tailoring the therapeutic approach upon each patient’s clinical features. To date, no study has addressed the role of synovial pathology to support the diagnostic approach and guide clinical management in children.

**Objectives:** This study aimed at investigating the diagnostic role of synovial biopsy in children presenting with arthritis and assess the prognostic significance of synovial histology in predicting clinical outcomes among patients with JIA.

**Methods:** Medical records of pediatric patients undergoing synovial biopsy between 1995 and 2020 were retrospectively reviewed. Synovial samples were analyzed histologically and immunohistochemically.

**Results:** Of 99 patients included, synovial biopsy was performed for diagnostic purposes in 65 cases allowing to correctly classify 79% of patients. At historical
analysis on 42 JIA samples, any difference emerged between JIA subsets (Table 1) or treatment-naïve and treatment-experienced subjects. Tissue analysis predicted subsequent disease course: higher number of layers of synovial lining predicted a worse disease course (>4 layers during follow-up) (median 4.5 [IQR 3.0] vs. 3.0 [IQR 2.5], p=0.035), even after adjusting for age at diagnosis and observation time (OR 2.2, 95% CI 1.3-3.9, p=0.007); subjects who had switched to bDMARDs had higher prevalence of subsynovial elementary lesions (55.6% vs 10.3%, p=0.005) and fibrin deposits in synovial lining (60.0% vs 22.6%, p=0.049), even after adjustment for observation time and age at diagnosis (OR 8.1, 95% CI 1.03-64.2, p=0.047). At immunohistochemistry on 31 JIA samples, higher CD3 expression was described in polyclonar compared to oligoclonar subset (p=0.040), while no differences were found between persistent and extended oligoclonar subsets (p=0.670). Patients with severe disease course had higher CD20+ cells percentage (OR 7, 95% CI 1.4–35.5, p=0.023), regardless of JIA subset and treatment exposure (Figure 1).

Conclusion: Immunohistochemical analysis on 31 JIA samples, any difference emerged between JIA subsets (Table 1) or treatment-naïve and treatment-experienced subjects. Tissue analysis might support the clinicians in the diagnostic approach of pediatric patients presenting with arthritis and guide the clinical management of JIA.

Background: Multisystem Inflammatory Syndrome in Children (MIS-C) is one of the most feared complications following SARS-CoV2 infection in children and adolescents. Few multinational multicenter studies from Latin America have been published. Objectives: To describe the clinical presentation, management, and outcomes of MIS-C in Latin America.

Methods: Observational, prospective and retrospective, multicenter study to gather information from 84 participating centers across 16 Latin American countries, between August January 1, 2020 and June 30, 2022.

Results: Of the 1,239 reported cases of MIS-C, 84.2% were previously healthy. The most frequent clinical manifestation in our studied population was abdominal pain (N=804, 64.9%), followed by conjunctival injection (N=784, 63.3%). The median days of fever at the time of hospital admission was 5 and a significant number of subjects required admission to an intensive care unit (N=569, 47.8%). At a total of 538 (47.2%) patients had an abnormal echocardiogram. Most of the subjects (N=1,106, 88.7%) were treated with intravenous immunoglobulin
Prevalence per 100,000 CYP under the age of 16 (31 for validated cases), varying from 38 (34) for CYP with JIA code, to 4.8 for White CYP to 1.1 for CYP with Mixed ethnic group. A total of 268 HES-validated cases were included and aggregated to broad ethnic groups, as defined by the Office for National Statistics (ONS). Incidence and prevalence rates by broad ethnic group were calculated using CYP under the age of 16 in CPRD, as of December 2011. Indirect standardisation was performed by age and region using ONS Census 2011 data, to account for varying population size and age structure across ethnic groups in England.

* Statistically significant when compared to ‘White’ ethnic group (p<.05). † Statistically significant when compared to ethnic group distribution in general population, p<.001 Chi-Square.

Conclusion: The incidence and prevalence of JIA amongst CYP in England differs by ethnic group, being highest amongst ‘White’ CYP and lowest amongst other ethnic groups, and is not in keeping with the known distribution of ethnic groups in the 1-16y England population. Understanding whether this reflects a health inequity or differences in the underlying biology of JIA needs further evaluation.

**Background:** Nailfold Video Capillaroscopy (NVC) is a simple, non-invasive diagnostic tool but studies with normal values for capillary density in healthy children are rare. Ethnic background seems to play a role in capillary density; however, this is not well substantiated yet [1, 2].

**Objectives:** In this work, we set out to evaluate influence of ethnic background, skin pigmentation and age on capillary density reading in healthy children. Secondary aim was to investigate whether there is a significant difference in density between different fingers within the same patient.

**Methods:** Capillaroscopic images from healthy children were obtained in a one-time visit videocapillaroscopy (×200 magnification) addressing the capillary density (i.e. number of capillaries per linear millimeter in the distal row). This parameter was compared to age, sex, ethnicity, skin pigment grade (I-III) and between eight different fingers, excluding the thumbs.

**Results:** We investigated 145 healthy children with mean age of 11.03 years (SD 3.51). The range of capillary density was 4-11 capillaries per millimeter. We observed a lower capillary density in the ‘grade II’ (6.4 ± 0.5cap/mm, p<0.001) and ‘grade III’ (5.9 ± 0.8 cap/mm, p<0.0001) pigmented-classified groups compared to the ‘grade I’ group (7.0 ± 0.7 cap/mm). We did not find a significant correlation between age and density in the overall group. The fifth fingers on both sides had a significantly lower density compared to the other fingers.

**Conclusion:** Healthy children <18 years with higher degree of skin pigmentation show a significantly lower nailfold capillary density. In subjects with an African/Afro-Caribbean and North-African/Middle-Eastern ethnicity, a significantly lower mean capillary density was observed compared to subjects with the Caucasian ethnicity (p<0.0001, and p<0.05, respectively). There were no significant differences between other ethnicities. No correlation was found between age and capillary density. The fifth fingers on both hands displayed lower capillary density compared to the other fingers. This needs to be taken into account when describing lower density in paediatric patients with connective tissue diseases.

**Background:** Systemic juvenile idiopathic arthritis (sJIA) accounts up to 15 % of all patients with JIA and is distinct from other disease categories due to the association of articular and extraarticular manifestations. The systemic Juvenile Arthritis Disease Activity Score (sJADAS) is a composite disease activity score validated specifically for use in sJIA that includes, beside the four components of the original JADAS, a fifth item aimed to quantify the burden of systemic features. The interpretation of scores on sJADAS requires criteria that identify the states of disease activity. These criteria can be used to monitor the disease course over time and to define therapeutic targets.

**Objectives:** To compare the clinical and laboratory data of each disease activity state in patients enrolled in the multinational study aimed to define the sJADAS cutoffs.

**Methods:** Data were extracted from a multinational cross-sectional dataset that included patients diagnosed as sJIA by ILAR criteria, recruited between February 2022 and November 2022. At study visit, each patient was categorized subjectively by the caring physician into one of the following disease activity states: inactive disease (ID), low (or minimal) disease activity (LDA), moderate disease activity (MDA), or high disease activity (HDA). Study data was collected through a standard case report form and entered into an electronic database.

**Results:** A total of 231 patients were enrolled in 29 centers in 12 countries. The mean age at diagnosis was 5.63 years. 87 patients (37.7%) were judged as having ID, 39 (16.9%) LDA, 46 (19.9%) MDA and 59 (25.5%) HDA. The comparison of the main clinical and laboratory features across patients with the four disease activity states is shown in the Table. Overall, the presence of extraarticular manifestations was more common in patients with MDA and HDA (P<0.00001), whereas fever, rash, hepatosplenomegaly, and lymphadenopathy were more frequent in HDA patients (p<0.00001). The count of active joints increased progressively from ID to HDA (p<0.00001). The mean values of physician global assessment of disease activity and systemic manifestations, as well as the mean values of acute phase reactants, were highest in patients with HDA, with gradual decrease from MDA to LDA to ID.

**Conclusion:** This preliminary analysis of the study data indicates that the subjective assessment of disease state by the caring physicians led to discriminate reliably patients with different level of disease activity. This evaluation will, then, serve as basis reference for rheumatology analyses aimed to identify the cutoffs for the main disease activity states in sJIA.

POS0749 TRANSITION READINESS AMONG FINNISH ADOLESCENTS WITH JIA

Keywords: Patient information and education, Self-management, Outcome measures

K. Mikola 1, K. Rebane 1, H. Kautilainen 2,3, K. Aalto 1
1New Children’s Hospital, Pediatric Research Center, Helsinki, Finland; 2Kuopio University Hospital, Primary Health Care Unit, Kuopio, Finland; 3Folkhalsan Research Centre, Biomedicum, Helsinki, Finland

Background: Juvenile idiopathic arthritis (JIA) is the most common persistent rheumatic condition in children [1]. Its nature is chronic (2) and in our own study 40% of patients were transferred to adult clinic when they reached the transition age [3]. A successful transition requires sufficient self-management skills to manage one’s chronic condition and all the tasks involved in it [4]. There are multiple practices to establish the transition readiness and self-management among the adolescents [5].

Objectives: The purpose of our study was to evaluate transition readiness in Finnish patients with JIA and estimate the usefulness of a specific questionnaire. We aimed to find forecasting values for a successful transition and study the possible consequences of an unsuccessful transition to the disease outcome.

Methods: Our questionnaire was inspired by the Canadian Good2Go questionnaire (www.sickkids.ca/en/patients-visitors/transition-adult-care), and it was part of the routine rheumatological visits in our clinic. Eighty-three patients filled it in between June 2011 and December 2013. The questionnaire was given to patients who were likely to be transferred into an adult clinic, that is patients with a long history of ongoing disease activity and ongoing medication. The questions evaluate the self-management in several aspects, e.g., independence in the disease management (medication, appointments, pain control), everyday life (school, future educational plans, mental support, exercise, sexual health), and substance abuse. We used 13 questions with three answer options (yes =2, partly= 1, or no= 0), higher score indicating better readiness. Patients filled in the questionnaire in the pediatric site. We also gathered information from the first adult visit to assess the success of the transition and its relation to disease activity. The transition was defined successful when the patient attended the first visit at an adult care independently, as scheduled, and the medication was carried out as agreed at last pediatric visit.

Results: The cut-off score for a successful transition by ROC-analysis was 24 (OR 6.11 (95% Cl: 1.71 to 1.43)). That is, the best estimate for successful transition is when the score is 24 or more. We were able to receive all necessary information to define the success of the transition from 77 patients. In 55 (71%) patients the transition was estimated as a successful. The mean score 22.5 (SD 2.2) in the transition readiness questionnaire is shown in the Figure 1. Seven patients (9 %) received the maximum score.

At the first adult visit, the DAS28 was assessed in 58 patients. If the transition was defined as unsuccessful (score<24), the DAS28 was higher, mean 2.21 (SD 1.14) and if the transition was defined as successful (score≥24) the DAS28 was better, mean 1.35 (SD 0.48), p<0.001.

Conclusion: We found this questionnaire a useful tool to evaluate transition readiness. Determination of a successful transition helps us to discover those adolescents who need more profound support to improve their self-management skills and thus enhance their transition process. An unsuccessful transition also has important impact on disease outcome.

POS0750 RELATIONSHIP OF CLINICAL AND PATIENT-REPORTED OUTCOMES WITH IMAGING MEASURES OF SYNOVITIS IN JUVENILE ARTHRITIS

Keywords: Patient reported outcomes, Inflammatory arthritides, Ultrasound

P. Vega Fernandez 1, K. Rogers 1, A. Cassedy 2, A. B. Meyers 2, T. Ting 1,2
1Cincinnati Children's Hospital Medical Center, Rheumatology, Cincinnati, United States of America; 2University of Cincinnati, Pediatrics, Cincinnati, United States of America; 3Cincinnati Children's Hospital Medical Center,
Background: In children with JIA, the use of outcomes measures for the assessment of disease course and health-related quality of life (HRQOL) contribute to improvement of the quality of care provided. However, these subjective outcome measures do not always accurately reflect the inflammatory disease burden and may be influenced by comorbid conditions. Musculoskeletal ultrason sound (MSUS) and contrast-enhanced MRI imaging measures of synovitis provide an objective assessment of JIA disease activity. A novel MSUS score for knee arthritis (MSUS-knee score) showed strong correlation with the combined Juvenile Arthritis MRI Scoring (JAMRIS) system in children with JIA.[1]

Objectives: To determine the relationship of clinical and patient-reported outcomes (PROs) measures with the MSUS-knee score and the JAMRIS system in children with JIA.

Methods: Children with a diagnosis of JIA who received a MSUS of the knee(s) were enrolled. Data collected included knee physical examination findings, disease activity assessment, the Child Health Assessment Questionnaire (CHAQ) and the pediatric PROMIS Mobility measure (t-score mean 50, standard deviation 10). The following measures were asked to the patients specifically for the examined knee: pain, swelling and morning stiffness. A comprehensive knee MSUS examination was performed on all participants by MSUS certified pediatric rheumatologist. MSUS images were scored by pediatric MSUS experts, who were blinded to clinical information using a semiquantitative scoring system (0-normal to 3-severe).[1] The MSUS-knee score was calculated by adding the abnormal B-mode MSUS scores (score 2 or 3) and the power doppler MSUS scores (score 1 to 3) from the views of MSUS-knee (MSUS-knee score-range: 0-15)[1]. A subset of participants received an MRI with and without contrast of the knee. MRI of the knee was scored for presence and severity of synovial thickening and joint effusion as per JAMRIS system[2]. Associations between clinical and PROs outcome measures and imaging measures were assessed using Spearman’s Correlation Coefficient.

Results: Forty-eight children (mean age of 12.1 years) contributed 60 visits. Twenty-four knee MRIIs were obtained following MSUS of the knee. Patient reported presence of knee swelling was strongly correlated with the MSUS-knee score and moderately correlated with the JAMRIS system. No other significant statistically associations were found between PROs assessing lower extremity pain and physical function, and overall disease status with imaging measures (Table 1).

Conclusion: Imaging measures of JIA disease activity could provide a more accurate assessment of JIA disease state, given low correlation with commonly used outcome measures. Integration of imaging measures into the shared decision-making in daily clinical practice may improve the quality of medical care. Future studies with a larger population are required.

MUSCULOSKELETAL INVOLVEMENT IMPAIRS QUALITY OF LIFE IN JUVENILE PSORIATIC ARTHRITIS

Keywords: Quality of life, Psoriatic arthritis, Ultrasound

Background: Juvenile psoriatic arthritis (JPsA) is one of the least common subtypes of JIA. Information on JPsA is mainly clinical, but scarce regarding the impact of musculoskeletal involvement on children’s quality of life.

Objective: To describe the clinical and ultrasound (US) characteristics of children with JPsA, and to assess their impact using a composite quality of life index, the PsAID (Psoriasis Arthritis Impact of Disease).

Methods: A multicentre cross-sectional observational study recruited consecutive JPsA patients, from January-2020 to May-2022. Inclusion criteria: 1/ age at onset ≤ 16 years, 2/ diagnosis by the prescribing physician based on one of the 2 JPsA diagnostic classification systems (ILAR or Vancouver). All were assessed clinically and US (independently) and completed two questionnaires: PsAID (Psoriasis Arthritis Impact of Disease) and CHAQ, to measure physical disability.

Results: The 48 children included (mean age at inclusion 11±4 years), 71% girls, 67% had oligoarthritis and 80% psoriasis in a first or second-degree relative. Mosty arthritis started before the psoriasis. The median time lag between the diagnosis and the onset of specific musculoskeletal manifestations was 1 year; interquartile range 0.5-2. ANA and HLAB27 were present in 19 (40%) and 5 (10%) of the children, respectively. A history of axial inflammatory symptoms was present in 3 (6%) patients, and unilateral sacroiliitis was confirmed by MRI in only one patient. Psoriasis and dactylitis were the most frequent manifestations identified (≥50%), while uveitis was less common (12%). Twenty-eight (87%) patients used methotrexate, 21 used anti-TNF agents and 14 needed corticosteroid infiltration. The population showed low clinical activity in the DAPSA composite activity index (md 3.5; range 0-25). Similarly, US showed a low number of affected joints but US was slightly superior to clinical examination, while US was clearly superior to detect enthesitis and dactylitis, particularly tendons of the fingers. The PsAID index (median 0.4; range 0-9.2) showed low correlation with CHAQ (r=0.3) and high with DAPSA (r=0.7); however, the correlation between PsAID and total joint count was low for both clinical and US assessment (r=0.4). The correlation between PsAID and total joint count was moderate for clinical (r=0.5) and low for US (r=0.4). Children with the presence of enthesitis and clinical dactylitis had a higher mean PsAID score than those without (dactylitis: p=0.002, and enthesitis: p<0.001).

Conclusion: The study supports the existence of an atypical pattern of late-onset JPsA characterised by a predominance of girls with peripheral involvement and little uveal involvement. Based on our results, dactylitis and enthesitis have a greater impact on the child’s quality of life than joint involvement per se. Studies with a larger sample size and/or disease activity are needed to confirm these findings.

Background: Dermatomyositis is an autoimmune disease that can present in children, adolescents (juvenile dermatomyositis JDM), and adults (adult dermatomyositis AD). The pathological hallmarks of DM are similar between JDM and AD, including skin rashes and proximal muscle weakness, however, the manifestations and prevalence of associated autoantibodies vary, depending on age of onset. Myositis specific antibodies (MSA) have been used as a prognostic tool to aid management of disease in both adult DM and JDM. In JDM, anti-TIF1γ is highly prevalent, and is the most common MSA in Caucasian patients. This MSA is associated with malignancy in adult DM [1]. We have previously shown that adult DM patients with cancer have significantly higher frequency and serological level of anti-TIF1γ IgG2 isotype [2]. However, there are limited data on anti-TIF1γ isotypes in JDM.

Objectives: To investigate anti-TIF1γ isotypes as a potential biomarker for clinical presentations in JDM patients.

Methods: We conducted a retrospective study to evaluate clinical features of anti-TIF1γ positive patients. This cohort includes 20 patients from French health-care centres and 11 patients from the UK healthcare centres. Serum samples were first tested for anti-TIF1γ using either in-house or immunoprecipitation. Within those with anti-TIF1γ antibodies, anti-TIF1γ isotypes including IgG1, IgG2, IgG3 and IgG4 were measured using a multiplex ALBIA assay developed by Aussy et al. (2019) [2].
Results: Out of 31 children, 54.8% (17) were Caucasian, followed by North Afri-
can (25.8%, n=7), and other minority groups. Male to female ratio was 14:17. All 31
patients had IgG1 isotype, and 14 had more than one isotype of anti-TIF1γ
antibody. Although IgG2 isotype of anti-TIF1γ has been shown to be a biomarker
for malignancy and mortality in adult DM, there were no reports of malignancy
in this paediatric cohort. In our JDM cohort, the rate of IgG2-positive was 25.8%
(8/31) which is lower than observed in adult DM of 55% [2]. Two cases in this
JDM cohort did: both were positive for IgG4, but both were negative for IgG2.
Interestingly, there were significant differences regarding IgG2 isotype of anti-
TIF1γ: antibody presence between ethnic groups (p = 0.008). Specifically,
although Caucasian patients were the majority, only 1 out of 8 IgG2 positive
cases was Caucasian. Between Caucasian and non-Caucasian groups, signif-
icant differences were observed when comparing the groups’ means (p = 0.02)
and variances (p = 0.01). Notably, 4/8 IgG2 positive were found in North African
population, making up 44.4% (4/9) of this ethnic group. We also showed that
anti-TIF1γ isotypes can change over time. Specifically, of 6 patients tested for
anti-TIF1γ isotypes at a second time point, 4 cases had changes in serological
levels of anti-TIF1γ isotypes: 2 had lower titer levels, 1 lost positive status for
IgG2 and IgG3, and 1 gained positive status for IgG4.
Conclusion: Our study indicates that there may be a relationship between anti-
TIF1γ IgG2 isotype and ethnicity. Importantly, although IgG2 is a biomarker
for cancer in adult DM, it is not associated with severe onset or manifestations
such as mortality or malignancy in JDM patients.

POS0754 PROTEASOME ACTIVITY TEST AS A POTENTIAL
CLINICAL TOOL FOR THE DIAGNOSIS OF CHRONIC
ATYPICAL NEUTROPHILIC DERMATOSIS WITH
LIPODYSTROPHY AND ELEVATED TEMPERATURE
(CANDLE) SYNDROME AND RELATED PROTEASOME
DISORDERS

Keywords: Diagnostic tests, Rare/orphan diseases, Genetics/epigenetics

Y. Levinsky1, O. Scheuermann2, R. Tal1, G. Amariyo1, L. Harel1, 1Schneider

Israel; 2Schneider Children’s Medical Center of Israel, Pediatrics B, Petah Tikva,
Israel

Background: Chronic atypical neutrophilic dermatosis with lipodystrophy and ele-
vated temperature (CANDLE) syndrome, is an interferonopathy caused by pro-
tosomal dysfunction. Clinical characteristics include early onset inflammation, nodular
rashes, hepatosplenomegaly, myositis, panarthritis, lipodystrophy and basal ganglion
calcifications. CANDLE and associated syndromes are grouped into the proteas-
osome-associated autoinflammatory syndromes (PRAAS). Our patient presented at age
of 3 months with features strongly suggestive of PRAAS. Genetic testing revealed a
novel proteasome variant classified as a variant of unknown significance (VUS).

Objectives: Functional testing of the proteasome was undertaken in order to
support the suspicion of PRAAS. Our aims are to describe the potential role of
this test for aiding in the diagnosis of PRAAS.

Methods: First, interferon signature was obtained and whole exome sequencing
was analyzed for the patient and her parents. Nest, samples of whole blood were
taken from the patient, parents and 3 healthy controls. PBMC were lysed using
activity preserving methods (active extraction). Samples were normalized using

BCA enzymatic assay. Activity of the proteasomal subunits was measured using
peptides specific to different subunits (caspase, chymotrypsin and trypsin activity).

Results: Interferon signature was abnormally high, suggestive of an interfer-
onopathy. Whole exome sequencing revealed a novel heterozygous variant in a
PSMB4, the gene that encodes for β1, a structural non-catalytic subunit of the
proteasome classified as a variant of unknown significance (VUS). A pilot analy-
sis of proteasome activity showed a 50% reduction in the catalytic activity of pro-
teasome subunit β1, indicating severe impairment of proteasomal activity, with
compensatory hyper-activation of the immunoproteasome subunit β2 (Figure 1).

Conclusion: Proteasomal activity testing may serve as a useful tool for the diag-
nosis of CANDLE/PRAAS in suspicious cases. Since JAK inhibitors may provide
an adequate therapeutic response, it is of great importance to timely diagnose
this disease in cases where the genetic results are equivocal.

Scienze Mediche Translazionali, Napoli, Italy; 4Università degli Studi di Napoli Federico II, Dipartimento di
Scienze Mediche Translazionali, Napoli, Italy

Background: In recent years, increasing attention has been paid to the devel-
opment of parent- and child-centered composite disease activity scores for
the assessment of health status of children with rheumatic diseases.

Results: Parent- and child-centered composite disease activity scores for

**Objectives:** This study is aimed to develop and test an entirely parent-centered composite disease activity score for JDM, named parent Juvenile Dermatomyositis Activity Index (parJDMAI). Two versions of the score, which differed in the fourth item included, were evaluated.

**Methods:** Both parJDMAI1 and parJDMAI2 include the following items: 1) parent assessment of skin disease activity (Parent Skin Scale) on a 0-5 scale, by giving 1 point to the presence of each of the following: i) rash on eyelids, ii) nose/checks, iii) knuckles, iv) trunk/arms, v) skin ulcers; 2) parent assessment of muscle disease activity (Parent Muscle Scale) on a 0-5 scale, by giving 1 point to the presence of each of the following: i) fatigue/discomfort, ii) muscle weakness, iii) muscle pain, iv) voice change; v) difficulty swallowing; 3) parent assessment of child's fatigue on a 0-10 visual analog scale (VAS) (0 = no fatigue; 10 = maximum fatigue). As fourth item, the parJDMAI1 includes the parent global assessment of child's wellbeing, measured on a 0-10 VAS (0 = best; 10 = worst), whereas the parJDMAI2 includes the parent global assessment of disease activity, measured on a 0-10 VAS (0 = no activity; 10 = maximum activity).

To give the four components of the tools the same weight, the scores of the Parent Skin and Muscle Scales were doubled. Thus, the total score of both instruments ranges from 0 to 40. Initial validation was conducted on a monocentric sample of 213 patients followed in standard clinical care and evaluated prospectively (number of visits = 577), and on a monocentric sample including 50 patients, all assessed at baseline and 32 also assessed after a median of 3.9 months (number of visits = 82). Validation analyses included calculation of the correlations between individual parJDMAI1 items and physician-centered JDM outcome measures, and between the total score of parJDMAI1 and parJDMAI2 with that of the global composite disease activity scores for JDM named JDMAI1 and JDMAI2. Because both JDMAI1 and JDMAI2 include the parent global assessment of child’s wellbeing, which is also part of parJDMAI1, we also tested the correlations of parJDMAI1 with reduced versions of JDMAI1 and JDMAI2, that included only the 3 physician-centered items. Spearman correlations were defined as low, moderate or high when $r_S$ was < 0.4, ≥ 0.4 and ≤ 0.7, or > 0.7, respectively.

**Results:** Correlations between individual components of parJDMAI1 and parJDMAI2 and physician-centered JDM outcome measures were low-to-moderate in the monocentric sample, but moderate in the monocentric sample. Likewise, correlations between the scores of parJDMAI1 and parJDMAI2 and that of original and reduced versions of JDMAI1 and JDMAI2 were strong in the monocentric sample, but moderate in the multicentric sample.

**Conclusion:** The new parent-centered composite disease activity scores revealed satisfactory measurement properties. That correlations with physician-centered outcome measures and original and reduced JDMAI versions were higher in the monocentric sample than in the multicentric cohort indicates that the proposed tools should be further tested in different clinical and cultural environments before their widespread use can be recommended.

**Background:** Evidence about the effectiveness of the tumor necrosis factor inhibitor adalimumab (ADA) in pediatric patients with non-infectious intermediate uveitis/pars planitis, posterior uveitis, and panuveitis is still limited.

**Objectives:** Aim of this study is to investigate the therapeutic role of ADA in a cohort of pediatric patients with non-ante unilateral uveitis.

**Methods:** This is an international multicenter study based on real-life data from pediatric patients treated with ADA due to non-ante unilateral uveitis. Data were drawn from the retrospective branch of the Autoinflammatory Disease Alliance (AIDA) registry dedicated to uveitis.

**Results:** 21 patients (36 affected eyes) were enrolled. Eleven patients (19 affected eyes) did not experience further ocular inflammation after ADA introduction; 10 cases (17 affected eyes) showed a partial response with reduced frequency of relapses (3 cases), reduced severity of relapses (3 cases) or reduced frequency and severity of relapses (4 cases). The number of ocular flares dropped from 3.91 to 1.1 events/patient/year after ADA introduction ($p=0.0009$). Macular edema and retinal vasculitis were respectively observed in 18 eyes and 20 eyes at the start of ADA and in 4 eyes and 2 eyes at the last assessment. The mean daily glucocorticoid dosage significantly decreased at the last assessment ($p=0.005$). As observed in Table 1, intermediate uveitis/pars planitis ($p=0.01$) and posterior uveitis ($p=0.03$) were more frequent among patients with full response to ADA; panuveitis was significantly more frequent among patients continuing to experience uveitic flares ($p=0.001$). Regarding the safety profile, a case of generalized adenopathy was observed.

**Conclusion:** ADA had a role in all pediatric patients with non-ante unilateral uveitis with a significant glucocorticoid sparing effect. Panuveitis seems to be more frequent among patients continuing to experience uveitic flares.
Table 1. Baseline features of patients showing a full control of ocular relapses (group 1) and those experiencing ocular relapses despite the improvement in the frequency and/or the severity of ocular flares. **Abbreviations: IBD: inflammatory bowel disease; IQR, interquartile range JIA: juvenile idiopathic arthritis; VKH: Vogt-Koyanagi-Harada syndrome; CS: corticosteroids.**

**UVEITIS AS PREDICTORS OF RELAPSE AFTER ANTI-TNF TREATMENT WITHDRAWAL IN JUVENILE IDIOPATHIC ARTHRITIS: AN ITALIAN MULTICENTER EXPERIENCE**

**Keywords:** bDMARD, Inflammatory arthritides, Prognostic factors

L. Macconi, M. Trevisan, V. Accardo, I. Pagnini, F. La Torre, E. Marrani, M. Cattalin, M. V. Mastrolia, A. Taddio, G. Simonetti, M. Meyer Children’s Hospital IRCCS, Rheumatology Unit, Florence, Italy; University of Florence, NeuroFARBA Department, Firenze, Italy; Institute of Maternal and Child Health, IRCCS Burlo Garofolo, Pediatric Department, Trieste, Italy; University of Florence, School of Human Health Science, Florence, Italy; Ospedale G. Giovanni XXIII; Azienda Ospedaliero Universitaria Consorziale Policlinico, Pediatric Rheumatology Center, Bari, Italy; ASST Spedali Civili di Brescia, University of Brescia, Pediatrics Clinic, Brescia, Italy

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. TNF inhibitors (TNFi) have dramatically changed the prognosis of this disease, but once achieved disease remission, it is not clear how and when to stop therapy. Our purpose is to describe a multicenter cohort of JIA patients treated with the first course of Adalimumab and Etanercept in whom therapy was discontinued to persistent remission and identify predictors of relapse.

**Methods:** In a multicentric Italian retrospective study (Florence, Brescia, Trieste and Bari), patients with oligoarticular or polyarticular JIA were enrolled if they stopped therapy for persistent remission after the first course of Adalimumab and Etanercept. We collected demographic, clinical and laboratory data at onset and during biologic treatment.

**Results:** 136 patients were enrolled (102 female, median age at onset 3 years (R1-15)), of whom 76 (55.9%) had oligoarticular JIA and 55 (40.4%) had uveitis. ANA positivity was found in 99/72.8% (Table 1). TNFi were started at median age of 6 years (R1-16), with a median time intercourse between TNFi initiation and diagnosis of 12 months (R0.5-96). Seventy-nine (59.3%) were treated with ADA, and 57 (40.7%) with ETA. Remission was achieved after a median time of 4 months (R1-32) and TNFi was discontinued after a median time of 30 months (R 6-90). TNFi were stopped in the 76.5% increasing the interval of administration, 18.4% reducing the dose, and 16.9% abrupt discontinuation. 106 patients (79.4%) relapsed after a median time of 6 months (R 0.5-96) for arthritis in 71 (66.9%), uveitis in 19 (17.9%), both in 18 (16.9%). Patients who relapsed were more frequently female (χ² 5.9 p < 0.014), younger at onset (median 3 vs 7 p < 0.001) and when TNFi was started (6 vs 9 m, p = 0.005) (Table 1). Patients who not-relapse suspended TNFi more frequently lengthening intervals of administration (χ² 5.2 p = 0.015). Relapse free survival curve after withdrawal evaluated with Kaplan-Meier showed that patients with uveitis had a significantly earlier relapse (Log Rank χ² = 12.8 p < 0.001).

**Conclusion:** Although this is a retrospective study, we highlighted that early age at onset and at TNFi initiation, presence of uveitis and a long time to start biologics seem to be significantly more frequent in subjects who relapse, while stop therapy lengthening the interval of drug administration might be protective.

K. Shehabden1, Y. Levinsky1, R. Tal2, S. Kagan3, T. Zaabi4, L. Harel1, G. Amarillo1,2, Tel Aviv University, Schmidt School of Medicine, Tel Aviv-Yafo, Israel; Schneider-Children's Medical Center, Pediatric Rheumatology Unit, Petah Tiqwa, Israel; Schneider-Children's Medical Center, Pediatric Department B, Petah Tiqwa, Israel

**Background:** Familial Mediterranean fever (FMF) is the most common autoinflammatory disease.

**REFERENCES: NIL.**

*DOI: 10.1136/annrheumdis-2023-eular-6073*
Without therapy, it may lead to the development of secondary amyloidosis. Treatment with colchicine leads to long-term remission in ~70% of patients. 5% are resistant to colchicine therapy (crFMF) and may be treated with monthly dose of canakinumab (anti IL-1beta). However, colchicine, the only drug proved to prevent secondary amyloidosis. Canakinumab is immunosuppressive as well as expensive.

**Objectives:** To compare on demand canakinumab (COD) dosage policy vs. canakinumab fixed frequency (CFF) policy.

**Methods:** Data from 3 pediatric rheumatology centers (Schneider, Sheba, Ram-bam) were collected regarding crFMF patients treated with canakinumab. crFMF patients treated according to the COD policy were given 1 dose of sc-cana-nimumb injection 4mg/kg (max 150mg), with subsequent doses administered only after an additional attack. CFF patients were given fixed 4 weekly doses according to the manufacturer instructions.

**Results:** Overall, 51 crFMF (25 COD vs. 26 FCC) with mean follow-up of 22.6 months were included. There were no significant demographic, clinical or genetic differences between the groups. The COD group received significantly lower cumulative canakinumab dosage during the follow-up period (15.6±8.95mg/kg vs.32.5±8.05mg/kg;P<0.001). There were no differences between groups in mean FMF attacks nor in mean CRP levels at the end of follow-up period. None of the COD group necessitated higher colchicine doses (0.05x±0.01mg/kg vs. 0.03x±0.01mg/kg;P>0.001).

**Conclusion:** COD treatment in crFMF patients is as effective as CFF treatment. Using COD can reduce drug expenses and decrease immunosuppression exposure without negatively influencing the disease control.

**Background:** Tocilizumab (TCZ) was approved for systemic juvenile idiopathic arthritis (sJIA) as an intravenous formulation in 2008 after its effectiveness and safety were shown in a world-leading clinical trial performed in Japan in 2002–2008.

**Objectives:** This study aimed to understand the long-term prognosis of patients participating in phases II (Study MRA011 JP), III (Study MRA316 JP), and III/IV (Study MRA324 JP). There were 148 participants in the clinical trial.

**Methods:** Information on eligible patients was obtained from 12 cooperating institutions approved by the Ethics Committee of Tokyo Women's Medical University and each institution. Patients who could be followed-up were referred and transferred to other hospitals or departments. The following long-term prognostic factors were assessed: treatment status, including the continuation of TCZ administration during the long-term course of sJIA, disease status (remission rate and clinical phenotype), complications, social adjustment, employment status, and health-related quality of life (HRQOL) scale.

**Results:** Results were collected for 132 cases from ten centers by December 2022. We examined 125 patients (58 males and 67 females) whose medical records were still available and whose final diagnosis was sJIA. The age of the study participants was 18.6 years at the time of the study, 4.3 years at onset, 8.8 years at first TCZ administration, 3.8 years from onset to the first TCZ administration, and 9.1 years from TCZ initiation (all median values). Of the 125 patients, 28 (22.4%) were in medication-free remission and were either under or completely followed-up. Of the 93 patients (74.4%) who continued therapy, 10 (10.8%) were moved to a subcutaneous version of TCZ, which is not yet licensed for the treatment of sJIA in Japan. Ten patients (10.8%) were switched to canakinumab (CAN) due to TCZ primary failure (5 patients), secondary failure (2 patients), side effects (1 patient developed anaphylaxis), or other reasons. Of the 124 patients, 44 (35.5%) changed from acute febrile sJIA to chronic arthritic sJIA, in which chronic arthritis was the primary pathology without systemic inflammation, and 17 of these patients still had active arthritis at the last observation. Corticosteroids were prescribed in 54 of 93 patients (58.1%). Except in one case of sudden death, the causes of death in the four cases that resulted in fatalities were macrophage activation syndrome, sJIA-related interstitial pneumonia, and disseminated aspergillosis. The most commonly observed complications were osteoporosis in 68 (54.4%), infections requiring hospitalization in 20 (25.0%), hypertension in 25 (20.0%). The EQ-SD-SL score was 0.91 (mean). The final mean height of the patients whose information was available after the age of 18 years (n = 62) was 157.7 cm for males (mean 170.4 cm in Japanese) and 144.3 cm for females (mean 156.7 cm in Japanese), showing a significant short stature. The college/university enrollment rate was as high as 88.4% (Japanese statistical data: 58.9%), and all but five students were employed.

**Conclusion:** Seventy-four percent of the patients continued treatment with TCZ or CAN, and conversion to chronic arthritic sJIA was observed in 35.5%. Despite issues such as growth retardation, social adjustment and employment status were promising, suggesting a contribution of sJIA management.

**REFERENCE:**

Juvenile idiopathic arthritis (JIA) is the most common systemic disease causing uveitis in childhood and adolescence. JIA-associated uveitis has an estimated prevalence ranging from 11% to 30%, being higher in patients with oligoarticular JIA (oJIA), especially in HLA-B27 positive patients. JIA can be classified according to the criteria of the International League of Associations for Rheumatology (ILAR). The most frequent type in the 2 groups (and the only one in JIA patients) is the spondyloarthritis-related arthritis (SpA-ERA), especially in HLA-B27 positive patients.

**Objectives:**

- To compare the demographic and laboratory characteristics and clinical outcomes of uveitis in oJIA and SpA-ERA patients.
- To evaluate the associations between power Doppler (PD) findings and b-mode synovitis in patients with JIA using a standardized scanning protocol and scoring system.
- To examine associations between PD findings and b-synovitis.

**Methods:**

- A retrospective single-center study of patients with oJIA and SpA-ERA followed in a tertiary hospital was conducted. ILAR classification criteria were fulfilled and sociodemographic, clinical, and treatment data were collected from medical records. Age at onset of uveitis, disease duration, acute-phase reactant proteins at diagnosis, and characteristics of uveitis including complications, medical and surgical treatments were collected. Statistical analysis was performed with independent samples t-test, Mann-Whitney U test, chi-square test and Fisher's exact test. Significance level was set at a p-value of 0.05.

**Results:**

- A total of 75 patients with oJIA (57 females, 76.0%) and 23 patients with SpA-ERA (6 females, 26.1%) were included. Thirty-five of 98 patients (35.7%) had uveitis at diagnosis, and the age at diagnosis of JIA was lower in oJIA patients (p=0.006). ANA positivity was significantly higher in the SpA-ERA patients (0.012) and HLA-B27 positivity was significantly higher in the SpA-ERA patients with uveitis group (0.002). No significant differences were found in the ESR and CRP values at diagnosis and characteristics depending on the JIA subtype, which leads us to think that possibly different immunologic mechanisms may be involved.

**Conclusion:**

In our study, uveitis manifested in 35.7% of the included patients with oJIA and SpA-ERA. Uveitis in oJIA patients had poorer outcomes, such as complications and eye surgery requirement. Uveitis seems to have different characteristics depending on the JIA subtype, which leads us to think that possibly different immunologic mechanisms may be involved.

Results: We evaluated bFGF level for children with JIA (min: 417715.6 pg/ml; max: 7089.28 pg/ml; mean: 1801.25 pg/ml). The average level of bFGF significantly increased in children with age of JIA onset from 15 to 18 years versus age of JIA onset up to 3 years (p = 0.009) and 11–14 years (p = 0.014). It was also found higher bFGF in patients with an average activity according JADAS-27 pattern compared to a low one (p = 0.0005). Activity according JADAS-27 pattern, levels of ESR, CIC, and ASL-O was associated with bFGF level. Mostly bFGF was correlated with ASL-O (among: boys: r=0.45, patients with oligoarthritis r=0.49, moderate disease activity according to JADAS-27 r=0.58, MTX treatment r=0.38, dose of MTX, 12.5-15mg/m2/week: r=0.50 p < 0.05), with CIC (among: patients with polyarthritis r=0.37, low disease activity according to JADAS-27 r=0.34, dose of MTX, less 10mg/m2/week: r=0.96 p < 0.05), with ESR (among: girls r=0.37, patients with polyarthritis r=0.38, p < 0.05).

Conclusion: Children with JIA had a higher bFGF level in patients with JIA onset after 15 years old and moderate disease activity; CIC and ESR were corresponded with high bFGF level. Presence of additional streptococcal infection impact on fibrosis formation in children with JIA.

CIRCULATING SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR (SUPAR) ASSOCIATES WITH JOINT DESTRUCTION IN JUVENILE IDIOPATHIC ARTHRITIS: A CASE-CONTROL STUDY WITH LONGITUDINAL FOLLOW-UP

Keywords: Inflammatory arthritides, Prognostic factors, Biomarkers

P. Lewander1, C. Dahle2, L. Wirstram3, J. Wetterström3, C. Silowal3

1Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping, Sweden; 2Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Infectious Immunology, Linköping, Sweden; 3Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping, Sweden

Background: Reliable biomarkers in the early stages of juvenile idiopathic arthritis (JIA) are scarce. The disease heterogeneity makes it clinically challenging to predict the risk of future permanent joint damage. Some indicators of poor outcome have been identified, e.g. rheumatoid factor (RF) and antibodies against cyclic citrullinated peptides (anti-CCP), but additional biomarkers with predictive potential are warranted in order to start optimal treatment before tissue damage occurs. The soluble urokinase plasminogen activator receptor (suPAR) has been reported as an easily measurable biomarker for prognosis and severity in several diseases, including adult rheumatoid arthritis, systemic lupus erythematosus and other inflammatory conditions [1]. However, to our knowledge, suPAR has never been studied in JIA.

Objectives: We asked whether suPAR could predict a more severe course with erosions in JIA.

Methods: 51 well-characterized patients with recent-onset or established JIA and 50 age- and sex-matched healthy control subjects were included. Blood sampling was performed at inclusion and sera were stored for later analysis of suPAR by suPARnostic ELISA (Virogates, Birkerød, Denmark). The patients were carefully followed over 3 years and erythrocyte sedimentation rate, C-reactive protein, RF, anti-CCP and antinuclear antibodies were analyzed as part of clinical routine. Signs of joint destructions were evaluated by radiographic investigation of affected joints. Data was evaluated using non-parametrical statistical methods.

Results: Overall, the levels of suPAR did not differ significantly between JIA and controls (Figure 1). Still, the subgroup of subjects with polyarticular disease showed higher suPAR than the controls (p<0.013). In addition, elevated suPAR levels were associated with joint erosions (p=0.022). In two individuals with erosions, high levels of suPAR were found despite absence of RF and anti-CCP.

Conclusion: We present new data on the biomarker suPAR in JIA. The results indicate that, in addition to RF and anti-CCP, analysis of suPAR could be of additional value in predicting the risk of joint erosions. Early analysis of suPAR could potentially guide treatment-decision-making in JIA, but our findings call for confirmation in larger cohorts.

SERUM BASIC FIBROBLAST GROWTH FACTOR IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Biomarkers, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

N. Shevchenko1,2, O. Pavlova1

1Department of Pediatrics, Kharkiv, Ukraine; 2Institute of Children and Adolescents Health Care of NAMS of Ukraine; 3Department of Rheumatology and Comorbid Conditions, Kharkiv, Ukraine

Background: Patients with rheumatic diseases are at high risk for poor outcomes in care when severe fibrosis occurs, as a result of tissue damage caused by chronic phase of persistent inflammation. Only limited data also controversial results are available on the fibrosis predictors in patients with juvenile idiopathic arthritis (JIA) on long-term methotrexate (MTX) treatment [1,2].

Objectives: To evaluate serum levels of basic fibroblast growth factor (bFGF) in children with juvenile idiopathic arthritis treated with methotrexate.

Methods: 104 patients with polyarthritis (50.96%) and oligoarthritis (40.38%), variants JIA (mean age 13.3 years, 59.62% female, mean age of JIA onset 7.2 years, mean disease duration 5.06 years) were included in this 4-years prospective study. In 104 children with JIA were treated with MTX 75.96% (vs. 24.04% not treated with MTX, 16.35% were prescribed MTX, but they didn't receive any dose yet on investigation day). Among patients treated with MTX 4.81% had dose less than 10 mg/m2/week, 32.69% 10-12.5 mg/m2/week, 31.73% 12.6-15 mg/m2/week, 6.73% over 15 mg/m2/week. bFGF levels were determined by bFGF ELISA kits (Elabscience, USA). Serum levels of bFGF were analyzed depending on patients' gender, age, and age of JIA onset, its variant, duration, activity, and presence of MTX in treatment and its dose. Levels of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), circulating immune complex (CIC) and antistreptolysin-O (ASLO) were analyzed in this study.

Conclusions: In this post hoc analysis, pts with JIA began with near normal height Z-scores and tocilizumab had no negative impact on height Z-scores after 92 weeks. Growth velocity was within the normal range for age up to Week 44. Catch-up growth was not observed, possibly due to the study duration being too short and the BL height Z-scores being near normal.

DOI: 10.1136/annrheumdis-2023-eular.2707
Background: The transition from pediatric to adult health care often challenging for young adults with rheumatic diseases. During the transition period, disruptions, diagnostic changes, and treatment differences may occur. The successful transition of the young adult patient to adult care is an important milestone in pediatric rheumatology. Objectives: In this study, we aimed to examine the diagnosis and treatment changes of transition patients and the characteristics of the transition period in our clinic.

Methods: This was retrospective observational study was carried out in Dokuz Eylul University Pediatric and Adult Rheumatology Department. Patients who followed-up in Pediatric Rheumatology Department transferred to the Adult Rheumatology Department within the last ten years and continued to visit at least once a year were included in this study. If the transition period of the patients was less than three months, it was defined as early transition. Demographic features and educational status, parental divorce, diagnostic changes, and diagnosis-specific treatment changes were recorded.

Results: In total, 962 transitional patients scanned and 210 of them met follow-up criteria. Of the patients, 117 (55.7%) were female, with a median age of 24 (IQR, 21 – 28). Most of patients followed-up juvenile rheumatoid arthritis (JIA) (n=79, 37.6%) and familial Mediterranean fever (FMF) (n=79, 37.6%). Median duration of pediatric rheumatology follow-up was 52 months (IQR, 23 – 87) and 47 (22.%) patients have been treated with biological therapies, with a different mechanism of action. The transition from pediatric to adult health care often challenging for young adults with rheumatic diseases. During the transition period, disruptions, diagnostic changes, and treatment differences may occur. The successful transition of the young adult patient to adult care is an important milestone in pediatric rheumatology.

Conclusion: We found that most of the patients who were followed-up in pediatric rheumatology in our center did not transition to the adult rheumatology in the same center. Less than half (46.7%) of the patients started to be followed up in adult rheumatology within the first 3 months. Treatment with biological agents was found associated with early transition. Since patients who were treated with biological agent needed for a doctor’s visit to reach the treatment was considered the main reason for these patients’ early transition. We found that Bachelor’s degree or higher educational status was associated with late transition. Patients often move to other cities for university, may be the reason of the late transition. Transition time did not associate with the rheumatologic diseases except FMF. The reason for the late transition in FMF can be explained by the admission to the hospital with frequent attacks. Transition may be challenging in pediatric rheumatology. The ideal transition to adult rheumatological care should start in the early adolescence period of the patients, planned transition visits may increase the rate of follow-up.

CHARACTERISTICS OF PATIENTS WITH DIFFICULT-TO-TREAT JUVENILE IDIOPATHIC ARTHRITIS AT ADULTHOOD IN FRANCE

Keywords: bDMARD, Descriptive studies, Prognostic factors

S. Hecouet2, M. Thomas3, A. Combier1, J. Wipf2, G. Touanga1, P. Quartier2, J. Avouac1, Y. Allanore1.1Cochin Hospital, Rheumatology, Paris, France, 2Necker Hospital, Immuno-Hématologie et Rhumatologie pédiatriques, Paris, France

Background: An effort to unify the variability of juvenile idiopathic arthritis (JIA) phenotypes was initiated in 1994 resulting in the current categories of systemic JIA, oligoarthritis (persistent or extended), rheumatoid factor (RF)-negative polyarthritis, RF-positive polyarthritis, psoriatic JIA, and enthesitis related arthritis. Recently, EULAR has proposed a definition of difficult-to-treat rheumatoid arthritis (D2TRA) and the concept was later extended to spondyloarthritis and psoriatic arthritis.

Objectives: The aim of this study was to describe difficult-to-treat JIA (D2TJIA) at adulthood based on the EULAR definition of D2TRA.

Methods: We stratified consecutive JIA patients treated at Cochín Hospital in Paris into two groups, a D2TJIA group and a non-D2TJIA group. Based on EULAR definition of D2TRA, we defined D2TJIA as JIAs failing at least two targeted therapies, with a different mechanism of action.

Results: In total, we identified 18 D2TJIA patients (mean age 27.4 years, 67% female) and 88 non-D2TJIA patients (mean age 29.1 years, 70% female). Regarding JIA subtypes, we observed significantly more systemic JIA in the D2T group (39% vs 14%, p=0.02). D2TJIA patients were more likely to have erosions on X-rays (82% vs. 55%, p=0.038). Regarding auto-antibodies, positive anti-CCP

Conclusion: Our work is the first to describe D2TJIA in France. It seemed interesting to raise the question of whether D2T JIA exists, and if so, what could be its potential definition and management. This may serve as a hypothesis and a basis for future reflections. As observed in rheumatoid arthritis, we report significant differences in circulating biomarkers between poly- and oligoarticular disease.

Methods: 60 patients with JIA (50 girls) age between 10–16 years were consecutively recruited at Oslo University Hospital and 60 age-and sex-matched controls were randomly drawn from the National Registry. The JIA group included 30 patients with persistent oligoarticular JIA (oligo disease) and 30 patients with extended oligoarticular or polyarticular disease RF +/- (poly disease). VAT (g) was estimated by dual-energy x-ray absorptiometry. Lipid profile, CRP and adipo-, cytokines (by ELISA) were analyzed. Differences between groups were tested with parametric or non-parametric analyses as appropriate and associations with univariate and multiple linear regression analyses.
