No statistical difference was observed for age, sex ratio, BMI, ACPA, or RF except for smoking (27.3% vs 15.6%) between patients with unacceptable pain or not. A strong correlation was observed between the decrease of VAS pain, DAS28-CRP and HAQ at all-time points. Among the patients with an unacceptable pain at 6 months, HAQ BL score was statistically higher (1.30 +/- 0.69 vs 1.15 +/- 0.67), while the BL DAS28-CRP scores were similar (4.66 +/- 1.41 vs 4.67 +/- 1.24). We identified also 20 patients with unacceptable pain throughout the 5 years follow-up, BL DAS28-CRP and HAQ values were statistically increased (5.4 +/- 1.1 vs 4.7 +/- 1.4 and 1.4 +/- 0.86 vs 1.2 +/- 0.62). By contrast, 31 patients reached a complete response defined by a VAS pain <4 + DAS28-CRP<3.2 + HAQ= 0.5 throughout the 5 years follow up). Baseline VAS pain, DAS28-CRP and the HAQ scores assessed at diagnosis were statistically lower in this group (38.9 +/- 28.4 vs 61.9 +/- 25.7, 4.3 +/- 1.1 vs 4.8 +/- 1.4 and 0.86 +/- 0.60 vs 1.2 +/- 0.71). All patients were treated according the standard of care, mainly with Methotrexate.

Conclusion: We demonstrate that control of pain is achieved in a majority of ERA patient in our cohort. Decrease of pain was correlated with decrease of the disease activity score, meaning that the positive effect is mainly related to inflammation in ERA.

Figure 2. Clinical response: VASp, DAS28-CRP and HAQ throughout the follow-up

Methods: In this monocentric five-armed study (ethical approval under Institutional Review Board #065/20), four groups of each 20 patients with RA, PsA, axSpA or SSc, and one control group consisting of 20 healthy individuals were collected and a somatosensory profile using the standardized procedure of QST was created for each one of the 100 participants. QST included both small fiber mediated stimuli and large fiber mediated stimuli, via all categories shown in Figure 1. The vibration detection threshold where the detection of vibration is ranked on a scale from zero to eight, with '8' being normal perception of vibration, serves as an example for large fiber mediated stimuli. Additionally, standard questionnaires incorporating laboratory parameters, joint manifestations and pain condition were used to determine disease activities (BASDAI, PASDAS, CDAI and mRSS).

Results: A preliminary data analysis of all 100 study participants found occurrence of allodynia in 5% of patients with SSc, 15% of RA, 25% of PsA, and 15% of all axSpA patients, compared with 0% in the control group. Considering the vibration detection threshold, there was little difference between all disease groups, also in comparison to the control group: SSc (mean ± SD: 779 ± 0.34), RA (mean ± SD: 76.6 ± 0.4), PsA (mean ± SD: 77.6 ± 0.34) and AxSpA (mean ± SD: 76.9 ± 0.57) and control group (mean ± SD: 79.8 ± 0.16).

Conclusion: The analysis for allodynia occurrence indicates the presence of sensory gain towards small fiber mediated stimuli in all four disease groups studied. Until now, our vibration detection threshold studies do not suggest a loss or gain of sensory function for large fiber mediated stimuli. The full analysis completion is expected in March 2023.

Figure 3: Small fiber mediated stimuli and large fiber mediated stimuli
Background: Pes anserine bursitis is one of the causes of painful knee syndromes. It limits physical activity and impairs the quality of life of a patient. Osteoarthritis (OA) of the knee is common predisposing factors for pes anserine bursitis. It is treated with non-steroidal anti-inflammatory drugs (NSAIDs), physiotherapy, injections of local anesthetics, and corticosteroids. This study examines the efficacy of local corticosteroid injection, Platelet-rich plasma (PRP) injection, and extracorporeal shock wave therapy (ESWT) as different modalities to alleviate pain and improve function in patients with pes anserine bursitis.

Objectives: This study examines the efficacy of local corticosteroid injection, Platelet-rich plasma (PRP) injection, and extracorporeal shock wave therapy (ESWT) as different modalities to alleviate pain and improve function in patients with pes anserine bursitis.

Methods: This randomized comparative clinical trial was performed between July 2021 and June 2022 in the rheumatology and rehabilitation department at Al-Azhar University Hospitals in Egypt on 180 patients diagnosed with chronic pes anserine bursitis according to Larson and Baum criteria. The enrolled patients were divided into three groups, each including sixty patients. Group I received a local corticosteroid injection of 40mg of methylprednisolone acetate/1ml (n = 60); Group II received a PRP injection (n = 60); and in Group III, ESWT (n = 60) was used. The Visual Analog Scale (VAS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) symptom subscales occurred in all study arms, but lack of differentiation from placebo (PBO) was thought to be due to inclusion of participants not at risk of KOA progression. A subsequent post-hoc analysis identified a subgroup at risk (SAR) enriched for disease progression [5]. Clinically meaningful change in WOMAC Pain and Function has been defined as ≥10 points (0-100 scale) [6,7], with this degree of worsening pain predictive of structural progression and knee replacement in KOA cohorts [8-10]; this endpoint has not been applied to evaluate symptomatic progression in DMOAD studies to date.

Conclusion: An examination of Pes anserine bursitis is essential and shouldn’t be missed in knee OA patients complaining of pain. Our findings show that local corticosteroid injection is more effective than PRP injection and ESWT for pain relief.

POS1348 EFFECTS OF SPIRIFERMIN ON A NOVEL OUTCOME OF OSTEARTHRIS SYMPTOM PROGRESSION: POST-HOC ANALYSIS OF THE FORWARD RANDOMIZED TRIAL

Keywords: Outcome measures, Clinical trials, Osteoarthritis

P. G. Conaghan¹, N. Katz¹,2, D. Hunter²,4, A. Guermazi²,3, M. Hochberg², K. Somberg⁵, J. Clive⁶, M. Johnson⁷, N. Goel⁸,⁹, ⁱ⁰, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; ²Tufts University, Department of Anesthesiology & Perioperative Medicine, Boston, MA, United States of America; ³Einh Sof Innovation, Boston, MA, United States of America; ⁴Sydney Musculoskeletal Health, Kolling Institute, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia; ⁵Rheumatology Department, Royal North Shore Hospital, St Leonards, Australia; ⁶Boston University School of Medicine, Radiology, Boston, MA, United States of America; ⁷VA Boston Healthcare System, Radiology, Boston, MA, United States of America; ⁸School of Medicine, University of Maryland, Baltimore, MD, United States of America; ⁹BrilSpark Inc., Research and Development, New York City, NY, United States of America; ¹⁰Duke University School of Medicine, Department of Medicine, Division of Rheumatology, Durham, NC, United States of America

Background: People with knee osteoarthritis (OA) (KOA) desire therapies which delay disease progression [1] supporting the need for disease-modifying OA drugs (DMOADs). Spirifermin, truncated recombinant human fibroblast growth factor-18, promotes chondrocyte proliferation and extracellular matrix production [2], improves cartilage biomechanical properties [3], and in the Phase 2 FORWARD study [4], dose-dependently increased knee cartilage thickness. In FORWARD, improvement from baseline in the Western Ontario and McMaster Universities OA Index (WOMAC) symptom subscales occurred in all study arms, but lack of differentiation from placebo (PBO) was thought to be due to inclusion of participants not at risk of KOA progression. A subsequent post-hoc analysis identified a subgroup at risk (SAR) enriched for disease progression [5]. Clinically meaningful change in WOMAC Pain and Function has been defined as ≥10 points (0-100 scale) [6,7], with this degree of worsening pain predictive of structural progression and knee replacement in KOA cohorts [8-10]; this endpoint has not been applied to evaluate symptomatic progression in DMOAD studies to date.

Objectives: Evaluate the effect of spirifermin on symptomatic progression of KOA.

Methods: In FORWARD, participants were randomized 1:1:1:1:1 to intra-articular PBO or spirifermin 30 µg or 100 µg every 6 or 12 months (Q6M or Q12M) for 18 months. WOMAC was collected Q3M and MRI performed Q6M. In the current Kaplan-Meier analysis, time to symptomatic progression (i.e., first occurrence of worsening [increase] of WOMAC Pain of ≥10 points with no improvement [≤9 point decrease] in WOMAC Function) was evaluated over 3 years. The individual treatment arms of the intent-to-treat population (ITT) and the SAR (i.e., baseline WOMAC Pain 40-90, mJSW of 1.5-3.5 mm) were analyzed, as well as the spirifermin 100 µg groups combined for additional power. Time to symptomatic progression was also analyzed by changes in cartilage thickness (decrease or no change/increase) for the populations with an evaluable MRI, i.e., the modified (m) ITT and SAR.

Results: The FORWARD ITT and SAR spirifermin individual treatment arms (Table 1) showed dose-dependent benefits in the time to symptomatic progression compared to PBO, with clinically meaningful and statistically significant separation from PBO for the spirifermin 100 µg groups combined (logrank p-value ITT=0.0282, SAR=0.0099) (Figure 1); separation from PBO was more pronounced in Egypt compared to the ITT. The spirifermin 100 µg groups combined also demonstrated less symptomatic progression than PBO regardless of an increase or no change/decrease in cartilage thickness in the mSAR and mITT.

</table>

x 2=0.123; x 4 = Q6M; ITT=intent-to-treat; SAR=subgroup at risk.

Conclusion: These post hoc results support the hypothesis that spirifermin may prevent symptomatic progression of KOA, with benefits seen in both ITT and SAR populations for the spirifermin 100 µg groups combined. As differences between the spirifermin- and PBO-treated groups were detectable in a 3-year time frame, time to symptomatic progression of KOA could be a meaningful endpoint for an
investigational DMOAD trial. Symptomatic and structural benefits of sprifermin need to be confirmed in the planned Phase 2b SPRING study.

A biomarker approach to data-driven identification of endotypes in knee OA patients

Keywords: Biomarkers, Osteoarthritis

Z. Lisowska-Petersen1,2, M. Toft Hannani2, M. Karsdal2, C. Bagø Jensen2, A. C. Bay-Jensen3, C. Thudium4, 1Danish Technical University (DTU), Department of Applied Mathematics and Computer Science, Kgs. Lyngby, Denmark; 2Nordic Bioscience, Immunoscience, Herlev, Denmark; 3Nordic Bioscience, Data Science, Herlev, Denmark

Background: Osteoarthritis (OA) is a heterogeneous and multifactorial disease. Despite its high prevalence, the underlying mechanisms of disease are not fully understood, and treatment options are limited. One of the challenges in understanding OA is the lack of clear subgroups or “endotypes” within the disease, which could help to identify specific causes and point to more targeted treatments. Recent research has suggested that molecular biomarkers may be able to help identify different endotypes of OA. For example, certain biomarkers may be elevated in OA patients with inflammation, while others may be elevated in patients with more severe cartilage degeneration.

Objectives: The objective of the study was to identify endotypes of OA using soluble biomarkers reflecting tissue turnover by applying unsupervised machine learning approaches.

Methods: Biomarkers of cartilage remodeling (CTX-II, C2M, T2CM, PRO-C2), bone remodeling (N-MID, UCTX-I, SCTX-I), and tissue inflammation (CRPM, VICM, C1M, C3M) were measured at baseline in the phase III clinical trials SMC01 (n=1176) and SMC02 studies (n=1030), testing efficacy and safety of SMC01 (n=1176) and SMC02 studies (n=1030), testing efficacy and safety of SMC02 (n=1030), testing efficacy and safety of SMC01 (n=1176)

The results of uni and multivariate analysis of associated factors with SB are presented in Table 1. In summary, the findings of this study suggest that distinct biomarker-based endotypes exist in OA and highlight that multiple mechanistic avenues may lead to joint deterioration. By identifying these endotypes, we may enable the development of more targeted treatments that are tailored towards the underlying cause of OA in individual subgroups of patients.

**Conclusion:** In the literature few studies discuss factors associated with sedentary behavior in patients with knee osteoarthritis. Our study shows that level of pain and disability are not associated with SB, on the contrary, educational level, socioeconomic status and depressive disorder are the principal factors associated with SB. Our study highlights the importance of therapeutic education and assessment of mental health to improve the management of patients with knee osteoarthritis.

**A PHASE 2, 104-WEEK STUDY OF REPEAT LORECIVIVINT INJECTIONS VISUALIZING SAFETY, EFFICACY, AND BONE HEALTH UTILIZING QUANTITATIVE COMPUTED TOMOGRAPHY (QCT) IN KNEE OSTEOARTHRITIS (OA-06)**

**Keywords:** Osteoarthritis, Imaging, Clinical trials

Y. Yazici1, C. Swearingen2, H. Ghandehari2, J. Britt3, S. Kennedy2, J. Tambiah4, N. Lane1, 1NYU Grossman School of Medicine, Rheumatology, New York, United States of America; 2Biosplice Therapeutics, Biostatistics, San Diego, United States of America; 3Biosplice Therapeutics, Clinical development and external innovation, San Diego, United States of America; 4University of California Davis, Medicine and Rheumatology, Davis, United States of America

**Background:** Knee osteoarthritis (OA) is a common joint disorder associated with pain, disability, and damage. There is unmet need for safe and efficacious treatments for symptoms and structural modification. Lorcicrivivint (LOR), an intra-articular (IA) CLK/DYRK inhibitor thought to modulate Wnt and inflammatory pathways, is in development as a potential knee OA treatment.

**Objectives:** To assess the safety and tolerability of repeated 6-month dosing of LOR in a 104-week trial (OA-06, NCT03727022). Additionally, to characterize joint-articular bone health with quantitative computed tomography (QCT) and regional bone health via dual energy x-ray absorptiometry (DXA).

**Methods:** Participants with ACR-defined clinical and radiographic knee OA, aged 40-80, and Kelgren-Lawrence (KL) grades 2-3 were randomized 1:1 to receive IA injections of 2 mL 0.07 mg LOR or vehicle PBO at baseline, 24, 52, 72 weeks. The trial was conducted in two 52-week phases, part A (baseline to week 52) and part B (week 53 to week 104), with part A completers invited into part B. Safety was assessed by collection of adverse events (AEs), and serious AEs (SAEs). Bone safety assessments included QCT to assess target and non-target knee BMD, DXA to assess spine and hip BMD and bone/ cartilage biomarkers. Exploratory efficacy was assessed by patient-reported outcomes (PROs). For bone imaging endpoints, change from baseline was estimated using baseline-adjusted ANCOVA.

**Results:** 101 participants (mean age 60.9±9.1 years, BMI 28.6±3.7 kg/m2, female 59.4%, KL2 52.5%) were enrolled. 77 participants completed part A and 53 completed part B. AE rates were similar between PBO and LOR, and no SAEs were deemed treatment related. There were no clinical bone health signals (no fractures, accelerated OA, osteoporosis) observed for LOR. Observed target knee QCT BMDs were similar between LOR and PBO (Figure 1). Change from baseline in BMD at Week 104 was -7.08 (12.34) mg/cm3 in LOR and -2.95 (8.65) mg/cm2 in PBO, estimated difference -4.05 [95% CI -11.21, 3.11], not significant. Trends in target knee BMDs for those with higher risk of decreasing BMD, (female and age 65-80), showed a mated difference -4.05 [95% CI -11.21, 3.11], not significant).

**Conclusion:** The incidence of AEs was similar between treatment groups and not affected by repeated injections of LOR. Multiple injections of LOR over 2 years did not appear to lead to any bone health adverse effects locally around the knee or regionally at spine or hip.

**COMPARISON OF VALIDATED QUESTIONNAIRES WITH CLINICAL ITEMS FOR THE MEASUREMENT OF CHANGE IN PAIN**

**Keywords:** Osteoarthritis, Pain

**References:**

C. Van der Meulen1, L. Van de Stadt2, F. Rosendaal3, M. Kloppenburg1, 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Reade, Rheumatology, Amsterdam, Netherlands; 3Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands

**Background:** Hand pain is a common symptom in hand osteoarthritis (OA). Questionnaires are used to measure and to monitor this pain over time. However, it is unknown whether these measurements reliably reflect patients’ experience.

**Objectives:** This study aimed to compare pain development scored by a validated questionnaire with pain development scored by a direct question to the patient.

**Methods:** Data from the first four years of the ongoing HOSTAS (Hand OSTeo-Arthritis in Secondary care) cohort were used. HOSTAS consists of patients with primary hand OA diagnosed by a rheumatologist. Pain was measured with the Australian/Canadian hand Osteoarthritis index (AUSCAN) pain subscale (range 0-20) at baseline and annually afterwards. Partway through the study, an annual anchor question was added asking participants whether pain had worsened, improved, remained stable or if they had never had pain, compared with the year before. Patients were included in the current analysis when change in AUSCAN pain and the anchor question were available for at least one year. Change in pain measured with AUSCAN was categorized according to the minimal clinical important difference (MDIC) of 1.49 between the yearly visits. Changes between annual visits on AUSCAN and the anchor questions were described and Cohen’s kappa was calculated for each category (increase, stable and decrease). Annual results were comparable between years, and so the years were pooled.

**Results:** In 307 patients, the mean age was 61.0 (SD 8.2), with 82% women and a mean BMI of 27.3 (SD 4.8). The baseline AUSCAN pain was 9.1 (SD 4.2). Over 4 years, 708 annual intervals with both change in AUSCAN and anchor questions were available. Of the 309 patients, 95 provided one interval, 74 provided two intervals, 87 provided three and 51 provided four. Results are described in Table 1. Figure 1 shows the mean changes in AUSCAN pain (of which 151

**Figure 1. Total Target Knee BMD over 104 weeks**

**DOI:** 10.1136/annrheumdis-2023-eular.1458
intervals patients (74%) indicated their pain had worsened on anchor questions), in 293 intervals 199 patients reported a stable level of pain (of which in 96 intervals (33%) indicated their pain had not changed) and in 212 intervals 176 patients reported a decrease in pain (of which 39% (19%) indicated their pain had improved) (Table 1). The most frequent answer was a worsening of pain, regardless of AUSCAN change. In total, in 286 out of 704 (40%) of the intervals, the anchor question was in accordance with the AUSCAN pain, with a Cohen’s kappa of 0.12.

**Conclusion:** There are large differences between changes in AUSCAN pain and experienced changes in pain when reported by the patient. The patient experiences worsened pain more often than is reflected in the AUSCAN pain. Although recall bias may play a role in the answers to the anchor questions, they are close to the real-world clinical practice, in which patients are often asked how the symptoms compare to last visit. This indicates a difference between change in pain perceived in the clinical setting and in research setting, which should be addressed in order to improve research on pain development.

**SEMIQUANTITATIVE ASSESSMENT OF KNEE OSTEOARTHRITIS-RELATED SYNOVITIS COMPARED TO CHRONIC INFLAMMATORY ARTHRITIDES: RELATION TO AGE AND IMPACT ON BONE/STRUCTURAL DAMAGE**

**Keywords:** Descriptive studies, Synovium, Osteoarthritis

P. Rubortone1, F. Leone1, L. Petricca2, S. Perniola3, D. Bruno3, M. R. Gigante4, C. Di Mario1, B. Tolusso5, G. Peluso2, E. Gremese1,3, M. A. D’agostino1,2, S. Alivernini1,2,5, M. M. Lizzio2.

**Background:** Knee Osteoarthritis (KOa) is one of the most frequent causes of pain and disability, representing a relevant clinical burden. Although it was largely considered a mostly mechanical-based pathology, low-grade synovial inflammation was found to contribute to radiographic progression and pain chronification [1].

**Objectives:** To evaluate the histological characteristics of synovial membrane in KOA patients compared to chronic inflammatory diseases as Rheumatoid (RA) and Psoriatic Arthritis (PsA) across disease phases.

**Methods:** 170 patients with KOA, 240 patients with RA, 92 patients with PsA naïve to pharmacological treatments and 200 patients with RA in sustained clinical and ultrasound remission (RA-r) underwent ultrasound-guided synovial biopsy of the knee and conventional X-rays. None of enrolled KOA patient had evidence of inflammatory condition (including chronic inflammatory diseases and crystal related arthritis). Synovial membrane samples were processed for histology (hematoxilin-eosin staining) for the semiquantitative assessment of synovitis degree (Krenn synovitis score [2] – KSS). Moreover, this analysis was implemented with the semiquantitative assessment of presence/absence of synovial lymphocytes, plasmocytes, myxoid degeneration and inflammatory perivascular aggregates. X-rays were scored for Kellgren-Lawrence score [3] (KLs) assessment.

**Results:** RA and PsA patients naïve to pharmacological treatment showed higher degree of synovial inflammation than patients with KOA as well as more likely presence of lymphocytes and plasmocytars aggregates. Considering the whole KOA population, total KLs directly correlated with age (R=0.041; p=0.008), thickness of synovial membrane (R=0.115; p<0.001) and Power Doppler score (R=0.142; p<0.001) at ultrasound evaluation, VAS pain (R=0.025; p=0.039) and KLs (R=0.54; p<0.0001). Stratifying KOA patients based on age categories, KOA patients aged ≥70 years had higher KSS (mean ±SEM, 2.46 ±0.179) and KLs (2.14 ±0.17) than younger KOA patients (KSS 1.98 ±0.113, p=0.0182 and KLs 1.25 ±0.101, p<0.001).

To distinguish residual inflammation from osteoarthritis-related synovitis, we compared KOA-derived synovial tissues with the ones of RA-r patients, showing that the degree of KOA-related synovitis is significantly higher (mean ±SEM, 2.10 ±0.09) than the subclinical residual synovitis detected in RA-r patients (1.77 ±0.08, p=0.0103).

**Conclusion:** KOA-related synovitis impacts on bone structural damage and is related to age, supporting the role of inflammation in KOA pathogenesis.

**REGRESSION TO THE MEAN FOR PAIN OUTCOMES IN CLINICAL TRIALS FOR KNEE OSTEOARTHRITIS**

**Keywords:** Epidemiology, Osteoarthritis, Pain

M. Englund1, A. Turkiewicz1, Lund University, Clinical Sciences Lund, Lund, Sweden

**Background:** Improvements in pain in clinical trials for osteoarthritis (OA) are largely contextual.(1) Given known fluctuations of osteoarthritis pain, a substantial proportion of contextual response could be explained by the regression-to-the-mean (RTM) phenomenon.

**Objectives:** To estimate the size of RTM for a typical OA trial with pain as outcome.

**Methods:** We included participants of Osteoarthritis Initiative who fulfilled inclusion criteria typically required for enrolment in a clinical trial. These included: age 40-79 years, symptomatic knee OA, Kellgren-Lawrence grade 2-3, use of pain medication more than half the days of a month in past 12 months, numerical rating scale (NRS) pain of 4 to 9 in the target knee. We studied observed changes in the mean levels of pain with respect to conditioning on current knee pain.

**Results:** We identified 459 subjects who fulfilled inclusion criteria on at least one annual follow-up between year 1 and year 8. In these subjects, the mean NRS pain level at each follow-up time point was similar, ~4.6, but at the time of fulfilling the inclusion criteria, the mean level of pain in the same subjects was 6.2 (Figure 1). The difference in NRS pain between the theoretical point of inclusion in a trial and one year after was -0.8 (95% confidence interval -0.8, -0.9).

**Figure 1.** Mean levels of pain among 459 persons fulfilling criteria for inclusion in a hypothetical knee osteoarthritis trial. Time 0 means the moment when fulfilling the criteria. Each line represents a cohort of subjects fulfilling criteria at one follow-up occasion (between year 1 and year 8 post baseline). Each person can be included multiple times.
Conclusion: RTM in a typical osteoarthrits trial is likely to explain as much as about 0.8 NRS point improvement on a 0 to 10-point scale. RTM is a powerful phenomenon that may mislead interpretation of effectiveness as it neither represents improvement from the intervention nor placebo response.

COMBINED ASSESSMENT OF CARTILAGE AND SUBCHONDRAL BONE IN OSTEOARTHRITIC AND NON-OSTEARTHRITIC KNEE JOINTS: A ULTRA-HIGH FIELD MRI STUDY

Keywords: Imaging

A. Bourard1, M. A. Hostin2,3, E. Soldar4,5, F. Suzan6,7, J. P. Mallet2,1, W. Theo3, M. Guye5, C. Chagnaud2,1, D. Bendahman4, S. Guis6,8,9, APHM, Rheumatology Department, Marseille, France; 1,2Aix-Marseille University, CNRS, CRMBM, UMR 7339, Marseille, France; 3Aix-Marseille University, Université de Toulon, CRNS, LIS, Marseille, France; 4Aix-Marseille University, CNRS, IUSTI (UMR 7343), Marseille, France; 5Aix-Marseille University, ISM, Marseille, France; 6Aix-Marseille University, APHM, Hospital de la Timone, Referral Centre for Neuromuscular Diseases and ALS, Marseille, France; 7Aix-Marseille University, APHM, Radiology Department, Marseille, France; 8INSERM 1097 UMR, Arthrites auto-immunes, Marseille, France; 9Aix-Marseille University, Medical School, Marseille, France

Background: Knee osteoarthritis (OA) is one of the most common degenerative diseases causing disability in elderly people. Although X-ray radiography is widely used as a diagnostic tool, several limitations have been identified [1]. MRI is a non-invasive imaging method widely used in order to assess articular and periarticular structures of the knee joint [2]. However, the image resolution provided by conventional MRI is not high enough to assess subchondral bone so that ultra-high field MRI (7 Tesla) has been proposed as an alternative of interest to compute bone microarchitectural parameters [3].

Objectives: We used ultra-high field MRI (UHF 7 Tesla MRI) to assess cartilage and subchondral bone microarchitecture in patients with mild and severe OA. For each patient, compartments classified as osteoarthritic were compared with non-ostearthritic compartments.

Methods: Twenty-four patients were divided into 3 groups according to the Kellgren Lawrence staging and 12 volunteers were recruited as controls. UHF MRI was used to calculate cartilage thickness (Tc), volume (Vc), and T2*. MRI sequences used were T1 3D gradient recalled echo sequence (T1 3D GRE) and sagittal T2* mapping. Bone microarchitecture was assessed on the basis of trabecular thickness (TbTh), trabecular number (TbN), trabecular space (TbSp), and bone volume fraction (BVf).

Results: For the medial tibial plateau, while Tc was unchanged between the two OA groups, Vc was decreased in patients with severe OA (Δ = -49%, p < 0.05). For the patella, Vc was decreased in patients with mild OA (Δ = -36%, p<0.05), while Tc was unchanged. Similar results were found for the lateral femoral condyle. The study of T2* cartilage relaxation (T2* mapping) revealed no statistically significant changes in all knee joint compartments. Computed TbSp in the lateral tibial plateau and patella was significantly higher in the mild OA group (Δtib lateral plateau = +25%; Δpatella = +31.5, p<0.05), whereas most subchondral bone parameters were unchanged. Medial femoral condyle cartilage volume was significantly correlated with patellar cartilage thickness r = 0.46 (p = 0.01). Medial tibial plateau cartilage thickness and patellar cartilage thickness were linearly related r = 0.587 (p = 0.05). Medial tibial plateau cartilage volume was significantly correlated with patella TbTh, r = 0.41 (p = 0.02)

Conclusion: Cartilage volume seems to be more sensitive than thickness for the assessment of cartilage changes in OA. TbSp would be a sensitive marker for the assessment of cartilage changes in OA. TbSp would be a sensitive marker for the assessment of cartilage changes in OA. TbSp would be a sensitive marker for the assessment of cartilage changes in OA.

ASSESSMENT OF THE EFFICACY OF COMBINATION OF ORAL ACETAMINOPHEN AND TOPICAL DICYFENAC IN OSTEOARTHRITIS PAIN: INSIGHTS FROM A MODEL-BASED META-ANALYSIS

Keywords: Osteoarthritis, Pain

V. Soold; L. Qin3, E. Cox1, I. Tocroniz3, O. Della Pasqua; L. Healeon (formerly GlaxoSmithKline Consumer Healthcare), Medical Affairs, Singapore, Singapore; 2Certara, Modeling & Simulation, Princeton, United States of America; 3University of Navarra, School of Pharmacy and Nutrition, Pamplona, Spain; 4GlaxoSmithKline, Clinical Pharmacology Modelling and Simulation, Brentford, United Kingdom; 5University College London, Clinical Pharmacology & Therapeutics Group, London, United Kingdom

Background: Osteoarthritis (OA) is a major cause of chronic pain and disability in older adults and currently affects approximately 300 million people worldwide [1]. In the absence of curative therapy, symptomatic drugs comprise the backbone of pain management in OA. However, acetaminophen provides inadequate relief and oral non-steroidal anti-inflammatory drugs (NSAIDs) exhibit significant gastrointestinal and cardiovascular toxicity which prohibit their long-term use in the elderly [2,3]. Although opioids can be an effective alternative in patients experiencing insufficient pain relief with other analgesics, concerns have been raised about the risk of side effects, addiction, and overdose deaths [4]. Therefore, there is a significant unmet need for effective and well-tolerated treatments. Acetaminophen and topical diclofenac are the most common complementary mechanisms of action targeting pain and inflammation, respectively, and are therefore attractive candidates for use in combination analgesia in OA pain [5,6,7]. Although ample clinical evidence exists on the monotherapy of acetaminophen or topical diclofenac in OA, there is a data gap for evidence on their combination.

Objectives: The present study aims to assess the effect of the combination of acetaminophen and topical diclofenac in OA and compare its performance to acetaminophen and diclofenac monotherapy using a model-based meta-analysis (MBMA) leveraging published summary-level data on the combination from OA as well as other acute pain indications [8].

Methods: Randomized controlled trials (RCTs) investigating the combination of acetaminophen and diclofenac in OA and acute pain settings were identified through systematic literature searches. MBMA was implemented to infer the efficacy of the combination in the population of interest. Pain score reduction on numerical rating scale (NRS), visual analogue scale (VAS) and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale along with opioid sparing effect (defined as reduced opioid dose without loss of analgesic efficacy) were selected as the clinical endpoints.

RESULTS: In the absence of RCTs on the combination in OA, MBMA was implemented in conjunction with extrapolation principles on trials in acute pain setting (11 RCTs, n=1396 patients). The combination demonstrated greater reduction in pain scores versus acetaminophen monotherapy in 8 of the 11 RCTs. Moreover, a parsimonious MBMA was developed on 5 RCTs allowing PCA, which revealed a statistically significant 32% lesser opioid use with the combination than with acetaminophen monotherapy (Figure 1). However, the combination effect was less conclusive versus diclofenac monotherapy.

Conclusion: The current analysis demonstrates greater pain reduction and opioid sparing efficacy for the combination versus acetaminophen monotherapy in the treatment of acute pain. Considering the overlap in pain transmission pathways between acute and chronic OA pain, the combination may be anticipated to exhibit similar performance on extrapolation to chronic OA pain. Overall, our research tries to bridge the gap in pharmacological and clinical evidence supporting the use of combination of acetaminophen and topical diclofenac in mild-to-moderate OA pain.

POS1359 SURGICAL DENERVATION TO TREAT PAIN IN HAND OSTEOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

Keywords: Systematic review, Osteoarthritis, Pain

C. Van der Meulen1, L. Van de Stadt2, A. Claassen3, F. Kroon4, M. Ritt5, F. Rosendaal6, S. Terpstra1, A. Vochteloo7, M. Kloppenburg1.

Background: Surgical denervation has been proposed as a treatment for pain in hand osteoarthritis (OA).

Objectives: We performed a systematic literature review to summarize the available evidence and propose a research agenda.

Methods: A systematic literature search was performed up to September 2022. Two investigators identified studies that reported on denervation for OA of the proximal interphalangeal joint (PIPJ), distal interphalangeal joint (DIPJ), metacarpophalangeal joint (MCPJ), or first carpalometacarpal joint (CMCJ). Reviews, comments, letters or editorials, studies in languages other than English and studies investigating other interventions, joints or conditions were excluded. Quality of studies was assessed with the Joanna Briggs Institute checklist for case series investigating other interventions, joints or conditions were excluded. Qual-

Results: The search yielded 213 articles from the PubMed, OVID and Cochrane databases. From these, 17 articles (reporting on 384 denervation surgeries in 351 patients) were selected. Twelve studies described CMCJ denervation, three described PIPJ denervation, and the others described DIPJ (n=1), MCPJ (n=1) or a mixture of MCPJ, PIPJ and DIPJ denervation (n=2). The surgical techniques varied greatly, both in incisions and in the nerves severed, even between studies investigating denervation of the same joint. The innervation of the joints in the hand is still subject to debate. Most of the studies were case series (n=16), and one was a non-randomized clinical trial. Sample size ranged from 3 to 60 participants. All studies had significant risk of bias. The studies consisted of patient groups with average age ranging from 55 to 65 and 60-75% female participants. The sixteen case series reported positive outcomes with respect to pain, function and patient satisfaction. Average pain decrease ranged from 3 to 8.1 on a 10-point numeric rating scale (NRS) (n=8 studies), with a 56-92% patient satisfaction rate (n=5) and mean increase in range of motion of 3.5-27 degrees (n=3). The non-randomized clinical trial reported no differences in outcome when comparing denervation to trapeziectomy. Adverse event rates ranged from 0-75% of denervation procedures. Sensory abnormalities occurred most, followed by the need for revision surgery and infections of the area of the surgery.

Conclusion: Surgical denervation for pain in hand OA shows promise, but the available evidence does not allow conclusions, as for example regression to the mean can strongly influence the observations in case series. More and higher quality evidence is needed before it can be recommended as part of standard care. On the research agenda are 1) the innervation of the joints, 2) the best surgical technique to sever all relevant nerves, and 3) perform high-quality randomized clinical trials to investigate the efficacy of surgical denervation in comparison to sham, 4) to investigate other interventions targeted at the innervating nerves, and finally 5) the safety of the different surgical denervation techniques.

POS1360 PATIENTS ARE ALWAYS RIGHT ASSOCIATION BETWEEN HUMIDITY LEVEL AND PAIN EXPERIENCE IN HAND OSTEOARTHRITIS

Keywords: Pain, Osteoarthritis

M. Pezo1, R. Lacoste Badie2, S. Tufflet3, A. Rousseau4, P. Richette4, B. Faure5, F. Berenbaum6, A. Courties7, J. Sellam1, 1Sorbonne Université, INSERM, Rhumatologie, AP-Hôpital Saint-Antoine, Paris, France; 2Sorbonne Université, Service de Pharmacologie Clinique et Plateforme de Recherche Clinique de l’Est Parisien (URCEST, CRB, CRF, URC), Hôpital Saint-Antoine, Paris, France; 3Université Paris Cité, Rhumatologie, Hôpital Lariboisière, Paris, France; 4Sorbonne Université, Rhumatologie, Hôpital de la Pitié-Salpêtrière, Paris, France

Background: While many patients with joint disease report pain changes according to meteorological factors (1), this common belief has not been clearly demonstrated and never been documented in hand osteoarthritis (HOA).

Objectives: We aimed to investigate the cross-sectional association between meteorological factors that are ambient temperature and humidity on HOA symptoms.

Methods: We used the baseline data from the prospective DIGICOD HOA cohort including patients with established symptomatic HOA. The clinical outcomes included aUASCAN-pain, AUSCAN-stiffness and AUSCAN-function sub scores, VAS-scale for pain during activity, number of spontaneous tender joints and tender joints at palpation. Meteorological data (from Météo France), ambient temperature and humidity, are defined as the mean value observed during the 3 days before inclusion (day of inclusion, D-1 and D-2). Considering non-normal distribution, each outcome was binarized by the median value, in order to define high and low symptoms intensity. Association between outcome and meteorological data were studied using two logistic regression models (separate models for temperature and humidity), adjusted for age, sex, group of Kellgren-Lawrence score of all hand joints and Hospital Anxiety Depression scale. Assumption of linearity between temperature or humidity and the logit of the outcomes being not verified, those two parameters were introduced in the models as categorical variables according to quartiles. Results are presented as odds ratio (OR) with 95% confidence intervals (CIs). The reference groups were respectively lower humidity and lower temperature quartile.

Results: We have studied 377 patients in whom all variables of interest were available (mean age a standard deviation (SD) 66.5 ± 7.4 years, 85% women). Median AUSCAN-pain subscore was 20/100 (IQR [8; 36]), median AUSCAN-stiffness subscore was 22/100 (IQR [7; 53]), median AUSCAN-function subscore was 32/100 (IQR [13; 55]), median VAS-pain during activity was 42/100 (IQR [22; 66]), median number of spontaneous tender joints was 0/30 (IQR [0; 2], median the surgical technique and outcomes of the surgery were extracted. Due to the nature of the data, no meta-analysis was performed. Data from the studies were pooled and minimal and maximal scores were estimated.
number of tender joints at palpation was 3/30 (IQR [2; 6]). Results of models for humidity are presented in Table 1. There was an association between humidity percentage and AUSCAN pain ≥ 20 for third quartile vs. first quartile (OR [79-83%] vs. [43-68%] = 1.99 (1.08 to 3.58), p = 0.03) and between humidity and VAS pain during activity ≥ 42 for second quartile vs. first quartile (OR 68-79%) vs. [43-68%] = 1.97 (1.06 to 3.63) p = 0.03). Considering patients with at least 1 spontaneous hand joint pain, an association was found for all 3 higher quartiles of humidity ([68-79%]; [79-85%] and [85-96%]) compared to the lower one ([43-68%]), but without dose-effect. There was no effect of humidity on AUSCAN stiffness or function, or number of tender joints at palpation. Temperature was not associated with any clinical outcomes (pain, function or stiffness).

Conclusion: This is the first study about impact of meteorological factors in HOA. While we did not find any association between temperature and symptoms, we found an association between humidity and pain. Although we cannot conclude on any causality between humidity and pain, our results support patient’s belief about influence of humidity on joint pain.

Table 1: Association between humidity and HOA symptoms: logistic regression models with systematic adjustment on sex, age, sum of Kellgren-Lawrence score for all hand joint and HAD score.

POS1361 THE INFLUENCE OF BASELINE DEMOGRAPHICS ON VARIABILITY OF OA PAIN ASSESSED BY WOMAC PAIN CHANGE FROM BASELINE IN INTERVENTIONAL TRIALS

Keywords: Biomarkers, Osteoarthritis, Randomized control trial

A. R. Bihlet1, P. Alexandersen1, J. R. Andersen3, Y. Li3, M. Karsdal3, C. Miller3

1Nordic Bioscience, Clinical Development, Søborg, Denmark; 2Sanos, USA; 3Nordic Bioscience, Clinical Development, Søborg, Denmark; 4Nordic Bioscience, Clinical Development, Søborg, Denmark

Background: Development of new products for OA treatment is difficult, partly due to excessive placebo response and high variability in patient-reported pain outcomes, and exclusion of trial subjects with potentially confounding pain from non-target joints may increase the effect size. This may in part be due to reductions in variability, and hence in standard deviation (SD) of the mean changes in pain scores, which improves the statistical power to detect differences between study groups. The impact of refining the study population in terms of added benefit to the SD and statistical power vs. added screen failures is poorly described.

Objectives: To investigate the impact of common demographic and pain characteristics on the SD of mean pain change from baseline in a large interventional OA trial database.

Methods: Data from 2 randomized controlled trials of oral salmon calcitonin in OA (1) were analyzed post-hoc. The SD of the mean change from baseline (SD-CFB) to Year 2 in the WOMAC knee pain score (0-100) was calculated. The SD-CFB was also calculated for subgroups (e.g. demographics, pain of the target and non-target knee). The sample size required to identify a statistically significant difference of at least 8 out of 100 between groups (with 80% power) was calculated, and the additional proportion of eligible subjects to be screen-failed if the particular subgroup was excluded was calculated to quantify the potential impact on the study feasibility.

Results: A total of 1,487 subjects had WOMAC pain data throughout the trial period. Results are shown in Table 1. Few clinical characteristics influenced the SD and hence the required sample size, except for Asian race, associated with a lower SD compared to Caucasians (19.71 vs. 21.85), to detect a significant difference. Exclusion of those with high BMI (≥ 35 kg/m²) led to a reduced sample size required of 113. Subjects with non-target knee pain above the median had higher pain variability and thus a larger sample size required to detect differences vs. those with pain scores below the median. However, exclusion of these groups required screen failing approx. extra 50% of the eligible population to achieve this. A less exclusive method was excluding subjects with non-target knee pain not exceeding that of the target knee. Radiographic characteristics did not influence the SD, except for those with a KL grade 3 or 4 of the non-target knee (Table 1). This observation requires further scrutiny.

Table 1. SD of mean n WOMAC pain change Sample size per group to detect mean WOMAC pain difference of 8 out of 100 (n) Proportion of eligible subjects screen failed if subgroup was excluded (%)

| All study completers | 21.58 | 1,487 | 115 | 0 |
| Male | 21.12 | 516 | 110 | 34.7 |
| Female | 21.62 | 971 | 117 | 65.3 |
| Age ≤ 64 yrs | 21.49 | 799 | 114 | 53.7 |
| Age > 64 yrs | 21.68 | 688 | 116 | 46.3 |
| BMI < 35 kg/m² | 21.45 | 1,316 | 113 | 88.5 |
| BMI ≥ 35 kg/m² | 22.53 | 171 | 125 | 11.5 |

Subgroups by Non-Target knee characteristics at Baseline

| KL grade 0 | 20.79 | 60 | 107 | 4.0 |
| KL grade I | 21.19 | 271 | 111 | 18.2 |
| KL grade II | 20.83 | 766 | 107 | 51.5 |
| KL grade III | 23.80 | 346 | 139 | 23.3 |
| KL grade IV | 17.55 | 42 | 76 | 2.8 |
| WOMAC Pain ≤ 35 (0-100) | 20.08 | 731 | 99 | 49.2 |
| WOMAC Pain > 35 (0-100) | 22.96 | 722 | 130 | 48.6 |
| Low VA5 (0-100, ≤ 37) | 19.39 | 714 | 93 | 48.0 |
| High VAS (0-100, > 37) | 23.54 | 722 | 136 | 48.6 |
| Nontarget knee WOMAC pain | 22.64 | 408 | 126 | 27.4 |
| Non-Target knee WOMAC pain | 20.84 | 1,024 | 107 | 68.9 |

Conclusion: High BMI and high baseline pain of the non-target knee may contribute negatively to the study power, however, the added study cost in terms of additional screened subjects required to replace those excluded based on these parameters should be carefully evaluated. The potential impact of these parameters on the magnitude of the difference between study groups was not evaluated and may also differ, with additional statistical implications.

POS1362 THE OA TRIAL BANK: UPDATE OF INDIVIDUAL PATIENT DATA META-ANALYSIS OF INTRA-ARTICULAR GLUCOCORTICOID IN PERSONS WITH KNEE AND HIP OSTEOPOROSIS

Keywords: Osteoarthritis

S. Yu1,2, M. Van Middelkoop3, M. Ferreira4, L. Deveza1,2, S. M. A. Bierma-Zeinstra3, V. Venkatesha3, D. Hunter1,2, 1Royal North Shore Hospital,
Background: Intra-articular (IA) glucocorticoid injections are often employed in the management of osteoarthritis (OA) patients, but in whom to best target treatment is unclear. OA clinical guidelines have advocated for the identification of predictors of response to different treatments, but no reliable subgroups with treatment effect have been found.

Objectives: This study aims to conduct an individual patient data (IPD) meta-analysis to evaluate the efficacy of IA glucocorticoid for knee or hip OA in specific subgroups of patients according to the baseline pain severity and inflammatory signs. This is an update on an IPD meta-analysis on IA glucocorticoid by the OA Trial Bank [1].

Methods: Randomised trials evaluating one or more IA glucocorticoid preparations in hip and knee OA, published from 2012 to May 2018, were selected from the literature. IPD of participant and disease characteristics and outcome measures were acquired. The primary outcome was pain severity at short-term follow-up (around 4 weeks). A two-stage IPD analysis was performed. Potential interaction effect of baseline severe pain (≥70 points, 0-100 scale) and signs of inflammation were studied using linear mixed-effects models. Analysis of trend was conducted, assessing if a baseline pain cut-off was associated with the threshold for clinically important treatment effect of IA glucocorticoid compared to placebo.

Results: Four out of 16 eligible randomised clinical trials (n=641) were combined with the existing OA Trial Bank studies (n=620), yielding n=1261 from eleven studies. Participants with severe baseline pain compared to those with less severe pain had greater pain reduction at mid-term (around 12 weeks) (mean reduction: -6.90 (95%CI -10.91; -2.90)), but not at short- or long-term follow-up. No interaction effects were found between inflammatory signs and IA glucocorticoid injections compared to placebo at all follow-up time-points (Table 1). Analysis of trend showed treatment response to IA glucocorticoid injections from baseline pain levels ≥50 (0-100 scale) and above (Figure 1).

Conclusion: This IPD meta-analysis demonstrated that in participants with severe baseline pain, clinically relevant response is seen at mid-term follow-up, suggesting that sustained response to IA glucocorticoid injection may be seen in a subgroup of OA participants. As baseline pain score increases, treatment response is seen in participants from moderate pain levels onwards. No concrete conclusions can be made on baseline inflammatory signs. Ongoing IPD studies with an increased number of studies are required.

POS1963 CIRCULATING GALECTIN-1 LEVELS IN INDIVIDUALS WITH KNEE AND/OR HAND OSTEOARTHRITIS – A HALLOA STUDY

Keywords: Biomarkers, Osteoarthritis

M. Andersson1,2,3, M. Zimmerman4, E. Brogren5, S. Bergman6, E. Fryk6, L. Strinberg6, P. A. Jansson9, 1Spenshult Resarch and Development Center., Halmst, Sweden; 1Halmst University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmst, Sweden; 2Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden; 3Helsingsborg Hospital, Department of Orthopaedics, Helsingborg, Sweden; 4Lund University, Department of Translational Medicine - Hand Surgery; Lund, Sweden; 5Skane University Hospital, Department of Hand Surgery; Malmö, Sweden; 6Spenshult Resarch and Development Center., Halmst, Sweden; 7University of Gothenburg, The Sahlgrenska Academy, Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden; 8University of Gothenburg, The Sahlgrenska Academy, SU Sahlgrenska, Department of Molecular and Clinical Medicine, Institute of Medicine, Gothenburg, Sweden

Background: Circulating galectin-1 levels are associated with metabolic diseases including obesity, diabetes type II, and subclinical inflammation [1]. These medical conditions are often seen as comorbidities of osteoarthritis (OA) in the knees and hands.

Objectives: The aim was to study longitudinal associations between circulating galectin-1 levels and radiographic knee OA (RKOA), radiographic hand OA (RHOA), and general OA (GOA, RKOA and RHOA).

Methods: This longitudinal study included 232 individuals from the Halland osteoarthritis cohort (HALLOA) (2) with knee radiographs at inclusion and at a two-year follow-up. Of the included individuals, 211 had hand radiographs at the two-year follow-up. Body mass index (BMI), and waist circumference (WC) were measured. Visceral fat area (VFA) was assessed by bioimpedance (InBody 770). Serum/plasma levels of HbA1c, glucose, and C-reactive protein (CRP≥10.0 mg/L) were measured according to the current laboratory standards in Sweden. CRP below 10.0 mg/L, was further analysed with a sensitive CRP ELISA method (Abnova). Insulin resistance was assessed by the triglyceride glucose index (TyG), Galectin-1, IL-1 beta, IL-6, and TNF alpha using Quantikine, ELISA (bio- techne, United Kingdom), RKOA was defined according to Ahlbäck, as grade 1 or more in at least one knee at two years follow-up; RHOA was defined according
to Kellogg and Lawrence as grade 2 or more in at least one joint at two years follow-up, GOA was defined as having RKOA and RHOA. Comparisons between groups at inclusion were performed using Mann-Whitney U test, chi-2, and univariate Logistic regression models for associations.

Results: At the two-year follow-up, 34% of the included individuals had RKOA, 42% had RHOA, and 50 individuals had GOA. Individuals with RKOA were older, more obese, and had higher median serum levels of HAIC1, CRP, and IL-6, but no increased serum level of galectin-1, Table 1. Age (OR 1.12; 95% CI 1.06-1.17) obesity (OR 1.04; 95% CI 1.01-1.06) and galectin-1 (OR 1.04; 95% CI 1.003-1.08) were associated with RKOA. Those with RHOA were older and had increased serum levels of HAIC1, galectin-1, Tyg index, and IL-6, Table 1. Age (OR 1.21; 95% CI 1.14-1.28), HA1C (OR 1.11; 95% CI 1.01-1.21), and galectin-1 (OR 1.05; 95% CI 1.03-1.10) were associated with RHOA. Individuals with GOA were older, more obese, had more inflammation, and increased levels of HAIC1 and galectin-1, table 1. Age (OR 1.30; 95% CI 1.18-1.45) and galectin-1 (OR 1.06; 95% CI 1.01-1.12) were associated with GOA.

Conclusion: Circulating galectin-1 seems to associate with OA, especially RHOA. More studies are needed to assess a potential underlying pathophysiological mechanism of galectin-1 in OA.

1York, York and Scarborough Teaching Hospitals: NHS Foundation Trust, York, United Kingdom; 2University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 3Stryker, Imorphics, Manchester, United Kingdom; 4Stryker, Imorphics, Austin, United States of America; 5University of Leeds, Leeds Musculoskeletal Biomedical Research Centre, Leeds, United Kingdom

Background: In Disease Modifying Osteoarthritis Drug (DMOAD) trials, cartilage loss may be assessed semi-quantitatively or quantitatively, although the latter is higher cost and more technically challenging. The MRI Osteoarthritis Knee Score (MOAKS) is the most commonly used semi-quantitative knee OA scoring system that assesses thickness of MOAKS cartilage morphology loss (tMOAKS) and denudation (dMOAKS) on the articular subregions of femur and tibia.

Objectives: This study aimed to compare the cross-sectional relationship and longitudinal responsiveness of MOAKS with the more accurate quantitative cartilage assessment.

Methods: Images and MOAKS scores from 297 participants with radiographic progression (groups 1 and 2) from the OAI FNIH sub-cohort were included. Quantitative cartilage thickness was measured using Active Appearance Models (AAMs). To facilitate direct comparison with MOAKS, novel quantitative measures of cartilage loss were matched to MOAKS regions (Q-MOAKS). Mean normative cartilage thickness was computed for each subregion (Figure 1) using FNIH controls (group 4). Q-MOAKS thickness loss score (tQCM) was based on the proportion of cartilage thickness over a subregion that was >95% normative thickness and denudation score (dQCM) was based on <5% normative thickness. Q-MOAKS area proportions were categorised into scores for as MOAKS (0: none, 1: 0-10%, 2: 10-75% and 3: >75%). Quantitative cartilage thickness (ThCtAB) was also measured in the central medial femur (cMf) and tibia (cMt). We compared MOAKS against Q-MOAKS and ThCtAB. Cross-sectional relationships between measures were assessed using Spearman’s rank correlation. Responsiveness was assessed at 1 and 2 years using bootstrapped standardised response means (SRM).

Results: Cross-sectionally, there was moderate correlation between MOAKS and Q-MOAKS denudation in the central medial femur (cMf r = 0.42, 95%CI:0.32,0.51) and tibia (cMt r = 0.51, 0.42,0.59). There was a poor correlation between MOAKS and Q-MOAKS thickness loss and denudation scores in all other regions. In the tibia (cMt), 61% (96/159) of knees with thickness loss tMCM = 2 (the 10-75% score) were also tQMC = 2 and 66% of denudation dMCM = 2 were also dQCM = 2. In the femur (cMf), the figures were 56% and 23%, MOAKS tMCM and dMCM were less responsive than Q-MOAKS tQCM and dQCM in most subregions (selected SRMs presented in Table 1). Q-MOAKS tMCM in cMt demonstrated the most responsive for all the scores (SRM=0.76 vs SRM = 0.20 for MOAKS tMCM), Quantitative cartilage thickness (ThCtAB) measures were most responsive. In the cMt region, the SRM= -0.46 (95% CI: -0.56,-0.33) at 1-year and 0.82 (-0.94,-0.72) at 2-years while the cMf SRM = -0.4 (-0.5,-0.28) at 1-year and -0.71 (-0.80,-0.60) at 2-years.
Conclusion: Quantitative measures or derived Q-MOAKS scores were more responsive than MOAKS. MOAKS appears to have better concordance with quantitative cartilage denudation than thickness loss, which might be explained by diagnostic accuracy for full thickness lesions being better than earlier grade lesions.

STRUCTURAL SEVERITY IN KNEE OSTEOARTHRITIS IMPACTS TREATMENT RESPONSE: A POST HOC POOLED ANALYSIS OF LOCORECIVINT CLINICAL TRIALS

Keywords: Imaging, Osteoarthritis, Clinical trials

Y. Yazici1, C. Swearingen2, H. Ghandehari1, L. Simsek2, G. Kennedy3, J. Tambiah3, T. McAlindon3. NYU Grossman School of Medicine, Rheumatology, New York, United States of America; 2Biosplice Therapeutics, Bioistostics, San Diego, United States of America; 3Aplin ImmuneSciences, Clinical Development, Seattle, United States of America; 4Biosplice Therapeutics, Clinical Development and External Innovation, San Diego, United States of America; 5Tufts Medical Center, Rheumatology, Boston, United States of America

Background: Osteoarthritis (OA) is a leading cause of disability globally, with disease burden expected to rise [1]. Unmet needs remain for safe and efficacious treatments for symptoms and structural modification. Difficulties assessing pain and joint structure in clinical trials exist due to disease heterogeneity. This post hoc analysis of locorecivint (LOR), an intra-articular (IA) CLK/ DYRK inhibitor thought to modulate Wnt and inflammatory pathways, examined the structural heterogeneity of participants enrolled in Phase 2 and 3 LOR trials and associated treatment responses within KL grade subgroups.

Objectives: To identify potential relationships between OA pain and knee joint structural damage which may aid future clinical trial design.

Methods: Data was analyzed from two Phase 2 (OA-02, NCT02536833; OA-04, NCT03122860), and two Phase 3 trials (OA-10, NCT04385303; OA-11, NCT03928184) trials. In all trials, participants had ACR-defined (clinical and radiographic) knee OA, Kellgren-Lawrence (KL) grades 2-3. For OA-04, OA-10 and OA-11, additional pain inclusion criteria included Pain Numeric Rating Scale (NRS) ≥10, ≥7 and ≥5 in the target knee and ≤4 in the contralateral knee. Baseline JSW for each study was compared using cumulative frequency distribution plots by KL grade; percentages of subjects with JSW < 3mm for each study was also summarized to provide a surrogate for loss of ~50% healthy JSW (Deep et al. JBJS 8999). For the trials which captured Pain NRS outcomes, treatment responses were assessed according to KL grade. For all treatment-related outcomes, change from baseline was estimated using baseline-adjusted ANCOVA at each timepoint.

Results: KL 2 participants with baseline mJSW < 3mm comprised 16% (OA-02), 21% (OA-04), 30% (OA-10) and 49% (OA-11). KL 3 participants with baseline mJSW < 3mm comprised 55% (OA-02), 53% (OA-04), 81% (OA-10) and 88% (OA-11) (Figure 1) Beneficial treatment effect of LOR vs. PBO was seen for KL 2 subgroup in OA-04 and OA-10, but not in OA-11. Beneficial treatment effect of LOR was seen only in OA-04 for KL 3 at week 12.

Conclusion: In this post hoc analysis, substantial heterogeneity in baseline mJSWs existed across LOR clinical trials within the KL grade 2-3 inclusion criteria. Participants with less structurally advanced knee OA showed greater pain treatment responses to 0.07 mg LOR compared to those with more advanced disease. These data support the hypothesis that the amount of OA structural damage is associated with the pain of knee OA and that earlier LOR intervention may improve outcomes.

EFFICACY OF DULOXETINE COMPARED TO NONSTEROIDAL ANTI-INFLAMMATORY DRUGS IN THE TREATMENT OF KNEE OSTEOARTHRITIS IN IRAQI KURDISTAN REGION

Keywords: Randomized control trial, Clinical trials, Osteoarthritis

A. Jalal1, N. Albarzini2. 1Kurdistan Board for Medical Specialties, Rheumatology, Erbil, Iraq; 2Hawler Medical University/College of Medicine, Rheumatology, Erbil, Iraq

Background: Osteoarthritis (OA) is the most common degenerative joint disease [1]. Knee OA is an insidious disease related to structural changes in the joint over many years. Duloxetine, a selective serotonin and noradrenaline reuptake inhibitor, seems to be effective in treating neuropathic and chronic pain conditions [8].

Objectives: The objective of this study was to assess the efficacy of duloxetine in comparison to nonsteroidal anti-inflammatory (NSAID) for the reduction of pain in Osteoarthritis.

Methods: A Randomized open labelled clinical trial of a 13-weeks done in Rizgary Teaching and CMC (Consultant Medical City) hospitals in Iraqi Kurdistan Region. From 5th of September 2022 to 2nd of January 2023 with Trial Registration ID (NCT05486028). Those eligible to enter the study were age ≥ 40 years, both genders were included, who will meet the American College of Rheumatology clinical and radiographic criteria for the diagnosis of osteoarthritis of the knee [8]. Patients were divided into two groups. The first group received Duloxetine tablet 30 mg for two weeks then titrated up to 30 mg BID. were compared to control group that received NSAID (nonsteroidal anti-inflammatory drug). End points were recorded at baseline then 2nd visits at 13 weeks. Measurement of pain severity was done by the weekly mean of the 24-h average pain scores in patients with osteoarthritis knee pain by Brief pain inventory (BPI). Another tool is (WOMAC) WESTERN ONTARIO AND MCMASTERS OSTEOARTHRITIS INDEX used for evaluation of pain in knee Osteoarthritis which involve three categories. The Patient Global Impression of Improvement (PGI-I) scale measured patients' perceived change in overall well-being (in response to therapy/treatment) and even side effects.

Results: Out of two hundred participants, forty-six participants were excluded: one hundred fifty-four were enrolled in the study. Their mean ages ±SD (57.38 ± 10.58, 58.47 ±12.03) in Duloxetine, NSAID group respectively. BPI-Severity average pain improved significantly after treatment with Duloxetine were 4.64 (95%CI:4.25 to 5.02) and P value was 0.00. BPI during 24-hour pain interfere with (activity, Mood, walking ability, work, relations with other people, sleep, enjoyment of life) were lower in Duloxetine group after treatment in comparison to control group (NSAID) 4.45 (95% CI:4.01 to 4.87), 5.47 (95%CI:5.11 to 5.82) respectively p value was significant < 0.001. The total WOMAC score after treatment in Duloxetine group decreased 31.74 (95%CI:27.05 to 36.42) while in NSAID groups were 42.46(95%CI:38.05 to 46.86), about (PGI-I) scale, the patients who treated with Duloxetine was much improved, much improved, minimally improved respectively so; total (46.1%) were improved, the p value were significant 0.00 and about adverse effect in Duloxetine group most common side effects were epigastric pain and headache(3.3), with one patient with nausea, one with tremor and one fatigability, the symptoms were mild they continue study with symptomatic treatment of side effects, and 4 in NSAID developed side effect.

Conclusion: Duloxetine reduced pain and improved function in patients with knee osteoarthritis, by reducing BPI inventory and WOMAC score, with much improvement on PGI scales in comparison to NSAID.
THE LONGITUDINAL ASSOCIATION OF HAND OA WITH PAID AND UNPAID WORK IMPAIRMENT AND RELATED COSTS: THE HOSTAS COHORT

Keywords: Patient reported outcomes, Epidemiology, Work-related issues

S. Terpstra1,2, L. A. Van de Stadt1, A. Boonen3, F. Rosendaal2, M. Kloppenburg2,3.
1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center, Clinical Epidemiology, Leiden, Netherlands; 3Maastricht University Medical Center, Rheumatology, Maastricht, Netherlands

Background: Hand osteoarthritis (OA) is associated with impairment in paid and unpaid work and contributes to societal burden and costs of OA. However, the longitudinal development of hand OA-related work impairment and related societal costs are unknown.

Objectives: To investigate the association of hand OA with paid and unpaid work productivity loss, hinder and societal costs longitudinally.

Methods: We used annual data of the Dutch Hand OSTeoArthritis in Secondary care (HOSTAS) cohort, consisting of patients with primary hand OA primary hand OA defined by the treating rheumatologist. Data from baseline to four years of follow-up was used. The Health and Labour Questionnaire (HLQ) was assessed over the last two weeks on (i) hand OA-related limitations and hours of productivity loss while at work, (ii) hours of sick leave, and (iii) limitations and hours of unpaid work replacement. Patients with HLQ data on >1 timepoint were included in this study. Societal costs of paid work productivity loss (=all hourly costs in order to employ a worker, such as salary and premiums) were estimated by multiplying the number of unproductive and sick leave hours due to hand OA by the estimated hourly costs of paid work in The Netherlands based on age and sex. Costs of unpaid work were estimated by multiplying the number of hours of unpaid work replaced by others by the Dutch gross average hourly salary of a household help (2021: €12.50). Costs were adjusted to 2021 values using conversion factors provided by the Dutch government, and to yearly values.

Results: 470 patients had data on more than one timepoint. Baseline data was available for 381 patients, of whom 256 patients (67%) completed four years of follow-up, and 215 (56%) completed all five follow-up moments. Of 256 patients

POS1368 WITHDRAWN
with baseline and four years follow-up, 113 (52%) had paid work at baseline and 104 (41%) at four years (Table 1 for patient characteristics). Unproductive hours at any timepoint were present for 85/470 patients (18%), for whom unproductive hours fluctuated over time (Figure 1). Median paid work hinder score (score range: 6-24) remained stable at 7 (interquartile range [IQR]: 6.8) over the study period. Unproductive hours at any timepoint were present for 85/470 patients (18%). Regarding unpaid work, 105/256 (41%) required unpaid task replacement by others due to hand OA at baseline, which remained stable over time (108/256 at four years (42%)). Unpaid work hinder was reported by 100/256 patients (39%) at baseline and 97/256 (38%) at four years. Costs related to loss of paid and unpaid productivity were incurred at baseline by 136/256 patients, with a median of €63 per patient ([IQR] 38;125) per two weeks (€1630 per patient (978;3261 per year)). At four years, these costs were present for 120/256 patients, with a median of €30 (38;100) per two weeks (€1304 (978;2609) per year).

Conclusion: Patients with hand OA experience significant impairment in paid and unpaid work participation over the years, which translates into substantial societal costs. Impairment and costs fluctuate on individual level but seem to remain stable over four years on group level.

Numbers represent (SD) mean unless otherwise specified. *median (interquartile range). Abbreviations: SD = standard deviation, BMI = Body Mass Index, HADS = Hospital Anxiety and Depression Scale, AUSCAN = Australian Canadian Osteoarthritis Hand Index.

This study aimed to characterize patients with an increase or decrease in pain, and to investigate which patients are likely to achieve a good clinical outcome after four years.

Methods: Four year data from the ongoing HOSTAS (Hand OsteoArthritis in Secondary care) cohort were used, consisting of 538 consecutive patients with primary hand OA diagnosed by their rheumatologist. Hand pain was measured with the pain subscale of the Australian/Canadian hand osteoarthritis index (AUSCAN, range 0-20) annually. Demographics, disease characteristics and patient characteristics were collected, as were the Short Form (SF-36) and Hospital Anxiety and Depression Scale (HADS). Change in pain was categorized as increase, stable or decrease according to the AUSCAN pain minimal clinical important difference (MCID, 1.6) between baseline and year 4. Good clinical outcome was defined as an AUSCAN pain score below the Patient Acceptable Symptom State (PASS) of 8.2 (Bellamy 2015). All patients with measurements at baseline and year 4 (MCID analysis) and at year 4 (PASS analysis) were included. Associations between determinants and change in pain or PASS were investigated using multinomial or binary logistic regression, respectively.

Results: Of 356 patients included in the MCID analysis, 83% were female, mean age was 60.6 years and mean AUSCAN pain score was 9.1. Over 4 years, pain decreased in 137, increased in 106, and 113 remained stable. In the decrease group, mean (SD) change in pain was -4.8 (2.8), in the stable group -0.1 (0.8), and in the increase 3.8 (1.9). Baseline BMI was positively associated with increase in pain. Health-related quality of life (HR-QoL) at baseline was positively associated with decrease in pain. Employment was positively associated with both increase and decrease in pain. HADS scores were negatively associated with decrease in pain (Table 1). Of 361 in the PASS analysis, 155 were below the PASS at baseline, and 177 were below the PASS after 4 years. Patient characteristics and disease characteristics at baseline were not associated with PASS after 4 years. Higher physical HR-QoL and lower pain level at baseline were associated with a higher chance of reaching PASS (data not shown).

Conclusion: Change in pain is associated with BMI, HR-QoL, mental wellbeing and employment status. Good clinical outcome is associated with physical health-related quality of life. These factors can help identify patients likely to achieve good clinical outcome and may aid stratified patient selection for trials.
Objectives: To investigate the association of the Kallman scale with clinical assessment parameters and the erosive subtype in a Czech population of HOA patients over 5 years.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. All patients were evaluated at baseline and follow-up examinations over 2 and 5 years.

Clinical examinations were performed by qualified rheumatologists. The number of clinically tender and swollen joints was recorded. Pain, stiffness, and function were assessed by the Australian/Canadian OSTEoARThritis Hand Index (AUSCAN) hand OA index.

Hand disability was evaluated based on the Algofunctional index. The visual analogue scale (VAS-pain) and the health assessment questionnaire (HAQ) was used for the assessment of pain and function/disability.

Results: Of 54 patients enrolled in this study, 129 subjects (89.3% females; mean age at baseline = 64.6±8.0 years) met the ACR classification criteria for HOA and were followed up over 5 years at the outpatient department of the Institute of Rheumatology in Prague. Out of these patients, 57 were diagnosed with the non-erosive form (87.7% females; mean age at baseline = 63.8±7.7 years) and 72 with the erosive form (90.3% females; mean age at baseline = 65.7±8.1 years), where erosive HOA was defined by at least one interphalangeal joint with radiographic signs of erosion. Firstly, we analysed each examination separately and found that the Kallman scale was significantly increased in patients with the erosive subtype (2.95 ± 3.12-fold, p < 0.001 for all) and associated with age in all examinations (β = 1.27 – 1.57; p < 0.001 for all).

Next, we used generalized additive modelling (GAM) to analyse data collected over five years and discovered the association of the scale with HOA subtypes and age (p < 0.01 for both). GAM also revealed associations of the Kallman scale with Algofunctional index, HAQ and the number of painful joints in all HOA patients (edf = 1, p = 0.041) and patients with non-erosive HOA (edf = 1.7, p = 0.027). Similarly, the scale was associated with the number of clinically swollen joints in all HOA patients (edf = 1, p = 0.041) and patients with non-erosive HOA (edf = 4, p = 0.046). Eventually, Algofunctional index (edf = 1.9, p = 0.02) was associated with the scale only in patients with HOA. Other parameters (e.g., AUSCANs) were insignificant.

Conclusion: Our 5-year longitudinal study revealed the associations of structural progressions with both subtypes and age at each time point. In contrast, functional impairments were associated with the progression only in non-erosive subset and all HOA patients. Further studies in a larger cohort of patients are needed to validate these data.
INNOVATIVE PAIN MANAGEMENT DEVICE USING MILLIMETRE BAND RADIATION: ELECTRONIC-PAIN KILLER. ASSESSMENT IN PATIENTS WITH PERIPHERAL OSTEOARTHRITIS. MONOCENTRIC, PROSPECTIVE, RANDOMISED IN CROSS-OVER DESIGN AND CONTROLLED TRIAL.

Keywords: Randomized control trial, Non-pharmacological interventions, Osteoarthritis

Background: Osteoarthritis (OA) is one of the most common chronic health conditions. Pain is a disabling, it affects about 50% of the world's population. For its management, the different guidelines recommend a combination of non-pharmacological and pharmacological treatments [1]. However, 90% of the patients in the stop osteoarthritis I and II survey believe that they are poorly managed in terms of their OA pain and we currently lack effective means to do so [2].

We propose to assess an innovative medical device (MD) for neuromodulation of pain in patients with peripheral OA. This MD is a wristband and consists of a very low-power millimetre wave transmitter. The application of these waves on the wrist, a highly innervated area, has neuromodulatory effects thanks to the synthesis and release of endorphins and the activation of the parasympathetic system.

Objectives: We conducted a clinical trial to evaluate if the regular use of this MD would reduce the pain felt by the patient as well as his consumption of analgesics and if it would improve quality of life.

Methods: This prospective study was performed between December 2020 and August 2022. Sixty patients with a peripheral OA and a pain score ≥4 on the visual analogic scale (VAS) was included and randomised in one of the two cross-over group. The randomization is stratified on the most painful OA localisation (upper/lower limbs). Patients of group A followed a 3-month period with their conventional treatment (CT) and after they get the device in add on for 3 months. The group B started by using for 3 months the MD added on CT and after they took the wristband. The duration of each session was 40 minutes. The intern memory of the MD allowed to measure this frequency of use. After 7 days of wristband use, a phone call was performed to ensure that patient had no difficulties with the wristband. A follow-up phone call was also made once a month to remind the patient to use wristband, to report data and to collect potential adverse events.

The primary outcome was the difference of pain score between the period with and without the wristband use. The primary outcome was collected on the VAS, analogic scale (VAS) was included and randomised in one of the two cross-over group. The randomization is stratified on the most painful OA localisation (upper/lower limbs). Patients of group A followed a 3-month period with their conventional treatment (CT) and after they get the device in add on for 3 months. The group B started by using for 3 months the MD added on CT and after they took only CT for 3 months. Between the 2 periods, there was a one-month wash-out with only CT. Patients were instructed to perform 1 to 3 sessions/day with the wristband.

The mean age of patients was 65.78±7.2 years old. At baseline all parameters were similar between the two groups except the number of male (group A: 5M; group B: 1M) and the body mass index (group A: 24.29±4.01 kg/m²; group B: 27.80±4.7 kg/m²).

The mean pain score at baseline was 6.17±1.43. For this cross-over study, there were no carryover, no sequence, and no period effect. The two groups difference on the pain score was significant (p<0.05) with a VAS of 4.57±2.0 in the MD group and 5.32±1.77 in the conventional treatment group. The effect size of the MD, calculated with the Cohen’s D formulae, was of 0.42. No serious adverse effect occurred.

Conclusion: We have demonstrated in this world first study the efficacy of this new medical device to reduce peripheral OA pain. Easy to use, discreet and safe, this free drug therapy opens a new field of OA pain treatment.

There was an inverse correlation between hand use and EHOA, confirming that EHOA is rather linked to systemic factors. Risk factors for both EHOA and IHOA were a longer disease duration, a higher aesthetic damage (notably in EHOA). There was an inverse correlation between hand use and EHOA, confirming that EHOA is rather linked to systemic factors.

Background: Osteophytes are common structural sign identified to be associated with knee osteoarthritis (OA) and has been included as a criterion for presence and progression of knee OA.

Objectives: Our aim was to investigate the association of possible tibiofemoral osteophyte with knee- joint-related physical examination in symptomatic knees without radiographically detected joint space narrowing.

Methods: We used the Osteoarthritis Initiative (OAI) open access database (http://www.oai.ucsf.edu), approved by the local institutional review boards. The OAI comprises data of 4,796 men and women aged 45–79 years at baseline. We selected subjects, from the following two sub-cohorts: 1) progression cohort, individuals with symptomatic knee OA (n=1,390); 2) incidence cohort, individuals at risk for knee OA (n=3,284). Crepitus was examined at baseline by placing the palm of the hand over the patella to detect the presence of a continuous grinding sensation during passive knee flexion-extension movement in the supine position. A positive bulge sign was considered as presence of knee joint effusion. We included subjects with no joint space narrowing but no or doubtful osteophyte in either knee at baseline based on fixed-flexion posterior-anterior knee radiographs.

We further required subjects to have answered YES to the following question at baseline: “Do you have knee pain, aching or stiffness for more than half the days of a month during the past 12 months?” We used unconditional logistic regression to evaluate the association between the presence of knee crepitus and/or effusion on physical examination within the OAI.

RESULTS: The relative (ICC coefficient) and absolute (SEM and SRD95) reliability of the LSSWT were 0.95, 0.49, and 1.35 respectively. The Pearson correlation coefficient between the LSSWT and the TUG was 0.69.

Conclusion: The analysis showed that the LSSWT has excellent reliability and high validity in hip OA. The low MCID of the LSSWT (1.35) shows its sensitivity and can be used as a responsive outcome measure of interventions and fall risk. The LSSWT also can be valuable in determining independent transferring ability, admissions, or discharges from/to healthcare/residential facilities.

POS1376 RELIABILITY AND VALIDITY OF THE LIE-TO-STAND-TO-WALK TRANSFER TEST IN HIP OSTEOARTHRITIS

Keywords: Safety, Outcome measures, Osteoarthritis

B. Unver1, K. S. Kacmaz2, V. Karatosun3; 1izmir Katip Celebi University, Physical Therapy and Rehabilitation, Izmir, Turkey; 2dokuz Eylul University, Orthopedics and Traumatology, Izmir, Turkey

Background: Falls represent a major health problem for older adults and often lead to disability and mortality. Each year 30% to 50% of community-dwelling older adults report a fall and almost 75% of falls occur in bedrooms or bathrooms, and 41% of all falls occur during transfers [1,2]. Patients with hip osteoarthritis (OA) have many hip and age-related dysfunctions including muscle weakness, sensory loss, gait and balance deficits, which all increase the risk of falls [3]. Task-specificity has been shown to be a critical factor in the effectiveness of fall-reducing interventions [4]. The Lie-to-Sit-to-Stand-to-Walk Transfer Test (LSSWT) was created to measure complicated transfer abilities in older people [5]. However, the LSSWT’s reliability and validity are not known in patients with hip OA.

Objectives: The aim of this study was to investigate the reliability, validity, and minimal clinically important difference (MCID) of the LSSWT in patients with hip OA.

Methods: Twenty-seven patients with hip OA were included in this study. Patients performed trials for the LSSWT and the Timed up-and-go (TUG) test. Between the trials, patients rested for an hour to prevent fatigue.

RESULTS: The relative (ICC coefficient) and absolute (SEM and SRD95) reliability of the LSSWT were 0.95, 0.49, and 1.35 respectively. The Pearson correlation coefficient between the LSSWT and the TUG was 0.69.

Conclusion: The analysis showed that the LSSWT has excellent reliability and high validity in hip OA. The low MCID of the LSSWT (1.35) shows its sensitivity and can be used as a responsive outcome measure of interventions and fall risk. The LSSWT also can be valuable in determining independent transferring ability, admissions, or discharges from/to healthcare/residential facilities.

DOI: 10.1136/annrheumdis-2023-eular.6170
Background: Lower back pain (LBP) and osteoarthritis (OA) are the most frequent musculoskeletal disorders in the general population significantly impacting patients’ quality of life. An adequate pain management is key. General practitioners (GPs) are the frontline decision-makers in the French primary care system. In France, paracetamol remains a first-line analgesic in LBP and OA, according to the national guidelines. Few data on the real-world paracetamol prescriptions in LBP and OA are available.

Objectives: This observational retrospective cohort study aimed to identify the paracetamol prescription patterns in LBP- and OA-related pain in real-world GP practice.

Methods: Prescription data from IQVIA’s French EMR database with a representative panel of approximately 1,200 GPs. Data collection was systematic, non-interventional, reflecting the daily clinical practice. Patients aged more than 18 years old presenting with LBP- and OA-related pain and receiving a paracetamol prescription during a 12-month consultation period in the majority of the patients in both indications. Paracetamol was prescribed alone (57% LBP, 78% OA). The most frequent associated medications were NSAIDs and grade II analgesics. Treatment discontinuation at Month 1 was the most frequent event (67% LBP and 52% OA). In case of treatment restart, paracetamol was prescribed again in 57% LBP and 81% OA patients. At Month 3, 78% LBP and 71% OA patients discontinued treatment.

Conclusion: Paracetamol remains a pivotal analgesic and is prescribed first-line in the majority of the patients in both indications. Paracetamol is the treatment of the given painful episode, with more than a half of patients discontinuing treatment at Month 1.

Background: Physical activity (PA) is highly recommended in patients with osteoarthritis. Despite the major benefits of PA and exercise, patients with knee osteoarthritis report low level of PA and engage more in sedentary behavior (SB). Understanding the perception of these patients towards exercise is essential to help find better interventions.

Objectives: The Aim of this study is to assess the perception of benefits and barriers towards exercise among patients with knee osteoarthritis and analyze the associated factors.

Methods: This is a cross-sectional study that was conducted from April to September 2022. Patients with knee osteoarthritis were included then classified on the basis of the Kellgren and Lawrence radiograph scale. Socio-demographic and clinical characteristics were collected. Level of PA was assessed using IPAQ-SF. Perceived benefits and barriers towards exercise was assessed using Perceived benefits and barriers to exercise scale (PBBS). Participants were also assessed for anxiety and depression (GAD-7) and (PHQ-9) scales respectively.

Results: A Total of 178 patients were enrolled in the study, with a mean (+SD) age of 58.48 ± 9.9 years, 86.2% of them were females, and 69.1% had comorbidities. Mean (+SD) VAS pain score upon walking was 4.78 ± 2.21. According to the Kellgren and Lawrence classification, 64.4% of the patients had OA grade 2 and 25.6% had grade 3. Mean of Lequesne scale was 9.8 ± 3.8. The mean of PBBS benefits scale was 94.35 ± 20.25. The Mean of PBBS barriers scale was 2701 ± 8.23. Top three ranked perceived benefits to exercise were (Mean ± SD): «Exercise improve my mental health» - 3.53± 0.62, «My disposition is improved with exercise » - 3.48± 0.63 and «Exercise decreases feelings of stress and tension for me » - 3.43± 0.65. Top three ranked perceived barriers to exercise were

Conclusion: In our study, the most highly ranked perceived benefits to exercise reported were items related to physical exertion. Some studies have found similar findings in patients with multiple sclerosis (1) and HIV female patients (2). Pain and handicap related to knee osteoarthritis were not associated with the perception of barriers to PA. The most highly rated perceived benefits to exercise were those related to improvements in mental health. Regular PA have shown to improve mood and fight depression, in addition depression often alter the perception of benefits and barriers to exercise as shown in our study. Screening and treating Depressive disorders is essential to help patient break the cycle.

POS1379 A NOVEL MEASURE OF END-STAGE KNEE OSTEOARTHRITIS REDUCES THE DURATION AND SAMPLE SIZE REQUIRED FOR OBSERVATIONAL STUDIES AND TRIALS

Keywords: Outcome measures, Osteoarthritis, Clinical trials

Z. Salis1, J. Driban2, T. Mcalindon3, A. Sainsbury-Salis4, The University of New South Wales, Centre for Big Data Research in Health, Kensington, Australia; Tufts Medical Center, Division of Rheumatology, Boston, United States of America; The University of Western Australia, School of Human Sciences, Perth, Australia

Background: Total knee replacement (TKR) has been used as an outcome measure in research into the causes and possible treatments for knee osteoarthritis (KOA). However, because KOA progresses slowly, and because TKR has a low incidence, research using TKR as an outcome measure necessitates long duration and/or large sample sizes. Moreover, TKR is influenced by multiple factors (such as education and income) besides the progression of KOA.

Objectives: We defined a novel outcome measure that signifies end-stage KOA (esKOA); and determined whether esKOA was sensitive enough to detect the effect of an exposure that is known to have a modest effect on reducing TKR, namely weight loss.

Methods: A knee was considered to have esKOA if any of the following two conditions were met: 1) moderate, intense, or severe KOA symptoms (i.e., the sum of the pain and disability scores on the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) ≥ 12) and severe radiographic knee osteoarthritis (RKOA), defined as a Kellgren and Lawrence Grade (KLG) of 4; or 2) intense or severe KOA symptoms (i.e., the sum of the pain and disability scores on the WOMAC ≥ 23) and frequent knee pain (i.e., knee pain on most days of one or more months in the past 12 months) and mild or moderate KOA (KLG = 2 or 3).

Results: The observational study included 7107 participants (58.4% female, mean ± SD age and BMI 61.4 ± 8.8 years and 29.2 ± 5.1 kg/m² at baseline, and an incidence of esKOA of 2.9, 6.8, and 10.4% at 1 - 1.25 years, 2 - 2.5 years, and 4 - 5 years, respectively, and a corresponding incidence of TKR of 0.1, 0.5, and 1.6%. While weight loss was associated with a reduced adjusted odds ratio (aOR) for both esKOA and TKR at 4 - 5 years (for 5% weight loss: 0.85 [95% CI 0.79 - 0.92] for esKOA and 0.79 [0.67 - 0.93] for TKR), weight loss was only associated with a reduced aOR for esKOA - and not TKR - at the earlier time point of 2 - 2.5 years (for 5% weight loss: 0.80 [0.72 - 0.90] for esKOA and 1.05 [0.76 - 1.45] for TKR). At 1 - 1.25 years, there was no association between weight loss and esKOA or TKR. The sample size required to detect a 50% reduction in the odds of esKOA was 6% to 13% of the sample size required for that of TKR (1271 participants versus 2186 at 4 - 5 years; 162 versus 1286 at 4 - 5 years). In the emulated trial, compared to the weight gain group (367 participants), the weight loss group (also 367 participants) had significantly lower odds of esKOA but not TKR at 4 - 5 years (0.43 [0.22 - 0.84] for esKOA and 0.39 [0.26 - 1.00] for TKR). There was no difference between the groups in the odds of esKOA or TKR at the earlier time point of 2 - 2.5 years in the emulated trial.

Conclusion: Given that our novel measure of esKOA could detect an association with weight loss at a time point 1.5 - 3 years earlier than TKR in an observational study, and in a sample size that was too small to detect an association with TKR at 4 - 5 years in an emulated trial, esKOA is recommended as a clinical measure for observational studies and trials investigating causes and possible treatments for KOA. Our powerful novel measure of esKOA enables shorter and smaller – hence cheaper – studies, which can boost the research on effective treatments for KOA.

DOI: 10.1136/annrheumdis-2023-eular.452
Background: With total hip arthroplasty (THA) utilization rising rapidly, [1] it is important to understand social determinants of health (SDOH) that contribute to disparities in THA outcomes.

Objectives: We sought to explore the relationship of multiple community-level SDOH with 90-day readmission, 90-day mortality, 1-year revision post-THA, and length of stay (LOS) using prediction modelling.

Methods: Our retrospective study using the Pennsylvania Health Care Cost Containment Council Database included 105,336 patients undergoing THA 2012-2018. Community-level variables include walkability index; median household income; and percent unpaid family workers, without health insurance and not in the labor force, above high school, above college, foreign-born, speaking languages other than English, with computer access, and with internet access. They were extracted from US census via geocoding. We trained explainable boosting machine using Generalized additive models to predict readmission, mortality, LOS, and revision. Resulting mean absolute scores (MAS) were aggregated to measure collective importance of the above “community-factors.”

Results: Predictive performance was best for mortality (AUROC=0.76); it was moderate for readmission (AUROC=0.66), revision (AUROC=0.58), and LOS (RMSE=0.41, R²=0.2). Community factors relatively contributed more to adverse outcomes than in all models. The top 3 predictors of readmission were discharge location, age, and comorbidities (MAS =0.24, 0.15, 0.13, respectively). The top 3 predictors of mortality were community factors, discharge location, and age (MAS=0.31, 0.24, 0.19, respectively). The top 3 predictors of revision were community factors, discharge location, and comorbidities (MAS=0.03, 0.01, 0.005, respectively). Lastly, the top 3 predictors for LOS were discharge location, community factors, and comorbidities.

Conclusion: In all THA outcome models, aggregated community factors were more important than individual race in predicting 90-day readmission, 90-day mortality, 1-year revision, and length of stay.

Clinical cases

POS1381
TRANSIENT PERIVASCULAR INFLAMMATION OF THE CAROTID ARTERY (TIPIC) SYNDROME: A RARE CAUSE OF CAROTIDDYNIE

Keywords: Vasculitis, Ultrasound, Rare/orphan diseases

C. Porpaccy1, C. Zimmermann1, R. Steinbach2, K. Redlich1. 1Klinik Hitzing, 2nd Dept of Medicine, Wien, Austria; 2Klinik Hitzing, Dept of Radiology, Wien, Austria

Background: Carotidynie defines localized, unilateral neck pain in the region of the carotid bifurcation and is a relatively frequent event with a myriad of causes. Differential diagnosis include mainly arterial dissection, large vessel vasculitis or chronic inflammatory or surrounding structures (e.g. lymphadenitis). We herein describe a patient with carotidynie caused by a TIPIC syndrome under follow up by ultrasound imaging.

Methods: The logig S8 from GE2 with 2 different linear probes was used. GE L8-18-D Hockey Stick probe. ML 6-15-D Matrix probe.

Case presentation: A 36 year old male patient was referred to our rheumatological outpatient department because of localized pain in the left lateral part of the neck, which persisted over two days. Swallowing of fluids or solid food was painful, but unimpaired. The patient mentioned no recent trauma, but he reported symptoms of an upper respiratory tract infection, without fever, two weeks before. Clinical investigation showed no signs of local swelling or palpable lymph nodes. ENT consultation ruled out inflammatory processes causing the symptoms including tonsillitis, pharyngitis or laryngitis. Analgesic treatment with tramadol was not effective. Laboratory investigations revealed slightly increased CRP and Erythrocyte Sedimentation Rate (ESR) values. ANA and subsets, as well as ANCA were negative. An ultrasound of the region showed a localized swelling of the media and adventitia of the left common carotid artery, involving half of the circumference over a length of 4 mm. Multiple lymph nodes with signs of inflammation were present on both sides of the vessel. No dissection or stenosis was detectable. Due to a typical clinical presentation and ultrasound appearance without carotid stenosis, typical localization at the distal part of the carotid communis artery the diagnosis of carotidynie or TIPIC was made. Treatment with nonsteroidal antiinflammatory drugs was initiated without any effect. Therefore, we initiated a treatment with steroids (0,3mg/kg body weight). 3 days after the beginning of the therapy the before unbearable pain nearly resolved. A MRA angiography of the vessel performed 5 days after the initiation of the steroid treatment showed an eccentric wall thickening with diameter of 5mm near the bifurcation of the common carotid artery, with a slightly increased enhancement of the carotid wall, but no further inflammatory structures. Awareness of this syndrome and its excellent visualization for diagnosis, exclusion of other pathologies and follow up by high resolution ultrasound could be useful to reassure patients about the benign nature of this syndrome and help the clinician to avoid more invasive imaging modalities.

Conclusion: The disease is first reported by Fay in 1927. Despite only a few case reports are available in the last 20 years and mostly one case only is reported. Usually an inflammatory process is suspected. Although a rare event sonography is capable to diagnose such vessel abnormality with high precision. Treatment with NSAIDs and, if not sufficient, eventually steroids are required.

POS1382
DON'T TURN A BLIND EYE - ANTERIOR CIRCULATION STROKE IN GIANT CELL ARTERITIS

Keywords: Remission, bDMARD, Vasculitis

S. M. Lao1, U. Dhamrah1, W. Chl1. 1Ichacn School of Medicine at Mount Sinai, Rheumatology, New York, United States of America

Background: Giant cell arteritis (GCA) is a form of systemic vasculitis involving large and medium sized vessels. It is more common in women and affects adults greater than 50 years old. Typical presentations include insidious onset of headache, scalp tenderness, jaw claudication, visual changes, and constitutional symptoms. Stroke is an uncommon complication of GCA with an incidence rate of 3% - 7% and usually occurs between the onset of arteritis symptoms and one month after initiating steroid therapy. GCA related strokes usually involve the verteobasilar artery and less commonly the carotid artery.

Objectives: To discuss a patient with GCA progression to strokes despite steroid therapy.

Methods: A 77 year old female with a history of hypertension, diabetes, uterine and breast cancer in remission presented to the hospital with right eye vision loss. She reported two weeks of blurry vision in her right eye, bilateral temporal headache, jaw claudication, weight loss, and loss of appetite. She denied prior similar episodes. Exam revealed scalp and right temporal artery tenderness, right eye vision loss. She had equal radial and brachial pulses, and 5/5 strength in bilateral lower extremities. Labs showed ESR 120 (ESR 0-38mm/hr) and C-reactive protein 62 (CRP 0-5mg/L). Patient was started on intravenous (IV) methylprednisolone 1g daily for presumed GCA, then tapered and discharged on oral methylprednisolone 48mg (1mg/kg) daily. Temporal artery biopsy confirmed GCA showing patchy moderate chronic inflammation in the intima and media with small lymphocytes, macrophages, and rare giant cells. On follow up she continued to have right eye vision loss, but improvement of other GCA symptoms. Within one month of her initial presentation, she returns to the hospital for left sided weakness, facial droop, and dysarthria.

Results: She endorsed compliance with methylprednisolone, aspirin, and atorvastatin. Computed tomography angiography (CTA) showed interval worsening of the severe stenosis of the clinoideal segment of the right internal carotid artery (ICA) now with near occlusion. Labs with ESR 33, CRP 0.02. Exam with 4/5 strength in the left upper extremity (LUE) and left lower extremity (LLE). On hospital day 3, she had fluctuating weakness in the LUE and methylprednisolone was increased to 1g daily. Repeat CTA with stable severe focal stenosis of the right clinoideal ICA. Cerebral angiogram showed multiple vessels in the anterior and posterior circulation with evidence of irregularity in the lumen suggestive of diffuse vasculitis but no evidence of atherosclerosis in the right ICA. On hospital day 6, weakness worsened in the proximal and distal LUE to 1/5 strength and LLE to 3/5 strength. Given concern for GCA progression she was started on IV tocilizumab 6mg/kg and had emergent angiography with right ICA angioplasty. Patient completed 5 days of IV methylprednisolone 1g and was tapered and discharged on methylprednisolone 48mg daily and tocilizumab 162mg subcutaneous weekly.

POS1383
ANTI-TIF-1-Y DERMATOMYOSITIS IN OVERLAP WITH GREAT VESSEL VASCULITIS: A CASE REPORT

Keywords: Vasculitis, Myositis

F D'Allesandro1, F. Fattorini1, L. Carl1, M. Cazzato1, M. Mosca1. 1Santa Chiara Hospital, Rheumatology, Pisa, Italy

Background: Dermatomyositis (DM) is systemic autoimmune diseases that are part of idiopathic inflammatory myopathies. The peak incidence is at the age of 50–60 years. The DM-related autoantibodies Anti-TIF-1-Y are found in DM associated with aggressive skin lesions. However, in adults above the age of 40, anti-TIF-1-Y antibodies are strongly associated with malignancy [1].

Objectives: The aim of the work is to illustrate a difficult management of anti-TIF-1-Y dermatomyositis in overlap with great vessel vasculitis.

Methods: In January 2022 a 77-year-old woman suffering only from arterial hypertension was beginning to develop retropalpebral and occipital rash, initially interpreted as an allergic reaction to an antihypertensive drug and treated with antihistamines without clinical benefit. Over the following weeks rhinolalia, mixed dysphagia, and Gottron’s papules developed simultaneously. She performed a laryngoscopy excluding a deficit of the vocal cords. In the suspicion of esophageal diverticulosis performed X-ray with gastrografin, showing no alterations of the esophagus, but thickened from the occlusion related to a major decresive episode and antidepressant therapy was initiated. In May 2022 worsening of muscle symptoms led the patient to go to the hospital again, with subsequent transfer to our rheumatological department. She was cachectic, dysphagic, with hypotension (MTM 35/80) and skin rash typical for DM. Therefore, some investigations were ordered, showing:

- High titer positivity for anti-TIF1-Y, PL-12, SSA-Ro52
- Significant retention in the oro-pharyngeal region at swallowing study
Methods: with a thematic content that is effective for the care of their disease and the reach for patients in any country in Latin America and the Caribbean and to have a greater reach for the entire population.

Background: Research Institute, Bogotá, Colombia to respect the criteria of social inclusion, which is a fundamental principle of the social intervention times in each session. The total estimated training time for the patient went from 22 months to be carried out in a period between 8 months and 1 year, considering that it will be the patient who will decide the number of sessions they want to see per day. In December 2022, an event for patients with Rheumatoid Arthritis was held and a demo of the platform was presented. The official launch of this digital educational program will be in the third quarter of 2023 and the training of 600 patients is expected this year.

1University of Bari, Rheumatology Unit - Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy; 2Royal Wolverhampton Hospitals NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom; 3City Hospital, Sandwell and West Birmingham Hospitals NHS Trust, Department of Rheumatology, Birmingham, United Kingdom; 4The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Centre for Musculoskeletal Research, School of Biological Sciences, Manchester, United Kingdom; 5Sanjay Gandhi Postgraduate institute of medical sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; 6Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinik Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; 7The Digital Rheumatology Network, Working Group, Lausanne, Switzerland; 8University Hospital Lausanne (CHUV), Switzerland, Department of Rheumatology, Lausanne, Switzerland

Background: Artificial Intelligence (AI) is emerging as a promising tool to improve clinical decision-making and enhancing patient care. In rheumatology, AI may enable precision medicine, allowing patient profiling, prediction and treatment personalization [1]. Healthcare professionals’ (HPs’) perceptions regarding implementation of AI in rheumatology have been not investigated sufficiently so far. Objectives: This international e-survey aimed to evaluate healthcare professionals’ attitudes towards AI’s potential benefits in managing patients with rheumatic diseases.

Methods: Artificial intelligence approaches in rheumatology - design for the future of patient education: design for a web platform for education in rheumatoid arthritis

Keywords: Education, Patient information and education, Patient reported outcomes

G. S. Rodríguez-Vargas1, F. Rodríguez2, N. Pinto-Flores3, L. Reale4, A. Rojas-Villarraga5, P. Santos-Moreno6. 1BIOMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia; 2BIOMAB - Center for Rheumatoid Arthritis, Patients Education, Bogotá, Colombia; 3Universitar, Expert Patient, Bogotá, Colombia; 4Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia

Background: In 2018, a multi-component educational program called Universitar was launched. This program was aimed at patients diagnosed with Rheumatoid Arthritis. In the process of training the patients, topics such as clinimetry, comprehensive treatment of the disease, healthy lifestyles, and the enhancement of personal and interaction skills were included. After 3 years of implementation of this program, the certification of 91 expert patients in rheumatoid arthritis was achieved. However, there is a major challenge for health education to have a greater reach for the entire population.

Objectives: The objective of this study is to design a digital education platform, with reach for patients in any country in Latin America and the Caribbean and with a thematic content that is effective for the care of their disease and the improvement of their quality of life.

Methods: A review and digital adaptation of the 3 educational levels of Universitar was made. It was considered feasible to maintain the 3 levels of education to respect the criteria of social inclusion, which is a fundamental principle of the multi-component educational program (Level 1: Basic Knowledge of the Disease Program, Level 2: Patient Empowerment Program for Effective Self-Management of the Disease and Level 3: Expert Patient Program). Contents were updated, the total training time was reduced and evaluation and measurement criteria were added for each educational level. A total of 104 educational sessions were reviewed, as well as the measurements included in the training process in aspects such as: the level of disease activity, autonomy and independence, quality of life and satisfaction with the educational program.

Results: The multi-component educational program was reconstructed, reducing the educational program from 104 to 84 educational sessions and minimizing the academic intervention times in each session. The total estimated training time for the patient went from 22 months to be carried out in a period between 8 months and 1 year, considering that it will be the patient who will decide the number of sessions they want to see per day. In December 2022, an event for patients with Rheumatoid Arthritis was held and a demo of the platform was presented. The official launch of this digital educational program will be in the third quarter of 2023 and the training of 600 patients is expected this year.
characteristics of participants and their trust in machine learning and AI (Figure 1, panel A, expressed as a boolean variable).

**Results:** Fifty-nine HPs (male n=36/58 respondents, 37.93%, 1 skipped) of mean age (±SD) 37.55 ± 10.12 years at a mean of 12.33 ± 10.54 years since graduation were considered for the analysis. Fifty-two out of 59 (88.14%), the largest part working in University Hospitals (45/58, 77.59%, 1 skipped). Thirty-seven out of 59 (62.71%) declared an open attitude in adopting machine learning tools for clinical prediction modelling for rheumatoid arthritis patients (Figure 1, Panel B).

More than half of the respondents were interested in a prediction horizon of ≥1 year (33/59, 55.93%, Figure 1 Panel C). The vast majority (51/59, 86.44%) liked having an AI-powered clinical prediction embedded in EHRs, preferring disease activity scores as the target outcome (54/59, 91.53%). Consistently, most of the participants considered that clustering algorithms assigning patients to phenotypes have room in clinical practice, (45/59, 76.27%) especially in treatments selection (46/58, 79.31%, 1 skipped) and early arthritis management (37/59, 63.79%).

Computer vision algorithms were considered of particular interest for the detection of erosions (39/59, 66.1%). Most of the participants agreed that machine learning could be beneficial to extract information from EHR (52/58, 89.66%). In particular, NLP was seen as a tool for capturing longitudinal changes among critical patient outcomes (36/58, 62.07%, 1 skipped). In general about an half of respondents (33/58, 56.90%), considered machine learning-based prediction as more powerful than conventional statistics in terms of clinical predictive modelling, especially for the potential of providing more sensitive analysis (39/57, 68.42%). Neither age, gender, and time from degree were associated with trust in machine learning.

**Conclusion:** The participants of this international survey showed an open and optimistic attitude regarding AI implementation in clinical rheumatology. Expectations were mainly centered on improving patient management by allowing for accurate mid-to-long term prognosis.

**HPR Interdisciplinary research**

**POST1386-HPR EFFECTIVENESS OF SUBCUTANEOUS METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS PERSISTENCE IN THE LONG TERM**

**Background:** Methotrexate (MTX) has been established as the headstone of treatment for rheumatoid arthritis (RA). However, many patients treated with oral MTX experience adverse events. For this reason, new forms have been developed, such as the subcutaneous presentation in a prefilled syringe, which improve tolerance, adherence and response to treatment.

**Objectives:** The aim of this study is to describe the effectiveness of treatment with subcutaneous MTX (SC MTX) in a prefilled syringe in a reference center for the management of patients with RA and the persistence of treatment during 5 years of follow-up.

**Methods:** Retrospective observational cohort study (1-Jan-2018 and 31-Dec-2022) in patients with RA, with more than one year of treatment with MTX SC; Patients <12 months with MTX SC and those who had concomitant biological therapies were excluded. Response to treatment was analyzed by DAS28.

**Results:** 1062 patients treated with MTX SC were analyzed. At the time of analysis, 877 patients persisted in treatment and 185 abandoned due to adverse events (17.4%). 190 received it as monotherapy, 285 in combination with other conventional DMARDs, 184 with a corticosteroid, and 218 with cDMARDs and a corticosteroid. 368 (42%) started therapy due to intolerance to the oral form of MTX, 259 (29.5%) to optimize the dose, 114 (13%) 10 mg and 234 (26.7%) 15 mg, while 509 patients (58%) did so to optimize the dose, 259 (29.5%) with 20 mg and 25 (28.5%) with 25 mg. At one year of follow-up, there was an increase in the number of patients who achieved low disease activity [573 (65.3%) remission and 139 (15.85%) low activity] and there was a decrease in patients with moderate activity and high (Figure 1). Of the 877 patients, 27.6% have remained in treatment between 12 and 24 months, 18.8% between 25 and 36, 19% between 37 and 48, and 34.5% for more than 48 months. Over the 5 years, a gradual increase in the percentage of patients achieving low disease activity is observed (Figure 2).

HPR Measuring health (development and measurement properties of PROs, tests, devices)

POS1387-HPR THE IMPACT OF PSYCHOEMOTIONAL MOOD DISORDERS ON MUSCULOSKELETAL PAIN IN PATIENTS WITH INFLAMMATORY JOINT DISEASES

Keywords: Pain, Prognostic factors, Quality of life

Background: Chronic inflammatory joint diseases such as rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) are among the most common rheumatic diseases that may cause musculoskeletal pain [1]. The genesis of pain is very complex and many different mechanisms are involved. It is the result of multiple biochemical reactions and is influenced by various degrees by biological, physiological and social factors. (2) The presence of pain is largely determined by the inflammatory activity of the underlying disease, but subjective factors that depend on the psycho-emotional state of the patient who is involved in the assessment of the severity of pain symptoms [3].

Objectives: The aim of the study is to assess the intensity of musculoskeletal pain - arthralgia and myalgia and its correlation with anxiety and depressive mood disorders among a Bulgarian cohort of patients with chronic inflammatory diseases.

Methods: A single-center, observational study including patients with RA, AS and PsA, discharged in the Rheumatology clinic, “St. Marina” UMBAL - Varna. All the patients were diagnosed according to the criteria for the specific inflammatory joint disease and were treated with a biological medication. Visual analogue scales (VAS) to assess pain intensity (muscular and joint) and Zung self-report scales for depression (SDS) and anxiety (SAS) were used. Laboratory acute phase indicators were used to find out which factors were most likely to be linked to CS.

Results: 130 patients with inflammatory joint disease (RA, AS, PsA) were included in the study. The average age of the study population was 56.37 years (from 21-76 years). 41.5% (n=54) of them were women, 58.5% (n=76) were men. No significant differences were found in evaluating the visual-analog scales for assessing joint and muscle pain between men and women (p=0.177 for joint pain and p=0.717 for muscular pain). On the other hand women scored higher on the anxiety and depression scales, and the difference was again significant (p=0.001 for the depression scale and p=0.001 for the anxiety scale). The self-assessment on the depression scale (SDS) shows a significant correlation with the self-assessment of muscle and joint pain, but the self-reported anxiety scale (SAS) showed a significant correlation only with the self-reported joint pain (SDS and VASm, p<0.008; SDS and VASa, p<0.001; SAS and VASm, p=0.031, SAS and VASa, p=0.004 respectively). Inflammatory indicators (predictors) determine about 8% of the variation of the two pain indicators - for joint pain - R square 7.8%, for muscle pain - R square 8.1%.

Conclusion: Musculoskeletal pain is one of the most common clinical presentations of inflammatory joint diseases. Chronic pain can lead to mood disorder. The intensity of the pain correlates with anxiety and depressive symptoms in these patients.

POS3388-HPR RELATIONSHIP BETWEEN CENTRAL SENSITIZATION AND PSYCHOLOGICAL FACTORS IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL, MULTICENTER STUDY

Keywords: Rheumatoid arthritis, Quality of life. Patient reported outcomes

Background: Affective distress (clinically significant depression, anxiety and stress) and central sensitization (CS) are consistently associated with the reported severity and quality of pain, physical disability, poor treatment outcomes, and inflammatory disease activity, and potentially with early mortality in rheumatoid arthritis (RA).

Objectives: We aimed to explore affective distress in patients with RA and determine how they connected to CS.

Methods: Used the CSI to measure CS and the Depression, Anxiety and Stress Scale - 21 Items (DASS-21) to evaluate the negative emotional states of depression, anxiety and stress. The total CSI score ranges from 0 to 150, a score of 40 or greater has been established to indicate CS. Each of the three DASS-21 scales contains 7 items, divided into subscales with similar content. Multiple regression analysis was used to find out which factors were most likely to be linked to CS.

Results: Overall we included 192 RA patients (age ranging from 22 to 86 years) with a mean disease duration of 5.95 (SD 13.75) years. The CSI score was ≥ 40 in 70/192 patients (36%). For the DASS-21 total score, a CI of 0.58 was obtained. The total DASS-21 score ranges from 0 to 210, a score of 40 or greater has been established to indicate CS. Each of the three DASS-21 scales contains 7 items, divided into subscales with similar content. Multiple regression analysis was used to find out which factors were most likely to be linked to CS.

Conclusion: Affective distress (clinically significant depression, anxiety and stress) and CS are common in RA patients. Screening and recognition of such psychosocial disorders may help patients achieve optimal disease control and a good outcome. Overall, our findings have implications for health policy and emphasize the significance of identifying high-risk fibromyalgia (FM) patients by monitoring CS as an indicator of severe disease.

HPR Epidemiology and public health (including prevention)

POS1389-HPR  AGE-SUBSET INCIDENCE AND PREVALENCE ANALYSIS OF JUVENILE SYSTEMIC SCLEROSIS IN THE UNITED STATES

Keywords: Real-world evidence, Systemic sclerosis, Epidemiology

J. Mattson1, H. Bao2, M. Flack3, K. Coeytaux3, 1Boehringer Ingelheim Pharmaceuticals Inc., Clinical Development Medical Affairs, Connecticut, United States of America; 2Boehringer Ingelheim Pharmaceuticals Inc., Global Epidemiology and RWE Center of Excellence, Connecticut, United States of America; 3Boehringer Ingelheim Pharmaceuticals Inc., Medicine, Inflammation, Connecticut, United States of America

Background: Juvenile systemic sclerosis (jSSc) is an extremely rare orphan disease. To date, there is very limited published data regarding incidence and prevalence of jSSc. Specifically, there are no published data on jSSc incidence rates by age group and only one Canadian report of jSSc prevalence rates by age group. These data are important given the significant developmental differences between age subsets.

Objectives: To evaluate jSSc age-subset incidence and prevalence using U.S. administrative claims data.

Methods: Children <18 years old with medical claims for SSC and who received methotrexate, mycophenolate mofetil, or cyclophosphamide at a pediatric age (<18 years old) were identified from the OPTUM Clininformatics claims database 2007-2021. jSSc patients were identified using ≥2 medical claims (710.1, 517.2 and 692.8 for ICD-9-CM codes and M34, M34.x for ICD-10-CM codes) for SSc on different dates within a 1-year period. Incidence and prevalence were estimated overall, by age group, and were age and sex adjusted using 2020 US census data. Both incidence and prevalence rates increased with age. Specifically, there are no published data on jSSc incidence rates by age group and only one Canadian report of jSSc prevalence rates by age group. These data are important given the significant developmental differences between age subsets.

Conclusion: jSSc is an extremely rare disease with incidence and prevalence rates increasing with age. Specifically, incidence and prevalence rates vary dramatically for different age subsets, with increasing rates at 10 years and older. To our knowledge, this is the first study to estimate jSSc incidence and prevalence rates by age group.

POS1390-HPR  HEALTH PROFILE AND QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A BRAZILIAN CITIZENS SURVEY

Keywords: Epidemiology, Systemic lupus erythematosus, Quality of life

P. Santana1, L. M. B. De Souza1, M. Antunes1, M. Pinheiro1, A. Cruz1, P. Januario1, A. Pasqual Marques1, 1University of São Paulo, Department of Physical Therapy, Audiology and Speech Pathology and Occupational Therapy, Medical School at University of São Paulo,., Sao Paulo, Brazil

Background: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory disease, multisystemic, of unknown cause, autoimmune, with periods of exacerbations and remissions, which may generate limitations in functional and occupational capacity. Brazil has high prevalence rates of SLE (20 to 150 cases per 100,000 inhabitants). The survival rate of these patients has increased in the last century (from 50% to 95%). This context raises questions about the social, health, and quality of life profile of the patient.

Objectives: To profile and evaluate the quality of life of patients with SLE residing in Brazil.

Methods: This is a cross-sectional study, in subjects aged ≥18 years, diagnosed with SLE and residing in Brazil. We applied online form through Google Forms and collected sociodemographic (age, sex, marital status, years of study, occupational activity, and self-reported race), clinical (Body Mass Index (BMI), duration of disease, presence of comorbidities and use of corticosteroids) and quality of life data through the Systemic Lupus Erythematosus Quality of Life (SLEQOL). Data analysis was descriptive (mean, sample standard deviation, and percentage).

Results: 642 volunteers were female (98.29%), aged between 18 and 73 years, and BMI of 27.3 ± 4.58. Greater representation from the Southeast region (60.12%); self-reported white race (54.98%); married marital status (39.88%), education with ≥12 years of schooling (64.64%), have already withdrawn from occupational activity (74.92%) and changed profession after SLE diagnosis (37.85%). The duration of SLE was ≥5 years (45.64%) and they have other diagnosed comorbidities (63.24%), and they use corticoid (62.62%). Quality of life had a score of 137.72 ± 51.89, closer to the minimum score (minimum score = 40 and maximum = 280; whereby, higher values correspond to worse quality of life).

Conclusion: Most of the sample is female as are already pointed out in other studies; the most recurrent self-reported race was white, unlike studies that the Afro-descendant race was more frequent. Throughout their illness, patients encounter physical, psychological, and social challenges, reflecting on their functional capacity, interfering with occupational activity (leaves of absence and sometimes changing professions) even with education ≥12 years of study. These changes can interfere with health-related quality of life. Care strategies aimed at decreasing the impact of the disease for the patient and his family are needed; as

POS1390-HPR  LUPUS NEPHRITIS PROFILE IN TUNISIAN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Keywords: Systemic lupus erythematosus, Autoantibodies, Clinical trials

M. Cherichi1, Y. Bousoukaya1, M. Elghali2, N. Sakhy2, M. Jiguirim3, S. Hammami1, 1Fattouma Bourguiba University Hospital, Internal Medicine Department, Monastir, Tunisia; 2Fattouma Bourguiba University Hospital, Immunology Laboratory Department, Monastir, Tunisia; 3Fattouma Bourguiba University Hospital, Rheumatology Department, Monastir, Tunisia

Background: Lupus Nephritis (LN) is associated with morbidity and worse survival and its clinical, the immunological and the follow-up profile varies between studies due to race and ethnicities differences. Previous studies have evaluated clinical and immunological factors associated with LN. Only few studies were done in the north African region.

Objectives: To define clinical, immunological and treatment differences according to the presence of lupus nephritis (LN) in Tunisian Systemic Lupus Erythematosus (SLE) patients.

Methods: We studied SLE 141 patients. A clinical examination and a laboratory evaluation were performed in all SLE patients at the onset of the disease.

Results: Of all patients, 26.24% presented LN. The mean age of patients with LN was lower than patients without LN (34.3 ± 14.61 years vs 40.46 ± 14.94 years). LN was associated with pleural effusion, pericarditis, higher SLEDAI score, higher levels of creatinine and proteinuria, lower rate of glomerular filtration, anemia, leukopenia, thrombocytopenia, necessity of immunosuppressive drugs, antibodies such as anti-dsDNA, anti-Sm, anti-Sm/RNP and anti-SSA/La. In terms of renal histopathological findings, when we combined class IV and V (proliferative nephritis), we found that this form was more prevalent (56.8%) and associated with higher rate of proteinuria, C-reactive protein and necessity of immunosuppressive drugs.

Conclusions: The north African studies in the term of Lupus Nephritis are scarce. Nonetheless, severe forms seem to be frequent with a high prevalence of proliferative nephritis in our study. Pleural effusion, anti-dsDNA positivity, leukopenia and thrombocytopenia are the predictive factors to develop LN.

HPR Interventions (educational, physical, social and psychological)

POS1392-HPR1 EFFECTS OF DIGITAL-BASED HIGH-INTENSITY TRAINING INTERVENTION IN INDIVIDUALS WITH AXIAL SPONDYLOARTHRITIS – A RANDOMIZED CONTROLLED PILOT STUDY (RCT)

Keywords: Spondyloarthritis, Non-pharmacological interventions

A. Torell1, M. C. Olsson2, Å. Andersson2, K. Malm3, I. Åberg2, E. Wiking2, E. Haglund2,4,5. 1Angelholm Hospital, Dept. of Rehabilitation, Angelholm, Sweden; 2Halmstad University Dept. of Environmental and Biociences, School of Business, Innovation and Sustainability, Halmstad, Sweden; 3Capio Movement, Dept. of Rheumatology, Halmstad, Sweden; 4Lund University Dept. of Clinical Sciences, Section of Rheumatology, Lund, Sweden; 5Spenshults Research and Development Centre, Halmstad, Sweden

Background: Physical exercise is an important treatment for individuals with axial spondyloarthritis (axSpA). Although high-intensity training (HIT) has been shown to reduce disease symptoms and risk of comorbidities without exacerbating disease activity (1), compliance tends to decrease over time. Increased knowledge is needed on how to optimize and tailor individual exercise programs for continued regular exercising and improved health.

Objectives: To study the effects of HIT on aerobic capacity, body composition, disease activity, physical function, health status and fatigue in individuals with axSpA after a 12-week intervention supported by digital coaching.

Methods: Twenty-two individuals (women, n=12), recruited from two rheumatology clinics in southern Sweden, were randomized to a HIT intervention group (HG, n=11) or a control group (CG, n=11). The HG completed three HIT sessions per week, including two interval training sessions (4x4 min), in self-selected activities for 12 weeks. The individuals in the HG were individually coached and had regular support from a physical therapist primarily by digital coaching. The CG continued exercising as usual. Assessment of aerobic capacity (VO2max), body composition (BMMI and visceral fat area [cm2]), disease activity (CRP [μg/ml], BASDAI, 0-10 worst-best), physical function (BASFI, 0-10 best-worst), health status (EQ5D, 0-1 worst-best, ASAS health index [ASAS-HI], 0-17 best-worst), and fatigue (fatigue severity scale [FFS], 0-7 best-worst) were sampled at baseline and after 12 weeks. Mean and standard deviation (SD) were used for descriptive statistics. Repeated measures analysis of variance (ANOVA) was used to investigate effect of group (HG/CG) and time (PRE*POST), with a post-hoc analysis using t-tests when ANOVA indicated a significant difference in main effects or interactions. A significance level of p<0.05 was used. Fisher’s exact test was used to study the effects over time for CRP (as dichotomized variable, > or < 4 μg/ml).

Results: Results presented are part of an ongoing RCT based on 19 individuals (women n=11) that have completed the 12-week follow-up analyses. The participants mean (SD) age was 48 (10) years, BMI 25 (4), VO2max 37 (6) mlO2/kg/min, and BASDAI 2.6 (0.3). No differences were present between the HG (n=9) and the CG group (n=10) at baseline for the studied variables. After 12 weeks of HIT an ANOVA interaction (p<0.05) showed that HG increased their VO2max (6.4 [3.6] mlO2/kg/min; p<0.001) but CD did not. For BMI, visceral fat area, disease activity (BASDAI), physical function (BASFI), fatigue (FFS) no differences in main effects or interactions were found (p>0.05). Health status (EQ5D) showed an ANOVA time main effect (p<0.001) where the HG increased their health status [0.10 [0.06] units; p=0.02] after 12 weeks, but CG did not. For health status measured with ASAS-HI no differences between groups were found. For dichotomized CRP values no differences were found in either of the group’s pre-post.

Conclusion: This pilot RCT shows that after 12 weeks of digital-based HIT intervention, the HG increased their aerobic capacity and EQ5D health status compared to CG, while body composition, disease activity, physical function, and fatigue did not show any significant differences between the groups.

POS1393-HPR1 THE INTERVENTION OF AN EXPERT PATIENTS GROUP IN RHEUMATOID ARTHRITIS IN AN INTEGRAL HEALTH MANAGEMENT MODEL

Keywords: Rheumatoid arthritis, Self-management, Patient information and education

P. Rodriguez1, G. S. Rodriguez-Vargas2, N. Pinto-Florez3, L. Reape3, P. Rodriguez-Linare3, A. Rojas-Villegas4, P. Santos-Moreno2. 1BIOMAB, Patients Education, Bogotá, Colombia; 2BIOMAB, Scientific Direction, Bogotá, Colombia; 3Universar, Expert Patient, Bogotá, Colombia; 4Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia

Background: Education for patients is a powerful tool that allows them to participate more efficiently in the relationship with their medical teams and to generate high adherence to their therapy. However, there is a high possibility of establishing lasting relationships between medical teams and patients thanks to the intermediation of expert patients. An expert patient is a person who has received education for the care of their health condition, the improvement of the relationship with their medical team and has been trained to educate, guide and support other patients who have the same health condition.

Objectives: The objective of this study is to implement a participation model that integrates expert patients into healthcare teams so that they can help other patients to learn about the benefits of a correct relationship between doctor and patient and to be more adherent to their treatment, becoming thus in a support axis in the medical care model.

Methods: After the training and certification of 50 expert patients in Rheumatoid Arthritis, a review of the literature was carried out to demonstrate intervention strategies in which expert patients have leadership roles and are integrated into comprehensive medical care models. Then, the patients received training dedicated to: knowledge of the health care model, the algorithm used for the intervention of the interdisciplinary team, the importance of therapeutic adherence in the treatment of a chronic disease, dimension and the characterization of patients, to determine a treatment by objectives (Treat to Target Strategy). Finally, expert patients were trained so that they can establish effective communication strategies with other patients in real time.

Results: The intervention will be carried out in groups between 2 and 3 patients and they will be able to interact with other patients in the medical center in a group or individual way. Expert patients will exchange experiences, conduct literature, and provide feedback to the medical team and other relevant information (see Figure 1). Likewise, a data collection will be carried out in each interaction to determine through a qualitative study the impact of the support of the expert patients. The duration of each day of intervention will be 6 hours, which denotes a reach of 72 patients per day and an impact on nearly 1,400 patients who come to the medical center per month.

publication date: 05/18/23

Figure 1: Introduction method of expert patients in core model

Keywords: Education for patients, Rheumatoid arthritis, Expert Patient, Bogotá, Colombia; Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia

Background: Education for patients is a powerful tool that allows them to participate more efficiently in the relationship with their medical teams and to generate high adherence to their therapy. However, there is a high possibility of establishing lasting relationships between medical teams and patients thanks to the intermediation of expert patients. An expert patient is a person who has received education for the care of their health condition, the improvement of the relationship with their medical team and has been trained to educate, guide and support other patients who have the same health condition.

Then, the patients received training dedicated to: knowledge of the health care model, the algorithm used for the intervention of the interdisciplinary team, the importance of therapeutic adherence in the treatment of a chronic disease, dimension and the characterization of patients, to determine a treatment by objectives (Treat to Target Strategy). Finally, expert patients were trained so that they can establish effective communication strategies with other patients in real time.

Results: The intervention will be carried out in groups between 2 and 3 patients and they will be able to interact with other patients in the medical center in a group or individual way. Expert patients will exchange experiences, conduct literature, and provide feedback to the medical team and other relevant information (see Figure 1). Likewise, a data collection will be carried out in each interaction to determine through a qualitative study the impact of the support of the expert patients. The duration of each day of intervention will be 6 hours, which denotes a reach of 72 patients per day and an impact on nearly 1,400 patients who come to the medical center per month.

Figure 1: Introduction method of expert patients in care model
Conclusion: It is important to create strategies that allow the education of patients towards therapeutic adherence and integrate them into healthcare teams, since the inclusion of expert patients in medical care models can generate high impacts on the doctor-patient relationship and improve the degrees of adherence in the population, thanks to the relationship between peers that will lead to a better understanding of the role of patients in their treatment.

Methods: Sixty patients with SSc (Female: 86.67%) completed three questionnaires: TEI Questionnaire Short-Form (TEIQue-SF); Short-Form Health Survey (SF-36); and demographic characteristics. A series of multiple linear regression models were used to analyze the data with dependent variables (DV) every dimension of SF-36 (Physical Functioning, Role-Physical, Bodily Pain, General Health, Vitality, Social Functioning, Role-Emotional, Mental Health) and independent variables TEI total and every TEI factor (Well-being, Self-control, Emotionality, Sociability).

Results: The average age of participants was 56.4±13.4 years and the mean disease duration was 7.7±7.5 years. TEI total was found to affect both physical and mental component summaries (p<0.001) and all 8 dimensions of the HRQoL (p<0.001). Well-being appeared to have a positive effect on Role-Physical, General Health, Vitality, Social Functioning and Mental Health. Self-control appeared to influence Physical Functioning and Pain, and Emotionality appeared to influence Role-Emotional. Sociability was not an important factor for any dimension of HRQoL (Table 1).

Conclusion: Understanding the relationship between TEI and HRQoL dimensions is important for the support and empowerment of SSc patients, as well as the establishment and implementation of appropriate psychotherapeutic interventions.

Perception Illness Score (BPIS). It consists of 9 items: 8 quantitative questions on a numerical scale ranging from 0 to 10, and one last item in the form of a qualitative question. The total score varies from 0 to 90, without predefined thresholds. The higher the score, the more threatening the patient’s perception of the disease is. The significance threshold was set at a p value of 0.05.

**Results:** Our study included 80 patients (G1: N= 40 and G2: N=40), 76 women and 4 men, with an average age of 59±9 years [42-77] in G1 and 53±10 years in G2 [37-74]. The mean disease duration was 15±6.24 years. RA was erosive in 90% of cases. Rheumatoid factor and/or ACPA were positive in 85% of cases. The mean delay between fibromyalgia and RA diagnosis was 49±7 months. Seventy-five percent of patients were on corticosteroids with an average dose of 10 mg per day of Prednisone equivalent. All patients were receiving a DMARD: methotrexate 85%, leflunomide 11.2%, and biologics 37.5%. The mean VAS pain was 6.3±1.8 cm in G1, and 5±1.1 cm in G2. The mean VAS fatigue was 6±2.3 cm in G1, and 4±0.9 cm in G2. The mean global patient assessment was 5.9±2 in G1, and 5±1.1 cm in G2. The mean DAS_28 ESR was 5±0.7 in G1, and 3±0.5 in G2. The mean morning stiffness duration was 30 minutes in G1, and 4±1.9 cm in G2. The mean BPIS was 71±9 in G1 vs 55±7.5 in G2 (p=0.05).

**Conclusion:** Our study showed that fibromyalgia aggravates catastrophizing and illness perception in patients with RA. It is important to remind the place of cognitive therapy in the management of these chronic conditions.

**SHARED DECISION MAKING ON SUBCUTANEOUS METHOTREXATE OPTIONS FOR RHEUMATOID ARTHRITIS PATIENTS, WHAT DOES THIS LOOK LIKE FOR PATIENTS AND HEALTHCARE PROFESSIONALS?**

**Keywords:** Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Best practices

**L. West**1, J. Painter2, H. Smith1, A. Davies1, F. Brown2, P. Liverrmore3, G. Zabate1, C. Jacklin1, A. Kent1. Nordic Pharma, - Reading, United Kingdom; 2Royal Wolverhampton Hospital Trust, Rheumatology Dept, Wolverhampton, United Kingdom; 3University Hospital Sussex, Rheumatology Dept., Brighton, United Kingdom; 4Cardiff & Vale University Hospitals, Pharmacy Dept., Cardiff, United Kingdom; 5Noah's Ark Hospital, University Hospital Wales, Paediatric Unit, Cardiff, United Kingdom; 6Great Ormond St Children's Hospital, Rheumatology and Clinical Academic Dept., London, United Kingdom; 7NHS Lothian, Rheumatology Dept., Edinburgh, United Kingdom; 8Clinical Director, National Rheumatoid Arthritis Society, - Berkshire, United Kingdom; 9Salisbury NHS Foundation Trust, Rheumatology Dept, Salisbury, United Kingdom

**Background:** Methotrexate (MTX) is the most commonly used rheumatoid arthritis (RA) drug and will often be the first drug prescribed to treat RA [1]. Enhanced bioavailability of subcutaneous (SC) administration of MTX and improved tolerability compared to oral MTX may make this route of administration preferable to the oral route in certain patients [2]. RA patients with ‘dexterity’ issues have physical challenges impacting their ability to use their SC MTX device, therefore making the need to offer choice of device to the individual patient to suit their needs important. Single device policy within hospitals is a major issue as it results in an inability for health care professionals (HCP) to offer a choice, deliver shared decision making and limits the ability to provide optimal disease management [3].

**Objectives:** The aims of this study were to quantify the cohort of UK RA patients with impairments affecting their ability to self-administer SC MTX, to explore whether such patients are treated any differently or experience inequity of care with impairments affecting their ability to self-administer SC MTX, to explore whether such patients are treated any differently or experience inequity of care, and to identify the challenges facing prescribers and patients of only having one device available for RA patients.

**Methods:** A 30-minute computer-assisted telephone interview (CATI) was performed during 15 May-24 June 2022. Twenty-nine UK HCPs (22 rheumatology nurses and 7 consultant rheumatologists) were included. CATI included questions categorised in 4 sections including how to choose a device and importance of patient choice (8 questions), impairment symptoms (7 questions), impairment management (5 questions), and challenges and progression (4 questions). Data was further validated using a virtual expert panel meeting with another group of HCPs working within rheumatology on 11 June 2022.

**Results:** 31% of HCPs feel there are significant challenges for some patients using a SC device specifically, those with reduced hand function or with active or significant disease, which results in being unable to self-inject leading to non-adherence to treatment. It was estimated that 23% of RA patients have impairment (mostly reduced manual dexterity) impacting their ability to self-administer. HCPs feel patients with impairments have different needs which are mostly identified during the patient assessment or device observation. 90% of HCPs stated they rely on patients telling them of any issues, however patients do not always raise their challenges with their device to their HCP. 90% of HCPs defined patient choice in terms of facilitating patients to make an informed decision. 83% of HCPs mentioned ability to use a device as the most important factor for choosing a device. 73% of hospitals only have one SC MTX device available. The current perception of ‘one device fits all’ is inconsistent with the Royal College of Nursing guidelines on SC MTX and the NHS Long Term Plan (regarding patient choice) [3].

Background: Systemic sclerosis (SSc) severely limits one’s ability to participate in paid employment, which may threaten an individual’s economic, social, physical, or mental well-being. No programs and very little resources exist to help people with SSc remain in the workforce despite the high prevalence of work disability. The few programs that do exist were developed for persons with other rheumatic conditions. One evidence-based program, Making it WorkTM (MIW), has the potential to be adapted to meet the specific work related problems faced by people with SSc.

Objectives: This study identified challenges in the work environment and supports received or desired by persons with SSc as a preliminary step to identify adaptations that could make the MIWTM more relevant to people with SSc.

Methods: Participants were recruited through virtual communication from the National Scleroderma Foundation and word of mouth to participate in one 2-hour virtual focus group. Participants were >18 years of age, currently employed or stopped work in the past 5 years, United States residents, English-speaking, and self-reported a diagnosis of SSc and that SSc affected their work ability. Participants were first asked about difficulties working with SSc. The facilitator created a list of challenges based on initial discussion, then participants identified the top five most challenging aspects according to their needs. Participants were then asked about supports received or desired to help maintain employment. Focus group notes and transcripts were analyzed to determine challenges and supports that must be addressed in an employment intervention for people with SSc.

Results: The sample included 14 participants (85.7% women, mean age 48.6±10.1 years, mean disease duration 7.7±7.4 years; 78.6% had diffuse SSc). 71.4% had college degrees and 71.4% were employed full time; 42.9% described their jobs as having mostly mental demands while 57.1% had both physical and mental demands. Important challenges prioritized by the most participants were: 1) challenges with physical tasks, particularly related to hand use [11, 78.6%]--“My hands are pretty messed up; typing is a challenge”; 2) fatigue [9, 64.3%]--“When you say fatigue, people are like, ‘Well, go take a power nap,’ but that’s not what it is; I could sleep 12-hours and still be exhausted”; 3) mental and emotional health, related to coping with how the unpredictability of SSc affects the body, identity, and employment [8, 57.1%];--“This disease does not just knock us down one time or challenge us on one level. It’s like one body system after another.” 4) You have to deal with the issues of your self-esteem, feeling like you’re different than everybody else, mourning that loss of ability or career or work ethic that you had prior to your diagnosis. Participants identified a variety of individualized strategies that enabled them to overcome challenges with SSc at work, including ways to plan ahead, adaptive equipment, and strategies to adapt job tasks. However, participants emphasized that in order to use these tools, it is most helpful to: 1) have the knowledge and advocacy skills to know what to ask for; 2) feel confident that asking for support or accommodations in the workplace will lead to a beneficial change, and 3) be able to problem solve with others (e.g., clinicians, work-related program, therapists, support group).

Conclusion: This study identified the prominent barriers and supports to employment from the perspectives of patients with SSc. While there is some overlap with issues reported by persons with other rheumatic conditions, there are also SSc-specific concerns. This information will be used to adapt the MIWTM intervention, and warrants further consideration for how to incorporate better supports.

ONLINE SCHOOL AS A METHOD OF INCREASING THE MEDICAL LITERACY OF PATIENTS WITH RHEUMATIC DISEASES

Keywords: Patient information and education

A. Nurmamedov1, N. Shuvalova2, S. Lezhnina2, E. Guryanova3, 1Mary Central Clinic, Department Internal Diseases, Mary Turkmenistan; 2Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation; 3Chuvash State University by I. N. Ulianov, Department of Healthcare Management and Economics, Cheboksary, Russian Federation

Background: Today, most of the population of Kazakhstan has access to the Internet. Due to this fact, the use of online schools for patients with rheumatic diseases seems to be a promising direction [1,2].

Objectives: The purpose of the study is to analyze whether online rheumatology schools can be used as one of the methods to improve the medical literacy of patients with rheumatic diseases.

Methods: A survey was conducted with 90 patients in the city of Astana attending an online school on RH from September 2021 to September 2022 after graduation. The online questionnaire included 20 questions (part A and part B). The questions in part A concerned the age of patients, gender, bad habits, heredity, sources of information about the school, and the desire to study at an online school. In part B, the questions concerned the novelty and quality of the information received. Patients had to choose one/several of the presented answers as a response. In some questions, a differentiated assessment was used on a 5-point scale, where 0 points is the minimum, and 5 is the maximum positive assessment. The lecture course consisted of 36 lectures and 6 practical exercises on rheumatic diseases. The questionnaire data were processed in Statistical Analysis Software15.0. Statistical significance was handled using Analysis of variance. Results: Part A. The number of patients under the age of 30 was 9 (10%), 31-40 years old - 41 (45.6%) respondents, 41-50 years old - 12 (13.3%) respondents, 51-60 years old - 17 (18.9%) respondents, over 60 years old - 11 (12.2%) respondents. 75 (83.3%) patients were women, 26 (28.8%) patients had bad habits. 17 patients (18.8%) knew about rheumatic diseases FROM relatives. Most of the participants received information about the online school from the clinic staff - 42 (46.7%) or FROM the clinic website - 27 (30.0%), from other sources - 21 (23.3%) respondents. 72 (80%) respondents noted their desire to attend such classes in the future. These data indicates on the interest of respondents of different age groups in improving the level of medical literacy in rheumatic diseases. Part B. 77 (85.5%) and 82 (91.1%) respondents learned about new risk factors for RD (the role of infection and stress), respectively. 39 (43.3%) patients understood the need to correct their lifestyle. A total of 26 (28.8%) respondents realized that they could independently control treatment. 92% of respondents rated the quality of the information received by the maximum score.

Conclusion: The online school can be used as one of the methods to improve the medical literacy of patients with rheumatic diseases.

ONLINE SCHOOL AS A METHOD OF INCREASING THE MEDICAL LITERACY OF PATIENTS WITH RHEUMATIC DISEASES

Keywords: Rheumatoid arthritis, Spondyloarthritis, Patient reported outcomes

G. I. Kinkiki1, N. B. Karaca1, S. Szezer2, B. Kelesgjo3, G. Kinkiki1, 1Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Department of Musculoskeletal Rehabilitation, Ankara, Turkey; 2Ankara Training and Research Hospital, Department of Rheumatology, Ankara, Turkey; 3Dyupak Yildirim Beyazıt Training and Research Hospital, Department of Rheumatology, Ankara, Turkey; 4Ankara University, Faculty of Medicine, Department of Rheumatology, Ankara, Turkey

Background: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are among the most common chronic diseases (joint) conditions. RA and AS are different types of arthritis. Living with RA or AS can significantly affect your quality of life, mental health, and emotional well-being.

Objectives: We report the preliminary results of an ongoing prospective observational study that compare the body awareness, physical activity, kinesiophobia, pain catastrophizing, and psychosocial status in individuals with rheumatoid arthritis and ankylosing spondylitis.

Keywords: Rheumatoid arthritis, Spondyloarthritis, Patient reported outcomes

DOI: 10.1007/s11882-018-0814-6
significantly more physically active compared to individuals with RA (p<0.005). Body awareness, kinesiophobia, pain catastrophizing and psychosocial status were similar between groups (p>0.05). In addition, disease activity was moderately correlated with body awareness, pain catastrophizing and kinesiophobia (p<0.05). Body awareness, kinesiophobia, pain catastrophizing and kinesiophobia in individuals with AS

**Conclusion:**
Treatment of RA and AS is similar, but there are key differences. According to our results, individuals with AS is more physically active than individuals with RA regardless of disease duration and disease activity. Health professionals can also focus on correlation between disease activity and higher body awareness, pain catastrophizing and kinesiophobia in individuals with AS.

**Methods:**
YASLE were recruited from two Lupus clinics in Toronto and Winnipeg. Semi-structured qualitative interviews were conducted individually via secure video conferencing. As this study was conducted during the coronavirus pandemic, participants were also asked about the pandemic impacts on their education experiences. All interviews were transcribed verbatim, double-coded and analysed using a reflexive thematic approach.

**Results:**
Twelve participants (2 males), 9 of childhood- and 3 adult-onset SLE (cSLE, aSLE) were interviewed. Nine participants (82%) were >25 years old. Five also worked while studying. Five were Asians, 5 were White, 2 of other ethnicities. Half have severe disease (central nervous system or renal involvement). Median duration of disease was 4.0 (25%-75% percentile, 1.8-5.3) years. The impacts of SLE on their education experience emerged in 5 themes:

1. Challenges imposed by SLE: Difficulties adjusting to the diagnosis, physical and cognitive symptoms of SLE. While most participants disclosed their diagnosis to their schools, some expressed hesitation.
2. Changes in aspirations: Education/career goals were modified by reducing course load or shifting to more sedentary or less cognitively demanding careers.
3. Coping and acceptance: More adaptive than maladaptive coping strategies were used to manage their SLE, including self-acceptance, pacing, planning and avoidance. All strived to do well in their studies despite SLE and were hopeful for their futures.
4. Facilitating factors for education success: Family and friends’ social support, individualized accommodations from school and parental financial support were identified.
5. Pandemic impacts: Virtual learning and flexible schedules enabled participants to adapt their schedules according to their physical conditions (e.g. pain, fatigue). However, fewer opportunities to interact in-person were viewed as challenges. Participants want hybrid options to continue even after the pandemic.

**Conclusion:** SLE affected students’ performance through physical symptoms, fatigue and cognitive dysfunction. Ongoing social and school supports help to support them. Maintaining the remote learning options may increase accessibility for them. These results identified opportunities for developing future supportive interventions for YASLE patients in their schooling which then better prepare them for future employment.

**REFERENCES:**
included in the study. mSASSS progression was defined as at least 2 units in mSASSS score increase on radiographs taken at least two years apart. An increase in mSASSS score and/or the development of new syndesmophyte was considered as radiographic progression.

Results: Age, age at diagnosis, symptoms duration and education level were significantly different between the patients with BMI<30 and BMI≥30. BASDAI, C-reactive protein and erythrocyte sedimentation rates were similar between groups. BasFI, BASMI, fasting blood glucose, triglyceride, total cholesterol, low-density lipoprotein levels and aspartate aminotransferase values measured in the same period were significantly higher in axSpA patients with BMI≥30. While baseline total and lumbar vertebral sMSSS scores were similar between the groups, cervical sMSSS scores were significantly higher in the BMI≥30 group. In our study group baseline BMI was positively correlated with radiographic progression (r=0.201; P<0.005) and the development of new syndesmophyte (r=0.134; P<0.05).

Conclusion: The results of this study showed that BMI was associated with both baseline and the progression of structural damage in axSpA patients. The effect of high BMI on structural damage may be related to mechanical factors. However, BMI was found to be associated with cervical, but not lumbar syndesmophytes at baseline. These findings might be the results of increase in proinflammatory cytokines such as TNF-alfa and IL-6 and the reduction of anti-inflammatory cytokines such as IL-10 and adiponectin secreted from dysfunctional adipose tissue.

LONGITUDINAL PILOT-STUDY EXPLORING CHANGES IN EDUCATIONAL NEED AMONG PATIENTS WITH NEWLY DIAGNOSED AAV USING ENAT

Keywords: Vasculitis, Patient information and education

S. Brolin1,2, I. Gunnarsson1,2, S. Pettersson1,2,1 Karolinska University Hospital, Department of Rheumatology, Stockholm, Sweden; 2Karolinska Institutet, Medicine, Stockholm, Sweden

Background: Previous studies have shown that disease duration associate with an increased need of educational support in ANCA associated vasculitis (AAV) [1]. Shorter disease duration showed to significantly increase educational needs although not yet investigated whether the disease duration or time itself is the deciding factor. Longitudinal studies using the Educational Needs Assessment Tools (ENAT) are in general scarce.

Objective: The aim of this pilot study was to explore how educational needs changes over two years among newly diagnosed patients with AAV using ENAT.

Methods: This pilot study included longitudinal data from the Rheumatology and Nephrology clinics at the Karolinska University Hospital in Sweden during 2009-2022. Inclusion criteria were being diagnosed with AAV (GPA, MPA and EGPA), minimum age of 18 years and literate in Swedish. Exclusion criteria was cognitive impairment interfering with literate capabilities. Disease activity was estimated using Birmingham Vasculitis Activity Score version 3 (BVAS). Educational needs were captured by patients' answers to the ENAT questionnaire at baseline and after 24 months. The ENAT consists of 39 questions, presented as total ENAT and seven domains (managing pain, movement, feelings, disease process, treatment, self-management and, support) each containing 4-7 items. Item answers ranging from ‘not at all important’ = 0, to ‘extremely important’ = 3.

Paired samples t-test was used to compare means between the two timepoints.

Results: 17 individuals (47% men) with GPA (n=15) and MPA (n=2) completed the questionnaire. At baseline mean age was 51 years, ranging from 20-66, and mean years of education 14.6. Mean disease duration at baseline was 0.2 years. All but three were newly diagnosed at baseline and 3 was diagnosed the year before inclusion. All individuals had an active disease, with a mean BVAS of 15.2, range 1-25. The mean total ENAT score decreased from 83.5 at baseline to 72.6 at 24 months (p=0.04) (Table 1). Change in individuals total ENAT scores ranged from +10 to -73. Educational needs decreased within two of the seven domains, ‘Self-help measures’ 15.4-12.9 (p=0.03) with individual score change ranging from +5 to -13 and ‘Treatment’ 16.8-12.1 (p=0.005) with individual score change ranging from +7 to -21 (Graph 1). Domains indicating lower educational needs at baseline were still low after 2 years. Over time the domain with highest educational needs shifted from ‘Self-help measures’ at baseline to ‘Disease process’ at follow-up.

Conclusion: This pilot study demonstrates that patients newly diagnosed with AAV expressed high educational needs at baseline compared to previous studies on both patients with established and newly diagnosed AAV [1]. The educational need decreased over time in total and within two of the domains but was still high after 24 months. Our findings point to the fact that patients need continuous educational support during the first years of diagnosis. To further explore patterns and clusters of changes in educational needs more data is needed, including data on what and how information and patient education is received.

Graph 1. Domain ‘treatments’ range 0-23 and ‘Self-help measures’ range 0-18 at baseline and after 24 months.

SLE, Sjöns’s and APS - aetiology, pathogenesis and animal models

Keywords: Systemic lupus erythematosus, Diet and nutrition, Cardiovascular disease

V. Orefice¹, F. Ceccarelli², C. Barbati¹, G. Buoncuore¹, C. Alessandri¹, C. Pirone¹, F. Conti¹.¹ - Lupus Clinic, Reumatologia, Dipartimento di Scienze Cliniche Internistiche Anestesiologiche e Cardiovascolari, Sapienza Università di Roma, Roma, Italy

Background: Circulating endothelial progenitor cells (EPCs) are widely demonstrated biomarkers of endothelial function. Their frequency and function varied in systemic lupus erythematosus (SLE) patients, with a significant association with subclinical atherosclerosis [1]. Caffeine, one of the most widely consumed products in the world, seems to improve endothelial cells number and EPCs migration in coronary artery disease both in mouse models and in patients [2]. We recently demonstrated the impact of caffeine on SLE disease activity status, in terms of SLE Disease Activity Index 2000 (SLEDAI-2K) values and serum cytokine levels [3].

Objectives: The aim of this study was to evaluate the possible role of caffeine intake on endothelial function in SLE patients, by assessing its effect on number and function of EPCs both ex vivo in SLE patients and in vitro in healthy donors (HD) treated with SLE sera.

Methods: We performed a cross-sectional study enrolling SLE patients, excluding patients with history of traditional cardiovascular risks factors. Caffeine intake was evaluated using a 7-day food frequency questionnaire. At the end of questionnaire filling blood samples were collected from each patient to assess circulating EPC percentage. EPCs were detected by using a flow cytometry analysis defined as KDR CD34 double positive cells. Subsequently, EPCs pooled from HD were co-cultured with caffeine at 0.5 mM and 1 mM with and without SLE sera. After 7 days, we evaluated the cells morphology and the ability to form colonies; moreover, we analyzed for the percentage of annexin V-positive (AV) apoptotic cells by flow cytometry analysis and for levels of autophagy and apoptotic markers LC3-II, p62 and Bcl2 by western blot, alone or in the presence of protease lysosomal inhibitors E64d and Pepstatin A. Finally, we performed a WB analysis to assess the A2AR/SIRT3/AMPK pathway.

Results: We enrolled 31 SLE patients (F:M 30:1, median age 43 years, IQR 18; median disease duration 144 months, IQR 180). We found a EPCs median percentage of 0.03% (IQR 0.04) observing a positive correlation between caffeine intake and circulating EPCs percentage (p=0.03, r=0.4). Moving on in vitro experiments, HD EPCs treated with SLE sera and caffeine showed an improvement in morphology and number of EPCs-CFU in comparison with those incubated without caffeine (p=0.0003). The colonies treated with SLE sera were poorly organized in comparison with HD: the addition of caffeine restored the colony structure. After treating HD-EPCs with SLE sera we observed an increase in AV positive cells and p62 values and a reduction of LC3-II and Bcl2 values; the addition of caffeine was able to significantly reduce AV positive cells and p62 values and to significantly increased LC3-II and Bcl2 values, without any significant differences between caffeine 0.5 mM and 1 mM (Figure 1-A-D). After E64d and pepstatin A treatment, both LC3II and p62 trend didn't change, compared to untreated cells. Finally, we observed after caffeine treatment, in comparison with SLE sera alone, a significantly reduction in A2AR levels leading to an increase in protein levels of SIRT3 and subsequently AMPK phosphorylation (Figure 1-E-G).

Conclusion: We demonstrated, for the first time, a protective role of caffeine on endothelial function in SLE patients. Caffeine intake positively correlated with the percentage of circulating EPCs in SLE patients; moreover, caffeine in vitro treatment was able to improve EPCs survival and vitality through the induction of apoptosis and the promotion of autophagy via A2AR/SIRT3/AMPK pathway.

**Background:** Pulmonary arterial hypertension (PAH) is one of the most important complications that seriously threatens the prognosis of patients with systemic lupus erythematosus (SLE), with complicated and unclear pathogenesis.

**Objectives:** Based on genomic studies and functional experiments, we aim to investigate candidate biomarkers and targeted therapy for the early diagnosis and timely treatment of SLE-PAH patients.

**METHODS:**
1. In order to screen susceptible genes of SLE-PAH, a number of 150 peripheral blood from SLE-PAH patients were subject to whole-exome sequencing (WES), and genome-wide association study (GWAS) was performed by comparing with 934 healthy controls.
2. The transcriptional expression levels on peripheral blood of SLE-PAH patients were examined by RT-qPCR to further evaluate the possible pathogenesis of the above screened genes.
3. Intervention experiments on human pulmonary artery endothelial cells (hPAEC) were performed to figure out the potential pathogenesis of the selected gene in vitro. RNA-seq and gene ontology were applied to identify the downstream pathways.

4. Established by pristane injection and hypoxia induction, SLE-PAH mice model was used to evaluate the pathogenicity and therapeutic value of selected gene. Pulmonary arterial pressure (PAP) was measured by right heart catheterization after tail-intravenous injection of therapeutic vectors.

**RESULTS:**
1. The tumor necrosis factor receptor-associated factor 5 (TRAF5) was identified as a susceptible gene of SLE-PAH based on WES and GWAS.
2. The significant reductions of TRAF5 on transcriptional level in peripheral blood of SLE-PAH patients were identified, indicating clinical diagnosis values.
3. Knockdown of TRAF5 significantly increased early apoptosis of hPAEC and triggered the pathogenesis of PAH through distinct pathways.

**Conclusion:** Lack of TRAF5 triggers the pathogenesis of PAH in SLE patients through inducing hPAEC abnormality. It is a susceptible gene of SLE-PAH and could be a candidate marker for diagnosis and therapy for SLE-PAH patients.
Background: Sex hormones have effects on the development, progression and severity of SLE, prevalently affecting women (F:M=9:1). The neuroprotective, neurotrophic and anti-inflammatory properties of a class of progesterone-derived NeuroActive Steroids (NASs), prompted numerous investigations about the potential of these GABAA receptor allosteric modulators. However, no data about NASs on neuropsychiatric SLE (NPSLE) are available.

Objectives: This exploratory pilot study aims to delve into a new unexplored landscape by assessing circulating NASs levels in NPSLE patients.

Methods: A cohort of 16 SLE patients without NP manifestations and 16 with new onset NP diffuse symptoms was enrolled. Mood disorders and cognitive dysfunction were defined according to the Center for Epidemiologic Studies Depression Scale (CES-D) and a battery of neuropsychological tests, respectively, interpreted by a neuropsychologist. A group of 8 healthy controls were measured by ELISA assay, as listed: Progesterone, Dieldroepiandrosterone (DHEA), Dieldroepiandrosterone-Sulphate (DHEA-S), Allopregnanolone. To appreciate differences between groups, women's fertile or menopausal subgroups were formed and p-value <0.05 has been set.

Results: Table 1 reports on data from the whole cohort. Progesterone levels in fertile women were significantly higher in the NPSLE versus HCs group (p=0.011). The Progesterone-direct metabolite, Allopregnanolone, was significantly increased in NPSLE compared to both groups of fertile SLE (p=0.026) and HCs females (p=0.027). Inversely, low levels of DHEA and DHEA-S in SLE patients versus HCs (p=0.025 and p=0.005) were found. Looking for NP symptoms, DHEA titer inversely correlates with cognitive deficit diagnosis (p=0.04), while depression diagnosis (62.5% of NPSLE cohort) correlates with Allopregnanolone levels (p=0.042). Moreover, depression severity measured by the CES-D score correlates with Progesterone (r=0.550, p=0.041) and Allopregnanolone (r=0.712, p=0.004; Figure 1). At multivariate analysis after correction for age, disease duration, SLEDAI and SDI, Allopregnanolone confirmed its independent correlation (β=0.712, p=0.004) with depression severity.

Conclusion: In this pilot study, we describe for the first time the unbalanced levels of circulating NASs in NPSLE patients with new onset neuropsychiatric diffuse manifestations. Moreover, in NPSLE patients, the diagnosis of cognitive deficit associates with circulating DHEA low levels and that of depression associates with Allopregnanolone high levels, significantly correlated also with the severity of this manifestation. Since the appropriate NASs balance is needed for optimal brain and neuro-immune function, our preliminary observations - that needs to be validated in larger studies - suggest a potential therapeutic role of these hormones in neuropsychiatric lupus.

Background: Systemic lupus erythematosus (SLE) is a severe multisystem disease, notably heterogeneous in terms of clinical course and therapeutic response, which converts it into a significant challenge at the diagnostic and treatment levels.

Objectives: This study investigated the serum proteomic and metabolomic profiles of SLE, in order to identify new mechanisms underlying relevant clinical patterns.

Methods: Proteomic and metabolomic approaches were used to assess the serum levels of 184 inflammation and organ damage-related proteins [by proximity extension immunoassay (PEA, Olink)] and 250 metabolic markers [by nuclear magnetic resonance (NMR) covering glycolysis metabolites, amino acids and 130 lipid measures (NMR, Nighntingale)] in consecutive SLE patients (n = 133) and age-matched healthy donors (HD) (n = 27). In parallel, an extensive clinical and analytical profile of recruited subjects was performed to evaluate the contribution of molecular profiles to the disease severity, unsupervised clustering analyses were developed.

Results: Thirty-six proteins related to inflammation and organ damage, and 17 metabolites were coordinately altered in the serum of SLE patients in relation to HD. Unsupervised clustering analyses differentiated 2 patient clusters (C1 and C2) presenting different proteomic profiles. Clinically, although no differences were found in terms of age or disease duration, patients belonging to C2 were characterized by a significantly higher status of disease activity (SLEDAI > 6) and prevalence of positivity for anti-ENA and anti-dsDNA antibodies than patients belonging to C2, along with a preponderance of patients with biopsy diagnosed lupus nephritis (LN), abnormal creatinine and proteinuria. Besides, this cluster comprised SLE patients with higher CV risk, revealed by an elevated incidence of atheroma plaques, dyslipidemia, and hypertension. Statistical analysis between clusters revealed 67 serum proteins deregulated, among which C1

Figure 1. Median value of NASs circulating levels on NPSLE/SLE/HCs fertile and menopausal female. *p-value ≤ 0.05; **p-value ≤ 0.01

displayed elevated well-recognized inflammatory cytokines and regulatory proteins of leukocyte activity ([IFN, IL, CSF-1, LIF-R, MCP-1, MCP-4, CCL, CXCL, MMP, PDL, 4E-BP1]), accompanied by proteins involved in renal damage (KIM1, LAT2, NPPC, ERBBBIP). Regarding metabolomic profile, comparative analysis between proteome clusters characterized increased levels of proatherogenic VLDL and LDL lipoprotein subsets in C1, and reduced levels of anti-atherogenic HDL lipoproteins subsets, total cholesterol, ketone bodies (acetate) and glycolysis related metabolites (lactate). Interestingly, statistically analyses showed that proteins and metabolites markers correlated significantly, suggesting potential interconnections related to different aspects of lupus pathology.

Conclusion: The present study showed a multi-omics landscape identifying molecular patterns that distinguished patients with high disease activity and lupus nephropathy, including several novel candidate proteins and metabolites markers. The study of the specific role and suitability of these mediators as SLE biomarkers would provide insights for the management of this complex autoimmune disorder.

Figure 1.
Methods: Punch biopsies were obtained from lesional skin from 6 patients with CLE and 5 patients with DM. Healthy or unaffected skin from 6 individuals was used as control material. Laser capture microdissection was used to isolate 1,000,000μm² of tissue within the LE and DM dermal inflammatory infiltrates or control dermis. The samples were analyzed by nano-LC tandem mass spectrometry. Qiagen Ingenuity pathway analysis was performed based on the obtained proteomic database, and identified canonical pathways were compared between CLE, DM, and controls.

Results: Comparing CLE vs controls we identified 246 pathways, while 51 of them were enriched (threshold p<0.05). Comparing DM vs controls 200 pathways were identified, while 72 were enriched. Canonical pathways enriched in both CLE and DM were those involved in antigen presentation, protein ubiquitination, acute phase response, interferon signaling, tRNA charging, and B cell development. Analysis of CLE vs DM showed 237 pathways, 70 of which were enriched (p<0.05). The top differentially enriched canonical pathways in CLE compared to DM included EIF2 signaling, complement system, LXR/RXR and FXR/RXR activation, acute phase response signaling, mTOR and granzyme A signaling, clathrin mediated endocytosis signaling, and coagulation system.

Conclusion: Canonical pathways enriched in both CLE and DM skin are associated with activation of innate and adaptive immune systems, including the interferon system. A major difference between CLE and DM was that the EIF2 pathway, involved in cellular stress and induction of cell death, was enriched in CLE. Enriched granzyme A signaling indicates cytotoxic T lymphocyte activity in CLE, which is in line with that the top differentially upregulated cytokine in CLE in the proteomics was IL-16 (1), as CD8 T lymphocytes are well-described expressors of IL-16. Further, results indicate differentially activated metabolic pathways and deposition of complement and coagulation components in CLE dermal infiltrate.

understanding of underlying disease mechanisms using a holistic and multiparametric approach is needed to improve current therapeutics.

**Objectives:** We aim to use a high-dimensional approach to characterise and compare immune signatures of adult-onset and childhood-onset SLE patients, as well as compare their immunological profiles with age-matched healthy controls. In the process, we hope to study the roles of B and T cells in SLE to better understand the adaptive immune response.

**Methods:** Peripheral blood mononuclear cells from adult-onset and childhood-onset SLE patients underwent mass cytometry. The adult-onset SLE group consists of 50 SLE donors (median age: 40 years) and 25 age-matched healthy subjects. The childhood-onset SLE group consists of 30 SLE (53, 14 years) and 17 age-matched healthy subjects. Data was analysed and visualized using the Extended Polydimensional Immunome Characterisation (EPIC) machine learning platform [2]. Normalization and FlowSOM clustering were performed with 43 functionally and phenotypically important immune markers. Mann Whitney U test identified significantly different cluster frequencies.

**Results:** Unsupervised analysis revealed multiple significant differences (p<0.05) between the adult-onset and childhood-onset SLE immunomes. Of note, an activated CD11c+TbetCD21+ B cell subset was significantly enriched in childhood-onset SLE (median: 0.42%, interquartile range 0.16-0.72%) versus adult-onset SLE (0.15%; 0.09-0.31%; p<0.001). These age-associated B cell subsets (ABCs) increase in prevalence with age and presence of autoimmune disease. A significant increase in childhood-onset SLE may offer us insights into the differences with adult-onset SLE; the former group tends to have more active disease over time. Transitional B cells (CD24CD38+) were also significantly increased in childhood-onset SLE (0.91%; 0.41-1.84%) compared to their adult counterparts (0.3%; 0.043-0.65%; p<0.001). In the T cell compartment, an activated CD45RA+CD21+ subset was expanded in childhood-onset SLE (0.41%; 0.23-0.68%) compared to adult-onset SLE (0.19%; 0.1-0.38%; p<0.001). CD21+ plays a key role in B cell activation and this cell subset is therefore of mechanistic interest. Another CD8CD45RA+BAFF+ T cell subset was enriched in adult-onset (1.95%; 1.24-2.86%) versus childhood-onset SLE (0.88%; 0.45-1.37%; p<0.001). B-cell activating factor (BAFF) supports autoreactive B cell survival in autoimmune disease and an anti-BAFF drug (belimumab) is FDA-approved for SLE. Despite increasing use of belimumab, not all patients respond equally, so BAFF inhibition alone may not adequately alter disease activity.

**Conclusion:** With a multiparametric unbiased approach comparing adult and paediatric SLE patients, we identified cell subsets that may be of immunopathologic pathways to facilitate improvements in SLE theragnostics.

**PRECLINICAL EVIDENCE FOR THE GLUCOCORTICOID-SPARING POTENTIAL OF A DUAL TLR7/8 INHIBITOR IN AUTOIMMUNE DISEASES**

**Keywords:** Tapering, Cytokines and chemokines, Systemic lupus erythematosus

**A. Deshmukh1, A. Pereira1, N. Geraci1, E. Zvetkovic1, M. Przetak1, M. Catalina1, E. F. Morand1, A. Bender1, B. Vaidyanathan1. 1EMD Serono Research & Development Institute, Inc., an affiliate of Merck KGaA, Research Unit – Neuroscience & Immunology, Billerica, United States of America; 2Monash University; School of Clinical Sciences at Monash Health, Melbourne, Australia

**Background:** Toll-like receptor 7 (TLR7) and TLR8 are single-stranded RNA-sensing endosomal pattern recognition receptors that evolved to defend against viral infections, however their dysregulation and activation by endogenous ligands has been implicated in autoimmune diseases including lupus. While glucocorticoids (GC) are effective, they have many undesirable effects that limit their use. In addition, resistance to GC, which was recently shown to be imparted by TLR activation and Type I interferon (IFN), is a major challenge for the treatment of patients with autoimmune diseases including lupus. New treatment approaches that allow for the use of lower doses of GC would be highly beneficial.

**Objectives:** To evaluate the GC-sparing effects of a dual TLR7 and TLR8 inhibitor (TLR7/8i).

**Methods:** Human peripheral blood mononuclear cells (PBMCs) from healthy donors were treated with TLR7/8i, dexamethasone, or both. Cytokine production was measured using an AlphaLISA immunosassay, gene expression was analyzed by NanoString and single-cell RNA sequencing, and effects on protein markers were evaluated by flow cytometry. In addition, the efficacy of combined TLR7/8i and dexamethasone treatment was evaluated in the MRL/lpr mouse model of lupus.

**Results:** Studies in human PBMCs revealed synergistic effects of TLR7/8i and GC on inflammatory cytokine production resulting in increased GC potency in the presence of TLR7/8i (Figure 1A), an effect that was most pronounced in myeloid cells, especially monocytes (Figure 1B). Gene expression analysis revealed that the combination of TLR7/8i plus GC substantially impacted myeloid cell clusters, particularly modules for IFN and GC response genes, as well as nuclear factor-kappa B-regulated cytokines. Treatment with TLR7/8i and GC in vivo was more efficacious than either agent alone, as evidenced by reduced proteinuria (Figure 1C) and improved survival.

**Conclusion:** These results demonstrate that TLR7/8 inhibition increases the potency of GC by alleviating TLR activation-dependent GC resistance in a cell type-specific manner. Our findings suggest a GC-sparing potential for TLR7/8i compounds and indicate that TLR7/8 inhibition may offer a new therapeutic strategy for the treatment of autoimmune diseases. The safety, efficacy and GC-sparing effect of the TLR7/8 inhibitor is being evaluated in patients with systemic and/or cutaneous lupus erythematosus in the randomized, double-blind, placebo-controlled Phase II WILLOW study (NCT05162586), which has a mandatory GC tapering schedule.

**Figure 1.** Dexamethasone and TLR7/8i have synergistic effects on (A) IL-6 production in R848-stimulated PBMCs, (B) TNFα production in monocytes, and (C) proteinuria in a mouse model of lupus.

TYPE I INTERFERONS INDUCE TIE2-MEDIATED ENDOTHELIAL CELL DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Cytokines and chemokines, Cardiovascular disease

C. Rafael Vidal1, B. Malvar Fernández2, S. Martínez-Ramos1, C. Mouríño Rodríguez1, I. Altábás González1, A. Floudas2, D. Veale1, U. Fearon2, J. Rodríguez1, I. Altabás González1, A. Floudas2, D. Veale3, U. Fearon2, J. Galicia Sur, Rheumatology, Vigo, Spain; Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland, Molecular Rheumatology, Dublin, Ireland; EULAR Centre of Excellence, St Vincent’s University Hospital, University College Dublin, Dublin, Ireland, Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland

Background: Endothelial cell (EC) dysfunction is a hallmark of Systemic Lupus Erythematosus (SLE) and has been generally accepted to be one of the important factors contributing to the higher risk of thrombosis and atherosclerotic events observed in SLE patients. Although the presence of traditional factors (smoking, diabetes, increased age, obesity) and the presence of autoantibodies are associated with atherosclerosis and thrombotic events, they do not completely explain the higher risk of these events in SLE, suggesting the existence of other mechanisms/factors. Tie2 is a tyrosine kinase receptor essential for vascular development and blood vessel remodeling through its interaction with its ligands angiopoietin-1 (Ang-1) and Ang-2. In homeostatic conditions, both Ang-1 and Ang-2 activate Tie2 signaling and induce vascular stabilization in a Tie2-dependent manner. However, inflammatory processes induce Tie1 cleavage, leading to the inhibition of Ang-1-induced Tie2 activation, and to the increase of Ang-2 now acting as a Tie2 antagonist, culminating in vascular dysfunction and EC activation [1,2]. Importantly, this process has been implicated in both atherosclerosis and thrombosis.

Objectives: As type I Interferons (IFN-α and IFN-β) are key cytokines in the pathogenesis of SLE, the aim of this study is to determine whether these cytokines induce Tie2 signaling-mediated endothelial cell dysfunction.

Methods: Serum levels of Ang-1, Ang-2 and Tie1 in SLE patients (n=48) and healthy control (HC, n=29) were measured by ELISA. Human Umbilical Vein EC (HUVEC) were stimulated with SLE serum (20%), IFN-α or IFN-β (1000 IU) for 5, 15, 30 min and 1, 2, 4, 6, 8, 12, 24, 48 and 72 hours and mRNA and protein expression of Ang-1, Ang-2, Tie1 and Tie2 were determined by quantitative PCR (qPCR) and ELISA, respectively. The phosphorylation of Tie2 was determined by Western Blot and HUVEC viability by calcein assay. The angiogenic capacity was measured by tube formation assay. Silencing assays were performed with siRNAs addressed to IFNAR1 and Tie1 receptors.

Results: Type I IFNs, mainly IFN-β, significantly reduced Tie1 and Tie2 levels. IFN-β stimulation significantly increased the secretion of the Tie1 ectodomain (sTie1). Both IFNs significantly reduced protein secretion of Ang-1 after 24h of stimulation. Also, IFN-β significantly reduced early time points (<4h). Furthermore, IFN-α and IFN-β stimulation reduced Tie2 activation (Figure 1). Both type I IFNs significantly reduced the viability of HUVEC. SLE serum increased Ang-2 and sTie1 secretion levels in HUVEC at early time points (<1h). We found reduced levels of Ang-1 and elevated Ang-2 and sTie1 in SLE patients compared to HC. Also, IFN-β induced tubule formation at short times (4h) and decreased at 24h. Remarkably, this effect was reversed by silencing the receptors Tie1 and IFNAR1.

Conclusion: Our results demonstrate that type I IFNs play a relevant role in the stability of endothelial cells by inhibiting Tie2 signaling, suggesting that these processes may be implicated in the cardiovascular events observed in SLE patients.

ENDOTHELIAL INFLAMMATING AND MITOCHONDRIAL DYSFUNCTION IN THE ANTI PHOSPHOLIPID SYNDROME

Keywords: Anti-phospholipid syndrome, Cardiovascular disease

C. Piericulescu1, R. Maughan1, L. Kabir2,3, A. Dabrowska1, K. Paschalaki1, D. Carling1, A. Randle1, D. Arachchilage1,2, J. Mason1,3, Imperial College London, National Heart & Lung Institute, London, United Kingdom; Imperial College London, MRC London Institute of Medical Sciences, London, United Kingdom; Imperial College London, Department of Immunology & Inflammation, London, United Kingdom; Imperial College Healthcare NHS Trust, Haematology, London, United Kingdom; Imperial College Healthcare NHS Trust, Rheumatology, London, United Kingdom

Background: Inflammaging, vascular ageing and mitochondrial dysfunction are important contributors to cardiovascular risk in the rheumatic diseases. In antiphospholipid syndrome (APS), endothelial dysfunction is underpinned by a thrombo-inflammatory state mediated by antiphospholipid antibodies (aPL). The contribution of endothelial senescence and metabolic disturbances is not known. To assess senescence, inflammation and metabolic function in ex vivo blood derived endothelial colony forming cells (ECFC), a novel source of patient endothelium.

Methods: ECFC were isolated from PBMC of 17 thrombotic APS and 11 healthy control (HC) donors, cultured in endothelial growth media containing 20% FBS. ECFC frequency, days from PBMC seeding to first colony appearance and days to initial passage (from P0 to P1) were similar between APS and HC. ECFC were phenotyped at P4 by flow cytometry (CD31+CD144+CD14+CD45- and assayed at P4-P5. Proliferation was measured by fluorescent EdU incorporation. Senescence was determined by staining for senescence-associated β-galactosidase activity (SA-β-gal) and nuclear DAPI, expressed as % senescent cells against total cell number. Mitochondrial function and glycolysis were assessed in live cells using extracellular flux assays (Seahorse). Molecular analysis was informed by RNA-seq (5 APS, 5 HC) and targets validated in the extended cohort at the mRNA and protein level. Data was analysed by non-parametric Mann-Whitney, ANOVA and Spearman’s correlation tests.

Results: Impaired proliferative capacity and a greater proportion of senescent cells were observed in APS vs HC ECFC (median % senescent, 13.1% vs 7.9%) (p<0.02). RNA-seq analysis revealed 266 differentially expressed genes in APS ECFC compared to HC ECFC. Also, IFN-β-stimulated ECFC using elevated inflammatory cytokines, chemokines, cell adhesion and fibrosis-remodelling molecules. Target validation at the mRNA level confirmed a hypoproliferative inflammatory phenotype in APS; elevated genes included C5CDNK2AP16 (late senescence), GADD45B (growth arrest, DNA damage); IFNA1 (cytokine), CXCL10 (chemokine), CD277/ PD1L1 (exhaustion), PTX3 (fibrosis-remodelling), SERPINE1 (fibrinolysis-remodelling), EDN1 (vasoconstrictor), all p<0.05. A positive correlation was noted between senescent and inflammatory gene expression (e.g. p=0.15 vs CXCL10, r=0.4).

Figure 1. Ang-1, Ang-2, Tie1 and Tie2 mRNA expression and protein secretion in HUVEC stimulated with IFN-α or IFN-β (1000 IU/ml) for the indicated time points. Means and SEM are shown. *p<0.05, **p<0.01 and ***p<0.001. Also, representative immunoblot of Tie2 phosphorilation in HUVEC stimulated with IFN-α or IFN-β (1000 IU/ml) for 24h is shown.
p=0.03). Uptregulation of selected targets was confirmed at the protein level (e.g. p16 and PDL1 by flow cytometry, APS vs HC p=0.02 and p=0.03 respectively). Diminished mitochondrial respiration and ATP production (p=0.01) coupled with elevated glycolysis (p=0.02) was seen in APS vs HC ECFC. Mitochondrial parameters positively correlated with proliferative capacity (r=0.5, p<0.01) and negatively correlated with senescence and inflammation (r=-0.4, p<0.05), indicating a relationship between endothelial health and mitochondrial function. Glycolysis negatively correlated with proliferation (r=0.8, p<0.01). Comparing ECFC from patients with previous cardiovascular events (CVE, n=9) vs those without (no-CVE, n=8) revealed more pronounced senescence and mitochondrial dysfunction in CVE, while greater loss of proliferative capacity was observed in no-CVE. Inflammatory markers varied between the two patient groups e.g. PTX3 was higher in CVE and CXCL10 in no-CVE. Collectively, these observations suggest different underlying biological processes in patients with severe thrombotic complications compared to those without.

Conclusion: We propose APS as a paradigm disease for immune-mediated endothelial ageing, defined by a hypoproliferative-senescent, inflamed and metabolically perturbed phenotype. Evidence for a more severe dysfunctional phenotype in ECFC from patients with CVE compared to no-CVE, agrees with published studies associating vascular ageing and mitochondrial damage with cardiovascular risk. Ongoing work is assessing the impact of ex vivo metabolically perturbed phenotype. Evidence for a more severe dysfunctional phenotype in ECFC from patients with CVE compared to no-CVE, agrees with published studies associating vascular ageing and mitochondrial damage with cardiovascular risk. Ongoing work is assessing the impact of ex vivo metabolic perturbation on cellular senescence and mitochondrial dysfunction in CVE, while greater loss of proliferative capacity was observed in no-CVE. Inflammatory markers varied between the two patient groups e.g. PTX3 was higher in CVE and CXCL10 in no-CVE. Collectively, these observations suggest different underlying biological processes in patients with severe thrombotic complications compared to those without.

Clinical, immunological and transcriptomic profiles (3) were compared between the groups. The PSYLUP cohort (from a study evaluating the psycho-social consequences of SLE) (4) was an independent cohort used to confirm the results found in the LUPUCE cohort.

**Results:** Type 2 scores ranged from 0 to 31, with a cut-off value of 14 (75th percentile) that was the chosen threshold to define the type 2 symptoms. The sample categorization was: minimal in 39%, type 1 in 37%, type 2 in 9% and mixed in 15%. The type 2 score was calculated in an independent cohort of 100 SLE patients (PSYLUP cohort). This showed a similar pattern of values to the LUPUCE cohort: the score ranged from 0 to 33, and 23% of patients were above the threshold of 14. Type 2 patients were older than minimal patients (52 vs. 31 years, p=0.016) and had a longer disease duration than type 1 and mixed patients (10 vs. 5 years and 10 vs. 2 years, p=0.011, respectively). Immunological data (evaluated anti-dsDNA antibodies, anti-dsDNA level, low C3 and/or C4) and modular interferon (IFN) signatures (modular IFN score, number of activated IFN modules and level of regulation of each IFN module) did not differ between the groups.

**Conclusion:** Patients with SLE can be categorized into four clinical groups using the SLEDAL score and our SF-36-derived type 2 score. This categorization is non-redundant with immunological or transcriptomic profiles and could prove useful to stratify patients in clinical trials.

**Background:** Systemic lupus erythematosus (SLE) is associated with autoimmune and allergic events along with impaired defensive responses. Dysregulated T-cell responses might account for this evidence but antigen-specific T-cell behaviour in SLE has not been characterised.

**Objectives:** To test for clinical/pathophysiological correlates of SLE immune dysregulation by characterising CD4+ T-cells selectively recognising key SLE-related, pathogen-derived and autoreactive responses and can accurately be detected through penicilloylated-albumin peptide T-cell reactivity. Antigen-specific (rather than total) T-cell reactivity assays to study epitopes were conducted.

**Methods:** Human leukocyte antigen (HLA) DRB1*0301 or 1101-positive subjects were selected from a cohort of 222 patients with SLE and compared with patients with Takayasu's arteritis (TAK) and healthy controls (HC). In silico analyses through the Immune Epitope Database identified suitable HLA-peptide epitope pairs from a list of autoantigens (histone H3 and H4), allergens (penicilloylated albumin) and pathogen-derived antigens (Epstein-Barr virus [EBV], nuclear antigens) based on the cohort clinical/serological profile. Fluorochrome-conjugated epitope-bound MHC tetramers were eventually built and used to detect antigen-specific CD4+ T-cells through flow cytometry. T-cell differentiation was assessed by CD45RA, CD62L and CD350 and polarisation by CD25, CD127, CD163, CD186 and CD194 staining. Epitope-specific reactivity was validated by multi-cytokine release assays and measurement of CD40L, CD137, OX40 and CD69 expression upon T-cell stimulation with the study peptides.

**Results:** Total stem-cell memory T-cells (TEM) were expanded in SLE compared to control groups. Histone-specific CD4+ T-cells were selectively found in SLE and clustered with anti-dsDNA antibodies. Only patients with beta-lactam allergy had anti-penicilloylated albumin T-cells. Anti-EBV-specific T cells were found in patients and controls (Figure 1A-C). Antigen-specific T-cell counts were reciprocally correlated. Histone-specific regulatory T-cells (Treg) were inversely correlated with SLEDAI-2K. Circulating histone- and EBV-specific effector memory T-cells (TEM) and Treg were lower in active SLE (Figure 1D-F). EBV-specific Treg decreased in patients transitioning from remission to active SLE. Immunosuppressive treatment was associated with expanded CD4+ histone-specific T-cells. In vitro T-cell reactivity assays to study epitopes were consistent with ex vivo evidence. Higher IL17F and IL5 levels were released in response to histones and higher ILS and IL22 in response to penicilloylated albumin-peptides in SLE. Defective anti-EBV IFN-γ, TNF and IL22 release was observed in active SLE compared to HC.

**Conclusion:** Histone-specific T-cell responses constitute a hallmark of SLE and might deflectively be regulated during active disease, promoting autoreactive effector peripheralisation into target tissues. Dysfunctional T-cell reactivity to EBV might also subvert a constitutional defect in the control of endogenous or exogenous viral stimuli and possibly contribute to autoreactivity through misdirection of precursors. Afferent responses to beta-lactam might also synergise with autoreactive responses and can accurately be detected through penicilloylated-albumin peptide T-cell reactivity. Antigen-specific (rather than total) T-cell dynamics might faithfully reflect the occurrence of key pathogenic events accounting for SLE immune dysfunction in response to multiple types of antigens and efficiently be used to track SLE phenotype heterogeneity.

**SINGLE CELL ANALYSIS REVEALING THE LECTIN BINDING PATTERN OF T-CELLS, NKT-CELLS, NK CELLS, B-CELLS AND MONOCYTE SUBSETS IN SYSTEMIC LUPUS ERYTHEMATOSUS**

**Keywords:** Systemic lupus erythematosus

E. Szabo1, G. Bodor2, L. Kovács3, G. Szebeni1,2, 1Biological Research Centre, Laboratory of Functional Genomics, Szeged, Hungary; 2Albert Szent-Györgyi Medical School and Health Centre, University of Szeged, Department of Rheumatology and Immunology, Szeged, Hungary; 3University of Szeged, Department of Physiology, Anatomy and Neuroscience, Faculty of Science and Informatics, Szeged, Hungary

**Background:** Cell surface glycosylation serves as a binding platform for endogenous lectin families such as galectins (Gals) or sialic acid immunoglobulin-like lectins (Siglecs) with well-known immunoregulatory functions. Several studies, including our own work [1], have shown that Gal-binding plays an important role in the pathogenesis of systemic lupus erythematosus (SLE) in animal models but their contribution to human SLE must be better elucidated. For these lectins to act, the appropriate glycan structures should be available on the target cells and should not be masked by alpha-2,6-sialylation which prevents binding of Gal-1, not Gal-3. Although cancerous diseases are well-characterized by an altered glycome, limited information regarding cell surface glycosylation is gathered for autoimmune diseases like SLE.

**Objectives:** In the current study, we aim to analyze the ability of certain immune subsets to bind Gal-1, Gal-3, sialic acid binding C-type lectin (Siglec-1), the fucose binding Aleuria aurantia lectin (AAL), the sialic acid binding Sambucus nigra Agglutinin (SNA) lectin in SLE patients versus healthy controls.

**Methods:** We collected peripheral blood mononuclear cells (PBMCs) from 19 new or relapsing SLE patients with active disease (mean age: 47.5, SLE-DAI-2K: 15.8, anti-dsDNA level: 76.4 IU/ml) with or without minimal immunosuppressive therapy and 19 age- and health-matched controls. Multicolor antibody panel was designed to identify the main peripheral immune subsets: CD4+ T-cells, CD8+ T-cells, CD4+CD8- T-cells, CD4+CD8+ T-cells; CD4+NKT-cells, CD8+NKT-cells, CD4-CD8-NKT-cells, CD4+CD8+NKT-cells; CD56+ NK cells; naive B-cells, memory B-cells, plasmablasts; classical monocytes, non-classical monocytes and intermediate monocytes. The five lectins (Gal-1, Gal-3, Siglec-1, AAL, SNA) were conjugated with different fluorophores for FACS. The binding of florochrome labeled lectins to each of these populations was assessed simultaneously by flow cytometry directly after thawing (resting state) and following activation.

**Results:** In our experiments with control PBMCs, titration and compensation of both antibodies and lectins were carried out and gating strategies were built to identify the above-mentioned immune subsets and their lectin binding characteristics. There were remarkable differences in lectin binding among different immune populations, e.g. classical and intermediate monocytes outperformed non-classical monocytes and lymphocytes in all lectin binding. Interestingly, naive B-cells were more sialylated (Median Fluorescence Intensity (MFI) Gal-1: 1189) or plasmablasts (MFI Gal-1: 16189) than both memory B-cells (MFI Gal-1: 2368; MFI SNA: 1263; MFI Gal-1: 16515). Similarly, highest binding of both antibodies and lectins were carried out and gating strategies were built (CytoStim), while B-cells and monocytes were activated by LPS.

**Conclusions:** The focus of this study is to identify relevant changes in the cell surface glycosylation of SLE immune subsets which is a unique approach and could contribute to a better understanding of the glyobiology of lupus.

**INCREASED INTERLEUKIN-6 (IL-6) RECEPTOR SHEDDING UNDER INTERFERON-Α AND IL-6 EXPLAINS LOW C-REACTIVE PROTEIN (CRP) LEVELS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)**

**Keywords:** Cytokines and chemokines, Systemic lupus erythematosus, Biomarkers

M. Hempel1, E. Klapproth2, B. Heschel1, N. Leuchten1, A. El-Armouche3, M. Aringer1, 1University Medical Centre and Faculty of Medicine TU Dresden, Division of Rheumatology, Department of Medicine II, Dresden, Germany; 2University Medical Centre and Faculty of Medicine TU Dresden, Department of Pharmacology, Dresden, Germany

**Background:** In active SLE, CRP levels are disproportionally low for increased IL-6 levels. While a molecular explanation is lacking, these low CRP levels have been associated with increased type I interferon signature in SLE. IL-6 signalling requires gp130 and the IL-6 receptor-α (IL-6R). Leukocytes and hepatocytes carry surface IL-6R (CD126). Other cells express only gp130 and require soluble IL-6 receptor (sIL-6R) for IL-6 signalling. This sIL-6R derives from membrane-bound CD126 shedded by metalloproteinases.

**Objectives:** To comprehensively analyze IL-6 and its signal transduction via signal transducer and activator of transcription (Stat) 3 in patients with SLE and in healthy individuals (HC).

**Methods:** We analyzed peripheral blood mononuclear cells (PBMC) and sera of 41 SLE patients and 71 HC. IL-6 and soluble IL-6 receptor (sIL-6R) were measured by ELISA. CD126 was stained with phycoerythrinc (PE)-labelled antibodies. PBMC were stimulated with recombinant human IL-6, fixed, permeabilized and stained with PE-labelled antibodies to phosphorylated Stat3 (pStat3) or control antibodies. Healthy PBMC were incubated for 24 hours with or without the addition of IL-6, IL-10, tumor necrosis factor (TNF), interferon-α (IFNα), or combinations of these cytokines. Flow cytometry was performed on a Becton Dickinson FACSCalibur fluorocytometer, determining percentages of CD126+ lymphocytes or the increase in pStat3 mean fluorescence intensity (MFI), sIL-6R in supernatants was detected by immunoprecipitation (IP) and immunoblotting.

**Results:** IL-6 was increased in SLE (median 3.64 vs 0.89 pg/ml in HC, p<0.0001). Significant correlations with SLE disease activity by ECLAM were found for serum IL-6 (Spearman r=0.40, p<0.01), but not CRP (r=0.29). CD126+ lymphocytes were decreased in SLE (median 46% vs. 61% for HC, Mann Whitney p=0.0001), in line with reduced IL-6 induced phosphorylation of Stat3 in SLE (median MFI 14.2 vs. 18.8 in HC, p=0.0044). In a mirror image of CD12, sIL-6R serum levels were increased in SLE (median 42.2 ng/ml vs. 38.6 ng/ml in HC, p=0.02). Stimulation of healthy PBMC with the combination of IL-6 and IFNα led to a reduction in CD126+ cells by 39±13% (p<0.0001) and to an increase in sIL-6R (normalized for IgG) (p=0.0055) (B) detected by IP and Western blotting, mimicking the in vivo situation.

**Conclusion:** The combination of type I interferon and IL-6, both of which are well known to be increased in SLE, leads to shedding of membrane bound CD126 to sIL-6R. This moves IL-6 effects from the liver, which produces CRP, well known to be increased in SLE, to the liver-bound IL-6R receptor. This moves IL-6 effects from the liver, which produces CRP, to other cells, effectively increasing IL-6 inflammatory effects while limiting CRP levels.

Background: All immune cells that contribute to the pathogenesis of systemic lupus erythematosus (SLE) derive from adult haematopoietic stem and progenitor cells (HSPCs) within the bone marrow (BM). We reasoned that the fundamental abnormalities in the disease can be traced back to HSPCs.

Objectives: I) To delineate human haematopoietic CD34+ progenitor subpopulations that may be involved in the pathogenesis of the disease and II) to identify deregulated pathways in each subpopulation in SLE as compared to healthy controls.

Methods: BM samples from 6 SLE patients and 5 healthy controls and 2 umbilical cord blood (CB) samples were used. CD34+ cells were isolated from BM and CB samples and single cell capture and RNA extraction were performed on Fludigm C1 IFC. Libraries were prepared and 75bp or 150bp paired-end sequencing was performed. Cells were excluded if total reads were <25,000, alignment rate was <50%, the number of detected genes (at least 1 count) was <200 and >6,000 and the percentage of reads mapping to mitochondrial genes was >20%. The Seurat and harmony R packages were used for normalization, marker identification and graph-based clustering. Pseudobulk differential expression (DE) analysis was performed using edgeR R package. Enrichment analysis was performed using EnrichR.

Results: A total of 426 out of 836 cells and 24,473 genes were used in the analysis. There was a statistically significant difference in the total number of detected genes between the three sample types (Kruskal-Wallis chi-squared=14.9, p<0.001) with CB samples expressing more genes compared to the other two sample types. The top 3,000 highly variable genes across cells were identified and loaded into a PCA and the top 10 principal components were provided as the input for the UMAP visualization which resulted in seven distinct clusters of cell types (Figure 1). Mutually exclusive markers, which were characteristic of each cell type were identified. Cluster 0 cells (T-like progenitors) uniquely expressed IL32 and CD3E, whereas cluster 1 (Myeloid-1 progenitors) uniquely expressed MMP8. Of note, there was a significantly lower proportion of SLE BM B-like progenitor cells (3.5% of total SLE BM cells) and SLE BM HSCs-3, characterized by primitive progenitors with low expression of the cell cycle gene MKI67 (4% of total SLE BM cells) compared to 10% B-like progenitors and 21% HSCs-3 of total healthy BM cells respectively. Following DE analysis between SLE and healthy BM there were statistically significant differences (FDR<0.1) in Myeloid-2 progenitors, with differentially expressed genes (DEGs) enriched for TNF signaling and DNA repair pathways, and in HSCs-1, with DEGs enriched for IFN alpha-beta signaling and heme metabolism. Interestingly, we observed an upregulation in the expression of IFN inducible genes, such as IFI44, IFI44L, in SLE compared to healthy in all three HSC subpopulations.

Conclusion: Single-cell RNA sequencing analysis from CD34+ progenitor cells from patients with SLE revealed both quantitative- as evidenced by decreased numbers of non-proliferating early progenitors, and qualitative differences- characterized by an IFN signature, which is known to drive loss of function and attrition of HSPCs. Chronic IFN exposure affects early hematopoietic progenitors in SLE, driving their proliferation and myeloid skewing and may account for the immune abberancies and the cytopenias in SLE.

AQUAPORIN EXPRESSION IN LUPUS NEPHRITIS: INSIGHTS INTO TUBULAR PATHOLOGY

Keywords: Systemic lupus erythematosus, Kidneys

Background: Lupus nephritis is a severe and life-threatening manifestation of systemic lupus erythematosus. Tubulointerstitial hypoxia is a key factor in the progression to end-stage renal disease. Numerous aquaporins are expressed by renal tubules and are essential for their proper functioning. Several mouse models have shown their involvement in the regulation of renal inflammation during acute stress episodes. However, the expression of aquaporins (AQP) in human lupus nephritis has been poorly studied.

Objective: The aim of this study is to characterise the tubular expression of AQP1, AQP2 and AQP3 which could provide a better understanding of tubulointerstitial stress during lupus nephritis.

Methods: This retrospective monocentric study was conducted at Erasme-HUB Hospital, Brussels with the approval of the ULB-Erasme Ethical Committee (P2020/710). A total of 37 lupus nephritis samples and 9 healthy samples collected between 2000 and 2020 were obtained from the biobank of the pathology department. Kidney biopsy sections were reviewed sectioning to the ISN/RPS 2018 classification. Immunohistochemistry was performed to detect AQP1, AQP2 and AQP3 and followed by digital image analysis. Digital image quantification analysis was performed using ImageJ software.

Results: We observed weak expression of AQP1 in glomeruli and strong expression on the apical side of proximal convoluted tubules in the cortex. In the medulla, it was confined to the descending loop of Henle and the vasa recta. AQP2 was exclusively expressed on the apical side of collecting tubules in both the cortex and the medulla. AQP3 was not detected in glomeruli, weakly expressed on the basolateral side of proximal convoluted tubules, and strongly expressed on the basolateral side of distal convoluted tubules and collecting tubules. No difference in staining location was found between healthy and lupus nephritis kidney biopsies. By digital quantitative analysis, we observed a significant decrease in AQP1 expression in the renal cortex (p<0.0001), a non-significant trend towards a decrease in AQP2 expression and a significant cortical and medullary decrease in AQP3 expression (p<0.001). This decrease was more pronounced in the subgroup of membranoproliferative glomerulonephritis (class III/IV), particularly for AQP3 (p<0.05). Within the subgroup of membranoproliferative glomerulonephritis, there was a strong negative correlation between both cortical and medullary AQP2 expression and interstitial inflammation (r=-0.5328; p<0.01). Decreased cortical AQP3 expression was strongly negatively correlated with interstitial fibrosis (r=-0.6651; p<0.001) and tubular atrophy (r=-0.6651; p<0.001).

Conclusion: We found a significant decrease in the expression of several AQPs in the parenchyma of lupus nephritis. We believe that this decrease is a feature of tubulointerstitial damage. Immunohistochemical analyses of AQPs on lupus nephritis samples could help to assess the tubulointerstitial hypoxia and cell damage and therefore renal prognosis.

UNRAVELING THE MYSTERIES OF THE CONNECTION BETWEEN GUT AND THE CHRONIC ACTIVATION OF THE IMMUNE SYSTEM IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Diet and nutrition, -Omics

Background: NETosis has been described to play a role in the pathogenesis of APS. IgG and sera of APS patients are known to induce NETosis [1], however the direct role of a[2]GPI on NETosis is not fully known.

Objective: The aim of this study is to evaluate the interplay between NETosis and a[2]GPI antibodies.

Methods: HD neutrophils were stimulated either with polyclonal a[2]GPI isolated from a serum pool of primary APS, with immunoglobulin isolated from HD (IgHD) or PMA. NETs were stained with anti-neutrophil elastase, SYBR green and DAPI. NET quantification was performed with NETQUANT, an automated approach. To evaluate the ability of a[2]GPI to bind to NET, HD neutrophils were stimulated with PMA and stained with anti-neutrophil elastase, SYBR green and with a[2]GPI and, as a control, with IgHD instead of a[2]GPI. Colocalization of a[2]GPI and NET signal was performed with Just Another Co-localization Plugin (JACoP). In order to evaluate the ability of a[2]GPI to bind to NETs and prevent DNA degradation, incubation with DNase I was also performed.

Results: Stimulation of HD neutrophils with a[2]GPI was able to induce a significantly higher number of NETs compared to stimulation with IgHD (77.6% vs 20%, p<0.0001). The prevalence of NETs in stimulated IgHD and unstimulated neutrophils was similar (20% vs 16%, p=ns). Two different shapes of NET were identified in neutrophils stimulated with a[2]GPI: "cloudy-like" and "spiky-like." Unlike IgHD, a[2]GPI binds to NETs (Figure 1), and the a[2]GPI signal colocalized with the anti-neutrophil elastase signal at 93.6%. In addition, we showed that a[2]GPI binding to NETs did not prevent NETs degradation by DNase.

Conclusion: a[2]GPI antibodies are able to induce NETosis and to bind to NETs.

Background: In a systemic lupus erythematosus (SLE) murine model, the translocation of a gut pathobiont induced an autoimmune response and death, which were prevented by antibiotics and a vaccine [1]. These findings suggest that the gut microbiota modulates SLE phenotype. Previously, we found increased circulating lipopolysaccharide (LPS) in SLE patients, which could be associated with decreased gut barrier integrity and translocation from the gut to the bloodstream [2]. We hypothesize that dysbiosis, impaired intestinal barrier integrity, and endotoxemia are crucial to the chronic activation of the immune system seen in SLE.

Objectives: To study diet, physical activity, body composition, gut microbiota, and gut permeability in SLE patients in comparison with healthy controls (HC).

Methods: Evaluation of HC and SLE patients (children and adults) who fulfill the 2019 EULAR/ACR SLE classification criteria. Individuals with inflammatory bowel disease, celiac disease, irritable bowel syndrome, diabetes, malignancy, or other immune-mediated diseases were excluded. The SLEDAI-2K score was used to evaluate disease activity. Diet and physical activity were assessed by three-day diet recall, PREDIMED, KIDMED, and the International Physical Activity questionnaires. Body composition was analysed by whole-body air-displacement plethysmography. Gut microbiota was studied by Next Generation Sequencing, with amplicon sequencing-based 16S rRNA analysis. The lactulose/manitol test, which directly assesses intestinal permeability, was quantified by mass spectrometry (LC-MS/MS). Serum markers of gut permeability and inflammation (zonulin, sCD14, IFABP) were measured by ELISA. The biological activity of LPS was assessed through serum-induced toll-like receptor 4 (TLR4) stimulation in a reporter cell line.

Results: We studied 16 HC (median age 35.5Y [14-50Y]; 88% females) and 45 SLE patients (11 children and 34 adults; median age 32Y [11-67Y]; 87% females; median age at diagnosis 19Y [8-43Y]; median disease duration 7Y [3M-29Y]; 64% had lupus nephritis; median SLEDAI-2K at sample collection 4). SLE patients had lower physical activity and higher sitting time, lower adherence to the Mediterranean diet, and higher fat mass than HC (p<0.05). In addition, SLE patients had a lower intake of α-linolenic acid and manganese (p<0.05). A decreased α-diversity of gut microbiota (p<0.05) was identified in SLE patients, reflecting dysbiosis. Lower adherence to the Mediterranean diet, higher zonulin levels, and longer SLE disease duration were significantly associated with decreased gut diversity in this cohort (p<0.05). The lactulose/manitol ratio was significantly higher in SLE patients compared to HC (p<0.05), reflecting greater gut permeability. Patients with lupus nephritis had a higher lactulose/manitol ratio than SLE patients without renal involvement (p<0.05). Interestingly, we found that zonulin was significantly increased in SLE patients (p<0.05). We also found significantly increased levels of sCD14 in SLE patients (p<0.05) and increased levels of IFABP, but only in adult patients (p<0.05). No significant correlation was observed between any evaluated biomarker and SLEDAI-2K.

Conclusion: Our data support the hypothesis that gut dysbiosis and higher intestinal permeability contribute to SLE pathogenesis, being two promising therapeutic targets in this disease.

I interferon (IFN) system. In SLE, type I IFNs directly and indirectly affect differentiation and survival of autoreactive B cells, partly by IFN induced release of B cell activating factor (BAFF). TANK-binding kinase 1 (TBK-1) is an important upstream mediator of type I IFN production, which has been implicated in several systemic autoimmune diseases [1]. Additionally, B cell intrinsic TBK-1 was recently shown to be essential for germinal center (GC) formation and proper B cell development in vivo [2]. Amleraxan (AMX) is a small molecule TBK-1 inhibitor, with the potential to block adaptive immune responses. From these studies, we hypothesize that AMX, by inhibition of TBK-1, could be a novel therapeutic option in SLE.

To determine whether AMX can inhibit type I IFN and IFN induced BAFF production, and to unravel its potential direct effects on B cells in human in vitro culture systems.

Methods: Cultured PBMC from healthy donors were stimulated with Imiquimod, CpG-A, Poly:IC, G3-YSd or 3p-hpRNA to induce type I IFN production through various routes, with or without presence of AMX. Production of type I IFN was assessed by a HEK IFN-alpha/beta reporter cell line and the ability of supernatants to induce transcription of the BAFF and MX1 genes was measured by real-time quantitative PCR. Sorted CD19+ B cells were cultured for 6 or 9 days under GC-like conditions with CD40L and IL-21 (4), as well as IFN, BAFF, and AMX at various concentrations. Viability and differentiation into CD38highCD27highCD138+/- cells was assessed by spectral flow cytometry. Immunoglobulin M and IgG were measured in supernatants by ELISA.

Results: AMX significantly inhibited production of type I IFN through all investigated endosomal and cytosolic routes (p<0.001). Moreover, supernatants from cells treated with AMX were unable to induce expression of BAFF and MX1. The inhibitory capacity of AMX in this setting was comparable to blocking of the interferon alpha/beta receptor (IFNAR) with a functional antibody. As could be expected, AMX did not affect expression of BAFF and MX1 upon IFNAR ligation, indicating no effect on signaling downstream of the receptor. To mimic an autoimmune setting, IFN and BAFF was added to the CD40L/IL-21 B cell culture system, resulting in increased B cell differentiation. Addition of AMX resulted in significantly decreased differentiation into CD38highCD27highCD138+/- cells (p<0.0001) without affecting cell viability. Correspondingly, production of IgM and IgG was lower in the AMX condition.

Conclusion: Our data demonstrate in vitro inhibitory effects of AMX on type I IFN production and B cell differentiation in primary human cells. Inhibition of TBK-1 is a promising therapeutic target for treatment of SLE warranting further investigations.

Cell biology, Adaptive immunity, Systemic lupus erythematosus

Objectives: Our aim was to evaluate the role of IL-10 -secreting cells in the pathogenesis of systemic lupus erythematosus.

Methods: We analyzed the percentages of IL-10 -producing lymphocytes either ex vivo (a standard negative control) or after brief stimulation with PMA and ionomycin, which activates all T -cells to produce cytokines. Surprisingly, 4 patients had very high levels of IL-10 production ex vivo, while the remaining patients produced some IL-10 only upon stimulation, similarly to healthy controls. We then divided our population into 2 groups according to disease activity: patients with SLEDAI ≥ 4 displayed significantly higher IL-10 production than inactive patients. To assess which cells were responsible for spontaneous IL-10 production, we analyzed the phenotype of IL-10+ cells. Spontaneously IL-10 secreting lymphocytes, those that expressed IL-10 and those that did not (Figure 1). Spontaneously IL-10 secreting cells were mainly CD4+ helper T-cells that expressed high levels of CCR6, CXCR5 and IL-7R.

Results: We looked at the percentage frequency of IL-10 -producing lymphocytes either ex vivo (a standard negative control) or after brief stimulation with PMA and ionomycin. CXCR5, which activates all T-cells to produce cytokines. Surprisingly, 4 patients had very high levels of IL-10 production ex vivo, while the remaining patients produced some IL-10 only upon stimulation, similarly to healthy controls. We then divided our population into 2 groups according to disease activity: patients with SLEDAI ≥ 4 displayed significantly higher IL-10 production than inactive patients. To assess which cells were responsible for IL-10 production, we analyzed the percentage of CD4+ and CD8+ cells either ex vivo (standard negative control) or after brief stimulation with PMA and ionomycin. We observed that ex vivo production of IL-10 by B helper T-cells was significantly higher in active disease than in inactive patients. We then divided the test population into additional subgroups according to disease activity: patients with SLEDAI ≥ 4 displayed significantly higher IL-10 production than inactive patients. Further analysis is needed to better characterize the spontaneously IL-10 producing lymphocytes in these patients.

Results: We confirmed an increased surface expression of Sialic acid-bind- ing Ig-like lectin-1 (Siglec-1) on CD14+ monocytes and further show increased Siglec-1 expression also on CD14+CD16- non-classical monocytes and conventional dendritic cells in anti-Ro/La-exposed compared to healthy control neo- nates. We did not observe any major differences in general populations such as CD4+, CD8+ or gamma delta T cells. However, we found a decreased frequency of regulatory CD4+FoxP3+T cells in the autobody-exposed newborns. In line with this, we observed an increase in conventional CD4+FoxP3+T cells and that these cells have less of a naïve phenotype with significantly lower frequency of CD62L+ and more CD69-expressing cells in the CD4+FoxP3+ population. Interestingly, Ro/La-exposed newborns also had less CD5+ expressing CD19+ B cells compared to healthy newborns, while the frequency of CD19+CD5- B cells was not affected. Further, we noted a decreased surface expression of CD19 and CD11b on both these CD19+subpopulations. Interestingly, for neonates born to mothers with high levels of all three of Ro52, Ro60 and La autoantibodies, we also found intracellular cytokine IFNγ and TNFα production in B cell, dendritic cell, and monocyte populations.

Conclusion: Together, our data provide valuable insights into the effects of Ro/La autobody exposure in utero on immune activation of both innate and adaptive immune cell populations in exposed fetuses, enhancing our understanding of the immunological basis of neonatal lupus.

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by an abnormal inflammatory response against nuclear antigens with consequent tissue damage. Autoreactive B cells and auto-antibodies have a fundamental role in SLE pathogenesis. Regulatory T cells (Tregs) physiologically maintain the immune tolerance and are impaired in SLE. Polyclonal Treg transfer obtained unsatisfactory results due to the low number of disease-relevant anti- gen-specific cells. Chimeric Antigen Receptors (CARs) are molecules capable of redirecting T cell specificity. CAR-Tregs proved effective in pre-clinical mouse models of autoimmune.

Objectives: We aimed at developing a CAR-Treg based product to be employed in SLE.

Methods: We isolated Tregs from Healthy Donors Peripheral Blood Mononuclear Cells (PBMCs) and expanded them with IL-2 and rapamycin. We transduced Tregs with a Lentiviral Vector encoding for a second-generation anti-CD19 CAR, considering the relevant role of autoreactive B cells and auto-antibodies in SLE.

Results: Engineered cells retained their immune suppressive capabilities upon polyclonal stimulation. Noticeably, they acquired new antigen-specific suppressive capacities, being able to block autologous B cell proliferation. We set up a humanized mouse model of SLE. In vivo, CAR-Tregs delayed the occurrence of B cell lymphopenia, producing immunomodulatory cytokines and without showing toxicity or reprogramming towards Th17 pro-inflammatory cells. In inflamed organs, CAR-Tregs restored the normal composition of the immune system.

Conclusion: In conclusion, we efficiently generated anti-CD19 CAR-Tregs and proved their efficacy both in vitro and in an in vivo humanized mouse model of lupus.

POS1433 RELATIONSHIP BETWEEN THE EFFECT OF BELUMUMAB ON IMMUNOPHENOTYPE AND THE DISCONTINUATION OF GLUCOCORTICOIDS IN PATIENTS WITH SLE: LOOPS REGISTRY, FLOW STUDY

Keywords: Systemic lupus erythematosus, Real-world evidence

Y. Miyazaki1, S. Nakayamada2, S. Kubo2, K. Sonomoto2, H. Tanaka3, K. Hanami4, S. Fukuyo5, A. Yamaguchi4, Y. Todokoro4, H. Miyata4, Y. Tanaka4, 1University of Occupational and Environmental Health, Japan, First Department of Internal Medicine, Kitakyusyu, Japan; 2University of Occupational and Environmental Health, Japan, Department of Internal Medicine (Molecular Targeted Therapy), Kitakyusyu, Japan; 3University of Occupational and Environmental Health, Japan, Department of Adult and Geriatric Nursing, Faculty of Nursing, Kitakyusyu, Japan; 4Hospital of the University of Occupational and Environmental Health, Japan, Department of Laboratory and Transfusion Medicine, Kitakyusyu, Japan

Background: The efficacy of belimumab (BEL) for maintenance therapy in patients with systemic lupus erythematosus (SLE) remains unclear. Furthermore, the effects of BLM on the peripheral blood immunophenotype in patients with SLE are unknown.

Objectives: Patients with SLE in the maintenance phase were analyzed to determine the relationship between the efficacy of BEL and peripheral immunophenotypes. This study aimed to identify patients with SLE for whom belimumab was optimal by clinical findings and peripheral immunophenotypes.

Methods: In this retrospective observational study, patients with SLE (n=110) in the maintenance phase (SELENA-SLEDAI < 10, glucocorticoid [GC] dose ≤ 0.2mg/kg/day) were assessed. Based on the standard human immune cell subset classification protocol by NIH/FOCIS, peripheral immunophenotypes were analyzed in SLE patients and age/gender-matched healthy controls (n=76), and were compared. The efficacy of BEL combined with standard-of-care (BEL+SoC group, n=64) was compared with SoC alone (SoC group, patients using either mycophenolate mofetil or hydroxychloroquine, n=46). Selection bias was adjusted by propensity score-based inverse probability of treatment weighting (PS-IPTW). Peripheral immunophenotypes were analyzed in the baseline and after six months for the SoC group and BEL+SoC group.

Results: The proportion of naïve-CD4 T-, CD8 T- and B cells were lower, and that of the memory CD4 T-, memory CD8 T-, class-switched memory B-, and IgD+CD27 B cells, and plasmocytes was higher in the SLE patients than in controls. No significant difference was observed in the patient background between the two groups after adjustment by PS-IPTW. Compared with the SoC group, the GC dose after one year was significantly lower (BEL+SoC, 1.7±2.3 vs. SoC, 5.4±4.8mg/day, p<0.0001) in the BEL+SoC group. In the BEL+SoC group, 31.3% (20/64) of patients discontinued GC, significantly more than the SoC group (BEL+SoC, 31.3% vs. SoC, 5.0%, p=0.0012). The relapse rate (BEL+SoC, 6.1% vs. SoC, 22.4%, p=0.0128) was significantly lower in the BEL+SoC group than in the SoC group. The incidence of infections was significantly lower in the BEL+SoC group compared to the SoC group before and after PS-IPTW. No significant difference between the two groups was observed in peripheral immunophenotypes at baseline. The proportion of activated Tfh cells (p=0.0323), IgD+CD27+ B cells (p<0.0001), and plasmocytes (p=0.0370) was significantly decreased six months after BLM introduction. In the BEL+SoC group, 18 (28.1%) who discontinued GC had no relapse for one year and showed a significantly lower proportion of IgD+CD27 B cells six months after BLM introduction (p=0.0387). These changes were not observed in the SoC group.

Conclusion: In maintenance-phase SLE, administration of BLM was able to achieve a reduction or discontinuation of GC dose while suppressing flare-ups. A reduction in IgD+CD27+ B cells due to BLM may help to control disease activity, and enable the reduction/discontinuation of GC in SLE patients in the maintenance phase.

POST1434
ABERRANT PHENOTYPE OF CIRCULATING ANTIGEN PRESENTING CELLS IN GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA

Keywords: Innate immunity, Vasculitis

R. Reitsma1, B. C. Hesselink2, K. Van der Geest3, W. Abdulahad2, A. Boots2, E. Brouwer2, P. Heeringa2, Y. Van Sloo1, Å. Seger1, Magnus Sahlgren1, 2, University of Medicine and Health, Örebro, Sweden; 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands

Background: Giant Cell Arteritis (GCA) and Polymyalgia Rheumatica (PMR) are overlapping diseases occurring exclusively in people older than 50 years. Antigen-presenting cells (APCs), including monocytes and dendritic cells (DCs), are main contributors to the immunopathology of GCA and PMR. In GCA tissues, DCs may be prone to activation, leading to chemokine production and recruitment of CD4+ T-cells and monocytes to the arterial wall. However, little is known about APC phenotypes in the peripheral blood at the time of GCA/PMR diagnosis.

Objectives: We aimed to investigate the phenotype of the circulating monocytes and DCs in GCA and PMR patients.

Methods: APCs among peripheral blood mononuclear cells (PBMCs) of treatment-naive GCA and PMR patients were compared to those in age- and sex-matched healthy controls (HCs) using flow cytometry (n=15 in each group). Using a 13-colour panel, we identified three monocyte subsets: classical (CD14+CD16-), intermediate (CD14+CD14+), and non-classical (CD14lowCD16+) monocytes. DC subsets were subdivided in CD303+CD11c+ plasmacytoid DCs (pDCs), CD11c+CD141+ conventional DCs (cDC1) and CD11c+CD14+ conventional DCs (cDC2). Each of these subsets was analysed for expression of pattern recognition receptors (Toll-like receptor 4 (TLR4), TLR2) and activation markers (CD86, Programmed Death- Ligand 1 (PD-1), CD40, HLA-DR, CD11c) by assessing the mean-fluorescence intensity of these markers. Data were analysed by conventional gating strategies and by unsupervised tSNE.

Results: GCA and PMR patients displayed a monocytes, which was due to increases in classical and intermediate monocyte counts, whereas the proportion of non-classical monocytes was reduced. Intermediate monocytes of GCA patients had significantly higher TLR2 expression, a similar trend was observed in non-classical monocytes of GCA and PMR patients. A divergent pattern was observed in the expression of activation markers on classical versus non-classical monocytes: classical monocytes of GCA/PMR patients appeared to be less activated, whereas non-classical monocytes showed an increased monocyte marker expression compared to HCs (Figure 1). Even though no differences were observed in DC counts in the peripheral blood, cDC2 counts correlated negatively with CRP levels (r<0.60 for GCA, r=0.55 for PMR).

Conclusion: Circulating non-classical monocytes, but not DCs, display an activated phenotype in GCA and PMR patients at diagnosis. These cells are thought to be pro-inflammatory, representing the end stage of monocyte maturation in the blood. In contrast, classical monocytes show reduced expression of activation markers in GCA and PMR patients, potentially signalling either an immature or exhausted phenotype.

Figure 1. CD11c expression on monocyte subsets and cDC2 for GCA patients, PMR patients and HCs.

Shown is the mean fluorescence intensity (MFI) of CD11c on the surface of monocyte subsets and CD14+ conventional dendritic cells (cDC2). Data are shown for patients with giant cell arteritis (GCA) or polymyalgia rheumatica (PMR) and age-matched healthy controls (HCs), n=15 for each group. Statistics by Mann Whitney U. CD11c expression data for pDCs (no CD11c expression) and CD11c expression on monocyte subsets and cDC2 for GCA patients, PMR patients and HCs.

POST1435
A GM-CSF AND IFN-Υ-DRIVEN PRO-INFLAMMATORY MACROPHAGE SIGNATURE IN POLYMYALGIA RHEUMATICA

Keywords: Cytokines and chemokines, Inmate immunity, Biomarkers

W. F. Jemmy1, A. Zhang2, M. Sandovic1, P. Heeringa3, A. Diepstra2, E. Brouwer2, K. Van der Geest1, 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands

Background: Polymyalgia rheumatica (PMR) is a common, rheumatic inflammatory disease. Synovial inflammation of the shoulder bursae and tendon sheaths is a hallmark feature of PMR. Data on the immune pathology of PMR are scarce, with glucocorticoid treatment remaining the mainstay treatment for this condition. An earlier study reported that macrophages dominate the inflammatory infiltrates in the synovium of PMR patients [1]. Recently, macrophages were identified as potent producers of IL-6 and GM-CSF in PMR bursa tissue [2,3], while a strong IFN-γ signature was observed among bursa T cells [4]. GM-CSF and IFN-γ might potentially skew macrophages towards a pro-inflammatory phenotype. To what extent bursa macrophages in PMR also produce other pro-inflammatory cytokines remains unknown.

Objectives: 1) To investigate the pro-inflammatory cytokine signature of bursa tissue macrophages in PMR.

Methods: Ultrasound-guided bursa tissue biopsies were obtained from 12 PMR patients with active disease. Immunohistochemistry staining for proinflammatory cytokines (IL-6, IFN-γ, IL-1β, TNF-α, IL-12, IL-23 and GM-CSF) and homeostatic cytokines M-CSF was scored quantitatively. Double immunofluorescence staining was performed linking cytokine expression to CD68+ macrophages. In vitro studies were performed with monocytes isolated from peripheral blood mononuclear cells of 8 patients with active PMR and 8 healthy donors. Monocytes were differentiated into macrophages during a 7-day culture in the presence of GM-CSF, with or without 24 hours co-incubation with IFN-γ on day 7 for additional polarization. Real-time qPCR was performed to determine expression of IL-6 in the cultured cells.

Results: CD68+ macrophages were the predominant immune cells in PMR bursa biopsies. IHC staining showed high expression (>60% of positive cells) of proinflammatory cytokines (IL-6, IFN-γ, IL-1β, TNF-α, IL-12, IL-23 and GM-CSF) and homeostatic cytokine M-CSF throughout the bursal tissue, while IFN-γ and IL-1β were moderately expressed (>35% of positive cells). Double immunofluorescence staining confirmed the expression of these cytokines by the bursa tissue macrophages. In vitro experiments showed a slight upregulation of IL-6 expression when monocytes were differentiated into macrophages by GM-CSF. In the presence of IFN-γ, a substantially stronger upregulation of IL-6 was observed. In essence, similar in vitro findings were observed for monocytes/macrophages obtained from PMR patients and healthy controls.

Conclusion: Macrophages are the predominant immune cells in PMR bursa tissue and produce a wide array of pro-inflammatory cytokines. GM-CSF and IFN-γ may contribute to the pro-inflammatory phenotype of macrophages in PMR, as indicated by their strong ability to promote IL-6 expression in vitro. This study provides the first glance on the complex cytokine network present in key tissues affected by PMR.

Figure 1. Hypothetic pathogenesis of PMR in bursa tissue. GM-CSF and IFN-γ, together with other factors in the bursa tissue steer monocytes to differentiate into macrophages that produce pro-inflammatory cytokines such as IL-6.

REFERENCES:
Objectives: Our objectives were to describe the immune cells of patients with Polymyalgia rheumatica (PMR) and to analyze their evolution under tocilizumab.

Methods: The SEMAPHORE trial (NCT02968217, (1)) was a randomized controlled trial including 121 patients with PMR dependent from glucocorticoids and to analyze their evolution under tocilizumab. Patients were enrolled in the rheumatology department of the Brest University Hospital, but did not have any history or presence of cancer, auto-immune disease or active infection and did not receive treatment with a known impact on the immune system. We analyzed age and sex-matched healthy controls (HC) were recruited in the rheumatology department of the Tours University Hospital.

Results: Samples were obtained for 40 PMR patients and 34 HC. At inclusion, in PMR patients, compared to HC, CD14+CD16+ monocytes were increased (80±1% vs 77±2%, p=0.01), CD14-CD16+ non-classical monocytes were decreased (4±0.3% vs 7±6.0%, p<0.0001), granulocytes were increased (63±2% vs 52±2%, p=0.0001), natural killer cells were decreased (8±1% vs 13±1%, p=0.007), and T cells were increased (70±2% vs 64±2%, p=0.02) with an enrichment in CD4+CD27− CD45RA− regulatory T cells (p=0.001). At week 12, in PMR patients receiving tocilizumab therapy, compared to PMR patients receiving placebo, granulocytes were lower (58±5% vs 73±2%, p=0.006) and monocytes were higher (8±1% vs 5±0.5%, p=0.02).

Conclusion: In patients with a PMR dependent from glucocorticoids, immune cells homeostasis is disturbed. Tocilizumab has an impact more pronounced on granulocytes and monocytes. Knowledge about immune disturbance in PMR might help to choose to use a targeted therapy when glucocorticoids are not sufficient.

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a small vessel vasculitis affecting multiple organ systems, including the kidney. Small vessels in the kidney include small-sized arteries (interlobular and afferent and efferent arterioles), capillaries (glomerular and peritubular capillaries) and venules. Objectives: Although crescentic ANCA glomerulonephritis (GN) is a common histological finding reflecting glomerular small vessel vasculitis, it is reasonable that manifestation of AAV could also contribute to interstitial small vessel vasculitis. Therefore, we here aimed to expand our current knowledge focusing on interstitial vasculitis in ANCA GN by systematic histological scoring of vascular lesions analogous to Banff.

Methods: A total number of 49 kidney biopsies with confirmed renal involvement of AAV at the University Medical Center Göttingen were retrospectively included between 2015 till 2020. A renal pathologist evaluated all biopsies and was blinded to clinical data collection and analysis.

Results: Since previous studies established that crescentic ANCA GN associates with severe kidney injury and acute deterioration of kidney function in AAV, we first systematically scored interstitial vasculitis in association with requirement of renal replacement therapy (RRT). Among all active and chronic tubulointerstitial lesions analogous to the Banff scoring system, the only association between severe kidney injury requiring RRT was observed for interstitial crescents in AAV reflected by peritubular capillaritis (ptc, p=0.0002) and arteritis (v, p=0.0069), affecting 5/49 (10.2%) and 11/49 (22.4%) of renal biopsies, respectively. Since it is known that severe deterioration of kidney function also correlates with crescentic ANCA GN, we next directly compared glomerular and tubulointerstitial lesions. The fraction of normal glomeruli was inversely associated with interstitial fibrosis (i), total (t) and inflammation in IFH (i-IFTA), whereas glomerular crescents were associated with interstitial inflammation (i), tubulitis (t) and total inflammation (t). In contrast, global glomerular sclerosis associated with less interstitial inflammation (i) but correlated with interstitial fibrosis (i) and tubular atrophy (t), confirming established mechanisms that chronic glomerular injury leads to tubular atrophy and interstitial fibrosis. Interestingly, no association between interstitial vasculitis (ptc and v correlating with severe kidney injury) and any glomerular lesion in ANCA GN (also correlating with severe kidney injury) was observed, thereby confirming that interstitial vasculitis contributes to severe kidney injury independent of ANCA GN. By contrast, short-term renal recovery from RRT was equal in both groups, suggesting a distinct association with acute decline of kidney function at disease onset.

Conclusion: Taken together, by using the Banff scoring system we here expand our current knowledge of renal interstitial lesions in AAV revealing peritubular capillaritis and arteritis as important histological alterations associated with severe kidney injury in a considerable subset of AAV. Furthermore, our findings that interstitial vasculitis did not correlate with crescentic ANCA GN imply that the characteristics of each vasculitis manifestation are independent and could further improve our understanding of renal vasculitides contributing to renal injury. These observations suggest that interstitial vasculitis in AAV may also affect long-term prognosis requiring further investigation.

Background: The pathogenesis of ANCA-associated vasculitis (AAV) remains largely unknown. Proteinase 3 (PR3)- and myeloperoxidase (MPO)-AAV are two categories of AAV with distinct genetic background, but mechanistic differences between the two are poorly characterized. We hypothesized that in-depth studies of the plasma proteome in patients with active AAV would provide clues to the molecular and cellular mechanisms behind these disorders.

Objectives: To improve our understanding of the disease mechanisms behind AAV and pathophysiological differences between PR3- and MPO-AAV.

Methods: Plasma samples were collected at six Swedish rheumatological and/or nephrological centers from 42 PR3-AAV and 25 MPO-AAV patients with active disease prior to commencement of therapy and from 136 healthy matched controls. All patients were classified into granulomatous with polyangiitis or microscopic polyangiitis according to the European Medicines Agency algorithm. Samples were analysed for the relative levels of 181 proteins associated with inflammation or cardiovascular disease, using proximity extension assay (OLINK Proteomics). Differentially expressed proteins (DEPs) between groups were analyzed using ANOVA, where proteins with a fold change ≥ 1.5 and adjusted p value < 0.05 were considered as significant DEPs. Partial least square discriminant analysis (PLS-DA) was used to identify proteins contributing most to PR3-AAV/MPO-AAV separation from healthy controls. The STRING database was used to analyse protein–protein interaction networks. Gene ontology, KEGG and Reactome databases were used for pathway enrichment analyses using ClueGO.

Results: In comparison with healthy controls, 63 DEPs were identified for PR3-AAV and 62 for MPO-AAV. Of these, 49 DEPs were common to both AAV groups. Pathway enrichment analysis of the 49 common DEPs identified IL-17, IL-10, TNF-α and NF-kappa B signaling and neutrophil chemotaxis among the significantly enriched processes. The 14 DEPs unique for PR3-AAV formed a functional and physical protein–protein interaction network in STRING analysis, with significant enrichment for regulation of B cell proliferation, activation of matrix metalloproteinases, collagen degradation and IL-17 and TNF-α signaling pathways. The 13 DEPs unique for MPO-AAV did not show any significant functional enrichment. Of the top 15 proteins contributing most to group separation in the PLS-DA analysis, 11 proteins where common to both PR3- and MPO-AAV and 4 proteins were unique for PR3-AVV and MPO-AVV, respectively (Table 1).

Conclusion: Combining quantitative proteomics and bioinformatics analyses, we identified a large group of DEPs characterizing both active PR3- and MPO-AAV and have determined their associated biological mechanisms. DEPs unique for PR3-AVV formed an interconnected protein network associated with biological processes of high relevance for AAV-pathogenesis. In conclusion, these findings may provide new insights into similarities and differences in the pathogenesis of MPO- and PR3-AAV.

Table 1. PLS-DA results showing the top 15 proteins contributing most to separation of PR3-AAV and MPO-AAV patients, respectively, from healthy controls.

DEREGULATION IN ADULT IGA VASCULITIS SKIN AS THE BASIS FOR THE DISCOVERY OF NOVEL SERUM BIOMARKERS

Keywords: -Omics, Vasculitis, Biomarkers

M. Baříček1,2, M. Hladík3, T.D. Toluay*, S. Sedín-Šmrtníková1, A. Höcsev1,2, K. Lakota1,4, 1University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 2University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia; 3Faculty of Mathematics, Natural Sciences and Information Technologies, University of Primorska, Department of Applied Natural Sciences, Koper, Slovenia; 4Faculty of Mathematics, Natural Sciences and Information Technologies, University of Primorska, Department of Biodiversity, Koper, Slovenia

Background: Immunglobulin A vasculitis (IgAV) is a small vessel leukocytoelastic vasculitis, characterized by vascular IgA deposits, and a variable clinical presentation. While IgAV might be self-limiting with a complete recovery, the severe acute form of the disease with gastrointestinal tract (GIT) and renal involvement may lead to significant morbidity, especially in adults. A skin or renal biopsy is still the golden standard for diagnosis. Currently, clinically used markers for IgAV cannot predict patients at risk for severe renal involvement and GIT complications with long-term consequences and which patients will exhibit a mild and self-resolving course limited to skin.

Objectives: This study aimed to use deregulated biological processes in patients’ skin to identify potential serum biomarkers in adult IgAV, enabling stratification of patients with different clinical presentation.

Methods: Skin biopsy samples were collected from treatment-naïve adult IgAV patients at the time of diagnosis. Among IgAV patients, 59 with active IgAV (n=59), and age-/sex-matched HC (n=3), RNA was isolated and 100 bp paired-end sequenced using the Illumina HiSeq 4000 platform (25.9 to 30.8 million reads were obtained per sample). Reads were mapped with Salmon tool against the human transcriptome (Ensemble Release 104). Differentially-expressed genes (log2 fold change ≥ 1, |padj| < 0.05) were computed using the R package DESeq2. Potential serum biomarkers were measured in sera of 59 IgAV patients and 22 healthy controls by magnetic bead-based multiplex assay using the Lumexin platform. Statistically significant differences between groups were determined by the Mann-Whitney U test (for 2 groups) and the Kruskal-Wallis test followed by Dunn’s post-test for multiple comparisons (≥ 3 groups). Spearman’s rank correlation was calculated to measure the correlation between parameters.

Results: Based on differentially-expressed genes and deregulated biological pathways in IgAV patients’ skin, we identified adipokines (fatty acid binding protein 4 (FABP4)), adiponectin, leptin, serpin A12 and angiotensin-like protein 4 (ANGPTL4)), extracellular matrix associated proteins (osteopontin and matrix metalloproteinase-1 (MMP1)) and acute phase protein lipopolysaccharide binding protein (LBP) that were measured in patients’ sera. We detected significantly higher serum levels of FABP4 (p < 0.001), leptin (p < 0.002), ANGPTL4 (p < 0.001), osteopontin (p < 0.001), MMP1 (p < 0.007) and LBP (p < 0.001) in adult IgAV patients, as compared with healthy controls. Most highly enriched biological pathways identified only in skin of IgAV patients with renal involvement were the Regulation of iloprost in adipocytes (padj 9.066 x 10^-10) and ECM-receptor interaction (padj = 4.2862 x 10^-10). Among the top 30 most differentially-expressed genes identified specifically in the skin of IgAV patients with renal involvement were LBP, LEP, SPP1, ADIPOQ, HP and RBP4. Serum levels of adiponectin (p=0.0043) and FABP4 (p=0.049) were significantly higher in patients with renal involvement as compared to those with gastrointestinal involvement. The level of adiponectin (p=0.018) was significantly higher in patients with skin-limited IgAV compared to patients with gastrointestinal involvement. LBP positively correlated with the levels of two routinely measured acute-phase proteins, C-reactive protein (CRP) (correlation coefficient = 0.550, p < 0.001) and serum amyloid A (SAA) (correlation coefficient = 0.545, p < 0.001), established markers of inflammation. Among adipokines, the level of ANGPTL4 positively correlated with CRP (correlation coefficient = 0.314, p < 0.001) and SAA (correlation coefficient = 0.528, p < 0.001).

Conclusion: We identified novel biomarkers of deregulated lipid metabolism and inflammation in adult patients with IgAV that are associated with internal organ involvement. Further analysis of their involvement in disease pathogenesis is warranted.

EVIDENCE FOR INCREASED RESPONSIVENESS TO INTERFERON TYPE I IN CD8+ T CELLS IN PATIENTS WITH GIANT CELL ARTERITIS

Keywords: Innate immunity, Cytokines and chemokines, Vasculitis

M. Van Nieuwland1,2, J. Esiri3, R. Reitsma2, W. Abdullah4, Y. Van Sleen2, M. Sardovici2, E. Brouwer2, L. Van Bon1. 1Hospital Group Twente, Rheumatology and Clinical Immunology, Almelo, Netherlands; 2University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Giant cell arteritis (GCA) is a vasculitis which can lead to severe complications when not timely recognized and treated. There is a need for the discovery of biomarkers to expedite the diagnostic process. Interferon type I (IFN-I) is increasingly recognized as a key player in a range of autoimmune diseases and might play a role in GCA pathogenesis [1]. However, evidence for IFN-I potentially linking innate and adaptive immune responses in GCA is limited. IFN-I activates the Janus kinase/signal transducers and activators of transcription (JAK-STAT) pathway, leading to an increased expression of interferon stimulated genes (ISGs).

Objectives: In this study, IFN-I involvement in GCA pathogenesis is explored.

Methods: Phospho-STAT1 (pSTAT1) expression was investigated in IFN-α-stimulated peripheral mononuclear cells (PBMCs) gated separately for CD8+ T-cells of patients with GCA (n=18), healthy controls (HC, n=15) and infection controls (n=11) by fluorescent cell barcoding and flow cytometry. Also, in 3 GCA patients and 3 HCs, single cell RNA sequencing was performed on PBMCs focusing on ISG expression. Furthermore, IFN-I induced myxovirus-resistance protein A (MxA) and CD8+ expression was investigated in temporal artery biopsies (TAB) of GCA patients (n=20) and GCA mimics (n=20) by immunohistochemistry.

Results: pSTAT1 expression was increased in IFN-α stimulated CD8+ T-cells from patients with GCA compared to both HC (p<0.05) and infection controls. Furthermore, Interferon Induced Transmembrane Protein 1 (IFITM1) mRNA expression was upregulated in peripheral blood CD8+ T cells (p<0.001). MxA was present in TABs of 13/20 GCA patients compared to 2/20 mimics and MxA location co-localized with CD8+ expression in the tissue.

Conclusion: Our results provide evidence for IFN-I involvement in GCA pathogenesis, with CD8+ T-cells as IFN-I responding effector cells. Increased pSTAT1, IFITM1 and MxA expression may reflect increased IFN-I responsiveness in CD8+ T-cells of GCA patients, both locally and systemically. These findings warrant further investigation regarding IFN-I induced biomarkers and IFN-I related novel therapeutic options.

OCULAR AND PERIPHERAL BLOOD IMMUNE PHENOTYPES SUGGEST TRANSLOCATION OF CD4++ MONOCYTES TO AN IMPORTANT EFFECTOR SITE IN BEHÇET’S DISEASE

Keywords: Cell biology, Behçet’s disease, -Omics

Y. Ozcugur1,2,3, Z. Lin1, G. Hatemi1,2, A. Cavers1, J. Nowatzky1,5. 1New York University Grossman School of Medicine, Department of Medicine, Division of Rheumatology, NYU Langone Behçet’s Disease Program, NYU Langone Ocular Rheumatology Program, New York, United States of America; 2Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey, 4New York University Grossman School of Medicine, NYU Langone Applied Informatics Laboratories, New York, United States of America; 5New York University Grossman School of Medicine, Department of Pathology, New York, United States of America

Background: Cellular immunity of Behçet’s Disease (BD) remains poorly understood. Previous work has provided clues pointing to most innate and adaptive immune cell types in BD, but strong signals from non-immunogenetic studies are rare and often inconclusive.

Objectives: Here we aimed to identify BD/HD discriminant single immune cell profiles in semi-biased and targeted approaches and determine their significance at a BD relevant effector site.

Methods: We utilized multi-parametric flow cytometry to dissect cellular phenotypes in PBMC of untreated BD patients (n=27) and HD (n=22) consisting predominantly of active ocular and major vascular BD subjects. Data were subjected to supervised machine learning (CITRUS) and results verified with targeted gating. We also analyzed anterior chamber (AC) fluid cells and autologous PBMC from BD uveitis subjects with scRNA seq.

Results: CITRUS identified CD16+, CD14low, CD4low, CD3-, CD19- cells as a BD/HD distinguishing cellular expression pattern at an FDR of >0.05. Targeted gating confirmed highly significant differences with large effect sizes in PBMC of BD vs HD for "non-classical" (CD14lowCD16hi) and "intermediate" (CD14+CD16+) monocytes at decreased frequencies compared to peripheral "classical" (CD14++CD16-) monocytes were more abundant in BD. PBMC in BD. CD14+ cells showed high abundance in the AC during BD uveitis and co-expressed CD16 far more frequently than CD14+ cells in autologous peripheral blood.

Conclusion: Significantly lower frequencies of CD16+ monocyte and DC subsets in PBMC of untreated active BD vs HD strongly point to their importance in BD. The high abundance of CD14+ cells with CD16 co-expression in the eye during uveitis relative to their frequency in autologous peripheral blood, suggests their transmigration or post-migrational interconversion within the eye during BD uveitis rather than a stochastic process.

AMELIORATION OF IGA VASCULITIS BY SUPPRESSION OF THE PATHOLOGICAL EXPANSION OF TFH17 CELLS

Keywords: Vasculitis, Animal models, Treat to target

X. Ma1, Q. Jiang2, Y. Shan3, X. Chi1, H. Jiang1. 1The First Hospital of China Medical University, Department of Pediatrics, Shenyang, China; 2Zhongshan City People’s Hospital, Department of General Pediatrics, Zhong Shan, China; 3University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan

Background: Immunoglobulin A vasculitis (IgAV), also named Henoch–Schönlein purpura, is a systemic vasculitis characterized by the deposition of IgA1-containing immune complexes in small vessels that often involves the skin, joints, gastrointestinal tract, and kidney [1-3]. Research indicated increased frequencies of circulating activated B cells and plasmablasts in IgAV, which may serve as the sources of rising IgA1 levels [4]. T follicular helper (Tfh) 17 cells are considered to support the activation of B cells and help germinal center (GC) B cells switch to high-affinity IgA production. In human, Th17 cells promote naive B cells to produce higher concentrations of IgA [5]. T cell-deficient mice that receive an adoptive transfer of Th17-Th17 cells show induced development of IgA-expressing GC B cells and an increase in the concentration of IgA. Transfer of non-Th17 phenotype CD4+ T cells leads to higher amounts of IgG in serum but fails to increase the serum IgA level [6]. Therefore, targeted therapy against Th17 cells may specifically inhibit the secretion of IgA and thereby ameliorate IgAV condition.

Objectives: Our previous study has confirmed that Th17 cells increase in the peripheral blood of IgAV patients [7]. However, there is no further study on the pathogenesis of IgAV. To evaluate the pathological role of Th17 cells in IgAV, we investigated the mechanism responsible for the differentiation of Th17 and the production of IgA in IgAV patients and IgAV rats respectively, and explored how to ameliorate IgAV by modulating Th17 generation.

Methods: Peripheral blood mononuclear cells from IgAV patients were analyzed by flow cytometry. In vitro culture was performed to assess the modulation of...

Scientific Abstracts	﻿ 
cytokine-induced phenotypes. IgAV rat model was established by intragastric
administration of mixed solution, intraperitoneal injection of ovalbumin and Freund’s adjuvant. IgAV rats were used to explore the therapeutic effects of IL-6
blockade and the regulatory functions of IL-6 and TGF-β-producing dendritic
cells in Tfh17 cells. Serum cytokine and IgA levels were measured by ELISA
while histopathological changes were evaluated by H&E and PAS staining. Flow
cytometry and immunofluorescence staining were used to detect T cell and GC
B cell phenotypes in circulation and tissues of IgAV rats.
Results: Frequency of CD4+CXCR5+CCR6+ Tfh17 cells were increased in IgAV
patients and associated with disease severity. IL-6 promoted the dendritic cell
production of TGF-β and Tfh17 differentiation. Blockade of IL-6 signaling using
tocilizumab inhibited Tfh17 differentiation, resulting in reduction of the germinal
center and IgA production. Suppression of Tfh17 cells using IL-6 blockade greatly
ameliorated clinical symptoms such as hemorrhagic rash and bloody stool and
decreased IgA deposition and mesangial proliferation in the kidney in IgAV rats.
Conclusion: Our findings suggest that suppression of Tfh17 differentiation can
alleviate IgA-mediated vasculitis and may permit the development of tailored
medicines for treating IgAV.

CORRELATION BETWEEN SAXON TEST AND
UNSTIMULATED SALIVARY FLOW RATE IN PATIENTS
WITH SUSPECTED SJÖGREN´S SYNDROME

Keywords: Sjögren syndrome, Diagnostic tests
M. Fernandez Castro1, M. J. Santos-Bornez1, C. Merino Argumánez1, J. Sanz1,

Majadahonda, IDIPHISA, Rheumatology, Majadahonda (Madrid), Spain
Background: Sjögren syndrome (SS) is a chronic systemic autoimmune disease
characterized by lymphocytic infiltration of the exocrine glands, which alters their
function producing dryness of the mouth, eyes and other mucous membranes.
The method used to quantify glandular hypofunction is by whole saliva flow stimulated and unstimulated (UWSF) [1], which takes between 5 and 15 minutes
(min).The Saxon test (St) [2], is another tool with the same objective but requires
less time: 2 minutes. In the literature, we only have found one study that compared the Saxon test with other diagnostic methods although it is developed in
patients without SS [3].
Objectives: To compare the Saxon test and UWSF in a cohort of patients with
suspected SS.
Methods: In a consecutive cohort of patients who attended the rheumatology
department for suspected SS, UWSF was measured (mL/5 min) and the Saxon
test (gr/2 min) was performed. The Index Reported by Patients with SS of the
EULAR (ESSPRI) was collected too. This is a patient-reported index designed
to assess the severity of patients’ symptoms (dryness, pain, somatic and mental
fatigue) in SS through an average of single 0–10 numerical scale for each domain.
To measure the UWSF, patients were asked to swallow their saliva before the
start of the test and then to spit into a container for 5 min. The St was performed
by calculating the difference in the weight of two pieces of sterile gauze that the

1075

patient chews for two minutes. A UWSF >0.25 mL/min and a St >2.75 g/2min
were considered normal, as well as and ESSPRI<5. Spearman’s rank correlation
coefficient (rs) was used to determine the correlation between both quantitative
variables. The Chisquare test and the Gamma test were used in the comparisons
between the groups (altered and normal) and the Mann-Whitney U in the comparisons of the quantitative variables based on the groups (altered and normal)
previously defined. P values <0.05 were considered statistically significant.
Results: We enrolled 199 patients (166 women), with a mean age ± standard
deviation of 55,1±13,7 years. The medians (Me) and interquartile ranges (IQR)
obtained were 1,50 (0.70 – 2.50) mL/5min for the UWSF, 2,31 (1,60-3,10) g/2min
for the St, 6,33 (3.67- 7.67) for ESSPRI and 7,00 (5,00-8,00) for ESSPRI-dryness
score. A direct and significant correlation between the St and the UWSF (rs=0,391;
P=2,236x10-7) was observed; 76 patients (38,2 %) presented an altered UWSF
and 107 patients (65,2 %) had an altered St. When we analysed the intensity of
the association between the different groups (altered/normal) of both variables,
we observed a direct and significant association (Gamma value=0,4, P=0,019)
between both tools. We also detected differences in the St between patients
with altered UWSF (Me: 1,72gr/2min; IQR: 1,04-2,50) and those with normal
UWSF (Me: 2,62 gr/2 min.; IQR: 1,95-3, 54) (P=3,9x10-6). Similarly, we observed
significant differences in UWSF values between patients with altered St (Me:
1,50 mL/5min IQR: 0,60-2,50) and those with a normal St (Me: 2,00 mL/5min
IQR: 1,00-3,00) (P=0,014). Regarding the ESSPRI, 129 (65,8 %) patients presented an altered ESSPRI and 153 (78,1%) had an altered ESSPRI-dryness
score. The group patients with ESSPRI-dryness score≥5 obtained significantly
lower scores on the St (Me: 2,10 g/2min IQR: 1,39-3.01), on the UWSF (Me:
1,5 ml/5min IQR: 0,6-2,0), and on the ESSPRI (Me:7,00 IQR:5,33-8,00) than
the normal ESSPRI-dryness score group: Me:2,98 g/2min, IQR:2,22-3,75, on St
(P=0,001); Me:2,45 ml/5min, IQR:1,50-3,50, on UWSF (P=6,547x10-5); Me: 3,17
IQR:1, 00-4.08, on the ESSPRI (P=1,17x10-15).
Conclusion: In patients with suspected SS, there is a direct and significant correlation between the St and the UWSF. Therefore, the St could be useful in the
initial assessment of oral gland dysfunction, to save time and/or to select patients
who require performing the UWSF.

EXTRAGLANDULAR INVOLVEMENT AND
AUTOANTIBODY STATUS AS RISK FACTORS
FOR CARDIOVASCULAR DISEASE IN PRIMARY
SJÖGREN’S SYNDROME (PSS): A 20-YEAR
FOLLOW-UP STUDY

Keywords: Autoantibodies, Sjögren syndrome, Cardiovascular disease
C. Sieiro Santos1, R. Rego Salgueiro2, P. Pérez-García1, J. Ordas Martínez1,
C. Moriano1, C. Álvarez Castro1, I. González Fernández1, E. Diez Alvarez1.

Complejo Asistencial Universitario de León, Rheumatology, León, Spain; 2ULS
Guarda, Internal Medicine, Guarda, Portugal
Background: Primary Sjögren’s syndrome (pSS) is an autoimmune disorder
characterized by chronic multisystem inflammation with shared pathophysiology
with SLE and RA. Cardiovascular events have emerged as major causes of morbidity and mortality in patients with autoimmune diseases however, the clinical
significance of cardiovascular disease in patients with pSS remains unclear.
Objectives: To study the association between cardiovascular disease and primary Sjögren’s syndrome (pSS) and analyze the risk of cardiovascular disease
accordingly to glandular/extraglandular involvement and anti-Ro/SSA and/or
Anti-La/SSB autoantibody status.
Methods: pSS patients fulfilling the 2016 ACR/EULAR classification criteria for
pSS was consecutively evaluated and followed in our department between 2000
and 2022. We evaluated the prevalence and clinical significance of cardiovascular risk factors with primary Sjögren’s syndrome (SS), focusing on the possible
association with clinical and immunological features, the therapies administered,
and the impact on cardiovascular disease. A two-tailed value of p<0.05 was
taken to indicate statistical significance. Potential risk factors associated with cardiovascular involvement were determined by multivariate regression analyses.
Results: A total of 102 pSS patients were included. 90% were female, with a
mean age of 65±24 years and a disease duration of 9.9 ±7 years. The baseline prevalence of comorbidities was 59% for hypertension, 29% for cardiovascular diseases, 34% for dyslipidemia, 15% of diabetes, 29% for obesity, 12%
had history of stroke and 17% had arterial/venous thrombosis. 39% of patients
had a history of smoking. Patients with extraglandular involvement had a higher


prevalence of cardiovascular risk factors, including arterial hypertension (OR 2.28 95% CI (1.03-5.09), p 0.04), dyslipidemia (OR 4.4 95% CI (1.18-16.7), p 0.003), LDL mean values (116±48 vs 99±44, p 0.03), uric acid (6.58±1.7 vs 4.3±1.05, p 0.04) and higher risk for myocardial ischemia (OR 4.09 95% CI (1.46-11.4), p 0.01) after adjustment for age, sex, disease duration, and the significant variables in the univariate analysis. Patients positive for both Ro/SSA and La/SSB autoantibodies had a substantially higher risk of arrhythmia (OR 3.4 95% CI (1.01-10.6), p 0.04), arterial and venous thrombosis (OR 5.5 95% CI (1.18-25.7), p 0.03) and stroke (OR 3 95% CI (1.02-8.8), p 0.04). In the multivariate logistic regression analysis, extradiglantal organ involvement (p<0.008), beta2microglobulin levels (p=0.001), the use of glucocorticoids (p=0.02), hypergammaglobulinemia (p=0.02), ESR levels (p=0.007) and an ESSDAI (Sjögren’s syndrome disease activity index)>13 (p=0.02) were found to be risk factors associated with cardiovacular events in pSS patients, meanwhile C3 levels (p=0.01) and treatment with HCQ (p=0.03) were protective factors. Anti-Ro/SSA and anti-La/SSB were significant predictors in univariate but not in multivariate analysis.

Conclusion: pSS patients are more vulnerable to cardiovascular diseases (CVDs). In addition to traditional CVD risk factors, we identified risk factors independently associated with cardiovascular involvement in pSS patients, which suggests the need for early detection and prevention measures to improve the prognosis in those patients.

Background: Within the group of inflammatory myopathies, Inclusion-Body Myositis (IBM) is a distinct pathology with clinical and histological features very different from other entities. In the literature, an association between primary Sjögren’s syndrome (pSS) and IBM has been previously reported.

Objectives: The aim of our study was to compare the inflammatory infiltrates between IBM associated or not with pSS and, among patients with pSS, between muscle and salivary gland.

Methods: We conducted a translational research project, from formalin-fixed and paraffin-embedded muscle biopsies of patients with IBM, associated with Sjögren’s syndrome (IBM+pSS) and sporadic (sIBM) forms, from 6 French expert centers, and salivary glands were collected when available. Imaging mass cytometry (IMC) multiplex immunostaining (37 markers) was used to quantify and decipher the composition of the inflammatory infiltrates within samples (Figure 1). Supervised and unsupervised statistical analyses were performed to compare IMC data between IBM-pSS and sIBM patients and muscle and salivary glands among patients with pSS.

Results: No statistically significant difference was encountered in our comparisons between IBM-pSS and sIBM muscle biopsies. Nevertheless, some trends were pointed and could merit further work in larger case series. Indeed, IBM-pSS samples (14 patients) tended to have more widespread inflammatory infiltrate than sIBM samples (7 patients) involving on average 4.8% versus 1.6% of muscle biopsy surface respectively (p=0.12). Macrophages and T cells were the predominant populations in both IBM-pSS and sIBM patients’ groups. Among T cells, CD8+ cells predominated compared to CD4+ cells in both groups. The proportion of plasma cells (CD138+ CD38+ CD27+) was higher in IBM-pSS than in IBM-pSS patients (medians of 14.7% and 8.5%, respectively, p=0.02), as was the proportion of B cells (median of 3.1% and 0.5%, respectively, p=0.14). Comparing salivary gland and muscle biopsies in patients with pSS, the plasma cells were predominant in the salivary gland with more numerous plasma cells and B cells and less numerous macrophages and T cells in salivary glands than in muscle samples. Nodular inflammatory infiltrate pattern containing B cells appeared to be restricted to pSS patients both in muscle and salivary gland biopsies.

Conclusion: Using for the first time IMC on muscle biopsy and salivary gland has allowed us 1) to point difference between IBM-pSS and sIBM and 2) similarities between salivary and muscle inflammatory infiltrates in patients with pSS samples. These differences suggest that IBM associated with pSS has a distinct pSS-related pathophysiology compared to sIBM, which could raise potential diagnostic and therapeutic applications.

Figure 1. Example of markers of multiplex immunostaining in salivary glands (A) and in muscle (B).

POS1446 VARIATION IN SYSTEMIC DISEASE ACTIVITY MEASURED WITH ESSDAI IN A PROSPECTIVE LONGITUDINAL COHORT OF PATIENTS WITH PRIMARY SJÖGRREN’S SYNDROME WITHOUT IMMUNOSUPPRESSIVE TREATMENT

Keywords: Outcome measures, Sjögren syndrome

L. De Woll 1, G. M. Verstappen 1, A. J. Steil 2, G. S. Van Zuiden 1, J. F. Van Nimwegen 2, A. Vissink 1, F. G. M. Kroese 3, S. Arends 1, H. Bootsma 1, University of Groningen, University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2 University of Groningen, University Medical Centre Groningen, Oral and Maxillofacial Surgery, Groningen, Netherlands.

Background: The EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) has been used as primary endpoint in many recent randomised clinical trials (RCTs) in patients with primary Sjögren’s syndrome (pSS). In multiple RCTs, a large placebo effect (>50%) was observed with the ESSDAI. Since patients are often included with a moderate or high disease activity (ESSDAI ≥5), this placebo effect may partly be due to regression to the mean [1]. Little data is available on the natural course of the ESSDAI in patients who are not treated with immunosuppressive therapies.

Objectives: To assess the variation in ESSDAI up to five years of follow-up in a cohort of pSS patients without immunosuppressive treatment.

Methods: This prospective longitudinal study included consecutive outpatients with pSS from the ongoing Registry of Sjögren Syndrome Longitudinal (RESULT) cohort who fulfilled the ACR/EULAR classification criteria for pSS and who reached at least two years of follow-up with available ESSDAI until December 2022. Patients who received immunosuppressive treatment (biological DMARDs, conventional synthetic DMARDs, including hydroxychloroquine, or prednisone) were excluded. Patients visited the outpatient clinic once a year, or on clinical indication more often, and at each visit the ESSDAI was recorded. All
available visits from baseline up to five years of follow-up were used for analyses. For the analysis at group level, yearly visits were used, defined as the nearest available ESSDAI within a time frame of ±6 months from the yearly visit. For analyses at individual patient level, all available ESSDAI scores were used. The largest change (Δ) in ESSDAI was calculated for each patient by subtracting the lowest ESSDAI from the highest ESSDAI score during follow-up.

Results: In total, 247 pSS patients fulfilled ACR/EULAR classification criteria and reached at least two years of follow-up with available ESSDAI. Of these, 142 patients did not receive immunosuppressive treatment and were included. 126 (89%) of these patients were female, median age was 53 years (IQR 43-65); median disease duration was 6 years (IQR 2-10) and 122 (87%) were anti-SSA positive. Median ESSDAI at baseline was 3 (IQR 1-6) and 93 (67%) patients had a low disease activity according to ESSDAI (score<5). At group level, ESSDAI remained stable during five-year follow-up (Figure 1A). At individual patient level, the ESSDAI varied in the majority of patients (Figure 1B). The median largest Δ (worsening or improvement) in ESSDAI was 4 (IQR 2-8, range 0-22). In total, 93 (65%) patients had a Δ of ≥3 points in ESSDAI, and 65 (46%) patients a Δ of ≥5 points at some point during follow-up. Of the 93 patients with an ESSDAI<5 at baseline, 50 (54%) patients remained in a low disease activity state during follow-up (median follow-up 40 months). Of the 46 (89%) patients who had a moderate or high disease activity (ESSDAI≥5) at baseline, 41 (89%) improved to a low disease activity for at least one visit (Figure 1B) and 37 (80%) patients reached the previously defined minimal clinically important improvement of ≥3 points improvement at some point during follow-up compared to baseline.

Conclusion: In this prospective longitudinal cohort of pSS patients without immunosuppressive treatment, a large variation in ESSDAI was observed during follow-up in individual patients, despite the median ESSDAI scores remaining stable at group level. This study underlines that natural variation in systemic disease activity measured with ESSDAI should be taken into account when using ESSDAI as study endpoint.

POS1447 "IF I HAVE SJÖGREN'S SYNDROME, I WANT TO KNOW IT AS EARLY AS POSSIBLE": PERSPECTIVES OF FIRST-DEGREE RELATIVES OF PEOPLE WITH SJÖGREN'S SYNDROME FROM AN INTERNATIONAL SURVEY

Keywords: Sjögren syndrome

A. Alunno1, F. Carubbi1, V. Ritschl2, S. Zenza4, A. Vieira5, K. Antonopoulou, V. C Romão6, M. J. Sousa Bandeira7, M. Stradner4, Internal Medicine and Nephrology Division, University of Udine, Department of Life, Health and Environmental Sciences, Udine, Italy; 2Medical University of Vienna, Institute for Outcomes Research, Vienna, Austria; 3Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Vienna, Austria; 4Division of Rheumatology and Immunology, Medical University of Graz, Department of Internal Medicine, Graz, Austria; 5Liga Portuguesa Contra as Doenças Reumáticas, Núcleo Síndrome de Sjögren, Lisbon, Portugal; 6Sjögren Europe, Zurich, Switzerland; 7Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Academic Medical Centre, Rheumatology Department, Lisbon, Portugal; 8Rheumatology research Unit, Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: In recent years, rheumatology research focused on first-degree relatives of people with rheumatic diseases, mainly rheumatoid arthritis, since they have a higher risk of developing the disease compared with the general population and offer a potential source of insight into the preclinical phase of the disease. However, evidence on preclinical Sjögren’s syndrome is still lacking.

Objectives: To explore the perspective of first-degree relatives of people with SS and inform the Pre-Sjögren's Syndrome Targeted Immunology Evaluation (PreStStige) study, conducted under the auspices of the EULAR Study Group on Sjögren's Syndrome (eSSential).

Methods: An online survey targeting first-degree relatives of people with SS was developed in English and translated into 11 languages (Italian, German, French, Spanish, Portuguese, Greek, Swedish, Finnish, Romanian, Norwegian and Maltese). The survey was launched and distributed via patient associations, forums, support groups, and in 3 Rheumatology participating centres (Austria, Italy and Portugal). Respondents without a diagnosis of SS were confronted with a scenario where they were offered a free rheumatology examination to assess whether they had symptoms suggestive of pSS. If so, they are advised to undergo additional exams (within a variable range of costs) to ascertain whether they have pSS. Surveys were accepted until January 10, 2023.

Results: Of 1064 people starting the survey, 677 respondents from 32 countries fulfilled the entry criteria (age >18 years, being a first-degree relative of a person living with pSS). 90% of respondents were siblings, 7% were offspring, and 3% were parents of pSS patients. Respondents were mainly females (80%), aged 30-49 years (31%) and 50-70 years (38%). 155 (23%) of respondents already had a diagnosis of SS, while 119 (17%) had a diagnosis of other autoimmune diseases (AD) (23/119, 19% had more than one AD). When asked about their perceived risk of developing SS or another AD, several respondents did not feel to be at higher risk being first-degree relatives of affected people (Figure 1). When confronted with an hypothetical scenario, over half of the respondents without a diagnosis of pSS (N=522) mentioned feeling either worried, sad or scared about the possibility of being diagnosed with pSS. Nonetheless, the majority of them (86% of 522) were keen on accepting a preclinical rheumatology consultation, with the main reason for that being, “If I have pSS/other autoimmune diseases, I want to know it as early as possible” (82%). Conversely, those that would decline a free rheumatology examination mainly justified their decision based on the absence of symptoms suggestive of pSS (56%). Among respondents that would accept a consultation, 84% would proceed further and perform additional exams if advised by the rheumatologist based on the detection of symptoms/signs suggestive of pSS. As above, the main reason was the possibility of achieving an early diagnosis. The respondents that accepted the free rheumatology consultation but would not proceed further even if the rheumatologist would identify red flags for pSS mentioned the economic aspect as the main barrier (specifying they would accept performing additional exams if free of charge).

Conclusion: Our study explored, for the first time, the perspective of first-degree relatives of people with SS highlighting an overall willingness to undergo preclinical examinations for an early SS diagnosis. Economic challenges (namely,
paying for diagnostic exams) have been identified as a barrier. The survey is still open and is being translated into additional languages to increase its reach. The results of the survey will inform the next steps of the Pre-Sjögren’s Syndrome Targeted Immunology Evaluation (PreSSige) study.

### POS1448

**INDIVIDUALS AT RISK FOR SJÖGREN’S SYNDROME – TWO-YEAR DATA OF THE PRESTIGE (THE PRE-SJÖGREN SYNDROME TARGETED IMMUNOLOGY EVALUATION) STUDY**

**Keywords:** Sjögren syndrome, Autoantibodies

S. Zenz1, P. Javorova1, L. Erlacher1, B. Drec3, A. Lackner1, D. Cornel1, J. Thiel1, M. Straden1. 1Medical University of Graz, Department of Rheumatology and Immunology, Graz, Austria; 2University of Brest, Department of Rheumatology, Brest, France

**Background:** Primary Sjögren’s syndrome (pSS) is a chronic autoimmune disease often diagnosed years after appearance of the first symptoms. Therefore, little is known about initial development of the disease. Anti-Ro antibodies can be found years before the first symptoms appear.

**Objectives:** To identify individuals at risk for pSS and follow up over 10 years to examine symptoms and immunopathology before and during the development of pSS.

**Methods:** This ongoing longitudinal study enrolled individuals at risk for developing pSS but have not met the ACR-EULAR classification criteria. We recruited three groups: A.) Anti-Ro positive individuals without any symptoms for an underlying systemic autoimmune disease; B.) First degree relatives of patients with a diagnosis of pSS AND an abnormal immunologic laboratory value (ANA ≥ 1:160 and/or anti-Ro- and/or rheumatoid factor*); and C.) Individuals with at least one feature of the ACR-EULAR classification criteria for pSS, but not fulfilling the criteria. At screening and at annual follow-up visits, demographic data, blood, urine and saliva samples were obtained. Salivary flow, Schirmer’s test, and salivary gland ultrasonography (SGUS) using Hocevar-Score were performed. A lip salivary gland biopsy (LSB) was obtained at the screening visit and repeated once when typical symptoms appeared within the follow-up visits. The primary endpoint was the development of definite pSS according to the ACR-EULAR classification criteria or a diagnosis of another systemic autoimmune disease.

**Results:** After two years, 53 subjects were recruited from all three groups, of whom 31 were enrolled in the study (Anti-SSA* n=25, relatives n=4, incomplete n=2). Most of the 22 screening failures were relatives who did not have an abnormal immunologic laboratory value. 29 individuals were female; they had a mean age of 49.6 ± 12.7 years (SD; standard deviation) and a mean body weight of 71.4 ± 15 kg. 11 individuals reported having a relative with an underlying autoimmune disease. The median ESSD1 was 0 (0-5; min-max). Individuals had a pathological stimulated whole saliva flow (mean 3.7 ± 1.4 g) and eight had pathological Schirmer’s test (left eye: mean 13.6 ± 11.1 mm; right eye: 13.2 ± 12.2 mm). Three of 14 individuals had a pathological SGUS score. All three individuals were recruited in the Anti-Ro* group. At screening visit, 11 LSB were performed (mean focus score of 0.53 ± 1.2) and one individual reached a focus score ≥ 1. So far, 18 individuals have completed the two-year visit. Two of them had pathological stimulated whole saliva flow (mean 3.85 ± 1.4 g) and five of them had pathological Schirmer’s test (left eye: mean 15.4 ± 13 mm; right eye: 14.5 ± 13 mm). The median ESSD1 was 0 [0-4]. Eight SGUS were performed with a mean Hocevar-Score of 5.6 ± 8. Within two years, four patients (13%) were diagnosed with pSS, one (3%) with systemic lupus erythematosus and one (3%) with rheumatoid arthritis.

**Conclusion:** This longitudinal study for the first time provides us with data on the evolution of pSS. Future recruitment at multiple centers and longer follow-ups will shed light on the earliest phase of pSS.

### POS1449

**CARDIOVASCULAR DISEASE IN PRIMARY SJÖGREN SYNDROME**

**Keywords:** Sjögren syndrome, Cardiovascular disease

C. L. Zippel1, S. Beider2, E. Kramer2, F. F. Konen3, T. Seeliger2, T. Skripuletz3, S. Hirsch4, A. Dopfer-Jablonska2, T. Witte1, K. Sonnenstein2, D. Ernst4. 1Hannover Medical School, Department of Rheumatology and Immunology, Hannover, Germany; 2Hannover Medical School, Department of Rheumatology and Immunology, Hannover, Germany; 3Hannover Medical School, Department of Neurology, Hannover, Germany; 4Hannover Medical School, Department of Cardiology, Hannover, Germany

**Background:** Primary Sjögren’s syndrome (pSS) is associated with an increased prevalence of traditional risk factors and cardiovascular diseases (CVDs).

**Objectives:** The study aimed to identify specific risk factors for CVD in pSS patients.

**Methods:** pSS patients with and without CVD were compared. All patients fulfilled the EULAR/ACR classification criteria. Patients with CVD presented at least one of the following manifestations: myocardial infarction, transient ischemic attacks, ischemic or hemorrhagic stroke, peripheral artery disease, coronary artery disease and carotid plaques. Data were collected by a standardized protocol and review of medical records.

**Results:** 613/12 (19.6%) pSS patients presented with CVD. Traditional risk factors such as hypertension, hypercholesterolemia and diabetes (≥ 0.05), pSS manifestations, in particular vasculitis (p < 0.033) and Raymond’s phenomenon (p = 0.018) were associated with CVD. Among patients with ischemic events (28/312, 9%), particularly cerebrovascular disease (n = 12/28, 42.9%), correlations with increased EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) (p = 0.039) and EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI) (p = 0.048) were observed. Age at first cerebrovascular event was 55.2 (48.9 – 69.6) years. Multivariate analysis confirmed hypertension (odds ratio (OR) 3.7; 95% confidence interval (CI) 1.87 – 7.18, p < 0.001), hypercholesterolemia (OR 31.3, 95% CI 1.63 – 5.72, p < 0.001), male gender (OR 0.4, 95% CI 0.17 – 0.78, p = 0.009), Raymond’s phenomenon (OR 2.5, 95% CI 1.28 – 4.82, p = 0.007) and CVD involvement (OR 2.7; 95% CI 1.00 – 33.71, p = 0.048) as independent CVD predictors.

**Conclusion:** Raymond’s phenomenon as well as vasculitis and high ESSDAI have shown a significant association to CVD. pSS patients with cerebrovascular events were younger than expected. Knowledge about risk factors may help clinicians to identify pSS patients at risk for CVD. After diagnosis of pSS, patients should be screened for risk factors such as hypertension and receive appropriate therapy to prevent or at least reduce sequelae such as infarction. However, further investigations are necessary in order to achieve a reliable risk stratification for these patients.

**Acknowledgements:** We would like to express our gratitude to the staff of the Rheumatology Outpatients Department at Hannover Medical School for their continual help in organization of patients and Reference styles.

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.1831

### POS1451

**3-YEAR ANALYSES OF AT-RISK ANA-POSITIVE COHORT: PROGNOSTIC VALUE OF CLINICAL AND INTERFERON BIOMARKERS TOWARDS AUTOIMMUNITY**

**Keywords:** Biomarkers, Sjögren syndrome, Systemic lupus erythematosus

M. Y. MD Yusof1,2, S. U. Hassan1, Z. Wigston1, A. Pascas1, J. Arnold1, L. M. Carter1, P. Emery1,2, E. Vital1,3. 1University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospitals NHS Trust; NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

**Background:** Autoimmune connective tissue disease (AI-CTD) arise from a common ‘At-Risk’ ANA-positive population in which clinical phenotype does not reliably predict progression. We previously showed that higher IFN-Score-B and family history were predictive of progression to meeting classification criteria at 12-months[1]. However, classification criteria may undergo revision and not capture all significant outcomes. There is limited data on longer-term outcomes since some may progress at later time-points.

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.2302

Figure 1. Respondents’ level of agreement with statements related to their perceived risk and attitude towards the development Sjögren’s Syndrome or other autoimmune diseases.
Objectives: To describe the 3-year outcomes of At-Risk individuals; to assess discriminative ability of baseline clinical and IFN-Score-B in predicting various progression endpoints at 1 and 3 years.

Methods: We conducted a prospective cohort study in At-Risk individuals (ANA-positive, non-specific symptoms of ≤1 year and treatment naive). Patients were assessed at baseline, then annually for 3 years. We used multiple RMD classification criteria, including the revised 2019 EULAR/ACR for SLE, and need for therapy, to group patients as below:

1. Absolute non-progressors (ANP) (no clinical criteria)
2. Undifferentiated CTD (UC-CTD) (2 clinical criteria but not fulfilling RMD criteria). This group was subdivided into those requiring an immunosuppressant (IS) excluding antimalarials only and those who did not
3. Year 1 progressors (meeting criteria for RMD by 1 year)
4. Late progressors (meeting criteria for RMD in Years 2-3)
5. Clinically significant disease (CSD) (progressors OR UC-CTD on IS)

Bloods were analysed for two IFN-stimulated gene expression scores previously described[2]. Discrimination of single or combined clinical and IFN-Score-B markers were assessed using ROC curve analyses.

Results: Of 148 patients, 132 (89%) were female, 107 (72%) were Caucasians, 48 (32%) had a family history of RMD, 56 (38%) were anti-dsDNA+. 56 (38%) had a family history of RMD, 56 (38%) were anti-dsDNA+, 8 (6%) had low C3 and/or C4 level. Number of established clinical criteria at baseline were 0 (30%), 1 (64%) and 2 (8%). Outcomes were: Year 1 progressors: 21 (14%) [SLE=14; pSS=6]; Late progressors: 12 (8%) [SLE=10; pSS=1; AS=1]; U-CTD on IS: 8 (5%); Combined baseline clinical and IFN biomarkers could be used to risk translate their use in clinical practice and inform early therapy trials in the “High Risk” individuals.

Conclusion: Inclusion criteria was patients ≥18 years that met 2016 ACR/EULAR criteria for Sjogren’s Syndrome. This group was subdivided into those requiring an immunosuppressant (IS) excluding antimalarials only and those who did not present severe organ affection. Patients with severe organ affection had a significantly higher proportion of male sex (56.3% vs 35.7%), higher median baseline ESSDAI (3.81 vs 1.06, p=0.00) and SSSDI (1.88 vs 1.02, p=0.04). Higher proportion of lymphoma (18.8% vs 3.2%, p=0.024), higher proportion of steroids (37.5% vs 0, p=0.00) and higher proportion of disease modifying drugs (37.5% vs 3.2%, p=0.00) were observed as well. The comparison of lymphocytic composition of the MSGB according to outcome 1 and outcome 2 are summarized in Table 1.

Conclusion: There were significantly increased number of total lymphocytes and number of infiltrates in the MSGB of patients that presented severe organ affection within 3 years of follow up. Also a significantly increased number of T cells, both CD4+ and CD8 cells, were observed in patients with severe organ affection.

PERIODONTITIS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: A NORWEGIAN NATION-WIDE REGISTER STUDY OF 10 086 PATIENTS

Keywords: Sjögren syndrome, Registries, Epidemiology

O. O. Aagaard1, A. Bolstad2, S. Lie3, B. T. Svanas Føvaag4. 1The Faculty of Medicine, University of Bergen, Bergen, Norway; 2Department of Clinical Dentistry, University of Bergen, Bergen, Norway; 3Department of Clinical Dentistry, University of Bergen, Bergen, Norway; 4Haukeland University Hospital, Bergen, Department of Rheumatology, Bergen, Norway

Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disorder characterized by focal lymphocytic infiltration of the exocrine glands causing dry eyes and dry mouth. Immunological mechanisms in pSS have similarities with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), which have increased risk for periodontitis [1]. Patients with pSS already have inferior oral health and information regarding a possible connection between periodontitis and pSS is sparse. There is a need to explore this further in a large-scale study.

Objectives: To investigate the association between periodontitis and primary Sjögren’s syndrome in a large national cohort.

Methods: We conducted a population-based study, where the cohorts were identified based on International Classification of Disease (ICD)-10-codes registered in the Norwegian Patient registry (NPR) January 2011 – December 2017. The outcome was the manifestation of periodontitis defined by either at least one registration of periodontal surgery or 6 or more registrations of systematic treatment of periodontitis in the Norwegian Control and Payment of Health Reimbursement (KUHR). To be included in the pSS cohort (n=10 086) patients had to have 4 or more registrations with M35.0 as the main diagnosis in NPR. This limit was set to minimize the risk of miscoding. The comparative cohort (n=310 573) entailed patients treated for assumed non-osteoeprotic fracture or having undergone hip- or knee replacement due to osteoarthritis during the study period. Only patients between 20 – 80 years of age were included, and patients with RA or SLE was excluded from the study population. Odds Ratio (OR) for periodontitis was calculated using logistic regression analyses adjusting for sex, age, diabetes mellitus (DM) 1 and 2, cardiovascular disease, smoking status, and alcohol consumption. The distribution of ILD patterns was in line with recent literature, with 24/52 (46.2%) defined by the recent definition of PPF in our cohort. 2. To identify specific factors associated to PPF in well characterized SS-ILD patients.

To identify specific factors associated to PPF in well characterized SS-ILD patients.

Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disorder characterized by focal lymphocytic infiltration of the exocrine glands causing dry eyes and dry mouth. Immunological mechanisms in pSS have similarities with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), which have increased risk for periodontitis [1]. Patients with pSS already have inferior oral health and information regarding a possible connection between periodontitis and pSS is sparse. There is a need to explore this further in a large-scale study.

to desaturation; 3/6 (6.5%) patients died because of ILD progression. Complete seriate evaluations including HRCT at 1-year distance were available for 17 patients: 8/17 (47.1%) were defined as PFP and 10/17 (58.8%) as non-PFP according to the ATS definition. The former group exhibited older age at diagnosis (p=0.001) and a UIP pattern in 5/8 vs 9/9 cases (p=0.06). Standard of care immunosuppressive treatment did not differ significantly between the two groups, while no patients were treated with antifibrotics.

**Conclusion:** The clinical phenotype of PFP is relatively common among SS-ILD patients and is associated with older age at diagnosis and a UIP pattern on HRCT. These characteristics may aid in the selection of patients eligible for antifibrotic therapy.

**Background:** Salivary gland ultrasonography (SGUS) is commonly used in primary Sjögren Disease (pSS) as a diagnostic tool [1]. It could also be used to monitor disease activity, but severity of SG US parenchymal abnormalities in relation to disease duration is not well characterized.

**Objectives:** To assess transversally the severity of ultrasound salivary parenchymal abnormalities in relation to pSS duration.

**Methods:** In this prospective cross-sectional international multicentric study, patients with pSS according to 2002 or 2016 ACR/EULAR classification criteria were included. Parenchymal abnormalities assessed by ultrasound within both parotid and sub-mandibular glands were reported on a standardized form and classified according to the semi-quantitative score of the OMERACT (global score and each item evaluated separately) [2]. Reliability between experts was measured after online training. Demographic, clinical and paraclinical data were also collected and patients were separated into 4 groups according to disease duration from the first buccal dryness symptoms (group A: < 5 years, group B: between 5 and 10 years, group C: between 10 and 20 years, group D: > 20 years of evolution).

The association between disease duration groups and SGUS parenchymal abnormalities was quantified in terms of odds ratio and its 95% confidence interval.

**Results:** 247 patients were consecutively included between May 2019 and February 2022 in 12 international centers. They were 47, 69, 78 and 53 in groups A, B, C and D, respectively. Women represented 94.7% of patients, with a median age of 58 [range 19-89] years old. Oral and ocular dryness were reported by 99.6% and 95.1% of patients, respectively. Salivary flow was abnormal in 74.7% of patients and Schirmer’s test in 82.1%. The focus score was ≥1 mm2 in 89% of patients. 85% of patients had positive anti-SSA and 59.6% had rheumatoid factor. The median ESSDAI score was 3 [0-48]. Considering for each patient the gland with the highest US OMERACT score, there was a global significant association between disease duration and OMERACT score (OR for 5 years duration: 1.23 [IC95%: 1.04; 1.47], p=0.02). When comparing groups A+B versus C+D on the OMERACT score, the OR was 1.95 [IC95%: 1.10; 3.48], p=0.02, while no significant difference was found when comparing group A versus B+C+D. Considering the item of the OMERACT score, there was not any statistical difference between the 4 groups in relation to the proportion of an/hypoechoic areas in the gland nor homogeneity or posterior border visibility. The only statistical difference between groups was found regarding the proportion of hyperechoic bands (p = 0.0009). When comparing group A versus B+C+D on this item, the OR was 2.55 [95%CI: 1.30-5.01], p=0.006.

**Conclusion:** This large international transversal study in patients with pSS found a positive association between global SGUS lesions evaluated by the OMERACT score and disease duration, with a significant difference only observed in the proportion of hyperechoic bands, when considering separately each item of the score. This may suggest a progressive fibro-adipous evolution of the gland across disease duration. The presence of diffuse hyperechoic bands (grade 3 in the OMERACT scoring system), corresponding to a higher disease duration group, could be useful in the future to stratify patients in clinical trials and to interpret SGUS modifications after treatment.

INTERSTITIAL LUNG DISEASE IN SJÖGREEN’S SYNDROME: PREVALENCE, PATTERNS, TREATMENT, AND PROGNOSIS

**Keywords:** Real-world evidence, Sjögren syndrome, Comorbidities

J. H. Koh1, Y. Park2, J. J. Lee3, H. Jeon4, S. J. Moon5, Y. H. Kim6, J. K. Min7, S. K. Kwok8, Uijeongbu St. Mary’s Hospital, The Catholic University, Division of Rheumatology, Department of Internal Medicine, Uijeongbu, Korea, Rep. of (South Korea); 9The Catholic University of Korea Seoul St. Mary’s Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 10The Catholic University of Korea Yeouido St. Mary’s Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 11Bucheon St. Mary’s Hospital, the Catholic university of Korea, Division of Rheumatology, Department of Internal Medicine, Bucheon, Korea, Rep. of (South Korea); 12Bucheon St. Mary’s Hospital, the Catholic university of Korea, Division of Rheumatology, Department of Internal Medicine, Bucheon, Korea, Rep. of (South Korea)

**Background:** Intestinal lung disease (ILD) is a potentially serious yet underdiagnosed manifestation of primary Sjögren’s syndrome (pSS).

**Objectives:** This observational study aimed to investigate the clinical, functional, and imaging characteristics of ILD in pSS, together with treatment and prognosis.

**Methods:** Longitudinal clinical and laboratory data of patients with pSS were extracted from three hospitals of the Catholic Medical Center through a clinical data warehouse, between March 1, 2012, and February 28, 2022. Predisposing factors for the development of ILD and acute exacerbation were identified using a logistic regression model.

**Results:** A total of 1,402 patients with pSS were included in this study (Female, 98%; median age, 55 years). Among them, 52 patients with pSS (7%) were diagnosed with ILD (21 biopsy-proven cases). Fibrosing nonspecific interstitial pneumonia (NSIP) was the most prevalent CT pattern in pSS-ILD (58%), followed by usual interstitial pneumonia (20%), and organizing pneumonia (16%). At the diagnosis with pSS-ILD, 64% of patients showed reduced diffusion capacity, and 54.3% of patients with pSS-ILD showed a restrictive functional pattern. The median follow-up period was 3.2 years. During follow-up, six patients died (6.5%) and 26 patients (28.3%) experienced acute exacerbation (AE). However, 64% of patients showed no AE without treatment. Lower baseline forced vital capacity (FVC) (Odds ratio (OR), 0.962, P = 0.026) and high neutrophil-to-lymphocyte ratio (OR, 3.59, P = 0.046) were significant predisposing factors for AE.

**Conclusion:** ILD accounted for 7% of the comorbidity of SS, and 64% showed stable lung function without treatment. AE was associated with NLR and baseline FVC.
Background: Sjögren’s syndrome (SS) is an autoimmune disease characterized by the presence of primary Sjögren’s syndrome (pSS), which is associated with an increased risk of interstitial lung disease (ILD). Accurate diagnosis and management of ILD in pSS patients are crucial. The objective of this study was to investigate the long-term course and prognostic factors for ILD progression in patients with pSS.

Methods: We conducted a single-center retrospective study in patients with pSS (n=120) who underwent at least one high-resolution computed tomography (HRCT) scan between March 2013 and February 2021. Clinical symptoms, laboratory data, and radiologist reviews were recorded. Multivariate logistic regression analysis was performed to identify independent risk factors for ILD progression.

Results: During the follow-up period (median, 2.8 years), ILD progressed in 39 patients (32.5%). Multivariate analysis revealed that elevated lactate dehydrogenase (LDH) levels (OR, 1.012; p=0.05) and increased coarseness score of fibrosis (OR, 1.403; p<0.001) were independent risk factors for ILD progression.

Conclusion: ILD progression in pSS patients is associated with elevated LDH levels and increased fibrosis coarseness. Early detection and intervention may be necessary to prevent ILD progression in pSS patients.

Background: It is well established that patients with inflammatory rheumatic diseases have an increased cardiovascular risk [1]. Most data exists for rheumatoid arthritis, but there are also a few studies for primary Sjögren’s syndrome (pSS)[2].

Objectives: Aim of our study was to investigate the extent of subclinical atherosclerosis in a large group of patients with pSS compared to control subjects without pSS. Secondary, correlations with clinical factors, such as organ involvement or antibody positivity, and disease activity were investigated.

Methods: From September 2021 to April 2022, pSS patients from the outpatient clinic of our hospital were consecutively included after informed consent. In addition, age- and sex-matched control subjects were recruited in a 2:1 ratio via multimedia call for participation. All pSS patients fulfilled current EULAR classification criteria for pSS and had a disease duration of at least 5 years. Participants with additional rheumatic or inflammatory diseases, tumor disease in the past 5 years, or end-organ manifestations of atherosclerotic disease were excluded. Data collection was performed by standardized questionnaire and Doppler ultrasonography for evaluation of plaque extent and intima-media thickness measurements (cIMT).

Results: Analysis included data from 199 pSS patients and 100 control subjects. 38 (19.4%) subjects of the pSS cohort were male and the median age was 56.92 years [50.50-65.21]. The median disease duration (since initial manifestation) of pSS patients was 136 months. The cohorts were analyzed for differences regarding to the cardiovascular risk profile: There were no significant differences in age, gender distribution, tobacco consumption, body mass index (BMI), pre-existing arterial hypertension, hypercholesterolemia, or diabetes mellitus. Similarly, there were no differences in LDL cholesterol, HDL cholesterol, or HbA1c in laboratory tests at enrollment. Only a positive family history for cardiovascular disease was significantly more frequent in the pSS cohort (p=0.003). After adjustment via propensity score matching, the pSS cohort was found to have a significantly greater intima-media thickness (p<0.001). When age was added as a covariate, there was an earlier onset of intima-media thickening recognizable in the pSS patients (p=0.014). Furthermore, there was a significantly more frequent occurrence of plaque in the pSS cohort (p=0.031). pSS-patients had a 1.82times increased odds of having plaque in comparison to the control cohort. Organ involvement in the pSS-cohort was associated with a thicker cIMT (p=0.025) and pSS-patients with organ involvement also showed a 1.74times increased odds of having plaque compared to pSS-patients without organ involvement.

Conclusion: pSS appears to accelerate the development and progression of atherosclerosis as an independent risk factor. It seems to promote not only an increased incidence of atherosclerotic changes, but also an earlier onset of wall thickening in the sense of vascular aging. An increased risk for patients with organ involvement was observed. Further longitudinal studies are required to answer the question if this subgroup of pSS patients in particular or all pSS patients could benefit from screening with Doppler ultrasonography and preventive medication with HMG-CoA reductase inhibitors or acetyl salicylic acid.

Background: Recently, a growing interest has arisen in investigating the association between patients’ serological profiles and the different clinical phenotypes in primary Sjögren’s syndrome (pSS). The double positivity for anti-Ro52/anti-Ro60 has been associated with B-cell hyperactivity and a more prominent INF-α signature. Whether the positivity of anti-La/SSB antibodies influences the clinical features of triple positive pSS patients at the time of diagnosis remains controversial.

Objectives: 1. To compare the clinical, biological, histological and ultrasonographic distinctive features of pSS patients presenting a triple positivity for anti-La/SSB and anti-Ro52/anti-Ro60 with those of patients with different serological profiles at the time of pSS diagnosis. 2. To specifically describe the presenting features of pSS patients with a triple positivity in comparison with the features of patients with a double positivity for anti-Ro52/anti-Ro60.

Methods: This is a cross-sectional study including newly diagnosed pSS patients (ACR/EULAR 2016 criteria) enrolled prospectively from 2018 to 2022. Patients were stratified in five groups according to the serological profile (i.e. seronegative, isolated anti-Ro52, isolated anti-Ro60, double positive and triple positive). Demographic, clinical, biological and histological data were compared among the groups. Ultrasonographic features of major and minor salivary glands were also analyzed. Data were presented as means±SD or as percentage frequency, as appropriate. Intergroup comparisons were made using the t-test/Mann–Whitney tests for continuous variables, the chi-square exact test for categorical variables.

Results: We included 199 pSS patients (M:F= 19:180, mean age 56±13.7 years), 33/199 (16.58%) were seronegative, 50/199 (25.12%) presented isolated anti-Ro52, 49/199 (24.62%) had double positivity, 55/199 (27.64%) had triple...
positivity and 12/199 (6.03%) presented isolated Ro60 antibodies. Triple positives were younger than seronegatives. No further differences in demographic features were detected among the groups. Triple positives were found to have a more complex infiltrate in the minor salivary gland biopsies than double positives with a higher mean Focus Score (2.34±2.05 vs 1.32±0.84, p=0.005) and a higher mean number of ectopic lymphoid structures (2.40±2.88 vs 1.21±1.25, p=0.004). Regarding major salivary glands ultrasound (SGUS), double positives and triple positives were found to have a score ≥2, according the OMERACT system, more frequently than the other groups (p = 0.001, Figure 1). Particularly, triple positives presented SGUS abnormalities more frequently than double positives (68.9 vs 43.6%, p=0.03). The same findings were observed for Ultra-high frequency ultrasonography (UHFUS) of minor salivary glands (Figure 1). Indeed, triple positives had the highest UHFUS scores (p=0.01). Furthermore, triple positives presented a higher ESSDAI score than the other groups including the double positives (p=0.001) due to a higher disease activity in the ESSDAI glandular and biological domains.

Conclusion: Triple-positive patients were characterized by a more severe glandular involvement documented by ultrasound and histology and by a higher disease activity. These results support the data suggesting that the separate detection of anti-Ro52, anti-Ro60 and anti-La/SSB may significantly contribute to patients’ stratification at the time of the diagnosis, thus paving new avenues for tailored approaches in pSS.

Methods: In 54 pSS patients, disease activity was assessed by the European League Against Rheumatism (EULAR) Sjögren’s Syndrome Disease Activity Index (ESSDAI) and the EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI). The salivary gland involvement was evaluated by ultrasound (USG) and elastography. USG and elastography were performed for the major salivary glands (Figure 1). Indeed, triple positives had the highest USG scores (p=0.01). Furthermore, triple positives presented a higher ESSDAI score than the other groups including the double positives (p=0.001) due to a higher disease activity in the ESSDAI glandular and biological domains.

Conclusion: Triple-positive patients were characterized by a more severe glandular involvement documented by ultrasound and histology and by a higher disease activity. These results support the data suggesting that the separate detection of anti-Ro52, anti-Ro60 and anti-La/SSB may significantly contribute to patients’ stratification at the time of the diagnosis, thus paving new avenues for tailored approaches in pSS.

MAJOR SALIVARY GLAND ULTRASOUND AND ELASTOGRAPHY FOR ASSESSMENT OF DISEASE ACTIVITY IN PATIENTS OF PRIMARY SJÖGREN’S SYNDROME

Keywords: Sjögren syndrome, Ultrasound

K Chandwar1, D. P. Misra2, K. Kishor2, P. Dogga1, D. Ekbohte6, J. Dixit1, A. Wakhlu2, V. Agarwal3, A. Wakhlu2, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India; 2King George’s Medical University, Clinical Immunology and Rheumatology, Lucknow, India; 3Apolomedics Super Speciality Hospitals, Clinical Immunology and Rheumatology, Lucknow, India

Background: Objectives: To assess major salivary gland involvement by ultrasonography and elastography in patients with Primary Sjögren’s syndrome (pSS), correlate the severity of ultrasonographic and elastographic involvement of major salivary gland with disease activity.

Methods: In 54 pSS patients, disease activity was assessed by the European League Against Rheumatism (EULAR) Sjögren’s Syndrome Disease Activity Index (ESSDAI) and the EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI). The salivary gland involvement was evaluated by the Hocevar and OMERACT score and Real time Elastography was performed for the salivary glands and were scored semiquantitatively.

Results: 54 patients of primary Sjögren’s Syndrome and 55 controls were included in the study. The patients were younger with a mean age of 37.61±11.56 years (Refer to Figure 1 for demographic and clinical data of pSS patients in the study). Mean USG/Elastography scores were significantly higher (p < 0.001) in cases than controls. ESSDAI correlated strongly with Hocevar Score and OMERACT and Moderately with Elastography. ESSPRI correlated well with Hocevar Score and OMERACT score but poorly with Elastography. All the scores differentiated sufficiently between high and activity efficiently (p<0.001), however, for the OMERACT(p=0.13) and Elastography score(p=0.083) the difference between moderate and low disease activity was not statistically significant. A multivariate linear regression analysis found an association with USG Scores with ESSDAI and ESSPRI, Elastography with ESSDAI and Disease duration.

Conclusion: The Hocevar score had a robust correlation with disease activity. The Elastography scores moderately correlated with disease activity and duration of disease. There was a near-complete correlation of USG scores with Uni-lateral, Parotid, and submandibularibulc scores.

POS1461 ADVANTAGES OF DOPPLER IN LABIAL SALIVARY GLAND ULTRA-HIGH FREQUENCY ULTRASOUND: CORRELATIONS WITH HISTOLOGICAL INFLAMMATION, PSS DIAGNOSIS, DISEASE ACTIVITY, AND PROGNOSIS

Keywords: Sjögren syndrome, Ultrasound, Prognostic factors

G. Fulvio1,2, F. Ferro1, R. Izzotti3, G. Governato1, S. Forzetti1, G. La Rocca1, I. C. Navarro Garcia1, V. Donati1, M. Mosca1, C. Baldini1, 1University of Pisa, Department of Clinical and Experimental Medicine - Rheumatology Unit, Pisa, Italy; 2University of Pisa, Department of Clinical and Translational Science, Pisa, Italy; 3University of Pisa, Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine - Unit of Dentistry and Oral Surgery, Pisa, Italy; 4Azienda Ospedaliero-Universitaria Pisana, Unit of Pathological Anatomy 2, Pisa, Italy

Background: Muscoskeletal Doppler US is currently used to estimate the level of inflammation and to differentiate between arthritis and degenerative disease. In addition, Doppler is associated with disease activity and damage, namely prognosis. Recently, a novel colour Doppler Score has been proposed for major salivary glands. However, clinical associations of salivary glands Doppler US are unclear, both in major salivary glands (MSG) and in labial salivary glands (LSG).

Objectives: To investigate potential associations between colour Doppler of LSG Ultra-High Frequency Ultrasound and histology, pSS diagnosis, clinical manifestations and prognosis.

Methods: From January 2021 to October 2022 consecutive patients, undergoing LSG biopsy, were enrolled in our cross-sectional study. LSG Ultra-High Frequency ultrasound (UHFUS) was performed with a 70 MHz probe, evaluating parenchymal inhomogeneity (score 0-3, as MSG four-grade OMERACT grey scale scoring system, GS-OMERACT) and vascularization (score 0-3, as MSG four-grade OMERACT colour Doppler scoring system, CD-OMERACT) and their sum (score 0-6, Total-OMERACT). Patients’ histological, biological and clinical features were collected. ACR/EULAR 2016 criteria fulfilment was the gold standard for diagnosis. LSG biopsy with a Focus Score (FS) >1 was considered positive. For statistical analysis, following tests were applied: Student’s t test, Mann-Whitney U test, contingency table analysis, Spearman’s correlation. Receiver operating characteristic analysis was calculated to assess the accuracy of UHFUS to predict histology inflammation and pSS diagnosis.

Results: 127 patients were enrolled: 61 pSS patients, 47 sicca controls and 20 sicca patients with other connective tissue diseases. GS-OMERACT predicted a positive biopsy with an area under the curve (AUC) =0.835. UHFUS inflammation prediction was increased considering both grey scale and colour Doppler (Total-OMERACT), with a sensitivity=80.4%, a Specificity=84.7% and an AUC raised to 0.875 (Figure 1A). In addition, CD-OMERACT revealed a higher accuracy for pSS diagnosis than GS-OMERACT (AUC 0.780 vs 0.735). Total-OMERACT score was characterised by a sensitivity of 78.7% and a specificity of 76.6% for pSS diagnosis (AUC 0.803, Figure 1B). Both GS-OMERACT and CD-OMERACT, in pSS patients, were correlated with serological activity: autoantibodies (SSA/Ro52, SSA/Ro60, SSB) IgG levels and Rheumatoid Factor. However, CD-OMERACT presented a stronger correlation than GS-OMERACT, and significantly correlated with low C3 and C4 (Table 1). Similarly, both GS and CD also correlated with total ESSDAI and separate lymph nodes, glandular and biological domains. The correlation observed was higher with Doppler signal than inhomogeneity. The latter also exhibited a significant correlation with renal activity. All 5 patients with LSG severe/atypical inflammatory infiltrate had GS-OMERACT score 3 and CD-OMERACT score 3 with a typical pattern: multiple very hypoechoic areas and high perilesional CD signal.

Conclusion: UHFUS Colour Doppler, combined with grey scale, allows a better detection of labial salivary glands inflammation. Compared to grey scale, CD offers a unique opportunity in patient’s phenotyping, due to its higher correlation with disease activity and pSS serological hallmarks. Eventually, a high doppler signal could be a key feature to identify more severe/atypical inflammatory infiltrate thus allowing the early recognition of lymphoproliferative complications.

POS1462 IMMUNOEDEMATOLOGIC FEATURES IN A COHORT OF PEDIATRIC PATIENTS WITH SJÖGREN’S SYNDROME: AN OVERLAP WITH AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME (ALPS)-LIKE DISORDERS

Keywords: Cytokines and chemokines, Sjögren syndrome

S. Ancona1, C. Morreale2, M. Di Filippo1, G. Simiele1, C. Lavarello1,3, C. Malattia1,3. 1University of Genova, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetic and Maternal Infantile Sciences (DINOOGM), Genova, Italy; 2ASP 1 Agrigento, P.O. Barone Lombardo, U.O. Pediatra e Neonatologia, Canicattì, Italy; 3IRCCS Istituto Giannina Gaslini, Clinica Pediatria e Reumatologia, Genova, Italy

Background: Childhood Sjögren’s syndrome (cSS) is a chronic autoimmune disease characterized by lymphocytic infiltration of salivary and lacrimal glands leading to their dysfunction [1]. Even though recurrent parotitis and sicca symptoms seem to be the most frequently reported features, cSS could have a wide range of clinical and laboratory manifestations such as autoimmune cytopenia, hypergammaglobulinemia, lymphadenopathy, fever and arthralgia [2]. These manifestations can also be seen in patients with autoimmune lymphoproliferative syndrome (ALPS). ALPS is a rare hematologic disorder characterized by an altered lymphocyte homeostasis due to a defective apoptotic mechanism [3]. In addition, cSS and ALPS are significantly associated with increased risk of lymphoid malignancy, most commonly non-Hodgkin lymphoma.

Objectives: To examine the prevalence of clinical and laboratory characteristics of ALPS in a cohort of pediatric patients with cSS in order to better characterize this autoimmune disorder and discover potential novel therapeutic targets.

Methods: Patients with cSS were recruited from the Paediatric Rheumatology Department at the Gaslini Children’s Hospital of Genova, Italy. All consecutive cSS patients were enrolled. LSG Ultra-High Frequency Ultrasound and histology, pSS diagnosis, clinical manifestations and prognosis were assessed. LSG biopsy with a Focus Score (FS) >1 was considered positive. For statistical analysis, following tests were applied: Student’s t test, Mann-Whitney U test, contingency table analysis, Spearman’s correlation. Receiver operating characteristic analysis was calculated to assess the accuracy of UHFUS to predict histology inflammation and pSS diagnosis.

Results: 127 patients were enrolled: 61 pSS patients, 47 sicca controls and 20 sicca patients with other connective tissue diseases. GS-OMERACT predicted a positive biopsy with an area under the curve (AUC) =0.835. UHFUS inflammation prediction was increased considering both grey scale and colour Doppler (Total-OMERACT), with a sensitivity=80.4%, a Specificity=84.7% and an AUC raised to 0.875 (Figure 1A). In addition, CD-OMERACT revealed a higher accuracy for pSS diagnosis than GS-OMERACT (AUC 0.780 vs 0.735). Total-OMERACT score was characterised by a sensitivity of 78.7% and a specificity of 76.6% for pSS diagnosis (AUC 0.803, Figure 1B). Both GS-OMERACT and CD-OMERACT, in pSS patients, were correlated with serological activity: autoantibodies (SSA/Ro52, SSA/Ro60, SSB) IgG levels and Rheumatoid Factor. However, CD-OMERACT presented a stronger correlation than GS-OMERACT, and significantly correlated with low C3 and C4 (Table 1). Similarly, both GS and CD also correlated with total ESSDAI and separate lymph nodes, glandular and biological domains. The correlation observed was higher with Doppler signal than inhomogeneity. The latter also exhibited a significant correlation with renal activity. All 5 patients with LSG severe/atypical inflammatory infiltrate had GS-OMERACT score 3 and CD-OMERACT score 3 with a typical pattern: multiple very hypoechoic areas and high perilesional CD signal.

Conclusion: UHFUS Colour Doppler, combined with grey scale, allows a better detection of labial salivary glands inflammation. Compared to grey scale, CD offers a unique opportunity in patient’s phenotyping, due to its higher correlation with disease activity and pSS serological hallmarks. Eventually, a high doppler signal could be a key feature to identify more severe/atypical inflammatory infiltrate thus allowing the early recognition of lymphoproliferative complications.
background: Sjögren’s syndrome (SS) represents a chronic autoimmune disease characterized by a relatively benign course. However, up to 40% of SS patients develop systemic extra-glandular involvement which, in turn, may lead to long-term damage accrual. Few studies assessed damage accrual in SS with a follow-up ranging from 5 to 10 years. Knowledge of long-term risk of damage and awareness of factors contributing to damage accrual in SS represent important issues to identify patients requiring a closer follow-up and to better stratify therapy.

Objectives: To examine disease damage progression every 5 years until 20 years of follow-up and disease related features associated with higher damage score at 20 years in a multicenter SS cohort.

Methods: A cohort of 252 SS patients fulfilling the 2002 AECG and/or 2016 ACR-EULAR classification criteria was retrospectively analysed. The following variables were collected at diagnosis and every 5-year timepoints until 20 years: demographic, clinical and serologic parameters; disease activity by ESSDAI; Charlson Comorbidity Index (CCI); disease damage by SSDDI and treatments. Patients were grouped according to damage degree at 20 years: “low/no damage”, LND (SSDDI ≤ 1) and “moderate/high damage”, MHD (SSDDI ≥ 2). Continuous variables were compared by Mann-Whitney U test and categorical variables by Chi-squared test of Fisher’s exact test, as appropriate. Significant variables at univariate analysis were included in a multivariable logistic regression analysis model with wild bootstrapping to account for collinearity and heteroscedasticity.

Results: A total of 50 patients (mean age at diagnosis 44±12 years, mean disease duration 24±5 years) had 20 year follow-up. Mean SSDDI increased from 1.2 (±1.5) at 5 to 1.5 (±1.7) at 10 years and from 1.5 (±1.7) at 15 to 2.04 (±2.2) at 20 years. Oral/ocular damage, peripheral nervous (PN) involvement and lymphoproliferative disease mainly contributed to damage accrual. Mean ESSDAI reduced from 6.4 (±3.7) at baseline to 4.9 (±4.4) and mean CCI increased from 1.6 (±0.8) to 3.5 (±1.6) at 20 years. At univariate analysis, MHD patients had significant higher median ESSDAI at all time-points and CCI at 5 and 20 years, higher frequency of parotid swelling at 5 years (35% vs 7%, p=0.021), low C4 (30% vs 3%, p=0.012) at 15 years and monoclonal component at 20 years (30% vs 7%, p=0.047) and lower of arthritis at 10 years (0% vs 23%, p=0.033) in comparison to LND. Patients with MHD had higher prevalence of glucocorticoid (GC) use at 20 years in comparison to LND (75% vs 27%, p=0.001). Multivariable logistic regression analysis model was able to correctly classify 87.5% of patients. None of the included parameters was independent predictor of outcome variable, likely due to a non-linear relationship among variables and the low subject number included.

Conclusion: This is the first study exploring disease damage at 20 year follow-up in SS patients. Notably, damage occurs early, increases already in the first 5-10 years and is mainly driven by oral and ocular damage, PN involvement and lymphoma. Higher disease activity at baseline and during follow-up and higher GC use, also reflecting a more active disease, represent two important variables contributing to damage. Thus, controlling disease activity since diagnosis and minimizing steroid prescription may reduce long-term damage accrual. Among disease-related features, appearance of parotid swelling in the first 5 years requires awareness. Surely, further studies are needed to identify, at diagnosis, patient phenotype at higher risk of long-term damage.

SLE, Sjögren’s and APS - clinical aspects (other than treatment)

**PO1464**

**DYSPHAGIA AND RELATED SYMPTOMS ARE FREQUENT, SEVERE AND HEAVILY AFFECT THE QUALITY OF LIFE OF PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME**

**Keywords:** Gastrointestinal tract, Sjögren syndrome, Quality of life

**A. Alunno** 1, F. Carubbi1, F. M. Mariani1, J. Cipollone1, M. Rossi1, C. Ferri1.

1Internal Medicine and Nephrology Division, University of Udine, Department of Life, Health and Environmental Sciences, Udine, Italy

**Background:** Dysphagia is the most frequent symptom reported by pSS patients with gastrointestinal involvement and may be related to a combination of hypoalimentation and oesophageal motility dysfunction.

**Objectives:** To explore the burden of dysphagia and related symptoms and the access to specialist care in patients with pSS.

**Methods:** Consecutive patients with pSS fulfilling the 2016 ACR-EULAR classification criteria and referring to our institution were interviewed. Patients reporting swallowing problems filled the Swallowing Quality of Life (SWAL-QOL) questionnaire. The SWAL-QOL includes 10 domains: food selection, burden, mental health, social functioning, fear, eating duration, eating desire, communication, sleep, and fatigue. It also explores presence and frequency of various symptoms such as cough, choke on food or liquids). Patients having sought for specialist care for dysphagia filled the SWAL Quality of Care (SWAL-CARE) questionnaire. The SWAL-CARE includes 2 domains to report on the clinical and general advice received (e.g. on food/drinks to avoid) and on the patient satisfaction. The scores of each domain (Likert scales) are transformed to a 0–100 metric with 100 indicating the most favorable variable and 0 the least favorable state. Disease activity (ESSDAI) and patient reported symptoms (VAS scales, ESSPRI, xerostomia inventory (XI) and Oral Health Impact Profile (OHIP)-14 were calculated at the time of enrolment.

**Results:** An interim analysis on 108 recruited patients as of December 4, 2022 was performed. Twenty-five patients (23%) reported swallowing problems. All SWAL-QOL domain scores and the total SWAL-QOL score were very low while symptom presence and frequency were very high. The most affected domains (mean value <30) were fear, mental health, fatigue and sleep (Table 1). The “mental health” and “social functioning” domains were more affected in people with shorter disease duration regardless of age (p<0.01). Conversely, the “burden” domain, reflecting the capability to cope with dysphagia, was more affected in younger people (p=0.03). A proportion of patients ranging between 48 to 84% reported having symptoms often or almost always and none of the patients responded “never” for any of the symptoms (Figure 1). When exploring how the extent of dryness relates to dysphagia, the VAS scales for xerostomia and xerotrachea did not differ between patients with or without dysphagia. However, patients with dysphagia had significantly higher scores of the XI and the OHIP-14 compared to those without (both p<0.01). No differences in terms of age, disease duration, autoantibody profile and disease activity emerged between pSS patients with or without dysphagia. Focusing on ESSDAI domains, we observed that all patients with dysphagia also had articular manifestations (p=0.01) while haematological manifestations were more frequent in patients without dysphagia (p=0.03). Of the 25 patients with dysphagia only 10 (40%) sought specialist care. Most of the patients judged the advice received poor (mean =10.4) and overall patient satisfaction was very low (mean= 28.5).

**Conclusion:** Our study demonstrated that dysphagia and related symptoms are frequent and severe in pSS, heavily impact on the patient quality of life and satisfactory specialist care remains an unmet need. Younger people and those with a shorter disease duration seem those whose QoL is more affected. We are currently increasing the patient cohort and planning further investigations in patients with dysphagia (e.g. oesophageal manometry) to better characterise the mechanisms underlying this problem in pSS.

**ASSOCIATION OF COMPLEMENT ACTIVATION AND TNFα WITH PREGNANCY PROGNOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME**

**Keywords:** Systemic lupus erythematosus, Anti-phospholipid syndrome, Biomarkers

**A. Isik1, S. Çınar2, S. Onder3, A. Bayram4, E. Yavuz5, T. Sarac Svirikoz6, I. Kalelioglu7, C. Cetin8, Y. Yalçinkaya9, A. Güle, M. İnanı, B. Artim-Esen1.**

1Istanbul University Istanbul School of Medicine, Internal Medicine, Istanbul, Turkey; 2Istanbul University Istanbul School of Medicine, Immunology, Istanbul, Turkey; 3Istanbul University Istanbul School of Medicine, Pathology, Istanbul, Turkey; 4Istanbul University Istanbul School of Medicine, Gynecology and Obstetrics, Istanbul, Turkey; 5Istanbul University Istanbul School of Medicine, Rheumatology, Istanbul, Turkey

**Background:** Complement activation is associated with adverse pregnancy outcomes in patients with systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS). TNFα is accused in the etiology of impaired placenta development and preeclampsia.

**Objectives:** We aimed to investigate the association of complement(c) activation and TNFα with poor pregnancy outcomes in patients with SLE/APS.

**Methods:** Four groups were examined: pregnant SLE/APS (n=37), non-pregnant SLE/APS(n=15), healthy pregnant (n=20) and healthy women (n=14). C3b, C5a and TNFα were tested by ELISA in the serum (s) samples taken at the last trimester of each pregnancy. Collected placental tissues were examined histopathologically and were stained for TNFα and C4d.

**Results:** sC3b levels and positivity rates were higher in pregnant SLE/APS compared to all other groups (p<0.05 for all). Pregnancy loss (18.9%) and preeclampsia (16.2%) were the most common pregnancy morbidities. Renal (30.5%) followed by hematologic (thrombocytopenia) (19.4%) were the most common flares in pregnant patients with SLE/APS and compared to patients without, they had significantly higher sTNFα levels (p<0.05). The frequency of sTNFα positivity were significantly higher in SLE/APS patients with preeclampsia (p<0.05). Sixty-six % of SLE/APS placenta had C4d deposition whilst none of the healthy ones were stained (p<0.001). Frequency of strong staining with TNFα in SLE/APS (75.8%) was significantly higher compared to healthy placentas (27.8%) (p<0.001). Decidual vasculopathy, decidual inflammation and villous infarction were significantly more frequent in SLE/APS (Table 1). Significant associations were found between these findings and preeclampsia, intrauterine growth retardation and the need for neonatal intensive care (p<0.001).

**Conclusion:** Results of our study shows TNFα and complement activation both at tissue level and serum, and supports their association with adverse pregnancy outcome in SLE/APS. Further work is necessary to test whether these biomarkers can be used for follow up and to explore whether TNFα and complement directed therapies may improve maternal/fetal prognosis in patients with SLE/APS.

**PREDICTORS OF NEUROPSYCHIATRIC FLARES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM FIVE PHASE III CLINICAL TRIALS OF BELIMUMAB**

**Keywords:** Outcome measures, Systemic lupus erythematosus, Clinical trials

L. Palazzo1, J. Lindblom1, N. Çetrez2, H. Åla1, I. Parodis1,2. Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden; Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden

**Background:** Neuropsychiatric (NP) flares in systemic lupus erythematosus (SLE) constitute a challenging issue for the clinician on many levels as they are rather unpredictable and include severe and potentially life-threatening manifestations [1]. The identification of clinical and serological profiles predictive of NP flares would be instrumental for early detection of NP involvement, thus allowing early treatment, and hopefully resulting in improved outcomes. The B-cell depleting agent belimumab has widely shown ability to reduce rates of flare in SLE (2), early treatment, and hopefully resulting in improved outcomes. Whether belimumab treatment protects against NP events remains unclear and warrants future investigation.

Methods: 1487 patients with SLE from Norway and Sweden who fulfilled ≥4 ACR-82 (97%), ACR-97 (98%) or SLICC2012 (94%) classification criteria were included in the study. Clinical data was collected from medical charts and causes of death were retrieved from death certificates. Patients were genotyped using the Global Screening Array or the Immunochip (Illumina). Established, independent SLE risk SNPs (p<5x10^-8, n=67) were selected and summary statistics for coronary artery disease (CAD) and MI were identified for each SNPs using the MRBase catalog. MR was conducted using the inverse variance weighted method as well as three additional MR methods, on the largest available dataset using a strict definition of MI (n=648, 450,280, 29,800, 18,280, 11,740, and 2072,146. The method was used for analysis of the largest available datasets for dialysis (n=648, 450,280, and 2072,146) and BI (n=11,622, 450,280, and 2072,146). SNP-manifestation associations from the datasets were used to construct weighted MI/CAD, BI and dialysis PRSs for each patient in the clinical cohort.

Results: The MR analysis revealed a significant association between the genetic risk of SLE and MI (p=0.01). The association was robust to outliers and pleiotropy and consistent across the investigated MR methods. No influence by confounding factors such as hypertension, smoking, alcohol consumption or hyperlipidemia was identified. Individually, 14 SLE SNPs displayed association with MI/CAD and were included in the CAD/MI PRS. In addition, we found an association between the SLE genetic risk and dialysis (p<0.05), whereas the association between SLE genetic risk and BI was not statistically significant (p=0.051). SLE SNPs displaying association with dialysis and BI were included in two separate PRSs. In the clinical cohort, 7.7% of patients had experienced at least one MI, with a mean age at the first event of 60 years. Patients with a CAD/MI PRS in the top quartile displayed a three-fold higher risk of MI (OR 3.04 (1.43-6.49), p<0.01) and a higher risk of ischemic heart disease (MI and/or angina pectoris) (OR 2.64 (1.37-5.11), p<0.01) compared with patients with a CAD/MI PRS in the lowest quartile. In total, 35% of patients fulfilled the ACR-82 nephritis criterion, and 5.8% had developed ESRD. Patients with a high dialysis PRS displayed a higher risk of nephritis (OR 1.72 (1.15-2.58), p=0.0079), however, a significant association was identified. Individually, 14 SLE SNPs displayed association with MI/CAD and BI and dialysis PRSs for each patient in the clinical cohort.

PO51469 1 LONGITUDINAL CHARACTERIZATION OF DISEASE COMPLEXITY AND FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS: DEVELOPMENT OF AN ELECTRONIC HEALTH RECORDS ALGORITHM

Keywords: Artificial intelligence, Best practices

1Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario A. Gemelli IRCCS, 2Fondazione Policlinico Universitario A. Gemelli IRCCS, UOC di Reumatologia, ROme, Italy; 3Fondazione Policlinico Universitario A. Gemelli IRCCS, Real World Data Facility, Gemelli Generator, ROme, Italy

Background: Systemic Lupus Erythematosus(SLE) is a heterogeneous disease, with a relapsing-remitting pattern that contributes to create difficulties for diagnosis and management. Besides, disease activity indices are not always able to capture the complexity of the disease over time and to guide therapy modification. Data mining and machine learning algorithms developed based on Electronic Health Records(EHR) could help in characterizing the disease complexity and electronic trajectory of evolution.

Objectives: to develop a machine-learning methodology to identify SLE phenotypes and flare trajectories in a large longitudinal database.

Methods: an observational retrospective monocenter study was performed using the EHR of our Tertiary Care University Hospital. Adult SLE patients (pts), with at least one hospital contact between January 2012 and December 2020, were included. For each patient, clinical reports including demographics characteristics, symptoms and clinical history retrieved from text notes recorded during the hospitalization and the outpatient visits, laboratory values, medication and laboratory prescriptions as well as therapy, were extracted from EHR (ICD9 710.0 and 695.4 to identify the pts). A predefinition of Natural Language Processing techniques (NLP) and abnormal laboratory parameters at each visit was used to identify: 1) presence of 8 different SLE clinical phenotypes (hematological, muco-cutaneous, articular, renal, systemic, neurologic, vascular involvement and serositis); 2) disease complexity based on the combination of the presence of single or multiple organ domains involved and therapy escalation (defined as low, medium, high complexity); 3) disease flares in each of the above clinical phenotypes. Data extraction, from unstructured data of EHR, was performed using topic models and rule-based techniques to build a usable data mart. A p-value<0.05 was considered as significant. Typical explorative analyses were also used to identify SLE phenotypes, together with longitudinal analyses, for the observation of evolution of complexity trajectories.

Results: A total of 1000 SLE pts with at least one contact were identified in our EHR; of them 477 presented at least one hospitalization and 255 pts presented at least one year of follow-up with a median of years of observation of 5.0 (3.0, 8.0). In the longitudinal cohort of 255 pts, the median number of outpatient clinic contacts was 14 (8-20) and of hospitalizations: 1 (0-2). The median number of clinical phenotypes identified at baseline was 4 (2.25-5), with 50.3% of pts having more than 3; and their distribution was: hematological(71.4%), muco-cutaneous(68.2%), articular(64.3%), renal(62.4%), vascular(34.9%), serositis(24.3%), systemic(16.5%), neurologically(16.1%). At baseline, SLE complexity was categorized as low, medium and high in 13.7%, 34.5% and 51.8% of cases respectively. During follow up the complexity of pts changed as reported in Figure 1, and 93% of pts had a flare. During longitudinal evaluation, 65.9% pts presented hematologic flare, 60% muco-cutaneous, 47.8% renal, 18.8% articular, 12.9% vascular, 78% systemic, 5.1% serositis and 3.9% neurologic. The median number of flares significantly increased with disease complexity ([3.5(2.0-6.0), 4.0(2.0-8.0), 6.3(0-9.2)] in pts with low, medium and high complexity respectively,p<0.05). Moreover, the severity of flares for each clinical phenotypes also increased according to the patient's complexity(p<0.05). Overall, 279 therapy escalations were made over the follow up time. 62% due to disease flares, and 38% due to other situations (e.g. intolerance, contraindications).

Conclusion: Machine learning algorithms can help to describe SLE heterogeneity and to characterize clinical phenotypes and trajectories of pts. Next step will be the evaluation of the present procedure on external cohorts to develop a tool able to identify situations needing more intensive and personalized care.

DOI: 10.1136/annrheumdis-2023-eular.5442
Background: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE), associated with considerable morbidity and an increased risk of end-stage kidney disease (ESKD). Despite various therapies used in clinical practice, a notable proportion of patients may not achieve sustained remission, leading to adverse disease outcomes.

Objectives: To review and summarize evidence on natural history of LN, burden of comorbidities, and real-world (RW) effectiveness of therapy in European patients with LN.

Methods: A targeted literature review was conducted using MEDLINE/Pubmed and Embase to identify studies in patients with LN. Search strategies were developed for the two databases to identify relevant peer-reviewed articles published in English from March 2012 - March 2022, and conference abstracts from 2019. All records were screened according to pre-specified inclusion/exclusion criteria. Studies conducted in a European setting were summarized.

Results: Of 4,216 identified records, 55 studies reported long-term outcomes of disease and RW effectiveness of treatment in European adults with LN. Up to 36% of patients with SLE developed LN, and nearly all LN cases occurred within 5 years of SLE diagnosis. Patients with LN often suffered from serious infection (19-35%), chronic kidney disease (CKD)/ESKD (6-22%), and cardiovascular disease (CVD) (26%), and were more likely to experience cardio- and cerebrovascular events than patients with SLE only (p<0.001). Immunosuppressive therapies contributed to increased infections and patients treated with high-dose steroids (>0.5mg/kg/day) had 5-times increased risk of infections compared to those on low-dose regimens. Patients with LN had a higher risk of mortality compared to patients with SLE or other lupus manifestations (p<0.001). The main causes of death among patients with LN were infections (8-32%), CVD (22-58%), or malignancies (5-27%). The majority of RW studies evaluated effectiveness of standard of care (SOC) induction and/or maintenance therapy, mostly with mycophenolate mofetil and cyclophosphamide. Treatment response rates varied across the studies likely due to heterogeneity in study design, drug dosing, and patient population; comparative studies did not find significant differences in response rates between the regimens. Overall, 30-86% of patients with LN achieved complete renal response/remission (CRR) within 1 year of starting SOC therapy, and 25-65% achieved CRR within 2 years. Patients who were non-responders after 1 year had a significantly increased risk of mortality and CKD compared to responders (p<0.005), highlighting the need to reach any degree of response. Over a 5-year period, one study reported that only 38% of patients maintained CRR while on SOC, further suggesting inadequate maintenance on existing therapies. Limited studies focused on treatment-experienced/refractory patients, with the majority evaluating rituximab (RTX)-based regimens. After 1 year of treatment, 29-64% of patients with refractory LN treated with RTX achieved CRR and 35% of patients with active LN despite SOC treatment with belimumab (BEL) achieved CRR. Despite initial response to current therapies, 20-25% of patients experienced a renal relapse/flare while on maintenance therapy, with one study noting significantly increased risk of proteinuric flares with azathioprine compared to other maintenance therapies (p=0.01). Very limited evidence was identified on the impact of therapy on extra-renal manifestations in patients with refractory LN, with few studies reporting improvements in SLEDAI scores with RTX after 1 year and with BEL over 2 years of treatment.

Conclusion: European patients with LN have substantial burden from comorbidities that contribute to poor long-term outcomes. Treatment with SOC also contributes to increased morbidity and mortality, particularly due to infections. Furthermore, despite initial response to treatment, a notable proportion of patients experience renal relapse, indicating a need for effective therapies that provide sustained remission.

Background: Systemic lupus erythematosus (SLE) is a heterogeneous, waning, multisystem autoimmune disease. The complexity and clinical unpredictability of SLE challenge the assessment of disease activity over time, especially in everyday clinical practice. Multiple clinical disease-monitoring instruments have been developed; however, they are limited in ability to detect the change in disease activity over time, too cumbersome to be utilized in daily practice, and do not include patient-reported outcomes (PROs).

Objectives: To construct a new disease activity score that will simplify and improve disease activity assessment in daily practice, and include PROs. Here we present the PRO component.

Methods: The new instrument for the assessment of SLE activity is comprised of 7 visual analog scales (VAS), which separately address the physician's global assessment and 6 organ systems. The PRO consists of 5 VAS questions that address general well-being, global disease activity, activities of daily living, medication compliance, and mood. The ASSESSLE PRO is compared to the Short Form Health Survey (SF-36), a 36-item, patient-reported survey of patient health.

We applied the ASSESSLE PRO to 46 consecutive patients with SLE attending the rheumatology clinic in 2 tertiary medical centers in Israel.

Results: Psychometric evaluation of the reliability of all 5 PRO questions indicated that question 4, regarding compliance, correlated poorly with the other items and lowered the reliability (Cronbach's α = 0.86, 95% CI [0.74, 0.85]). Following the omission of question 4, Cronbach's α was recalculated, leading to increased internal reliability (Cronbach's α = 0.86, 95% CI [0.82, 0.90]). All other remaining items had a satisfactory correlation with the other items ("item-other" correlation between 0.58-0.70). Therefore, the score was computed as the mean of the 4 remaining questions. Aiming to compare the ASSESSLE PRO to the SF-36 survey, the Spearman correlation coefficient between absolute scores was computed and a strong and significant effect was found (R=0.85, p<0.0001). (Figure 1).

Conclusion: The ASSESSLE PRO is a short PRO that allows a reliable, reproduceable and simple PRO form showing excellent correlation with the SF-36. Following the omission of question 4, regarding patient compliance, the ASSESSLE PRO consists of only 4 questions, as compared to the SF-36 which requires a response to 36 items. The ASSESSLE PRO seems to have significant advantages due to its intuitive VAS questions and brevity which allows use of this PRO in everyday practice and may increase the validity of disease activity evaluation of SLE when combined with the physician's assessment.

co-diagnosis in 49.1% of patients undergoing OP vs 26.0% in patients not receiving OP. Undergoing an OP (with or without arthroscopy) did not impact on long term survival (logrank p = 0.16).

Conclusion: There is a high burden of joint damage in lupus patients as one in six patients required an OP at a rate seven times that of controls. These data illustrate that joint symptoms in lupus patients need careful evaluation, including imaging studies [3] and comprehensive strategies to reduce long term joint damage.

To determine the average employment trajectories of young adult former college graduates with SLE.

Objectives: To determine the change in employment trajectory of adult former college graduates with SLE.

Methods: In this study, we quantified circulating autoantibodies in the Accelerating Medicines Partnership (AMP) LN longitudinal cohort to identify novel serum biomarkers of LN classification and treatment response and to provide insights into the pathogenesis of LN.

RESULTS: 841 participants (85.4% females): 253 (CaNIOS) and 588 (UT). Mean age (standard deviation, SD) at baseline (cohort entry) was 23.1 (SD 3.7) years. Patients’ age: 38.2% (18-20 years), 19.3% (21-23 years), 21.9% (24-26 years), 20.7% (27-30 years), 403 (47.9%) were cSLE, 85.5% completed high school. Median disease duration was 3.3 (0.74-6.2, 25th-75th percentile, P) years. Median follow-up was 2.9 (0.9-6.3, 25th-75th percentile, P) years. At baseline, 16.6% were employed. 5.6% were unemployed and 77.8% were NLF. 42 work disabled, 226 homemakers, 386 students. 374/6615 (5.6%) visits showed state changes. 58% occurred in the NLF group. YASLE patients have the highest probabilities of remaining in the same employment state as baseline (Table 1). With increasing age, there was a reduced rate of staying employed (0.69 to 0.64). Those unemployed showed low probability to become employed (0.28 to 0.38). The NLF group has static rate of transition to employment (0.65), without expected increase with age.

Conclusion: YASLE patients showed minimal or no increase in transitions into employment from non-employed states, and no increase in employment with age as expected in the general young adult population. This could suggest a lowered labour force attachment in YASLE patients, suggesting difficulties in establishing employment during young adulthood. Future work should focus on YASLE patients’ perceived barriers and facilitators for employment, to target interventions for supporting patients’ employment.

Results: Most LN patients exhibited autoantibodies against chromatin (78%); dsDNA (70%), Sm/RNP (63%), C1q (56%), RNP (54%), and Sm (52%) (Figure 1A). Patients with proliferative LN (class III, IV, III+V, or IV+V) had higher positivity rates of several autoantibodies, including those against dsDNA, chromatin, and C1q, compared to patients with membranous LN (class V) (Figure 1A). Similarly, patients with pure proliferative (class III or IV) and mixed (class III+V or IV+V) LN had significantly higher titers of these autoantibodies compared to those with mesangial (class I or II), membranous, and advanced sclerosis (class VI) LN (Figure 1B-D). Furthermore, increased titers of these autoantibodies were associated with higher odds of having proliferative LN. Proliferative LN patients with a complete treatment response exhibited a significant decline in several autoantibodies including anti-dsDNA, C1q, chromatin, Smith, and ribosomal P (Figure 1F). Autoantibody levels remained relatively stable in partial- and non-responder proliferative LN patients, as well as in patients with membranous LN.

Figure 1.

Conclusion: LN patients exhibit heterogeneous autoantibody profiles associated with ISN/RPS classification. Specifically, levels of autoantibodies against dsDNA, C1q, chromatin, and ribosomal P may serve as noninvasive biomarkers of proliferative LN. In patients with proliferative but not membranous LN, a decline in the titers of several autoantibodies, including many not routinely measured over time, such as anti-Sm, was associated with treatment response, suggesting a possible role in LN pathogenesis. In addition, these autoantibodies may serve as early biomarkers of treatment response.

POs1477 DISEASE FLARES AFTER SARS-COV-2 MRNA VACCINATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ARE ASSOCIATED WITH DISEASE ACTIVITY BEFORE VACCINATION

Keywords: COVID, Vaccination/immunization, Systemic lupus erythematosus

J. Kikuchi1, Y. Kondo1, S. Kojima1, S. Kasai1, Y. Sakai1, M. Takeshita1, K. Hiromoto1, S. Saito1, H. Fukui1, K. Suzuki1, Y. Kaneko1. 1Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: While some reports suggest the development and flare of autoimmune inflammatory rheumatic diseases after vaccination, the frequency of disease flare after vaccination in patients with systemic lupus erythematosus (SLE) has been reported to be low. When we assess risk-benefit balance of vaccine administration, it is crucial to understand the effect of vaccines in patients with SLE. However, SARS-CoV-2 mRNA vaccines are new types of vaccines, and little is known about the effectiveness and safety of the vaccines and factors associated with disease flare in patients with SLE after SARS-CoV-2 mRNA vaccination.

Objectives: To elucidate the effect of SARS-CoV-2 mRNA vaccinations including adverse reactions to vaccines, neutralizing antibody titres and disease flare rates and their variables and the associated factors in patients with SLE.

Methods: We enrolled the uninfected patients receiving two doses of vaccine (BNT162b2 or mRNA-1273) between June and October 2021. The neutralizing antibodies in peripheral blood, adverse reactions, and disease flares defined by the SELENA-SLEDAI Flare Index were evaluated four weeks after the second dose of vaccine. The neutralizing antibodies were measured using the STACIA SARS-CoV-2 Neutralization Antibody Test (MBL Corporation, Nagoya, Japan), and the cut-off level of seroconversion was defined as an antibody concentration of more than 1.67 U/mL.

Results: Ninety SLE patients were enrolled. The median age was 46.5 years, and the disease duration was 9.0 years. The median SLEDAI before vaccine administration was 2. Four weeks after the second dose of vaccination, 19 (21.1%) were still negative for neutralising antibodies. Adverse reactions were observed in 88.9%, including fever above 37.5°C in 20.8%. Factors associated with negative neutralising antibodies were older age, anemia (Hb ≤ 11 g/dL), mycophenolate mofetil (MMF) use (p=0.030 [55 years vs 44 years]), p=0.014 [36.8% vs 11.3%], and p=0.029 [42.1% vs 16.9%, respectively]. Regarding disease activity, SLEDAI modestly but significantly increased significantly vaccination (p=0.016, median change 0 [IQR: 0–1]). Thirteen (14.4%) and 4 (4.4%) patients experienced flares and severe flares (nephritis in 3 and vasculitis in 1, respectively). High titers of SLEDAI, anti-dsDNA antibodies, rash, and azathioprine use were associated with flares in univariate analysis (p=0.046, p=0.034, p=0.037 and p=0.038, respectively, Table 1). Multivariable logistic regression analysis showed that high levels of SLEDAI and anti-dsDNA antibodies were associated with flares. Types of vaccines, neutralising antibody titres, and frequency of adverse reactions were not relevant for flares.

Conclusion: Older age, anemia, and MMF use are associated with negative seroconversion of neutralising antibodies. Residual disease activity before vaccination is a risk factor for flares.

Table 1. Factors associated with flares after second vaccination.

**Framingham risk score (FRS)** [1]. However, it is unknown how the QRISK3, the risk score established in the United Kingdom (UK), can estimate the ASCVD risk of Japanese SLE patients in comparison to the risk score validated for the Japanese population.

**Objectives:** To compare two algorithms for ASCVD risk estimation, QRISK3 and Hisayama study score [2], a general risk calculator used in Japan Atherosclerosis Society (JAS) guideline for Prevention of Atherosclerotic Cardiovascular Diseases 2022, in our cohort of Japanese SLE patients.

**Methods:** We performed a cross-sectional study in SLE patients attending Kyoto University Hospital by using questionnaires and laboratory tests. In primary prevention subjects without high-risk comorbidities (peripheral artery disease, chronic kidney disease, diabetes) and aged 40 to 79, both the Hisayama study score based on traditional risks (sex, systolic blood pressure, glucose intolerance, serum lipid and smoking) and QRISK3 (ethnicity was selected as “Other Asians”) were calculated to estimate the ASCVD risk over the next 10 years.

**Results:** Among 335 patients enrolled, 105 were eligible for both ASCVD risk calculators. QRISK3 estimated 46 patients as high risk (score >10%), while the Hisayama study score classified no patients as high risk. The patients classified as high risk by QRISK3 had significantly higher Hisayama study score (4.71 [3.99-5.43] vs 2.28 [1.77-2.80], p<0.0001) and more traditional risks, such as old age (59.8 [57.6-62.1] vs 48.1 [46.8-49.4], p<0.0001), current smoking (9 [19.5%] vs 3 [5%], p=0.02) and hypertension on treatment (22 [47.8%] vs 7 [11.8%], p<0.0001) than the patients with low-moderate risk (Table 1). QRISK3 estimated 46 patients as high risk (score >10%), while the Hisayama study score was positively correlated with the Hisayama study score (r=0.4945, p<0.0001). As a result of using QRISK3, the proportion to achieve target values for serum low-density lipoprotein cholesterol (LDL-C) recommended by the JAS guideline were 94.3% and 69.5% respectively.

**Conclusion:** QRISK3 classified more Japanese SLE patients as high risk of ASCVD when compared to the Hisayama study score. Lipid management might be insufficient according to QRISK3. The validation of QRISK3 by longitudinal studies should be warranted in Japanese SLE patients.

significant differences in autoantibody profiles were detected between deceased and non-deceased patients.

**Conclusion:** We observed a bimodal distribution of causes of death, with SLE, malignancy and infection more likely to cause early deaths, and cardiovascular disease more likely to cause later deaths. Across the whole cohort, patients lived longer than was expected. However, a third of patients still died early, suggesting future work should focus on addressing these highest risk patients. Across the cohort proportionally more male than female patients died. This may reflect known differences in life expectancy between genders, but highlights male patients as a group with persisting poorer mortality outcomes. No significant differences in autoantibody profiles were observed between patients that died versus those that survived. This may be because the entire cohort is enriched for positive serology, perhaps making it less likely that differences will be identified.

**DESCRIBING RENAL FUNCTION TEST USE IN REAL-WORLD DIAGNOSIS AND MONITORING OF LUPUS NEPHRITIS PATIENTS IN EUROPE**

**Keywords:** Systemic lupus erythematosus, Real-world evidence

B. Asin, A. Eberhardt, A. Fernandes, D. Clamp, E. Goddard, Otsuka Pharmaceutical Europe LTD, Wexham, United Kingdom; Otsuka Pharma GmbH, Frankfurt, Germany; Otsuka Pharmaceutical Development & Commercialization Inc., Rockville, United States of America; Adelphi Real World, Bollington, United Kingdom

**Background:** Lupus nephritis (LN) is a severe renal manifestation of the autoimmune disease lupus. Tests for renal function, such as estimated glomerular filtration rate (eGFR), should be standard in the diagnosis and monitoring of patients with renal disease as recommended by the Kidney Disease Improving Global Outcomes (KDIGO) Chronic Kidney Disease (CKD) Working Group [1]. These tests are important to identify renal function decline and prompt interventions to prevent further disease progression. It has been found that use of eGFR is low in Italy for CKD patients [2] but data on real-world testing in other countries is limited.

**Objectives:** To understand renal function test use by nephrologists in the diagnosis and monitoring of LN patients in Europe in a real-world clinical setting.

**Methods:** Data were sourced from the Adelphi Lupus IV Disease Specific Programme™, a point-in-time survey of nephrologists and their LN patients conducted in France, Germany, Italy, Spain and the United Kingdom in April – October 2021. Nephrologists completed patient record forms covering each patient’s management, including tests and assessments used for diagnosis and monitoring. The data was analysed descriptively.

**Results:** 72 nephrologists provided data for 376 LN patients. Overall, 20% of LN patients in the sample did not have a Glomerular Filtration Rate (GFR) or eGFR test documented to diagnose their condition. The use of these tests at diagnosis was lower in Germany and Italy (≤72%) compared to the other countries where use was over 80%. Of all the patients without GFR/eGFR at diagnosis, only 43% had an alternative renal test completed (e.g. urine protein, creatinine clearance (CrCl), albumin-to-creatinine ratio (ACR) or other urinalysis test (including urine protein creatinine ratio)). Across Europe, the use of GFR/eGFR to monitor patients with LN was 85% or above, apart from Italy where 31% of patients did not have either test. In patients without GFR/eGFR for monitoring, the use of alternative renal tests was higher than at diagnosis (60% vs. 43%). However, 40% of those patients received no other renal test (e.g. urine protein, CrCl or ACR) to monitor their condition.

**Conclusion:** GFR/eGFR are key markers of renal function as discussed in the KDIGO recommendations [1], but this analysis observed lower-than-expected use of GFR/eGFR among nephrologists. This was especially apparent in Germany and Italy. There may be even less use of these tests among non-nephrology specialties. Lower-than-expected use of these recommended tests indicates a need for improvement in the diagnosis and monitoring of LN patients in Europe. This suboptimal management may be affecting patient outcomes, but further research is needed to assess this. Results are subject to recall bias which was minimised by asking survey respondents to use patient medical records for the completion of forms.

*Patients with available data. Abbreviations: eGFR, Estimated Glomerular Filtration Rate; GFR, Glomerular Filtration Rate; LN, Lupus Nephritis; UK, United Kingdom*
Background: Systemic lupus erythematosus (SLE) has heterogeneous organ manifestations that occur in different combinations at an individual patient level. Current SLE clinical trial eligibility criteria and efficacy endpoints, based on legacy disease activity measures, have multiple weaknesses. Understanding the frequency with which different organ manifestations are represented in contemporary SLE cohorts is required, to allow focus on the most frequent and impactful manifestations of disease in both eligibility criteria and endpoints.

Objectives: To report the prevalence of disease activity in individual organ domains in SLE patients, both overall and in patients meeting the most common SLEDAI-2K ≥6 (Table 1).

Methods: We used data from a multinational SLE cohort, prospectively collected between 2013 and 2020. We analysed data from 4,102 patients with criteria-defined SLE, who contributed 42,345 visits with complete SLEDAI-2K assessments. Disease activity assessed using SLEDAI-2K was categorised according to activity in 9 organ systems (OSS): serositis (S), musculoskeletal (MUSK), renal (R), cutaneous (CUT), haematological (H), neurological (NEU), musculoskeletal and haematological (M&H), serositis and musculoskeletal (S&M), and serositis and haematological (S&H). Proportions of organ-specific disease activity in the overall cohort, and stratified by total SLEDAI-2K ≥6 or <6, were calculated.

Results: In the overall cohort, 3,659 patients (89.2%) had SLEDAI-2K ≥6 on at least one visit (31,290 visits, 73.9%). Serological disease activity was the most prevalent in the cohort overall, affecting 75.5% of patients at least once, followed by renal (41.6%), cutaneous (36.5%), musculoskeletal (20%) and haematological (19%) activity. Infrquent active manifestations affecting <5% of patients were serositis (3.4%), vasculitis (3.4%), CNS (3.0%) and fever (3.0%). Further we examined the prevalence of domain-specific disease activity in patient visits stratified by a SLEDAI-2K cut-off of 6 (Table 1). In patient visits with a SLEDAI-2K ≥6 (n = 10,031 visits, 24% of total) the most common manifestations were serological (90%) and renal (73%), followed by cutaneous (26%) and musculoskeletal (14%). Conversely, 73% of visits with renal, 6.7% with cutaneous, 5.8% with haematological and 1.3% with musculoskeletal activity did not have a SLEDAI-2K ≥6 (Table 1).

*P-values derived from Pearson’s Chi-Squared tests.

Conclusion: Serological, renal, cutaneous, musculoskeletal and haematological manifestations predominate in patients with active SLE in our cohort, with other organs only rarely affected. Measures of improvement in SLE trial endpoints could focus on measuring change in these systems, and omit detailed analysis of rare events. Conversely, a notable proportion of patients with active disease in commonly affected organ domains had SLEDAI-2K <6, meaning they would be excluded from clinical trials. Incorporation of organ-specific activity measures and inclusion criteria for SLE clinical trials may overcome this limitation and improve recruitment to and results of trials.

PES1482 PREDICTORS AND CLINICAL SIGNIFICANCE OF LUPUS LOW DISEASE ACTIVITY STATE 12 MONTHS AFTER LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Kidneys, Treat to target
Background: Lupus nephritis (LN) is a significant comorbidity that affects around 50% of patients with systemic lupus erythematosus (SLE). Complete or partial renal response 12 months after LN is an important treatment target. Low disease activity in extra-renal domains by achieving LLDAS may also contribute to one of the critical treatment goals in LN patients [1]. However, the predictors of LLDAS in LN patients and the renal-specific benefits of LLDAS were also not fully understood.

Objectives: To investigate the predictors of LLDAS at 12 months post-LN and the clinical usefulness of achieving this state in LN patients.

Methods: Patients with biopsy-proven LN during 2010-2020 were included. Baseline demographics, blood parameters and urinalysis results were recorded. Patients were then followed up every 4 months to repeat blood tests and urinalysis. Renal response and LLDAS were assessed at 12 months post-LN, and any future relapses were recorded. Complete renal response (CRR) was defined as proteinuria ≤0.5g/day with normal estimate glomerular filtration rate (eGFR); partial renal response (PRR) was defined as a reduction in proteinuria by ≤50% with near normal eGFR. LLDAS was attained by meeting: (1) SLE Disease Activity Index ≤4 with no major organ activity; (2) no new lupus disease; (3) physician global assessment ≤1; (4) prednisolone dose ≤7.5mg; (5) standard maintenance immunosuppressants [1]. Relapse was a biopsy-proven LN after an initial treatment response of proteinuria reduction of ≤50% or to subnephrotic range. We assessed the predictors of LLDAS at 12 months post-LN and performed time-to-relapse survival analysis.

Results: 143 LN patients were included with a median follow-up duration of 10.4 years. At 12 months, 57 (40%), 14 (10%) and 69 (48%) patients achieved CRR, PRR and LLDAS, respectively. Among 136 patients who achieved treatment response, 30 (22%) patients developed LN relapse after a median of 2.98 years. LN at age greater than 30 or the presence anti-smith autoantibodies had significantly lower odds of reaching LLDAS at 12 months after LN, with odds ratio of 0.35 (p = 0.047) and 0.30 (p = 0.043) respectively (Table 1). Patients reaching CRR/PRR and LLDAS both had a significantly lower chance of relapse with p = 0.014 and p = 0.002 respectively (Figure 1).

Conclusion: Age of LN and anti-smith autoantibodies are predictors of LLDAS 12 months post-LN. We advocate LLDAS as a target for LN patients as LLDAS attainment lowers the risk of future relapse.

Conclusion: These data suggest that GC-free remission is an achievable goal in SLE patients with today’s drugs, and in our cohort GC-free remission is also a GC-free remission in most of patients. Our study also confirms that GC withdrawal has important advantages in term of organ-damage sparing. Of note, the early achievement of remission during the disease history is associated with a good probability of GC withdrawal over time.

Results: We included a total of 343 patients, in whom self-esteem was analyzed. SxO was assessed in 280 patients, since 62 did not complete the CSFQ-14 questionnaire. Most patients were female (67%), the mean age was 41 years (±12) and mean BMI was 25.65 kg/m² (±4.9). The mean SLEDAI and SLICC scores were 2.45 (±2.72) and 0.8 points (±1.04), respectively. The mean score for the RSES was 32.09 (±5.84) in females and 33.57 (±4.97) in males. The BSES was 189.5 (±473) in females and 207.1 (±36.6) in males. There was no association between these scores and prednisone dosage, BMI, or SLLEDAI and SLICC scores. We found that SxO is associated with lower global self-esteem (p<0.0001) and lower body self-esteem (p<0.0001), according to their respective scores (see Table 1). Also, a correlation between both self-esteem questionnaires (BSES and RSES) and CSFQ-14 scores was found. Interestingly, the correlation was higher in the male population (r=0.45, p=0.008 and n=0.47 p=0.006 for BSES and RSES, respectively) than in women (r=0.25, p=0.001 and n=0.18 p=0.004) in both scores. The multivariate analysis showed that age (p=0.003, 0.96 [0.94-0.98 95% CI]) and lower global self-esteem (p=0.013, 1090 [1-1.14 95% CI]) were independent risk factors for SxO. We observed a trend related to lower body self-esteem scores (p=0.055, 1.007 [1-1.15 95% CI]) as a risk factor. Other variables, such as prednisone, major depressive disorder and BMI did not show an association with SxO (see Table 1).

Conclusion: To our knowledge, this is the first study to demonstrate a reliable association between body-self-esteem and SxO in SLE patients, particularly in male patients. Considering the high impact of both self-esteem and sexual function on quality of life, our findings reinforce the importance of routinely acknowledging the biopsychosocial aspects (and not only the disease-related ones) in the medical care of these patients.

POS1485 SEMIOQUANTITATIVE ASSESSMENT OF SYNOVIAL INFLAMMATION ON US-GUIDED SYNOVIAL TISSUE BIOPSIES OF SYSTEMIC LUPUS ERYTHEMATOUS COMPARSED TO OTHER CONNECTIVE TISSUE DISEASES AND RHUMATOID ARTHRITIS

Keywords: Systemic lupus erythematosus, Synovium

D. Di Mario1, L. Petrice2, V. Varriano3, M. R. Gigante2, S. Perniola3, D. Bruno3, B. Tolusso1, S. Alivernini1,2, E. Gremese1,2, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Immunology Research Core Facility.

Background: Patients with rheumatic diseases, particularly systemic lupus erythematosus (SLE), present with greater sexual dysfunction (SxD) than patients with other chronic diseases. SxO is multifactorial and may be linked to both disease-related and psychological factors, as well as hormonal imbalance and drug treatment. Self-image and self-esteem, which have not been thoroughly studied in SLE patients, may be related to sexual interest and thereby may also affect sexual function.

Objectives: We addressed the association between body self-esteem, global self-worth and sexual functioning in SLE patients.

Methods: We performed a transversal study in a tertiary care center in Mexico City. Patients ≥18 years old who fulfilled EULAR/ACR criteria for SLE were included. Body self-esteem was assessed by the Body Self-esteem Scale (BSES) and global self-esteem by the Rosenberg’s Self-Esteem Scale (RSES). Sexual function was evaluated by the CSFQ-14 questionnaire. Disease activity and damage was assessed by the SLLEDAI and SLICC scores, respectively. Relevant demographic, clinical and serological characteristics were recorded. We used univariate and multivariate analysis to determine association between variables. Statistical analysis was performed using SPSS (V.25).
Systemic Lupus Erythematosus patients might experience the development of arthritis clinically resembling other forms of chronic joint inflammation. However, to date, no systematic analysis of the histological composition of synovitis was performed in SLE patients.

Objectives: To dissect the inflammation degree and the histological composition of synovial tissue of SLE patients compared with other Connective Tissue Disorders (CTD) and naive to treatment Rheumatoid Arthritis (RA).

Methods: Seventy-five patients with connective tissue diseases [n=30 SLE, n=13 Sjogren Syndrome (SS), n=19 Undifferentiated Connective Tissue Disease (UCTD), n=13 other CTD] were included in the study. Thirty-four naive to treatment RA patients were included as comparison. Each patient underwent ultrasound-guided minimally invasive synovial tissue biopsy at the study entry. Each synovial tissue sample was processed for H&E staining for the Krenn Synovitis Score (KSS) assessment by a pathologist blinded to clinical characteristics [1].

This evaluation was implemented with the additional assessment of lymphocytes and plasmacells presence, and with the assessment of the microanatomical organization in terms of inflammatory aggregates presence.

Results: Considering the whole cohort, SLE patients showed comparable synovial inflammation in terms of KSS compared to SS and other CTD (p>0.05 for both). However, synovial tissue of SLE patients showed significantly milder inflammation when compared to naive to treatment RA (p=0.002) and more severe compared to UCTD (p<0.009), mainly in terms of inflammatory infiltrate (p=0.015). Moreover, among SLE cohort, patients with Rhupus showed higher KSS compared to SS (p=0.03), mainly for synovial hyperplasia (p=0.016) and comparable synovial inflammation than naive to treatment RA (p=0.05). Considering the composition of the inflammatory infiltrate, synovial tissue of SLE patients was enriched of lymphocytes compared to synovial tissue of SS patients (p=0.0028), UCTD (p=0.014) and other CTD (p=0.018), similarly than synovial tissue of naive to treatment RA (p=0.05).

Moreover, SLE patients showed, at synovial tissue level, higher rate of plasmacells compared to SS (p=0.038) despite significantly lower than naive to treatment RA (p=0.007). Interestingly, among the whole SLE cohort, synovial tissue of Rhupus patients was enriched of plasmacells compared to synovial tissue of SLE patients (p=0.04). Finally, considering the microanatomical organization of synovial inflammation, SLE patients showed lower rate of synovial aggregates compared to naive to treatment RA (p=0.03), considering the latter having similar aggregate rate compared to Rhupus patients (p=0.23).

Conclusion: Synovitis in SLE patients, despite milder than in naive to treatment RA, is characterized by more severe features compared to other CTD. In particular, Rhupus patients show a degree of synovial inflammation in terms of KSS and microanatomical organization comparable to naive to treatment RA, supporting the need to dissect pathogenetic pathways driving this clinical phenotype.

DOI: 10.1136/annrheumdis-2023-eular.5463
Background: Anti-Ro60 and anti-Ro52 antibodies are associated with different connective tissue diseases (CTDs) [1]. However, the clinical significance of anti-Ro antibodies is not always consistent among different global regions.

Objectives: To investigate the clinical characteristics of patients with anti-Ro antibodies.

Methods: A total of 1596 patients with anti-Ro antibodies were included in the study. Demographic, clinical, and serological data were compared between individuals with different profiles of anti-Ro antibodies: patients with anti-Ro52 antibodies alone, patients with anti-Ro60 antibodies alone, and patients with combined anti-Ro52 and anti-Ro60 antibodies.

Results: Of the 1596 patients, 1362 (85.3%) were female, the mean age was 45.5 years, and systemic lupus erythematosus (SLE) (46.0%) and Sjögren’s syndrome (SS) (19.0%) were the most common CTD diagnoses. Among the patients with anti-Ro52 antibodies alone, idiopathic inflammatory myopathy (18.8%) and SLE (17.6%) were the most common CTD diagnoses. The coexistence of autoantibodies of this group was significantly lower compared with those of the other two groups (3.7% vs. 0.6% vs. 1.9%, p < 0.001) (Figure 1). In addition, the patients with isolated anti-Ro52 antibodies were more likely to suffer from interstitial lung disease (35.5% vs. 13.7% vs. 1.9%, p < 0.001) and pulmonary arterial hypertension (10.1% vs. 5.3% vs. 3.6%, p < 0.001) compared with the other two groups of patients (Table 1). Compared with patients with isolated anti-Ro52 or anti-Ro60 antibodies, the patients with combined anti-Ro52 and anti-Ro60 antibodies were more likely to suffer from xerophthalmia and xerostomia. Furthermore, hypoimmunocomplementemia, hyperglobulinemia, and proteinuria were particularly prevalent in patients with anti-Ro60 antibodies.

Conclusion: Different profiles of anti-Ro antibodies were significantly associated with different phenotypic features in CTDs, indicating the potential diagnostic and prognostic value of these antibodies in clinical practice.

LUPUS DAMAGE INDEX REVISION – INITIAL ITEM REDUCTION PHASE

Keywords: Organ damage, Systemic lupus erythematosus

B. Kundakci1, M. Barber2, A. E. Clarke2, S. Johnson3, I. N. Bruce1, 1University of Manchester Centre for Epidemiology Versus Arthritis, Faculty of Biology, Medicine and Health, Manchester; United Kingdom; 2University of Calgary, Division of Rheumatology, Cumming School of Medicine, Calgary, Canada; 3University of Toronto, Division of Rheumatology, Department of Medicine, Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western and Mount Sinai Hospitals; Institute of Health Policy, Management and Evaluation, Toronto, Canada

Background: An international initiative is underway to develop a revised systemic lupus erythematosus (SLE) organ damage index (SDI) using a multi-phase process that is supported by the SLE International Collaborating Clinics (SILICC), American College of Rheumatology (ACR) and Lupus Foundation of America (LFA). The first two phases (evaluating the construct of damage and item generation through literature review and an international Delphi exercise) were previously reported [1,2], and 220 candidate items were generated.

Objectives: To report the initial reduction phase results of a five-phase process for developing a revised SDI.

Methods: An international two-part Delphi exercise asked SLE experts and patients to rate 220 items for how appropriate they were for inclusion in a revised SDI on a 9-point Likert scale (where 1 = not at all appropriate and 9 = completely appropriate) considering the new construct of damage in SLE [1]. The definitions of items in plain English were provided for the patient representatives. In the first part of the item reduction Delphi round, participants were asked to suggest any additional items. In the subsequent Delphi round, participants were presented their own rating, median scores and 25th-75th percentiles for each item. They were given the opportunity to revise their rating. Items with ratings less than or equal to 4.0 or 9.0 were considered for removal.

Results: A total of 143 out of 146 participants who completed the first round Delphi for the item generation were invited for the item reduction rounds. Completion rates for the second and third Delphi rounds for the item reduction were 95% and 91.7% respectively. Appropriateness rating scores included the full range of scoring possibilities from 1 to 9. Participants suggested 53 potentially new items, however only 6 were retained, as others were duplicates or invalid.

226 items were presented to re-rate for appropriateness. There was stability in terms of summary median scores and 25%-75% percentiles for each item. Thirty-six items had a median score of less than or equal to 4. Figure 1 shows the number of candidate items identified at different stages of the project. All original SDI items were retained with group median appropriateness scores of 7, 8 and 9; the exceptions were upper gastrointestinal tract surgery (median appropriateness score 5) and osteomyelitis (median appropriateness score 5).

Figure 1. Number of candidate items identified at different stages of Phase II/III during revised SDI development

Phase II: Item generation

220 candidate items

Phase II: Item generation (expansion) (Additional items coming from second Delphi round)

226 candidate items

Phase III: Item reduction (Initial item reduction) (Median scores of 4 or less were removed)

190 candidate items

Keywords: Organ damage, Systemic lupus erythematosus
Conclusion: The item reduction phase using Delphi methods reduced the candidate items for consideration. All original 1996 SDI [3] items were retained in this step. Further steps are now underway to refine and rationalize this candidate list.

POS1490 WITHDRAWN

Keywords: Cardiovascular disease, Biomarkers, Systemic lupus erythematosus

M. Fredi1, S. Bertocchi1, E. Pedretti1, R. Rovelli1, A. Drera2, F. Ravasio2, M. Riccardi2, L. Serafini2, I. Cavazzana1, E. Vizzardi2, F. Franceschini1.
1ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 2ASST Spedali Civili and University of Brescia, Cardiology Unit, Brescia, Italy

Background: Cardiovascular involvement is common in patients with SLE and heart rhythm disorders are frequent in addition to the manifestations included in the classification criteria ACR/EULAR 2019. Previous studies provided evidence that anti-Ro/SSA-positivity is an independent risk factor for marked QTc prolongation; suggesting that subjects who are anti-Ro/SSA-positive may represent a subgroup with an increased predisposition to ventricular arrhythmias, particularly when other QT-prolonging risk factors are concomitantly present [1].

Objectives: The aim of this study is to estimate the prevalence of QTc-prolongation in a monocentric cohort and to evaluate possible correlation with the presence of anti-Ro/SSA-antibodies and other QT-prolonging risk factors.
Methods: An electrocardiographic study (EGC) was proposed to patients affected by SLE consecutively attending our Lupus Clinic from November 2021 to March 2022. All subjects were tested for anti-Ro/SSA-antibodies. Exclusion criteria included: severe valvulopathies, hypertrophic or dilated cardiomyopathy, previous implantation of pacemaker or implantable cardioverter-defibrillator. QTc measurement was calculated using the Bazett’s formula and QTc-prolongation was defined according to American College of Cardiology (ACC)/American Heart Association (AHA) recommendations (QTc>470 ms for males, QTc>480 ms for females) [2]. Data on 24-hour ECG holter were available in 26 patients.

Results: One hundred and forty-one patients with SLE, consecutively attending our clinic, accepted to undergo an ECG, 128 (91%) females, 13 (9%) males; 124 (88%) Caucasians (median age 53.2 [IQR 42.3-58.7], median disease duration 20.0 years [12.0-28.2]). Median QTc was 415 ms [IQR 394-436]; only 4/141 (2.8%) all Caucasian and female, had a prolonged QTc (Table 1).

HT: hypertension, D: dyslipidaemia

Sixty-eight (48%) patients were positive for anti-Ro/SSA-antibodies. No significant differences were observed between anti-Ro/SSA-positive vs. negative patients in term of QTc intervals [416.0 [395-437] ms vs 413.0 [392-432] ms; p=0.545] using Mann-Whitney Test. Other electrocardiographic alterations were found: 4 first-degree atrioventricular blocks, 25 bundle branch blocks (BBB), 31 repolarization anomalies, 1 Wolff-Parkinson-White. Patients were grouped according to hydroxychloroquine (HCQ) therapy and antibody profile into 4 groups: HCQ+Ro/SSA+ (58, 39.7%), HCQ+Ro/SSA-/ (58, 41.1%), HCQ-Ro/SSA+ (12, 8.5%) and HCQ-Ro/SSA- (15, 106%); no statistical differences (p=0.178) were observed in QTc length comparing the 4 groups using ANOVA test. Twenty-six (18.4%) underwent a 24-hour ECG holter evaluation. None of these patients had a QTc prolongation, and no major electrocardiographic anomalies were found. These patients were divided in 4 groups (as previously done for all patients). No statistical differences were found comparing the QTc of groups of patients (p=0.783).

Conclusion: These preliminary data show a lower prevalence of QTc prolongation compared to previous studies, with no differences between anti-Ro/SSA-positive and anti-Ro/SSA-negative patients. Otherwise, considering previous studies which observed a role of anti-Ro/SSA antibodies as an independent risk factor for QTc prolongation, further analysis will be performed in order to identify standardized markers for cardiovascular risk stratification. The evaluation of 24-hour ECG Holter in a larger number of patients and the characterization of anti-Ro/SSA (anti-Ro/SSA-52kD and anti-Ro/SSA-60kD) are ongoing.

Background: The prevalence of depression and associated factors in systemic lupus erythematosus (SLE) are not well known and there are no longitudinal studies addressing this relevant subject in SLE.

Objective: We aimed to evaluate the prevalence of self-perceived depression in patients with SLE and associated factors in a large, multicenter cohort (REALISER-PROS). 

Methods: Prospective longitudinal study of patients with SLE (1997 ACR criteria) answering positively to the depression question of the Lupus Impact Tracker (LIT) questionnaire (namely: “I was depressed” question number 7 (LITQ7), over 4 years of follow-up (5 annual visits, V1 to V5). Self-perceived depression was addressed as “depression any time” or “depression most of time”, according to the kind of answer to the LITQ7 (answers 1,2 or 3 and answers 3 or 4 respectively). Only patients with no missing values in the covariates, making possible run longitudinal models, were included in the multivariable analysis. The following covariates, with potential impact in depression, were considered: SLEDAI, age, etc.
duration of the disease, SLICC/ACR DI (SDI), fibromyalgia, Charlson index, smoking, BMI, menopause, sedentary lifestyle, marital status, unemployment and glucocorticoid use. Friedman test was used to test if the change in repeated measures was significative. Generalized estimating equation (GEE) models with binomial response, were built exploring the associations of individual longitudinal determinants with longitudinal assessment of depression. The best model was selected using quasi-likelihood under the independence model information criterion (QIC).

**Results:** A total of 1463 were included. Mean age: 55 (DS±13.59) years, 90% were female. Mean duration of the disease: 14 (±8.59) years. Fibromyalgia was present in 5.7% (76/1343). Corticosteroids use ranged from 49.4% to 57%, depending on the visit. Median SLLEDAI ranged from 0 to 2 and SDI ranged from 1 to 2. Prevalence of “depression any time” was 89.9% (1104/1228) and 34.6% (200/578) were in depression “most of time” Up to 26.5% (153/578) answered to LITQ7 “depression most of time” in the five visits; 89.7% of the patients which perceived themselves as depressed at least in 2 out of 5 visits. Only 6.9% of the patients with previous diagnosis of depression answered “0” to the Q7 of LIT (“none of the time”). Only following covariates showed changes, statistically significant, during the follow up: SLEDAI, SDI, Charlson and glucocorticoids use (Friedman test). Patients with “depression any time” develop more damage at V5 than patients without depression (answer to LITQ7=0) (p = 0.0093, T-test). In the GEE binomial analysis considering all the predefined covariates, that included only patients with no missing values for any of them (namely, 155 patients), fibromyalgia (OR 2.79; 95%CI: 1.28-6.05), unemployment (OR 1.95; 95%CI 1.02 -3.73), and glucocorticoids use (OR 1.88; 95%CI 1.18-2.99) were significant associated with “depression any time”.The best model (accoring QIC) displayed a statistically significant association only with fibromyalgia (OR 2.90; 95%CI: 1.58-5.33) and glucocorticoids use (OR 1.85; 95%CI: 1.17-2.93). Neither SDI nor unemployment reached significance only with fibromyalgia (OR 2.90; 95%CI: 1.58-5.33) and glucocorticoids use (OR 1.85; 95%CI 1.17-2.93). No SDI nor unemployment reached significance just (Table 1). Without entering glucocorticoids, SLLEDAI turns significative only with fibromyalgia (OR 2.79; 95%CI: 1.28-6.05), unemployment (OR 1.95; 95%CI 1.02 -3.73), and glucocorticoids use (OR 1.85; 95%CI 1.17-2.93). Neither SDI nor unemployment reached significance only with fibromyalgia (OR 2.90; 95%CI: 1.58-5.33) and glucocorticoids use (OR 1.85; 95%CI 1.17-2.93). Neither SDI nor unemployment reached significance only with fibromyalgia (OR 2.90; 95%CI: 1.58-5.33) and glucocorticoids use (OR 1.85; 95%CI 1.17-2.93). Neither SDI nor unemployment reached significance only with fibromyalgia (OR 2.90; 95%CI: 1.58-5.33) and glucocorticoids use (OR 1.85; 95%CI 1.17-2.93).

**Conclusion:** The prevalence of self-perceived depression is high in SLE. Longitudinal data analysis suggests a causal relationship between glucocorticoids use, fibromyalgia and self-perceived depression.

Pons-Estel1, V. I. Bellomio1, M. García1. GESAR LES, Rheumatology, Buenos Aires, Argentina

Background: The pathophysiology of Systemic Lupus Erythematosus (SLE) involves genetic and acquired immune dysregulation, both of which predispose patients to infection. Infections are a leading cause of hospital admission, intensive care unit admission and death.

Objectives: To evaluate the frequency and associated factors of hospitalizations due to infections in patients with SLE.

Methods: Cross-sectional study carried out with the RELESSAR trans registry. Patients with SLE (ACR 1997 criteria) were included. Sociodemographic variables, autoantibodies, manifestations of the disease, comorbidities and activity and chronicity index were analyzed. A serious infection was defined as one that required hospitalization. We evaluated number and localization of the infections, microorganisms and treatments received during the admissions and these variables were compared between patients hospitalized versus not hospitalized.

Results: A total of 1515 patients participated in the registry and 815 patients had been admitted: 41 cases were hospitalized due to infection exclusively and 162 patients of both infection and flare of the disease (total = 203). The mean time of admissions was 1.42 (SD 0.99). Graphic 1 shows the number of serious infections per patient. The most frequent localization was the respiratory tract and bacterial were the most frequently microorganism isolated. We compared 203 patients and 646 patients not hospitalized (Table 1). In multivariate analysis, age at SLE diagnosis (OR 0.96 95%CI 0.94-0.98, p< 0.001), level of education (OR 0.89 95%CI 0.83-0.94, p< 0.001), pericarditis (OR 3.25 95%CI 1.89-5.60, p< 0.001), low complement (OR 0.16 95%CI 1.33-10.10, p< 0.001), SLICC index (OR 1.98 95%CI 1.61-2.37, p< 0.001) and 10-30 mg/dl of prednisone (OR 3.70 95%CI 1.66-9.00, p< 0.002), 30-60mg/dl of prednisone (OR 8.40 95%CI 3.58-21.5, p< 0.001), azathioprine (OR 1.67 95%CI 1.02-2.73, p= 0.042), mycophenolate (OR 2.15 95%CI 1.27-3.67, p=0.005) and IgG (OR 8.25 95%CI 2.33-39.3, p<0.003) were variables independently associated to hospitalization due to infection.

Conclusion: Almost 25% of patients presented at least one hospitalization due to infection, being the respiratory infections the most frequent. Lower age at diagnosis, lower educational level, higher damage score, low complement, pericarditis, high steroids doses and immunosuppressant increased the chance of having an admission due to serious infection. As well as the treatment with IgG, an association that we can only explain by the reason that we only indicate it in severe and active infected patients.

LOW INTENSITY OF C1Q DEPOSITION WITH RENAL IMMUNOFLUORESCENCE PREDICTS LONG-TERM POOR RENAL PROGNOSIS IN LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Prognostic factors, Kidneys

K. Hiramoto1, H. Hanakaki1, K. Saito1, H. Fukui1, J. Kikuchi1, S. Saito1, Y. Kaneko1. 1Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Although the prognosis of lupus nephritis (LN) has been improved due to recent advances in diagnosis and treatment, its long-term renal outcome is still poor. In spite of previous studies that investigated a number of prognostic factors, association of long-term renal outcome with renal histological findings focusing on immunofluorescence has been little elucidated.

Objectives: To clarify renal histological and immunofluorescent findings associated with deterioration of renal function in LN.

Methods: Consecutive patients with biopsy-proven LN class III/IV from 2008 to 2017 in our hospital were included in the study. They were classified into two groups: patients with deterioration of renal function and those without. The deterioration of renal function was defined as more than 30% decline in estimated glomerular filtration rate (eGFR) from baseline. Clinical characteristics and renal histological findings with immunofluorescence at the time of LN diagnosis were compared between the two groups.

Results: Sixty-nine patients (class III/IV; 34; class III/IV-V; 21; class V 14) were included in the analysis. Renal function was deteriorated during 5 years observation in 12 patient (17.4%). There was no significant difference in age (48 vs 42 years, p=0.16), disease duration (11.4 vs 9.8 years, p=0.65), and urinary protein-to-creatinine ratio (2.3 vs 2.5 g/gCr, p=0.58) between the deterioration and non-deterioration groups. The treatment regimens including maximum prednisolone dose (41 vs 47 mg/day, p=0.14), cyclophosphamide use (42 vs 54%, p=0.53) and mycophenolate mofetil use (0 vs 24%, p=0.11) were also not different. Regarding renal histopathological findings, while proportion of III/IV class (83 vs 79%, p=1.00), activity index (1 vs 4, p=0.14), and chronicity index (4 vs 3, p=0.19) were not different between the two groups, intensity of C1q deposition in renal immunofluorescence was significantly weaker in the deterioration group than the non-deterioration group; proportion of C1q deposition in renal immunofluorescence ≥1+ was 100% in the deterioration group compared to 47% in the non-deterioration group (p=0.006). When we divided the patients according to the intensity of C1q deposition, the cumulative deterioration rates of renal function were significantly different (p=0.01, Figure 1). The patients with low intensity of C1q deposition (≤1) had a lower positivity of serum anti-dsDNA antibody (75 vs 96%, p=0.04) and a higher serum C3 levels (54 vs 40 mg/dl, p=0.03) at LN diagnosis. Anti-SSA antibodies tended to be higher in the deterioration group than the non-deterioration group (80 vs 64%, p=0.43).
Conclusion: Low C1q deposition in renal immunofluorescence at LN diagnosis is associated with poor renal prognosis in LN.

PREVALENCE OF SARCOPENIA IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Sarcopenia, Motor function, Systemic lupus erythematosus

E. Pena1, R. Cavalcante De Espirito Santo2, L. Dos Santos1, L. Denardi Dória1, S. Pilotti1, D. Nóbrega de Moraes1, A. L. Mallmann1, A. A. Gasparin1, V. Hax1, T. Muniz Fighra2, P. M. Spritzer2, R. Chakr1, R. Xavier1, O. Monticielo4, Teixeira Keijinkai Hospital, Center for Recurrent Pregnancy Loss, Sapporo, Japan

Background: Sarcopenia is a muscle disease that leads to decreased physical functionality, increased risk of falls, fractures, hospitalization and mortality [4,5]. The sarcopenia still needs to be better understood in SLE. Therefore, more studies are necessary to assess the sarcopenia prevalence and the impact on SLE patients.

Methods: This was a single-center, retrospective longitudinal study of female patients in our center from 2020 to 2021. Clinical and laboratory data were retrieved from medical records and questionnaires. Anti-β2GPI/HLA-DR antibody is associated with arterial thrombosis

Results: We evaluated 704 patients, including 66 (obstetric or thrombotic) APS, 13 primary APS, and 78 asymptomatic aPL carriers, that comorbid 260 Systemic Lupus Erythematosus (SLE) or Mixed Connective tissue diseases (MCTD). Seventy-seven patients had one or more histories of arterial thrombosis, and 14 patients of them had a history of both arterial and venous thrombosis. The titers were significantly higher in patients with arterial and venous thrombosis than in those without thrombosis. In cases with aGAPSS<10 or triple positive aPL, the titers tended to be higher. The ROC showed that the sensitivity, specificity, and area under the curve (AUC) for arterial thrombosis were 33.8%, 91.4%, and 0.60 with a cutoff value of 172.359 U/ml. By the multivariable logistic regression analysis from multiple imputation, the odds ratio of anti-β2GPI/HLA-DR antibody ≥172.359 was 5.11(95% confidence interval: 2.84-9.19; P<0.001) (Table 1). When adding the cutoff value to conventional cardiovascular risk factors improved the AUC from 0.677 to 0.730 (p = 0.088). Determined net reclassification improvement and integrated discrimination improvement were statistically significant (Figure 1). Conclusion: Anti-β2GPI/HLA-DR antibody is associated with arterial thrombosis in females with various systemic rheumatic diseases.

FOllOW-UP MONOCENTRIC COHORT WITH UP TO 40 YEARS OF EVENTs IN SYSTEMIC LUPUS ErythematOSUS

Objectives: To assess the prevalence of sarcopenia in SLE patients and its associations with clinical parameters.

Methods: In this cross-sectional study, women with SLE (18 to 50 years old) were included. The following data were collected: disease duration, disease chronicity (SLICC/ACR-DI), disease activity (SLEDAI-2k), treatment regimen, quality of life (SLEQoL), physical activity level (IPAQ, min/week), muscle strength by handgrip test (kg) and chair stand tests (seconds), Appendicular skeletal muscle mass (ASM, kg) was evaluated. The mean of SLE disease activity index by IPAQ was 58.3 ± 40.50 min/week. The majority of patients (83.7%) showed low physical activity level (IPAQ). The patients presented muscle strength by the handgrip test of 24.7 ± 9.01 kg and 14.3 ± 6.68 kg using the chair stand test. Eight patients (16.3%) showed low muscle strength by the handgrip test and twenty-four patients (49%) showed low muscle strength by the chair stand test. The mean of ASM was 17.03 ± 2.32 kg. Ten patients (20.4%) had low muscle mass. The prevalence of sarcopenia was 16.3% following the EWGSOP2 criteria. On the other hand, we did not find severe sarcopenia. In addition, we did not find a relationship among sarcopenia and age, disease duration, disease chronicity, disease activity, cumulative corticosteroid dose, quality of life, and physical activity level (p > 0.05).

Conclusion: The prevalence of sarcopenia was 16.3% in patients with SLE. Almost half of our patients had low muscle strength in the chair stand test (49%) and only 16.3% had low muscle strength by handgrip test. Furthermore, sarcopenia is not associated with clinical parameters. Therefore, further studies should be developed to assess risk factors for sarcopenia in patients with SLE.

COMORBIDITIES AND SAFETY EVENTS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Real-world evidence, Systemic lupus erythematosus, Epidemiology

W. Krueger1, D. Feger1, A. Friedman2, T. Doan3, K. D'Silva3, AbbVie, Global Epidemiology, Pharmacovigilance & Patient Safety, North Chicago, United States of America; 2AbbVie, Immunology, North Chicago, United States of America

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with multiorgan involvement. High disease activity may drive the development of comorbidities and safety events in SLE.

Objectives: To assess the prevalence of comorbidities and history of safety events at the time of Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) assessment and the incidence of newly diagnosed comorbidities and safety events post-SLEDAI assessment among a prevalent cohort of adult SLE patients ≥18 years old.

Methods: This was a retrospective observational cohort study using the OM1 SLE Registry data from January 2013 to February 2022 (OM1, Inc., Boston, MA). The index date was defined as the first observed or estimated SLEDAI score with the occurrence of safety event or occurrence of SLE case over a 6-month risk period. The baseline period included all observed time prior to and including the index date. The follow-up period for identifying incident comorbidities and safety events included all available data after the index date. Incidence rates were stratified by disease activity.

Results: Among 10,837 patients, mean age was 52 years and 92% were female. The most common existing comorbidities were hypertension (44%), fibromyalgia (32%), anemia (29%), dyslipidemia (29%), thyroid disease (26%), obesity (25%), depression (22%), rheumatoid arthritis (22%), anxiety (19%), and Sjögren’s syndrome (18%). History of safety events at baseline most commonly included any infection (11%), abdominal liver function tests, hepatitis, or acute liver injury (ALI) (8%), elevated creatinine or acute kidney injury (AKI) (6%), and any malignancy (5%). Most patients were treated with first-line therapy for SLE (glucocorticoids and/or immunosuppressants) during follow-up (89%). Use of second-line (methotrexate, azathioprine, leflunomide) and third-line (belimumab, anifrolumab, mycophenolate mofetil, mycophenolic acid, tacrolimus, cyclosporine, vopoconitin, rituximab) SLE therapies were less common (29% and 30%, respectively). During follow-up, 36% of patients had no disease activity, 28% had mild activity, 22% had moderate activity, and 14% had severe activity. Greater disease activity was associated with higher rates of incident hypertension, dyslipidemia, anxiety, thyroid disease, end-stage renal disease or dialysis, chronic liver disease/cirrhosis, avascular necrosis, seizures or epilepsy, and Sjögren’s syndrome. The most common incident safety events regardless of disease activity were the infection (30.7 per 1000 person-year [PY]), abnormal liver function tests, hepatitis, or ALI (20.3 per 1000 PY), and elevated creatinine or AKI (17.9 per 1000 PY). Correlation between incident safety events and disease activity varied by outcome.

Conclusion: Many common comorbidities occur more frequently among patients with higher SLE disease activity. The association between disease activity and the incidence of safety events was less clear. SLE-related systemic inflammation, comorbidities, and effects of SLE treatment (both positive and negative) likely contribute to patients’ risk profiles.

FACTORS ASSOCIATED WITH CARDIOVASCULAR EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN A MONOCENTRIC COHORT WITH UP TO 40 YEARS OF FOLLOW-UP

Keywords: Systemic lupus erythematosus, Cardiovascular disease, Anti-phospholipid syndrome

N. Farina1, J. Webster2, W. Luo2, D. Garelick2, S. Moreira Pinto4, D. Isenberg2, A. Rahman3, 1IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology; Allergy and Rare Diseases, Milan, Italy; 2University College London, Centre for Rheumatology Research, Division of Medicine, 4Institut für Klinische Medizin, Technische Universität München; 3The Zabludowicz Center for Autoimmune Diseases, Rheumatology Unit, TelHashomer, Israel; 4Centre Hospitalier Póvoa de Varzim e Vila do Conde, Internal Medicine Service, Póvoa de Varzim, Portugal

Background: Systemic lupus erythematosus (SLE) is associated with an increased cardiovascular risk. Several traditional and disease-specific risk factors have been shown to correlate with the occurrence of cardiovascular events (CVE) in patients with SLE. However, results of previous studies are diverse.
Objectives: The objectives of this study were to report number, type and those factors associated with CVE in patients with SLE in a large, single-centre, ethnically diverse cohort with a long follow-up duration.

Methods: Medical records of patients treated at the Lupus Clinic at University College London Hospital (UCLH) between 1979 and 2020 were retrospectively reviewed. Data about CVE, traditional cardiovascular risk factors, demographic and disease features, and treatment history were collected. Only patients with complete available information were included in the study. Regression analyses were performed to identify factors associated with CVE.

Results: Four hundred and nineteen patients were included in the study. Maximum follow-up length was 40 years. Seventy-one (17%) patients had at least one CVE. Forty (50%) events were VTE, 26 (32.5%) were CVA, and 14 (17.5%) were CAD. Mean age at CVE was 44 (SD 12) years. Median time from diagnosis to CVE was 8 (IQR 4-15) years. Descriptive comparative analysis showed an increased prevalence of hypercholesterolemia (41% vs 28%, p-value=0.035), diabetes (10% vs 4%, p-value=0.027), and antiphospholipid antibodies (aPL) positivity (58% vs 27%, p-value<0.001) among patients with CVE. Furthermore, these patients were treated less frequently with hydroxychloroquine (80% vs 89%, p-value=0.049). However, univariable analysis (Table 1) showed that only aPL positivity was significantly associated with CVE. This association was confirmed at multivariable analysis (p<0.001). Survival curve for CVE according to the presence of aPL is shown in Figure 1. When analysing different types of CVE, aPL were specifically associated with both venous thromboembolic events (p-value<0.001) and cerebrovascular events (p-value=0.007). Dedicated subanalyses revealed that cumulative glaucomatocoid dose (p-value=0.010) and a diagnosis of SLE before 2000 (p-value<0.001) were also significantly associated with CVE.

Conclusion: Cardiovascular disease is highly prevalent among patients with SLE and is associated with aPL, glucocorticoid therapy, and diagnosis before 2000.

Figure 1. Survival curves for cardiovascular events according to the presence of antiphospholipid antibodies. aPL, antiphospholipid antibodies.

LUPUSNET – A FEDERATED MODEL/NETWORK TO SUPPORT REAL-WORLD DATA RESEARCH IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Real-world evidence, Registries

J. Schreiber1, M. Van Speybroeck2, F. Zazzetti3, W. Noel2, T. A. Simon4, F. Lavie5, Janssen-Cilag, Immunology, Neuss, Germany; Janssen Pharmaceutica, IT-EMEA, Beerse, Belgium; Janssen Medical Affairs Global Services, LLC, Immunology, Buenos Aires, Argentina; Physicians Research Center, LLC, Immunology, NJ, United States of America; The Janssen Pharmaceutical Companies of Johnson & Johnson, Rheumatology, Paris, France

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with a broad range of clinical manifestations and a high unmet need. Real-world data on SLE are available and currently scattered across more than 50 registries worldwide. The Lupus Federated Data Network (LupusNet) is an interdisciplinary initiative that aims to standardize data and harmonize methodology to create a large, global SLE database from existing registries.

Objectives: This initiative will allow the analysis of real-world data across lupus registries worldwide.

Methods: The central paradigm of LupusNet is a federated model whereby the data reside with the respective registries/data owners and analyses are executed at the local center. As data from different sources have different infrastructures, the Observational Medical Outcomes Partnership (OMOP) common data model (CDM) will be used to standardize data into a common format. Standardization will reduce the heterogeneity in data structure and semantics, allowing for uniform data analysis, collaborative research, large-scale analytics, and sharing of sophisticated tools and methodologies. LupusNet will include prospective, observational registries designed to capture real-world data on demographics, treatments, and outcomes in patients with SLE. Other data, including data originating from randomized clinical trials, will also be part of this initiative.

Results: Currently, 6 registries representing 4 regions of the globe and ~30,000 lupus patients are engaged at the start of this initiative. Examples of the types of data from each registry that are available for standardization and harmonization in LupusNet are shown in Figure 1. Other lupus registries that may be interested in participating in this initiative should contact the authors. Participating registries are not required to collect all types of data to be included in the initiative. Contact the LupusNet team at www.lupusnet.org.

Conclusion: Through the standardization of global registry data, LupusNet hopes to demonstrate the potential of real-world evidence to answer important questions related to SLE with the ultimate goal of improving patient outcomes.

HERPES ZOSTER INCIDENCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE COHORT STUDY

Keywords: Real-world evidence, Systemic lupus erythematosus

N. Sternpnieiczka1, A. Steffenst2, K. Kim1, A. Jorga3, C. Beilt4, M. Ducharme5, H. Trenz6, D. Singer1, GSK, Medical Affairs, Philadelphia, United States of America; Optum, HEOR, Eden Prairie, United States of America; GSK, Medical Affairs, New York, United States of America; GSK, Value Evidence and Outcomes, Durham, United States of America

Background: Herpes zoster (HZ) results from reactivation of the varicella-zoster virus and is characterized by a painful dermatomal rash. HZ is associated with increased healthcare costs and reduced patient quality of life.

Objectives: To estimate HZ incidence in patients with systemic lupus erythematosus (SLE) and in a general immunocompetent adult population in the United States.

Methods: This retrospective cohort study used administrative claims data (Optum Research Database) to identify adults (≥18 years) between October 2015 and May 2022 who were assigned to one of two cohorts based on ICD-10-CM diagnosis codes: SLE cohort and immunocompetent cohort. Patients with diagnosis codes for other immunocompromising conditions (ICC) were excluded from the immunocompetent cohort and from the main SLE cohort to create a sub-cohort (SLE without other ICC). The immunocompetent cohort represented a random sample of 1 million individuals meeting the cohort criteria. Indexing occurred at the later of 12 months of continuous enrollment (CE) or the first SLE diagnosis for the SLE cohorts, and after 12 months of CE for the immunocompetent cohort. Patients with HZ vaccination prior to index or a HZ diagnosis in the 12-month baseline period were excluded. Patients were followed for a variable period from index until the earlier of an incident HZ diagnosis or censoring event (HZ vaccination, disenrollment, death, or the end of the study period). Overall incidence rates of HZ were estimated in each cohort and stratified by age at index, and by baseline disease severity for the SLE cohorts using a published algorithm [1].

Results: The SLE cohort included 60,430 patients, among which 21,206 comprised the SLE without other ICC cohort. The immunocompetent cohort included 1,000,000 patients. Mean (standard deviation) age and percent female for the SLE (55 [15] years; 89% female) and for the SLE without other ICC (53 [16] years; 89% female) cohorts were higher compared to the immunocompetent (46 [18] years; 50% female) cohort (p < 0.001). For the SLE cohort, HZ incidence (95% confidence interval [CI]) per 1,000 person-years was 19.72 (18.93-20.55) overall and 16.27 (15.04-17.58) and 21.50 (20.48-22.56) per 1,000 person-years for patients aged 18-49 and ≥ 50 years, respectively. HZ incidence (95% CI) for the SLE without other ICC cohort was 14.03 (12.83-15.32) per 1,000 person-years.

REFERENCES: NIL.
Overall (18-49 years: 11.24 [9.61-13.07]; ≥50 years: 16.08 [14.39-17.91]). HZ incidence (95% CI) for the immunocompetent cohort was 5.45 (5.35-5.74) per 1,000 person-years (18-49 years: 3.46 [3.35-3.57]; ≥50 years: 8.57 [8.37-8.77]). HZ incidence rates in the BLE cohorts increased with baseline disease severity (Table 1).

Conclusion: HZ incidence was high among patients with SLE. HZ prevention strategies in this population may be warranted.

Background: Lupus nephritis (LN) is one of the most frequent serious Lupus manifestations and it is an important risk factor for overall morbidity and mortality in patients with SLE. Despite potent anti-inflammatory and immunosuppressive therapies, it persists with a significant number of patients who progress to chronic renal failure. 

Objectives: To evaluate the prevalence of LN and the characteristics of patients with this complication in search of a potential higher risk profile for the development of kidney disease.

Methods: It was a retrospective, observational and analytical study; based on the database of the national registry of SLE of the Argentine Society of Rheumatology (RELESSAR). Adult patients who met the ACR 1997 Classification Criteria for SLE were included. Sociodemographic data, time of disease evolution, and delay in diagnosis were collected. The antibody profile, activity indices (SLEDAI), comorbidities (Charlson), treatments and damage (SDI) were determined. Patients with current or past LN were compared with those without LN.

Results: 1502 patients were analyzed, of which 643 (42.8%) had LN. The predominant histological classes were class IV in 253 cases, class III in 81, class II in 78, and class V in 33 patients. In the univariate analysis, patients with LN were characterized by being more frequently of mestizo origin (p<0.001), having a younger age at entry into the registry (p<0.001), less delay in diagnosis in months (p<0.001) and longer disease duration (<0.001). They also presented higher SLEDAI in the last evaluation (p<0.001) as well as low complement levels (p<0.001) and a higher frequency of positive anti-SM antibodies (p<0.001) and anti-dsDNA antibodies (p<0.001). The treatments received any time were Azathioprine (47.0% vs 7.37%, p< 0.001), mycophenolate mofetil (47.0% vs 7.37%, p< 0.001), mycophenolic Acid (5.59% vs 0.39%, p<0.001) and Belimumab (3.7% vs. 8.03%, p<0.001). The multivariate analysis is described in Table 1.

Conclusion: In the RELESSAR registry, the prevalence of LN was 42.8%. These patients were characterized by being more frequently of mestizo origin, younger at last evaluation, and of lower socioeconomic level. There was also a correlation with the global activity of the disease as well as with low complement levels and anti-SM antibodies positive. Within the comorbidities there was a strong association with arterial hypertension. We also highlight the negative association with acute cutaneous lupus and with the presence of antiphospholipid antibodies.

THE IMPACT OF HIGH-RISK ANTIPHOSPHOLIPID ANTIBODES PROFILE ON MAJOR ORGAN DAMAGE PROGRESSION IN SYSTEMIC LUPUS ERYTHEMATOSUS: CSTAR MULTIPLE PROSPECTIVE COHORT STUDY

Keywords: Organ damage, Autoantibodies, Systemic lupus erythematosus

D. Yufang1, J. Zhao1, Q. Wang1, X. Tian1, M. Li1, X. Zeng1. 1Peking Union Medical College Hospital (PUMCH), Rheumatology, Beijing, China

Background: With the improvement in survival, the prevention of cumulative organ damage has become a major goal in the management of systemic lupus erythematosus (SLE). Patients with autoimmune disease suffered from an increasing risk of cardiovascular disease (23-3 events per 1000 patient-years [1]). Although antiphospholipid (aPLs) antibodies, including anticardiolipin antibodies, anti-β2 glycoprotein I, and lupus anticoagulant, were associated with vascular events in antiphospholipid syndrome, the role of aPLs in SLE patients was not yet determined.

Objectives: Based on the Chinese SLE treatment and research (CSTAR) multi-center prospective study, we aimed to identify the predictive value of high-risk aPLs on cumulative organ damage progression in SLE.

Methods: Demographic characteristics, autoantibody profiles, clinical manifestations, disease activity status, and organ damage were collected at baseline. High-risk aPLs profile was defined according to 2019 EULAR recommendations for APS [2] (the presence of lupus anticoagulant, or double or triple aPL positivity, or the presence of persistently high aPLs titers).

Results: A total of 2132 SLE patients with full follow-up data were recruited and 424 (19.9%) showed high-risk aPLs profiles. 453 (21.2%) patients developed new organ damage during a mean follow-up of 4.40±2.64 years, and 143 (31.6%) are cardio-cerebral vascular damage. At baseline, patients with high-risk aPLs profile have a higher rate of neurological involvement (12.5% vs 7.6%, p<0.001). As shown in Figure 1, cox regression analysis showed that high-risk aPLs profile can predict new-onset organ damage (HR=1.99, 95% CI, 1.63-2.43, p<0.001) and cardio-cerebral vascular damage (HR=7.83, 95% CI, 5.56-11.03, p<0.001). After adjusted of gender(male), age, smoking history, diabetes mellitus, hypertension, and other SLE related potential confounders, high-risk aPLs profile was still found to be an independent predictor which can predict cardio-cerebral vascular events (HR=7.12, 95% CI, 5.03-10.14, p<0.001) (Figure 1).

Figure 1. (A) Cumulative probability of new-onset organ damage in patients with or without high-risk aPLs profile. (B) Cumulative probability of cardio-cerebral vascular damage in patients with or without high-risk aPLs profile. (C) Risk factors of cardio-cerebral vascular damage in SLE patients.

Conclusion: SLE patients with high-risk aPLs profile warrant more care and surveillance of cardio-cerebral vascular events during follow-up.

IDENTIFYING DETERMINANTS OF FAVOURABLE AND POOR PHYSICAL FUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM AN INTERNATIONAL COLLABORATIVE STUDY

Keywords: Systemic lupus erythematosus, Comorbidities

S.Y. Lee1, A. Holloway2, E. Nikiphorou1,3, I. Parodi3,4, N. Ravichandran5, J. Day1,2,3, M. Joshi6, S. Saha7, K. Jagatia1, W. Katchamart1,2, P.A. Goo1,2, B. Vaidya1,3, T. Velikova1,5, P. Sen1,6, S. Katsuyuki Shinjo1, V. Agarwal1,2, A. E. Gracia-Ramos24, C. Vinicio Caballero25, H. Chinoy26,27, V. Agarwal1,2, A. E. Gracia-Ramos24, L. Gupta5,6,30,31.
Background: Systemic lupus erythematosus (SLE) can result in impaired daily physical function through various mechanisms including active disease, chronic damage, and mental health symptoms that are common in the disease. However, the key drivers of reduced physical function are poorly understood, and no large-scale global studies investigating this have been conducted to date.

Objectives: To investigate key factors that contribute to impaired physical function in SLE globally.

Methods: SLE patients were identified from the COVAD 2 database, a global register of more than 20,000 respondents. Healthy controls (HC) were included to compare differences in physical function using the Patient Reported Outcome Measurement Information System (PROMIS) questionnaire. Demographics, medication, comorbidities, disease activity, Global Physical Health (GPH) and Global Mental Health (GMH) were collected. Multivariable regression analysis was used to identify contributing factors to favourable or poor physical function (measured by PROMIS Physical Function shortform PF-10a score).

Results: 979 SLE patients and 3358 HC were included in analysis. Patients with SLE had significantly lower PF-10a score as compared to HCs (median 42, IQR 36-47 vs median 49, IQR 45-50, p<0.001). Determinants of physical function status in patients with SLE are summarised in Table 1. Briefly, factors associated with poor physical function included increasing age (-0.042, 95% CI -0.074 to -0.015, p=0.002**), higher pain visual analogue scales (VAS) (-2.889, 95% CI -3.042 to -2.736, p<0.001), and fatigue (VAS) (-1.459, 95% CI -1.853 to -1.057, p=0.031) but not depression contributed to a lower physical function score. Higher Pain Visual Analogue Scales (VAS) (-2.889, 95% CI -3.042 to -2.736, p<0.001) and Fatigue (VAS) (-1.459, 95% CI -1.853 to -1.057, p=0.031) but not depression contributed to a lower physical function score. Higher Pain Visual Analogue Scales (VAS) (-2.889, 95% CI -3.042 to -2.736, p<0.001) and Fatigue VAS (VAS) (-1.459, 95% CI -1.853 to -1.057, p=0.031) but not depression contributed to a lower physical function score.

Conclusion: Patients with SLE show significantly reduced physical function compared with HCs. Key contributors to poor physical function include intercurrent diabetes and ILD. Screening for, and aggressive early treatment of these conditions may confer improved long-term function. As expected, higher levels of pain and fatigue were associated with poor physical function. Methotrexate use was also identified as a contributing factor to reduced function, which could represent its use in articular manifestations that limit physical function. Importantly, use of hydroxychloroquine was associated with favourable physical function, adding to the well-recognised benefits of this drug in SLE.

IC3B/C3 RATIOs MORE STRONGLY CORRELATE WITH SLE DISEASE ACTIVITY IN AFRICAN-AMERICANS COMPARED WITH WHITES

Keywords: Biomarkers, Systemic lupus erythematosus

D. Sen1, V. Strand2, O. Fu3, A. Kim1
1Washington University School of Medicine, Medicine, St. Louis, United States of America; 2Stanford University School of Medicine, Rheumatology/Immunology, Stanford, United States of America; 3Tufts University - School of Arts and Sciences, Community Health, Medford, United States of America

Background: Complement activation is a hallmark of SLE pathophysiology. We previously found that iC3b/C3 ratios associated with active disease and clinically meaningful changes in SLE disease activity. Since SLE is more severe in non-white populations, we hypothesized that iC3b/C3 ratios would be a more sensitive marker of disease activity in nonwhite populations.

Objectives: We examined the relationship of iC3b/C3 ratios between African-American (AA) and White SLE subjects using SLEDAI and SLEDAI-2K scores.

Methods: 159 adult SLE patients treated at the Washington University Lupus Center were enrolled in this observational study. 83 patients with 3-7 study visits were used for this longitudinal analysis. C3 and C4 were measured by nephelometry; iC3b by a lateral flow assay using an investigational medical device. SLE disease activity was measured using the SLEDAI 2K Responder Index-50 instrument. Statistical analyses were performed using SAS v9.4. Multilevel regression models examined associations for SLE disease activity. Ordinal logistic regression models with generalized estimating equation modeling (GEE) examined associations for clinically meaningful changes since the outcome variable is ordinal. Odds ratios and 95% confidence intervals were estimated using Proc GLIMMIX and Proc GENMOD.

Results: iC3b/C3 ratios and C3 associated with active disease in AA and White SLE. The association of the iC3b/C3 ratio in AA was stronger (Figure 1). In addition, AA with SLE associated C4, ESR, and dsDNA with active disease, while Whites associated with CRP. In multiple regression analysis, iC3b/C3 ratios were not associated with remission impact on HRQoL and long-term outcomes.

Conclusion: iC3b/C3 ratios correlated with clinically meaningful changes in SLE disease activity. Since SLE is more severe in non-white populations, we hypothesized that iC3b/C3 ratios would be a more sensitive marker of disease activity in nonwhite populations.

Background: Improvement on health-related quality of life (HRQoL) in patients with Systemic Lupus Erythematosus (SLE) remains a challenge. There is limited data on the level of agreement on remission according to physician and patient and remission impact on HRQoL and long-term outcomes.

 سبيل المثال، يمكننا استخدام هذه المعلومة في تحليل البيانات أو في جمعها للاستفادة من المعلومات المتاحة في الورقة. لكننا نحتاج إلى مزيد من المعلومات للقيام بذلك. فعلى سبيل المثال، يمكننا استخدام المعلومات المتاحة في الورقة لإجراء تحليلات وجمع بيانات عنطل وهيكل القلب أو أي شيء آخر يأهله. ولكننا نحتاج إلى مزيد من المعلومات للقيام بذلك. فعلى سبيل المثال، يمكننا استخدام المعلومات المتاحة في الورقة لإجراء تحليلات وجمع بيانات عنطل وهيكل القلب أو أي شيء آخر يأهله.
Objectives: To investigate the prevalence and level of agreement between remission according to physician and patient criteria and to evaluate the impact of remission on HRQoL in patients with SLE.

Methods: Prospective study of patients included in RELESSER-PROS, a multicenter register of SLE patients. Protocol of the register has been previously described [1]. Remission according to physician was defined in agreement with DORIS 2021 criteria: clinical SLEDAI 0, physician global assessment ≤2 on a 0-10 Likert scale (equivalent to ≤0.5 on a 0-3 scale), stable low-dose prednisone (≤5mg) and stable immunosuppressive/biologic agents if remission on therapy. Remission according to patient was defined as SLAQ (Systemic Lupus Activity Questionnaire) question 1 with no flare in the last 3 months (score 0). Patients were classified in three groups according to remission status by DORIS, SLAQ or both. Level of agreement was assessed using kappa statistics. Acceptable level of agreement was considered if kappa >0.60.

Results: 1102 patients, with a follow-up of at least 2 years (data from 3 visits available) were included in this analysis. Patient characteristics according remission status at baseline are presented in the Table 1. At baseline, remission by DORIS was present in 16.1%, by SLAQ 16.7% and 2.45% by both. Remission by DORIS was more frequent among patients with higher education, on immunosuppressant and biological therapy and patients with history of hospitalization; remission by SLAQ was more frequent among women, obese patients, and those on antimalarials (p<0.05). Symptoms reported in patients who considered themselves in remission were mainly cutaneous and articular (53.3%). Mean SLEDAI in patients on remission by SLAQ was 3.28 (3.78). Patients in remission by DORIS had significantly better results in patient reported outcomes (PRO) measured by EQ-5D and LIT (p<0.05). Level of agreement in remission according to physician and patient was 78.04% (k=0.061) at baseline, 63.39% (k=0.030) and 62.73% (k=0.099) in year 2 and 5 respectively. Kappa level of agreement was low.

Conclusion: Our results reflect low level of agreement between physician and patients in terms of remission status with increasing disagreement in the follow-up. Patients in remission by DORIS shows better results in EQ-5D and LIT.

Conclusion: Our study proposes that persistent aPLs-positive women with APO have three major clinical subtypes. Cluster 1 contains patients with a predisposition to SLE. Patients in cluster 2 majorly present PI combined with aPLs-IgG subtype, while cluster 3 present EM with aPLs-IgM subtype. The individualized risk stratification assessment of these patients will help to develop different treatment strategies and improve the pregnancy outcome.

POS110 IDENTIFICATION OF THE MINIMAL REQUIRED DURATION OF RENAL-EXTRARENAL REMISSION ASSOCIATED WITH REDUCED RISK OF CHRONIC KIDNEY DISEASE AND OF DAMAGE ACCRUAL IN LUPUS NEPHRITIS

Keywords: Remission, Treat to target, Systemic lupus erythematosus

M. Gatto1, G. Frontini2, M. Calatroni3,4, F. Reggiani3,4, B. Trezzi5, S. Quaglini6, R. A. Sinico7, L. Iaccarino1, G. Moroni1,4, A. Doria8,1 University of Padova, Unit of Rheumatology, Department of Medicine, Padua, Italy; 2San Paolo Hospital, ASST SS Paolo e Carlo, Unit of Nephrology and Dialysis, Milan, Italy; 3IRCCS Humanitas Research Hospital, Nephrology and Dialysis Division, Milan, Italy; 4Humanitas University, Department of Biomedical Sciences, Milan, Italy; 5Università Degli Studi di Milano Bicocca, Department of Medicine and Surgery, Milan, Italy; 6Università di Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy

Background: There is an increasing need for data exploring the effect of remission on kidney-oriented outcomes and terminal organ damage in patients with lupus nephritis (LN).

Objectives: To investigate the effects of renal-extrarenal clinical remission on chronic kidney disease (CKD) development and organ damage accrual in patients with LN.

Methods: We performed a multicentric retrospective cohort study on biopsy-proven LN patients with at least five years follow-up, in whom we assessed (i) the minimum duration of remission able to prevent CKD (serum creatinine <1.0mg/dl with eGFR <60ml/min/1.73 m2 and inactive urinary sediment, confirmed by at least three determinations for at least 3 months); (ii) the impact of remission on organ damage, evaluated by the SLICC Damage Index (SDI). Renal-extrarenal clinical remission was defined as serum creatinine <1mg/dl, eGFR>60ml/min/1.73m2, proteinuria <0.5g/24h and cSLEDAI=0, lasting for at least one year. Cox regression was used to test the effect of different durations of remission on CKD and SDI accrual. The minimum duration of remission needed to prevent CKD was estimated through Kaplan-Meier curves. The potential relationship between persistent renal-extrarenal clinical remission and SDI was assessed by Spearman correlation between percentage of follow-up spent in remission and annual increase in SDI.

Results: 303 LN patients were included (females 86.5%, mean follow-up 14.8 (9.8-22.0) years). 84.8% achieved renal-extrarenal clinical remission that persisted for 8.70 (5.40-13.30) years. Overall, 17.6% patients developed CKD after a median of 14.1 (8.9-20.9) years. Patients achieving remission developed CKD significantly less frequently than patients never achieving remission (12.1% vs. 56.6%, p<0.001). Among patients with at least 10-year follow-up (n=224), a remission duration of at least 2 years protected from CKD development (HR95%CI 1.017 (1.005-1.028); p=0.004). Among patients with at least 10-year follow-up (n=224), a remission duration of at least 2 years protected from CKD development (HR95%CI 1.017 (1.005-1.028); p=0.004). Among patients with at least 10-year follow-up (n=224), a remission duration of at least 2 years protected from CKD development (HR95%CI 1.017 (1.005-1.028); p=0.004).

Conclusion: Renal-extrarenal clinical remission is an achievable treatment target which protects against CKD development and SDI increase in patients with LN. At least 3 years of renal-extrarenal clinical remission confers significant protection against renal function deterioration and chronic damage, hence emerging as a desirable therapeutic target for LN.

POS111 PERSISTENCE OF RENAL-EXTRARENAL REMISSION AND EFFECT ON RISK OF SLE FLARES AND OF CHRONIC KIDNEY DISEASE IN PATIENTS WITH LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Kidneys, Remission

G. Moroni1,2, M. Gatto3, G. Frontini2, M. Calatroni3,4, S. Quaglini1, F. Reggiani1,3, B. Trezzi1, L. Iaccarino1, R. A. Sinico7, A. Doria8,1 University of Padova, Unit of Rheumatology, Department of Medicine, Padua, Italy; 2San Paolo Hospital, ASST SS Paolo e Carlo, Unit of Nephrology and Dialysis, Milan, Italy; 3IRCCS Humanitas Research Hospital, Nephrology and Dialysis Division, Milan, Italy; 4Humanitas University, Department of Biomedical Sciences, Milan, Italy; 5Università Degli Studi di Milano Bicocca, Department of Medicine and Surgery, Milan, Italy; 6Università di Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy

Background: How renal and extrarenal remission affects risk of flares and of chronic kidney damage (CKD) development in systemic lupus erythematosus (SLE) patients with active lupus nephritis (LN) was not clearly disentangled.

Objectives: To investigate the effect of maintained or interrupted renal-extrarenal clinical remission on the risk of SLE flares and CKD development in LN.

Methods: We conducted a retrospective cohort study on biopsy-proven LN patients in whom we evaluated (i) the probability of achieving and maintaining renal-extrarenal clinical remission; (ii) the impact of renal-extrarenal clinical remission on the risk of SLE flares and CKD development (defined as serum creatinine >1.0mg/dl with eGFR <60ml/min/1.73 m2 and inactive urinary sediment, confirmed by at least three determinations for at least 3 months); (i) the predictors of renal-extrarenal clinical remission. Renal-extrarenal clinical remission was defined as serum creatinine <1mg/dl, eGFR>60ml/min/1.73m2, proteinuria <0.5g/24h and cSLEDAI=0 lasting for at least one year. Time to renal-extrarenal clinical remission, the likelihood of its maintenance and the risk of SLE flares were estimated through Cox regression.

Results: 303 patients were included in the study. Over a 14.8-year-follow-up, 46 patients never achieved while 257 achieved remission after a median of 1.44 (0.69-3.58) years from initial therapy for LN. In 142 out of 257 patients, remission ended after a median of 3.6 (2.30-5.90) years due to SLE flares. 115 patients maintained an uninterrupted remission for 9.5 (5.8-14.5) years. At multivariate analysis, age >40 years (OR95%CI 1.017 (1.005-1.028); p=0.004), hydroxychloroquine use (OR95%CI 1.384 (1.109-1.661); p=0.021) and absence of arterial hypertension (OR95%CI: 0.699 (0.425-0.975); p= 0.011) were independent predictors of renal-extrarenal clinical remission. CKD occurred in 56% of patients who had never reached renal-extrarenal clinical remission, in 21.8% of those who lost remission due to SLE flares and in none of those who maintained remission permanently (p<0.0001). Five, 10 and 15 years after the beginning of

POS151 IDENTIFYING HIGH-RISK PROFILE IN PRIMARY ANTIPHOSPHOLIPID SYNDROME THROUGH CLUSTER ANALYSIS: FRENCH MULTICENTRIC COHORT STUDY

Keywords: Epidemiology, Cardiovascular disease, Anti-phospholipid syndrome

Hôpital Saint-Antoine, AP-HP, Sorbonne Université, Service de Médecine Interne et Inflammation-Immunopathology-Biotherapy Department (DMI 3ID), Paris, France; CHR-U de Brest, Service de Médecine Interne, Brest, France; 3Centre Hospitalier Universitaire d’Angers, Service de Médecine Interne et Immunologie Clinique, Angers, France; 4CHRU et université de Tours, Service de Médecine Interne, Tours, France; 5Hôpital Tenon, AP-HP, Sorbonne Université, Service de Hémostase et Hématologie Biologique, Paris, France, France; 6Hôpital Tenon, AP-HP, Sorbonne Université, Service de Dermatologie et Vénérologie, Paris, France; 7Hôpital Pitie-Salpêtrière, AP-HP Centre de Recherche de Saint-Antoine, INSERM, UMRs 938, Sorbonne Université, Service des Urgences Cébraro-Vascularis, Paris, France; 8CRSA INSERM, UMRs 938, Hôpital Saint-Antoine, AP-HP, Sorbonne Université, Service de Rheumatologie, Paris, France; 9Hôpital Tenon, AP-HP, Sorbonne Université, Service de Néphrologie, Paris, France; 10Hôpital Saint-Antoine, AP-HP, Sorbonne Université, Service de Cardiologie, Paris, France; 11AP-HP, Hôpital Saint-Antoine, Sorbonne Université, Service d’hémato-oncologie, Paris, France

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by thrombosis (arterial, venous or small vessel) or obstetrical events, or chronic persistent antibodies (aPL), according to the Sydney classification criteria. Many studies have performed cluster analyses among patients with primary APS and associated autoimmune disease, but none has focused solely on primary APS.

Objectives: We aimed to perform a cluster analysis among patients with primary APS and asymptomatic aPL carriers without any autoimmune disease, to assess its prognostic value.

Methods: In this multicenter French cohort study we included all patients with persistent APS antibodies (Sydney criteria) measured between January 2012 and January 2019. We excluded all patients with systemic lupus erythematosus or other systemic autoimmune diseases. We performed hierarchical cluster analysis on the factor analysis of mixed coordinates results with baseline patient characteristics to generate clusters.

Results: We identified four clusters: cluster 1, comprising “asymptomatic aPL carriers”, with low risk of events during follow-up; cluster 2, the “male thrombotic phenotype”, with older patients and more venous thromboembolic events; cluster 3, the “female obstetrical phenotype”, with obstetrical and thrombotic events; and cluster 4, “high-risk APS”, which included younger patients with more frequent triple positivity, antinuclear antibodies, non-criteria manifestations, and arterial events. Regarding survival analyses, asymptomatic aPL carriers relapsed less frequently than the others, but no other differences in terms of relapse rates or deaths were found between clusters.

Conclusion: We identified four clusters among patients with primary APS, one of which was “high-risk APS”. Clustering-based treatment strategies should be explored in future prospective studies.

REFERENCES:
Background: Systemic Lupus Erythematosus (SLE) is an autoimmune chronic disease characterized clinically by periods of flares and remission. Although its pathophysiology has not yet been well understood, it is well documented that SLE courses with systemic inflammation, as well as affection to specific organs [1]. Lupus nephritis (LN) is the most common complication and cause of death appearing in SLE patients, often leading to end-stage renal disease [2]. A type I interferon (IFN) signature is present in SLE, however, there is no consensus on which genes are expressed in LN. We performed a metaanalysis through integrative bioinformatics to identify differentially expressed genes (DEGs) in patients with LN.

Objectives: We aimed to identify and assess overlapped DEGs of patients with LN through integrative bioinformatics and functional enrichment analysis.

Methods: We designed a search strategy in the Gene Expression Omnibus platform to identify datasets of expression profiling by array of kidney samples of patients with LN. The inclusion criteria were: 1) Presence of healthy controls in the datasets, and 2) Analysis of data with GEO2R. The exclusion criteria were: 1) Incomplete information in the datasets, and 2) Failure to identify cases and controls, respectively. We aimed to identify overlapped DEGs of patients with LN, in which the IFN signature is present.

</tbody>
</table>

Conclusion: We aimed to identify and assess DEGs of patients with LN and recognize the ones with the strongest interactions. Our results suggest that type I IFN is crucial on the pathophysiology of LN, and STAT1 can serve as a possible therapeutic target for treating LN. We propose further in vivo studies to validate these results, given that they can serve as diagnostic biomarkers and even possible therapeutic targets for LN treatment.

Prevalence and Clinical Features of Late and Very Late Onset Systemic Lupus Erythematosus

Keywords: Systemic lupus erythematosus, Outcome measures

I. A. Gennaio1, M. Zen1, E. Fuzzi1, M. Gatto1, M. Larosa1, L. Iaccarino1, A. Doria1. 1University of Padua, Department of Medicine, DIMED, Padua, Italy

Background: Whether late-onset (LO) SLE is associated with a different, more benign disease course and better prognosis than early-onset SLE is still controversial.[1-3]

Objectives: To describe the prevalence and clinical features of LO-SLE and very late onset (VLO) SLE and to compare their outcomes with those of non-LO SLE.

Methods: We performed a retrospective study using prospectively collected data from our cohort involving 516 patients with SLE (ACR criteria) followed between 2008 and 2022. Patients older than 50 or older than 60 years at SLE onset were defined as LO-SLE and VLO-SLE, respectively. Demographic data, and clinical and treatment history were retrieved from clinical charts. SLEDAI-2K, daily prednisone dose, SLICC Damage Index (SDI), and low disease activity (according to LLDAAS definition) [1] at last follow-up in 2022 were assessed. Early mortality, within 10 years after diagnosis, was assessed in patients diagnosed in the last 15 years.

Results: Among 516 SLE patients regularly followed, 38 (7.4%) were LO-SLE: mean±SD age at diagnosis 56.5 ±5.7 years (range 50-72), females 78%. Of them, 10 (2% of the overall cohort) were VLO-SLE: mean±SD age at diagnosis 65 ±4.0 years (range 60-72), females 60%. Compared to early-SLE patients, LO-SLE patients had more frequently skin involvement and positive antiSSA/SSB antibodies (Table 1). Compared to non-LO-SLE, no difference in life-threatening manifestations was observed, including renal and neuropsychiatric involvement. The same trend was found in VLO-SLE. Accordingly, the use of immunosuppressants (including types of drugs) and biologics was similar (Table 1). At last follow-up, SLEDAI-2K was lower in LO-SLE patients (1±2 vs. 2±3, p=0.01), whereas the proportion of patients on glucocorticoids (21% vs 37%) and in LLDAAS (84% vs 74%) was similar to that observed in non-LO-SLE. Despite that, SDI was higher in LO-SLE (2, range 0-8) than in non-LO-SLE patients (1, range 0-10, p=0.004) but after excluding items possibly related to aging (cataract, osteoporosis, low GFR, malignancy) the difference was not significant anymore. Among 165 patients diagnosed in the last 15 years, mortality was similar in LO and early-onset SLE, although deaths within 10 years after diagnosis (2 cases) all occurred in early-SLE patients.

Conclusion: MSK manifestations have similar clinical impact and immune profile across ARMDs. Current therapies used are similar: ANA-arthritis is therefore a homogenous and impactful population for basket trials.

ACKNOWLEDGEMENTS: NIL.

DOI: 10.1136/annrheumdis-2023-eular.3612
Objectives: To assess the frequency of accrual damage in antiphospholipid syndrome (APS) and to evaluate the association with different laboratory and clinical APS aspects.

Methods: Medical records of 274 patients, 231 (84.3%) female and 43 (15.7%) males with a mean (±SD) age at diagnosis of 37.8 (±11.5) years, followed prospectively from 1990 to 2021, were reviewed.

Results: Ninety-six (35%) presented pregnancy morbidity alone, 140 (51.1%) thrombosis alone and 38 (13.9%) both thrombosis and pregnancy morbidity. A single, double or triple antiphospholipid antibodies (aPL) positivity was registered respectively in 82 (29.9%), 78 (28.5%) and 114 (41.6%) of the patients. Following a mean (±SD) follow up of 208.4 (±17.1) months, a total of 58 (21.2%) organ damage accrual was recorded. This included neurological damage in 19 (32.8%) patients, hemiparesis in 9, epilepsy in 7 and cognitive dysfunction/dementia in three cases, cardiac valvopathy in 4 (6.9 %) patients of which 3/4 (75%) require valve replacement with mechanical valve in two cases and bioprosthetic valve in one case. Chronic heart failure was found in 4 (6.9%) patients, chronic renal failure in 15 (25.9%), amputation due to peripheral arterial thrombosis in 5 (8.6%), visual loss in 2 (3.4%), post thrombotic syndrome in 6 (10.3%), arterial insufficiency in one (1.7%). Some of the patients present more than one organ dysfunction. Both thrombotic and thrombocytic and pregnancy morbidity subsets were significantly associated with a higher rate of damage accrual compared with pregnancy morbidity alone, respectively p<0.0001 (OD 40.7; 95% CI: 6.9-418.8) and p<0.0001 (OD 61.9; 95% CI 10.5-659.7). Moreover, the presence of microangiopathy as well as the presence of both venous and arterial thrombosis were significantly associated with damage accrual, respectively (p<0.0001, OD 10.99; 95% CI 5.72-23.8) and (p=0.001). Regarding laboratory subsets, triple aPL positivity was significantly associated with a higher rate of damage accrual compared to single and double aPL, respectively p<0.0001 (OD 9.6; 95% CI: 3.7-23.5) and p<0.0001 (OD 4.8; 95% CI: 2.2; 10.81). At the multivariate analysis only microangiopathy was an independent risk factor for damage accrual (p=0.001).

Conclusion: Overall, our data show a higher frequency of damage accrual in APS patients. Microangiopathy was an independent risk factor for damage accrual. These findings should be in mind when counselling APS patients and might help guide clinicians in therapeutic decision.

PULMONARY INVOLVEMENT IN LUPUS IS ASSOCIATED WITH ENHANCED MORBIDITY: A MULTICENTRE STUDY

Keywords: Lungs, Systemic lupus erythematosus, Autoantibodies

M. Gerosa1,2, G. A. Ramirez3, L. M. Argolini1, I. Scotti1, C. Artusi1, L. Moroni3, E. Bozzolo4, M. R. Pellizzoni5, L. Cavallolo6, L. Dagna6, R. Caporali1,2,3. ASST Gaetano Pini-CTO, Lupus Clinic, Department of Clinical Rheumatology, Milan, Italy

Objectives: To assess the prevalence and clinical impact of the spectrum of SLE-related pulmonary manifestations and their association with patient autoantibody profiles in a large SLE cohort and to describe the effectiveness of different therapeutic approaches in distinct clinical settings.

Methods: Patients followed at the Lupus Clinics of ASST G. Pini-CTO and San Raffaele Hospital (Milan, Italy) were enrolled. Data regarding demographics, disease characteristics, autoantibody profile, pulmonary manifestations, damage accrual and treatment were collected. The lung manifestations were recorded: pleurisy, acute lupus pneumonitis, interstitial lung disease (ILD), alveolar haemorrhage, pulmonary embolism, arterial pulmonary hypertension and shrinking lung syndrome.

Results: Of the 471 SLE patients enrolled, we identified 78 patients (16.5%) displaying at least one pulmonary manifestation. Epidemiological data on each patient were recorded in Table 1. The most frequent lung manifestations and manifested at disease onset in most cases (56%). Patient home environment (urban vs countryside) did not seem to impact the risk of developing lung disease. Damage accrual was relevant, as 2/3 of patients displayed at least 1 point increase in SLICC Damage Index (SDI) after the onset of lung involvement in comparison to baseline. All patients received at least one steroid course. Immunosuppressive treatment choices and efficacy differed among distinct manifestations: only half of the patients with pleurisy received immunosuppression, mainly azathioprine, with 100% of improvement, while 80% of cases of ILD received immunosuppression, predominantly mycophenolate, with a 50% risk of non-response. By comparing demographics and clinical characteristics among cases and controls, we found a significantly lower median age at disease onset (p=0.002) and a higher frequency of male sex (18% vs 9%; p=0.07), joint involvement (p=0.02) and constitutional symptoms (p=0.02) in patients with lung involvement, while no differences were observed in the autoantibody profile, including anti-dsDNA and anti-ENA autoantibodies.

Conclusion: Our study confirms that, in addition to the known epidemiological burden of pleurisy, other types of pulmonary involvement can complicate the disease course and contribute to damage accrual. In particular, ILD can frequently occur and respond to immunosuppressants in only half cases. Consistent with the association of lung involvement with increased morbidity, higher-risk categories for severe disease such as males and subjects with early-onset SLE were more represented among patients with pulmonary manifestations.

**Background:** Clinically evident kidney disease eventually occurs in up to one-half of SLE patients.

**Objectives:** To describe sociodemographic, clinical, serological and treatment characteristics of a multicenter and multienhene Latin American SLE cohort of patients with or without lupus nephritis (LN).

**Methods:** GLADEL2.0 is an ongoing observational cohort. Patients were categorized according to renal involvement: Group I (LN never); II (prevalent renal involvement currently inactive); III (prevalent renal involvement, currently active) and IV (incident renal involvement). Demographic, clinical manifestations, treatments, disease activity were examined at baseline. A descriptive cross-sectional analysis was performed.

**Results:** A total of 991 SLE patients were included, 884 (89.2%) female and 556 (68.3%) Mestizos (Amerindian and European ancestry). Median (IQR) age at cohort entry was 35 (28-45) years and disease duration were 67 months (18-139). Patients with incident LN had a higher proportion of males, were younger, had shorter disease duration, and were more frequently Mestizos. Pericarditis and anti-dsDNA were less frequent in group I and MMF in groups I and IV (Table 1). A predominance of class IV (9%) was evidenced in 510 patients in which a kidney biopsy was performed.

**Conclusion:** Baseline characteristics of GLADEL2.0 well characterized lupus patients’ cohort with or without LN are described with distinct demographic, clinical and laboratory patterns that will allow both centralized laboratory evaluation of urinary biomarkers and exploratory biomarker analyses including transcriptome and their impact on the outcome of these patients.

Inês1,4, *Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 1Centro Hospitalar Baixo Vouga, Rheumatology, Aveiro, Portugal; 2Centro Hospitalar de Leiria, Rheumatology, Leiria, Portugal; 3University of Beira Interior, Faculty of Health Sciences, Covilhã, Portugal; 4Centro Hospitalar de Trás-os-Montes e Alto Douro, Rheumatology, Vila Real, Portugal; 5Universidade NOVA de Lisboa, Comprehensive Health Research Center, Lisboa, Portugal; 6Hospital Nélio Mendonça, Rheumatology, Funchal, Portugal; 7Hospital de Braga, Rheumatology, Braga, Portugal; 8Centro Hospitalar de Lisboa Ocidental, Rheumatology, Lisboa, Portugal; 9University of Coimbra, Faculty of Medicine, Coimbra, Portugal; 10Centro Hospitalar Universitário do Algave, Rheumatology, Faro, Portugal; 11Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal; 12Unidade Local de Saúde da Guarda, Rheumatology, Guarda, Portugal

Background: The Systemic Lupus Erythematosus Disease Activity Score (SLE-DAS) has been recently developed and validated, providing improved accuracy and sensitivity for changes in SLE disease activity in comparison to SLE Disease Activity Index 2000 (SLEDAI-2K) [1]. New recommendations to standardize the Physician Global Assessment (PGA) scoring may improve its reliability [2].

Objectives: To assess the intra- and interrater reliability of SLE-DAS, SLEDAI-2K and PGA for measuring SLE disease activity.

Methods: A set of 24 clinical vignettes were abstracted, each from a real clinical visit of patients followed at an academic lupus clinic. These vignettes were selected to include a wide spectrum of SLE manifestations, organ-system involvement, and global severity of disease activity. Abstracted data were presented in a standardized format, including demographic, past medical history, current clinical picture and treatment, laboratory, and other workup assessments. A group of 19 raters were recruited as a random multicenter sample of Rheumatologists. All raters completed a preliminary training session on scoring rules for SLE-DAS, SLEDAI-2K and PGA. Each rater scored each clinical vignette with SLE-DAS, SLEDAI-2K, and PGA through an online survey. The scoring was repeated in a second round 7-14 days after the first one. The clinical vignettes were randomly ordered for each round. Inter and intra-rater reliability of each instrument was estimated using the intraclass correlation coefficient (ICC) with 95% confidence intervals (95% CI), based on single-measurement, absolute agreement, with a two-way random effect or two-way mixed-effects model, respectively.

Results: The 19 raters included 8 rheumatologists and 11 rheumatology trainees from 11 hospitals, with a mean of 12.1±7.1 years of rheumatology practice, respectively, and 78.9% of the participants assess ≤5 SLE patients per week in their regular clinical practice. The 24 clinical vignettes included 83.3% female patients, with a mean of 38.5±17.9 years of age. Active SLE organ involvement included: skin rashes (20.8%); arthritis (12.5%); nephritis (12.5%); thrombocytopenia (12.5%); cardiac/pulmonary involvement (12.5%); mucocutaneous vasculitis (8.3%); serositis (8.3%); neuropsychiatric lupus (8.3%). Systemic vasculitis, myositis, alopecia, hemolytic anemia, and leukopenia were each present in 4.2% of the vignettes. Hypocomplementemia and/or high anti-dsDNA were present in 75.0%. Twenty-one percent of the cases were in remission. All raters completed the survey, totaling 912 case assessments. Scores attributed by the raters ranged from 0.37 to 49.53 in SLE-DAS, 0 to 24 in SLEDAI-2K, and 0.0 to 3.0 in PGA. The interrater reliability was good for SLE-DAS and SLEDAI-2K, and moderate for PGA. The intra-rater reliability was excellent for SLE-DAS, and good for SLEDAI-2K and PGA (Table 1).

Table 1: Interrater and intra-rater reliability of SLE-DAS, SLEDAI-2K and PGA.

<table>
<thead>
<tr>
<th>Instrument</th>
<th>ICC (95%CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SLE-DAS</td>
<td>0.877 (0.857-0.934)</td>
</tr>
<tr>
<td>SLEDAI-2K</td>
<td>0.812 (0.717-0.896)</td>
</tr>
<tr>
<td>PGA</td>
<td>0.704 (0.578-0.828)</td>
</tr>
</tbody>
</table>

CI: confidence interval; ICC: intraclass correlation coefficient.

Conclusion: SLE-DAS presents high intra- and interrater reliability for measuring SLE disease activity. The high reliability of SLE-DAS is an important quality both in clinical practice and research, allowing consistent scoring among different clinicians including those who are not SLE experts.

Psoriatic arthritis - treatment

CHARACTERISTICS OF DIFFICULT TO TREAT PSORIATIC ARTHRITIS: A COMPARATIVE ANALYSIS

Keywords: Psoriatic arthritis, bDMARD

C. Philippeau1, A. Marty-Ané,1, C. Martin,1, P. Philippe1, J. Paccou1, B. Cortel1, R. M. Flipo1, J. G. Letarouilly1. Lille University Hospital, Rheumatology, Lille, France; 2 Lille University Hospital, Statistics, Economic Evaluation, Data-management Unit, Lille, France

Background: The concept of difficult-to-treat rheumatoid arthritis (D2T RA) has recently emerged. It is defined by the persistence of disease activity and the failure of at least 2 bDMARDs of 2 different mechanisms of action (MoA) [1]. In this definition, the period of time during which the treatments have failed is not included. The D2T concept has not yet been applied with consensus in psoriatic arthritis (PsA).

Objectives: To study the characteristics of patients with D2T PsA to better identify the potential causes of treatment failure. The 2nd objective was to study a sub-group of D2T PsA patients with a predefined time criteria.

Methods: A monocentric retrospective longitudinal study was performed in a tertiary center. PsA diagnosis was based on CASPAR criteria. Patients were followed up from February 2004 to August 2022. Patients starting a bDMARD with a minimum of 2-year follow-up were included. D2T PsA patients were defined as patients who received more than 2 bDMARDs with different MoA among bDMARD available. These patients were compared to non-D2T PsA patients (nD2T PsA) using statistical tests. Very D2T PsA patients were defined as patients who received at least 2 bDMARDs in less than 2 years during the time of follow-up.

Results: 150 patients were included, 49 were D2T PsA and 101 nD2T PsA. Baseline characteristics are presented in the Table 1. No statistical difference was found between the 2 groups regarding main comorbidities, including fibromyalgia and depression. In the D2T PsA group, 91.7% and 69.1% of patients received an anti-TNF-alpha as the 1st and 2nd lines of treatment; anti-IL17 drugs represented 0% and 12.2% of 1st and 2nd lines; anti-IL-12/23 represented 8% and 18.4% of prescriptions in 1st and 2nd lines. After 3 lines, 38.8% of patients had received 3 bDMARDs with different MoA. 30.6% received 2 bDMARDs with different MoA. D2T patients were categorized as very D2T PsA. When compared to the rest of the 17 patients were categorized as very D2T PsA. At the time of the end of the study, D2T PsA group, no significant difference was observed. Proportion of men was 64.7% (p=0.39). Mean age was 55.0±8.3 yo (p=0.87) and mean BMI was 30.4±6.5 kg/m² (p=0.65).

Changes in Serum Cytokines by Week 24 Correlate with Long-Term Efficacy of Gusekumab Through 2-Years in Bio-Naïve Adults with PsA

Keywords: Psoriatic arthritis, Randomized control trial, Biomarkers

S. Siebert1, G. Schett2, S. P. Raychaudhuri3,4, M. Guma5, W. Chen2, S. Gaso6, S. D. Chakravarty7,8, M. Shah9, P. Rahman10,11; 1 University of Glasgow, School of Infection and Immunity, Glasgow, United Kingdom; 2 FAU Erlangen-Nürnberg, Internal Medicine 3, Erlangen, Germany; 3 University of California Davis, School of Medicine, Division of Rheumatology, Allergy and Clinical Immunology, Sacramento, CA, United States of America; 4 VA, Northern California Health Care System, Sacramento, CA, United States of America; 5 University of California San Diego, Division of Rheumatology, Allergy and Immunology, Department of Medicine, La Jolla, CA, United States of America; 6 Janssen Research & Development, LLC, Immunology, Spring House, PA, United States of America; 7 Janssen Scientific Affairs, LLC, Immunology, Horsham, PA, United States of America; 8 Drexel University College of Medicine, Division of Rheumatology, Philadelphia, PA, United States of America; 9 Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, PA, United States of America; 10 Memorial University of Newfoundland, Craig L Dobbin Genetics Research Centre, Discipline of Medicine, Division of Rheumatology, St John’s, NL, Canada

Background: The IL-23p19 inhibitor gusekumab (GUS) has shown robust efficacy vs placebo (PBO) in phase 3 DISCOVER-1 and -2 studies of adults with active psoriatic arthritis (PsA) [1,2], with continuous overall clinical improvement observed through 2 years of DISCOVER-2 [3]. GUS has previously been shown to significantly reduce levels of inflammatory biomarkers associated with PsA over 24 weeks [4].

Objectives: To assess whether earlier changes (by Week [W] 24) in serum biomarker levels associate with long-term (W100) clinical response to GUS.

Methods: DISCOVER-2 enrolled biologic-naïve adults with active PsA ≥6 months defined by the CASPAR criteria, swollen and tender joint counts ≥5, and C-reactive protein (CRP) ≥0.6 mg/dL. Patients (pts) were randomized 1:1:1 to GUS 100mg at W0, W4, then every 4 weeks (W4W); GUS at W0, W4, then GUS or PBO [2]. Using Spearman linear regression and General linear model, serum cytokine levels determined in GUS-treated pts (pooled W4QW8W) were assessed for: 1) correlations between reductions in cytokine levels, including selected Th17 cytokines (IL-17A, IL-17F, IL-22), acute phase cytokines (CRP, serum amyloid protein A [SAA], IL-6), and γ-δ-defensin 2 (BD-2), from baseline (BL) at W24 and in PsA disease severity from BL at W100, measured by changes in Disease Activity in Psoriatic Arthritis [DAPSA] scores, Psoriatic Arthritis Disease Activity Score (PASDS), and Psoriasis Area and Severity Index (PASI) scores (significant correlation: >0.25 and p<0.05); and 2) associations between changes in selected cytokine levels from BL through W24 and achievement of ACR50 response at W100.

Results: BL demographics, disease severity, and medication use of GUS-treated DISCOVER-2 pts with available biomarker data (N=100) were consistent with the overall GUS-treated DISCOVER-2 population (N=493). With GUS treatment, PASI score change from BL at W100 correlated with changes from BL at W24 in serum BD-2, IL-17A, IL-17F, and IL-22 levels (all >r0.25, p<0.05; Table 1), though PASDAS and DAPSA score change at W100 did not correlate with changes in these biomarkers at W24. DAPSA score change at W100 correlated with changes at W24 in serum IL-6, W100 ACR50 responders (N=53) to GUS also demonstrated significantly lower serum CRP, SAA, and IL-6 levels at W24 than nonresponders (N=39) [p<0.05; Figure 1].

Conclusion: This analysis reported correlations between earlier changes in Th17 cytokine levels and long-term reductions in PASI scores, and associations between earlier changes in acute phase cytokine levels and long-term ACR50 response with GUS. The substantial reductions in these cytokines from BL at W24 may portend durable improvements in skin and joint symptoms of PsA.

Shaded cells represent significant correlation between cytokine levels and clinical activity (r>0.25 and p<0.05).

Methods: ATTRIA is a prospective registry of patients receiving bDMARD therapy for rheumatic diseases collecting data on efficacy, safety and quality of life of all patients treated in the Czech Republic. Adult patients with psoriatic arthritis treated with secukinumab were included in the analysis. The monitored indicators were survival on therapy, DAS 28 ESR, response to treatment according to EULAR, HAQ, EuroQol, physician-assessed psoriasis, dactylitis, enthesitis, nail involvement, physical function and ability to work. Patients were described at the beginning of secukinumab treatment and after 3, 6, 12, 18, and 24 months through absolute and relative frequencies in categorical variables and means with standard deviations (SD) and medians with 5th and 95th percentiles when describing continuous variables. Survival on therapy was computed through the Kaplan-Meier method. Statistical analyses were conducted using IBM SPSS Statistics (version 25.0).

Results: A total of 426 patients were included in the study, of which 237 were women and 189 were men. The average age at the start of treatment was 51 ± 12 years, duration of the disease 10 ± 8 years. About 40% of patients were bDMARD naïve, 60% had failed 1 or more bDMARDs. At the start of secukinumab treatment, 66.4% were on concomitant csDMARD therapy, with 47% receiving methotrexate (MTX) in monotherapy or in combination with other csDMARDs. Survival on therapy was 79.1% (95% CI: 75.0; 83.3) at 1 year, 69.6% (95% CI: 64.6; 74.6) at 2 years, and 53.6% (95% CI: 44.8; 62.5) at 5 years of treatment. The reason for treatment discontinuation was primary non-response (30.6%), secondary non-response (47.6%) and adverse effects (6.5%). Mean DAS 28 had decreased from initial 5.0 ± 1.3 to 2.5 ± 1.1 after 2 years of treatment. Remission (DAS 28 < 2.6) was achieved by 54.1% and low disease activity (DAS 28 ≤ 3.2) was achieved by 74.8% of patients still on secukinumab (Figure 1). There was also a significant improvement in the assessment of physical function and quality of life (HAQ, SF 36, EuroQol). The prevalence of heel enthesitis decreased from 12.2% to 1.5%, prevalence of dactylitis from 22% to 4.7%, and prevalence of moderate to severe nail involvement from 33.2% to 3.8% during the first 2 years of treatment. 43.8% (95% CI: 32.2; 55.4) were able to resume work and 13.9% (95% CI: 8.7; 19.0) of PsA patients lost their jobs during the first two years of treatment. The overall safety of the treatment was good with no unexpected serious side effects.

Figure 1. Achieving remission and a state of low disease activity with secukinumab in the treatment of PsA in the Czech national registry ATTRIA

Conclusion: This analysis of patients in a national registry demonstrated a robust and long-term effect of secukinumab in the treatment of individual PsA domains: arthritis, dactylitis, enthesitis, nail involvement, psoriasis, quality of life and in increasing work capacity in patients with PsA.

DURABLE CLINICALLY-MEANINGFUL IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE, FATIGUE, PAIN, AND WORK PRODUCTIVITY AMONG PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS TREATED WITH RISANKIZUMAB AT WEEK 100

**Keywords:** Psoriatic arthritis, Patient reported outcomes

L. E. Kristensen1, A. M. Soliman2, B. Padilla3, K. Papp3, A. Ostor4, Copenhagen University Hospital, The Parker Institute, Copenhagen, Denmark; AbbVie Inc, n/a, North Chicago, United States of America; Proalty Medical Research, Alliance Clinical Research, Waterloo, Canada; Cabrin Hospital, Monash University and Eumretis Research, Canberra, Australia

**Background:** Risankizumab (RZB) demonstrated efficacy and safety in the treatment of psoriatic arthritis (PsA) in a phase 3 trials KEEPsAKE-1 (NCT03673508), patients with an inadequate response to disease-modifying antirheumatic drugs (DMARD-IR), and KEEPsAKE-2 (NCT03671148), DMARD-IR and inadequate responders to biologics.

**Objectives:** This analysis aims to assess the durability of the RZB treatment response on health-related quality of life (HRQoL) and patient-reported outcomes (PROs) in patients with PsA at Week 100.

**Methods:** In the KEEPsAKE 1 and 2 trials, patients were randomised 1:1 to receive RZB 150 mg or PBO in the 24-week double-blind period. During the open-label maintenance period, all patients received RZB 150 mg. This analysis evaluated observed cases of RZB-treated patients who achieved minimal clinically important differences (MCIDs) in PROs at Week 24. Results are presented as the percentage of patients, of those who achieved MCIDs at Week 24, who maintained MCIDs in PROs from Week 52 to Week 100. MCIDs included a ≥10-point decrease in Patient’s Global Assessment (PGA), ≥10-point decrease in Pain, ≥35-point decrease in Health Assessment Questionnaire – Disability Index (HAQ-DI), ≥4-point decrease in Functional Assessment of Chronic Illness FACIT – Fatigue, ≥2.5-point increase in 36-Item Short Form Survey (SF-36) physical component summary (PCS), ≥1-point decrease in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), ≥1-point decrease in morning stiffness, and ≥20% reduction in Work Productivity and Activity Impairment (WPAI); Presenteeism; ≥15% in Work Productivity Loss, and ≥20% in Activity Impairment.

**Results:** In KEEPsAKE 1, 54–68% and 31–52% of RZB-treated patients and PBO to PsA patients achieved MCIDs across PROs at Week 24, respectively. In KEEPsAKE 2, 44–67% and 33–47% of RZB-treated patients and PBO to PsA patients achieved MCIDs across PROs at Week 24, respectively. Among the patients who achieved MCIDs at Week 24 in KEEPsAKE 1, a high percentage of RZB and RZB to PsA patients achieved MCIDs from Week 52 to 100 in PGA (RZB: 85.3–88.9%; PBO: 88.7–91.4%), Pain (RZB: 84.7–88.4%; PBO: 87.0–90.9%), and HAQ-DI (RZB: 80.7–90.8%; PBO: 82.6–84.3%) (Figure 1). In KEEPsAKE 2, similarly high percentages of RZB and PBO to RZB-treated patients maintained MCIDs in PGA (RZB: 77.0–80.5%; PBO: 78.4–84.0%), Pain (RZB: 77.2–85.6%; PBO: RZB: 84.3–94.2%), and HAQ-DI (RZB: 74.0–83.8%; PBO: RZB: 89.6–95.8%). At Week 100, 77.6–88.9% and 73.5–95.5% of RZB and PBO to RZB-treated patients, respectively, in KEEPsAKE 1 maintained MCIDs in FACIT-Fatigue, SF-36 PCS, BASDAI, morning stiffness, and WPAI; similar results were demonstrated in KEEPsAKE 2 (RZB: 73.1–96.4%; PBO: RZB: 76.2–100.0%) (Table 1).

**Conclusion:** In KEEPsAKE 1 and 2 trials, the majority of RZB-treated patients with PsA who achieved MCIDs in PROs at Week 24 maintained responses through Week 100. Achieving MCIDs at Week 24 is associated with sustained and clinically meaningful changes in HRQoL.

Background: Major adverse cardiovascular events (MACE) are some of the numerous comorbidities associated with psoriasis (PsO) and psoriasis arthritis (PsA). Previous studies addressed the contribution of sufficient anti-inflammatory therapy for PsO and PsA in decreasing MACE incidence. Objectives: Assessing the risk of developing MACE in patients with pre-existing PsO treated with different treatment regimens; topical treatment, conventional disease-modifying anti-rheumatic drugs (cDMARDs), and biologic disease-modifying anti-rheumatic drugs (bDMARDs) which had not previously studies sufficiently on real-world data.

Methods: We conducted a retrospective exploratory study with real-world data using the databases of the third largest Israeli health maintenance organization, ‘Muehedeet’ which covers approximately 1,300,000 subjects. All patients of ‘Muehedeet’ diagnosed with PsO from January 2000 until January 2020 were included in the analysis. Overall, 61,003 patients with PsO were detected. In addition, each PsO patient was paired with four control subjects by gender, age, and ethnicity (general, Arabic, or Orthodox). We defined PsO and PsA according to physicians’ diagnoses. MACE included patients with either cerebral vascular accident (CVA), ischemic heart disease (IHD), or peripheral artery disease (PVD). The date of the MACE incident was defined by the first occurrence of one of the diagnoses. We classified the patients diagnosed with PsA into a separate group; thus, patients were categorized according to their diagnosis (control, PsO or PsA). Furthermore, we analyzed the patients by the most advanced treatment prescribed to the patient; sub-grouped 1- topical therapy, sub-grouped 2 - cDMARDs (methotrexate or sulfasalazine), sub-grouped 3 - bDMARDs (anti-TNF, anti-IL17, or anti-IL12/23 agents) (Table 1). The Incident cases of MACE were analyzed according to the different lines of therapy mentioned above. In addition, Time-dependent Cox proportional hazard models were used to evaluate the adjusted risk of developing MACE by treatment group.

Results: 287,392 patients were included after exclusion by the defined criteria, contributing a total of 2,997,001 patient-years. Adjusted Cox proportional hazards regression analysis showed that the risk of developing MACE in PsO patients treated with topical treatment and those treated with cDMARDs was significantly higher in comparison to controls (Topical, HR: 1.1, CI: 1.02 - 1.1, p-value: <0.001; cDMARDs, HR: 1.2, CI: 1.0 - 1.5, p-value: 0.05). Yet, the risk of developing MACE in PsO patients treated with bDMARDs was not significantly different compared to controls (HR: 1.1, CI: 0.82 - 1.5, p-value: 0.55). On the contrary, the risk of developing MACE in all treatment groups of PsA patients was found to be significantly higher in comparison to controls (Topical, HR: 1.6, CI: 1.45 - 1.7, p-value: <0.001; cDMARDs, HR: 1.4, CI: 1.2 - 1.6, p-value: <0.001, bDMARDs, HR: 1.8, CI: 1.35 - 1.89, p-value: <0.001) (Figure 1). This analysis was adjusted to gender, body mass index (BMI), age of PsO diagnosis, lifetime diagnosis of diabetes mellitus type 2 (DM2), dyslipidemia, hypertension (HTN), and chronic heart failure (CHF); notably, male gender, higher BMI, older age, DM2, dyslipidemia, HTN, and CHF were all associated with a greater risk of developing MACE.

Conclusion: Despite that the psoriasis and arthritis severity is higher in patients treated with bDMARDs than cDMARDs, the difference was not significant. Furthermore, patients treated with bDMARDs had a protective effect on the risk of developing PsA.

Background: The prevalence of nail disease in patients with psoriatic arthritits (PsA) ranges between 41% and 93% [1]. Psoriatic nail disease is intimately linked to adjacent distal interphalangeal joint (DIP) disease, and it is important to ascertain whether DIP-nail complex behaves differently under different biological therapies.

Objectives: The aim of this analysis was to comparatively assess the effect of ixekizumab (IXE) and adalimumab (ADA) at the individual digit level in improving nail and joint disease, in patients with PsA and concomitant nail involvement.

Methods: This post hoc analysis included patients from SPIRIT-H2H (NCT01515511) treated with either IXE or ADA who had baseline nail disease (NAPSI total score >0) and DIP involvement in at least one simultaneous digit, with either tenderness, swelling or both, at the individual digit level for each hand. Proportions of patients having a NAPSI total score >0 and proportions of patients having DIP involvement (tenderness or swelling) were evaluated at baseline and Week 24; post-baseline assessments were compared between treatment arms using Fisher’s exact test.

Results: Of the intent-to-treat population of SPIRIT-H2H (N=566), 354 patients had a NAPSI total score >0 and DIP involvement (swelling or tenderness) in at least 1 digit simultaneously at baseline (IXE, N=186 and ADA, N=168). Of these patients, significantly fewer IXE- vs. ADA-treated patients had a NAPSI total score of >0 at Week 24 (p<0.05 for 8/10 digits; Table 1) and numerically fewer IXE- vs. ADA-treated patients had DIP involvement at Week 24 across all 10 digits (p<0.05 for 4/10 digits; Table 1). Numerically fewer IXE- vs. ADA-treated patients had joint tenderness at Week 24. A similar pattern of improvement was seen out to Week 52 (Table 1).

Conclusion: In this analysis, in patients from SPIRIT-H2H with psoriatic arthritis who had nail involvement and DIP involvement at baseline, patients treated with IXE had less nail involvement, less DIP involvement and less tenderness compared to those treated with ADA at Week 24.

REFERENCE:

Figure 1.
Background: The prevalence of cardiometabolic diseases including obesity and diabetes are higher in patients with psoriatic arthritis (PsA) than those without PsA. Apremilast (APR) is associated with weight loss and a reduction in HbA1c. Objectives: To evaluate the effects of APR on cardiometabolic parameters over 52 weeks in patients with active PsA from 5 pooled phase 3 trials.

Methods: Data from 5 randomized, placebo-controlled, phase 3 studies (PAL-ACE 1–4 and ACTIVE) in patients with active PsA receiving APR 30 mg BID were pooled. Included in this analysis were patients who were treated with APR for 52 weeks. Changes from baseline to Week 52 in low and high density lipoprotein (LDL, HDL), body mass index (BMI), and HbA1c were assessed and stratified by baseline level of these parameters and Week 52 disease activity (Clinical Disease Activity Index for Psoriatic Arthritis [cDAPSA]) remission/low disease activity (REM/LDA) vs moderate/high disease activity (ModDA/HDA).

Results: Data from 781 patients with PsA who received APR were pooled (mean age: 50 years, 55% female). Mean LDL was 119.6 mg/dL in the overall population at baseline and decreased by 2.0 mg/dL on average at Week 52 (Figure 1). The greatest decreases were seen in patients with the highest LDL levels at baseline (Figure 1). Similar favorable changes in HDL were observed. A total of 34/65 (52.3%) moved from the high LDL category (≥160 mg/dL) at baseline to borderline (>129 – <160 mg/dL) or normal (≤129 mg/dL) at Week 52 and 25/24 (10.3%) moved from the high HDL category (>40 – ≥60 mg/dL) to normal (<40 mg/dL) at Week 52. Greater changes in HbA1c were seen in patients who were prediabetic or diabetic at baseline. Furthermore, 60/119 (50.4%) patients who had prediabetes changed to normal HbA1c levels and 10/25 (40.0%) moved from diabetes to pre-diabetes.

Conclusion: APR treatment was associated with improvement in cardiometabolic parameters observed across psoriatic disease activity groups. The most favorable changes were seen in patients with high LDL, low HDL, obesity, or diabetes at baseline. These findings suggest that those with a high burden of comorbid cardiometabolic diseases and active PsA treatment may gain benefit beyond joint disease with APR. However, these findings require larger, prospective studies.

McInnes Grant/research support from: AbbVie, Amgen, Bristol Myers Squibb, Celgene, Eli Lilly, Galapagos, Gilead, Janssen, Novartis, Pfizer, and UCB – grant/research support or consulting fees, Grant/research support and consultant, Dafna D Gladman Consultant of: AbbVie, Artifical Intelligence, Real-world evidence, Psoriatic arthritis

Methods: The most influencing predictor was patient global assessment (PGA) at BL, followed by PhGA, number of pretreatments with biologics, tender joint count and age (Figure 1 A). AUROC of the best prediction model was 0.68 in validation cohort. Sensitivity and specificity were 0.62 and 0.64, respectively. Applied XAI approach showed that lower BL values of all main predictors have higher probability of reaching LDA at w16. The highest probability was evident in biologic-naive patients (Figure 1 A). The approach also provided visual explanations of patient-individual predictions: Variables with values shown in green color increased probability of reaching LDA at w16, whereas red ones showed the opposite effect (Figure 1 B). Conclusion: A promising prediction model accuracy of LDA in PsA patients treated with SEC could be reached and validated. Identified main predictors at BL, such as PGA and number of pretreatments with biologics, and their direction of influence on the prediction mostly match the existing clinical knowledge [4]. The analysis showed that XAI can provide useful clinical insights in patient-individual predictions, potentially guiding PsA treatment decisions in future.

POS1528 PREDICTION OF LOW DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH SECUKINUMAB IN REAL WORLD – DATA FROM THE GERMAN AQUILA STUDY

Keywords: Artificial Intelligence, Real-world evidence, Psoriatic arthritis

A. Vodencarevic1, J. Brandt-Juergens2, D. Peterlik3, B. Gmeiner1, U. Kiltz4,5, 
1Novartis, Novartis Pharma GmbH, Nürnberg, Germany; 2Rheumatology, Schwerpunktpraxis, Berlin, Germany; 3Rheumazentrum Ruhrgebiet, Herne und Ruhr-Universität Bochum, Herne, Germany

Background: Secukinumab (SEC) proved to be an effective treatment for PsA patients under SEC treatment in routine clinical care. Objectives: Using real-world data from the German non-interventional study AQUILA [2], the main objectives were (1) to predict LDA in individual PsA patients with psoriatic arthritis (PsA) in previous randomized clinical trials [1]. There is only limited knowledge on prediction of low disease activity (LDA) and treatment strategy in PsA patients under SEC treatment in routine clinical care. Using real-world data from the German non-interventional study AQUILA [2], the main objectives were (1) to predict LDA in individual PsA patients with PsA treated with SEC through machine learning methods and (2) to identify the most important predictors and their influence on the prediction using explainable artificial intelligence (XAI).

Methods: Data of 1041 PsA patients from the AQUILA study were used. Thirty-three demographic, clinical and treatment parameters at baseline (BL) served as input data to develop prediction models. LDA was defined as physician global assessment (PhGA) ≤ 2 at week (w) 16 (+/- 6 w). Samples were divided into training (70%) and validation (30%) cohorts. Ten different prediction models were applied and compared. Model performance was measured using area under the receiver operating characteristic curve (AUROC) which represents the probability that a randomly selected patient with LDA will have higher prediction than a patient with moderate/high disease activity. Additionally, sensitivity that a randomly selected patient with LDA will have higher prediction than a patient with moderate/high disease activity. Furthermore, sensitivity that a randomly selected patient with LDA will have higher prediction than a patient with moderate/high disease activity. The analysis showed that XAI can provide useful clinical insights in patient-individual predictions, potentially guiding PsA treatment decisions in future.

POS1529 DOMAINS IMPACTING MINIMAL DISEASE ACTIVITY NON-ACHIEVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS AND INADEQUATE RESPONSE TO TNF-RECEPTOR GUSELKUMAB (COSMOS)

Keywords: Clinical trials, Psoriatic arthritis, Outcome measures

1Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; 2Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy; 3Humanitas University, Pieve Emmanuele, Rheumatology and Clinical Immunology Unit, Milan, Italy; 4University of Erlangen, Department of Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; 5Lariboisière Hospital, AP-HP, Rheumatology Department, Paris, France; 6Rheumatology Department, Hospital Clinic, Barcelona, Spain; 7Janssen, Scientific Affairs, LLC, Brussels, Belgium; 8McGill University, Department of Pediatrics, Montreal, Canada; 9USS Medical Research, Inc, Scientific Affairs, Montreal, Canada; 10Janssen, Scientific Affairs, LLC, Zug, Switzerland; 11Johnson & Johnson, Middle East FZ LLC, Dubai, United Arab Emirates; 12Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom
Background: Sustained minimal disease activity (MDA) is achieved by a minority of patients (pts) receiving biologics for psoriatic arthritis (PsA) [1]. Pt-reported MDA domains are less frequently achieved than physician-reported domains [2,3]. Here, we assessed MDA achievement in pts with PsA and inadequate response to 1–2 tumour necrosis factor inhibitors (TNF-IR).

Objectives: Identity PsA disease domains and factors contributing to the lack of MDA achievement at Week (W)48 for TNFI-IR PsA pts treated with guselkumab (GUS) using data from the Phase 3b COSMOS trial.

Methods: In COSMOS, adults with active PsA (swollen/tender joint counts [SJC/TJC] each ≥3) and TNFI-IR were randomized 2:1 to subcutaneous GUS 100 mg or placebo (PBO) at W0, W4, then every 8 weeks. PBO pts crossed over to GUS at W16 (early escape) or W24 (planned). MDA was defined as fulfilment of ≥5/7 domains: tender entheses (Leeds Enthesitis Index [LEI]; 0–6) ≤1; Health Assessment Questionnaire – Disability Index (HAQ-DI; 0–3) ≤0.5; pt pain (0–100) ≤15; Psoriasis Area and Severity Index (PASI; 0–72) ≤1; Pt Global Assessment (PtGA; 0–100) ≤20; SJC (0–68) ≤1; and, TJC (0–68) ≤1. Fibromyalgia (pFM) was defined at baseline (BL) using TJC minus SJC ≥7 as a proxy [3]. A longitudinal trajectory of achieving each MDA domain through W48 was derived (non-responder imputation). Time to achieving each domain was assessed with Kaplan–Meier analyses; to account for differences in scales and domain strictness, scores were also normalized to SJC (0–66) scale. Response predictors (for pts not meeting each MDA domain criteria at BL) were identified using multivariate regression for time to achievement (Cox proportional hazards) and W48 achievement (logistic) of MDA.

Results: GUS pts (n=189) showed improvement from BL in all MDA domains, with overall W24/48 response rates (%) of: LEI (74.5/79.9); HAQ-DI (26.1/37.0); pt pain (14.7/37.0); PASI (66.8/61.5); PtGA (24.5/39.9); SJC (46.2/63.0) and TJC (57.2/63) respectively. Time to achievement of minimal scores for LEI, SJC, and PASI were faster than for PtGA, HAQ-DI, pt pain and TJC for native-scale scores; when normalized, PtGA, HAQ-DI and pt pain showed a slower response (Figure 1). Higher BL HAQ-DI and worse fatigue (lower functional assessment [FACIT]-fatigue score) were significantly associated with longer time to HAQ-DI ≤0.5; these factors plus older age predicted W48 non-achievement of HAQ-DI ≤0.5 (Table 1). Worse BL pt pain and fatigue were significant predictors of longer time to pt pain ≤15; these factors plus pFM predicted W48 non-achievement of pt pain ≤15. Worse BL fatigue was also significantly associated with longer time to PtGA ≤20 and W48 non-achievement of PtGA ≤20. Higher TJC, methotrexate (MTX) use and no pFM at BL were significantly associated with longer time to TJC ≤1; higher BL TJC, MTX and older age predicted W48 non-achievement of TJC ≤1.

Conclusion: GUS provided sustainable improvement in all MDA domains through W48. Physician-reported domains (LEI, PASI and SJC) were achieved faster than pt-driven domains (PtGA, HAQ-DI, pt pain and TJC). BL domain scores, worse fatigue and MTX use (for TJC only) were inversely correlated with MDA in the refractory domains.

Background: While data on real-life retention of SEC in patients (pts) with PsA is accumulating, there are few data on predictive factors of this retention.

Objectives: To assess if objective signs of inflammation (OSI) were predictive of SEC retention at 1 year.

Methods: French retrospective study collecting between Oct 2019 and May 2022 data from PsA pts a) having initiated and received at least one dose of SEC between Aug 2016 and Aug 2018 (cohort 1) and Sep 2018 and Nov 2020 (cohort 2) b) with at least a 1 year follow-up period. Retention rate of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following within the 3 months before initiation of SEC: CRP > 5, confirmed

Figure 1. Time to achieve MDA for each domain with GUS treatment

Scientific Abstracts
clinical dactyliitis, confirmed clinical synovitis or ultrasonography power-Doppler positive synovitis. The following a priori baseline prespecified factors of SEC retention at 1 year (cohort $\geq$ 1 OSI, age, sex, BMI, smoking, axial feature, history of arthritis or synovitis/pсорiatis/over/IBD, diagnostic delay, disease duration, SEC line (L) of biologic/targeted synthetic (b/ts)DMARD, SEC dose, csDMARD, corticosteroids at initiation, history of fibromyalgia/ depression) were analyzed by cox model regression. Only variables with $\leq$20% missing data were included in the model after multiple imputation and stepwise selection (significance level for entering variables $\leq$ 20%; for removing variables $\leq$ 15%). OSI and cohort variables were forced into the model whatever their significance level or rate of missing data.

**Results:** 842 pts (male: 38.6%, mean age: 52.5 $\pm$ 12.3 years, mean disease duration: 8.7 $\pm$ 8.5 years) from 50 centers were included in the analysis. At initiation of SEC, 63.0% of pts had $\geq$ 1 OSI and respectively 15.6%, 24.2% and 60.0% were in 1st, 2nd and $\geq$ 3rd (L) of b/ts DMARD. The 1 year retention rate for SEC was 64% [95%CI: 61%–68%] and was numerically greater in 1st L vs 2nd and $\geq$ 3rd L (77% [95%-84%], 65% [59-72%], 61% [57%-66%] respectively). The 1 year retention rates of SEC were 65% [61%-69%] and 69% [62%-75%] respectively for OSI+ and OSI- at SEC initiation. In multivariate analysis after adjustment, OSI was not identified as predictive factor of SEC discontinuation at 1 year (HR=1.19 (9.03;15.2), p=0.169). The others predictive factors identified are listed in Table 1.

Interpretation for predictor: HR> 1: the hazard of discontinuation at 1 year is X times higher in category vs reference.$ without imputation for missing data# adjusted on cohort and OSI

**Conclusion:** In this large cohort of PaSa patients, the overall retention rate of SEC was 64% at 1 year in daily practice. Previous exposure to b/tsDMARD, concomitant corticosteroids at initiation of SEC and history of fibromyalgia were associated with an increased risk of SEC discontinuation at 1 year while concomitant csDMARD at initiation of SEC and age $\leq$ 40 year with a decreased risk.

**Background:** Monoclonal antibodies targeting the interleukin (IL)-23p19 subunit are effective in the treatment of psoriatic disease but have different molecular attributes that may translate to differences in clinical efficacy. Within this class, guselkumab (GUS) is a fully human IgG1 monoclonal antibody with a native Fc region, while risankizumab (RIS) is a humanised IgG1 antibody with a mutated Fc region. Binding of these therapeutic antibodies to Fcγ receptor (FcγR) I, also known as CD64, is of interest, as CD64+ IL-23-producing myeloid cells are increased in infected tissue of patients with psoriatic disease [1]. Furthermore, the incidence and prevalence of psoriatic arthritis increases with the severity of psoriasis [2], and joint disease activity is positively correlated with frequency of peripheral CD64+ monocytes [3].

**Objectives:** Functional characteristics of the antigen-binding and Fc regions of GUS and RIS were compared.

**Methods:** IL-23 binding affinity was evaluated in vitro using a kinetic exclusion assay (KinExA) and surface plasmon resonance. In vitro cellular potency was measured by impact on IL-23-induced signal transducer and activator of transcription 3 (STAT3) phosphorylation in human peripheral blood mononuclear cells. Binding of GUS and RIS to FcγRs was assessed in cells transfected with individual FcγRs. Primary human “inflammatory” monocytes differentiated with granulocyte-macrophage colony-stimulating factor and interferon-γ (IFN-γ) were induced to produce IL-23 via toll-like receptor stimulation and used to assess binding of GUS and RIS to CD64 and potential capture of endogenously secreted IL-23 by flow cytometry. The potential for GUS binding to CD64 on IFN-γ primed monocytes to trigger activation was assessed using a 41-plex cytokine bead assay.

**Results:** GUS and RIS displayed comparable picomolar binding affinity for IL-23 and equivalent high potency for inhibiting IL-23-induced STAT3 phosphorylation. GUS showed strongest binding to CD64 compared with other FcγRs, whereas RIS had negligible binding to any FcγR. GUS, but not RIS, showed dose-dependent Fc-mediated binding to CD64 on primary human “inflammatory” monocytes. Moreover, CD64-bound GUS was able to simultaneously capture IL-23 endogenously secreted from the same cells (Figure 1). GUS binding to CD64 on monocytes did not induce cytokine production.

**Conclusion:** GUS, but not RIS, simultaneously binds CD64+ myeloid cells via its Fc region and neutralises IL-23 with high affinity and potency. Our in vitro data suggest a mechanistic benefit through enrichment of GUS within infected tissue of patients with psoriatic disease, where CD64+ IL-23-producing myeloid cells are increased, such that GUS potentially neutralises IL-23 at its site of production. These findings may contribute to differences in clinical-therapeutic profiles between antibodies.
WHAT IS THE REAL IMPACT OF DEPRESSION ON CLINICAL RESPONSE TO THERAPY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS?

Background: The Psoriatic Arthritis (PsA) Impact of Disease-12 (PsAID-12) questionnaire assesses PsA impact from the patient (pt) perspective [1]. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17A and IL-17F, has shown superior efficacy vs placebo (PBO) and tolerability to 16 weeks (wks) in pts with PsA [2,3].

Objectives: To assess the efficacy of BKZ from the pt perspective, over 16 wks of treatment, using data from two phase 3 trials.

Methods: Analysis of pts with PsA randomised to subcutaneous BKZ 160mg every 4 wks vs PBO in BE OPTIMAL (NCT03895203; N=712, biologic DMARD-naïve pts) and BE COMPLETE (NCT03896581; N=400, tumour necrosis factor alpha inhibitor-inadequate responders). PsAID-12 total and single-item domain scores range from 0 to 10; higher scores indicate worse status. Change from baseline (CB) data and clinically meaningful within pt improvement response (threshold: decrease of ≥3 from baseline [BL] when respective PsAID-12 score ≥3 at BL) for total and single-domain scores were calculated. Missing data imputed using multiple imputation (continuous) and non-responder imputation (binary).

Results: Of 1,112 pts randomised to BKZ or PBO, 96.5% completed Wk 16. BL characteristics were generally similar between treatment groups within trials; mean age: 49.3 years, BMI: 29.5 kg/m², years since diagnosis: 7.2; 46.6% male. Similar differences between BKZ and PBO results were found for single-item domain responders, for example BKZ 16 PsAID-12 pain score response rate: 46.5% BKZ, 18.7% PBO; skin problem score response rate: 68.5% BKZ, 21.4% PBO (Table 1). Clinically meaningful response rate for Wk 16 PsAID-12 total score: 41.9% BKZ, 8.4% PBO with results similar in both pt populations (Figure 1).

Conclusion: By Wk 16, over half of BKZ-treated pts reported clinically meaningful improvements in most PsAID-12 single-item domain scores assessing PsA-specific symptoms and impact. Results may support shared treatment decisions.

Ritchlin, University of Bath, Royal National Hospital of Rheumatic Diseases, and Department of Life Sciences, Centre for Therapeutic Innovation, Bath, United Kingdom; 2Harvard Medical School, Brigham and Women's Hospital, N/A, Boston, Massachusetts, United States of America; 3University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Fukuoka, Japan;
Background: Given the chronic, long-term nature of psoriatic arthritis (PsA), sustaining high levels of disease control with treatment is important. Assessing the maintenance of response in patients (pts) that achieve treatment targets is of interest, particularly as pts can experience loss of response with long-term therapy [1]. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated rapid, statistically significant and clinically meaningful joint and skin efficacy responses at Week (Wk) 16 versus placebo (PBO), in pts with PsA [2,3]. Responses were sustained to Wk 52 [4].

Objectives: To report the maintenance of response in joint and skin efficacy outcomes to 52 wks in BKZ-treated pts with PsA who were responders at Wk 16.

Methods: BE OPTIMAL (NCT03895203) included a 16-wk double-blind, PBO-controlled period, and a 36-wk active treatment-blind period. Biologic disease-modifying antirheumatic drug (bDMARD)- naïve pts were eligible if they had adult-onset, active PsA with ≥3 tender and ≥3 swollen joints, and ≥1 active psoriasis lesion. A history of previous PsA therapy was allowed. Pts were randomised 3:2 to subcutaneous BKZ 160 mg every 4 wks (Q4W), PBO or reference arm (adalimumab 40 mg every 2 wks). At Wk 16, PBO pts switched to subcutaneous BKZ 160 mg Q4W (PBO/BKZ). Maintenance of response is reported as the percentage of BKZ-treated pts who achieved a response at Wk 16, who maintained that response at Wk 52. Data are reported for pts randomised to subcutaneous BKZ 160 mg Q4W at baseline. Endpoints include American College of Rheumatology (ACR)20/50/70, Psoriasis Area and Severity Index (PASI)75/90/100, minimal and very low disease activity (MDA, VDA), and Disease Activity Index for Psoriatic Arthritis (DAPSA) remission or low disease activity (REM+LDA; ≤4) and remission (REM; ≤4) responses. Wk 16 responders are reported using non-responder imputation (NRI); maintenance of response to Wk 52 is reported using NRI and observed case (OC) data. The number of treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ, including pts who switched from PBO to BKZ at Wk 16.

Results: At baseline, 431 pts were randomised to BKZ 160 mg Q4W, 217/431 (50.3%) had psoriasis affecting ≥3 body surface area (BSA); 414/431 (96.1%) pts completed Wk 16 and 383 (88.9%) completed Wk 52. The majority of pts who achieved responses at Wk 16 maintained their response at Wk 52, across a range of joint and skin outcomes (Figure 1). At Wk 16, 268 (62.2%), 189 (43.9%) and 105 (24.4%) pts achieved ACR20/50/70, respectively. Of those responders, ACR20/50/70 responses were maintained at Wk 52 by over 80% of pts: 88.4%, 86.6%, 82.9% (NRI); 92.9%, 91.1% and 87.9% (OC). Of 217 pts with psoriasis affecting ≥3% BSA at baseline, 133 (61.3%) and 103 (47.5%) achieved PASI90/100 at Wk 16. The majority of pts maintained the response at Wk 52: 82.7%, 79.6% (NRI); 90.0%, 89.1% (OC). The same pattern was observed for the novel parameters of efficacy. 194 (45.0%) pts achieved MDA at Wk 16; of those, 85.6% (NRI) and 90.7% (OC) maintained their response at Wk 52. A high proportion of Wk 16 responders also maintained their response at Wk 52 for VDA, DAPSA REM+LDA and DAPSA REM (Figure 1). To Wk 52, 555/702 (79.1%) pts reported ≥1 TEAE whilst receiving BKZ; 46 (6.6%) reported serious TEAEs. Conclusions: With BKZ treatment, a high proportion of Wk 16 responders maintained robust efficacy responses to Wk 62, including across joint, skin and composite outcomes. The safety profile of BKZ was consistent with previous reports [2,3].

Background: Guselkumab (GUS), a fully human IL-23p19 subunit inhibitor, was associated with improved radiographic progression through W100. For 4VAS, significantly less radiographic progression through W100 was observed in GUS-treated pts vs PBO, including pts with active PsA [3]. The recently developed 3 Visual Analogue Scale (VAS) and 4 VAS scores are the first short multidimensional composite measures specifically for use in PsA routine clinical care [4].

Objectives: Determine whether early improvement in 3VAS/4VAS predicts radiographic change through W100.

Methods: DISCOVER-2 included biologic-naive pts with active PsA (≥5 swollen and ≥5 tender joint counts [SJC/TJC]; CRP ≥0.6 mg/dL) randomized (1:1:1) to GUS 100 mg Q4W at W24. In the current analysis, only pts randomized to GUS were included (N=493), pooling Q4W and Q8W. Response at W8 was defined as achievement of low disease activity (LDA) in 3VAS (≤3.4), 4VAS (≤3.5), RAPID3 (≤6), DAPSA (≤14), and PASDAS (≤3.2). Association of W8 response with outcomes from baseline (BL) to W100 in total PsA-modified van der Heijde-Sharp (vdH-S) score was assessed with the independent samples t-test and generalized linear models adjusting for known BL determinants of radiographic progression (vdH-S score, age, gender, and CRP). Pairwise correlations and agreement in LDA classification between the endpoints assessed were assessed with Pearson’s correlation coefficient and the kappa statistic, respectively.

Results: Among GUS-treated pts not meeting the respective endpoints at BL (32.9%, 31.6%, 12.4%, 17.8%, and 10.8% achieved LDA in 3VAS, 4VAS, RAPID3, DAPSA, and PASDAS, respectively, at W8. LDA achievement in 3VAS (0.86 vs. 2.15, p=0.03), RAPID3 LDA (0.74 vs. 1.80, p=0.049), DAPSA LDA (<0.05 vs. 2.08, p=0.001), and PASDAS LDA (0.58 vs. 1.87, p=0.006) at W8 were associated with significantly less radiographic progression through W100 (Figure 1). For 4VAS, achievement of remission (≤1.71 vs. 1.84, p=0.043), but not LDA (1.12 vs. 2.01, p=0.142), was also associated with improved radiographic outcome. In multivariate analyses, improved response to GUS treatment at W8 in all endpoints assessed was associated with numerically less radiographic progression through W100. 3VAS and 4VAS at W8 showed strong correlations with RAPID3 (r3VAS=0.787; r4VAS=0.877) and PASDAS (r3VAS=0.793; r4VAS=0.790) and moderate correlations with DAPSA (r3VAS=0.466; r4VAS=0.524), whereas fair to moderate agreement (kappa range: 0.325-0.545) in LDA classification was noted.

Conclusion: Approximately one-third of GUS-treated patients achieved early response (W8 LDA) in 3VAS/4VAS, which was associated with reduced rates of radiographic change, as was early response in the other outcomes assessed. These results suggest that, in addition to their usefulness in assessing disease activity in routine clinical care, 3VAS and 4VAS, the former being more sensitive, may predict long-term radiographic changes.

downstream anti-inflammatory effects of TYK2 inhibition, including IL-6 and tumor necrosis factor alpha [3,4].

Objectives: To characterize the effect of DEUC on pain across different instruments, and alignment across pain instruments, in patients in the phase 2 PsA trial.

Methods: Patients with PsA (N=203) were randomized 1:1:1 to PBO, DEUC 6 mg once daily (QD), or DEUC 12 mg QD. Three instruments were used to assess pain up to week 16: (1) Patient Global Assessment of Pain visual analog scale (Pain VAS), scored from 0-100; (2) Psoriatic Arthritis Impact of Disease (PsAID) Pain instrument, scored from 0-10; and (3) 36-item Short-Form Health Survey (SF-36) Bodily Pain question, which asks patients to rate their pain on a scale of 1-6 ranging from “none” to “very severe.” Mean change from baseline (BL) in pain scale scores, the proportion of patients who reported meaningful improvements in pain, and Pearson’s correlation between pain scales (Pain VAS and PsAID Pain) and disease efficacy measures were evaluated.

Results: BL mean Pain VAS score was 64.1 and BL mean PsAID Pain score was 6.4, and scores were generally similar across treatment groups. Percentages of patients who reported improvements in Pain VAS (Figure 1) and PsAID Pain were consistently greater with DEUC treatment compared with PBO, with improvements in pain being similar between males and females across instruments. The pain assessments correlated with one another both at baseline (Table 1) and over time through week 16, with some divergent responses to pain questions also being observed. At baseline, both assessments of pain strongly correlated with Psoriatic Arthritis Disease Activity Score (PASDAS) and with Patient Global Assessment of Disease Activity (PGa) (Table 1).

Conclusion: A higher proportion of patients with PsA treated with DEUC reported clinically meaningful improvements in pain compared with PBO. Patient-reported pain was overall well-correlated across instruments; however, some divergence was also observed.

BIMEKIZUMAB EFFICACY AND SAFETY IN BIOLOGIC DMARD-NAÏVE PATIENTS WITH PSORIATIC ARTHRITIS WAS CONSISTENT WITH OR WITHOUT METHOTREXATE: 52-WEEK RESULTS FROM THE PHASE 3 ACTIVE-REFERENCE STUDY BE OPTIMAL

Keywords: Clinical trials, Psoriatic arthritis

Background: Given the chronic nature of psoriatic arthritis (PsA), understanding long-term efficacy and safety of biologic monotherapy or therapy in combination with ongoing methotrexate (MTX) is of interest. Studies have shown reduced efficacy of tumor necrosis factor inhibitors without MTX than with MTX [1]. Bimekizumab (BKZ), a monolgal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has shown efficacy and tolerability to 52 weeks (wks) in patients (pts) with PsA [2].

Objectives: To report BKZ efficacy and safety to Wk 52 from the phase 3 study BE OPTIMAL in bDMARD-naïve pts with PsA, with or without ongoing concomitant MTX.

Methods: BE OPTIMAL (NCT03895203) comprised a 16-wk double-blind placebo (PBO)-controlled period and a 36-wk active treatment-blind period. Pts were randomized 3:2:1 subcutaneous BKZ 160 mg every 4 wks (Q4W); subcutaneous ADA 160 mg Q4W. Pts could not adjust their background medication during the 16-wk PBO-controlled period. Efficacy and safety were evaluated by concomitant MTX use at baseline (BL). Missing data were imputed using non-responder (discrete) or multiple (continuous) imputation.

Results: 781/852 (90.3%) pts completed Wk 52 (+ MTX: 454/497 [91.3%] – MTX: 307/355 [86.5%]). BL characteristics were generally similar +/- MTX: mean age 48.1 ± 19.4 years, BMI 29.1 ± 29.4 kg/m², 5.7 ± 6.2 years since diagnosis, 47.3% vs 46.2% male, 49.5% vs 50.4% with psoriasis affecting ≥3% body surface area. To Wk 52, the proportion of BKZ-randomised pts who achieved ACR50, PASI50, and Psoriatic Arthritis Response Criteria (PASi100) were similar regardless of BL MTX use. Fewer pts receiving ADA – MTX achieved ACR50 or PASi vs at Wk 52 compared to ADA + MTX (Figure 1). Other Wk 52 efficacy
responses on BKZ were generally of a similar magnitude +/- MTX (Table 1). To Wk 52, pts with ≥1 treatment-emergent adverse event +/- MTX: PBO/BKZ 124/158 (78.5%) vs 89/113 (78.8%), BKZ 214/252 (84.9%) vs 150/179 (83.8%), ADA 63/82 (77.8%), NRS 58 (82.6%).

Conclusion: BKZ treatment demonstrated consistent sustained clinical efficacy across disease manifestations to Wk 52 in bDMARD-naïve pts with PsA, irrespective of concomitant MTX. BKZ was well tolerated in pts with PsA with or without MTX.

DOI: 10.1136/annrheumdis-2023-eular.1694
Conclusion: This comprehensive integrated analysis of GUS safety demonstrated a favorable safety profile across a broad population of pts irrespective of the BL characteristics assessed. Overall, safety event rates in GUS-tx pts were comparable to or lower than PBO during short-term follow-up. Frequent and serious infections remained low and stable through long-term follow-up.

SAFETY AND EFFICACY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS AND INADEQUATE RESPONSE TO BIOLOGICS: 3-YEAR RESULTS FROM THE PHASE 3 SELECT-PSA 2 STUDY

Keywords: Psoriatic arthritis, Targeted synthetic drugs, Safety

1. Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, WA, United States of America; 2. AbbVie Inc, Immunology, North Chicago, IL, United States of America; 3. Kapp Clinical Research and Probiotic Medical Research, Waterloo, ON, Canada; 4. VIB Center for Inflammation Research, Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium; 5. Nippon Life Hospital, Department of Orthopaedics, Osaka, Japan; 6. Pontificl Catholic University of Rio Grande do Sul, Rheumatology, Porto Alegre, Brazil; 7. University of Bath, Department of Life Sciences, Bath, United Kingdom

Background: The efficacy and safety of upadacitinib (UPA) in patients (pts) with psoriatic arthritis (PsA) and inadequate response to ≥1 biologic disease-modifying antirheumatic drug (bDMARD-IR) have been demonstrated up to 56 and 104 weeks of treatment [1,2].

Objectives: To assess the long-term safety and efficacy of UPA in bDMARD-IR pts with PsA through 152 weeks of treatment in the SELECT-PSA 2 study.

Methods: Pts were randomized to receive UPA 15 or 30 mg once daily (QD), or placebo (PBO) for 24 weeks, followed by blinded switch to UPA 15 or 30 mg QD for pts initially randomized to PBO. After 56 weeks, pts continued their assigned dose up to 152 weeks in an open-label extension (OLE). Following approval of the 15 mg QD dose, the protocol was amended and all pts on UPA 30 mg QD were switched to the approved dose (earliest switch at week 116). Endpoints assessed at 152 weeks included: % of pts achieving 20/50/70% improvement in Psoriasis Area and Severity Index (PASI75/90/100), 75/90/100% improvement in Psoriasis Area and Severity Index (PASI75/90/100), 75/90/100% improvement in Psoriasis Area and Severity Index (PASI75/90/100), and 75/90/100% improvement in Psoriasis Area and Severity Index (PASI75/90/100), respectively.

Results: Of the 641 pts randomized to receive UPA 15 or 30 mg QD, or PBO followed by UPA 15 or 30 mg QD (n=211, 218, 106, and 106, respectively), 478 entered the OLE. Improvements in efficacy outcomes with UPA observed at week 152.

EARLY SKIN AND EARLY ENTHESITIS RESPONSES IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH GUSEKULUMAB ASSOCIATE WITH LONG-TERM RESPONSE: POST HOC ANALYSIS THROUGH 2 YEARS OF A PHASE 3 STUDY

Keywords: Enthesitis, Psoriatic arthritis, Skin

L. Coates1, J. Ramirez2, D. McGonagle3, S. Aydin4, M. Zimmermann5, F. Nantel6, M. Shawi7, E. Rampakakis8, P. Nash9, P. J. Background: Gusekumab (GUS), an IL-23p19 inhibitor, has demonstrated efficacy in psoriatic arthritis (PsA) across key Group for Research and Assessment of Psoriasis (PsO) and Psoriatic Arthritis (GRAPPA)-recommended domains [1-2]. Skin disease and enthesitis have been identified as disease manifestations with a higher likelihood of response than others [3].

Objectives: In this analysis we: (a) Determined whether early skin and/or enthesal response predicts future response in other PsA domains; (b) Evaluated the trajectory for achieving skin/entheseal responses by 52 weeks (W) in patients (pts) without early responses.

Methods: Pts in the DISCOVER-1 and DISCOVER-2 (D1/2) studies were adults with active PsA despite standard therapies. D1 pts had ≤3 swollen and ≥3 tender joints (SJC/TJC) and C-reactive protein (CRP) ≥0.3 mg/dL; D2 pts had SJC ≥5, TJC ≥5, and CRP ≥0.6 mg/dL. 31% of D1 pts received 1-2 prior TNF inhibitors; D2 pts were biologic-naive. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (W4); GUS 100 mg at W0, W4, then every 8 weeks (W8); or placebo. These post hoc analyses included only pooled GUS W4 and W8 pts (N=746).

Early skin response was defined as Psoriasis Area and Severity Index (PASI) score ≤1 at W16 and skin visual analogue scale (VAS) ≤15mm at W16 among pts with a baseline (BL) PASI score >1 and skin VAS >15mm (first assessment time for both); early enthesal response was defined as Leeds Enthesitis Index (LEI) score ≤1 at W8; and categories of early response were defined as skin VAS ≤15mm only vs LEI score ≤1 only vs combined skin VAS ≤15mm & LEI score ≤1 vs none at W8. Potential responses at W24 & W52 included achievement of minimal disease activity (MDA), Disease Activity in PsA (DAPSA) low disease activity (LDA) or remission, DAPSA50, and enthesis/dactylitis resolution. Associations between early skin/entheseal response and W24/W52 response were assessed with crosstabulations and logistic regression.

Results: Early skin response associated with greater odds of achieving W24 MDA, DAPSA LDA, DAPSA remission, and DAPSA50, but not enthesis or dactylitis resolution (Figure 1). Early enthesal response associated with greater odds of achieving all W24 outcomes, including resolution of enthesis or dactylitis, with the exception of DAPSA remission; DAPSA remission was achieved by a greater proportion of early responders, though the association was significant only at W52. In pts with both BL PsO and enthesitis, early responders in both domains were even more likely to subsequently demonstrate MDA, DAPSA LDA, DAPSA50, DAPSA remission only at W52, and dactylitis resolution than pts with individual responses. Among pts who did not achieve early responses, approximately half did so by W52.

Conclusion: Early skin and enthesal responses predicted long-term clinical response, including disease remission. A synergistic effect was observed, in which pts with BL PsO and enthesitis exhibiting early response in both domains were more likely to achieve later clinical response. These results highlight the importance of early response in these two domains on the trajectory of long-term pt outcome.

LONG-TERM EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS: 3-YEAR RESULTS FROM THE PHASE 3 SELECT-PSA 1 STUDY

Keywords: Psoriatic arthritis, Safety

I. Moninnes1, K. Kato2, M. Mageye2, J. F. Merola3, M. Kishimoto4, D. Haaland5, Y. LiF, Y. Liu, J. Liu6, R. Lippe7, P. Wung8, 9University of Glasgow, College of Medical, Veterinary, and Life Sciences, Glasgow, United Kingdom; 1AbbVie, Inc, Immunology, North Chicago, United States of America; 2Case Western Reserve University School of Medicine, Rheumatology, Cleveland, United States of America; 3Harvard Medical School, Brigham and Women's Hospital and Harvard Medical School, Boston, United States of America; 4Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Mitaka, Japan; 5McMaster University, Hamilton, ON, Canada; 6The Waterside Clinic, Barrie, ON, Canada; 7AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany

Background: Upadacitinib (UPA) improved symptoms in patients (pts) with psoriatic arthritis (PsA) with prior inadequate response or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug (nbDMARD-IR) through week (wk) 104 or ≥2 years of treatment in SELECT-PsA 1 [1].

Objectives: To evaluate efficacy and safety of UPA vs adalimumab (ADA) through wk 152 or 3 years from the ongoing long-term open-label extension of SELECT-PsA 1.

Methods: Pts were randomized to receive UPA 15 mg (UPA15) or UPA 30 mg (UPA30) once daily, ADA 40 mg (ADA) every other wk, or placebo (PBO). At wk 24, PBO pts switched to UPA15 or UPA30. Following approval of UPA15, the
protocol was amended so pts on UPA30 switched to UPA15 (earliest at wk 104). Efficacy was assessed through wk 152, and safety through June 13, 2022.

**Results:** Of 1704 pts randomized, 911 completed 152 wks of treatment. The proportions of pts achieving ≥20%/50%/70% improvement in American College of Rheumatology criteria (ACR20/50/70), minimal disease activity (MDA), and ≥75%/90%/100% improvement in Psoriasis Area and Severity Index at wk 152 were generally consistent with those at wk 104. UPA had greater ACR20/50/70 and MDA responses vs ADA, and a greater mean change from baseline (BL) in Health Assessment Questionnaire-Disability Index, pt’s assessment of pain, and Bath Ankylosing Spondylitis Disease Activity Index vs ADA. Change from BL in modified total Sharp/Van der Heijde score were similar between UPA30 and ADA, and numerically higher with UPA15 (Table 1). The overall UPA safety profile remained unchanged (Figure 1). UPA had numerically higher rates of serious infection (SI), herpes zoster (HZ), anemia, lymphopenia, creatine phosphokinase (CPK) elevation, and non-melanoma skin cancer (NMSC) vs ADA. Increases for SI, HZ, anemia, and CPK elevation with UPA were dose dependent. Rates of major adverse cardiovascular events, venous thromboembolism, and malignancy excluding NMSC were low and generally similar across groups. The most common cause of death was COVID-19.

**Conclusion:** Efficacy of UPA in nbdMARD-IR pts with PsA was maintained through 3 years of treatment. No new safety signals were identified.

**Figure 1. EAERs of Treatment-Emergent Adverse Events**

**RESULTS:** Of 1704 pts randomized, 911 completed 152 wks of treatment. The proportions of pts achieving ≥20%/50%/70% improvement in American College of Rheumatology criteria (ACR20/50/70), minimal disease activity (MDA), and ≥75%/90%/100% improvement in Psoriasis Area and Severity Index at wk 152 were generally consistent with those at wk 104. UPA had greater ACR20/50/70 and MDA responses vs ADA, and a greater mean change from baseline (BL) in Health Assessment Questionnaire-Disability Index, pt’s assessment of pain, and Bath Ankylosing Spondylitis Disease Activity Index vs ADA. Change from BL in modified total Sharp/Van der Heijde score were similar between UPA30 and ADA, and numerically higher with UPA15. The overall UPA safety profile remained unchanged (Figure 1). UPA had numerically higher rates of serious infection (SI), herpes zoster (HZ), anemia, lymphopenia, creatine phosphokinase (CPK) elevation, and non-melanoma skin cancer (NMSC) vs ADA. Increases for SI, HZ, anemia, and CPK elevation with UPA were dose dependent. Rates of major adverse cardiovascular events, venous thromboembolism, and malignancy excluding NMSC were low and generally similar across groups. The most common cause of death was COVID-19.

**Conclusion:** Efficacy of UPA in nbdMARD-IR pts with PsA was maintained through 3 years of treatment. No new safety signals were identified.
Background: The Psoriatic Arthritis Impact of Disease (PsAID) is a patient-reported questionnaire assessing multiple domains in patients with psoriatic arthritis (PsA), developed under the aegis of EULAR, and recommended by OMERACT and GRAPPA. To be usable in different contexts, translations and cross-cultural validations are necessary. Arabic is the sixth most-spoken language in the world; however, many patient-reported outcomes are not available in Arabic.

Objectives: To translate, culturally adapt and validate the PsAID-12 questionnaire in Arabic, to study its psychometric properties, and to evaluate its association with the demographic and disease characteristics of PsA patients.

Methods: This multicentric multinational study was conducted by the Arab League of Associations of Rheumatology (ArLAR) research group (ARCH). Validated methodologies were applied. (A) Phase 1: Translation of PsAID-12 into Arabic, including a double translation, synthesis by a steering committee, and back-translation, and cognitive debriefing with feasibility and timing assessment with a sample of patients with PsA in four countries. (B) Validation phase: Cross-sectional study, with a longitudinal part for reliability testing, conducted in thirteen Arab countries. Patients were consecutive adult patients, diagnosed with PsA (rheumatologist opinion + CASPAR criteria), literate, and agreeing to participate. Data collected: (1) From the patient: PsAID-12 in Arabic, demographic and disease information, Health Assessment Questionnaire (HAQ), Patient Global Assessment for pain and disease activity (PGA), Fibromyalgia Rapid Assessing Tool (FIRST) and Patient Health Questionnaire (PHQ4). (2) From the rheumatologist: Disease Activity in Psoriatic Arthritis (DAPSA) score. Psychometric properties of the PsAID-12 were investigated: internal consistency (Cronbach’s α), construct validity (Spearman correlation with DAPSA, HAQ, PGA, FIRST, PHQ4), and test-retest reliability (intraclass correlation coefficients (ICCs) and Cohen kappa at one week). (C) Factors associated with high PsAID-12 total score (defined as >= 4) were explored using multivariable binary logistic regression.

Results: A total of 554 patients were recruited; mean age was 45 years (SD 13), 57% were females. The mean PsAID score was 3.86 (SD 2.33). Internal consistency was excellent (Cronbach’s α = 0.95). The correlation coefficients with other measures were moderate to strong (range, 0.63 to 0.78 (Figure 1). Test-retest reliability (N=138 patients) was excellent (ICC 0.95 (95%CI 0.86;0.93) and agreement between the first and second measurements was substantial (Cohen kappa 0.797).

In the multivariable analysis, factors associated with a higher PsAID were PGA, FIRST, and PHQ4 (after adjustment for axial involvement, education, gender, and CRP).

Conclusion: The Arabic PsAID is a consistent, reliable, and feasible measure in patients with PsA. The correlation with other PsA-related measures appears similar to the correlation noted in other cultures and languages. The PsAID appears to be a stable measure of impact across cultures. These results support the recommendation to use the PsAID for clinical practice and research purposes.

results were maintained or further improved from week 24 to 52 for both limited
and extensive SJC patients (Figure 1)
Conclusion: RZB is efficacious in reducing signs and symptoms of PsA in
patients, regardless of patterns of joint involvement. More patients in the limited
joint involvement group achieved stringent treatment targets such as MDA and
DAPSA remission at both weeks 24 and 52.

and Musculoskeletal Medicine, Leeds, United Kingdom; 4Pfizer Inc, Clinical
Affairs, City of Makati, NCR, Philippines; 5Pfizer Canada ULC, Inflammation and
Immunology, Kirkland, QC, Canada; 6Griffith University, School of Medicine,
Brisbane, Australia
Background: Patients (pts) with psoriatic arthritis (PsA) exposed to tumour
necrosis factor inhibitors (TNFi) may have attenuated response or higher adverse
event (AE) risk with subsequent treatment. Tofacitinib efficacy/safety in PsA pts
was shown in 3 Phase (P)3 trials and 1 long-term extension (LTE) trial.
Objectives: Assess long-term safety/efficacy of tofacitinib in TNFi-inadequate
responder (IR) and biologic disease-modifying antirheumatic drug (bDMARD)naïve PsA pts.
Methods: Pooled data from P3 trials (NCT01877668/NCT01882439/
NCT03486457) of PsA pts receiving ≥1 tofacitinib dose and 1 LTE trial
(NCT01976364) of PsA pts receiving tofacitinib 5 mg BID (dose switching allowed
after 1 month) were stratified by TNFi-IR or bDMARD-naïve status at P3 trial
baseline (BL). Safety assessed in P3/LTE trials. Efficacy assessed in LTE trial
only to Month (M)36 (longitudinal models, data as observed): MDA and HAQ-DI
(≥0.35 improvement) response rates and change from BL (∆) in PASDAS. Data
reported as all tofacitinib (pts receiving ≥1 tofacitinib dose) or constant tofacitinib
5 mg BID (pts assigned to tofacitinib 5 mg BID in P3/LTE trials or placebo→tofacitinib 5 mg BID in P3 trials and maintained this dose).
Results: 408 TNFi-IR (incl. 29 TNFi-exposed with unknown IR status) and 562
bDMARD-naïve pts from P3/LTE trials were assessed. Differences in P3 trial BL
characteristics in TNFi-IR vs bDMARD-naïve pts included longer disease duration (all tofacitinib, mean: 8.9 vs 5.6 years), higher HAQ-DI scores (mean: 1.2
vs 0.9) and a higher proportion (%) of pts aged ≥65 years (9.6 vs 7.7) and from
North America (27.5 vs 8.0). Treatment-emergent AE (TEAE) incidence rates
were higher in TNFi-IR vs bDMARD-naïve pts; serious AE (SAE), serious infection (SI) and herpes zoster (HZ; all tofacitinib) incidence rates were numerically
higher in TNFi-IR vs bDMARD-naïve pts (confidence intervals [CIs] overlapped;
Table 1). Deaths, malignancies excl. non-melanoma skin cancer (NMSC), NMSC,
major adverse cardiovascular events (MACE) and venous thromboembolism
(VTE) events were observed (Table 1). Tofacitinib response/improvements were
sustained to M36 in pts remaining in LTE trial, regardless of prior treatment. At all
time points, TNFi-IR vs bDMARD-naïve pts had lower MDA response rates and
slightly lower HAQ-DI response rates (Figure 1) and ∆PASDAS (all tofacitinib/
constant tofacitinib 5 mg BID: M1 -2.3/-2.5 vs -2.9/-3.0; M6 -2.5/-2.8 vs -3.0/-3.1;
M12 -2.7/-2.9 vs -3.0/-3.2; M24 -2.9/-3.1 vs -3.2/-3.4; M36 -3.0/-3.2 vs -3.1/-3.4).

Concomitant csDMARD required at start of P3 trials; allowed but not required in LTE
trialMedian exposure (range), days: b988 (1, 1544); c744 (1, 1715)dAdjudicatedn, number of
pts with events; PY, pt-years


Conclusion: For pts remaining in LTE trial, tofacitinib efficacy was greater in bDMARD-naïve vs TNFi-IR pts; response was maintained over time in both groups. Incidence rates were higher for TEAEs and numerically higher for SAE, SI and HZ (all tofacitinib) in TNFi-IR vs bDMARD-naïve pts. Results consistent with other advanced PsA treatments. Limitations included small event numbers, as observed data and BL characteristic differences.

Background: Risankizumab (RZB) is a selective interleukin (IL) 23 p19 subunit monoclonal antibody that inhibits IL-23. RZB 150 mg, n=183) were used for this analysis. A commercially available multiplexed Proximity Extension Assay platform was used to evaluate the levels of 92 inflammation-related protein biomarkers (BMs) and were consistent with those reported in the total population for the clinical study. At baseline, the relative levels of 10 BMs (chemokine ligand 20 [CCL20], IL-17A, IL-17C, IL-24, IL-6, S100 calcium-binding protein A12 [S100A12], osteoclast M [OSM], vascular endothelial growth factor A [VEGFA-A], C-X-C motif chemokine ligand 1 [CXCL1] and colony stimulating factor 1 [CSF-1]) positively correlated with at least 1 baseline disease activity measure. IL-6 was significantly and positively correlated with the inflammation marker high sensitivity C-reactive protein (hsCRP) and musculoskeletal endpoint (Psoriatic Arthritis Disease Activity Score [PASDAS]). CCL20, IL-17A, IL-17C, and BD-2 (BMs known to contribute to psoriasis) were correlated with baseline PASI. RZB treatment significantly decreased IL-17A, IL-17C, IL-6, and BD-2 compared with PBO treatment at week 4 (the earliest time-point when samples were available), with further decreases continuing through week 24 (Figure 1). In patients with PsA treated with RZB the decrease in IL-6 correlated with PASDAS improvement, while the decrease in BD-2 correlated with PASI improvement.

Title: IL-23, a cytokine that is important in the generation, maintenance, and proliferation of Th17 cells, serves as a major contributor to the pathophysiology of PsA [3]. Treatment with the IL-23 inhibitor RZB downregulated biomarkers associated with musculoskeletal and skin-related disease activity, and resulted in a favorable clinical response for patients with active PsA. Further investigation is needed to assess the possible relationship between changes in IL-23-related biomarkers at week 4 and long-term clinical response.

Sinai, Dermatology, New York City, United States of America

**Background:** Up to 40% of patients with psoriasis (PsO) develop psoriatic arthritis (PsA), which can have a significant impact on health-related quality of life (HRQoL). Among patients with both PsO and PsA (PsO/PsA) who are treated with a biologic agent, individual symptom profiles and response to treatment can vary, with many patients switching biologic agents over their disease course. Whether patient-centred factors, beyond skin clearance, influence biologic switching remains unexplored in the medical literature.

**Objectives:** To evaluate the association of psoriatic disease burden with biologic agent switch among patients with PsO/PsA in a real-world setting.

**Methods:** This study included data from the CorEvitas PsO Registry, a prospective, multicentre, non-interventional registry that collects data at ~6-month intervals. Biologic therapy initiations by patients with plaque PsO and dermatologist-diagnosed PsA or history of ≥3 PsO Epidemiology Screening Test (PEST) score who initiated a biologic agent at a registry visit and had ≥1 visit in the subsequent 30 months between April 2015 and August 2021 were included in this study. Disease burden at each follow-up visit after biologic initiation was defined by combinations of Psoriasis Area and Severity Index (PASI) level (≤10 vs >10) with Dermatology Life Quality Index (DLQI) level (≤5 vs >5) or patient-reported joint outcomes (VAS-100 level ≤40 vs >40) [2]. The outcome of biologic switch was defined as a start of a different biologic agent within 45 days of discontinuing the initial biologic, was assessed at each follow-up visit. Proportional hazards regression was used to calculate hazard ratios (HR) and 95% confidence intervals (CIs) to evaluate associations between disease burden categories and biologic switch, adjusted for age, sex, race, ethnicity, duration of PsO, baseline disease burden category, body mass index (BMI), employment status, number of comorbidities, and treatment history.

**Results:** There were 2,580 patient-initiations included in this study. The mean age at patient-initiation was 52 years (Standard Deviation=13) and 52% occurred in females. Over 56% of patient-initiations were obese (BMI≥30), and 27% had at least one comorbidity. Twenty percent of patient-initiations switched biologic agents over 30 months of follow-up after a median (Interquartile Range) of 6.5 (4.6, 12.4) months of treatment. Patients with combined highest skin involvement and impact on HRQoL (PASI=10 & DLQI=5) were 14 times more likely to switch biologic (HR=14.2; 95% CI: 10.7, 18.9) than those with the lowest combined skin involvement and impact on HRQoL (PASI<10 & DLQI≤5). Patients with DLQI>5 were over five times more likely to switch biologic vs the DLQI≤5 group among patients with PASI≤10 (HR=5.25; 95% CI: 4.23, 6.51) and nearly twice as likely to switch compared to those with PASI>10 (HR=1.70; 95% CI: 1.06, 2.71). Similarly, patients with joint pain ≥40 had nearly a four times higher likelihood of switching vs the pain <40 group among those with PASI≤10 (HR=3.78; 95% CI: 2.91, 4.92) and tended to be more likely to switch biologic in patients with PASI≤10 (HR=1.35; 95% CI: 0.79, 2.33).

**Conclusion:** Patients with PsO/PsA treated in a real-world clinical setting with more significant disease burden due to impaired HRQoL (DLQI and joint pain) after initiation were more likely to switch biologic agents, regardless of PASI level. These findings suggest that patient-centred factors, as well as skin clearance, have an important impact on the occurrence of biologic agent switch and the management of patients with PsO/PsA.

**Background:** BDMARD treatments in patients with psoriatic arthritis (PsA) are initiated after insufficient response to csDMARD either in monotherapy or by in parallel continuing csDMARDs. Here, the value of MTX in combination with BDMARDs in PsA is still unclear. We designed an investigator-initiated, randomized, placebo-controlled trial (IIT) in active PsA to examine the potential impact of MTX-continuation or -initiation parallel to newly started UST on different outcomes beyond clinical examination (MSUS; PsASon22 score) [1].

**Objectives:** To compare sensitive imaging efficacy outcomes measured by MSUS changes [PsASon22] from weeks 4 and 24. Results were compared between the groups with prior MTX treatment (UST+ ongoing MTX or UST+PBO) and with new initiation of MTX to UST (UST+MTX) (stratified to ongoing or new onset of MTX treatment).

**Methods:** A total of 186 patients with active PsA (defined as TJC4=2, SJC4=2 [88/66 joint count] and DAS28<3.2) were screened for eligibility. 173 patients were randomized to UST+MTX (new or ongoing) or UST+PBO, 84 patients were included in the subgroup analysis with MSUS scoring of PsASon22 at BL, weeks 4 and 24. Results were compared between the groups with prior MTX treatment (UST+ ongoing MTX or UST+PBO) and with new initiation of MTX to UST (UST+ new MTX or UST+PBO) according to the study design.

**Results:** BL data were well-balanced between treatment groups (UST+MTX, n=44; UST+PBO, n=40) and subgroups with exception of slightly higher age (mean age 53.3 years) and more (45%) female patients in the UST with ongoing MTX group. All baseline data are shown in Table 1. After UST initiation, improvement of inflammatory activity measured by MSUS using PsASon22 score was seen early at week 4 in all treatment groups. The improvement was delayed in patients with previous MTX failure (“prior MTX”) and, in overall less pronounced compared to the patients without previous MTX treatment (Figure 1). At week 24,

**POS1549 BETTER DRUG SURVIVAL ON MONOCLONAL ANTIBODIES COMPARED TO ETANERCEPT IN FIRST LINE ANTI-TNF THERAPY IN PATIENTS WITH PSORIATIC ARTHRITIS MAY BE DUE TO DIFFERENTIAL THERAPEUTIC RESPONSE IN SKIN INVOLVEMENT: A PROPENSITY SCORE-MATCHED ANALYSIS FROM THE NATIONWIDE CZECH ATTRA REGISTRY**

Š. Tichý1, L. Nekvindová2, J. Bananovič2, P. Pavelka3, P. Horák4, J. Vencovský5, J. Zavalač3. 1Institute of Rheumatology, Department of Rheumatology of the 1st Faculty of Medicine and Rheumatology Institute, Prague, Czech Republic; 2Institute of Biostatistics and Analyses, Ltd, Institute of biostatistics and analyses, Brno, Czech Republic; 3Institute of Rheumatology, Department of Rheumatology of the 1st Faculty of Medicine and Rheumatology Institute, Prague, Czech Republic; 4University Hospital Olomouc, Third Department of Internal Medicine - Nephrology, Rheumatology and Endocrinology, Olomouc, Czech Republic; 5Institute of Rheumatology, Department of Rheumatology of the 1st Faculty of Medicine and Rheumatology Institute, Prague, Czech Republic

Keywords: Psoriatic arthritis, Skin, bDMARD

Figure 1. Drug survival of etanercept vs. other TNF inhibitors in patients with PsA.
Background: Etanercept is an agent of specific molecular structure and its efficacy in extraarticular disease differs from monoclonal antibodies. This could affect drug survival in some rheumatic diseases with a larger presence of extraarticular involvement.

Objectives: To compare the drug survival of etanercept to monoclonal anti-TNF antibodies in psoriatic arthritis and describe the response of skin disease to treatment in the two groups.

Methods: Patients with PsA starting first-line biological treatment from 01/01/2012 to 30/06/2020 were enrolled from the Czech ATTRA registry and split into two groups as either being treated with etanercept (ETA) or any other anti-TNF. Propensity scores were calculated using covariates based on statistically significant differences in the baseline characteristics and clinical relevance (Table 1). PS was then used to match 81 etanercept to 160 other TNFi patients. We performed a Kaplan-Meier survival analysis and checked for statistical significance using the log-rank test. We calculated survival rates at set time points, median survival time in each group and the hazard ratio of etanercept for drug discontinuation. The Physician global assessment of psoriasis variable (measured on a numerical rating scale 0-5) was sorted in categories of mild (0-1), intermediate (2-3) and severe (4-5) and respective percentages were calculated in the propensity-matched groups at 3, 6, 12 and 24 months. Pearson's chi-squared test or Fisher's exact test were used to check the differences for statistical significance.

Results: We found significantly worse drug survival on ETA compared to other TNFi at each time point (Figure 1). The median survival time on ETA was 35.8 (95% CI 25.1 – 46.6) months compared to 65.7 (95% CI 51.9 – 76.9) months on other TNFi. The HR of ETA for treatment termination was 1.61 (95% CI 1.11 - 2.34), p=0.011. At baseline, there were no differences in skin disease severity. The percentages of mild, intermediate and severe skin disease were 22.2%, 59.3% and 18.5% on etanercept and 25.0%, 55.6% and 19.4% on other TNFi, p=0.325. At 3 months, skin disease was significantly more severe in ETA with 50.0%, 44.8% and 5.2% compared to 76.2%, 23.8% and 0% on other TNFi, p=0.001. At 12 months, the respective percentages were 66.6%, 31.9% and 2.1% on ETA and 84.7%, 15.3% and 0% on other TNFi, p=0.015; at 24 months 62.9%, 59.3% and 18.5% on etanercept and 84.7%, 15.3% and 0% on other TNFi, p=0.853. At 3 months, skin disease was more severe in ETA with 50.0%, 44.8% and 5.2% compared to 76.2%, 23.8% and 0% on other TNFi, p=0.011. At baseline, there were no differences in skin disease severity.

Conclusion: Etanercept had worse drug retention than monoclonal antibodies in PsA. Patients treated with ETA had more severe skin disease during follow-up compared to those treated with other TNFi, which could lead to earlier switching to another drug.

Conclusion: The biological drug switching rate due to inefficacy in our study was 12.20 per 100 patient-years. In this description study, we have identified some clinical disease manifestations and therapy regimen factors that might affect the drug switching due to inefficacy on PsA. TNF inhibitor (TNFi) seems to be the drug with the lowest rate of switching due to inefficacy in our study.

IL-13 INHIBITION USED FOR ATOPIC DISEASES IS ASSOCIATED WITH RISK OF PSORIATIC ARTHRITIS

Keywords: Spondyloarthropathies, Psoriatic arthritis, Genetics/epigenetics

S. S. Zhao, K. Hyrich, Y. Xu, A. Barton, J. Bowes, University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; NIHR Manchester Biomedical Research Centre, Centre for Dermatology Research, Manchester, United Kingdom; University of Manchester, Centre for Genetics and Genomics; Versus Arthritis, Manchester, United Kingdom

Background: Inhibitors of the IL-13 pathway, such as dupilumab and tedokimab, are licensed to treat atopic diseases such as eczema and asthma. Mucosal skeletal adverse events that resemble enthesitis and psoriatic arthritis (PsA) after dupilumab initiation have been reported, but evidence is limited to case reports and spontaneous pharmacovigilance with uncertain causal inference. Naturally occurring genetic variation in drug targets can provide insight into their potential adverse effects.

Objectives: To investigate whether genetically proxied IL-13 inhibition (IL-13i) increases risk of PsA and other spondyloarthropathy-related diseases.

Methods: Dupilumab is recognised to reduce eosinophil count in clinical studies; we therefore used it as the biomarker of IL-13i. We instrumented IL-13i using missense (protein coding) variants within the IL13 gene that are associated with circulating eosinophil count at genome-wide significance (p<5x10^-8) in a study of 563,946 individuals. Outcome genetic associations were taken from studies of PsA, spondyloarthropathy, ulcerative colitis, anklyosing spondylitis, and iritis. To examine instrument validity, we used atopic eczema and asthma as positive control outcomes, and rheumatoid arthritis as a negative control. We used the ratio method, with estimates scaled to per standard deviation (SD) increase in eosinophil count.

Results: One missense variant, rs25041, was selected to proxy IL-13i. Genetically proxied IL-13i was associated with increased risk of PsA (OR 37.39; 95% CI 11.52, 121.34), psoriasis (OR 20.04; 4.38, 92.01), Crotin’s disease (OR 3.49; 1.38, 8.81), but not ulcerative colitis, anklylosing spondylitis or iritis. IL-13i was associated with reduced risk of positive control outcomes, but not with the negative control (Table 1).

Conclusion: Genetically proxied IL-13 inhibition is associated with increased risk of PsA, spondyloarthritis and Crotin’s disease, which may be a class effect relevant to...
other IL-13 that are not yet reported to have Th17-type adverse events. These findings are compatible with the hypothesis that Th2 cytokines IL-4/-13 may act as a restraint toward Th17-type disease activation in some organs. Clinicians assessing adverse events after dupilumab initiation may be aware of incident PsA and related features. This study demonstrates the value of genetic instrumental variables in evaluating rare adverse events in the study of drug safety.

PS14065

A PROOF-OF-CONCEPT STUDY EVALUATING THE USE OF FUNCTIONAL BRAIN MAGNETIC RESONANCE IMAGING IN ASSESSING TREATMENT RESPONSE IN PSORIASIC ARTHRITIS PATIENTS

Keywords: Psoriatic arthritis, Pain, Imaging

E. Espartal1, X. Michelenal, S. Marsal2, A. Roviral2, A. Erral2, 1Val Hebron University Hospital, Rheumatology Department, Barcelona, Spain; 2Val Hebron University Hospital, Section of Neuroradiology (Department of Radiology, IDI), Barcelona, Spain

Background: Inflammatory cytokines can alter the way the central nervous system processes pain as shown in patients with rheumatoid arthritis [Rech et al., 2013]. However, the relationship between TNF inhibitor inhibition and pain processing in individuals with psoriatic arthritis (PsA) has not been investigated.

Objectives: To assess the feasibility of functional magnetic resonance imaging (fMRI) paradigm to estimate the response to pain and the effect of treatment in PsA patients (pts).

Methods: 6 pts with active PsA eligible to start a TNFi were included: 3 were naive to biological disease modifying anti-rheumatic drugs and 3 were experienced. Four healthy subjects (HS) were also included. Subjects were scanned in a 3.0T scanner at baseline (BL) and week 1 (W1) after starting treatment. Each acquisition included 2 fMRI runs. The physician selected a swollen and tender joint (affected joint) and a control joint in the contralateral hand (non-affected joint). First, the brain pain response was investigated pressing the non-affected joint followed by the affected joint. The fMRI effect of pressure was represented for each subject individually, for each time point (p<0.0001 uncorrected level, minimum extension 10 voxels). We provided a descriptive analysis of the differences in PsA pts brain response between BL and W1 and the clinical response evaluated by the percentage of improvement of Disease Activity in Psoriatic Arthritis (DAPSA) score and visual analogue scale pain (VASp) change.

Results: All subject’s demographic characteristic and PsA patients’ clinical response are shown in Table 1. Brain response to pressure in HS produced activation in the sensory motor cortex, with more or less involvement of additional areas in the prefrontal, parietal and temporal cortex. In PsA pts with a higher treatment response (PsA 1, 2, 5), the brain response to pressure did not show any activation at BL whilst sensory motor cortex activation was seen at W1, with amygdala and insula activation in pts PsA 2 and 5 and prefrontal and frontal activity in pts PsA 1 and 2. In those with less response (PsA 3, 4, 6), the sensory motor cortex was activated at BL with little changes when evaluated at W1 (Figure 1). No evident differences in brain response activation were observed between naive and TNFi experienced patients.

Conclusion: The proposed fMRI paradigm seems to be a promising candidate to predict response to treatment with TNF inhibitors in PsA patients. Studies with more patients are needed to confirm our preliminary results.

Figure 1: Brain fMRI response to pressure of the non-affected joint (green) and the affected joint (red) overlaid on top of the structural image. Upper panel corresponds to a patient with clinical improvement (PsA1) and lower panel to a patient that did not respond (PsA3) at baseline (left column) and week 1 (right column). Differences are observed in the sensorimotor cortex activation between patients: there is an increase in the activation after week 1 in PsA1 while PsA3 showed activation at baseline but not in week 1.

POS1606

DIFFERENTIAL AND COMBINATORIAL MECHANISM OF ACTION OF GOLIMUMAB AND GUSELKUMAB IN ULCERATIVE COLITIS INDUCTION TREATMENT: IL-23 BLOCKADE DRIVES RESTORATION OF NORMAL EPITHELIELUM AND MUCOSAL HEALING

Keywords: Clinical trials, Organ damage, Remission

P. Desai1, P. Branigan1, D. Richards1, D. Megnaola1, M. Vetter1, D. Cua1, T. Freeman1, 1Janssen Research & Development, LLC, Immunology, Spring House, PA, United States of America; 2Leeds Biomedical Research Centre, University of Leeds, Leeds, United Kingdom
Background: The combination treatment of golimumab (GOL), a tumor necrosis factor-alpha (TNFα) antagonist, and guselkumab (GUS), an interleukin (IL)-23 inhibitor was shown to induce higher rates of clinical remission, endoscopic improvement, and histologic remission than each monotherapy in a randomized phase 2 induction study in TNFα-naive patients with moderate-to-severely active ulcerative colitis (UC) (VEGA; NCT03662542).

Objectives: To investigate the underlying mechanism of action of GOL, GUS, and the combination (GUS+GOL).

Methods: Colon biopsies were obtained at screening and at Week 12 in patients who received GOL (n=48), GUS (n=52), or GUS+GOL (n=50). Tissue transcriptional profiles were determined with RNA-seq. Differentially expressed genes were analyzed in the context of cell-type specific transcriptional modules by first defining a gene correlation network and unsupervised network clustering. We then developed a method to create a single-cell-derived co-expression network using published UC single-cell data to provide high-resolution gene modules associated with specific cell types and pathways. Gene set variation analysis (GSVA) was used to quantitatively assess changes in specific biologic modules in the context of responder and non-responder analyses.

Results: By Week 12, combination therapy induced a greater magnitude of transcriptional changes in the colon compared with each monotherapy (Table 1). These genes were associated with IL-23/Th17/myeloid-related processes, inflammation, and epithelial homeostasis. Significant changes were observed in Th17 cells and inflammatory epithelial cell modules in patients that achieved endoscopic improvement (subscore 0 or 1) at Week 12 compared with non-responders (Table 1). The magnitude of change relative to baseline was greater in the GUS monotherapy and GUS+GOL arms compared with GOL alone. These changes were consistent with a decrease in crypt destruction in responders at Week 12, as observed by histologic changes in the Goebes score. Genes modulated by GUS+GOL were indicative of greater suppression of inflammation, particularly myeloid cell activation and inflammatory fibroblast development. In contrast, genes modulated by either GUS or GUS+GOL were associated with increased epithelial normalization and decreased Th17 activity compared to GOL alone.

Conclusion: Combination induction with GOL+GUS for 12 weeks drove a greater reduction in inflammation and improvement in epithelial homeostasis compared to each monotherapy, demonstrating the differential and complementary mechanisms of action of TNFα and IL-23 blockade. Combination therapy drives a significant increase in the overall magnitude of response with marked improvement in the restoration of normal epithelium.

POS1607 BIOLOGIC THERAPIES FOR PSORIASIS DECREASE FUTURE RISK FOR DEVELOPING PSORIATIC ARTHRITIS

Keywords: bDMARD, Disease-modifying drugs (DMARDs), Psoriatic arthritis

A. Dotan, N. Ben-Shabat, D. McGonagle, H. Amital, A. Wattel, Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Israel, Sackler Faculty of Medicine, Tel-Aviv University, Department of Medicine ‘B’; Ramat-Gan, Israel; The Leeds Teaching Hospitals NHS Trust & Leeds Institute of, University of Leeds, Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: Psoriasis (PsO) is an inflammatory skin disorder with an estimated worldwide prevalence of 2–4% [1]. Psoriatic arthritis (PsA) is highly associated with higher severity of PsO, present in up to 30% of patients and 0.3–1.0% of the global population and PsA typically develops after PsO [1,2]. There are some contradictory studies in relationship to the impact of biological therapies for PsO in relation to the prevention of PsA. Objectives: To ascertain whether biological therapies for pre-existing psoriasis (PsO) may reduce the incidence of psoriatic arthritis (PsA) according to different treatment regimens for PsO ranging from topical therapy to biological therapy. Methods: We conducted a retrospective exploratory study with real-world data from the third largest Israeli health maintenance organization, ‘Meuhedet’ which covers approximately 1,300,000 subjects. All patients of ‘Meuhedet’ diagnosed with PsO from January 2000 until January 2020 were included in the analysis. Overall, 61,003 patients with PsO were detected. In addition, each PsO patient was paired with four control subjects by gender, age, and ethnicity. Patients diagnosed with PsA before the diagnosis of PsO or less than six months after were excluded from the analysis. We defined PsO according to physicians’ diagnoses. Patients included patients with either peripheral or axial arthritis. Patients were classified according to their treatment: Group 1-topical therapy, phototherapy or no therapy, Group 2 - conventional DMARDs (cDMARDs; methotrexate or sulfasalazine), Group 3 -biologics DMARDs (bDMARD) The incident cases of PsA were analyzed according to the aforementioned different lines of therapy. Patients in the bDMARDs group were further sub-grouped according to the first-line prescribed treatment. Time-dependent Cox proportional hazard models were used to evaluate the adjusted risk of developing PsA by treatment group. Data analysis was conducted with Python Software Foundation, Python Language Reference, version 3.9.12, R version 4.2.0, RStudio (RStudio Team, 2020), and the ‘Survival’ package (v3.2; Therneau, 2020).

Results: 58,671 patients were included contributing a total of 628,228 patient-years. This analysis was adjusted to gender, body mass index (BMI), age of PsO diagnosis, time from psoriasis diagnosis to the group treatment, and number of biological treatments lines. Adjusted Cox proportional hazards regression analysis showed that the risk of developing PsA in PsO patients treated with bDMARDs was significantly higher in comparison to those treated with topical therapy (HR: 2.76, CI: 2.19 – 3.48, p-value: <0.001). On the contrary, the analysis also showed that the risk of developing PsA in PsO patients was significantly decreased in those treated with biological agents in comparison to topical therapy (HR: 0.62, CI: 0.42 – 0.90, p-value: <0.014).

Conclusion: PsO patients treated with cDMARDs are at higher risk of developing PsA in comparison to those treated with topical therapy alone which may reflect the severity of extent of psoriasis in the c DMARD group been linked to PsA. Biological therapy decreased risk of developing PsA in comparison to topical therapy.

REFERENCES:
Background: Psoriatic arthritis (PsA) is a chronic, progressive disease associated with psoriasis that can lead to joint damage, disability, and increased mortality. Early diagnosis and management of inflammation is essential for improving clinical outcomes. Methotrexate (MTX) is the recommended first-line treatment for early PsA patients with polyarthritis and relevant skin involvement, however many patients are unresponsive to therapy. MicroRNA (miRNA) modulation gene expression at a post-transcriptional level and constitute a promising source of biomarkers that could enable the future personalization of treatment plans.

Objectives: To identify a set of miRNAs that serve as biomarkers for MTX treatment response by comparing miRNA expression between responders and non-responders before initiation of therapy.

Methods: From our prospective PsA database we identified biologic-naive PsA patients satisfying the CASPAR criteria before the initiation and 6 months after MTX treatment. Articular response to MTX was defined as achieving treatment target of low disease activity (4 ≤ DAPSA < 14) or remission (DAPSA < 4). Cutaneous response to MTX was defined as a reduction of at least 50% in PASI score. miRNA expression was evaluated in biobanked serum samples through next-generation sequencing. Differential expression was assessed by linear modelling with empirical Bayes moderation (using the Limma R package). Linear models were corrected for sequencing batch, age, sex, ethnicity, BMI, smoking, use of NSAIDs, MTX treatment duration and dose. Enrichment of biologic pathways corresponding to gene targets of the identified miRNAs was examined using the integrative tool pathDIP by restricting the analysis to literature curated pathways and experimentally detected protein-protein interactions with a prediction confidence of 0.99.

Results: 70 biologic-naive, PsA patients were included in the study. Articular and cutaneous response to MTX was observed in 28.57% and 34.28% of patients, respectively. Pretreatment expression of miR-127-3p was significantly lower in patients showing an articular response to MTX (p<0.001). Of note, miRNA 127 expression has been associated with a protective effect in inflammatory lung fibrosis and osteoarthritis[1]. A set of 7 miRNAs (miR-155-5p, miR-140-3p, miR-432-5p, miR-382-5p, miR-532-5p, miR-139-3p, and miR-379-5p) were significantly associated (p<0.01) with cutaneous response to MTX treatment (reaching a reduction of 50% in PASI) present lower expression of miR-127-3p. B. Patients showing articular response to MTX treatment (reaching treatment target of low disease activity or remission: DAPSA score below 14) present lower expression of miR-127-3p. B. Patients showing cutaneous response to MTX treatment (reaching a reduction of 50% in PASI) present lower expression of miR-140-3p and miR-332-5p and higher expression of miR-155-5p, miR-432-3p, miR-382-5p, miR-139-3p and miR-379-5p.

Conclusion: We identified miR-127-3p as a biomarker of cutaneous response, and 7 other miRNAs as biomarkers of cutaneous response to MTX treatment in PsA patients.

NO BURN-OUT IN PEDIATRIC-ONSET BEHÇET’S DISEASE PATIENTS DURING ADULTHOOD FOLLOW-UP

Keywords: Behçet’s disease

T. Bozkurt1, M. Karabacak2, H. Karatas1, S. Kutluğ Ağaçkıran3, T. Ergun2, H. Direskeneli1, F. Albaz-Onel1. 1Marmara University School of Medicine, Department of Internal Medicine, Istanbul, Turkey; 2Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3Marmara University School of Medicine, Department of Dermatology, Istanbul, Turkey

Background: Although onset of Behçet’s Disease (BD) is common in the second or third decade, initial symptoms occur under the age of 16 years in 4–26% of the patients [1].

Objectives: In this study we aimed to assess the clinical course of pediatric onset BD in adulthood period.

Methods: The files of 1114 BD patients were reviewed retrospectively. 51 (4.6%) (F:M=21:30) pediatric-onset BD patients were included in the analysis. Demographic and clinical characteristics, follow-up and treatment data of the patients were recorded from files.

Results: The median age at diagnosis was 16 (14-17) years, and the median follow-up duration was 51 (26-96) months. Of all patients, 33.3% (n=17) had ocular involvement, 27.5% (n=14) had vascular involvement, 17.6% (n=9) had central nervous system involvement, and 3.9% (n=2) had gastrointestinal system involvement. Erythema nodosum was more common in females (p=0.008) and vascular involvement was more common in males (p=0.025). At the end of follow-up, 32 (62.8%) patients had major organ involvement, half of them had at the time of diagnosis. Forty-seven (M:27:F:20) patients had a follow-up with median of 50 (20-82) months in adulthood period. Thirty-one (65.6%) patients had major organ involvement. While 20 (64.5%) patients had major organ involvement in the pediatric period, 11 (35.5%) patients developed major organ involvement in adulthood. Overall, 19 (40.4%) patients had active disease manifestations (relapse and/or new major organ involvement) in adulthood follow-up. Of these patients, 11 (57.9%) had new major organ involvement, 7 (38.8%) had a relapse of the same organ, and one (5.3%) had both new major organ involvement and a relapse. The disease course of patients is seen in Table 1.

Conclusion: Our results show that, about half of the pediatric-onset BD patients still have active disease manifestations (mainly new major organ involvement) in adulthood period.

THE SIGNIFICANT ASSOCIATION OF HLA-A26 WITH UVEITIS AND GASTROINTESTINAL INVOLVEMENT IN PATIENTS WITH BEHÇET’S DISEASE IN A MULTICENTER STUDY

Keywords: Behçet’s disease

T. Nakajima1, H. Tsui1, R. Inaba1, R. Saito1, K. Nishimura2, A. Morinobu1. 1Kyoto University, Rheumatology and Clinical Immunology, Kyoto, Japan; 2Kurashiki Central Hospital, Endocrinology and Rheumatology, Kurashiki, Japan; 3Kobe University, Rheumatology and Clinical Immunology, Kobe, Japan

Background: Specific haplotypes of human leukocyte antigen (HLA) are associated with susceptibility and disease activity of Behçet’s disease (BD). However, the clinical importance of HLA-A26 in BD is not well recognized compared to that of HLA-B51.

Objectives: This study aimed to examine the association between HLA-A26, HLA-B51, clinical manifestations, and disease severity in BD, especially focusing on HLA-A26 possession.

Methods: This study was a multicenter cross-sectional observational study and patients with BD were enrolled from 2006 to 2021. All patients met the International Criteria for BD [1] or the diagnostic criteria of the Behçet’s Disease Research Committee of Japan [2]. Disease severity was evaluated using Krause score reflecting the entire spectrum of disease manifestations [3]. Both serotypes and genotypes were accepted for HLA typing.

Results: In total, 200 patients were enrolled in this study. Uveitis was observed in 95/196 patients (48.5%) and gastrointestinal involvement in 57/167 patients (34.1%). HLA haplotypes were identified for HLA-B51 (n = 52/106, 49.1%), HLA-A26 (n = 25/88, 28.4%), and both HLA-B51 and HLA-A26 (n = 68/88, 68.8%). While HLA-A26 showed no significant association with clinical manifestations without adjustment for HLA-B51, HLA-A26 possession showed a higher frequency of uveitis (HLA-A26 positive vs. negative: n = 6/8, 100% vs. n = 16/32, 50.0%, respectively, p = 0.03) and higher Krause scores (median: 7 vs. 5, respectively, p = 0.02) under conditions with HLA-B51. Furthermore, the association between uveitis and gastrointestinal involvement was influenced by HLA-A26: HLA-A26 possession was associated with a higher frequency of uveitis in patients with gastrointestinal involvement (HLA-A26 positive vs. negative: n = 5/9, 55.6% vs. n = 0/21, 0%, respectively, p = 0.001), as well as for gastrointestinal involvement in patients with uveitis (HLA-A26 positive vs. negative: n = 5/11, 45.5% vs. n = 0/24, 0%, respectively, p = 0.001). All 5 patients with both uveitis and gastrointestinal involvement had HLA-A26 (HLA-A26 positive vs. negative: n = 5/21, 23.8% vs. n = 0/58, 0%, respectively, p = 0.001).

Conclusion: HLA-A26 was associated with severity of BD and uveitis in patients with HLA-B51, and was associated with coexistence of uveitis and gastrointestinal involvement. This study suggested the importance of confirming HLA-A haplotype in patients with BD.

AN OBSERVATIONAL MULTICENTER STUDY COMPARING THE EFFECTIVENESS BETWEEN TNF INHIBITORS AND APREMILAST ON ORAL ULCERS OF BEHÇET’S DISEASE

Keywords: Behçet’s disease
Background: Recurrent oral and genital ulcers are the most nagging clinical manifestations of Behçet’s disease (BD) and colchicine should be used first for the treatment and prevention of ulcers relapse. In contrast, TNF-α inhibitors (TNFi) are helpful in resistant cases, leading to a rapid improvement of mucosal lesions [1]. More recently, the phosphodiesterase-4 inhibitor apremilast was evaluated in two RCTs showing a significant improvement of oral ulcers compared to placebo [2, 3]. Moreover, several observational studies also investigated the effectiveness of apremilast in BD patients with mucosal ulcers [4].

Objectives: To date, there are no comparative data about the effectiveness between TNFi and apremilast in mucocutaneous involvement of BD. The present study aims to compare the effectiveness between TNFi and apremilast on oral ulcers of BD.

Methods: Data on patients classified as BD (according to International Criteria for BD and International Study Group criteria) who underwent apremilast or TNFi for refractory oral ulcers from March 2017 to January 2022 in 7 tertiary rheumatology centers (6 Italian and 1 Spanish) were retrospectively analyzed. Retrieved data including demographics and clinical characteristics were collected. We also recorded the presence of active oral aphthosis at either baseline, 3-month and 6-month follow-up as well as the occurrence of oral ulcers during the intervals between visits. Patients on TNFi were considered controls for nearest-neighbour propensity score (PS)-matching (neighbours for replacement matching, minimum 1, maximum 4). PS is an epidemiological tool used for the adjustment of non-randomized longitudinal studies. It is a conditional probability of being exposed to a disease given an asset of covariates. In brief, this was carried out using the patients’ age, disease duration and gender, with a selected caliper of 0.2. Chi-square test was used to test difference between proportions of patients with active aphthosis in both groups at different follow-up times.

Results: Among 159 patients with BD on TNFi or apremilast, the matching algorithm retrieved 84 patients. More in detail, 28 patients in the apremilast group and 58 patients in TNFi group. All had active aphthosis at treatment start. Clinical and demographic characteristics of patients at baseline are reported in Table 1 and Figure 1 and 2. Concerning proportion of patients with active oral aphthosis, no difference was observed either at 3-month (p=0.60) and 6-month (p=0.66) follow-up visits (Figure 2). Consistently, the rate of flares in the time intervals between visits was not different between groups (46.1% vs 37.9% from month 0 to 3, p=0.47; 34.62% vs 34.48% from month 3 to 6, p=0.99).

Conclusion: The main limitations of our study are the small sample size and the short-term follow-up. Nevertheless, we provide evidence that apremilast and TNFi show similar effectiveness, inducing a meaningful and early benefit in BD patients with refractory oral ulcers.

POS1555 MEASUREMENT OF COMMON FEMORAL VEIN WALL THICKNESS IS A USEFUL DIAGNOSTIC TOOL TO DIFFERENTIATE OCULAR BEHÇET’S DISEASE FROM OTHER INFLAMMATORY UVEITIS

Keywords: Ultrasound, Behçet’s disease

S. Kutlu1 Ajakçakaran1, E. Kardes2, A. Ajakçakaran3, H. Direshkeneli1, F. Alibaz-Oner1. 1Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2University of Health Sciences, Umraniye Training and Research Hospital, Department of Ophthalmology, Istanbul, Turkey; 3University of Health Sciences, Umraniye Training and Research Hospital, Department of Radiology, Istanbul, Turkey

Background: Diagnosis of Behçet’s Disease (BD) can be challenging, especially in patients presenting with single major organ involvement. Our group showed that common femoral vein (CFV) wall thickness measured by Doppler ultrasonography (US) can be a non-invasive diagnostic method [1] and can also be used to diagnose incomplete BD [2]. Since ocular involvement of BD may result in irreversible vision loss if untreated, it is important to diagnose without delay and initiate immunosuppressive therapy promptly.

Objectives: In this study, we aimed to assess the discriminative role of CFV wall thickness measurement in uveitis associated with BD compared to other inflammatory uveitis.

Methods: Patients with BD uveitis (n=41) and age-gender matched 58 non-BD uveitis patients were included in the study. Demographics, clinical characteristics, and treatment data were recorded during routine visits. CFV wall thickness was measured by an experienced and blinded radiologist on the same day.

Results: Twenty-four (58.5%) of BD patients and 23 (39.7%) of non-BD patients were male. All BD patients had panuveitis. 3 (3.0%), 8 (8.1%), 8 (8.1%) of non-BD patients have anterior uveitis due to sarcoidosis, HLA-B27 positivity, ankylosing spondylitis, respectively, and 7 (7.1%) had idiopathic anterior uveitis. 12 non-BD patients had panuveitis caused by sarcoidosis. The most common complaint was decreased visual acuity in both groups. Right CFV (0.73 mm± 0.07) wall thickness of BD patients was significantly higher than left CFV (0.67 mm± 0.08) and left CFV (0.57 mm± 0.07) wall thickness of non-BD patients (p < 0.01).

Conclusion: Diagnosis of ocular BD can be challenging, especially when there is no other clinical finding or organ involvement specific to BD. Our results suggest that measurement of CFV wall thickness by Doppler US can be helpful for the differentiation of ocular BD from other causes of inflammatory uveitis in daily practice.

Background: The arthritis that occurs in Behçet’s disease (BD) is considered to be an oligoarthritis but one of the intractable symptoms related to quality of life [1]. Apremilast is effective for oral ulcers in BD, but its efficacy against arthritis has not been well established.

Objectives: This study aims to determine the effect of apremilast treatment on arthritis in BD.

Methods: Patients diagnosed with BD disease between January 2011 and June 2022 who had a history of arthritis within the past five years were included in this study. Patients with Behçet’s disease treated with apremilast were compared with those not treated (control group). Frequency of oral and genital ulcers, skin lesions, arthritis, and other typical domains of Behçet’s disease, evaluated every 3 months for 12 months. The number of tender and swollen joints and DAS28 as indicators of arthritis activity and Behçet’s disease activity form (BDCAF) as an indicator of disease activity were investigated retrospectively.

Results: There were 55 patients with Behçet’s disease available for analysis in this study, 16 of whom were treated with apremilast. There was no clear difference between the two groups for pre-existing BD disease domains. Active lesions at the beginning of the analysis included significantly more oral ulcers and skin pustules in the apremilast group than in the control group, but there was no significant difference in the incidence of arthritis (Table 1). Similarly, there were no significant differences in the number of swollen joints, tender joints, or serum CRP levels between the two groups. The frequency of having arthritis was present in 56.3% of the apremilast group at baseline and decreased in the apremilast group at 3 and 6 months, but remained unchanged in the control group (Figure 1). In the apremilast group, not only did oral ulcers, genital ulcers, and skin pustular lesions improve after 3 and 6 months, but DAS28 and BDCAF also significantly decreased after 3 months (DAS28: p = 0.0010, BDCAF: p = 0.0019).

Conclusion: Apremilast is effective against arthritis as well as skin mucosal lesions in BD and could be one of the treatment strategies for arthritis in BD.

P. Tricopiane1, G. Raffone1, A. D’antonio1, E. Greco1, S. Modica1, A. Bergamini2, M. S. Chianese1.1University of Reggio Calabria, For Vergata, Rheumatology Allergology and Clinical Immunology, Rome, Italy

Background: Hereditary angioedema (HAE) due to C1 esterase inhibitor protein (C1INH) deficiency is a rare disorder (1:5000) that is characterized by widely variable and potentially fatal attacks of acute pain in the lower limbs, including muscle wasting, fascial swelling and, in severe cases, skin tissue ulceration which are generally self-limiting. The defect of C1INH allows for a dysregulated kallikrein–kinin pathway, and thus for the overproduction of bradykinin B2 receptors. The resulting increased vascular permeability induces painful angioedema attacks most often involving the hands. Musculoskeletal ultrasound (MSUS) enables evaluation of the soft tissues, providing additional and more accurate assessment of inflammation and visualization of structural damage.

Objectives: To explore the potential damage at the site of angioedema attack, we performed an U/S study of hands and wrists in consecutive C1INH-HAE patients referring to the HAE Reference Centre at “Tor Vergata” University Hospital in Rome (Italy).

Methods: Consecutive C1INH-HAE patients underwent biochemical analyses and, in the same day, MSUS evaluation that has been performed by an expert rheumatologist at wrists and hands. The US (Esaote MyLab™X75, 4-15 MHz) semi-quantitatively graded subcutaneous tissue edema, synovitis/tenosynovitis-like lesions, erosions, oedematoses, and bone edema according to the 2021 Outcome Measures in Rheumatology (OMERACT). HAE Quality of Life Questionnaire (HAE-QoL) and HAE Activity Score (HAE-AS) were registered.

Results: 94 C1INH-HAE patients from 50 independent families (aged 43.2 ± 17 yrs) has been included, with 60% females and 20.6% smokers. All patients experienced recurrent acute attacks at the hands: a third of the cohort (31.3%) was on long-term-prophylaxis at the time of the study and 20% of subjects had the last acute attack more than 12 months before. In 75% of the cohort, the HAE-QoL described a mild-moderate QoL and HAE-AS showed a mild disease activity. Smokers were prevalent among patients in high disease activity than in patients in low disease activity (P<0.05). High level of C-reactive protein (≥5 mg/dl) has been documented in 13.8% of patients while rheumatoid factor and anti-cyclic-citrullinated- peptide-antibody (ACPA) resulted in rare cases (2.1% for both). A vitamin D deficiency (< 7 ng/dl) has been registered in 3.6% of patients although insufficient vitamin D (7-30ng/dl) resulted in 50% and hyperuricemia (>7mg/dl) in 4% of cases. ANA titer≥1:160 occurred in 25.5%. The joint pain at the hands/wrists have been reported by 70% of patients: patients with joint pain showed a lower mean C1INH antigen level and a higher number of attacks in the last 3 months than patients without (P<0.05). Patients with at least 1 US lesion (62.8%) were significantly older and affected by a greater number of angioedema attacks than patients without lesions (37.2%, P<0.05 for both). US lesions were mainly represented by oedematoses (63.5%) and cartilage damage (35.3%). Synovitis/tenosynovitis and potentially at least 1 joint has been documented in 44.7% of the cohort but a positive Power Doppler signal was revealed in rare cases (2.1%). The subcutaneous tissue edema resulted in a third of the cohort (29.8%). Cartilage damage and subcutaneous edema was similarly distributed among hands and wrists. The distal radioulnar joints were the most affected (25.5%) while metacarpophalangeal was affected in 17.6% of cases. Synovitis/tenosynovitis was mild-moderate in 98% of cases. In patients showing subcutaneous tissue edema, it was documented in 78.2% of cases at the hands and in 21.3% at the wrists.
LONG-TERM SAFETY OF CANakinumab IN AUTOINFLAMMATORY PERIODIC FEVER SYNDROMES – 48-MONTH DATA FROM THE RELIANCE REGISTRY

Keywords: Innate immunity, Real-world evidence, Rare/orphan diseases

Background: Autoinflammatory periodic diseases (AID) can be treated with the tumor necrosis factor receptor-associated periodic syndrome (TRAPS) on CANakinumab (CAN). CAN has been shown to be safe and effective in controlled trials and routine clinical practice.

Objective: To investigate the safety and tolerability of CANakinumab in adult and pediatric (age ≥2 years) patients with AID who routinely receive CAN in clinical practice.

Methods: RELIANCE is a prospective, non-interventional, observational study in Germany enrolling pediatric (age ≥2 years) and adult patients with a clinically confirmed diagnosis of AID who routinely receive CAN. Efficacy and safety parameters are recorded at baseline and assessed at 6-month intervals.

Results: Data from N=232 patients (n=229 with baseline visit yet documented) diagnosed with autoinflammatory diseases enrolled in the RELIANCE registry between October 2017 and December 2022 were included in the present interim analysis. Median age of the total study cohort was 20.0 years (2–80 years), 52% were female and median duration of CAN treatment before study entry was 2 years (0–15 years). During the study, 898 adverse events (AE) occurred in N=164 patients (71%). Among the most common AE classified as suspected adverse drug reactions (ADR) were decreased neutrophil count (8 events, IR 1.46), increased inflammatory markers (12 events, IR 2.19), nasopharyngitis (14 events, IR 2.55) and pyrexia (17 events, IR 3.10). In N=35 patients (15%), a total of 98 serious adverse events (SAE) were reported. Of these events, 31 SAE were classified as suspected adverse drug reactions (SAE; Table 1). During the last 3 years of observation within the study, incidence rates (IR) decreased from 76.21 to 51.44 (ADR) and 7.44 to 5.66 (SAE). Patients receiving greater than standard dose CAN experienced higher levels of ADR/SAE compared to patients under less than standard and standard dosing. How much high dosage or severity of disease contribute to this phenomenon remains unclear. AE related dose reductions have not been reported.

Conclusion: The 48-month interim data of the RELIANCE study confirm sustained safety of long-term treatment with CAN in the entire study population.

THE CHARACTERISTICS OF THE PATIENTS UNDER NINTEDANIB TREATMENT DUE TO INTERSTITIAL LUNG DISEASES ASSOCIATED WITH CONNECTIVE TISSUE DISEASES

Keywords: Sjögren syndrome, Lungs, Systemic sclerosis

F. Tekgoz1, S. Colak1, E. Cimen Gunes1, N. Ocal2, D. Dogan2, C. Tasci2, M. Cinar1, S. Yilmaz1. 1University of Health Sciences, Gulhan Faculty of Medicine, Rheumatology, Ankara, Turkey; 2University of Health Sciences, Gulhan Faculty of Medicine, Pulmonology, Ankara, Turkey

Background: Nintedanib provides a decline in the reduction of forced vital capacity (FVC) in patients with progressing lung fibrosis. Objectives: To assess demographical, clinical, and radiological characteristics of the patients with connective tissue diseases (CTDs) associated interstitial lung disease (ILD), who were under nintedanib treatment.

Methods: This retrospective observational study was conducted with the patients who received nintedanib for progressing lung fibrosis associated with CTDs. The patients who had followed up between January 2020 and December 2022 included in the study. The demographical, clinical, and radiological data were obtained from patients’ files.

Results: Twenty-two (14.8%) patients (11 male/11 female) with CTD related ILD who had a mean age of 65.9 ± 7.6 received nintedanib. The median disease duration was 43.8 (3.8-101.8) months for ILD. Eighteen (81.8%) patients had a ILD diagnosis prior to an ILD diagnosis. The median duration for nintedanib treatment was 10.5 (7-14.8) months. Eight (36.4%) patients had Sjögren's syndrome, 7 (31.8%) patients had systemic sclerosis, 15 (68.2%) patients had rheumatoid arthritis, and 2 (9.1%) patients had undifferentiated CTD. Ten (45.5%) patients had a history of smoking. Only one patient was using nintedanib 150 mg/day due to gastrointestinal intolerance. Hypertension was the most frequent comorbidity in 5 (22.2%) patients, and the second most frequent one was pulmonary hypertension in 3 (13.6%) patients. During 6 minutes walking test, 12 (55.5%) patients had desaturation. According to high-resolution computed tomography (HRCT) findings, 18 (81.8%) patients had usual interstitial pneumonia (UIP) pattern, and 4 (18.2%) patients had non-specific interstitial pneumonia (NSIP) pattern. The most frequent parenchymal pattern was UIP (p = 0.05). There was no mortality in the study group. Twelve (55.5%) patients had received at least one immunosuppressive treatment. Nintedanib was initiated due to the progression of fibrosis in HRCT in half of the patients with connective tissue diseases (CTDs) associated interstitial lung disease (ILD) who were under nintedanib treatment. Combined with nintedanib, cyclophosphamide (1 patient), rituximab (3 patients), and mycophenolate mofetil (4 patients) were used. The most common side effect of nintedanib was diarrhea.

CTD= Connective tissue disease, ILD= Interstitial lung disease. NSIP= Non-specific interstitial pneumonia, UIP= Usual interstitial pneumonia, FVC= Forced vital capacity, CT= Computerized tomography/ Mean (SD), ‘Median (I-Q-Q).”

Conclusion: Nintedanib is a promising agent for progressing lung fibrosis in patients with CTD-related ILD. Since physicians can safely combine it with immunosuppressive agents, more patients will benefit in the course of time. Prospective studies with longer follow-up, and larger samples are necessary to examine the role of nintedanib on lung fibrosis.
RSF as important: steroid duration, total joint count (TJC), study site, maximum steroid dose, ICI type, shoulder arthritis, >1 DMARD and number of IRAEs. For classifying arthritis control, the following variables were found to be important in both sCART and RSF: steroid duration, >1 DMARD, elbow arthritis, age, cancer type, TJC and first DMARD (Table 1). The Figure 1 shows the sCART for arthritis control.

**Conclusion:** Both methods, sCART and RSF, demonstrated the important influence of steroid duration on arthritis control and cancer progression. Machine learning methods demonstrated the potential prognostic importance of specific joint involvement for each outcome - knee for time to arthritis control and shoulder and wrist for cancer progression.

Conclusion: The results of our study demonstrate a high prevalence of low handgrip strength, up to 79% among young patients with JIA. In these participants, lower BMI, lower total BMD and arms, legs, total lean mass and SMI, longer disease duration, higher disease activity by JADAS27 and articular index damage JADAI-A, and higher percentage fat were linked to reduced handgrip strength.
as well as blood samples for biobanking, are collected at study visits at baseline and after 3,6 and 12 months. Patients are treated at the discretion of the treating rheumatologist in collaboration with the oncologist.

**Results:** Between August 2018 and January 2023 56 patients have been included at 4 centers (DH, UNN, ÅH, HSN). 49 patients had de novo disease and 7 patients had flare of preexisting rheumatic disease (RA n=5, PsA n=2). Polyarthritus was the dominant phenotype in 45% of the patients followed by olioarthritus and monoaarthritus (Figure 1). Joint distribution was heterogenic: 7 patients were positive for RF/anti-CCP, of whom 5 had preexisting RA. Disease characteristics at baseline are presented in Table 1. The mean Clinical Disease Activity Index (CDAI) score was 18, corresponding to a level of moderate disease activity. Throughout the study period anti-rheumatic treatment has been given to the following proportions of patients: i.a steroid injection:45%, prednisolone: 71%, methotrextate: 30%, anti-TNF: 21%, tocilizumab: 1.7%, seukinkumab: 1.7%, ustekinumab: 1.7%, lefunomide: 1.7%, apremilast: 1.7%. Death has been registered in 13 (23%) patients, of whom 10 patients had received prednisonone, 3 patients had received methotrextate and 1 patient had received anti-TNF treatment.

**Background:** Autoimmune inner ear disease (AIED) is a rare entity that presents with sensorineural hearing loss. In the US, the incidence rate is less than 5 per 100,000 people [1]. The pathophysiology behind the disease is thought to be a humoral and cell-mediated process that damages the cochlea [2]. Clinical presentation is characterized by fluctuating, asymmetric hearing loss that tends to progress over time. Half of patients with AIED present with vestibular (eg, dizziness, vertigo, imbalance) and other ear symptoms (eg, tinnitus, ear pressure and aural fullness) [2,3]. Diagnosis of AIED remains challenging as no diagnostic test has demonstrated high sensitivity or specificity [1]. Diagnosis remains clinical and based on response to corticosteroids, which suggests the disease’s autoimmune nature. Corticosteroid-sparing agents have been used with various degrees of success [1-4].

**Objectives:** The aim of our study was to describe our experience treating patients with AIED with immunosuppressive therapy.

**Methods:** We performed a retrospective chart review of patients diagnosed with AIED at all Mayo Clinic locations for the past 10 years. AIED was diagnosed based on 3 main characteristics: progressive fluctuating hearing loss, response to high-dose corticosteroids, and audiometric evidence supporting sensorineural hearing loss. We recorded audiography results at the time of diagnosis and 1 and 3 months after treatment. We divided treatment efficacy into 2 categories: subjective (patient-reported) and objective (audiometric) improvement.

**Results:** Thirty-one patients met the inclusion criteria; the mean age was 48.5 years and 17 were women. Patients were initially evaluated by the Department of Otorhinolaryngology and 29 patients were subsequently referred to the Department of Rheumatology with a mean of 12.2 weeks after the first evaluation. While initial hearing loss was more commonly unilateral (21 [67.7%]), it remained unilateral in only 8 (25.8%) patients. Tinnitus, aural fullness, and ear pressure were the 3 most common ear symptoms, followed by imbalance, vertigo, dizziness, and discharge. Treatment with corticosteroids showed improvement of hearing and vestibular symptoms during the first month, but no further improvement by the end of the third month. Other immunosuppressive medications were used with various degrees of response (Table 1). Methotrextate was the second most used therapy with 11 of 17 patients reporting an improvement in symptoms.

**Conclusion:** Prompt treatment of these patients is vital to prevent irreversible hearing loss. Corticosteroids remain the criterion standard initial treatment; however, our study supports potential use of corticosteroid-sparing agents such as methotrextate for long-term therapy. Our study has some limitations including small patient population and a retrospective design.

Objectives: This cohort study aims to describe the prevalence and features of systemic phenotype of pericarditis characterized by pleurapulmonary involvement, fever, and elevation of C-reactive protein (CRP), comparing this phenotype with other forms of pericarditis.

Methods: All patients in our center were enrolled in a prospectively maintained registry from 2019 to 2022. 412 patients with idiopathic recurrent pericarditis were analyzed. “Systemic” subset was defined as the presence of all of the following criteria: fever > 38 °C, CRP higher than 2 times normal values, pleural effusion detected with any imaging techniques. The absence of any of the 3 criteria was defined as “isolated” subset.

Results: We found that 211 (51.2%) of 412 patients presented the systemic subset and the variables significantly associated with this subset in univariate analysis (p<0.001) were: higher mean age of onset 45.5 (±SD 16.4) years, higher mean CRP values 128.8 (95% CI 117.8-139.8) mg/L, higher proportion of pericarditis with 10 (19%) or 3 (1.5%), higher mean leukocyte count 13143.3 (95% CI 12790.4-13496.2) vs 9910.3 (95% CI 9556.2-10264.4)/mm³, higher mean neutrophil number 10402.5 (95% CI 10082.1-10723) vs 6779.8 (95% CI 6505.2-7054.4)/mm³ and lower mean lymphocyte count 1693.9 (95% CI 1621.9-1765.8) vs 2079.3 (95% CI 1979-2179.6)/mm³. As results the neutrophil-to-lymphocyte ratio was higher in systemic phenotype: 6.5 (95% CI 6.2-6.9) vs 3.4 (95% CI 3.3-3.6). Anti-IL1 therapy was started more frequently in the systemic subgroup (55/211, 26%) than in the isolated subset (15/201, 7.5%) (p<0.001). On multivariate analysis neutrophil count and lymphopenia, were statistically associated with the systemic subset (p < 0.001).

Conclusion: These results demonstrate the clinical relevance of the systemic phenotype in a referral center and confirm its analogy with the autoinflammatory diseases, suggesting a pivotal role of IL1 in the genesis of this subset.

SOLVING SARCOIDOSIS: A TRANSCRIPTOME-BASED META-ANALYSIS OF CLINICAL SARCOIDOSIS STUDIES ILLUSTRATES SHARED PATHOPHYSIOLOGY, EXAMINES MEDIATORS OF FIBROSIS, IDENTIFIES CANDIDATE BIOMARKERS AND SUGGESTS A THERAPEUTIC MECHANISM OF JAK INHIBITION

Keywords: -Omics, Biomarkers, Rare/orphan diseases

J. Lindquist1, J. Rosenbaum2, M. Friedman. 1Oregon Health and Science University, Arthritis & Rheumatic Diseases Division, Portland, United States of America; 2Legacy Devers Eye Institute, Ophthalmology, Portland, United States of America

Background: Sarcoidosis is a systemic, non-caseating granulomatous disease driven by a dysregulated immune response to environmental antigens. Disease manifestations are driven by both active inflammation and resultant fibrosis in a wide variety of tissues, but the dynamics and mediators of these two states are not well understood. Diagnosis relies on imaging and biopsy and treatment typically includes steroids. JAK inhibitors have been utilized as steroid-sparing therapies for cutaneous and pulmonary sarcoidosis, however the mechanism is unclear.

Objectives: We performed a meta-analysis of 20 transcriptome studies on clinical sarcoidosis to explore perturbed pathways, examine mediators of fibrosis, prioritize candidate biomarkers, and study the JAK/STAT pathway.

Methods: We searched publicly available data repositories for clinical sarcoidosis datasets with healthy controls and at least 3 biological replicates evaluated with transcriptome analysis and found 20 studies (14 microarray and 6 RNAseq), comprising 316 sarcoidosis patients and 383 healthy controls. The majority of samples came from peripheral blood; tissue-based samples included lung, skin, anterior orbit, lacrimal gland and lymph nodes. We performed differential gene expression on each of the 20 studies independently with Limma (microarray) and DESeq2 (RNAseq). Results were merged for the 17,705 genes that were evaluated by at least 9 of the studies. For microarray studies, data from the probe with lowest adjusted p-value and largest absolute fold change (FOLD) was selected. Genes were selected for pathway enrichment analysis if at least 10 studies identified them as differentially expressed. Candidate biomarkers were genes that were consistently differentially expressed in both tissue and peripheral samples with a fold change magnitude of at least 1.5x. Pathway enrichment analysis was performed with Reactome. We mined our dataset with 232 fibrosis related genes identified by the FibROAD project and the 11 central genes of the JAK/STAT pathway.

Results: We prioritized 2,349 genes that were differentially expressed in the majority of the datasets. Unsupervised clustering of these studies showed a distinct difference between peripheral and tissue sample types. Of the 15 biomarker candidates, some have been associated with sarcoidosis (ie STAT1, ITGA6, LEP1) and others have been reported in tuberculosis (ie GBP5, ANKRD22), however the majority have not been associated with either (ie RHOH, SPTBN1, UBASH3A). Pathway enrichment identified significant perturbation of interferon signaling and antigen presentation which supports two established mechanisms of sarcoid pathophysiology: an abnormal TH1 response and existence of MHC risk alleles. Qualitative exploration of the JAK/STAT pathway (Figure 1) shows a predominant upregulation of the pathway, most strongly in STAT1 and JAK2. We prioritized 25 fibrosis related genes that were significantly differentially expressed in at least 10 of our studies and included STAT1, HBEFG, FOXP1 and JAK2.

Conclusion: This meta-analysis summarizes the current transcriptional landscape of sarcoidosis, including pathophysiology, mediators of fibrosis, biomarkers and therapeutics targeting the JAK/STAT pathway. We hypothesize that JAK2 may be an important therapeutic target for sarcoid by disrupting the JAK/STAT component of an abnormal TH1 response as well as a possible JAK2/STAT1 associated fibrosis mechanism.

Reference: Cited inline.

Figure 1. Meta-analysis of 11 JAK/STAT pathway genes show significant differential expression which is most notable in STAT1, JAK2 and STAT2. Red indicates higher expression (log2FC change) in sarcoid compared to control.

OUTCOMES AND PREDICTORS OF CHRONIC IMMUNE CHECKPOINT INHIBITOR INDUCED INFLAMMATORY ARTHRITIS: DATA FROM THE CANADIAN RESEARCH GROUP OF RHEUMATOLOGY IN IMMUNO-ONCOLOGY (CARI) RETROSPECTIVE COHORT

Keywords: Inflammatory arthritides, Malignancy, Prognostic factors

A. Ladouceur1, L. Gonzalez Arreola2, S. Jamai2, M. Hudson2, J. Pope3, S. Hoa4, J. Roberts5, D. Moon6, A. Karmali2, T. Nevskaya3, E. Schmidt1, N. Toban8, L. Cho2, T. Barnetche1, C. Yé6, McGill University, Medicine, Montreal, Canada; 2University of British Columbia, Medicine, Vancouver, Canada; 3University of Western Ontario, Medicine, London, Canada; 4Université de Montréal, Medicine, Montréal, Canada; 5Dalhousie University, Medicine, Halifax, Canada; 6University of Alberta, Medicine, Alberta, Canada; 7CHU de Bordeaux, France
Background: Immune checkpoint inhibitors (ICI) improve overall survival and progression-free survival in many types of malignancies and are the new pillar of cancer treatment [1]. ICIs harness a patient’s own immune system to fight their cancer. However, this activation of the immune system can result in off-target immune-related adverse events (irAEs). One of the most disabling irAE is inflammatory arthritis (ir-IA) [2] affecting up to 75% of those treated with ICI [3]. Unlike most irAE which usually resolve within a few months, ir-IA can become chronic and persist even after ICI cessation, requiring long-term immunosuppression [4]. The factors associated with chronic ir-IA and its significance regarding tumor outcomes remain largely unknown. With the increasing use of ICI in the adjuvant therapy, it is important to understand predictors and outcomes of chronic ir-IA in order to best counsel patients.

Objectives: To determine predictors and outcomes of chronic ir-IA in cancer patients exposed to ICI.

Methods: The CanRIO group, established since 2018, includes 9 academic sites in Canada and aims to describe the clinical presentation, management and outcomes of patients who developed rheumatic irAE (Rh-irAE) or those with pre-existing autoimmune diseases exposed to ICI using standardized data collection. The sites pooled data to develop a retrospective cohort of patients identified as having a Rh-irAE. We identified patients who developed ir-IA defined by new onset joint tenderness or synovitis in the absence of pre-existing rheumatic disease and who had at least 3 months of follow-up following ICI cessation. Chronic ir-IA was defined as having either persistent symptoms of ir-IA or the continued use of prednisone or DMARDs 3 months after ICI cessation.

Results: The CanRIO Retrospective Cohort included 193 ir-IA individuals of which 54 met our inclusion criteria. Forty-five of 54 (83%) had chronic ir-IA. Fifteen (33%) were female. Nineteen (42%) patients with chronic ir-IA had melanoma, 14 (31%) lung cancer and 8 (18%) genito-urinary cancer. Thirty-three (73%) were treated with anti-PD-1/PD-L1, 14 (31%) with combination and none with anti-CTLA-4 only. Thirty-five (78%) were treated with conventional DMARDs and 1 (2%) with biologic DMARDs. Univariable logistic regression showed that ir-IA was more likely to become chronic in those with peripheral synovitis compared with those who did not have peripheral synovitis at presentation, (Table 1). Patients with chronic ir-IA had greater overall survival and progression-free survival compared with those with acute ir-IA (log rank tests, p<0.01), (Figure 1).

Conclusion: A large proportion of ir-IA becomes chronic. The presence of synovitis at presentation is associated with arthritis persistence. Ir-IA is associated with improved overall survival and progression-free survival.

**Conclusion:** Anakinra was found to be a safe and effective agent against colchicine-resistant pericarditis, notably recurrent pericarditis. Long-term treatment should be anticipated when initiating treatment and dose tapering should be kept in mind for patients in remission. Relapses should be watched for attentively in tapering and anakinra should be resumed promptly in case of a recurrence. Furthermore, anakinra is important in sparing cortisone treatment.

**CONTRIBUTION OF GENETIC ANALYSIS TO THE DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER**

**Keywords:** Genetics/epigenetics

H. Akar1, D. Gün Bilgic2, O. Soysoy Gündüz3, Manisa Celal Bayar University, Internal Medicine, Manisa, Turkey; Manisa Celal Bayar University, Medical Genetics, Manisa, Turkey; Manisa Celal Bayar University, Rheumatology, Manisa, Turkey

**Background:** Familial Mediterranean fever (FMF) affecting mainly Mediterranean and Middle Eastern populations is an autosomal recessive hereditary disease caused by mutations in the Mediterranean fever (MEFV) gene. It is characterized by periodic attacks of fever and inflammation affecting serosal membranes. The most common symptoms of the disease are fever, abdominal pain, arthritis, erysipelas-like erythema, pleuritis, and pericarditis. Patients are usually treated by life-long colchicine, which has been shown to be effective in preventing the attacks of FMF as well as the development of amyloidosis. FMF diagnosis remains often difficult due to the lack of pathognomonic laboratory findings. The definitive clinical classification of FMF is made by Tel Hashomer criteria [1]. Genetic analyses may support the clinical diagnosis of patients for mutation complications.

**Objectives:** This study aimed to not only investigate the contribution of MEFV mutations to FMF diagnosis but also to show whether there is a phenotype-genotype correlation in the same patient population.

**Methods:** We evaluated 12 MEFV gene mutations screened with a commercial kit based on real-time polymerase chain reaction technique in 1064 adults between January 2016 and November 2021. We were able to interview 208 of 484 people with AAA mutations by telephone. We investigated whether they were diagnosed with FMF according to Tel Hashomer criteria or clinician opinion, and whether they had previously used colchicine before IL-1 inhibitor treatment. The rate of giving colchicine with the diagnosis of FMF in patients with MEFV mutation (39.7%) was found to be significantly higher than those without mutation (p=0.001). Of the 208 patients with genetic mutations which we interviewed by telephone, 89 (42.8%) met the Tel Hashomer criteria. The most detected mutations in patients meeting Tel Hashomer criteria were M694V (46.1%), M680I (24.7%), V726A (8.9%), and E148Q (8.9%) respectively. The positive significant associations were found between M694V and M680I homozygous mutations and definitive diagnosis according to Tel Hashomer criteria (p=0.001, p=0.021, respectively). A negative correlation was found between E148 heterozygous mutation and diagnosis (p=0.002). When the relation between genetic mutations and clinical findings was examined, it was shown that there was a positive correlation between fever and M694V, and between abdominal pain and M680I (p=0.000, p=0.007, respectively). Patients with the E148Q mutation had significantly less fever and abdominal pain (p=0.026, p=0.017, respectively).

**Conclusion:** Considering that approximately one-fifth of those undergoing genetic testing are diagnosed with FMF, it can be concluded that unnecessary genetic testing is performed in our hospital. In clinical practice, the presence of MEFV gene mutations M694V and M680I is helpful for FMF diagnosis. E148Q mutation were not been found to be associated with both the diagnosis and the clinical findings. Genetics plays a critical role in confirming the diagnosis, but it should never take the place of a clinical diagnosis. The clinicians should be aware of the indications and limitations of genetic testing and know how to interpret the results.

RESULTS:

Methods:

Objective: In addition to IS treatment, usually, 7.5-30 mg/day prednisolone was administered for ILD was more frequently initiated for patients with NSIP than for UIP. The study found that female patients had a higher prevalence of ILD compared to male patients in terms of gender among patients with UIP. Immunosuppressive (IS) treatment prior to ILD, 20 (13.3%) patients were diagnosed with ILD prior to CTD, and 54 (35.5) patients had non-CTD. According to computed tomography findings, 86 (57.7%) patients had non-CTD, 20 (13.3%) patients were diagnosed with ILD prior to CTD, and 54 (35.5) patients had non-CTD.

Background: Interstitial lung disease (ILD) is a critical manifestation of connective tissue diseases (CTDs) that may cause morbidity and mortality.

Objectives: This study aimed to evaluate the clinical and demographic characteristics and treatment of the patients who had CTD-related ILD.

Methods: This retrospective observational study includes patients who followed up with CTD-related ILD in a tertiary rheumatology outpatient clinic between January 2020 and December 2022. Patients’ files were assessed retrospectively for demographic, clinical, and radiologic data.

Results: There were 149 patients (86 Female/53 Male) with a mean age of 62.6±11.8. The CTD types of the patients were Sjogren’s syndrome (SS) in 49 (32.7%) patients, rheumatoid arthritis (RA) in 47 (31.3%) patients, systemic sclerosis (SSc) in 50 (26.7%) patients, undifferentiated CTD in 9 (6%) patients, inflammatory myositis in 6 (4%) patients, and systemic lupus erythematosus (SLE) in 4 (3%) patients. The median disease duration was 62.6±11.8 months for ILD. Patients with NSIP were more frequent in the SSc group (48 patients, 32.2%), followed by RA patients with NSIP (42 patients, 28.1%), and then patients with RA patients with LIP (7 patients, 4.5%).

Gender, n (%) 2 (2.3) 1 (2.1) 0 (0) 0 (0)

RA = Rheumatoid arthritis, SSc = Systemic sclerosis, LIP = Lymphocytic interstitial pneumonia, OP = Organizing pneumonia, LIP = Lymphocytic interstitial pneumonia, n = number of patients, CTD = Connective tissue disease, ILD = Interstitial lung disease, NSIP = Non-specific interstitial pneumonia, UIP = Usual interstitial pneumonia, OP = Organizing pneumonia, LIP = Lymphocytic interstitial pneumonia, mean ± standard deviation.

Conclusion: ILD is a critical manifestation of CTDs. IS biologic treatment options may be required during the management of CTD-related ILD.

Methods:

Objective: The study aimed to evaluate the clinical and demographic characteristics, treatment, and outcomes of patients with FMF over 50 years of age.

Methods: This retrospective analysis was conducted at the University of Health Sciences, Gulhane Faculty of Medicine, Pulmonology, Ankara, Turkey. The study included 149 FMF patients over 50 years of age. The demographic and clinical characteristics of the patients were assessed, and the outcomes of treatment were analyzed.

Results: The study found that 96 (64.4%) patients were female, and the mean age was 62.6±11.8 years. The most common CTD types included SS in 49 (33.7%) patients, RA in 22 (14.8%) patients, SLE in 7 (4.7%) patients, and undifferentiated CTD in 9 (6%) patients. The median disease duration was 58 (24-134.5) months for ILD, 35.5 (12-65.8) months for ILD.

Keywords: Real-world evidence, Rare/orphan diseases, Inmate immunity
Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany. Patients with clinically confirmed diagnoses of TRAPS who routinely receive CAN are enrolled to evaluate efficacy and safety of CAN. The study is based on standard clinical practice conditions. Disease remission by physicians’ assessment, disease activity and fatigue by patients’ assessment, days absent from school/work due to study indication, and inflammatory markers were assessed at baseline and at 6-monthly intervals.

Results: The interim analysis of TRAPS patients enrolled by December 2022 includes data from baseline (N=21), 18- (N=12) and 30-month visits (N=10). At baseline, median age was 15 years (3–43 years) and median duration of prior CAN treatment was 1 year (0–4 years). The proportion of female patients was 67%. At month 30, 3 patients received standard dose CAN, 4 patients greater than standard dose CAN and 2 patients lower than standard dose CAN. Preliminary results indicate stable remission by physicians’ assessment (in 62.5% of patients), low disease activity by patient’s assessment (1.5 out of 10) and inflammatory markers within normal limits (Table 1). However, a fatigue score of 4 out of 10 might contribute to the impairment of social life reported by patients. One patient was affected by N=9 serious adverse events, none of which was classified as drug related.

Conclusion: The present interim data from TRAPS patients indicate that long-term CAN treatment is safe and effective. Patient reported fatigue and impairment of social life leave room for further improvement. Further RELIANCE interim and end-of-study data will be analyzed to assess efficacy and safety of long-term CAN treatment in patients with TRAPS.

Figure 1. Skin manifestations in SAPHO syndrome.
The course of the disease was mostly recurrent (54%) with asymptomatic periods between flare-ups. About half of the patients (44%) in follow-up currently have active disease.

**Conclusion:** Our cohort presented axial involvement like other series and significant peripheral involvement. The most frequent skin condition was PPP. Half of the patients in our cohort required bDMARD, with ABL being the most widely used.

**Objectives:** This report describes an atypical initial presentation of peri-orbital inflammation and neurological manifestations associated with this newly recognized syndrome.

**Methods:** This is a case report.

**Results:** An 82-year-old male with insulin-treated diabetes mellitus type II, protein-tapering hyperplasia and chronic atrial fibrillation, presented with persistent unilateral peri-orbital swelling and pain for 6 months. An initial evaluation in the ophthalmology department with biopsy showed no evidence of malignancy, myositis, vasculitis, or IgG4-related disease. Due to significantly elevated inflammatory markers (CRP 250-300mg/L, ESR around 100 mm/h), the patient received high-dose glucocorticoids (60 mg Prednisolone) with a good clinical response. During the tapering of Prednisolone, the patient developed a maculopapular skin rash in the lower extremities. Skin biopsy showed signs of urticaria-like dermatitis, while immunofluorescence examination was negative. In the following months, he was hospitalized three times due to recurrent fever, generalized weakness, fatigue, and general asthenia. Extensive evaluation regarding infectious and non-inflammatory causes was negative. An extensive autoimmune panel (including ANA and ANCA) was tested and came out negative. CT scan of the thorax and abdomen was unremarkable. During the last hospitalization, he developed expressive aphasia and facial paresis. MRI of the brain showed signs of leptomeningeal enhancement. Examination of the cerebrospinal fluid showed pleocytosis (leucocyte count 124, with monocytes), while all cultures were negative. He came to the rheumatology department in November 2022 for further evaluation. He had generalized myalgias and arthralgias but no arthritis. The skin rash had disappeared. The inflammatory markers were still highly elevated and he had a mild anemia, normocytic and normochromic, but no thrombocytopenia or leukopenia. PET-CT scan showed hyperactive bone marrow, while subsequent biopsy showed normal hematopoiesis without signs of dysplasia and no vacuoles. Endoscopic evaluations revealed no pathological findings. Prednisolone was re-introduced after PET-CT with good regression of the symptoms. Repeated MRI of the brain showed regression of the area with enhancement while all neurological symptoms had subsided. A few weeks later, we received the result of the genetic testing showing a mutation of the UBA1 gene, confirming the diagnosis of VEXAS. Our patient had already started methotrexate as a cortisone-sparing agent and started tapering off Prednisolone, so far with reasonable clinical response.

**Conclusion:** VEXAS syndrome should be suspected in elderly patients (especially males) with systemic inflammation when other common conditions are excluded. Orbital/periorbital inflammation and neurological manifestations can occur and should raise the suspicion of VEXAS.

**Methods:** Bilateral lower extremity common femoral veins (CFV) were examined with Doppler ultrasound in cranio-caudal direction for the presence of thrombi, occlusion, venous insufficiency, and arterial occlusive disease. WTV was measured using the methodology described by Alibaz-Oner F et al. [1]. All measurements were performed thrice, and the arithmetic mean of them was given as the result. We also assessed the internal jugular vein (IJV) in one patient but not in the other due to the jugular veins catheter. VEXAS patients had thickened walls on ultrasound in all examined large veins.

**Results:** Demographic and clinical features of the VEXAS patients are presented in Table 1. WTV in BS seemed significantly greater than non-inflammatory DVT (0.34±0.1 mm) but not significant with the anti-phospholipid syndrome (APS, 0.49±0.1 mm) [2]. Our VEXAS patients had WTV greater than BS and APS suggesting remarkable vein inflammation. Patients with extensive thrombosis (Case#1) had the most severe WTV of CFV on the affected side, while the latter case (Case#2) had equivalent WTV in both CFVs.

**Conclusion:** Consequently, our findings suggest that venulitis might be one of the features of VEXAS syndrome and the underlying mechanism for thrombosis. Further studies are needed to clarify the role of inflammation in venous thrombotic diseases.

**Background:** VEXAS syndrome is an often fatal, X-linked disease characterized by hematological dysplasia overlapping with severe autoimmune manifestations. Thrombosis, predominantly as unprovoked venous thrombosis, has been reported in up to 56% of VEXAS patients. Although chronic inflammation, vasculitis, endothelial dysfunction, disrupted anticoagulant mechanisms, or thrombotic antibodies are suggested mechanisms, the exact pathogenesis of thrombosis is yet to be elucidated. VEXAS has clinical similarities with Behcet’s syndrome (BS), a systemic vasculitis involving arterial and venous vessels of all sizes. Recently, venous wall thickening (WVT) on Doppler ultrasound has been shown to be a highly sensitive and specific (>80%) finding for the diagnosis of BS. Given the clinical and pathological similarities with BS, we thought venulitis might be the underlying cause of thrombosis in VEXAS syndrome.

**Objectives:** Herein, we report venulitis in two consecutive VEXAS patients with the demonstration of severe thickening of the walls of large veins.

**Methods:** Bilateral lower extremity common femoral veins (CFV) were examined with Doppler ultrasound in cranio-caudal direction for the presence of thrombi, occlusion, venous insufficiency, and arterial occlusive disease. WTV was measured using the methodology described by Alibaz-Oner F et al. [1]. All measurements were performed thrice, and the arithmetic mean of them was given as the result. S. Bindoli1, E. Bertoldi2, A. Doria1, C. Baggio1, P. Sfriso1. 1University of Padova, Rheumatology Unit-Department of Medicine, Padova, Italy; 2University of Verona, Rheumatology Unit-Department of Medicine, Verona, Italy

Background: VEXAS syndrome is a novel described autoinflammatory entity for which the diagnosis is defined by somatic mutations in the UBA1 X-linked gene in hematopoietic progenitor cells. The clinical manifestations are heterogeneous, ranging from autoinflammatory symptoms to the presence of underlying hematologic disorders. Response to treatment in VEXAS is very poor and to date the therapeutic strategies adopted are only partially effective. However, recently described cohorts of VEXAS patients treated with Janus-Kinases Inhibitors (JAK-kin) demonstrated that these drugs can be effective for the treatment of several manifestations related to the disease.

Objectives: To describe the case of a 65-year-old man affected by VEXAS who was successfully treated with the selective JAK-1 inhibitor filgotinib.

Methods: We present the case of a 65-year-old man, diagnosed with a myelodysplastic syndrome (MDS) grade 3, sec WHO, 2016) one year earlier, presenting with a recent history of leukocytoclastic vasculitis, deep vein thrombosis, tenosynovitis, and ear chondritis. He was admitted to the hospital for hyperpyrexia (39° TC), increased inflammatory markers, macrocytic anemia with Hb 7.7 g/L and MCV 104 fL and requiring multiple blood transfusions, and shortness of breath caused by a pleural effusion; after excluding neoplastic conditions, infections, and other potential mimickers (such as vasculitis), a genetic analysis was performed, revealing the somatic mutation Met41Leu (c.121A>C) in the UBA1 gene. Methylprednisolone was started from 16 mg/day (not reducible for recurrent flares). A peripheral blood smear was stained with May Grunwald-Giemsa stain- ing to perform a cytogenic evaluation of leucocytes. Oil immersion microscopy with 1000× magnification was applied for the analysis.

Results: Following the diagnosis of VEXAS, the patient started filgotinib 200 mg/ day, with a subsequent clinical and biological improvement that allowed for a slow reduction of glucocorticoids. After 15 month his laboratory exams showed: Hb 9.4 g/L, MCV 106 fL, C-reactive protein (CRP) 2.24 mg/dL. At peripheral blood smear, the patient had granulocytes with morphological changes, including cytoplas- mic vacuoles (2%), immature neutrophils (28%) such as band neutrophils, hyposegmentated neutrophils, and pseudo Pelger Huët-like morphology. Vacuol- ated/activated monocytes (4.5%) and nuclear abnormality (bincucleated cells, buds) were also observed.

Conclusion: VEXAS syndrome is a new genetically-determined rare disease that requires a prompt treatment to avoid a rapid worsening. Glucocorticoids often represent the first line therapy and blood transfusion support is usually required; however, given the promising results derived from recently published cohorts, JAK-inhibitors, in particular selective JAK-1 (filgotinib, upadacitinib), or JAK2/3 blockers (ruxolitinib), may represent a suitable therapeutic approach.

VEXAS SYNDROME IN A PATIENT WITH BIOPSY POSITIVE GCA AND IMAGING PROVEN LARGE VESSEL VASCULITIS TREATED WITH TOCILIZUMAB

Keywords: Comorbidities, Vasculitis, Rare/orphan diseases

A. Uogwe1, J. Keay1, A. Zariff1, E. E. P. Hutt1. 1Cambridge University Hospitals, Rheumatology, Cambridgeshire, United Kingdom

Background: VEXAS syndrome (Vaccules, E1 enzyme, X-linked, autoinflamma- tory, somatic) was first reported in late 2020 in 25 men, mostly in their fifth decade of life or after, with adult-onset concomitant autoinflammatory disease and myeloid dysplasia (Beck et al., 2020). It is the first for a proposed new subset of haematological/autoinflammatory diseases and its underlying pathophysiology is thought to be governed by monogenic, somatic missense mutations affecting Met-41 of the myeloid-restricted UBA1 gene. This results in deranged cellular ubiquitination and a broad range of clinical manifestations (Beck et al., 2020).

Objectives: We describe the case of a patient with the ultimate unifying diagnosis of VEXAS syndrome with an initial presentation of cranial GCA and PET-CT proved large vessel vasculitis. Immunosuppressive regime was challenging due to patient co-morbidities including brittle diabetes and myelodyplastic syndrome.

Methods: Case report.

Results: A 73-year-old gentleman with a history of type 2 diabetes mellitus was admitted with persistent fever, recurrent orbital swelling, thrombophlebitis and severe weight loss of 30kg over 24 months. A wide infectious screen revealed no source with ongoing symptoms despite antibiotic therapy.

Prior review at the bone marrow failure clinics had revealed a macrocytic anae- mia with a Haemoglobin of 96g/L, MCV of 105.1FL and thrombocytopenia of 117 X10^9. Bone marrow biopsy revealed hypercellularity with trilineage dyspla- sia however genetic screening did not detect the UBA1 missense mutation. CT scan revealed perivascular stranding and thickening around the origin of the right carotid and subclavian artery. PET CT scan showed high tracer uptake in the wall of the ascending aorta, subclavian, carotid arteries and bone marrow. New onset headache, jaw pain, scalp tenderness and shoulder stiffness prompted a tempo- ral artery biopsy which revealed lymphohistiocytic inflammatory infiltrates in the intima with focal loss of internal elastic lamina. 60mg of prednisolone led to dra- matic resolution of symptoms and inflammatory markers. A diagnosis of VEXAS was revisited due to the unique combination of inflammatory and haematologi- cal features.Repeat bone marrow biopsy using a newer version of haem oncol- ogy gene panel was positive for UBA1 missense variant in exon 3 (c.122T>C, p.Met41Thr.). Vacuoles were found to be present on erythroid precursor cells. He developed fatigue, rashes and CRP >100 on tapering down prednisolone to 20mg OD. SC Tocilizumab was introduced rather than Methotrexate and Leflunomide due to bone marrow failure. SC Tocilizumab was switched to Intravenous form to optimise bioavailability. He is clinically stable on IV tocilizumab with slower wean of steroid. He suffers with heavy burden of steroid toxicity, including weight gain, erratic blood sugars, steroid induced acne, hypertension and recurrent infection.

Conclusion: VEXAS, should be explored as a potential unifying diagnosis in conditions of overlap between autoinflammatory and haematological condition. Treatment paradigm is still evolving with no current standardised regime hence fraught with uncertainty between high risk of morbidity/mortality from uncontrol- lored and poorly treated inflammation versus iatrogenic complications from ster- oid therapy. There is a research gap pertaining to patient cohorts with specific patterns of systemic disease.

A CASE SERIES OF VEXAS SYNDROME IDENTIFIED IN THE WEST MIDLANDS, UNITED KINGDOM

Keywords: Rare/orphan diseases

M. Ford1, T. Khan1. 1Warwick Hospital, Rheumatology, Warwick, United Kingdom; 2Birmingham City Hospital, Rheumatology, Birmingham, United Kingdom

Background: VEXAS (vaccules, E1 enzyme, X-linked, autoinflammatory, somatic syndrome) was first described in 2020 when a mutation in ubiquitin activ- ating enzyme 1 (UBA1) was identified in three patients [1]. This adult-onset autoinflammatory and haematological disease primarily affects males over the age of 50 years. The clinical features are diverse but commonly include skin lesions, non-infectious fever, weight loss, lung involvement, arthralgia/arthritis, relapsing chondritis, ocular symptoms, venous thrombosis, and lymphadenopa- thy. Most corticosteroids are effective, high doses are often required to con- trol the disease and the ideal standard of care, including the choice and efficacy of steroid-sparing agents, is yet to be defined.
**Objectives:** After identifying three cases of VEXAS in our region within a 6-month period, our objective was to present each case alongside the current knowledge of the condition in order to increase the awareness amongst clinicians.

**Methods:** We examined each case, comparing the clinical features, investigations, management, and events leading to the diagnosis.

**Results:** The cases are presented in the table below.

HPR Patients’ perspectives, functioning and health (descriptive: qualitative or quantitative)

Keywords: Vitamin D, Systemic sclerosis, Systemic lupus erythematosus

F. Sarı1, D. Saracı2, S. Bayram3, S. Bagılan Yentür4, N. G. Toren5, D. Oskay6, A. Tufan7
1Bingöl University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Bingöl, Turkey; 2İzmir Kâtip Çelebi University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, İzmir, Turkey; 3Gazi University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Ankara, Turkey; 4First University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Elazığ, Turkey; 5National Human Genome Research Institute, Inflammatuar Disease Section, Rockville Pike, United States of America

Background: Vitamin D is one of the fat-soluble vitamins and is also a group of sterols that are hormone and hormone precursors. Vitamin D deficiency and/or insufficiency have been found to be associated with many chronic diseases, including cancer, metabolic syndrome, and autoimmune diseases. Vitamin D is involved in modulation of immune responses in autoimmune disorders including multiple sclerosis, asthma, diabetes mellitus, connective tissue disorders such as rheumatoid arthritis (RA) or systemic lupus erythematosus (SLE). In addition, previous studies conducted in other patient populations indicate that higher vitamin D levels are related to higher exercise capacity, muscle strength, and better lung function.

Objective: The purpose was to investigate the effects of vitamin D deficiency on exercise capacity, respiratory muscle strength, and peripheral muscle strength in patients with connective tissue disease (CTD).

Methods: This cross-sectional observational study included CDT (SLE and systemic sclerosis (SSc)) patients and healthy participants. Serum 25(OH)D, calcium, and phosphorus levels were measured and Vitamin D levels 10.0-20.0 ng/mL defined insufficiency and levels <10.0 ng/mL defined deficiency. The exercise capacity, respiratory muscle strength, and peripheral muscle strengths were set as the primary outcomes of the study. Secondary outcomes included evaluation of physical activity, dyspnea, pain, emotional status, fatigue, and quality of life.

Results: There were 23 SLE (36.8±10.06), 21 SSc (44.38±14.63), and 24 healthy controls (37.62±11.74). Compared to healthy controls, CTD groups with vitamin D deficiency had significantly lower respiratory muscle strength (p<0.001), peripheral muscle strength (knee extension and shoulder flexion) (p<0.05), exercise capacity (p<0.05), physical activity (p<0.05), and quality of life (p<0.05) while having significantly more dyspnea (p<0.001), pain (p<0.01), fatigue (p<0.001), anxiety, and depression (p<0.05).

Conclusion: The results of our study indicate that vitamin D deficiency is associated with reduced muscle strengths and related symptoms and complaints in CTD patients, hence, in order to increase the efficacy of rehabilitation and treatment programs, attention should be paid to vitamin D levels and should be corrected appropriately.

POS1583-HPR | IMPACT OF TELERHEMATOLOGY ON EXERCISE CAPACITY, RESPIRATORY MUSCLE STRENGTH, AND PERIPHERAL MUSCLE STRENGTH IN PATIENTS WITH CONNECTIVE TISSUE DISEASES

Keywords: Systemic lupus erythematosus, Outcome measures, COVID

L. Almalıoh1, H. Almalez2, H. Alzuhairi3, A. Bedawi4, L. Hassen1, S. Alzomia1, B. Alani3, S. Alahmar1, K. N. Astina1, N. Khalili1, M. A. Omaïr1, M. Bedawi1, 1King Saud University, Rheumatology Unit, Department of Medicine, Riyadh, Saudi Arabia; 2King Saud University, Clinical pharmacy, Riyadh, Saudi Arabia

Background: The utilization of telemedicine has been rapidly growing among patients with rheumatic disease especially following COVID-19 pandemic. The ease and convenience seems to dominate the reasons of such growth. Yet the effect of this approach on patients with systemic lupus erythematosus (SLE) is yet to be revealed.

Objectives: In this study, we aimed to examine the effect of telemedicine in SLE patients on the outcome of disease activity.

Methods: This is a case-cross over study nested within the national prospective cohort of SLE, Saudi Arabia. SLE patients who fulfils the SLICC classification criteria within the period between March 2020 to March 2021 and have been assessed at three-time point with three months’ time difference between assessments according to standardized protocol were included. Telemedicine was conducted at first point while in person assessment were used for second and third points. Primary outcome was difference in SLEDAI-2K score. Primary analysis was conducted using GEE model and adjusted for potential confounders including demographics, medications and changes in steroid doses. Several sensitivity analyses were conducted to mitigate selection and time varying confounders.

Results: A total of 92 participants were included. Majority of them were females (88%), with a mean (±SD) age of 36 (±13) mean (±SD) disease activity scores at baseline as follows: SLEDI 5 (±5); SRI 3.8 (±3.5); SDI 1 (±1). Mean difference of SLEDI score of -1.64% (95% CI -2.773 -0.510), p=0.005" between telemedicine and follow up visits. Adjusted value and mean with mean difference in Figure 1. Results were consistent in all sensitivity analyses.

Conclusion: We found that the Telemedicine assessment was associated with much higher disease activity score compared to in person in subsequent assessments which may suggest potentially overestimation of disease activity and later assessment accuracy. Cautious adoption is suggested in SLE patients with active disease.

Disclosure of Interests: None Declared.

Methods: A retrospective review of electronic medical records of ITP patients from University of Malaya Medical Centre in Kuala Lumpur was conducted from January 2000 to June 2022. All adult patients with a diagnosis of ITP, verified by treating physicians, who fulfilled inclusion criteria within the time period were included into the study. Patients who subsequently developed SLE were identified. Patients with known SLE who developed secondary ITP after SLE diagnosis were excluded from the study. Data collected included age, sex, race/ethnicity, basic demographics, initial symptom presentation, comorbidities, and blood tests including hemoglobin and platelet levels upon initial presentation of ITP.

Results: Total of 181 ITP patients who fulfilled the inclusion criteria were recruited; 25 (13.8%) were males, 84 (46.4%) patients were of Chinese race and 30 (17.6%) were of Indian race. Eleven (6%) patients developed SLE with a mean age of ITP presentation at 35 years. There were no Indian race ITP patients who developed SLE in comparison to other races (p=0.01). Patients who developed SLE had lower haemoglobin at ITP diagnosis (8.0 [4.08] vs 11.8 [2.83] g/dL, p=0.005) and also lower levels of platelets upon diagnosis of ITP (3.0 [2.00-10.75] vs 24.0 [6.00-53.25] x10^9/L, p=0.025) in comparison to ITP patients who do not develop SLE. There were no differences in initial symptom presentation or comorbidities between the 2 groups.

Conclusion: Our study found that there are racial differences and differences in hematological presentation upon diagnosis of ITP in patients with ITP who subsequently develop SLE. However, further larger studies are required to further explore the differences, especially in the Asian population.

POS1587-HPR | DISABILITY IN AN ITALIAN COHORT OF RHEUMATIC DISEASES: A MIXED METHOD STUDY FOR THE ANALYSIS OF THE PHENOMENON AND PROPOSALS FOR NURSING APPROACH

Keywords: Descriptive studies, Nursing, Quality of life

M. R. Melis1, K. El Aoudy2, T. Baci3, E. Corvi3, E. Coli3, C. Fantauzzo3, C. B. Antonini3, T. Gamberdella1, O. Manni1, T. Picci2, M. Zolferino1, M. Matucci-Cerinic1, S. Guiducchi1, Careggi Hospital, Rheumatology, Florence, Italy, University of Florence, Science in Nursing, Florence, Italy

Background: Rheumatic diseases are heterogeneous clinical conditions that often lead to functional disability with consequent impairment of Quality of Life (QoL). Assessing the risk factors of disability is required to find improvement strategies geared toward patient empowerment and implementation of current health services.

Objectives: The aim of the present observational-descriptive study was to analyse the impact of disability in an Italian cohort of rheumatic patients and suggest nursing intervention hypotheses to approach disability-related problems and improve QoL in rheumatology patients.

Methods: Data collection was carried out through in-person or remote interviews with rheumatic patients of a Rheumatology Unit in Florence, Italy. The interviews aimed at observing the patients' performances of daily activities and the following questionnaires were administered: Short Form-12 (SF-12) for QoL, Health Assessment Questionnaire (HAQ-DI) for disability, Visual Analogue Scale (VAS) for pain, Work Productivity and Activity Impairment Questionnaire: General Health (WPAI:GH) for workability. Afterwards, the nursing group met to discuss the results and, based on recent literature, propose strategies for approaching the patient with disabilities in daily clinical practice.

Results: 21 rheumatic patients were interviewed. For mental and physical health SF-12 showed scores of 47.6 and 46.1, respectively. Pain level averaged 2.2 score, while disability index as assessed with HAQ-DI was 0.3 score. As for the workability, 50% of the sample interviewed work on average for 33.6 hours with a mean of 2.6 hours of absence from work due to the disease. Lastly, 6.25% report work suspension with disability pension due to illness. Nursing intervention hypotheses to curb disability in ITP patients and improve QoL in rheumatology patients are summarized as follows in Figure 1.
Disease Activity in Patients with Ankylosing Spondylitis: A Preliminary Study

Keywords: Pain, Spondyloarthritis, Patient reported outcomes

N.B. Karaca1, G.I. Kinkki2, S. Sezer3, B. Keleoglu1, G. Kinkki1, Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey; 2Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Department of Musculoskeletal Rehabilitation, Ankara, Turkey; 3Ankara Training and Research Hospital, Department of Rheumatology, Ankara, Turkey; 4Diyakapi Vidyam Beyazit Training and Research Hospital, Department of Rheumatology, Ankara, Turkey; 5Ankara University, Faculty of Medicine, Department of Rheumatology, Ankara, Turkey

Background: Ankylosing spondylitis (AS) is a rheumatic disease that affects patients in a biopsychosocial framework due to its chronic inflammatory nature. It is known that patients with AS experience negative body judgment and insecurity and anxiety about their bodies [1], high levels of fear of movement, depression [2], low level of physical activity [3].

Objectives: The aim of this study was to investigate the effects of disease activity (DA) on depression, physical activity, pain catastrophizing, fear avoidance, and body awareness in patients with ankylosing spondylitis.

Methods: Thirty AS patients were included in the study. Socio-demographic informations of patients were collected. The mean age of the patients was 40.27 ± 10.38 years. Beck Depression Inventory (BDI), Physical Activity Questionnaire-Short Form (IPAQ-SF), Pain Catastrophizing Scale (PCS), Tampa Scale for Kinesiophobia (TSK), and Body Awareness Questionnaire (BAQ) were used for depression, physical activity, pain catastrophizing, kinesiophobia and body awareness levels of the patients, respectively. DA was measured with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and a score of four and higher than four was considered active.

Results: Patients characteristics were similar between the groups (p>0.05). A statistically significant difference was observed in PCS (p= 0.004), TSK (p=0.007), and BAQ scores (p=0.015) when the groups were compared (Table 1). The patients in the low DA group had mild depression, and the group with high DA had moderate depression. Catastrophizing pain and fear of movement were higher in the group with higher DA; body awareness level was lower (p<0.05). A high kinesiophobia level was detected in both groups.

Conclusion: It was observed that high disease activity negatively affected catastrophic thoughts, body awareness, and kinesiophobia in patients with AS. These parameters should be considered in the management of disease activity in AS patients for optimum results.

BREASTFEEDING IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

Keywords:
- Pregnancy and reproduction
- A. Carrazo Chapa1, D. C. Rubio Torres1, D. Ramos1, S. M. Delgado Ayala1, G. Sandoval1, C. M. Skinner Taylor1, L. Pérez Barbosa1, J. A. Cardenas-de la Garza1, D. A. Galarza-Delgado1. Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico

Background: The World Health Organization recommends exclusive breastfeeding for the first 6 months of life and then starting complementary feeding while continuing breastfeeding until 2 years of age or older [1]. However, women with autoimmune rheumatic diseases (ARDs) face barriers of ignorance regarding medications that are compatible with breastfeeding and the control of their disease activity. It has been reported that some women did not follow through with their desire to breastfeed due to concerns about their ARDs medications, the baby’s health, and low milk supply. Nowadays, international guidelines agree that most drugs used in rheumatology are compatible with breastfeeding [2].

Objectives: To describe the frequency of breastfeeding in women with ARDs.

Methods: An observational, cross-sectional and descriptive study. A survey on breastfeeding was carried out on patients with ARDs who had ever been pregnant, belonging to the Pregnancy and Reproductive Health Clinic for Rheumatic Diseases (CEER) of the University Hospital “Dr. José Eleuterio González”, Rheumatology, Monterrey, Mexico.

Results: A total of 63 patients were included, with a mean age of 38.84 (±7.49). The diagnosis most frequently reported was rheumatoid arthritis with 35 (55.6%), followed by systemic lupus erythematosus with 9 (14.3%). Other diagnoses were antiphospholipid syndrome, juvenile idiopathic arthritis and undifferentiated connective tissue disease each one with 1 (1.6%) respectively, primary Sjögren’s syndrome, scleroderma and spondylarthritis each one with 2 (3.2%) respectively and others with 10 (15.9%). The urban area was the most common place of residence with 61 (96.8%), while only 2 (3.2%) patients habited in the rural area. College education was the most predominant education level with 33 (52.4%). The sociodemographic and breastfeeding characteristics are found in Table 1. 49 (77.8%) of the patients referred that they had breastfed their last child. Regarding the duration, 3 (6.1%) reported having continued to breastfeed for less than 1 month and 24 (49%) for less than 6 months, being the cessation of milk production being the main cause of abandonment with 10 (37.1%) in those who breastfed for less than 6 months. Of the 14 (22.2%) patients who did not offer to breastfeed, the most frequent reason they reported was low milk production with 4 (28.6%), followed by their illness with 3 (21.4%). The other reasons can be observed in Figure 1.

Conclusion: Most of the surveyed patients with ARDs provided breastfeeding, however, more than half of them discontinued it before 6 months, with cessation of milk production being the most frequent reason.

UTILISING THE PERSPECTIVES OF PATIENTS WITH FIBROMYALGIA ON PHYSICAL ACTIVITY PROMOTION: A QUALITATIVE STUDY

Keywords: Fibromyalgia, Physical therapy/physiotherapy, Qualitative research methods
Background: Physical activity (PA) promotion remains a significant clinical challenge in patients with fibromyalgia (FM) despite its evidenced beneficial impact on health outcomes [1]. Integrating behavior change theory into PA interventions ensures efficient interventions through the understanding of PA behaviors [2].

Objectives: The aim of this study was to determine the behaviours, needs and beliefs of patients with FM regarding PA interventions with the use of Social Cognitive Theory (SCT) constructs.

Methods: A Qualitative study was designed using semi-structured interviews according to 5 SCT constructs (ie, Behavioral Capability, Outcome Expectations, Self-efficacy, Self-regulation, Social Support). Female patients with FM, aged between 18-65 years (n=10) were interviewed for 30-60 minutes. Data were audio recorded, transcribed verbatim and analyzed using the content analysis technique. Besides two researchers independently conducted the thematic analysis.

Results: Totally nine main themes were determined. Key themes comprising the behavioural capability were: 1) lack of knowledge on PA and 2) person-centered approach. Outcome expectations are associated with health benefits. It emerged that self-efficacy is affected by four themes as follows: 1) past negative experiences, 2) environmental barriers, 3) personal barriers and 4) follow up. Besides, incorporating the PA into daily life were categorized as self-regulation and 1) constructive social dialogs categorized as social support parameters of the theory. The themes, subthemes and supporting quotations related to the SCT structures are summarized in Table 1.

Conclusion: This study revealed the factors, needs, and beliefs related to PA behaviour in FM patients based on SCT and provided suggestions for how SCT constructs could be used to develop the optimal PA intervention. Future research should design PA interventions for FM patients based on behaviour change theories and evaluate the efficacy of these interventions.

POS1594-HPR  A REGIONAL MULTICENTRE REVIEW OF THE DELAY TO DIAGNOSIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS- HOW WELL ARE WE DOING? RESULTS FROM THE SCAN GROUP (UK)

Keywords: Health services research, Spondyloarthritis, Best practices

G. Dulay1, C. Boys2, A. Chan3, A. Coy4, M. Devin5, L. Goh6, A. McDougall7, K. Rigler2, J. Tomkins6, D. Wallis6, E. Williams7, 1Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom; 2Basingstoke and North Hampshire Hospital, Rheumatology, Basingstoke, United Kingdom; 3Royal Berkshire Hospital, Rheumatology, Reading, United Kingdom; 4Salsbury NHS Foundation Trust, Rheumatology, Salisbury, United Kingdom; 5Dorset County Hospital, Rheumatology, Dorchester, United Kingdom; 6University Hospital Southampton, Rheumatology, Southampton, United Kingdom; 7Royal Hampshire County Hospital, Rheumatology, Winchester, United Kingdom

Background: Due to the insidious onset and non-specific nature of axial spondyloarthritis (AxSpA), there is often a significant delay to diagnosis. The average delay to diagnosis in the UK is 8.5 years [1]. This is associated with several adverse sequelae including poor disease-related quality of life and worse overall health outcomes [2,3]. In addition, there is substantial health-economic costs associated with this. Recent modelling data in the UK, commissioned by the National Axial Spondyloarthritis Society (NASS), demonstrated the average financial cost of this delay to be £89,000 (221,000 Euros) per person affected [1]. There is a focus on reducing diagnostic delay for patients with AxSpA. The SCAN (South Central Axial Spondyloarthritis Network) is a network of NHS (National Health Service) Rheumatology departments in hospitals across south-central UK. The group comprises of; doctors, nurses and physiotherapists. SCAN has a working interest in service development.

Objectives: The SCAN group carried out a service evaluation to establish the average delay to diagnosis for patients with AxSpA across our region. Data was gathered from a total of 7 hospitals within the SCAN region. We also aimed to assess the degree of variability across the 7 different hospitals. The baseline data will be used to support potential implementation of service development initiatives, which in turn, will aim to ultimately reduce the delay to diagnosis for patients with AxSpA across the SCAN region.

Methods: Retrospective patient data was collected from 7 different hospitals within the SCAN network area. Data was gathered on 5-10 sequential cases of newly diagnosed AxSpA at each hospital. A total of 65 cases were included in our dataset. Data was collected on; date of symptom onset, date of diagnosis, age and gender.

Results: Chart 1 summarises our main findings across the 7 different hospitals.

Average (mean) time taken to receive a diagnosis of AxSpA across 7 hospital units

Chart 1.

Based on our representative sample from our region, the overall average (mean) delay to diagnosis in the SCAN area hospitals is 4.6 years. This is new data. The average age of the patients was 37 years old and 70% of the patients were male. The range for delay to diagnosis across the 65 cases was from 1 month to 30 years. The observed variability between the hospitals may be related to sample size, differences within local referral systems or reflective of areas where primary care education has been undertaken. Whilst acknowledging the relatively modest size of the sample, this regional multicentre dataset has allowed us to importantly establish what our average delay to diagnosis is for patients within the SCAN region. This valuable information will provide support for planning and implementation of further regional service improvements.

Conclusion: Our data suggests the delay to diagnosis within our region is significantly shorter than the national average (4.6 years versus national average 8.5 years). However, this delay remains unacceptable and is likely to be associated with worse disease-related quality of life and a wider detrimental socio-economic impact. The SCAN group will consider introducing changes to the referral processes (e.g., an agreed single referral proforma with local education). We may also aim to replicate any successful local arrangements in place at those hospitals with the shortest delay to diagnosis. We aim to re-evaluate the delay to diagnosis across the SCAN region in 12-36 months where we are optimistic of demonstrating further progress with reducing diagnostic delay for our patients with AxSpA.

Grenoble Alpes, LabCom Telecom4Health, CNRS, Inria, Grenoble, France

Background: Increasing demand and shortage of specialists lead to long waiting times for initial appointments in rheumatology care [1]. These result in diagnostic delays in several rheumatic diseases, with the longest total delay reported for patients with axial spondyloarthritis (axSpA) [1]. Telemedicine, including symptom checkers (SC), capillary self-sampling, and electronic patient-reported outcomes (ePRO) could enable patients to prepare a standardized pre-visit assessment at home. Additionally, fast-track appointments supported by medical students could complement this standardized assessment to enable fast diagnostic assessments and ultimately accelerate start of therapy.

Objectives: This qualitative study was embedded in a clinical trial that investigated a new diagnostic pathway for patients with suspected axSpA, including telehealth tools and fast-track visits supported by medical students. The aim of this qualitative study was to explore patient experiences with this new care model.

Methods: Patients, purposively selected to reflect a heterogeneous sample in terms of age, gender, education and occupation, participated in an explorative, qualitative study using semi-structured phone interviews. Interview data was analyzed using structured qualitative content analysis.

Results: Qualitative interviews were conducted with twenty patients with suspected axSpA (Table 1). Patients perceived the initial consultation supported by students to be equivalent to standard rheumatology care. Patients considered the student consultation to be a valuable option to relieve workforce shortage in rheumatology care. The overall experience with the students was described as holistic and thorough by patients. Some participants pointed out that rheumatic patients often have long medical histories and, thus, may find it difficult to engage with initial care provided by lead by students. Patients reported that using SC and performing capillary blood collection helped to better assess their disease status and promote mindfulness in this regard. Some patients described that the SC-questions were unspecific, which led to difficulties answering them. Furthermore, several patients requested a free-text note section to specify their standardized ePRO data. Patients considered the capillary blood collection to be helpful, especially in regard of travel and time savings. Reported disadvantages of self-administered blood collection were uncertainties about the amount of material and the unsustainable packaging material.

Table 1. Patient characteristics

</tbody>
</table>

Conclusion: Patients perceived the new diagnostic pathway as an efficient and high-quality alternative to standard axSpA-care. Particularly, savings in time and travel were considered favourable by the interviewed patients. Personal comments or chat options could provide an even more individual patient experience.

POS1597-HPR  ASSESSING THE USE OF VOICE COMMANDS IN THE CLINICAL SETTING

Keywords: Artificial intelligence, Health services research

J. Martínez1,2, R. Andev3, R. Luigmans3. 1Centro Hospitalar e Universitário de Lisboa Norte, Centro Académico de Medicina de Lisboa, Rheumatology Department, Lisbon, Portugal; 2Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina, Unidade de Investigação em Reumatologia, Lisboa, Portugal; 3University of Oxford, Oxford, UK, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: Artificial intelligence (AI) could reduce the administrative workload of clinicians, thus allowing them to focus more on clinical work. AI-powered voice-recognition programs can record appointments and request additional diagnostic tests through automatic flows generated by specific voice commands, reducing the administrative burden. Although some clinicians consider these programs helpful in the clinical setting, others consider them challenging to learn and not to save time.

Objectives: To investigate the impact of voice commands in clinical practice: i) on time spent on different tasks (clinical and administrative) during the appointment, ii) on the accuracy of records, iii) on patients' and clinicians' satisfaction.

Methods: We undertook a single-centre prospective quality improvement project between 26/10/22 and 20/12/22 in the rheumatology department of Nuffield Orthopaedic Centre - Oxford University Hospitals. We included patients attending general rheumatology (GR), complex musculoskeletal (CMSK) and vasculitis clinics, performed by clinicians using voice commands (group 1, N=1) and clinicians not using voice commands (group 2, N=4). The voice command program used was Dragon Medical One. We defined “using voice commands” when this tool was used to insert a pre-prepared text template or order diagnostic exams. One investigator attended the clinics and timed the tasks performed during the appointment. Clinicians and patients answered questionnaires attributing satisfaction scores from 0 (very unsatisfied) to 10 (very satisfied). Univariate analysis was performed, as appropriate, using SPSSV25.

Results: Data regarding 80 appointments were collected: 40 from group 1 and 40 from group 2. The proportion of the clinic types in groups 1 and 2 was: GR 52.5% vs. 0%; CMSK 0% vs. 40%; and vasculitis 47.5% vs. 60%, respectively. There were no differences between the groups regarding new and follow-up patients or face-to-face and phone clinics. Group 1 finished recording the consult in a shorter time than group 2 (means/SD: 5.6±1.8 min vs. 8.9±3.7 min, p<0.001). The time spent with the patient (means/SD: 16.9±7.0 vs. 17.7±7.6, p=0.637) and not to save time. There were no differences between the groups concerning patient satisfaction levels.

Conclusion: We report that voice commands: (i) were useful in reducing the time spent recording the consultation but did not influence the time spent with the patient or the time spent ordering diagnostic tests; (ii) resulted in a higher number of spelling mistakes but not clinically significant errors; and (iii) improved patients satisfaction at most levels and did not influence patients' satisfaction. Medical staff should be trained to adopt this technology, and developers should focus on improving accuracy and misspelling minimization.

Keywords: Autoantibodies, Biomarkers

Z. Mustufi1, R. Letton1, K. Harrold1, R. Chowdhury2, A. Tugnait3, P. Emery2, S. Pavit3, K. Manka2, 1University of Leeds, School of Dentistry, Leeds, United Kingdom; 2Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Musculoskeletal Medicine, Leeds, United Kingdom

Background: Rheumatoid autoimmunity may be initiated at mucosal sites such as the periodontium. Patients with RA and anti-CCP+ at-risk individuals have an increased prevalence of periodontal disease (PD) [1]. PD is often asymptomatic and diagnosed by clinical examination. We hypothesised that comprehensive periodontal assessment of CCP+ at-risk individuals would identify PD, which would be amenable to treatment with a single course of non-surgical periodontal therapy (NSPT).

Objectives: To determine the periodontal disease phenotype in anti-CCP+ at-risk individuals and to investigate the feasibility/efficacy of a course of NSPT.

Methods: Anti-CCP+ at-risk individuals with musculoskeletal symptoms but no clinical synovitis (‘CCP+ at risk’) were recruited from the Leeds CCP cohort. All participants had a high anti-CCP level (>3 X ULN) and had periodontal screening by a dentist, including radiographs. Clinically significant PD was defined as clinical attachment loss ≥4mm on at least two non-adjacent teeth, ≥4mm of cumulative probing pocket depth (minimum 4mm per site). Those with PD were offered NSPT. Periodontal indices were recorded before and after NSPT. Treatment completion occurred when PD had stabilised, as determined by clinically significant reduction in bleeding/probing indices.

Results: Seventy-two CCP+ at-risk were offered screening; 51 (71.8%) accepted. The main reason cited for declining was time pressures, 31/51 (59%) subjects had clinically significant PD and were offered NSPT. Of these, 15 have completed treatment over a median of three treatment sessions (median timeframe 17 weeks). The remaining participants are receiving ongoing treatment. The mean age for patients with PD was 51.22 and 64.5% were female. Seven (22.6%) patients were current smokers, 16 (51.6%) ex-smokers and 8 (25.8%) never smokers. Mean baseline scores were: 49.41% plaque free, 15.14% bleeding, 21.46% mild pocketing, and 4.42% deep pocketing. Radiographic assessment revealed a predominantly mild (stage I/II) disease phenotype; 8 (25.8%) stage I, 11 (35.4%) stage II, 9 (29%) stage III, and 3 (9.7%) stage IV PD. Plaque free scores improved by 27.89% (p<0.05), demonstrating high patient motivation. Bleeding indices, (indicating gingival inflammation) reduced from 16.32% (SE 9.91) to 8.49% (SE 4.13) <0.05 and probing (%)* from 10.02% (SE 21.88) to 79.12% (SE 25.23) <0.05.

Conclusion: Routine periodontal assessment of anti-CCP+ at risk individuals identifies a mild and treatable phenotype of periodontal disease. Periodontal screening and treatment with a course of NSPT is acceptable to at-risk individuals and results in effective treatment of periodontal disease. This approach may form part of future personalised strategies for RA prevention.

BACKGROUND: healthy lifestyle is known to prevent the progression of rheumatic and musculoskeletal diseases (RMDs). Despite contemporary improvements in RMD clinical care, the management of lifestyle factors has received less attention. Underlying causes may be the lack of awareness and insufficient evidence, but patient and physician education may also play a role.

Objectives: to collect and review currently available materials for health promotion on lifestyle factors for people with RMDs across Europe: assessment of current materials and implementation needs.

Keywords: Patient information and education, Non-pharmacological interventions, Education

Verstappen5.6, 1University of Oviedo, Area of Immunology, Oviedo, Spain; 2Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Department of Metabolism, Oviedo, Spain; 3San Rafaelle Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy; 4Vita-Salute San Rafaelle University, Vita-Salute San Rafaelle University, Milano, Italy; 5University De Lorraine, APEMAC, Cosnes-et-Romain, France; 6University of Lausanne, Swiss National Centre of Competence in Research LIVES - Overcoming vulnerability: Life course perspectives, Lausanne, Switzerland; 7University De Lorraine, Inserm, CHRU Nancy, Nancy, France; 8The University of Manchester, Centre for Epidemiology Versus Arthritis, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; 9University of Southampton Highfield Campus, MRC Versus Arthritis Centre for Musculoskeletal Health and Work, Southampton, United Kingdom; 10Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Wythenshawe, United Kingdom

Background: In the past, health lifestyle was known to prevent the progression of rheumatic and musculoskeletal diseases (RMDs). Despite contemporary improvements in RMD clinical care, the management of lifestyle factors has received less attention. Underlying causes may be the lack of awareness and insufficient evidence, but patient and physician education may also play a role.

Objectives: To collect and review currently available materials for health promotion on lifestyle factors for people with RMDs across Europe and to assess their implementation needs.

Methods: Materials on lifestyle factors (diet, weight control, physical activity, work participation, alcohol consumption and smoking) were collected from health professionals in rheumatology and patient associations through EULAR and EMUNET channels.

Results: 38 materials from 11 countries were retrieved (Table 1), including North, South, and Central European regions. Documents (22) or leaflets (12) were the most frequent materials. The most reported factor was diet (23) followed by physical activity (17), whereas information on work participation was scarce [2]. The materials were more commonly focused on rheumatoid arthritis (8), although documents for people with RMDs in general were also frequent (12). Only eight materials included scientific references. Although 23 materials contained some kinds of recommendations, two were evidence-based, whereas the rest contained general statements. Materials were mostly available in the official national language, and 16 were accessible on the internet, whereas no information on accessibility or treatment of periodontal disease. This approach may form part of future personalised strategies for RA prevention.

reach was obtained for the remainder. Significant limitations across implementation domains (process model, determinant frameworks, and evaluation) were observed, mostly due to flawed knowledge generation, poor identification of barriers and facilitators, and lack of evaluation frameworks. **Conclusion:** although materials on lifestyle factors were common, they were not always available at the national level across Europe. Current materials are hallmark of a lack of consistency in formats, layouts, content, focus, lack of scientific evidence and patient involvement. Major impediments for implementation were found. These findings will inform the implementation of EULAR-endorsed recommendations on lifestyle factors for people with RMDs.

**Keywords:** Disease-modifying drugs (DMARDs), bDMARD

**Background:** Pharmacovigilance is the science that is responsible for the detection, notification, and monitoring of possible drug adverse events (DAE) that occur with the administration of medications. In the pharmaceutical service process, the information generated through its programs constitutes evidence that provides a solution to the management of drug-related problems, especially those obtained by biotechnology.

**Objectives:** The aim of this study is to show the main DAEs and drug adverse reactions (DARs) with the use of anti-TNF (Anti-Tumor Necrosis Factor) drugs detected by the Pharmacovigilance program of an IPS specialized in rheumatology during the period 2018-2022.

**Methods:** The current method carried out in the institution is the so-called **Spontaneous Notification.** A retrospective review of the DAE and DAR detected by an institutional Pharmacovigilance program with the use of Anti-TNF drugs, in patients with autoimmune diseases, during the period 2018-2022, was carried out. Indicators were established through descriptive statistics to measure the frequency of DAE and DAR.

**Results:** 408,914 medical records were reviewed, the Table 1 shows the comparative percentages of DAE and DAR detected by the program between conventional disease-modifying antirheumatic drugs (csDMARDs) and biologics during the follow-up period. The Pharmacovigilance program had growth in the detection of DARs with the use of anti-TNF drugs, strengthening knowledge in the information for these. The causality with the anti-TNF was established, being the DAE classified as probable and the DAR as possible. Of the total subgroup of patients treated at the institution for medication application (46,832), notifications were received as follows: (Infliximab 17 , Etanercept 17 , Adalimumab 22, Goli-mumab 15, Certolizumab 51). Additionally, dermatological reactions are the most recurrent types of reactions. Herpes is found as the main DAR with Certolizumab.

**Disclosure of Interests:** None Declared.

**POS1601-HPR** ADVERSE EVENTS AND ADVERSE REACTIONS WITH THE USE OF ANTI-TNF’S DETECTED BY THE PHARMACOVIGILANCE PROGRAM OF A SPECIALIZED RHEUMATOLOGY CENTER

**Keywords:** Disease-modifying drugs (DMARDs), bDMARD

W. Rivero1, P. Rodríguez-Linares2, F. Rodríguez2, G. S. Rodríguez-Vargas1, A. Rojas-Villarraga1, P. Santos-Morenoc2; 1BIOMAB - Center for Rheumatoid Arthritis, Pharmaceutical Chemist, Bogotá, Colombia; 2BIOMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia; 3BIOMAB - Center for Rheumatoid Arthritis, Patients Education, Bogotá, Colombia; 4Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia

**Background:** Pharmacovigilance is the science that is responsible for the detection, notification, and monitoring of possible drug adverse events (DAE) that occur with the administration of medications. In the pharmaceutical service process, the information generated through its programs constitutes evidence that provides a solution to the management of drug-related problems, especially those obtained by biotechnology.

**Objectives:** The aim of this study is to show the main DAEs and drug adverse reactions (DARs) with the use of anti-TNF (Anti-Tumor Necrosis Factor) drugs detected by the Pharmacovigilance program of an IPS specialized in rheumatology during the period 2018-2022.

**Methods:** The current method carried out in the institution is the so-called **Spontaneous Notification.** A retrospective review of the DAE and DAR detected by an institutional Pharmacovigilance program with the use of Anti-TNF drugs, in patients with autoimmune diseases, during the period 2018-2022, was carried out. Indicators were established through descriptive statistics to measure the frequency of DAE and DAR.

**Results:** 408,914 medical records were reviewed, the Table 1 shows the comparative percentages of DAE and DAR detected by the program between conventional disease-modifying antirheumatic drugs (csDMARDs) and biologics during the follow-up period. The Pharmacovigilance program had growth in the detection of DARs with the use of anti-TNF drugs, strengthening knowledge in the information for these. The causality with the anti-TNF was established, being the DAE classified as probable and the DAR as possible. Of the total subgroup of patients treated at the institution for medication application (46,832), notifications were received as follows: (Infliximab 17 , Etanercept 17 , Adalimumab 22, Golimumab 15, Certolizumab 51). Additionally, dermatological reactions are the most recurrent types of reactions. Herpes is found as the main DAR with Certolizumab.
in the last year. According to the results obtained, Certolizumab is the drug that has presented the most adverse reactions during the follow-up period (Figure 1).

**Conclusion:** Dermatological reactions are the most frequent with anti-TNF drugs. Infliximab and Certolizumab stand out for this type of commitment. Studies are needed in populations from the same country to compare these results and generate more knowledge.

**Keywords:** Pain, Quality of life

C. Chiraz1, R. Fakhfakh2, N. El Amri2, D. Khalifa2, E. Bouajina2. 1Sahloul Hospital, Physical Medicine and Rehabilitation, Sousse, Tunisia; 2Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

**Background:** Catastrophizing is a common behavior in patients with chronic pain. It is a negative cognitive-affective response to pain. It is thought to be associated with the persistence and exacerbation of chronic pain.

**Objectives:** To determine the prevalence and the associated factors of catastrophizing in rheumatic diseases (RD).

**Methods:** A cross-sectional study on patients with RD followed in the rheumatology department of hached hospital. Biological and clinical data were collected from medical records. Depression and anxiety were evaluated by the HAD scale (Hospital Anxiety and Depression scale). Quality of life was assessed by the SF-12, which is a self-assessment scale of quality of life that is a shortened version of the SF-36. Catastrophizing was assessed by the Pain catastrophizing scale (PCS). A PCS score of 30 or more represents a high level of catastrophizing.

**Results:** Our study included 60 patients with RD: 44 patients with rheumatoid arthritis (RA), 12 patients with ankylosing spondylitis (SpA) and 4 patients with psoriatic arthritis (PsA). The mean age was 48.83 years (73.33% female). The mean PCS score was 31.10. The prevalence of high catastrophizing (PCS ≥ 30) was 73.3% in all patients: 72.7% of patients with RA, 66.7% with SpA and 100% with PsA. A high catastrophizing score was found in 91.7% of anxious patients and 95% of depressed patients. No statistically significant association of catastrophizing with age nor gender was noted. Catastrophism was significantly associated with depression, anxiety (p < 10^-4) and pain VAS (p = 0.001). The decrease in quality of life assessed by the physical (PCS12) and mental (MCS12) components of the SF12 was significantly associated with catastrophizing (p < 0.01).

**Conclusion:** In our study more than two-thirds of the population had high PCS scores with a significant correlation with pain VAS, anxiety and depression and a low quality of life score.

GUT MICROBIOTA IMBALANCE IN INFLAMMATORY ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Inflammatory arthritides

X. Y. Yin1,2, D. Qiao2, G. X. Wang2, X. Song1, Q. Y. Su1,2, H. Zhu2, Q. Yu1, P. F. Li1, X. Li1,2, S. Y. Zhang1,2, Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China

Background: Inflammatory arthritis (IA) is a group of autoimmune arthritis characterized by a pro-inflammatory/anti-inflammatory imbalance of local mediators[1] [2]. Research on the influence of gut microbiota(GM) on systemic IA has exploded in the past decade. GM changes may be a crucial regulatory component in systemic IA[3]. However, the link between them has yet to be fully elucidated.

Objectives: This study aims to study the GM composition of IA to provide evidence for its potential role in the pathogenesis, progress, and treatment of IA.

Methods: We systematically searched the trials for PubMed, EMBASE, Web of Science, Medline, Wanfang database, VIP, CNKI, and CBM database from the establishment of the database to January 1, 2023. Standardized mean difference (SMD) and 95% confidence interval (CI) were calculated to assess alterations in α-diversity and the abundance of certain microbiota families in IA. Literature quality was evaluated according to the requirements of systematic review, and meta-analysis was performed using STATA v12.0.

Results: A total of 70 studies, including 3,322 patients and 4,412 healthy controls, were identified. Compared with HCs, the GM of patients with IA has a lower Simpson index(SMD= -0.307, 95%CI -0.509, -0.106) and Shannon index(SMD= -0.184, 95%CI -0.344, -0.024). When specific IA was examined, significant decreases were observed in rheumatoid arthritis(Simpson index: SMD= -0.558, 95%CI -0.891, -0.225; Shannon index: SMD= -0.608, 95%CI -0.935, -0.281; ACE: SMD= -0.414, 95%CI -0.697, -0.132; Chao1: SMD= -1.373, 95%CI -1.960, -0.786; evenness index: SMD= -1.863, 95%CI -3.181, -0.544); psoriatic arthritis(Simpson index: SMD= -0.733, 95%CI -1.367, -0.099); osteoarthritis(Chao1: SMD= -0.793, 95%CI -1.096, -0.491) and gout(Simpson index: SMD= -1.037, 95%CI -1.959, -0.115). In other diseases, we found that the α-diversity index was higher than that of the HCs group(reactive arthritis(Shan- non index: SMD= 0.697, 95%CI 0.265, 1.130; ACE: SMD= 1.878, 95%CI 1.375, 2.380; Chao1:SMD= 0.835, 95%CI 0.398, 1.273; InvSimpson: SMD= 0.823, 95%CI 0.386, 1.260; Observed species: SMD= 2.004, 95%CI 1.491, 2.517); osteoarthritis(evenness index: SMD= 0.488, 95%CI 0.047, 0.928); ankylosing spondylitis(InvSimpson: SMD= 0.525, 95%CI 0.272, 0.777); Juvenile idiopathic arthritis(Observed species: SMD= 1.672, 95%CI 1.100, 2.243). Furthermore, to exclude sequencing methods influence on species abundance detection, we conducted a subgroup analysis of Observed species. The results showed that the observed species abundance through high-throughput sequencing was higher(SMD=1.376, 95%CI 0.394, 2.358) and 16S rRNA gene sequencing was lower(SMD= -0.842, 95%CI -1.575, -0.108) than that of HC. At the phylum level, there was a significant reduction in Firmicutes(SMD= -0.455, 95%CI -0.796, -0.114) and Fusobacteria(SMD= -0.422, 95%CI -0.692, -0.152). At the genus level, the abundance of Bacteroides(SMD=0.896, 95%CI 0.003, 0.003) was higher and Faecalibacterium(SMD= -0.380, 95%CI -0.713, -0.047) was lower. The two groups had no significant differences in Bifidobacterium and Butyricicoccus[3].

Conclusion: Our research showed a definite relationship between IA and GM. Further diet and drug therapy research are needed to explore the relationship between human GM and IA.

THE GENETIC BACKGROUND OF ANKYLOSING SPONDYLITIS INDICATES A STRONG CORRELATION WITH OTHER AUTOIMMUNE DISEASES

Keywords: Inflammatory arthritides, Genetics/Epigenetics, Spondyloarthritides

L. Papageorgiou1,2, M. Zervou3, T. Zormpa3, R. Golfinopoulou3, D. Vlachakis3, G. Bertisias3, G. Goulielmos3, E. Eliopoulos1, 1Agricultural University of Athens, Department of Biotechnology, Athens, Greece; 3University of West Attica, School of Health and Care Sciences, Athens, Greece; 3University of Crete, Medical School, Heraklion, Greece

Background: Ankylosing Spondylitis (AS) is considered to be a rare autoimmune disease that has been studied in genetic level the last decades [1]. The cases reported suggest that there might be an improvement in disease diagnosis with an overlap by other autoimmune diseases [2]. Patients can be diagnosed and the clinical symptoms are in alignment with a diagnosis of the disease. Meanwhile, novel studies propose various genetic factors that may be related to the disease has emerged. Most of the patients carrying various subtypes of the HLA-B27 gene, such as B2702, B2703 and B2710, are at an increased risk of developing AS [3]. Importantly, the relationship between the genetic factors and the development of the disease is still remains unclear.

Objectives: To create the disease genomic grammar (DGG) with the most credible genetic and epigenetic variants as well as and single nucleotide polymorphisms (SNPs) causing the basis for the development of AS and identify the correlation with other candidate autoimmune diseases [4].

Methods: AS related publications have been analyzed with the use of data mining and semantic techniques for the extraction of information regarding SNPs associated with the disease and the estimation of a candidate DGG. The extracted SNPs have been filtered, evaluated, annotated, and classified in the DGG, using several layers of information from well-known biological databases including dbSNP LitVar, ClinVar, OMIM and KEGG. Moreover, the AS DGG has been further analyzed towards identifying the hidden connections with other autoimmune diseases.

Results: A holistic genetic map of the AS DGG with 658 related SNPs has been estimated and the specific sub-clusters with crucial SNPs have been correlated with several other autoimmune disease including RA, PS, CD and SE (Figure 1). This indicates that AS has a common genetic background as many other autoimmune diseases [5]. The candidate DGG of the AS has been estimated using the SNPs annotated information and 3 major clusters of SNPs have been estimated. The DGG of the AS, 85% responds to non-coding regions and 15%
patients and healthy control groups. IL17A serum levels and clinical and laboratory parameters were measured using the enzyme-linked immune sorbent assay (ELISA) technique.

Results: RA patients showed higher IL 17A serum levels than the control group (121.9 ± 24.3 ng/dl vs 20.4 ± 2.6 ng/dl, P < 0.001). RA patients showed a higher frequency of rs2275913 G allele than healthy subjects (P = 0.01). Patients carrying GG genotype showed higher values of all disease severity parameters including Rheumatoid Factor (52.79 ± 16.65 IU/ml, P < 0.001) and Anti-Cyclic Citrullinated Peptide Antibody (30.6 ± 14.86 U/ml, P < 0.001). The high-risk GG genotype carriers had higher IL17A serum levels than the GA and AA genotype carriers (129.74 ± 23.03 ng/dl vs 107.49 ± 19.85 ng/dl, P < 0.001).

Conclusion: The major allele of IL17A rs2275913 polymorphism was associated with higher IL17A serum levels, and greater RA severity. It is thus very likely that the rs2275913 polymorphism of IL17A gene is associated with an increased risk of RA, as well as with higher severity in Egyptian RA patients.

Background: Interleukin 17A (IL17A), one of the IL-17 family, performs a critical role in the inflamed synovial tissue of Rheumatoid Arthritis (RA) patients. Several studies have been performed to investigate the role of IL 17A rs2275913 gene polymorphism in RA pathogenesis, however, data about its role in RA severity and activity is inconsistent.

Objectives: We aimed to investigate the influence of IL17A rs2275913 polymorphism on IL17A serum levels in Egyptian RA patients and disease severity and activity.

Methods: The study included 100 healthy subjects and 100 RA patients. Gene polymorphism rs2275913 was measured by Taqman genotyping assay in both
novel Bioinformatic tools may assist in the better understanding of this polygenic disease, while its association with RA and other ADs is a helpful step towards comprehending the shared biological pathways leading to autoimmunity. The data resulting from our study can be utilized towards the development of an application designed to assist clinical diagnosis by using the patients’ genomic data, like the integrated bioinformatics tools Demetra for endometriosis [6] and Epione for SLE [7].

CHANGES OF SALIVARY MICROBIAL COMMUNITY IN PATIENTS WITH PERIODONTITIS

Keywords: Prognostic factors, Adaptive immunity, Biomarkers
C. Wang1,2, J. Qiao2,3, Y. Li1, M. J. Chang1,2, R. X. Qi1, S. X. Zhang2,3, Q. Yu1, P. F. He1, 3Shanxi Medical University, School of Management, Taiyuan, China; 4The Second Hospital of Shanxi Medical University, School of Management, Taiyuan, China; 5Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 6Shanxi Medical University, Medical Data Sciences, Taiyuan, China

Background: Periodontitis (PD) is a chronic, progressive polymicrobial disease[1]. In the context of the microbiome in the pathogenesis of rheumatic disease, microorganisms located in the periodontal tissues play an important role as potential initiators of immune-mediated inflammatory conditions at distant sites[2]. Studies have shown that the microbiota associated with PD is different from that in health, and the chronic inflammatory response induced by salivary microbiota plays an important role in the development of PD.

Objectives: Study to evaluate and quantify the differences in the composition of salivary microbiota in patients with PD, and investigate the correlation between salivary microbiota in patients with PD and clinical variables.

Methods: In the same race, 34 salivary samples of patients with PD and 28 salivary samples of periodontal health controls (HC) were collected for 16S rRNA gene sequencing. Compare salivary microbiota alpha-diversity, beta-diversity and microbial composition (at the phylum and genus levels) were used to determine differences in salivary microbiota characteristics between periodontitis patients and periodontal health controls. LefSe analysis was carried out to identify differentially abundant genera. The correlation between different taxa and clinical variables was calculated by the Spearman rank test.

Results: Consistent with the observed diversity trend, compared with periodontal health, the richness of patients with periodontitis is relatively high (P<0.05, Figure 1a), which indicates that the diversity of salivary microbiome in patients with periodontitis is significantly higher. The Beta diversity based on Bray Curtis distance at the species level demonstrated a significant differences in microbial communities between periodontitis patients and periodontal health (analysis of variance, r2=0.094, p=0.001, Figure 1b). At different phylogenetic levels, the 10 selected taxonomic biomarkers showed strong discrimination ability, with log10 LDA score >4.0 (Figure 1c-d). Specifically, at the phylum level, the Firmicutes phylum frequency of periodontitis patients is lower, while the Spirochaetota frequency is higher. Patients with periodontitis have more genus Treponema at the genus level (Figure 1c-d). PICRUSt analysis found that in the KEGG pathway, the function of microbial genes related to amino acid metabolism in the salivary microbiota of periodontitis patients was higher (Figure. 1h). Treponema was positively correlated with periodontal probing depth (PPD). Total, plaque index (PI) and periodontitis extent Cx. Spirochaetota was positively correlated with PPD Total, PI (p<0.05, Figure 1).

Conclusion: Specific salivary microbiota played an important role in the pathogenesis of periodontitis, which may help to diagnose or determine individual susceptibility to periodontitis by detecting salivary microbiota.

Background: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease characterized by a very heterogeneous clinical picture that makes diagnosis and follow up of these patients difficult.

Objectives: Identify correlations between clinical, immunological and genetic biomarkers with clinical manifestations in SLE in Paraguayan patients.

Methods: Retrospective study of data from medical records and immunological and genetic studies of patients with SLE from Paraguay. A descriptive analysis was performed based on the type of variable. HLA allele frequency (DPA1, DRB1, DQA1, DQB1, and DRB1) was calculated and univariate logistic regression analysis was performed between each of the explanatory variables and the presence/absence of each of the phenotypes. The odds ratio (OR), the 95% confidence interval (95%CI), and the p-value were recorded. Associations with a p-value less than 0.05 were considered statistically significant associations.

Results: 104 patients with SLE were included, 86% female with a mean age value of 32.80 ± 10.36 years. An association was identified between anti-dsDNA and the presence of the renal phenotype and anti-dsDNA with the absence of the joint and hematological phenotype. The IgM isotype RF was associated with the absence of the renal phenotype. HLA DQB1* 02:02 and HLA DRB1* 07:01 associated with cutaneous phenotype were identified. An association was identified between the age of onset of the disease and the presence of the joint phenotype. No other associations were identified with the other variables studied.

Conclusion: Possible clinical, immunological and genetic biomarkers of phenotypes have been identified in patients with SLE of Paraguayan origin.

AB0007  DYNAMIC INTERPLAY OF FUNCTIONALLY DISCORDANT CD4+HLA-DR+ SUBSETS WITH A COMMON PATHOLOGICAL ONTOGENIC ORIGIN IN HUMAN ARTHRITIS

Keywords: Rheumatoid arthritis, Synovium, Adaptive immunity

J. Y. Leong1, P. Kumar1, A. J. M. Lim1, S. H. Tay1, S. Hazirah1, J. G. Yeo1, C. Chua1, P. Chen1, A. M. Lajam1, A. Consolaro2, M. Gattorno3, C. T. Ng3, T. Arkachaisri3, A. Martin3, S. Albani3, 1Singhealth/Duke-NUS Academic Medical Centre, Translational Immunology Institute, Singapore, Singapore; 2University of Genoa and G Gaslini Institute, Second Paediatric Division, Genova, Italy; 3Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 4KK Women’s and Children’s Hospital, Division of Medicine, Singapore, Singapore

Background: We have previously described the presence of pathogenic-like lymphocyte (CPLs; CD4+HLA-DR+) subset within the circulation, that is phenotypically similar to their synovial counterparts. CPLs are inflammatory T effectors that correlate with disease activity and possess a TCR repertoire with strong synovial overlap. We also discovered a similar inflammation-associated T-regulatory (iaTreg; CD4+HLA-DR+) circuitary subset, that is activated, suppressive, poised to migrate to inflamed site and sharing TCR between the peripheral and synovial compartments. iaTreg and CPL were found to be phenotypically quite similar. Their striking similarity, inspired the hypotheses of a common ontology driven by the synovial micro-environment, and whether their functionally discordant roles, pointed to an undetermined dynamic interplay.

Objectives: In this study, we seek to establish if a common disease ontology exists between synovial CPLs/iaTregs in human arthritis and why CPLs continue to perpetuate synovial inflammation.

Methods: We performed mass cytometry analysis of PBMCs from RA patients and healthy adults. CD4 subsets from active JIA PBMCs, paired JIA SFMCs and healthy paediatric controls were sorted for bulk RNA sequencing. Cpg profiling of FoxP3 TSDR site was performed for synovial iaTregs. Treg suppression assays were performed in iaTregs for healthy paediatric controls, paired JIA PBMCs and SFMCs.

Results: Mass cytometry analysis of RA patients revealed memory induction of CPLs and iaTreg as compared with healthy adults. Importantly, CPLs/iaTregs from RA patients demonstrated reactivity to the dnaJP1 peptide, which is a pro-inflammatory epitope in RA patients, thus underscoring disease relevance. Circulatory JIA CPLs/iaTreg subsets displayed transcriptomic convergence, exhibiting (a) common pathway dysregulations, (b) restriction in TCR repertoire and (c) common transcription factor drivers, suggesting a common pathogenic
ontogeny. This phenomenon is further reinforced across the spatial/disease continuum, with synovium CPLs/iaTregs presenting common dysregulated pathways including IFNγ signalling. In particular, TCR clonotype sharing in CPLs/iaTregs is higher in the synovium, suggesting a common antigenic origin. To understand the dynamic interplay between CPLs and iaTregs, we assess the regulatory capacity of iaTregs. Epigenetic profiling of CpG sites on the FoxP3 TSDR promoter, revealed typical Treg demethylation status within iaTregs, indicating a stable lineage. Suppression assays reveal that iaTreg rather than non-iaTregs were poised to suppress disease T effectors from JIA PBMC/SFMC, with higher rates of suppression. This is in contrast with healthy controls, where iaTregs were inferior in suppression, mirroring their disease ontology. Despite superior suppression from iaTreg in SFMC T effectors, synovial CPLs were resistant to suppression from iaTreg as compared with synovial Non-CPLs. Destabilisation assays in iaTregs, reveal a drop in FoxP3 levels in the presence of IFNg, suggesting a role for IFNg in CPL evasion of suppression.

Conclusion: Our study highlights the disease relevance of CPLs/iaTregs in human arthritis, whilst revealing evidence of a common pathological ontology, for CPLs/iaTregs, that is antigenically driven by the inflammatory synovium environment. The dynamic interplay between CPLs/iaTregs, could be tilted towards suppression evasion through IFNg, allowing for continual synovium inflammation.

AB0008 ROLE OF IL-23/Th17 AXIS CYTOKINES IN RHEUMATOID ARTHRITIS

Keywords: Cytokines and chemokines, Rheumatoid arthritis

J. Meher1, S. Patil1, M. S. Siddiqui1, R. Nanda2. 1AIIMS, Raipur, General Medicine, Raipur, India; 2AIIMS, Raipur, Biochemistry, Raipur, India

Background: Rheumatoid arthritis (RA) is an autoimmune inflammatory arthritis driven by an inflammatory cascade of different cytokine families. IL-23/Th17 axis cytokine (IL-23, IL-17) has been studied as a key pathway for disease development and its association with disease severity, joint erosion and functional outcome [1], but the data supplementing to support the hypothesis is lacking and conflicting. Also, there is a paucity of data on the role of IL-23/Th17 axis cytokines in an Indian subset of patients.

Objectives: The objective was to find the correlation between serum cytokines (IL-17, IL-23) and clinical parameters of Rheumatoid arthritis patients, e.g., disease activity (DAS28) and functional status.

Methods: This cross-sectional observational study was conducted in General Medicine OPD from 2021 to 2022. ACR/EULAR 2010 classification criteria was used to diagnose RA. Eighty-four consecutive RA patients were recruited after taking consent. Serum IL-17 and IL-23 levels were measured by the ELISA method. Clinical and laboratory parameters, DAS28-ESR, and HAQII were recorded. Data were analyzed to find the correlation between cytokine and disease parameters, and compare cytokine levels in different subgroups.

Results: The study showed a higher proportion of females than males (n=76,90.5% vs n=8,9.5%). Advanced RA had higher IL-17 and IL-23 levels (r=0.229, p=0.038; r=0.098, p=0.016, respectively). Among the inflammatory marker, only CRP correlated positively with IL-23 (r=0.269, p=0.014). Both IL-17 and IL-23 levels showed a significant, weak positive correlation with the disease activity DAS28 (r=0.183, p=0.097 & r=0.125, p=0.259, respectively). There was no difference in IL-17 and IL-23 levels among the disease severity group (p=0.130 & p=0.215). It was also noted that IL-17 was positively correlated with IL-23 (r=0.221, p=0.044). Among the cytokines, only IL-23 had shown a statistically positive correlation with functional status (HAQII) (r=0.284, p=0.09). IL-23 level differed significantly between males and females (p=0.013). Also, advanced RA had higher IL-17 level than early RA (p=0.028). Neither IL-17 nor IL-23 level showed any difference between the subgroup e.g., age (younger RA vs elderly RA), obesity (obese vs nonobese), DMARDs or steroid (user vs naive), serology status (RF vs RF– CCP vs CCP–).

Conclusion: Serum IL-17 levels were high in advanced RA as compared to early RA. Both IL-17 and IL-23 correlated positively with the swollen joint count. Only IL-23 was directly correlating with CRP and functional status. Both IL-17 and IL-23 had a weak, insignificant positive correlation with disease activity, and there was no difference in cytokines level among severity classes. Even DMARD-, steroid use did not affect the cytokines level.

IL-17 receptor activation triggers transformations of acute synovitis to chronic persistent arthritis [2]. IL-23/IL-17 may be a factor for advanced erosive disease development, which need further research. Hence, blocking IL-23 and IL-17 at an early stage may diminish IL-17 activity, retard the progression to chronic inflammatory arthritis and advanced disease.

AB0009 UNTREATED EARLY RHEUMATOID ARTHRITIS PATIENTS HAVE AN ABNORMAL DISTRIBUTION OF B AND FOLLICULAR T HELPER CELL SUBSETS IN PERIPHERAL BLOOD

Keywords: Adaptive immunity, Rheumatoid arthritis

C. Tomé1, R. L. Teixeira1,2, S. C. Barreira1,2, P. Martins3, J. Polido-Pereira1,2, A. Valido3, M. J. Saavedra1,2, C. Ponte1,2, R. Barros5, V. C. Romão1,2, L. Graca1, J. E. Fonseca1,2, R. A. Moura1. 1Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Rheumatology Research Unit, Lisbon, Portugal; 2Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, EPE, Centro Académico de Medicina de Lisboa, Rheumatology Department, Lisbon, Portugal

Background: Disturbances in B cell immune responses have been implicated in rheumatoid arthritis (RA) pathogenesis since the first weeks of RA development. However, the mechanisms responsible for these immune alterations remain unclear. Follicular helper T (Tfh) cells are crucial for B cell maturation, activation and class-switching as well as for germinal center (GC) formation, whereas follicular regulatory T (Tfr) cells can modulate the GC reaction by suppressing Tfh and B cells. Objectives: The main goal of this study was to analyze the frequency and phenotype of B, Tfh and Tfr cells in peripheral blood of untreated early RA patients when compared to patients with early non-RA polyarthritides, established RA and healthy controls.

Methods: Blood samples were collected from 35 untreated early polyarthritides patients (<1 year of disease duration), who later evolved into RA (early RA, ERA) (n=23) or other diagnoses (early non-RA, ENRA) (n=12); established seropositive RA patients (n=62) treated with methotrexate and a group of age- and sex-matched healthy controls (n=20). Peripheral blood mononuclear cells were isolated and the frequency and phenotype of B, Tfh and Tfr cells were evaluated by flow cytometry.

Results: ERA patients had similar frequencies of B, Tfh and Tfr cells in circulation when compared to ENRA, established RA and controls. Nevertheless, ERA patients had significantly lower frequencies of pre-switch memory B cells (IgD+CD27+) and higher levels of double negative B cells (IgD+CD27–), CD21low CD38low B cells and plasmablasts (IgD+CD38+) in peripheral blood when compared to controls. Furthermore, the frequencies of PD-1+ICOS+ Tfh cells and Th2-like Tfh cells were significantly increased in ERA patients when compared to controls, but not in Tfr cells, in circulation when compared to healthy controls. Our results suggest a pre-activation state of B and Tfh cells since early RA development, which supports a role of these cells in disease physiopathology.

AB0010 FERROPOTOSIS PROMOTES DYSFUNCTION OF NTREG BUT NOT ITREG IN RHEUMATOID ARTHRITIS

Keywords: Adaptive immunity, Cell biology, Rheumatoid arthritis

J. Chen1, J. Zhao2, X. Shi1, Y. Liu1, Y. Jiang2, Y. Pan1, S. Zheng3, 1The Third Affiliated Hospital of Sun Yat-sen University, Department of Internal Medicine, Division of Rheumatology, Guangzhou, China; 2The Third Affiliated Hospital of Sun Yat-sen University, Department of Internal Medicine, Division of Rheumatology, Department of Clinical Immunology, Guangzhou, China; 3Affiliated Hospital of Sun Yat-sen University, Department of Internal Medicine, Division of Rheumatology, Department of Clinical Immunology, Guanzhou, China;
Background: Magnetic resonance imaging and histological studies have shown that iron levels are dysregulated in rheumatoid arthritis (RA) patients, with iron accumulation in gray matter and a considerable loss in healthy white matter. Iron accumulation in RA environment is closely related to immune disorders. Deferoxamine (DFO) is an iron complexing agent that has been shown to attenuate RA development. It has previously been reported that the suppression function of natural regulatory T cells (nTreg) is impaired in RA patients. It is still unclear how iron disrupts immune cells dysfunction in the RA milieu, and whether regulating iron is beneficial for Treg cell expansion and function maintenance.

Objectives: The purpose of this work is to identify the underlying gene expression profile of ferroptosis in Autoimmune dysregulated RA-Treg, and to investigate the possible application of TGF-induced Treg (iTreg) in the treatment of RA.

Methods: We established a collagen-induced arthritis (CIA) mouse model, a typical animal model of autoimmune arthritis, and performed single cell RNA-sequencing (scRNA-seq) to discover different Treg populations in the joints of CIA mouse models. We also analyzed RNA-seq data from imidazole ketone erastin (IKE), a ferroptosis inducer treated nTreg and iTreg.

Results: Data from single-cell RNA sequencing further identify two groups of Treg cells that have distinct susceptibility to RA challenges, with the ferroptosis-susceptibility Treg associated with an increased insulin-like growth factor 1 (IGF1)-related transcriptome. Mechanistically, IGF1 receptor (IGF1R) activates the AKT-mTOR pathway, increases aerobic glycolysis, promotes Treg conversion toward Th17 differentiation and increases pro-inflammatory cytokines production. Moreover, RNA-sequencing analysis indicated that imidazole ketone erastin (IKE), a ferroptosis inducer, increases the expression of ferroptosis-associated genes in nTreg but not iTreg, and iTreg attenuated arthritis progression in the IKE-aggregated CIA model.

Conclusion: Our findings suggest that increasing IGF1 and glycosylation account for Treg dysfunction and inflammation in RA, and the novel iTreg may serve as a potential candidate for RA therapy.

**AB0012 ANALYSIS OF THE EXPRESSION OF T-BET IN B LYMPHOCYTES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

Keywords: Systemic lupus erythematosus, Biomarkers, Cell biology

E. Marasco1, G. M. Moneta1, C. Braçaglia1, I. Caiello1, C. Farroni2, R. Carsetti2, F. De Benedetti1. 1Bambino Gesù Children Hospital, Unit of Rheumatology, Rome, Italy; 2Bambino Gesù Children's Hospital, B Cell Physiopathology Unit, Rome, Italy

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease causing significant morbidity and mortality. B cells play a central role in SLE pathogenesis. T-bet, is a transcription factor promoting T helper-1 development. B cells expressing T-bet are expanded in aging, chronically infected individuals, and murine models of autoimmunity [1, 2].

Objectives: The aim of our work is to analyze the expression and regulatory mechanisms of the transcription factor T-bet in B cells of patients with systemic lupus erythematosus (SLE).

Methods: The intracellular expression of T-bet was evaluated by flow cytometry in the different subsets of B lymphocytes of SLE patients and controls (HD). Peripheral blood mononuclear cells (PBMCs) were stimulated in vitro with IFNγ and IFNα and the expression of T-bet was evaluated by flow cytometry. The clinical characteristics of patients were analyzed by Multiple Factor Analysis (MFA).

The analysis was carried out with the software R.

Results: We performed B cell staining and assessed the expression of T-bet in B cell subsets in patients with SLE and HD. We observed a significant expansion of naïve B cells and double negative (DN) B cells expressing T-bet in patients with SLE compared to HD (Figure 1A-B). An expansion of T-bet+ naïve B cells above the 99th percentile of HD (>1% of total naive B cells) was evident in 68% of patients; 47% of patients showed an expansion of T-bet+ DN B cells above the 99th percentile of HD (>22% of total DN B cells). We assessed if patients with expanded T-bet+ naïve or DN B cells showed significant clinical differences from patients without the expanded subpopulations. To this end we collected clinical and laboratory parameters (SLEDAI, organ involvement as classified in the BILAG, damage with SDI, serology). Patients with expanded T-bet+ naïve B cells, distributed differently from patients with no expansion of T-bet+ naïve B cells (Figure 1C). The first dimension was the most informative in separating the two groups of patients: significantly higher values were reported for patients with expanded T-bet+ naïve B cells. No differences were observed for patients with and without expanded T-bet+ DN B cells (Figure 1C).

We investigated in vitro if the expression of T-bet in B cells was driven by interferons. We stimulated PBMCs of HD with IFNγ or IFNα and assessed the frequency of T-bet+ B cells: both interferons induced the expression of T-bet in naïve (CD19+CD27-) and memory (CD19+CD27+) B cells (Figure 1D). Interestingly, when cells were stimulated with IFNγ in the presence of IFNα-blocking antibodies the expression of T-bet was not induced.

Conclusion: Altogether, T-bet+ naïve B cells are expanded in patients with SLE and define a group of patients with clinically different disease from patients without out expanded T-bet+ Naïve B cells. The expression of T-bet is induced specifically by IFNγ and not by IFNα.

**AB0013 LONGITUDINAL CHANGES IN VARICELLA ZOSTER VIRUS (VZV)-SPECIFIC T CELL IMMUNITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH DIFFERENT JAK INHIBITORS**

Keywords: Adaptive immunity, Rheumatoid arthritis, Targeted synthetic drugs

S. Moustafà1, C. G. Gialouri1, K. Thomas2, C. Koutsianas1, C. Tsalapaki1, A. Panagiotopoulos1, E. Mavrea1, K. Antonatou1, E. Hadziyannis1, D. Vassilopoulos1. 1Joint Academic Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine, General Hospital of Athens “Hippokration”; 2Department of Medicine and Laboratory, Clinical Immunology-Rheumatology Unit, Athens, Greece; 3National and Kapodistrian University of Athens, School of Medicine, Atikion General Hospital, Chaidari, Greece., 4th Department of Internal Medicine, Athens, Greece

Background: Targeted synthetic agents such as the JAK inhibitors (JAKi) used for the treatment of various inflammatory diseases, including rheumatoid arthritis (RA), have been associated with increased risk for VZV reactivation and herpes zoster (HZ). Although this has been attributed to decreased T cell surveillance of latent VZV, detailed data on the effect of the different JAKi on VZV-specific T cell immunity are limited.

Objectives: To study longitudinally the kinetics of VZV-specific T cells in RA patients treated with different JAKi (baricitinib-BARI, tofacitinib-TOFA, upadacitinib-UPA) or methotrexate (MTX, control group).

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from RA patients before and after 4 and 12 weeks of treatment with JAKi or MTX. PBMCs were stimulated in vitro for 18 hours either specifically with VZV antigen (VZV lysate) or non-specifically with a polyclonal stimulus (Staphylococcus aureus enterotoxin B, SEB) and anti-CD28/49d. The percentage of CD4+CD69+ effector T cells as well as of VZV specific CD4+CD69+ T cells expressing IFNγ were measured by flow cytometry.

Results: 22 patients with active RA were included; 16 were treated with JAKi (BARI n=7, TOFA n=4, UPA n=5) and 6 with MTX. For the JAKi group, 88% were females with median age and disease duration of 62 and 8 years, respectively, and mean baseline DAS28-ESR of 5.6, while in the MTX group, 100% were females with median age and disease duration of 57 and 0.5 years and mean DAS28-ESR of 5.5, respectively. Treatment with JAKi for 12 weeks did not change significantly the % of the overall population of CD4+CD69+ T cells stimulation in vitro with VZV or SEB (p=0.3). Similarly, there was no significant change in the % of SEB-stimulated CD4+CD69+IFNγ+ T cells between pre-treatment and after 12 weeks of JAK1 treatment (median, from 0.1% to 0.75%, p=0.370, Figure 1a). In contrast, there was a significant decrease in VZV-specific CD4+CD69+IFNγ+ T cells between these 2 time points (median, from 0.049% to 0.01%, p=0.001, Figure 1b). The decrease in VZV-specific T cells was similar between the 3 different JAKi (Figure 1c).

Conclusion: Treatment of RA patients for 12 weeks with JAKi significantly reduced VZV-specific T cells without affecting the overall effector T cell population. The effect on VZV specific T cell immunity was similar with the 3 different JAKis. Further preliminary findings provide novel information regarding the effect of JAKi on VZV-specific T cell immunity.
Immune Responses to Vaccination Against Herpes Zoster (HZ) in Patients with Rheumatic Diseases Under Treatment with JAK-Inhibitors: Our Preliminary Results

Keywords: Adaptive immunity, Vaccination/Immunization, Real-world evidence

C. Sieiro Santoló,1,2, A. López Robles,1,3, Álvaro Castro1,3, S. Calleja Antolín,1,3, C. Moriano1, E. Diez Alvarez1, J. M. García Ruiz de Morales,1,3, Complejo Asistencial Universitario de León, Rheumatology, León, Spain; Universidad de León, Universidad de León, León, Spain; Complejo Asistencial Universitario de León, Immunology, León, Spain

Background: Shingrix is a recombinant inactive vaccine available for prevention of herpes zoster (HZ) infection, recently approved for patients with rheumatic diseases under treatment with JAK-inhibitors. Because of its novelty, scant information is available on Shingrix vaccine responses in patients with immune mediated rheumatic diseases (IMRD).

Objectives: To investigate the antibody responses to the HZ vaccine in selected rheumatic diseases treated with JAK-inhibitors (JAKI) pre- and post-Shingrix vaccination (weeks 4–6) and to identify factors associated with reduced immunogenicity.

Methods: Patients with selected rheumatic diseases under treatment with JAKI underwent two series of IM Shingrix vaccine (0.5mL each) administered 2 months apart. Bloodwork was performed 4-8 weeks following 2nd dose of vaccine to assess post- vaccination antibody response. Pre and post vaccination response was then compared using Anti Varicella Zoster Virus IgG Multiplex Flow Immunoassay (MFI). Blood lymphocyte distributions (CD3+, CD4+, CD8+) and NK cells, total serum IgG and IgM levels, and VZV-IgG and IgM, were investigated pre- and post-Shingrix vaccination (weeks 4–6).

Results: 38 patients were included, 79% were female with a median age at inclusion of 57±10.5 years. 21% of patients had rheumatoid arthritis, 8% had systemic lupus erythematosus, 16% had psoriatic arthritis, 16% had ankylosing spondylitis and 5% had dermatomyositis. VHZ IgG antibody levels and distributions of lymphocyte subpopulations in peripheral blood pre- and post-immunization are represented in Table 1. Positive humoral responses were observed in 86% of patients. Mean changes VHZ-IgG antibody between post- and pre-vaccination sera were 4.6±0.33 and 1.8±1.98 (p<0.0001), respectively. After immunization, the number of T cells (CD3+, CD4+, CD8+) and NK cells remained relatively unchanged however, the number of B cells (CD19+) increased significantly from 147±156 to 780±62→475.5 significantly (p<0.0001). There was a 2.5-fold increase in antibody titers after immunization in RA patients, a 2.4-fold increase in SLE patients, a 2.0-fold increase in AP patients, a 2.5-fold increase in AS patients and a 3.5-fold increase in DM, with no significant difference between the different patients' subgroups. Results from multivariate regression analysis adjusted by age, gender, disease duration, treatments and glucocorticoid and MTX cumulative dose, showed a negative correlation between VHZ-IgG and age >65 years (β=-34, p 0.03), disease duration (β=0.58, p 0.04) and glucocorticoid cumulative dose (β=-0.42, p 0.02).

Conclusion: Our preliminary results show preserved seroconversion rates and VHZ-IgG antibodies and concurrently increase the number of CD19+ B-cells and total serum IgG in patients with rheumatic diseases under treatment with JAKI.

**Background:** Following treatment of autoimmune disease with anti-CD20 monoclonal antibody, Rituximab, insufficient B cell depletion relates to poor clinical response, in particular an expansion of memory B cells [1].

**Methods:** Peripheral blood samples from 6 rituximab naïve (RTX-N) patients with autoimmune rheumatic diseases (active systemic lupus erythematosus and rheumatoid arthritis), 6 patients previously treated with rituximab (RTX-T); and 6 healthy controls (HC) were obtained. B cell subpopulations were defined using the relative expression of IgD and CD27 using flow cytometry.

**Results:** Patients in the RTX-N group had significantly higher frequency of CD19+CD20-B cells (median=25.9% of total B cell, compared to 1.26% in HC), p =0.0022. CD19+CD20-B cells were predominantly swMBC and DN cells. All of these cells to contribute to disease activity in autoimmune disease, is it now time to seek alternative strategies targeting CD19 in order to overcome rituximab resistance?

**Figure 1.**

Figure above demonstrates the cycle of B lineage cells which originate in the bone marrow and migrate into the peripheral circulation and into lymphoid tissues such as lymph nodes and the spleen. In germinal centres the naïve B cells mature into memory B cells which then differentiate into tissue resident switched memory B cells (CD27+ IgD+), or double negative memory B cells entering the peripheral circulation (CD27-, IgD-) or plasma blasts and plasma cells of which the long-lived ones reside in the bone marrow. Proportions of CD19+CD20+ v CD19+CD20- B cells are demonstrated pictorially within each subpopulation. The CD19+CD20- B cells cannot be targeted by anti-CD20 monoclonal antibodies such as rituximab, and therefore alternative strategies to target CD19 may help to overcome rituximab resistance in autoimmunity.
IMPACT OF AN EX-NOVO INDUCED ADAPTIVE IMMUNE RESPONSE ON CXCL13 SERUM LEVELS IN ESTABLISHED AUTOANTIBODY-POSITIVE RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Inflammatory arthritides, Cytokines and chemokines

F. Bozzali Cassone1-3, M. Mansoubi1, T. Luvaro2, I. Mazzucchelli1,2, B. Xoxi1,3, L. De Stefano2, S. Bugatti3, C. Montecucco1,2, A. Manzo1,2
1University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy; 2Fondazione IRCCS Policlinico San Matteo, Division of Rheumatology, Pavia, Italy

Background: C-X-C motif chemokine ligand 13 (CXCL13) is a chemokine involved in the recruitment of B cells in secondary lymphoid organs and ectopic inflamed sites. Recent studies in animals models and in healthy individuals have shown that serum levels of CXCL13 correlate with GC activity after immunization, pointing at their role as an early biomarker of the adaptive immune response. In rheumatoid arthritis (RA) CXCL13 systemic expression has been shown to be upregulated. However, the factors involved in CXCL13 systemic upregulation and its significance as putative biomarker in patients with autoimmune diseases are currently unclear.

Objectives: To analyze the dynamics of CXCL13 systemic expression over time in RA after controlled induction of an adaptive immune response.

Methods: Fifty-five autoantibody-positive RA patients with established disease under stable treatment with b/tsDMARDs and with no evidence of previous SARS-CoV-2 infection were included in the study. All patients received two doses of the BNT162b2 vaccine at a three weeks interval. Serum samples were collected at the time of the first BNT162b2 dose (baseline - BL), after three weeks at the time of the second dose (post dose 1 – PD1) and after two further weeks (post dose 2 – PD2). At each time point CXCL13 (pg/mL) and SARS-CoV-2 anti-spike protein antibody titres were measured.

Results: The majority of patients were female (n=42, 76%) and both ACA and RF positive (n=42, 76%). All patients were receiving stable b/tsDMARD treatment (anti-CTLA4: 23 patients [41.8%], JAKi: 16 [29%], anti-IL-6: 8 [14.5%] and anti-TNF alpha: 8 [14.5%]). At baseline the median (IQR) CXCL13 values were 81.1 (58.6-125) and all patients were negative for SARS-CoV-2 anti-spike protein antibody. Effective immune confirmation was confirmed in all patients, in particular in 22/55 (40%) after the first dose and in 55/55 (100%) after the second dose, with a significant increase in SARS-CoV-2 anti-spike protein IgG antibody titer at PD2 (median [IQR], 142 [95,4-224]). Despite the effective induction of an adaptive immune response, no significant changes in the median (IQR) values of CXCL13 were observed at PD1 (three weeks after induction: 92.2 [61.8-141]) and PD2 (two weeks after booster: 74.2 [56-126]) with respect to each other and compared to baseline (Friedman p-value=0.947). Sub-analyses based on patients’ stratification according to the b/tsDMARD treatment, confirmed a non-significant variation in CXCL13 titers between baseline, PD1 and PD2 in all groups (Friedman p-value=0.911). Further sub-analyses limited to patients with baseline-PD1 value of CXCL13 >100 pg/mL (to exclude potential biases derived from high starting value of CXCL13 titers on the delta of response) confirmed the absence of significant changes (Friedman p-value=0.237).

Conclusion: At the time-point analysed, the induction of an adaptive immune response per se does not appear sufficient to impact on the expression dynamics of serum CXCL13 in established autoantibody-positive RA.

Cytotoxic chemical assessment in Treg cells of Psoriatic Arthritis by inhibition of IL23 (in real life) and its correlation with clinical remission

Keywords: Psoriatic arthritis, Cytokines and chemokines

F. J. Navarro Blasco1, S. Pascual2. 1University General Hospital of Elche, Spain., Rheumatology, Elche, Spain; 2Universidad de Alicante, Biotecnology and Immunology, San Vicente del raspeig, Spain

Background: Psoriatic arthritis (PsA) is a heterogeneous chronic entity with multiple clinical domains that evades to irreversible damage both organic and psychological. Therapeutic recommendation guidelines advise differentiated therapies according to the dominant clinical domain (e.g., peripheral arthritis, dactylitis, enthesitis, spondylitis, cutaneous or nail psoriasis). Moderate-severe involvement requires the use of targeted biological or synthetic medication. Primary and secondary failures or intolerances often force the change of therapeutic target in order to achieve greater efficiency. The interrelation of cytokines (mainly IL23, IL17, and IL10) in their pathogenesis at the “in vitro” level seem proven, but does not occur after stimulation in culture, showing an increase in both populations of Tregs (IL10-IL17) of the controls that did not occur in AP patients in remission. This differs from RA patients in remission in which Tregs expressing IL10 is increased, as an expression of the different immunological mechanisms in both pathologies. Likewise, the Treg phenotype has been described with double marker RORyt/FOXP3 and IL17 production. The plasticity of the T-cell compartment allows the immune response to adapt to the local environment. This is further emphasized by the recent recognition that Tregs themselves can differentiate into IL-17-producing cells, particularly when exogenous IL-17, IL-23, or IL-21. In patients with psoriatic arthritis, IL-10 levels are increased. The inhibition of IL23 would be suppressing this production hence the double lack of response (IL10-IL17) of AP patients in remission.

DOI: 10.1136/annrheumdis-2023-eular.772
Background: Recurrent pericarditis (RP) affects up to 30% of patients after a first episode of acute pericarditis. The effectiveness of anakinra, an IL-1 receptor antagonist (IL-1r), has been established in recent clinical trials and multicenter studies. Currently, the treatment with anakinra in RP is limited.

Methods: An international, multicenter, retrospective registry including 18 recruiting centers from five countries (Italy, Greece, Slovenia, Canada, United States) was designed to investigate the disease characteristics of patients with recurrent pericarditis undergoing complete discontinuation of the anti-IL1r treatment.

Objective: To explore key factors for successful anakinra tapering and discontinuation and to investigate potential predictors of disease relapse after complete biologic treatment suspension.

Results: A total of 149 patients who had fully discontinued anakinra (59.6% female, median age 51.7 years) were included in the present registry. Most patients had idiopathic aetiology (109; 73.2%) while a first episode of pericarditis after post-cardiac injury syndrome (PCIS) or related to systemic diseases was established in 30 and 10 cases (20.1% and 6.7%, respectively), with a median of 3 prior recurrences (interquartile range 2-4). Patients started anakinra treatment after a median time of 12 months (IQR 5-24) after a first episode of acute pericarditis, followed by a period at anakinra full-dosage with a median duration of 6 months (IQR 3–12). Among patients who experienced a recurrence (54 cases; 36.2%), 39 were female (72.2%, p = 0.019). Moreover, we observed a significant reduction in the recurrence of flares after an early introduction of anti-IL1r treatment from first pericarditis episode (mean median time 10 months; IQR 4-18 vs 14 months; IQR 14-29; p = 0.004).

Conclusion: The main preliminary findings of this global registry suggest that an early introduction of anakinra in patients with RP, corticosteroid-dependent and not responding to colchicine, significantly reduces the recurrence of flares after discontinuation.

AB0022 IL-23 POSITIVE NEUTROPHIL IS THE MAIN CELL SUBTYPE IDENTIFIED FROM SYNOVIAL FLUID OF PSORIATIC ARTHRITIS WITH THE POTENTIATION OF NEUTROPHIL EXTRACELLULAR TRAPS FORMATION

Keywords: Psoriatic arthritis

Y P Tsao1, 2, S. T. Chen3, 1Taipei Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Medicine, Taipei, Taiwan, Republic of China; 2National Yang Ming Chiao Tung University, Institutes of Clinical Medicine, Taipei, Taiwan, Republic of China

Background: Psoriatic arthritis (PsA) is a systemic autoimmune disease. Interleukin-23 (IL-23) and IL-17 are two main cytokines involving in the pathogenesis of psoriasis (PsO) and PsA. The origin and maintenance of IL-23 is the stakeholder of disease progression in PsA and should be carefully evaluated.

Objectives: To validate the role of neutrophils in maintaining the inflammation in PsA joint.

Methods: Synovial fluid from PsA was obtained from swelling knee joints, and the immune cells were classified by flowcytometry. The IL-23 positive cells were evaluated with marker of CD66b, CD16, and CD14. Neutrophils from healthy donor were collected and treated with interferon-α (IFN-α) and proteoglycan (PGN) for mimicking the neutrophils activation in PsO/PsA patients. Subsequent evaluation neutrophil extracellular traps (NETs) formation was conducted.

Results: 10 PsA joints fluid was collected. Among active and chronic PsA synovial fluid, neutrophil is the most abundant cell type identified among IL-23 positive cells (ranging from 65-90%). The t-SNE plot for mapping the repertoire of IL-23 containing cells confirmed the majority cell subtype with CD66b positive neutrophils. After stimulating neutrophils from healthy donor with IFN-α and PGN revealed increasing IL-23/19 expression after 16 hours stimulation. The NETs formation is profound and IL-23/19 containing NETs material could be identified.

Conclusion: IL-23 containing CD66b+ neutrophil is the main cell type in synovial fluid of PsA, which might be activated by inflammatory factors and release IL-23 with NETs material to promote type 17 T cell differentiation in joints.

AB0023 GLUCOCORTICOIDS AND TNF INHIBITOR EXERT NOVEL REGULATORY MECHANISM THROUGH LAG-3 MODULATION IN SYNOVIAL CELLS

Keywords: Disease-modifying drugs (DMARDs), bDMARD, Synovium

S. Gertel1, V. Furer1, A. Polachek1, O. Elkayam1, 1Department of Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Affiliated to the Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel., Rheumatology, Tel Aviv-Yafo, Israel

Background: Intra-articular (IA) injections of glucocorticoids (GCs) are clinically effective for the treatment of synovial inflammation in patients with persistent arthritis. TNF inhibitors (TNFi) utilization for IA injections was also reported with a varying efficacy [1, 2]. The mechanism of action of GCs and TNFi on regulatory mediators in the synovium is not fully understood. LAG-3 is a regulatory molecule that promotes suppressive immune response. LAG-3 expression could be regulated through multiple mechanisms, including modulation by different drugs.

Objectives: To investigate whether the regulatory mechanism of GCs and other anti-rheumatic drugs is mediated through change in LAG-3 expression in synovial cells derived from psoriatic arthritis (PsA) patients ex-vivo.

Methods: Synovial fluid mononuclear cells (SFMCs) derived from nine PsA patients were cultured ex-vivo with GCs (betamethasone (BET) and methylprednisolone acetate (MPA)), Methotrexate (MTX), TNF, IL-17A, IL-12/23, and IL-1 receptor inhibitors namely: (Infliximab (FX), Secukinumab, (SEC), Ustekinumab, (UST), and Anakinra (ANK), respectively) or with medium alone. After 5 incubation days, %CD45+LAG-3+ cells were measured. We further assessed if the drugs effect on SFMCs cell numbers in culture was accompanied with LAG-3 modulation. LAG-3 distribution on CD45, CD3, and CD14 cells was analyzed by flow cytometry (FACS).

Results: SFMCs treated with GCs showed a significant increase in %CD45+LAG-3+ cells (BET 1µg/ml, 6.8±1.3; BET 10µg/ml, 7.1±1.4; MPA 1µg/
ml, 6.7±1.3; and MPA 10µg/ml, 9.4±2.0, *p < 0.002, respectively), while IFX showed only a small increase of these cells' population (2.0±0.3, *p = 0.08) compared to the medium (1.0±0.3). Other treatments, including SEC, UST, ANK and MTX had no effect on %CD45+LAG-3+ cells compared to the medium, (1.0±0.2, 0.8±0.2, 0.8±0.2 and 0.9±0.2, respectively) (Figure 1A). After 5 days in culture, GCs (MPA) and IFX reduced SFMCs cell counts but this change was statistically significant only for GCs (21±5.1X10⁵/well, *p < 0.01 and 41±5.1X10⁵/well, respectively), while MTX had no effect compared to the medium (49±4.8X10⁵/well and 51±5.1X10⁵/well, respectively) (Figure 1B). In this culture setting, GCs significantly increased the %LAG-3+CD14+ cells (12.8±2.1, *p < 0.001) compared to the medium (0.9±0.4) but not the %LAG-3+CD3+ cells (Figure 1C and D).

Conclusion: Our data shows that GCs immunosuppressive activity is mediated through LAG-3 up-regulation in SFMCs. Within the drugs tested, this activity was exclusively mediated by GCs and to a lesser extent by a TNF inhibitor. GCs reduced the SFMCs cell numbers and concomitantly up-regulated LAG-3 expressing cells, mainly in monocytes. This emphasizes that monocytes seem to be the main mediators of the GCs immunosuppressive effect.

GENE EXPRESSION OF ABCG2, ALPK1, SLC22A12 AND IL-1β IN PERIPHERAL BLOOD LEUKOCYTES OF GOUT PATIENTS WERE CORRELATED WITH THEIR COMORBIDITIES AND HYPERURICEMIA

Keywords: Innate immunity, Gout, Crystal arthritis

A. López Macay1, K. Martínez Flores2, J. Fernández-Torres2, Y. Zamudio2, F. Sanchez Muñoz2, D. Clavijo-Cornejo3, 1Instituto Nacional de Rehabilitación LGII, Líquido Sinovial, Mexico City, Mexico; 2Instituto Nacional de Rehabilitación LGII, Líquido Sinovial, Mexico, Mexico; 3Instituto Nacional de Cardiología, Inmunología, Mexico city, Mexico; 4Instituto Nacional de Rehabilitación LGII, Reumatología, Mexico, Mexico

Background: Genes ABCG2, SLC22A12 (URAT1), and ALPK1 have been strongly associated with dysfunction of urate metabolism in patients with gout [1], but it is unknown how these transporters are expressed in patients with acute or chronic gout. Studies in murine and in vitro models have suggested that the enzyme ALPK1 kinase and the urate transporters ABCG2 and URAT1 may be involved in urate dysregulation and inflammation due to the presence of monosodium urate crystals [2-3]. It is important to know if the patient with acute or chronic gout can differentially express these genes in different tissues. Likewise, it is necessary to know if the patient's comorbidities may be associated with the expression of these transporters or pro-inflammatory molecules such as ALPK1 or IL-1β.

Objectives: To analyze the expression of urate transporters ABCG2, SLC22A12 and inflammation molecules ALPK1 and IL-1β in peripheral blood leukocytes from gout patients and to compare them with their metabolic profile and with the gene expression of people without gout and without hyperuricemia.

Methods: A total of 36 chronic and acute patients and 52 controls were recruited, ABCG2, SLC22A12 and inflammation molecules ALPK1 and IL-1β gene expression was evaluated by quantitative real-time PCR. Correlations of gene expression with clinical and laboratory parameters of patients were also analyzed.

Results: IL-1β was significantly increased in Peripheral blood monocytes cells (PBMCs) of patients when compared with their polymorphnuclear leukocytes
Methods: DA1<4). Next to that, we investigated presence of circulating NETs in plasma of patients with iSLE will eventually develop SLE, but it is unclear which patients meeting sufficient criteria required for the classification of SLE. Up to 55% of SLE (iSLE) defines a group of patients with symptoms typical of SLE but not classified according to the Systemic Lupus International Collaborating Clinicians (SLICC) criteria. Patients with iSLE had to meet at least one clinical and one immunological criterion but less than four SLICC criteria in total. LDGs were measured with flow cytometry. Single data points represent individual cases. Median and interquartile range are depicted per group. Stars represent p-values for pairwise comparison calculated with Mann Whitney tests. *p <0.05, ** p<0.01, *** p<0.001. HCs: healthy controls; iSLE: incomplete systemic lupus erythematosus, SLE: systemic lupus erythematosus.

Results: Statistics were performed for pairwise comparison. A two-tailed p-value of ≤ 0.05 was considered statistically significant.

Circulating plasma NETs were measured by using a previously validated sandwich enzyme linked immunosorbent assay. Low density granulocytes (LDGs) measured with flow cytometry. Single data points represent individual cases. Median and interquartile range are depicted per group. Stars represent p-values for pairwise comparison calculated with Mann Whitney tests. *p <0.05, ** p<0.01, *** p<0.001. AB0025

LOW-DENSITY GRANULOCYTES AND NEUTROPHIL EXTRACELLULAR TRAPS IN INCOMPLETE SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Innate immunity, Systemic lupus erythematosus, Biomarkers

S. Henning1, T. Reimers1, B. Doornbos-van der Meer2, H. Bootema1, K. De Leeuw1, J. Westra1, 1University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with a complex and only partly understood pathophysiology, while incomplete SLE (iSLE) defines a population of patients with symptoms typical of SLE but not meeting sufficient criteria required for the classification of SLE. Up to 55% of patients with iSLE will eventually develop SLE, but it is unclear which patients are at risk of progression. [1] Neutrophil dysfunction, among which aberrant neutrophil extracellular trap (NET) formation driven by low density granulocytes (LDGs), has been implicated in SLE pathogenesis. [2] However, the role of neutrophil dysfunction in early forms of SLE is still unclear.

Objectives: The aim of this study was to investigate whether LDGs are elevated in the peripheral blood mononuclear cell (PBMC) fraction of iSLE patients, compared to healthy controls (HCs) and SLE patients with quiescent disease (SLE-DAl-4). Next to that, we investigated presence of circulating NETs in plasma of iSLE as well as SLE patients and HCs.

Methods: Circulating plasma NETs were measured cross sectionally in 38 iSLE patients, 30 SLE patients with quiescent disease and 12 HCs while LDGs were measured in 18 iSLE patients, 13 SLE patients and 14 HCs. SLE patients were classified according to the Systemic Lupus International Collaborating Clinics (SLICC) criteria. Patients with iSLE had to meet at least one clinical and one immunological criterion but less than four SLICC criteria in total. LDGs, has been implicated in SLE pathogenesis. [2] However, the role of neutrophil dysfunction in early forms of SLE is still unclear.

Objectives: The aim of this study was to investigate whether LDGs are elevated in the peripheral blood mononuclear cell (PBMC) fraction of iSLE patients, compared to healthy controls (HCs) and SLE patients with quiescent disease (SLE-DAl-4). Next to that, we investigated presence of circulating NETs in plasma of iSLE as well as SLE patients and HCs.

Results: Proportions of LDGs and NET-levels were significantly increased in iSLE patients compared to HCs, as shown in Figure 1. The proportion of LDGs and circulating plasma NETs was similar between SLE and iSLE patients.

Conclusion: Our data shows significantly higher amounts of LDGs and circulating NETs in the iSLE and SLE cohort compared to healthy controls, suggesting that aberrant NET formation and clearance is present in early stages of the disease. In future studies, we aim to investigate the correlation between LDGs, circulating NETs and other immunological parameters, such as complement C3 and C4, and anti-dsDNA levels.

REFERENCES:
Results: Neutrophils from healthy donors exhibit enhanced NET formation when incubated with from SLE patients' plasma (P<0.001), compared to HC plasma. Their NETs are decorated with ox-mtDNA (P<0.01), SLE patients' mtDNA elicits increased NETs (P<0.001) decorated with ox-mtDNA (P<0.001), which are both not entirely abolished after DNase1 treatment. Formation of NETs and ox-mtDNA extrusion seems to be partially regulated through the type I IFN pathway; JAK inhibition with tocaitinib diminishes, however not entirely, NET formation and ox-mtDNA release (56% and 60% decrease, respectively). mtDNA amounts correlate with 8-OHdG (R²=0.87; P<0.0001) and type I IFN levels (R²=0.60; P<0.001) in SLE patients' plasma. aPL Ab-positive SLE patients were characterized by higher primary plasma levels of mtDNA (P=0.004), but not nDNA, compared to aPL Ab-negative SLE patients. Interestingly, aPL Ab-positive and aCL Ab-positive SLE patients' plasma demonstrated a higher proNETotic capacity.

Conclusion: Oxidative damage of mtDNA promotes the formation of NETs, is particularly interferogenic, and NETs relate to the antiphospholipid antibody positivity in SLE patients' circulation. Circulatory ox-mtDNA might promote endothelial damage and vasculitis in SLE. A significant link between aPL, namely aCL IgG, and circulating mtDNA in SLE patients was evident, potentially aggravating the inflammatory state linked to disease severity and promoting thrombotic events.

AB0027 ANTI-INFLAMMATORY EFFECTS OF TNF INHIBITOR AND METHOTREXATE ON IMMUNE CELLS FROM PERIPHERY AND SYNOVIAL FLUID: EX-VIVO STUDY

Keywords: Disease-modifying drugs (DMARDs), bDMARD

S. Gertel1, V. Furer1, A. Polache1, O. Elkayam1, From the Department of Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; Affiliated to the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, Rheumatology, Tel Aviv-Yafo, Israel

Background: Methotrexate (MTX) and TNF inhibitors (TNFi) are pivotal treatments for inflammatory arthropathies. Even to date, the mode of action of these drugs on various inflammatory cell populations is not well characterized.

Objectives: To study the impact of MTX and TNFi on the proliferation of peripheral blood mononuclear cells (PBMCs) and the intermediate monocytes (CD14+CD16+) frequency in synovial fluid mononuclear cells (SFMCs). The study focused on monocytes expressing the CD16+ as these cells promote synovial inflammation producing pro-inflammatory cytokines, including: TNF, IL-1β, and IL-6.

Methods: In this pilot exploratory study, we analyzed ex-vivo healthy donors PBMCs (n=19) proliferation without or with phytohemagglutinin (PHA) and PHA in the presence of MTX and/or TNFi. Next, the effect of these drugs on %CD14+CD16+ cells derived from psoriatic arthritis (PsA) patients SFMCs (n=11) was determined. Both assays were analysed by flow cytometry.

Results: Healthy donors PBMCs proliferation was inhibited by MTX (0.01 µg/ml and 0.1 µg/ml; 41.9±2.3 and 86.3±1.8, respectively) and to a lower extent by TNFi (infliximab, IFX) (1 µg/ml and 10 µg/ml; 43.1±2.5 and 49.4±2.5, respectively), whereas the combination of IFX 10 µg/ml and MTX 0.1 µg/ml led to the highest inhibition (91.0±2.0) (Figure 1 A and B). In PsA patients derived SFMCs, IFX 10 µg/ml significantly reduced (p<0.01) the %CD14+CD16+ cells (5.5±1.3) as compared to medium control (10.9±2.4), whereas MTX 0.1 µg/ml had only modest effect on this cell population (10.2±1.4). The combination of IFX 10 µg/ml and MTX 0.1 µg/ml resulted in the greatest reduction of %CD14+CD16+ cells (5.1±1.1) (Figure 1 C and D).

SFMCs from PsA patients (n=11) were co-cultured for 7 days with the drugs or with medium alone. (C) Representative plots showing CFSE-labeled healthy subject PBMCs. In the upper panel: Proliferation was measured either without PHA (no proliferation) or with PHA alone (maximal proliferation). Proliferation extent is shown in the left side of each plot. Lower panel: PHA with different drugs. Each image indicates %proliferation inhibition exerted by each drug. (B) Graph shows mean %proliferation inhibition, *p<0.05, **p<0.01.

AB0028 LEUCOCYTE ABNORMALITIES IN SYNOVIAL FLUID OF DEGENERATIVE AND INFLAMMATORY ARTHROPATHIES

Keywords: Inflammatory arthritides, Cytokines and chemokines

C. Baggio1, R. Luisetto2, C. Boscaro2, A. Scanzani, R. Ramonda1, M. Albiero2, P. Striolo3, F. Oliverio1, 1University of Padova, Rheumatism Unit - Department of Medicine, Padova, Italy; 2University of Padova, Department of Surgery, Oncology and Gastroenterology-DISCOG, Padova, Italy; 3University of Padova, Department of Medicine; Veneto Institute of Molecular Medicine, Padova, Italy; 4University of Padova, Department of Woman's and Child’s Health, Padova, Italy
Background: Genome damage has been related to the induction of autoimmune processes, chronic inflammation, and apoptosis. Recent studies suggest that some rheumatological disease are associated with overall genomic instability in the T cell (1-2). However, no data regarding leucocytes abnormalities in synovial fluid (SF) and their relationship with inflammation are available.

Objectives: The aim of this study was to investigate cellular phenotypes in SF collected from patients with different inflammatory arthropathies, including rheumatoid arthritis (RA), psoriatic arthritis (PsA), crystal-induced arthritis (CIA) and non-inflammatory arthropathies such as osteoarthritis (OA).

Methods: SFs were collected by arthroscopy from swollen knees of untreated adult patients with RA (n = 6), PsA (n = 12), CIA (n = 10), and OA (n = 7). Total white blood cell (WBC) count was performed using a Bürker counting chamber. Differential leucocyte count was performed by microscopic examination of 300 cells on May Grunwald Giemsa-stained preparations (MGG). Crystal search was performed using compensated polarized light microscopy. MGG staining was used for studying cellular morphology and to perform a cytoflourescent evaluation of leucocytes. All slides were examined for micronuclei (MN) and nuclear abnormalities (NA) included binucleated cells, and karyolitic, karyorrhectic, and pyknotic cells. The following cytokines, chemokines and growth factors were measured in SFs using commercially available ELISA kits: interleukin (IL)-1β, IL-6, IL-8, IL-10, TNFα, and TNFβ. The expression levels of factors involved in apoptosis such as BCL-2, BAK, BID, BAD and BAX were measured by real-time quantitative PCR (qPCR). Caspase-3 activity was determined using commercially available colorimetric assay kit.

Results: We found high percentage of MN in SF from CIA and RA compared to the OA group (p<0.05) and a high frequency of pyknotic cell in RA (p<0.05) and CIA patients (p<0.01). The percentage of karyonkotic and karyorrhectic cells were higher in RA patients with respect to OA and PsA patients (p<0.05). A correlation between pyknosis and immature polymorphonuclear cells with local inflammatory indices was observed. A strong positive correlation between local inflammatory cellular indices including WBC and PMN and the cytokines IL-1β, IL-6, IL-8, IL-10 was found. The study of apoptosis process revealed an increased BAX expression in CIA (p<0.05) and RA (p<0.08) compared to OA and PsA, while Bcl-2 was higher in CIA (p<0.05). Caspase-3 activity was increased in SF from RA patients compared to OA and PsA (p<0.05) and correlates with inflammatory and anti-inflammatory cytokines (IL-1β, IL-8, IL-10).

Conclusion: Our results showed that inflammatory SF are associated with genomic instability and abnormal cell subsets. A deeper knowledge of different abnormal cell subsets and their function could lead to a better understanding of the mechanisms underlying in the resolution of inflammation in these diseases.

OSTEOMODULIN DOWN-REGULATION IS ASSOCIATED WITH OSTEARTHRITIS DEVELOPMENT

Keywords: Animal models, Osteoarthritis, Cartilage

J. Zappa1, Q. Tong2, R. Van der Cruyssen3,4, F. M. F. Cornelis5, C. Lambert6, T. Pinto Coelho6, J. Grisart7, E. Kague2, R. Lories5,8, M. Muller9, D. Elewaut4,10, C. Hammonds11, T. Nuriakhmetova2, A. Nuriakhmetov3, I. Akhtiamov4, M. Karimov1, Y. Henrotin1,7,11.

Background: Osteoarthritis (OA) is associated with metabolic and structural changes in all joint tissues. Subchondral bone sclerosis, cartilage degradation, and synovial inflammation are the main hallmarks of OA [1–3]. OMD is a keratin sulfate proteoglycan, a member of the small leucine-rich proteoglycan (SLRP) family. OMD was first identified in bone where it is involved in the mineralization process [4,5]. Our previous work demonstrated that in the secretome of osteoblasts, OMD was one of the most differentiating factors between osteoblasts originating from the sclerotic and non-sclerotic zone of OA subchondral bone [3]. OMD levels were lower in the supernatant of osteoblasts coming from the sclerotic area.

Objectives: The present study examined if OMD is involved in bone and cartilage damages occurring during OA development.

Methods: We used Omd knock-out (KO) or overexpressing male mice and mutant zebrabfish to study in vivo the impact of OMD on skeletal development and aging. We investigated the influence of OMD on the severity of cartilage and bone damage induced by destabilization of the medial meniscus in these mice. We also analyzed the animals' gait using the CatWalk XT system. The effect of OMD gene expression on the gene expression profile of OA cells in monolayer culture was analyzed by RNA sequencing method. Finally, OMD binding to RANKL was assessed using a solid phase binding assay.

Results: In wild-type mice, we identified OMD mainly in bone and calcified cartilage. Tibial growth plate significantly decreased in all genotypes with age but to a lesser extent in the KO mice than in other genotypes. In KO mice, the calcified cartilage layer was thinner in the medial tibial plateau and thicker in the tibial lateral plateau than in the wild-type, while total cartilage thickness was not different between genotypes. We also demonstrated that Omd deficiency led to thicker and less porous bone and subchondral bone sclerosis. Omd knock-out mice spontaneously developed more severe OA cartilage lesions in the medial

DISBALANCE OF SYNOVIAL FLUID CYTOKINES IN CHRONIC KNEE SYNOVITIS

Keywords: Synovium, Cytokines and chemokines

M. Karimov1, T. Nuriakhmetov2, A. Nuriakhmetov3, I. Akhtiamov4. Tashkent Medical Academy, Traumatology, Orthopedic and Military Surgery, Tashkent, Uzbekistan; 2Kazan State Medical University Hospital therapy, Kazan, Russian Federation; 3Republican Clinical Hospital, Orthopedics No. 2, Kazan, Russian Federation; 4Kazan State Medical University,Traumatology, Orthopedic and Military Surgery, Kazan, Russian Federation

Background: One of the most important issues of orthopedics remain long-stand- ing synovitis despite the treatment after traumas and arthroscopy even after removal of mechanical irritating factor (meniscal resection, chondroplasty). In the long term prolonged treatment of arthritis may lead to irreversible joint damage progression. Current generally accepted strategy is to start the treatment as early as possible which affects the following disease course. Due to this, the study of pathogenic features of posttraumatic synovitis is of interest as based on them, the choice of the most specific and effective treatment may be made.

Objectives: To study the features of cytokine levels changes in synovial fluid in knee synovitis.

Methods: The prospective study of patients with long-standing knee synovitis included knee arthroscopy and outcome registration, measurement of cytokines in aspirated prior to surgery synovial fluid using flow fluorometry.
tibial plateau than the wild-type during aging. In contrast, OMD production did not influence cartilage and bone changes induced by median meniscus destabilization. The gait pattern of mice was abnormal in KO compared to the wild-type genotype whereas a shorter swing phase and smaller paw contact intensity was observed in the wild-type – which developed more severe cartilage lesions than wild-type. In osteoblast culture, OMD down-regulated some genes involved in the extracellular matrix organization and up-regulated other genes responsible for the collagen network degradation. Finally, OMD bound to RANKL and inhibited osteoclastogenesis.

**Conclusion:** Alterations of the OMD expression modify bone and cartilage metabolism and structure. OMD helps to preserve bone and cartilage integrity and a local decrease in its production leads to the development of OA mainly by increasing subchondral bone sclerosis and thinning the calcified cartilage.

**AB0031 ASSOCIATION BETWEEN OMEGA-3/6 FATTY ACIDS AND OSTEOPOROSIS: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY**

**Keywords:** Osteoporosis, Validation, Biomarkers

S. Wei1,2, Y. Lu1,2,3, S. Song1,2,3, J. Qiao1,2,3, S. X. Zhang1,2,3, Y. Li1,2,3. 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microeology, Taiyuan, China; 3Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China

**Background:** Osteoporosis (OA) is the most common degenerative disorder worldwide. Accumulating evidence has demonstrated the associations of omega-3 and omega-6 PUFAs with the disease activity and inflammatory mediators of OA, omega-3 polysaturated fatty acids (PUFAs) are recognized for their anti-inflammatory properties[1], while omega-6 FAs are inflammatory mediators that are increased in joints with OA[2]. However, the evidence of causal links of omega-3 and omega-6 PUFAs on the risk for OA remains inconclusive.

**Objectives:** This study was conducted to evaluate the causal relationships between omega-3/6 and OA by performing the two-sample Mendelian randomization (MR) analysis.

**Methods:** The data set of this study was from the publicly available genome-wide association study (GWAS). The genetic instrumental variables for omega-3/6 were derived from the UK Biobank (UKB) and included 114,999 participants. Summary statistic data for OA originated from a meta-analysis of GWAS with an overall 50,508 subjects of European ancestry. In the MR Approach, the IV analysis is based on three strict assumptions, namely that IV should be strongly correlated with exposure, independent of confounding factors associated with direction and outcome, and influence outcome solely through exposure. We screened SNPs with genome-wide significance (P < 5 x 10^-8). To ensuring that the SNPs were valid and independent, we removed the linkage disequilibrium (LD) between the SNPs at r^2 < 0.001, and <1,000kb in size. Furthermore, the secondary phenotype of each SNP was retrieved to ensure that it was not associated with OA. The F statistic > 10 indicated a relatively strong estimated effect of IVs. Subsequently, two-sample Mendelian randomization analyses were conducted with inverse variance weighted (IVW), MR-Egger regression and weighted median methods. Sensitivity analyses were then conducted to assess the robustness of our results.

**Results:** The inverse-variance weighted (IVW) method revealed that higher omega-6 levels were correlated inversely with the risk of OA ([β = -0.08, 95% CI [-0.16 to -0.00], P = 0.01], but no causal effect of omega-3 on the risk OA was observed ([β = -0.04, 95% CI [-0.10 to -0.02], P = 0.15]. The causal estimates from MR-Egger and weighted median methods revealed completely concuring effect directions ([β < 0, p < 0.05]. Cochran’s Q of IVW analysis showed that there was heterogeneity among SNPs (P < 0.05), it does not affect the results of IVW, which shown the reliability of our results. MR-Egger regression analysis demonstrated that SNPs could have no-horizontal pleiotropy between omega-6 fatty acids and risk of OA (P > 0.05). Moreover, Results of the leave-one-out method suggested that MR results were not influenced by individual SNPs.

**Conclusion:** This study revealed that the high level of omega-6 predicted by genes can reduce the risk of OA. This implies that supplementing omega-6 fatty acids in our diet may be a potential nutritional modality for the prevention of OA.

**AB0032 LOCAL EXPRESSION OF miRNAs IN OSTEOPOROSIS PATIENTS**

**Keywords:** Osteoporosis, Biomarkers

R. Shumnalieva1, D. Kachakova2, R. Kaneva2, Z. Kolarov2, S. Monov1. 1Medical University-Sofia, Department of Rheumatology; Clinic of Rheumatology, Sofia, Bulgaria; 2Medical University – Sofia, Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria

**Background:** Microribonucleic acids (miRNAs) comprise a class of small non-coding RNAs that negatively regulate the gene expression on posttranscriptional level. Altered expression of miRNAs has been described systemically as well as locally in the inflamed joints of patients with osteoarthritis (OA) [1-3].

**Objectives:** The aim of our study was to evaluate the synovial fluid (SF) expression of miRNA-146a (miR-146a), miR-155, miR-193b in OA patients and to determine their role as potential diagnostic biomarkers for this disease.

**Methods:** 16 OA patients were included in the analysis. Expression levels of miR-146a, miR-155 and miR-193b in SF samples were determined by qPCR (SybrGreen technology) and compared to healthy controls (HCs). Relative changes of gene expression levels of the studied miRNAs were calculated by 2^-∆∆CT method. SPSS v20 was used for statistical analysis.

**Results:** OA SF showed statistically significant overexpression of miR-146a (in 75.00%), of miR-155 (in 66.75%) and of miR-193b (in 75.00%) when compared to HCs and these miRNAs could be used to differentiate OA from HCs (p=5.9x10^-5, p=0.043 and p=5.5x10^-5, respectively). Receiver operating characteristic (ROC) curve analysis was constructed in order to evaluate the diagnostic accuracy of the studied miRNAs in SF to distinguish OA from HCs by using relative expression (RQ) values. Area under the curve (AUC) for miR-146a was 0.830 (95% CI=0.674-0.885, with 75.00% sensitivity and 72.70% specificity, p=0.004), AUC for miR-155 was 0.767 (95% CI=0.582-0.952, with 75.00% sensitivity and 54.50% specificity, p=0.020) and AUC for miR-193b was 0.801 (95% CI =0.622-0.981, with 87.50% sensitivity and 63.60% specificity, p=0.009). There was a correlation between the SF expression levels of miR-146a and miR-193b and the radiographic stage of the disease (p=0.0071 and p=0.0105, respectively). SF levels of miR-146a and miR-155 correlated with the SF cell count (p=5.16x10^-3 and p=0.0188, respectively).

**Conclusion:** We found an altered SF expression of miR-146a, miR-155 and miR-193b in OA patients when compared to HCs and these miRNAs could serve as potential diagnostic biomarker for inflammatory OA. Larger sets are needed to confirm the diagnostic accuracy of the studied miRNAs in OA.
Orthopedic Surgery, Kobe, Japan. Joint destruction by RPOH. Tofacitinib may be an effective intervention before the occurrence of significant operative treatment modality is available for RPOH. Based on the present results, tofacitinib can suppress STAT3 activation in the synovial tissues in the hip joint with RPOH after incubation with the potential STAT3 inhibitors. This study aimed to investigate suppression of phosphorylated STAT3 in the synovial tissues from the hip joint with RPOH after incubation with the potential STAT3 inhibitors. Methods: Synovial tissues near the acetabular notch of the hip joint were obtained from four RPOH patients with femoral head destruction at the time of total hip replacement. Whereas the initial radiograph showed no typical feature of OA within 12 months after the onset is associated with increased serum levels of matrix metalloproteinase-3 (MMP-3), Interleukin-6 (IL-6) signaling activates STAT3, resulting in MMP-3 production in OA synovial fibroblasts in culture. The IL-6/gp130-associated Janus kinases/STAT3 axis plays a critical role in mediating inflammatory signal. No information is currently available on STAT3 activation in the synovial tissues in the early stage of RPOH. Recently, tofacitinib and meloxicam have been shown to inhibit STAT3 activation. Objectives: This study aimed to investigate suppression of phosphorylated STAT3 in the synovial tissues from the hip joint with RPOH after incubation with the potential STAT3 inhibitors. Results: The serum concentration of MMP-3 in each RPOH patient were obtained for 4 RPOH patients with femoral head destruction at the time of total hip replacement. Whereas the initial radiograph showed no typical feature of OA such as joint space narrowing, formation of osteophytes or bone cysts, each patient developed chondrolysis with bone destruction. Duration between the disease onset and operation were 5-7 months. The serum concentration of MMP-3 was determined within 2 weeks before operation. The tissue samples were incubated for 1 hour with or without tofacitinib or meloxicam. Immunohistochemical examination was performed using anti-human CD3 antibody, anti-human CD68 antibody and anti-human phospho-STAT3 antibody. The number of phospho-STAT3-positive cells was counted in the three different areas of the synovium at a magnification of X 400. A mean percentage was calculated as phospho-STAT3-positive cells in all cell counts out of the three high-power fields in each of the four patients. The strongest effects were found for shikonin with IC50 values of 1.2 ± 0.1 μM. Shikonin counteracts the inflammatory response by massively reducing the expression of the pro-inflammatory mediators. The phosphorylation level of ERK changed slightly. pJNK and pp38 showed a significant increase, and the downstream targets cEBPα and MEF2c may play a role in the cartilage homeostasis. STAT3 phosphorylation decreased significantly and has a chondroprotective function through the regulation of cyclin D1 and Sox9. NGS data showed a highly significant difference in gene expression under the influence of shikonin. Conclusion: Our results demonstrate for the first time that shikonin derivatives have extensive effects on the inflammatory processes, MAPKs, the IL6/STAT3 downstream regulation and the DNA repair gene expression pattern in healthy and OA chondrocytes. The serum concentration of MMP-3 in each RPOH patient were obtained for 4 RPOH patients with femoral head destruction at the time of total hip replacement. NEXT GENERATION SEQUENCING AND SHIKONIN EFFECTS ON HUMAN PRIMARY ARTICULAR OSTEOARTHRITIS CHONDROCYTES

Keywords: Osteoarthritis
B. Lohberger1, P. Sadoghi1, A. Leitner1, N. Kretschmer2, B. Steinecker-Pfenninger1, Medical University Graz, Department of Orthopedics and Trauma, Graz, Austria; 1University of Graz, Department of Pharmacognosy, Graz, Austria; 2Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Saalfelden, Austria

Background: Osteoarthritis (OA) is one of the most common joint disorders, leading to functional disability, especially in people aged over 50 years, causing loss to the economy and affecting social development [1]. Drugs addressing the underlying biological causes of OA are not currently available [2]. Objectives: Naturally occurring naphthoquinone derivatives, such as shikonin and derivatives thereof, were shown to inhibit inflammatory processes and chondrocyte apoptosis by regulating the PI3K/AKT pathway in a rat model of OA [3]. The corresponding regulatory mechanisms in human OA chondrocytes and their influence by shikonin have not yet been investigated. To develop new therapeutic approaches, we investigated the effect of shikonin derivatives on inflammation, MMP expression, the regulation of MAPK signalling, and the gene expression patterns of DNA repair metabolism and the cell cycle in human healthy (HC) and OA chondrocytes (pCH-OA).

Methods: Viability was assessed using the CellTiter-Blue assay. Inflammation and the cell cycle in human healthy (HC) and OA chondrocytes (pCH-OA).

Results: Both HC and pCH-OA showed a dose-dependent decrease in viability after treatment. The strongest effects were found for shikonin with IC50 values of 12.3 ± 0.1 μM. Shikonin counteracts the inflammatory response by massively reducing the expression of the pro-inflammatory mediators. The phosphorylation level of ERK changed slightly. pJNK and pp38 showed a significant increase, and the downstream targets cEBPα and MEF2c may play a role in the cartilage homeostasis. STAT3 phosphorylation decreased significantly and has a chondroprotective function through the regulation of cyclin D1 and Sox9. NGS data showed a highly significant difference in gene expression under the influence of shikonin.

Conclusion: Our results demonstrate for the first time that shikonin derivatives have extensive effects on the inflammatory processes, MAPKs, the IL6/STAT3 downstream regulation and the DNA repair gene expression pattern in healthy and OA chondrocytes.

CHEMOKINES (IL-8 & GRO-α) AND CXCR1/2 PATHWAY INDUCES SENESCENCE INDUCTION IN CHONDROCYTES

Keywords: Cytokines and chemokines, Cartilage, Osteoarthritis
A. K. Aryan1; A. K. Srivastava2; M. K. Rai2; L. Gupta3,4,5; D. P. Misra2; V. Agarwal2.
1Sanjay Gandhi Post Graduate Institute of Medical Sciences (SGPGIMS), Clinical Immunology & Rheumatology, Lucknow, India; 2Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology & Rheumatology, Lucknow, India; 3Royal Wolverhampton Hospital NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom; 4City Hospital, Sandwell and West Birmingham Hospitals, Department of Rheumatology, Birmingham, United Kingdom; 5The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Centre for Musculoskeletal Research, Manchester, United Kingdom

Background: Tumor Necrosis Factor-α (TNF-α) and Interleukin(IL-1) are well-known in the induction of senescence in chondrocytes and play an important role in the pathogenesis of Osteoarthritis (OA). However, targeting these pathways has not yielded promising results. The chemokines IL-8(CXCL8) and GRO-α(CXCL1), as well as the CXCR1/2 pathways, are known to mediate inflammation and apoptosis. However, the precise role of these chemokines in the
pathogenesis of OA is unknown. We hypothesize that the CXCR1/2 signaling pathway is involved in the induction of senescence in chondrocytes.

Objectives: To evaluate the role of chemokines and CXCR1/2 pathway in induction of senescence in chondrocytes derived from patients with OA and healthy chondrocyte cell.

Methods: Healthy primary chondrocytes (HPC) cell lines and human primary chondrocyte cells derived from patients diagnosed with OA and healthy chondrocytes cell.

Results: This study showed that the % of β-GAL in the HPC were almost negligible. However, showed significantly higher % in OPC(p<0.001). Moreover, when stimulated with IL-8, exhibited markedly increase in the positive blue cells in both HPCs and OPCs in a time dependent manner (p<0.001) at 24 hrs., 48 hrs., 72 hrs. and 96 hrs.). In line with results of HPC and OPC stimulated with IL-8, OPC also showed higher % of senescence when induced with Gro-α(p<0.001) at 24 hrs., 48 hrs., 72 hrs. & 96 hrs (Figure 1(A)(B)(C)). Since TNF-α and IL-1β reported to have role in induction of senescence in chondrocytes, we have examined the [γ]-H2AX in HPC and OPC treated with TNF-α and IL-1β and found significant higher % of blue stained in the OPC(Table 1). These results were further validated by fold change expression of senescence induced genes P16INKa and UPAR at time dependent manner. We observed higher fold change expression of P16INKa in IL-8 induced OPC at 24 hrs. (p=0.001); at 48 hrs. (p<0.001); at 72 hrs. (p=0.03) and at 96 hrs. (p<0.001) with that of IL-8 induced HPC. However, stimulation with Gro-α showed increase in the expression of P16INKa in a time dependent manner(at 24 hrs., 48hrs., 72hrs. and 96 hrs.) in both HPCs and OPCs. Similarly, the expression of UPAR in IL-8 induced OPCs at 24 hrs.(p=0.69); at 48 hrs.(p=0.05); at 72 hrs. (p<0.001) and at 96 hrs. (p=0.01) with that of Gro-α induced HPC. While the expression of UPAR in Gro-α induced OPCs and HPCs showed increase in a time dependent manner(at 24 hrs., 48 hrs., 72 hrs. and 96 hrs.). Flow-cytometric analysis revealed that induced cells were negative expression for apoptotic markers viz., Annexin V and PI.

Conclusion: Overall, this study highlights that IL-8 and Gro-α induce senescence in chondrocytes, a key event in the pathogenesis of OA. However, CXCR2 pathway may be explored further for therapeutic potential.

HIGH THROUGHPUT siRNA EFFICACY SCREENING USING FLUORESCENCE SYSTEM

Keywords: Cartilage, Osteoarthritis, Genetics/Epigenetics

M. Deniz1, L. Hakim Pouri, A. S. Thorup, F. Dell’accio1, T. The William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom

Background: Osteoarthritis (OA) is characterized by loss of articular cartilage, bone remodelling and pain. It is a leading cause of disability in the elderly population. Currently, there are no disease modifying drugs to stop progression of OA. One bottleneck in clinical translation is that the cartilage extracellular matrix is avascular and impenetrable for large macromolecules. siRNA induces highly specific gene silencing and can be used for targets that are ‘undruggable’. A novel therapeutic target that has been identified for treatment of OA include using siRNA to silence receptor tyrosine kinase-like orphan receptor 2 (ROR2) which offers great potential in improving pain outcomes and structural integrity in OA mice (Thorup et al., 2020). However, efficacy of ‘naked’ siRNA is limited as it is instantly targeted for degradation by nucleases. To improve utility of siRNA as a therapeutic modality, chemical modifications can be introduced to the siRNA backbone, and it can be coupled with carrier molecules.

Objectives: To identify RNA backbone modifications to achieve long-term silencing in joint tissues following intra-articular injection.

Methods: Cos7 cells transfected with a lentivirus encoding GFP and one specific clone was selected and expanded for downstream experiments (Eldridge et al., 2016). Transfections were performed using JetPrime. Modified siRNA was generated by Integrated DNA Technologies.

Results: As a screening system, we optimized a microtitre plate system coupled with live fluorescent detection to measure GFP expression in cell monolayers. The fluorescence system uses a 96-well plate and allows for repeat measurements over time, without the need to harvest samples at each timepoint. Using this system, we compared 5 different modifications were compared. The best modification allowed to silence GFP in GFP-expressing cells for at least 10 days. The best modification was coupled with atelocollagen and administered via intra-articular injections into mice expressing GFP ubiquitously. After 3 weeks, GFP was efficiently silenced in the full thickness of the cartilage.

Conclusion: Chemical modifications of the RNA backbone and coupling with atelocollagen affords stable gene silencing in cartilage for at least 3 weeks. This technology enables fast, dose-dependent loss of function experiments in animal models of osteoarthritis. This methodology could be developed in the future to therapeutically target pathogenic molecules that are out of reach of traditional biologics such as transcription factors.

GENETIC EVIDENCE REVEALS A CAUSAL ROLE OF WHITE BLOOD CELL COUNT IN OSTEOARTHRITIS

Keywords: Genetics/Epigenetics, Osteoarthritis

Q. Wang1,2, X. Ma1,2, Y. Niu1,2, Q. Yu3, P. F. He4, X. Li1,2,4, S. X. Zhang1,2,4. 1Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China; 2Shanxi Medical University, Key Laboratory of Cellular Proliferation, Taiyuan, China; 3Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China; 4The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: Osteoarthritis (OA) is increasingly recognized as a disease with a significant inflammatory component (1). Signs of inflammation such as synovitis can be identified in OA patients using magnetic resonance imaging (MRI) and ultrasonographic imaging. The white blood cell count in synovial tissue has been considered useful in the assessment and diagnosis of arthritis. However, the causal relationship between the white blood cell count and OA has yet to be well.
Objectives: To investigate associations between white blood cell count and OA. Methods: Mendelian randomized analysis (MR) was performed using white blood cell count as exposure data and OA as outcome data. This study included 173 480 individuals of European ancestry for exposure traits from three extensive UK studies[2]. The random effects inverse variance weighting (IVW) method was used for the primary analysis, and the weighted median and MR-Egger methods were supplemented for analysis. Then, we performed Cochran’s Q test, MR pleiotropy residual sum and outlier (MR-PRESSO), to test for heterogeneity and horizontal multiplicity. The sensitivity analysis was also performed to verify the robustness of the primary results of the MR analysis.

Results: IVW method showed that knee or hip (OR=0.942, 95% CI:0.895-0.990, P =0.019), knee (OR=0.944, 95% CI:0.886-1.007, P =0.041) and hip (OR=0.929, 95% CI:0.868-0.995, P=0.0359) had a protective effect on white blood cell count. After removing the confounding factors, we identified a significant causal association between white blood cell count and OA by IVW using residual single nucleotide polymorphisms (157 remaining in knee, 159 remaining in hip, and 159 remaining in knee or hip). P values of IVW were less than 0.05, indicating a significant causal relationship. Further sensitivity analyses validated the robustness of the MR results.(Figure 1)

Conclusion: There was a significant causal relationship between white blood cell count and OA. This is meaningful for the prevention and treatment of OA in the future.

Interestingly, around 20% of patients experience chronic postoperative pain and the reason for this is not fully understood. Pain in OA is multifactorial and low-grade chronic inflammation has been indicated as a potential cause. Pre-clinical evidence suggests that pro-inflammatory mediators, such as interleukin 6, can sensitize the peripheral and central nerves and these molecules might be associated to clinical pain. Clinical evidence has demonstrated differences in pro-inflammatory mediators when comparing patients with OA and healthy individuals. A recent study has linked these profiles to chronic postoperative pain after TKR but an in-depth analysis, as seen for neuropathic and widespread pain, is needed to advance the field. Currently, no specific biomarkers have been identified, despite initiatives on focused molecular inflammatory mediators. In an attempt to advance the field, a comprehensive analysis of an extensive network of cytokines, chemokines, and growth factors could identify the role of low-grade inflammation in patients with OA and potentially stratify patients more prone to experiencing pain.

**Objectives:** This study aimed 1) to evaluate preoperative serum levels of 92 inflammatory biomarkers in KOA patients compared to healthy controls, 2) to investigate preoperative differences of inflammatory biomarkers within different subgroups of patients with KOA and link these subgroups to clinical pain before and after TKR surgery.

**Methods:** Blood samples from preoperative patients with KOA scheduled for TKR (n=200) and healthy participants (n=39) were collected. After centrifugation of the serum was frozen at -80°C until analysis. Serum samples were analyzed for inflammatory markers using the OLINK inflammation panel, which included 92 protein markers. Clinical pain was assessed using a Visual Analog Scale (VAS). Moreover, patients completed the Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire before and 12 months after TKR. Multivariate data analysis was performed to identify differences between patients and controls. Hierarchical cluster analysis (HCA) and Orthogonal Partial least squares discriminant analysis (OPLS-DA) was used for comparing groups (patients vs controls) and to identify subgroups within patients. T-tests were used to evaluate difference within the KOA cohort in terms of VAS and KOOS scores before and 12 months after TKR.

**Results:** Multivariate analysis showed that 12 proteins were differentially expressed between patients and controls (P<0.05). Hierarchical cluster and OPLS-DA analysis identified two patient subgroups (pat-1, n = 46; pat-2, n= 72) and 23 proteins were dysregulated comparing these two groups (p<0.01). Post-operative VAS and KOOS assessments were significantly different between the two subgroups (p<0.05).

**Conclusion:** The present study suggest a low-grade inflammation in patients with KOA when compared to healthy pain free subjects. Additionally, this study suggests that a high inflammatory subgroup for patients with KOA exist and this group is likely to have more clinical and worst function 12-months after TKR.

**DIFFERENTIALLY EXPRESSED GENES IN PATIENTS WITH OSTEOARTHRITIS**

**Keywords:** Biomarkers, -omics, Osteoarthritis

R. Martinez1, C. Elizondo Solís1, A. Montoya Rosales2, M. Salinas Carmona1, N. Macías-Segura1, 1Servicio y Departamento de Inmunología, Service and Department of Immunology, Monterrey, Mexico; 2UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico

**Background:** Osteoarthritis (OA) is a chronic degenerative disease that affects the joints, causing symptoms of arthralgias, swelling, loss of flexibility, etc. It is the most common rheumatic disease with an estimate of 27 million patients in the US [2]. Its pathophysiology is not yet well understood, as it is thought to be a result of multiple factors that induce metalloproteases, synovial angiogenesis and inflammatory cytokines that leads to inflammation and cartilage destruction [3]. To better understand the molecular mechanisms underlying this disease, we performed a meta-analysis with integrative bioinformatics.

**Objectives:** We aimed to obtain and assess overlapped differentially expressed genes (DEGs) in datasets of patients with OA through functional enrichment and protein-protein interactions (PPI).

**Methods:** We designed a search strategy in the Gene Expression Omnibus platform to identify datasets of gene expression profiling by array of patients with osteoarthritis. The inclusion criteria were: 1) Presence of healthy controls in the datasets, and 2) Analysis of data with GEO2R. The exclusion criteria were: 1) Incomplete information in the datasets, 2) Failure to identify case and controls, and 3) Gene expression by RNAseq; DEGs were selected when p < 0.05 and Logfold change > 2. We assessed the genes with DAVID database, and PPI through String and Cytoscape; and performed a prediction analysis of possible therapeutic targets.

**Results:** 6 datasets fulfilled the inclusion criteria, and 128 overlapped DEGs were identified. DAVID database yielded the top 3 Biological Processes involving those genes (Table 1). Cytoscape detected 3 clusters in which those genes interact, and irRegulon proposed CHD1 gene as a possible therapeutic target to regulate the entire cluster (Figure 1).

**Table 1. Top 3 biological processes involving overlapped DEGs among the datasets.**

**Conclusion:** We aimed to identify and assess DEGs involved Osteoarthritis pathophysiology, as well as predict a possible therapeutic target. Our results suggest that immune processes involving B-cell activation and phagocytosis, as well as complement activation underlie OA pathophysiology. Validation of these results in patients with OA is needed since they can serve as possible diagnostic biomarkers. Further research is necessary to analyze the other clusters, and CHD1 characterization as a possible therapeutic target.

1Peter the Great St. Petersburg Polytechnic University, Graduate School of Service and Trade, Saint-Petersburg, Russian Federation
Background: EX - poorly studied extracellular vesicles, 30-150 nm in diameter, found in various biological fluids and have high functional activity, including immunomodulatory effects.

Objectives: The participation of EX in the development of complex connective tissue immunopathology requires further study. The aim of the work was to study EX of SF in GA.

Methods: SF of knee joints of 12 patients with GA with active synovitis and 7 conditional donors postmortem (D) were researched. EX was isolated by ultrafiltration and double ultracentrifugation (105 g). EX was identified by transmission electron microscopy and flow cytometry. Electromotive force (EM) determined by the automated microscop e. Registration of the active forms of oxygen (O2F2) was carried out by EPR. The activity of Cu-Zn superoxide dismutase (Cu-Zn SOD) and SOD, as well as DNA and RNA levels, was estimated by employing classical biochemistry methods.

Results: The EX population undergoes significant morphological changes in GA: EX become smaller, their diameter decreases by an average of 2.5 times, and the value of the negative surface charge changes to 45.5%. EM EX at GA differs by the autoimmunomodulatory effects.

Conclusion: The molecular mechanisms of GA progression are associated with the ability of EX to influence intercellular communication, epigenetically reprogram various target cells, activate protein biosynthesis, and be carriers of a number of mediators. Violation of exosomal immune intercellular communications, apparently, underlies the development of a variety of pathologies, including systemic connective tissue diseases.

SEROUS ADMINISTRATION OF RECOMBINANT HUMAN BONE MORPHOGENETIC PROTEIN-2 AND OSTEOPROTEGERIN-FC ENHANCES THE DIFFERENTIATION OF OSTEOSTBALS

Keywords: Bone diseases, Osteoporosis

C. N. Son1, H. J. Choi1,2, J. M. Kim1, S. H. Kim1. Keimyung University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of (South Korea); 2Gyeongbuk Provincial College, Emergency Medical Technology, Gyeongbuk, Korea, Rep. of (South Korea)

Background: Osteoprotegerin (OPG) is an intrinsic antagonist of the RANKL. A recent study reported that RANKL reverse signaling in osteoblasts may prepare osteoblasts for further maturation and that vesicular RANK stimulates osteoblast differentiation. Hence, OPG is expected to accelerate osteoblastogenesis by affecting RANKL reverse signaling.

Objectives: We compared the level of differentiation from preosteoblasts to osteoblasts by serially administrating recombinant human bone morphogenetic protein-2 (rhBMP-2), involved in bone formation and regeneration, and osteoprotegerin-immunoglobulin Fc segment (OPG-Fc), an osteoclast inhibitor.

Methods: The MC3T3-E1 preosteoblast cell line was differentiated for one, three, and seven days with a treatment of OPG-Fc in 10–200 ng/mL concentration and the cell viability was evaluated by Cell Counting Kit-8 analysis. The level of differentiation from MC3T3-E1 cells to osteoblasts was determined by alkaline phosphatase activity. The level of runt domain-containing transcription factor 2 (Runx2) and osteopontin (OPN) manifestation, involved in osteoblast differentiation, was examined by real-time polymerase chain reaction and western blotting.

Results: During MC3T3-E1 cell differentiation, the differentiation level was high with one-day treatment using 100 ng/mL OPG-Fc. The treatment with 50 ng/mL rhBMP-2 for seven days, followed by one-day treatment with 100 ng/mL OPG-Fc produced the highest differentiation level, which was approximately 5.3 times that of the control group (P < 0.05). The expression of Runx2 mRNA significantly increased, reaching 2.5 times the level of the control group under the condition of seven-day treatment with rhBMP-2 and one-day treatment with OPG-Fc (P < 0.001). The expression of Runx2 protein significantly increased to approximately 5.7 times that of the control group under the condition of seven-day treatment with rhBMP-2, followed by one-day treatment with OPG-Fc (P < 0.01). The expression of OPN protein showed no change from that of the control group under various conditions of rhBMP-2 and OPG-Fc combinations.

Conclusion: Differentiation ability of preosteoblasts to osteoblasts was strong with serial treatment and rhBMP-2, followed by OPG-Fc. Runx2 and OPG mRNA levels and Runx2 protein levels increased. These results imply that the combination of OPG-Fc and rhBMP-2 increased osteoblast differentiation efficacy.

INTERLEUKIN-18 BINDING PROTEIN REGULATES THE APOPTOSIS AND NECROTICITY OF FIBROBLAST-LIKE SYNOVIOCYTIES AND CHONDROCYTES IN RHEUMATOID ARTHRITIS

Keywords: Adaptive immunity, Rheumatoid arthritis, Cartilage

S. H. Lee¹, H. K. Min², H. R. Kim¹. ¹Konkuk University School of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea); ²Konkuk University Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: Interleukin (IL)-18 plays a pro-inflammatory role in rheumatoid arthritis (RA), and its decoy receptor IL-18 binding protein (IL-18BP) has a potential therapeutic role.

Objectives: We investigated the role of IL-18BP on the joint destruction process of RA by accessing the effects of IL-18BP on fibroblast-like synoviocytes (FLSs) and chondrocytes.

Methods: Peripheral blood mononuclear cells (PBMCs) from patients with RA and healthy controls were cultured under T cell proliferative conditions with 10, 50, or 100 ng/ml of IL-18BP. After three days of culture, flow cytometry for CD4+ T cells was performed using various IL-18BP concentrations. The apoptosis and necrosis of FLSs and chondrocytes were measured by flow cytometry using annexin V and propidium iodide (PI) and western blot using TNF-α stimulation with IL-18BP (10, 50, and 100ng/ml).

Results: Differentiation of CD4+ IL-17A and CD4+ IL-4+ cells decreased and that of CD4+ CD25hi Foxp3+ and CD4+ interleukin (IFN)-γ+ cells increased on addition of IL-18BP to cultured RA patient-driven PBMCs. RA-FLS migration ability was not suppressed by IL-18BP after 12 or 24h. IL-18BP increased annexin V+ FLS level and reduced annexin V+ chondrocyte level in a dose-dependent manner, whereas PI+ annexin V- FLS and chondrocyte levels were suppressed by 50, 100 ng/ml IL-18BP in culture.

Conclusion: The administration of IL-18BP regulated the type 17 helper T cell/ regulatory T cell imbalance and attenuated the production of pro-inflammatory cytokines. IL-18BP further increased FLS apoptosis and decreased the necrosis of FLS/chondrocytes and apoptosis of chondrocytes suggesting the joint preserving potential of IL-18BP.

CXCL14 IN EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS

Keywords: Cytokines and chemokines, Biomarkers, Rheumatoid arthritis

S. Lomholt¹, L. Hunskjær¹, S. R. Greisen¹,², W. Kragstrup¹,²,³. ¹Department of Biomedicine, Aarhus University, Department of Biomedicine, Aarhus, Denmark; ²Aarhus Universitetshospital, Department of Rheumatology, Aarhus, Denmark; ³Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark

Background: Single cell sequencings studies have identified a CXCL14+ fibroblast cluster in synovial tissue. This CXCL14+ cluster express CD34 and correlate to lower DAS28 and swollen joint count, while being similar between genders, age or sex status [1]. The biological role of CXCL14 in rheumatoid arthritis (RA) is unknown, but CXCL14+ synovial fibroblasts have been shown to express abundant GAS6, which regulate remission functions in MerchX-CD206+ synovial tissue macrophages [2]. This may suggest an anti-inflammatory or pro-remission role of the CXCL14+ synovial fibroblast cluster in specific RA pathotypes [1].

Objectives: Our study aimed to investigate soluble CXCL14 in plasma and synovial potential and its connection to long term joint deterioration and disease activity in RA.

Methods: We used optimized commercial CXCL14 ELISA kits to investigate CXCL14 levels in 3 cohorts. 1) Plasma samples from patients with early RA (eRA) from the methotrexate arm of the CIMESTRA trial (N=80) [3]. 2) Plasma and synovial fluid from patients with established RA included at time of therapeutic arthrocentesis (the INART cohort) (N=41). 3) Plasma from matched healthy controls (HC) (N=44).

Results: Plasma CXCL14 was significantly higher compared to synovial fluid, median 2.3 ng/ml. CXCL14 levels in the two compartments correlate. Plasma and synovial fluid CXCL14 were not influenced by gender, ACPE, smoking status, disease duration or time since sampling. Age and rheumatoid factor status may affect plasma CXCL14 levels, but this was not consistent in both RA cohorts. Analysis showed a significant higher amount of plasma CXCL14 in patients with RA from the INART cohort, median 6.9 ng/ml, compared to eRA, median 4.8 ng/ml and HC, median 4.3 ng/ml. Plasma CXCL14 did not change significantly in patients with eRA after 1 year of treatment. Baseline plasma CXCL14 in patients with eRA significantly correlated to baseline tender joint count, but not DAS28, swollen joint count or total sharp score.

Baseline plasma CXCL14 correlated to DAS28 after 5 years of treatment. Evaluating DAS28 after 11 years of treatment we observed a difference between patients in remission (DAS<2.6) and patients with active disease (DAS28 ≥ 2.6). For patients in remission, baseline CXCL14 correlated inversely with DAS28, whereas this correlation was positive in patients with active disease (Figure1). No associations were present between CXCL14 and change in total sharp score over a 11-year period.

Conclusion: Soluble CXCL14 can be measured in both plasma and synovial fluid from patients with RA. Plasma CXCL14 levels are higher compared to synovial fluid but a significant correlation is present between to two compartments. This suggests plasma CXCL14 as a potential proxy for CXCL14 activity in the joint and joint fluid. CXCL14 was not affected by gender, disease duration, smoking or 1 year of CMDARD treatment. Baseline CXCL14 correlated to higher DAS28 in the CIMESTRA cohort after 5 years and in patients with active disease after 11 years. Interestingly, we noticed that baseline CXCL14 may associate to lower DAS28 in patients in remission after 11 years. Together, this may support previous studies associating CXCL14 to an active anti-inflammatory (positive CXCL14/DAS28 correlation in active disease group) and pro-remission (negative CXCL14/DAS28 in remission group) role in RA.

Yoshida1, K. Murakami2, H. Tsukamoto2, Y. Nakayama1, R. Saito1, D. Diet and nutrition, Animal models, Inflammatory Arthritis

Background: Epoxy fatty acids (EPA), cytochrome P450 (CYP)-mediated metabolites of polyunsaturated fatty acids (PUFA), have anti-inflammatory effects[1]. However, EPA is quickly converted to an inactive form by the soluble epoxide hydrolase (sEH). In recent years, the efficacy of sEH inhibitors (sEHI) has been reported in a variety of diseases[2–4]. However, compared to ω-3 epoxides, such as epoxyeicosatrienoic acids (EET) derived from arachidonic acid (AA), there are few reports on ω-3 epoxides, epoxygenated epoxygenized acid (EEO) from eicosapentaenoic acid (EPA) and epoxygenated arachidonic acid (EDP) from docosahexaenoic acid (DHA5), and their effects on arthritis are not well understood.

Objectives: To investigate and compare the effects of ω-6 and ω-3 epoxides on inflammatory arthritis.

Methods: Collagen-induced arthritis (CIA) was treated with three different diets (ω-6 PUFA rich, ω-3 PUFA rich, and Control) and two types of drinking solutions, one containing sEH and the other containing only polyethylene glycol as a solvent control (total 6 groups, 8 mice each). Pathological and clinical scores were evaluated, and feces were collected before the onset of arthritis (day 25) for intergroup comparative analysis of bacterial flora.

Results: In all the dietary groups, there was a tendency for arthritis scores to decrease with sEHI administration, but the incidence of arthritis, arthritis scores, and pathological scores decreased dramatically in the group fed with the ω-3 rich diet and sEHI combination. The groups fed the ω-6 rich diet and sEHI combination showed some arthritis. However, the ω-3 rich diet and sEHI combination group showed an increase in a certain specific bacterial strain.

Conclusion: ω-3 epoxides were found to be more effective in reducing arthritis, and changes in intestinal bacteria may have influenced this pathological change.

**IL-37 ALLEVIATES TNF-α-INDUCED PYROPTOSIS OF RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES BY INHIBITING THE NF-κB/GSDMD SIGNALING PATHWAY**

**Keywords:** Rheumatoid arthritis, Cytokines and chemokines, Animal models

C. Ren1,2, Q. Shu2, J. Chen3, Q. Che4, L. Shujie4, Q. Che3, L. Shujie4, Q. Che3, L. Shujie4, Q. Che3, L. Shujie4, Q. Che3, L. Shujie4

**Background:** Pyroptosis is crucial to rheumatoid arthritis (RA) by inducing and aggravating inflammation. TNF-α is abundant in fibroblast-like synoviocytes of RA (RA-FLSs) and plays a key role in pyroptosis by inducing nuclear factor (NF)-κB activation. Additionally, interleukin (IL)-37 is involved in autoimmune diseases and induces pyroptosis induced by TNF-α and in RA patients with healthy controls.

**Objectives:** To investigate the effects and mechanism of IL-37 on RA-FLS pyroptosis induced by TNF-α and the effect in collagen-induced arthritis (CIA) model.

**Methods:** A quantitative reverse-transcription polymerase chain reaction (qRT-PCR) and Western blotting were used to examine cell pyroptosis. We selected the optimal concentration for the following experiments and detected the signal pathway of IL-37 on pyroptosis of RA-FLSs by quantitative reverse-transcription polymerase chain reaction (qRT-PCR) and Western blotting. Finally, we validated the therapeutic effects of IL-37 on CIA rat model in vivo.

**Results:** IL-37 inhibited inflammation in vitro and in vivo and reduced pyroptosis-related protein expression in RA-FLSs. Furthermore, we determined that nuclear factor κB (NF-κB) signaling is required for GSDMD-mediated pyroptosis in RA-FLSs.

**Conclusion:** IL-37 alleviates TNF-α-induced pyroptosis of RA-FLSs by inhibiting NF-κB/GSDMD signaling. Additionally, our data revealed a novel mechanism for IL-37 in RA-FLSs, suggesting a new potential therapy for IL-37 to treat RA.

**A RAPID HEMAGGLUTINATION ASSAY FOR ACPA DETECTION IN PATIENT BLOOD**

**Keywords:** Rheumatoid arthritis, Autoantibodies, Diagnostic tests

I. Kruis1, A. Van der Heijden2, M. Salden1, Q. Hu1, 1Radboud University - Institute for Molecules and Materials, Biomolecular Chemistry, Nijmegen, Netherlands; 2Novio Catalpa BV, R&D, Nijmegen, Netherlands

**Background:** Anti-citrullinated protein antibodies (ACPA) are the most specific serological marker of rheumatoid arthritis (RA) and are produced by about 75% of RA patients. The presence of ACPA early in the disease, even before onset of clinical symptoms, facilitates early diagnosis and ACPA is among the most prominent classification criteria for RA.[1] Importantly, early diagnosis and immediate start of treatment is strongly correlated with improved outcomes. Several ACPA-detection assays are available for clinical use, which nearly all are based on the same principle: ELISA or related assays with cyclic citrullinated peptides or citrullinated proteins.[2] While these methods can be automated in modern diagnostic laboratories, they are ill-suited for low-volume laboratories or resource-poor environments.

**Objectives:** The aim of this study was to develop a rapid and easy to perform assay for ACPA detection. The assay is based on ACPA-dependent agglutination of erythrocytes and can be executed with whole blood.

**Methods:** An agglutination mediator was developed by protein engineering. Addition of this mediator to (diluted) blood samples results in hemagglutination when ACPA are present. After optimization of the assay with RA serum-spiked blood samples, the applicability was assessed by the analysis of fresh blood samples from 100 RA patients and from 100 psoriatic arthritis (PsA) patients as a control group. Anti-CCP2 and RF levels in these patient samples were determined by standardized ELISAs.

**RESULTS:** IL-37 inhibited inflammation in vitro and in vivo and reduced pyroptosis-related protein expression in RA-FLSs. Furthermore, we determined that nuclear factor κB (NF-κB) signaling is required for GSDMD-mediated pyroptosis in RA-FLSs.

**Conclusion:** IL-37 alleviates TNF-α-induced pyroptosis of RA-FLSs by inhibiting NF-κB/GSDMD signaling. Additionally, our data revealed a novel mechanism for IL-37 in RA-FLSs, suggesting a new potential therapy for IL-37 to treat RA.
Results: The agglutination mediator that was generated is based on a single-chain antibody fragment that binds to glycoprotein A[3] one of the major surface proteins of erythrocytes. It is conjugated to a citrullinated peptide that is efficiently recognized by ACPA. In the presence of erythrocytes and ACPA the mediator induces agglutination of the erythrocytes, which can be detected by the naked eye. The addition of the mediator resulted in detectable agglutination in 64% percent of the RA patients samples. Agglutination correlated well with the results obtained with a commercial anti-CCP2 ELISA for ACPA detection. Efficient agglutination was observed with only 7% of the IgG samples. No correlation with rheumatoid factor levels was observed.

Conclusion: An ACPA-dependent hemagglutination mediator was generated. This agglutination mediator allows the rapid and efficient detection of ACPA by hemagglutination in human blood samples.

AB0050 EVALUATION OF THE ASSOCIATION BETWEEN CIRCULATING NON-CODING RNA CIRC. 0005567 AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS BIOLOGICAL FUNCTION IN THE CELL LINE MODEL

Keywords: Genetics/Epigenetics, Biomarkers, Rheumatoid arthritis

M. Ciesla1, K. Kwaśniak2, B. Kolarz3, 1University of Rzeszów, Centre for Innovative Research in Medical and Natural Sciences, Rzeszów, Poland, 2University of Rzeszów, Centre for Innovative Research in Medical and Natural Sciences, Rzeszów, Poland; 3University of Rzeszów, Department of Rheumatology, Rzeszów, Poland.

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune disease that leads to chronic inflammation of synovial tissue, ultimately causing joint damage, disability and premature mortality. Disease affects about 1% of the global population. Circular RNAs (circRNAs) are non-coding molecules and are generated through back splicing, during which the 5′ and 3′ ends are covalently joined. Consequently, the lack of free ends makes them stable and resistant to exonuclease cleases, and they become more suitable biomarkers compared with linear RNAs that are degraded by exonucleases. Consequently, the lack of free ends makes them stable and resistant to exonuclease cleases, and they become more suitable biomarkers compared with linear RNAs that are degraded by exonucleases.

Objectives: The aim of the study was to find an association between circ_0005567 plasma levels and disease activity in RA patients and to evaluate its molecular function.

Methods: A total of 66 individuals, 39 RA patients, and 27 healthy controls. RA patients were selected based on disease activity and RA patients with high disease activity (DAS28 >5,1) and remission (≤2,6) were included. RNA was extracted from plasma and quantitative real-time PCR was used to analyze the expression level for circ_0005567 in RA patients was elevated compared to the control group (mean±SD; 173.6±123.8 vs 108.9±81.03, p=0.017). In the cell line model we found an association between silencing circ_0005567 and elevated miR-194 concentration and elevated concentration of three mRNAs: KPNA1, HBEGF, TLN2.

Conclusion: The expression level for circ_0005567 was related to genes that are significant for the pathogenesis of RA. For example, HBEGF gene expression in fibroblasts plays a role in the remission of rheumatoid arthritis, and KPNA1 was reported as seed gene related to RA. Due to the fact that circRNAs are stable and resistant to degradation, plasma concentration of circRNAs may be a new potential epigenetic markers of RA and disease activity.

AB0051 DESCRIPTION OF PULMONARY INVOLVEMENT IN THE RAT ADJUVANT-INDUCED ARTHRITIS MODEL

Keywords: Rheumatoid arthritis, Animal models, Lungs

E. Dalix1, C. Pareti1, M. Maalouf2, S. Peyroche1, A. Vandenhosische1, H. Marote2,3, 1University of Jean Monnet, INSERM, U1059-SAINTBOISE, Saint-Etienne, France; 2University Hospital Saint-Etienne, Department of Rheumatology, Saint-Etienne, France

Background: Intestinal lung disease (ILD) is detected until 60% of patients with rheumatoid arthritis (RA), but is clinically significant in around 10% of cases. It is one of the leading causes of disease and death in RA patients. High levels of anti-cyclic citrullinated peptide (CCP) autoantibodies are associated with co-occurrence of pulmonary disease and RA [1]. Moreover, the pulmonary fibrosis marker mucine (MUC-1) was described to be a predictive indicator for ILD [2]. The adjuvant-induced arthritis (AIA) model is commonly used to investigate arthritic diseases due to some pathophysiological similarities to human arthritis [3].

Objectives: The first objective of this study was to investigate the pulmonary involvement occurring in the rat AIA model. The second objective was to investigate the presence of potential biomarkers such as CCP and MUC-1.

Methods: This study was performed from lungs from 64 AIA rats and 6 control rats without arthritic. Lungs were collected to perform histological and immunological analyses. Pulmonary disease was measured with a score based on the percentage of lung damage and the thickness of the alveolar walls (0: absent, 1: mild, 2: moderate, or 3: severe). CCP and MUC-1 immunostaining was also performed.

Results: A nonspecific interstitial lung disease was detected in the lungs of 80% of AIA rats, whereas only half control rats developed it. A heterogeneous percentage of lung damage was observed, which correlated with the thickness of the alveolar walls but not with arthritis severity. Granulomas were observed in the most affected lung tissues, with a slight fibrosis at their periphery. The number of CCP markings correlated positively with the percentage of lung damage in AIA rats. MUC-1 was found homogeneously in the lung tissue of control and AIA rats, but more prominently in the periphery of granulomas in AIA rats.

Conclusion: We have described the pulmonary involvement in the AIA rat model, which developed the extra-articular complication similar to RA-ILD. We identified CCP and MUC-1 as potential biomarkers of this pulmonary involvement. Thus, the lung may be a site of initiation of CCP immunity. The AIA model will then allow a better understanding of RA-ILD, which may lead to earlier diagnosis and the potential development of new targeted therapies.

Genetic evidence reveals causal link between rheumatoid arthritis and mTOR proteins: A mendelian randomization study

Keywords: Genetics/Epigenetics, Rheumatoid arthritis

Z. J. Yuan1,2, R. Zhao1,2,3, J. Y. Li1,2, M. K. Yao1,2, S. Y. Liu Yue1,2, S. X. Zhang1,2,3, X. Li1,2,3, C. Wang1,2,3 1Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microbiology, Taiyuan, China; 2Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China; 3The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease with hyperplasia of joint tissue and synovial inflammation. And the mammalian target of rapamycin (mTOR) is a serine/threonine protein kinase, which relates with cellular metabolism, promotes cell growth and inflammatory process. Some studies show that some downstream proteins of mTOR are associated with RA, but having no directly genetic evidence.

Objectives: We conducted mendelian randomization (MR) study to discover the genetically and statistically causal association between mTOR and RA.

Methods: A two-sample MR study was applied to investigate the association. Firstly, the GWAS data of 14 downstream proteins of mTOR, including plasma-RP-S6K, EIF-4EBP2 and so on were obtained from the 3,301 European samples. And a summary statistic involved 14,361 cases and 43,923 controls was also acquired from the IEU OpenGWAS database. Meanwhile, we extracted single-nucleotide polymorphisms (SNPs) which were related with mTOR (< 1.0×10^-5) and satisfied the three assumptions for MR analysis as instrumental variables (IVs). Then, inverse variance weighting (IVW), weighted median (WM), and MR-Egger regression were performed for MR statistical analysis by R Studio with packages “TwoSampleMR”. Additionally, MR Pleiotropy RESidual Sum and Outlier (MR-PRESSO) analysis was conducted to detect outlier instrument and remove pleiotropy. A leave-one-out analysis was conducted to avoid bias caused by a single SNP.

Results: Our study showed that no indication supporting the fact that the 14 downstream proteins of mTOR were causally associated with RA risk. The 15 SNPs of RP-S6K, 12 SNPs of EIF-4EBP2 and so on were selected as IVs for each 14 proteins. MR results showed that there was no causal relationship between RP-S6K and RA (OR = 1.03, CI: 0.89 - 1.20, P = 0.68). The results were for EIF-4EBP2 (OR = 0.90, CI: 0.74 - 1.06, P = 0.18) and the other 12 proteins. No single SNP significantly biased the causal effect of mTOR and RA. No significant directional horizontal pleiotropy between each 14 downstream proteins and RA was presented.

Conclusion: Our study showed that a cause-effect connection did not appear to exist between mTOR proteins and RA, the findings of this study increased our understanding of the genetic associations, and may provide novel insights into the functional mechanism underlying the associations between SNPs and mTOR and RA.

**RESULTS**

No significant changes were observed for both sclerostin and LRP5/6 between erosive and non-erosive patients and at 6-month post-treatment. However, the expression of sclerostin in IHC stains of synovial tissues was significantly increased in TNF-non-dominant patients compared to those who were TNF-dominant. Sclerostin and LRP5/6 expression was localised to different cell populations in synovial tissue.

**CONCLUSION**

Bulk assessment of sclerostin and other bone biomarkers within synovial tissue does not currently demonstrate a relationship with clinical outcome. However, further assessment of sclerostin and other biomarkers of bone activity in specific cell types, within synovial tissue, can provide further insights into the role of sclerostin and Wnt pathway molecules in bone homeostasis in the context of RA and may provide biomarkers of erosive disease progression.

**ACKNOWLEDGEMENTS:** We would like to thank all patients for their essential collaboration.

transcription PCR (RT-qPCR). The expression of OX40L was analyzed in the presence of RANKL or TNF at the early and late stage of osteoclast differentiation.

**Results:** The expression of OX40L was increased by RANKL and TNF at the early stage of osteoclast differentiation (day 3) in a TNF dose-dependent manner. IMB-101 decreased RANKL-induced osteoclastogenesis via downregulating NFATc1 expression (Figure 1). IMB-101 further reduced P.U.1, RANK and NFATc1 expression during early stage of osteoclast differentiation (day 3) compared to TNF inhibitor or TNF inhibitor and OX40L inhibitor (n=3).

**Conclusion:** Our data suggested that IMB-101 might have a beneficial effect on imbalance of the bone resorption in RA especially by suppressing osteoclast differentiation.

**Background:** The chronic inflammatory disease Rheumatoid Arthritis (RA) is characterized by synovial inflammation promoting cartilage and bone degradation when left untreated. Interaction between infiltrating immune cells, such as CD4+ T cells and activated fibroblast-like synoviocytes (FLS) might contribute to joint inflammation ultimately amplifying progressive joint destruction.

**Objectives:** To elucidate the interaction of stimulated FLS and CD4+ T cells within an inflammatory environment and to define its impact on synovial inflammation.

**Methods:** To define the effect of inflammatory mediators, FLS were stimulated with different pro- and anti-inflammatory cytokines. Transcriptional changes were measured using RNA sequencing (RNA-seq). Co-cultures of cytokine pre-treated FLS and fluorescence activated cell sorting (FACS)-purified naive CD4+ T cells were established. Using high-content fluorescence microscopy combined with bioinformatic image analysis, cell-cell interactions were visualized and quantified. The consequence of FLS co-culturing on CD4+ T-cell development was addressed by flow cytometry of re-isolated CD4+ T-cells.

**Results:** RNA-seq on cytokine-stimulated FLS revealed cytokine-specific gene expression profiles. In line, we observed cytokine-specific patterns of interaction with CD4+ T-cells which could be further observed in flow cytometry data of T cell activation, proliferation and differentiation. Cytokine-stimulated FLS signatures could be detected in transcriptomic data of RA patient synovial tissue samples.

**Conclusion:** In this study, we highlight the roles of FLS in orchestrating inflammation-associated synovial tissue remodeling and how cytokine induced CD4+ T cells – FLS interactions impact on T-cell development.

**Establishment of Novel 3D Spheroid-Based Model of Rheumatoid Arthritis Synovial Tissue to Investigate the Interaction Between Different Cell Types**

**Keywords:** Rheumatoid arthritis, Synovium

E. Philippen1, J. P. Van Hamburg2, F. Khodaoustvaskasi2, L. Van Rooen3, C. J. Van der Laeken2, S. Tas1

1Amsterdam UMC, locatie AMC, Department of Rheumatology and Clinical Immunology/Experimental Immunology, Amsterdam, Netherlands; 2Amsterdam UMC, locatie VUMC, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands

**Background:** Rheumatoid Arthritis (RA) is a progressive and systemic autoimmune disorder associated with chronic and destructive inflammation of the joints. The hallmark of RA are synovial cell proliferation, extensive neoangiogenesis and infiltration of numerous immune cells into the synovial tissue. In vitro approaches simulating RA synovial tissue are crucial in preclinical and translational research to expand our knowledge on RA human pathophysiology and to test new diagnostic and therapeutic applications.

**Objectives:** Here, we present the engineering of a spheroid-based model of RA synovial tissue which mimics the close interaction between cells and key pro-inflammatory mediators present in the inflamed synovium.

**Methods:** Following differentiation in 20ng/ml GM-CSF for 6-7 days, monocyte-derived macrophages were cultured with RA fibroblast-like synoviocytes (RA-FLSs) and endothelial cells (ECs) for 24 hours to allow for spheroid formation. Three RA-FLS/EC/macroage ratios were tested: 1:2:0.4, 1:2:0.8 and 1:2:1.6. Then, the spheroids were placed in a collagen-based matrix for 40 hours to study spheroid outgrowth in 3 dimensions. The spheroids were either unstimulated, or cultured in the presence of growth factors VEGF/BFGF or RA splanvial fluid. Sprout formation and cell migration were quantified for all conditions using confocal microscopy and digital image analysis.

**Results:** Addition of macrophages to the previously established 3D model of RA angiogenesis consisting of ECs and RA-FLSs resulted in close interaction of macrophages with RA-FLSs and ECs within the spheroid structure. The optimal ratio between RA-FLSs, ECs and macrophages in our system was established as 1:2:0.8, based on the proportions of macrophages that remained within the core and migrated throughout the matrix as well as the effect of stimuli on sprout formation. Addition of growth factors (VEGF/BFGF) significantly promoted spheroid outgrowth compared to the unstimulated condition in the new model (p<0.01).
Background: Monocytes are key players in initiating and maintaining inflammation by producing proinflammatory cytokines and S100 proteins in rheumatoid arthritis (RA). Several studies demonstrated that epigenetic drugs affecting DNA methylation can modulate the production of proinflammatory mediators.

Objectives: This study aimed to test specific DNA methylation inhibitor (RG108) and activator (budesonide) in the regulation of proinflammatory cytokines and RA monocytes was performed. Cell viability was determined in THP-1 monocytic cell line following RG108 and budesonide treatment. Pro- and anti-inflammatory cytokines were validated by qRT-PCR following cell line following RG108 and budesonide treatment.

Methods: RNA sequencing (RNA-seq) analysis of healthy controls (HC) and RA monocytes had significantly increased levels of S100A8 (2,2-fold, p=0.024), S100A9 (1,9-fold, p=0.017), S100A11 (1,2-fold, p=0.007), S100A12 (1,6-fold, p=0.007), MYD88 (1,2-fold, p=0.008), AK3 (1,8-fold, p=0.009), IQGAP1 (1,4-fold, p=0.02), and decreased level of IL10RA (0,7-fold, p=0.011), TGIF1 (0,3-fold, p=0.046) transcripts. In addition, stimulation of THP-1 cells with budesonide (DNA methylation activator) statistically reduced expression of S100A8 (3,0-fold, p= 0.0390), S100A9 (4,4-fold, p= 0.0317), S100A12 (3,3-fold, p= 0.0260), IL-8 (6,8-fold, p= 0.0286) and TNF (7,5-fold, p= 0.007). In contrast, THP-1 monocytic cell line treated with RG108 (DNA methylation inhibitor) had an increased level of S100 family (S100A8, -A9, -A11, -A12) and TNF genes. ELISAs analysis also revealed significant increased levels of S100A8 (p = 0.0116), S100A11 (p = 0.0138), and S100A12 ( p = 0.0296) proteins in RA patients compared to HC sera, similar in early RA sera compared to HC S100A8 (p = 0.0024), S100A11 (p = 0.0020) and S100A12 ( p = 0.0059). Moreover, protein levels of S100A8 (p=0.0005), S100A11 (p=0.0007) and S100A12 (p=0.0005) in the synovial fluid of advanced RA patients compared to HC serum were significantly elevated. All these data suggest that a protein of the S100 family may be a promising biomarker of RA progression. In ROC analyses, serum levels of S100A8 and S100A12 proteins were more specific (area under the curve (AUC)=0.78, p=0.006 and AUC=0.87, p=0.0006) respectively in RA patients than CRP levels. In addition, results indicate that S100A8 and S100A12 can serve as a better biomarker of high disease activity than CRP levels.

Conclusion: We have demonstrated that S100 family proteins are increased in RA monocytes (transcriptomics) similar to enhanced S100 production in sera and synovial fluids (ELISA) in RA patients. Our data suggest that the proteins S100A8 and S100A12 in particular are strongly increased during ongoing inflammation, so they could be used as a better biomarker of disease activity than CRP. Interestingly, S100 proteins can be regulated by epigenetic drugs, suggesting their potential use in the targeting of RA inflammation.

RESULTS:

The potential role of the T2 family of extracellular ribonucleases (RNASET2) as circulating biomarker in rheumatoid arthritis

Keywords: Rheumatoid arthritis, Biomarkers

F. Angelik, S. Piantoni, M. Passari, S. Scutera, V. Salvi, T. Schioppa, R. Sparr, F. Sozio, L. Tiberio, D. Bosio, F. Acquati, S. Sozzani, T. Musso, A. Del Prete, L. Andreoli, A. Sapienza University of Rome, Laboratory Aided to Istituto Pasteur Italia-Fondazione Cenci Bolognetti, Department of Molecular Medicine, Rome, Italy

Background: Circulating biomarkers with diagnostic and prognostic value in early Rheumatoid Arthritis (RA) are still an unmet need, especially for the subgroup of seronegative RA [e.g., negative for anti-citrullinated peptides autoantibodies (ACPA) and/or rheumatoid factors (RF)]. In a recent gene-based genome-wide association analysis (GWAS) study, RNASET2 was identified as a potential susceptibility gene [1-3]. Furthermore, the extracellular ribonuclease RNASET2 was demonstrated to be involved in the regulation of several immune processes [4].

Objectives: The aim of this study was to analyse RNASET2 serum levels in a cohort of RA patients upon their disease activity, in comparison with healthy controls (HC).

Methods: Forty consecutive patients with RA (75% female, 55% seropositive) with a median age (25%-75% percentile) of 55 years (45-68) and a CRP-DAS28 index of 3.09 (2.50-3.70), and 25 sex and age-matched HC were enrolled in the study. RNASET2 serum levels were assessed through a commercial HELISA test (Wuhan Fine Biotech Co., China).

Results: Serum levels of RNASET2 were higher in RA patients than in HC [29.42 (17.73 – 69.82) vs 18.15 (12.15 – 28.35) ng/mL; p= 0.001]. Among patients with RA, there were no differences between RNASET2 levels in seropositive or seronegative ones [33.14 (16.79 – 74.89) vs 29.01 (17.83 – 49.89) ng/mL; p=0.308]. Furthermore, there were no differences in RNASET2 serum levels between patients in treatment with corticosteroids or not [42.09 (18.11 – 78.78) vs 23.42 (18.29 – 43.87) ng/mL; p=0.239]. RNASET2 serum levels were significantly different across 3 groups of RA patients identified upon the CRP-DAS28 score (high plus moderate disease activity -group A; low disease activity -group B; remission -group C) (p = 0.024). RNASET2 levels were higher in both group A and B as compared to group C [56.73 (30.22 – 79.67) - 83.72 (52.68 – 113.89) vs 25.43 (20.15 – 39.85) ng/mL; p= 0.005 & p= 0.0006} respectively in RA patients than CRP levels. In addition, results indicated a potential diagnostic biomarker in RA. Higher levels of RNASET2 clustered as a potential diagnostic biomarker in RA. Higher levels of RNASET2 clustered in RA patients as compared to HC. Low levels of RNASET2 seem to characterize the remission phase of RA. These preliminary results deserve to be expanded in larger cohorts of RA patients, patients with other form of chronic arthritis and other pathological and healthy controls.

Conclusion: This is the first description of circulating serum levels of RNASET2 as a potential diagnostic biomarker in RA. Higher levels of RNASET2 clustered in RA patients as compared to HC. Low levels of RNASET2 seem to characterize the remission phase of RA. These preliminary results deserve to be expanded in larger cohorts of RA patients, patients with other form of chronic arthritis and other pathological and healthy controls.
AB0060 ANALYSIS OF THE HUMAN GUT MICROBIOME AND NUTRITION PATTERNS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Diet and nutrition, Gastrointestinal tract

Methods: A subset of the FoCus (Food chain plus) cohort (a cross-sectional survey of the general population in northern Germany) with RA and matched controls without RA (matched for age, gender, body mass index and diagnosis of Type 2 Diabetes mellitus [T2D]) was investigated regarding their nutrition patterns and gut microbiome in a case-control analysis. Nutrition patterns were derived from Food Frequency Questionaires (FFQ) and analyzed by hierarchi- cal cluster analysis. The gut microbiota composition was analyzed by 16S rRNA gene sequence data clustered into operational taxonomic units (OTUs). Microbiome composition was analyzed by alpha- (phylodiversity, Shannon index, Chao index) and beta-diversity measures (Bray-Curtis distance, Jaccard index) and by hurdle-models.

Results: We identified n = 94 individuals with RA and n = 94 matched controls (mean age 57 years, SD 12.9; mean BMI 31.1, SD 8.9). Interleukin 6 was significantly higher in the RA group compared with controls (p=0.012), while no differences were observed between groups for HOMA-Index, CRP, lipoprotein (a) or triglycerides. Nutrition data from FFQs was used in a hierarchical cluster analysis, resulting in two main clusters (the second one defined by a significantly higher intake of vegetables, fruit and dairy products). Nutrition clusters did not differ significantly between RA cases and controls (p=0.228). When comparing the composition of the intestinal microbiota between RA patients and controls (adjusted for nutrition cluster and IL-6), significant differences in the beta-diversity were detected using Bray-Curtis distance (p=1.82e-9) and Jaccard index (p=1.82e-9). Hurdle-models of the core measurable microbiome identified three candidate species OTUs (Flavonifractor and 2x Blautia). No significant differences in alpha diversity was observed when analyzed by species richness (p=0.9), Shannon (p=0.3) and Chao index (p=0.6).

Conclusion: Participants suffering from RA had significant differences in the composition of the gut microbiome compared to controls matched for age, BMI, gender and T2D after adjusting for nutrition patterns and IL-6. Investigating differences in the functional capacity of the altered gut microbiota in RA may better characterize a possible link of gut microbes to the development of RA.

AB0061 ENDOTHELIN-1 AS A POTENTIAL CANDIDATE TO SHED LIGHT ON THE CHALLENGE OF INTERSTITIAL LUNG DISEASE DIAGNOSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Lungs, Biomarkers, Rheumatoid arthritis

Methods: Peripheral venous blood was collected from 21 RA-ILD+ patients and two comparative groups: 25 RA-ILD- patients and 21 idiopathic pulmonary fibrosis (IPF) patients. All the subjects were recruited from the Rheumatology and Pneumology departments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. Serum levels of ET-1 were determined by ELISA.

Results: RA-ILD+ patients showed increased levels of ET-1 compared to those with RA-ILD- (p<0.01, Figure 1A). Interestingly, the ability of serum ET-1 levels to discriminate patients with RA-ILD+ from those with RA-ILD- was further confirmed by receiver operating characteristic curves (area under the curve: 0.77, p<0.01, Figure 1B). The optimal cutoff value for ET-1 showing the best sensitivity and specificity was 1.02 pg/mL. Moreover, patients with RA-ILD+ presented similar levels of ET-1 than those with IPF (p=0.50, Figure 1A). Additionally, a negative correlation between ET-1 serum levels and both forced vital capacity and forced expiratory volume at first second was disclosed in patients with RA-ILD+ (r=-0.56, p=0.04 and r=-0.65, p=0.01, respectively).

Conclusion: Our study suggests that ET-1 levels are linked to lung injury and worse lung function, supporting its role as a potential biomarker of ILD in RA patients.

ABUNDANCE AND ACTIVATION OF MEMORY B-CELLS CHARACTERIZE SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS WITH EARLY TREATMENT RESPONSE

Keywords: Rheumatoid arthritis, Synovium, Biomarkers

A. Khmelevskaya1, M. Houtman1, K. Buerki1, C. Pauli1, F. Rivellese2, E. Prediletto3, C. Pitzalis1, O. Distler1, A. Ciurea1, C. Ospelt1, R. Micheroli1. 1University Hospital Zurich, University of Zurich, Zurich, Switzerland; 2University Hospital Zurich, University of Zurich, Department of Pathology, Zurich, Switzerland; 3William Harvey Research Institute, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: A relevant percentage of patients with rheumatoid arthritis (RA) do not respond to individual (40%) or all available disease modifying anti-rheumatic drugs (5–20%). A recent study using synovial bulk RNAseq from a phase 4 trial has shown that humoral immune response gene signatures are associated with response to rituximab and tocilizumab [1]. Other biomarkers that can predict early response to alternative DMARDs are still lacking.

Objectives: This study, performed in a real-life clinical care setting, aimed at characterizing synovitis of RA patients with an early drug response on a single-cell level to identify potential biomarkers and molecular signatures.

Methods: Synovial tissue was obtained by ultrasound-guided synovial biopsy from inflamed joints. Four patients were defined as early responders not meeting the D2T EULAR definition criteria (median (IQR) number of treatments 1.5 (2.5)) [2], but meeting 2022 ACR/EULAR remission within 3 months on the DMARD started after the synovial biopsy. Five patients met the D2T EULAR definition criteria (median (IQR) number of treatments 7 (1)). Two out of five from the D2T group went into ACR/EULAR remission 3 months after the biopsy following DMARD initiation (abatacept (n=1) and upadacitinib (n=1)). Both groups fulfilled the ACR/EULAR classification criteria for RA. 6000 cells were targeted for single-cell encapsulation (10X Genomics workflow v3.1). Libraries were sequenced on NovaSeq6000. The following R packages were used: Cell Ranger, Seurat, Harmony, PCAtools.

Results: Clinical characteristics (sex, age, swollen joint count, C-reactive protein, body mass index, smoking status) were comparable between the two groups, except for the presence of autoantibodies (all D2T compared to only one early responder patient were seropositive). The patients in the early responder group received the following drugs after the biopsy: methotrexate plus certolizumab (n=1), methotrexate alone (n=1) or abatacept (n=2). Patients in the D2T group had received a median of seven treatments before the biopsy; 29,408 cells were integrated for scRNA-seq analysis (mean of 3,267 cells after quality control filtering per patient). Unsupervised dimensionality reduction analysis showed 8 principal components (PCs) explaining all variations in gene expression between samples. PC6 was significantly associated with the early responder/D2T categorization, accounting for 6.72% of the sample variation. Immunoglobulin genes (IgH-, IgL-) and Prostaglandin D2 Synthase (PTGDS) and B-cell antigen receptor complex-associated protein alpha chain (CD79A) were among the top 100 genes associated with early response to treatment (PC6) (Figure 1A). Analysis of the average expression of these genes in the early responder and D2T group revealed expression mostly in B cells and plasma cells (Figure 1B). Comparing the proportions of cell populations using graph-based clustering showed no significant differences between early responder and D2T patients. Further clustering of the primary cell populations also did not show changes in proportions except for B cells: the proportions of NR4A1+ memory B cells (B cells recently receiving antigen stimulation) were higher in early responder compared to D2T patients (mean 48%±10 vs 36%±10, p-value = 0.0547) (Figure 1C). Analysis of differentially expressed genes in B cells between early responder and D2T patients revealed 62 genes differentially expressed (p-value<0.05, average fold change >2 or <0.3). Still, only six of these genes were among the top 100 genes associated with PC6 (Figure 1D).

Conclusion: Synovitis in rheumatoid arthritis patients with early treatment response was associated with activation of B cells and an abundance of NR4A1+ memory B cells. This finding in a real-life cohort is in concordance with previous results showing an association of humoral immune activation and response [1] and sets the path for future biomarkers predicting early response in RA.

from arthritis-associated osteoclastogenic macrophages (AtOM), characterized by CX3CR1 and FOXM1 expression. However, the relationship between MoOC and DCCOC with AtOM is unknown[1].

Objectives: To investigate the phenotype of osteoclasts differentiated from dendritic cells.

Methods: Bone marrow cells or bone marrow derived dendritic cells were cultured with RANKL-M-CSF for 6 days to generate MoOC or DCCOC.(2) Osteoclast differentiation was assessed by TRAP staining. NFATc1, CX3CR1 and FOXM1 mRNA expression was evaluated with whole cultured cells, OC or undifferentiated cells, residing by OC collected by laser microdissection. Fluorescent immunostaining of cultured cells was used to analyze protein expression, and IL-6 or TNF-α was added during OC differentiation to assess effects on OC differentiation, CX3CR1 and FOXM1 expression.

Results: MoOCs and DCCOCs differentiation was confirmed by TRAP staining and NFATc1 mRNA expression in whole cultured cells on day 6 of RANKL-M-CSF culture. The expression of CX3CR1 mRNA was significantly higher in DCCOC than in MoOC. In DCCOCs recovered by microdissection on day 4, confirmed significantly higher expression of CX3CR1 mRNA compared to MoOCs. Comparison of CX3CR1 mRNA expression with residing undifferentiated cells resulted in significantly higher expression in DCCOCs, but not in MoOCs; Immunostaining on day 6 showed nuclear translocation of FOXM1 in both DCCOCs and MoOCs. IL-6 or TNF-α stimulation decreased viable cells in a concentration-dependent manner, with TNF-α promoting MoOC differentiation and IL-6 promoting DCCOC differentiation.

Conclusion: Compared to MoOCs, DCCOCs expressed significantly higher CX3CR1 and FOXM1 from early stage of development specific to progenitor of inflammatory osteoclasts in in vivo. In addition nuclear translocation of FOXM1 suggested its role in gene regulation during OC differentiation. In addition enhancement of OC differentiation by IL-6 is suggesting the usefulness of IL-6 inhibition for the pathophysiology of joint destruction in rheumatoid arthritis.

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by chronic proliferation of synovial cells and destructive polyarthritis. Various kinds of cells are involved in the pathogenesis of RA, including myeloid cells, lymphocytes, and synovial fibroblasts. It has been reported that there are abnormal myeloid cells in bone marrow of RA patients (Ochi, et al., Arthritis Res. Ther., 2007). In addition, myeloid cells differentiate into monocytes/macrophages, which can thereafter differentiate into osteoclasts that mediate bone destruction in RA. In fact, we have previously reported CD14+ monocytes differentiated from induced pluripotent stem cells (iPSCs) derived from RA patients expressed more mRNA of receptor activator of nuclear factor-kappa B (RANK) than those from a healthy donor, non-onset family member (NOF), resulting in the accelerated osteoclastogenesis (Ito, et al., The 36th annual meeting of the Japanese society of inflammation and regeneration, 2015). However, the question remains if distinct monocyte differentiation besides high RANK expression may also be involved in the accelerated osteoclastogenesis in RA.

Objectives: To investigate whether there is distinct monocyte differentiation between a RA patient and NOF.

Methods: iPSCs have been established from skin fibroblasts from a RA patient. For the controls, NOF of the patient are recruited as a donor in order to adjust hereditary background as much as possible. Monocytes were induced from each iPSC clone culture on feeder-free conditions using a previously reported method (Cui, et al., Front. Cell Dev. Biol., 2021). Floating cells were sequentially collected on days 10, 14, 18 and 22 during induction of monocytes from iPSCs. Surface phenotypes and the expression of differentiation markers of monocytes were analyzed with flow cytometry using the corresponding antibodies.

Results: RA-iPSCs differentiated into CD43+ (hematopoietic marker) cells earlier than NOF-iPSCs did (the data shown in Table 1). In addition, the proportion of CD45+ in CD43+ cells (myeloid progenitors) was achieved in 93.0±4.8% (RA) and 51.0±21.3% (NOF) on day 18 (p=0.029) (the data shown in Table 1). The proportion of CD11b+CD45+ cells (monocytes and granulocytes) derived from RA-iPSCs was not significantly different from that from NOF-iPSCs. However, the proportion of CD45+ in CD11b+CD45+ (monocytes) derived from RA-iPSCs was significantly higher than that from NOF-iPSCs (the data shown in Table 1). CD45+ in CD11b+CD45+ cells were mostly CD14+ cells. The proportion of CD115+, macrophage colony-stimulating factor receptor (MCSF-R), in CD14+ cells induced from RA-iPSCs tended to increase compared with NOF-iPSCs.(the data shown in Table 1).

Conclusion: Hematopoietic stem cells differentiate into myeloid progenitors in monocyte differentiation in RA earlier than those in NOF. Moreover, they differentiate into more CD45+CD11b+CD45+ monocytes which are likely to express more MCSF-R as compared with those in NOF. We speculate that these distinct monocyte differentiation may play in accelerated osteoclastogenesis in RA.

LOW-DOSE RADIOTHERAPY ATTENUATES EXPERIMENTAL AUTOIMMUNE ARTHRITIS BY INDUCING LYMPHOCYTE APOPTOSIS

Keywords: Animal models, Adaptive immunity, Rheumatoid arthritis

Y. H. Cheon1, B. G. Kim1, H. S. Choi2, Y. Cho3, H. M. Jeon4, J. Y. Heo4, S. I. Lee5, B. K. Jeong6, M. Kim7. Disclosure of Interests: None Declared.

Background: Disease-Modifying Anti-Rheumatic Drugs (DMARDs) have therapeutic effects on rheumatoid arthritis (RA) through the modulating immune responses of systemic and synovial. However, DMARDs be used for an extended period, drug-related adverse effects can be a severe problem. Therefore, it is necessary to develop a treatment strategy to minimize the adverse effects of DMARDs, such as infection, abnormal liver function tests, and hematological abnormalities.

Objectives: Radiation therapy is one of the crucial therapeutic strategies for cancers. Low-Dose Radiotherapy (LDRT), the total dose may be given in fewer treatments or over a shorter period, has been tried to treat various inflammatory diseases, but its theoretical basis is poor. Therefore, this research aims to elucidate the mechanism and standardization of LDRT for RA.

Methods: The CIA (collagen-induced arthritis) and K/BxN mice used an experimental arthritic model representing RA. At the point of the highest arthritis symptoms, CIA and K/BxN mice were treated with LDRT. Then, the clinical score of the fore or hind paws was measured twice a week for 30 days. After 30 days of LDRT, the mice were sacrificed. Splenocytes, popliteal and inguinal lymph nodes were cultured by flow cytometry to measure the level of activation, proliferation, inflammatory-cytokines, and apoptosis of immune cells. To evaluate whether LDRT is effective on human immune cells, RA patients’ PBMC were treated with LDRT and analyzed by flow cytometry.

Results: LDRT did not affect the lymphocyte activation, proliferation, differentiation, and inflammatory cytokine secretion. However, LDRT enhanced lymphocyte apoptosis and decreased immune cell numbers and clinical scores in CIA and K/BxN mice. In addition, the degree of cartilage destruction was reduced by treating with LDRT in K/BxN mice. Likewise, the proportion of apoptotic lymphocytes was increased by LDRT in PBMC of a patient with RA, not fibroblast-like synoviocytes (FLS). Thus, these findings suggest that LDRT can be a new therapeutic strategy with minimal adverse effects for RA.

PIM KINASES AS POTENTIAL THERAPEUTIC TARGETS IN INFLAMMATORY ARTHRITIDES

Keywords: Biomarkers, Cell biology, Inflammatory arthritides

E. Assemani1, J. Ciampi1, S. Naidi1, V. Scuroc1, L. Mancarella1, V. Brusi1, L. Lisi1, F. Ursini1,2, S. Neril,1 IRCCS Istituto Ortopedico Rizzoli, Medicine and Rheumatology Unit, Bologna, Italy; University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy.

Background: Proviral integration site for Moloney murine leukemia virus (PIM) 1 kinase and its family members (PIM2 and PIM3) regulate several cellular functions including survival, proliferation and apoptosis. These proteins have been extensively studied in tumorigenesis, whereas their role in autoimmune and chronic inflammatory diseases remain unclear. PIM kinases are involved in T-cell amplification and differentiation in inflammatory Th1 and Th17 effectors T cells subsets. Recent studies suggest that the expression of PIM1 is upregulated in fibroblast-like synoviocytes and CD4+ T cells from patients with rheumatoid arthritis (RA). However, data are
lacking regarding the potential role of PIM kinases in spondyloarthritis (SpA) such as psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA).

**Objectives:** To explore the potential role of PIM kinases in inflammatory arthritis, we evaluated PIM kinase expression at gene and protein level in patients with RA, PsA, and AxSpA compared to healthy controls (CTR).

**Methods:** PIMs expression was analysed in 26 (11 RA, 7 AxSpA, and 8 PsA) biologic DMARDs (bDMARDs)-naïve arthritis patients and 13 controls. PIMs mRNA levels were determined in total RNA extracted from freshly isolated peripheral blood mononuclear cells (PBMC) by real-time semi-quantitative PCR. Protein levels were quantified in serum by ELISA test. Data were analysed by Kruskal Wallis test followed by Dunn’s correction for multiple comparisons.

**Results:** All the samples showed expression of PIM1, 2, and 3 kinases both at gene and protein level, with PIM3 being the less expressed protein. A trend towards lower expression of PIM1 was appreciated in AxSpA samples compared to other groups, reaching statistical significance only for serum protein levels compared to controls (p < 0.05). No significant differences were found in PIM2 and PIM3 expression, although all arthritis patients showed a trend towards higher serum levels compared to controls, not mirrored at gene expression levels.

**Conclusion:** PIM1 mRNA expression in PBMCs seems to mirror PIM1 protein expression in the serum in all groups, supporting this molecule as a candidate biomarker. Controls, RA and PsA patients displayed similar levels, whereas AxSpA patients showed a trend towards reduced PIM1 levels deserving further investigation. Conversely, serum PIM2 and PIM3 levels did not mirror PIM2 and PIM3 gene expression in resting PBMC. Unlike PIM1, the expression of PIM2 and PIM3 have never been studied in PsA and AS, and additional data are required to explore the potential relevance of PIM2 and PIM3 in SpA pathophysiology. Further studies are also required to evaluate PIM kinase modulation after in vitro cell stimulation, the differential expression in PBMC subpopulations, and the impact of disease activity and concurrent disease-modifying medications.

Amsterdam UMC, locatie VUMC, Angiogenesis Laboratory, Department of Experimental Oncology, Amsterdam, Netherlands; 5. Amsterdam UMC, locatie VUMC, Department of Radiology & Nuclear Medicine, Amsterdam, Netherlands

**Background:** The role of pathological angiogenesis is widely recognized in cancer and various inflammatory diseases, including rheumatoid arthritis (RA). RA, angiogenesis and inflammation are mutually dependent and play a cooperative role in the disease progression. Angiogenesis mainly relies on the interaction of vascular endothelial cells (ECs), fibroblasts, macrophages, and the extracellular matrix. This phenomenon not only promotes the infiltration of inflammatory cells into the joints, resulting in more synovial inflammation and structural damage. In this process, a number of soluble and cell surface-bound angiogenic mediators are involved providing candidate targets for diagnosis and therapy [1, 2]. Anti-angiogenesis strategy has been widely used in tumor treatment and its potential value in RA as a single or in combination therapy need to be further explored.

**Objectives:** To assess potential anti-angiogenic candidate compounds with different mechanisms of action in preclinical models of angiogenesis for exploitation as candidate agents for molecular imaging and/or therapeutic purposes.

**Methods:** Two in vitro models of angiogenesis were employed in this study: (i) a scratch assay assessing the closure rate of scratches made in human microvascular endothelial cells (HMEC-1) [3] in the presence of the chemokine CXCL11 (in respect to GAPDH) 2.46 ± 0.57, (ii) a 3D-spheroid model of angiogenesis composed of ECs and fibroblasts, assessing the impact of drugs on EC sputum formation after 40 h of incubation. Sprout quantification was performed via confocal microscopy and digital image analysis [2]. Candidate anti-angiogenic compounds examined in this study included: sunitinib (pan-kinase inhibitor), a small molecule NF-κB-inducing kinase inhibitor (NIK), tofacitinib (selective JAK1/3 inhibitor) and fluclitide (RGD-peptide targeting αvβ3 and αvβ5 integrins) and tested in concentration range of 0.1-10 μM. An MTT-proliferation inhibition assay was used to monitor any drug-induced cytotoxicity.

**Results:** In scratch assays, sunitinib showed irreversible inhibition (max 75% at 10 μM after 24 h incubation) compared to NIKi which had a transient inhibitory effect (max 59% at 10 μM after 4 h incubation). No apparent effects were observed for tofacitinib up to concentrations of 10 μM. Interestingly, flucitide, induced morphological changes at concentration of 0.1 μM, impairing scratch closures. Next, the anti-angiogenic effects of the compounds were verified in the 3D-spheroid model that more closely mimics the in vivo situation. Here, marked blockade of sputum formation was noted at 0.1 μM for sunitinib, and 1.25 μM for NIKi, tofacitinib and fluclitide. MTT assays indicated that none of the observed drug-effects were due to induction of cytotoxicity at the indicated concentrations.

**Conclusion:** This study identified various compounds (sunitinib, NIKi, tofacitinib and fluclitide) exhibiting potential anti-angiogenic properties in vitro, encouraging their further evaluation as radionuclide imaging and therapeutic agents for diagnosis and therapeutics in vivo.

**THE METABOLITES WERE ALTERED IN PATIENTS WITH RHEUMATOID ARTHRITIS**

**Keywords:** Biomarkers, Rheumatoid arthritis

P Wu1, J. An2, C. Wang3. 1. The Second Hospital of Shanzhi Medical University, the Department of Rheumatology, Taiyuan, China; 2. The Fifth Hospital of Datong, the Department of Rheumatology, Datong, China

**Background:** Rheumatoid arthritis (RA) is characterized by persistent synovitis and abnormal antibodies production[1].The discovery of follicular helper T cells (Tfh) and follicular regulatory T cells (Tfr) has added a new understanding of the mechanisms of antibody production in RA such as anti-cyclic peptide containing citrulline (anti-CCP) [2]. The gut microbiota-derived metabolites are also important in regulating immune system to balance disease and health. And the altered gut microbiota-derived metabolites have been found to be involved in RA patients[3]. However, the relationship between gut microbiota-derived metabolites and Tfr/Tfh cells has not been comprehensively evaluated in RA patients to date, which is the focus of our study.

**Objectives:** We detected the gut microbiota-derived metabolites and the expression of Tfr and Tfh cells in new-onset RA patients, and then analyzed the relationship between gut microbiota-derived metabolites and Tfr/Tfh cells.

**Methods:** 17 patients with new-onset RA from the Second Hospital of Shanzhi Medical University were recruited. And 13 sex- and age-match healthy controls
(HCs) were enrolled. Fecal samples were collected to determine the gut microbiota-derived metabolites by LC-MS/MS-based nontargeted metabolomic. And blood samples were collected to detect the expression of circulating Tfr and Tfh cells by flow cytometry.

**Results:** The fecal metabolite profiles between RA and HC groups were different (Figure 1A, B). There were 61 differential annotated metabolites in RA including 34 metabolites upregulated and 27 metabolites downregulated compared to HCs (Figure 1C, D). The KEGG pathway enrichment analysis of the differentially abundant metabolites showed that there were only four pathways were the main pathways related to RA including biosynthesis of unsaturated fatty acids, arginine biosynthesis, tryptophan metabolism as well as alanine, aspartate and glutamate metabolism (Figure 1E). And eleven differentially abundant metabolites were involved in the four mainly altered pathways. The correlation heatmap of the association of the eleven differentially abundant metabolites with indicators of RA was shown in Figure 2A. It also suggested that arachidonic acid was negatively associated with the number of Tfr cells (r=-0.645, P=0.006) and the c-Tfr/c-Tfh ratio (r=-0.623, P=0.009).

**Conclusion:** There was an obvious difference in the fecal metabolite profiles between RA and HCs. Arachidonic acid was identified as the potential biomarker of RA, and the increased arachidonic acid was negatively associated with Tfr cells by flow cytometry and is affected by inflammatory-associated factors. Vigeo is a mixture of fermented extracts of Eleutherococcus senticosus Maxim (ESM), Acanthopanax japonica (Michx.) Nakai (AJN), and Atractylodes japonica Koidzumi (AJK) manufactured using the traditional Korean nukur fermentation method. Although the bioactive effects of ESM, AJN, and AJK have already been reported, the pharmacological effects of Vigeo have not been proven.

**Objectives:** In this study, we investigated whether Vigeo had inhibitory effects on RA and its intracellular mechanisms using a type II collagen-induced arthritis (CIA) mouse model.

**Methods:** CIA was induced in DBA/1 mice by immunization with bovine type II collagen. The mice were administered orally with Vigeo (200 and 500 mg/kg/day, i.g.) from days 21 to 42 after immunization. The clinical scores, hind paw swelling, and histopathological finding were evaluated in the paw of CIA mice. The levels of tumor necrosis factor α (TNF-α), interleukin (IL)-6, and IL-1β in the serum were measured by enzyme-linked immunosorbent assay.

**Results:** The results showed that Vigeo 500 mg/kg treatment significantly alleviated the severity of the disease, based on the reduced hind paw swelling and clinical scores, compared with untreated CIA mice. Compared with untreated CIA mice, Vigeo 500 mg/kg treatment inhibited the levels of TNF-α, IL-6, and IL-1β in the serum.

**Conclusion:** Our results suggest that anti-inflammatory effects of Vigeo against collagen-induced arthritis in mice may be due to its ability to inhibit pro-inflammatory mediators. Vigeo may be a promising potential therapeutic reagent for arthritis treatment.

PROTEOMIC ANALYSIS OF CARDIOMETABOLIC AND CARDIOVASCULAR BIOMARKERS FOR THE DIAGNOSIS OF RHEUMATOID ARTHRITIS. REGULATION BY METHOTREXATE AND JAK INHIBITORS

Keywords: Biomarkers, Cardiovascular disease, Rheumatoid arthritis

Background:

Patients with rheumatoid arthritis (RA) have a high risk of suffering cardiovascular disease. The cardiovascular and cardiometabolic proteome analysis in RA patients may provide disease biomarkers and insights into the biological pathways that contribute to cardiovascular risk.

Objectives:

1) To evaluate the changes in the cardiometabolic and cardiovascular serum proteome in two cohorts of active RA patients: newly diagnosed (naïve-treated) and well-established disease and its relationship with the clinical cardiovascular II panels) was performed in the serum using Olink Proteomics

Methods:

1) Cross-sectional study in two cohorts of RA: patients at diagnosis (n=25) and patients with established disease (evolution time>25 years, n=25), naïve-treated) and well-established disease and its relationship with the clinical characterization and 2) to analyze the modulation of the levels of these proteins by methotrexate and tocilizumab.

Results:

There were no statistical differences between the RA at diagnosis and Rheumatoid arthritis disease groups in age and DAS28. The evolution time average in the RA-established disease group was 37.48±11.79 years. One hundred and seven proteins were significantly increased in the serum of RA patients at diagnosis, among these 47 proteins were elevated in RA patients with established disease. The PCA analysis showed that the alteration of these proteins could discriminate between RA patients and healthy donors. The molecules that more significantly increased in the RA at diagnosis group were SAA4, ST6GAL1, CCL18, TNC, GLC2, IL6, SORT1, TNFRSF1A, AGRP, and CD4. In addition, the top ten molecules significantly elevated in RA patients with the established disease were SAA4, CCL18, ST6GAL1, CRTC1, ANGPTL3, TNFRSF1A, LEP, Gal-9, SORT1, and TRAIL-R2. The increase of these proteins was associated with the inflammation shown by the correlation with C reactive protein (CRP) levels and DAS28. The elevated levels of SAA4 (serum amyloid A protein-4) discriminated between RA patients and healthy donors with high sensitivity and specificity (AUC=0.95). Treatment with methotrexate in RA patients at diagnosis reduced the levels of 64 proteins (50% of the altered proteins) while tocilizumab modulated the expression of 30 proteins (50% of the altered proteins) in RA patients with established disease after 6 months. These reductions were associated with a decrease in CRP and DAS28 levels.

Conclusion:

1) The cardiovascular and cardiometabolic serum proteome is altered in RA patients at diagnosis and after a long time of the disease evolution and chronic treatments, 2) SAA4 may represent a biomarker for the diagnosis of RA with high sensitivity and specificity, 3) Methotrexate and tocilizumab specifically modulate the alteration on the serum proteome after six months of treatment alongside the reduction of clinical inflammatory and disease activity markers.

PRESENCE AND EFFECT OF MUSCLE GDF-8 AND GDF-11 IN THE SYNOVIAL FLUID OF PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Synovium

M. L. Gasparini Vieira1,2, R. T. Pedro1, J. Miranda de Souza Silva1, M. Farinoni1,2, S. Dalmon3, M. Piccoli4, M. Dos Santos5, B. Bartokosi6, R. Cavaliere Do Espirito Santo7, S. Hax8, R. Xavier9,10, Hospital de Clínicas de Porto Alegre, Laboratório de Doenças Autoimunes, Serviço de Reumatologia, Porto Alegre, Brazil. 2. Universidade Federal do Rio Grande do Sul, Programa de Pós-Graduação em Medicina: Ciências Médicas, Porto Alegre, Brazil. 3. Hospital de Clínica de Porto Alegre, Serviço de Reumatologia, Porto Alegre, Brazil.

Background:

Myokines, such as the growth differentiation factor (GDF) 8 and 11, have the function of regulating autocrine and paracrine activities on muscle tissue metabolism. In Rheumatoid Arthritis (RA), there is increased expression of GDF-8 in the synovial membrane compared to osteoarthritis (OA) patients, more specifically by fibroblast-like synoviocytes (FLS). On the other hand, the GDF-11 treatment appears to have a protective effect against the development of experimental arthritis. Therefore, more studies evaluating the serum and synovial membrane levels of the GDF-8 and GDF-11 in RA patients are needed to better define their possible roles in this disease.

Objectives:

To evaluate the GDF-8 and GDF-11 in serum and synovial membrane levels in RA patients and to assess their in vitro effect on FLS.

Methods:

Patients diagnosed with RA and patients with knee OA with the indication of knee arthrocentesis were included in the study. Disease activity was assessed by Clinical Disease Activity Index (CDAI). The evaluation of serum and synovial fluid levels of GDF-8 and GDF-11 was performed by ELISA. FLS were isolated from the synovial fluid of RA patients, and cell viability was determined in the presence and absence of GDF-8 and GDF-11 (10nM; 20nM and 50nM) for 24h and 48h by the MTT assay. Kolmogorov-Smirnov, Mann-Whitney U and Spearman’s correlation tests were performed using SPSS version 20.0 (accepted at p ≤0.05).

Results:

As preliminary data, samples from 11 patients with RA and 5 patients with knee OA were evaluated. GDF-8 synovial fluid levels were lower than serum levels in RA patients (p=0.007) and were negatively correlated with disease duration (r=-0.884, p=0.02). GDF-11 levels in synovial fluid were also lower than in serum in RA (p=0.018) and were higher in RA patients than in the OA group (p=0.052). Furthermore, treatment with different concentrations of GDF-8 and GDF-11 did not affect FLS viability.

RA, rheumatoid arthritis; OA, osteoarthritis; SD, standard deviation; CDAI, clinical disease activity index; IQR, interquartile range.

Conclusion:

In this preliminary research, we found lower GDF-8 and GDF-11 synovial fluid levels than in serum in RA patients and higher GDF-11 serum levels in the RA group compared to the OA group. This result could be related to local compensatory mechanisms against the inflammatory state. In vitro, both GDF-8 and GDF-11 did not induce proliferation or death of FLS, and more studies are undergoing to analyze their impact on the FLS phenotype. Our results contribute to the knowledge about the participation of myokines in the pathogenesis of RA.

REFERENCES:

Background: Progress has been achieved with the introduction of biologics for the management of inflammatory/autoimmune diseases such as rheumatoid arthritis (RA), however such medications induce immune suppression, which is nonselective to the pathogenesis of the disease, resulting in higher rates of infections. Therefore, there are unmet medical needs in the treatment of such diseases, which should be addressed by novel approaches. Accumulating evidence suggests that extracellular vesicles (EVs) play a role in the establishment, maintenance and modulation of autoimmune processes.

Objectives: In the current study, we hypothesized that isolation of circulating autologous tissue-specific homing EVs from RA patients - may improve the delivery of current FDA-approved anti-inflammatory drugs, which will be encapsulated into these EVs. The drug-loaded EVs will be injected back to the diseased subjects and will naturally find their way to the inflamed tissue.

Results: Indeed, we found that autologous labeled EVs, expressing joint/synovia-specific homing receptors (e.g. vWf3 integrin), derived from blood of diseased arthritic mice (collagen antibody-induced arthritis model), can be directed toward the inflamed synovia, using in vivo imaging system (IVIS). Moreover, we show that these EVs strongly express glucose transporter 1 (mGLUT1) which in turn, improve their therapeutic potential to be loaded with anti-inflammatory drugs using glucose-coated gold nanoparticles (GNPs). Finally, we show that EVs derived from plasma of RA patients overexpresses vWf3 integrin and taken up by LPS/TNF-α-treated activated human synovial cell line in vitro.

Conclusion: Overall, we show the potential of autologous circulating EVs of RA patients to serve as natural nanocarrier for current FDA-approved drugs. We believe that this strategy will increase the specificity and efficiency of current treatment, therefore it will reduce side effects and will improve the quality of life of RA patients and potentially other autoimmune disease patients.

García1. 1Galicia Sur Health Research Institute (IIS Galicia Sur), SERGAS-UVIGO, Rheumatology & Immuno-mediated Diseases Research Group (IRIDIS), Vigo, Spain

Background: Several studies have shown that different semaphorin family members are involved in the pathogenesis of rheumatoid arthritis (RA). On one hand, our group has demonstrated that (Sema)phorin 3B and Sema3F are reduced in RA patients and play a protective role. On the other hand, Sema4A and Sema4D are increased in RA patients and are associated with inflammatory processes (Garcia, 2019; Igea, 2022).

Objectives: The aim of this study is to determine the role of Sema4B in the pathogenesis of RA.

Methods: Gene expression of Sema4B was obtained from the gene expression array available in Gene Expression Omnibus-NCBI (GSE77298). Fibroblasts-like synoviocytes from RA patients (RA-FLS) (n=8) were stimulated 4 and 24 h with Sema4B (200ng/ml), TNF (10ng/ml) or the combination of both. Peripheral blood mononcytes from RA patients (n=12) were differentiated into M1 macrophages by culturing in the presence of IFN-γ (10 ng/ml) for 6 days. Afterwards, macrophages were stimulated 24 h with Sema4B (200ng/ml), LPS (10ng/ml) or the combination of both. The expression of inflammatory mediators was determined by quantitative PCR (qPCR) and ELISA. Viability and migration of FLS were determined using calcein assays and wound closure assays, respectively.

Results: Sema4B expression was significantly higher in the synovial tissue and FLS of RA patients compared to healthy controls (HC) and osteoarthritis patients (OA), respectively. A significantly higher expression of SEMA4B in the synovium and FLS of RA patients compared to, respectively, was found. Interestingly, TNF stimulation induced the expression of SEMA4B by RA-FLS. Functional studies showed that Sema4B did not affect the viability of FLS but increased their migratory capacity. Moreover, Sema4B alone did not induce the expression of inflammatory mediators (data non shown), but significantly enhanced the TNF-induced expression of IL6, IL8, TNF, CCL2 and MMP3 (Figure 1A) and the secretion of TNF. Finally, Sema4B alone did not modulate the expression of inflammatory mediators in macrophages, but significantly enhanced the LPS-mediated expression of TNF, CCL2, and MMP1 (Figure 1B), as well as the TNF protein secretion.

Conclusion: Our data demonstrate that, in an inflammatory context, Sema4B induces FLS migration and the production of inflammatory mediators by FLS and macrophages. These results suggest that Sema4B is involved in inflammatory processes observed in the RA synovium and might be a potential therapeutic target in the treatment of RA.

AB0078 EARLY ARTHRITIS: IS JAK-STAT SIGNALLING KEY TO DISEASE PROGRESSION?

Keywords: Innate immunity, Targeted synthetic drugs, Inflammatory arthritis

R. L. Teixeira1,2,3, C. Tomé2, A. R. Faicaz2, V. C. Romão3, J. E. Fonseca1,2, I. Alcobia3, R. A. Moura4. 1Centro Hospitalar Universitário de Lisboa Norte, Hospital de Santa Maria, Centro Académico de Medicina de Lisboa, Rheumatology Department, Lisboa, Portugal; 2Instituto de Medicina Molecular, João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Instituto de Fisiologia e Biologia do Desenvolvimento, Lisboa, Portugal; 3Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Instituto de Histologia e Biologia do Desenvolvimento, Lisboa, Portugal

Background: Janus kinase inhibitors (JAKi) are a new therapeutic class approved for the treatment of chronic arthritis. JAKi suppress the activity of STAT tyrosine kinases, interfering with the signaling pathway which is critical for immune cell proliferation, survival and differentiation. Our group has demonstrated that early treatment with a JAKi, in animal models, abrogates disease and prevent bone damage. We hypothesize that JAK-STAT pathway is key to chronic arthritis onset and its early inhibition might have a major effect on disease control.

Conclusion: Our data demonstrate that, in an inflammatory context, Sema4B induces FLS migration and the production of inflammatory mediators by FLS and macrophages. These results suggest that Sema4B is involved in inflammatory processes observed in the RA synovium and might be a potential therapeutic target in the treatment of RA.

Objectives: The main goal of this study is to characterize the JAK-STAT signaling pathway activation in unremitting early arthritis patients.

Methods: Peripheral blood mononuclear cells were isolated from blood samples obtained from unremitting early arthritis patients (<12 months of disease duration). Frequency, phenotype and STAT phosphorylation (by mean fluorescence intensity, MFI) levels were evaluated on T and B cells, monocytes and dendritic cells (DC) by flow cytometry. A group of age and sex-matched healthy individuals was included for comparison.

Results: The frequency of total CD19+ B cells was similar between patients and controls, although patients presented a significantly decreased level of pre-switch memory B cells when compared to controls. No significant differences were observed in naïve, post-switch memory, double negative B cells, transitional B cells and plasmablasts. The frequency of total CD3+ T cells, CD14+ monocytes and DCs was similar, however patients had significantly decreased levels of plasmacytoid DCs. In addition, we found that STAT3 phosphorylation levels were significantly increased in B cells and DCs in early arthritis patients. The STAT1, STAT5 and STAT6 phosphorylation levels were similar in T and B cells, monocytes and DCs, when compared with the control group.

Conclusion: Alterations in the frequencies of circulating memory B cell subsets and pDCs, but not in T cells and monocytes, are found in unremitting early arthritis patients when compared to healthy controls. Changes in STAT3 phosphorylation MFI levels observed in B cells and DCs from early arthritis patients in comparison to controls support an early activation of JAK-STAT pathway in the initial phase of arthritis and a role of these cells in disease pathogenesis.

Background: An autoimmune disease that causes inflammation and bone and cartilage deterioration is rheumatoid arthritis (RA). In the pathogenesis of RA, oxidative stress and pro-inflammatory cytokines are important factors. The main polyphenol in black tea, theaflavin (TFs), has been used medically to treat a variety of inflammatory illnesses by reducing inflammation and reactive oxygen species (ROS).

Objectives: The medications available to treat RA have a variety of side effects. The current study was designed to assess the anti-arthritis properties of theaflavin in a mouse collagen-induced arthritis model.

Methods: In order to induce arthritis in DBA/1 mice, type II collagen was administered intradermally. From days 21 through days 42, different doses of theaflavin (50 and 100 mg/kg/day) were orally administered. To determine the effect of theaflavin on collagen-induced arthritis, histological analyses were conducted. In addition, the generation of reactive oxygen species (ROS), nitric oxide, and the activities of enzymatic antioxidants (superoxide dismutase, glutathione peroxidase, catalase, and glutathione reductase) in the joint homogenate of mice were examined. The levels of TNF-α, IL-6, and IL-1β were also measured by ELISA to detect inflammation.

Results: Our results showed anti-oxidant and anti-inflammatory effects of theaflavin in arthritis mice. Histopathological studies corroborated the anti-arthritis properties of theaflavin. The compound was found to be effective in lowering ROS and nitric oxide levels while increasing enzymatic antioxidant levels. Theaflavin therapy also reduced TNF-α, IL-6, and IL-1β levels.

Conclusion: In mice with arthritis, theaflavin was successful in reducing inflammation and oxidative stress. These results suggest that theaflavin may be used in conjunction with other treatments to manage RA.

IMBALANCE OF MONOCYTE/MACROPHAGE POLARIZATION IN PERIPHERAL BLOOD AND SYNOVIAL FLUID OF RHEUMATOID ARTHRITIS PATIENTS

Keywords: Innate immunity, Rheumatoid arthritis

S. Soldano1, E. Gotelli1, P. Montagna1, R. Campitiello1, A. Sulli1, V. Smith2,3, M. Cutolo1. University of Genova, IRCCS Policlinico San Martino Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Genoa, Italy; 2Ghent University Hospital, Department of Rheumatology, Ghent, Belgium; 3Ghent University, Department of Internal Medicine, Ghent, Belgium

Background: Macrophages strongly contribute to the pathogenesis of rheumatoid arthritis (RA), initiating the inflammatory response, the joint damage, but also may promote the resolution of inflammation and the restoration of tissue immune-homeostasis [1,2]. This seems to be related to an unbalanced immunological response mediated by macrophages through their polarization into "classically" and "alternatively" activated phenotypes (M1 and M2) [3,4]. However, little is known about the M1 and M2 phenotype of their circulating precursors (monocytes) in the peripheral blood (PB) and the synovial fluid (SF) of RA patients.

Objectives: To characterise the polarization status (M1 and M2) of PB and SF monocytes of RA patients together with their distribution in the monocyte subsets by flow cytometry (FC).

Methods: Nineteen RA patients not yet treated with biological DMARDs (mean age 62±14 years), who fulfilled the 2010 ACR/EULAR classification criteria for RA and treated in accordance with EULAR recommendation, as well as 19 age-matched healthy subjects (HSs) were enrolled after signed informed consent.

Figure 1. TF ameliorated the severity of arthritis in CIA mouse models. (a) Representative photographs depicted the swollen and reddened rear paws of four animal groups 42 days following the initial vaccination. (b) Accumulated clinical arthritis scores in each leg ranged from 0 to 4 and were evaluated every three days using a visual scoring system. The changes in body weight of normal control or CIA mice treated with or without TF were recorded every three days till day 42. (c) TNF-α, IL-6, and IL-1β inflammatory cytokine protein levels in arthritis mouse hind paw tissues. On day 42, CIA in DBA/1 mice hind paw homogenates were taken from the normal control, vehicle-treated, or TF-treated (50 or 100 mg/kg) groups of mice. The cytokine profiles were measured using ELISA according to the techniques given. ** p < 0.01 and * p < 0.05 showed statistically significant differences in two-way ANOVA compared with the vehicle-treated CIA group
PB and SF cells were collected from each RA patient, whereas only PB cells were collected from HSs. The expression of CD14 and CD16 surface markers allowed to identify the monocyte population and the monocyte subsets: "classical"(CD14+CD16−), "intermediate"(CD14+CD16+) and "non-classical"(CD14+CD16+). The M1 phenotype (M1 monocytes) was identified by the evaluation of CD80, CD86, TLR2 and TLR4, whereas the M2 phenotype (M2 monocytes) was identified evaluating CD204, CD163 and CD206 surface markers. Results were expressed as percentage of positive cells over total leukocytes from PB and SF. Statistical analysis was carried out by Mann-Whitney non-parametric test.

Results: In RA patients, the percentage of CD14+CD16+ monocytes was significantly higher in PB compared to that in HS (p<0.001), and it was higher in SF compared to PB (p<0.05). The percentage of CD14+CD16+ monocytes was significantly increased in RA-PB compared to HS-PB and RA-SF (p<0.01; p<0.05). RA patients were characterized by an increased percentage of M1 monocyte (CD80+CD86+TLR2+TLR4+CD204+CD163+CD206+cells) in PB compared to HSs and compared to RA-SF. The percentage of M2 monocytes (CD204+CD163+CD206+CD80+CD86+TLR2+TLR4+cells) was also increased in RA-PB compared to HS-PB and to RA-SF, but this increase was lower and not significant than that observed for M1 monocytes. Moreover, the M1-M2 monocyte ratio was 8:1 in RA-PB. Therefore, in RA patients, circulating M1 monocytes belonged to the "non-classical" subset, whereas M2 monocytes belonged to the "classical" subset. The percentage of circulating mixed M1/M2 monocytes (CD80+CD86+TLR2+TLR4+CD204+CD163+CD206+cells) was higher in RA patients compared to HSs. Moreover, in RA patients, the percentage of these cells was higher in SF than in PB and they primarily belonged to the "intermediate" monocyte subset. Interestingly, the highest percentage of M2 and mixed M1/M2 monocytes was observed in PB and SF of RA patients receiving a higher daily (25mg) and cumulative glucocorticoid dosages.

Conclusion: The results confirm that RA is an immune-inflammatory disease mainly mediated by both M1 monocytes and macrophages, as demonstrated by the increase in the percentage of circulating M1 monocytes. Glucocorticoids might contribute to the M1 to M2 transition, which characterizes RA patients under remission by increasing mixed M1/M2 and M2 monocyte percentage.

GLUTATHIONE PEROXIDASE 3 IS A NOVEL CLINICAL DIAGNOSTIC BIOMARKER AND POTENTIAL THERAPEUTIC TARGET FOR NEUTROPHILS IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis

T. Chen1, Y. Zhao1,1. West China Hospital, Department of Rheumatology and Immunology, Chengdu, China

Background: Neutrophils have a critical role in the pathogenesis of rheumatoid arthritis (RA) with immune system dysfunction. However, the molecular mechanisms of this process mediated by neutrophils still remain elusive.

Objectives: The purpose of the present study is to identify hub genes in neutrophils for diagnosis and treatment of RA utilizing publicly available datasets.

Methods: Gene expression profiles were downloaded from the Gene Expression Omnibus (GEO), the Gene Expression Portal of Kyoto Encyclopedia of Genes and Genomes enrichment analysis were used to conduct significantly functional analysis and crucial pathways. The resulting co-expression genes modules and Genomes enrichment analysis were used to conduct significantly functional analysis and visualization by Cytoscape. Flow cytometry was conducted to detect reactive oxygen species (ROS) levels in neutrophils.

Results: Neutrophils underwent transcriptional changes in synovial fluid (SF) of RA patients, different from peripheral blood of healthy controls or patients with RA. Especially, glycolysis, HIF-1 signaling, NADH metabolism, and oxidative stress were affected. These hub genes were strongly linked with classical glycolysis-related genes (ENO1, GAPDH, and PKM) responsible for ROS production. The antioxidant enzyme glutathione peroxidase 3 (GPX3), a ROS scavenger, was first identified as a hub gene in RA neutrophils. Neutrophils from patients with autoimmune diseases had markedly enhanced ROS levels, most notably in RA SF.

Conclusion: This research recognized hub genes and explored the characteristics of neutrophils in RA. Our findings suggest that the novel hub gene GPX3 is involved in the neutrophil-driven oxidative stress-mediated pathogenesis of RA. It has the potency to be a target for neutrophil-directed RA therapy.

AGE-RELATED GENES USP2 AND ARG2 ARE INVOLVED IN THE REDUCTION OF IMMUNE CELL INFILTRATION IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis, -omics

O. Cheng1, Y. Du1, H. Wu1. The Second Affiliated Hospital of Zhejiang University School of Medicine, Rheumatology, Hangzhou, China

Background: As the prevalence of rheumatoid arthritis (RA) in the elderly is increasing, rheumatologists are increasingly concerned about this group of patients. There is a large gap between the clinical manifestations and biological markers of elderly patients with RA (EYRA, age > 60) and younger patients with RA (YPRA, age ≤ 60), in part from the differences in the immune system in different age groups. The current understanding of EYRA remains insufficient.

Objectives: For better understanding of the mechanism of RA disease progression and subsequent treatment options, here we focused on the changes of immune cell infiltration in YPRA and EYRA.

Methods: P package "ssGSEA" and "GSEA" were used to identify the changes in immune cell infiltration and immune-related pathways. P package "WGCNA" and "DEseq2" were used to screening and verifying age-related differentially expressed genes (DEGs). Hub genes were identified by Cytoscape and cyto-Hubba. ROC (receiver operator characteristic) analysis was performed to determine the prediction and value of biomarkers. Spearman correlation analysis was conducted to evaluate the correlation between hub age-related genes and immune cells.

Results: In early RA patients (defined as within 12 months of onset of symptoms), there were no differences in the infiltration of 28 types of immune cells between younger and older patients. However, in established RA patients, several immune cells were markedly decreased in older patients, including activated B cells, immature B cells, natural killer cells, CD56dim natural killer cells, MDSCs, monocytes, effector memory CD8+T cells, regulatory T cells, type 1 T helper cells, type 17 T helper cells and T follicular helper cells. Moreover, 78 age-related DEGs related to amino acid and glycophospholipid synthesis and metabolism were identified by WGCNA and DEseq screening. AGMAT, ARG2, OMD, USP2, IL4I1, and ISG15 were obtained by construction of molecular interaction regulatory networks. After verification by GEO validation set and our own RA synovial samples, only two genes, USP2 and ARG2, were still upregulated in EYRA after verification (Figure 1) and ARG2 and USP2 could effectively distinguish YPRA and EYRA and had potential as biomarkers.

Conclusion: In conclusion, this study is the first to systematically analyze changes in immune cell infiltration between younger and older RA patients and obtain hub age-related genes, which may provide the basis for illuminating the pathogenesis of RA and informing treatment strategies.
CD14+CD90+ CELLS IN PERIVASCULAR AREAS OF RHEUMATOID ARTHRITIS SYNOVIAL TISSUES HAVE POTENTIAL TO DIFFERENTIATE INTO DENDRITIC CELLS

Keywords: Rheumatoid arthritis, Synovium

Background: We have previously reported that CD14+ dendritic-shaped cells show a dendritic morphology under the electron microscopy and engage in a pseudoemperipolesis phenomenon with lymphocytes. CD14+ dendritic-shaped cells express CD90 in the perivascular areas of RA synovial tissues. In addition, the CD14+CD90+ cells are considered to be derived from CD14+CD90+ cells in the perivascular areas, which may be involved in RA inflammation as dendritic cells.

Results: ELISAs were measured in the culture supernatants at days 0, 4, 8 and 12 using validated III, and VI collagen formation (PRO-C1, PRO-C3 and PRO-C6, respectively), nM, either alone or in combination from day 0 and the treatments changed twice α[0.5 nM] or TNF- β[1 nM], IL-1 β.

Methods: The in-a-Jar model. Briefly, the fibroblasts were cultured in 0.4% fetal bovine serum DMEM, ficoll (to create a crowded environment) and ascorbic acid for 12 days.

Conclusion: The combination of both growth factors and cytokines may be directing components, and upon activation the production increases. The healthy synovial membrane consists of multiple ECM components, including type I, III and VI collagen[1]. The ECM composition of the fibrotic and fibro-inflamed membrane is unclear. We have previously shown that TGF-β increases the formation of type I, III and VI collagens in osteoarthritis (OA) fibroblasts-like synoviocytes (FLS)[2]. Both IL-1 and TNF-α receptors have been found in the synovium of rheumatoid arthritis (RA) patients[1]. We hypothesize that both fibrosis and inflammation are likely to be present in arthritis diseases at the same time. And that the interplay between different disease drivers is crucial for the structural manifestation. Therefore, the combination of both growth factors and cytokines may be directing the composition of the synovial ECM in the joint.

Objectives: The objective of this study was to characterize the effect of inflammation on the fibrotic response of OA FLS using biomarkers of collagen formation.

Methods: Primary human FLS were isolated from synovial membranes, from OA patients undergoing total knee replacement (n=4) and cultured in the Scar-in-a-Jar model. Briefly, the fibroblasts were cultured in 0.4% fetal bovine serum DMEM, ficoll (to create a crowded environment) and ascorbic acid for 12 days. The fibroblasts were stimulated with TGF-β[1] (1 nM), IL-1α[0.5 nM] or TNF-α[0.5 nM], either alone or in combination from day 0 and the treatments changed twice a week. Non-stimulated fibroblasts were used as control. Biomarkers of type I, III, and VI collagen formation (PRO-C1, PRO-C3 and PRO-C6, respectively), were measured in the culture supernatants at days 0, 4, 8 and 12 using validated ELISAs.

Results: Treatment with IL-1α or TNF-α alone did not affect PRO-C1, PRO-C3 or PRO-C6, compared control (Figure 1A). TGF-β[1] increased the total release of PRO-C1 and PRO-C6, compared to control (p<0.001, Figure 1A). The total release of PRO-C3 did not increase, while at day 12 the PRO-C3 level was higher compared to control (p<0.05; data not shown). Both IL-1α and TNF-α in combination with TGF-β[1] decreased PRO-C1 (p<0.01, Figure 1A; decrease of 32-53%, Figure 1B) and PRO-C6 compared to TGF-β[1] alone (p<0.001, Figure 1A; decrease of 56-78%, Figure 1B). TNF-α in combination with TGF-β[1], increased the release of PRO-C3 (p<0.01, Figure 1A; increase of 172-264%, Figure 1B), while the combination with IL-1α did not seem to affect the PRO-C3 response compared to TGF-β[1] alone (Figure 1A; increase of 48% to decrease of 39%, Figure 1B).

Conclusion: The combination of inflammatory cytokines and TGF-β[1] leads to a differential effect on formation of ECM components such as type II collagen. These findings suggest that the presence of an inflammatory component, may be important for the development of a fibrotic component in joint diseases. Consequently, this also underlines the need for a better understanding of the molecular mechanisms driving the joints diseases.

Background: Ankylosing spondylitis (AS) is a common chronic inflammatory autoimmune disease affecting the sacroiliac joint and spine, with or without systemic symptoms such as peripheral arthritis[1]. The etiology of AS is still unclear, which is affected by genetic risk factors and the environment, especially microbiome. In addition, growing evidence suggests that the influence of the microbiota extends beyond the gut and affects the systemic immune system[2]. The relationship between the gut microbiome and AS has been well documented. However, the causal relationship between the gut microbiome and AS has yet to be well studied.

Objectives: This study aimed to evaluate the causal relationship between the gut microbiome and AS using a two-sample Mendelian randomization (MR) study.

Methods: Gut microbiome genome-wide association study (GWAS) data were extracted from the MR-base platform. Data on AS have been obtained from genome-wide association data collected by the UK Biobank (968 cases and 336,191 healthy controls). First, we identified SNPs associated with the gut microbiome by genome-wide significance level (p < 1 × 10^-8). Then, a two-sample MR study was conducted to examine the association of gut microbiome and AS, including the inverse-variance weighted (IVW) method, MR-Egger, and Weighted median (WM). In addition, we also performed Cochran's Q test, MR pleiotropy residual sum and outlier (MR-PRESSO), and leave-one-out sensitivity test to test for heterogeneity, horizontal multiplicity, and stability of results.

Results: Ruminococcaceae was positively associated with the risk of AS (OR=0.998, 95%CI =0.997, 0.999, p =0.037), Butyrivibrio (OR=1.01, 95%CI =1.00, 1.03, p =0.042), Coprooccus3 (OR=1.01, 95%CI =1.00, 1.03, P =0.042), and Defluvialeaceae (OR=1.01, 95%CI =1.00, 1.02, p =0.04) were negatively correlated with the risk of AS. (Figure 1) In addition, no apparent heterogeneity or horizontal pleiotropy were observed in the sensitivity analysis.

Conclusion: This study supports a causal relationship between gut microbial composition and risk for AS, thus providing novel insights into the gut microbiota-mediated development mechanism of AS.

ANTIBODIES OF THE IMMUNOGLOBULIN G AND A ISOYOTE TO NOVEL PEPTIDES IN EARLY AXIAL SPONDYLOARTHRITIS PATIENTS

Keywords: Biomarkers, Spondyloarthritis, Autoantibodies

P. Ruytinx¹, P. Vandomael¹, D. Quaden¹, E. Luyten¹, P. Geusens²,3, J. Vanwijck⁴, A. Troldborg¹, K. De Vlam¹,², V. Somers¹,². ¹UHasselt, Biomedical Research Institute, Department of Immunology and Infection, Diepenbeek, Belgium; ²Department of Rheumatology, ReumaClinic, Genk, Belgium; ³University Maastricht, Department of Rheumatology, Maastricht, Netherlands; ⁴UHasselt, Faculty of Rehabilitation Sciences, REVAL - Rehabilitation Research Center, Diepenbeek, Belgium; ¹University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium; ²KULeuven, Skeletal Biology and Engineering Research Center (SBE), Dept Development and Regeneration, Leuven, Belgium

Background: There is an unmet need for biomarkers to identify patients with axial spondyloarthritis (axSpA), as clinical manifestations often overlap with other disorders. Previously, we identified immunoglobulin G (IgG) antibodies to 3 Hasselt University (UH)-axSpA peptides which could provide a novel tool for diagnosis of a subset of axSpA patients [1].

Objectives: The aim of this study was to identify novel IgA antibodies in early axSpA patients and to determine their diagnostic potential in combination with previously determined IgG antibodies against UH-axSpA-IgG antigens.

Methods: An axSpA cDNA phage display library constructed from axSpA hip synovium, was used to screen for novel IgA antibodies in plasma from early axSpA patients. The diagnostic value of these antibodies against novel UH-axSpA-IgA and previously identified UH-axSpA-IgG antigens was determined in two independent axSpA cohorts [UH cohort and the Leuven spondyloarthritis biologics cohort (BioSPAR)] in healthy controls and in patients with chronic low back pain (CLBP) using ELISA.

Results: We identified antibodies to 7 novel UH-axSpA-IgA antigens, of which 6 correspond to non-physiological peptides and 1 to the human histone deacetylase 3 (HDAC3) protein. IgA antibodies against 2 of these 7 novel UH-axSpA-IgA antigens and IgG antibodies against 2 of the previously identified antigens were significantly more present in axSpA patients from the UH cohort (18/70, 25.7%) and the (Bio)SPAR cohort (26/164, 15.9%), compared to controls with CLBP (2/66, 3%). Antibodies to this panel of 4 antigens were present in 21.1% (30/142) of patients with early axSpA from the UH and (Bio)SPAR cohorts. The positive likelihood ratio for confirming early axSpA using antibodies to these 4 UH-axSpA antigens was 70. So far, no clinical correlation existed between the novel identified IgA antibodies and inflammatory bowel disease could be identified.

Conclusion: Screening an axSpA cDNA phage display library for IgA reactivity resulted in the identification of 7 novel UH-axSpA-IgA antigens, of which 2 show promising biomarker potential for the diagnosis of a subset of axSpA patients, in combination with previously identified UH-axSpA-IgG antigens.

COMPLEMENT IN THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS (AXSPA). INVESTIGATIONS IN A CROSS-SECTIONAL COHORT (OPTIREF) OF PATIENTS SUSPECTED OF AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Innate immunity

C. E. Mistegaard¹,²,³, A. Trolldborg²,³, A. G. Loft³, S. Thiel², L. Spiller², V. Rios Rodriguez², B. Muche², J. Rademaker², A. K. Weber², S. Lueders³, S. Stieper³, D. Poddubnyy⁴, F. Prölt³. ¹Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; ²Aarhus University, Department of Biomedicine, Aarhus, Denmark; ³Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; ⁴Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease without specific diagnostic biomarkers. However, recent evidence suggests an involvement of the innate immune system in the pathogenesis of axSpA [1]. The lectin pathway of complement activation serves essential functions in the innate immune system, regulates homeostasis and development. We have previously shown the lectin pathway proteins (LPPs) L-ficolin and M-ficolin to be elevated in axSpA-patients compared with clinically relevant controls with unspecific low back pain (uLBP).

Objectives: To investigate the diagnostic potential of LPP levels in patients recruited from a well-defined cross-sectional prospective cohort (OptiRef), including newly diagnosed axSpA-patients and uLBP-patients.

Methods: Serum samples were obtained from 515 individuals from the OptiRef cohort; 151 newly diagnosed axSpA-patients and 364 uLBP-patients [2]. All patients were assessed according to a standardized protocol, incl. clinical information as demographics, SpA features, symptom duration, and disease activity. Routine lab tests (HLA-B27 and CRP) were performed. Imaging (x-ray and MRI) was performed if deemed clinically relevant. Serum levels of all 10 LPPs (MBL, CL-L1, M-ficolin, H-ficolin, L-ficolin, MASP-1, MASP-2, MASP-3, MAP19, and MAP44) and the complement activation product C3dg were measured by immunoassays.

Results: Patient characteristics are shown in Table 1. L-ficolin, MASp-2, and C3dg serum levels were increased in axSpA-patients compared with uLBP-patients, whereas CL-L1 and MASp-3 serum levels were decreased (Figure 1). After adjustments for CRP, C3dg serum levels remained significantly increased in axSpA-patients, whereas M-ficolin and MASp-3 serum levels were decreased in axSpA-patients. The diagnostic potential of combining either L-ficolin, MASp-3, and C3dg with HLA-B27 increased specificity to 93-95% compared with HLA-B27 alone (77%) but decreased sensitivity to 29-33% compared with HLA-B27 alone (83%). In a univariate logistic regression analysis, CL-L1, MASp-2, and C3dg were associated with an axSpA-diagnosis, and C3dg and MASp-3 remained significant in a multivariate logistic regression analysis.

Conclusion: In this study, serum levels of C3dg, MASp-3, and CL-L1 differed significantly between axSpA-patients and uLBP-patients after adjustment for CRP. Although combining HLA-B27 with measurements of L-ficolin, MASp-3, and C3dg increased diagnostic specificity for axSpA, it seems unjustified due to the concomitant loss of sensitivity. However, both C3dg and MASp-3 were associated with the axSpA-diagnosis in multivariable logistic regression, indicating the complement system's involvement in axSpA-pathogenesis. This should be further investigated.

ANALYSIS OF CUMULATIVE DOSES OF METHOTREXATE IN THE HEPATIC DISEASE RISKTHROUGH IN VIVO AND IN VITRO APPROACHES IN PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Disease-modifying drugs (DMARDs)

1IMIBIC/University of Cordoba/Reina Sofia Hospital, University of Cordoba, Rheumatology Service, Cordoba, Spain; 2IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain; 3IMIBIC/University of Cordoba/Reina Sofia Hospital, Cell Biology, Physiology and Immunology, Cordoba, Spain; 4IDISCAM/Hospital General de Tomelloso, Gastroenterology, Tomelloso, Spain

Background: Liver abnormalities, particularly non-alcoholic fatty liver disease (NAFLD) are strongly associated with psoriatic arthritis (PsA). In the last decades, the possible hepatotoxic effects of methotrexate in PsA have been studied, however, up to date, the results are controversial.

Objectives: 1) to evaluate the liver damage risk in PsA patients and its relationship with clinical features of the disease; 2) to determine the influence of cumulative doses of methotrexate by in vivo and in vitro approaches.

Methods: A cross-sectional study was performed on 326 subjects: 155 PsA patients, 87 NAFLD non-PsA patients, and 84 healthy donors (HDs). Clinical and laboratory parameters, liver disease biomarkers, and several indexes to evaluate the risk of suffering hepatic steatosis or fibrosis were evaluated. Cumulative doses of methotrexate were calculated retrospectively. Mechanistic studies were carried out on hepatocytes (HEPG2 cell line) treated with cumulative doses of methotrexate for up to 72 hours and 150µM. The changes in the levels of 11 inflammatory proteins on the hepatocytes were analyzed using PEA technology (ClinKit Target 96 Inflammation panel, Cobiomic Biosciences).

Results: using a NAFLD non-PsA BMI, age and sex-matched cohort, a cut-off value of hepatic steatosis index (HSI) (35.68; AUC=0.865 <0.0001) was calculated to distinguish NAFLD patients from HDs. Taking this value into account, PsA patients showed a significantly high risk of suffering NAFLD vs HDs, 65% respect to 22%. In addition, PsA patients with a high risk for steatosis displayed a significant prevalence of insulin resistance, obesity, type 2 diabetes mellitus, and arterial hypertension compared to PsA patients with no risk. Interestingly, these PsA patients also showed significantly elevated levels of triglycerides, complement component 3, DAPSA, c-reactive protein, and erythrocyte sedimentation rate. Next, PsA patients were divided into two groups depending on mean cumulative doses of methotrexate (<1.5 gr for no hepatotoxic risk group and >1.5 gr for the hepatotoxic risk group). Patients with more than 1.5gr of methotrexate cumulative dose showed significantly lower levels of acute phase reactants and no significant differences in metabolic profile or liver disease biomarkers. However, fibrosis-4 score (FIB-4) was significantly elevated in the group of hepatotoxic risk and positively correlated with cumulative doses of methotrexate. Although, this association was influenced by the age variable and not due to the levels of transaminases or platelets. On the other hand, in vitro treatment of hepatocytes with methotrexate for 24h induced the expression of 19 inflammatory proteins out of 92. These changes were not significantly altered after 72 hours of treatment with methotrexate added each 24h.

Conclusion: 1) PsA patients with a high risk of liver disease show elevated rates of cardiometabolic comorbidities, inflammatory clinical markers and disease activity suggesting the link between metabolic alterations and the clinical features of PsA with the development of NAFLD, 2) PsA patients with high cumulative doses of methotrexate had no alteration of hepatic enzymes and indexes and 3) High cumulative doses of methotrexate in vitro did not show a significant impact on hepatocyte cells compared to low doses. Conclusion: It was observed that IHc reactivity for TGF-β1 and IL17A was higher in patients who needed biologics after 5 years of following. Early increased synovial immunohistochemistry reactivity of IL17A and TGF-β1 in psoriatic arthri-tis and rheumatoid arthritis patients could predict the need to use biologics.

1 in psoriatic arthri-synovial immunohistochemistry reactivity of IL17A and TGF-β higher in patients who needed biologics after 5 years of following. Early increased periodicity was long. But at the same time, all SpA patients were examined with the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS) using clinical and laboratory data.

Results: Among 61 SpA subjects, 83.6% were men, mean [SD] age was 43.2 [12.3] years and mean disease duration was 13.8 [9.1] years. Mean BASDAI was 2.6 [1.7] and mean ASDAS-2CRP was 16 [1.1]. SASP-SCR was positive in 5 controls (0.4 [0.3-6.4] pg/ml for IL-17 and 57.7 [50.5-108.8] pg/ml for IL-23), albeit not significant (p=ns). Interestingly, significantly higher serum IL-23 was observed in patients with non-radiographic axial SpA (n=30, 13.1 [8.7-49.4] pg/ml) than advanced ankylosing spondylitis (AS) (n=41, 9.7 [7.9-12.6] pg/ml) (p=0.039), but not with IL-17 (13 [0.8-3.7] pg/ml in nrAXSpA vs. 13 [0.5-6.8] pg/ml in AS, p=ns). Nevertheless, no significant difference regarding serum IL-17 and IL-23 levels was found between patients with less active SpA (ASDAS-2CRP ≤2.1, n=44) and more active SpA (ASDAS-2CRP >2.1, n=13). No associations of serum level of IL-17 and IL-23 levels with other clinical parameters including disease dura-tion, synodesmophyte, tumor necrosis factor inhibitors use were found.

Conclusion: Peripheral blood IL-23/IL-17 concentrations did not show the associ-ation with inflammatory burden of the disease. However, the level of serum IL-23 was higher in patients with nrAXSpA than in those with advanced AS. IL-17 might dissociate from IL-17 in advanced AS and play an important role only at early stage of axSpA.

THE CAUSAL RELATIONSHIP BETWEEN MULTIPLE SCLEROSIS AND PSORIASIS: A TWO-SAMPLE MENDELIAN RANDOMIZED STUDY

Keywords: Psoriatic arthritis, Randomized control trial

Y. Xu1,2,3, Y. Chen4,5, J. Zeng1,2,3, J. Han1,2,3, Y. Xue1,2,3, L. Shi4,5, J. Zhao1,2,3, H. Tao1,2,3, X. Li1,2,3, Y. Zhang1,2,3, Z. Sheng1,2,3, J. Zhang1,2,3, X. Zhang1,2,3, S. Zhao1,2,3, C. Zhang1,2,3.

Background: Psoriasis is an immune-related, chronic inflammatory skin disease. The disease often presents with clearly delineated areas of erythematous patches on the skin covered with silvery scales[1]. As the research progresses, more and more evidence suggests that multiple sclerosis may help reduce the occurrence of psoriasis.

Objectives: To explore whether there is a causal relationship between having multiple sclerosis and obtaining psoriasis.

Methods: We used a 2-sample Mendelian Randomization (MR) method to evaluate the causal effect of multiple sclerosis on psoriasis. Multiple sclerosis (MS) and psoriasis (Ps) Ps summary data from IEU database (https://www.mrcieu.ac.uk). The multiple sclerosis cohort consisted of 9,722 samples and 17376 controls. The psoriasis cohort consisted of 4510 samples and 212242 controls. To reduce bias due to race-related confounding factors, the genetic background of the study population was limited to European ancestry. In the MR Approach, the IV analysis is based on three strict assumptions, namely that IV should be strongly correlated with exposure, independent of confounding factors associated with both exposure and outcome, and influence outcome solely through exposure[2]. We screened for significant (p<5×10-06) and approximately independent (r 2 <0.01) genome-wide single nucleotide polymorphisms (SNPS) and retained only SNPS with scores over 10 that were considered sufficiently strongly associated. To estimate the causal relationship between exposure and outcome, inverse variance weighting (IVW), MR-Egger regression, and weighted median methods were used. Mendelian random multivariate residuals and outliers, Cochran Q test and MR-Egger regression were used for sensitivity analysis.

Results: MR Statistics showed that genetic prediction of multiple sclerosis was associated with a reduced risk of psoriasis (IVW: OR=0.698,95%CI= 0.5788-0.843 P=2.098-e-2), which we found to be statistically significant as the weighted
median method (OR=0.827, 95%CI= 0.760- 0.898p =4.476e-06), MR-Egger also showed a similar effect (OR=0.668; 95%CI= 0.482-0.926 P = 2.184e-02). Cochran’s Q test (Q=522.685; p=9.057e-51) found potential heterogeneity. MR-egger regression (P=1.164, intercept=0.043) was used to test the nonexistent horizontal multi-directivity. Similarly, we examined the level of pleiotropy again with MR-PRESSO’s global test, and the results showed no evidence of horizontal pleiotropy. In addition, no SNP was found to be a significant factor affecting the association in the residual analysis.

Conclusion: Our results provide causal evidence for the effect of multiple sclerosis on psoriasis risk. This Mendelian randomization study showed a causal relationship between multiple sclerosis and the risk of psoriasis. Multiple sclerosis may help reduce the burden of psoriasis.

AB0099 CLONORCHIS SINENSIS-EXCRETORY/SECRETORY PROTEIN AMELIORATES INFLAMMATION IN ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Animal models

Y. J. Lee1,2, M. J. Kim3, H. I. Lee1, S. C. Shim4, E. J. Won5, T. J. Kim1.
1Chonnam National University Medical School and Hospital, Department of Parasitology and Tropical Medicine, Gwangju, Korea, Rep. of (South Korea); 2Graduate School of Chonnam National University, Department of Biomedical Sciences, Gwangju, Korea, Rep. of (South Korea); 3Chonnam National University Medical School and Hospital, Department of Parasiotology and Tropical Medicine, Gwangju, Korea, Rep. of (South Korea); 4Daejeon Rheumatoid & Degenerative Arthritis Center, Chungnam National University Hospital, Department of Rheumatology, Daejeon, Korea, Rep. of (South Korea)

Background: Ankylosing spondylitis (AS) is a sort of inflammatory arthritis that affects axial skeleton, peripheral joints, and certain extra-articular organs, including the eyes, skin, and gut. Recently, many attempts have been made to use parasite administration (e.g., ingestion of eggs of the nematode Trichuris suis) as a new modality for treating inflammatory disorders. Our group published that Clonorchis sinensis protein attenuated inflammation in AS.

Objectives: Thus, this study aimed to assess the therapeutic potential of Clonorchis sinensis-Excretory/Secretory protein (Cs-ESP) as an anti-inflammatory drug. Our study was conducted in a murine model of human rheumatoid arthritis. PloS One (2011) 6(8):e23453.

Methods: Treatment with Cs-ESP resulted in no reduced cell viability of PBMCs or SFMCs. In experiments culturing PBMCs and SFMCs, the frequencies of IFN-g and IL-17A producing cells were significantly reduced after Cs-ESP treatment. In the SKG mouse model, Cs-ESP treatment significantly suppressed arthritis and enthesis.

Conclusion: We provide the evidence demonstrating that Cs-ESP can ameliorate clinical signs and cytokine derangements in AS.

AB0100 TO STUDY THE T CELL AND CYTOKINE PROFILE IN ANKYLOSING SPONDYLITIS WITH EFFECTS OF TACROLIMUS AND TADALAFIL ON THE CYTOKINES IN-VITRO

Keywords: Adaptive immunity, Spondyloarthritis

P. Mehta1, K. Singh2, M. K. Rai3, D. P. Misra1, V. Agarwali2,1King George’s Medical University, Clinical Immunology and Rheumatology, Lucknow, India; 2Sanjay Gandhi Post Graduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India

Background: Most studies have shown mixed results of Interleukin (IL)17 and IL-23 levels in patients with Ankylosing Spondylitis (AS) compared to controls; with animal studies showing a good correlation between activation of IL 23-IL
Serum TGF-β

Serum IL-23 -0.01(-0.1-0.08) 0.8

Serum IL-17 -0.01(-0.05-0.03) 0.5

Model 3

CD4+PD1+/CD25+ -0.2(0.4- -0.02) 0.03*

CD4+Th17/CD25+ 3.5(0.7 -6.3) 0.02*

CD4+PD1+ -0.3(-0.7 -0.1) 0.07

CD4+Th17 1 .4(0.6-2.2) 0.003**

Conclusion: observed with IL-17 or IL-23. (Figure 1)

There was a significant decline in TGF-β between cytokines or T cell profiling with Modified Stokes Ankylosing Spondylitis disease, clinical parameters, disease activity indices, cytokine and T-cell profile were significantly elevated in AS compared to HC. When stratified by duration of disease, clinical parameters, disease activity indices, cytokine and T-cell profile were significantly elevated in the peripheral blood in AS.

Results: Twenty-five patients [28(24-36),M:F , 7 .3:1] were enrolled with 90% HLA-B27 positivity. The majority had moderate-high disease activity as per ASDAS CRP and were on NSAIDs(24), complementary medications (7) and two each on methotrexate and sulfasalazine. Serum IL-17 and TGF-β were drawn and sera stored; PBMCs were isolated and cultured. Serum and PBMC culture supernatant (CS) were measured for IL-17, IL-23 and TGF-β. These cytokines were measured at baseline, after stimulation with anti-CD3CD28 antibodies, and after treatment with tacrolimus(10M/Ml), tadalafil(10M/Ml) and both the drugs combined by ELISA(R&D systems, USA). The T cell profile was characterized by flow cytometry (CD4 Th17, CD4 PD1, CD4 Th17 PD1 and CD4 CD25). Statistical analysis was done using GraphPad prism v9.

There was no difference in the cytokine and T-cell profile across early and late disease and not on biologic therapy were recruited and their demographic, clinical profile, disease activity and radiologic indices were recorded. Age and sex matched healthy controls (HC, n=21) were also recruited. Peripheral blood was drawn and sera stored; PBMCs were isolated and cultured. Serum and PBMC culture supernatant (CS) were measured for IL-17, IL-23 and TGF-β. These cytokines were measured at baseline, after stimulation with anti-CD3CD28 antibodies, and after treatment with tacrolimus(10M/Ml), tadalafil(10M/Ml) and both the drugs combined by ELISA(R&D systems, USA). The T cell profile was characterized by flow cytometry (CD4 Th17, CD4 PD1, CD4 Th17 PD1 and CD4 CD25). Statistical analysis was done using GraphPad prism v9.

Conclusion: Serum IL-17 and TGF-β were elevated in the peripheral blood in AS. There was no difference in the cytokine and T-cell profile across early and late disease. A significant decline in TGF-β levels was seen with combined tacrolimus and tadalafil. This needs further exploration in a larger sample size with subgroup characterization as well as testing on synovial fluid and joint tissue samples.

AB0102 POTENTIAL BIOMARKERS TO PREDICT TNF INHIBITORS OUTCOME IN PSORIATIC ARTHRITIS

Keywords: bDMARD, Psoriatic arthritis, Biomarkers

A. Makos1, J. H. Kuiper2, R. Amarsena3, O. Kehoe1. 1Keele University School of Medicine at the RJAH Orthopaedic Hospital, Centre for Regenerative Medicine, Keele, United Kingdom; 2Keele University School of Pharmacy and Bioengineering at the RJAH Orthopaedic Hospital, Centre for Regenerative Medicine, Keele, United Kingdom; 3The Robert Jones and Agnes Hunt Orthopaedic Hospital NHS Foundation Trust, Rheumatology, Gobowen, United Kingdom

Background: Psoriatic Arthritis (PsA) is a chronic immune-mediated inflammatory disease characterized by axial and peripheral arthritis, dactylitis, nail changes and most of the time, is associated with psoriasis. Patients are initially treated with conventional Synthetic Disease-Modifying Anti-Rheumatic Drugs (csDMARDs), but if they do not respond to these, they are treated with biologics, particularly TNF inhibitors (TNFi) which are common first-line biologics. However, about 40% of patients do not or only partially respond to TNFi. Blood biomarkers predicting response to TNFi would allow patients to be treated earlier with a more appropriate drug [1].

Objectives: We studied pro- and anti-inflammatory cytokines and adaptive immune cells that could be used as biomarkers for TNFi outcome. Predicting responses to TNFi will help clinicians to choose a more appropriate treatment for patients.

Methods: Blood from patients with PsA (n = 8) was analysed before starting TNFi and compared with blood from patients with rheumatoid arthritis (RA) (n = 8). PsA patients were characterised as ‘psoriasis positive’ and ‘psoriasis negative’. Patients were followed at 3 and 6 months after treatment (n = 6). Leukocytes were isolated with lymphoprep and their phenotype was characterised by flow cytometry.

**CD45, CD3, CD4, CXCxR3, CCR6, HLA-DR, CD8, CD25 and CD127. Levels of 12 cytokines in plasma were measured using a cytokine kit (MACSplex Cytokine 12 Kit, Human, Miltenyi Biotec Ltd, UK). Clinical data from patients were collected to determine treatment outcome.**

**Results:** Mean level of TNFα was higher in our RA patients (6.2 pg/ml) compared to our PsA patients (4.6 pg/ml). Initial analysis of clinical data suggested that our PsA patients without psoriasis (n = 2) responded better to TNFi than those with active psoriasis (n = 4) at 3 months and 6 months after treatment, with a clear reduction in the number of tender joints (‘psoriasis positive’: 6.65 vs 1.67; ‘psoriasis negative’ 11.5 vs 6.67) and swollen joints (‘psoriasis positive’: 2 vs 0.67; ‘psoriasis negative’: 3.50 vs 0). The mean proportion of activated Th17 cells was higher in our patients with active psoriasis (5.1% of Th17 cells) than those without psoriasis (3.6% of Th17 cells). The mean level of IL-12 and INFγ was higher in the ‘psoriasis positive’ group (respectively 129.2 pg/ml and 266.1 pg/ml) compared to our PsA patients (4.6 pg/ml). Initial analysis of clinical data suggested that PsA patients have a lower level of TNFα because of other pro-inflammatory cytokines potentially involved in the inflammatory process. IL-12 can induce IFNγ production by Th1 cells and is involved in the IL12/IL23 axis in psoriasis pathogenesis. IFNγ can induce Th1 and Th17 cells expansion through myeloid dendritic cells activation. In PsA, the high levels of IL-12 and IFNγ involved in psoriasis pathogenesis might be one of the reasons for a poor response to treatment, but larger sample sizes are needed to find a biomarker that could be used routinely by clinicians, and to determine if the same biomarker can also be used for other types of arthritis such as rheumatoid arthritis.

**Keywords:** Spondyloarthritis, Enthesitis, Inflammatory arthritides

Z. Zhao1,2,3, F. Liu1,2,3, Z. Wang1,2,3, S. Song1,2,3, J. Qiao1,2,3, S. X. Zhang1,2,3, X. Li1,2,3, 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microbiology, Taiyuan, China; 3Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China

**Background:** Psoriatic arthritis (PsA) is a chronic, immune-mediated arthropathy mainly affecting the peripheral joints, spine, and sacroiliac joints[1] The key pathogenic mechanisms are ‘uncontrolled’ fibroblast-like synoviocytes (FLS), along with the proliferation of endothelial cells (EC) and T cells. Growing evidence found that the proliferation of these cells of psoriatic arthritis are dependent on the PI3K-akt-mTOR kinase system.[2]

**Objectives:** This study aimed to investigate the causality between key mTOR kinase cascade proteins and psoriatic arthritis.

**Methods:** We used a 2-sample Mendelian randomization (MR) method to evaluate the causal effect of five mTOR-dependent circulating proteins on psoriatic arthritis. Data about mTOR-related gene expression (eIF4A3, eIF4E2, eIF4E-BP2, eIF4G3, RP-S6KA) in plasma were obtained from the publicly available proteomics-GWAS INTEVAL study (https://www.phpc.cam.ac.uk/ceu/proteins/), which included 3,622 plasma protein assays from 3,301 participants. PsA relative single nucleotide polymorphisms (SNPs) as the instruments. For the other four common mTOR related targets, we have not found a causal relationship between them and PsA including eIF4A3 (IVW: OR = 0.912,95% CI:0.748,1.111; p = 0.359), eIF4E-BP2 (IVW: OR = 0.842,95% CI:0.789,1.031; p = 0.075), eIF4G3 (IVW: OR = 0.768,95% CI:0.709,1.135; p = 0.366) and RP-S6KA (IVW: OR = 0.893, 95% CI: 0.767,1.040; p = 0.146). To verify the robustness of our model, we performed sensitivity analysis. No potential heterogeneity was found by Cochran’s Q test (Q=6;311; p=0.852), MR-Egger regression (P=0.425, intercept=0.038) found no horizontal pleiotropy. Similarly, the result of MR-PRESSO test found no evidence of horizontal pleiotropy. In summary, this 2-sample mendelian randomization study found a causal protective association of eIF4E2 with psoriatic arthritis. This novel result provides the scope to develop new therapeutics targeting PI3K/Akt/mTOR signaling pathway in psoriatic arthritis.

**Acknowledgements:** We would like to acknowledge the Rheumatology clinical team and research nurses at the RAJH Orthopaedic Hospital, and PsA and RA patients for participating in the study. Disclosure of Interests: None Declared.

**AB0104**

THE CAUSAL EFFECT OF LIPID METABOLISM ON THE RISK OF PSORIATIC ARTHRITIS: A MENDELIAN RANDOMIZATION STUDY

**Keywords:** Genetics/Epigenetics, Psoriatic arthritis

Y. Ji1, J. Zhu2, H. So1, P. Wong1, L. S. Tam1, D. Wu2, 1The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China; 2Shiuian Provincial People’s Hospital, Department of Rheumatology and Immunology, Sichuan, China

**Background:** Psoriatic disease, including psoriatic arthritis (PsA) and psoriasis, is driven by a combination of genetic, biomechanical, metabolic, and microbial factors which promote an aberrant immune response and the consequent development of chronic disease.[1] Genetic evidence has indicated that body mass index and glycemic control are associated with an increased risk of psoriasis and PsA, and also with an increased risk of cardiovascular disease.[2] However, the causal relationship between serum lipids and risk of incident PsA remains unclear.

**Objectives:** To investigate whether lipid metabolites are causally associated with incident psoriatic arthritis (PsA), in comparison with rheumatoid arthritis (RA) and ankylosing spondylitis (AS).

**Methods:** The publicly available summary-level findings from two genome-wide association studies (GWAS) were used to identify loci influencing circulating metabolites as exposure and a GWAS for PsA (n=1,637, control=212,242, RA (n=6,236, control=147,221), AS (n=1,462, control=164,682) as the outcome. Bi-directional Mendelian randomization (MR) analysis and multivariable MR analysis were used in main and validation analysis.

**Results:** In the main analysis, pooled data suggested a causal association of PsA risk with total cholesterol (P=0.005), cholesterol esters (P=0.003), free cholesterol (P=0.009), total lipids (P=0.004), phospholipids (P=0.010), and concentration of particles (P=0.005) in large low-density lipoprotein (LDL); total cholesterol (P=0.009), cholesterol esters (P=0.006), total lipids (P=0.009), phospholipids (P=0.002), and concentration of particles (P=0.009) in medium LDL; total cholesterol (P=0.001), total lipids (P=0.001), concentration of particles (P=0.001) in small LDL (Table 1). Multivariable MR analysis identified cholesterol esters in large LDL as the strongest causal risk factor for PsA (P=0.017) (Table 1). In validation analysis, genetically predicted cholesterol (P=0.004), cholesterol esters (P=0.001), and total lipids (P=0.003) in LDL; cholesterol esters in large LDL (P=0.006); phospholipids (P=0.007) and concentration of particles...
Results: When selecting SNPs associated with IL-7, in the situation of the genome-wide significant threshold of $P < 5 \times 10^{-8}$ and LD $r^2 = 0.001$, we finally obtained 9 IVs that could be used in the subsequent steps. Based on the IVW mode with high statistical power, a prudent and credible causal relationship was demonstrated between IL-7 and AS [IVW: $P = 0.025$, OR(95%CI) = 0.999(0.999 1.000)]. As the level of IL-7 increased, the risk of developing AS also decreased, proving that IL-7 was a protective factor for this disease (Figure 1a). The Cochran Q test (Q test $p = 0.99$) showed a good homogeneity among studies. The results of a leave-one-out sensitivity analysis suggested that causal associations were not strongly influenced by any of the selected IVs (Figure 1b). Funnel plot results (Figure 1c) and the intercept of the MR-Egger regression (Figure 1d) further showed that pleiotropy did not bias the causal effect in this study.

Conclusion: Our research results show that IL-7 is causally associated with the pathogenesis of AS, which enables the early detection of AS, this findings have great clinical value.

CAUSAL ASSOCIATION BETWEEN IL-7 LEVELS AND ANKYLOSING SPONDYLITIS: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

Keywords: Biomarkers, Genetics/Epigenetics, Inflammatory arthritides

C. Wang1,2, Y. X. Chen1,2, Z. J. Li2, Y. Li1, T. Huang1, D. Y. Xue3, S. X. Zhang2,4, Q. Yu1.

Background: Ankylosing spondylitis (AS) is an immune-mediated inflammatory arthritis that affects the axial skeleton. Currently, the cause of AS is still not known, so there is no way to prevent AS. Interleukin-7 (IL-7) is a restrictive and non repetitive cytokine, mainly produced by epithelial and stromal cells. The relationship between IL-7 and some inflammatory cytokines such as AS has been discussed in recent advances in the pathogenesis of AS, but a direct effect of IL-7 on AS has not been demonstrated[1].

Objectives: To clarify the causal relationship between IL-7 and AS, we used two-sample Mendelian randomization (MR) to prove that IL-7 is a protective factor for this disease.

Methods: To clarify the causal relationship between the IL-7 family members and AS, we used two-sample Mendelian randomization (MR).

SNP, single-nucleotide polymorphism; Significant results are in bold.

CAUSAL RELATIONSHIP BETWEEN IL-17 FAMILY MEMBERS AND THEIR RECEPTORS AND ANKYLOSING SPONDYLITIS: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

Keywords: Spondyloarthritis, Cytokines and chemokines, -omics

Y. X. Chen1,2, X. Y. Guo1,2, C. Wang3,2, J. Q. Bai2,2, J. Q. Qiao2,4, S. X. Zhang2,4, P. P. He2, Q. Yu1,3, Shanxi Medical University School of Basic Medical Sciences, Taiyuan, China; 2Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 3Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China; 4Shanxi Medical University, Medical Data Sciences, Taiyuan, China

Background: Ankylosing spondylitis (AS) is an axial rheumatic and spinal disease based on autoimmune and genetic susceptibility that affects the sacroiliac joints and the spine[1]. Interleukin 17 (IL-17) as an inflammatory cytokine positively correlated with disease activity in AS patients[2]. However, the causal relationship between the IL-17 family and its receptors and AS is inconclusive.

Objectives: The aim of this study was to discover the causal association between the IL-17 family members with their receptors and AS.

Methods: To clarify the causal relationship between the IL-17 family members and AS, we used two-sample Mendelian randomization (MR).
We selected single-nucleotide polymorphisms (SNPs) from genome-wide association studies (GWAS) which included IL-17 family members and their receptors (N = 3301) and AS (Ncase = 968, Ncontrol = 336,191). Confounding factors were excluded, heterozygosity and lateral polymorphisms were examined and corrected.

**Results:** We found that IL-17RB level was significantly causally associated with AS (IVW OR=1.0007, 95%CI 1.0002–1.0011, P = 0.0020, Figure 1a). Sensitivity analysis also confirmed the absence of horizontal polymorphism (MR-Egger intercept = 6.59B9x10^(-5), P = 0.5158, Figure 1b) and heterogeneity (IVW Q = 10.7388, Q_pval = 0.5514) that biased the causality. The leave-one-out sensitivity test showed that no single SNP strongly affected the causal relationship between IL-17RB and AS (Figure 1c). Furthermore, funnel plot symmetry suggests that our study fits the IV hypothesis (Figure 1d). However, our results show no significant causal relationship between AS and other IL-17 family members and their receptors.

**Conclusion:** Our results show that IL-17RB is a protective factor for AS. We offer a new insight into the drug targets of AS.

**A CAUSAL EFFECT OF IL-10 LEVELS ON THE RISK OF ANKYLOSING SPONDYLITIS: A MENDELIAN RANDOMIZATION STUDY**

**Keywords:** Spondyloarthritis, Cytokines and chemokines

Y. X. Chen1,2, J. O. Bai1,2, C. Wang3,4, L. L. Zheng1, J. Qiao1, S. X. Zhang1,4, Q. Yu1, P. F. He1,4, Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China; 2Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 3Shanxi Medical University, School of Management, Taiyuan, China; 4Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China; 5Shanxi Medical University, Medical Data Sciences, Taiyuan, China

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory immune response disease mainly presenting with fibrosis of the sacroiliac joint and calcification [1]. Interleukin-10 (IL-10) is a factor that suppresses Th17 cell activity and induced Treg cells to achieve immunosuppression. Observational studies show that IL-10 may be one of the important contributing sources of important inflammatory cytokines for AS [2], but the causal relationship between them is not clear.

**Objectives:** The objective was to investigate the casual association between AS and IL-10.

**Methods:** The GWAS summary statistics of IL-10 and AS (Ncase = 968, Ncontrol = 336,191) were downloaded from the IEU GWAS database in the study. After a series of screens, SNPs strongly associated with exposure were included as instrumental variables (IVs). The results are from using robust analyses with three two-sample different assumptions (Inverse variance weighting (IVW), Weighted median (WM) and MR-Egger). Meanwhile, we used MR-Egger intercept test, Cochran’sQ test and leave-one-out sensitivity analysis for assessment to avoid the biasing effects of potential genetic variation, horizontal pleiotropy and heterogeneity. MR-PRESSO outlier test was used to identify and eliminate horizontal pleiotropy.

**Results:** Our result showed that the level of IL-10 has a causal relationship with the risk of developing AS (IVW OR=0.9992, 95% confidence interval (CI) 0.9985-0.9999, P = 0.03, Figure 1a, 1b). Increasing the IL-10 level can reduce the risk of AS disease. MR-Egger intercept test (MR-Egger intercept = -1.5705x10^-5, P = 0.5158, Figure 1b), Cochran’s Q test (IVW Q = 4.3071, Q_pval = 0.8284), leave-one-out sensitivity analysis (Figure 1c) and the funnel plot (Figure 1d) suggest almost no bias in the study, indicating that the MR was robust.

**Conclusion:** Our results indicate a protective role for IL-10 in AS, suggesting that elevated IL-10 levels may be able to alleviate the inflammatory response in AS, providing new insights into AS treatment.

**THE ASSOCIATION BETWEEN ELEVATED SERUM IL22 AND THE CLINICAL DIAGNOSIS OF AXIAL SPA.**

**Keywords:** Biomarkers, Inflammatory arthritides, Spondyloarthritides

1Hospital General Universitario Gregorio Maraño, Rheumatology Department, Madrid, Spain; 2Complexo Hospitalario Universitario de A Coruña, Department of Rheumatology-INIBIC, A Coruña, Spain; 3Complexo Hospitalario Universitario de A Coruña, INIBIC, A Coruña, Spain; 4Complexo Hospitalario Universitario de A Coruña, INIBIC, A Coruña, Spain; 5Complexo Hospitalario Universitario de A Coruña, INIBIC, A Coruña, Spain.
Background: Interleukin-22 (IL-22) is produced by T helper type 1, type 17, type 22 cells, and type 3 ILC, being probably a marker of osteogenic differentiation and new bone formation. Diagnosis and treatment are commonly delayed due to different clinical presentations that lead the patient to progressive articular damage. In recent studies, it seems that the serum levels of IL-22 are elevated in axial spondyloarthritids (AxSpA) and do not allow differentiation between AxSpA and other joint inflammatory disorders.

Objectives: The present research aimed to analyze serum cytokines as possible biomarkers regarding inflammation and bone destruction/regeneration in four rheumatic diseases.

Methods: Serum samples were acquired from patients with psoriatic arthritis (PsA), rheumatoid arthritis (RA), osteoarthritis (OA), and AxSpA. Serum levels of TGF-β1, IL-23, IL-6, IL-17A, IL-22, Dkk1, Sclerostin, BMP2, BMP4, Wnt1, and Wnt5a were measured by enzyme-linked immunosorbent assay (ELISA). All these data were analyzed and compared with the demographic, clinical, analytical, and radiological characteristics of the patients. Statistical analysis was performed using the SPSS version 23 program (IBM SPSS Statistics). Values of \( p < 0.05 \) were considered statistically significant.

Results: The serum samples were obtained from 35 patients (PsA n=11, RA n=7, OA n=13, AxSpA n=5). All these patients were previously treated with NSAIDs and corticosteroids (oral/intraarticular); 4 were treated with csDMARDs, but no patient received anti-TNF agents or biologic therapy. Prevalence of AxSpA was 20% (7/35). All patients were diagnosed by rheumatology and gastroenterology to prevent disability and loss of function.

Conclusion: Serum levels of IL-22 are elevated in patients with clinical diagnoses of AxSpA and could be an independent serum biomarker of this disease.

Conclusion: We report a high prevalence of IBD associated SpA in patients presenting for evaluation of arthralgia to a multidisciplinary clinic. Diagnosis and management of SpA in the context of IBD can be challenging and warrants a multidisciplinary approach to timely diagnosis and management. Combined efforts to make treatment changes to induce and maintain disease remission can lead to improvement in morbidity in these patients. This study highlights the characteristics of patients with IBD associated SpA and demonstrates the value of integrated management in clinical practice.
Feasibility of an IL-17A assay in patients with axial spondyloarthritis

Background: The cheomine C-X-C Motif Chemokine Ligand 10 (CXCL10) has been found to be elevated in those patients with psoriasis (PsO) who will develop psoriatic arthritids (PsA), thus being proposed as a predictor of joint involvement [1]. CXCL10 progressively declines in those PsO patients until the diagnosis of PsA is fulfilled. In parallel, with the duration of the disease [2]. In contrast, CXCL10 remains invariable over time in the rest of PsO patients. Subclinical ultrasound synovitis may be considered a pre-disease state of PsA [3]. CXCL10 serum levels in patients with preclinical PsA are still unknown.

Objectives: To better characterize the preclinical phase of PsA and to assess the relationship of CXCL10 serum levels with subclinical joint involvement in PsO patients.

Methods: 62 patients with PsO without PsA were included, all of them naive to biological therapy. Ultrasonography (US) was performed on the wrist and metacarpophalangeal 1–5 joints (MCP), proximal interphalangeal 1–5 joints (PIP), and distal interphalangeal 2–5 joints (DIP) bilaterally, and grey scale (GS) synovitis were scored semiquantitatively (0–3) using the OMERACT scoring system. Serum CXCL10 levels were also determined by ELISA in all the patients.

Results: 31 men and 31 women were recruited. GS synovitis ≥1 was present in 30 patients, 10 men and 20 women, while only 7 patients exhibited GS synovitis ≥2, 4 men and 3 women. The mean log10CXCL10 was inferior in patients showing any grade of GS, both in the whole group and after stratifying by sex (Table 1), although the difference was only statistically significant for grade 1 of GS in men (p=0.02) and grade 2 of GS in women (p=0.02).

Conclusion: PsO patients with subclinical synovitis show lower serum levels of CXCL10 than patients without it, as occurs in patients with established PsA. This finding confirms a close relationship between this biomarker and joint involvement in PsO and supports its potential use as a predictor marker in the preclinical phase of PsA.

SLE, Sjöns's and APS - aetiology, pathogenesis and animal models

**AB0112 IT IS SAFE AND EFFECTIVE TO USE HUMAN CXCL5 TO TREAT MURINE LUPUS**

**Keywords:** Systemic lupus erythematosus, Cytokines and chemokines, Animal models

D. Guo,1 F. Lim,1 C. T. Ng,2,3 A. Low,2,3 X. Fan1,2,1 Singapore General Hospital, Clinical Translational Research, Singapore, Singapore; 2Singapore General Hospital, Rheumatology and Immunology, Singapore, Singapore; 3Duke-NUS Medical School, SingHealth Duke-NUS Medicine, Singapore, Singapore

**Background:** As a novel myeloid/neutrophil-targeting therapy for systemic lupus erythematosus (SLE), the therapeutic efficacy of administering mouse (m) CXCL5 to lupus-prone mice have been demonstrated by our group recently.[1,2]

**Objectives:** The aim of this study is to examine the pre-clinical safety and establish the pharmacokinetic (PK) response of human (h)CXCL5 to ease the commercialization and bring our discovery from bench to bedside.

**Methods:** Immediate and accumulative liver and kidney toxicity were determined by alanine transaminase and aspartate transaminase activity and urinary albumin-to-creatinine ratio. T lymphocytes (TACR), mCXCL5 expression in major internal organs (e.g., kidneys, lungs, liver, heart, brain and spleen) was determined by immunofluorescent staining on snap-frozen sections. Whether administering hCXCL5 promoted cancer cell growth was examined in both in vitro and in vivo renal cell carcinoma models. Haematological toxicity and circulating immunity, cell counts for white blood cells, red blood cells, monocytes, neutrophils, T cells and B cells, were evaluated in both Institute of Cancer Research (ICR) healthy and MRL/lpr (Fas+) lupus-prone mice. PK study of hCXCL5 was performed in both ICR healthy and Fas–/– lupus-prone mice intravenously.

**Results:** Our study showed that it was safe to administer CXCL5. There was no liver or kidney toxicity or cancer inducing effects. There was no further inflammation caused by hCXCL5 administration. Major components of the immune system were also not compromised. PK study showed that blood endogenous mCXCL5 levels were not altered by exogenous hCXCL5 administration in ICR healthy mice, but increased in Fas–/– lupus-prone mice. Blood exogenous hCXCL5 was only detectable within 24 hours post-administration and the peak levels were positively correlated with the administration dosage. Mice survival was improved and reversely correlated with administration dosage.

**Conclusion:** It is safe and effective to use hCXCL5 to treat murine lupus.

**AB0114 INCREASED EXPRESSION OF SEMAPHORIN 4A IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS ASSOCIATION WITH THE ACTIVITY OF LUPUS NEPHRITIS**

**Keywords:** Systemic lupus erythematosus, Biomarkers, Animal models

Y. Choi,1 E. K. Lee,2 K. M. Kim,3 M. S. Lee,4 C. H. Lee,4 C. H. Chung,5,6,7,8 H. Yoo1,2 Jeonbuk National University Medical School, Internal Medicine, Jeonju, Korea, Rep. of (South Korea); 2Jeonbuk National University, Medical Science, Jeonju, Korea, Rep. of (South Korea); 3Jeonbuk National University Medical School, Pathology, Jeonju, Korea, Rep. of (South Korea); 4Wonsuk University Hospital, Internal Medicine, Iksan, Korea, Rep. of (South Korea)

**Background:** Semaphorin (SEMA), initially identified as a neural guidance molecule, has been recently highlighted for its role in regulating the immune response.

**Methods:** We immunized intraperitoneally C57Bl/6 mice (n = 5/group) with recombinant SARS-CoV-2 spike protein (1µg per injection) or vehicle (phosphate buffered saline [PBS]). Figure 1A. The first injection was mixed with Alum as an adjuvant, and the other injections were diluted in PBS, administered intraperitoneally every 5 days, 16 times in total. Five days after the final injection, the mice were sacrificed to retrieve serum. We measured anti-spike and anti-dsDNA IgG using ELISA. The serum from 5-34-week-old C57Bl/6 Jpr autoimmune mice were used as positive control. Briefly, 96-well plate were coated overnight with either spike protein (0.2µg/mL) or call thymus DNA (0.1µg/mL); after precoating with poly-L-lysine 0.05mg/mL. After blocking with PBS-BSA, the diluted serum samples were incubated on the plate for 2 hours at room temperature. Plate-bound IgG were revealed using an alkaline phosphatase-conjugated anti-mouse IgG (1:5000). For anti-dsDNA IgG measurement, the serum of an autoimmune mice was used as a reference standard and the result expressed in unit per mL.

**Results:** After immunization, the phenotype of control and spike-immunized mice was clinically similar. All the immunized mice were exempt of proteinuria (Figure 1B). Only the mice which were injected with spike protein developed measurable amounts of anti-spike IgG as determined by ELISA, while those injected with PBS and the C57Bl/6 Jpr mice did not (Figure 1C). None of the mice in the immunization group developed measurable anti-dsDNA IgG (Figure 1D).

**Conclusion:** In our study, the repetitive exposure of C57Bl/6 mice to the SARS-CoV-2 spike antigen did not lead to autoimmunity. Although these results are reassuring, large scale epidemiological studies are needed to evaluate the incidence of autoimmune diseases in individuals with multiple exposure to SARS-CoV-2 antigens.

**REFERENCES:**
Among seven categories of SEMA, Class 4A SEMA (SEMA4A) involves the T cell-mediated immune responses through the expression of itself in dendritic cells. **Objectives:** This study aimed to investigate the expression of SEMA4A in systemic lupus erythematosus (SLE) and the association between the expression of SEMA4A and the activity of lupus in the lupus mouse model and patients with SLE.  

**Methods:** The expression of SEMA4A was measured from peripheral blood mononuclear cells (PBMCs) in healthy controls and patients with SLE by polymerase chain reaction. Bone marrow-derived dendritic cells (BMDCs) and renal tissues from control mice and Toll-like receptor (TLR)-7 agonist (R848)-induced lupus mice were investigated for the expression of SEMA4A using Western blotting and immunofluorescence assay. Immunohistochemistry was performed to examine the expression of SEMA4A in the kidneys of the patients with SLE and they were analyzed according to the activity index of lupus nephritis.

**Results:** The expression of SEMA4A of PBMCs was elevated in the patients with SLE (n=20, 3.86±0.80) compared to those of healthy control (n=20, 1.0±0.37). SEMA4A is constitutively expressed by dendritic cells, so we analyzed the expression of SEMA4A in BMDCs of TLR-7 agonist (R848)-induced lupus murine group and control group. The SEMA4A was highly expressed in the BMDCs of the lupus group (2.06±1.67) compared to the control group (1.0±0.29). The immunocytochemistry also showed enhanced fluorescence intensity of SEMA4A in BMDCs of the lupus mouse group (19.57±6.37) compared to the control group (10.43±6.87). The kidneys, one of the main target organs of SLE, were analyzed for the protein level of SEMA4A in the murine lupus group and control group. The western blotting of the whole kidney and isolated glomeruli showed a marked expression of SEMA4A in the lupus group compared to the control group. The mean fluorescence intensity of SEMA4A in the kidneys of lupus mice was significantly enhanced compared to the control group (6.51±0.47 vs. 3.75±0.13). In the analysis of immunohistochemistry of SEMA4A in the kidneys of the patients with SLE, the positivity of SEMA4A staining was markedly higher in lupus nephritis with higher activity score (≥10) (80%) compared to those of lupus nephritis with lower activity score (<10) (0%).

**Conclusion:** The expression of SEMA4A is significantly increased in the dendritic cells and kidneys of the lupus murine group and the patients with SLE compared to the control group. The expression of SEMA4A in the kidneys in the patients with SLE correlates with the severity of lupus nephritis. These results indicate the possible contribution of SEMA4A in the pathogenesis of SLE and the potential of targeting SEMA4A for the treatment of SLE.

**Background:** Metformin is a biguanide oral hypoglycemic agent that is widely used as a first-line drug treatment for type II diabetes. In addition, metformin is also used in the treatment of certain autoimmune diseases, such as systemic lupus erythematosus (SLE). It plays a key role in the pathogenesis of SLE through pathways such as inhibiting type 1 IFN, regulating T effector cells and proinflammatory cytokines. However, the causal relationship of the metformin-in-related targets on the risk of SLE is still unclear.

**Objectives:** The purpose of this study was to assess the causal effect of metformin targets (AMPK, MCI, GDF 15 and GLP 1/ GCG) on the risk of SLE using Mendelian randomization (MR).

**Methods:** Genetic variants including downstream and 100kb upstream of encoding five genes were selected as candidate tool variants. The SNP was further screened as in low linkage disequilibrium \((r^2 < 0.3)\) and associated with HbA 1c \((P ≤ 0.05)\). The Genome-wide association study (GWAS) of HbA 1c comes from the Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGICC) \((n = 88,355)\). The SLE data \((n = 5,201, ncontrol = 9,066)\) are pooled from publicly available GWAS. Two-sample MR was performed using inverse variance weighted (IVW), MR-Egger, and weighted median (WM) to obtain causal estimates of metformin-related targets and risk of SLE. In addition, sensitivity analysis, outlier (MR-PRESSO) and leave-one-out analysis were conducted to test the heterogeneity and level pleiotropy of the results.

**Results:** Genetically predicted increase in HbA1c instrumented by GDF 15 variants was associated with increased risk of SLE \((GDF 15 p = 0.028)\). However, genetically predicted AMPK, MGC3, and MCI, and GLP 1/ GCG were not associated with SLE risk \((p = 0.122, 0.105, 0.762, 0.361)\) (Figure 1). No outlier between GDF 15 and the risk of SLE was identified via the MR-PRESSO test. The leave-one-out analysis verified the robustness of the outcomes.

**Conclusion:** This study suggests that the GDF 15 gene may be a plausible mechanism of action to reduce the risk of SLE and provides critical evidence to guide future clinical trials of metformin.

3. E. Kaan1,2,3, T. Brunekreef1, J. Drylewicz3, L. Van den Hoogen1,2, H. Lewis4,2, J. M. Van Laar5, M. Van der Vlist1,2, H. Olten1, M. Linper5,2, University Medical Center Utrecht, Center for Translational Immunology, Utrecht, Netherlands; 2University Medical Center Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands; 3Oncode Institute, Oncode Institute, Utrecht, Netherlands

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by a variety of disease symptoms and an unpredictable clinical course. SLE can lead to premature death as a result of disease activity or because of treatment side effects. This underlines the urgency to identify patients at risk for a complicated disease course, and the need to tailor therapy. Stratification based on immunological manifestations such as autoantibodies, upregulation of type I interferon (IFN) regulated genes (IFN signature) and neutrophil extracellular trap (NET) formation via NETosis can help to improve treatment outcome in SLE.

**Objectives:** Here we study the association between SLE-related autoantibodies, the IFN signature and NET formation in patients with SLE, which could lead to improved tools for patient stratification and more targeted treatment options.

**Methods:** We studied the association between the IFN signature and plasma induced NET formation with 57 autoantibodies in 25 patients with SLE. The presence of an IFN signature was determined using the sum of standardized mRNA expression of IF44, IFITM1, SERPING1, and LYY6 in monocytes from SLE patients. Plasma induced NET formation was studied with quantitative live imaging. The threshold for the presence of an IFN signature or NET formation were both set at 2 SD above the mean of a group of healthy controls. With principal component analysis (PCA) and hierarchical clustering we associated autoantibody concentrations with the IFN signature and NET formation. This study was a separate analysis from larger cohorts, of which results have been previously published.[1,2]

**Results:** We observed two distinct clusters with the PCA: one cluster contained mostly patients with an IFN signature, and another cluster contained a mix of patients with IFN and without IFN an IFN signature. Patients with (NET) and without (noNET) plasma induced NET formation were equally distributed between the clusters. PCA1 explains 22.7% of total variability, and is mainly driven by antibodies against histones, RibP2, RibP0, EphB2, RibP1, PCNA, dsDNA, and nucleosome. Hierarchical cluster analysis confirmed the two clusters (Figure 1). In addition, we found a trend towards increased concentrations of autoantibodies against EphB2, RibP1, and RNP70 in patients with an IFN signature. We found a negative correlation of NET formation with anti-FcER and anti-PmScl100.

**Conclusion:** We identified a subgroup of patients with an IFN signature who express increased concentrations of antibodies against DNA and RNA-associated proteins. We did not find positive associations between autoantibodies and plasma induced NET formation. Our study further strengthens the evidence of a correlation between RNA-binding autoantibodies and the IFN signature. As the IFN signature currently is not part of the standard follow-up for patients, partially due to its associated costs, a profile of DNA and RNA-binding autoantibodies might be used for patient stratification, especially related to anti-IFN treatment.

DIAGNOSTIC PREDICTIVE VALUE OF SOLUBLE PSLG-1 AND THEIR LIGANDS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Biomarkers, Autoantibodies, Systemic lupus erythematosus

E. San-Antonio1, J. Sanchez-Abad1, A. M. Manzano1, A. Muñoz-Callejas1, E. Vicente-Rabanales2, J. Garcia Perez2, S. Castañeda2, A. Urzainqui2

Background: Rheumatic diseases are generally diagnosed in advanced stages. Systemic lupus erythematosus (SLE) are systemic inflammatory autoimmune disease characterized by presence of autoantibodies against DNA and nuclear proteins and a wide variety of clinical symptoms (Fava 2019, Wang 2019). Actually, it has not curative treatment (Mathias 2020). Therefore, the search for biomarkers for SLE diagnosis in earlier stages and its derived complications is mandatory (Thanou 2021, Wan 2018). Adhesion molecules are crucial to leukocytes infiltration to inflammation sites (Ponthieux 2004, Ivetic 2019, Tinoco 2019). Therefore, search for biomarkers of SLE diagnosis in earlier stages and its derived complications is mandated (Thanou 2021, Wan 2018). Adhesion molecules are crucial to leukocytes infiltration to inflammation sites (Ponthieux 2004, Ivetic 2019, Tinoco 2019).

Methods: Levels of P-selectin, E-selectin, and ADAM8 were measured in serum of patients with SLE (Gonzalez-Tajuelo 2017, Skeoch 2014, da Rosa Franchi 2018). They were compared to healthy controls.

Objectives: To study the possible involvement of adhesion molecules in the development of disease, we have analysed the pattern of PSLG-1 serum levels together with its main ligands P- E- and L-selectins and ADAM8 in SLE patients.

Methods: Serum samples from 52 SLE patients, 36 inactive (SLE) and 16 active (SLE) and 55 healthy donors (HD) sex and age matched group per decade were collected and proteins levels were measured by available ELISA kits: Human PSLG-1/CD162 kit (Novus Biologicals, Colorado, USA), Human Selectins/CD62 kits C6D2E, CD62L and CD62P (Diaclone, France), and Human ADAM8 (A Disintegrin And Metalloprotease 8) Kit (Elabscience, Texas, USA).

Results: SLE patients showed a statistically significant increase of PSLG-1, E-Selectin and ADAM8 and decrease of L-Selectin serum levels with respect to HD. No difference were observed between inactive and active SLE patients. Patients with anti-dsDNA and/or anti-SSA autoantibodies showed lower serum level of PSLG-1 and higher level of L-Selectin and ADAM8 compared to patients with absence of these autoantibodies. Importantly, the expression profile of these proteins revealed that L-Selectin/ADAM8 ratio in SLE patients is a good predictor marked in a multivariable binary logistic regression model (OR=1,701, CI: 1.188-2.450, p<0.005). Receiver operating characteristic (ROC) curve presented an area under curve (AUC) of 0.80 and the optimal cut off value maximizing sensitivity (98%) and specificity (48%) jointly corresponded to ratio<2,06. In this model the 97% of patients were correctly grouped.

Conclusion: SLE patients show significantly different serum levels of PSLG-1, E-Selectin, L-Selectin and ADAM8 with respect to healthy controls. This specific profile of serum protein levels could be a potentially valuable tool for the early diagnosis of SLE.

EVALUATION OF P-GP AND MRP-1 EXPRESSION ON PLASMA CELLS AND TH17 LYMPHOCYTES IN PERIPHERAL BLOOD AND BONE MARROW OF LUPUS NEPHRITIS

Keywords: Adaptive immunity, Systemic lupus erythematosus, Kidneys

K. Singh1, D. P. Misra1, S. Katyar2, V. Agarwal2, S. Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Clinical Immunology and Rheumatology, Lucknow, India; S. Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Hematology, Lucknow, India

Background: P-glycoprotein (p-gp) and multidrug resistance protein 1 (MRP-1) contribute towards resistance to glucocorticoids and/or immunosuppressive drugs in lupus nephritis (LN). Long-lived plasma cells (PCs) persistently produce antibodies and are resistant to most immunosuppressive therapies including B-cell depletion. Elevated T helper 17 lymphocytes (Th17) are associated with resistant LN phenotypes. We hypothesise the overexpression of p-gp and MRP-1 on these two cell types which might eventually contribute towards drug-resistant phenotype in LN.

OBJECTIVES:

1. To evaluate the frequency of peripheral blood PCs and Th17 cells expressing p-gp and MRP-1 in LN compared with healthy controls (HCs).
2. To evaluate the frequency of PCs expressing p-gp in bone marrow of LN.

Methods: Patients with LN fulfilling the 2019 ACR/EULAR classification criteria and HCs were recruited after written informed consent. p-gp and MRP-1 expression on peripheral PCs (CD45+ + CD138+), p-gp expression on Th17 (CD4+ IL-17+), and regulatory T lymphocytes (Treg, CD4+ CD25+ FoxP3+) were determined using flowcytometry (BD FACS Canto II). Proportions of T lymphocytes were normalized to Tregs. Frequencies of P-gp+ PCs were enumerated in bone marrow aspirate of two patients and one control. Results were expressed as median (interquartile range, IQR). Inter-group comparisons were performed with Mann-Whitney U test. p-value were corrected for multiple testing using Bonferroni-Sidak method. Statistical significance was set at p<0.05.

Results: Twenty-one LN [17 females, median (interquartile range – IQR) age 26 (23.25-35) years] and 10 controls [7 females, median (IQR) age 28 (27–31) years] were recruited. Of 21 LN, 13 had active disease (66% had low complements, 59% had elevated anti-dsDNA). Median SLEDAI-2K score of LN patients was 12 (2-21). In peripheral blood, overall PCs as well as PCs expressing P-gp or MRP-1 were increased in LN than in HC. Th17/Tregs ratio, p-gp-expressing Th17 lymphocytes and MRP-1-expressing Th17 lymphocytes were significantly increased in LN compared to HC (Table 1). p-gp expressing Th17 lymphocytes and PCs were significantly increased in active LN than in inactive LN (Table 1).

As an exploratory analysis, p-gp-expressing PCs were more prevalent in bone marrow aspirate of LN than non-lupus controls (Figure 1).

Conclusion: We observed for the first time an increased frequency of P-gp and MRP-1-expressing PCs and Th17 lymphocytes in the peripheral blood of LN, which were also associated with disease activity. Whether these cell populations contribute to refractory LN requires evaluation.

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the presence of antinuclear antibodies (ANA). Monitoring of anti-dsDNA antibody levels may reflect disease activity, by contrast a single anti-RBP antibody determination is thought to suffice for clinical purposes. Recent data suggests that ANA levels may decrease over time secondary to the natural history or to treatments.

Objectives: To investigate the trend of ANA and anti-dsDNA titers over time in children with a diagnosis of SLE.

Methods: We enrolled 15 children with SLE. ANA and anti-dsDNA testing were carried out in all patients from diagnosis every 3-4 months for 2 years. ANA were defined as negative for titers < 1:80. Laboratory parameters, clinical and demographic data was obtained in all patients from diagnosis every 3-4 months for 2 years. ANA were defined as negative for titers < 1:80. Statistical analysis was performed with SW R_v. 4.0.3.

Results: Following 2 years of follow-up, all patients had ANA titers significantly lower than at time of the onset (MWW, p=0.0002) (Figure 1A). After two years of follow-up, 11 patients (73%) remained ANA positive (group 1), while 4 patients (26%) became negative (group 0). At time of diagnosis no significant differences in ANA titers (MWW, p=0.74) nor in disease activity, measured by SLEDAI, (MWW, p=0.88) were observed (table 1; Figure 1E). No significant differences in organ involvement were observed (Table 1). Assessing the change over time in ANA titers, the 2 groups of patients showed 2 different patterns: in group 0, ANA titers quickly declined and disappeared in the first 6 months after diagnosis; in group 1, ANA titers declined more slowly, remaining positive at 2 years (Figure 1C). ANA pattern (by IFA) was also evaluated, changes from homogenous pattern to speckled was observed during follow up (Figure 1B). Both C3 and C4 increased, with no different patterns between the 2 groups (Figure 1D). Similarly, anti-dsDNA antibodies titers declined over time with no clear different patterns between the groups (Figure 1C). We also analyzed the levels of IGS at last of follow-up, observing significant differences between the groups (MWW, p=0.018) with higher levels of IGS in ANA+ patients (Figure 1F).

Conclusion: Our analysis showed 2 different patterns in the reduction of ANA titers over time in children with SLE, with 26% of them becoming ANA negative after 6 months from diagnosis and remaining persistently negative during follow up. Our data have important implications, specifically for the recruitment of patients into clinical trials, where the latest classification criteria of SLE require ANA positivity as entry criterion. A seronegative state may represent a different subcategory of patients with SLE with specific pathogenetic pathways, possibly independently from autoantibodies. Therefore, further studies are needed to confirm our data.

Systemic lupus erythematosus, Biomarkers

Background: Systemic Lupus Erythematosus (SLE) is a heterogeneous systemic autoimmune disease with protean clinical manifestations[1]. Although the long-term outcomes with SLE have greatly improved, increased organ damage is associated with poor prognosis in a number of patients. The type I interferon signature, a hallmark of SLE, is not an ideal treatment target or outcome predictor[2, 3], suggesting other critical immunological pathways might contribute to disease pathogenesis.

Objectives: To explore key immunological pathways and gene markers in SLE more precisely, we performed a systematic analysis of transcriptional data from 27 immune cells in the blood and from single cells in the skin and kidney.

Methods: We included a large RNA-seq data from a total of 64 SLE and 62 control with 27 immune cells. Integrated analyses were conducted to find key pathways and driver genes in SLE pathwayogenesis. The expression of COX5A between SLE phenotypes was compared in two independent cohorts. Single-cell RNA sequencing(scRNA-seq) data from skin and kidney were used to further determine the association of COX5A expression with organ damage.

Results: We found that lymphocytes in SLE showed an overall active immune-no-metabolic state when compared to healthy controls, and oxidative phosphorylation (OXPHOS) is the most significant metabolic pathway that differs between SLE and HC, especially for effector T cells. Besides, the OXPHOS enrichment score was significantly correlated with IFN response molecular signature across various T cell subtypes. Particularly, we identified an OXPHOS hub gene, COX5A, as a key driver in SLE T cells. COX5A expression was significantly higher in effector T cells than those in naive T cells and showed associations with SLE clinical phenotypes including disease activity index, flare, and organ damage. Furthermore, we revealed that high expression of COX5A in T cells contributes to skin and kidney involvement of SLE through scRNA-seq analysis.

Conclusion: Our results identified OXPHOS signature is a prominent feature in SLE T cells. The key gene of OXPHOS, COX5A, showed associations with IFN response molecular signature, severity, skin, and kidney involvement of SLE, which supported that COX5A as a potential candidate biomarker of severity and organ damage of SLE.

ENTEROCOCCUS GALLINARUM IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS.

Keywords: Descriptive studies, Outcome measures, Systemic lupus erythematosus

Background: Systemic Lupus Erythematosus (SLE) is associated with epithelial defects and disrupted intestinal barrier, risking bacterial translocation and promoting systemic inflammation, known as dysbiosis, which is associated with increased disease activity [1]. Enterococcus gallinarum has been previously linked to gastrointestinal autoimmunity disorders like ulcerative colitis, hepatitis and primary sclerosing cholangitis [2]. However, little is known about E. gallinarum prevalence in SLE.

Objectives: To describe the prevalence of E. gallinarum in SLE stool samples, as well as clinical and laboratory characteristics.

Methods: A cross-sectional, descriptive study was conducted at the University Hospital "Dr. José Eleuterio González", in northern Mexico. We included adult patients who met current criteria for SLE and had recent (<3 months) paraclinical routine tests, including acute phase reactants. Patients with other autoimmune other chromatin components, like histones and nucleosomes. These antibodies are known to characterize a SLE subgroup with early disease onset and increased occurrence of nephritis.

Objectives: We investigated how anti-nuclear autoantibody (ANA) specificities associate with pro-inflammatory cytokines in two ethnically different cohorts of SLE patients, from Sudan and Sweden.

Methods: We included 93 Sudanese and 480 Swedish SLE patients. Serum levels of autoantibodies against dsDNA, Sm, Sm/12RNP complex, 12RNP, SSA/Ro52, SSA/Ro60, SSB/La, ribosomal P, PCNA and histones were quantified with a bead-based multiplex immunooassay; with positive reactions determined as above the 98th percentile among respective national controls. In the Swedish cohort another bead-based multiplexed immunooassay including anti-nucleosome antibodies was also used. Relative levels of 73 plasma biomarkers were determined with Proximity Extension Assay technique except for Interferon gamma-induced protein (IP-10) in the Swedish cohort that was quantified by ELISA.

Adjusted p values were considered significant when <0.05.

Results: Among Sudanese patients, levels of 5/7 biomarkers showed significant associations to ANA-associated antibodies. Anti-histone antibodies showed the strongest positive correlations with interferon-inducible factors (monocyte chemoattractant protein [MCP-1] and IP-10, monocyte chemoattractant protein-3 [MCP-3] and S100 calcium-binding protein A12 [S100A12]), and negative correlation with stem cell factor (SCF); F(P values) were 0.15(0.04), 0.18(0.008), 25(0.001), 0.13(0.04) and 0.31(<0.0001) respectively. Biomarker associations remained significant for anti-histone antibody after adjustment for age and sex. Also, anti-dsDNA antibodies associated with MCP-3 (0.13(0.04)), IP-10 (0.13(0.03)) and S100A12 (0.13(0.04)), but when combining with anti-histone in the same regression model, anti-dsDNA associations were lost while anti-histone antibodies remained. Positive associations with lower F(P values) were found also for anti-ribosomal P antibodies with MCP-1, MCP-2 and C-C motif ligand 19 (CCL-19), and for anti-Sm with IP-10. Validation analysis among Swedish patients for MCP-1, IP-10, S100A12 also demonstrated significantly stronger associations to anti-histone and anti-nucleosome antibodies compared to anti-dsDNA and other ANA specificities, and in combined regression models, anti-dsDNA either became non-significant or considerably less significant than anti-histone/nucleosome antibodies. When excluding anti-histone or anti-nucleosome positive patients, the associations between interferon-inducible factors MCP-1/1P-10 and anti-dsDNA were lost. In contrary, when excluding anti-dsDNA positive patients, associations with anti-histone and anti-nucleosome remained significant. SA100A12 associations with anti-dsDNA antibodies remained significant after exclusion of anti-histone positive patients, but were lost when excluding anti-nucleosome positive patients.

Conclusion: Using uni- and multi-variate analyses as well as patient stratification, levels of mainly IFN-induced inflammatory biomarkers correlate stronger with anti-histone and anti-nucleosome antibodies compared to other ANA specificities including anti-dsDNA. Our results, from two lupus cohorts with different ethnicities, suggest that autoantibodies against DNA-complexes or DNA-associated proteins rather than anti-dsDNA antibodies per se may drive the induction of the interferon signature in SLE.

diseases, chronic infections, pregnancy, cancer, abdominal surgery or gastrointestinal bleeding were excluded. Demographic, clinical data, as well as Anti-nuclear antibodies and complement were obtained from records. No participant received antibiotics, probiotics or sanitibiotics 3 months prior to the study. DNA was extracted with the DNeasy PowerLyzer PowerSoil DNeasy kit, Qiagen, Hilden, Germany) according to the manufacturer’s specifications. *E. gallinarum* was detected by endpoint polymerase chain reaction assay.

**Results:** Sixty patients were included, where most subjects were women (51, 85%). Mean age was 41.79 ± 16.8 and time of diagnosis 107.03 months ± (95.46). *E. gallinarum* and Enterooccus spp were found in 7 (11.6%) cases. The most frequent MEX-SLEDAI parameter was arthritis in 34 (56.6%) cases, followed by acute cutaneous lupus in 23 (38.3%). Clinical manifestations and paraclinical findings are shown in Table 1. We found a significant difference in *E. gallinarum* positive patients in creatinine levels (0.98 ± 0.72, p < 0.0032), ESR (11.14 ± 19.49, p < 0.0311) and frequency of seroconvert (57.14% vs 75.4%, p < 0.001). When analyzing ESR by age-adjusted upper limit, significance was lost (p > 0.4).

**Conclusion:** Prevalence of *E. gallinarum* in SLE stool samples was 11.7%. Seroconvert, higher mean creatinine and lower mean ESR was more common in *E. gallinarum* positive subjects. Further research is needed to better understand *E. gallinarum* dysbiosis in SLE.

**Background:** Activated T cells make a significant contribution to inflammation in systemic lupus erythematosus (SLE). Their ability to secrete proinflammatory cytokines and express activating NK receptors allows them to mediate inflammation. We know that cellular metabolism regulates the activation of T cells. A phase II study has reported on efficacy of DMF in cutaneous lupus [1]. Evidence from patients with multiple sclerosis indicates that dimethyl fumarate (DMF), an electrophile, targets cellular metabolism to modulate T cell activation and function [2]. However, the potential of DMF to modulate T cell metabolism and activation in SLE is not known.

**Objectives:** We investigated whether DMF modulates T cell metabolism, activation and function and secretions in samples from patients with SLE in a series of in vitro experiments.

**Methods:** All experiments were performed using isolated T cells from freshly drawn whole blood samples from patients with SLE. T cells were isolated using negative selection using Stem cell or Miltenybe magnetic bead separation kit. Isolated T cells were activated with anti-CD3 and IL-2 and incubated with either DMF at 25μM concentration or DMSO alone for three or seven days at 37°C and 5% CO2 before harvesting and analyzing on BD FACs flow cytometer. Analysis of cytokines in supernatants was performed using cytokometric bead arrays. Flowjo software was used to analyse flow cytometry files. Graph Pad Prism software was used to perform statistical analysis.

**Results:** In Seahorse experiments, after three days of incubation dimethyl fumarate (DMF) inhibited the oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) in isolated T cells when compared with samples incubated with vehicle, dimethyl sulfoxide (DMSO). Our results revealed that DMF significantly inhibited: 1) aerobic glycolysis and oxidative phosphorylation in activated CD4+ T cells from patients with SLE (n=4), in vitro; 2) T cell activation and proliferation as assessed by a reduction in the frequency of CD69 (n=4) and Ki67 (n=2) positivity, respectively. Collectively, these results suggest that DMF inhibits T cell activation and proliferation in samples with patients with SLE. After 7 days of incubation, DMF significantly inhibited the expression of activating NK receptors CD158a and NKG2D on CD4+ T cells whereas DMF seemed to have a trend toward enhancing the expression of inhibitory NK receptors NKG2A and CD158b (n=6). After 7 days of incubation, DMF significantly reduced CD4+ T cell intracellular expression of IFN-γ, TNF-α, IL-17 and secretion of pro-inflammatory cytokines IFN-γ and TNF-α in supernatants (n=8).

**Conclusion:** Our data indicated that DMF modifies metabolic programming, both glycolysis and oxidative phosphorylation, to inhibit activation, proliferation, and secretion of proinflammatory cytokines from CD4+ T cells from patients with SLE. These results provide strong mechanistic rationale for considering dimethyl fumarate as a novel therapeutic agent to treat systemic lupus erythematosus.

**SPECIFIC AUTOANTIBODY CONTENT OF CIRCULATING IMMUNE COMPLEXES IN SLE – PHENOTYPIC CHARACTERIZATION AND CLINICAL ASSOCIATIONS**

**Keywords:** Biomarkers, Autoantibodies, Systemic lupus erythematosus

**E. Fuzzi**, 1, A. Svanyvisi, 2, C. Westerberg, 1, A. Zickert, 1, I. Gunnarsson, 1, J. Rönnef, 1, E. Svenningson, 1, K. Karolinska Institut, Division of Rheumatology, Department of Medicine, Solna, Sweden; 2 Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden

**Background:** Systemic Lupus Erythematosus (SLE) is characterised by autoan-tibody production and immune complex (IC) formation. The relative abundance of different autoantibodies within circulating ICs as compared to serum in SLE is hitherto unclear; moreover, the clinical relevance of the IC-carried fraction of SLE-specific and associated autoantibodies is mostly unknown.

EXPRESSION OF β2 MICROGLOBULIN IN SALIVARY GLAND EPITHELIAL CELLS OF PATIENTS WITH SJÖGREN SYNDROME

Keywords: Sjögren syndrome, Biomarkers

E. Simoncelli1, S. Colafrancesco1, C. Barbati1, G. Buoncuore1, R. Izzo1, C. Alessandri1, F. Conti1, R. Priori1,4, Sapienza University of Rome, Rheumatology Unit, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy;2,Unicamillus, Saint Camillus International University of Health and Medical Science, Rome, Italy

Background: Salivary glands epithelial cells (SGECs) activation and loss of homeostasis play a key role in primary Sjögren Syndrome (pSS) [1]. High serum and saliva levels of β2-microglobulin (β2-M) have been described [2] in pSS, however, the exact origin of this molecule is still unclear. Our preliminary data from single cell analysis on pSS salivary glands treated with immunosuppressors show a downregulation of this protein in SGECs following treatment.

Objective: Aim of this study is to evaluate the expression of β2-M in pSS SGECs and to dissect its modulation in inflammatory conditions.

Methods: To mimic the inflammatory microenvironment of pSS, a human salivary gland (HSG) cell line was treated (48h) with 1) Poly-I:C (40 µg/ml), 2) LPS (50 µg/ml), 3) culture medium (untreated). The HSG expression of β2-M (Ab anti-β2-M) was evaluated by flow cytometry along with the expression of apoptotic [annexin V (MBL)] and activation [ICAM-1 (Ab anti-CD54)] molecules. Ex vivo expression of β2-M was then assessed in SGECs deriving from both pSS patients (n=3) and sicca (controls) (n=3).

Results: In the HSG cell line treated with both Poly I:C and LPS a significant increase in β2-M was documented [mean fluorescence index (MFI): untreated=1 (1-1), Poly-I:C=2.46 (1.5-3.9), LPS=1.13 (1-13); p=0.003]. The increased expression of β2-M was paralleled by an increase in ICAM-1 (MFI: untreated=1 (1-1), Poly-I:C=1.61 (1-2.5), LPS=1.26 (1-12); p=0.06) and annexin V (mean%; untreated=76% (9-18), Poly-I:C=14.3% (9-18), LPS=8% (6-11); p=0.003).

In SGECs from pSS a higher expression of β2-M was detected as compared to controls (MFI: pSS=2.5 (2-3) vs sicca=1 (0.5-1.5) (Figure 1). Conclusion: Our preliminary data suggest that β2-M is actively expressed by SGECs in pSS and that its exposure is driven by the local inflammatory milieu. Such expression is particularly interesting in view of the already demonstrated capacity of β2-M to activate pro-inflammatory pathways and to influence cellular viability and autoantigens exposure [3]. Functional studies are currently ongoing to dissect the potential pathogenic role of β2-M in pSS.

ANTIGENIC ASSESSMENT FOR THE β2GPIox-PF4 COMPLEX IN A MONOCENDENT COHORT OF PATIENTS WITH APS, THROMBOSIS DURING SARS-COV-2 INFECTION AND VITT

Keywords: Autoantibodies, Vaccination/Immunization, Anti-phospholipid syndrome

F. M. Ucci1, F. Villani2, A. Capozzi2, M. De Michele1, S. Truglia1, S. Mancuso1, L. Rapiño1, G. Tripodi1, V. Manganello1, G. Rilanto2, R. Misasi3, M. Sorice3, F. Contí1, C. Alessandri1. 1Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rheumatology Unit, Rome, Italy; 2Sapienza University of Rome, Molecular Medicine, Rome, Italy; 3Sapienza University of Rome, Experimental Medicine, Rome, Italy; 4Sapienza University of Rome, Emergency Department Stroke Unit, Department of Human Neurosciences, Roma, Italy

Background: Platelet factor 4 (PF4) is a protein with a pro-clotting function expressed by activated platelets with a high affinity for anionic glycosaminoglycans present on the platelet surface. It has been shown that the positively charged surface of PF4 tetramer interacts with the negatively charged regions of β2glycoprotein I (β2GPI) domains, stabilising the link between the antigen and the phospholipid surface, thus increasing the possibility of binding with the respective antibodies. In particular, a tetramer of PF4 selectively binds two molecules of β2GPI, favouring the dimerisation of the same, which is crucial in platelet activation and therefore in thrombotic manifestations of antiphospholipid syndrome (aPS), PF4 may be a common denominator in syndromes such as aPS and heparin-induced thrombocytopenia (HIT), which share similar clinical manifestations as thrombocytopenia and thrombosis. Other syndromes, which share the same clinical and laboratory features of HIT despite not having previously received heparin, appear to be associated with the presence of anti-PF4 antibodies. Such pathologies could only be explained by HIT antibodies with heparin-independent platelet-activating properties. One of these could be vaccine-induced Immune thrombotic thrombocytopenia (VITT) post-somministration of ChAdOx1 nCoV-19 vaccine. Recent studies have shown structural similarities between heparin and β2GPI, which may be responsible for thrombotic events in those infected with SARS-CoV-2 and VITT, who never had heparin. In particular, oxidised-β2GPI (β2GPIox) may mimic heparin by structural analogy and link to PF4. Considering the structural similarities between heparin and β2GPl ox, and demonstrating the immunogenicity of the hypothesised complex in APS, the alternative molecule could be represented by β2GPl ox itself, thus explaining the thrombotic events following vaccination in subjects who have never received heparin.

Objectives: The aim of the study is to test the potential immunogenicity of the β2GPl ox-PF4 complex and the presence of antibodies against this complex in patients with aPS, thrombosis during infection with SARS-CoV-2 or VITT.

Methods: 34 patients with proven diagnosis of APS, 17 patients with thrombosis related to infection SARS CoV-2 and 3 patients with VITT were enrolled. Only one aPS patient received heparin prior to testing. Antibodies to the β2GPl ox-PF4 complex were evaluated by home made ELISA immunoenzyme testing. Competitive inhibition (homologous) experiments of the bond of PF4 with β2GPl ox in the fluid phase were conducted in order to verify the binding specificity.

Results: Anti-β2GPl ox-PF4 antibodies were detected in 11 of 34 aPS patients (32%) and all VITT patients (100%), while none of covid-19 patients tested positive. In particular, oxidised-β2GPI (β2GPIox) may mimic heparin by structural analogy and link to PF4. Considering the structural similarities between heparin and β2GPl ox, and demonstrating the immunogenicity of the hypothesised complex in APS, the alternative molecule could be represented by β2GPl ox itself, thus explaining the thrombotic events following vaccination in subjects who have never received heparin.

Conclusions: The results of this study show a new antibody positivity in aPS and VITT.

In particular we have identified a high prevalence of anti-β2GPl ox-PF4 antibodies which selectively binds two molecules of β2GPI, favouring the dimerization of the same, which may be responsible for thrombotic events in those infected with SARS-Cov-2.

DIFFERENTIAL EXPRESSION OF PROTEINS IN PATIENTS WITH SUSPECTED SJÖGREN’S SYNDROME

Keywords: Biomarkers, Cytokines and chemokines, Sjögren syndrome

M. J. Santos-Boronen1, M. Fernandez Castro2, C. Merino Arguménez1, J. Sanz1, J. Campos Esteban1, N. De la Torre Rubio2, P. Navarro Palomo1, M. Pavia Pascual1, M. Machattou1, M. C. Sánchez Fernández3, P. D. Brongos Díaz4, H. Godoy2, B. García-Magallón2, C. Benadílio Mateos2, L. F. De Villa1, C. Isasi Zaragoza1, J. L. Andreu Sánchez1, A. Sánchez1. 1Hospital Universitario Puerta de Hierro Majadahonda, IDIPIHSIA, Rheumatology, Majadahonda (Madrid), Spain

Background: Sjögren’s Syndrome (SS) is a chronic systemic autoimmune disease characterized by involvement of the exocrine glands in addition to a wide spectrum of systemic manifestations. At present, conventional biomarkers do not respond to unresolved needs regarding diagnosis, stratification of phenotypes and appropriate effective therapies[1]. SS is an orphan disease and new biomarkers could constitute potential future therapeutic targets[2].

Objectives: The purpose of this study was to carry out an exploratory analysis in six serum and saliva samples from suspected SS patients to identify protein biomarkers to distinguish SS patients who were diagnosed with SS from those who were not.

Methods: We selected six patients from a cohort of 199 consecutive patients attended the rheumatology department for suspected SS: 3 patients who met SS classification criteria from 2002 and/or 2016 who were diagnosed with SS by a rheumatologist and 3 patients who did not meet SS classification criteria who were not finally diagnosed. Serum samples were collected and centrifuged at 1800g, divided into aliquots and stored at -80°C. Saliva samples were cold collected to prevent degradation of proteins, centrifuged at 1800g and stored at -80°C. A semiquantitative analysis of protein expression was performed using the “Proteome Profiler Human XL Cytokine Array Kit” arrays from R&D system that detects 105 proteins containing interleukins, chemokines, inflammatory factors and other soluble proteins. Analytical optical densities were quantified using ImageJ software. The extent of the analysis was compared between SS patients and non-SS patients using an unpaired Student’s t test and a measure of the odds of an analyte happening in one group compared to the odds of the same analyte happening in another group (OR: odds ratio) is shown. Statistical analysis were performed using Microsoft Excel software. P values ≤0.05 were defined as significant and values of 0.1 < P < 0.05 were considered as borderline.

Results: We found increased serum levels of CD14 (OR:1.21; P < 0.033), EGF (OR:1.18; P = 0.050), IP-10 (OR: 1.23; P = 0.090) Pentranx 3 (OR:1.32; P = 0.095) and VEGF (OR:1.41; P = 0.091) in patients diagnosed with SS who met SS classification criteria, compared with patients who did not meet SS classification criteria who were not diagnosed, although only in the case of CD14 and EGF, statistical significance was reached. In saliva samples, we found significantly increased values of ICAM1 (OR:1.67; P = 0.019), IL-6 (OR:1.20; P = 0.042) and IL-19 (OR:1.51; P = 0.039) in patient who did not meet SS classification criteria, compared with patients who did.

Conclusion: Sjögren’s syndrome patients presented significantly higher levels of CD14 and EGF in serum, as well as significantly decreased levels of ICAM1, IL-6 and IL-19 in saliva, compared to patients who did not meet SS classification criteria. It is necessary to confirm these results in a larger cohort of patients.

EXPLORING LONG-NON-CODING RNA GASE IN SLE PATIENTS AND ITS RELATION TO INTERFERON SIGNATURE

Keywords: Genetics/Epigenetics, Systemic lupus erythematosus

G. Maghraby1, M. Elmeniawy2, H. Mostafa3, O. Shaker2, M. Habib3, R. Elghory4. 1Faculty of Medicine Kasr Al-Ainy, Cairo University, Internal Medicine, Cairo, Egypt; 2Faculty of Medicine Kasr Al-Ainy, Cairo University, Biochemistry and Molecular Biology, Cairo, Egypt; 3Faculty of Medicine Kasr Al-Ainy, Cairo University, Ophthalmology, Cairo, Egypt

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.6134
Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease with diverse pathogenesis. Excessive apoptosis and impaired clearance of apoptotic cells are the primary drivers of Interferon I (IFN) signaling pathways. Upregulation of the long noncoding RNA Growth arrest-specific 5 (GAS5) was found to be associated with apoptosis [1]. Oncological studies discovered that GAS5 is regulated by IFN signaling pathways and acts as a positive feedback loop on IFN response [2]. In a mouse model, GAS5 was linked to SLE susceptibility [4]. However, the exact mechanism is still unknown. Furthermore, GAS5 has been proposed to act by interfering with glucocorticoid action, with a key role in regulating glucocorticoid resistance and sensitivity [5].

Objectives: To evaluate the expression levels of GAS5 in serum of SLE patients in comparison with healthy controls, assess their relation to SLE Disease Activity Index 2000 (SLEDAI-2K) and Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage Index (SDI), and explore their association with each of the 3 IFN-stimulatory genes (MX1, IFI44L, IFIT1) as well as IFN signature to elucidate how GAS5 shares in the pathogenesis of SLE.

Methods: 30 adult SLE patients and 20 age and sex-matched healthy controls were enrolled. SLE disease activity and damage were assessed by SLEDAI-2K and SDI respectively. The expression levels of GAS5 as well as 3 IFN-stimulatory genes (MX1, IFI44L, IFIT1) were measured by quantitative real-time PCR. IFN signature score was calculated as described in a previous study [6].

Results: GAS5 expression levels were insignificantly upregulated in SLE patients compared to control (p-value 0.11). At cut-off value 13-fold change, GAS5 could discriminate SLE from control (AUC 0.63) with high specificity 100 % and modest sensitivity 63%. Their expression levels were not associated with SLEDAI-2K or SDI scores. GAS5 levels were positively correlated with the cumulative dose of steroids in the last 6 months. However, it was not statistically significant. GAS5 was significantly correlated with IFIT1 gene expression (p-value <0.001) and IFN signature score (p-value 0.005) in SLE patients (Figure1), these findings were not previously reported.

Conclusion: GAS5 may be considered a diagnostic biomarker for SLE, but it is not a reliable biomarker for disease activity or damage. GAS5 is suggested to be incorporated into the IFN signaling pathway in SLE raising possible contribution in SLE pathogenesis.

KYNURENINE PATHWAY CAN BE A POTENTIAL BIOMARKER OF FATIGUE IN PRIMARY SJOGREN’S SYNDROME

Keywords: Biomarkers, Sjögren syndrome

H. W. Park1, Y. Park1, J. Lee1, J. H. Koh2, M. J. Kim3, S. H. Park3, S. K. Kwok1,2
1The Catholic University of Korea Seoul St. Mary’s Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Uijeongbu St. Mary’s Hospital, The Catholic University, Department of Internal Medicine, Uijeongbu, Korea, Rep. of (South Korea); 3The Catholic University of Korea Songjeong Campus, Catholic Research Institute of Medical Science, Seoul, Korea, Rep. of (South Korea)

Background: Primary Sjögren’s syndrome (pSS) is a chronic autoimmune disease with low quality of life caused by various constitutional symptoms and glan- dular dysfunction. Although fatigue is one of the most frequent symptoms in pSS, its etiology or biomarkers are poorly elucidated.

Objectives: We investigated potential relationship between severity of fatigue and the kynurenine pathway in pSS.

Methods: Clinical data and blood samples of 81 patients were obtained from a prospective cohort for pSS and compared with age- and sex-matched healthy controls (HC). Severity of fatigue was defined according to the fatigue domain scores in the ESSPRI. Potential biomarkers related to the kynurenine pathway were determined using ELISA.

Results: Of the total, 44 patients were defined as the "severe fatigue (ESSPRI fatigue ≥ 5)" group, whereas 37 as the "less fatigue (ESSPRI fatigue < 5)" group. Serum tryptophan levels in the severe fatigue group were significantly lower while those of kynurenine were higher. Serum interferon gamma, IDO1, and quinolinic acid levels were mostly higher in the less fatigue group. Kynurenine/tryptophan ratios were distinctly higher in the severe fatigue group than both HC and the less fatigue group (p < 0.001). This ratio showed a strong degree of positive correlation (r = 0.624, p < 0.001) with severity of fatigue in pSS while the other markers showed fair degrees of correlation.

Conclusion: Serum markers related to the kynurenine pathway, especially the kynurenine/tryptophan ratio, may be associated with severity of fatigue in pSS. These results can provide guidance for further investigations on fatigue in pSS.

**ASSOCIATION OF CYTOKINE AND CLINICAL EVALUATION BASED ON ULTRASOUND OF SALIVARY GLAND GRADE CLASSIFICATION IN PATIENTS WITH EARLY PRIMARY SJÖGREN’S SYNDROME**

**Keywords:** Imaging, Sjögren syndrome, Cytokines and chemokines

Y. F. Chen¹, Y. F. Fang¹, ¹Chang Gung Memorial Hospital, Rheumatology, Allergy and Immunology, Taoyuan city, Taiwan, Republic of China

**Background:** Primary Sjögren’s syndrome (pSS) is a chronic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands, the presence of anti-SSA/Ro, anti-SSB/La antibody and hypergammaglobulinemia.

**Objectives:** To investigate the clinical manifestations in patients with early primary Sjögren’s syndrome (pSS), and cytokine difference based on the severity score under salivary gland ultrasonography.

**Methods:** Forty-six newly diagnosed patients with early pSS were enrolled and divided into mild (score 0-1) and severe (score 2-3) groups according to the salivary gland ultrasonography grade (SGUS) scores at baseline. Clinical evaluation, ESSPRI and ESSDAI index values, sicca symptoms of mouth, salivary capacity, and serum autoantibody and cytokines were investigated.

**Results:** Mean age of pSS patients at diagnosis were 50.02 ± 12.4 years and the mean duration of sicca symptoms were 1.4 years. ESSPRI (EULAR Sjögren’s syndrome patient report index) and ESSDAI (EULAR Sjögren’s syndrome disease index) scores were 5.71 and 5.37, respectively. The higher prevalence of rheumatoid factor (p=0.04), antinuclear antibody (p=0.009) and elevation of total IgG (p=0.08) were found in severe group than in mild group. In addition, elevated titer of IL-18, IL-31 and IL-33 were detected in patients with pSS than in healthy subjects, but there were shown no statistical significance between mild and severe groups.

**Conclusion:** Salivary gland ultrasonography grade (SGUS) scans may help physician diagnose pSS. Clinical manifestation including the low production of saliva and autoantibody production such antinuclear antibodies, rheumatoid factor, and anti-SSA antibody were found. The elevated titer of IL-18, IL-31 and IL-33 in patients may be implicated in the pathogenesis of pSS.

seen in gardiquimod-stimulated mouse BMCs collected from C57BL/6 mice and exposed in vitro to afimetoran, which showed a significant increase in predni-
solone-induced apoptosis of pDCs and B cells compared to baseline control or
prednisolone alone. A similar trend was seen in vivo for BMCs collected from
NZB/W mice dosed with combinations of afimetoran and prednisolone.

Conclusion: Afimetoran, either alone or in combination with prednisolone,
showed efficacy in NZB/W mice with moderate disease. It also reversed the
resistance of bone marrow pDCs and B cells to prednisolone-induced apoptosis.
These data confirm that afimetoran, an equipotent TLR7/8 antagonist, has the
clinical potential to be steroid-sparing.

DYSAUTONIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CROSS-SECTIONAL STUDY

Keywords: Cardiovascular disease, Systemic lupus erythematosus, Diagnostic tests

S. Barak Lanciano1, U. Nussinovitch2, Y. Levy3, T. Aliv University, Sackler Faculty of Medicine, TEL AVIV; Israel; Wolfson Medical Center, Cardiovascular Division, Holon, Israel; 3Meir Medical Center, Internal Medicine Department, Kfar Saba, Israel

Background: Systemic lupus erythematosus (SLE) is a chronic, inflammatory, autoimmune disease associated with increased cardiovascular risk. Impaired autonomic nervous system (ANS) function (dysautonomia) is one of the causes and a marker of increased cardiovascular risk. Heart rate variability (HRV) is an accepted method of ANS evaluation. Pupillary light reflex (PLR) test is indicative of ANS dysfunction in healthy adults. The efficiency of PLR test for ANS evaluation among SLE patients has yet to be reported.

Objectives: To evaluate ANS function among SLE patients using PLR and HRV testing. The secondary objective was to assess the correlation between PLR and HRV tests among patients with SLE and to evaluate whether they are correlated.

Methods: A cross-sectional study was conducted. Forty-nine SLE patients and a matched group of 87 healthy volunteers were recruited. The participants were questioned about risk factors and other conditions that affect the ANS. Autonomic functions were evaluated by HRV and PLR testing. Strength of correlations were also evaluated.

Results: Maximum pupil diameters (PDmax) and maximal constriction PDmax were significantly lower in the SLE group (4.80±0.13 mm vs. 5.59±0.15 mm, p<0.01 and 4.01±0.44 mm vs. 5.94±0.51 mm, p<0.01, respectively). Compared with controls, the SLE patients had significantly lower values of NNS0 (number of successive RRI intervals that differ by more than 50ms). 12.78±3.78 vs. 25.08±2.84, p = 0.031), pNN50 (percentage of pNN50, 4.03±1.30 vs. 10.11±3.69), p = 0.031)

Conclusion: Patients with SLE have excessive parasympathetic activity, manifested as decreased HRV parameters and indices reflective of heart rate response to autonomic maneuvers. Similar results demonstrated by pupillary autonomic function. PLR test may be used as an alternative to HRV testing due to its simplicity and reproducibility.

Background: Monocytes -key regulators of the innate immune response- are actively involved in the pathogenesis of systemic lupus erythematosus (SLE). Monocytes and macrophages constitute a major cellular compartment derived from hematopoietic myeloid precursors. Monocyte-macrophage lineage cells exhibit versatile immunoregulatory, inflammatory and tissue repairing capabilities and play an instrumental role in the development of systemic lupus erythematosus (SLE). Abnormal activation of autoreactive T and B cells in SLE could also be caused by dysregulated cytokine production by monocytes. Monocytes in SLE display excess production of the B-lymphocyte stimulator (BlyS) which promotes the survival and proliferation of B cells.

Objectives: We sought to identify novel compounds that might serve as mono-
cyte-directed targeted therapies in SLE.

Methods: We performed mRNA sequencing in monocytes from 15 patients with active SLE and 10 healthy individuals. Disease activity was assessed with the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). Leveraging the drug repurposing platforms LINCS, CLUE and L1000CDS[2], we identified perturbagens capable of reversing the SLE monocyte signature. We identified transcription factors and microRNAs (miRNAs) that regulate the transcriptome of SLE monocytes, using the TRUST and miWalk databases, respectively. A gene network integrating implicated transcription factors and miRNAs was constructed, and drugs targeting central components of the network were retrieved from the DGI database, in order to build a final drug-protein interaction network.

Results: Inhibitors of the NF-κB pathway, compounds targeting the heat shock protein 90 (HSP90), as well as a small molecule disrupting the Pim-1/NFATc1/ NLRP3 signaling axis were predicted to efficiently counteract the aberrant mono-
cyte gene signature in SLE. Based on our network-based drug repurposing

ASSOCIATION OF STAT1, STAT4 AND JAK2 IMMUNOEXPRESSSION WITH THE GRADE OF MONONUCLEAR CELL INFILTRATION IN MINOR SALIVARY GLAND BIOPSY IN PATIENTS WITH PRIMARY SJÖGREEN’S SYNDROME

Keywords: Sjögren syndrome, Prognostic factors

M. Maślińska1, M. Grabowska2, A. Wajda3, K. Kostyra-Grabczak4, A. Paradowska-Gorycza5.1 National Institute of Geriatric, Rheumatology and Rehabilitation, Early Arthritis Clinic, Warsaw, Poland; 2Pomeranian University, Department of Histology and Developmental Biology, Szczecin, Poland; 3National Institute of Geriatric, Rheumatology and Rehabilitation, Department of Molecular Biology, Warszaw, Poland

Background: Signal transducer and activator of transcription 4 (STAT4) is an important for Interferon-γ induction (type 2 IFN signaling). Whereas type 1 IFN signaling pathway depends on signal transducer and activator of transcription 1 (STAT1) and Janus kinase 2 (JAK2). JAK2 is a non-receptor tyrosine kinase that plays a role in signal transduction via others type II receptors including IFN-γ, IFN-α, IFN-β. The IFN signature in Sjögren’s syndrome and overexpression of IFN-1 and IFN-2 in minor salivary glands biopsy (MSGBs) were described.

Objectives: The aim of the study was to analyze the immunoeexpression of STAT4, STAT1 and JAK2 in biopsies of MSG depending on the severity of mononuclear cell infiltration (focus score, FS) in patients with primary Sjögren’s syndrome(pSS).

Methods: The study group consisted of 64 patients with pSS aged 48.25±16.47. 89% of the subjects were women. MSGBs were routinely stained with HE for conventional histopathological examination with determination of FS. Monoclonal antibodies were used to determine the immunoeexpression of the STAT1, STAT4, and JAK2. Quantitative Computer Image Analysis of Immunoeexpression (ScanScope AT2 scanner) has been conducted. The percentage of positive immunostaining for each protein was determined in 20 HPF in each group of patients according to FS. Results were analyzed using TIBCO Statistica v. 13.3 Obtained values failed normal distribution assumption, therefore the non-parametric Kruskal–Wallis test with Dunn’s multiple comparison test for post hoc analysis was used to assess the differences between the groups. p < 0.05 were considered to be statistically significant.

Results: 33% pSS patients were characterized by FS=1; 30%-FS= 3; FS=0 – 9%. 3% and 2% of patients revealed FS=5 and FS=6, respectively. In MSGBs JAK2-, STAT1-, and STAT4-immunopositive cells were observed. The various nuclear and cytoplasmic immunoeexpression of JAK2, STAT1 and STAT4 in acinar and ductal cells and also in lesions displaying immune-cell infiltration were observed. However the immunoeexpression of STAT4 in the nucleus was relatively rarely found. The percentage of JAK2-, STAT1- and STAT4-positive cells in FS = 0 was significantly lower in comparison with FS equal or greater than 3. However for STAT4, already in FS=2 there was a stronger signal compared to FS=0. The percentage of JAK2- and STAT1-positive cells in MSGB in FS = 0 was statistically insignificant in comparison with FS = 1 and 2. There was no statistical significance in the percentage of STAT4- positive cells in patients with FS = 0 in comparison with FS = 1 (Figure 1). mRNA level of STAT4 in whole blood in patients with pSS revealed the opposite trend. The increase of FS was correlated with the decreased mRNA level of STAT4.

Conclusion: Notably, in the case of STAT4 immunoeexpression increased with increasing FS. Interestingly, mRNA level of STAT4 determined in the whole blood decreased with increasing FS (data not shown).

The question remains why the immunoeexpression of STAT4 in nucleus was relatively rarely found, and what is the impact of the dynamics of STAT4-dependent gene expression on the pathogenesis of pSS. In studied patients STAT4 activity dominates in MSGB infiltrates which confirms the role of this factor in the pathogenesis of pSS.

INTERFERON STIMULATED GENES IN CD4 T CELLS ARE ASSOCIATED WITH PYROPTOSIS PATHWAYS IN PATIENTS WITH LUPUS

Keywords: Systemic lupus erythematosus, -omics

S. J. Lee1, B. A. Kim1, 1Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Internal Medicine, Daegu, Korea, Rep. of (South Korea)

Background: Single cell RNA sequencing (scRNA-seq) of kidney tissues in patients with lupus has led to landscape of complete cellular composition and states for immune and non-immune cells. These studies suggested type I interferon (IFN) signatures prime inflammatory responses. However, there is a lack of knowledge regarding the characteristics of subsets of IFN stimulating genes (ISG) high expressed cells.

Objectives: Here we investigated immune cell compositions between peripheral blood mononuclear cells (PBMCs), skin and kidney tissues in patients with lupus using scRNA-sequencing, We characterized a subset of ISG high CD4 T cells, which are commonly expressed across PBMCs, skin and kidneys of lupus but not skins of healthy.

Methods: scRNA-seq dataset of PBMCs, skin and kidney tissues in patients with lupus were collected. We integrated and analyzed immune cell compositions from this scRNA-seq dataset. We focused on subset of ISG high expressed CD4 T cells and characterized top 200 genes of this subset.
Results: There is one subset of ISG high expressed CD4 T cells in the lupus PBMCs, kidneys, and skins but not in the healthy skins. This ISG high expressed CD4 T cells have the greatest number of type I interferon signatures and gas- tronomically D gene, which is related to pyroptosis of cells, among top 200 genes. We further investigated pyroptosis pathway genes in the subsets of CD3 T cells. Interestingly, the subset of ISG high expressed CD4 T cells have most increased pyroptosis related upstream regulating genes including IRF1, GBP1, CASP4 and CASP1. Furthermore, this subset highly expressed inflammasome gene such as NLRP3.

Conclusion: There are ISG high expressed CD4 T cells across tissues of lupus. Those cells highly expressed pyroptosis related pathway genes. Further investigation is needed to characterize association between ISG and pyroptosis.

FIRST-IN-HUMAN INVESTIGATION OF HYDROGEN VOLTAGE-GATED CHANNEL 1 (HVCN1) EXPRESSION AND LEVELS OF MYELOPEROXIDASE AND OXIDIZED DNA (8-OHGD) IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUSUS (SLEOX STUDY) – AN INTERIM ANALYSIS

Keywords: Systemic lupus erythematosus, Cell biology

Background: Within the still poorly understood pathogenesis of systemic lupus erythematosus (SLE) granulocyte neutrophils have been shown to play a key role. In our research on mouse models, we found that important functions of neutrophils are regulated by the hydrogen voltage-gated channel 1 (HVCN1), whose deficiency causes an SLE-like autoimmune disorder in old mice [1]. Among other effects, HVCN1 regulates the secretion of myeloperoxidase (MPO) and the release of neutrophil extracellular traps (NETs) in mice, thereby controlling inflammation. Based on this knowledge and a previous gene array analysis of CD16+ peripheral blood cells from SLE patients that showed reduced HVCN1 mRNA expression in neutrophils [2], we hypothesize that reduced HVCN1 expression leading to increased MPO and NET release might be a pathomechanism observable in humans that could contribute significantly to the pathogenesis and disease activity in SLE.

Objectives: This first-in-human trial prospectively assesses HVCN1 protein expression of leukocytes and plasma levels of MPO and 8-OHdG in correlation with clinical disease activity in SLE patients and matched healthy controls, in order to gain deeper understanding of SLE pathogenesis.

Methods: In this prospective study (ethical approval obtained under Institutional Review Board #112/22), 50 patients with SLE and 50 healthy controls are investigated. HVCN1 expression in peripheral blood leukocytes and plasma levels of myeloperoxidase (MPO) and oxidized DNA (8-OHdG), accompanied by application of the SLEDAI-2k assessment for clinical disease activity and recording of further clinical (demographics, patient and treatment history) and laboratory data (autoimmune, urine and routine serum diagnostics). HVCN1 protein expression is quantified by flow cytometry (BD FACS Symphonv A5) via targeted HVCN1 staining (Alomone labs anti-HVCN1 rabbit IgG and Invitrogen anti-rabbit IgG, Alexa Fluor 488). Previous processing steps include leukocyte staining (CD45, CD14, CD15 and CD16), cell fixation and permeabilization. Reference quantification of HVCN1 protein expression via Western Blot and further mRNA and DNA measurements are planned. MPO and 8-OHdG levels will be quantified by ELISA and mass spectrometry.

Results: The preliminary analysis of 18 SLE patients revealed a statistically significant positive correlation between SLEDAI-2k scores and HVCN1 protein expression (Pearson correlation coefficient: 0.563; p=0.015). Also, within the typical SLEDAI-2k disease activity categories, there was a clear tendency towards ascending HVCN1 protein quantities expressed with every severity category step-up [see Figure 1]. Further analysis is ongoing.

Conclusion: Unlike previous studies, our preliminary SLEOx trial data suggests a positive correlation of HVCN1 protein expression and SLE activity. General HVCN1 upregulation following leukocyte activation in response to disease activity (among other factors) could be one explanation. Validation in a larger study cohort is currently underway.

CHARACTERIZATION OF SERUM CYTOKINE PROFILE IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS

Keywords: Cytokines and chemokines, Systemic lupus erythematosus

Z. Rahme1, M. Gatto1, A. Ghirarrdello1, C. Cruciani1, F. Pettorossi1, A. Zaramella2,3, C. Franco1, A. Doria1.
1University of Padova, Department of Medicine, Rheumatology Unit, Padova, Italy; 2University of Padova, Department of Surgery, Oncology and Gastroenterology (DISCOG), Padova, Italy; 3Veneto Institute of Oncology IOV-IRCCS, Gastroenterology Unit, Padova, Italy

Background: Cytokines (CKs) are known to play a role in the pathogenesis of lupus nephritis (LN), yet their role as biomarkers is still debated.

Objectives: To describe the CKs picture in patients with active LN and to assess possible clinical correlates in LN course.

Methods: A prospective cohort study including patients with active biopsy-proven LN was performed. Serum CKs were assessed at the time of diagnosis and at 3 subsequent time points (3, 6 and 12 months) during follow-up. Clinical and serological data were collected for further analysis. BLyS (B Lymphocyte stimulator) and interleukin (IL)-37 were measured by ELISA assays (Quantikine BAFF, R&D, USA, detection limit DL 0.02 ng/mL; IL37 ELISA kit, Adipogen, Switzerland, DL 0.01 ng/mL); IL-2, IL-10, IL-17A and IL-18 (pg/mL) by Luminex multiplex assay (Millipore, USA, DL 0.6 pg/mL for all), according to the manufacturers’ instructions. Measurements for IL-37 and BLyS were matched with sera of sex- and age-matched healthy subjects (HC). Mann-Whitney test was used for comparisons between two independent groups, Wilcoxon log-rank test for paired comparisons at different time points, Spearman’s correlation coefficient for associations between CK and between CK and clinical features.

Results: Twenty-seven patients with active LN (mean±SD age 41.7±4.17, 78.8% women) were included for initial CK analysis at the time of LN activity. At baseline (T0), BLyS levels were significantly increased in LN compared with HC (median [range]: 1.67 [0.32-6.40] vs. 0.563 [0.265-1.408]; p<0.0001); IL-37 was significantly reduced in LN compared with HC (median [range]: 0.016 [0.001-0.291] vs. 0.056 [0.001-1.147]; p=0.0185). At T0, median (range) levels of IL-2, IL-10, IL-17A and IL-18 were: IL-2 0.640 (0.372-8.12), IL-10 2.60 (0.106-8.66), IL-17A 2.10 (0.138-20.18), IL-18 243.10 (28.20-950.30). The longitudinal association study between CK levels of the entire cohort revealed a trend of inverse correlation between IL-37 and BLyS (r=-0.281, p=0.06) and a direct correlation between BLyS and IL-18 (r=0.330, p=0.04) and between IL-2 and IL-17A (r=-0.470, p=0.001) (Figure 1). A subset of 17 patients (70.6% F, mean age at renal flare 34.3±18.6, mean duration of disease at the time of renal flare 4.9±1.95, caucasian ethnicity n=14, 82.3%), was followed-up prospectively: 7 (41.18%) had biopsy-proven (III-IV class) proliferative glomerulonephritis. Proteinuria at T0 was 2.19±1.35 g/24h. All patients were treated with pulsed glucocorticoids (GCS, 750-2500 mg) followed by oral GCS (0.3-0.5 mg/kg/day prednisone equivalent) and immunosuppression. Higher titers of IL-18 were present in the sera

DOI: 10.1136/annrheumdis-2023-eular.4258
of patients with proliferative forms of LN ($p=0.053$) and with a higher SLEDAI-2K score at T0 ($p=0.0759$). A significant correlation was found between IL-2 and a lesser extent of IL-17, with anti-dsDNA antibodies (IL2: r=-0.6098, $p=0.0094$; IL-17: r=-0.4591, $p=0.0638$). High levels of IL-17 correlated with low C3 at T0 ($r=-0.5085$, $p=0.0372$). No significant longitudinal changes in CKs levels nor correlation with clinical features were observed.

**Conclusion:** Patients with proliferative LN and higher SLEDAI-2K scores displayed higher levels of IL-18, thus supporting IL-18 likely role in the pathogenesis of LN. We documented a correlation between IL2 and higher titers of anti-dsDNA antibodies and an inverse correlation between IL-17 and C3 at baseline, suggesting a contribution of CKs to LN onset. Our study was limited by the small sample size, limiting retrieval of significant data on CK levels and clinical-laboratoric changes at different time points, demanding further studies.

other cytokines didn’t correlate with disease status. CIC levels significantly differ-
entiated active from inactive disease (p<0.001).

References:
Significantly increased in active SLE and should be evaluated in further studies.

Background:
In the development of various illnesses including autoimmune diseases, many studies proving the crucial role of gut microbes are gradually being reported. Alterations of gut microbiota can lead to abnormalities in the host immune system, causing autoimmune, which can act as pathogenesis of systemic lupus erythematosus (SLE).

Objectives: The purpose of this study was to analyze the diversity and taxo-
nomic composition of the gut microbiota affecting SLE and to investigate their association with disease activities.

Methods: Fecal samples of 38 patients with SLE in Ajou Lupus Cohort and 52 age and sex-matched healthy volunteers were provided by the same protocol. We analysed the components of the gut microbiota in feces via 16S RNA next-gen-
eration sequencing, and evaluated alpha and beta diversities. Demographic, laboratory, and medication data of SLE patients were obtained through medical records, and Pearson correlation analysis was performed to analyze the associ-
ation between disease activity and gut microbiota.

Results: We observed a significant decrease in species richness in the beta diversity analysis by NMDs plots compared to controls in the SLE group. Compared with SLE and healthy controls (HCs), significant differences were found at phylum, genus, species levels in the taxonomic composition. At the species level, there were 7 species with a significantly higher relative abundance and 7 species with a lower relative abundance in the SLE group compared to the HCs, of which the reduction of Faecalibacterium prausnitzii and Prevotella copri (p = 0.001 and p = 0.001, respectively) played an important role in SLE. Pearson correlation analysis suggested that Faecalibacterium prausnitzii was positively correlated with complement 3 and 4 (r = 0.44 and r = 0.49, respectively), and Prevotella copri was positively correlated with total lymphocytes (r = 0.45).

Conclusion: There was a significant difference in the composition and diversity of gut microbiota between SLE patients and healthy controls in Korean population. In particular, Faecalibacterium prausnitzii and Prevotella copri, which are greatly reduced in patients with SLE, are expected to provide potential targets for new treatment.

VORINOSTAT IMPROVES THE PATHOGENESIS OF SLE MODEL MICE BY SUPPRESSING IFN-I AND TLR7/8 SIGNALS

Keywords: Systemic lupus erythematosus
T. Hirayama1,2, H. Konaka1,3, Y. Kato1,2, H. Takamatsu2,3, A. Kumanogoh1,2,4
1Graduate School of Medicine, Osaka University, Department of Respiratory Medicine and Clinical Immunology, Suita city, Japan; 2Immunology Frontier Research Center (IFReC), Department of Immunopathology, Suita, Japan; 3Nippon Life Hospital, Department of Internal Medicine, Osaka, Japan; 4Institute for Open and Transdisciplinary Research Initiatives, Integrated Frontier Research for Medical Science Division, Suita, Japan

Background: SLE is a systemic autoimmune disease caused by impaired innate and acquired immune tolerance, resulting in increased Type I IFN (IFN-I) and aberrant B cell development, in which cGAS and TLR 7/8 signaling play critical roles. TLR7/8 and cGAS signal is activated due to the overexpression of TLR7/8 and cGAS, which leads to increased IFN-I production. Activation of TLR7/8 signaling also leads to the development of abnormal B cell populations, including short-lived plasma blasts, double negative B cells (DNB), and active native B (NAB). It suggests that signaling pathway via TLR7/8 and cGAS would be a good therapeutic target for SLE. Therefore, we screened agents that inhibit the induction of interferon-stimulated genes (ISGs) by LPS, R848 or cGAMP stimulation using an approved drug library and found that vorinostat inhibits ISG induction upon cGAMP and LPS stimulation.

Objectives: The purpose of this study is to elucidate the mechanism by which vorinostat suppresses IFN-I production and to demonstrate that vorinostat improves the severity of the disease phenotype in SLE-prone mice.

Methods: We investigated the effect of vorinostat on the expression and phosphorylation of TBK1, IRFs, IRF5, and IRF7, upon LPS or cGAMP stimulation, as well as on the in vitro differentiation of human B cells into plasma cells by a culture medium containing R848. Additionally, the effect of Vorinostat on the severity of SLE-prone mice, such as NZB/W F1 mice and SAVI mice with point mutations in STING, was also investigated.

Results: Vorinostat inhibited TBK1 phosphorylation and subsequent nuclear translocation of IF3 and expression of IRF5 and IRF7. Consequently, the expression of IFN-β and ISGs were suppressed. Additionally, differentiation of human B cells cultured in R848-containing medium into plasma cells was inhibited in the presence of vorinostat. Furthermore, vorinostat improved the disease severity of NZB/W F1 mice, including survival, proteinuria, and glomerulonephritis, and decreased autoantibody titer and TLR7 expression. Vorinostat also ameliorated the disease severity of NZB/W F1 mice, such as NZB/W F1 mice and SAVI mice with point mutations in STING, was also investigated.

Conclusion: We found vorinostat ameliorates the disease severity of SLE prone mice by inhibiting IFN-I production and pathogenic B cell development via suppressing the downstream signal of TLR7/8 and cGAS. This finding represents a new therapeutic candidate for SLE.

PHARMACOLOGICAL CHARACTERIZATION OF GLPG3667, A SELECTIVE TYK2 INHIBITOR, SUPPORTS DEVELOPMENT IN DERMATOMYOSIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Myositis, Targeted synthetic drugs, Systemic lupus erythematosus

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that transduces signalling from type 1 interferons (IFN), interleukin (IL)-12/ IL-23 and the IL-10 family of cytokines. Genetic analyses show an association of TYK2 variants with risk of inflammatory and autoimmune diseases. In addition, clinical data obtained with deucravacitinib (a TYK2 selective inhibitor) in SLE patients suggest that inhibition of TYK2 could be beneficial to patients with inflammatory diseases driven by type I IFN such as systemic lupus erythematosus (SLE) and dermatomyositis (DM).

Objectives: We describe here GLPG3667, a TYK2 inhibitor in development for treatment of DM and SLE.

Methods: Potency and selectivity of GLPG3667 on TYK2 was assessed using radioactive, luminescent and fluorescent biochemical assays. Peripheral blood mononuclear cells (PBMC) and human whole blood assays for various Janus kinases (JAK)-dependent pathways were performed to assess GLPG3667 potency and selectivity, using flow cytometry or ELISA. GLPG3667 pharmacological activity was investigated in a psoriasis mouse model driven by IL-23. In healthy human volunteers (NCT04097938), pharmacodynamic activity of GLPG3667 was evaluated by measuring signal transducer and activator of transcription (STAT) phosphorylation using flow cytometry. Selectivity was assessed by analysing the impact of GLPG3667 on IFNα, IL-2 and granulocyte-macrophage colony-stimulating factor (GM-CSF) pathways. Biological effects of orally administered GLPG3667 in humans were assessed using transcriptomic analysis of blood cells after in vivo IFNα (1 million IU of Intron-A) challenge in healthy volunteers.

Results: Biochemical assays showed that GLPG3667 displayed a nanomolar potency on TYK2 with a >3-fold selectivity over the other JAK kinases. In human PBMC activated with phorbol myristate acetate and ionomycin calcium salt, GLPG3667 showed comparable potency (around 50 nM) on the IFNα and IL-23 pathways. Potency of GLPG3667 was >14-fold and >19-fold higher in the IFNα pathway vs the IL-2 and GMCSF pathways in human PBMC and whole blood, respectively. In mice, dermal ear inflammation driven by IL-23 was prevented by GLPG3667 with a minimal effective dose of 3 mg/kg given orally once daily. This effect was associated with a decrease in neutrophil infiltration and STAT3 phosphorylation at sites of inflammation. In healthy human volunteers, GLPG3667 completely inhibited IFNα-induced STAT1 and STAT3 phosphorylation but did not impact IL-2 or GM-CSF-induced STAT5 phosphorylation. GLPG3667 strongly inhibited the expression of IFNα-response genes induced by in vivo IFNα challenge in healthy human subjects.

Conclusion: GLPG3667 demonstrated selectivity for TYK2 relative to the three other JAK family members in biochemical and cellular assays, and in human whole blood assays ex vivo and in vivo during a phase 1 study in healthy human volunteers. Pharmacological effects of GLPG3667 were demonstrated in a mouse model of psoriasis driven by IL-23 and in human healthy volunteers challenged with IFNα. These data support the development of GLPG3667 in autoimmune diseases driven by type 1 IFN such as DM and SLE.

GENETIC EVIDENCE REVEALS A CAUSAL ROLE OF BLOOD LEUKOCYTE COUNTS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus

Y. Zhang1,2, K. Fan1-2, Z. Han1,2, Q. Yu1, P. F. He1, X. Li1, S. X. Zhang1, 1Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, T aiyuan, Shanxi Province, China; 2Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, T aiyuan, Shanxi Province, China; 3Shanxi Medical University, Shang Key Laboratory of Big Data for Clinical Decision Research, T aiyuan, Shanxi Province, China; 4The Second Hospital of Shanxi Medical University, Department of Rheumatology, T aiyuan, Shanxi Province, China

Background: Blood leukocyte counts are important biomarkers for the onset of systemic lupus erythematosus (SLE)[1-3]. However, the causal relationship is unclear.

Objectives: We implement a two-sample Mendelian Randomization (MR) analysis to investigate the potential association.

Methods: The summary statistics of blood leukocyte counts were available from public databases (n=172435)[4]. All genetic variants significantly associated with blood leukocyte counts (p<5×10 –8) were used as instrumental variables (IVs). Then, the linkage disequilibrium (LD) was excluded (distance threshold = 10,000 kb, r 2 = 0.001). In this study, the inverse variance weighted (IVW) method, the MR-Egger method, and the weighted median (WM) were used to estimate the causal effect of the blood leukocyte counts and SLE. In addition, Cochran’s Q test, MR pleiotropy residual sum and outlier (MR-PRESSO), and leave-one-out analysis were implemented as sensitivity tests.

Results: We selected 119 independent SNPs as IVs in the MR analysis of total WBC. Higher blood leukocyte counts were associated with a lower risk of SLE (OR:0.629, 95% CI: 0.436-0.907 , P: 0.013) by IVW method (Figure 1). However, the results of Cochrane Q statistics showed heterogeneity (p<0.05). Therefore, we used the random-effects model[6].

Conclusion: Our study predicted genetically that individuals with lower blood leukocyte counts face a higher risk of SLE, which was consistent with the previous observational studies.

Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models

Keywords: Animal models, Systemic sclerosis

H. Mutsuda1, M. Kondo1, R. Ohno1, A. Ishii2, M. Piruzyan1, K. Funayama1, Y. Ono1, A. Iwamura1, T. Endou2, T. Akashi2, T. Tomari2, N. Uchiyama2, O. Kanai3, P. Blzyczek4, D. Distler5, Mitsubishi Tanabe Pharma Corporation, Research Unit/Immunology & Inflammation, Yokohama, Japan; 2Mitsubishi Tanabe Pharma Corporation, DMKP Research Laboratories, Yokohama, Japan; 3Mitsubishi Tanabe Pharma Corporation, Safety Research Laboratories, Fujisawa, Japan; 4University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland

Background: Autotaxin (ATX) is the lysophosphatidic acid (LPA)-producing enzyme. Targeted small-molecule therapies to ATX have been shown to be potentially effective in systemic sclerosis (SSc) treatment, but the clinical benefit and role of selective ATX inhibition remain unexplored.

Objectives: To explore the potential of MT-5562F, a novel oral selective inhibitor of ATX, as a therapeutic agent for SSc by evaluating its efficacy and toxicity in preclinical models.

Methods: MT-5562F and a free form of MT-5562F (MT-5562Fp) were evaluated, and other ATX inhibitors (zirataxest and cudetaxest) were used as comparators in the in vitro assays. The in vivo efficacy of MT-5562F in collagen-induced lung fibrosis was assessed using fluorescent substrate Aplastim UltraRed. The effects of MT-5562F on IL-6 and connective tissue growth factor (CTGF) production in TGF-beta induced dermal fibroblasts from healthy donors and lung fibroblasts from idiopathic pulmonary fibrosis patients were evaluated in vitro. Cell toxicity was evaluated in human pulmonary alveolar epithelial cells (HPAECip), human lung fibroblasts from idiopathic pulmonary fibrosis patients (DHL-IFP) and lung microvascular endothelial cells (HMVEC-L) by cell counting. The plasma concentration of MT-5562F and LPA production were evaluated in C57BL/6 mice. The effects of MT-5562F on skin and lung fibrosis were evaluated in murine SSc models induced by bleomycin (BLM).

Results: MT-5562F, zirataxest, and cudetaxest inhibited the enzyme activity of human ATX with IC50s of 0.45, 4.93, and 2.77 mmol/L, respectively. MT-5562F and zirataxest inhibited the enzyme activity of mouse ATX with IC50s of 0.15 and 10.9 nmol/L, respectively. MT-5562F concentration-dependently inhibited TGF-beta-induced IL-6 and CTGF production in human dermal fibroblasts from healthy donors and lung fibroblasts from IPF patients. MT-5562F showed minimal effects on cell viability using lung structural cells such as alveolar epithelial cells (HPAECip), pulmonary fibroblasts (DHL-IFP) and endothelial cells (HMVEC-L) even at the maximum dissolved concentration (60 μmol/L). On the other hand, zirataxest showed more cytotoxic effects than MT-5562F on cell viability in vitro. MT-5562F did not show any specific off-target interference on receptor binding and kinase profiling assays. In vivo, MT-5562F and zirataxest (10, 30 mg/kg) dose-dependently reduced plasma LPA concentration in mice according to the plasma drug exposure and mouse ATX inhibitory activity, and MT-5562F showed more sustained effects compared with zirataxest. Therapeutic treatment with MT-5562F (30, 60 mg/kg, once daily) significantly suppressed skin thickening and the numbers of myofibroblasts in pre-established subcutaneous BLM-induced skin fibrosis model. Therapeutic treatment with MT-5562F (30, 60 mg/kg, twice daily) and zirataxest (30 mg/kg, twice daily) showed significant reduction of the average Ashcroft score and collagen severity score in the BLM-induced lung fibrosis, together with the reduction of the biomarker LPA. All doses of MT-5562F significantly reduced the expression of inflammatory and fibrotic mediators such as C-reactive protein, IL-6Ra, epidermal growth factor receptor (EGFR) and perlsit in bronchoalveolar lavage fluid.

Conclusion: Our results suggest that MT-5562F is a selective and potent ATX inhibitor. It is expected to be a safer compound comparing other ATX inhibitors under development and it may offer a good option to treat lung and skin fibrosis in SSc.

IDENTIFICATION OF CANDIDATE MiRNA MOLECULES AS BIOMARKERS IN INTERSTITIAL PNEUMONIA WITH AN UNDERLYING AUTOIMMUNE DISEASE. A DISCOVERY COHORT FROM THE NERA PROJECT

Keywords: Biomarkers, Lungs -omics

M. J. Rodriguez1, M. C. Vegas Sánchez2, B. López-Muñiz2, F. Romero Bueno3, C. Vadiol3, M. A. Nieto4, L. Cebrán Méndez2, H. Godoy5, R. Laporta6, L. Abasolo7, G. Bonilla8, L. Gómez Carrera8, O. Sanchez Pernau9, Hospital Universitario Fundación Jiménez Díaz, Pulmonology, Madrid, Spain; 2Hospital Universitario Fundación Jiménez Díaz, Immunology, Madrid, Spain; 3Hospital Universitario Infanta Leonor, Pulmonology, Madrid, Spain; 4Hospital Universitario Fundación Jiménez Díaz, Rheumatology, Madrid, Spain; 5Hospital Clinico Universitario San Carlos, Rheumatology, Madrid, Spain; 6Hospital Clinico Universitario San Carlos, Pulmonology, Madrid, Spain; 7Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain; 8Puerta de Hierro Majadahonda University Hospital, Pulmonology, Majadahonda, Spain; 9La Paz University Hospital, Pulmonology, Madrid, Spain; 10La Paz University Hospital, Rheumatology, Madrid, Spain

Background: A group of patients with chronic interstitial pneumonia (IP) have an underlying autoimmune disease -typically a connective tissue disorder (CTD) -. In turn, autoimmune-related IP (AIP) processes are highly heterogeneous as regards to their clinical presentation, extra-pulmonary features and risk of fibrotic progression. A better understanding of clinically-relevant disease phenotypes is needed in order to tailor therapies.

Methods: We analyzed non-coding RNAs which orchestrate multiple biological processes by regulating mRNAs via cleavage or translation repression. Circulating levels of miRNA molecules provide excellent information about pathogenic processes in complex diseases, help identify specific disease subgroups and therapeutic targets.

Methods: We have conducted NGS of small-noncoding RNA in patients with AIP and controls in the NERA project and been selected as a priority project by the Special Multidisciplinary Clinics from the participating centers. The study composition comprised 29 subjects (24 cases, 5 controls; 93% women, 87% newly diagnosed patients). Sixty seven % of the patients were diagnosed with interstitial pneumonitis with autoimmune features (AIP) and all patients had a pulmonary dominant disease at the time of blood sampling. IGEAN genomic services and a NextSeq (illumina Inc.) instrument were used. For statistical comparisons, the sample was further segregated according to clinical diagnosis, radiographic pattern, evidence of fibrosis in HRTC, relative levels of Krebs von den Lungen (KL-1) and type of autoantibodies (classified into those potentially-associated to vasculopathy, the ones typically associated to rheumatoid arthritis, and non-specific ANA). The association was considered true for a p level < 0.02 and a low false discovery
rate (FDR), p < 0.1). DIANA tools including the Tarbase v8.0 were used to assess functional pathways with GO and KEGG analysis. **Results:** As compared to the healthy controls, patients with IP showed higher levels of let-7i-5p (1.9-fold, p < 0.01), miR-483-5p (3.5-fold, p < 0.0005) and the miR-320 family. Fibrotic disease was associated to an up-regulation of the let-7i cluster, miR-151a-5p (2.04-fold, p < 0.01), miR-185-5p (2.4-fold, p < 0.01), miR-320a-3p (2-fold, p < 0.016), miR-320e-2 (2-fold, p < 0.016) and miR-423-5p (1.9-fold, p < 0.01). Besides, there was an up-regulation of both let-7i-5p levels (3.55-fold, <p < 0.005) and miR-483-5p (4.78-fold, p < 0.005) in patients with HfLS. On the other hand, patients with vasculopathy-related autoantibodies had a characteristic microRNA signature, with an up-regulation of the miR-10 and miR-30 families as well as levels of miR-320b (2.77-fold, p < 0.005), miR-330c (3.71-fold, p < 0.005) and miR-320d (3.84-fold, p < 0.005), in addition to miR-483-5p (4.2-fold, p < 0.005), miR-675-5p (7.74-fold, p < 0.005) and miR-1283 (7.40-fold, p < 0.005). The cluster dendogram showed association between miR-10a, miR-10b, miR320c and miR320d regulated processes, with an enrichment in the Hippo signalling, the TGFβ pathway and the fatty acid biosynthesis. **Conclusion:** Or data suggests a common miRNA signature in patients with AIP, which includes 2 miRNA molecules, miR-483-5p and miR-320a, which have already been identified in patients with CTD and IP. In addition, a specific microRNA pattern was found in those patients with a “SSc-like” autoantibodies, pointing to the existence of particular driving processes in this subtype of disease. Confirmation of these findings and validation of targets in a larger sample is warranted in order to advance to a pathophysiologic classification of AIP. **Acknowledgements:** This work has been conducted with funding from a ISCIII AES2020 grant (P120/00250) and a Boehringer Ingelheim External Research Grant 1199-0499 **Disclosure of Interests:** None Declared. **DOI:** 10.1136/annrheumdis-2023-eular.4005 **AB0149**

**THE EXPRESSION AND REGULATION OF NOX4 IN DAMAGED MYOBLASTS IN INFLAMMATORY MYOPATHY**

**Keywords:** Myositis, Adaptive immunity

H. R. Kang1, J. Y. Kim5, S. U. Kim5, E. Y. Lee3, H. S. Kwon5, S. Ban5, 1Seoul National University Graduate School, Interdisciplinary Program in Cancer Biology Major, Seoul, Korea, Rep. of (South Korea); 2Seoul National University Graduate School, Integrated Major in Innovative Medical Science, Seoul, Korea, Rep. of (South Korea); 3Seoul National University Hospital, Department of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 4Seoul National University, Department of Cancer biology, Graduate School of College of Medicine, Seoul, Korea, Rep. of (South Korea)

**Background:** Idiopathic inflammatory myopathy (IM) is a rare autoimmune disease characterized by proximal muscle weakness, elevated muscle enzymes, inflammation in the muscle. If the muscle is already damaged in IM, it may not regain full strength even after treatment. Also the mechanisms that contribute to muscle weakness in myositis are currently unknown. Nox is the main source of ROS production in various cells types, and is also the source of mitochondrial ROS. Excessive expression of Nox4 is characteristic of sclerosis, fibrosis, and cardiac related diseases, and it had been reported that knock down of Nox4 lowers the production of superoxide and hydrogen peroxide. However, the effect of Nox4 in myositis has not been reported.

**Objectives:** We investigated the expression and role of Nox4 in damaged myoblasts of myositis.

**Methods:** Myoblasts were isolated from IIM patients who underwent muscle biopsy in Seoul National University Hospital between February 2019 and February 2021. Skeletal muscle cell (SMC) was purchased. Myoblasts and SMCs were treated with cytokine mixture (IFN-r, IL-6, IL-15) or PBS for 30 minutes. The expression of Nox4, MyoD and myosin heavy chain (MYH) in myoblast and myotube was analysed by Western blot. For inhibition of Nox4, OKT157383 (inhibitor of Nox4) was treated before the cytokine stimulation.

**Results:** Myoblasts from IIM patients express higher level of Nox4 compared to healthy myoblasts. When treated with cytokine mixture (IFN-r, IL-6, IL-15), healthy myoblasts or SMC mimicked inflammatory myositis and showed increased expression of Nox4 and decreased expression of MYH similar to myositis phenotype. Nox4 inhibitor suppressed Nox4 expression and MyoD overexpression in inflammatory myoblasts.

**Conclusion:** We showed that Nox4 expression is increased in myoblasts from IIM patients and is associated with impaired muscle regeneration. Nox4 inhibition attenuated Nox4 and MyoD overexpression in inflammatory myoblasts.

**REFERENCES:**

**Methods:**

- **Objectives:** Cardiac fibroblasts and their interaction with immune cells play a crucial role in myocardial healing and tissue remodelling following myocardial injury. In this study, we investigated the role of DYSF, a protein involved in TGF-β signalling, in cardiac fibroblasts.

- **Background:** Myocardial fibrosis, ultimately leading to heart failure (HF), represents a point of convergence for most cardiac disorders. Heart involvement is a common finding in autoimmune rheumatic patients, suggesting a mutual regulation between DYSF and TGF-β stimulation.

- **Methods:** Adult cardiac fibroblasts were isolated from the left atria of patients undergoing heart transplantation due to end-stage HF caused by inflammatory cardiomyopathy (n=5) and from unaffected myocardium of brain-dead donors (Ctrl, n=5). Protein quantification was performed using liquid chromatography tandem-mass spectrometry (LC–MS/MS), and the data analysis was done using pathway enrichment analysis [2]. Selected gene knockdown was achieved through Lipofectamine 2000-mediated siRNA transfection of human foetal PMBCs from 5 idiopathic PAH (iPAH) patients and 16 age- and sex-matched SSc-PAH patients. PMBCs were isolated from 32 age- and sex-matched SSc-PAH in particular.

- **Results:**
  - **Quantitative proteomic analysis of adult cardiac fibroblasts revealed 14 differentially expressed proteins (adj. p<0.05) in HF compared to Ctrl.** The identified proteins belong to biological pathways mainly involved in ECM remodeling and associated with several pathologies, such as atherosclerosis, muscular dystrophy and myocardial ischemia. The most upregulated protein in HF fibroblasts was dysferlin (DYSF, log2FC=5.78, adj. p<0.005), which is known to promote sarcolemma repair in skeletal muscle fibres and cardiomyocytes. Further in vitro study showed that TGF-β stimulation significantly upregulates DYSF gene (n=4, p<0.001) and protein (n=3, p<0.001) expression in cultured HCFs. DYSF silencing upregulated COL1A1 expression in untreated (n=4, p<0.05) and TGF-β-stimulated (n=4, p<0.05) HCFs. On the protein level, DYSF knockdown upregulated the profibrotic transcription factor FOSL2 in untreated HCFs (n=9, p=0.004) and following 72h of TGF-β stimulation (n=9, p<0.001). In turn, FOSL2 silencing in HCFs significantly upregulated DYSF protein level (n=5, p<0.0001) after 72h of TGF-β stimulation, suggesting a mutual regulation between DYSF and FOSL2. Further analysis of autophagy-related proteins revealed that DYSF silencing increases LC3BII expression (n=6, p<0.05) and downregulates P62 (n=6, p=0.01) in TGF-β-stimulated HCFs. Finally, we observed reduced viability of cells subjected to DYSF knockdown in both untreated (n=4, p<0.01) and TGF-β-stimulated (n=4, p<0.05) conditions. DYSF silencing was also associated with decreased ATP production in TGF-β-treated HCFs (n=8, p<0.05).

- **Conclusion:** Proteinomic profiling of human cardiac fibroblasts supported by in vitro analysis identified DYSF as an anti-fibrotic protein compensatory upregulated under immunofibrotic conditions and involved in TGF-β-FOSL2-autophagy axis regulation. This newly proposed candidate may serve as a potential therapeutic target for stimulating fibroblast-induced myocardial regeneration.

**SYSTEMIC SCLEROSIS-RELATED PULMONARY ARTERIAL HYPERTENSION: INNOCENT BYSTANDER OR COVERT ACCOMPlice?**

**Methods:** Peripheral blood mononuclear cells (PBMCs) were harvested from 16 SSc-PAH patients. PBMCs were isolated from 32 age- and sex-matched SSc-nonPAH patients with similar skin distribution and autoantibodies. Finally, PMBCs from 5 idiopathic PAH (PAH) patients and 16 age- and sex-matched healthy controls were collected. Cells were treated with or without uric acid in
soluble form for 24 hours, and subsequently cytokine production was measured by Luminox, and mRNA levels were assessed using qPCR.

Results: Baseline expression of interleukin (IL)-1β and IL-6 was similar in SSc-PAH, SSc-nonPAH, iPAH and healthy controls. On mRNA level, uric acid stimulated PBMCs was similar in SSc-PAH and SSc-nonPAH patients. Similarly, on protein level, production of IL-1β, IL-6 and TNF-α was increased in PAHs from SSc patients compared to iPAH patients and healthy controls. Interestingly, we observed that uric acid-stimulated PBMCs from SSc-PAH patients produced significantly more IL-1β, IL-6 and TNF-α compared to SSc-nonPAH patients.

Conclusion: In this study we demonstrate that soluble uric acid orchestrates an excessive inflammatory response by facilitating more enhanced IL-1β, IL-6 and TNF-α production in SSc-PAH compared to SSc-nonPAH, iPAH and healthy controls. These findings suggest that uric acid not only has a role in the development of SSc-PAH but also contributes to the development of SSc-PAH.

MECHANOTRANSDUCTION VIA MYOSIN II ISOFORMS IN DEVELOPMENT OF SKIN FIBROSIS WITHIN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Cytokines and chemokines, Skin

B. Russo¹, M. Shutoya¹, G. Romanescu¹, N. Brembilla², W. H. Boehncke².

²Hôpitaux Universitaires de Genève (HUG), Dermatology and Venereology, Genève, Switzerland

Background: Skin fibrosis, the hallmark of systemic sclerosis (SSc), is a complex inflammatory process leading to excessive extracellular matrix (ECM) deposition and increased stiffness in the dermis [1]. The mechanical properties of the extracellular environment can be sensed by the cells and transformed into intracellular signalling and gene expression regulation in the process of mechanotransduction. The upregulation of mechanotransduction has been linked to the progression of fibrosis in SSc, particularly through the Rho-ROCK-dependent myosin II pathway, which activates intracellular contractility [2]. Nonmuscle myosin II itself is expressed as three isoforms (NMIIA, NMIB, NMIIC) with common and unique functions. However, the specific role of Rho activation and distinct NMII isoforms in SSc pathogenesis is unknown.

Objectives: To investigate the role of NMII isoform regulation in the development of skin fibrosis in SSc.

Methods: The expression of NMIIA and NMIB, as well as their activation through phosphorylation of Myosin Light Chain (MLC) were evaluated by immunofluorescence in primary fibroblasts from four SSc and four healthy donor (HD), which were stimulated with rTGFβ. The NMII contractility was inhibited with Y-27632, a small molecule inhibitor of ROCK that phosphorylate MLC, or blebbistatin, a small molecule that inhibit NMII. The production of IL-6 and type-I collagen by fibroblasts was assessed by ELISA.

Results: We have observed a re-distribution of NMII isoforms within the intraacellular contractile system and increased MLC phosphorylation in cultured SSc fibroblasts compared to HD. A similar phenotype was observed in HD fibroblasts primed with TGFβ. Treatment of TGFβ-primed HD fibroblasts with Y-27632 or blebbistatin substantially reduced IL-6 and collagen I production.

Conclusion: Our data point to an altered actomyosin cytoskeleton dynamics and force distribution in SSc fibroblasts and indicate that NMII isoforms are required for the TGFβ-dependent secretion of inflammatory cytokines and collagen deposition by fibroblasts.

POTENTIAL DIAGNOSTIC AND PROGNOSTIC SIGNIFICANCE OF ANTI-CARBAMYLATED PROTEIN ANTIBODIES IN THE SPONDYLOARTHROSIS

Keywords: Spondyloarthritis, Biomarkers, Autoantibodies

E. Favaro¹, E. Grapsis¹, M. Prete¹, V. Racanelli¹, F. Perosi¹. ¹University of Bari Medical School, Department of Interdisciplinary Medicine, Bari, Italy

Background: Spondyloarthritis (SpA) include a group of inflammatory rheumatic diseases with different clinical manifestations. The diagnosis of SpA is still a challenge in clinical practice, in that specific serological markers are still missing. Recently, anti-carbamylated protein antibodies (anti-CarP Ab) have been detected in patients with psoriatic arthritis (PsA) and their levels appear to be associated to disease activity [1].

Objectives: The aim of this explorative study was to evaluate the potential role of anti-CarP Ab in the diagnosis and prognosis of peripheral enthesitis or arthropathy (E/A).

Methods: Serum samples and clinical data from 91 patients with peripheral E/A, of which 43 with PsA, 8 patients with uSpA and 40 with E/A responding to disease-modifying antirheumatic drugs (DMARDs) not fulfilling ASAS inclusion criteria (ASAS-) were included. Anti-CarP Ab were detected by indirect ELISA. Serum anti-CarP were also determined in 35 healthy donors (HD).

Results: Anti-CarP Ab were detected in both PsA (14%) and E/A ASAS- (5.2%) patients, being their prevalence significantly higher in PsA patients than in HD (chi-square p=0.019). No anti-CarP Ab were detected in uSpA. Kendall’s correlation analysis showed that in the whole E/A population, anti-CarP Ab levels directly correlated with disease activity (p=0.047), plantar fasciitis (p=0.037) and family history of psoriasis (p=0.012). Anti-CarP Ab levels were also directly correlated with the presence of autoimmune thyroiditis in PsA subgroup (p=0.02), and with family history of psoriasis in E/A ASAS- subgroup (p=0.016).

Conclusion: This study suggests an association of anti-CarP Ab levels and disease activity in peripheral E/A. Whether the presence of anti-CarP Ab in E/A ASAS- may predict evolution in PsA remains to be assessed.

SYNERGISTIC EFFECT OF AT1R-AUTOANTIBODIES AND EXTRACELLULAR VESICLES IN SSC PATHOGENESIS

Keywords: Systemic sclerosis, Innate immunity, Autoantibodies

A. Hackel¹, R. Akkarazadeh¹, M. Leiber², A. Müller², G. Riemekasten².
¹University Clinic Schleswig-Holstein, Lübeck, Germany, Clinic of Rheumatology and Clinical Immunology, Lübeck, Germany
Background: Systemic sclerosis, a rare chronic inflammatory disease, are characterized by immune system activation, vasculopathy, and fibrosis of the body organs. Emerging evidence have so far indicated that autoantibodies (abs) directed against G protein-coupled receptors (GPCRs) particularly contribute to the SSc pathogenesis and induce the release of inflammatory and profibrotic proteins by immune cells such as monocytes [1-3]. Increased levels of autoantibodies against the angiotensin II type 1 receptor (AT1R abs) have been found in SSc patients [4-5], which are associated with increased secretion of extracellular vesicles (EVs) [6]. Interestingly, upregulated CCL18 levels could be associated with AT1R-EVs in SSc patients [8]. EVs play an important role in the pathogenesis of diseases by packing and transfer of AT1R to different tissues and immune cells, exemplary shown by activated cardiomyocytes leading to higher responsiveness to angiotensin [10].

Methods: Monoclonal AT1R ab (AT1R mab) has been generated by hybridoma technique, sequenced and recombinantly expressed in HEK cells. Human peripheral blood monocytes and monocytic cell lines were stimulated by the recombinant monoclonal anti-human AT1R ab and, in comparison, in the presence or absence of EVs precipitated from sera of SSc patients versus sera of HD. The response of the monocytes was measured via CCL18 secretion by ELISA.

Results: We compared CCL18 release, a profibrotic cytokine, of mononuclear cells upon stimulation for 24h with the AT1R mab in presence or absence of sera EVs (SSc vs. HD). The recombinant monoclonal anti-human AT1R antibody induced secretion of CCL18 by monocytes. Our data indicate that EVs together with AT1R mab have an effect on monocyte activation and CCL18 secretion. Remarkably, combination of SSc-EVs, but not of HD-EVs, with the recombinant AT1R mab showed an additive effect on monocyte activation and CCL18 response (Figure 1).

Figure 1. CCL18 levels released by monocyte cells after stimulation with EVs and AT1R mab or isotype.

Stimulation with SSc EV + AT1R mab (n=4), HD EV + AT1R mab (n=3), AT1R mab control, SSc EV + isotype (n=4), HD EV + isotype (n=3) and isotype control. One-way ANOVA was used to test for statistical significance (p<0.05, **p<0.01, ***p<0.001).

Conclusion: The secretion of pro-fibrotic CCL18 by human monocytes in response to a monoclonal AT1R antibody as well as to SSc IgG indicates that anti-AT1R abs are involved in the SSc pathogenesis. Further, this effect could also be due to SSc-EVs potentially presenting anti-GPCR abs to their receptors on immune cells.

THE POSITIVE EFFECT OF VITAMIN D3 AND \( \alpha \)-TOCOPHEROL ACETATE ON PULMONARY ARCHITECTONICS IN AN EXPERIMENTAL MODEL OF SYSTEMIC SCLEROSIS

Keywords: Animal models, Lungs, Systemic sclerosis

B. Doskaliuk1, L. Zaiats1, R. Yatsyshyn2. Ivano-Frankivsk National Medical University, Pathophysiology, Ivano-Frankivsk, Ukraine; Ivano-Frankivsk National Medical University, Internal Medicine #1 Clinical Immunology and Allergology, Ivano-Frankivsk, Ukraine

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by a wide range of clinical manifestations. One of the main targets of this pathology is the pulmonary system. In turn, SSc-associated damage of lung structures is characterized by a significant negative impact on the survival and quality of life of patients.

Objectives: Therefore, we aimed to assess the possible favorable influence of vitamin D3 (VD3) and \( \alpha \)-tocopherol acetate (ATA) on the morphological structure of lungs' parenchyma in the experimentally induced SSc.

Methods: We assembled our experimental animals into three groups: a control group (CG) (20 animals), an experimental group (EG) #1 (25 animals), and #2 (25 animals). Experimental animals were mature laboratory rats, belonging to the Wistar line, and were 180-220 g of weight. Animals in EG #1 were injected with sodium hypochlorite (NaClO) according to the reported previously schedule [1] for SSc modeling purposes. Laboratory animals of the CG were receiving isotonic solution according to the same scheme. In EG #2, rats were subjected to intramuscular injections of ATA solution 10 mg/100 g of body weight, and of a VD3 solution 1000 IU/100 g of body weight for 3 weeks (second half of the experiment performance). All three groups of animals were removed from the experiment 8 weeks after its beginning. The lung tissue specimens were examined with light (Leica DM750, x200 magnification) microscopy. Data distribution was evaluated with descriptive statistics, and a p<0.05 was considered statistically significant. Statistical analysis was carried out using IBM SPSS version 26. Results: The lung parenchyma samples obtained from CG did not show statistically significant deviations from the normal histological picture. (Figure 1A). The histological analyses of lung specimens of experimental animals revealed non-specific interstitial pneumonia (NSIP) which is the most common type of SSc-associated interstitial lung disease (ILD) (Figure 1B). There were productive and sclerotic modifications of the interalveolar septum, their infiltration by the lymphoid and plasma cells with significant disfigurement of alveolar structure. (Figure 1B) Furthermore, the sclerotic alteration of the alveolar-capillary barrier was less prominent compared to EG #1 specimens. The Ashcroft score was significantly higher in EG#1 (3.7±0.6) compared to EG#2 (1.8±0.3) (p<0.05) and CG (0.6±0.1) (p=0.05).

Conclusion: This study confirms the positive effect of vitamins D3 and \( \alpha \)-tocopherol acetate on morphological structure of pulmonary parenchyma in the preclinical model of SSc.

Background: There is growing evidence supporting an association between gut microbiota and the risk of systemic sclerosis (SSc)[1]. However, the causal relationship between gut microbiota and SSc remains ambiguous.

Objectives: A two-sample Mendelian randomization (MR) analysis was performed to reveal the causal relationship between gut microbiota and SSc.

Methods: We obtained data on intestinal flora from the MR-base website [2] and 218,499 samples for systemic sclerosis from the IEU database for a two-sample MR analysis. Inverse variance-weighted estimates indicated that genus Collinsella (odds ratio(OR) = 8.982, 95% confidence interval(CI): 1.571-51.366, P = 0.014), genus Actinobacteria (OR = 5.746, 95% CI: 1.247-26.491, P = 0.025), genus Ruminococcaceae (OR = 5.500, 95% CI: 1.477-20.477, P = 0.011) had a risk effect on SSc (Table 1). According to the results of the reverse MR analysis, SSc had no significant causal effect on intestinal flora. No significant heterogeneity or horizontal pleiotropy of instrumental variables was found.

Results: Inverse variance-weighted estimates indicated that genus Collinsella (odds ratio(OR) = 8.982, 95% confidence interval(CI): 1.571-51.366, P = 0.014), genus Actinobacteria (OR = 5.746, 95% CI: 1.247-26.491, P = 0.025), genus Ruminococcaceae (OR = 5.500, 95% CI: 1.477-20.477, P = 0.011) had a risk effect on SSc (Table 1). According to the results of the reverse MR analysis, SSc had no significant causal effect on intestinal flora. No significant heterogeneity or horizontal pleiotropy of instrumental variables was found.

We aimed to investigate the role of early use of quadruple therapy (high dose steroids, one dose of cyclophosphamide, tofacitinib, rituximab) in patients with anti-MDA5 Ab-positive DM with RP-ILD when treated early with quadruple therapy.

Methods: This is a retrospective case series involving 4 patients with anti-MDA5 Ab-positive DM with RP-ILD from 2019 to 2021. They were treated with quadruple therapy. Their clinical outcomes including survival and adverse events were evaluated.

Results: At initial diagnosis of RP-ILD, all patients were given pulse methylprednisolone and 1 dose of cyclophosphamide. Tofacitinib was started within 2 weeks, followed by rituximab. 3 patients achieved clinical and biochemical improvement over time, with reduction of glucocorticoids by 6 months. Of the 4 patients, 1 required ICU stay and died. Severe adverse events were observed, most of which were infective complications.

Background: MDA5 autoantibodies have been associated with an amyopathic form of dermatomyositis, with a subset developing RP-ILD with high mortality of 50%, despite intensive immunosuppressive therapies like high dose prednisolone, cyclophosphamide and calcineurin inhibitors.[1] Tofacitinib and rituximab have also been used as single agents, mainly as salvage therapy. [2]

Objectives: We aimed to investigate the role of early use of quadruple therapy (high dose steroids, one dose of cyclophosphamide, tofacitinib, rituximab) in patients with anti-MDA5 Ab-positive DM with RP-ILD.

Conclusion: We report a general improvement of survival in anti-MDA5 Ab-positive DM with RP-ILD when treated early with quadruple therapy.

Vasculitis - aetiology, pathogenesis and animal models

AB0162

RELATIONSHIPS BETWEEN THE SIGNALING PATHWAY OF BAFF/APRIL AND CIRCULATING B CELLS IN ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Keywords: Vasculitis, Cytokines and chemokines

Y. Shimopjima, D. Kishida, T. Ichikawa, R. Takamatsu, S. Nomura, Y. Sekijima. Shinshu University School of Medicine, Department of Medicine (Neurology and Rheumatology), Matsumoto, Japan

Background: Increased production of B-cell activation factor of the TNF family (BAFF) and a proliferation-inducing ligand (APRIL) have been identified in anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV). BAFF and APRIL exhibit biological activities by binding to three different types of receptors: BAFF-receptor (BAFF-R), transmembrane activator and calcium regulator on thyrocyte (TACI), and B-cell maturation antigen (BCMA). Meanwhile, it is uncertain how these three receptors could express or be altered depending on disease activity in AAV.

Objectives: We investigated the characteristics of circulating B cells, serum levels of BAFF, and APRIL, as well as the expression of their binding receptors on B cells, and the relationships among them in patients with AAV.

Methods: This study used peripheral blood samples from 24 patients with active AAV (a-AAV), 13 with inactive AAV (i-AAV), and 19 healthy controls (HC). The proportion of B-cell subsets, including CD19+ cells, CD19+CD27-CD38- (immature B) cells, CD19+CD27+CD38+ (memory B) cells, and CD19+CD27-CD38+ cells (plasmablasts/plasma cells: PB/PC), and their expressing BAFF-R, TACI, and BCMA were analyzed using flow cytometry. Serum levels of BAFF, APRIL, and interleukin (IL)-6 were also evaluated using an enzyme-linked immunosorbent assay. The relationships among these experimental results were statistically analyzed using univariate regression analyses.

Results: The proportion of PB/PC was significantly higher in a-AAV than in HC (p < 0.001), Higher serum levels of BAFF, APRIL, and IL-6 were significantly observed in a-AAV than in HC (p < 0.001), while serum levels of BAFF and APRIL were significantly higher in i-AAV than in HC (p = 0.003 and p = 0.005, respectively). BAFF-R expression on memory B cells was significantly lower in the patients with a-AAV and i-AAV than in the HC (p = 0.017 and p = 0.006) but not significantly different between patients with a-AAV and i-AAV. Expression of TACI was significantly higher in a-AAV and i-AAV than in HC on CD19+ cells (p = 0.011 and p = 0.028, respectively), immature B cells (p = 0.014 and p = 0.002, respectively), and PB/PC (p = 0.013 and p = 0.011, respectively), despite not being significantly different between the patients with a-AAV and i-AAV. The regression analyses demonstrated that the population of memory B cells was positively associated with serum APRIL levels (coefficient 0.071, 95% confidence interval [CI] 0.035 to 0.106, p = 0.0004) and BAFF-R expression (coefficient 0.0001, 95% CI 0.00006 to 0.0002, p = 0.002).

Conclusion: Decreased expression of BAFF on memory B cells and increased expression of TACI on CD19+ cells, immature B cells, and PB/PC, as well as increased serum levels of BAFF and APRIL, were significantly demonstrated even in patients with remission AAV. Our results suggested that the signalling of BAFF/APRIL and their receptors was piovally implicated in the generation of B cells. Furthermore, persistently activated signaling of BAFF/APRIL may lead to disease relapse.

Background: The pathophysiology of Takayasu arteritis (TAK) is incompletely understood. Gene expression profile of peripheral blood mononuclear cells (PBMCs) in TAK has been scarcely studied and may provide new insights into its pathogenesis.

Objectives: To identify and functionally annotate differentially expressed genes (DEGs) in immunosuppressive-naive TAK compared with healthy controls (HCs).

Methods: Fifteen immunosuppressive-naive TAK [10 Females, mean (SD) age 34.13(13.28) years] and 10 healthy controls (HC) [8 females, mean (SD) age 31.8(4.57) years] were recruited after obtaining written informed consent. After isolating PBMCs, RNA was extracted using Trizol method. RNA quality was checked using Nanodrop. Whole gene transcriptome signature was assessed using Affymetrix Genechip Human Exon microarrays. Analysis of gene expression from raw CEL files was normalized (group-averages with standard deviations and gene-level limma) to generate CHP files which were analysed for DEGs (up- and down-regulated), filtered on fold-change in TAK versus HC (≥2 or ≤-2) and p value < 0.05. Thereafter, functional annotation of up- and down-regulated genes was performed using Database for Annotation, Visualization, and Integrated Discovery (DAVID) to evaluate Gene Ontology (GO) clusters and processes.

Results: Of 135750 genes, 558 genes passed filter criteria (up-regulated 185 - Coding 33 (17.84%), micro RNA 1 (0.54%), multiple complexes 93 (50.27%), non-coding 23 (12.43%); down-regulated 373 - Coding 50 (13.5%), miRNA 61 (16.35%), multiple complexes 35 (9.38%), non-coding 190 (50.94%)) (Volcano plot in Figure 1). After functional annotation for 111 up-regulated genes identified on DAVID, two clusters were generated. Cluster 1 (enrichment score 2.20) comprised hemoglobin complex, oxygen transport activity, heme binding, and oxygen binding pathways. Cluster 2 (enrichment score 0.70) comprised JNK cascade, protein kinase activity, and protein phosphorylation. Sixty-seven up-regulated processes were identified (Table 1). Functional annotation for 14 down-regulated genes identified on DAVID identified one cluster (enrichment score 0.76) comprising extracellular exosomes, cytokine, nucleoplasmic, cytoplasmic and protein binding pathways. Four down-regulated processes were identified (Table 1).

Conclusion: We identified an up-regulation of processes related to protein-specific domain binding, serine/threonine kinase activity, magnesium ion binding, oxygen transporter activity, and various cellular components in TAK than in HC.

BIOMARKERS ASSOCIATED WITH GIANT CELL ARTERITIS IN PATIENTS WITH POLYMYALGIA RHEUMATICA FEATURES

Keywords: Vasculitis, Biomarkers

A. Ramon1,2, H. Greigert3,4, C. Cladière2, M. Ciudad2, P. Ornetti1, J. F. Maillefert1, B. Bonnotte2,3, M. Samson2,3.

Background: Polymyalgia Rheumatica (PMR) is a frequent inflammatory rheumatism associated with giant cell arthritis (GCA) in 16-21% of cases. GCA is characterised by large vessel vasculitis which is absent in isolated PMR [1]. The identification of serum biomarkers reflecting vascular involvement could allow the selection of PMR patients without GCA.

Methods: Patients were prospectively enrolled in Dijon University Hospital, France. At inclusion, no patient had yet received glucocorticoids or immunosuppressive treatment. All PMR patients fulfilled 2012 ACR/EULAR classification criteria [2] and GCA was ruled out by at least an exam evaluating temporal arteries (biopsy and/or color doppler ultrasound) and another evaluating large vessels (angio-CT or FDG-PET/CT). All GCA patients fulfilled the 2022 ACR/EULAR classification criteria [3]. Usual clinical, biological, and therapeutic data were recorded at diagnosis. Several serum biomarkers were measured by Luminex assays: CD141, CD146, CD31, ICAM-1, VCAM-1, ANGPTL-4, ANGPTL-6, and C3L1. Student t test or Mann-Whitney test were performed to compare data, as appropriate. The significance threshold was set at P<0.05 (two-tailed). Analyses were performed with Graphpad PRISM software.

Results: Fifty patients with PMR without GCA (isolated PMR) and 33 patients with PMR and GCA overlap were included. In PMR/GCA overlap patients, 14 (42.4%) had aortitis. Serum level of CD141 was significantly higher in the PMR/GCA overlap group in comparison to isolated PMR group (mean = 6854 pg/mL vs. 5558 pg/mL, p = 0.003). The area under cover (AUC) was 0.68 (CI0.56; 0.80). No differences were found regarding serum levels of ANGPTL-4 (p = 0.39), ANGPTL-6 (p = 0.22), CD146 (p = 0.74), CD31 (p = 0.35), C3L1 (p = 0.75), ICAM-1 between PMR/GCA and PMR/GCA overlap. Likewise, no significant differences were found for the usual markers of inflammation between both groups: ESR (p = 0.22), CRP (p = 0.39) or fibrinogen (p = 0.92). Comparison between PMR without GCA and PMR/GCA overlap with aortits found higher level of ANGPTL-4 and ANGPTL-6 in isolated PMR patients (median = 160.7 ng/mL vs. 128.9 ng/mL, p = 0.04) and 4.3 ng/mL vs. 3.1 ng/mL (p = 0.02), respectively). CD141 was positively correlated with CD146 (r = 0.40; p = 0.08), CD31 (r = 0.34; p = 0.05) and VCAM-1 (r = 0.42; p = 0.05) in isolated PMR patients. ANGPTL-4 and ANGPTL-6 could be interesting serum biomarkers to select aortitis in patients with PMR features.

Conclusion: This study found lower serum concentrations of CD141 in PMR patients without GCA versus those having PMR and GCA overlap. However, the diagnostic performance of CD141 does not appear to be sufficiently discriminative to rule out GCA in PMR patients. ANGPTL-4 and ANGPTL-6 should be considered as potential novel targets for aortic involvement during GCA.

IGAV AND IGAN: A SINGLE ENTITY REGARDING CD40, BLK AND BANK1 POLYMORPHISMS

Keywords: Adaptive immunity, Vasculitis

Background: In this work, we investigated the potential role of adaptive immunity in the pathogenesis of idiopathic giant cell arteritis (IGAV) and idiopathic giant angiitis nodosa (IGAN). IGAV and IGAN are both vasculitides with aetiologies and pathogenic mechanisms still unclear. The CD40-CD40L interaction is an important part of adaptive immunity, mediating immune activation. This study aimed to determine the role of the CD40-CD40L interaction and its polymorphisms in the susceptibility to IGAV and IGAN.

Results: This study found lower serum concentrations of CD141 in PMR patients without GCA versus those having PMR and GCA overlap. However, the diagnostic performance of CD141 does not appear to be sufficiently discriminative to rule out GCA in PMR patients. ANGPTL-4 and ANGPTL-6 could be interesting serum biomarkers to select aortitis in patients with PMR features.
Background: IgA vasculitis and IgA nephropathy (IgAN) are inflammatory conditions that share pathophysiological mechanisms, being B-cells crucial players in both diseases [1]. In this regard, some authors have suggested that IgAV and IgAN may represent different outcomes of a continuous spectrum of a disease [2]. In addition, CD40, BLK and BANK1 are relevant genes involved in the development and signalling of B-cells and are also identified as susceptibility loci for several immune-mediated diseases [3-6].

Objectives: To determine whether IgAV and IgAN may be different outcomes of a single disease, by assessing the CD40, BLK and BANK1 genetic pattern.

Methods: Three genetic variants within CD40 (rs1983382, rs1535045, rs4813003), three genetic polymorphisms within BLK (rs2254546, rs2736340, rs2618476) as well as two BANK1 genetic variants (rs10516487, rs37331917) were genotyped in 380 Caucasian patients diagnosed with IgAV, 90 patients diagnosed with IgAN and 1,012 ethnically matched healthy controls. The eight polymorphisms selected were previously associated with several inflammatory diseases [3-6].

Results: Similar genotype and allele frequencies were observed in IgAV patients when compared to those with IgAN, when CD40, BLK and BANK1 variants were analyzed independently (Table 1). In addition, no statistically significant differences were observed between patients with IgAV and healthy controls as well as between patients with IgAN and healthy controls, when CD40, BLK and BANK1 genetic variants were analyzed independently (Table 1). Similar results were disclosed when haplotype frequencies of CD40, BLK and BANK1 were compared between patients with IgAV and those with IgAN, as well as between patients with IgAV and healthy controls and between IgAN and healthy controls.

Conclusion: Our results reveal a similar CD40, BLK and BANK1 genetic distribution in IgAV and IgAN, supporting that IgAV and IgAN may represent different outcomes of a single disease.

AB0167 SINGLE-CELL SPATIAL TRANSCRIPTOME ANALYSIS IDENTIFIES DISEASE-SPECIFIC FBROBLASTS IN RHEUMATOID VASCULITIS

Keywords: Vasculitis, Rheumatoid arthritis, Biomarkers

Background: Spatial transcriptome analysis is an advanced technique that adds spatial information to gene expression analyses to identify differences in gene expression based on the location in specimen tissues. It can also provide disease-specific gene expression data in individual cells. This method has the potential to identify important gene expression related to disease pathogenesis, which cannot be obtained through conventional bulk analysis. CosMo® Spatial Molecular Imaging (SMI) is a platform for spatial transcriptome analysis of formalin-fixed paraffin-embedded tissue samples at subcellular resolution (NanoString® Technologies, Seattle, WA, USA). The use of high-plex in situ hybridization followed by cyclic hybridization of immunofluorescent detection reagents and imaging enables the localization and identification of approximately 1,000 RNA targets in situ, and antibody-based, machine learning-augmented cell segmentation with nuclear and membrane markers localizes these targets to individual cells[1]. Cutaneous vasculitis is characterized by vasculitis of small-sized vessels of the skin and causes skin lesions, such as purpura or ulcers, resulting in a low quality of life. A variety of autoimmune diseases can cause cutaneous vasculitis, but its pathogenesis is unknown. In particular, cutaneous vasculitis associated with rheumatoid arthritis (RA) (referred to as rheumatoid vasculitis) is often difficult to treat and is associated with high rates of premature mortality[2]. Histologically, cutaneous vasculitis associated with autoimmune diseases is characterized by fibrinoid degeneration or neutrophilic inflammation, which may target to individual cells[1]. Cutaneous vasculitis is characterized by vasculitis of small-sized vessels of the skin and causes skin lesions, such as purpura or ulcers, resulting in a low quality of life. A variety of autoimmune diseases can cause cutaneous vasculitis, but its pathogenesis is unknown. In particular, cutaneous vasculitis associated with rheumatoid arthritis (RA) (referred to as rheumatoid vasculitis) is often difficult to treat and is associated with high rates of premature mortality[2]. Histologically, cutaneous vasculitis associated with autoimmune diseases is characterized by fibrinoid degeneration or neutrophilic inflammation.
vasculitis; however, these findings are nonspecific and do not lead to a precise diagnosis.

**Objectives:** In the present study, we aimed to identify disease-specific cell types and gene expression via single-cell spatial transcriptome analysis of skin tissues from patients with autoimmune disease-associated cutaneous vasculitis. This can lead to improved diagnosis, pathogenesis understanding, and treatment.

**Methods:** Single-cell spatial transcriptome analysis was performed using NanoString’s CosMx™ SMI on tissues from vasculitis associated with five autoimmune diseases, including rheumatoid vasculitis, and a case with toxic rashes as controls. Following data collection, NanoString's data processing pipeline was used to identify transcripts, define cell locations and boundaries, and count the number of transcripts per cell to determine the expression profiles for each cell. Cell types were inferred from these expression data using InSilicoType[3] and a reference Human Cell Atlas skin dataset. Immunostaining was performed to validate the identified gene markers.

**Results:** A total of 35,503 cells and 4,530,981 transcripts were analyzed. Clustering of cells based on gene expression levels revealed cells with a high expression of several specific genes, including MMP1, in rheumatoid vasculitis. CosMx™ SMI analysis revealed that these cells were primarily located in the perivascular area (Figure 1A). Immunostaining with anti-MMP1 antibody (1:100; ab52631, Abcam) revealed that the cells were histologically fibroblasts (Figure 1B). These findings revealed that fibroblasts expressing MMP1 are specific to rheumatoid vasculitis. MMP1 is highly expressed in synovial fibroblasts in RA and plays a substantial role in disease pathogenesis[4]. Our results suggest that disease-specific fibroblasts expressing MMP1 are involved in the pathogenesis of rheumatoid vasculitis. The pathological roles of MMP1 and other markers merit further investigation.

**Conclusion:** Single-cell spatial transcriptome analysis revealed fibroblasts specific to rheumatoid vasculitis. The result of this study might contribute to understanding of etiology and treatment of rheumatoid vasculitis.

**IMBALANCE IN THE TAXONOMIC COMPOSITION OF GUT MICROBIOTA IN TAKAYASU ARTERITIS**

**Keywords:** Gastrointestinal tract, Vasculitis

T. Shirai1, S. Watanabe2, N. Shinozaki2, K. Baba3, H. Yamasaki2, T. Ishii1, H. Fujii1, 1Tohoku University Hospital, Rheumatology, Sendai, Japan; 2Cycinso, Inc., Research Project Office, Tokyo, Japan

**Background:** Takayasu arteritis (TAK) is one form of the large vessel vasculitis and predominantly affects young female. TAK sometimes coexists with other inflammatory diseases which include ulcerative colitis (UC) and spondyloarthropathy. Recent evidences revealed close genetic background between TAK and these diseases, and we found the common autoantibodies against endothelial protein C receptor among TAK and UC. These evidences suggest the common underlying pathophysiology among these diseases. UC and spondyloarthropathy are known to be associated with dysbiosis. Therefore, the involvement of dysbiosis in the pathogenicity of TAK is possible. However, little is known regarding the composition of gut microbiota in TAK.

**Objectives:** This study aimed to investigate whether there existed the imbalance in the taxonomic composition of gut microbiota in TAK.

**Methods:** 31 patients with TAK who satisfied the classification criteria of American College of Rheumatology 1990 and 31 background-matched healthy controls (HC) were included in this study. Feces were collected from each individual, and fecal microbial DNA was isolated. 16S rRNA gene amplicon sequencing was performed to analyze the microbiota. Microbial richness and β-diversity were compared among HC and TAK, and the differences in the abundant taxa were analyzed by the LEfSe algorithm.

**Results:** The clinical background of each group was as follows; the mean age, 41 years; female, 87%. The disease activity of TAK was assessed using the Indian Takayasu arteritis score (ITAS)-A, and 17% were in an active disease status when they collected feces. Then, 16S rRNA gene amplicon sequencing was successfully performed using microbial DNA extracted from the collected feces. Microbial richness was compared between HC and TAK using the Shannon index, which revealed significant decrease of microbial richness in TAK patients (P=0.02), β-diversity between HC and TAK was next investigated, and approximately half of the patients with TAK were clearly separated from the clusters of HC. Therefore, the presence of dysbiosis in TAK was confirmed even in the condition in which most of patients with TAK were in inactive status. Analysis of composition of microbiomes (ANCOM) showed abundance of eight and 10 genera in TAK and HC, respectively with the cut-off of centered log ratio as 1. Cladograms showed changes in the microbiota, in which each level of phylum, class, order, family, and genus were related. Differential microbiota at the genus level were observed at a linear discriminant analysis threshold of >2.0. Altered microbial genera in our study included enrichment of Streptococcus, Lactobacillus, Veillonella, Enterococcus, Dialister, Actinomyces, Sardovia, Selenomonas, Rothia, and Campylobacter. More numbers of genera were depleted in TAK, which included Bacteroides, Phascolarctobacterium, Dorea, Parasutterella, Barnesiella, and Acidaminococcus. Importantly, enrichment of oral bacteria species was documented in most of the patients with TAK. Among them, two cases were complicated with infectious endocarditis during the treatments with tocilizumab, suggesting the contribution of dysbiosis for such complication in TAK.

**Conclusion:** Significant imbalance of gut microbiota was observed in TAK. The diversity of fecal microbiota was reduced in TAK, and altered genera were relevant for the exacerbation of inflammation. Dysbiosis could be related to the exacerbation of inflammation and the complications in TAK.

Background: Neutrophils play a key role in ANCA-associated vasculitis, where they are both targets of autoimmunity and facilitators of vascular damage.

Objectives: This study analyzed the production of reactive oxygen species (ROS) in neutrophils from patients with granulomatosis with polyangiitis (GPA) and investigated its associations with IL-1-related cytokines and proteinase 3 (PR3).

Methods: Thirty-eight GPA patients with a disease flare were included in the NEUTROVASC prospective clinical study. ROS production was evaluated in peripheral blood neutrophils of patients with active GPA and compared to the same patients after 12 months of immunosuppressive treatment in remission as well as to healthy controls. Associations between ROS production, membrane expression of PR3 on neutrophils and serum levels of IL-1-related cytokines were analyzed.

Results: Under basal conditions, neutrophils from patients with active GPA produced less ROS compared to neutrophils from healthy controls. While there was no intrinsic defect in ROS production when using a pharmacological trigger, there was a robust defect in ROS production in response to physiologic mediators combined with TNF in GPA neutrophils compared with healthy control neutrophils. Serum levels of IL-1-related cytokines were significantly increased in GPA patients, particularly in those with kidney involvement, and levels of these cytokines returned to normal in remission. There was a positive correlation between membrane PR3 expression and ROS production in GPA patients, but not in healthy controls. Similarly, there was a positive correlation between PR3 expression and the serum levels of IL-1-related cytokines in GPA patients.

Conclusion: Our data suggest that membrane expression of PR3 links ROS production and regulation of inflammation in patients with GPA and may be a potential therapeutic target.

Background: Polymyalgia rheumatica (PMR) is a chronic, inflammatory disorder characterized by aching and stiffness in the proximal regions of the extremities and elevated markers of inflammation. PMR and giant cell arteritis (GCA) are two conditions frequently coexisting [1,2], with increased incidence of large vessel vasculitis and aneurysm development found at long term follow-up. Furthermore, PMR can be one of the manifestations of GCA in 20-40% of cases [3]. The etiology of the diseases are still largely unknown, and specific serological markers, including to monitor arterial disease, are lacking. Recent studies have shown that mitochondrial dysfunction may play a central role in immune activation and could be a potential source of antigens, including mitofusin-1 (MFN1), in autoimmune diseases [4,5,6].

Objectives: To determine whether patients with PMR, with or without overlapping GCA, have elevated levels of markers of platelet activation (e.g. thrombospondin-1, TSP-1), and mitochondrial autoantibodies (e.g. anti-MFN1).

Methods: Plasma levels of anti-MFN-1 IgG and TSP-1 were measured in healthy controls (HC) (n=30) and patients with PMR (n=60), before and after treatment with glucocorticoids using in-house and commercial ELISAs, respectively.

Results: Plasma levels of anti-MFN-1 IgG and TSP-1 were elevated in patients with PMR, compared with HC, both before and after treatment with corticosteroids (p<0.001). The highest levels of anti-MFN-1 and TSP-1 were found before treatment of corticosteroids (p<0.001). Co-existence of GCA did not affect levels of either anti-MFN1 or TSP-1, nor treatment response to corticosteroids. Elevated levels of TSP-1 were found to be significantly elevated in patients with symptoms from hips/glutes (n=39) as compared to patients without these symptoms (n=13), median (P25-P75) 27.11 ug/mL (22.5-53.0) vs 19.6 ug/mL (14.1-273), p=0.046. Lower concentration of anti-MFN1 IgG was found in patients with symptoms from the spine (n=31) in comparison with those without symptoms from the spine (n=21), median (P25-P75) 0.37 U/mL (0.270-0.57) vs 0.54 U/mL (0.470-0.96), p=0.043.

Conclusion: Increased levels of anti-MFN-1 IgG and TSP-1 were found in PMR patients and decreased significantly after treatment with corticosteroids, although still significantly higher than HC. The highest concentration of TSP-1 was found in individuals with symptoms from hips/glutes. Increased concentrations of anti-MFN-1 and TSP-1 are suggested as novel biomarkers for PMR and further, could serve as potential biomarkers for treatment response.

Background: Several mucosal immune defence polymorphisms have an impact on IgΔA production by plasma cells in the mucosa [1]. In this regard, genetic variants have been previously reported as susceptibility loci for IgA nephropathy [1]. Given the pathophysiological similarities described between IgA nephropathy and Immunoglobulin-A vasculitis (IgAV) [2, 3], mucosal immune defense polymorphisms may also be implicated in the pathogenesis of IgAV.

Objectives: To determine whether mucosal immune defence polymorphisms represent novel genetic risk factors for the pathogenesis of IgAV.

Methods: 6 mucosal immune defence polymorphisms previously described as susceptibility loci for IgA nephropathy (ITGAM-ITGAX for IgA nephropathy (rs2412971)) were selected. These 6 genetic variants were genotyped in healthy controls and patients with IgAV. Moreover, no statistically significant differences were observed in the genotype and allele frequencies of these polymorphisms when IgAV patients and healthy controls were compared.

Results: No statistically significant differences were observed in the genotype and allele frequencies of mucosal immune defence polymorphisms when IgAV patients and healthy controls were compared (Table 1). Moreover, no statistically significant differences were disclosed in the genotype and allele frequencies of the 6 polymorphisms selected when patients with IgAV were stratified according to the presence/absence of gastrointestinal manifestations. Likewise, similar genotype and allele frequencies of these polymorphisms were disclosed in patients with IgAV stratified according to the age at disease onset and to the presence/absence of gastrointestinal manifestations.

Conclusions: Our results reveal that mucosal immune defence polymorphisms do not contribute to the genetic background of IgAV.

Objectives: To compare the tumor outcomes in our cohort of GCA vs controls who had TA biopsies. To select a line-up of CD3, IFG, IL12 and FRB as potential anti-tumor proteins and compare their expression in GCA+ TA tissue that did not develop tumors versus GCA -negative tissues that developed tumors. To assess the persistence of this line-up over time.

Methods: We performed a retrospective chart review of GCA subjects and controls to assess development of tumors over long-term follow up. Formalin-fixed paraffin embedded tissue sections were obtained from both groups and immunohistochemical stains were performed using CD3, IFG, IL12 and FRB antibodies. Results: 40 GCA and 40 controls demonstrated similar follow-up durations (76.5 vs 70.1 years; NS), time-to-incident cancer (21 vs 62 mos; NS) and deaths from cancer (5% vs 17.5%; NS). GCA subjects were older than controls (77.2 vs 69.7 years; p=0.004). Cancer incidence is lower in GCA than controls (25% vs 47.5%; p=0.036). The incident cancers in GCA include 8 basal or squamous cell skin cancer (BCC/SCC) and 1 each of chronic lymphocytic leukemia, thyroid, esophageal and angiosarcoma. The controls had 6 BCC/SCC and 2 breast, skin melanoma and lymphoma, and 1 each of tonsil, parotid, colon, lung, renal, prostate, myelodysplastic syndrome and metastatic disease of unknown primary. Histopathology/IHC Findings: FRB was selectively expressed in macrophages and correlated with IFG, IL12 and CD3 expression. FRB, IFG, IL12 and CD3 expres-

Conclusion: GCA has a lower risk of cancer which was associated with a chronic FRB+macrophage and Th1-polarized anti-tumor autoimmunity.

AB0177 ESTIMATING CAUSALITY FOR POLYARTERITIS NODOSA WITH IL-1, AND IL-10: MENDELIAN RANDOMISATION ANALYSES

Keywords: Cytokines and chemokines, Vasculitis

Y. Zhang1,2, R. Zhao1,2,3, H. Zhang1,2, Y. Hou1,2, S. X. Zhang1,2,3, X. Li1,2,3, C. Wang1,2,3, 1Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China; 2Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China; 3Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Polyarteritis nodosa (PAN) is a primary form of vasculitis characterized by inflammation of primarily medium-sized arteries[1]. Although the etiology of vasculitis is not fully understood, it has been suggested that cytokines (including interleukin-1 (IL-1) and interleukin-10 (IL-10)) are significantly associated with a high susceptibility to vasculitis[2, 3]. However, there is no relevant research to explore the causality and direction of this association between interleukin and PAN.

Objectives: In this study, we intended to detect the causal association between PAN and interleukin using two-sample Mendelian randomization (MR) analysis.

Methods: The summary statistics of PAN were obtained from the FinnGen consortium release data (82 cases and 213145 controls). We also selected genetic instruments associated with IL-1 and IL-10 from the study of Sun et al. (13301 sample size). Initially, SNPs associated with interleukin at the genome-wide significance threshold (p<1x10^-8) were extracted. Afterwards, We used a two-sample mendelian randomization analysis to explore the causal associations between PAN with IL-1, and IL-10. The inverse variance weighted (IVW) was the primary approach to calculating the effect estimates. To increase the IVW estimates, we also used other MR methods, such as MR-Egger, Inverse variance weighted,万亩 grain. We did not find evidence to support a causal association between IL-1α, IL-1β, and IL-10, and PAN.

Conclusion: The results of this study based on genetic data did not support a causal relationship between PAN and IL-1, IL-10.

AB0178 POSTURAL DEFECTS IN CHILDREN AT EARLY SCHOOL AGE - CROSS-SECTIONAL STUDY

Keywords: Physical therapy/physiotherapy, Lifestyles

A. Baranowska1, M. Sierakowska1, A. Owczarczuk2, B. Olejnik3, A. Lankau1, 1Medical University of Białystok, Department of Integrated Medical Care, Faculty of Health Sciences, Białystok, Poland; 2Medical University of Białystok, Faculty of Health Sciences, Białystok, Poland; 3Medical University of Białystok, Department of Developmental Age Medicine and Pediatric Nursing, Białystok, Poland

Background: The physical posture of a person is a movement habit which is formed on a morphological and functional basis, associated with everyday activity. During a person’s life, body posture changes, especially during growth. The first critical period for physical posture is the age of 7-10 years. It is associated with a change in the current lifestyle, with the transition from a large freedom of movement to staying in a sitting position at school for several hours [1-3].

**PAIN SENSITIZATION IN FIBROMYALGIA: THE CROSS-SECTIONAL ASSOCIATIONS BETWEEN MEASURES OF QUANTITATIVE SENSORY TESTING AND FIBROMYALGIA SEVERITY**

**Keywords:** Fibromyalgia, Patient reported outcomes, Biomarkers

P. Steen Pettersen1, T. Haugmark1, I. J. Berg1, T. Neogi2, H. B. Hammer1, H. A. Zangi1,3, I. K. Haugen1, S. Arendt Provan1,4. 1Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; 2Boston University School of Medicine, Section of Rheumatology, Boston, United States of America; 3Vid University College in Oslo, Faculty of Health, Oslo, Norway; 4Inland Norway University of Applied Sciences, Public Health, Elverum, Norway

**Background:** Whether patient's experience of fibromyalgia severity is related to measures of pain sensitisation assessed by quantitative sensory testing is not clear. How disease duration effects the relationship between disease severity and pain sensitisation changes is also unknown.

**Objectives:** To examine the associations between pain sensitisation and fibromyalgia disease severity, as measured by the Polysymptomatic Distress scale (PDS) and Fibromyalgia Impact Questionnaire (FIQ). Secondly, to examine the impact of disease duration on the associations.

**Methods:** Participants were recruited from referrals to a hospital clinic and the diagnosis verified by a specialist rheumatologist. Patients self-reported PDS and FIQ. Quantitative sensory testing included assessments of pressure pain threshold (PPT), temporal summation (TS) and conditioned pain modulation (CPM) were performed. PPT was tested 3 times at 5 predifined sites (a non-painful interphalangeal joint, dorsal radio-ulnar joint, lateral epicondylic of the elbow, middle surface of the trapezius muscle, and tibialis anterior muscle) using an algometer (FPX1 25). The pressure at which the patient first reported a slight pain was recorded, and the mean PPT values at each site and for all measurements (aggregated mean) were calculated. Lower PPT's indicate more pain sensitization. TS was estimated using probes of increasing weight that were tapped against the radioulnar joint. Pain was recorded on a numeric rating scale for the 1st, 5th, and 10th tap of the probe that elicited a pain ≤ 4 on a 0-10 scale. The maximum difference in pain between the 1st and either 5th or 10th tap was calculated, and an increase in pain during repetitive stimuli indicate TS. PPT was also tested before and after a conditioning stimulus with a blood pressure cuff around the contra-lateral arm, and the ratio of the PPT's (post:pre) was calculated. A positive ratio indicates adequate CPM. Cut-offs of pain sensitization were defined as PPT < median, TS ≥ 2 and CPM < 1. Disease duration was dichotomized at ≤ 5 vs. > 5 years. The associations between quantitative sensory testing and disease severity were explored in linear regression models adjusted for age, sex and body mass index and interactions with disease duration were explored.

**Results:** A total of 78 patients (90% women, mean age 40.9 years (SD 73)) were recruited. In linear regression models, aggregated mean PPT was weakly associated with the PDS score, the FIQ total score and the pain, fatigue and depression components (Table 1). The mean PPT's from the trapezius and tibialis anterior muscles were also weakly but significantly associated with several components of the PDS and FIQ. TS was weakly associated with the anxiety and depression components of FIQ while there was no association between CPM and PDS or FIQ (Table 1). We found no evidence of disease duration being an effect modifier for the associations.

**Conclusion:** In this cohort of patients with clinically verified fibromyalgia, pain sensitisation was weakly associated with self-reported disease severity. Disease duration did not impact on the relationship. Our results point to the multifactorial nature of the fibromyalgia symptom burden.

PAIN SENSITIZATION IN ADOLESCENCE: MUSCULOSKELETAL PAIN HISTORY AND EXPERIMENTAL PAIN RESPONSES IN A POPULATION-BASED COHORT STUDY

Keywords: Pain, Patient reported outcomes, Epidemiology

R. Lucas1, M. Brandão1, F. Fernandes1, S. Holden2, M. Talih3, T. Graven-Nielsen4. Instituto de Saúde Pública da Universidade do Porto (ISfUP), EPIUnit, Porto, Portugal; 5Aalborg University Centre for Neuroplasticity and Pain, Aalborg, Denmark; 6Faculdade de Medicina da Universidade do Porto - FMUP, CISPFEM, Porto, Portugal

Background: Prolonged exposure to pain may induce sensitisation through neuroplastic processes, resulting in gain/loss of function and alteration of signal processing, and probably playing an important role in the experience and chronification of pain. Quantitative sensory testing (QST) assesses responses to standardised stimuli, allowing for an estimation of the effects of health conditions on somatosensory function [1]. Sensitized pain mechanisms are often reported in adults with musculoskeletal pain conditions, but population-based pediatric studies are lacking.

Objectives: To investigate the association between reported musculoskeletal pain history (based on complementary criteria) and pain sensitisation measures at age 13 years in a population-based cohort. We hypothesised that adolescents reporting more adverse musculoskeletal pain experiences would have higher pain sensitivity, impaired anti-nociceptive and/or facilitated pro-nociceptive mechanisms.

Methods: We analyzed data from 1496 adolescents of the population-based Generation XXI birth cohort study in Porto, Portugal. Pain history was collected using the Luebeck Pain Questionnaire (self-reported at 13 years, parent-reported at 7 and 10 years). Musculoskeletal pain was considered present if reported in the back, neck, shoulder, upper/lower limbs, hips, or widespread musculoskeletal. Three case definitions for adverse musculoskeletal pain history were used: 1) chronic (3+ months) musculoskeletal pain at age 13; 2) musculoskeletal pain with an impact on daily living (school and/or hobbies) at age 13; and 3) musculoskeletal pain at age 13 together with previous musculoskeletal pain reports at ages 7 and/or 10 (reported in previous data collection waves). Lower limb cuff pressure algometry was collected using the Luebeck Pain Questionnaire (self-reported at 13 years, parent-reported at 7 and 10 years). Musculoskeletal pain was considered present if reported in the back, neck, shoulders, upper/lower limbs, hips, or widespread musculoskeletal. Three case definitions for adverse musculoskeletal pain history were used: 1) chronic (3+ months) musculoskeletal pain at age 13; 2) musculoskeletal pain with an impact on daily living (school and/or hobbies) at age 13; and 3) musculoskeletal pain at age 13 together with previous musculoskeletal pain reports at ages 7 and/or 10 (reported in previous data collection waves). Lower limb cuff pressure algometry was conducted at age 13 using a computerized system coupled with a visual analogue scale for pain intensity rating. We extracted pain sensitivity (pain detection and tolerance thresholds), conditioned pain modulation (CPM, changes in thresholds in the presence of a distant painful conditioning) and temporal pain summation (TSP, changes in pain intensity to ten phasic painful cuff stimulations). Non-parametric tests were used to compare QST parameter distributions.

Results: Adolescents with musculoskeletal pain at age 13 who had a history of musculoskeletal pain at ages 7 and/or 10 had lower pain tolerance thresholds compared to the remaining sample (mean 40.2 vs. 49.0 kPa, p=0.020) and lower pain detection threshold point estimate (14.5 vs. 18.2, p=0.072). Slightly lowered pain tolerance was also found in adolescents with musculoskeletal pain with an impact on daily living at age 13 (42.4 vs. 49.0, p=0.091). No differences were found for pain sensitivity measures according to the presence of pain lasting 3+ months at age 13. No differences were found for CPM-effects and TSP-effects according to pain history regardless of the case definition used.

Conclusion: Repeated musculoskeletal pain up to age 13 years may contribute to lower pain tolerance in the general adolescent population. This does not seem to be the case when reported pain experiences are recent or when the outcomes are temporal pain summation or conditioned pain modulation. In this community-based sample the vast majority showed no sign of altered central pain processing but a small fraction with longer pain experiences may reveal some pain sensitization at age 13 years.

CONDITIONED MEDIA FROM PRIMARY OA CHONDROCYTES AFFECT THE BEHAVIOUR OF PHEOCHROMOCYTOMA PC 12 CELLS

Keywords: Pain, Cartilage, Osteoarthritis

R. Steinecker-Frohnwieser1, S. Toegel2, V. Galianz2, L. Weigl3. Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Department for Rehabilitation, Saalfelden, Austria; 4Department of Orthopedics and Trauma-Surgery, Medical University of Vienna, Department of Orthopedics and Trauma-Surgery, Vienna, Austria; 5Department of Special Anesthesia & Pain Therapy, Medical University of Vienna, Department of Special Anesthesia & Pain Therapy, Vienna, Austria

Background: Osteoarthritis (OA) is the most common joint disease characterized by progressive degradation of articular cartilage, synovial hyperplasia, bone remodeling and angiogenesis [1]. Symptomatic painful OA leads to psychological distress and significant restrictions in daily living. Shortening of work life accompanied by an exponential rise in healthcare costs causes OA to become a major socio-economic burden [2]. Although, OA induced pain represents the most frequent cause of chronic pain, its mechanisms are poorly understood and treatments are not satisfactory [3].

Objectives: It is of great interest to investigate whether OA-induced changes in chondrocyte metabolism can affect neurons. Neurons with increased expression of neurogenic markers could contribute to enhanced pain perception. An investigation of the influence of conditioned media from primary OA chondrocytes on PC12 cells may serve to elucidate interactions.

Methods: PC12 cells, have been treated with conditioned media from primary OA chondrocytes (pCH-OA) and tested for changes in expression by RNA sequencing. Expression of neurogenic markers nestin, microtubule-associated protein 2 (Map2) and tyrosine hydroxylase (TH) from PC12 cells after treatment were analyzed by qPCR. Screening of the conditioned media for relevant factors was performed by using a cytokine/chemokine profiler array. Electrophysiological measurements were performed by the patch clamp method on rat dorsal root ganglia neurons (DRGs) treated with specific cytokines.

Results: RNA sequencing of treated PC12 cells showed changes in expression profile when cells were treated with conditioned media from pCH-OA and HC control chondrocytes compared with standard differentiation and growth media, respectively. Specific qPCR for the neuronal differentiation markers nestin, Map2, and TH showed an increase in expression in PC12 cells induced by most of the conditioned media from pCH-OA cells tested. In particular, Map2 and TH were increased by treatment in almost all conditioned media (n=14). Results of a cytokine proteome profilier array showed high levels of IL6, IL8, and MCP1 in conditioned media from pCH-OA cells of different patients. Treatment of DRGs with an interleukin cocktail altered the electrophysiological behavior tested by the patch-clamp technique and provided the first evidence that chondrocytes might secrete neuromodulatory substances.

Conclusion: Changes in the electrophysiological behavior of neurons caused by OA and the identification of the responsible metabolites should help to shed more light on the process of neuronal sensitization and pain generation in the development of OA in more detail and at the molecular level. In addition, the results also suggest that there are individual responses in individual patients. This information lays the groundwork for explaining why differences in pain perception may vary among OA patients and why there are different pain phenotypes in OA.

**DEVELOPMENT AND VALIDATION OF THE PLACEBO SENSITIVITY QUESTIONNAIRE (PSQ): CAN THE PSQ PREDICT PLACEBO ANALGESIA RESPONSIVENESS?**

**Keywords:** Treat to target, Pain, Prognostic factors

E. Camerone1, G. Tosi2, M. Di Magro1, D. Romano1, Università degli Studi di Milano-Bicocca, Department of Psychology, Milan, Italy

Background: People respond to placebo to different degrees, and some do not respond at all (Frisalidi et al., 2018). Several studies investigated whether there are psychological aspects that predict these differences, but the results remain heterogeneous (Horing et al., 2014; Kern et al., 2020)

**Objectives:** Here, we develop and validate the Placebo Sensitivity Questionnaire (PSQ), an instrument that measures behaviors potentially related to placebo responsiveness. The idea is to treat placebo as a personality trait, with its own dimensions and its set of marker behaviours, instead of a phenomenon determined by multiple personality traits as it has been done up to now.

**Methods:** 330 individuals completed the initial version of the PSQ along with 9 additional scales measuring psychological traits associated with placebo responsiveness. These data were used to reduce the dimension of the PSQ, identifying a shorter set of predictive items, and to bring evidence of construct validity. A second experiment, currently ongoing, tests the predictive validity of the PSQ using a classic placebo analgesia experimental paradigm. Here, healthy volunteers are administered a placebo cream, presented as a potent analgesic, and receive noxious stimulations by means of thermal stimulation.

**Results:** Principal component analysis revealed a 3-factor structure – Symptoms Exaggeration, Seek for Support, Alternative Medicine Beliefs - and the number of items was reduced from 40 to 19. Construct validity indicated that the PSQ correlates with most of the scales previously associated with placebo responsiveness. For the predictive validity study, which is in due course at the time of this abstract submission, we hypothesise that the PSQ will be successful in discriminating a priori placebo sensitivity and non-responders.

**Conclusion:** The PSQ has the potential to become an important tool for researchers and clinicians working with pain, moving us a step forward toward personalized pain management.

**SENSORY PROFILING IN CLASSICAL EHLERS-DANLOS SYNDROME: EVIDENCE FROM A CASE-CONTROL STUDY REVEALS PAIN CHARACTERISTICS, SENSORY CHANGES AND IMPAIRED PAIN MODULATION**

**Keywords:** Pain, Genetics/epigenetics

M. Colman1,2, D. Wille1,2, I. De Wandele2, L. Rombaut2, A. M. Malfait3,

Background: The Ehlers-Danlos syndromes (EDS) are a paradigm group of rare heritable connective tissue disorders caused by pathogenic defects in genes involved in biosynthesis, fibrillogenesis, and/or supramolecular organization of collagen fibrils in the extracellular matrix (ECM). Joint hypermobility, skin hypertextensibility, abnormal wound healing and easy bruising are among the cardinal clinical features. The classical EDS type, caused by defects in type V or rarely type I collagen, is the most prevalent genetically elucidated EDS type [1]. (Chronic) pain is highly prevalent in individuals with EDS and is one of the foremost reasons these individuals seek medical attention. There is a high use of analgesics, surgery, and physical therapy but these treatment modalities often bring only modest relief at best, and some are associated with unwanted side effects. Few studies, almost exclusively conducted in the molecularly unexplained hypermobile EDS type, have brought limited evidence for neuropathic pain and decreased intra-epidermal nerve fiber density. Interestingly, functional and structural abnormalities of the nervous system and associated pain-related behaviors have also been described in mouse models of EDS [2]. Comprehensive human studies on pain prevalence and pain mechanisms in molecularly solved EDS types are however currently not available, thereby representing a major gap in the study of pain in EDS.

**Objectives:** The primary aim of this cross-sectional study was to identify the sensory profile of individuals with cEDS. Secondly, we aimed to identify the pain characteristics and the emotional-cognitive burden in cEDS.

**Methods:** Nineteen individuals with molecularly confirmed cEDS and 19 healthy matched control were recruited. Sensory profiling included sensitivity to innocuous and noxious stimuli of multiple modalities (electrical, thermal, vibration, touch, pressure) and a parallel and sequential conditioned pain modulation protocol. Moreover, pain characteristics and emotional-cognitive factors that are known to influence pain processing were studied using a set of validated questionnaires (PD-Q, DN4, HADS, HAQ, SF-36, C3, PVAQ, TAMPA scale).

**RESULTS:**

+/-: statistically significant differences; - non-significant

The cEDS cohort showed an altered sensory profile. Higher (p<0.04) detection thresholds for vibration stimuli at the lower limb were found indicating the presence of hypesthesia. Reduced/ altered thermal sensitivity was found with significantly more (p<0.001) paradoxical thermal sensations at the lower limb (usually to heat). Lower pain thresholds were found to mechanical (p<0.001) stimuli at both the upper and lower limbs and to cold (p=0.005) stimulation at the lower limb indicating hyperalgesia. Using a parallel conditioned pain paradigm, significantly (p=0.005 and p=0.046) smaller antinociceptive responses were shown in cEDS suggestive of impaired central pain inhibition.

**Conclusion:** This study represents the first systematic investigation of pain in a genetically defined EDS type. With evidence for sensory changes and impaired pain modulation in cEDS, we provide new insights on the possible role of the ECM in the development and persistence of pain.

INVESTIGATION OF THE RELATIONSHIP BETWEEN PATIENTS WITH ARTHROPLASTY AND PATIENTS WITHOUT ARTHROPLASTY FOR LOWER EXTREMITY OSTEOARTHRITIS IN TERMS OF PAIN COPING STRATEGIES, FUNCTIONAL STATUS AND QUALITY OF LIFE.

Keywords: Quality of life, Osteoarthritis, Pain

B. Malkocy1, N. Elibo2, V. Karatosun3, 1Ege University, Department of Physiotherapy and Rehabilitation, Institute of Health Sciences, Izmir, Turkey; 2Ege University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Izmir, Turkey; 3Dokuz Eylul University, Department of Orthopedics and Traumatology, School of Medicine, Izmir, Turkey

Background: Osteoarthritis (OA) is the most common joint disease worldwide and a major source of pain, disability, and socioeconomic cost [1]. Most of the pain or functional disability induced by these diseases can be improved by the surgery. Arthroplasty currently is considered the international gold standard of treatment the knee and hip joints osteoarthritis [2]. In the literature it was defined that pain can be exacerbated and inhibited by the psychological variable. Except the surgical trauma and social factors, the psychological factors have huge influence on the occurrence of the pain [3]. Pain coping strategies are the person’s responses to manage pain and they are generally classified as active and passive strategies. While active strategies identify as controlling the pain or functioning despite the pain, passive strategies identify as withdrawing and surrendering control over the pain [4]. Pain is very effective factor on the patients’ outcomes after arthroplasty. Some psychological coping strategies have been introduced to minimize the effects of pain, but there are no guidelines to follow to reduce pain, because the psychological interventions are different based on the surgery types, technique mechanism and pain specific information [5].

Objectives: This study aims to investigate the relationship between patients with arthroplasty and patients without arthroplasty for lower extremity osteoarthritis in terms of coping with pain, functional status and quality of life.

Methods: Twenty patients with bilateral arthroplasty (mean age 62.75±12.22) and thirty-two patients with OA (mean age 58.87±9.22) were included in the study. The Pain Coping Inventory (PCI), Timed Up and Go Test (TUG), 5 Times Sit to Stand Test (FTSST), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Short Form (SF)-12 Quality Life Questionnaire administered to the patients.

Results: Demographics were statistically similar in both the lower extremity arthroplasty group (LEAG) and osteoarthritis group (OAG). PCI passive total score, PCI passive worrying, PCI passive retreating, PCI passive resting, PCI active total, PCI active distraction and PCI active reducing demands scores were similar in the groups. PCI active pain transformation score was significantly lower in the OAG. TUG and FTSST were similar in groups. WOMAC pain, WOMAC stiffness, WOMAC physical function and WOMAC total scores were significantly higher in the OAG. SF12 PCS and SF12 total scores were significantly higher in the LEAG than in the OAG. SF12 MOS score was similar between the groups.

Conclusion: This study demonstrated that LEAG have better pain transformation, pain intensity, stiffness, patient reported function and physical component of quality of life compared to OAG. Surgery has been effective in improving function and reducing pain according to the results. The difference in active pain transformation in PCI between groups is thought to be related to this. However, it was determined that psychosocial approaches should be included in pain management in the rehabilitation program of patients with OA and arthroplasty.

THE EFFECT OF KNEE JOINT LOSS ON PROSTHESIS AWARENESS IN LOWER LIMB AMPUTEES

Keywords: Patient reported outcomes, Physical therapy/physiotherapy, Quality of life

G. Karakaş1, S. Topuz2, 1Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

Background: In knee disarticulation, transfemoral and hip disarticulation amputations, unlike transfemoral amputations, the anatomical knee joint is replaced by a prosthetic knee joint. In amputations where the natural knee joint is not preserved, compared to transfemoral amputations; It has been stated that it is difficult to reach the normal functional level and more energy is spent [1]. The closer the amputation level is to the proximal, the more restrictions the amputee has in activities of daily living [2].

Objectives: In this study, we compared the ability of forgetting the prosthesis, which is an indicator of adaptation with the prosthesis, of amputees with and without an anatomical knee joint in daily life activities. The aim of this study is to examine the effect of loss of the knee joint on the ability to forget the prosthesis in daily life in amputees.

Methods: Lower limb amputees aged 18-65 years, who used prostheses for at least 6 months were included in this study. Prosthesis awareness was evaluated with the Forgotten Joint Score-12 (FJS-12) amputee version [3]. The FJS-12 amputee version consists of 12 questions about awareness of the artificial limb during daily living activities. The raw scores are transformed to range from 0 to 100 points, with high scores indicating as a percentage (%) the extent to which the patient can forget the artificial limb, that is, adapt them to their lives. Amputees were divided into two groups with and without knee joint loss. The prothetic awareness scores of the two groups were compared. Independent sample t-test was used to compare the data.

Results: 29 transfemoral amputees (mean age: 37.17 ± 11.05 years; Body Mass Index: 25.21 ± 3.02 kg/m2) were included in the knee joint group. A total of 26 amputees (mean age: 35.07 ± 10.29 years; Body Mass Index: 23.77 ± 3.59 kg/m2) were included in the group without knee joint, including 5 knee disarticulations, 18 transfemoral and 3 hip disarticulations. The groups were similar in terms of mean age, body mass index, and years of prosthesis use (respectively p=0.470; p= 0.143; p=0.980) When the FJS-12 total score means of the groups with and without knee joint were compared, there was a statistically significant difference between the two groups (p=0.017; Z=2.337).

Conclusion: This study showed that loss of the knee joint affects the way amputees perceive their prosthesis. In the absence of a anatomical knee joint, amputees’ attention to their prosthesis is increasing. Amputees with a knee joints focus less on their prostheses in daily life activities. Our study revealed that the knee joint, which is frequently used in activities of daily living, is also a determining factor in the adaptation of amputees to the prosthesis.

**Rheumatoid arthritis - prognosis, predictors and outcome**

**AB0187**
**CONSIDERATIONS OF REALISTIC TREATMENT GOALS BASED ON PREDICTORS OF FRAILTY PROGRESSION IN PRE-FRAIL PATIENTS WITH RHEUMATOID ARTHRITIS: A MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY.**

**Keywords:** Real-world evidence, Prognostic factors, Rheumatoid arthritis

Y. Ohashi¹, N. Takahashii, Y. Sobue², M. Suzuki³, R. Sato¹, M. Maeda¹, D. Kihara¹, K. Kishimoto¹, K. Terabe¹, S. Asai¹, S. Imagama¹, Nagoya University Hospital, Orthopaedic Surgery, Nagoya, Japan; ²Aichi Medical University Hospital, Orthopaedic Surgery, Nagakute, Japan; ³Japanese Red Cross Nagoya Daiichi Hospital, Orthopaedic Surgery, Nagoya, Japan

**Background:** Frailty is a common geriatric syndrome that involves an elevated risk of catastrophic declines in health and function [1]. Rheumatoid arthritis (RA) is an autoimmune disease that causes synovitis in the joints, resulting in a high prevalence of joint deformity (0.5–10% in Japan) [2]. Japan is one of the world’s most rapidly aging societies [3]. Many older adults in Japan are in the pre-frailty category (4), and older RA patients are generally at a greater risk of frailty than the general population. Against this backdrop, the present study aimed to examine predictors of frailty progression in RA patients. Pre-frailty patients with RA were focused on because, in the short term, they are more prone to frailty than robust patients.

**Objectives:** To examine the predictors of frailty progression in pre-frail patients with RA

**Methods:** A total of 287 RA patients who were pre-fraility in 2020 were evaluated on the basis of our observational study data. Of the patients, 55 were robust, 186 were pre-frailty, and 46 were frailty in 2021 and were assigned to the Better, Stable, and Worse groups, respectively. After comparing the characteristics of the patients in the three groups at baseline, the two-year change was assessed with respect to use of DAS28-ESR, HAQ-DI, and methotrexate (MTX); biological and targeted synthetic disease-modifying antirheumatic drugs (b/ts-DMARDs); and steroids. The Better and Stable groups were compared to clarify the difference between the two groups. The Stable and Worse groups were compared by univariate analysis. The predictors of transitioning to the Worse group were assessed by logistic regression analysis.

**Results:** At baseline, mean DAS28-ESR for all groups exhibited low disease activity levels, but only the Worse group deteriorated, eventually reaching moderate disease activity levels. The Better and Stable groups maintained sub-low disease activity over two years (Figure 1A). HAQ-DI in the Worse group was significantly higher than in the other two groups. However, comparing HAQ-DI in the Stable and Better groups, the Stable group was substantially worse (Figure 1B), although there were no differences in the other factors, suggesting an irreversible gap between the two groups. There were no differences in MTX and steroid use among the groups, although the rate of steroid use in the Worse group was slightly higher than in the other two groups over two years (Figure 1C, 1D). On the other hand, b/ts-DMARDs in the Stable group were higher than in the other two groups (Figure 1E). This suggested that most patients in the Stable group required a combination of MTX and b/ts-DMARDs to maintain treat-to-target strategy, unlike the Better group. In comparing the Stable and Worse groups, age, DAS28-ESR, and non-use of b/ts-DMARDs were predictors of frailty progression (Table 1).

**Conclusion:** DAS28-ESR and non-use of b/ts-DMARDs were predictors of frailty progression over two years in pre-frail patients with RA. The ideal treatment goal is to improve from pre-frailty to robust, but a realistic goal is not to worsen from pre-frailty to frailty by using a combination of MTX and b/ts-DMARDs.

**AB0188**
**A BIOINFORMATIC APPROACH TO IDENTIFYING SENSITIZING THERAPEUTICS FOR RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, -omics

J. Raisan¹, J. Gibson², D. Zhang³, A. Bjurson⁴, Ulster University, Life and Health Sciences, Londonderry, United Kingdom

**Background:** Rheumatoid Arthritis (RA) is a systemic and chronic autoimmune disorder that has significant impact on quality of life and work capacity for the patient. Treatment and management of RA is aimed at gaining control of inflammation and alleviating pain, however, achieving remission and low disease activity with minimal toxicity is frequently not possible with the current suite of drugs. Additionally with escalating de novo drug development costs, alternate bioinformatic approaches which scope the potential to repurpose already licenced compounds and their ability to work synergistically have become attractive.

**OBJECTIVES:**
1) Develop, test and refine a bespoke connectivity mapping based bioinformatic pipeline, DrugExpress, with capability of mining treatment response gene signatures using public RNAseq and microarray datasets.
2) Verify treatment response signatures and prioritise novel drugs to generate a list of robust sensitising drugs.

**Methods:** Public RNAseq (GSE198629) and microarray datasets (GSE93777 and GSE24742) were mined based on the presence of DAS score, clinical features, sample size and technological platform. R/Bioconductor packages and Perseus software were used to pre-process and carry out differential expression (DE) analysis to obtain a list of differentially expressed genes (DEGs), based on the cut off criteria of padj < 0.05 and a minimal 2-fold change of expression, and derive gene signatures characteristic of treatment response. DEGs from multiple datasets were combined to create a master gene list consisting of 21 DEGs. Gene Ontology (GO) enrichment analysis was performed on the genes in the master list to identify the top biological pathways. A list of inferred genes involved in each of these pathways was compiled to determine the overall direction of expression with response to treatment. DEGs in the master list were extracted and mapped to Affymetrix probe-set IDs to create treatment response gene signatures to be entered into a scssMap search for candidate drugs. Connectivity mapping (CMap) analysis was used to establish networks between DEGs in the gene signature and FDA approved drugs. P-value and connection score of each reference drug in the CMap was obtained and used to determine statistical significance and perturbation stability.

**Results:** GO enrichment analysis performed on the master gene list identified the top 3 pathways: transport of connexons to the plasma membrane, oligomerization of connexins into connexons, and gap junction assembly. CMap analysis identified a total of 36 statistically significant compounds with a perturbation stability score of 1. Candidate compounds were selected based on whether they enhanced a theoretical response phenotype. The top 3 ranked compounds (by p value) which would induce theoretical reduction in disease activity were: ciclosporin (p-value = 0.0001), demecarium bromide (p-value = 0.0002) and 2-aminobenzensulfonamide (p-value = 0.0002).

**Conclusion:** The analysis using the DrugExpress pipeline illustrates the process of treatment response DEG extraction from public expression datasets.

These response signatures can be used for CMap analysis to predict new compounds for treatment refractive patients and can potentially simulate the effective changes observed in responders. Next step in the pipeline would be to implement in silico toxicity screening methods to identify any contraindications with existing treatments.

THE BEST CARDIOVASCULAR RISK ALGORITHM FOR PREDICTING THE PRESENCE OF CAROTID PLAQUE IN WOMEN WITH RHEUMATOID ARTHRITIS

Keywords: Gender/diversity issues, Rheumatoid arthritis, Cardiovascular disease

I. J. Colunga-Pedraza1, J. R. Azpiri-López2, D. Á. Galarza-Delgado1, V. González-González1, V. M. Beltran-Aguilar1, A. G. Arias Peralta1, N. de Avila González1, J. A. Cardenas-de la Garza1, G. García-Arellano1, V. Hospital Universitario Dr. José Euleterio González, Rheumatology, Monterrey, Mexico; 2Hospital Universitario Dr. José Euleterio González, Cardiology, Monterrey, Mexico

Background: Atherosclerotic cardiovascular disease is the leading cause of death in patients with rheumatoid arthritis (RA). Chronic inflammation increases cardiovascular risk (CVR) in these patients [1]. Heart disease remains the most likely cause of death for women, and a higher risk is established than for men [2].

Objectives: To compare six CVR algorithms with carotid ultrasound findings in women with RA and to identify the algorithm with the cutoff point with the best sensitivity for carotid plaque (CP) detection.

Methods: Cross-sectional, and descriptive study. Patients aged 40 to 75 years who met the ACR/EULAR 2010 classification criteria for the diagnosis of RA. Patients with a history of cardiovascular disease were excluded. CVR was calculated using 6 algorithms: ACC/AHA 2013, FRS-Lipids, FRS-BMI, RRS, QRISK3 and SCORE2. Carotid ultrasound was performed on all study participants, and the presence of CP, defined as diffuse carotid intima-media thickness (cIMT) ≥1.2mm or focal thickness ≥0.5mm, was assessed. Subclinical atherosclerosis was defined as the presence of CP or a cIMT ≥0.8mm. An ROC curve analysis was performed and the cutoff points for each algorithm were determined using the Youden index. Area under the curve (AUC) sensitivity, specificity, and likelihood ratios (LR) were calculated. A value of p≤0.05 was considered statistically significant.

Results: A total of 158 women with a diagnosis of RA were included. The prevalence of CP was 32.3%. Results are shown in Figure 1.

Conclusion: The FRS-Lipids algorithm was one of the best algorithms for the detection of CP in women, with the best sensitivity compared to the other algorithms, however, in the low-risk group none of the algorithms proved to be sufficiently effective in predicting CVR. Therefore, we suggest to consider carotid ultrasound as part of the evaluation in women with RA.

GENDER DIFFERENCES IN OSTEOPOROSIS RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS REFERRED FOR BONE DENSITY ESTIMATION – AN OBSERVATIONAL STUDY

Keywords: Osteoporosis, Epidemiology, Rheumatoid arthritis

M. D. Bokobza de la Rosa1, Z. Sultan2, M. Bukhari3,4, 1Lancaster University, Medical School, Bailrigg, United Kingdom; 2University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom; 3Medical School, Lancaster, United Kingdom; 4University Hospitals of Morecambe Trust, Rheumatology, Lancaster, United Kingdom

Background: Rheumatoid arthritis (RA) is associated with a loss of bone density and fragility fractures [1]. There are few studies that compare bone loss by gender.

Objectives: To study a cohort of RA patients referred for bone mineral density (BMD) estimation.

Methods: RA patients referred to a district BMD scanner in the northwest of England between 2004 and 2019 were included. The cohort was divided by gender and the prevalence of fracture, and risk factors for fractures modelled. Initially, traditional risk factors as defined by FRAX® were compared between men and women and subsequently the ability of those risks to predict fractures were modelled. For the characteristic of secondary osteoporosis, only coeliac disease was included. Comparison was made using Chi-squared test for categorical variables and t-test for continuous variables. Predictors of fracture were modelled using logistic regression.

Results: 2072 patients, mean age 66.97 years (s.d. 11.34) were included, of whom 1628 (78.6%) were females. The mean age was significantly higher in Males at 68.02yrs compared to Females at 66.69yrs (p=0.0284), Height (171.62cm) and Weight (80.97) was higher in males and History of fractures was higher in females (33.11% vs 23.42% - p<0.001), Excess alcohol (6.08% vs 2.58% - p<0.001) and Steroid therapy (46.4% vs 28.62% - p<0.001) were higher in males. All other characteristics had no significant difference except lumbar spine BMD which was higher in men (-0.24 vs -0.82 - p<0.001). A summary of the differences is shown in Table 1.

Yellow – Statistically significant with P<0.05

Conclusion: The study identifies gender differences in the risk factors for fractures in rheumatoid arthritis patients. This will have implications when assessing fracture risk using FRAX® underestimating fracture risk in this population. FHx of fractures was only significant in fractured RA females. Steroid therapy had an idiosyncratic effect and was seen as protective; this was previously described in this cohort [3]. Being a current smoker was only a significant risk factor in males. Finally, Left and Right NOF and lumbar spine BMD were significantly smaller in both fractured genders making a reduced BMD on these sites an important risk factor to consider in any patient with RA.

The strength of this study was the large cohort of rheumatoid arthritis patients included while it was limited by lack of detail on disease activity, treatment and duration. A variety of significant data was found, but further work is required.

Figure 1. ROC curves of the cardiovascular risk algorithms.
to find accurate differences between the risk factors associated with fractures in both genders with RA.

Background: Consideration is needed when using Janus kinase (JAK) inhibitors to treat RA in pts aged ≥65 years or those with cardiovascular (CV) risk factors. The JAK1 preferential inhibitor FIL was generally well tolerated in clinical trials[1]; safety has not been determined in a real-world setting.

Objectives: To report baseline characteristics and up to 6-month safety data from the first 480 pts treated with FIL in the FILOSOPHY study (NCT04871919), and analyze two mutually exclusive subgroups: all FIL-treated pts and CV-risk-positive pts.

Methods: FILOSOPHY is an ongoing, phase 4, non-interventional, European study of pts with RA who have been prescribed FIL for the first time and in accordance with the product label in daily practice. Baseline characteristics and the incidence of select adverse events (AEs) are assessed in pts aged ≥65 years and/or with ≥1 CV risk factor (Table 1), and in those aged <65 years with no CV risk factors.

Results: As of the end of June 2022, 480 pts had been treated: 441 received FIL 200 mg and 39 received FIL 100 mg. Of the 480, 148 (30.8%) were aged ≥65 years; 332 (69.2%) were aged <65 years. In total, 86 (17.9%) were former smokers, 81 (16.9%) were current smokers and 203 (42.3%) were non-smokers (data were missing for 110 pts [22.9%]). In addition to smoking, the most frequent CV risk factors included a history of hypertension (32.3%), a history of dyslipidemia (10.2%) and a family history of myocardial infarction (8.5%; Table 1). 23 pts (4.8%) discontinued treatment due to AEs. Of the 354 pts aged ≥65 years or with ≥1 CV risk factor, infections affected 64 pts (18.1%), 34 (9.6%) had dyslipidemia (10.2%) and a family history of myocardial infarction (8.5%; Table 1). As of the end of June 2022, 480 pts had been treated: 441 received FIL 200 mg and 39 received FIL 100 mg. Of the 480, 148 (30.8%) were aged ≥65 years; 332 (69.2%) were aged <65 years. In total, 86 (17.9%) were former smokers, 81 (16.9%) were current smokers and 203 (42.3%) were non-smokers (data were missing for 110 pts [22.9%]).

ANALYSIS OF ULTRASOUND FINDINGS IN PATIENTS WITH DIFFICULT TO TREAT RHEUMATOID ARTHRITIS

Keywords: Ultrasound, bDMARD, Rheumatoid arthritis

T. Okano1, K. Mamoto1, Y. Yamada1, S. Anno2, A. Yamagai3, Y. Domae3, S. Washida4, Y. Yoshida5, T. Koike6,7, H. Nakamura1,8, Osaka Metropolitan University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan; 2Yodogawa Christian Hospital, Department of Orthopedic Surgery, Osaka, Japan; 3Osaka Metropolitan University Hospital, Central Clinical Laboratory, Osaka, Japan; 4Osaka Metropolitan University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDSD), Osaka, Japan; 5Shirahama Hamayu Hospital, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan

Background: In recent years, the concept of D2TRA (difficult-to-treat rheumatoid arthritis) has become widespread, and D2TRA patients are defined as a state in which activity cannot be controlled even with the use of various molecular-targeted drugs. In this study, we investigated the ultrasound findings of D2TRA patients. However, ultrasound findings in D2TRA patients are unknown.

Objectives: In this study, we investigated the ultrasound findings of D2TRA patients.

Methods: A total of 750 RA patients who underwent ultrasound examination were included. Ultrasound examination was performed at the of bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and
Conclusion: The definition of D2TRA is resistant to multiple mode of bDMARDs/ JAKI. Although, disease activity and inflammatory markers tended to be worse in D2TRA group, there was no statistically significant difference in this study. However, ultrasound findings were significantly worse in D2TRA. Suppression of synovitis might be important to prevent D2TRA. REFEERENCE:

PATIENT-PHYSICIAN DISCORDANCE IN GLOBAL ASSESSMENTS AMONGST SOUTH AFRICANS WITH RA

Keywords: Patient reported outcomes, Rheumatoid arthritis, Outcome measures

S. A. Dini1, B. Hodkinson1. 1University of Cape Town, Rheumatology Division, Department of Medicine, Observatory, Cape Town, South Africa

Background: Discordance between the patient global assessment (PGA) and physician global assessment (PGaH) is well reported in rheumatoid arthritis (RA) and can lead to suboptimal care[1]. There are no published studies on discordance in South African (SA) patients.

Objectives: To measure and explore patient-physician discordance amongst RA patients attending a tertiary SA hospital.

Methods: Consenting adults (≥18 years) with RA completed demographic, clinical and patient-reported outcome measures including Health Assessment Questionnaire-Disability Index (HAQ-DI), FACIT fatigue scale, Hospital Anxiety and Depression Scale (HADS), Brief Pain Questionnaire-short form (BPI-SF), and EuroQOL five dimensions questionnaire (EQSD). Poor socio-economic status (SES) was defined using a pooled index. The Clinical Disease Activity Index (CDAI) was calculated based on the swollen and tender joint counts (SJC and TJC), PGA and PhGA visual analogue scale. Patients were categorized into high, moderate or low disease activity (HDA, MDA and LDA) states. Discordance was calculated subtracting the PhGA score from the PGA and positive discordance was defined as a difference of >2.5 points. Discriminants of PGA and PhGA were also analyzed.

RESULTS: Of 550 patients (467 females), the mean (SD) age and disease duration were 55.8 (12.9) and 10.5 (9.7) years, most were in LDA (47.8%), and 371 (67.4%) had poor SES. Positive discordance was seen in 136 patients (24.7%). Fifteen patients with negative discordance (PGA-PhGA < -2.5) were excluded from this analysis. Comparing concordant and positive discordant patients, there were no significant differences in age, sex, disease duration, SES, RA therapy or number of comorbidities, nor in fatigue, HAD-DI, or HADS. The discordant group had significantly lower SJC, TJC and PhGA. More patients in the discordant group were in LDA (58.1% vs. 45.4%), with fewer in MDA (32.4 % vs. 29.1 %) and HDA (9.6% vs. 25.6%). In logistic regression analysis, the discordance group included more fibromyalgia (FMS) patients, reported higher pain severity score and a higher EQSD level sum score, with problems with usual activities being the only statistically significant domain (p<0.001). In logistic regression analysis, pain severity score and problems with usual activities on EQSD were predictors of positive discordance. Pain was the main determinant of PGA (R² 0.24, p<0.001) and SJC was the main determinant of PhGA (R² 0.44, p<0.001).

LWW 05/13/23 4 Color Fig(s): 21:35 Art: 06_EUROAB-2023-PO05-06

21:35
Objectives: To identify the characteristics of the PRN and factors affecting its progression.

Methods: In this study, 417 patients with RA according to the ICD-10 code from the hospital database and who had at least one computed tomography (CT) were identified. The RA diagnosis of the patients were confirmed by examining the medical files (history, physical examination, radiography and laboratory evaluations). Then, chest CTs of the patients with confirmed RA diagnosis were examined by an experienced radiologist. To classify pulmonary nodules as ‘pulmonary rheumatoid nodule’, following inclusion and exclusion criteria were used. For inclusion: 1) nodules with changing dimension on follow-up, 2) At least two nodules with different dimensions, 3) Cavitory nodule at any chest CT. For exclusion: 1) Solitary nodules OR all nodules ≤ 5mm and without follow-up OR no change on follow-up. Biggest nodule was named as dominant nodule. Then, patients were grouped according to status of progression. Progression was defined as growth or new nodule formation.

Results: Of 680 RA patients who had pulmonary nodules in chest CT, 208 (30.6%) patients were classified as having PRN. Of these patients, 135 had at least one control chest CT for PRN follow-up and were included in the study. The median disease duration from diagnosis of RA to baseline CT with PRN was 6.74(0.1-33.9) years. Before the baseline CT, 59 (43.7%) patients were receiving methotrexate and it was discontinued in 22 (37.2%) patients after RPN detection. 39 (28.3%) patients had PRN progression on their final chest CT. The RA diagnosis of the patients were confirmed by examining the medical files and who had at least one computed tomography (CT) were identified. The median duration between baseline and final CT was 1.58(0.04-33.81) years. Anti-CCP positivity(OR 3.39, 95% CI 1.15-9.94), usage of bDMARDs between baseline and last CT (OR 2.48, 95% CI 1.1-5.5), cavitation (OR 3.31, 95% CI 1.5-7.4) and diameter of dominant nodules at baseline CT (OR 1.03, CI %95 1.00-1.07) were significantly associated factors with progression in RPN.

Conclusion: Our study shows that there are multiple factors that predict RPN progression. Especially the presence of cavitory nodules and seropositivity is important. Although clinicians tend to discontinue MTX when RPN is detected, the remaining exposure Ivs did not show a causal relationship with RA, including IL-17A(95%CI = 0.990-1.210, p = 0.078), IL-17C(95%CI = 0.890-1.139, p = 0.910), IL-17B(95%CI = 0.904-1.119, p = 0.913), IL-17D(95%CI = 0.843-1.137, p = 0.778), IL-17RD(95%CI = 0.876-1.104, p = 0.773). More importantly, sensitivity analysis showed no heterogeneity or pleiotropy in any of the above results.

IMPACT OF ANTI-RHEUMATIC TREATMENTS ON THE INDIVIDUAL COMPONENTS OF THE ACR COMPOSITE SCORE IN PATIENTS WITH RA: REAL-WORLD DATA FROM TWO REGISTRIES

L. Bessette1, M. Movahedi2,3, D. Choquette4, L. Coupal4, C. Bombardier2,3,5, E. Keystone1,5, Laval University, Rheumatology, Quebec City, Canada; 2Toronto General Hospital Research Institute, Ontario Best Practice Initiative, Toronto, Canada; 3University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; 4Institut de Rhumatologie de Montréal, Rhumadata, Montreal, Canada; 5University of Toronto, Medicine, Toronto, Canada

Background: Standard criteria for measuring treatment efficacy in patients with RA include ACR response rates, which require meeting a threshold of ≥ 20/50/70% improvement in several physician- and patient-reported measures, including tender and swollen joint counts (TJC and SJC, respectively; primary criteria) and at least 3 of 5 secondary criteria (Physician (Ph) global assessment (GA), Patient (Pt) GA, Pain, HAQ-DI, and CRP).

Objectives: The purpose of the analysis was to evaluate the impact of csDMARDs, TNF inhibitors (TNFi), and tocilizumab (TOFA) on each ACR score component in real-life practice.

Methods: Clinical data of RA patients with a CDAI >10 at the time they started a csDMARDs (all biologic naïve), TNFi or TOFA were pooled from two registries: Ontario Best Practices Research Initiative (OBRI) and RHUMADATA. Endpoints summarized descriptively included proportions of pts achieving ACR20/50/70 responses, ≥ 20/50/70% improvements and mean percent improvement in individual ACR components (TJC, SJC, PhGA, PIGA, Pain, HAQ-DI, and CRP) at Month (M6).

Results: A total of 669 pts were included (csDMARD, n=157; TNFi, n=252; TOFA, n=260). At baseline, patients starting TOFA had longer disease duration, failed more bDMARDs and used more corticosteroids than csDMARDs and TNFi. The CDAI was similar between the 3 groups. ACR50 response rates were numerically lower for the TOFA group (Table 1). The ACR70 response was similar in the 3 groups. An overall higher proportion of patients in all three-medication groups achieved ≥20/50/70% improvement in primary ACR components vs secondary components. Among secondary components, ≥20/50/70% improvement rates were numerically highest for PhGA and lowest for HAQ-DI and pain. The improvement in the SJC and TJC were numerically similar between all groups (Table 1). Among ACR20/50/70 responders for all medications, mean percent improvement was more than 80% for primary components, and ranged from 30% to 80% for secondary components (Figure 1).

Conclusion: In this real-world practice analysis, physician-reported measures (TJC, SJC, and PhGA) contribute slightly more to overall ACR20/50/70 responses, compared with Pt-reported outcomes (PRoRs; PIGA, Pain, and HAQ-DI). In the ACR20 response group, a lower-level outcome, the improvement of the SJC and TJC, exceeded 80%. Pain was the most important factor in achieving an ACR50 for pts treated with TOFA, possibly reflecting the different effects of JAKI on pain.

PARASYMPATHETIC ACTIVITY IS NEGATIVELY ASSOCIATED WITH DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS – RESULTS OF AN EXPLORATORY PROSPECTIVE STUDY

Keywords: Comorbidities, Rheumatoid arthritis

J. Muck1,2, K. Schippert1,2, M. Sluszniak3, C. Reuter1,2, D. Vossen4, M. Schneider1,2, G. Pongratz1,2, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Department of Rheumatology, Düsseldorf, Germany.

Background: Rheumatoid Arthritis (RA) is often associated with autonomic dysfunction, which is presumably playing a role in the pathogenesis of the disease and may contribute to disease activity [1, 2]. Accordingly, patients with RA show reduced heart rate variability (HRV) [3].

Objectives: The aim of this prospective pilot study was to examine a possible connection between disease activity and activity of the autonomic nerve system in patients with RA.

Methods: In the non-randomized prospective exploratory study, patients with active RA and an upcoming change in treatment were included. Assessments were performed at baseline before treatment initiation (T0) and after 3 months (T1), including the Disease Activity Score 28 (DAS28-CRP), HRV measurement, and the physician and patient global assessment (PGA, PtGA). HRV was measured through a 5-minute ECG with finger electrodes, using Kardia App®. Total variability was measured by the variance of RR intervals over the temporal segment (Total Power) as well as by standard deviation of the average RR intervals (SDRR). Root Mean Square of successive differences (RMSSD) and percentage of pairs of adjacent RR intervals differing by more than 50 milliseconds (pRR50) were used for estimating parasympathetic activity. In addition, blood concentrations of Neuropeptide Y (NPY) and vasoactive intestinal peptide (VIP) were measured as surrogate parameters for activity of the sympathetic (NPY) and parasympathetic (VIP) nervous system. Statistical analysis was performed using linear regression analysis.

Results: A total of 40 patients was included. Our results showed an overall improvement in both disease activity measured by DAS28-CRP (p = 0.001; SMD = 1.393) and HRV (Total Power: p = 0.014; SDRR = p = 0.0023) between visits (Table 1). DAS28-CRP was inversely associated with parasympathetic activity (p = 0.0494). PtGA also correlated inversely with pRR50 (p < 0.0001). RMSSD as another parasympathetic indicator was negatively predictive for percentage change of PGA (p = 0.019). Patients with lower parasympathetic activity at baseline had a higher change in disease activity than patients with higher parasympathetic activity at baseline.

DAS28 disease activity score 28, HRV heart rate variability, ms milliseconds, PGA physician global assessment, PtGA physician patient global assessment, RMSSD Root Mean Square of successive differences, SD1 Simple Disease Activity Index, SDRR standard deviation of the average RR intervals, SMD standardized mean difference

Conclusion: The results of our prospective study underline the importance of the autonomic nerve system regarding disease activity and prognosis in RA. Higher parasympathetic activity was associated with lower disease activity. Patients with initially lower parasympathetic profile and higher disease activity benefited to a greater extent from initiation or change of therapy. In our study, the specific blood parameters NPY and VIP showed no relevant association with disease activity and treatment response.

Keywords: Prognostic factors, Rheumatoid arthritis, Autoantibodies

J. Heutz1, M. W. Schreurs2, A. Van der Helm – van Mil3, P. De Jong4, 1Erasmus Medical Center, Rotterdam, Netherlands; 2Erasmus MC, Immunology; Rotterdam, Netherlands; 3Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands

Background: The EULAR research agenda states that new biomarkers are needed to stratify patients and to predict therapeutic response or lack of response in rheumatoid arthritis. Currently, IgG anti-citrullinated protein antibody (ACPA) and IgM rheumatoid factor (RF) are used as poor prognostic factors for treatment decisions in RA. The mucosal origin hypothesis of RA renewed the interest in the role of IgA isotype autoantibodies for disease pathogenesis. However, the value of IgA ACPA and RF for prognostication of treatment response under a treat-to-target approach is not clear to date.

Objectives: To evaluate the prognostic value of IgA ACPA and RF by considering ‘quick-attained and persistent remission’ (DfR) and biological use in an early (rheumatoid) arthritis population.

Methods: All patients from the treatment in the Rotterdam Early Arthritis Cohort (tREACH) trial with available baseline sera were included. The tREACH trial is a multicentre, stratified, single-blinded trial with a treat-to-target approach. IgA ACPA and RF isotypes were measured by automated fluorescence enzyme-immuno assay (FEIA) in baseline sera. The prognostic value of positivity for IgA ACPA and RF was evaluated for three outcome measures: (1) quick-attained (at 6 months) and persistent (to 2 years) remission, analysed with logistic regression analysis; (2) achievement of DfR for at least 6 months over a 2 year follow-up period, analysed with survival analysis; and (3) incidence biological use over 2 years, analysed with mixed effects logistic regression analysis. Results were stratified for IgG ACPA, since it is known that IgG ACPA is related to lower (DMARD-free) remission rates and more biological use.

Results: IgA isotypes of ACPA and RF were measured in baseline sera of 480 tREACH patients. 66% was female, mean age was 53 years, median symptom duration 21 weeks, and median swollen joint count 5. A positive IgA ACPA titre was present in 109 (23%) patients and most of them also had a IgG ACPA result above the cut-off value for positivity (n=102, overlap of 94%). Positive IgA RF on the other hand was present in 172 (36%) of patients, which overlapped with IgM RF for 90% (n=154). Double positivity for IgA and IgG ACPA (n=102) revealed lower DfR rates after 2 years compared to IgG ACPA positivity alone (6% and 11%, respectively, Figure 1A), although this finding was not significant (p=0.09).

No differences were observed in ‘quick-attained and persistent remission’ and biological use for both IgA ACPA and RF, after stratification for IgG ACPA.

Conclusion: IgA isotypes of ACPA and RF almost completely overlap with the commonly measured isotypes (IgG ACPA and IgM RF, respectively). In addition, both an IgA ACPA and IgA RF response do not predict persistent remission, DfR and biological use in this treat-to-target population. Based on these results, there is no rationale for measuring these isotypes in newly diagnosed (rheumatoid) arthritis patients in daily clinical practice.

Figure 1. Quick-persistent (6-24 months) remission, DMARD-free remission and biological use over 2 years in (A) Iga/IgG ACPA positive patients vs. IgG ACPA positive patients, with IgA/IgG ACPA negative patients as a reference group; and in (B) IgA RF/IgG ACPA positive...
patients vs. IgA RF negative/IgG ACPA positive patients, with IgA RF/IgG ACPA negative patients as a reference group.

IMPROVEMENT OF SLEEP IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS ACHIEVING REMISSION OR PAIN RELIEF WITH UPADACITINIB: RESULTS FROM THE POST-MARKETING OBSERVATIONAL SLEERA STUDY

Keywords: Rheumatoid arthritis, Quality of life, Real-world evidence

T. Hügle1, H. Prillwitz2, B. Moeller3, D. Kyburz4, J. Dudler5, K. Schmiedeberg1, M. Harer Kuster6, P. Roulin7, A. Rubbert-Roth8, 1Lausanne University Hospital, Department of Rheumatology, Lausanne, Switzerland; 2Rheumatologisches Versorgungszentrum Weinfelden, Rheumatologie, Weinfelden, Switzerland; 3Inselspital, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland; 4University Hospital of Basel, Department of Rheumatology, Basel, Switzerland; 5HF Fribourg, Department of Rheumatology, Fribourg, Switzerland; 6Cantonal Clinic St Gallen, Division of Rheumatology, St Gallen, Switzerland; 7AbbVie AG, Immunology, Cham, Switzerland

Background: Sleep impairment is a common clinical condition in the rheumatoid arthritis (RA) population, which has been reported in over 60% of patients[1]. Although few longitudinal studies demonstrated change from baseline on sleep quality with advanced therapies[2,3], none of them described the clinical meaningfulness of these changes by subjective and objective measures.

Objectives: The SLEERA study aims to investigate the impact of upadacitinib (UPA), a selective and reversible JAK inhibitor, on sleep quality in a real-world RA population in Switzerland, by using a validated patient-reported measure, the Pittsburgh Sleep Quality Index (PSQI)[4], and an actigraphy-based objective measure with the GT9x wearable.

Methods: SLEERA is a sub-study of UPHOLD, an international, multicenter, prospective, non-interventional, open-label, observational cohort study (NCT04497957) that assesses sleep quality in a real-world population of adult Swiss patients with moderate-to-severe active RA, initiating treatment with UPA 15mg once daily according to the product label and with the treatment decision made prior to study participation. This primary interim analysis reports data for all enrolled patients up to 3 months after treatment start. Results are presented for the total sample using descriptive measures reflecting sample size (N), average values (standard deviation) for each visit and average change scores (standard deviation) for follow-up visits up to month 3. All data were analyzed as observed, with no imputation of missing data.

Results: Of the 39 patients (87% female) included in this study, 35 completed the follow-up visit at month 3. The mean age and disease duration were 59.5 (13.9) years and 7.0 (8.3) years, respectively. The mean initial DAS28-CRP was 4.1 (1.0). At baseline, 76% of patients showed subjective sleep impairment (defined by PSQI >5) and 51% had objective poor sleep efficiency (defined by actigraphy sleep efficiency <85%) (Table 1). At month 3, upadacitinib showed significant improvement in the PSQI total score with a decrease of 2.26 (2.92, p value <0.001), as well as other subjective outcomes. The proportion of objective poor sleepers decreased to 38%, while sleep efficiency and physical activity outcomes in total remained unchanged. However, patients achieving DAS28- CRP remission or absence of pain after 3 months of treatment showed higher improvements in both subjective and objective measures compared to those who did not achieve DAS28-CRP remission or have residual pain (Figure 1).

Conclusion: In this Swiss cohort, a high proportion of RA patients exhibited sleep impairment as shown by subjective and objective measures. Patients treated with upadacitinib significantly improved their subjective sleep quality after 3 months. Higher improvements for both subjective and objective sleep measures were observed in patients achieving remission or absence of pain. This research provides evidence of sleep impairment in RA patients which can be improved following a treatment, and further supports the importance of remission when assessing disease treatment goals.

"IT SURPRISED ME A LOT THAT THERE IS A LINK": A QUALITATIVE STUDY OF THE ACCEPTABILITY OF PREVENTIVE PERIODONTAL TREATMENT FOR INDIVIDUALS AT-RISK OF RHEUMATOID ARTHRITIS

Keywords: Qualitative research methods, Rheumatoid arthritis, Patient information and education

Background: Current evidence suggests that periodontitis could be a causal risk factor for rheumatoid arthritis (RA) onset and progression, and periodontal treatment may improve disease activity in patients with established RA [1, 2]. Earlier periodontal intervention in individuals at-risk of RA could provide a unique opportunity to delay progression or prevent RA entirely.

Objectives: To explore the acceptability of preventive periodontal treatment among individuals at-risk of RA and healthcare professionals from dental and medical backgrounds.

LWW 05/13/23 4 Color Fig(s): 21:35 Art06_Euroab-2023-P005-06
Methods: This was a qualitative study using a phenomenological approach. Anti-CCP positive at-risk individuals with musculoskeletal symptoms but no synovitis were recruited from the Leeds CCP cohort, and healthcare professionals were recruited through the Leeds Rheumatology professional network. Individuals semi-structured interviews were conducted via video or telephone. Interviews were audio-recorded and transcribed verbatim. Data were analysed thematically.

Results: Nineteen at-risk participants (ten women; age range 35-70) and 11 healthcare professionals (rheumatology clinicians, dentists, general practitioners, commissioners) participated. Three themes (six subthemes) were identified as important to understand factors that may influence participants’ acceptance of preventative periodontal treatment to reduce the risk of RA: i) understanding risk (knowledge of shared risk factors; information and communication); ii) oral health perceptions and experiences (personal challenges for dental intervention and oral health maintenance; external barriers); iii) oral health treatment and maintenance (making oral health changes to prevent RA; acceptability of participation in periodontal research to prevent RA). The majority of at-risk participants lacked awareness of the association between oral health and the risk of developing RA, and perceived a lack of knowledge of this link among dentists. Healthcare professionals highlighted disjion between dentistry and medicine due to commissioning and financial barriers, and inadequate training. Preference for information provision relating to oral health as a risk factor varied extensively among all participants. At-risk participants discussed oral health issues, but oral health was less of a priority when compared to comorbidities that had a bigger impact on daily life, e.g. irritable bowel syndrome. Both groups of participants perceived that dental anxiety, the cost of dental treatment, and difficulty in accessing NHS dentists were barriers to seeking dental care. Participation in a clinical trial involving preventive periodontal treatment was perceived to be acceptable for most at-risk participants. Comparatively, taking medication to prevent RA was perceived to be less acceptable. Facilitators to trial participation included reducing risk, access to a dentist, and not having to pay for treatment. At-risk patients with dental anxiety indicated that seeing the same dentist at every visit was important.

Conclusion: The impact of poor oral health may not be well understood by individuals at-risk of RA. Information relating to this risk factor should be tailored to the individual and is a key first step before clinical trial involvement. Whilst periodontal disease is common in individuals at-risk of RA, both at-risk participants and healthcare professionals identified that seeking dental treatment can be hindered by dental anxiety, treatment costs and a shortage of dentists. Future trials involving preventive periodontal treatment should take into account what has been identified as important by this group of individuals at-risk of RA.

Background: In the last decade there have been multiple attempts to characterize patients with refractory rheumatoid arthritis (RA). In 2020, EULAR proposed a definition for difficult-to-treat RA (D2TR-A) to standardize this population. The mechanisms leading to D2 TR-A are varied and not fully understood. A better understanding of clinical profile of this specific population may be helpful to support rheumatologists in their clinical decisions.

Objectives: To determine the prevalence of D2TR-A in a multicenter national registry (BIOBADASER) and to investigate the influence of the initial successive lines of treatment (LoT) in the development of D2TRA.

Methods: Longitudinal and prospective cohort study of patients with RA from BIOBADASER (a multicenter national registry of adverse events of biologics and targeted therapies in rheumatic diseases). Patients were classified as refractory if failure to at least 2 biologics or targeted synthetic disease modifying antirheumatic drugs (b/tsDMARDs) with different mechanisms of action (MoA) and as D2TRA if refractory RA who presented moderate to high disease activity according to DAS 28-ESR at their last visit. The comparator group included patients with refractory RA but low disease activity/remission. The therapeutics groups were stabilized as TNFi inhibitors (TNFi), JAKi-inhibitors (JAKi) and other biological therapies non-TNFi bDMARD. Demographic, clinical and therapeutic data on the 1st and 2nd LoT were compared between groups.

Results: A total of 3852 patients with RA with at least one year follow up were included in the analysis, 1612 (42%) had refractory RA and 348 (9%) D2TRA. Patient and therapeutic characteristics are shown in Table 1. No differences were found between D2TRA and non-D2TRA in clinical variables except for age, being patients with D2TRA significantly older. The use of JAKi as their first or second LoT was more frequent in patients with non-D2TRA although no statistical significance was reached.

Conclusion: Around 40% of patients were classified as refractory RA in our registry but only 9% as D2-RA. Earlier treatment with JAKi was more frequent in the non-D2TRA group. Further research should analyse the influence of LoT on the development of D2TRA.

REAL WORLD EXPERIENCE OF MODERATE DISEASE ACTIVITY STATE (MDAS) RA PATIENTS OVER 4-YEAR FOLLOW-UP

Keywords: Inflammatory arthritides, Pain, Fibromyalgia

M. Gibson1, N. Ladhah Hassan2, L. B. Kirkham3, Guy’s Hospital, Department of Rheumatology, London, United Kingdom

Background: In recent years despite improved therapies for RA, there is an increased awareness of persistent pain in people with RA. Before the pandemic we assessed a large group of patients with RA with comprehensive joint ultrasound (US) and for presence of fibromyalgia (FM) meeting 2010 ACR diagnostic criteria. When combinations of synovitis and/or FM were made we noted 4 groups

</table>

**Objectives:** To assess the progress and outcomes patients with RA with different well defined pain states during 4 years of follow up including the COVID19 pandemic.

**Methods:** The TITRATE-ULTRASOUND patient cohort categorised patients with RA into 4 groups depending on the presence or absence of FM and the presence or absence of power doppler synovitis (PD, defined as positive PD signal in ≥2 joints in a 44 joint US). We identified 72 patients with active RA (DAS28 3.2 – 5.1) from this cohort with sufficient clinical data during the study period and collected the following data on each follow up encounter: visit type, treatment changes and disease activity measures. In the COVID19 pandemic follow up visits were largely virtual without the ability to collect physician assessed disease activity scores. Progress assessment was performed as to whether the patient had improved, no change or worse with a numerical value of +1, 0 and -1 at each visit to calculate a score tracking patient progress over the pandemic. Statistical analysis was performed using 1-way ANOVA to assess for difference between the 4 groups.

**Results:** 72 patients were assigned into the following categories: FM-PD- (n = 12); FD-PD+ (n = 18); FM+PD- (n = 29); FM+PD+ (n = 13). Table 1 shows baseline characteristics of the 4 groups and reveals no significant differences. Further follow-up data analysis can reduce such bias.

**Conclusion:** Over the follow-up period we show the management of RA patients without active power doppler synovitis or fibromyalgia did not differ significantly from other categories of patients. Similar numbers of visits, treatment escalations, csDMARDs and corticosteroid prescriptions were observed. This illustrates how it can be difficult to define the specific causes of disease activity without access to US. Despite similar management strategies, FM-PD- patients tended towards worse progress scores, suggesting a potential unmet need in such patients.

**GENETICALLY PREDICTED EOSINOPHIL COUNT IS ASSOCIATED WITH INCREASED RHEUMATOID ARTHRITIS SUSCEPTIBILITY**

**Keywords:** -omics, Rheumatoid arthritis

T Chong1, R. Gopalarathinam2, D. Hughes3, S. S. Zhao4. 1University of Manchester, School of Biological Sciences, Faculty of Biological Medicine and Health, Manchester, United Kingdom; 2Southport and Formby District General hospital, Division of Rheumatology, Southport, United Kingdom; 3University of Liverpool, Department of Health Data Science, Liverpool, United Kingdom; 4University of Manchester, Centre for Epidemiology Versus Arthritis, Division of Musculoskeletal and Dermatological Science, School of Biological Sciences, Faculty of Biological Medicine and Health, Manchester, United Kingdom

**Background:** Increasing evidence shows that eosinophils – white blood cells typically linked to atopic and parasitic diseases – are involved in regulating adaptive immune responses. Baseline eosinophilia has been associated with poor prognosis in early arthritis patients, while synovial regulatory eosinophils are associated with rheumatoid arthritis (RA) remission [1,2]. However, the role of eosinophils for RA susceptibility is unclear. Traditional observational designs are limited by reverse causation, that is, RA onset or prodrome may influence eosinophil count and/or function. Using genetic variants in instrumental variable analysis can reduce such biases.

**Objectives:** To investigate the association between genetically predicted circulating eosinophil count and RA risk using genetic instrumental variable analysis.

**Methods:** We selected uncorrelated (r² < 0.001) and significant (p-value < 5x10⁻⁸) single nucleotide polymorphisms (SNP) as genetic instruments for circulating eosinophil count from a genome wide association study of 563,085 individuals. Genetic association data for RA was obtained from 22,350 cases and 74,823 controls. We included psoriatic arthritis (PsA; 3,609 cases, 9,192 controls) and osteoarthritis (OA; 177,517 cases, 649,173 controls) as negative control outcomes, and asthma (56,167 cases, 352,255 controls) and atopic eczema (10,788 cases, 30,047 controls) as positive controls. We used the ratio method and meta-analytical estimates from each SNP using the inverse-variance weighted method. We used weighted median, mode and the Egger method to test for horizontal pleiotropy (i.e., violation of the model assumption that genetic instruments only affect the outcome through the exposure).

**Results:** Circulating eosinophil count was instrumented using 484 SNPs that explained 11% of variance, with a mean F statistic of 157 suggesting adequate instrument strength. For each standard deviation increase in eosinophil count, risk of RA was increased (OR 1.60; 95% CI 1.35, 1.89; p-value=6.9x10⁻⁸). Genetically predicted eosinophil count was not associated with risk of PsA and OA negative controls, but were associated with increased risk of asthma and eczema positive controls (Figure 1). Pleiotropy robust sensitivity analyses showed consistent estimates.

**Figure 1.** Association between genetically predicted circulating eosinophil count and risk of rheumatoid arthritis and control outcomes.

**Conclusion:** This study provides genetic data to support a causal relationship between circulating eosinophil count and RA susceptibility. Eosinophils may play a causal role in RA aetiology and, if these results are replicated in future studies, may represent a novel predictor of RA onset and potential modifiable factor for RA prevention.

**RA TREATMENT EFFECTS IN WRIST MRIS, DETERMINED BY DEEP LEARNING**

**Keywords:** Artificial intelligence, Rheumatoid arthritis, Imaging
T. Hassanzadeh1, D. Shamoni1, Y. Li2, M. Reijnierse3, A. Van der Helm – van Mil2, B. Stoel1*. Leiden University Medical Center, Division of Image Processing, Department of Radiology, Leiden, Netherlands; 2Leiden University Medical Center, Department of Radiology, Leiden, Netherlands; 3Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands

Background: Determining the response to early treatment of Rheumatoid Arthritis (RA) or the at-risk stages for RA from MRI scans requires sensitive and specific measurements of imaging biomarkers of inflammation. Employing artificial intelligence (AI), especially deep learning, can be an option to measure RA treatment effects.

Objectives: We aimed to assess the ability of deep learning to determine treatment response by distinguishing MRIs of the wrist between treatment and placebo arms (as proxy for treatment effects) from the TREAT-EARLIER trial.

Methods: Wrist MRIs (contrast enhanced T1-weighted TSE fat suppressed sequences) were collected from 236 patients clinically suspect arthritis at four time points (baseline, with 4, 12 and 24 months follow-up) to determine the response to treatment by intramuscular methylprednisolone followed by methotrexate during one year [1]. 3D wrist MRI data were reconstructed in super-resolution from axial and coronal images. Since a statistically significant treatment effect was determined previously by RAMRIS [1], we used these 3D wrist MRI data from baseline and after 4 months to classify patients into treatment arms by a 3D convolutional neural network. Five different inputs were explored for training the model: 1) a difference image (baseline image simply subtracted from follow-up); 2) the combination of baseline and follow-up image; 3) the combination of baseline and difference image; 4) change maps (AI-based maps containing changes between two time points); and 5) the combination of baseline and change maps (see bottom panel in Figure 1).

To evaluate the proposed model, 10-fold cross-validation was repeated five times with five different splits, and the area under the receiver operator curve (AUC) was reported.

Results: The mean (±SD) AUCs are presented in Table 1. As shown, the combination of different MRIs obtained promising results. Specifically the combination of baseline images and AI-based extracted change maps could improve the accuracy. Compared to a setting where follow-up and baseline scans were simply ‘subtracted’, this improved the prediction of treatment from 0.72 to 0.76.

Table 1. Obtained AUC using Wrist MRI. (BL: baseline MRI; FU: Follow-up MRI; Diff: Difference image; and CM: Change Map)

Conclusion: The results show that deep learning models using baseline and follow-up MRI specifically AI-extracted change maps can accurately determine treatment response in CSA patients.

KEYWORDS: Rheumatoid arthritis, Prognostic factors, Comorbidities

N. Luciani3, E. Barone3, E. Brunetta1, M. De Santis2, A. Ceribelli1, M. Caprioli1, G. M. Guidelli1, A. Sonaglia1, D. Renna2, N. Isailovic2, C. Selmi3, IRCCS Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy; 1IRCCS Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy

Background: Despite the growing number of available drugs for Rheumatoid Arthritis (RA) and the significant improvement in disease management, numerous patients continue to fail multiple lines of DMARDs. The EURAL definition of Difficult to Treat Rheumatoid Arthritis (D2T-RA) is based on 3 criteria: the failure of 2 or more b/tsDMARDs with different mechanism of action, the persistence of signs of active disease despite treatments, and the clinician or patients’ perception of a “problematic” management. There is limited evidence on the prevalence of D2T-RA in real life and the factors associated with this entity.

Objectives: To characterize D2T-RA cases in a real-life cohort of patients.

Methods: We retrospectively collected data of patients with RA fulfilling the ACR/EULAR 2010 classification criteria who attended our outpatient clinics between January 2019 and November 2022. The comparison between D2T-RA and other patients was performed using T-, Mann-Whitney and Chi-Square tests while logistic regression models analyzed the impact of principal clinical features and comorbidities on outcome variable, adjusted for confounders.

Results: Eighty-seven/400 (21%) patients enrolled met the DT2-RA criteria. No significant differences were found in median age (no-D2T 62±12 vs. D2T 64±15, p = 0.6), median disease duration (no-D2T 64±9 vs. D2T 64±9 years, p=0.9) and gender (female 77%, p=0.9). D2T-RA had similar autoantibody profile, prevalence of interstitial lung disease, C-reactive protein levels at diagnosis, number of tender and swollen joints at diagnosis and major comorbidities (hypertension, dyslipidemia, COPD, depression, autoimmune thyroiditis). At univariate D2T-RA correlated, without reaching statistical significance, with diabetes (p=0.055), a previous history of major cardiovascular events (p=0.071), previous or current history of smoking (p=0.081) and GRED (p=0.079). Of note, D2T-RA significantly correlated with fibromyalgia (p=0.004), previous surgical intervention to treat RA (p=0.01), peripheral arthropathy (p=0.035), obesity (p=0.023) and evidence of erosions at diagnosis (p=0.045). The multivariate analysis confirmed the correlations between D2T-RA and baseline erosions (p=0.034, OR 2.23 IC 1.06-4.69), obesity (p=0.041, OR 2.05 IC 1.03-4.09) and fibromyalgia (p=0.004, OR 3.28 IC 1.47-7.32) regardless of age and gender or, in the case of fibromyalgia, obesity. Conclusion: Our data support the importance of comorbidities to determine D2T-RA which is not influenced by the autoantibody profile. In particular, fibromyalgia and obesity likely increase the probability of a DMARDs multi-failure. Data on baseline erosions and a previous history of surgery possibly suggest that a better timing of intervention with earlier treatments may reduce the risk of D2T-RA.

Background: Rheumatoid arthritis (RA) is one of the most common diseases worldwide with a need for rehabilitation despite recent advances in pharmacological treatment options. Furthermore, data show a numerical increase in years of life with disability in RA patients in Germany from 1990 to 2017. Limitations in work participation (WP) also remain highly prevalent.

Objectives: To investigate the development of different domains of WP (unimpaired WP, presenteeism, and absenteeism) at the patient level under drug therapy over 12 months to understand the impact of pharmacological paired WP, presenteeism, absenteeism, and no employment) at the patient level.

Methods: The multicenter ERFASS study prospectively enrolled seropositive RA patients with an active flare of disease initiating treat-to-target (T2T) drug therapy over 12 months [1]. Patients were enrolled between 01/2018 and 12/2019. We examine the different domains of WP in working-age patients (18-65 years) excluding students and old-age pensioners using the WPAI of patients with a complete dataset at all three measurement time points (month 0, 6 and 12).

Keywords: Remission, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

S. B.1, A. Kumar P H1, M. Gopalakrishnan1, M. K. Garg1. 1All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India

Background: Remission is a state, not change or transition with absence of disease activity in rheumatoid arthritis (RA) [1]. Remission at 6 months has been shown to predict future good outcomes such as arresting radiographic progression and better functional status at 12 and 24 months [2]. ACR EULAR have endorsed Boolean2.0 in the revised remission criteria in 2022 [3]. None of these participants were recruited from India. In this ongoing study, we compare the various remission criteria in patients with RA in our setting.

Objectives: To compare the performance of various remission criteria (Disease Activity Score 28 (DAS28 ESR), Disease activity Score 28 CRP (DAS28 CRP), Simple Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), Boolean2.0, and BooleanX) in patients with RA presenting to our rheumatology clinic, at Jodhpur, India.

Methods: A longitudinal study was initiated in July 2021 after Ethics Committee approval. Demographic and treatment details were collected after written informed consent. Remission criteria were calculated at 6 months follow up. We analysed agreement between the Boolean- and index-based criteria SDAI, CDAI, DAS28 ESR and DAS28 CRP. The study is an ongoing study, with a calculated sample size of 165.

Conclusion: This study provides evidence of external validation of the newly proposed modification of the Boolean ACR/EULAR remission criteria; however, we found that the Boolean2.0 criteria did not exhibit agreement with index-based remission definitions in the Indian population from our centre. Our results replicate the findings that a Boolean definition using 2 cm as threshold for patient global assessment of disease activity (Boolean2.0) yields better agreement than Boolean [2]. With the validation Boolean2.0 in our settings, our data support the revised ACR/EULAR remission criteria as a target in clinical practice.

VALIDATION OF REVISED 2022 ACR/EULAR REMISSION CRITERIA FOR RHEUMATOID ARTHRITIS PATIENTS

Keywords: Outcome measures, Rheumatoid arthritis

C. B. Prasad1, V. Dhir1, G. Naidu1, S. K. Sharma1, A. Sharma1, S. Jain1. 1Post Graduate Institute of Medical Education and Research, Clinical Immunology and Rheumatology Unit, Department of Internal Medicine, Chandigarh, India

Background: Remission has become a key target in the management of rheumatoid arthritis (RA) patients [1]. In 2022, American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) has revised the Boolean based remission criteria in RA by increasing the patient global assessment of disease activity (PIGA) threshold to ≤2cm (range 0–10 cm). This has not been validated in an Asian Indian cohort of RA patients [2,3].

Objectives: To validate ACR/EULAR remission criteria for RA: 2022 revision in Asian Indian RA patients by using data of an ongoing clinical trial.

Methods: For the purpose of validating the remission criteria, data generated at our center from an ongoing clinical trial (SMART study) which enrolled patients with active seropositive RA, who were 18–60 years old with disease duration ≤5 years was used. This is a 24-week multicenter, open-label RCT to compare efficacy of split versus non-split doses of methotrexate (MTX). For this analysis, data from both groups was analyzed together. Patients are started on oral MTX 15mg/week which was escalated every two weeks by 5mg, to reach a maximum dose of 25mg/week by 4 weeks. At the end of 16 weeks, if Disease Activity Score 28 (DAS28) >3.2 another DMARD can be added. Disease activity was measured using the DAS28, Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI) at 24 weeks. Proportion of patients achieving remission with index-based (SDAI≤3.3 & CDAI≤2.8) and ACR/EULAR Boolean-based criteria was compared. The proposed PIGA threshold of 2cm (Boolean2.0) (range 0–10cm) was compared with the original threshold of 1 cm (Boolean1.0) as well as with 1.5 cm, 2.5 cm and no PIGA (Boolean X) for remission. Agreement (Cohen's kappa) was assessed between Boolean-based and index-based criteria.

RESULTS:
For the purpose of validating the remission criteria, data generated at our center from an ongoing clinical trial (SMART study) which enrolled patients with active seropositive RA, who were 18–60 years old with disease duration ≤5 years was used. This is a 24-week multicenter, open-label RCT to compare efficacy of split versus non-split doses of methotrexate (MTX). For this analysis, data from both groups was analyzed together. Patients are started on oral MTX 15mg/week which was escalated every two weeks by 5mg, to reach a maximum dose of 25mg/week by 4 weeks. At the end of 16 weeks, if Disease Activity Score 28 (DAS28) >3.2 another DMARD can be added. Disease activity was measured using the DAS28, Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI) at 24 weeks. Proportion of patients achieving remission with index-based (SDAI≤3.3 & CDAI≤2.8) and ACR/EULAR Boolean-based criteria was compared. The proposed PIGA threshold of 2cm (Boolean2.0) (range 0–10cm) was compared with the original threshold of 1 cm (Boolean1.0) as well as with 1.5 cm, 2.5 cm and no PIGA (Boolean X) for remission. Agreement (Cohen's kappa) was assessed between Boolean-based and index-based criteria.

Trial registration number: CTRI/2021/02/031361.

Trial: This study included 125 patients, majority being females (105 (84%)), with mean (±SD) age of 42.8 (±10.8) years and mean (±SD) disease duration of 2.2 (±1.5) years. At 24-weeks, using the index based (SDAI and CDAI) criteria, remission was achieved in 24.8% and 24% of patients respectively. Among the various Boolean criteria, remission occurred in only 21.6% using the original Boolean1.0. This increased with Boolean2.0 to 23.2%, and further increased with Boolean2.5 and Boolean X (Figure 1). The highest agreement between SDAI or CDAI-defined remission was found to occur with Boolean2.0-defined remission rather than Boolean1.0 (or 1.5, 2.5 or X) defined remission (Table 1). Also, there was strong agreement (0.89 (95% CI 0.79–0.99)) between SDAI and CDAI-defined remission criteria.

Conclusion: We validated the performance of revised 2022 ACR/EULAR remission criteria for RA in Asian Indian RA patients and found the higher agreement of Boolean2.0 (rather than Boolean1.0) with index-based remission cutoffs.

CAN RAHMENATITIS IMPACT OF DISEASE (RAID) SCORE BE USED AS A PATIENT REPORTED OUTCOME BASED TARGET IN A TREAT-TO-TARGET APPROACH: A PROSPECTIVE STUDY FROM INDIA

Keywords: Patient reported outcomes, Rheumatoid arthritis, Treat to target

P. S. Kumar1, A. Kumar P H2, M. K. Ganji3, M. Gopalakrishnan1. 1All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India

Background: Rheumatoid arthritis impact of disease (RAID) is a well validated patient reported outcome (PRO) in patients with Rheumatoid Arthritis (RA) [1]. RAID score involves the active participation of patients and can be easily calculated at the comfort of home with minimal training and assistance or while the patient is waiting to see the doctor in the outpatient department. It is helpful in giving an idea of the overall well-being of the patient and takes into account sleep and depression which are the unmet needs in RA treatment. However, the effectiveness of RAID as a patient reported outcome and the optimal RAID score which can be used as a target for treat-to-target approach has not been studied in the Indian population.

Objectives: To determine if the RAID score can be used as a PRO target along with a clinician reported disease activity score for managing patients with RA under a treat-to-target approach. To establish an acceptable cut-off for the RAID score which can be used as a target in patients with RA and validate it against disease activity indices.

Methods: We prospectively enrolled patients with RA diagnosed using ACR/EULAR 2010 criteria in our tertiary care centre, at Jodhpur, India from March 2021 to May 2022 and followed them over 6 months after their written informed consent and Ethics Committee approval (AIIMS/IEC/2021/3370). DAS28, patient assessment of global disease activity (PIGA), Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), RAID score and modified Boolean indices (2) were calculated at enrolment and 6 months. Binary logistic regression analysis was used to determine if RAID could reliably predict DAS28 <3.2 and Boolean remission indices at enrolment and 6 months. DAS28 ≤3.2, CDAI ≤10 and SDAI ≤11 were considered as the target as per EULAR recommendations, with remission and low disease activity as acceptable goals to achieve while treating patients with RA.

Results: We included 156 patients with a mean age of 47.0±12.3 years, 86.5% were females. Among them, 23.4% patients had DAS28 ≤3.2, 11.7% had SDAI ≤11, 13.6% had CDAI ≤10 while only 0.6% were in Boolean and Boolean2.0 remission. At 6 months, 110 patients were followed up and among them, 78.6% had achieved DAS28 ≤3.2, 66.0% had achieved SDAI ≤11, 68.9% had achieved CDAI ≤10 while only 19.9% had achieved remission according to Boolean remission criteria. However, Boolean2.0 criteria showed that 20.9% were in remission. RAID score could reliably and independently predict DAS28, SDAI, CDAI, PIGA and Boolean2.0 criteria. We constructed multiple Receiver Operating Characteristic (ROC) curves to determine the optimal cut-off of RAID for defining low disease activity and remission using SDAI, CDAI, DAS28 and Boolean2.0 remission criteria (Figure 1). We noted that the RAID score of 2.32 had 85.7% sensitivity and 76.1% specificity in predicting SDAI ≤11 and 87.5% sensitivity and 74.3% specificity in predicting CDAI ≤10. Further, RAID score of 2.32 had a sensitivity of 86.4% and specificity of 72.5% in predicting DAS28 ≤3.2 and a sensitivity of 55.9% and specificity of 81.2% in predicting remission as per Boolean2.0 criteria.

Conclusion: RAID score can be used as a reliable and validated PRO in patients with RA. We also propose a cut-off of a composite RAID score of 2.32 as an additional target to achieve while treating patients with RA in the Indian population.

OUTCOME BASED TARGET IN A TREAT-TO-TARGET (RAID) SCORE BE USED AS A PATIENT REPORTED OUTCOME BASED TARGET IN A TREAT-TO-TARGET APPROACH: A PROSPECTIVE STUDY FROM INDIA

FUNCTION AND PAIN IN KNEE JOINTS IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER TOTAL KNEE ARTHROPLASTY

Keywords: Osteoarthritis, Rheumatoid arthritis

M. Karim1, S. Lashkina2, T. Nurakhmetov2, I. Gilmudtinov3, A. Nurakhmetov4, S. Artashhev4, I. Akhtiamov5, 1Kazan Medical Academy, Traumatology, Orthopedics and Military Surgery, Tashkent, Uzbekistan; 2Kazan
State Medical University, Hospital Therapy, Kazan, Russian Federation; 2Republican Clinical Hospital, Orthopedics No. 2, Kazan, Russian Federation; 3Kazan State Medical University, Traumatology, Orthopedic and Military Surgery, Kazan, Russian Federation

Background: Total knee arthroplasty (TKA) in patients with rheumatoid arthritis (RA) is considered the most effective intervention reducing knee pain and improving knee function. However, higher risk of late complications and worse surgery outcomes may be observed in patients with active disease.[1]

Objectives: To study the knee joint function and pain before and after the TKA in patients with rheumatoid arthritis.

Methods: 69 RA patients (10 (14.5%) males and 59 (85.5%) females) with an average age of 59 [52; 64] years were included into the study group. 81 osteoarthritis (OA) patients (58 (68.6%) males and 33 (31.4%) females) aged 66 [54; 80] years, were included into the control group. 23.2% of RA patients had a highly active disease at the moment of intervention. All patients underwent cemented TKA and completed Oxford Knee score (OKS) before the surgery, after discharge and 1 and 3 months after the surgery. Knee pain was assessed using VAS score also before intervention, straight after and 3 and 12 months after the surgery. All analyses were performed using SPSS version 23.0 (IBM Corp., Armonk, NY, USA). A p value of less than 0.05 was considered statistically significant.

Results: Patients in RA group had significantly lower preoperative OKS results, than OA patients (25.0 [23.5; 27.0] versus 29.0 [26.5; 30.0], p=0.00, Mann-Whitney) as well as lower postoperative OKS results before the discharge (34.0 [34; 38] versus 40.0 [35; 40], p=0.00, Mann-Whitney). 3 months after the intervention OKS scores were significantly lower in RA group (43.0 [42; 44] versus 43.0 [42; 44], p=0.00, Mann-Whitney). The same was found for OKS scores 12 months after the surgery (44.0 [44; 47] versus 44.0 [44; 47], p=0.0,382, Mann-Whitney). Pain intensity in RA patients varied from 60 to 90 mm according to VAS prior to surgery and was lower than among OA patients (80.0 [80; 90] versus 90.0 [80; 100], p=0.00, Mann-Whitney) which can be explained by patients’ higher pain tolerance due to “usual” pain in RA. The same tendency was observed immediately after the intervention (55.0 [50; 60] versus 60.0 [50; 70], p=0.00, Mann-Whitney). 1 year after the intervention RA patients reported higher VAS scores probably due to RA activity (20.0 [20; 20] versus 10.0 [10; 15], p=0.00, Mann-Whitney).

Conclusion: The effectiveness of TKA for pain reduction and improvement of knee function in patients with RA was comparable to that among patients with OA. RA patients had significantly lower preoperative OKS results, than OA patients but high OKS results were observed in both groups 1 and 3 months after surgery. Pain intensity in RA patients varied from 60 to 90 mm according to VAS prior to surgery and was lower than among OA patients. 1 year after the intervention RA patients reported higher VAS scores probably due to RA activity.

EQ5D SCARES ARE NOT AFFECTED BY AGING

Keywords: Outcome measures, Rheumatoid arthritis, Patient reported outcomes

I. Yoshii1, Nishiya2, Yosii Clinic, Mucusloskeletal Medicine, Shimoto City, Japan

Background: Estimating cost-effectiveness in the treatment of rheumatoid arthritis (RA) has received increasing attention in recent years as a large number of new drugs have been developed and generated through huge development costs and soaring drug cost.

Results: A total of 419 patients in whom 113 were male and 306 were female, were recruited in the study. Mean age at baseline was 68.1 and mean follow-up period was 65.3 months. Vx, Vy, and Vz significantly correlated with SDAI at all periods of BL, 1Y, and LT. Vx significantly correlated with HAQ-DI at all periods, whereas Vx and Vy significantly correlated with PS-VAS at all periods. Vx significantly correlated with SDAI at all periods of BL, 1Y and LT. Mean dHAQ and dSHS were defined as the dependent factor, and the other parameters including the three coordinates of JIV were defined as the independent variable. Then, correlation between these parameters were statistically examined also using linear regression analysis.

Conclusion: These results demonstrated that Vx, Vy, and Vz suggested significant correlation with other clinical parameters, especially Vz which represents affected joints in the lower extremities significantly correlates with important patient-reported outcomes.

VALIDATION OF JOINT INDEX VECTOR FOR PATIENT WITH RHEUMATOID ARTHRITIS

Keywords: Validation, Outcome measures, Rheumatoid arthritis

I. Yoshii1, S. Nishiya2, Yosii Clinic, Mucusloskeletal Medicine, Shimoto City, Japan; 2Kurashiki Medical Center, Rheumatology, Kurashiki, Japan

Background: There are only few indices that can estimate joint involvement in both upper and lower extremities in patients with rheumatoid arthritis (RA).

Objectives: One indicator can measure involvement on both upper and lower joint and large and small joint. The index developed by Nishiyama is called “Joint Index Vector”, which can represent the affected state of upper and lower joints as well as large and small joints by using three-dimensional coordinates. The aim of this study is to validate the efficacy and availability in clinical practice using monitoring data from RA patients.

Methods: Patients who started treatment for RA after January 2016 and whose Simplified Disease Activity Index (SDAI), Health Assessment Questionnaire Disability Index (HAQ-DI), Pain Score with Visual Analog Scale (PS-VAS), and EuroQol 5th dimension (EQ5D) were monitored at each visit and Sharp/van der Heijde score (SHS) was monitored annually were included in the study. The JIV represents the joint prevalence of the upper limb in X coordinates (Vx), the joint prevalence of the lower limb in Y coordinates (Vy), and the difference in joint prevalence between large and small joints in Z coordinates (Vz).[1]. The relationship between each clinical parameter and three elements of the JIV was evaluated statistically. Each parameter was defined as the dependent factor, and the three elements of the JIV were defined as the independent factor, and correlation was examined by linear regression analysis. Three elements of the JIV were defined as the independent factor, and correlation was examined by linear regression analysis. These procedures were performed at the first visit (BL), 1 year after the first visit (1Y), and at te last visit (LT). Additionally, the change in the HAQ score and SHS at 1Y and LT. dHAQ and dSHS were defined as the dependent factor, and the other parameters including the three coordinates of JIV were defined as the independent variable. Then, correlation between these parameters were statistically examined also using linear regression analysis.

Results: A total of 419 patients in whom 113 were male and 306 were female, were recruited in the study. Mean age at baseline was 68.1 and mean follow-up period was 65.3 months. Vx, Vy, and Vz significantly correlated with SDAI at all periods of BL, 1Y, and LT. Vx significantly correlated with HAQ-DI at all periods, whereas Vx and Vy significantly correlated with PS-VAS at all periods. Vx significantly correlated with SHS at 1Y and LT. Vz significantly correlated with EQ5D at 1Y and LT. Mean dHAQ and dSHS were defined as the dependent factor, and the other parameters including the three coordinates of JIV were defined as the independent variable. Then, correlation between these parameters were statistically examined also using linear regression analysis.

Conclusion: These results demonstrated that Vx, Vy, and Vz suggested significant correlation with other clinical parameters, especially Vx which represents affected joints in the lower extremities significantly correlates with important patient-reported outcomes.

MAGNITUDE OF THE INFLUENCE BY JOINT INVOLVEMENT ON HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX SCORE

Keywords: Rheumatoid arthritis, Outcome measures, Validation
Background: The Health Assessment Questionnaire Disability Index (HAQ-DI) is the best-known index for measuring functional capacity in patients with rheumatoid arthritis (RA). This index is well known to be influenced by disease activity, aging, joint deformities and pain. However, these parameters are related to each other and it remains unclear how joint involvement affects HAQ-DI in RA patients.

Objectives: The aim of this study is to determine how joint involvement affects HAQ-DI in RA patients using a retrospective cohort study.

Methods: Patients with RA who have been monitored since the first visit for tenderness and swelling of the whole body and limb joints, patient’s global assessment (PGA), evaluator’s global assessment (EGA), pain score using a visual analog scale (PS), and HAQ-DI at every visit were included in the study. The patient’s mean age, HAQ score, PGA, EGA, C-reactive protein (CRP), and Sharp/van der Heijde score (SHS) were collected. Joint Index Vector (JIV) was used as an index of joint lesions. JIV represents the joint prevalence of the upper limb in X coordinates (Vx), the joint prevalence of the lower limb in Y coordinates (Vy), and the difference in joint prevalence between large and small joints in Z coordinates (Vz) [1]. The average value of the triaxial coordinates of the JIV was also collected. As a preliminary study, the correlation between the mean HAQ score of all cases collected and other parameters such as patient gender and serum albumin level (ALB) was evaluated using multivariate linear regression analysis. Statistical significance was set as less than 5.0%.

Results: A total of 601 patients in these 166 males and 435 females data were used in the study. The HAQ score positively correlated with male gender, older age, higher SHS, higher PGA, lower EGA, higher PS, higher Vx and higher Vz with beta values of 0.09, 0.22, 0.17, 0.19, -0.12, 0.17, 0.07, and 0.11, respectively. The HAQ score at baseline positively correlated with older age, higher PGA, higher CRP, higher PS, higher SHS, and higher Vx at baseline with beta values of 0.26, 0.13, 0.21, 0.14, 0.10, and 0.26, respectively. The HAQ score at one year after the baseline positively correlated with older age, higher PS, and higher SHS at the baseline, and annual change of the PS with beta values of 0.26, 0.25, 0.22, and 0.15, respectively. The annual change of the HAQ score positively correlated with higher SHS and higher Vx at the baseline, and higher annual change of PS, Vx, Vy, and Vz with beta values of 0.04, 0.11, 0.067, 0.43, and 0.09, respectively.

Conclusion: These results indicate that there is a close association between HAQ scores and aging, degree of pain, and joint deformities, and in addition, joint involvement also influences HAQ scores. In particular, changes in HAQ scores are governed by joint involvement. The effect of disease activity on HAQ scores will be largely governed by joint involvement.

Keywords: Rheumatoid arthritis, Telemedicine

Background: Therapeutic adjustment is of major importance in the treat to target strategy proposed for rheumatoid arthritis (RA). This aspect can be challenged in teleconsultation given the multiplicity of treatments, efficacy/safety issues of RA therapies and the absence of clinical examination. These could lead the physician to prefer modifying the treatment in face-to-face visit rather than in teleconsultation.

Methods: To evaluate how clinicians adapted RA therapies in teleconsultation.

Results: Retrospective monocentric routine care cross-sectional study conducted in the Rheumatology department of Cochin Hospital. We reviewed electronic medical report (EMR) to identify all teleconsultations performed by telephone or video consultation in a 2-year period and extract data of interest. We compared treatment adaptation performed in teleconsultation to treatment adaptation that requested a face-to-face visit following teleconsultation. Treatment adaptation was defined by the introduction of a new treatment, modification of treatment dose and/or route or discontinuation of the treatment. This treatment adaptation may be motivated by efficacy or safety issues. Different treatment classes were considered: corticosteroids, methotrexate and targeted biologic/synthetic therapies (b/tsDMARDs).

Results: We included 187 patients (150 females, 80%) who had a teleconsultation performed, with a mean age of 58.1±16 years and a disease duration of 13±11 years. Positive rheumatoid factor and positive anti-CCP antibodies were detected in 125 (67%) and 139 (74%) patients respectively. 96 patients (51%) had erosive disease. A total of 56 therapeutic adaptations were collected: 34 were performed in teleconsultation and 22 requested face-to-face visits (Table 1). Demographics and RA disease characteristics did not differ between patients who had therapeutic adaptations performed during teleconsultation or during face-to-face visits. Corticosteroid and methotrexate were more likely to be adapted in teleconsultation compared to face-to-face visits (16/34, 47% vs 2/22, 9%, p=0.003 and 15/34, 44% vs 1/22, 5% p=0.002, respectively). Interestingly, methotrexate was adapted in teleconsultation for both efficacy and safety issues, leading to dose increase/reduction, switch from oral to subcutaneous route, or drug discontinuation. In the other hand, targeted therapies were preferentially initiated or modified during face-to-face visits which all included clinical examination, lab tests and power doppler ultrasonography (19/22, 86% vs. 3/34, 9%, p<0.001).

Conclusion: Corticosteroids and methotrexate were mainly adapted in teleconsultation without requesting a face-to-face visit, supporting their flexibility in teleconsultation and clinician’s confidence in their use, even at a distance from the patient. In the other hand, b/tsDMARDs were preferentially adapted in face to face consultation, highlighting the need of a careful evaluation of disease activity by clinical examination before modifying this class.

Keywords: Remission, Patient reported outcomes, Quality of life

Results: 130 RA patients were recruited (Table 1), 69% were female, mean age of 60.1 yrs and disease duration of 11.5 yrs. There was no significant difference in seropositivity between responder and non-responder groups (~75% RF+, ~69% ACPA+), 69% were treated with advanced therapy (biologic/targeted synthetic DMARDs), primarily TNFis.

• 26% of patients were in CR, 32% in LDA & 42% NR. Significant differences in QoL-primary endpoint were noted between CR/LDA patients vs NR group. The difference in QoL index score (EQ5D-5L) for patients in CR and LDA vs those in remission alone, suggest QoL is considerably higher in patients in CR compared even to those in LDA.

• Joint pain (VAS), fatigue (FACT-F) and function (HAQ-DI) scores all yielded strong negative correlations, indicating that CR/LDA patients had significantly better outcomes than those with MDA/HDA (Figure 1). A similar pattern was seen amongst patients in CR vs LDA, although significance was not achieved.

• In addition, more impaired productivity was noted in CR vs CR/LDA regarding ability to work and perform regular ‘non-work’ activities.

• Comorbidities were common, affecting over 90% of the non-responder group and 74% of patients in CR. The NR group had higher proportions of patients with cardiac, gastrointestinal, psychiatric and vascular disorders vs patients in CR/LDA.

• With respect to HRU, more patients in the NR group required medical visits for both RA and non-RA reasons vs patients in CR/LDA.

• Of the 54 patients in MDA/HDA, the study found there was a plan to add or switch DMARD, for only 32% of patients.

^ Patients in either full or part time employment * Sick leave in the past 6 months
Background: Continuation of methotrexate (MTX) treatment is recommended in both MTX responder and non-responder elderly-onset RA (EORA) patients. However, there are insufficient data on its effectiveness and long-term safety, although we have previously reported that a treat-to-target (T2T) strategy targeting low disease activity (LDA) is safe and effective in the prospective CRANE cohort of MTX-naive EORA patients [1, 2].

Objectives: To identify factors predicting failure to achieve LDA by month 6 in EORA patients starting MTX, and effectiveness and safety of MTX over 5 years in MTX responders and non-responders.

Methods: MTX-naive patients (mean age 73.8 years, n=163) from the CRANE cohort [2] had started MTX with moderate-to-high disease activity. Maximum dose of MTX was 0.19±0.06 mg/kg/week with folate supplementation. Treatment was adjusted to target LDA. Treatment intensification using biological disease-modifying antirheumatic drugs (bDMARDs) for EUFLAR-unresponsive patients by month 3 and moderate-high disease activity at month 6 was applied. MTX non-responders was defined as no LDA and/or initiation of bDMARDs by month 6. Primary outcomes were achievement of Simplified disease activity index (SDAI) ≤3.3 (LDA) and discontinuation of MTX due to adverse events (AEs). Secondary outcomes were achievement of remission and Health Assessment Questionnaire Disability Index (HAQ-DI) ≤0.5, and incidence of serious AEs.

Results: At week 24, 77 (47.2%) patients achieved LDA without bDMARDs (MTX responders), and of the remaining 86 (MTX non-responders), 35 (21.5%) had started bDMARDs by month 6 and 51 (31.3%) had moderate-to-high disease activity on MTX at week 24. At baseline, MTX non-responders had longer disease duration, higher SDAI and HAQ-DI, higher prevalence of erosion score ≥2 (modified total sharp score) and chronic lung disease (CLD), but baseline glucocorticoid use was similar. Multivariable analysis identified CLD as a predictor of MTX non-respondiveness. Regarding long-term outcomes, 14 (18.2%) of the 77 MTX responders and 55 (64%) of the 86 MTX non-responders received intensified treatment with bDMARDs within 5 years. MTX was continued in 65 (94.2%) of the 69 patients at the start of bDMARDs. The cumulative rate of MTX discontinuation due to AEs was similar in MTX responders and non-responders (34.0% and 33.1%) as was the time to discontinuation of MTX due to AEs. The time to discontinuation of MTX for any reason was also similar. SDAI LDA and HAQ-DI ≤0.5 achievement by year 5 applying the last observation carried forward (LOCF) method was 92.2% and 74.0% respectively for MTX responders and 77.9% and 53.9% for MTX non-responders, respectively (p=0.01 for SDAI LDA and 0.001 for HAQ-DI). SDAI remission at year 5 by LOCF was similar (62.6% and 52.3%) in MTX responders-vs-non-responders. The time to serious AEs was also similar, as was the cumulative incidence of serious AEs over the 5 years was 32.6% and 44.3% in MTX responders-vs-non-responders.

Conclusion: CLD was a predictive factor of non-achievement of LDA by month 6 in EORA patients starting MTX, and early application of bDMARDs may be inadequate for treating EORA with CLD at baseline. The 5-year long-term outcome for MTX responders was excellent, and continuation of MTX was tolerable even in MTX non-responders. Treatment intensification on MTX could be an optimal T2T strategy for EORA.

THE ASSOCIATION BETWEEN LAUGHTER AND FRAILTY IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE FAIRY STUDY

Keywords: Rheumatoid arthritis, Patient reported outcomes

M. Suzuki1, T. Kojima2, Y. Ohashi1, R. Sato1, D. Kirihara1, M. Maeda1, K. Kishimoto1, K. Terabe1, S. Asai1, S. Imagama1. 1Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan; 2Nagoya Medical Center, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan

Background: In the treatment of rheumatoid arthritis (RA), advances in drug therapy have led to better control of disease activity. However, RA is a systemic chronic inflammatory disease that causes frailty, a fragile state of mind and body. It is important for RA patients, who are prone to physical anxiety due to poor disease control and frailty, to be able to smile and live their lives. While there is anxiety about the disease, daily laughter may be helpful in resolving anxiety and preventing frailty. Although there have been reports on laughter and health, there are no reports on RA and laughter, so we decided to conduct a new study on laughter.

Objectives: The purpose of this study was to investigate the association between disease activity, laughter, and frailty in RA patients.

Methods: Data were obtained from participants in the Fairy Study (The prospective cohort study of frailty in patients with rheumatoid arthritis to extend healthy life expectancy), a prospective cohort study of frailty in RA patients at Nagoya University Graduate School of Medicine. A frailty questionnaire was administered to 243 RA patients from February 2021 to January 2022. Patients’ subjective assessment of Kihon checklist for frailty (KCL), the 25-question Geriatric Locomotive Function Scale (GLFS-25), Health Assessment Questionnaire Disability Index (HAQ-DI), Beck Depression Inventory-II (BDI-II), and frequency of laughter were investigated using a self-administered questionnaire. The frequency of laughter was divided into four levels: “Almost every day”, “1-5 days per week”, “1-3 days per month”, and “Almost every day” and “1-5 days per week” and “Almost ever or almost never” [2], and the association with each item was analyzed by analysis of variance. The frequency of laughter was divided into two groups: “Almost every day, 1-5 days per week” and “1-3 days per month” and “Almost ever or almost never” [2], and multivariate logistic analysis was conducted to examine factors affecting laughter.

Results: Mean age (standard deviation) was 65.5±10.4 years at baseline. 85.6% were female, duration of disease was 13.1±9.9 years. Disease activity score (DAS28)-CRP was 1.92±0.84, KCL was 4.7±3.7, GLFS-25 was 15.1±13.6, HAQ-DI was 0.37±0.51, and BDI-II was 10.7±8.0. Regarding drug therapy, 67.9% of the patients used Methotrexate and 23.0% used glucocorticoid. The frequency of laughter was divided into two groups: “Almost every day, 1-5 days per week” and “1-3 days per month” and “Almost ever or almost never”, and multivariate logistic analysis was conducted to examine factors affecting laughter.

Interventions not only for disease activity but also for frailty may be helpful in achieving a healthy state with appropriate interventions [2]. We hypothesize that interventions such as laughter may contribute to reducing disease activity and improving frailty in RA patients. It is important for RA patients, who are prone to physical anxiety due to poor disease control and frailty, to be able to smile and live their lives.

Background: Rheumatoid arthritis (RA) is a systemic chronic inflammatory disease that causes joint symptoms due to inflammation in bones and joints, leading to physical dysfunction due to loss of activities of daily living. With advances in the treatment of RA, it has become possible to achieve the goal of treatment to a state in which joint destruction causes little deformity and no physical disability. However, RA is a disease that causes not only physical dysfunction but also generalized fatigue due to chronic inflammation. Therefore, there is a decrease in patient satisfaction due to pain and physical fatigue, which may lead to a decline in daily life. Frailty, a state of physical and mental frailty due to decreased physical and mental function and social connectedness, is a condition that can easily lead to functional disability in daily living and the outcome of requiring long-term care [1]. RA is known to cause pain and limited range of motion of joints as the disease activity worsens, which may contribute to frailty. Since frailty is reversible and patients can return to a healthy state with appropriate interventions [2], it is expected that appropriate interventions will help maintain and improve the functions of daily living.

Objectives: The purpose of this study was to investigate factors associated with improvement from frailty in RA patients.

Methods: Of 460 RA patients (a observational study, T-FLAG study) who completed a questionnaire on frailty including the Kihon Checklist (KCL) from June 1st, 2020 to August 2022, 321 patients who were Frailty/Pre-frailty at baseline were included. After 2 years, patients who had improved from frailty to pre-frailty/robust or pre-frailty to robust were included in the improvement group, and the other patients were included in the non-improvement group. Multivariate analysis was used to examine the factors associated with improvement at 2 years. The cutoff values of the factors related to improvement were calculated by ROC analysis.

Results: Mean age (standard deviation) was 67.1±13 years at baseline, 76.7% were female, duration of disease was 12.5±10 years, and BDI was 22.1±4.0. There were 83 patients (25.9%) in the improvement group. There were significant differences in age at baseline (63 vs. 68 years), DAS28-ESR (2.57 vs. 3.06), HAQ-DI (0.19 vs. 0.65), and KCL score (7.0 vs. 8.7) in the improvement group vs. the non-improvement group. There was no significant difference in gender (76% vs. 77%), disease duration (10 vs. 12 years) and BMI (21.8 vs. 22.3 years). Multivariate analysis revealed that age (OR: 0.97, 95% CI: 0.95-0.99) and HAQ-DI (OR: 0.19, 95% CI: 0.08-0.42) were independent factors associated with improvement (Table 1). The age and HAQ-DI cutoff values related to improvement were 72 years (sensitivity 73.5%, specificity 44.1%) and 0.25 points (sensitivity 78.3%, specificity 82.4%).

specificity 58.9%). The cutoff value of HAQ-DI was used to examine the rate of improvement group in the two groups. In the HAQ-DI≤0.25 group, 40.1% of patients were in the improvement group, while only 11.5% were in the improvement group in the HAQ-DI>0.25 group, indicating a significant difference between the two groups (P<0.001).

**Conclusion:** Age and HAQ-DI were found to be indices for improvement in RA patients. Since frailty is a state in which physical and mental vitality declines with age, it is important to know age, which is a reversible state of frailty. In addition, among the multifactorial components of frailty, a low HAQ-DI, an assessment of physical function, may indicate the possibility of improving from a frailty state with appropriate intervention.

common RA patient subset in clinical practice, possibly leading to refractory RA, defined as resistance to multiple drugs with different mechanisms of action and persistence of physical symptoms and/or high disease activity (hDA). Real-life studies examining the impact of switching/swapping versus not switching/swapping therapies in RA active patients are still limited.

**Objectives:** To evaluate predictors of therapy switch/swap in a population of patients with refractory RA who already failed ≥ 1 biological/targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD), not reaching predefined target at 6-months after starting subsequent lines of DMARDs.

**Methods:** This single-center study retrospectively included 117 patients evaluated at our Clinic from 2019 to 2022. During subsequent 3- and 6-months T2T visits, disease activity through 28-joint disease activity score (DAS28), organ damage, treatment changes and composite disease activity indices were recorded. Chi square and Fisher’s exact test was used for comparison of dichotomous variables and one-way analysis of variance (ANOVA) for continuous variables. Threshold of statistical significance was defined as a p-value < 0.05.

**Results:** 66 patients (56.4%) did not achieve remission or low-disease activity target 6 months after starting b/tsDMARD; among them, 47/66 (71.2%) were in MDA, 11/66 (16.6%) in HDA and 8/66 (12.1%) were lost at follow up. 24/66 patients (36.4%) switched/swapped therapy at 6-months follow up. Longer disease duration correlated with treatment continuation (p=0.04). HDA at 6-months was a strong predictor of treatment change (p=0.009), as well as drug suspension for all reasons (e.g., safety issues, lack of therapeutic efficacy reported in medical records; p < 0.001). Major results from ANOVA are summarized in Figure 1: Evaluator’s Global Assessment (EGA) at 6-months significantly correlated with treatment switch (p=0.007), while patients taking drugs from more time tend to be switched less frequently (p=0.01). Remarkably, we did not find any correlation between the variations of DAS28, Global Health (GH), swollen joint count (SJC), tender joint count (TJC), Health Assessment Questionnaire (HAQ), Visual Analogue Scale (VAS) for Pain, steroid dependence. Similarly, baseline erosions, seropositivity, or number of prior DMARDs did not influence the outcome.

**Conclusion:** In our retrospective cohort study, drug switching seems not linked to a more severe disease. Examining disease activity indexes, neither baseline data nor PRs, but only 6-months EGA, appears statistically significant. While a number of explanations might be offered, including limitations of the current RA measurement tools, such as DAS28, and the limited sample size, our findings are concerning, suggesting that probably, in real-practice, a sort of physician “general impression” rather than objective findings of disease activity still guide therapeutic switching.

**AB0225 WHAT FACTORS INFLUENCE RA PRESENTATION AT DIAGNOSIS?**

**Keywords:** Rheumatoid arthritis, Prognostic factors, Epidemiology

**D. Di Giuseppe, J. Asking, H. Westerlund, Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden**

**Background:** Researchers have mostly focused in understanding which factors influence the risk of rheumatoid arthritis (RA) and its progression. However, little is known on the determinants of disease presentation at diagnosis. This is a fundamental prerequisite for studies focusing in understanding disease progression.

**Objectives:** To estimate the association between demographic and disease-related factors and high disease activity (HDA) of RA at diagnosis by a rheumatologist.

**Methods:** Data from newly diagnosed RA patients between October 2004 and May 2018 from the Epidemiological Investigation of RA study (EIRA) will be included in these analyses. The outcome of interest is high disease activity, defined as having either DAS28 ESR >5.1 or DAS28 CRP>4.6. Patients without an HDA evaluation at baseline (defined as recorded in a visit between 40 days before and 75 days after EIRA inclusion) have been excluded from the analyses. Odds ratios (ORs) and their 95% confidence intervals (CIs) of HDA were estimated through a mixed model with region as random intercept, to account for between regions variations.

**Results:** A total of 1665 patients were included in this study, of which 995 (60%) had HDA at diagnosis. In the univariate analyses, young age at diagnosis (50-59 years: OR=0.76 (0.59-1.00)), longer symptom duration (>365 days: OR= 0.51 (0.37-0.71)), and diagnosis in more recent years (≥2015: OR= 0.66 (0.48-0.91)) were inversely associated with HDA, while being underweight (BMI <18.5: OR= 2.17 (1.04-4.51)), low education (<9 years: OR= 1.41 (1.09-1.82)), and being seronegative (OR=1.78 (1.39-2.28)) had higher odds of HDA. Sex, shared epitope, and cigarette smoking were not associated with HDA at diagnosis. In the multivariable analyses, age and education were no longer associated with HDA.

**Conclusion:** In this study we observed that sex, symptoms duration, calendar time, living alone, serostatus were associated with high disease activity at diagnosis, while age, sex, education, shared epitope, and cigarette smoking were not. Younger age at diagnosis and recent diagnosis (<2015) were inversely associated with HDA at diagnosis.

**AB0226 PREDICTORS OF RESPONSE AFTER CESSATION OF JAKI THERAPY IN PATIENTS WITH RA**

**Keywords:** bDMARD, Rheumatoid arthritis, Remission

**D. C. Diederen, P. Durez, L. Jenaerts, R. Westhovens, P. Verschueren, 3 Vrije Universiteit Brussel, Biostatistics and Medical Informatics Research Group, Department of Public Health, Brussels, Belgium; 2Université Catholique de Louvain, Pôle de Pathologies Rhumatismes Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Bruxelles, Belgium; 1Cliniques Universitaires Saint-Luc, Department of Rheumatology, Bruxelles, Belgium; 5Reuma-Instituut Hasselt, Department of Rheumatology, Brussels, Belgium; 6Université Hospitals Leuven, Department of Rheumatology, Leuven, Belgium; 4KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium**

**Background:** In a previous study based on data from the Belgian register ”Tool for Administrative Reimbursement Drug Information Sharing” (TARDIS[1]), IL6 inhibitors showed a better clinical response after JAKI cessation compared to other b/tsDMARDs. However, considerable baseline differences in demographic and clinical variables, and previous exposure to advanced therapies were found between treatment groups, which could have influenced our results.

**Objectives:** We aimed to find predictors of short-term response after cessation of JAKI therapy in patients with RA.

**Methods:** Patients were selected from TARDIS for this analysis if they had stopped JAKI therapy and initiated a subsequent therapy between registration and December 2021. Patients were grouped per subsequent therapy: TNFi, Abatacept, IL6 inhibition or JAKI. Rituximab was excluded as patients are reimbursed on RA flare in Belgium. Linear and logistic regression models were constructed to establish predictors of clinical response. DAS28 change between baseline and first follow-up, DAS28 remission (DAS28<2.6) and DAS28 low disease activity (LDA, DAS28<3.2) at first follow-up were taken as dependent variables. Following variables were included in the models: age, disease duration, b/tsDMARD naive treatment group and baseline characteristics. TNFi, Abatacept, IL6 inhibition or JAKI therapy was initiated in 33% (63/193), 11% (20/193), 18% (34/193) and 39% (76/193) of patients respectively. Remission and LDA were reached in 42% (81/193) and 63% (122/193) of patients respectively. Common predictors for achieving remission and LDA were baseline HAQ and not receiving abatacept (Figure 1). Variables positively associated with a higher DAS28 change were initiation of subsequent therapy between registration and December 2021. Patients were grouped per subsequent therapy: TNFi, Abatacept, IL6 inhibition or JAKI. Rituximab was excluded as patients are reimbursed on RA flare in Belgium. Linear and logistic regression models were constructed to establish predictors of clinical response. DAS28 change between baseline and first follow-up, DAS28 remission (DAS28<2.6) and DAS28 low disease activity (LDA, DAS28<3.2) at first follow-up were taken as dependent variables. Following variables were included in the models: age, disease duration, b/tsDMARD naive treatment group and baseline characteristics. TNFi, Abatacept, IL6 inhibition or JAKI therapy was initiated in 33% (63/193), 11% (20/193), 18% (34/193) and 39% (76/193) of patients respectively. Common predictors for achieving remission and LDA were baseline HAQ and not receiving abatacept (Figure 1). Variables positively associated with a higher DAS28 change were initiation of subsequent therapy between registration and December 2021.

**Results:** In total, 193 RA patients, who had stopped JAKI therapy and had complete baseline and follow-up data, could be included. Table 1 shows baseline demographic and clinical characteristics. TNFi, Abatacept, IL6 inhibition or JAKI therapy was initiated in 33% (63/193), 11% (20/193), 18% (34/193) and 39% (76/193) of patients respectively. Remission and LDA were reached in 42% (81/193) and 63% (122/193) of patients respectively. Common predictors for achieving remission and LDA were baseline HAQ and not receiving abatacept (Figure 1). Variables positively associated with a higher DAS28 change were baseline HAQ (Relative Risk (RR) 0.02 (0.01, 0.03), TJc (0.06 (0.01, 0.12), 0.07 (0.10 (0.03, 0.16)) and CRP (RR 0.02 (0.01, 0.03)), while baseline HAQ (RR 0.60 (-0.88, -0.31) and not receiving abatacept (RR 0.70 (-1.25, -0.15)) were negatively correlated with DAS28 change in the adjusted multivariate linear regression model.

Table 1. Patient characteristics at the start of next treatment after failing the first JAKI therapy

Legend: Number given are mean ± SD or number, proportion. TNFi = tumour necrosis factor inhibitor; JAKI = Janus Kinase inhibitor; HAQ= health assessment questionnaire; PGA= Patient Global assessment; CRP= C-reactive protein; ESR= erythrocyte sedimentation rate; TJc= tender joint count; SJc= swollen joint Count; DAS28 = disease activity score based on the 28-joint DAS; Missing HAQ(0-3) scores were imputed by regression using age and HAQ(0-60) scores, the sum of the scores (0-3) on all (20) individual HAQ questions.
Conclusion: This explorative analysis reveals that after adjustment, patients who have worse functionality and receive abatacept compared to other b/ts DMARDs may show worse clinical outcome in patients with RA. The treatment effect should be further explored, but caution is warranted as the sample size was relatively small and indication bias cannot be excluded.

EARLY RHEUMATOID ARTHRITIS DIAGNOSIS:
PRIMARY CARE PHYSICIAN’S PERSPECTIVE AND NEEDS

Keywords: Education, Rheumatoid arthritis

C. Bourgeois Avella1, M. Sánchez Lucas1, J. Molina Collada1, J. Martínez-Barrion, J. M. Álvarez Gracia1, J. Rivera1, J. Omedo1, G. Fernandez Plana2, I. Castrejón1, 1Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain; 2Centro Salud Ibiza, Primary Care, Madrid, Spain; 3Centro de Salud Dr Cirajas, Primary Care, Madrid, Spain

Background: Primary care physicians (PCPs) play a crucial role in early recognition and rapid referral of patients with inflammatory arthritis to improve early management and patient outcomes. However, there is limited information on perceived barriers for referral and areas of improvement [1]. The purpose of this study is to explore the perspective and needs of PCPs to guide a specialist’s referral program.

Objectives: To explore the perspective and needs of primary care physicians (PCPs) to guide a specialist’s referral program at an academic rheumatology center in Madrid and to identify areas of improvement to facilitate early referral for early rheumatoid arthritis.

Methods: A PCPs-rheumatology early referral program (REUCARE) has been initiated at our area in January 2022 with 257 PCPs participating. Up to May 2022, 88 patients have been referred, however only 24 (27%) fulfill inclusion criteria. In order to improve the referral strategy, a survey has been developed in collaboration with primary care investigators to explore areas of improvement. The survey included 5 domains covering: PCPs demographics, previous knowledge about RA, level of confidence, factors and potential barriers influencing referral and interest on rheumatological training. Data were captured using four-point Likert scales, yes/no question or free text, and were analyzed descriptively.

Results: E-mail invitations were sent to 257 PCPs through their primary care center coordinator and completed by 26 (10% response rate). More respondents were women (76%) in practice for over more than 20 years who reported having 30-40 patients per day and only 1-5 patients diagnosed of RA in the last year. The majority (83%) reported additional rheumatological training besides medical school, however they were no familiar with the incidence and prevalence of the disease. Around 67% were aware of the importance of early diagnosis and treatment, however they felt not very confident making the initial diagnostic (61% “somehow confident” and 35% “not confident”). Most PCPs considered the waiting time for rheumatology prolonged (65%) and very prolonged (21%) and reported insufficient feedback information from rheumatologists (60%). Main reasons for delay from PCPs perspective were nonspecific initial symptoms of the disease (48%) followed by rheumatology long waiting list (39%) (Figure 1).

Figure 1. Predictors of remission or LDA

Conclusions: Although 77% indicated using additional resources to improve their knowledge in RA, all participants stated that they would be interested in receiving more information on early diagnosis, being the preferred resources a specific e-consult (87%), updated mini guidelines (76%) and face-to-face meetings with rheumatologists.

Conclusion: Most PCPs are aware of the importance of early diagnosis and management of RA but feel uncomfortable making the initial diagnosis. Non-specific initial symptoms and long waiting lists for rheumatology are the main reasons for delay from PCPs perspective. Resources to improve referral, including e-consult and specific guidelines, are in need as part of the actual referral program.

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Previously, we stratified the patients with rheumatoid arthritis-associated interstitial lung disease (RA-ILD) into four distinct groups according to their change of percent predicted forced vital capacity using trajectory analysis: persistently improving, stable, slowly declining, and rapidly declining. [1] Till October 2020, a total of twelve patients died, of which eight patients died even though they belonged to either stable or slowly declining groups. Therefore, it advantages additional biomarkers benefits to anticipate poor prognosis.

Objectives: To analyze whether serum Kreb von Lungen 6 (KL-6) predicts mortality among patients with stable or slowly declining % FVC pred. trajectory group.

Figure 1. POC’s perception for delay in assessing patients with RA for early treatment

Most patients had stable or slowly declining lung function. Among the patients with slowly declining lung function, serum KL-6 levels were significantly higher than those with stable lung function at baseline and during the 24-month follow-up period. Serum KL-6 levels increased with disease activity, and the predictive value of serum KL-6 for mortality was higher in patients with slowly declining lung function. These results suggest that serum KL-6 levels may be useful for predicting mortality in patients with slowly declining lung function in RA-ILD.
Methods: The Korean RA-ILD (KORAIL) cohort is the prospective observational cohort. Patients diagnosed with RA based on either 1987 or 2020 ACR criteria and with ILD based on CT scans had been recruited from six tertiary medical hospitals in Korea from January 2015 to July 2018 and followed for 3 years. Pulmonary function tests and chest CT scans were conducted annually. Serum KL-6 level at enrollment was measured by Nanopia KL-6 assay (SEKISUI, Japan). The cut-off value of KL-6 was referenced in the previous report.[2] Kaplan-Meier Log-rank tests and Cox proportional hazard analysis were conducted using SPSS statistics 21.0.

Results: Among patients with stable (n=68) and slowly declining (n=54) lung function groups, three and five patients died, respectively. The mean age of the stable disease group was statistically significantly higher than that of the slowly declining group (64.9±7.7 years vs 67.9±6.8-year-old, p=0.03). There was no significant difference between groups in the proportion of males (n=21 vs 19, p=0.70) or ever-smokers (76.1% vs 66.7%, p=0.31), and the mean duration of RA or ILD (RA duration 8.6±8.8 vs 6.7±7.1 years, p=0.21; ILD duration 3.2±3.6 years vs 2.5±2.9 years, p=0.25). Serum KL-6 levels at baseline were comparable between groups (636.3±454.6 U/mL vs 590.6±547.3 U/mL, p=0.62). The hazard ratio for death in the KL-6>1000U/mL compared with the KL-6<1000U/mL was 3.77 (95% confidence interval, 0.90-15.8, p=0.07) in an unadjusted model and 4.05 (95% CI, 0.68-24.2, p=0.13) in a model adjusted for age, sex, history of smoking (Figure 1).

Conclusion: In RA-ILD, patients with serum KL-6>1000U/mL at baseline tend to have 3.8 times as high mortality as those with serum KL-6<1000U/mL, although not statistically significant. The current study result implies that serum KL-6 level can be a useful tool to predict poor prognosis even in the case when the lung function of patients is stable or slowly declining.

IS IT POSSIBLE TO STOP TAKING GLUCOCORTICOIDS IN RHEUMATOID ARTHRITIS WHILE USING THE SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS?

Keywords: Rheumatoid arthritis

G. Mykytenko1, O. Iaremenko2. Bogomolets National University, Internal Medicine 3, Kyiv, Ukraine; 2Bogomolets National University, Internal Medicine 3, Kyiv, Ukraine

Objectives: to investigate the possibility of withdrawing glucocorticoids (GC) or reducing their dose to the target (<7.5 mg/d in terms of prednisone) when using traditional synthetic disease-modifying antirheumatic drugs (DMARD) in patients (pts) with rheumatoid arthritis (RA); to study independent prognostic factors that affect the continuation of taking GC.

Methods: 270 patients with RA (women - 86.6%) aged 51.2 ± 0.71 years, with a disease duration of 50.2 ± 3.82 months were examined. Rheumatoid factor (RF) was found in 84.8% of individuals, antibodies to cyclic citrullinated peptide (ACCP) - in 66.6%, DMARD therapy included methotrexate (n = 91), leflunomide (n = 95), sulfasalazine (n = 51), hydrochloroquine (n = 3) or its combination (n = 126). Statistical analysis was performed using program SPSS 22.0. Certain disagreements average values were estimated using non-parametric of the Mann-Whitney criterion for quantitative signs and criteria χ² for frequency indicators. To identify independent factors that affect the possibility of canceling GC, the method of logistic regression analysis was used with the calculation of the risk ratio (RR) and 95% confidence interval (95%CI). In order to identify the decisive factor affecting the possibility of achieving the target dose of GC, a stepwise logistic regression analysis of multivariate models was performed. The difference was considered probable at p<0.05.

Results: During 3 years of study, GC was canceled in 33% of pts in the period from 3 to 30 months (mostly in the first 6 mth). Among those who continued to take GC, the target dose (<7.5 mg/d) was achieved only in 32.6% of pts. Among pts continuously receiving GC, compared with pts who discontinued GC, there were probably more women (89.5% vs. 80.8%, p<0.05), ACCP-positive pts (88.4% vs. 55.0%, p<0.01), with higher DAS (ESR) values (5.29 ± 1.0 vs 4.84 ± 0.15, p<0.05) and more pronounced structural changes on the X-ray scale (43.4 ± 2.42 vs 32.4 ± 2.71, p<0.05). According to the logistic regression analysis, the risk of continuing GC treatment was probably associated with female gender (RR 2.39 (1.09–4.97)), elderly pts (RR 1.02 (1.001–1.04)), ACCP-positivity (RR 3.73 (1.26–11.0)), disease activity by DAS (ESR) (RR 1.19 (1.01–4.43) and structural joint changes (RR 1.01 (1.005–1.02)). Only the initial dose of GC ≥ 7.5 mg/d was associated with the inability to reach the target dose of GC during the entire follow-up period (RR 6.32 (2.0–19.5)).

Conclusion: Despite of the treatment with traditional synthetic DMARD, only a third of RA pts can cancel GC, mainly in the first 6 mths. For the pts who continue taking GC, the target dose can be achieved in 33% of them. Independ- ent predictors of the impossibility of GC discontinuation are female gender, old age, ACCP-positivity, higher RA activity according to DAS (ESR) and more pronounced joint destruction at the initial stage. A negative prognostic factor in achieving the target dose of GC is their initial dose ≥ 7.5 mg/d.

COMPARATIVE FUNCTIONAL ABILITY OF PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS AFTER TOTAL KNEE ARTHROPLASTY

Keywords: Osteoarthritis, Rheumatoid arthritis

M. Karimov1, S. Lapshina2, T. Nuriakhmetova2, I. Gilmutdinov3, A. Nuriakhmetov2, S. Ardashev2, I. Akhtiamov2, V. Tashkent Medical Academy; Traumatology, Orthopedic and Military Surgery, Tashkent, Uzbekistan; 3Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation; 3Republican Clinical Hospital, Orthopedics No. 2, Kazan, Russian Federation; 4Kazan State Medical University, Traumatology, Orthopedic and Military Surgery, Kazan, Russian Federation

Background: Patients with rheumatoid arthritis (RA) often require adequate disease control prior to total knee arthroplasty (TKA). At the same time, they may have worse outcomes and late complications compared to osteoarthritis (OA) patients.

Objectives: To study the functional abilities of RA patients undergoing TKA compared to OA patients using the KSS scoring system.

Methods: The study included 150 patients: 69 patients (46%) with RA and 81 patients (54%) with OA. 32% of them were males and 68% were females. Th average age of patients with RA was 59.0 [52; 64] years, while in OA group it was 66.0 [61; 73] years. Among patients with RA, 60.9% had moderately active RA, 23.3% had mild disease course, 14.8% had inactive disease. All patients underwent cemented TKA. All of them also completed KSS score prior to surgery, immediately after that and 3 and 12 months after the discharge. Statistical analysis was performed using SPSS version 23.0 (IBM Corp., Armonk, NY, USA). A p value of less than 0.05 was considered statistically significant.

Results: Prior to intervention patients with RA had significantly lower KSS scores compared to OA patients (45.0 [40; 55] versus 60.0 [50; 60], p<0.000). An improvement of KSS became comparable between the two groups (83.0 [74; 84] versus 82.0 [80.5; 85], p=0.754, Mann-Whitney). 3 months
after the intervention RA patients had significantly higher KSS scores than prior to surgery (Mdn=88.0, n=69 versus Mdn=40.0, n=69, z=-2.23, p<0.00) or at discharge (Mdn=88.0, n=69 versus Mdn=83.0, n=69, z=-2.25, p<0.00, Wilcoxon test). The same trend was observed for KSS completed 12 months after the surgery (Mdn=93.0, n=69 versus Mdn=88.0 in KSS 3 months after the surgery, n=69, z=-2.26, p<0.00). At the same time, the results of KSS were comparable between RA and OA groups and 12 months after the intervention (88.0 [88; 88] in RA group versus 88.0 [87; 89] in OA group, p=0.772, Mann-Whitney; 94.0 [93; 95] in RA group versus 94.0 [93; 95] in OA group, p=0.702, Mann-Whitney, respectively).

Conclusion: The functional abilities of patient with RA after TKA did not differ from those among OA patients regardless of diseases activity despite, the fact that among RA patients KSS scores were significantly lower prior to surgery. KSS scores of RA patients improved 3 and 12 months after the intervention and were comparable to OA group.

Results: Subjects were 186 Vo and 167 RA patients in 2019. In RA, average age was 65.8 ± 12.7 years, 143 patients (85.6%) were female, average disease duration was 13.8 ± 11.8 years and DAS28-ESR was 3.10 ± 1.45. Compared with Vo, Physical Component Summary (PCS) (Vo 46.9 ± 12.2, RA 34.1 ± 18.0: p<0.01), Mental Component Summary (MCS) (Vo 52.2 ± 9.5, RA 49.4 ± 9.5: p<0.01) and VT (Vo 50.5 ± 10.1, RA 44.0 ± 10.8: p<0.01) were significantly lower in RA patients. In multiple linear regression analysis, RA was a significant decreasing factor of PCS (β=-12.8, 95%CI=-15.7 - -9.89: p<0.01), MCS (β=-2.75, 95%CI=-4.68 - -1.82: p<0.01) and VT (β=-3.01, 95%CI=-4.57 - -1.45: p<0.01). In RA patients, multiple linear regression analysis shows that VAS (β=-0.06, 95%CI=-0.12 - -0.00: p=0.03), ESR (β=-0.09, 95%CI=-0.16 - -0.02: p=0.02), and mental health component of the SF-36-MH (β=0.35, 95%CI=0.42 - 0.68: p<0.01), were significant affecting factor for VT. (Table 1)

Conclusion: In this study, RA was a significant QOL declining factor. High VAS score, high ESR values and low mental health score were associated with fatigue in patients with RA.

Table 1. Summary of multiple linear regression analysis for fatigue (vitality score of SF-36) in patients with rheumatoid arthritis.

Keywords: Rheumatoid arthritis, Cardiovascular disease
Background: Traditional risk factors do not fully explain the increased risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA). [1] The Hp2-2 genotype is known to confer a lower anti-oxidant and higher inflammation effect when compared to the non Hp2-2 genotype. [2]

Objectives: This study aims to investigate the association of Hp genotype with CVD in patients with RA.

Methods: Sixty-nine with CVD cases and 207 gender and ethnicity matched control (without CVD) with allocation of 1:3, were retrieved from the Tan Tock Seng Hospital RA registry from 1 Jan 2000 to 31 Dec 2020. Hp genotype was determined using TaqMan-based real-time polymerase chain reaction (PCR) and the State of Hungary and co-financed by the European Social Fund in the framework of TAMOP-4.2.4-A/2-11/2-2012-00050 (Z.S.).

Conclusion: The Hp 2-2 genotype is known to confer a lower anti-oxidant and higher inflammation effect when compared to the non Hp2-2 genotype.

Background: Routine Assessment of Patient Index Data 3 (RAPID3) is a patient-reported outcome (PRO) that can be used to assess the condition of rheumatoid arthritis (RA) patients using only a questionnaire that can be completed in a short time. It is useful as a simple method for assessing disease activity. In previous reports, RAPID3 could be used as an assessment similar to Disease Activity Score 28 (DAS28), a common disease activity assessment index. However, in the treatment of RA, there are unmet needs in which patients have low satisfaction with treatment, even though they are in remission according to disease activity assessments such as DAS28. To investigate the cause of this discrepancy, we decided to conduct a study using RAPID3 as a subjective patient assessment and DAS28 as a general disease activity measure.

Objectives: The purpose of this study was to investigate the association between disease activity and RAPID3 in RA patients.

Methods: The data for this study were obtained from the Tsurumi-Fraity and Locomotive Syndrome of Rheumatoid Arthritis for Globalization (T-FLAG), a observational study involving three centers. A PRO questionnaire was administered to 467 RA patients between June 1 and August 31, 2020. Disease activity was assessed using the RAPID3, DAS28-28R, DAS28-ESR, Clinical Disease Activity Index (CDAI), and Simplified disease activity index (SDAI). The RAPID3 (30 points total) consists of three domains: physical function (0-10), pain (Visual Analogue Scale 0-10), and Patient global assessment (PGA) of disease activity (0-10). It consists of three domains, divided into disease activity categories as follows: <1 low disease activity: 3.1-6.9, moderate disease activity: 6.1-12 high disease activity: >12). PRO assessment was performed using PGA, Health Assessment Questionnaire Disability Index (HAQ-DI), Kihon checklist (KCL), carotid intima-media thickness (IMT) and pulse-wave velocity (PWV) by ultrasound. We also performed simultaneous PET-CT assessment of joints and vessels.

Results: Twenty-six patients completed the study. Tofacitinib treatment significantly decreased VEGF (p=0.019), PIGF (p=0.019), IL-6 (p=0.001), cathK (p=0.04) and galectin 3 levels (p=0.013) after 12 months of treatment. Seropositive patients had increased bFGF, PIGF and NT-proBNP levels (p=0.05). Uni- and multivariable regression analysis indicated variable correlations of baseline and 12-month TNNV, IL-6, bFGF, PIGF, NT-proBNP and PECAM-1 with IMT, as well as as synovial and vascular inflammation as determined by PET-CT (p<0.05).

Conclusion: Tofacitinib suppressed the production of multiple angiogenic biomarkers. Number of these biomarkers are involved in carotid atherosclerosis, as well as synovial and vascular inflammation.

Disclosure of Interests: This research was supported by the European Union and the State of Hungary and co-financed by the European Social Fund in the framework of TAMOP-4.2.4-A/2-11/2-2012-0001 ‘National Excellence Program (Z.S.) by the European Union grant GINOP-2.3.2-15-2016-00050 (Z.S.) and by the W118341 investigator-initiated research (IIIR) grant obtained from Pfizer US (Z.S.) I have no acknowledgements to declare.

and the 25-question Geriatric Locomotive Function Scale (GLFS-25). We compared the disease activity categories using DAS28-CRP and RAPID3.

**Results:** The mean age (± standard deviation) was 66±13, female was 73%, disease duration was 11±10, RAPID3 was 5.6±5.2, DAS28-CRP was 2.19±1.03, HAQ-DI was 0.46±0.66, and KCL was 6.6±4.4. RAPID3 and DAS28-CRP showed a strong correlation with a correlation coefficient of 0.743, and CDAI and SDAI as other disease activity assessment methods also showed a strong correlation (CDAI: r=0.883, SDAI: r=0.880). On the other hand, the HAQ-DI and GLFS-25, which are PRO assessments of physical function, showed strong correlations, but the KCL, which includes psycho-social assessments along with physical function assessments, showed a slightly weaker correlation (r=0.507). Morning stiffness was not correlated with RAPID3 (r=0.206). In the disease activity category, 59.5% of patients had RAPID3 and DAS28-CRP in the same category (RAPID3 = DAS28-CRP). In addition, RAPID3 belonged to the worse category than DAS28 in 31.3% of cases (RAPID3 > DAS28-CRP). The group with RAPID3 > DAS28-CRP (31.3%) vs. the group with RAPID3 = DAS28-CRP (59.5%) showed no significant differences in age, gender, and tender/swollen joint count (Table 1). On the other hand, there were significant differences between the two groups in disease duration (14 vs. 11 years), PTA (36 vs. 14mm), HAQ-DI (0.84 vs. 0.29), KCL (8.5 vs. 5.8), and GLFS-25 (28 vs. 13).

**Conclusion:** In this study, we showed that the correlation between RAPID3 and disease activity assessment was quite strong. In the disease activity category, approximately 60% of all patients had similar DAS28-CRP and RAPID3. However, the discrepancy between DAS28-CRP and RAPID3 may be caused by physical dysfunction and frailty. Therefore, it is important to achieve clinical remission and improve PRO in RA treatment as an intervention to address unmet needs.

THE REDUCTION OF CIRCULATING LEVELS OF SERUM CALPROTEIN IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT

**Keywords:** Biomarkers, bDMARD, Rheumatoid arthritis

S. E. L. Della Pina1, S. Piantoni1, E. Garrafa2,3, M. Vezzoli1, A. Caprol1, L. Franzoni1, I. Cavazzana4, P. Airo1, F. Franceschini1,1. Rheumatology and Clinical Immunology Unit, ASST Spedali Civili and University of Brescia, Brescia, Italy; Department of Clinical and Experimental Sciences, Brescia, Italy; 2ASST Spedali Civili, Brescia, Italy; Department of Laboratory Diagnostics, Brescia, Italy; 3University of Brescia, Italy; Department of Molecular and Translational Medicine, Brescia, Italy

**Background:** The research of new biomarkers is still an unmet need in the field of rheumatoid arthritis (RA), especially for patients (pts) without rheumatoid factor and/or anti-citrullinated peptides positivity (seronegative RA), and for those without the elevation of inflammatory markers, such as the C-reactive protein (CRP) [1]. Calprotectin (CLP) is a heterodimeric complex of two calcium binding proteins which is expressed in granulocytes and monocytes. It mediates cell differentiation, activation, migration, apoptosis and the production of pro-inflammatory factors [2]. Recent studies showed that CLP synovial fluid levels are higher in RA pts and that its serum levels might directly reflect the synovitis severity [3].

RHEUMATOID ARTHRITIS CLINICAL ACTIVITY IS NOT ASSOCIATED TO CARDIOVASCULAR RISK AS MEASURED BY TRADITIONAL RISK SCALES

**Keywords:** Cardiovascular disease, Rheumatoid arthritis

J. R. Azpíri-López1, I. J. Colunga-Pedraza2, D. A. Galaza-Delgado3, V. M. Beltran-Aguilar,1,2, V. Gonzalez-Gonzalez1,2, A. A. Arias Peraíta1, N. De Avila Gonzalez1, J. A. Cardenas-de la Garza1, G. Garcia-Arellano2,1. Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico; 1Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico

**Background:** Rheumatoid arthritis (RA) patients have a higher cardiovascular risk (CVR) than the general population, being atherosclerotic cardiovascular disease the main cause of mortality [1]. Such increased could be explained by traditional CVR factors and chronic inflammatory state of disease. Clinical activity of disease, which is evaluated by DAS-28, is a parameter that denotes the current disease activity status [2].

**Objective:** To compare CVR, by six scales: ACC/AHA ASCVD 2013, Framingham lipid and BMI, SCORE2, QRISK3 and Reynolds risk score, according to clinical activity of RA patients using DAS-28 CRP.

**Methods:** Descriptive, comparative and cross-sectional study. We enrolled RA patients between 40 and 75 years old who fulfilled ACR/EULAR 2010 classification criteria and recruited in the Rheumatology service from a tertiary care hospital, in Monterrey, Mexico. Patients were divided by time of disease evolution

Background: Rheumatoid Arthritis (RA) represents a huge burden for patients' quality of life and there are still relevant unmet needs in its management due to uncovered patients’ needs even once sustained remission is achieved.

Objectives: This study aimed to investigate disease burden, treatment priorities and preferences across disease phases comparing patients’ and physicians’ perspectives.

Methods: Consultants or residents in rheumatology (across Academic and non-academic hospitals) and patients with RA both aged ≤40 years were reached by an anonymous online survey between November 2021 and November 2022, designed by the SIReyoung commission. For each included RA patient, demographic and clinical parameters (RA diagnosis timing, current and previous treatments) were collected. For each included physician demographic, education and professional profile details were collected.

Results: Two-hundred seventy-four consultants or residents in rheumatology and 90 RA patients, both aged ≤40 years, completed the online survey. All Italian regions were equally represented for both physicians’ and patients’ subgroups. Considering the patients’ disease referral status, 26(28.9%) received RA diagnosis at the very early stage (≤3 months), 33(36.7%) at early stage (3-12 months) and 31(34.4%) after 12 months from symptoms’ onset. When asked for the priority in treatment objectives, the survey revealed a different priority among the subgroups with a higher importance given to fatigue resolution (p<0.0001) and morning stiffness reduction (p<0.0001) by patients and to radiological damage (p<0.001) and disability reduction (p<0.0108) by physicians, while comparable priority was given by the 2 groups to pain relief, physical function restoration and work-ability recover (p<0.05 for all). When asked about the factors that could improve RA management, the survey revealed higher agreement scores for patients compared to physicians in educational need (p<0.0001), increase of outpatient visits and access to treatment (both p<0.0001) and use of digital apps (p<0.0001). Stratifying patients based on self-perceived disease control, 30(33.3%) were well controlled, 52(57.8%) moderately controlled and 8(8.9%) very poorly controlled. When questioned about their will to treatment modification once sustained remission status is achieved, patients showed a higher agreement of maintaining the treatment unchanged (p=0.0002) and a higher fear of modification consequences (p<0.0001) compared to physicians, mostly if not guided by the treating rheumatologist or out of established decisional algorithms.

Conclusion: Young patients with RA and young rheumatologists have variable agreements on treatment aims and priority. In particular, when dealing with the sustained remission status, a shared decisional algorithm between physicians and patients is needed to reduce patients fear and improve their empowerment.

IMPACT OF DISEASE ACTIVITY ON SLEEP DISORDERS IN RHEUMATOID ARTHRITIS: A CROSS SECTIONAL STUDY ABOUT 100 PATIENTS

Keywords: Rheumatoid arthritis, Lifestyles

M. Brahem1, B. Jebali1, S. Abdelatif1, R. Sarraj2, O. Jomaat1, H. Hach1, Y. Mohamed1, Hôpital Universitaire Tahar Star, Service Rhumatologie, Mahdia, Tunisia
Results: We included 63 patients (52 women and 11 men). The mean age was 68.17±4.35 years. The median duration of disease progression was 11 years with an IQR of [4-16]. The mean DAS28 was 3.72±1.46. The mean HAQ was 1.6±0.58. The median value of GNRI was 68.17±4.35 with an IQR of [68.17-125.12] and extremes ranging from 70.06 to 145.02. According to the GNRI, 58 patients (92.1%) had a GNRI > 98 indicating no nutritional risk, 2 patients (3.2%) were low risk with GNRI between 92 and 98, no patient had a GNRI between 82 and 92 indicating moderate risk and 3 patients (4.8%) had a GNRI < 82 indicating a high risk of malnutrition-related complications. After statistical analysis, we found significant association between GNRI and DAS28 score (p=0.05). We also found a significant association between GNRI and higher ESR (p=0.03). CRP (p<0.001) and higher daily doses of corticosteroids (p=0.024). However, we did not find significant association between the GNRI and advanced age (p=0.11), duration of RA progression (p=0.07), VAS of pain (p=0.2) or with HAQ score (p=0.06).

Conclusion: Our results showed that the GNRI is associated with DAS28, inflammatory biomarkers and higher corticosteroid doses. The GNRI could be used as a simple and reliable tool to assess both nutritional status and disease activity in RA elderly patients.

AB0244 ROLE OF FATIGUE IN DIFFICULT TO TREAT RHEUMATOID ARTHRITIS PATIENTS OUTCOME

J. P. Otazu Maudelle1, D. Freites1, M. Rodriguez Laguna2, C. Hormigo1, M. P. Alvarez Hernandez2, A. Madrid Garcia1, L. Abasolo1, L. Leon1, Hospital Clinico San Carlos, Rheumatology, Madrid, Spain; "Instituto de Investigacion Sanitarla San Carlos (IdiSSC), Rheumatology, Madrid, Spain

Background: In difficult to treat rheumatoid arthritis patients (D2T RA), a wide spectrum of factors may contribute to the persistence of signs and/or symptoms, although these are not always directly related to inflammation (eg, functional disability, pain and fatigue). Of these, fatigue is still the least evaluated and taken into account.

Objectives: To identify the role of fatigue in D2T RA.

Methods: Cross-sectional study. 143 patients followed up in the rheumatology outpatient clinic of Hospital Clinico San Carlos, Madrid, Spain were included. Data were collected between July 2018 and November 2022. All patients met the ACR/EULAR 2010 criteria and they were in treatment with Biological agents (anti-TNF and Non anti-TNF) or Targeted Synthetic DMARDs (jakinibs). D2T RA was defined based on EULAR criteria (treatment failure, signs suggestive of currently active/progressive disease, and management being perceived as problematic by the rheumatologist and/or patient). Main variable: Fatigue was assessed by the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ). Covariates: Sociodemographic and disease-related variables. Statistical analysis. A descriptive and comparative analysis was carried out for the different variables. To identify factors independently associated to D2T RA a multivariable logistic regression was applied. Results were expressed as OR with their corresponding 95% CI. A value of p < 0.05 was consider as statistically significant.

Results: The study population comprised 143 patients and 22 (15.38%) developed D2T RA. The D2T RA group were older, with a higher DAS28 and disability. Sociodemographic, clinical, disease-related variables, and the fatigue scores used in the study are showed on Table 1. In our final logistic regression model, OR: 1.05; p=0.017 and fatigue were independently associated with D2T RA (OR: 1.04; p=0.011).

Conclusion: Despite the absence of an explicit mention of fatigue in the definition of AR D2T, it appear to be a main factor explaining the D2T RA outcome. The evaluation and management of fatigue should be one of the objectives in the treatment of patients with RA.

AB0245 IMPACT OF EXTRA-ARTICULAR RHEUMATOID ARTHRITIS MANIFESTATIONS ON ATLANTOAXIAL SUBLUXATION

Keywords: Prognostic factors, Osteoporosis, Rheumatoid arthritis

H. Ferjani1, H. Betaieb1, D. Ben Nessib1, D. Kaffel1, K. Maatallah1, W. Hamdi1, 1Mohamed Taeib Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatology, Mannouba, Tunisia

Background: The cervical spine is frequently affected during RA. It’s the third joint location after the hands and feet [1].

Objectives: The objective of our work was to investigate the association between atlanto-axial subluxation (AAS) and the presence of extra-articular manifestations (EAM).

Methods: This is a cross-sectional comparative, single-center and hospital-based study of 102 RA patients (ACR/ EULAR 2010). Population was divided into two groups: Group 1 (study group) including 51 patients with AAS and Group 0 (control group) including 51 RA patients without AAS. AAS was defined as: the presence of an anterior C1C2 diastasis on the cervical spine radiograph in hyperflexion and/or by the presence of anterior, posterior, lateral or rotational C1C2 dislocation on MRI with/or without inflammatory signal.

Results: The study group (G1) consisted of 37 women and 14 men (M/F sex ratio = 0.37). The control group (G0) consisted of 40 women and 11 men (M/F sex ratio =0.29). The mean age was 60.3± 14.1 and 59 ± 11.3 years in G1 and G0, respectively. Median disease duration was 144 [6-480] and [5-216] months in G1 and G0 respectively. In G1, the median time to onset of AAS was 48 months [0-492]. At AAS diagnosis, EAM were present in 49% of G1 patients: dry ocular syndrome in 2 patients, Bone densitometry, performed in 34 patients, was normal in 26.5% of cases. Osteoporosis and osteopenia were found respectively in 35.3% and 38.2% of patients. In analytical study, patients of G1 had higher prevalence of EAM (p<0.001) and osteoporosis (p=0.012). Though, no association was found between the presence of AAS and osteoporosis (p=0.79).

Conclusion: In this work, patients with AAS had significantly more EAM and osteoporosis. A regular monitoring of cervical spine radiographic assessment in these patients is highly recommended to prevent such complication.

AB0246 IMPACT OF RHEUMATOID ARTHRITIS DISEASE ACTIVITY ON PATIENT’S NUTRITIONAL STATUS

Keywords: Quality of life, Diet and nutrition, Rheumatoid arthritis

H. Boussaïl1, D. Souissi2, S. Miladi2, A. Fazaa2, M. Yasmine2, L. Souabni2, K. Ouerineche2, S. Kassad2, S. Chekili2, K. Ben Abdelghani2, A. Lasfar2, 1Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia; 2Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) is a potentially destructive chronic inflammatory disease that can be responsible for a deterioration of quality of life. Deformities, loss of autonomy and depression can lead to malnutrition in these patients.

Objectives: The aim of this study was to evaluate the impact of RA disease activity on the patient’s nutritional status.

Methods: We conducted a cross-sectional study including RA patients according to the ACR/EULAR 2010 criteria. Sociodemographic data and disease parameters were collected. RA activity was assessed using the Disease Activity Score (DAS28), Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Nutritional status was assessed by the Mini-Nutritional Assessment (MNA). Then, the patients were divided into two groups: Group 1: no risk of malnutrition if the MNA score was >23.5 and Group 2: risk of malnutrition (if the MNA score was between 17 and 23.5) or poor nutritional status (if the MNA score was <17). The significance value “p” was set at 0.05.

Results: A total of 30 patients were included. The gender ratio was 0.43 with a female predominance. The mean age was 57.8±13.8 years [25-79]. The most frequent comorbidities were arterial hypertension (43.3%), diabetes (20%) and gastric ulcer (16.7%). RA was immunopositive and erosive in 80% of cases. The mean duration of the disease was 14.4 years [13-23]. More than half of the patients had moderate activity (55.2%) were on corticosteroids, 48.3% were on methotrexate, 27.6% were on biotherapy, 13.8% were on sulphasalazine and 6.9% were on hydroxychloroquine. The mean value of the visual analogue pain scale was 4.7 [0-9] and the mean value of the patient’s global assessment was 5 [2-9]. The mean ESR and CRP values were 50.6mm [3.9-131] and 22.2mg/l [0.9-77], respectively. The mean DAS28ESR was 4.2±3.1[1.4-9] reflecting moderate activity. The mean body mass index was 25.1±4.46kg/m² [16.8-39] and the mean brachial muscle circumference was estimated at 26.1±3.6cm [20-31]. The mean DAS28 ESR score was higher in G2, but the difference was not statistically significant. A significant association was noted between RA activity level and patient nutritional status (p=0.017).

In patients with high activity, 71.3% were at risk of malnutrition and one patient was in poor nutritional status. Among patients with moderate activity, 42.8% were at risk of malnutrition and 50% had normal nutritional status. Among patients with low activity, the majority (80%) had normal nutritional status.

Conclusion: Our study shows an impact of RA disease activity on the patient’s nutritional status. The higher the disease activity, the higher the patient’s risk of malnutrition.

Rheumatoid arthritis - prognosis, predictors and outcome

**AB0247** WHICH PARAMETERS INFLUENCE DOMESTIC AND OCCUPATIONAL PRODUCTIVITY IN RHEUMATOID ARTHRITIS

**Keywords:** Quality of life, Work-related issues, Rheumatoid arthritis

S. Miladi1, W. Belha1, F. Alia1, H. Boussa2, M. Yasmine1, K. Ouanniche1, S. Leila1, S. Kassab1, S. Cheki2, K. Ben Abdelghani1, A. Laatara1, Hospital Mongi Slim, Rheumatology, Marsa, Tunisia

**Background:** Rheumatoid arthritis (RA) is a chronic rheumatism that mainly affects young adults. It has an impact on the patient’s quality of life and professional abilities.

**Objectives:** The aim of this study was to evaluate the influence of RA activity, its impact, and its functional impact on patients’ domestic and professional productivity.

**Methods:** We conducted a cross-sectional study over an 8-month period. Seventy adult patients diagnosed with RA for more than a year and receiving an antirheumatic therapy were interviewed. We assessed disease activity by the Disease Activity Score (DAS28), the impact of RA by the Rheumatoid Arthritis Impact of Disease (RAI-D), and functional impairment by the Health Assessment Questionnaire (HAQ). The impact of RA on domestic and professional productivity over the last month was assessed by the Rheumatoid Arthritis Specific Work Productivity Survey (WPS-RA).

**Results:** We noted a female predominance (63 women and 7 men) with an average age of 57.8 ± 10.6 years [29-81]. At the time of the study, 13 (19%) patients were employed, 4 (6%) were unable to work because of RA while the rest were either unemployed or retired. The mean DAS28 was 3.31 ± 1.13 [1.14-5.92]. The DAS28 was positively correlated with the degree of interference of RA on domestic work (p=0.001), professional work (p=0.005), and the decrease of domestic productivity (p=0.012) and professional productivity (p=0.021). Absenteeism was not influenced by RA activity (p=0.109). The average RAID score was 4.72 ± 2.11 [0.6-9.48]. The RAID score was positively correlated with the degree of interference of RA on domestic work (p<0.001) and professional work (p=0.013). No correlation was noted between the impact of RA and the decrease of domestic productivity (p=0.511), professional productivity (p=0.109) or the absenteeism (p=0.248). The mean value of HAQ score was 1.04 ± 0.61 [0.2-6.0]. We noted a positive correlation between the HAQ score and the degree of interference of RA at domestic work (p<0.001) as well as the interference of RA at professional work (p=0.012). The decrease of domestic productivity (p<0.133) and professional productivity (p>0.128) as well as the absenteeism (p<0.125) were not correlated with the functional impairment of RA.

**Conclusion:** According to these results, RA activity, impact, and functional impairment influenced mainly the degree of RA interference at work and domestic work. Productivity was essentially correlated with RA activity. Absenteeism was not influenced by any of the parameters studied previously.

**AB0248** USEFULNESS OF THE C-REACTIVE PROTEIN TO ALBUMIN RATIO IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

**Keywords:** Rheumatoid arthritis, Biomarkers

M. Arthaud1, M. Ghali1, J. Mahboub1, S. Zour1, J. Bejis1, M. Touzi1, N. Berengu1,1 Fatouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia

**Background:** C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are commonly used to assess rheumatoid arthritis (RA) activity. New biomarkers have been developed, such as the CRP to albumin ratio (CAR), which has been proposed as a new inflammatory marker for monitoring disease activity in RA [1].

**Objectives:** The aim of our study was to evaluate the relationship between the CAR and RA parameters in a population of elderly patients.

**Methods:** We conducted a cross-sectional study including patients followed up for RA and aged 65 years or older, CRP albumin, ESR, osnornucoid and haptoglobin levels were dosed. We calculated the CAR for each patient.

**Results:** Sixty-three patients (11 men and 52 women) were included. The mean age was 68.17±4.35 years. The median duration of disease progression was 11 years with an IQR of [4-16]. The median CRP was 8.33±2.8 l/m L. Mean albumin level was 4.13±0.58 g/L. The median ESR was 47 mm at 1 hour. The mean osmornucoid level was 1.29±0.46 g/L. The mean haptoglobin value was 2.07±0.97 g/L. The mean CAR value was 0.51±0.81 [0.01-3.72]. After statistic analysis, we found a significant association between the CAR and the DAS28 (p=0.03). In addition, CAR was positively correlated with ESR, CRP and Orosomucoid (p<0.01, p=0.01 and p=0.002, respectively). In addition, this ratio was significantly associated with HAQ score (p<0.01), and was higher in patients with major functional impairment (HAQ=2) (p=0.002). However, we did not find significant association between CAR and age, duration of evolution, VAS of pain, seropositivity, structural damage or with the use of corticosteroids.

**Conclusion:** Our study showed the association of the CAR with DAS28, inflammatory biomarkers and functional impairment among elderly RA patients. This suggests that this ratio could be a reliable tool as a prognostic index to assess disease activity and inflammation in this population.

**AB0249** RHEUMATIC QUANTITATIVE 0–10 PHYSICIAN ESTIMATES OF INFLAMMATION, DAMAGE, AND DISTRESS IN RHEUMATOID ARTHRITIS: VALIDATION AGAINST REFERENCE MEASURES

**Keywords:** Rheumatoid arthritis, Fibromyalgia, Outcome measures

N. Rodwell1,2,3, G. Hassett2,3, P. Bird1, T. Pincon4, J. Descallar2,3, Liverpool Hospital, Rheumatology, Liverpool, Australia; Ingham Institute for Applied Medical Research, Rheumatology, Liverpool, Australia; UNSW Sydney, Medicine and Health, Sydney, Australia; RUSH University Medical Center, Rheumatology, Chicago, United States of America

**Background:** A physician global assessment (DOCGL) distinguishes active from control treatments in rheumatoid arthritis (RA) effectively in clinical trials. However, RA trials select for patients who have high inflammatory activity, generally only 5-30% of all RA patients. In routine care, DOCGL, and all clinical RA measures and indices, may be elevated not only by inflammatory activity but also by joint damage and/or patient distress, complicating interpretation of RA indices and clinical decisions. A Rheumatic checklist provides feasible physician 0-10 subscale estimates of inflammation (DOCINF), damage (DOCDAM), and distress (DOCSTR), in addition to DOCGL.

**Objectives:** To analyze criterion validity and specificity of 0-10 Rheumatic physician estimates for inflammation, damage, and distress, by comparing these estimates to reference RA core data set measures, as well as joint deformity/limited motion (DJC), radiographic scores and indices for FM and DEP.

**Methods:** A cross-sectional assessment was performed at one routine care visit in Liverpool, Australia. Rheumatologists recorded Rheumetric, with 4-0.10 scales for DOCLG, DOCINF, DOCDAM, DOCSTR, and 28 joint counts for swelling (SJC), tenderness (TJC), and limited motion/deformity (DJC), laboratory tests, and radiographic scores. Patients completed a multidimensional health assessment questionnaire (MDHAQ), which includes RAID3 (routine assessment of patient index data), FAST4 (fibromyalgia assessment tool), and MDS2 (MDHAQ depression screen). Rheumatic estimates of inflammation, damage and distress were compared to reference and other measures using correlations and linear regressions.

**Results:** In 173 RA patients, variation in Rheumetric DOCINF was explained significantly by SJC and inversely by disease duration, DOCDAM by DJC, radiographic scores, and physical function, and DOCSTR by fibromyalgia and depression. Conclusion: Rheumetric DOCINF, DOCDAM, and DOCSTR estimates were correlated significantly and specifically with reference measures of inflammation, damage, and distress, documenting criterion validity.

**AB0250**

**PATIENT BELIEFS AND FEARS IN RHEUMATOID ARTHRITIS ASSESSED BY QUESTIONNAIRE FOR ARTHRITIS DIALOGUE**

**Keywords:** Rheumatoid arthritis, Quality of care

R. Sarraj1, M. Brahemi1, O. Jomaa1, A. Ben Salem2, B. Jebali1, S. Abdellatif1, H. Hachtli, Y. Mohamed2. 1Taher Star University Hospital, Rheumatology, Mahdia, Tunisia

**Background:** Misinterpretation of patient beliefs can complicate shared decision making in rheumatoid arthritis (RA) leading to inadequate treatment adherence.

**Objectives:** The aim of this study was to determine patients' beliefs and fears about their disease and its treatment.

**Methods:** This is a cross sectional study conducted among patients diagnosed with RA based on ACR/EULAR criteria. All patients completed the Arthritis Dialogue Questionnaire (QuAD) which included 21 opinion statements that they scored from 0 (totally disagree) to 10 (totally agree). A score of more than 7 was interpreted to mean that the person significantly agreed with the opinion. The beliefs in this questionnaire include those that are supported by scientific evidence and those that are inconsistent with current medical opinion.

**Results:** A total of 56 RA patients were included in this study. There were 53 females (94.6% of cases) and 3 males (5.4%). The mean age of participants was 51.5 ± 11.7 years [21-74 years]. The average duration of disease was 11.5 ± 8.6 years [1-40 years]. The mean of DAS 28 ESR and DAS 28 CRP were respectively 3.4 ± 1.5. The socio-economic status was low in 14 patients (25% of cases). 19.6% of patients were illiterate and 50% of patients had no education beyond primary level. Twenty-four patients (42.8%) believed that the onset of RA and its flare-ups were due to physical overload. As a result of these false beliefs, these same patients did not believe that doing sport or a physical activity can reduce flare-ups. Sixteen patients (28.5%) believed that RA was triggered by an emotional shock and 10 (17.8%) patients considered that flare-ups of the disease are triggered by psychological factors. The belief that the disease has a genetic cause was reported by 11 patients (19.6%). Uncertainty about disease progression was reported by 31 patients (55.3%) and 19 patients (33.9%) thought that all treatments have negative effects in the long term. The relationship between change in the weather and disease flare-ups was reported by 10 patients (17.8%).

**Conclusion:** The most widely held beliefs were related in our study to uncertainty about disease progression, physical and psychological factors that may trigger the disease, and fears about side effects of treatments. It is important to understand patients' beliefs about RA in order to optimize the adherence to treatment and to encourage patients to take up healthy lifestyles and habits that are beneficial for their disease management.

**AB0252**

**IMPACT OF ADHERENCE TO THE MEDITERRANEAN DIET ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Diet and nutrition

S. Rekk1, S. Noucer1, S. Boussaid2, S. Rahmouni3, K. Zouaoui1, H. Sahli1, M. Elleuch1. 1Rabta, Rheumatology, Tunisia

**Background:** The Mediterranean diet (MD), mainly consists of olive oil, cereal products, fresh or dried fruit and vegetables, nuts, a moderate amount of dairy and meat, and many condiments and spices, has been suggested to have a beneficial effect on mortality and cardiovascular diseases. However, there is limited evidence regarding its impact on rheumatoid arthritis (RA) disease activity.

**Objectives:** The aim of this study was to assess association between adherence to MD and disease activity in RA patients.

**Methods:** In this cross-sectional study, we included patients with RA in remission or low disease activity. Patients with intestinal disease and smokers were not included. Socio demographic data (age, sex, educational level and living area) were recorded. Tender and Swollen Joint Count (T/SJC), Disease Activity Score (DAS28), Clinical Disease Activity Index (CDAI) and Score Disease Activity Index (SDAI) were used to assess disease activity. Levels of C-reactive protein (CRP) and hemoglobin (Hb) were determined. Medication (paracetamol, Non Steroidal Anti-inflammatory Drugs (NSAIDs) and Disease-modifying anti-rheumatic drugs (DMARDs)) were recorded. We assessed MD adherence through a 14-item questionnaire in RA patient. The MD adherence score was classified as follows: good adherence (≥ 10 points) and low and medium adherence (< 9 points). We divided patients into two groups: G1: good adherence and G2: low and medium adherence to MD. We compared parameters of G1 and G2 using the Mann-Whitney U test.

**Results:** We enrolled 39 patients (34 female) with mean age of 52.74 ± 11.31 [20-74] years. Most of patients lived in rural area (61.5%). Half of patients (53.8%) had primary school level. The mean disease duration was 8.68 ± 6.6 years. The mean CRP and Hb levels were respectively 2.9 ± 9.67 [0-21] and 11.72 ± 1.14 [10-14]. The mean DAS28, CDAI and SDAI were respectively: 2.06 ± 0.71 [3-1.3], 5.46 ± 3.4 [1-10] and 8.26 ± 5.62 [2-28]. The most of patients were on paracetamol (53.9%) and conventional synthetic DMARDs (82.1%). NSAID were used by 35.9% of patients. The mean MD score was 9.1 ± 2.67 [4-12]. G1 enrolled 20 patients and G2 19. No significant differences emerged in the distribution of sex, age, living area and CDAI level between two groups. G1 had significantly lower disease activity in comparison to G2: (median [extreme]) TJC {0 [0-1]} vs 1 [0-2], p=0.02, DAS28 [1.7 [1-3.1]] vs 2.2 [1.7-3.1], p=0.001, CDAI [2 [1-7]] vs 9 [3-11] p<0.001 and SDAI [4 [2-9] vs 11 [5-30], p=0.001. No significant differences was observed in SJC and CRP level, p=0.11 and p=0.22 respectively. However, Hb levels were higher in G1 {13 [13-14]} than in G2 {10 [10-13], p<0.001. G2 had higher paracetamol and NSAID consumption with 84.3% and 57.9% vs 57.9% and 84.3 % respectively. Less use of biological DMARD were observed in G1 since all patients were on conventional synthetic DMARDs.
Conclusion: In our study, higher adherence to a MD was associated with reduced RA activity, symptomatic treatment consumption and more remission and low disease activity with conventional synthetic DMARD. Therefore, nutrition therapy could be a promising adjunct to pharmacological therapy in RA. Further studies are needed to confirm these findings.

AB0253 IDENTIFICATION OF FACTORS ASSOCIATED WITH A WORSE OUTCOME - EXITS- IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SEVERE INFECTION

Keywords: Prognostic factors, Rheumatoid arthritis

P. Vela Casasempere1,2,3, L. Vegara Viceda1, S. Gomez-Sabatera3, R. Cañoh-Alameda3,1, Universidad Miguel Hernández (UMH), Medicina, San Juan de Alicante, Spain; 2, General University Hospital of Alicante, Reumatología, Alacant, Spain; 3, Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL), GRUPO 16, Alicante, Spain

Background: Infections constitute an important and frequent cause of morbidity and mortality in patients with chronic inflammatory and systemic autoimmune rheumatic diseases. In rheumatoid arthritis (RA), this increased risk has been related to the immune system alterations inherent to the disease, the drugs used to control it (corticosteroids, DMARDs and immunosuppressants) and associated comorbidities. Most studies focus on the search for factors associated with the development of infections but do not explore the worst outcome: patient failure.

Objectives: To identify factors that help to predict an unfavorable outcome (exitus) after a severe infection in patients with rheumatoid arthritis.

Methods: This study was a retrospective case-control study at a single institution over a 10-year period. Patients with a diagnosis of rheumatoid arthritis with hospital admission for infection from January 1, 2010, to December 31, 2019 (pre-pandemic SARS-COV-2) were selected. The main variable was exitus due to the infectious episode. We collected: age, sex, time of evolution of RA, previous treatment and at the time of admission, number of admissions for infection, location of the infection, comorbidities, and other associated serious diseases. The statistics included a descriptive analysis of the different variables (expressed as median and interquartile range -iQR- for quantitative variables and percentages for qualitative variables), and the association study using the χ2 test or Fisher’s exact test for qualitative variables, and t-student or Mann-Whitney U and Kruskal Wallis for quantitative variables.

Results: We obtained 152 patients (71.7% female, 28.3% male), with a total of 214 episodes of admission for infection (115 patients with 1 episode (75.7%), 25 (16.4%) with 2 episodes, 6 being the maximum number of episodes recorded). The median age at admission was 77 years, and the median time of RA evolution was 8 years (IR 4-16). The location of the infection responsible for admission was mainly respiratory and urinary. Forty-eight patients died in the episode (31.6% of the sample, 15 males and 33 females, median age 81.5 years (IR 69.5-86.5)). Comparing the patients with unfavorable outcomes (exitus) with the rest, we only found a statistically significant difference in the number of previous admissions (p=0.011), and in the coexistence of some other serious disease (exitus 85.4%, rest 61.5%, p=0.003). There were no differences by sex, age, time of RA evolution, drugs, location of the infection, or comorbidities.

Conclusion: A history of hospital admission due to infection, and having another serious disease, are factors associated with an unfavorable outcome (exitus) in patients with RA admitted for an infectious process.

AB0255 CORRELATION BETWEEN PATIENT GLOBAL ASSESSMENT AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: ANY CHANGE OVER TIME?

Keywords: Outcome measures, Patient reported outcomes, Rheumatoid arthritis

M. Yasmine1, E. Hanneh1, S. Miladi1, A. Fazaa1, H. Boussaa1, K. Ouenniche1, L. Souabni1, S. Kassab1, S. Chekili1, K. Ben Abdelghani1, A. Latlar1. Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia

Background: Nowadays, the utility of smartphone application for patients with rheumatic diseases, especially rheumatoid arthritis (RA) is well established and codified [1]. Indeed, patient-centered smartphone applications have the potential to assist with the adoption behavior and maintenance of self-management behaviors [2].

Objectives: The purpose of our study was to investigate the willingness of RA patients to use smartphone applications for managing their disease.

Methods: This was a cross-sectional survey conducted in our rheumatology department including patients with RA, fulfilling the ACR/EULAR 2010 criteria. Sociodemographic data were initially collected. Patients were invited to answer a questionnaire regarding their willingness to accept smartphone application as part of their management strategies. We evaluated their points of view and suitability by inquiring about their experience with smartphones, as well as the previous applications used. Moreover, additional questions probed the patients’ willingness to pay for this monitoring app.

Results: The study included 40 RA patients. There was a female predominance with a sex ratio of 0.11. The mean age was of 52.25±14.4 years [21-78]. The mean disease duration was of 11.97±6.69 years [1-29]. Regarding the educational level, 10 patients (25%) were illiterate, 14 (35%) had primary education, 11 (27%) had secondary education, and 5 patients (13%) were university graduates. Most of them (60%) were unemployed, and 13% were retired. As for marital status, 37 patients (92%) were married, and 1 was divorced. According to the patients, the two main reported mobile phone utility concerned the ability to communicate with other individuals (48%) and internet navigation (52%). None of them had uploaded a healthcare application before and only 4 patients had previously contacted their doctor via text messages or e-mail. Overall, 67% of the respondents agreed on the usefulness of a patient-centered smartphone app and 65% were willing to accept this alternative as a model of care. Similarly, most of the patients refused to pay for the app (63%). The adherence to the smartphone app was significantly higher among females compared to males (p<0.011). Moreover, willingness to accept these applications was associated with a higher level of education without reaching a statistically significant correlation (p=0.07). There was no association between the marital, profession, age or disease duration and the acceptability of the smartphone app (p=0.418, p=0.246, p=0.382 and p=0.527 respectively).

Conclusion: Findings from this study showed that RA patients were not as reluctant to accept a health-related smartphone app. The willingness to adopt these applications was associated with a higher level of education without reaching a statistically significant correlation (p=0.07). There was no association between the marital, profession, age or disease duration and the acceptability of the smartphone app (p=0.418, p=0.246, p=0.382 and p=0.527 respectively).

AB0254 ACCEPTABILITY OF A SMARTPHONE APPLICATION AMONG TUNISIAN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Self-management, Quality of care

A. Fazaa1, H. Boussaa1, K. Ouenniche1, S. Miladi1, M. Yasmine1, L. Souabni1, S. Kassab1, S. Chekili1, K. Ben Abdelghani1, A. Latlar1. Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia

Background: Patient-reported outcomes (PROs) such as the Patient Global Assessment (PGA) are included in the definition of disease activity in rheumatoid arthritis (RA). Major determinants of the PGA are pain severity, functional limitations and fatigue. In contrast, the correlation with more objective measures of inflammation is weaker. In the early stages of the disease, the PGA might in turn more strictly reflect the patient’s perception of condition.

Objectives: The aim of this study was to investigate the correlations between the PGA and disease parameters in patients with RA over time.

Methods: We conducted a prospective study including patients with RA (ACR/EULAR 2010). Demographic data and the following disease parameters were collected at inclusion and at 12 months follow-up: PGA, pain Visual Analog Scale (VAS), tender joint count (TJC), swollen joint count (SJC), Erythrocyte Sedimentation Rate (ESR), C Protein Reactive (CRP), Disease Activity Score 28 (DAS28), and Health
Assessment Questionnaire (HAQ). Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy – Fatigue (FACT-F) which is a short 13-item questionnaire validated in RA. The score FACT-F ranges between 0 and 52. Fatigue was considered mild if the FACT-F score was ≥40, moderate if 20<FACT-F<40 and severe if FACT-F<20. A p value inferior to 0.05 was considered significant.

Results: We included 100 RA patients (84 women and 16 men) with a mean age of 49.5±10 years old [18-65]. The mean disease duration was 87.3 months [1-360]. Rheumatoid Factor (RF) and Anti-Citrullinated Protein Antibodies (ACPA) were positive in 75% and 72.6%, respectively. At inclusion, the mean PGA was 47.8cm [0-100] and the mean pain VAS was 80.8cm [0-100]. The mean TJC and SJC were 5.3 [9-36] and 1 [9-3], respectively. The mean levels of ESR and CRP were 38.1mm [10-120] and 10.8mg/l [2-61], respectively. The mean DAS28 ESR was 3.68 [1.90-8.33] and the mean HAQ score was 0.9 [0-2.75]. The mean FACTF score was 27.1 [5-51] in RA patients versus 46.2 [5-52] in healthy controls (p<0.001). Among RA patients, 57% had moderate fatigue and 26% had severe fatigue. A significant positive correlation was noted between PGA and TJC (r=0.508, p<0.001), SJC (r=-0.531, p<0.001), pain VAS (r=0.763, p<0.001), ESR (r=0.364, p<0.001), DAS28 ESR (r=0.743, p<0.001) and HAQ (r=0.660, p<0.001). A significant negative correlation was noted between GPA and FACTF score (r=-0.658, p<0.001). At 12 months follow-up, the correlations became stronger between PGA and TJC (r=0.664, p<0.001), SJC (r=0.673, p<0.001), pain VAS (r=0.893, p<0.001), ESR (r=0.536, p<0.001), DAS28 ESR (r=0.867, p<0.001), HAQ (r=0.686, p<0.001), and FACTF score (r=-0.792, p<0.001). A positive correlation was also noted between PGA and disease duration (r=0.205, p=0.045).

Conclusion: Disease activity, functional limitation, pain and fatigue directly correlate with PGA. This relation seems to strengthen over time as RA patients gain the ability to better understand and assess their illness.

ARE CRP/ALBUMINE, PLATELET/LYMPHOCYTE, NEUTROPHIL/LYMPHOCYTE RATIO INDICATORS OF SPONDYLOARTHITIS ACTIVITY?

Keywords: Biomarkers, Cell biology, Spondyloarthritis

Z. Ammoun1, N. Aksabili, H. Bourkhime2, T. Harzy2,1, Medicine Faculty of Fez, Rheumatology, Fez, Morocco; 1University Hospital Center of Fez, Rheumatology, Fez, Morocco; 1Faculty of Medicine of Fez, Epidemiology, Fez, Morocco

Background: Spondylitis is a chronic inflammatory rheumatism that most often affects young adult males. In recent studies it has been reported that the platelet ratio (PLR) and neutrophil lymphocyte ratio (NLR) are important in demonstrating a marker of inflammation.

Objectives: Our objective is to study the relationship between the value of CAR, PLR, NLR, and the BASDAI score.

Methods: A cross-sectional study including patients with spondyloarthritis according to ASAS 2009 criteria. For each patient CAR, PLR, NLR and BASDAI score were calculated.

Results: 112 patients were included in this study. The average age was 46.9 (+/-12.7) years, the ratio M/F is 129, the mean duration of the disease is 7.8 years, 68.8% of the axial spondyloarthritis are severe, 70.5% of spondyloarthritics are radiographic, the average EVA pain is 61.6, 54.5% of patients have a BASDAI≥44, the average CRP is 30.16, the average SR (sedimentation rate) is 32.77, 41.7% of patients have stage III sacroiliitis, 93.9% have bilateral sacroiliitis. The average CAR is 0.88 (+/-1.84), the mean PLR is 157.6, the mean NLR is 3.32, the mean CAR is 0.88. In the bivariate analysis, the CAR ratio was significantly associated with BASDAI (p=0.038), CRP is also significantly associated with BASDAI (p=0.028).

Conclusion: The CAR can be a practical measurement tool in the follow-up of patients with axial spondyloarthritis axial spondyloarthritis because it can be used quickly under routine ambulatory conditions, in correlation with the BASDAI.

GENETIC EVIDENCE REVEALS A CAUSAL ROLE BETWEEN LEUKOCYTE COUNTS AND THE RISK OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

Y. Zhang3, Q. Qiu2, J. Hu2, J. Hou2, Q. Yu2, P. F. He2, X. Li4, S. X. Zhang4, 5Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, Shanxi Province, China; 2Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microbiology, Taiyuan, Shanxi Province, China; 4Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, Shanxi Province, China; 5The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China

Background: Accumulating inflammatory leukocytes in articular tissues is the hallmark feature of rheumatoid arthritis (RA). However, no relevant study indicates whether there is insidious causation between leukocyte count (LC) and the risk of RA. Traditional observational studies were susceptible to bias from confounding and reverse causation. It was necessary to estimate an exact correlation between LC and the risk of RA.

Objectives: This study aimed at evaluating the correlation between LC and the risk of RA by performing two-sample Mendelian Randomization (MR).

Methods: This study selected single nucleotide polymorphism (SNPs) associated with exposure (LC) from a genome-wide association study (GWAS), which included 171846 European ancestry participants and wiped off confounding factors. The association estimates of these SNPs with the risk of RA were obtained from another GWAS, including 14361 RA cases and 42923 controls. Upon SNPs were compared with SNPs related to the risk of RA and performed harmonization analysis to wipe off the irrelevant or inconsistent site SNPs. Ultimately, the remaining SNPs were selected as instrument variables (IVs). Then, we utilized two-sample Mendelian randomization (MR) to evaluate whether LC was causally associated with the risk of RA. Furthermore, Cochran’s Q test, MR pleiotropy residual sum and outlier (MR-presso), and leave-one-out analysis were performed as a sensitivity test.

Results: A total of 70 independent SNPs were selected as IVs in the MR analysis of total WBC. Higher leukocyte counts were associated with a higher risk of RA (OR=1.025, 95% CI: 0.998-1.053, p-value=0.038) by the IVW method (Figure 1). The MR-Egger regression test did not reveal any evidence of directional pleiotropy (intercept = -0.0002, stand error (SE) = 0.008, p = 0.981). In addition, leave-one-out sensitivity analysis showed similar findings, which further emphasized the effectiveness and stability of the causation. However, in the Cochran’s Q test, it turned out [Cochran’s Q statistic= 69, p-value=3.472e-10], suggesting heterogeneity exists. For this reason, the processed steps were rechecked, and finally got, the conclusion that heterogeneity is produced from sysmatics.

Conclusion: This study indicated the insidious causation between LC and the risk of RA. Further studies are warranted to determine how related pathways may contribute to the unnormal LC to promote the comprehension of the pathology of the happening of RA and access more therapeutic methods.

PREPULSE INHIBITION OF THE BLINK REFLEX -A PUTATIVE MARKER OF "FIBROMYALGIANESS" - IS ALTERED IN PTS WITH RHEUMATOID ARTHRITIS COMPARED TO HEALTHY CONTROLS, BUT NOT PREDICTIVE FOR PAIN LEVEL OR THERAPEUTIC RESPONSE TO BDMARDS

Keywords: bDMARD, Fibromyalgia, Rheumatoid arthritis

Acknowledgements: NIL.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.3392
Background: Concomitant fibromyalgia (FM) is highly prevalent in pts with RA. In FM patients, altered abnormalities in processing of sensory stimuli including abnormal subcuticular sensorimotor integration measured using prepulse inhibition (PPI) have been described [1]. PPI is a robust neurophysiological phenomenon in which a weak sensory event leads to reduction in magnitude of the reflex response that would be otherwise elicited by a reflex-eliciting stimulus presented 30–500 ms later. Its physiological purpose is to protect salient from irrelevant information at the subcortical level, thereby preventing undesired motor reactions. In RA patients, abnormal processing of sensory information may affect subjective aspects of disease activity indices, and thus influence treatment decisions.

Objectives: We aimed to investigate, whether PPI may serve as a predictive marker of FM in pts with RA starting their first targeted therapy.

Methods: PPI was measured in 15 patients with RA before initiation of treatment with bDMARDs, and 50 healthy controls (HC). We examined the effect of a weak electrical stimulus to the index finger (prepulse) on the blink reflex magnitude induced by electrical stimuli delivered to the supraorbital nerve at interstimulus interval 100 ms. To analyze the degree to which PPI affects baseline actual pain (VAS-NRS), patient global assessment PGA, discordance between PGA and EGA (expert global assessment) calculated as PGA minus EGA we performed univariate linear regression analyses using VAS-NRS, PGA, and PGA minus EGA as dependent variables. We selected the following predictive variables: age, sex, BMI; disease duration; erosive disease; SJC; TJC; pain; VAS, ESR; MAH; ACPA. We used standardised β to compare the strengths of the relationships. We also analyzed the contribution of PPI to therapeutic response in month 3 and 6.

Results: As compared to HC, patients with RA were older, reported higher pain levels, and their mean PPI scores were significantly lower (Table 1). In RA pts PPI was neither predictive for baseline actual pain, PGA, or EGA-PGA, nor for therapeutic response in pts with RA.

Conclusion: Lower PPI in RA patients may reflect abnormal filtering of afferent information flow to the brain. Together with previous findings in FM, our results suggest abnormal subcortical sensory information may be involved in nocicepial pain in RA patients. However, PPI was neither predictive for baseline level of pain, PGA, or EGA-PGA, nor for therapeutic response in pts with RA.

PREDICTIVE VALUE OF C-REACTIVE PROTEIN/ALBUMIN RATIO(CAR) FOR THE DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE COHORT STUDY

Keywords: Rheumatoid arthritis

N. Öz1, M. T. Duruöz1. 1 Marmara University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Istanbul, Turkey

Background: Rheumatoid arthritis (RA) is a chronic, systemic and disabling autoimmune disease with inflammatory synovitis. Many biochemical factors are used as diagnostic, activation and prognostic markers in certain diseases. The C-reactive protein/albumin ratio (CAR) is an inflammatory marker that is considered to have prognostic value in many disease. The CAR has shown high value in colorectal cancer, inflammatory bowel disease and ANCA-associated vasculitis activity.

Objectives: In this study, we aimed to evaluate the predictive value of CAR for disease activity in RA patients.

Methods: This prospective study included 144 RA patients who fulfilled the 2010 revised criteria of the American College of Rheumatology (ACR) for RA. The demographic characteristics of the patients, duration of the disease and clinical characteristics of the patients such as the 28-joint Disease Activity Score based on the erythrocyte sedimentation rate (DAS28-ESR), Visual Analogue Scale, Health Assessment Questionnaire-Disability Index were collected. Labotaruvy finding such as erythrocyte sedimentation rate, CRP, albumin were noted. The CAR ratio was obtained by dividing the CRP level with albumin level. Based on the DAS28-ESR level, the included patients were categorized into two groups, namely, inactive to mild active RA (n=69; DAS28-ESR level <3.2) and moderate to highly active RA (n=75; DAS28-ESR level ≥3.2). These group were compared with the parameters described above.

Results: One hundred ten patients (76.4% female) with mean age 52.3 SD 11.8 years were recruited into the study. Age and disease therapy duration of the patients were similar in both groups. Female gender was significantly higher in the DAS28-ESR ≥3.2 group. Patients who DAS28-ESR ≥3.2 had a significantly higher CAR compared to those who did not (0.11 SD 0.09 vs. 0.20 SD 0.16, p<0.001) (Table 1). Multivariate logistic regression analyses revealed that CAR was an independent predictor of moderate to highly active RA (OR: 2.180, 95%CI: 1.307–3.637; p=0.003). A receiver operating characteristic curves analysis yielded that the optimal cut-off value of CAR for moderate to highly active RA was 0.126 with sensitivity 64.0% and specificity 66.2% (AUC: 0.683, 95%CI: 0.507-0.769, p<0.001) (Figure 1).

Conclusion: Based on the study findings, we were able to show that simple and easily obtained CAR could be an independent predictor of disease activity in rheumatoid arthritis patients.

AB0260 DISABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: RELATIONSHIP WITH ALEXITHYMIA.

Keywords: Quality of life, Rheumatoid arthritis

Y. Shairovsky1, Y. Shkarinovsky1, M. Stanislavchuk1. 1National Pirogov Memorial Medical University, Vinnytsya, Department of Internal Medicine №1, Vinnytsya, Ukraine

Background: Rheumatoid arthritis (RA) is the chronic, destructive, immune-mediated inflammatory process that has a gradient course and causes disability of approximately 50% over the next 5 years of the disease. Acute pain syndrome, which is accompanied by RA, often leads to a violation of the psycho-emotional sphere with manifestations in the form of depression, anxiety and alexithymia. Alexithymia defined as a personal emotional disorder that characterized by difficulty in identifying and describing subjective feelings. As there are insufficient data on disability in patients with RA in combination with alexithymia, we screened patients with RA, investigated the level of disability and found a connection with alexithymia.

Objectives: To investigate the level of disability in patients with rheumatoid arthritis and clarify a probable connection with alexithymia.

Methods: RA patients diagnosed according to the ACR/EULAR 2010 classification criteria (Daniel Aletaha et al., 2010). The presence of alexithymia was determined by TAS-20 – «Toronto Alexithymia Scale» questionnaire (Greame J. Taylor, D. Ryan, R. Michael Bagby, 1994). Disability was determined by a questionnaire DRI – «The Disability Rating Index» (Bo A. Salen, Erik V Spangfort, Ake L. Nygren and Rolf Nordemar, 1994).[1] RA activity was assessed with the Disease Activity Score (DAS28), Simplified disability activity index (SDAI), Clinical disease activity index (CDAI), functional status with the Health Assessment Questionnaire (HAQ), pain intensity was determined by the Visual Analogue Scale (VAS).

Statistical analyses were performed using IBM Statistics SPSS 20. Results are presented as mean with standard deviation (M ± SD).

Results: The study included 146 patients with RA (90.7% of women). The average age of the patients was 50.1 ± 12 years, and the duration of the disease ranged from 1 to 21 years (7.4 ± 4.7). Among 146 examined, alexithymia (TAS-20 ≥ 61) was detected in 36 people (24.7%). All patients had different level of disability detected by the DRI questionnaire, with scores ranging from 5.4 to 79.8, and the average value was - 31.1 ± 17.1. In patients without alexithymia, the disability was 26.8 ± 14.8, in patients with alexithymia – 44.5 ± 16.8. Functional ability in individuals with RA without alexithymia according to the HAQ was 0.9 ± 0.6, in contrast to the group of patients with RA and alexithymia - 1.7 ± 0.6. The significance of the differences between groups depending on the presence of alexithymia according to functional ability and intensity of pain was at the level of p < 0.05; and disability - at the level of p < 0.01. A direct strong correlation was established between alexithymia and disability, functional ability and VAS: DRI (r = 0.514; p < 0.01); HAQ (r = 0.450; p < 0.01); VAS (r = 0.457; p < 0.01). We found that the presence of alexithymia in patients with RA was associated with an increased risk of functional disability. Odds ratios are used to identify the risk of functional disorders in patients with RA. RA patients with TAS-20 score ≥ 61 had an odds ratio of 7.57 [95% CI: 2.13 – 26.98] (p < 0.002) for moderate functional disability and 21.47 [95% CI: 4.82 – 95.61] (p < 0.0001) for severe functional disability by HAQ, and 14.98 [95% CI: 4.48 – 50.13] (p < 0.0001) by DRI.

Conclusion: The alexithymia in patients with rheumatoid arthritis is associated with a bigger disability, as well as with impaired functional ability and severity of pain syndrome. We concluded that alexithymia may be considered as a risk factor of the disability in patients with RA.

AB0261 PREVALENCE OF HEART VALVULAR REGURGITATION ACCORDING TO THE TIME OF DISEASE EVOLUTION IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Heart, Rheumatoid arthritis, Imaging

D. Á. Galizar-Delgado1, I. J. Colunga-Pedraza1, J. R. Azpiri-López2, V. M. Beltran-Aguilar3, V. Gonzalez-Gonzalez1, G. A. Arias Peralta4, N. De Avila Gonzalez1, J. A. Cardenas-de la Garza1, G. Garcia-Arellano5. 1Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico; 2Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico

Background: Rheumatoid arthritis (RA) patients are at higher risk of developing cardiovascular (CV) diseases, both ischemic and non-ischemic, than the general population [1]. Inflammatory status and fibrotic changes at cardiac valves in these patients predispose them to higher risk of valve diseases, which could be detected by echocardiography [2].

Objectives: To determine the prevalence of valvular regurgitation, according to the time of disease evolution in RA patients.

Methods: Descriptive, comparative, and cross-sectional study. We enrolled RA patients between 40 and 70 years old who fulfilled ACR/EULAR 2010 classification criteria and recruited in the Rheumatology service from tertiary care hospital. Patients were divided by time of disease evolution into quartiles. A transthoracic echocardiogram performed by a certified cardiologist blinded to clinical data. Normality was assessed by Kolmogorov-Smirnov test. Variables with normal and non-normal distribution were described by media and standard deviation, such as median and interquartile range (p25-p75), respectively. Differences between groups was analyzed by ANOVA, Kruskal-Wallis test or Chi-squared, accordingly.

Results: We included 151 RA patients. Demographic characteristics are in Table 1. Overweight/obesity was found between 62-87% of patients, hypertension between 26-34%, and Type 2 Diabetes mellitus between 8-26%. The tricuspid valve was the most affected (73-84%). There was no differences in prevalence of valvular regurgitation.

Conclusion: RA patients have a high prevalence of valvular regurgitation, which could predispose them to develop heart failure, therefore it is important to consider echocardiography in the approach of this population, despite not showing an increase.

AB0262 FATIGUE PATTERNS IN DIFFICULT TO TREAT RHEUMATOID ARTHRITIS PATIENTS

Keywords: Quality of life, Rheumatoid arthritis, Mental health

J. P. Otaño Maudet1, D. Freites1, M. Rodriguez Laguna2, C. Hormigos3, M. P. Alvarez Hernandez1, A. Madrid Garcia2, L. Abasolo1, L. Leon2. 1Hospital Clínico San Carlos, Rheumatology, Madrid, Spain; 2Instituto de Investigación Sanitaria San Carlos (IdiSSC), Rheumatology, Madrid, Spain

Background: Fatigue study is scarce in D2T RA. The experience of fatigue is multidimensional, implying complex, multicausal pathways.

Objectives: to identify the factors associated with fatigue on its different subscales (Physical, Living, Cognitive and Emotional).

Methods: Cross-sectional study. 22 patients with D2T RA were included; patients were being followed up in the rheumatologist outpatient clinic of Hospital Clínico San Carlos, Madrid, Spain. Data were collected between July 2018 and November 2022. All patients met the ACR/EULAR 2010 criteria and they were in...
treatment with Biological agents (anti-TNF and Non anti-TNF) or Targeted Synthetic DMARDs (jakinibs). Outcome: Difficult to treat Rheumatoid Arthritis Patients (fulfillment of EULAR criteria). Male variable: Fatigue was assessed by the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ) and the Bristol Rheumatoid Arthritis Fatigue Numerical Rating Scale (BRAF-NRS). Covariates: Sociodemographic and disease-related variables. Statistical analysis: A descriptive analysis was carried out for the different variables. To identify factors independently associated to BRAF-MDQ and its subscales, multivariable linear regression was applied. Results were expressed as coef with their corresponding 95% CI. A value of p < 0.05 was considered as statistically significant.

**Results:** A total of 22 (15.38%) patients were found D2T RA, comprising of 11 females (50%) with a mean age of 62.82±13.45 years and mean disease duration of 17.76±8.47 years. RF was positive in 59% of patients. Regarding comorbidities, 32% had dyslipidemia, 28% hypertension, 10% vascular disease, 27% hypothyroidism and 23% depression. The DAS28-ESR mean score of the patients were 4.10 ± 0.67. The factors affecting the global fatigue and its different subscales was evaluated in multivariate analyze **Table 1.** Our results shows a different correlation structure between disease and treatment factors and the different dimensions of the BRAF-MDQ. Patients who reported high disability scores had more global fatigue, while those with a poor patient global health assessment perceived more physical fatigue. In addition, an association was observed between depression and cognitive fatigue. Male sex and positive RF was associated with less living fatigue. In addition, an association was observed between depression and cognitive fatigue. Male sex and positive RF was associated with less living fatigue. Male sex and positive RF was associated with less living fatigue.

**Conclusion:** It is important to evaluate fatigue in a multidimensional perspective, each of the different subscales could be modulated by different factors. The results of our study indicated that disability predicts global fatigue, however, other factors can configure different patterns of fatigue in D2T RA patients, and identify them is key to the approach of this complex symptom.

THE INFLUENCE OF HEREDITY ON RHEUMATOID ARTHRITIS: EXAMINING THE DISTINCT CHARACTERISTICS IN PATIENTS WITH A FAMILY HISTORY

Keywords: Prognostic factors, Rheumatoid arthritis

H. El-Kasmi1, N. Akaabi2, I. El Mezouar2, M. Omani3, T. Harzy2, 1Laboratory of Epidemiology, Clinical Research and Community Health, Faculty of Medicine and Pharmacy, Sidi Mohammed Ben Abdellah University, Fes, Morocco.

BACKGROUND: NIL.

Objectives: The aim of this study was to describe the particularities of patients diagnosed with rheumatoid arthritis (RA) who have a family history of the disease.

Methods: In this retrospective study, a total of patients diagnosed with RA between the years 2011 and 2022 were included. The primary aim of the study was to investigate the relationship between different parameters such as age of disease onset, Disease Activity Score using C-reactive protein(DAS CRP), serological profile, erosive character,extra-articular manifestations, and use of biotherapy. Data were collected from the medical records of the patients, and analyzed using statistical test such chi-squared, Fisher’s exact test and t-test.the level of significance was set at p<0.05.the study design included a thorough data cleaning process.

RESULTS:

The study included 407 patients with a mean age of 58.86 years ± 12.441, and a sex ratio of 6 (F/M). The mean DAS 28 score was 4.35 ± 1.31, mean CRP: 22.25 ± 37.23 (p=0.05).the study design included a thorough data cleaning process.

AB0267  DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS STRATIFIED BY HEMOGLOBIN LEVELS: A MULTI-CENTER STUDY

Keywords: Descriptive studies, Rheumatoid arthritis, Clinical trials

M. Al-Mazedi1, R. Rajan2, A. Al-Herz2, A. Alsafer2, M. Al-Jarallah3, R. Dashi2, P. Setiya1, K. Saleh4, A. Al-Awadhi5, E. Hasan3, K. Mokadam2, A. Gharem6, A. Alenizi6, Z. Kobalava7,8. The Public Authority For Applied Education & Training - Head Office, Dept. of Medical Laboratory Technology, Shuwaikh Industrial, Kuwait; 2Sabah Al-Ahmad Cardiac Center, Department of Cardiology, Al Kuwait, Kuwait; 3Al-Amin Hospital, Department of Rheumatology, Al Kuwait, Kuwait; 4American University of Kuwait, Department of Management, Salimya, Kuwait; 5GBPUAT, Department of Agrometeorology, Pannagiar, India; 6Farwaniya Hospital, Department of Rheumatology, Sabah Al Nasser, Kuwait; 7Kuwait University, Department of Medicine, Faculty of Medicine, Kuwait City, Kuwait; 8Mubarak Al-Kabeer Hospital, Department of Rheumatology, Jabiya, Kuwait; 9Al Jahra’ Hospital, Department of Rheumatology, Al Jahra, Kuwait; 10Peoples’ Friendship University of Russia, Department of Internal Medicine with the Subspecialty of Cardiology and Functional Diagnostics, Moscow, Russian Federation

Background: Anaemia is a multifactorial, pervasive, extra-articular manifestation that is a significant burden in RA. The most common types of anaemia in RA are chronic anaemia and iron-deficiency anaemia. A number of existing studies observed anaemia in 24.0%–70.8% of RA patients.

Objectives: The primary objective of this study was to examine the association between haemoglobin (Hb) levels and disease activity in patients with rheumatoid arthritis (RA).

Methods: This retrospective study obtained data from adult RA patients with Hb reports from the Kuwait Registry for Rheumatic Diseases (KRRD). Patients were recruited from four public hospitals in Kuwait between February 2013 and February 2022. The cohort was stratified into two groups: low Hb (anemic, ≤ 110 g/L) and high Hb (non-anemic, > 110 g/L). Demographic, treatment, clinical, and laboratory characteristics were used to compare the two Hb cohorts. Multivariate and univariate statistical analyses were used to analyse the data.

Results: The total number of patients visited (N) was 11393 and consecutive patients with RA diagnoses and Hb data (Nv) was 1584. Both Nv and Np were included in the study. Of these, 72.5% (n = 8620) had high Hb levels and 27.5% had low Hb levels (n = 3133). The average age of the cohort was 55.9±12.5 years. Logistic regression analysis revealed that a greater number of non-Kuwaiti patients had anaemia than Kuwaiti patients [adjusted odds ratio (aOR), 1.34; 95% confidence interval (CI): 1.16-1.56; P<0.001]. Patients who received biologic treatment were more likely to be non-anemic [aOR, 1.33; 95% CI:1.23-1.45; P<0.001]. Additionally, the study demonstrated that patients with anaemia had greater odds of acquiring Disease Activity Score 28-joint count (DAS28) ≥ 3.2 as opposed to DAS28 < 3.2 [aOR, 0.74; 95% CI:0.61-0.90; P =0.002].

Conclusion: Lower haemoglobin levels in RA are independent predictors of disease activity.

Acknowledgments: I would like to acknowledge Kuwait Registry for Rheumatic Diseases (KRRD), for providing us the needed data.

AB0269  RHUMATOID FACTORS ISOTYPES DIAGNOSTIC SENSITIVITY AND SPECIFICITY IN RHUMATOID ARTHRITIS PATIENTS IN TUNISIA

Keywords: Rheumatoid arthritis, Biomarkers, Diagnostic tests

R. Ben Tekaya1, J. Mahboub1, M. Elghali2, N. Hafhouni3, A. Saad1, S. Zour1, I. Beja1, M. Touzi1, N. Sakiy2, N. Bergaoui1, 1Hospital University Fattouma Bourguiba, Rheumatology Department, Monastir, Tunisia; 2Hospital University Fattouma Bourguiba, Immunology Department, Monastir, Tunisia

Background: Rheumatoid factor (RF) is a well-established marker for the diagnosis and classification of rheumatoid arthritis (RA). Most studies have evaluated IgM RF or isotype-non-specific total RF tests.

Objectives: We evaluated the importance of rheumatoid factor isotype in this study.

Methods: An international cohort consisting of samples from 52 RA patients and 57 patients suffer from other rheumatologic diseases were tested for IgA, IgM and IgG RF. Clinical and biological data were collected.

Results: IgM, IgA, and IgG were positive in RA patients 96.15%, 88.46% and 17.3% respectively. The sensitivity of IgG RF for the diagnosis of RA was the lowest 16.7%, IgA RF sensitivity was lower than IgM RF (87.8% vs 95.5%). The specificity of IgM, IgA and IgG RF for the diagnosis of RA were (29.8 %vs 61.4 %vs 89.4% respectively). Double positivity for RF IgM and RF IgA had a higher specificity for RA than RF IgM or RF IgG (92.6% vs 29.8% vs 89.4%). However, combined positivity for IgA RF, IgM RF, and IgG ACDA had higher specificity and lower sensitivity for RA classification than positivity for either antibody.

Conclusion: IgA RF showed lower sensitivity than IgM RF. The combination of IgG RF with IgM RF and ACDA did not improve the sensitivity of RA classification. Combined positivity (IgA-RF/IgG-RF/ACDA) increased specificity.

PREDICTIVE FACTORS OF CARDIAC IMPAIRMENT IN RHEUMATOID ARTHRITIS

Keywords: Imaging, Heart, Comorbidities

M. Brahimi, R. Sarrai, H. Ibn Hadj Amor, A. Ben Salem, S. Katriem, R. Rouabha, E. Hamraie, H. Hachtel, Y. Mohamed. Taher Star University Hospital, Rheumatology, Mahdia, Tunisia; Taher Star University Hospital, Cardiology, Mahdia, Tunisia

Background: In view of the insidious and serious nature of cardiac involvement in rheumatoid arthritis (RA), systematic screening for these diseases and the identification of risk factors is of paramount importance in order to preserve and improve patients’ quality of life and life expectancy.

Objectives: The objective of our study is to determine the predictors of cardiac involvement.

Methods: We performed a cross-sectional study conducted in Taher Star Hospital, Mahdia, Tunisia. Each patient underwent a transthoracic echocardiography (TTE) coupled with Strain technique. The comparison between a qualitative variable and a qualitative variable was made by the Student’s t test if the qualitative variable follows the normal law, if not, the Mann-Whitney test was used. The multivariate study was done by binary logistic regression. A p value <0.05 was considered statistically significant.

Results: Seventy-two patients with RA were included in our study. There was a clear female predominance with a sex ratio of 0.7. The mean age of RA patients was 52.9 ± 11.7 years (21-75 years). The mean duration of disease progression was 12.4 ± 9.9 years (6-40 years). The means of DAS28 (CRP), DAS28 (ESR) and HAQ score were respectively 3.4 ± 1.4 [1.2-6.7]; 3.9 ± 1.4 [1.4-7.4] and 0.9 ± 0.7 [0-2.5]. 51.4% of patients had an increased ESR and 37.5% of cases had an increased CRP (CRP>6). Corticosteroid therapy was used in 94.4% of patients with a mean duration of 5.9 ± 5.2 years. 120 patients were identified as having ILD, or who have had a high-resolution computed tomography (HRCT) scan in the prior 2 years, will not be eligible. Patients will undergo an HRCT scan, which will be assessed centrally by two thoracic radiologists. Data will be collected on comorbidities, pulmonary function. It is planned that up to 1200 patients will be enrolled at approximately 30 sites in the USA, UK, France, Italy, Spain.

Results: The results of this study will elucidate the prevalence of RA-ILD, and features of RA-ILD on HRCT, in the study population and enable development of a probability score for RA-ILD based on a multivariable model incorporating risk factors. The area under the receiver operating characteristic (ROC) curve, specificity, sensitivity and predictive value of the model for predicting the presence of RA-ILD on HRCT (yes/no) will be reported.

Conclusion: This prospective multi-national cross-sectional study will enable development of a screening tool for RA-ILD, guided by risk factors, to identify patients with RA who should be screened for ILD using HRCT.

Disclosure of Interests: This study is supported by Boehringer Ingelheim International GmbH (BI)

Disclosure of Interests: NIL.

Conclusion: Our study proved an association between cardiac involvement and disease activity. Therefore, early and appropriate management of RA may decrease the risk of cardiac impairment.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.2421
Disease activity was measured with help of DAS28. All patients were examined using the same protocol, ESR, CRP and ViD level were assessed. S1 healthy patients with the same statistical data were included in the control group.

Results: 68.08% of examined patient were female and 31.91% - male. Duration of the RA at the moment of the study was 5.2±1.1 years and mean DAS28 score was 4.8±1.2. According to our study significant negative correlation between levels of ViD and DAS28 score was found (p=0.02), correlations between CRP, ESR were also found, but the results were not significant. The mean ViD level in patient group was 13.5±8.3 ng/mL and in control group 38.4±2.6 ng/mL. The difference of ViD levels between groups was significant (p<0.05).

Conclusion: According to our data, levels of ViD are lower among patients with RA, especially among patients with high activity. Taking that into consideration, the levels of ViD should be assessed in patients with RA and insufficiency of ViD should be corrected in the course of Ra treatment.

INTERSTITIAL MATRIX DESTRUCTION IS A CENTRAL PATHOLOGICAL FEATURE OF RHEUMATOID ARTHRITIS

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Biomarkers

A. C. Bay-Jensen1, S. Holm Nielsen1, C. Thudium1, M. Karsdal2. 1Nordic Bioscience, ImmunoScience, Herlev, Denmark; 2Nordic Bioscience, Fibrosis Biology, Herlev, Denmark

Background: The interstitial matrix is the ground substance of all connective tissues, such as bone, skin, tendons, internal organs, and ligaments[1]. Type I collagen (COL1) is not only the most abundant protein, but also crucial for tissue integrity and stability as it act as the skeletal network of most organs. COL1 is organized in fibrils and connecting other extracellular matrix proteins to form a dynamic tissue. In bone, COL1 is 80% of the total protein amount and 95% of the total collagen amount, and thereby bone is by far the most COL1 rich tissue[1]. Matrix metalloproteinase (MMP) driven COL1 degradation is a central feature of in the pathogenesis of rheumatoid arthritis (RA) resulting in the release of C1M into the circulation. The common soluble biomarkers in RA are measures of inflammatory factors such as CRP, thus there is room for blood-based biomarkers reflecting tissue destruction.

Objectives: MMP-mediated tissue destruction may be a central part of inflammatory disorders, albeit overlooked. The biomarker C1M was developed more than a decade ago[2]. C1M originates from soft tissue turnover (from the action of MMP-2, -9, and -13)2), not bone, thus very different from the bone degradation biomarker CTX-I. The aim was to review the literature to provide an overview on the potential context of use of assessing MMP-mediate COL1 degradation in RA, according to the FDA BEST guidelines[2].

Methods: PubMed and google scholar were searched for full-text original articles in English using the keywords C1M, biomarker, and rheumatoid arthritis. The search period was set to 2011 to 2022, included. Also, we limited the included articles to those assessing blood levels of C1M in clinical RA samples and animal models, thus excluding articles assessing the biomarker assessed in cell cultures or in silico models.

Results: 396 titles were identified of which 14 were full text, English written articles. The figure provides the main conclusions of the 14 articles. C1M was 2-4 times elevated in patients with RA compared to healthy donors or to patients with undifferentiated arthritis (UA) and is increased in a rat model of RA (orange box). C1M release is inhibited by biologics, such as anti-IL6 receptor, anti-TNFs, and Jak inhibitors, and was shown to be associated with disease activity (blue box). C1M was predictive of treatment response (purple box) and associated with disease progression (green box).

Conclusion: MMP-mediated COL1 degradation was more than 100% elevated in RA, suggesting that tissue destruction is actively ongoing in these patients. Tissue destruction was prognostic for further joint damage. Only those treatment that strongly inhibited this tissue destruction was efficacious. In alignment, changes in tissue destruction were predictive for efficacy.

EFFECT OF RHEUMATOID ARTHRITIS ON BONE MINERAL DENSITY AND ITS RELATIONSHIP WITH INFLAMMATORY MILIEU IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Osteoporosis, Rheumatoid arthritis

R. Sivaprasad1, M. Gopalakrishnan1, S. Khichar1, R. Shukla3, K. Shukla3, M. K. Garg1. 1All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India; 2All India Institute of Medical Sciences, Endocrinology, Jodhpur, India; 3All India Institute of Medical Sciences, Biochemistry, Jodhpur, India

Background: Rheumatoid arthritis (RA) is a inflammatory disorder, associated with significant systemic and local bone loss. Factors determining bone mineral (BM) loss in rheumatoid arthritis (RA) are important. This study aimed to determine the occurrence and predictors of low bone mineral density (BMD) in patients with RA.

Objectives: To estimate Bone Mineral Density in patients with Rheumatoid arthritis. To determine the frequency and risk factors for osteopenia/osteoporosis in patients with Rheumatoid arthritis.

Methods: PubMed and google scholar were searched for full-text original articles in English using the keywords Rheumatoid arthritis, osteoporosis. The search period was set to 2011 to 2022, included. Also, we limited the included articles to those assessing bone mineral density (BMD) and its relationship with inflammatory milieu in RA patients.

Results: 37 articles were included for the systematic review. Of these 22.7% (8/37) were prospective cohort studies, 21.6% (8/37) were cross-sectional studies. Of the 37 articles, 39% (14/37) were conducted in patients with RA, while the remaining 61% (23/37) were conducted in patients with osteoporosis. The majority of the articles were conducted in patients with RA.

Conclusion: Rheumatoid arthritis was significantly associated with osteoporosis in patients with RA. The relationship between bone mineral density and inflammatory milieu in patients with RA is complex and multifactorial.

DOi: 10.1136/annrheumdis-2023-eular.3254

Acknowledgements: NIL.

DOi: 10.1136/annrheumdis-2023-eular.32706
Methods: We studied 102 RA patients diagnosed using ACR/EULAR 2010 at our Rheumatology clinic in Jodhpur, India from January 2021 to August 2021 after written informed consent and Ethical Committee approval. We collected the clinical, demographic, treatment history and calculated disease severity with Disease Activity Score (DAS28 CRP) and Clinical Disease Activity Index (CDAI). BMD was assessed (Dual-energy X-ray absorptiometry scanner-Hologic Corp, model no-Horizon A S/N 303237M). Serum samples for Interleukin-1 (IL-1) and Interleukin 6 (IL-6) were collected and stored at -80°C and analysed by ELISA.

Results: In the study population, with mean age of 46.7±12.3 years, median disease duration of 48±36 months, mean DAS28 CRP score of 4.5±1.2, mean CDAI value of 18.6±8.58 prevalence of osteopenia and osteoporosis calculated using T score were found to be 43.1% and 15.7% at left hip, 42.2% and 16.7% at lumbar spine, 16.8% and 17.6% at left forearm respectively(Table 1, Figure 1). There was significant variation in BMD across various age categories at lumbar spine (P value=0.031) and left forearm (P value < 0.0001). There was statistically significant reduction in BMD with higher disease activity at hip (p value<0.019), however significance was not observed at lumbar spine and forearm. There was no significant association between BMD and CDAI. There was statistically significant difference in the lumbar spine BMD across the DAS 28 CRP <3.2 and DAS 28 CRP >3.2 subgroup. Lower values of BMD were observed in female patients, RF positive patients and established RA patients but these were not statistically significant. There was statistically significant correlation between BMD and CDAI value of 18.6±8.58 prevalence of osteopenia and osteoporosis calculated for assaying inflammation and disease activity in RA patients while serum homocysteine can be used as a sensitive marker for assessing inflammation and disease activity in RA patients. Serum neopterin can be used as a predictor of RA extra articular complications.

SERUM LEVELS OF HOMOCYSTEINE, LEPTIN AND NEOPTERIN AS MARKERS OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis

M. Gamal1,2, Y. Gaza1, M. Ghaff1, 1Dubai Hospital, Rheumatology, Dubai, United Arab Emirates; 2Al-Azhar University, Rheumatology, Cairo, Egypt

Background: Rheumatoid arthritis (RA) is a chronic, systemic disorder characterized by the presence of many proinflammatory cytokines that have been involved in the pathogenesis, comorbidity, and premature mortality, due to increased atherosclerotic heart disease[1], homocysteine is an independent risk factor for coronary heart disease, stroke, and an independent predictor for cardiovascular mortality in atherosclerotic patients[2]; leptin is a component of cytokines that mediates immune response and plays an important role in the T-cell related inflammatory process.[3] Neopterin is a pteridine derivative produced by monocytes and macrophages primarily as a response to interferon-gamma stimulation induced by the activation of the cellular immune system.[4]

Objectives: To investigate the relationship between serum levels of homocysteine, leptin and neopterin and clinical & laboratory parameters of disease activity in patients with rheumatoid arthritis.

Methods: This study included 80 RA patients and age & sex-matched 80 healthy controls. RA patients were divided into two groups (A&B) depending on the presence or absence of Extra-articular manifestations. There was 40 with Extra-articular manifestations (9 patients with Cutaneous vasculitis, 7 with Nodules, 6 with Neuropathy, 5 with Reynaud’s phenomenon,7 with secondary sjoegen, 2 with Fealty’s syndrome, 2 with Intestinal nphritis, 2 with Intestinal nphritis).

Results: In the RA group (A+B), mean serum homocysteine, leptin and neopterin levels were (11.79 ± 8.72 μmol/L), (22.43 ± 7.37 mg/dl) and (3.83 ± 1.84 nmol/L) respectively with No statistically significant difference was found between RA and control groups regarding serum Leptin (p=0.674). While a significant difference was found between RA and control groups regarding serum Neopterin (< 0.001) & homocysteine, (< 0.001). Also, In RA groups (A, B) there was a statistically significant difference regarding serum Neopterin (p= 0.03) and DAS 28 ESR (p= 0.05). there was a Positive significant correlation between serum (neopterin - Hcy) and ESR, TNF-α, IL-6, and DAS-28 (p < 0.05) while no significant correlation was found between serum (neopterin- homocysteine) and CRP (p > 0.05).

Conclusion: Serum lepton cannot be considered of value as an marker of disease activity in RA patients. Serum neopterin can be used as a sensitive marker for assaying inflammation and disease activity in RA patients while serum homocysteine can be used as a predictor of RA extra articular complications.

NAILFOLD VIDEO CAPILLAROSCOPY SUPPORT THE DIAGNOSIS OF OVERLAP CONNECTIVE TISSUE DISEASE: A PILOT STUDY IN A SAMPLE OF RHEUMATOID ARTHRITIS PATIENTS

Keywords: Diagnostic tests, Rheumatoid arthritis
Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease characterized by arthritis and a range of extra-articular organ involvement. Altered microcirculation is an important contributor to the inflammatory reaction characterizing RA and is involved in synovitis and systemic organ manifestations[1]. Nailfold video capillaroscopy (NVC) is a reliable, safe and highly sensitive method for evaluating the morphology of microcirculation and detailed alterations[2].

Objectives: The objective of the study was to evaluate the microcirculation in adult RA patients by using NVC and to identify morphological and quantifiable NVC parameters with possible correlations with clinical and laboratory findings.

Methods: NVC was performed at baseline on 8 fingers of both hands of 25 RA patients (EULAR/ACR 2010 criteria) (mean age 68.5±13.47 years, mean disease duration 14.6±8.6 years)[3]. Different NVC parameters microvascular damage were detected and analyzed, such as microvascular architecture, capillary morphology and loss of capillaries (linear/mm). The results were categorized into "non-scleroderma" pattern, such as "normal" and "non-specific alterations"; as well as "scleroderma" and "scleroderma-like" pattern. The RA patients were treated (at the time of the analysis) with low dose glucocorticoids, NSAIDs and cDMARDs (see Table 1). Statistical analysis was performed by non-parametric tests.

Results: The patient's mean age at the time of NVC was 62.68±12.68 years and they consisted mostly of women (84%). The caucasian cohort was composed of 21 females and 4 males (5.25:1). The patient's mean age at the time of NVC was 62.68±12.68 years and they consisted mostly of women (84%). The caucasian cohort was composed of 21 females and 4 males (5.25:1). The patient's mean age at the time of NVC was 62.68±12.68 years and they consisted mostly of women (84%). The caucasian cohort was composed of 21 females and 4 males (5.25:1).

Conclusion: The results of present study confirm in sample size that a specific pattern, like "Early" scleroderma NVC pattern was observed in 1 patient (4%), showing giant capillaries and microhaemorrhages. "Sclero- derma-like" capillaroscopic pattern was found in 2 patients (8%) with the following features: dilatations, giant capillaries, microhaemorrhages, abnormal capillary shape with ramifications and reduced mean capillary number per linear mm. NVC observation of "Early" scleroderma pattern and "Scleroderma-like" pattern in 3 patients (12%), suggested the coexistence of an overlap syndrome (most likely MCTD), also supported by clinical and autoantibodies specificities. No specific RA NVC pattern was detectable. No statistically significant correlations were found between different NVC parameters and autoantibodies or specific RA clinical features.

DOI: 10.1136/annrheumdis-2023-eular.4761
Methods: The study evaluated the structural capillaroscopic parameters using video-capillaroscopy (NVC). Applying the tonometry method, the augmentation index (AiX) was calculated, as well as its adjustment to a heart rate of 75 (AiX75). Additionally, pulse wave velocity (PWV), and mean intima-media thickness (cIMT) of the two common carotids, as well as central systolic and diastolic blood pressure (cSBP, cDBP), were calculated in each patient.

Results: A total of 32 patients with a mean age of 63.06±11.05 years were studied. At the same time, the existence of ramified capillaries was significantly correlated with PWV (p<0.03, p=0.023), while the existence of crossed capillaries was inversely correlated with cSBP (p=0.43, p=0.016). Based on the measurements performed in each capillary, a significant correlation was found between the internal capillary diameter and cSBP (p=0.36, p=0.043). In 16 patients the subcapillary venous plexus was visible and this finding was significantly correlated with the mean value of left cIMT (p=0.005).

Conclusion: The findings of this small study indicate an association between NVC alterations and markers of atherosclerosis in patients with RA.

FACTORS AFFECTING QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Quality of life

M. Brahimi1, R. Sarrà2, B. Jebali1, O. Jomaa1, M. Hassayoun1, S. Abdellatif1, H. Hachfi1, Y. Mohamed1. 1Täher Star University Hospital, Rheumatology, Mahdia, Tunisia

Background: Rheumatoid Arthritis (RA) has an important impact on patients’ quality of life (Qol), affecting both physical and mental domains of well-being.

Objectives: This study aims to assess the Qol of RA patients based on the Short Form Health Survey-36 (SF-36) questionnaire and to evaluate the associated factors.

Methods: This is a cross-sectional study including patients with RA disease. Each patient answered to the SF-36 Questionnaire assessing quality of life, which evaluates 8 domains: physical functioning (PF), bodily pain (BP), role limitations due to physical health problems (RP), role limitations due to personal or emotional problems (RE), mental health (MH), social functioning (SF), energy/fatigue or vitality (VT), and general health perceptions (GH).

Results: We included 78 patients with a mean age of 52.9±11.3 years and a female preponderance (88.5%). The mean duration of disease progression was 11.1±9.5 years. The average of patient global health, numbers of swollen and tender joints were respectively 51.4 ± 2.2, 3.7 ± 3.2 and 8.6 ± 7.6. Two thirds of patients had moderate to severe disease activity (DAS 28 >3.2). The mean Health Assessment Questionnaire (HAQ) was 1.3 ± 0.8, Hospital Anxiety and Depression Scale (HADS) showed that 16.7% of patients had anxiety and 18% had depression. The SF-36 global score was 52.3 ± 24.8 [15.5-92.8] with an impaired Qol (SF-36 <66.7) in 51 (65.4%) patients. Among the eight domains, the most affected domain was the “role limitations due to physical health problems” (RP) with a mean of 45.4±20.3. Impaired Qol was associated with disease activity parameters: number of swollen joints (p=0.01), number of tender joints (p=0.01), patient global health (p=0.02) and DAS 28 score (p=0.01). Patients with high functional disability (HAQ ≥ 1), high scores of depression and anxiety had poor quality of life (p<0.01). No significant associations were found between Qol and age, gender or duration of disease activity.

Conclusion: RA has a significant physical, psychological and social impact on affected patients. This impairment of Qol was associated with disease activity, functional impact and psychological disorders. Therefore, it is necessary to improve these parameters for a better management of the disease.

PREGNANCY, BIRTH OUTCOMES, AND BREASTFEEDING IN CHRONIC RHEUMATIC DISEASES WOMEN

Keywords: Pregnancy and reproduction

K. Maatallah1, L. Kharrou1, H. Ferjani1, D. Ben Nessim2, D. Kaffel1, W. Hamdi1.

Kassab Orthopedics Institute, Ksar Said, Rheumatology, Tunis, Tunisia

Background: Parenthood is usually challenging in chronic rheumatic diseases, such as rheumatoid arthritis (RA) and spondyloarthritides (SpA). It seems to be affected by the disease state and pharmacological therapies [1,2].

Objectives: We aimed to assess pregnancy, birth, and breastfeeding outcomes in patients with RA and SpA.

Methods: We conducted a cross-sectional study including patients followed for RA or SpA. We collected the following data: age, disease duration, erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) levels, disease activity was assessed using DAS28 score for patients with RA and ASDAS-CRP scores for patients with SpA. We asked patients about their pregnancies, birth outcomes, and breastfeeding. Statistical analysis was performed using SPSS software.

Results: Forty-six women were included. They were 23 RA patients and 23 SpA patients. The mean age was 50.2 ± 13.1 years. The mean disease duration was 9.64 ± 8.27 years. The mean ESR and CRP levels were 40.45 ± 33.12 mm and 15.22 ± 24.21 mg/L. The mean DAS28-ESR and ASDAS-CRP were 5.25 ± 1.21 and 2.7 ± 0.6, respectively. Forty-one women were married, 3 were divorced and 2 were widowed. The mean age at the marriage was 24.9 ± 6.66 years. Half of the patients suffered from infertility (n=23). Eight of them never had kids (17%). The mean numbers of gestation and parity were 3 ± 2 [0-7] and 2 ± 1 [0-6], respectively. Seven patients discontinued their treatment to get pregnant without discussing it with their rheumatologists (15%). Only 6 patients had complications during their pregnancies (16%). Complications were abortion in 5 cases and preeclampsia with premature birth in one case. Twenty-five patients gave natural vaginal birth (66%), 7 patients gave birth by C-section (18%), and 6 patients needed obstetrical forceps to give birth (16%). Two patients had a post-partum hemorrhage. The mean term birth was 39.18 ± 1.44 weeks of amenorrhea. Thirty-four patients had breastfed the children (74%). The mean breastfeeding duration was 13.76 ± 8.8 months. Eight patients reported impairment of breastfeeding due to their diseases (21%). Birth with cesarean section was associated with a younger age at the onset of the disease (32.75 ± 5.73 vs 43.16 ± 10.3 years, p=0.031). DAS28-ESR and ASDAS-CRP were higher in patients who had cesarean section but the difference was not significant (DAS28: 5.12 ± 0.45 vs 4.34 ± 0.79, p=0.08; ASDAS: 3.04 ± 0.9 vs 2.59 ± 0.6, p=0.3). Furthermore, younger age was associated with impaired breastfeeding (39.4 ± 9.23 vs 56.11 ± 11.27 years, p=0.01). Discontinuing the treatment was associated with infertility (p=0.003), a younger age of the patient (40.8 ± 7.82 vs 51.33 ± 14.47 years, p=0.002), older age at the marriage (34 ± 6 vs 23.21 ± 5.02 years, p=0.042), and higher CRP (22.08 ± 27.56 vs 8.18 ± 8.36 mg/L, p=0.04).

Conclusion: Our results are consistent with other studies [2], caesarean section rates seem to be high in RA and SpA patients [3]. Strikingly, our youngest patients were the ones that discontinued their treatment to get pregnant. This highlights the importance of informing and discussing pregnancy with patients with chronic inflammatory diseases.

THE ALBUMIN LEVEL AND THE ACTIVITY OF RHEUMATOID ARTHRITIS, WHAT CORRELATION?

Keywords: Rheumatoid arthritis, Descriptive studies

F. E. Chekkouri1, A. Mougou1, I. El Bouchti1. 1centre Hospitalo-Universitaire Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco
Background: Inflammation during rheumatoid arthritis (RA) can cause changes in the serum levels of certain proteins, including albumin. Our study aims to find a link between albumin level and disease activity.

Objectives: The objective of our study was to study the correlation between the albumin level and the indices of RA activity.

Methods: Descriptive and comparative study including patients with RA between 2007 and 2021. Statistical data analysis was performed using SPSS version 20 software. The correlation between albumin level and RA activity indices was assessed using Pearson's correlation coefficients (p-values).

Results: 260 patients were included. The average age was 49.91 years, with a female predominance in 86.9% of cases. The average duration of evolution was 4.64 years. Chronic polyarthritis was the most frequent mode of revolution (74.2%), it was deforming in 64.1% of cases. Structural damage was present in 84.8% of patients, RA was seropositive for ACPR in 82.9% and seronegative for RF in 775% of cases. The mean ESR and CRP levels were 44.08 mm/h and 32.68 mg/l respectively. Hypoalbuminemia was found in 41.1% of patients with an average albuminemia of 36.5 ± 6.78 g/l. The mean DAS28-CRP was 5.26 and the mean CDUAI was 35.75. Patients with severe activity had more frequent hypoalbuminemia than those with moderate and low activity (67% vs 22% and 7%). A significant negative correlation was found between the albumin level and the DAS28-CRP (r = 0.24, p = 0.003), on the other hand the CDUAI score was not correlated with the albumin level (r = 0.22, p = 0.16). There is a significant correlation between albumin level, CRP level and ESR (r = -0.27, p = 0.001).

Conclusion: These results suggest that the albumin level could provide additional information on the intensity of inflammation in RA.

AB0283 THE IMPACT OF POLLUTION ON DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: A 112 PATIENT GROUP STUDY

Keywords: Rheumatoid arthritis, Prognostic factors, Geographical differences

H. Tebbaa1, A. Rafii1, H. Arabii1, A. Mougli1, I. El Bouchti1, Centre Hospitalier Universitaire Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco

Background: Air pollution is incriminated in a large number of respiratory and cardiovascular pathologies. More recently, the role of particulate matter from pollution has been studied in autoimmune diseases and in particular in rheumatoid arthritis (RA).

Objectives: The objective of our study is to evaluate the impact of air pollution measured by the quality index (AQI) on different disease parameters during rheumatoid arthritis.

Methods: We included in this study 112 patients with seropositive rheumatoid arthritis, residing in different regions of southern Morocco. Inclusion criteria were: established rheumatoid arthritis, duration of residence exceeding one year in the same region. Exclusion criteria were: specific professional exposure to industrial pollutants and passive and active smoking. The air pollution level was evaluated by the new ATMO index which classifies the air quality in five levels: Good, average, degraded, bad, very bad and extremely bad according to the concentration of the four air pollutants. The following parameters were collected: duration of disease progression, age, number of exacerbations per year, the mean DAS28 CRP during the last year, the mean CRP during the last year, the time of anamnesis, the number of hospitalizations, an univariate and multivariate analysis evaluating the association and the correlation with the different parameters was carried out by the SPSS 2021.

Results: 112 patients were included. The female sex represents 66%. The different regions included in the study were: Marrakech in 68 cases with an AQI of 47, Safi in 9 cases with an AQI of 21, Beni Mellal in 6 cases with an AQI of 29, Sidi Rehal in 1 case with an AQI of 1, Dernane in 2 cases with an AQI of 29, Ouarzazate in 4 cases with an AQI of 25, Azilal in 10 cases with an AQI of 34, Zagora in 4 cases with an AQI of 21, Youssoufa in 1 case with an AQI of 9, Guelmine in 7 cases with an AQI of 17. The average DAS28 was 3.11. The mean CRP was 23.1 mg/l. The average number of hospitalizations during the last year was 2.5. The average number of exacerbations in the last year was 5.6. The use of level 1 analgesic was noted in 22%, level 2 in 13%. A positive correlation was found between the number of exacerbations and AQI (p = 0.011, r = 0.69), CRP and AQI (p = 0.013, r = 0.71).

Conclusion: The associations between rheumatoid arthritis and air pollution seem complex, it can be considered as a risk factor aggravating rheumatoid arthritis, and these hypotheses have to be demonstrated on a larger sample.

AB0284 EVALUATION OF THE RELATIONSHIP BETWEEN SERUM NETRIN-1 LEVEL AND PATIENT CHARACTERISTICS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

G. Ozan1, S. Ertən2, S. C. Güven3, A. Kor4, F. Eren5, P. Akyüz Dağış6, Y. Mardas7, I. Dogan2, K. Gökk8, O. Küçükşahbin9, B. Armagan2, S. Neşeliolu2, S. Başer4,
Background: Although many predictors have been proposed to predict rheumatoid arthritis (RA) disease activity, most of these markers are not specific to RA and their levels can be affected by many other factors. The need for ideal markers to predict disease activity in RA continues. The association of netrin-1 with RA disease activity has not been evaluated before.

Objectives: This study aimed to investigate the plasma levels of the netrin-1 molecule in RA patients and its relationship with RA disease activity.

Methods: Sixty RA patients and 41 age and sex-matched healthy volunteers were included in this study. An ELISA kit (Elsabscience, Texas, USA; catalog number: E-EL-H2328; lot number: G2WTX2S25W) analyzed by quantitative sandwich enzyme immunoassay method was used to calculate netrin-1 values. Disease Activity Score-28 (DAS-28) and Clinical Disease Activity Index (CDAI) were calculated to measure disease activity, and Rheumatoid Arthritis Disease Impact (RAID) score was calculated to measure disease-related deterioration in the quality of life.

Results: Netrin-1 serum levels were similar in RA and healthy controls (respectively, 64.4 [35.8-551.4] and 65 [35.8-436.6], p=0.786). No significant correlation was found between levels of Netrin-1 and DAS-28, DAS-28-ESR, CDAI, and RAID scores (p>0.05).

Conclusion: Netrin-1 is not elevated in RA patient serum and its levels are not correlated with RA disease activation scores.

AB0285 MANAGEMENT OF ATLANTO-AXIAL SUBLUXATION IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Prognostic factors, Disease-modifying drugs (DMARDs)

S. Miladi1, S. Boudid1, A. Fazaa1, H. Boussaï1, M. Yasmine1, K. Quenniche1, S. Kassa1, C. Selma1, K. Ben Abdelehmani1, A. Lataar1. Monji Slim Hospital, Rheumatology, Tunis, Tunisia

Background: Recent studies have shown that around 86% of Rheumatoid Arthritis (RA) have cervical spine involvement [1]. The synovial inflammation in the upper cervical spine causes instability. Atlanto-axial subluxation (AAS) is the most frequent injury of the cervical spine in RA.

Objectives: Our study aimed to assess the medical management of AAS in our RA patients.

Methods: We conducted a retrospective, monocentric study, including patients fulfilling the ACR/EULAR 2010 criteria for RA. All patients had a confirmed AAS on MRI of the cervical spine findings. Disease activity was assessed using the disease activity score 28 (DAS-28). Treatment received by each patient, before and after the occurrence of AAS, was noted.

Results: We included 19 patients with a confirmed AAS. The mean age was 62±14.91 years. Male to female ratio was 0.5. The mean disease duration was 19.27±8.04 years. RA was erosive in all patients and immunopositive in 87% (n=13). When AAS occurred, twelve patients were on csDMARDs. The mean DAS28 ESR was 5.25±1.1. According to DAS28ESR, high disease activity was noted in 10 patients (66.7%). Methylprednisone was the most frequent treatment used (n=9, 60%). An association of Methylprednisone and sulfasalazine was prescribed in 5 cases (33%). Two patients were using leflunomide. Three patients were on bDMARDs. Nine patients (60%) received bolus steroid therapy. These patients had a vasculatized synovial pannus on MRI findings. Four patients remained on the same DMARDs. An association of sulfasalazine to methylprednisone was performed in 6 patients. A change from csDMARDs to bDMARDs was undergone in only two patients (from sulfasalazine to rituximab, and from leflunomide to etanercept). A switch of bDMARDs was performed in three patients: from infliximab to rituximab in one case, and from rituximab to tocilizumab in two others. Surgical treatment was indicated in three patients for neurological complications, but the patients did not agree to proceed with the surgery.

Conclusion: AAS is a potentially lethal complication of RA. The use of bolus steroid therapy can be handy to reduce acute inflammation. However, adjustment of DMARDs is needed to better control RA activity and to slow its progression.

Keywords: Disease-modifying drugs (DMARDs), Safety, Rheumatoid arthritis

T. Hisaishi, Y. Hisashi1,5, M. Harigai 1.

Objectives: To determine the optimal DMARD selection for treatment of RA patients with decreased kidney function, we compared the retention rates of patients receiving tumor necrosis factor inhibitor (TNFi), interleukin-6 inhibitor (IL-6), and abatacept (ABT) in RA patients using data from the IORRA cohort, the real-world data registry of Japanese RA patients.

Methods: Renal function was calculated using the Japanese versions of the equations for estimated glomerular filtration rate (eGFRcr). Decreased renal function was defined as eGFRcr < 60 mL/min/1.73m². Among RA patients enrolled in the IORRA cohort between 2003 and 2020, data from patients with decreased kidney function who started bDMARDs were extracted. Renal function and use of bDMARDs by the extracted patients were identified in their medical records. Reasons for discontinuation were classified as ineffectiveness, adverse events, or other reasons. Retention rates due to ineffectiveness or adverse events caused by TNFi (adalimumab or adalimumab biosimilar [ADA], certolizumab pegol [CZP]), etanercept or etanercept biosimilar [ETN], golimumab [GLM], infliximab or infliximab biosimilar [IFX]), IL-6i (tocilizumab [TCZ], sarilumab [SAR]) and ABT spanning 36 months were calculated using the Kaplan-Meier method, and adjusted hazard ratio (aHR) of discontinuation of each bDMARD was calculated using the Cox proportional hazard model, with adjustment for age, sex, disease duration, clinical disease activity index (CDAI), methotrexate (MTX)/prednisolone (PSL) use, and previous bDMARD use at baseline.

Results: A total of 238 treatment courses administered to 191 patients with decreased renal function were included. Median eGFRcr = 52.5 mL/min/1.73m² (interquartile range: 43.3–71.7). The number of bDMARD users was as follows: TNFi, 143 (ADA, 15; CZP, 5; ETN, 67; GLM, 30; IFX, 26); IL-6i, 59 (all were TCZ); and ABT, 36. Respectively, ABT users were older than IL-6i users, and TNFi users had higher eGFRcr, and a higher proportion of MTX and previous DMARD use than the other groups. Sex, seropositivity, CDAI, health assessment questionnaire, and the proportion of PSL use were similar between groups. The retention rates at 36 months were 59.9%, 72.9%, and 61.7% for TNFi, IL-6i, and ABT, respectively, aHR of discontinuation when TNFi served as reference was 0.60 (95% confidence interval: 0.32–1.00) for IL-6i, and 0.85 (95% confidence interval: 0.44–1.64) for ABT.

Conclusion: Because the retention rate of IL-6i was numerically high compared with TNFi and ABT in this study, IL-6i may offer a treatment advantage in RA patients with decreased renal function.

RHEUMATOID ARTHRITIS PATIENTS WITH INTERSTITIAL PNEUMONIA NEED APPROPRIATE TREATMENT ENHANCEMENT TO RECOVER FROM FRAILTY: A MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY

Keywords: Rheumatoid arthritis, Comorbidities, Lungs

Y. Ohashi1, N. Takahashi2, M. Suzuki3, Y. Sobue4, R. Sato5, M. Maeda5, D. Kihira6, K. Kishimoto7, K. Terabe8, S. Asai9, S. Imagama1
1 Nagoya University Hospital, Orthopaedic Surgery, Nagoya, Japan; 2 Aichi Medical University Hospital, Orthopaedic Surgery, Nagakute, Japan; 3 Japanese Red Cross Nagoya Daiichi Hospital, Orthopaedic Surgery, Nagoya, Japan; 4 Nagoya University Hospital, Orthopaedic Surgery, Nagoya, Japan

Background: Frailty is a common geriatric syndrome that embodies an elevated risk of catastrophic health and physical function declines among older adults [1]. Rheumatoid arthritis (RA) is an autoimmune disease that causes synovitis in the joints, resulting in joint deformity with a high prevalence (0.5-1.0% in Japan) [2]. Japan is one of the world’s most rapidly aging societies [3], and older RA patients are generally at a greater risk of frailty than the general population. Most patients with comorbidities such as pulmonary, renal, and liver dysfunction are more prone to become frailty in the short term than healthy people [4], as well as poor control of disease activity in RA patients [5]. Against this background, the present study aimed to investigate factors associated with frailty in RA patients, including their comorbidities.

Objectives: This study investigates factors associated with frailty in RA patients. Methods: 656 RA patients were evaluated from our observational study data in 2022. Of the patients, 152 were frailty, and 504 were not frailty assigned to the frailty group and the non-frailty group, respectively. Both patient characteristics were compared in univariate analysis. The factors associated with frailty were assessed by logistic regression analysis. As a sub-analysis, patients who have Interstitial pneumonia (IP) history and patients who did not were assigned to the IP (n=102) and non-IP (n=554) groups, respectively, to clarify differences between both groups.

Results: The frailty group was older (mean: 73.6 ±66.8 years) and had a higher DAS28-ESR (mean: 3.67 vs. 2.66) than the non-frailty group. DAS28-ESR (OR: 1.85, P<0.001) and IP history (1.74, P=0.043) were associated with frailty (Table 1). The IP group was older (mean: 73.3 ±67.5 years), had a higher DAS28-ESR (mean: 3.30 vs. 2.80) (Figure 1 A), a higher HAQ-DI (mean: 0.32 vs. 1.19) (Figure 1 B), lower use of methotrexate (MTX) (26.5% vs. 62.9%), and higher use of steroid (44.1% vs. 26.8%) than the non-IP group. There was no difference in the use of biological and targeted synthetic disease-modifying antirheumatic drugs (b/ts-DMARDs) between both groups (38.3% vs. 37.3%) (Figure 1 C). The IP group had a higher frailty proportion than the non-IP group (20.6 vs. 37.3%) (Figure 1 D). Conclusion: DAS28-ESR and IP history were associated with frailty in RA patients. Most RA patients with IP had frailty with insufficient treatments, i.e., low use of MTX, high use of steroid, and low use of b/ts-DMARDs. They might recover from frailty through appropriate control of disease activity using b/ts-DMARDs, which are easy to use for patients with comorbidities.

COMORBIDITY CLUSTERS IN PATIENTS WITH RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH DISEASE ACTIVITY AND PREDICT SURVIVAL PROGNOSIS

Keywords: Prognostic factors, Rheumatoid arthritis, Comorbidities

C. S. Crowson1, E. Atkinson1, E. Myasoedova2, V. Kronzer2, B. Kimbrough2, C. Kodihalata3, E. Lovering4, R. Kumar2, J. M. Davis3,4,5,6,5,6,5 Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America; 2 Mayo Clinic, Rheumatology, Rochester, United States of America

Background: Comorbidities are common in patients with rheumatoid arthritis (RA), but there is little information regarding distinct comorbidity patterns in patients with RA and how these patterns impact disease activity and mortality.

Objectives: To examine clusters of patients with RA based on comorbidities, the association between these clusters and RA disease activity, and their impact on mortality.

Methods: In this retrospective, population-based study, residents of a geographically well-defined area with prevalent RA on 1-1-2015 were identified. Patients were followed for vital status until death, last contact or 12-31-2021. Clinical Disease Activity Index (CDAI) was obtained from the medical visit closest to the prevalence date (±1 year). Diagnostic codes were retrieved for 5 years prior to the prevalence date. Using 2 codes ≥30 days apart, 56 comorbidities were defined. Latent class analysis (LCA) was used to cluster patients based on comorbidity patterns with the optimal number of clusters determined by Bayesian Information Criterion. Standardized mortality ratios (SMR) were used to assess differences in mortality across the clusters.

Results: A total of 1643 patients with prevalent RA (72% female; 94% white; median age 64 years, median RA duration 7 years) were studied. Comorbidities were present in 1548 (94%) of the subjects with 5+ comorbidities present in 980 (59%) subjects. LCA identified 4 clusters of patients. Although only comorbidities were used in the LCA, the clusters differed by age, sex, number of comorbidities, smoking status, body mass index (BMI) and RF/anti-CCP positivity (Table 1). Cluster 1 (n=686) included younger patients who were less likely to smoke and had fewer comorbidities compared to other clusters. In contrast, cluster 4 (n=134) included older patients with 6+ comorbidities who were more likely to have smoked. Cluster 2 (n=200) included younger patients with 6+ comorbidities and high prevalences of depression and obesity, while cluster 3 (n=623) included the remaining patients with 3+ comorbidities consisting mainly of hypertension, hyperlipidemia and back pain. Cluster 1 had no increased mortality based on US lifetables (SMR 0.8; 95% confidence interval [CI]: 0.55-1.1). Cluster 2 had the worst survival (SMR 3.5; 95% CI 2.8-4.4). Cluster 2 also had poor survival (SMR 1.6; 95% CI 1.03-2.23), while the poor survival in cluster 3 was less pronounced (SMR 1.2; 95% CI 0.99-1.4). Data on CDAI were available on 656 RA patients were mostly like those without CDAI except they were slightly less pronounced (SMR 1.2; 95% CI 0.99-1.4). Data on CDAI were available on 656 RA patients were mostly like those without CDAI except they were slightly

Conclusion: Clustering of patients with RA based on comorbidity profiles identified distinct groups exhibiting different prognosis. This demonstrates comorbidities congregate in some patients, leading to poor prognosis, while others...
experience fewer comorbidities and better survival than people without RA. The cluster with both better survival and more remission despite a high proportion of seropositivity is intriguing.

AB0290 FACTORS ASSOCIATED WITH DEVELOPMENT OF MENTAL ILLNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING BIOLOGICAL AND TARGETED SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS: A POPULATION-BASED STUDY

Keywords: Targeted synthetic drugs, bDMARD, Mental health

H. H. Chen1,2, W. C. Chao1,3,1 National Chung Hsing University, Department of Post-Baccalaureate Medicine, Taichung, Taiwan, Republic of China; 2 Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 3 Taichung Veterans General Hospital, Department of Critical Care Medicine, Taichung, Taiwan, Republic of China

Background: Rheumatoid arthritis (RA) is a leading chronic inflammatory systemic disease worldwide, and increasing evidence have shown under-recognised impacts on mental health. However, the assessment and management of mental health is somehow not included in the T2T despite increasing evidence have shown that mental illnesses, particularly depression and anxiety, were not only highly prevalent in patients with RA but also associated with control of disease activity. In the present study, we used a population-based database with 10,852 patients with RA who had initiated biological or targeted synthetic disease modifying antirheumatic drugs (b/tsDMARDs) to address the incidence of mental illness and to investigate risk factors for mental illness.

Objectives: This population-based study aim to address the incidence and risk factors of mental illness among patients with RA starting b/tsDMARDs therapy.

Methods: We used the 2001–2020 Taiwanese National Health Insurance Research Database to identify patients with RA receiving b/tsDMARDs. The primary outcome was newly developed mental illness, including anxiety and mood disorders, among spouses. We performed a Cox regression analysis to determine factors associated with mental illness. The results were presented as hazard ratios (HR) with 95% confidence interval (CI).

Results: We enrolled 10,852 patients with RA and had received b/tsDMARDs. Of them, 7,854 patients received tumor necrosis factors inhibitors (etanercept n=3,322; adalimumab n=2,689; golimumab n=1,346; certolizumab n=490; infliximab n=7), 1,693 patients received non-TNFi bDMARDs (tocilizumab n=856; abatacept n=837), and 1,305 patients were treated with tsDMARD (tofacitinib n=1,192; baricitinib n=113). We found that 13.62% of enrolled patients developed mental illness, with the incidence was 4,054 per 100,000 person-year. Those receiving tocilizumab (aHR 0.65, 95%CI 0.51–0.82), abatacept (aHR 0.69, 95%CI 0.55–0.87) and tsDMARDs (aHR 0.59, 95%CI 0.47–0.73) had a lower risk of mental illness compared with receiving TNFi. We also found that old age (aHR 1.02, 95%CI 1.01–1.02), low income (aHR: 1.16, 95% CI: 1.04–1.29), use of cyclosporine (aHR: 1.20, 95% CI: 1.05–1.38), and use of steroid higher than 5mg/day (aHR: 1.23, 95% CI: 1.02–1.48) correlated with incident mental illness.

Conclusion: This population-based study investigated the incidence and risk factors of mental illness among the patients with RA receiving b/tsDMARDs. Our findings highlight the need for vigilance of mental illness in patients with RA.

AB0290 EFFECT OF FILGOTINIB ON PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS IN THE PHASE 3 FINCH 1, 2 AND 3 STUDIES

Keywords: Clinical trials, Rheumatoid arthritis, Pain

Background: Patients (pts) with rheumatoid arthritis (RA) often experience substantial pain despite treatment, and pain control is considered an important treatment outcome. The FINCH 1–3 studies demonstrated the efficacy and acceptable safety of the preferential Janus kinase (JAK) 1 inhibitor filgotinib (FIL) in pts living with RA.

Objectives: This post-hoc analysis of the FINCH studies assessed specific effects of FIL on pain.

Methods: FINCH 1–3, randomized, double-blind trials of FIL 100 mg and 200 mg (FIL100/200). In FINCH 1, pts with an inadequate response (IR) to methotrexate (MTX) received FIL, adalimumab (ADA) or placebo (PBO) + MTX for 52 weeks. In FINCH 2, pts with an IR to biologic disease-modifying anti-rheumatic drugs (DMARDs) received FIL or PBO + conventional synthetic DMARDs for 24 weeks. In FINCH 3, MTX-naive pts received FIL or MTX or MTX for 52 weeks. For each treatment group, pts reported pain on a 100-mm visual analog scale (VAS). Scores of ≤10 mm reflected limited to no pain; scores of ≤20 mm indicated health status was not negatively affected by pain.[1] Time to first VAS score of ≤10 mm was assessed. The proportion of pts who achieved remission (as per Disease Activity Score 28 with C-reactive protein [DAS28-CRP] <2.6 or Clinical Disease Activity Index [CDAI] ≤2.8) at Week 24 was evaluated. Of pts who achieved DAS28-CRP or CDAI remission, the proportion who also reported VAS pain scores of ≤10 mm or ≤20 mm was determined.

Results: In FINCH 1, there was a higher probability of achieving a VAS pain score of ≤10 mm with FIL200 vs ADA + MTX or PBO + MTX; responses were better or comparable with FIL100 vs other treatment arms (Figure 1). Similar findings were observed in FINCH 2 and 3 for FIL vs PBO and MTX, respectively. In FINCH 1, the proportion of pts achieving DAS28-CRP remission was greater with FIL200 + MTX (46.4%) and comparable for the FIL100 + MTX (35.2%) vs ADA + MTX arms (35.7%, Table 1). Further, the proportion of pts who achieved VAS pain scores of ≤10 mm and ≤20 mm in addition to DAS28-CRP remission was 26.3% and 35.8%, respectively, in the FIL200 + MTX group, compared with 17.2% and 24.6% in the ADA + MTX group (Table 1). In FINCH 2 and 3, a
greater proportion of pts in the FIL groups achieved remission vs the PBO or MTX arms, respectively. A greater proportion of pts achieved pain responses in addition to DAS28-CRP remission in the FIL groups of FINCH 2 and FINCH 3 compared with PBO or MTX, respectively. Findings were similar when CDAI remission was assessed.

Conclusion: FIL positively affected pain parameters across the FINCH studies as early as Week 2, with responses sustained over time (up to Week 52 [FINCH 1 and 3] and Week 24 [FINCH 2]). In FINCH 1, FIL200 had a particularly favorable impact when pain response and remission were assessed together. Similar findings were seen with FIL compared with PBO and MTX in FINCH 2 and 3, respectively. These findings suggest that JAK inhibition may offer potential added value with respect to patient-reported pain outcomes when treat-to-target goals are met.

Methods: RA patients using the CSI and investigate the relationship with disease activity.

Objectives: RA being analysed with CSI.

Background: Although CSS is a well-recognized entity in chronic pain, few reports of CSS in patients with rheumatoid arthritis (RA) continued to report moderate-to-high pain and fatigue [1], indicating that chronic pain can interfere with disease activity assessment. And chronic pain has linked to central sensitization syndromes (CSSs) of pain [2]. The central sensitization inventory (CSI) is a valid and reliable tool for detecting CSS, its severity, and associated synapses (CSSs) of pain [3].

However, factors associated with the risk of VTE have been barely studied in RA. Increased risk of venous thromboembolism (VTE) has been reported in rheumatoid arthritis (RA) compared to the general population [1]. However, factors associated with the risk of VTE have been barely studied in RA.

Methods: We performed a retrospective, cross-sectional study on 269 consecutive RA patients (70 males and 196 females; mean ± SD = 69.9 ± 12.2 years, range: 27–92 years; mean ± SD, disease duration: 12.9 ± 10.4 years, range: 0–55 years; mean ± SD: DAS28CRP: 1.89 ± 0.78; range: 0.99–4.88). Patients were included in the study if they fulfilled the 2010 ACR/EULAR clarification criteria attending the one-day hospitalization program of the Rheumatology department, Cochin hospital, in 2021. We used the electronic medical report to identify the occurrence of VTE in 2021 and the visit was 3.6±4.8 months. Among these 12 VTE patients, 9 were women (vs. 59±15, p=0.14). Age >65 years was more frequent in patient with VTE (58% vs. 27%, p<0.001).

Conclusion: In RA patients, CSI was not associated with inflammation (CRP or ESR) but was related to subjective assessment (PGA or pain VAS), functional impairment, and disease activity (CDAI). CSS may influence disease activity assessment, and CSS treatment may improve functional impairment.

DOI: 10.1136/annrheumdis-2023-eular.1916
vs. 33%, p=0.064), 7 (58%) patients with VTE had a history of previous VTE (vs. 3%, p<0.001), 6 (50%) were hospitalized up to 6 months before the event (vs. 6%, p<0.001), 3 (25%) experienced surgery up to 3 months before the event (vs. 2%, p<0.001) and 4 (33%) had a history of fracture (vs. 3%, p=0.001). No difference was observed regarding body mass index, the frequency of smoking, neoplasia, recent travel (up to 3 months) and estrogen/antidepressant therapies. No patient had thrombophilia. Regarding RA characteristics, patients with VTE were more likely to present extra-articular manifestations (67% vs. 33%, p=0.015) and higher CRP levels (20±40 mg/L vs. 6.4±14.5 mg/L, p=0.006). They also received more frequently corticosteroids (63% vs. 50%, p=0.025) and JAKi (25% vs. 8%, p=0.041). Disease duration, autoantibody status, frequency of erosions, DA28 and treatment with methotrexate or bDMARDs did not differ between these 2 groups. Logistic regression analysis identified the following risk factors independently associated with the occurrence of VTE: history of previous VTE, hospitalization up to 3 months before the occurrence of VTE, surgery up to 6 months before the occurrence of VTE and treatment with JAKi (Table 1).

**Conclusion:** History of VTE was identified as the strongest risk factor of the occurrence of VTE. Our results suggest a specific warning on recent hospitalization and surgery as precipitating events to VTE. As recommended by the PRAC JAKI should be used with caution in patients with risk factors for VTE.

**INFLAMMATION AND IMMUNOMODULATORY THERAPIES INFLUENCE THE RELATIONSHIP BETWEEN ATP-BINDING CASSETTE TRANSPORTER A1 (ABCA1)-MEDIATED CHOLESTEROL EFFUX AND CORONARY Atherosclerosis in Rheumatoid arthritis**

**Keywords:** Rheumatoid arthritis, Imaging, Cardiovascular disease

G. Karpouzas1,2, B. Papotti3, S. Ormseth4, M. Palumbo5, E. Hernandez2, M. P. Adorni6, F. Zimet7, M. Budoff2, S. Ronda3.

**Background:** Cholesterol efflux capacity (CEC) measures the ability of high-density lipoprotein (HDL) to remove cholesterol from atherosclerotic plaques. It is mediated by various membrane transporters exporting cholesterol from HDL particles based on their maturation. It is ususally lower in CEC associated with coronary atherosclerosis independently of HDL-C levels in RA or whether CEC itself or its impact on atherogenesis are influenced by inflammation or RA-specific therapies. Conventional and biologic DMARDs are atheroprotective while corticosteroids are proatherogenic. ATP-binding-cassette membrane transporter A1 (ABCA1) exports cholesterol to apo A1 or lipid-poor HDL particles.

**Objectives:** We here explored associations between ABCA1 CEC and coronary atherosclerosis and whether inflammation and disease-specific therapies influence this relationship.

**Methods:** Coronary atherosclerosis (noncalcified, partially or fully calcified plaque and coronary artery calcium (CAC) score) was evaluated with computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 6.9±0.4 years. ABCA1 CEC was measured in J774 macrophages as previously described. Multivariable negative binomial regression evaluated associations of ABCA1 CEC with plaque numbers at baseline and follow-up. Robust logistic regression assessed the association of ABCA1 CEC with CAC progression (>2.5 U difference in square root CAC scores).

**Results:** ABCA1 CEC was not associated with baseline atherosclerosis. Inflammation, prednisone, methotrexate or bDMARD use did not influence the relationship between ABCA1 CEC and baseline plaque. However, both baseline and cumulative inflammation modulated the relationship between ABCA1 CEC and plaque progression. Each standard deviation (SD) increase in ABCA1-C associates with 41% fewer new plaques in patients with low (<median) baseline ESR but 67% more new plaques in those with high (>median) ESR (p for interaction = 0.021). For time-weighted mean daily prednisone dose, each SD increase in ABCA1 associated with 31% fewer new plaques in unexposed patients (p for interaction vs. high exposure group = 0.034), as well as 53% fewer and 2.4 times more new calcified plaques in the unexposed and high exposure groups respectively (p for interaction unexposed vs. high exposure = 0.004). Higher ABCA1 CEC (per SD) was linked to 2.2 times higher adjusted likelihood of CAC progression in methotrexate nonusers but not in users (p for interaction = 0.018). Likewise, each SD increase in ABCA1 CEC associated with 2.7 times more new plaques in baseline bDMARD nonusers and 35% fewer new plaques in users (p for interaction ≤ 0.001).

**Conclusion:** ABCA1 CEC attenuated plaque progression exclusively in patients with low baseline and cumulative inflammation as well as with baseline methotrexate and bDMARD recipients. In contrast, ABCA1 CEC associated with plaque progression in baseline corticosteroid recipients and those receiving high time-weighted daily average prednisone dose during follow-up. In uncontrolled or inadequately treated disease ABCA1 CEC fails to counteract and may in fact contribute to the proatherogenic state promoted by inflammation and oxidation. The latter also occurs during treatment with prednisone, known to promote intracellular cholesterol accumulation. When RA is sufficiently treated and controlled, ABCA1 CEC effectively performs its atheroprotective function.

PREVALENCE OF CARDIOVASCULAR DISEASES AND TRADITIONAL CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A REAL-LIFE EVIDENCE FROM BIOSTAR NATIONWIDE REGISTRY

Keywords: Cardiovascular disease, Rheumatoid arthritis

Methods: Patients with rheumatoid arthritis (RA) have increased morbidity and mortality due to cardiovascular (CV) comorbidities. The association of CV diseases (CVD) and traditional CV risk factors have been debated, depending on patient and RA characteristics. The study aimed to find the prevalence of CVD and CV risk factors in patients with RA.

Results: We analyzed 124 RA patients with a mean age of 55.1 ± 12.8 years. There was a female preponderance (79.6%). The prevalence rate of CV was 4.6% (n=33). The frequencies of the diseases in the MACE category were ischemic heart disease in 27, congestive heart failure in 5, peripheral vascular disorders in 3, and cerebrovascular events in 3 patients. The patients with CVD (Group 1) were significantly male, older, and had higher BMI (p=0.027, p<0.001, and p=0.041). Obesity (33.4%) and hypertension (27.2%) were the two CV risk factors most frequently. Male sex (HR=0.085, 95% CI 0.028-0.257, p=0.001) and hypertension (HR=4.63, 95% CI 1.251-17.134, p=0.022) were independent risk factors for CVD.

Conclusion: The prevalence of CVD in RA patients was 4.6%. Some common risk factors for CVD in the general population, including male sex, older age, and hypertension, were evident in RA patients. The independent risk factors for developing CVD in patients with RA are male sex, older age, and hypertension.

THE REAL IMPACT OF DEPRESSION AND ANXIETY ON RHEUMATOID ARTHRITIS PATIENTS: A COHORT STUDY

Keywords: Patient reported outcomes, Quality of care, Health services research

Methods: A retrospective analysis including patients diagnosed with RA, according to the 2010 ACR/EULAR criteria, who started their first patient reported outcomes, Quality of care, Health services research with either depression or anxiety. The proportion of patients achieving disease activity and worse disease outcomes, depression and anxiety are not widely considered in routine care of arthritis patients.

Results: A total of 357 patients with RA were included. Eighty-two per cent were females (82%). The mean age was 54 ± 11.01 years and the median disease duration was 10 years [min 0.5, max 45]. Rheumatoid Factor (RF) was positive in 75% of patients and Antibodies to Citrullinated Peptides (anti-CCP) in 82%. The prevalence of depression and anxiety were 34.7% and 23.5%, respectively. Both groups (RA depressed/anxiety) had statistically significant differences concerning gender. Patients with RA and depression/anxiety were significantly more likely to be women and had a lower disease duration. Depressed patients showed a younger RA onset. Unemployed patients were more likely to be depressed. Other factors such as education, smoking or alcohol consumption were not significantly associated. Baseline depression/anxiety was associated with increased patient's global assessment and number of painful joints but not with levels of acute phase reactants. Treatment with conventional synthetic DMARD and/or glucocorticoids did not have any significant association with either depression or anxiety. The proportion of patients achieving disease

### AB0298

**SAFETY OF THE JAK INHIBITORS IN COMPARISON WITH THE TNF INHIBITORS IN RHEUMATOID ARTHRITIS: REAL WORLD DATA FROM THE HONG KONG BIOLOGICS REGISTRY**

**Keywords:** Targeted synthetic drugs, bDMARD, Rheumatoid arthritis

**C. C. Mok**, H. So°, C. Ho°, 1Queen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR); 2Prince of Wales Hospital, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR); 3Queen Mary Hospital, Medicine, Hong Kong, Hong Kong (SAR)

**Background:** The recent Oral Surveillance study has raised concerns about major cardiovascular events and malignancies related to tofacitinib in older rheumatoid arthritis (RA) patients with cardiovascular risk factors.

**Objectives:** To compare the incidence of major adverse cardiovascular events (MACEs) and cancer and infective complications in RA patients using the JAK (JAKis) and TNF inhibitors (TNFis).

**Conclusion:** The recent Oral Surveillance study has raised concerns about major cardiovascular events and malignancies related to tofacitinib in older rheumatoid arthritis (RA) patients with cardiovascular risk factors.

**Disclosure of Interests:** None declared.
Methods: A retrospective analyses of data retrieved from the Hong Kong Biologies Registry from 2008 to 2021 were performed. Patients with RA (fulfilling the EULAR/ACR criteria) who had ever been treated with the JAK or TNF inhibitors were included. Withdrawal rates due to inefficacy or serious adverse events (SAEs) were compared between the two groups, along with the incidence of MACEs, cancer, infective complications and all-cause mortality. The hazard ratios (HRs) of these outcomes were calculated for the JAKis with reference to the TNFis and adjusted for confounding factors in regression models.

Results: A total of 2471 courses of JAKis (n=551) and TNFis (n=1920) were used in 1732 RA patients (83.7% women, age 53.8±12.5 years; follow-up 6431 patient-years). The most frequent JAKi and TNFi prescribed were tofacitinib (81%) and etanercept (37%). Users of the JAKis, compared to the TNFis, had significantly longer RA duration, older age and were more likely to have atherothrombotic risk factors (diabetes mellitus, hypertension, hyperlipidemia, previous coronary heart disease) and a past history of malignancy. The withdrawal rate of the JAKis was significantly lower than the TNFis due to clinical inefficacy or occurrence of SAEs (p<0.001 by survival analyses). A total of 15 and 40 MACES developed in the JAKi and TNFi group of patients, respectively (incidence 1.34 vs 0.75 per 100 patient-years; p=0.22, adjusted for age, sex and follow-up duration). Moreover, there was no significant difference in the incidence of new cancers between the two groups (0.81 [JAKi] vs 0.85 [TNFi] per 100 patient-years; p=0.25). The adjusted HRs of MACE and cancer in the JAKi users were 1.36[0.62-2.96] (p=0.44) and 0.87[0.39-1.95] (p=0.74), respectively. Rates of infections were significantly higher in the JAKi than TNFi users (16.3 vs 9.9 per 100 patient-years; p=0.02), particularly herpes zoster (3.49 vs 0.94 per 100 patient-years; p<0.001) reactivation. The incidence of tuberculosis infection was similar between the two groups (0.45 [JAKi] vs 0.60 [TNFi]; p=0.21). All-cause mortality occurred in 8 patients in the JAKi group and 25 in the TNFi group and the difference was not statistically significant (0.72 vs 0.47 per 100 patient-years; p=0.54).

Conclusion: In a real-life setting, the JAKis have a better retention rate than the TNFis in patients with RA. There is no increase in the incidence of MACES, cancers and all-cause mortality observed with the JAKis in comparison to the TNFis, adjusted for age, sex and other confounding factors. However, infective complications, particularly herpes zoster, are more common in the JAKi users.

AB0299
THE RISK OF ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS IS COMPARABLE TO THE GENERAL POPULATION IN THE TREAT-TO-TARGET ERA

Keywords: To treat to target, Rheumatoid arthritis, Comorbidities

W. Bian1, Y. Hao1, H. Huang1, W. Xie1, Y. Wang1, X. Deng1, Y. Geng1, L. Ji1, X. Zhang1, J. Zhao1, Z. Zhang1. Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Patients with rheumatoid arthritis (RA) suffer from an increased cardiovascular disease (CVD) risk compared with the general population. This is due to the fact that systemic inflammation not only accelerates the progress of RA but also promotes the development of atherosclerotic plaque.[1] Intima-media thickness of the carotid artery (cIMT) is considered as a reliable marker of the presence and the burden of atherosclerosis.[2] Since the treat-to-target (T2T) strategy was first introduced into RA management in 2010, it has been widely proved that patients treated with an underlying T2T strategy could obtain clinical remission more rapidly and achieve higher clinical remission rate.[3] However, what’s the effect of a better controlled disease on the development of atherosclerosis?

Objectives: To compare the prevalence and incidence of carotid atherosclerosis monitored by ultrasound between patients with RA treated guided by a T2T strategy and gender-matched controls, as well as identify risk factors of atherosclerosis aggravation among RA patients.

Methods: We used data from a longitudinal prospective cohort of RA patients and a community-based atherosclerosis cohort in the general population. Age and gender-matched participants were picked up by propensity score matching to be compared in their clinical characteristics and the process of atherosclerosis. And then a comparison was made according to the traditional CVD risk factors and RA-related factors between RA patients with carotid atherosclerosis progress (CAP) and without. A Cox proportional hazards regression model was operated to find out the risk factors of carotid atherosclerosis progress in the patients with RA.

Results: A total of 182 patients with RA were included. After a median 28 months of follow-up, 91.76% of patients reached remission or low disease activity target. The mean (or median) cIMT in RA patients was increased significantly after the follow-up, and 39 participants were recognized as CAP. Age at entry (HR 1.095, 95% CI 1.043, 1.149, P<0.001) and time adjusted body mass index (HR 1.127, 95% CI 1.011, 1.257, P=0.030) were identified by the multivariate Cox regression model as the independent risk factor of carotid atherosclerosis progress for this group of RA patients. The prevalence of carotid atherosclerosis between 80 RA patients and 400 age, gender-matched controls, was compared, and no significant difference was found, no matter at the baseline (52.50% vs 49.67%, P=0.652)[Figure 1A] or the endpoint of the follow-up (53.75% vs 54.75%, P=0.870)[Figure 1B]. The incidence of carotid atherosclerosis during the follow-up between 50 RA patients and 50 age, gender, and BMI- matched controls was also comparable[28.00% vs 28.00%, P=1.0][Figure 1C].

Conclusion: Compared with the general population, the patients with RA treated adhering to a T2T strategy presented with a similar incidence and prevalence of atherosclerosis. Among disease well-controlled RA patients, RA-related factors have little impact on the carotid atherosclerosis progress.

REFERENCES:
Objectives: In this paper, bidirectional two-sample Mendelian method was used to focus on the genetic factors related to ILD and RA, and to explore the causal relationship between ILD and RA in the pathogenesis.

Methods: A two-sample bi-directional Mendelian randomization (MR) approach was conducted to investigate the causal relationships between RA and ILD. Summarized statistics for RA (14,361 RA cases and 43,923 healthy controls (HCs)) and I LD (1,969 cases and 196,986 HCs) were obtained from an available meta-analysis of published genome-wide association studies (GWAS). Relevant single nucleotide polymorphisms (SNPs) were selected by executing quality control steps (p < 1.0 × 10^-5) from the GWAS summary results. MR analyses progressed mainly using inverse variance weighted (IVW), weighted median (WM), and MR-Egger regression methods. For assessing the robustness of the results, we also carried out sensitivity analysis to assess heterogeneity and pleiotropy, such as MR-Egger, leave-one-out and MR pleiotropy residual sum and outlier (MR-PRESSO).

Results: Our study discovered a bidirectional causal effect between RA and I LD. The presence of I LD may increase the risk of RA by 12.8% (OR: 1.128, 95%CI: 1.03-1.256, P = 0.029). Similarly, the existence of RA may increase the risk of I LD by 9.4%. In addition, reverse MR analysis found that RA also influenced the risk of I LD significantly (OR: 1.094, 95%CI: 1.023-1.171, P = 0.009). Sensitivity analysis showed no pleiotropy but have heterogeneity (Q = 0.030) in reverse MR analysis.

Conclusion: MR analysis supported a potential causal relationship between RA and I LD. In RA and I LD, no matter which disease the patient has, it will greatly increase the risk of another disease. This study increases the emphasis on therapeutic or defensive interventions for patients with RA or I LD in the future to reduce severe complication and mortality.

REFERENCES:

Fig. 1(A) The scatter plots for MR analyses the causal effect between I LD and RA using the conventional IVW, MR-Egger, and Weighted median. (B) Funnel plot of inverse variance weighted, MR-Egger's multi- ple validity test for IVW, with the vertical line in the middle indicating the sum of different effect sizes. (C) Results of the leave-one-out-one in MR heteroscedasticity analysis. It was performed by removing one SNP at a time to explore whether any single SNP drove causal association. After each SNP was removed, the IVW method was conducted to estimate the effect of the remaining SNPs on the outcome, thus evaluating the stability of effect sizes. (D) Forest plot of MR results by IVW, MR Egger and Weighted median.

Background: The recent EULAR recommendations [1,2] suggest using JAK-inhibitors (JAKis) for treating RA patients. These drugs include both selective (upadacitinib and filgotinib) and unselective (tofasitnib and baricitinib) JAKis.

Objectives: To describe JAKis’ discontinuation rate and to determine predictors of JAKis’ discontinuation in a real life setting.

Methods: All patients with RA treated with JAKis were prospectively followed up for at least 12 months in this multicentric study carried out on 23 Italian centres. For each patient, the following variables were collected: sex, age, disease duration, smoking, BMI, comorbidities (diabetes, hypertension, hypercholesterolemia, cancer, major cardiovascular events), positive RF/ACPA, cDMARDs at baseline, prednisone at baseline, previous use of JAKis, discontinuation, time to discontinuation, JAKis line of treatment, DAS28-ESR at baseline, 6 and 12 months. Statistical analyses were performed using R (2022.12.0).

Results: 864 patients were included (Table 1). 487 (55.2%) received baricitinib, 213 (24.6%) tofasitnib, 111 (12.8%) upadacitinib and 62 (7.2%) filgotinib. 192 (22.2%) patients discontinued JAKis after a median time of 334 days (IQR 154.5-879.5). Among them, a statistical difference was found between selective-JAKis and other JAKis (p=0.03, 14.6% of selective JAKis vs 85.4% of other JAKis); finally unselective JAKis were discontinued later than selective JAKis (p<0.001, median 401.5 days, IQR 197.5-976 for unselective JAKis vs median 74 days, IQR 129-212 for selective JAKis). Discontinuation’s causes are reported in Figure 1. Notably, VZV infection determined JAKis withdrawal in 4 patients and pulmonary embolism/deep venous thrombosis in 6 patients (both with baricitinib). Regarding discontinuations’ causes, no differences between selective JAKis and other JAKis were found with factor logistic regression model. At multivariate analysis, predictors of discontinuation were prednisone at baseline (OR 1.48, p=0.03), treatment with unselective JAKis (OR 1.79, p=0.01), and line of treatment (OR 1.29 p<0.001).

Conclusion: Our study showed that only a minority of patients discontinued JAKis. Among discontinuation’s causes, no differences between selective JAKis and other JAKis were found. Predictors of JAKis discontinuation were prednisone at baseline, treatment with unselective JAKis and line of treatment (with more advanced lines of treatment associated with a higher risk of discontinuation).

Legends to Table 1: RA: rheumatoid arthritis; SD: standard deviation; BMI: Body Mass Index; RF: Rheumatoid Factor; ACPA: Autoantibodies against citrullinated peptides/proteins; MACE: Major cardiovascular events; PND: prednisone; IQR: interquartile range; DAS28-ESR: Disease Activity Score-28 for Rheumatoid Arthritis with ESR; cDMARDs: conventional Disease-modifying antirheumatic agents; JAKis: JAK inhibitors.
Disclosure of Interests: None declared.

RESULTS: The severity of fatigue in rheumatoid arthritis (RA) has hardly improved in recent decades, leaving a large unmet need. Fortunately, not all RA-patients suffer from persistent fatigue, but the subgroup of patients who suffer the most is insufficiently recognizable at diagnosis. As disease activity is partly coupled to fatigue, Disease-Activity-Score (DAS)-components may associate with the course of fatigue.

Objectives: We aimed to identify the RA-patients who remain fatigued by studying DAS-components at diagnosis in relation to the course of fatigue over a 5-year follow-up period in two independent early RA-cohorts.

Methods: 1560 consecutive RA-patients included in the Leiden Early-Arthritis Cohort and 415 RA-patients included in the iREACH-Cohort were studied. Swollen Joint Count (SJC), Tender Joint Count (TJC), Erytrocyte Sedimentation Rate (ESR) and Patient Global Assessment (PGA) were studied in relation to fatigue (VAS, 0-100mm) during 5-years using linear mixed models.

Results: Higher TJC and PGA at diagnosis were associated with a more severe course of fatigue. The SJC, in contrast, showed an inverse association; patients with mono- or oligo-arthritis at diagnosis remained more fatigued. The combination of aforementioned characteristics revealed that patients presenting with a mono- or oligo-arthritis and PGA≥50 remained the most fatigued over time (+20mm versus polyarthritis with PGA<50), whilst the DAS-course over time was not different. This subgroup comprised 14% of the early RA-population. Data from the iREACH-cohort showed similar findings.

Conclusion: RA-patients who remain the most fatigued are characterized by mono- or oligo-arthritis and high PGA (VAS≥50) at diagnosis. This understanding may enable early-intervention with non-pharmacological approaches in dedicated patient groups.

ASSESSMENT OF SEXUAL DISORDERS IN TUNISIAN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Quality of life

J. Mahbouba1, M. Arshadou2, M. Ghai3, S. Zour1, I. Beija1, M. Touzi1, N. Bergou1, Fatoum Bourguiba Hospital, Rheumatology, Monastir, Tunisia

Background: Sexual dysfunction is common in patients with rheumatoid arthritis (RA), but is often under-estimated.

Objectives: The aim of this study was to assess the sexual function and to identify the associated factors of sexual disorders in Tunisian RA patients.

Methods: This is a cross-sectional study conducted in the Rheumatology department of Monastir in Tunisia including patients followed for RA. Functional impact was assessed by the Health Assessment Questionnaire (HAQ) and Rheumatoid Arthritis Quality of Life (RAQoL). Disease activity was evaluated using the DAS28 score. Sexual function was assessed for women by a self-assessment questionnaire: the Female Sexual Function Index (FSFI) including several parameters: desire, arousal, lubrication, orgasm, satisfaction and pain. For men, it was evaluated by the Sexual Health Inventory (SHIM) assessing erectile dysfunction.

Results: One hundred patients were included. There were 85 women and 15 men. The mean age was 55.88 ± 10.5 years. Sixty out of 85 women were sexually active. Thirty-five women (58.3%) had sexual dysfunction (FSFI ≤ 26.55). Lack of arousal and loss of desire were the most reported disorders with mean scores of 2.33 and 2.58 respectively. Among the 15 men, nine were sexually active. Only one had normal sexual activity. Erectile dysfunction was the most common disorder with a mean score of 11. After statistical analysis, significant association was found between sexual dysfunction assessed by FSFI and SHIM total scores and increased age (p=0.01 and p=0.005, respectively). More intense pain (visual analog scale) was significantly associated with sexual disability in women and men (p=0.01 and p=0.05, respectively). A significant correlation was found between lower FSFI score and higher disease activity by the DAS28 (p=0.001).

Concerning the relationship with RA functional impact: we noted that among women, the alteration of arousal and satisfaction domains of the FSFI were correlated with higher HAQ (p=0.05 and p=0.004, respectively). In men, there was a significant association of lower SHIM score with HAQ and RAQoL (p=0.015 and p=0.001, respectively).

However, there was no significant association between sexual dysfunction and the duration of RA progression, biological inflammatory syndrome, joint deformities, sturtural damage or the used treatments.

Conclusion: Our study showed that sexual dysfunction is frequent in women and men with RA, and that these disorders can affect their quality of life. Therefore, the sexual life of RA patients should be considered as one of the important therapeutic targets in the global management of this disease.

HOW DOES PSYCHOLOGICAL TRAUMA AFFECT THE COURSE OF RHEUMATOID ARTHRITIS?

**Keywords:** Rheumatoid arthritis

A. Nurmamedov1, S. Lezhenva2, N. Shuvalova3, E. Guryanova2, 1Mary Central Clinic, Department rheumatology, Mary; Turkmenistan; 2Chuvash State University by I. N. Ulianova; Departament of Healthcare Management and Economics, Cheboksary, Russian Federation; 3Kh. Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation

**Background:** Psychological trauma is a short-term or long-term stressful event associated with a sense of extreme threat or catastrophe. Psychological trauma predisposes to the development of a systemic inflammatory process. Dysregulation of the immune response occurs, which leads to an increase in the rate of aging of immune cells and changes in gene expression in immune cells, contributing to the development of autoimmune immunity [1]. The effect of psychic trauma on the decrease in IL-6 promoter methylation in patients with rheumatoid arthritis was revealed [2].

**Objectives:** The purpose of the study: to evaluate the impact of psychological mental trauma on the course of rheumatoid arthritis.

**Methods:** The study was conducted from September 2021 to September 2022. 80 patients with RA of varying severity were examined. Inclusion criterion was a European Antirheumatic League diagnosis of RA (EULAR/ACR 2010). The age of the patients ranged from 20 to 69 years. (Mean age of patients was 48 +/- 6.24). Most of the examined women - 85%. The study was carried out in two stages. The first stage is (screening). All patients admitted to the hospital were divided into the level of situational and personal anxiety according to the Spielberger questionnaire modified by Yu.L. Khanina. The results obtained were interpreted: up to 30 points - a low level of anxiety, 31-45 points corresponded to the average level, over 45 points - a high level of anxiety. At the second stage (39 patients with medium and high levels of situational and/or personal anxiety), a survey was conducted, consisting of two blocks. The first block revealed the psychotraumatic factor by groups. 1. Shock injuries (a situation that threatens a person's life, various types of violence). 2. Injuries of loss (loss of a loved one, job, property). 3. Relationship trauma (betrayal, family relationship discomfort). 4. Others. The second set of questions assessed the relationship between the course of RA and psychic trauma, especially the onset of the disease. Statistical processing of the results was carried out in MS Office Excel programs.

**Results:** Almost half of 39 (48.7%) patients entered the second stage of the study, i.e., they had an average or high level of situational and/or personal anxiety. Shock injury was observed in 3 (3.75%) patients, loss trauma in 5 (6.72%) patients, relationship trauma in 29 (36.25%) patients, other causes indicated in 2 (2.5%) patients. Acute trauma was detected in 5 (6.25%) patients, chronic trauma in 32 (40%) patients, 2 (2.5%) patients found it difficult to answer. In the analysis of the second block of questions of the questionnaire, 31 (38.75%) patients note the relationship between PT and worsening of the course of RA. Deterioration in the form of increased pain syndrome was noted by 37 (46.25%) patients, an increase in edema of the affected joints was noted by 30 (37.5%) patients, a decrease in mobility in the joints was noted by 26 (32.5%) patients. Most of the 36 patients note that about 2 months passed from the moment of PT to the worsening of the course of RA. In 2.5% of patients, the onset of RA disease with a history of acute PT was observed.

**Conclusion:** Psychological trauma worsens the course of RA. This deterioration manifests itself in the form of an increase in pain, an increase in swelling of the affected joints, and a decrease in joint mobility. In the treatment of patients with RA, it is necessary to use a multidisciplinary approach involving psychologists and psychotherapists in order to timely identify and treat psychological trauma.

JAK INHIBITORS DO NOT WORSEN RA-ILD: COMPARISON OF CHANGES IN CT IMAGES AND KL-6/SP-D LEVELS BETWEEN PERIODS WITH BIOLOGICS AND WITH JAK INHIBITORS IN THE SAME INDIVIDUALS

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, Lungs

A. Tanaka1, R. Koike1, R. Sato1, A. Kikuchi1, S. Komatsu1, A. Hasegawa1, T. Hiyama1, E. Fukasawa1, M. Miyao1, S. Arai1, T. Owada1, R. Maezawa1, M. Arima1, K. Kurasawa1, T. Hiyama1, E. Fukasawa1, M. Miyao1, S. Arai1, T. Owada1, R. Maezawa1, M. Arima1, K. Kurasawa1

Background: Interstitial lung disease (ILD) is a serious organ involvement that influences the prognosis of RA patients and limits RA therapy. The association between RA activity and ILD progression has been suggested. However, the effects of biologics (Bio) on ILD are controversial; several studies showed that Bio increased ILD-related death, whereas others reported that Bio stabilized the progression of ILD.

Objectives: To clarify the effects of Jaki on RA-ILD by comparing the changes in CT images and KL-6/SP-D levels between periods with biologics and with JAK inhibitors in the same individuals.

Methods: Participants were consecutive RA patients who received Jaki from June 2014 to April 2022. Among them, patients who received Bio prior to Jaki therapy underwent analysis of changes in CT images and serum KL-6/SP-D levels in the same individuals. Change in CT images of pulmonary abnormalities, such as reticular pattern, was assessed by CT score: the extent of lesions of 6 lung fields was scored as follows: score 0 (absent), 1 (-25 %), 2 (25–50 %), and 3 (50%-). The CT scan score for each patient was obtained by adding the score for each field (max 18).

Results: Patients included in the analysis were 79 RA patients, M/F; 34/45. When they started Bio, their mean age was 59.3 years old, disease duration was 17.7 years, positive for anti-CCP antibody in 82.9%, and positive for RF in 83.5%. They received 1.5T MRI machine was used to scan the thorax in accordance with the EWGSOP2 criteria. A 1.5T MRI machine was used to scan the thorax in accordance with the EWGSOP2 criteria. The mean MRI-CSA-25 was 151.00 cm² for patient with sarcopenia, 275.57 cm² for sarcopenic patients was identified at 182 cm² (AUC-ROC = 0.894).

Conclusion: The frequencies and severities of worsening in the CT imaging, particularly reticular opacities, were less in patients with JAKi than in Bio. JAKi did not worsen ILD but rather may stabilize it.

Figure 1. Illustrative magnetic resonance image of a segmented muscle region of the thigh at a 25 cm above the knee joint (MRI-CSI-25) of a 50-year-old female patient, acquired as a 2D FLASH gradient-echo. Group muscles are color-coded: rectus femoris (RF), vastus lateralis (VL), vastus intermedius (VI), and vastus medialis (VM), the four muscles composing the hamstrings muscles (HAMST) [biceps femoris short head (BFB), biceps femoris long head (BFL), semitendinosus (ST) and semimembranosus (SM)], and adductors (ADDC) [adductor longus, brevis, magnus, pectineus, sartorius and gracilis (GR)]. The delineations between adductors muscles were not so obvious at proximal part, all adductors' muscles were segmented together, except for the gracilis which was easily recognizable. Note the exclusion of non-muscular elements (blood vessels, nerves) in the manual segmentation.

AB0308 QUANTIFICATION OF SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS BY MEASURING THE CROSS-SECTIONAL AREA OF THE THIGH MUSCLES WITH MAGNETIC RESONANCE IMAGING

Keywords: Comorbidities, Imaging, Rheumatoid arthritis

F. Salaffi1, M. Carotti2, A. C. Poliseno2, L. Ceccarelli3, S. Farah1, M. Di Carlo1, A. Giovagnoni1, 1Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy, 2Università Politecnica delle Marche, Radiology Clinic, Ancona, Italy, 3IRCSS Ospedale Sant’Orsola-Malpighi, Radiology Clinic, Bologna, Italy

Background: Sarcopenia is a prevalent condition in patients suffering from rheumatoid arthritis (RA), estimated to affect 31% of them. Magnetic resonance imaging (MRI) allows the measurement of cross-sectional area of muscle and volume of a muscle and the visualization of its morphological features and their distribution. Quality deterioration of the muscle, characterised by the presence of adipose tissue (defined as myosteatosis) and of fibrous connective tissue (defined as myofibrosis), is best diagnosed with MRI.

Objectives: To determine the utility of CSA measurements on MRI, at the level of the thigh muscles, to estimate muscle mass in discriminating RA patients with sarcopenia from those without.

Methods: Consecutive female RA patients were enrolled for this cross-sectional study. Patients were assessed for disease activity, radiological damage, handgrip strength, physical performance and for the presence of sarcopenia, identified in accordance with the EWGSOP2 criteria. A 1.5T MRI machine was used to scan the high muscles. A dimensional region growth algorithm (Horos112) showed to be semi-automatically segment the muscles cross-sectional areas (CSAs, in cm2) on MRI images located 25 cm above the knee joint (MRI-CSI-25) (Figure 1). The MRI-CSI-25 was obtained by summing the areas of the individual muscles. MRI-CSI-25 was correlated (Pearson's r) with the other variables, and its optimal cut-off point (Youden index) for sarcopenia diagnosis was identified in relation to the EWGSOP2 criteria.

Results: 32 RA female patients were studied, 34.4% diagnosed as sarcopenic. The mean MRI-CSI-25 was 151.00 cm² for patient with sarcopenia, 275.57 cm² for patient without sarcopenia (p <0.001). MRI-CSI-25 correlated significantly with measures of physical performance, and disease activity, but not with radiological damage or age. The MRI-CSI-25 optimal cut-off point in discriminating sarcopenic patients was identified at 182 cm² (AUC-ROCR = 0.894).

Conclusion: MRI-CSI-25 can differentiate sarcopenic versus non-sarcopenic RA patients, representing an imaging biomarker of this condition.

Figure 1. Illustrative magnetic resonance image of a segmented muscle region of the thigh at a 25 cm above the knee joint (MRI-CSI-25) of a 50-year-old female patient, acquired as a 2D FLASH gradient-echo. Group muscles are color-coded: rectus femoris (RF), vastus lateralis (VL), vastus intermedius (VI), and vastus medialis (VM), the four muscles composing the hamstrings muscles (HAMST) [biceps femoris short head (BFB), biceps femoris long head (BFL), semitendinosus (ST) and semimembranosus (SM)], and adductors (ADDC) [adductor longus, brevis, magnus, pectineus, sartorius and gracilis (GR)]. The delineations between adductors muscles were not so obvious at proximal part, all adductors’ muscles were segmented together, except for the gracilis which was easily recognizable. Note the exclusion of non-muscular elements (blood vessels, nerves) in the manual segmentation.
Methods: This was a prospective observational cohort, single-center study. Data were analyzed from 52 RA-UIP patients. Twenty-four were treated with TOF (5 mg twice daily) plus IGU. Twenty-eight were treated with Methotrexate (MTX)/Leflunomide (LEF) plus conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs). A clinically relevant response was defined as a decrease in disease activity score 28-joint count CRP (DAS28-CRP) score and high-resolution computed tomography (HRCT) scores from baseline. Deterioration and regression were respectively defined by an increase or decrease of at least 10% of the overall disease extent according to HRCT, whereas changes of less than 10% defined stability. Clinical indicators were compared between the two groups to evaluate the efficacy.

Results: A total of 24 RA-UIP patients treated with TOF plus IGU and 28 treated with MTX/LEF plus csDMARDs were enrolled and followed up for 6 months. The DAS28-CRP of the TOF plus IGU group was significantly lower than that of the MTX/LEF plus csDMARD group at 6 months. The FVC% was significantly improved after 6 months of treatment; the change from baseline was more significant than the MTX/LEF plus csDMARD group (1.36±2.42, P=0.038) vs. 1.89±2.33, P=0.031). TOF plus IGU group had a significantly higher HRCT fibrosis scores improvement (-0.17±2.52) than the MTX/LEF plus csDMARD group (1.36±2.24, P=0.031). TOF plus IGU group had a significantly higher response rate than the MTX/LEF plus csDMARD group, 4.6±1.9, 6.4±3.0 vs. 4.6±2.3, P=0.038 respectively.

Conclusion: Our results indicated that TOF plus IGU could simultaneously relieve RA and RA-UIP, and be better than the MTX/LEF plus csDMARDs with a higher response rate in RA-UIP, which may be potential for dual treat-to-target.

by a trained specialist, to evaluate subclinical atherosclerosis. Subclinical atherosclerosis was defined as carotid intima-media thickness (CIMT) >0.9mm and/or presence of carotid plaques. The 2008 Framingham score, QRisk III and mod- ified mSCORE were used for CV risk stratification. Quantitative variables were presented as means and qualitative as frequencies. Chi square test was performed for comparisons between dichotomous variables and T Student for con- tinuous, and p ≤ 0.05 for statistical significance. Kappa coefficient was performed between scales, interpreted as: ≤ 0 as no agreement and 0.01–0.20 as none to slight, 0.21–0.4 as fair, 0.41–0.60 as moderate, 0.61–0.80 as substantial, and 0.81–1.00 as almost perfect agreement. All patients signed informed consent.

Results: 100 were included, 87% were women, with a mean age of 51±13.3 years and mean disease duration 130.9±102.64 month. 9 (9%), 13 (13%) and 5 (5%) were classified as high risk according to the QRiskIII, Framingham 2008 and ScoreM scales respectively. 27.14% of patients had subclinical atherosclerosis, exceeding by 14% the high-risk patients according to the Framingham classification, while mSCORE and QRiskII underestimated cardiovascular risk in 22 and 18 individuals, respectively. The kappa coefficient for agreement of high-risk patients according to QRiskIII was 0.593 (moderate concordance) relative to Framingham 2008 while ScoreM had a Kappa coefficient of 0.401 (fair concordance) relative to Framingham 2008.

Conclusion: In contrast to the estimation scales frequently used in clinical prac- tice, which have a tendency to underestimate the risk in patients with rheumatoid arthritis, these results show that the cardiovascular risk demonstrated through ultrasonography of the carotid vessels more effectively characterizes high-risk patients.

ANALYSIS OF THE MALIGNANCY-RELATED SAFETY OF ABATAcept FOR RHEUMATOID ARTHRITIS IN CLINICAL PRACTICE

Keywords: Malignancy, bDMARD, Rheumatoid arthritis

Y. Kunishita1, K. Harita1, C. Honda1, Y. Lizawa1, M. Mitsuhashi1, S. Ohta1, T. Igarashi1, S. Nagaoaka1,1Yokohama Minami Kyosai Hospital, Department of Rheumatology, Yokohama, Japan

Background: In 2019, a study based on post-marketing surveillance data in Japan reported that ABT was as effective and safe in elderly patients with rheumatoid arthritis (RA) as non-elderly[1]. However, there were inconsistent reports on the impact of ABT on malignancies which are more common in the elderly. We aimed to explore the risk of malignancy with the use of ABT in our clinical practice.

Methods: A total of 276 patients were included, of which 61 had previous malignancies when starting ABT. The age of starting ABT was significantly higher in the PM group (72.5 ± 10.6 vs. 68.5 ± 13.0, years-old, p = 0.025), and the rate of methotrexate use was significantly lower in the PM group (29.5 vs. 51.2%, p = 0.0028), although there were no significant differences in other patient backgrounds between the groups (Table 1). The disease activity improved significantly at three months after starting ABT in both groups, and DAS28-CRP remission was maintained after that. There was no significant difference in disease activity between the groups from starting ABT to 60 months after. There were no significant differences in the continuation rates for 1-year and 5-year of ABT between the groups (86.3 vs. 86.6%, and 70.5 vs. 65.7%, respectively, Figure 1). There were 14 cases of occurrence and recurrence or progression of malignancy during the observation period. The incidence of malignancy was 1324.6 per 100,000 person-years, and there were no differences in the risk of malignancy in a Japanese national survey of similar age. Despite the significantly older patient population in the PM group, the 5-years incidence rate of malignancy was no significant difference between the groups. Binomial logistic analysis was performed using factors such as age, disease duration, history of previous malignancy, concomitant disease and medications, and disease activity at starting ABT. However, no predictive risk factors were found to be associated with the development or relapse of malignancy during ABT use in this study.

Conclusion: In our clinical practice, ABT was effective and safe in both patients with and without previous malignancy.

ASSOCIATION BETWEEN DISEASE ACTIVITY AND CHANGES IN FIBROSIS-4 INDEX LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH METHOTREXATE FOR A SHORT PERIOD

Keywords: Rheumatoid arthritis, Descriptive Studies, Comorbidities

N. Namura1, K. Kamada2, T. Hagiwara2, K. Takahashi2, K. Matsui1
1Hyogo Medical University, Division of Allergology and Rheumatology, Department of Internal Medicine, Nishinomiya, Japan; 2Takarazuka City Hospital, Rheumatology, Takarazuka, Japan; 2Hyogo Medical University, Department of Medical Statistics, Nishinomiya, Japan

Background: Liver fibrosis and liver damage are major concerns associated with long-term side effects in patients with rheumatoid arthritis (RA) treated with methotrexate (MTX). Recently, fibrosis-4 index (FIB-4) has often been used as an indicator of liver fibrosis. However, most studies examining the association between MTX and liver fibrosis, including FIB-4, have involved patients with RA treated with MTX for an extended period. To the best of our knowledge, no study has reported associations between FIB-4 and disease activity in patients with RA after using MTX for a short period.

Objectives: We focused on FIB-4 as an indicator of liver fibrosis in patients with RA treated with MTX in phase I and aimed to evaluate the changes in FIB-4 level in these patients for a short period.

Methods: Patients diagnosed with RA at our hospital and who had not received MTX before diagnosis (using the 2010 ACR/EULAR criteria) were included. Patients with hepatitis virus infection, alcoholism, or severe obesity were excluded from the study. Patients unable to continue using MTX for more than 12 months and those who used a maximum dose of MTX of 10 mg/week or less during the observation period were excluded. Patients' clinical and functional data were recorded at baseline and at all subsequent visits (6 and 12 months). We used the Mann–Whitney U test to compare aspartate transaminase (AST), alanine aminotransferase (ALT), and FIB-4 levels between the baseline and each observation period. Multiple regression analysis was performed to examine the effect of the cumulative MTX dose on the changes in FIB-4 levels from baseline to 6 and 12 months, after adjusting for factors involved in RA.

Results: A total of 144 patients were examined. The median FIB-4 levels increased from baseline to 6 and 12 months (p < .001). Multiple regression analysis revealed that the cumulative MTX dose was a factor independently influencing the changes in FIB-4 levels. Therefore, to identify predictors other than the cumulative MTX dose for changes in FIB-4 levels, we performed multiple linear regression analysis, adjusting for sex, body mass index (BMI), CRP, MMP-3, mHAQ, RF, ACPA, DAS28ESR, and FIB-4 level at baseline, defining the changes in FIB-4 level from baseline as the dependent variable. The factors independently influencing the changes in FIB-4 level were DAS28ESR (β = 0.107) at 6 months and DAS28ESR (β = 0.066) at 12 months. DAS28ESR at baseline affected the changes in FIB-4 level from baseline to both observation periods. There was also a significant correlation between the change in FIB-4 from baseline to each period and the DAS28ESR (p < .001). Further, a mediation analysis was performed for the association between DAS28ESR and the changes in FIB-4 level, considering the cumulative MTX dose as a mediator. The results indicated that the cumulative MTX dose did not mediate the relationship between DAS28ESR at baseline and the changes in FIB-4 level at either observation period.

Conclusion: The cumulative MTX dose did not affect the changes in FIB-4 level over a short period. In contrast, disease activity in patients with RA before MTX administration showed an effect on the changes in FIB-4 level. Clinicians should be more careful regarding liver fibrosis after MTX administration when treating patients with higher disease activity before treatment.

UNDERSTANDING DISEASE PREDOMINANCE AND COMORBIDITY PROFILES AMONG SEROPOSITIVE AND SERONEGATIVE RHEUMATOID ARTHRITIS PATIENTS IN PUERTO RICO

Keywords: Rheumatoid arthritis, Comorbidities, Autoantibodies

F. Arenal-Cruz1, G. Jobson2, E. Villanueva2, J. Zhu3, 1Bristol Myers Squibb, Health Economics and Outcome Research, Guaynabo, Puerto Rico; 2Mu Sigma, Offshore delivery, Bangalore, India; 3Bristol Myers Squibb, Medical Affairs, Guaynabo, Puerto Rico; 1Bristol Myers Squibb, Center for Observational Research and Data Science, Princeton, United States of America

Background: Prevalence of rheumatoid factor (RF) and/or anti-cyclic citrullinated peptide antibody (ACPA) positivity in US patients with rheumatoid arthritis (RA) is around 70% [1]. Seropositive RA status, defined by positivity for RF and/ or ACPA, is associated with poor disease prognosis [2]. Little is known about the prevalence of RA, percentages of seropositive RA versus seronegative RA, and the comorbidity profile and infections of the seropositive and seronegative RA populations in Puerto Rico. Therefore, to identify predictors other than the cumulative MTX dose for changes in FIB-4 levels from baseline to 6 and 12 months (p < .001). OMAR INITIATION IN OLDER ADULTS WITH NEW DIAGNOSIS OF LATE-ONSET RHEUMATOID ARTHRITIS

Keywords: Real-world evidence, Rheumatoid arthritis, Disease-modifying Drugs (DMARDs)

J. Lee4, N. Singh5, R. Yang1, U. Makris1, J. Bynum1, 1University of Michigan Hospital, Internal Medicine, Ann Arbor, United States of America; 2University of Washington, Internal Medicine, Seattle, United States of America; 3University of Texas Southwestern Medical Center: Library, Internal Medicine, Dallas, United States of America; 4VAMC Dallas, Internal Medicine, Dallas, United States of America

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory arthritis, affecting millions of people worldwide. The prevalence of RA among Puerto Ricans was 1.03%. Of 141 patients with RA, 56.7% of them were seropositive. Within eligible seropositive (n=53) and seronegative (n=42) RA patients for the evaluation of comorbidities and infections, the mean (SD) of age were 50.75±12.93 and 49.36±11.22 years (d = 0.11), respectively. Most patients were females (79.25% for SP vs 71.43% for SN, d =0.18) and had commercial insurance (92.45% for SP vs 97.62% for SN, d =0.24). The mean (SD) of Charlson Comorbidity Index scores were 0.79±1.17 vs 0.64±1.01 (d=0.14) for seropositive and seronegative respectively. For both seropositive and seronegative cohorts, the most prevalent comorbidities were hyperlipidemia (37.74% vs 30.95%, d=0.14), hypertension (33.96% vs 66.67%, d=0.69) and Type II diabetes (24.33% vs 21.43%, d=0.07) respectively. The most frequent infections were those happening in the urinary tract (18.87% for SP vs 14.29% for SN, d=0.12). In the follow-up period, the crude IR/100-person year was 79.34 and 33.45 for hyperlipidemia; 42.74 and 32.46 for T2DM; 27.47 vs 29.46 for hypertension, and 19.93 vs 25.00 for urinary tract infection for seropositive and seronegative RA cohorts, respectively.

Conclusion: This study found that the prevalence of RA among Puerto Ricans was similar to that reported in US mainland, with most (56.7%) presenting seropositive RA. We also observed a substantial burden of comorbidities among both seropositive and seronegative RA patients. Future studies with a large sample size are warranted.

REFERENCES:
Background: The number of older adults living with rheumatoid arthritis (RA) is growing as the world population is aging. Older adults with RA are less likely to receive disease modifying anti-rheumatic drug (DMARD) due to these medications being effective and generally well tolerated in older adults. Up to one-third of the older RA population are diagnosed after the age of 65 and have late-onset RA (LORA). Older adults with LORA experience more symptomatic and progressive disease, and yet, their treatment in usual care is not well understood.

Objectives: To evaluate initiation of DMARDs in older adults with new diagnosis of LORA.

Methods: In this retrospective observational study, using 20% Medicare data from 2009-2017, we identified adults 66 years of age or older with new diagnosis of LORA without any DMARD use during the 12 months prior to cohort entry. Information on baseline patient characteristics and DMARD initiation during the first 12 months after LORA diagnosis were collected. We also assessed concomitant use of glucocorticoids (GCs) and opioids that are not disease modifying but can improve symptoms of RA.

Results: We identified 25,139 older adults with new diagnosis of LORA in continuous fee-for-service Medicare. Average age at LORA diagnosis was 76.9 (SD 7.6). 76.4% were female, 76.7% were non-Hispanic white, 37.2% had low-income subsidy, and 63.1% had three or more comorbid conditions. Less than one third were initiated on some form of DMARD (28.8%) during the first 12 months after LORA diagnosis. Among those on any DMARDs (N=7252), 87.7% were initiated on some form of DMARD (28.8%) during the first 12 months after LORA diagnosis were collected. We also assessed concomitant use of glucocorticoids (GCs) and opioids that are not disease modifying but can improve symptoms of RA.

Results: Among those on any DMARDs (N=7252), 87.7% were initiated on some form of DMARD (28.8%) during the first 12 months after LORA diagnosis were collected. We also assessed concomitant use of glucocorticoids (GCs) and opioids that are not disease modifying but can improve symptoms of RA.

Santiago de Compostela, Spain
Background: It has been shown that periodontal disease, together with the
presence of other germs, may play an important role in the development and
maintenance of rheumatoid arthritis (RA). In particular, Porphyromonas gingivalis (Pg), a large anaerobic gram-negative bacteria, produces the extracellular
proteases arginine-gingipain and petidyl-arginine deiminase, which contribute
to oral periodontal destruction but also promote peptide citrullination, inducing
the synthesis of anti-citrullinated peptide antibodies that have been linked to the
onset of rheumatoid disease, its severity and its perpetuation[1,2].
Objectives: The purpose of the present work is to characterize patients with RA
who are carriers of Pg in the oral cavity.
Methods: Oral flora has been analyzed by semiquantitative PCR for 5 germs
involved in periodontal disease, which includes Pg (Peiropoc-Genspeed biotect)
in 236 RA patients and 84 healthy controls, obtained from an outpatient clinic of
non-inflammatory conditions: 172 women and 63 men, mean age 57.69 years.
Correspondence analyses were performed with Pearson’s test for different nonparametric variables and Mann-Whitney test for continuous variables.
Results: Presence of Pg was detected in 80 patients with RA(34%) and in 28 controls (33.7%). The mean age of the carriers was slightly higher (62.04; p>0.05) and
the majority were women (72.5%). 22.5% of the smokers were carriers of Pg, while
10.8% were in the control group (p= 0.16). The mean activity, measured by DAS28
was 2.05 in carriers and 2.66 in non-carriers, with no significant differences (p=0.84).
The mean CRP in carriers was 0.47 and in the overall RA of 1.08 (p=0.61) and the
mean ESR was 13.37 in carriers and 16.83 in noncarriers (p=0.11). Anti-CCP were
found in 55% of Pg carriers and in 72% of noncarriers (p=0.009). The functional
capacity measured by HAQ was 0.245 in carriers vs 0.442 in non-carriers (p>0,05).
Interestingly, in all the cases where Pg was identified, other bacteria capable of causing periodontal disease were also detected, especially Tanerella forsythia.
Conclusion: The presence of Prophyromonas gingivalis is more frequent in
older and smoker patients with RA. Pg in the oral flora of patients with RA does
not seem to contribute to a greater severity of the disease, in terms of functional capacity or activity, as well as in its measurement parameters. It should be
noted that whenever Pg has been detected there is co-infection with other germs
involved in periodontal disease.

Barcelona, Biochemistry and Molecular Genetics, Barcelona, Spain
Background: Neutrophil extracellular traps (NETs) may play a pathogenic role
in rheumatoid arthritis (RA)[1]. Elevated circulating NETs have been found in
RA plasma, but their relationship with synovial inflammation and antirheumatic
therapy including biologics and JAK inhibitors (JAKi) is unclear.
Objectives: To evaluate whether plasma levels of NETs remnants in patients
with established RA are associated with disease activity or type of antirheumatic
therapy (biologics or JAKi).
Methods: Observational cross-sectional study. RA patients (ACR/EULAR 2010)
receiving treatment with IL6 inhibitors (IL6i), JAKi, or TNF inhibitors (antiTNF)
were consecutively included regardless of disease activity and previous therapy.
Controls were RA patients with high disease activity (≥ 4 swollen joints), regardless of treatment, as was a second control group of healthy blood donors. Clinical disease activity indexes (DAS28, SDAI, CDAI) and laboratory parameters
of inflammation, including high-sensitive CRP (hsCRP) and calprotectin were
evaluated. Plasma levels of elastase-DNA (EN-DNA) and histone-DNA complex
(H3-DNA) (NETs remnants) were examined by ELISA. We analysed NETs remnant levels and clinical variables using Spearman’s correlation test.
Results: 111 patients (90.1% female, 85.6% seropositive (RF and/or ACPA), mean
age 56.45 years and mean RA duration 15.9 years) were included: 83 received
biologics (53 IL6i and 30 antiTNF) and 28 JAKi (19 baricitinib and 9 tofacitinib).
Mean DAS28 and CDAI were 3.00 and 10.5, respectively. Controls were 18 active
RA patients (mean DAS28 5.72 and CDAI of 34.9), 11 without biological or JAKi
treatment [Table 1]. 30 healthy blood donors were also analysed. NETs levels of
patients under biologic or JAKi therapy showed no significant differences with
healthy controls. No significant differences were observed in NETs values according to the type of therapy. In the control group of patients with high disease activity,
plasma NETs were higher than in the main group (treated with JAKi or biologics),
but only with statistically significant in H3-DNA levels (EN-DNA 2.96 (sd 5.42) vs
1.25 (sd 1.03) p=0.03; H3-DNA 2.67 (sd 4.52) vs 1.36 (sd 1.15) p >0.05). The two
NETs were strongly correlated (ρ=0.97; p<0.001). A weak correlation between
NETs and clinical disease activity (DAS28, CDAI, SDAI) was found, but not with
laboratory parameters of inflammation including calprotectin.
Conclusion: NETs are elevated in active RA patients but weakly correlated
with clinical disease activity. Patients with established RA under biologic or JAKi

**DAS28 WITH THREE VARIABLES PERFORMANCE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT CONCOMITANT FIBROMYALGIA**

**Keywords:** Rheumatoid arthritis, Fibromyalgia

S. Miladi1, B. A. Hiba1, F. Ali1, S. Ben Yaouc1, H. Bousaa1, M. Yasmine1, K. Ouerfiniche1, K. Selma1, C. Selma1, K. Ben Abdelghani1, L. Ahmad1. 1Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia

**Background:** Several studies have shown that rheumatoid arthritis (RA) patients with concomitant fibromyalgia (FM) can cause an overestimation of the disease.

**Objectives:** The aim of this study was to evaluate the performance of the DAS28 V3 in a cohort of RA patients with and without concomitant FM.

**Methods:** Cross-sectional observational study that included consecutive patients with diagnosis of RA (ACR/EULAR 2010 criteria) with and without concomitant FM (ACR 2016). Demographic and RA characteristics were collected. All patients underwent a clinico-biological and an ultrasound (US) assessment of RA activity. US examination included the assessment of synovial/tenosynovial hypertrophy in grey scale and in Power Doppler (PD). P<0.5 was accepted for significance.

**Results:** Eighty patients distributed into 40 patients in each group were recruited. Epidemiological and RA characteristics were comparable between the two groups. Subjective activity parameters were higher in RA with FM group (p<0.05).

**Conclusions:** Our study confirms that DAS28 V3 score would represent a better alternative for the clinico-biological assessment of disease activity in RA patients with concomitant FM.

**HIGH PREVALENCE OF HYPOALBUMINEMIA IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Diet and Nutrition

P. W. Jia1, J. Pan1, Y. W. Zou1, H. W. Zheng1, J. D. MA1, Z. M. Ouyang1, Q. Zhang1, T. Wu1, Y. Lu1, L. Dai1. 1Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology and Immunology, Guangzhou, China

**Background:** Hypoalbuminemia is associated with worse medical conditions in chronic diseases and surgery outcomes. The concentration of serum albumin in patients with rheumatoid arthritis (RA) has been reported to decline. However, less is known about the prevalence and severity of hypoalbuminemia in RA patients and its association with RA disease.

**Objectives:** To investigate the association of hypoalbuminemia with RA disease characteristics and its potential mechanism in RA.

**Methods:** This cross-sectional study collected clinical data from a Chinese RA cohort, including disease activity, physical function, and radiographic assessment. Serum levels of albumin and inflammatory cytokines including soluble interleukin 2 receptor (sIL-2R), IL-6, TNF-α, IL-8, and IL-1β were detected. According to the level of serum albumin, RA patients were divided into four groups as normal albumin (≥ 35.0 g/L), mild hypoalbuminemia (30.0 - 34.9 g/L), moderate hypoalbuminemia (25.0 - 29.9 g/L) and severe hypoalbuminemia (< 25 g/L).

**Results:** Among 1510 RA patients recruited in the cohort, 880 RA patients were eligible for analysis. Their mean age was 53.5 years old and 77.2% were female. There were 879 patients with active RA (CDAI > 2.8). The prevalence of hypoalbuminemia was 48.2% (429/890) in all RA patients and 50.9% (398/782) in active RA. The prevalence of hypoalbuminemia increased with age, disease activity, but decreased with BMI (all P trend < 0.05, Figure 1). Compared with those with normal albumin, RA patients with hypoalbuminemia were older, had lower BMI, higher levels of ESR and CRP, higher disease activity, and higher HAQ-DI. RA patients with hypoalbuminemia had higher levels of serum inflammatory cytokines, including sIL-2R, IL-6, TNF-α and IL-10 than those without, regardless of the severity of hypoalbuminemia. Moreover, the level of albumin was negatively correlated with all six inflammatory cytokines (r range from -0.124 to -0.334, all P < 0.001). Multivariate ordinal logistic regression analysis showed that BMI (adjusted odd ratio (OR) = 0.889) and IL-10 (AOR = 0.971) were negatively, age, ESR, CRP, previous treatment with glucocorticoids, sIL-2R, IL-6, and IL-8 were positively associated with hypoalbuminemia in RA patients (AOR range from 1.001 to 1.671, all P < 0.05).

**Conclusion:** Our data show high prevalence of hypoalbuminemia in patients with active RA which is associated with high inflammation. These data imply the importance of the control of inflammation and nutrition supply. Further prospective study is needed in future.

Disclosure of Interests: None Declared.

**SACROILITIS AND ACPO POSITIVE: IS THIS AN ASSOCIATION OF RHEUMATOID ARTHRITIS AND SPONDYLOARTHITIS? ABOUT 16 CASES**

**Keywords:** Psoriatic arthritis, Spondyloarthropathy, Rheumatoid arthritis

H. Arabi1, H. Tebaa1, A. Mougui1, I. El Bouchn1. 1CENTRE HOSPITALIER-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Department of Rheumatology, Marrakech, Morocco, Rheumatology, Marrakesh, Morocco

**Background:** Rheumatoid arthritis (RA) and spondyloarthritis (SpA) in particular psoriatic arthritis (RP) are two distinct inflammatory rheumatisms having in common destructive peripheral involvement.

**Objectives:** We report a series of chronic inflammatory rheumatism with features of RA and SpA.

**Methods:** Descriptive retrospective study including patients with chronic inflammatory rheumatism, collected in the rheumatology department over a period of 10 years (2009-2019).

**Results:** 16 patients were included. The average age was 45.94 ± 12.10 years [28-71], with a female predominance of 87.5%. The mean age at onset of symptoms was 34.69 ± 12.71 years [14-52]. The disease duration was 11.25 ± 10.44 years. History was dominated by hypertension and smoking in 12.5%. A history of familial rheumatism and cutaneous psoriasis was found in only one patient. The revealing symptomatology was dominated by chronic polyarthritides in 75%, polyarthritis in 18.8%
and mono-arthritis in one case. Deformities were described in 43.8%. On the immunological assessment, the mean ACRA was 191.25 ± 155.68 [36-500]. Rheumatoid factor and Anti-nuclear antibodies were positive in 50% and 37.5% respectively. HLAB27 was done in 2 patients, 1 of whom was positive. Sjögren’s syndrome was present in 37.5% of patients. A biological inflammatory syndrome was found in the majority of patients with an average ESR and CRP of 37.38 and 20.41 respectively. Radiographic sacroilitis was noted in 56.3%, and the rest were non-radiographic. Synodesmophytes were noted in 3 patients (18.8%). Covi- tis was present in 12.6%. Structural damage in 61.3% made of erosions, geodes and pinching with reconstruction images in 4 patients. Patients were treated with corticosteroid therapy in 87.5%, methotrexate in 62.5%, sulfasalazine in 43.8%, and biotherapy in 25% of cases with anti-TNF alpha type.

**Conclusion:** These associations pose difficulties in diagnosis and management. A more in-depth study of these patients can help with an accurate diagnosis and therefore with optimal management.

**APPLICATION OF NOVEL REFERENCE VALUES FOR 24-HOUR PROFILE OF CENTRAL SYSTOLIC BLOOD PRESSURE IN RHEUMATOID ARTHRITIS: CORRESPONDENCE WITH PERIPHERAL BLOOD PRESSURE AND CLINICAL ASSOCIATIONS OF HYPERTENSIVE PHENOTYPES**

**Keywords:** Comorbidities, Heart, Cardiovascular disease

R. Rahmadzhanova,1, G. Farías,2, E. Troitskaya,3, R. Osipyants3, S. Vel'makina3, Z. Kobalava2,1, Osh State University, Internal Medicine, Osh, Kyrgyzstan;2Universidad Tecnica de Manabi, Internal Medicine, Manabi, Ecuador;3RUDN University, Internal Medicine, Moscow, Russian Federation

**Background:** Prognostic significance of 24-h profile of peripheral BP is well-known. The growing insights in the role of arterial stiffening in cardiovascular disease led to the viewpoint that vascular risk must be more closely associated with central than brachial BP. While the upper limits for clinic and ambulatory peripheral BP have been routinely used for a long time and the reference values for central clinical BP have been developed some years ago, the hypertensive threshold for 24-h central BP hasn’t been investigated until 2022.

**Objectives:** To apply novel reference values of 24-h central SBP (cSBP) in the patients with rheumatoid arthritis and to characterize the hypertensive profile.

**Methods:** The study group included 85 patients with RA (females 77.6%, age: 59.7±14.3 (Ma±SD) years, HTN 65%, median HTN duration 6.6 years, RA dura- tion – 7 years seropositive RA 65%, mean DAS-28(CRP) 3.7±1.1) and control group (40 patients matched by gender, age and risk factors). All patients with HTN received antihypertensive therapy. Office peripheral BP was measured with a validated oscillometric device, 24-hour ABPM was performed with BPlavassir, and arterial stiffness – by application tonometry. CV risk was calculated by mSCORE (EULAR recommended modified version). The upper limits for non- central SBP were 125 mmHg for daytime, 115 mmHg for nighttime and 120 mmHg for 24-h BP. P<0.05 was considered significant.1

**Results:** Mean central SBP in patients with RA was 123±21 mmHg (108±13 mmHg in normotensive and 132±20 in hypertensive patients, p<0.05). Hyperten- sive patients with RA vs controls were characterized by significantly higher frequency of elevation of daytime cSBP (44.1% vs 12.5%, p<0.01) and a trend to higher frequency of elevation of nighttime cSBP (58.8% vs 37.5%, p<0.09) and 24-h SBP (47.1% vs 25%, p<0.05). In normotensive RA patients compared to controls cSBP was elevated in 71% vs 0% for daytime, 14.3% vs 0% for nighttime and 71% vs 0% for 24H BP respectively (p<0.05 or the trend). All patients with normal peripheral ambulatory SBP (daytime, nighttime and 24-h) had normal central ambulatory SBP. 2 patients with elevated 24-h pSBP and 5 patients with elevated nighttime pSBP had normal cSBP while 2 patients with normal daytime pSBP had elevated cSBP. Patterns of diurnal index were similar for peripheral and central SBP (the discordance was observed only in 4 patients who were dippers by peripheral BP and non-dippers by central). Patients with RA and cen- tral 24-h BP elevation compared to patients with normal profile had higher ESR, longer RA duration, higher frequency of obesity, HTN, longer dura- tion of HTN, higher cPPWV, central pulse pressure, stiffness gradient (cPPWV, crPPWV, CAVI) and higher CV risk. There were significant correlations between central 24-H BP elevation and ESR, hypertension-related parameters (PPW, pulse pressure, stiffness gradient, CAVI) and SCORE index.

**Conclusion:** The first application of novel reference values of ambulatory cSBP in RA showed that cSBP elevation is highly prevalent and in hypertensive indi- viduals the frequency of daytime cSBP elevation is higher than in controls. Not only hypertension related parameters but also high ESR may be the markers of 24-h cSBP elevation.

**RELATIONSHIP BETWEEN PHYSICAL BALANCE ABILITY AND PHASE ANGLE OBTAINED BY BIOELECTRICAL IMPEDANCE ANALYSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

**Keywords:** Quality of life, Rheumatoid arthritis, Sarcopenia

M. Tada,1 Y. Matsumoto2, Y. Yamada3, K. Manda1, N. Hidaka1, T. Koike6

1Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan;2Osaka Metropolitan University Graduate School of Human Life and Ecology; Nutrition, Osaka, Japan;3Osaka Social Medical Center Hospital, Orthopaedic Surgery, Osaka, Japan;4Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan;5Koryokai Hospital, Orthopaedic Surgery, Osaka, Japan

**Background:** We have reported that a decrease in phase angle (PhA), an index of cell membrane fragility, nutritional status, and muscle strength, measured by bioelectrical impedance analysis (BIA), is associated with falls in patients with rheumatoid arthritis (RA) [1]. Since a decline in physical balance ability is thought to be related to falls, assessing physical balance ability is important, and in recent years, assessment of physical balance ability has been included in the diagnostic criteria for sarcopenia. The PhA reflects muscle status and may be related to physical balance ability, but the relationship between physical balance ability and the PhA in RA patients is unclear.

**Objectives:** To examine the relationship between physical balance ability and the PhA in RA patients.

**Methods:** A cross-sectional analysis of 89 RA patients (78% female, mean age: 66.7±14.3 years) was performed. The PhA was evaluated at 50kHz on a BIA device (MC-780A, TANITA, Japan). Assessment of physical balance ability was performed with a muscle function analyzer (SM-200, TANITA), which can assess physical balance ability based on changes in load during standing up from a chair. Of the indices obtained by the muscle function analyzer, lateral balance was evaluated by dividing the lateral direction change value (Vx vs Vw) by the load variation value (Vw kg vs Vw). The balance score, which is the score of the stability time (stable time) from the point after the maximum load value and Vx/Vw compared to the reference value, was also assessed. The associations of PhA with Vx/Vw being above the median and the z-score of Vx/Vw and of the balance score being above -0.5 were tested by logistic regression analysis, and the associ- ation between Vx/Vw and the PhA as continuous variables was tested by multiple regression analysis. The cutoff value of PhA for the balance score z-score of -0.5 was calculated by receiver-operating characteristic (ROC) curve analysis. Results: Even after adjusting for covariates (sex, age, BMI, ADL, disease activity, and medication status), the PhA was significantly associated with Vx/Vw greater than the median [odds ratio (OR): 0.44, 95% confidence interval (CI): 0.19-0.995] and z-score > -0.5 (OR: 0.42, 95% CI: 0.19-0.93). Multiple regression analysis adjusted for covariates also showed that the PhA was significantly associated with Vx/Vw (β =-0.22, p=0.023). A balance score z-score > -0.5 was significantly associ- ated with a PhA above the 75th percentile (OR: 0.42, 95%CI: 0.19-0.97). The cutoff value of the PhA for a balance score z-score of -0.5 was 4.87° (AUC = 0.64, p = 0.32) for men and 4.30° (AUC = 0.78, p < 0.001) for women.

**Conclusion:** The PhA may be related to physical balance ability.

**REFERENCE:**

**Disclosure of Interests:** None declared.
Methods: the occurrence of AEs related to MTX. RA treatment has advanced significantly disease-modifying antirheumatic drug. RA patients had adverse events (AEs) (C-OPERA study) [2]. Thus, RA patients on MTX should always be aware of complications and AEs.

Objectives: Since RA patients with frailty have more comorbidities than those with non-frailty, complications of RA or RA drugs are also expected to increase. The purpose of this study was to clarify whether frailty in RA patients influences the occurrence of AEs related to MTX.

Methods: Of 538 RA patients (an observational study, T-FLAG study) who visited us in 2020, 320 used MTX. After 2 years of follow-up, we investigated final follow-up date and AEs leading to MTX discontinuation. Frailty was defined as a score of 8 or more on the Kihon Checklist (KCL). Logistic regression analysis was performed to determine factors associated with MTX discontinuation due to AEs. MTX retention rates were calculated by Kaplan–Meier analysis, and crude retention rates were compared using the log-rank test.

Results: Of the 320 patients (249 females) in this study, 23 patients (7%) discontinued MTX due to AEs. AEs included liver disorder (26.1%), MTX pneumonia (21.7%), decreased renal function (13.0%). There were no patients with MTX discontinuation due to inefficacy. Mean age at baseline (standard deviation [SD]) was 62.8 (11.9)/64.5 (13.9) years (MTX discontinuation/ MTX continuation), MTX dose was 8.1 (2.8)/8.1 (2.9) mg, Clinical Disease Activity Index (CDAI) was 6.1 (6.1)/5.6 (7.3), KCL was 9.0 (5.0)/5.8 (4.0) point (p<0.05), and frailty (OR: 2.77, 95%CI: 1.16–6.61), adjusting for age and sex. The rate of MTX retention (at 1 year, and 2 years) was significantly lower in subjects with frailty (91.2%, and 86.6%) than in those with non-frailty (96.2%, and 95.1%) respectively. Comparing the patient characteristics at baseline in subjects with frailty and non-frailty, mean age, KCL, and the proportion of MTX discontinuation due to AEs were significantly higher in subjects with frailty.

Conclusion: Our finding suggest that frailty was the significant factor of MTX discontinuation due to AEs, and the rate of MTX retention was significantly lower in the subjects with frailty compared to non-frailty. Moreover, the subjects with frailty had significantly higher mean age and disease activity, suggesting that frailty comprehensively reflects a bad condition. Frailty is significantly associated with poor physical function, and poorer physical function is reportedly associated with a poorer response to treatment [3]. Poor physical function (physical frailty) may make patients more prone to MTX discontinuation due to AEs. These findings suggest that frailty is a comprehensive index with high predictive power for MTX discontinuation due to AEs. Therefore, the occurrence of MTX AEs should be carefully monitored when using MTX in RA patients with frailty.

AB0324 DEVELOPMENT OF A MOBILE APP TO SUPPORT SELF-MANAGEMENT IN INDIVIDUALS WITH INFLAMMATORY ARTHRITIS

Keywords: Self-management, Rheumatoid arthritis, Artificial Intelligence

Y. El Miedy1, B. M. Elnady2, S. Abd-Elmaksoud2, O. El Miedy3, D. Palmer4, N. Fouda5, M. H. Abu-Zaid6, W. Elwakil7, W. Hassani1, I. Aabda3, Canter bury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; 2Faculty of Medicine Benha University, Rheumatology and Rehabilitation, Banha, Egypt; 3Faculty of Medicine Benha University, Psychiatry, Banha, Egypt; 4University College London, Computer sciences, London, United Kingdom; 5North Middlesex University Hospital, Rheumatology, London, United Kingdom; 6Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; 7Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; 8Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt; 9Faculty Of Medicine Kasr Al-Ainy, Cairo University, General Medicine, Cairo, Egypt

Background: EULAR has recently highlighted the vital role of digital health in standard practice and the possibility to enhance the self-management abilities of the patients. Self-management strategies play an important role in improving clin- ical outcomes in patients with inflammatory arthritis. Smartphone technology has the potential to engage the patients with their treating health care professionals through suitable self-monitoring and easy access to information. In addition, having a more accurate summary of self-reported fluctuations in symptoms, psychosocial problems and behaviors can help both the patients and the treating health care professionals better understand the patient’s condition, identify barriers to self-man- agement, and assess treatment effectiveness and additional health care needs. However, evidence regarding these supporting digital tools, including smartphone apps, is currently very limited. So far there is no comprehensive mobile app developed to facilitate the collaboration between the patients and their treating physicians.

Objectives: 1.To provide basic data on system requirement specifications for a mobile app to self-manage inflammatory arthritis. 2. Identify the targets, characteristics of the app, and correlations between the system requirements and the established behavior change techniques.

Methods: A participatory action research design was adopted to inform the app developer of the major themes recognized as the main pillars for the app develop- ment, implementing artificial intelligence. Qualitative data were collected using multiple methods in several workshops. Participants were 2 Rheumatologists, 1 rheumatology nurse specialist, 1 rheumatoid arthritis patient, 1 psoriatic arthritis patient, 1 patient Ankylosing spondylitis, and an App/ machine learning engineer. A taxonomy was used to determine the degree of correlation between the system requirements and established behavior change techniques.

Results: The app targets the optimization of self-management and provide non-medical management approach. The major theme that emerged were: 1.collect self-reported patient reported outcomes (disease functional ability, quality of life, motivation), 2. Collect information on patient demographics, comorbidity(ies), disease activity status (self-reported disease activity score), past and current medications, 3. Identify the individual patient’s target to be achieved, 4. Develop a patient profile that focuses on the patient’s disease activity status, well-being, targets and attitude, 5. Using artificial intelligence, construction of a personal- ized, evidence-based disease self-management program based on recommen- dations from medical guidelines, municipal standards, and state-of-the-art clinical research; 6. implementation of personalized recommendations into the patient’s daily life by providing short daily tasks that accelerate positive behavior change. 7. a calendar feature for goal setting, planning, and recording of (HRQoL) perfor- mance and progress, 8. a small community feature for positive feedback, support from patients and support the patient in coping with symptoms, daily fatigue, and further disease-related symptoms, 9. Implementation of cognitive behavioral techniques, meditation and relaxation methods, 10. adapt a reward system to motivate ends for using the app, and, 11. Format the app interface.

Conclusion: These findings highlight the potential of implementing digital ther- apy to encourage self-management and engagement with health care profes- sionals. Non-medical management of patients with inflammatory arthritis. The results of this work suggest that using an app-based personalized disease management program may reflect significantly on several measures of patient-reported out- comes and disease activity in patients with RA/PsA/SpA. Future feasibility testing in a prospective study will firmly establish the reliability, efficacy, and cost-effectiveness of such an app intervention for this cohort of patients.

DEVELOPMENT OF A MOBILE APP FOR DISEASE-SPECIFIC COGNITIVE BEHAVIOR THERAPY MANAGEMENT IN INDIVIDUALS WITH RHEUMATOID ARTHRITIS

**Keywords:** Cognitive Function, Self-management, Rheumatoid arthritis

B. M. Eladny1, S. Abd-Elmaksood2, O. El Miedany3, Y. El Miedany4, 1Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Banha, Egypt; 2Faculty of Medicine Banha University, Psychiatry, Banha, Egypt; 3University College London, Computer Sciences, London, United Kingdom; 4Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom

**Background:** EULAR has recently highlighted the vital role of digital health in standard practice and the possibility to enhance the patient’s quality of life. Cognitive Behavior Therapy (CBT) plays an important role in improving clinical outcomes in inflammatory arthritis patients. The aim of CBT is to boost patients' self-efficacy for pain management, or their confidence in their ability to control their pain, and lessen the interference that pain causes in their everyday lives. CBT does this by educating patients on how to develop more efficient coping mechanisms to deal with everyday pain sensations and enhance functionality and quality of life. So far, no comprehensive mobile app has been developed to facilitate the collaboration between patients and their CBT therapist, especially with those having monetary and physical constraints related to their disease. Objective: 1. To gather from psychiatric data on system requirements for a mobile app to provide constructed CBT program for RA patients. 2. Identify the target audience, characteristics of the app, and correlations between the system requirements and the established CBT.

**Methods:** To identify the major themes recognized as the main pillars for app development and inform the app developer/machine learning engineer, a participatory action research design was implemented. Qualitative data were collected using multiple methods in four workshops. Participants were 2 Rheumatologists, 1 rheumatology nurse specialist, 1 Psychiatrist rheumatoid arthritis patient, and an App developer. A taxonomy was used to determine the degree of correlation between the system requirements and established cognitive behavioral therapy techniques.

**Results:** The app targets the optimization of patient-reported outcomes and quality of life to provide a non-medical management approach via modifying Disease-specific dysfunctional beliefs and behaviors using cognitive and/or behavioral exercises in a structured manner. The major themes identified were: 1. collect self-reported patient-reported outcomes (disease functional ability, quality of life, motivation), 2. Collect information on patient demographics, comorbidity(ies), disease activity status (self-reported disease activity score), plus past and current medications, 3. Identify the individual patient's target to be achieved, 4. Develop a patient profile that focuses on the patient's perpetuating factors, 5. Construction of a personalized, evidence-based disease management program based on recommendations from medical guidelines, medical standards, and state-of-the-art clinical research; 6. Implementation of a personalized CBT program for Effective Coping, Life Goals, Pain Management, Emotional Responses, Managing Change, Self-Esteem, Relationships; 7. A calendar feature for goal setting, planning, and recording of physical activity performance and progress. 8. A small community feature for positive feedback, support from peers and support the patient in coping with stress, sadness, depression, pain, fatigue, and further disease-related symptoms. 9. Implementation of relaxation exercises, 10. Adapt a reward system to motivate end users for using the app.11. Help the patients learn ways to cope with increased resilience to disease-related episodes.12. Format the app interface.

**Conclusion:** These findings highlight the potential of implementing digital CBT to encourage RA patients to be able to cope with their disease, change wrong beliefs, allow them to retain jobs, socialize normally, and engage with healthcare professionals. The results of this work suggest that using an app-based personalized disease management program may reflect significantly on several measures of patient-reported outcomes and disease quality of life in RA considering all conventional and psychological CBT barriers. Future feasibility testing in a prospective study will firmly establish the reliability, efficacy, and cost-effectiveness of such an app intervention for this cohort of RA patients.

**IMPACT OF ANTI-CITRULLINATED PROTEIN ANTIBODIES AND RHEUMATOID FACTOR ON BONE MINERAL DENSITY CHANGE IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH DENOSUMAB

**Keywords:** Autoimmune diseases, Osteoporosis, Rheumatoid arthritis

S. Ann1, T. Okano2, T. Kokei3,4, H. Nakamura3, 1Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; 2Osaka Metropolitan University Hospital, Orthopaedic Surgery, Osaka, Japan; 3Osaka Metropolitan University Hospital, Center for Joint Degenerative Diseases, Osaka, Japan; 4Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan

**Background:** Osteoporosis is one of the major comorbidities in patients with rheumatoid arthritis (RA). A low bone mineral density (BMD), especially in the femoral neck, was associated with the presence of anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF). However, there are few reports investigated the influence of autoantibody on BMD change in patients with RA after osteoporosis treatment.

**Objectives:** There are a lot of evidence that denosumab increased BMD in patients with osteoporosis, and improved bone erosion in patients with RA. We evaluated the BMD change in patients with RA treated denosumab, and assessed the effect of autoantibody, such as ACPA and RF.

**Methods:** This study included 196 RA patients (187 female; mean age, 71 ± 9.0 years; mean disease duration, 178 ± 15.3 years; mean DAS28-CRP, 2.9 ± 1.2) who fulfilled the criteria of osteoporosis and treated with denosumab. Disease activity of RA was treated according to EULAR recommendation 2022. BMD at the lumbar spine, proximal femoral and femoral neck were evaluated by dual energy X-ray absorptiometry at baseline and 12 months after denosumab treatment. We evaluated the influence of ACPA and RF for BMD change.

**Results:** Improvement ratio of BMD at the lumbar spine, proximal femoral and femoral neck were 6.4% (p<0.01), 3.4% (p<0.01) and 1.6% (p<0.1) after 12 months treatment. There were no differences in BMD at the lumbar spine, proximal femoral and femoral neck before denosumab treatment between 101 ACPA-positive patients and 30 ACPA-negative patients (0.77 vs 0.77 g/cm², p=0.68; 0.58 vs 0.61 g/cm², p=0.13; 0.48 vs 0.47 g/cm², p=0.7), between 128 RF-positive patients and 42 RF-negative patients (0.75 vs 0.76 g/cm², p=0.47; 0.59 vs 0.59 g/cm², p=0.68; 0.47 vs 0.46 g/cm², p=0.12). Improvement ratio of BMD at the lumbar spine, proximal femoral and femoral neck were 6.1% (p<0.01), 3.6% (p<0.01) and 1.8% (p<0.01) in ACPA-positive patients, 5.8% (p<0.01), 2.3% (p<0.01) and 3.7% (p<0.01) in ACPA-negative patients after 12 months treatment. Although there were no differences between ACPA-positive patients and ACPA-negative patients in BMD change at the lumbar spine (p=0.08) and proximal femoral (p=0.72), BMD change at femoral neck in ACPA-positive patients were lower than ACPA-negative patients (p=0.03). Improvement ratio of BMD at the lumbar spine, proximal femoral and femoral neck were 6.6% (p<0.01), 3.5% (p<0.01) and 1.1% (p<0.47) in RF-positive patients, 6.5% (p=0.04), 2.5% (p<0.01) and 2.0% (p=0.06) in RF-negative patients after 12 months treatment. There were no differences between RF-positive patients and RF-negative patients in BMD change at the lumbar spine (p=0.08), proximal femoral (p=0.66) and femoral neck (p=0.45). Multivariate linear regression analysis revealed that low BMD at baseline (β=-0.35, p<0.01) and ACPA positive (β=-0.2, p<0.04) inhibited the improvement of BMD at femoral neck (table 1).

**Table 1. Multivariate linear regression analysis of risk factors to inhibit the improvement of BMD at femoral neck in patients with RA.**

**RA, rheumatoid arthritis; BMD, bone mineral density; ACPA, anti-citrullinated protein antibodies; RF, rheumatoid factor; b/tsDMARDs, biologic and targeted synthetic disease-modifying antirheumatic drugs.**

**Conclusion:** Denosumab improved BMD at the lumbar spine and proximal femoral in patients with RA independently regardless of ACPA and RF. ACPA-positive patients were difficult to improve BMD at femoral neck despite denosumab treatment.

**DEVELOPING A CLINICAL ASSESSMENT TOOL FOR DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW AND FEASIBILITY ASSESSMENT

**Keywords:** Rheumatoid arthritis, Inflammatory arthritides
Background: Management of difficult-to-treat rheumatoid arthritis (D2T-RA) is challenging since poor treatment response also incorporates non-inflammatory symptoms that can mimic or amplify pain and scores on composite disease activity measures. Identification of modifiable non-inflammatory factors is vital to improve health outcomes and minimise harm from inappropriate escalation of drug therapy.

Objectives: To develop and assess feasibility of a systematic, evidence-based clinical assessment tool for the identification of modifiable non-inflammatory factors in D2T-RA.

Methods: A systematic literature search of PubMed, Embase and Web of Science databases for studies pertaining to D2T-treatment refractory RA was undertaken from database inception to October 2021. Studies were screened against inclusion/exclusion criteria, and further excluded if deemed to have a high risk of bias. Data pertaining to factors associated with treatment non-response were extracted from eligible papers and categorised to inform composition of the clinical assessment tool. Through patient involvement, the proposed tool’s components were assessed for their feasibility and ease of capture in an outpatient setting. Eight patients fulfilling EULAR definition of D2T-RA were recruited from a single centre. Clinical data and responses to relevant questionnaires mapped to the clinical tool, including: Patient Health Questionnaire-9 (PHQ-9), Brief Illness Perception Questionnaire (B-IPQ), Beliefs about Medicines Questionnaire-Specific (BMO-S), Functional Assessment of Chronic Illness Therapy – Fatigue (FACT-F) and Medication Adherence Re却t Scale-5 (MARS-5) were collected.

Results: 1154 records were screened, of which eight studies informed the development of a clinical assessment tool. Modifiable factors including raised BMI, smoking status, non-adherence, and co-morbidities, such as fibromyalgia and worse mental health were identified and incorporated into an initial tool. These factors were apparent and readily assessed within a local cohort of D2T-RA patients (Table 1). In summary, data from this cohort revealed a low burden of classified fibromyalgia, mild depression severity, and responses in keeping with a high illness concern. Despite general acceptance of pharmaceutical treatments, ‘ever’ non-adherence, classified as a response other than ‘never’ within the MARS-5 questionnaire was noted in two, five, and three patients regarding steroids, csDMARDs and b/tsDMARDs respectively.

Results presented as median (IQR); *n (%); n=6

Conclusion: Following a systematic review of the literature, we identified several modifiable factors that inform the development of a clinical assessment tool in D2T-RA and can be readily evaluated in an outpatient setting. A holistic approach is required to address both inflammatory and non-inflammatory aspects of D2T-RA. The development of an evidence-based clinical assessment tool is the first step in providing this, by identifying and targeting patient-specific non-inflammatory modifiable factors, in conjunction with pharmacological escalation.

**EFFECTS OF BIOLOGICAL-DMARDs ON THE SERUM URIC ACID LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Keywords: Rheumatoid arthritis

Y. Miwa, Y. Miwa, Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Yokohama, Japan; Showa University School of Nursing and Rehabilitation Sciences, Department of Nursing, Yokohama, Japan

Background: Hyperuricemia associated with rheumatoid arthritis (RA) has been reported to be a risk factor for cardiovascular disease. It has been reported that uric acid (UA) levels decrease with the use of leflunomide and increase with tumor necrosis factor (TNF) inhibitor therapy. However, the effects of long-term biological disease-modifying antirheumatic drugs (bDMARDs) therapy and non-TNF inhibitor biologic therapy on UA levels have not been reported.

Objectives: We aimed to investigate the changes in UA levels during TNF and non-TNF inhibitor therapy.

Methods: Patients with RA treated with bDMARDs from 2008 to 2018 were studied based on the All Showa University of RA (ASHURA) database. The association between uric acid level reduction and treatment was evaluated in 629 patients treated with the bDMARDs, and the medical records of 256 patients with available uric acid levels were included. The following background factors were investigated: age; sex; type of bDMARDs; dosage of methotrexate and prednisolone; usage of conventional synthetic DMARDs, dyslipidemia drugs, hyperuricemia drugs, and nonsteroidal anti-inflammatory drugs; body mass index; smoking history; HbA1c; presence or absence of hypertension and dyslipidemia; and serum creatinine, C-reactive protein, and matrix metalloproteinase-3 levels. We also used the simplified disease activity index (SDAI) to evaluate RA disease activity. The analysis was performed in two groups, TNF inhibitor-treated group (148 patients) and the non-TNF inhibitor-treated group (108 patients, tocilizumab and abatacept). The primary endpoint was UA levels before and after six months and one year, respectively (p=0.193). There was a difference in the type of drug but no difference in the duration of administration by repeated-measures ANOVA.

Conclusion: Our study suggests that TNF inhibitor therapy may affect an increased percentage of patients with hyperuricemia. On the other hand, non-TNF inhibitor therapy may not affect the increased rate of patients with hyperuricemia, and bDMARD treatment has a mild effect on UA levels in patients with RA.

**THE IMPACT OF WEIGHT ON FOOT INVOLVEMENT DURING RHEUMATOID ARTHRITIS**

Keywords: Rheumatoid arthritis

K. Zouali1, S. Boussaid1, S. Rekik1, S. Jini1, S. Rahmoun1, H. Aljani2, H. Sahli1, M. Elleuch1, 1 La Rabta Hospital, Tunisia, Rheumatology, Tunis, Tunisia; 2Yasminette Ben Arous Hospital, Rheumatology, Ben Arous, Tunisia

Background: Overweight and obesity are highly common in patients with Rheumatoid Arthritis (RA), with probable impact on bearing foot joints.

Objectives: The aim of the present study was to explore the associations between Body Mass Index (BMI) and measures of foot health (foot pain, foot-related activity limitation, foot synovitis and deformities) in patients with RA.
Methods: A cross-sectional study was conducted on 50 patients with RA consulting a rheumatology department with different complaints. Domains of foot health studied comprised: foot pain (Numeric Rating Scale), foot-related activity limitation (Foot Function Index), foot synovitis (Metatarsophalangeal Joint Count), and foot deformity (Platto Score).

Results: The mean age was 45.48 ± 10.3 years [20-76], most were female (82%), and most patients had moderately long disease duration (12.12 ± 7.67 years). RA was often moderately active (mean DAS28: 3.25 ± 0.98). Sixty six percent of our population were overweight or obese with a mean BMI 29 Kg/m². The average foot pain intensity was 5.78 ± 6.17. The mean FFI pain subscale was 40.15 ± 17.5, and the mean WOMAC pain subscale was 30 ± 13.2. Seventy percent of our patients had chronic foot pain (> 6 months). The heel was the most symptomatic location (62%). Podoscopic examination showed flat feet in 46% of cases, hollow feet in 20%, a valgus heel and varus heel were noted in 34% and 12% of cases respectively. The mean tendon foot count was 5.9 ± 1.7. The mean of swollen foot joint was 2.2 ± 1.55. The average of the foot structure index (Platto score) was 7.8 ± 2.73. Hallux valgus was the most common deformity (74%) followed by claw toe in 43.5% of cases and then subluxation of MTP joints in 26%. Concerning foot-related activity limitation, the mean FFI score of Disability subscale was 32 ± 14.2 and the mean WOMAC score of physical functioning subscale was 33.8 ± 13.96. Half of our patients suffered from problems fitting their shoes because of claw toe, heel pain and Hallux valgus in 40%, 36% and 32% of cases respectively. Our study showed that higher BMI was associated with lower foot health in many of the studied measures. Patients with higher BMI reported significantly more foot pain (p = 0.001), more foot-related activity limitations: for both scales: FFI (p = 0.01; B = 2.17) and WOMAC (p<0.01; B = 20.64), more foot deformities assessed with Platto score (p = 0.02; B = 4.76), more foot synovitis (p = 0.02; B = 4.66) and more problems with footwear (p = 0.05). However, in our population, higher BMI was significantly associated with less radiological joint damage (p = 0.01) and lower feet sharp score (B = -13.9, P = 0.06).

Conclusion: Despite our findings of a possible protective effect of obesity on structural damage, obesity is still, as seen in this and many other studies, an important cause of increased pain, increased functional disability and impaired quality of life in patients with RA that requires special interventions.

EVALUATION OF THE ASSOCIATION BETWEEN MOOD DISORDERS AND THE REGION OF THE AFFECTED JOINTS IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY

Keywords: Rheumatoid arthritis
K. Tokunaga1, H. Oshikawa1, T. Nishino1, T. Matsui1, S. Tohma1, Japanese Red Cross Kumamoto Hospital, Department of Rheumatology, Kumamoto, Japan; 1National Hospital Organization Sagamihara National Hospital, Department of Rheumatology Research, Clinical Research Center for Allergy and Rheumatology, Kanagawa, Japan; 1National Hospital Organization Tokyo Medical Center, Department of Rheumatology, Tokyo, Japan

Background: The prevalence of mood disorders, such as anxiety and depression, is higher in patients with rheumatoid arthritis (RA) than the general population. Even in the absence of a formal mood disorder, a significant number of RA patients have anxiety, and 992 (11.2%) had depression. The mean HADS-anxiety (A) in the non-anxiety, and anxiety groups were 3.61 (SD = 2.70) and 13.24 (SD = 2.29), respectively. Moreover, mean HADS-depression (D) in the non-anxiety, and anxiety groups were 3.30 (SD = 3.30) and 10.45 (SD = 3.87), respectively.

The mean HADS-A in the non-depression and depression groups were 3.67 (SD = 3.03) and 7.75 (SD = 4.40), respectively. Lastly, mean HADS-D scores in the non-depression and depression groups were 5.15 (SD = 2.62) and 12.73 (SD = 1.90), respectively. In logistic regression analysis, anxiety was associated with lower/large, and small joints, along with female sex, smoking history, and use of PSL. Moreover, depression was associated with upper/large and lower/large joints, along with female sex, lower BMI, disease duration, smoking history, use of PSL, non-use of MTX, and CRP.

Conclusion: Anxiety and depression were associated with the region of the affected joints, but in different patterns. When assessing the patient’s mood in RA, the distribution of affected joints should also be noted.

CHEST HIGH-RESOLUTION COMPUTED TOMOGRAPHY IN PATIENTS WITH LONG STANDING RHEUMATOID ARTHRITIS: IS THERE ANY BENEFIT?

Keywords: Rheumatoid arthritis, Imaging, Lungs
K. Tahir1, N. Akasbi1, I. El Mezouar1, T. Harzy1, 1University Hospital Center Hassan II, Rheumatology, Fez, Morocco

Background: Pulmonary involvement is a frequent and severe extraarticular manifestation of rheumatoid arthritis (RA). Chest high resolution computed tomography (HRCT) have been shown to be of interest in the detection and characterization of morphological changes in the lungs of RA patients.

Objectives: The aim of our study was to investigate the prevalence and types of pulmonary involvement in patients with longstanding RA using chest HRCT.

Methods: A retrospective study was conducted in a single rheumatology hospital including patients diagnosed as having RA according to the ACR-EULAR 2010 criteria from April 2018 to April 2022. Longstanding RA was defined as disease duration > 2 years. All patients underwent chest X-ray and chest HRCT.

Results: Our study included 148 patients with longstanding RA. The cohort was predominantly female (87%) with a mean age 60.58 ± 11.79 years. 8 patients (5.4%) had a history of smoking. Mean age at RA onset was 44.77 ± 13.62 years and disease duration was 14.75 ± 7.55 years. The mean BMI was 28.19 ± 6.47 Kg/m². RA was seropositive in 95.3%, erosive in 91.2% and deforming in 66.2% of our subjects.
Methotrexate was used in 142 patients (95.9%), 41 patients (27.7%) were complaining of respiratory symptoms: dyspnea (n=20, 13.5%), cough (n=11, 7.4%), and both (n=10, 6.8%). The chest X-ray abnormalities were present in 41 patients (27.7%)—abnormal spirometry was found among 49.4% of subjects. Pulmonary HRCT abnormalities were found in 66.8% of patients and the most common were: subpleural micronodules (25%), bronchiectasis (23.6%), and non-septal linear opacities (16.9%), pulmonary nodules (11.5%), ground glass opacity (10.8%), reticulation (8.8%) and honeycombing (8.8%). The presence of HRCT pulmonary lesions was associated with smoking history (p=0.020), seropositivity (p=0.010), respiratory symptoms (0.002) and chest X-ray changes (p<0.0001). However, there were no significant association with the other clinical, biological, radiological and therapeutic criteria.

**Conclusion:** Our study confirms that a large proportion of patients with long-standing RA has abnormal findings in chest HRCT even in those with no chest X-ray findings or respiratory symptoms. RA patients should undergo chest HRCT to detect pulmonary abnormalities as early as possible.

### AB0332 APPLICATION IN CLINICAL PRACTICE OF THE SCREENING CRITERIA FOR INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS PROPOSED BY SER-SEPAR IN A COHORT OF RHEUMATOID ARTHRITIS: PRELIMINARY STUDY

**Keywords:** Rheumatoid arthritis, Diagnostic Tests, Lungs

**Background:** A screening tool has recently been proposed by two scientific societies (Spanish Society of Rheumatology and Pneumology), combining clinical and serological data to improve the detection of interstitial lung disease (ILD) in rheumatoid arthritis (RA) [1].

**Objectives:** To apply a new ILD screening tool in a cohort of patients with RA in order to determine its prevalence, and evaluate the burden of complementary exams generated for this purpose derived from its thorough application.

**Methods:** Observational and single-center cross-sectional study of a cohort of RA patients under active follow-up at the Rheumatology Service of the Vall d’Hebron. The sample will be all the patients who attend the clinic routinely. Of the 109 patients for whom chest X-rays and LFTs were recommended, in 26 (24%) have been performed, due to usual delay in the pneumology service for LFTs. A restrictive pattern was detected in 4 patients (15.4%), half of whom also presented a decrease in DLCO. HRCT in those patients is still pending. 50% of the LFTs performed were normal and in the rest of the cases alterations compatible with other respiratory pathologies have been observed.

**Conclusion:** The application of this screening algorithm is allowing to diagnose patients with asymptomatic ILD. However, the costs of performing the various complementary exams and its effect in treatment decisions in this profile of patients must continue to be studied.

### AB0333 PERIODONTITIS AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: A CASE CONTROL STUDY

**Keywords:** Rheumatoid arthritis

**Background:** Different studies have estimated a higher risk of dental and periodontal abnormalities in patients with rheumatoid arthritis (RA), but it is often under-diagnosed.

**Objectives:** In this context, we conducted this study, whose objectives were to evaluate the frequency and the type of oral and periodontal abnormalities in patients with RA compared to control subjects and to determine the predictive factors of the periodontal disease.

**Methods:** This is a case control study conducted during the period between July 2020 and June 2022. The oral and osteoarticular examination was performed for each patient. The different dental and periodontal indices were calculated: CAO index, plaque index (PI) and gingival index (GI).

**Results:** Sixty patients diagnosed with RA according to the ACR/EULAR 2010 classification and 71 control patients were included. The mean age of patients with RA was 51.5 ± 12.4 years [21-78 years] and that of the control group was 47.2 ± 12.8 years [22-74 years]. The oral examination showed poor oral hygiene based on the plaque index (PI). The frequency of moderate to abundant plaque

**Disclosure of Interests:** None Declared.

**DOI:** 10.1136/annrheumdis-2023-eular.3644
accumulation (Plx score 2) was comparable between the two groups with non-significant difference (91.7% versus 94.4%; p=0.5). Regarding dental caries, the median CAO was greater in the RA group than in the control group with a significant difference at 2 years (2.1±0.5 vs 1.9±0.3, p=0.01). The mean numbers of missing and decayed teeth in RA patients were higher than those found in controls (3.3±4.6 vs 2.3±3.06; 1.9±2.3 versus 1.3±9.22 respectively). Analysis of the superficial periodontal status showed that 88.3% of RA patients had gingivitis compared with 90.1% of controls. The mean gingival index was 1.72±0.8 in RA group versus 1.76±0.7 in control group without a significant difference. As for the alteration of the deep periodontium, 53.3% had periodontal pockets and/or gingival recessions compared to 19.8% of controls with a statistically significant difference (p=0.01). This involvement in RA patients was significantly correlated with disease activity DAS 28 and the importance of the CRP level (p=0.02, p=0.03 respectively). Tooth mobility was experienced by 28.4% of RA patients versus 10.1136/annrheumdis-2023-eular.5404

AB0334 PREVALENCE AND ASSOCIATED FACTORS OF MULTIMORBIDITY IN PATIENTS WITH STABILIZED RHEUMATOID ARTHRITIS. DATA FROM THE CRHREAR REGISTRY

Keywords: Comorbidities, Real-world evidence, Rheumatoid arthritis
M. Rojas-Giménez1, S. Daza-Caballero2, M. Parra-Moreno2, M. Á. Puche, L. M. Rojas-Giménez1, M. Parra-Moreno2, M. Á. Puche, L. M. Rojas-Giménez1, A. Escudero Contreras1, Reina Sofia University Hospital, Rheumatology, Córdoba, Spain. Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), GC05 Group, Cordoba, Spain. University of Cordoba, Medical Surgical Sciences, Cordoba, Spain., Rheumatology Department, Cordoba, Spain; Reina Sofia University Hospital, Rheumatology, Córdoba, Spain, Rheumatology Department, Córdoba, Spain

Background: Patients with Rheumatoid Arthritis have an increased risk of developing comorbidities that contribute to increased worse quality, disability and mortality. Knowledge of comorbidity is important when attempting to identify the conditions most associated with the greatest morbidity and mortality. However, comorbidities in RA are often underestimated despite their impact on disease activity and treatment outcomes.

Objectives: To evaluate the prevalence of multimorbidity in a cohort of patients with stabilized Rheumatoid Arthritis (RA) and the factors associated with such condition.

Methods: Cross-sectional observational study of a cohort of patients with RA according to the ACR/EULAR 2010 criteria of the CRhREAR registry of the Reina Sofia University Hospital of Córdoba. Multimorbidity was defined, according to the WHO, as the presence of two or more chronic diseases, in addition to RA. Comorbidities included in the Charlson index were collected, in addition to others such as arterial hypertension (HT), dyslipidemia (DL), diabetes mellitus, depression, osteoporosis, intestinal lung disease, and thyroid pathology. Other socio-demographic and patient-related variables were collected. Statistical analysis: descriptive, bivariate analysis and multivariable logistic regression to evaluate variables independently associated with multimorbidity.

Results: A total of 233 patients were included (mean age 63.6 (13.4) years and 70.4% women). More than 70% were ACPA and RF positive. 99.1% had used any csDMARDs ever, n (%) 71 (47.0%) 27 (32.9), 0.292, bDMARDs ever, n (%) 71 (47.0%) 27 (32.9), 0.249. The most frequent comorbidities included in the Charlson index were arterial hypertension (45.1%) vs 2 PSA patients (4.4%, p = 0.07). Results from a sex- and age-adjusted comparison between the two groups with a significant difference were (p=0.01). The mean numbers of missing and decayed teeth in RA patients were higher than those found in controls (3.3±4.6 versus 2.3±3.06; 1.9±2.3 versus 1.3±9.22 respectively). Analysis of the superficial periodontal status showed that 88.3% of RA patients had gingivitis compared with 90.1% of controls. The mean gingival index was 1.72±0.8 in RA group versus 1.76±0.7 in control group without a significant difference. As for the alteration of the deep periodontium, 53.3% had periodontal pockets and/or gingival recessions compared to 19.8% of controls with a statistically significant difference (p=0.01). This involvement in RA patients was significantly correlated with disease activity DAS 28 and the importance of the CRP level (p=0.02, p=0.03 respectively). Tooth mobility was experienced by 28.4% of RA patients versus 10.1136/annrheumdis-2023-eular.5404

AB0335 INCIDENT CHRONIC KIDNEY DISEASE IN PATIENTS WITH RHEUMATOID AND PSORIATIC ARTHRITIS – A COMPARATIVE ANALYSIS

Keywords: Psoriatic arthritis, Kidneys, Rheumatoid arthritis
T. Hartl1, D. Dahlby2,3, S. Costello4, M. O’Shaughnessy5,3, S. Harvey5,8,1 University College Cork, School of Medicine, Cork, Ireland; 2 University College Cork, School of Public Health, Cork, Ireland; 3 University College Cork, HRB Clinical Research Facility, Cork, Ireland; 4 Cork University Hospital, Department of Biochemistry, Cork, Ireland; 5 Cork University Hospital, Department of Renal Medicine, Cork, Ireland; 6 Cork University Hospital, Department of Rheumatology, Cork, Ireland

Background: Patients with inflammatory joint conditions have a high prevalence of comorbidities including chronic kidney disease (CKD) [1]. The data pertaining to CKD in rheumatoid arthritis (RA) is limited [2], however and its association with psoriatic arthritis (PsA) remains unclear. Renal disease in RA and PsA is clinically important as it can lead to restrictions in the management of the primary disease, and is also associated with increased all-cause morbidity and mortality [3].

Objectives: To determine and compare the rate of incident CKD in patients with rheumatoid and psoriatic arthritis and to determine the rate of estimated glomerular filtration rate (eGFR) change over time.

Methods: Patients with RA and PsA who were first diagnosed between 1st January 2005 and 31st December 2010 were included in this retrospective, longitudinal analysis. All eGFR values, calculated using the Modification of Diet in Renal Disease equation, for each patient were collected from time of diagnosis until 31st December 2020. Demographic details, disease-specific characteristics, the presence of cardiovascular disease at baseline and anti-rheumatic drug use at each appointment were recorded. Generalized additive models (GAMs) were used to smooth the eGFR trajectories for each patient, and mixed-effects models were then used to estimate crude linear trends in eGFR across the period of observation. The primary outcome measure was diagnosis of CKD, defined as patient’s eGFR falling below 60ml/min/m2 for a period of at least 90 days in their smoothed eGFR trajectory.

Results: The patient sample (n = 159) included 114 RA and 45 PSA patients. RA patients were less likely to be male (39 vs 51%, p = 0.2) and older (mean age at baseline 52 vs 46 years, p < 0.001) than PsA patients. They also tended to have moderately lower eGFR upon initial observation (78 vs 83 ml/min/m2, p = 0.07). Baseline comorbidity profiles were broadly similar between the two groups. Treatment profiles were also similar, but with RA patients prescribed DMDs at 69% of their appointments on average vs 56% in PSA patients (p = 0.003). There were 22 incident cases of CKD in the RA patients (19%), vs 7 in the PsA patients (16%, p = 0.6), and 17 RA patients died during the observation period (15%) vs 2 PSA patients (4.4%, p = 0.07). Results from a sex- and age-adjusted
mixed effects models suggested that eGFR trajectories tended to slowly decline on average in PSA patients (−0.22 ml/min/m² per year, p vs no trend = 0.14), but increased on average (0.79 ml/min/m² per year) among RA patients (p for interaction < 0.001).

Conclusion: Incident CKD diagnosis was high in both patient populations. While rate of eGFR decline was greater in patients with PsA, overall rates of CKD progression were greater in RA patients. The use of corticosteroids and DMARDs was used in a similar proportion to the literature.

AB0336  RHEUMATOID ARTHRITIS AND UPPER DIGESTIVE TRACT BLEEDING: ASSOCIATED FACTORS BETWEEN THE USE OF NSAIDS AND CORTICOSTEROIDS

Keywords: Safety, Rheumatoid arthritis, Gastrointestinal tract

W. Carvajal-Gutiérrez1, M. A. Cisneros-Cisneros1, O. J. Caixto2,3, E. C. Vera-Parras2,3, M. A. Meneses-Toro2,3, M. A. Vega-Baez1, D. A. Álvarez-Vargas1, A. C. Usategui-Ruíz1, J. A. Prada Rueda1, M. C. Romero2,3, J. M. Bello-Guerrero2,3, H. Hospital Medical, Internal Medicine Department, Bogota, Colombia;1Universidad Nueva Granada, Medicine School, Clinical Immunology Group, Bogota, Colombia;2Hospital Medical Central, Rheumatology and Immunology Department, Bogota, Colombia;3Hospital Medical Central, Gastroenterology Department, Bogota, Colombia;4Universidad El Bosque, Cellular and Molecular Immunology Group/ INMUBO, Bogota, Colombia

Background: Rheumatoid arthritis (RA), with a prevalence of 0.52% in Colombia, is an autoimmune disease with erosive joint involvement associated with significant manifestations in other organs and systems. RA has been associated with a greater risk of upper gastrointestinal bleeding (UGIB), highlighting the greater exposure to non-steroidal anti-inflammatory (NSAID) and corticosteroids [1].

Objectives: Describe the safety profile with emphasis on UGIB associated with the use of NSAIDs and corticosteroids in patients with RA treated at the Central Military Hospital.

Methods: Analytical cross-sectional study of patients diagnosed with RA according to EULAR/ACR 2010 classification criteria between 2015-2021, describing the clinical and demographic variables and evaluating the association with UGIB. Patients with variceal UGIB were excluded. A bivariate and multivariate statistical analysis was performed by binary logistic regression. Approved by the institutional ethics committee.

Results: 405 individuals were evaluated, 80.5% were female, UGIB was present in 16 patients (4%). ESR was elevated in 60.9% and CRP in 67.9%. Rheumatoid factor (RF) >20 U/mL was positive in 68.6% and anti-CCP in 62.30% of the total population; 100% of the UGIB group were RF+ (p=0.006) and anti-CCP+ (p=0.002). DAS28 presented a median of 5.1 (IQR=3.7-6.0) in UGIB group, while 6.25% used NSAIDs (p=0.07), while 62.5% used corticosteroids (p=0.04). NSAIDs doses and time of use did not present statistical differences between both groups (p=0.640 and p= 0.80). Neither does the type of NSAIDs (p=0.480). There were no significant differences regarding the type of corticosteroid (p=0.441) or the time of use (p=0.847); however, there were differences in doses used (p=0.036). As a result of logistic regression, the presence of anemia was identified with ORA 12.3 (95% CI 1.4-110.3), HAQ moderate or severe disability with ORA 76 (95% CI 1.4-39.9) and DAS28-CRP ORA 0.52 (95% CI 0.29-0.94) as factors associated with UGIB.

Conclusion: Our RA population shows an adequate control of disease activity. Lower use of NSAIDs is reported compared to other populations and the use of corticosteroids and DMARDs was used in a similar proportion to the literature.

In patients with RA and UGIB, there were no statistically significant differences regarding NSAIDs and corticosteroid use. The presence of anemia, greater disability, and high levels of activity were associated. The study group presented a lower proportion of UGIB compared to the evidence published to date.

AB0337  MENTAL HEALTH AND RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

S. Baliga1, R. Samantb, C. Balakrishnan1, Father Muller Medical College, Rheumatology, Boloor mangalore, India;2P D Hinduja National Hospital and Research Centre, Mumbai, Rheumatology, Mumbai, India;3P D Hinduja National Hospital and Research Centre, Mumbai, Rheumatology, Mumbai, India

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disorder characterised by symmetrical involvement of small and large joints of the body. It has a prevalence of 0.5 – 1% in the world, affecting more commonly women [1]. Due to the inflammatory burden of the disease, RA patients develop articular damage of various joints causing disability, reduced quality of life, and reduced life expectancy[2,3]. Patients with long standing or severe disease can also manifest with extraarticular symptoms. These in addition to chronic pain and disability can affect mental status of the patients [4]. Poor quality of sleep, anxiety and depression have been thought to contribute to the disease flare. [5] DMARDs are the best treatment offered to control disease activity in patients with rheumatoid arthritis. However it is important to emphasize that sleep, depression and stress have also an important role to play in the disease management. Treatment of depression, improvement of sleep quality in addition to DMARDS should always be kept in mind. Through this study we attempt to find there is any correlation of mental health with disease activity in RA.

Objectives: To find the prevalence of depression, anxiety, and disturbed sleep in RA patients. To find the correlation of depression, anxiety and quality of sleep with disease activity in RA.

Methods: A cross sectional study was done on RA patients in a tertiary care centre from western India. A questionnaire-based study was conducted among adult RA patients attending Rheumatology clinic at P D Hinduja Hospital Mumbai between March 2020 to July 2021. Depression was assessed using Beck depression scale, anxiety using Becks anxiety scale and sleep quality using sleep quality scale.

Results: A total of 200 RA patients within 5 years of disease were included in the study. Out of 200 patients, majority (84%) were females. The prevalence of depression, anxiety and disturbed sleep in our RA population was 23.5%, 27.5% and 44.5% respectively. Using Spearman correlation, we found a positive correlation of depression (Figure 1), anxiety and disturbed sleep with disease activity using DAS 28 score. We also found a positive correlation of number of joints involved with pain (PAS) scores, depression with anxiety, anxiety with both depression and disturbed sleep and poor sleep quality with anxiety.

Figure 1: Correlation between Disease activity using DAS Score and Depression Score.

- The p-value of the test is <0.0001. DAS Score and Depression Score are significantly correlated with correlation coefficient 0.29 and P-value <0.0001.
Conclusion: Depression, anxiety, and sleep disturbance is significantly higher in patients with early RA. Rheumatologists in addition to assessing disease activity in RA should also include assessment of the mental health. Early evaluation and intervention might result in better outcomes, reduce disease burden and avoid unnecessary immunosuppressive drug escalation.

Conclusion: Occurrence and presentation of MetS differed between inflammatory arthritides. The impact of these risk factors on CV risk profile was stronger in PsA compared to RA, and showed no progression in one year. This suggests the implication of different mechanisms, which may require distinct CV preventive strategies in PsA and RA.

METABOLIC SYNDROME AND ITS COMPONENTS HAVE A DIFFERENT PRESENTATION AND IMPACT ON THE CARDIOVASCULAR RISK PROFILE OF PATIENTS WITH PSORIATIC AND RHEUMATOID ARTHRITIS

Keywords: Comorbidities, Cardiovascular disease, Inflammatory arthritides

F. Atzeni, L. La Corte, M. Cirillo, M. Giallanza, J. Rodríguez-Carrio.
1. University of Messina, Rheumatology Unit, Department of Experimental and Internal Medicine, Messina, Italy; 2. University of Oviedo, Department of Functional Biology, Oviedo, Spain; 3. Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Department of Metabolism, Oviedo, Spain

Background: Patients with inflammatory arthritides have a higher cardiovascular (CV) risk than the general population. Traditional CV risk factors are involved, while the impact of the metabolic syndrome (MetS) is less defined. Whether MetS clinical presentation and its components are comparable across conditions is unclear.

Objectives: To compare the prevalence of MetS and their components, and the impact on the CV risk profile, in psoriatic arthritis (PsA) versus rheumatoid arthritis (RA).

Methods: a retrospective analysis with follow-up of real-world PsA (CASPAR criteria) and RA (2010 EULAR/ACR classification criteria) patients referred to a rheumatology clinic was performed. Demographical, clinical data and presence of CV risk factors were evaluated from patient charts using national guidelines, both at baseline and after 12-months of follow-up. MetS was defined according to the American Heart Association (AHA)/National Heart, Lung, and Blood Institute (NHLBI) criteria. Univariate and multivariate models were used to compare the impact of the MetS and its components in patients with PsA versus RA.

Results: PsA patients (n=78) were younger (45.23 (16.99) vs 60.81 (13.19) years, p=0.001), exhibited lower disease duration (18.86 (48.43) vs 176 (169.77) months, p=0.001) and prevalence of autoantibodies (RF: 7.7 vs 58.7%, ACPA: 7.9 vs 57.6%; both p<0.001) than their RA counterparts (n=92). PsA patients were more likely to present with MetS (40(51.3%) vs 25(27.2%), p=0.003) and dyslipidemia (56(71.8%) vs 26(28.3%), p=0.001) compared to RA. No differences were observed for smoking (22(28.2%) vs 26(28.3%), p=0.836), diabetes (26(38.3%) vs 33(35.9%), p=0.823 and hypertension (44(56.4%) vs 51(55.4%), p=0.749). These differences were maintained after adjusting for age. Multivariate analyses revealed that hypertension (OR 11.818 [95% CI: 2.048–58.053, p=0.002) and dyslipidemia (OR 5.190 [95% CI: 1.187–24.092, p=0.035) were predictors of MetS in PsA, and no effect was observed for diabetes (p=0.066) smoking (p=0.367), age (p=0.445) or sex (p=0.445); whereas diabetes (OR 15.58, [95% CI: 2.41–100.45, p=0.004), hypertension (OR 20.44, 95% CI: 2.58–161.05, p=0.002) and dyslipidemia (OR 43.29 [95% CI: 6.82–274.75, p<0.001) predicted MetS in RA, and no effect of age (p=0.473), sex (p=0.615) or smoking (p=0.317) was noted. No effect was observed for autoantibodies or treatments received. Despite the history of CV events was similar between disorders (PsA: 22(28.2%) vs RA 24(26.1%), p=0.602), differences in predictors were found. Multivariate analyses revealed that hypertension and MetS predicted CV history in PsA, whereas dyslipidemia was the only factor predicting CV history in RA (Table 1). Associations were stronger in PsA, and total variance explained in each model differed across groups.

AB0338

ANEMIA OF INFLAMMATION: A PREDICTOR OF COEXISTING IRON DEFICIENCY IN MEASURED BY NOVEL RETICULOCYTE INDICES, AS ANEAEMIA OF INFLAMMATION

Keywords: Comorbidities, Diagnostic Tests, Biomarkers

P. Singh, V. Ingle, R. Joshi, D. Joshi, A. Kotnis. AIIMS Bhopal, General Medicine, Bhopal, India; AIIMS Bhopal, Pathology and Lab Medicine, Bhopal, India; AIIMS Bhopal, Biochemistry, Bhopal, India

Background: Anemia of inflammation (AI) can be referred to as the proverbial “Starvation amidst plenty” as body iron stores are unavailable for...
the erythron[1]. Anemia of iron deficiency(AID) is prevalent in developing countries and often coexists with AI [2]. There is no simple, single static iron or red blood cell parameter, which reliably predicts iron deficiency in patients with AI. The erythron is in a state of flux; modulated by physiologic demands (e.g., hemoglobin(Hb) levels, tissue hypoxia), metabolic substrates (e.g., iron, Vitamin B12, Folic acid, etc), and pathologic states (e.g., inflammation, malignancies, etc). Therefore, even at the risk of oversimplification, it may be hypothesized that dynamic tests are needed to determine limiting factors for erythron responsiveness.

**Objectives:** This study aimed to evaluate the performance of novel reticulocyte (Ret) indices Reticulocyte Hemoglobin (RetHb) and Immature Reticulocyte Fraction (IRF) in identifying coexistent iron-deficient states in AI. We correlated the change in RetHb & IRF with an increase in Hb after intravenous iron in AI.

**Methods:** In this study, we used intravenous iron in patients with AI (hemoglobin<10gm/dL and serum ferritin <500ng/ml) and employed changes in Ret parameters - RetHb/IRF to predict coexisting iron deficiency ‘Iron challenge test’. All participants received intravenous iron sucrose after sensitivity testing (100mg day 1 and 400mg Day 3). An increase in Hb of at least 1gm/dL at one month was considered a positive iron response & diagnostic of coexistent iron deficiency with AI. Change in RetHb/IRF on 3rd day from baseline was compared in iron responders(AID with AI) vs non-responders (AI only).

**Results:** Out of 62 patients who were enrolled, 46 patients completed the study protocol & were finally analyzed for the study. The majority of the participants had chronic autoimmune inflammatory disorders (Rheumatoid arthritis-30 Ankylosing Spondylitis-5, Systemic Lupus Erythematosus-4, Sjogren -1, Psoriatic arthritis-1) while the rest were Chronic liver disease/Chronic heart disease. About 63% of participants were iron responders and therefore, considered to have AID with AI; while the rest were iron non-responders and considered to have predominant AI. There was no significant difference between the change in RetHb/IRF amongst responders and non-responders at 72 hrs (Table 1). Baseline serum iron parameters (Serum iron, Total Iron Binding Capacity, % Saturation, Serum ferritin) and Red blood cell (RBC) indices (Mean corpuscular volume, Mean Corpuscular Hb) were also not statistically different in iron responders vs non-responders.

**Conclusion:** Diagnosing and treating coexisting iron deficiency in AI is a clinical conundrum. In this study, a significant proportion of AI (37%) didn’t respond to intravenous iron at 1 month. Baseline iron parameter like serum ferritin% saturation and RBC Mean corpuscular volume didn’t predict response to iron in this study. Change in novel automated Ret indices (RetHb and IRF) failed to predict response to iron and therefore, failed to diagnose co-existent iron deficiency in AI. Dynamic studies demonstrating erythron responsiveness to iron therapy using “point of care” automated hematologic parameters may provide a template for further studies.

**MULTI-DRUG RESISTANT RA IS ASSOCIATED WITH HIGHER BASELINE DISEASE ACTIVITY, MULTI-MORBIDITY, AND LOWER QUALITY OF LIFE: ANALYSES FROM THE R4RA BIOPSY-DRIVEN CLINICAL TRIAL

**Keywords:** Comorbidities, Clinical Trials, Rheumatoid arthritis

**Background:** We have recently described a fibroblast/stromal signature in patients with multi-drug resistant Rheumatoid Arthritis (MDR-RA). However, MDR-RA is known to be extremely heterogeneous, with multiple clinical and pathogenic factors potentially contributing to multi-drug resistance.

**Objectives:** Define the association of MDR-RA with clinical and demographic factors.

**Methods:** Patients with multi-drug resistant RA (MDR-RA), defined as failure of 3x biDMARDs with a different mechanism of action (TNF-inhibitor, tocilizumab and rituximab) were identified from the R4RA clinical trial (n=40) and compared with first-line responders to either rituximab or tocilizumab (n=72) for: disease activity scores, including composite indexes and individual components; baseline demographics, including co-morbidities, and quality of life scores (HAQ and SF-36 domains); synovitis, assessed by ultrasound and immunohistochemistry.

**Results:** MDR-RA patients did not differ significantly from first-line responders in terms of age, disease duration and ethnicity, as shown in Table 1. MDR-RA patients were treated more often with csDMARDs combination, while the number of previous anti-TNF did not differ. Baseline disease activity was significantly higher in MDR-RA compared to first-line responders. This difference was mainly driven by tender joints, while there were no significant differences for 28 swollen joints count, pain, and patient/physician global health scores (Table 1). Ultrasound scores and synovial pathotype distribution were not significantly different between MDR-RA and responders, but responders had a numerically higher power doppler score and significantly higher sub-lining macrophages, in line with the known association of synovial macrophages with treatment response. The incidence of individual comorbidities such as diabetes, hypercholesterolemia, hypertension, anxiety/depression, and obesity was non significantly different between MDR-RA and responders; however, the prevalence of multi-morbidities was significantly higher in MDR-RA patients, as 50% had more than 2 comorbidities compared to 22.8% of responders (p=0.0343). Finally, MDR-RA patients had significantly lower FACIT fatigue scores and worse scores for multiple SF-36 domains (physical functioning, emotional well-being, social functioning, and general health). Although the difference in baseline disease activity was mainly driven by tender joints, the longitudinal assessment of disease activity across 48 weeks showed persistently elevated tender and swollen joint counts, pain, and global health scores in MDR-RA patients compared with responders (Figure 1).

**Conclusion:** MDR-RA, defined as lack of response to 3x biologics with different mechanisms of action, is associated with worse disease activity baseline and multi-morbidity. There were no specific associations with pain scores, but MDR-RA had a huge impact on multiple quality-of-life domains. At follow-up, MDR-RA was associated with persistently elevated disease activity scores, including both higher tender and swollen joints, in keeping with persistently active inflammatory disease.
